ADDRESSEE LIST

RE: Draft Environmental Impact Report for Revisions to the Kern County Zoning Ordinance – 2015 C, focused on Oil and Gas Local Permitting (COMMENT PERIOD EXTENSION)

Dear Interested Party,

The County of Kern will be extending the comment period of the above referenced DEIR from the original date of August 24, 2015 to **September 11, 2015**. Also, attached is a revised Notice of Availability reflecting revisions to the comment period. Please be advised the scheduled hearing date of October 5, 2015 at 5:00 PM, before the Kern County Planning Commission, has not changed. The Public hearing will be held at the Chambers of the Board of Supervisors, First Floor, Kern County Administrative Center, 1115 Truxtun Avenue, Bakersfield, California.

Comments can be also be submitted at one of our additional public workshops that will be held at **6:00 p.m.** at the following locations and dates:

Shafter Veterans Building, Room 2, 309 California Avenue, Shafter CA	**August 10, 2015**
Taft Veterans Hall, Room 1, 218 Taylor Street, Taft, CA	**August 17, 2015**

If you have any questions regarding this matter or would like to submit comment, please contact me directly at (661) 862-8607 or by email at MynkC@co.kern.ca.us.

Sincerely,

Christopher B. Mynk, AICP
Supervising Planner

Re: Extending Comment Period for Draft EIR

Dear Ms. Oviatt and Mr. Mynk:

The Center for Biological Diversity, the Center on Race, Poverty and the Environment, Earthjustice, the Natural Resources Defense Council and Sierra Club ("Environmental Advocates") request a 60-day extension to comment on Kern County's draft environmental impact report ("DEIR") for the Amendment to Title 19-Kern County Zoning Ordinance Chapter 19.98 (Oil and Gas Production) for Oil and Gas Permitting. Environmental Advocates seek sixty (60) days more than the minimum 45-day public review period to comment on the DEIR.

The extension request is eminently reasonable given the vast scope of the DEIR, which evaluates zoning ordinance changes that, if adopted, seek to create ministerial permitting for almost every activity related to oil and gas production in Kern County. A recent news article reports that Kern County has spent two and half years and employed 125 people, mostly consultants and three full-time staff, on preparing the DEIR.[1] To date, the oil industry has paid 12.2 million dollars in accrued costs for this DEIR.[2] By any measure, this DEIR is a massive

RE: Request for Extension of Time Period for Public Review and Comment on Draft Environmental Impact Report (focused on Oil and Gas Local Permitting)

Dear Ms. Oviatt and Mr. Mynk,

I am writing this letter on behalf of my company, Gardiner Family, LLC, a local farm real estate holding company in Kern County. We are aware of the County of Kern's preparation of a Draft Environmental Impact Report ("DEIR") regarding the new permit process for oil and gas activities and associated analyses, and we appreciate the opportunity to review the 1,800+ pages of the DEIR and 5,800+ pages of Technical Appendices. However, the time provided for the public comment period of 45 days is simply too short to allow meaningful review and comment on such a massive document.

As stated in the cover letter of the DEIR, 45 days is the **minimum** time period for public review of the DEIR. A longer period of time for the comment period is appropriate given the scope, length and highly technical nature of the EIR.

We can appreciate the tremendous effort that has obviously been devoted in preparing the DEIR and associated Technical Appendices. We would like the necessary time allotted to review the documents and provide thorough and meaningful comments. In addition, this is an important opportunity to engage the public in the review process. Therefore, we respectfully request that the comment period be extended to allow for a public review period of 90 days, with the comment period closing on October 6, 2015. At the very least, the County should extend the public comment period to 60 days, which we understand is routinely provided for complex EIRs.

Sincerely,

Keith Gardiner, Manager
Gardiner Family, LLC

SUBJECT: Request for Extension of Time to Review and Comment on Draft Environmental Impact Report

Dear Ms. Oviatt and Mr. Mynk,

HOPKINS AG, INC. is a local farming operation in Kern County. We are aware that Kern County has prepared a draft Environmental Impact Report regarding the new permit process for the oil and gas activity. We appreciate the opportunity to review the 1800+ pages of the DEIR and 5800 pages of technical data. However, the time period of 45 days is simply too short to review and comment on such a massive document. A longer period of time for the comment period is appropriate due to the length and technical nature of the EIR.

We are starting our 2015 harvest period, making it difficult to devote sufficient time to read and review in such a short period. We appreciate the effort that has been devoted in preparing the DEIR, and would like the necessary time to review the documents and provide meaningful comments. This is an important opportunity to engage the public in the review process; therefore, we are requesting that the comment period be extended for a period of 90 days, or October, 2015.

Respectfully yours,

Michael D. Hopkins

July 20, 2015

Lorelei Oviatt

I am writing concerning the comment period for the Draft EIR on Oil and Gas permitting. Our company needs more than 45 days to discern how this proposed structure will impact our surface rights and the potential impact below and above ground.

We have farmland without mineral rights. Our farmland currently has neglected well heads, abandoned wells, storage tanks in disrepair, and debris left by oil companies. We have limited control over what they are doing to our land. And we have no idea how the below ground might be compromised by their negligence.

At over 1800 pages in the Draft EIR plus additional documents, there needs to be adequate time for a prudent analysis. Our experience with oil companies leads us to be very cautious with new ideas without a true understanding of our risks.

Please, we ask that you extend the public comment period to the maximum length. They have had substantial time to develop their plan. Please, give us enough time to realize it's true impact to us. Don't rush this important decision.

Sincerely

John Romanini

Respectfully yours,

Michael D. Hopkins

effort and, if approved with the concurrent zoning ordinance, will affect Kern County communities and the environment for at least the next 25 years.

In order to respond adequately to this massive undertaking and the multiple issues that the project poses, Environmental Advocates seek 60 more days than the minimum public review period. DEIR identifies "significant and unavoidable" harm for a number of environmental categories. Moreover, there is no statutory or regulatory deadline forcing the adoption of these ordinances or DEIR at any particular time. Despite the length and complexity of this report, and the fact it was issued during the summer when many people already have scheduled vacations, the current deadline for public comments is set at the statutory minimum of 45 days.

Furthermore, two additional reports that are directly related to this DEIR were released virtually at the same time, and, therefore, were not adequately incorporated into the DEIR as required. On July 1st, 2015, the Final Environmental Impact Report on SB-4, "Analysis of Oil and Gas Well Stimulation Treatments in California," was issued. On July 9th, 2015, a day after the DEIR was issued, the California Council on Science and Technology (CCST) released the final volumes of its report on the environmental effects of well-stimulation techniques. It was well-publicized that the CCST report would be released on July 9th, but the County released its DEIR without analyzing this independent scientific assessment of well stimulation treatments in California. Since the County did not take into account these additional voluminous studies, Environmental Advocates must now review and analyze how those studies impact the analysis and findings in the DEIR.

For the foregoing reasons, Environmental Advocates respectfully request an extension of sixty (60) days more than the minimum public review period to submit a comment. Comments would then be due on October 23rd, 2015.

RE: Request for Extension of Public Comment Period on Draft EIR re: Oil and Gas Permitting Changes

Dear Ms. Oviatt and Mr. Mynk,

I am writing on behalf of Sequoia Riverlands Trust, an accredited regional land trust that works with willing landowners in the Southern San Joaquin Valley, including Kern County, to conserve farmland and rangeland. We understand that your office has prepared a Draft Environmental Impact Report ("DEIR") regarding proposed changes to the permitting process for oil and gas activities and associated analyses, and we appreciate the opportunity to review the 1,800+ pages of the DEIR and 5,800+ pages of Technical Appendices. However, the 45-day public comment period is simply too short to allow meaningful review and comment on such a massive document.

As stated in the cover letter of the DEIR, 45 days is the **minimum** time period for public review of the DEIR. A longer comment period is appropriate given the scope of this project, the length and highly technical nature of the DEIR, and the legitimate interest of the public in a thorough and meaningful review process. **Therefore, we respectfully request that the public comment period be extended from 45 to 90 days, with a deadline for written comments of October 6, 2015.** If this is not possible, we would request that it at least be extended to 60 days, as is routinely done for complex EIRs.

Thank you for your consideration.

Sincerely,

Adam Livingston

RE: Request for Extension of Time Period for Public Review and Comment on Draft Environmental Impact Report (focused on Oil and Gas Local Permitting)

Dear Ms. Oviatt and Mr. Mynk,

I am writing this letter on behalf of my company, Sierra Land & Farming, LLC, a local farming operation in Kern County. We are aware of the County of Kern's preparation of a Draft Environmental Impact Report ("DEIR") regarding the new permit process for oil and gas activities and associated analyses, and we appreciate the opportunity to review the 1,800+ pages of the DEIR and 5,800+ pages of Technical Appendices. However, the time provided for the public comment period of 45 days is simply too short to allow meaningful review and comment on such a massive document.

As stated in the cover letter of the DEIR, 45 days is the **minimum** time period for public review of the DEIR. A longer period of time for the comment period is appropriate given the scope, length and highly technical nature of the EIR. Furthermore, we have received this enormous document for review right at the beginning of almond harvest, making it difficult at best to devote sufficient time to read and review in such a short timeframe.

We can appreciate the tremendous effort that has obviously been devoted in preparing the DEIR and associated Technical Appendices. We would like the necessary time allotted to review the documents and provide thorough and meaningful comments. In addition, this is an important opportunity to engage the public in the review process. Therefore, we respectfully request that the comment period be extended to allow for a public review period of 90 days, with the comment period closing on October 6, 2015. At the very least, the County should extend the public comment period to 60 days, which we understand is routinely provided for complex EIRs.

Sincerely,

Santos Martinez, Member

RE: Request for Extension of Time Period for Public Review and Comment on Draft Environmental Impact Report (focused on Oil and Gas Local Permitting)

Dear Ms. Oviatt and Mr. Mynk,

I am writing this letter on behalf of my company, South Valley Farms, a local farming operation in Kern County. We are aware of the Kern County's preparation of a Draft Environmental Impact Report ("DEIR") regarding the new permit process for oil and gas activities and associated analyses, and we appreciate the opportunity to review the 1,800+ pages of the DEIR and 5,800+ pages of Technical Appendices. However, the time provided for the public comment period of 45 days is simply too short to allow meaningful review and comment on such a massive document.

As stated in the cover letter of the DEIR, 45 days is the **minimum** time period for public review of the DEIR. A longer period of time for the comment period is appropriate given the scope of this project and the length and highly technical nature of the EIR. Furthermore, we have received this enormous document for review right at the beginning of harvest for our almond and pistachio trees, making it difficult at best to devote sufficient time to read and review in such a short timeframe.

We can appreciate the tremendous effort that has obviously been devoted in preparing the DEIR and associated Technical Appendices and would like the necessary time allotted to review the documents and provide thorough and meaningful comments. This is an important opportunity to engage the public in the review process. Therefore, we respectfully request that the comment period be extended to allow for a public review period of 90 days, with the comment period closing on October 6, 2015. At the very least, the County could extend the public comment period to 60 days (with the comment period closing on September 8, 2015 – given the weekend and Labor Day), which we understand is routinely provided for complex EIRs.

Sincerely,

RE: Request for Extension of Time Period for Public Review and Comment on Draft Environmental Impact Report (focused on Oil and Gas Local Permitting)

Dear Ms. Oviatt and Mr. Mynk,

Thanks for the tremendous effort required in preparing this DEIR document. Of course, a document of this size and complexity surely wasn't written in forty five days and it would seem most appropriate that the public be granted the courtesy of an unrushed review. I believe a ninety day comment period would be sufficient.

Thanks in advance for your kind consideration

Kind regards,

Bryan Bone

Re: Request for Extension of Time Period for Public Review and Comment on Draft Environmental Impact Report (focused on Oil and Gas Local Permitting)

Dear Mrs. Oviatt:

On behalf of 1,400 members of the Kern County Farm Bureau, I am writing to thank you and your staff for your hard work in preparing the final draft of the Oil and Gas Draft Environmental Impact Report ("DEIR"). We appreciate your time and commitment in regards to the many agricultural stakeholders meetings you hosted in preparation for this DEIR. The many growers who attended these meetings are aware of the intense nature of this document and will forever be grateful that you welcomed their suggestions and guidance in this process.

As you may know, this time of year is very busy for our growers and ranchers as many of them are in the middle of harvest season. We have been asked from some of our members to ask for an extension of the comment period. Given the length of this DEIR and the time it would take our members to review the entire document and prepare comment, we are asking you to consider an extension. We suggest extending the comment period to 60 days, giving us an extra 15 days to review the agricultural impacts of this document.

Kern County is the second largest agricultural producing county in the nation and as a Farm Bureau, we want to thank you again for your proactive relationship with our growers and your willingness to make yourself available to us. We hope we can continue this dialogue with you and our Board of Supervisors to provide meaningful solutions for Kern County.

Sincerely,

Greg Wegis
President

Subject: Draft Environmental Impact Report for Revisions to the Kern County Zoning Ordinance – 2015 C, focused on Oil and Gas Local Permitting - Request for Extension of Time Period for Public Review and Comment

Dear Ms. Oviatt and Mr. Mynk,

The North Kern Water Storage District (North Kern or District) appreciates the opportunity to review and comment on the subject Draft EIR. The EIR is of keen interest to the District since operation of the District's project to supply water to 60,000 acres of highly productive farmland routinely intersects with local oil operations.

Unfortunately, given the District's current singular focus on meeting landowner's water supply needs through the historic drought on the Kern River (the District relies on the Kern River for more than 90% of its surface water supplies), the District does not have resources available to review the voluminous documents comprising the Draft EIR (the Draft EIR itself (approximately 1,800 pages) and the Technical Appendices (approximately 5,800 pages)) within the allotted 45 day review period. Consequently, the District hereby requests that the County extend the current 45 day comment period for the Draft EIR (which is the minimum time period for public review) to at least 60 days and preferably 90 days. This additional review time is essential to allow the District to provide meaningful comments on the Draft EIR and will also assist the County in meeting its obligations for public disclosure and review under CEQA.

Very truly yours,

Richard Diamond
General Manager

RE: Request for Extension of Time Period for Public Review and Comment on Draft Environmental Impact Report (focused on Oil and Gas Local Permitting)

Dear Ms. Oviatt and Mr. Mynk,

I am writing this letter on behalf of my company, OMDC, LLC, a local farming operation in Kern County. We are aware of the County of Kern's preparation of a Draft Environmental Impact Report ("DEIR") regarding the new permit process for oil and gas activities and associated analyses, and we appreciate the opportunity to review the 1,800+ pages of the DEIR and 5,800+ pages of Technical Appendices. However, the time provided for the public comment period of 45 days is simply too short to allow meaningful review and comment on such a massive document.

As stated in the cover letter of the DEIR, 45 days is the minimum time period for public review of the DEIR. A longer period of time for the comment period is appropriate given the scope of this project and the length and highly technical nature of the EIR. Furthermore, we have received this enormous document for review right at the beginning of harvest for our almond trees, making it difficult at best to devote sufficient time to read and review in such a short timeframe.

We can appreciate the tremendous effort that has obviously been devoted in preparing the DEIR and associated Technical Appendices and would like the necessary time allotted to review the documents and provide thorough and meaningful comments. This is an important opportunity to engage the public in the review process. Therefore, we respectfully request that the comment period be extended to allow for a public review period of 90 days, with the comment period closing on October 6, 2015. At the very least, the County should extend the public comment period to 60 days, which we understand is routinely provided for complex EIRs.

Sincerely,

Edwin A. Camp

RE: Request for Extension of Time Period for Public Review and Comment on Draft Environmental Impact Report (focused on Oil and Gas Local Permitting)

Dear Ms. Oviatt and Mr. Mynk,

I am writing this letter on behalf of my company, R29, LLP, a local farming operation in Kern County. We are aware of the County of Kern's preparation of a Draft Environmental Impact Report ("DEIR") regarding the new permit process for oil and gas activities and associated analyses, and we appreciate the opportunity to review the 1,800+ pages of the DEIR and 5,800+ pages of Technical Appendices. However, the time provided for the public comment period of 45 days is simply too short to allow meaningful review and comment on such a massive document.

As stated in the cover letter of the DEIR, 45 days is the minimum time period for public review of the DEIR. A longer period of time for the comment period is appropriate given the scope of this project and the length and highly technical nature of the EIR. Furthermore, we have received this enormous document for review right at the beginning of harvest for our almond trees, making it difficult at best to devote sufficient time to read and review in such a short timeframe.

We can appreciate the tremendous effort that has obviously been devoted in preparing the DEIR and associated Technical Appendices and would like the necessary time allotted to review the documents and provide thorough and meaningful comments. This is an important opportunity to engage the public in the review process. Therefore, we respectfully request that the comment period be extended to allow for a public review period of 90 days, with the comment period closing on October 6, 2015. At the very least, the County should extend the public comment period to 60 days, which we understand is routinely provided for complex EIRs.

Appendix D-1

Kern County Zoning Ordinance Amendments Public Workshop Notes

This page intentionally left blank.

Revisions to the Kern County Zoning Ordinance, 2015 C

Oil and Gas Activities

Joint Briefing Workshop

Lorelei H. Oviatt, AICP
Director
Kern County Planning
And Community Development Department

July 27,2015

Oil and Gas Activities

- San Joaquin Valley Portion
  - 2.3 Million Acres – existing and potential
- Largest oil producing county in California
- 2012- 43,000 active wells – 78% of all wells in CA
- 80% of oil and natural gas produced in state.

California State Law

- Local government controls land use through zoning
- Underground and drilling activities managed by State Division of Oil, Gas and Geothermal – DOGGR
- California Environmental Quality Act – implemented by either State or local government
- State constitution and Attorney General preempt local regulation of underground oil and gas extraction activities

Local Permitting Program Elements

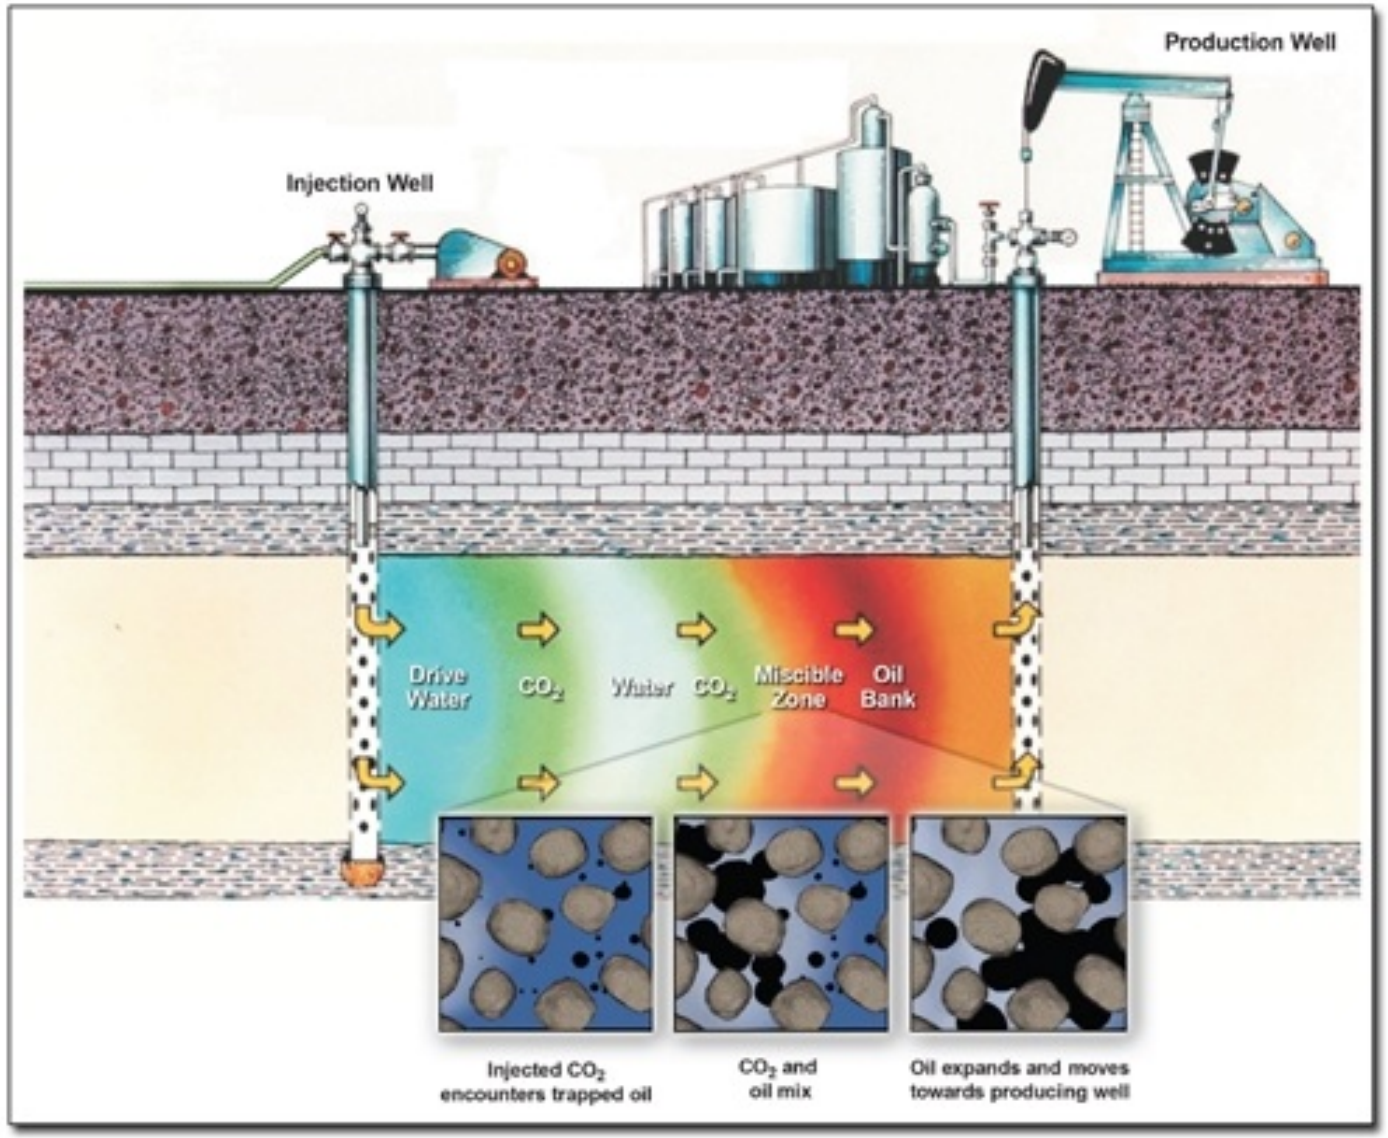
- Amendments to the Kern County Zoning Ordinance Text
- New Local Permit and Process
- Environmental Impact Report = Mitigation
- New GIS Gateway and Electronic Permit System
- New Staffing + Fees
- New Programs (Small Producers Assistance, Legacy Program)

California Oil Activities
Well Drilling

- Drilling a hole = wellbore
- Range in depth down to 10,000 feet
- Metal pipe= casing placed and cement pumped
- Cement pushes out around the bottom of casing

  flows up space between wellbore and casing to surface
- Cement hardens – forms bond
- Holes made in casing opposite reservoir
- Oil or Gas moves into the casing and up to surface

Explanation of Injection Well Process



California Oil Activities
Well Plug and Abandonment

- Oil or gas reservoir depleted or nothing found
- Cement places in the wellbore or casing at regulated intervals to act as seal
- Cement plugs required
  - Zone plugs – across the reservoir
  - Across the base of fresh water
  - Surface plug
  - Other plugs may be required
  - Hole is filled with drilling mud

California Oil Activities Groundwater protection

- During drilling, specially designed fluid pumped and circulated through wellbore and to surface

- Function of Drilling Fluid:
  - Lifts rock cuttings to the surface
  - Cool the drill bit
  - Counteract downhole formation pressure to keep out groundwater and prevent mixing
  - Well completion – casing cemented in wellbore

California Oil Activities
Well Stimulation

- Hydraulic Fracturing : high pressure injection of a mix of fluids and substances into a reservoir
- Vertical wells – conventional reservoirs
- Pressure fractures rock creating channels
- Fluids removed – substance (sand) keeps channels open
- Oil or Gas flows to surface
- Fluid mix is primarily water with small percentage of chemicals

Study Area

- Project Area
  - 3700 Square Miles (2.3 million acres)
  - San Joaquin Valley Floor Portion of Kern County
  - Excludes all City/State and Federal Jurisdictions
  - Includes all State and Federal Minerals under Private Surface

- Subareas
  - Project Area Split into Three Subareas
    - Western – West of I-5 Corridor
    - Central – Between SR-99 and I-5
    - Eastern – East of SR-99

Study Area

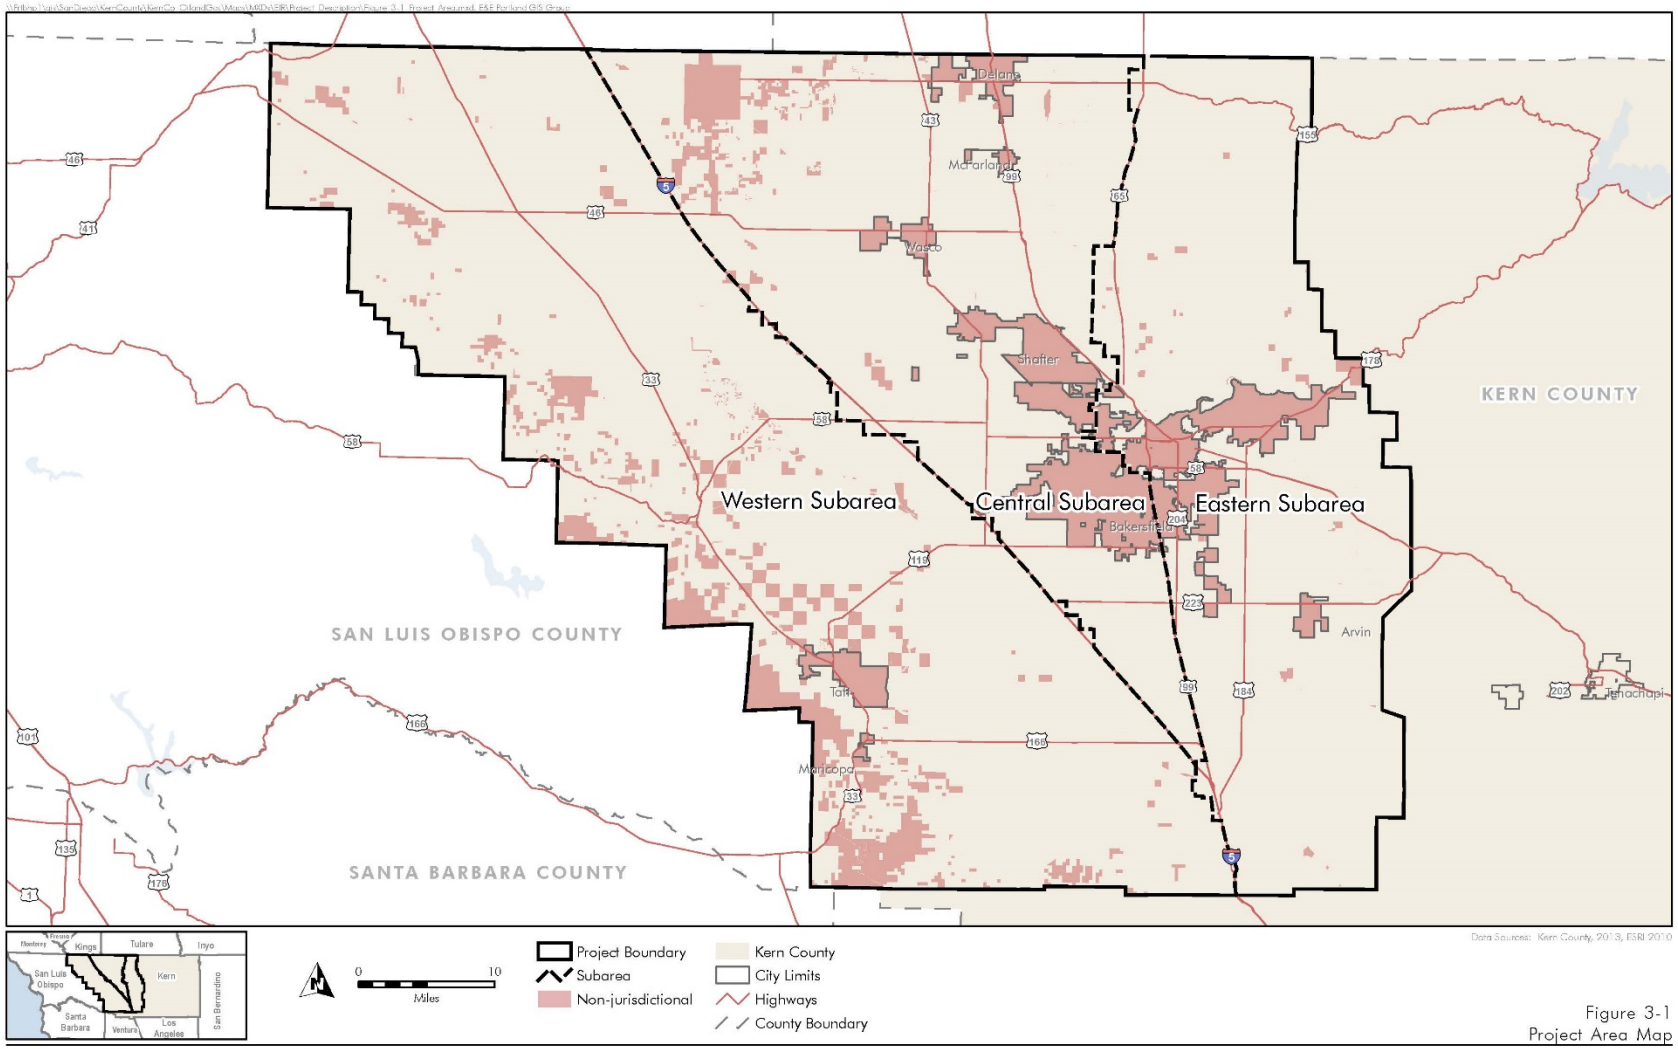


Figure 3-1
Project Area Map

Existing Zoning Ordinance

- Chapter 19.98 (Oil and Gas Production)
  - Allows for “Unrestricted” Drilling on Lands Zoned: A, A-1, M-2, M-3 and NR
  - Allows for “Ministerial” Drilling on Lands Zoned: M-1, RF, DI and PE
  - Conditional Use Permit on Lands Zoned: E, R-1, R-2, R-3, CO, C-1, C-2, CH and PL
  - Currently Prohibited on Lands Zoned: MP and OS

Permitting

- New Tier System for Identifying Lands for Oil and Gas Activities showed as a figure in the ordinance
  - Tier 1 Area
    - Tier 1 is shown as the area in which current oil and gas activity is the primary land use. The well and activity densities preclude almost all other uses
  - Tier 2 Area
    - Tier 2 includes all lands within the following agricultural zone districts that are not within Tier 1 and are Zoned A or A-1

Permitting

- Tier 3 Area
  - Tier 3 is shown as zone districts where historic drilling activity have been or could have been approved as “Unrestricted” or “Ministerial” under the existing Zoning Ordinance, and those areas that are not categorized as Tiers 1 or 2

- Tier 4 Area
  - Tier 4 consists of all zone districts where oil or gas exploration and production activities are currently or proposed to be allowed with a CUP

Permitting

- Tier 5 Area
  - Tier 5 are areas include current and future Specific Plan boundaries either adopted with a SP Zone District or include specific provisions for oil and gas. Oil or gas activities would be allowed with a CUP or as permitted by the regulations contained within the adopted Specific Plan(s)

- Non-Jurisdictional and Prohibited Use Areas
  - Areas where Kern County currently does not have land use authority, including lands under jurisdiction of the Federal Government, State of California, and incorporated cities. Also includes OS Zoned Land where use is prohibited

Permitting (Tier Map)

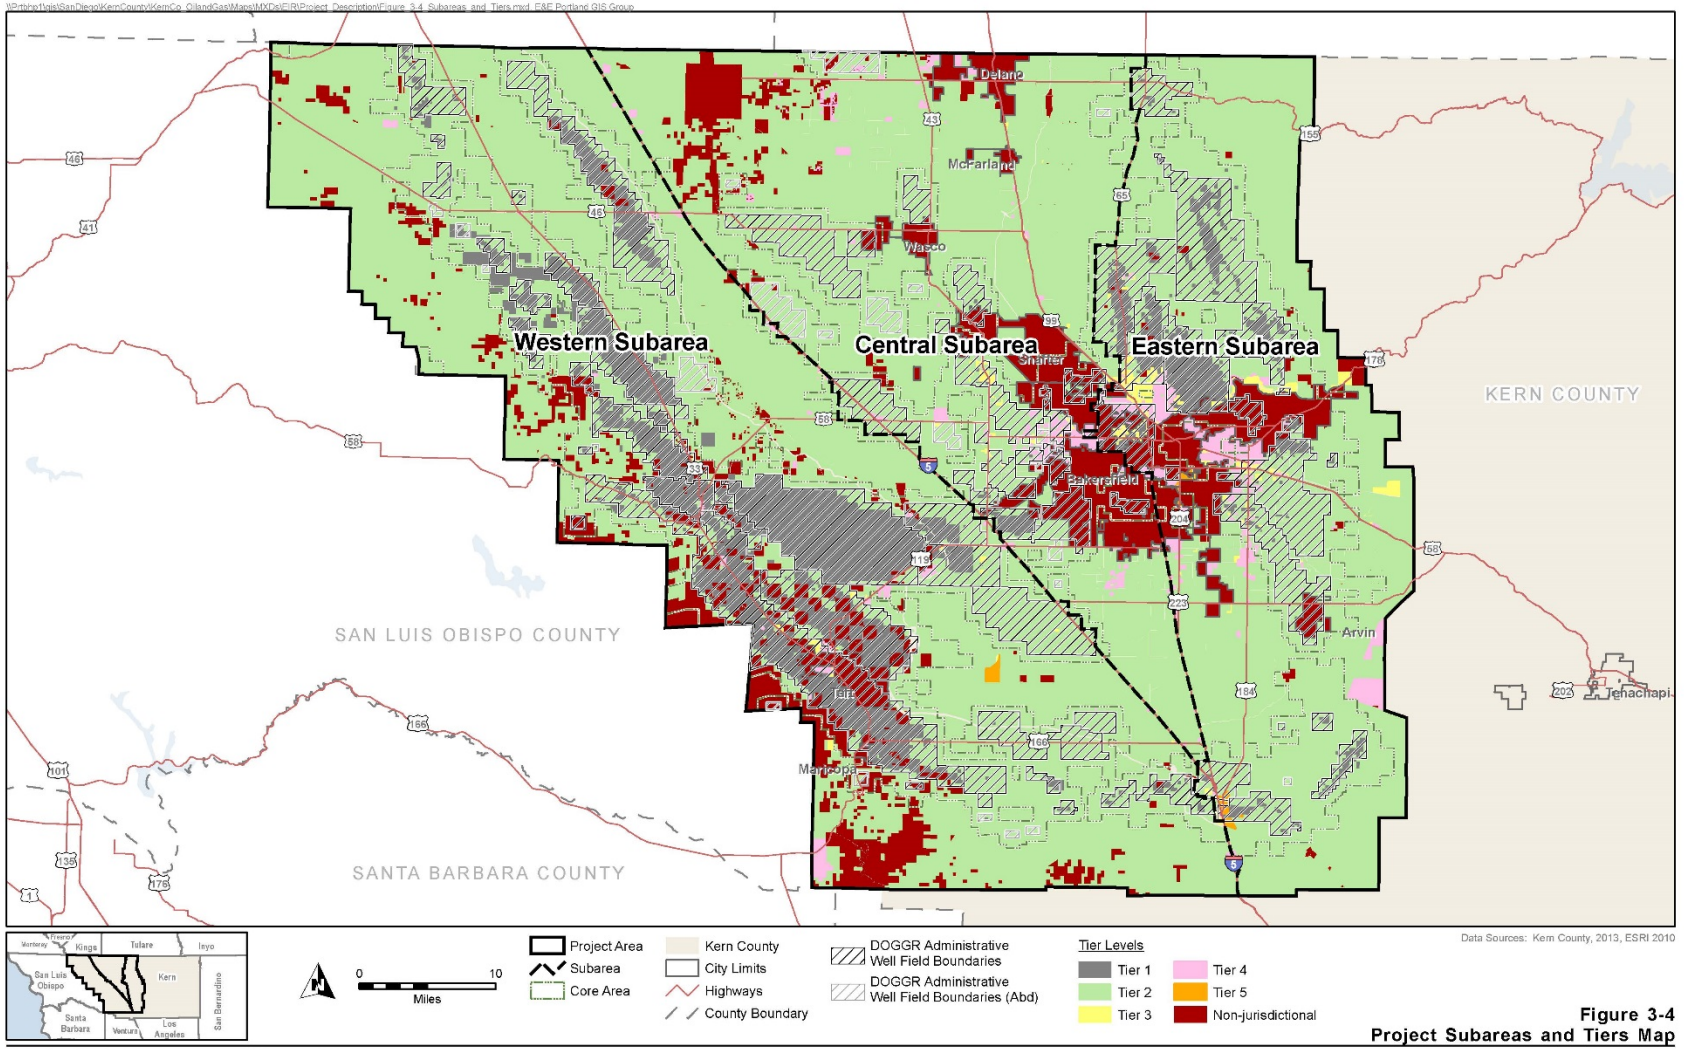

Figure 3-4
Project Subareas and Tiers Map

Admin. Draft Environmental Impact Report
Amendment to Chapter 19.98 (Oil and Gas Production) - Kern County Zoning Ordinance

June, 2015

General Over View

- Oil and Gas Conformity Review
- One Pathway – Tier 1
- Two Pathways – Split Estate – Tier 2,3,5
- Notification of Surface Owner in all pathways
- Signature of Surface Owner required on Site Plan for Tier 2, 3 and 5.

Permitting

- Oil and Gas Conformity Review Process
  - 30 days before – notify surface owner
  - 1st Review – 7 business days
  - 2nd Review - 3 business days
  - 3rd Review – mandatory in-person meeting for assistance
  - Self Certification of compliance
  - Prior to any activity covered – operator to have both Kern County permit and DOGGR permit

Permitting

- Minor Activity Review Process
  - 1st Review – 7 business days
  - 2nd Review - 3 business days
  - 3rd Review – mandatory in-person meeting for assistance
  - Self Certification of compliance
  - Prior to any activity covered – operator to have both Kern County permit and DOGGR permit [and other applicable permit(s), e.g., from Air District or Water Board]

Split Estate

- Private Land:
  - Surface owner and mineral owner different
- Private Land:
  - Surface owner owns surface down to 500 feet, or Mineral owner different but does not own surface
- Private/Federal Land:
  - Surface owner owns private surface
  - Federal government owns minerals (BLM)

Surface Owners Concerns

- Failure to contact the owner for discussions
- O&G site plans fail to accommodate surface operations
- Lack of maintenance of operations during and after construction
- Disagreement with O&G operators and DOGGR over management and definition of Idle and Abandoned wells

Industry Concerns

- Additional time and money to obtain County permits
- Giving surface owners more rights than are allowed by law that impede the mineral owners right to drill
- After full compliance with all standards allowing for more opportunities to add uncertainty to process.

Split Estate

No signature on Site Plan (Tier 2,3, 5)

- Oil and Gas Conformity Review Process
  - 30 days before – notify surface owner
    - (runs concurrently with state law Civil Code notice requirement)
  - 1st Review – 30 calendar days
    - Invitation for educational meeting with Surface Owner
  - 2nd Review - 30 calendar days

Split Estate

No signature on Site Plan (Tier 2, 3 and 5)

- Permit Issued –30 Calendar Day Waiting period
- Building inspector on site for compliance as well as expert consultants as needed – all costs paid by applicant.
- At any time – surface owner signature = 7 day permit review or self-certification
- Prior to any activity covered – operator to have both Kern County permit and DOGGR permit

- Minimum 120 Day pathway without signature
  - (90 days longer than required for compliance with state Civil Code notice requirement)

Small Producers Assistance

- 1 to 3 wells in a calendar year
  - Not a subsidiary of a larger company that drills more than 3 wells per year
- Handbook explaining all steps and include examples to use
- County Consultant – standard cost per acre for biology, cultural, drainage and even site plan prep – optional

Revisions to the Kern County Zoning Ordinance, 2015 C

Oil and Gas Activities

Joint Briefing Workshop

Lorelei H. Oviatt, AICP
Director
Kern County Planning
And Community Development Department

July 27,2015

California Environmental Quality Act CEQA

- TO INFORM Decision makers about significant environmental effects
- TO IDENTIFY ways environmental damage can be avoided
- TO PREVENT avoidable environmental damage
- TO DISCLOSE to the public why a project is approved even if it leads to environmental damage

Process

- Notice of Preparation
  - Circulated on August 30, 2013
  - Workshops Held in:
    - Bakersfield
    - Taft
    - Lost Hills
    - Shafter

Draft EIR

- State Clearinghouse Number: 2013081079

- Review Period: July 8, 2015 – August 24, 2015
- Draft EIR available on Planning Website:
  - http://pcd.kerndsa.com/planning/oil-gas-zoning-amendment
  - http://pcd.kerndsa.com/planning/environmental-documents/421-oil-gas-deir

Ministerial Permits

- CEQA applies to any action when a project requires discretionary approval by a state or local governmental body.
- Projects may also require ministerial approvals that must comply with general plans and local ordinances such as building permits or marriage licenses.
- These ministerial permit approvals cannot be denied as long as the proponent meets the specifications detailed in the permit or license requirements, including applicable CEQA mitigation measures.
- CEQA does not apply when only ministerial approval is necessary. Under the proposed ordinance amendments, most O&G activities will require ministerial permits including compliance with County ordinance and EIR mitigation measures, and compliance with other laws

DEIR Contents

- 2 Volumes (Chapters 1-11) and Appendices
  - Project-Level Analysis
- Baseline = 2012
- Maximum New Wells per Year: 3647
- Average New Wells: 1800-2000

Agricultural Resources
Chapter 4.2

- Total Acres of Prime/Unique/Statewide Farmland in Tier 2: 828,973
- Maximum Acres of Conversion per Year: 298
- Maximum Acres of Conversion in Tier 2 (25 Years): 7,450

Agricultural Resources

Chapter 4.2

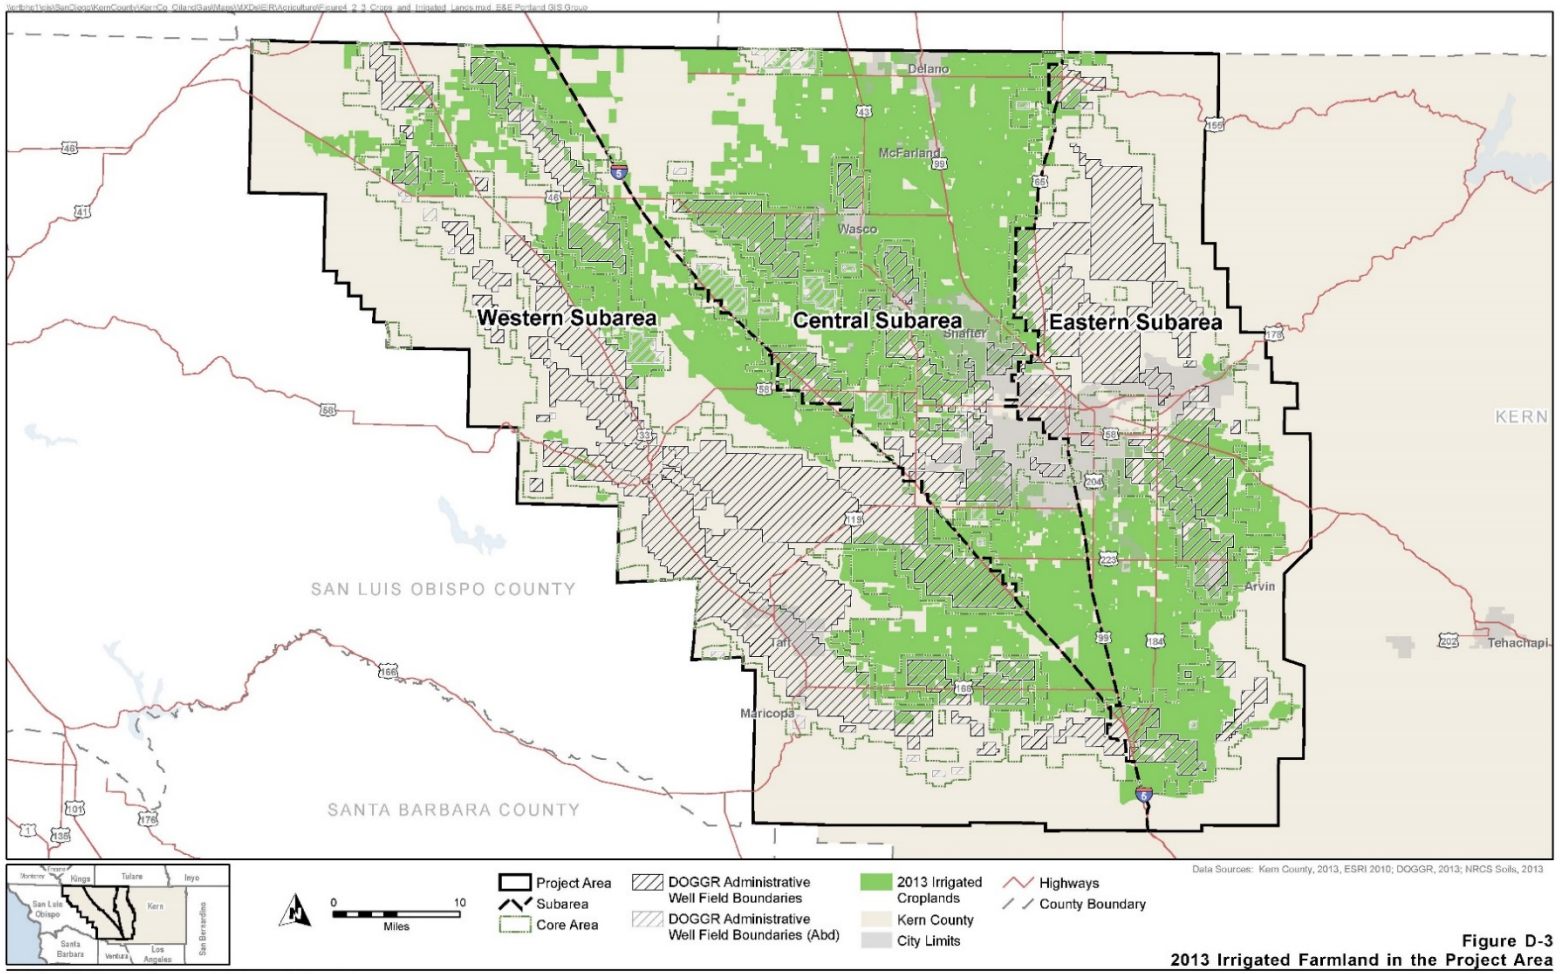

Figure D-3
2013 Irrigated Farmland in the Project Area

Agricultural Resources
Chapter 4.2

- Mitigation Measures
  - Minimize ag land disturbance (e.g., use existing roads)
  - Require Compensation of Loss of Ag Land at a Ratio of 1:1
  - Protection of Crops From:
    - Surface Water Runoff
    - Stormwater Control
    - Spill Prevention
    - Dust
- Level of Significance:
  - Project Level: Less Than Significant with Mitigation
  - Cumulative: Significant and Unavoidable

Air Quality
Chapter 4.3

- Criteria Pollutants (Tons per Year):
  - ROG – 11,551 (2016) to 14,300 (2035)
  - NOx – 22,281 (2016) to 16,658 (2035)
  - PM^{10} – 2,747 (2016) to 3,358 (2035)

- Criteria Pollutants (Tons per Well, Max 3647 Wells/per Year): 3.22 (2016) to 2.12 (2035)

Air Quality
Chapter 4.3

- Mitigation Measures
  - Reduction in criteria pollutants through:
    - Dust minimization measures
    - Payment of fees or completion of applicant initiated programs, both through an Emission Reduction Agreement (ERA)

- Level of Significance:
  - Project Level: Less Than Significant with Mitigation, Significant and Unavoidable for Odors
  - Cumulative: Significant and Unavoidable

Green House Gas Emissions

Chapter 4.7

- Project Annual GHG Emissions (CO_{2e}/Year): 25.96 Million Metric Tons
- Methane emissions will be limited by new CARB Rules expected to be adopted by end of 2015
- Project Annual GHG Emissions (Tons per Well): 6500
- Covered Emissions of 25,000 MT or more of CO_2e per data year are covered under the Cap-and-Trade Program

Green House Gas Emissions

Chapter 4.7

- Mitigation Measures
  - Oil and Gas Facilities not exceeding may voluntarily opt-in to Cap-and-Trade
  - Reduction in criteria pollutants through payment of fees or completion of applicant initiated programs, both through an Emission Reduction Agreement (ERA)

- No Net-Increase of GHG Emissions (e.g., through ERA) for emissions not subject to Cap-and-Trade)

- Level of Significance:
  - Project Level: Less Than Significant with Mitigation, Significant and Unavoidable for Conflicts with GHG policies
  - Cumulative: Significant and Unavoidable

Health and Safety

Chapters 4.7, 4.8, 4.12, 4.14

- Management and Mitigation
- Pipelines
  - Identify All Proposed and Existing Pipelines
  - Provide Integrity Testing and future monitoring for Lines within 200 Feet of A Sensitive Receptor
- Well Stimulation
  - Comply with all New State Regulations (SB4)

Health and Safety

Chapters 4.7, 4.8, 4.12, 4.14

- Noise
  - Identify all Sensitive Receptors (Residences, Schools, Churches, Hospitals, etc.) within 3,000 feet of Drilling pad
- Well Placement a minimum of 190 Feet from Sensitive Receptors
  - Provide Noise Analysis for Deeper Drilling Activity

Health and Safety

Chapters 4.7, 4.8, 4.12, 4.14

- Health Risk Assessment
  - Identify all Sensitive Receptors within 3,000 feet of Drilling
  - Well Placement a minimum of 367 Feet from Sensitive Receptors for Wells over 10,000 Deep

- Fire
  - First 2000 wells drilled for industrial firefighting vehicle (not to exceed $850,000)

Health and Safety

Chapters 4.7, 4.8, 4.12, 4.14

- Sheriff
  - Per well for funding for County Sheriff's Department for the Rural Crimes Unit
- Transportation and Traffic
  - Payment per well for roads maintenance of roads utilized by the oil and gas industry
- Level of Significance:
  - Project Level: Less Than Significant with Mitigation
  - Cumulative: Less Than Significant with Mitigation

Estimated Permitting Costs Per Well

- County Permit Fees $1190
- Sheriff Mitigation $425
- Fire equipment $150 (2- 3 years only)
- Traffic $1500

$3265 per well

Variable:

Air – Emissions reductions - $16,459 to $8,000 to ??

Biology - $3200 to $1200 to ?? a newly disturbed acre

Loss of Ag Land - $2500 to $1200 an acre

Water

Chapters 4.9, 4.17

- Cumulative Over Draft in a Single-Dry Year:
  - 750,710 AF (2015) to 817,127 AF (2035)

- Project M&I Water Demand (per Year)
  - 9,660 AF (2015) to 11,760 AF (2035)

- Produced Water Generated (per Year)
  - 125,877 AF (2012)
- Water Used for Well Stimulation: 589 AF
- Total Well Stimulations from 2011-2014:1986

Water

Chapters 4.9, 4.17

- Mitigation Measures
  - Prepare drainage Plans for Potential Run-off
  - Injection Activities subject to Underground Injection Control
  - Oil and Gas Applicants to increase re-use of Produced Water with appropriate treatment and monitoring
  - Coordination/Participation with County on formation Groundwater Sustainability Agency and Plan

- Level of Significance:
  - Project Level: Significant and Unavoidable
  - Cumulative: Significant and Unavoidable

Biological Resources
Chapter 4.4

- Estimated New Disturbance (Acres/Year): 4,856

- Mitigation
  - Reduction in potential take of a protected species through:
    - Worker Education
    - Avoidance and Minimization
    - Preconstruction surveys
    - Habitat compensation at a ratio of ½:1 to 1:1

Biological Resources

Chapter 4.4

- Tools
  - Valley floor HCP and Potential NCCP – In progress
  - DataBasin - Website displays resource information along with other special data within the Project Area. Website is a science-based mapping and analysis platform that supports learning, research, and sustainable environmental stewardship (www.databasin.org)

- Level of Significance:
  - Project Level: Less Than Significant with Mitigation
  - Cumulative: Significant and Unavoidable

Cultural Resources
Chapter 4.5

- Estimated archeological density of one site per 53 Acres within Project Area
- Native American archeological density of one site per 463 Acres within Project Area
- Mitigation
  - Reduction in destruction of potentially significant cultural remains or artifacts through:
    - Worker education
    - Preconstruction surveys
- Level of Significance:
  - Project Level: Less Than Significant with Mitigation
  - Cumulative: Significant and Unavoidable

Alternatives
Chapter 6.0

- **Alternatives Eliminated from Further Consideration**
- Eight were eliminated from further consideration found to be infeasible or failed to meet project objectives. Include:
  - Drilling Ban on Agriculturally Productive Land
  - Drilling Ban on All Lands
  - Larger Project Area
  - More Well within Project Footprint
  - Fewer Wells within the Project Footprint
  - Offsite, Renewable Energy (Wind and Solar
  - Zero Net Gain

Alternatives

Chapter 6.0

- **Alternatives Analyzed in the EIR**
  - Alternative 1: No Project Alternative
  - Alternative 2: Conditional Use Permit Required Alternative
  - Alternative 3: Reduced Ground Disturbance Alternative
  - Alternative 4: No Hydraulic Fracturing Alternative
  - Alternative 5: Low-Emission Enhanced Oil Recovery Alternative
  - Alternative 6: Recycled Water Alternative

- **Environmentally Superior Alternative**
  - Alternative 5, the Low-Emission Enhanced Oil Recovery

Findings

CEQA Sections 15091, 15093 and 15097

- Presented in Staff Reports

Revisions to the Kern County Zoning Ordinance, 2015 C

Oil and Gas Activities

Shafter Workshop

August 10,2015

Lorelei H. Oviatt, AICP

Director

Kern County Planning

And Community Development Department

Oil and Gas Activities

- San Joaquin Valley Portion
- 2.3 Million Acres – existing and potential
- Largest oil producing county in California
- 2012- 43,000 active wells – 78% of all wells in CA
- 80% of oil and natural gas produced in state.

California State Law

- Local government controls land use through zoning
- Underground and drilling activities managed by State Division of Oil, Gas and Geothermal – DOGGR
- California Environmental Quality Act – implemented by either State or local government
- State constitution and Attorney General preempt local regulation of underground oil and gas extraction activities

Local Permitting Program Elements

- Amendments to the Kern County Zoning Ordinance Text
- New Local Permit and Process
- Environmental Impact Report = Mitigation
- New GIS Gateway and Electronic Permit System
- New Staffing + Fees
- New Programs (Small Producers Assistance, Legacy Program)

California Oil Activities Coverage

- Well Drilling
- Well Plug and Abandonment
- Groundwater Protection
- Well Stimulation
- Related Land Use Impacts on Surface

Study Area

- Project Area
  - 3700 Square Miles (2.3 million acres)
  - San Joaquin Valley Floor Portion of Kern County
  - Excludes all City/State and Federal Jurisdictions
  - Includes all State and Federal Minerals under Private Surface

- Subareas
  - Project Area Split into Three Subareas
    - Western – West of I-5 Corridor
    - Central – Between SR-99 and I-5
    - Eastern – East of SR-99

Study Area

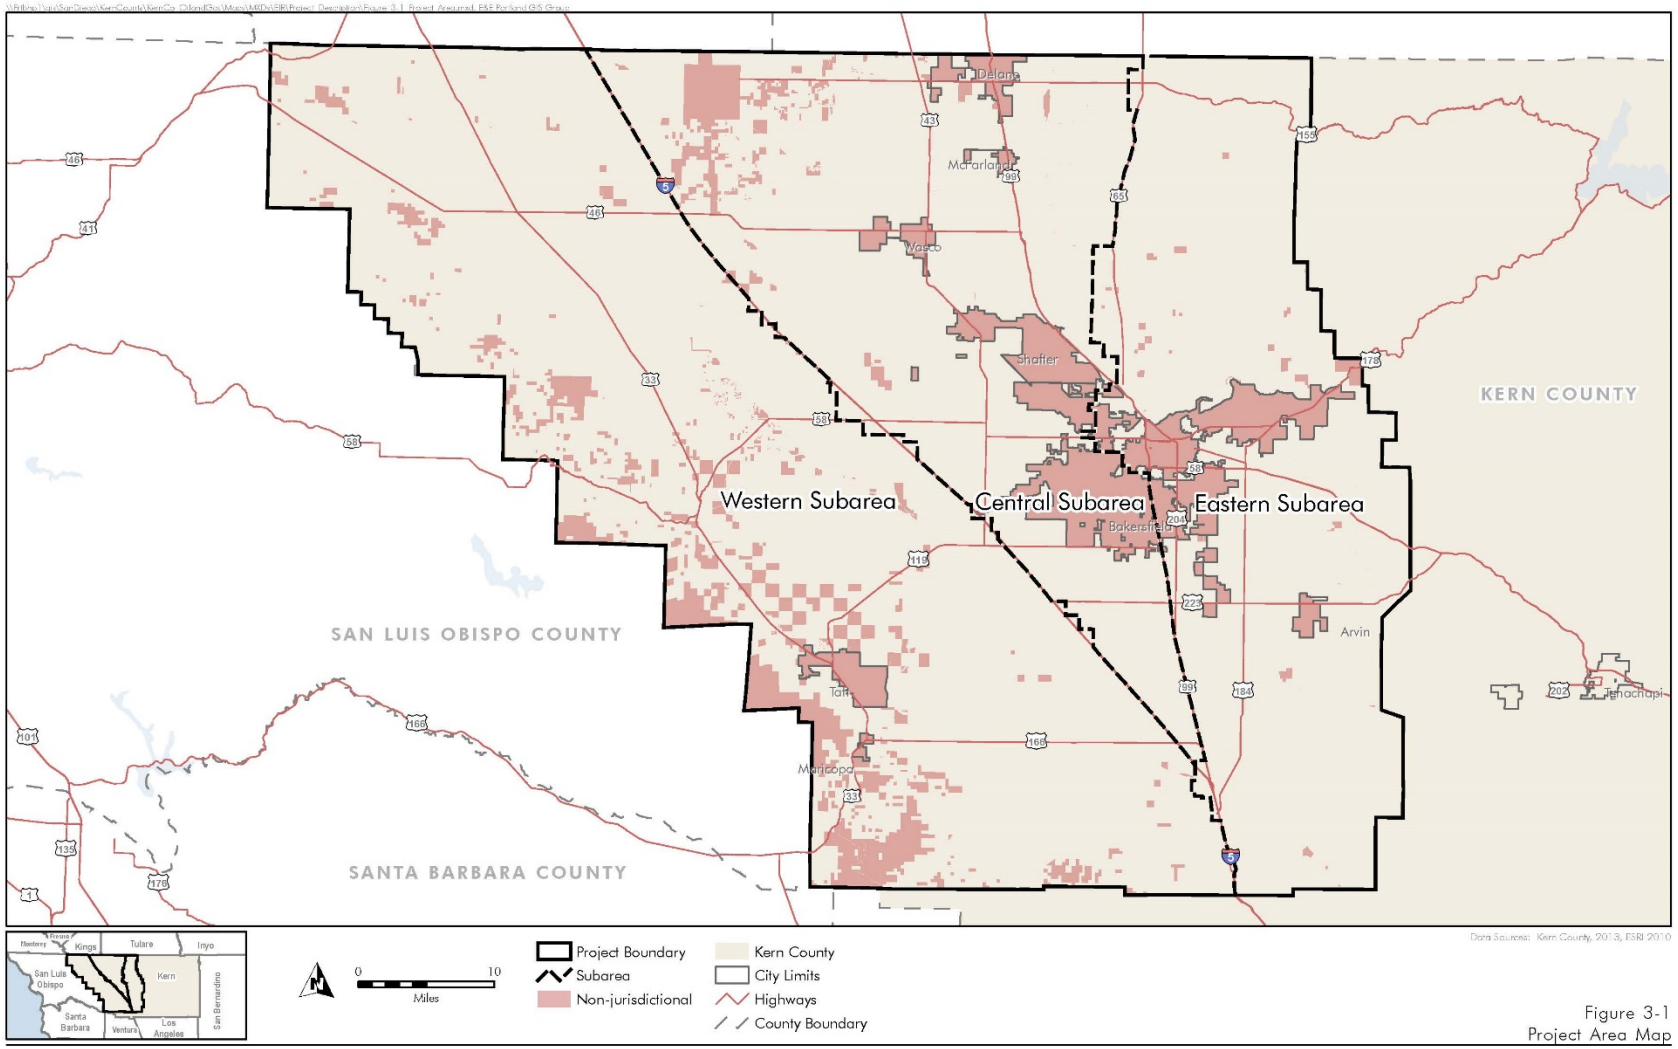

Figure 3-1
Project Area Map

Permitting

- New Tier System for Identifying Lands for Oil and Gas Activities showed as a figure in the ordinance
  - Tier 1 Area – Oil and gas primary land use
  - Tier 2 Area –mixed lands –Ag and Oil
  - Tier 3 Area – historical drilling – not in Tier 1 or 2
  - Tier 4 Area – Needs a Conditional Use Permit
  - Tier 5 Area – Specific Plan areas
  - Non-jurisdictional – Federal, State or Cities

Permitting (Tier Map)

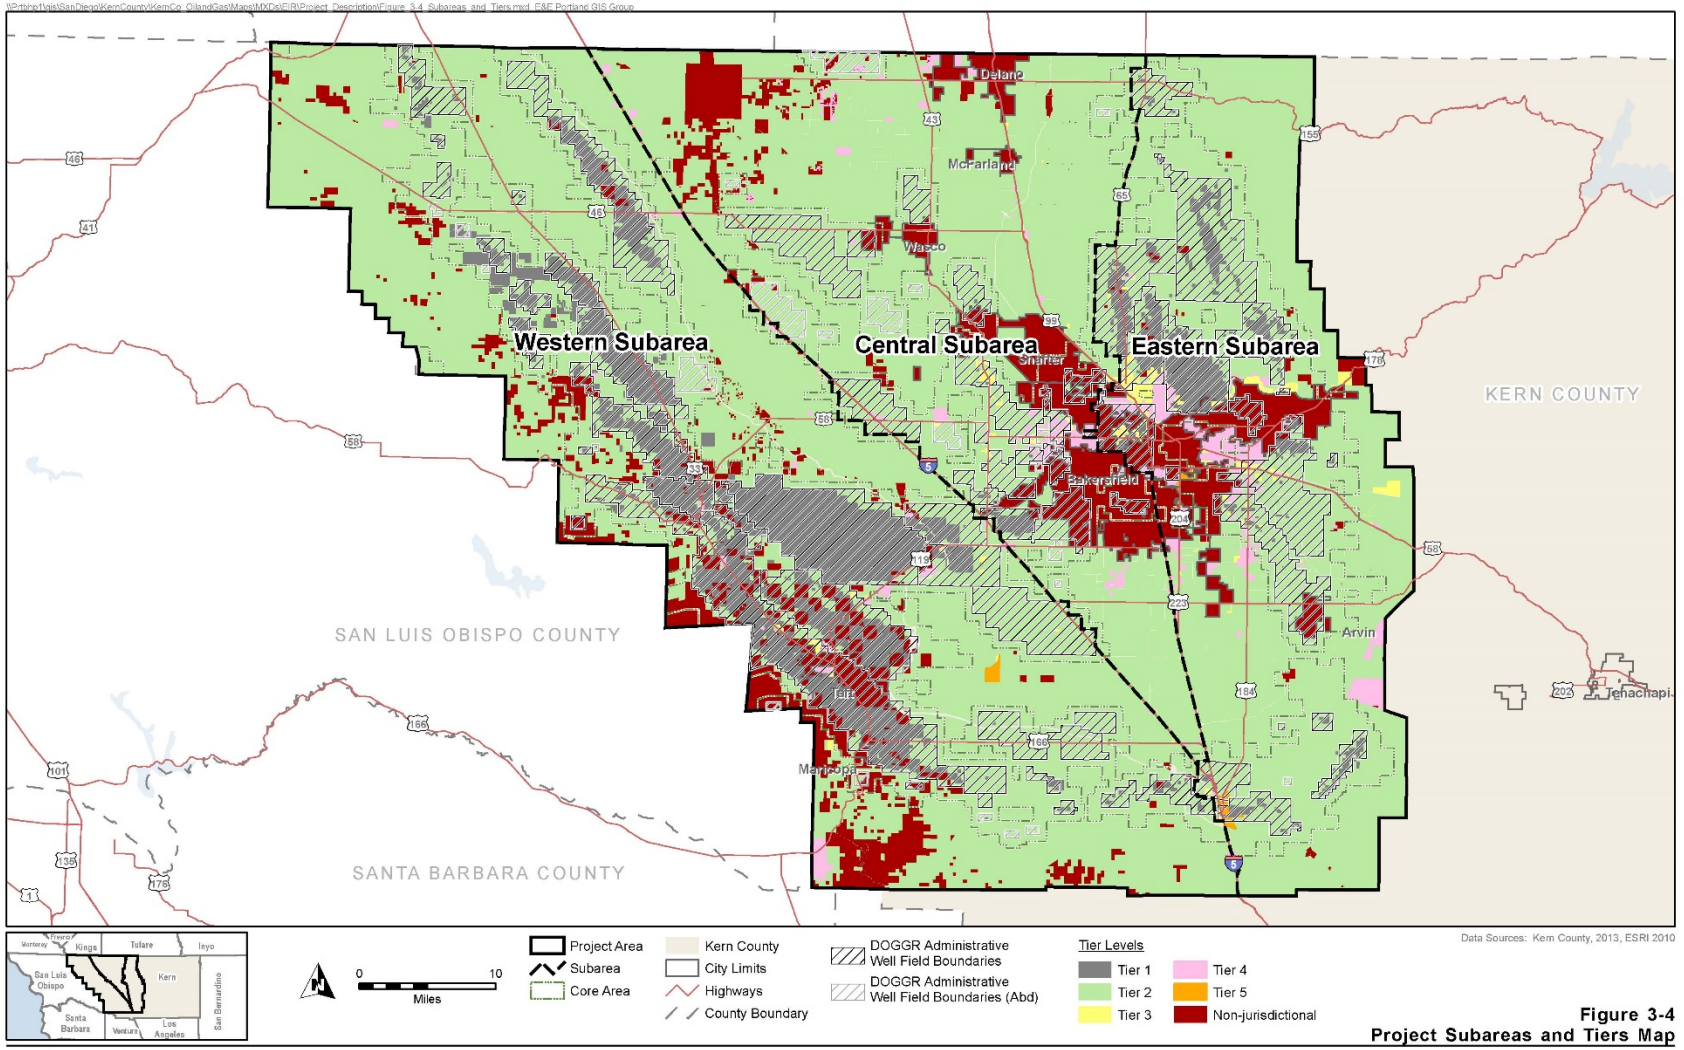

Figure 3-4
Project Subareas and Tiers Map

Admin. Draft Environmental Impact Report
Amendment to Chapter 19.98 (Oil and Gas Production) - Kern County Zoning Ordinance

June, 2015

General Over View

- Oil and Gas Conformity Review
- One Pathway – Tier 1
- Two Pathways – Split Estate – Tier 2,3,5
- Notification of Surface Owner in all pathways
- Signature of Surface Owner required on Site Plan for Tier 2, 3 and 5.

Permitting

- Oil and Gas Conformity Review Process
  - with Signature of Surface Owner (7 day + 3 day)
- Oil and Gas Conformity Review Process
  - without Signature of Surface Owner (120 days)
- Minor Activity Review
- Like a Building Permit – Checklist compliance

Split Estate

- Private Land:
  - Surface owner and mineral owner different

Private Land:

Surface owner owns surface down to 500 feet, or

Mineral owner different but does not own surface

Private/Federal Land:

Surface owner owns private surface

Federal government owns minerals (BLM)

Related Programs

- Small Producers Assistance

- Surface Owners Education Workshops
- Community Education Workshops
- Legacy Oil Activity Program

California Environmental Quality Act CEQA

- TO INFORM Decision makers about significant environmental effects
- TO IDENTIFY ways environmental damage can be avoided
- TO PREVENT avoidable environmental damage
- TO DISCLOSE to the public why a project is approved even if it leads to environmental damage

Process

- Notice of Preparation
  - Circulated on August 30, 2013- Workshops

Draft Environmental Impact Report

Review Period – July 8, 2015 to Sept 11, 2015

DEIR Contents

- 2 Volumes (Chapters 1-11) and Appendicies
  - Project-Level Analysis
- Baseline = 2012
- Maximum New Wells per Year: 3647
- Average New Wells: 1800-2000

Summary Impacts

- Agricultural Resources
  - Maximum conversion per year : 298 acres = 7,450 Acres in 25 years

- Air Quality
- Criteria Pollutants (Tons per Year):
- ROG – 11,551 (2016) to 14,300 (2035)
- NOx – 22,281 (2016) to 16,658 (2035)
- PM^{10} – 2,747 (2016) to 3,358 (2035)

- Criteria Pollutants (Tons per Well, Max 3647 Wells/per Year): 3.22 (2016) to 2.12 (2035)

Oil and Gas M&I, Agricultural, and Urban M&I Average Year Demand in Study Area (AF)

	2015	2035
Oil and Gas	9,660	11,761
Agriculture	2,872,945	2,872,945
Urban M&I	237,029	301,736
Total	3,119,634	3,186,442

Summary Selected Mitigation

- AGRICULTURAL RESOURCES
- Minimize ag land disturbance (e.g., use existing roads)
- Require Compensation of Loss of Ag Land at a Ratio of 1:1
- Protection of Crops From:
  - Surface Water Runoff
  - Stormwater Control
  - Spill Prevention
  - Dust

- AIR QUALITY
  - Reduction in criteria pollutants through:
    - Dust minimization measures
    - Payment of fees or completion of applicant initiated programs, both through an Emission Reduction Agreement (ERA)

Health and Safety

Chapters 4.7, 4.8, 4.12, 4.14

- Pipelines
  - Identify All Proposed and Existing Pipelines
  - Provide Integrity Testing and future monitoring for Lines within 200 Feet of A Sensitive Receptor
- Well Stimulation
  - Comply with all New State Regulations (SB4)

Health and Safety

Chapters 4.7, 4.8, 4.12, 4.14

- Noise
  - Identify all Sensitive Receptors (Residences, Schools, Churches, Hospitals, etc) within 3,000 feet of Drilling pad
- Well Placement a minimum of 190 Feet from Sensitive Receptors
  - Provide Noise Analysis for Deeper Drilling Activity

Health and Safety
Chapters 4.7, 4.8, 4.12, 4.14

- Fire
  - First 2000 wells drilled for industrial firefighting vehicle (not to exceed $850,000)
- Sheriff
  - Per well for funding for County Sheriff's Department for the Rural Crimes Unit
- Transportation and Traffic
  - Payment per well for roads maintenance of roads utilized by the oil and gas industry

Water

Chapters 4.9, 4.17

- Mitigation Measures
  - Prepare drainage Plans for Potential Run-off
  - Injection Activities subject to Underground Injection Control
  - Oil and Gas Applicants to increase re-use of Produced Water with appropriate treatment and monitoring
  - Coordination/Participation with County on formation Groundwater Sustainability Agency and Plan

Alternatives
Chapter 6.0

- Alternatives Eliminated from Further Consideration
- **Alternatives Analyzed in the EIR**
  - Alternative 1: No Project Alternative
  - Alternative 2: Conditional Use Permit Required Alternative
  - Alternative 3: Reduced Ground Disturbance Alternative
  - Alternative 4: No Hydraulic Fracturing Alternative
  - Alternative 5: Low-Emission Enhanced Oil Recovery Alternative
  - Alternative 6: Recycled Water Alternative

- **Environmentally Superior Alternative**
  - Alternative 5, the Low-Emission Enhanced Oil Recovery

Review and Public Comment

- Workshops: July 27, August 10 – Shafter, August 17 - Taft

Revisions to the Kern County Zoning Ordinance, 2015 C

Oil and Gas Activities

Taft Workshop

August 17,2015

Craig M. Murphy

Division Chief

Kern County Planning & Community Development Department

Oil and Gas Activities

- San Joaquin Valley Portion
- 2.3 Million Acres – existing and potential
- Largest oil producing county in California
- 2012: 43,000 active wells – 78% of all wells in CA
- 80% of oil and natural gas produced in state.

California State Law

- Local government controls land use through zoning
- Underground and drilling activities managed by State Division of Oil, Gas and Geothermal – DOGGR
- California Environmental Quality Act – implemented by either State or local government
- State constitution and Attorney General preempt local regulation of underground oil and gas extraction activities

Local Permitting Program Elements

- Text Amendments to the Kern County Zoning Ordinance
- New Local Permit and Process
- Environmental Impact Report = Mitigation
- New GIS Gateway and Electronic Permit System
- New Staffing + Fees
- New Programs

  (Small Producers Assistance, Legacy Program)

California Oil Activities Coverage

- Well Drilling
- Well Plug and Abandonment
- Groundwater Protection
- Well Stimulation
- Related Land Use Impacts on Surface

Study Area

- Project Area
  - 3,700 Square Miles (2.3 million acres)
  - San Joaquin Valley Floor Portion of Kern County
  - Excludes all City/State and Federal Jurisdictions
  - Includes all State and Federal Minerals under Private Surface
- Subareas
  - Project Area Split into Three Subareas
    - Western – West of I-5 Corridor
    - Central – Between SR-99 and I-5
    - Eastern – East of SR-99

Study Area

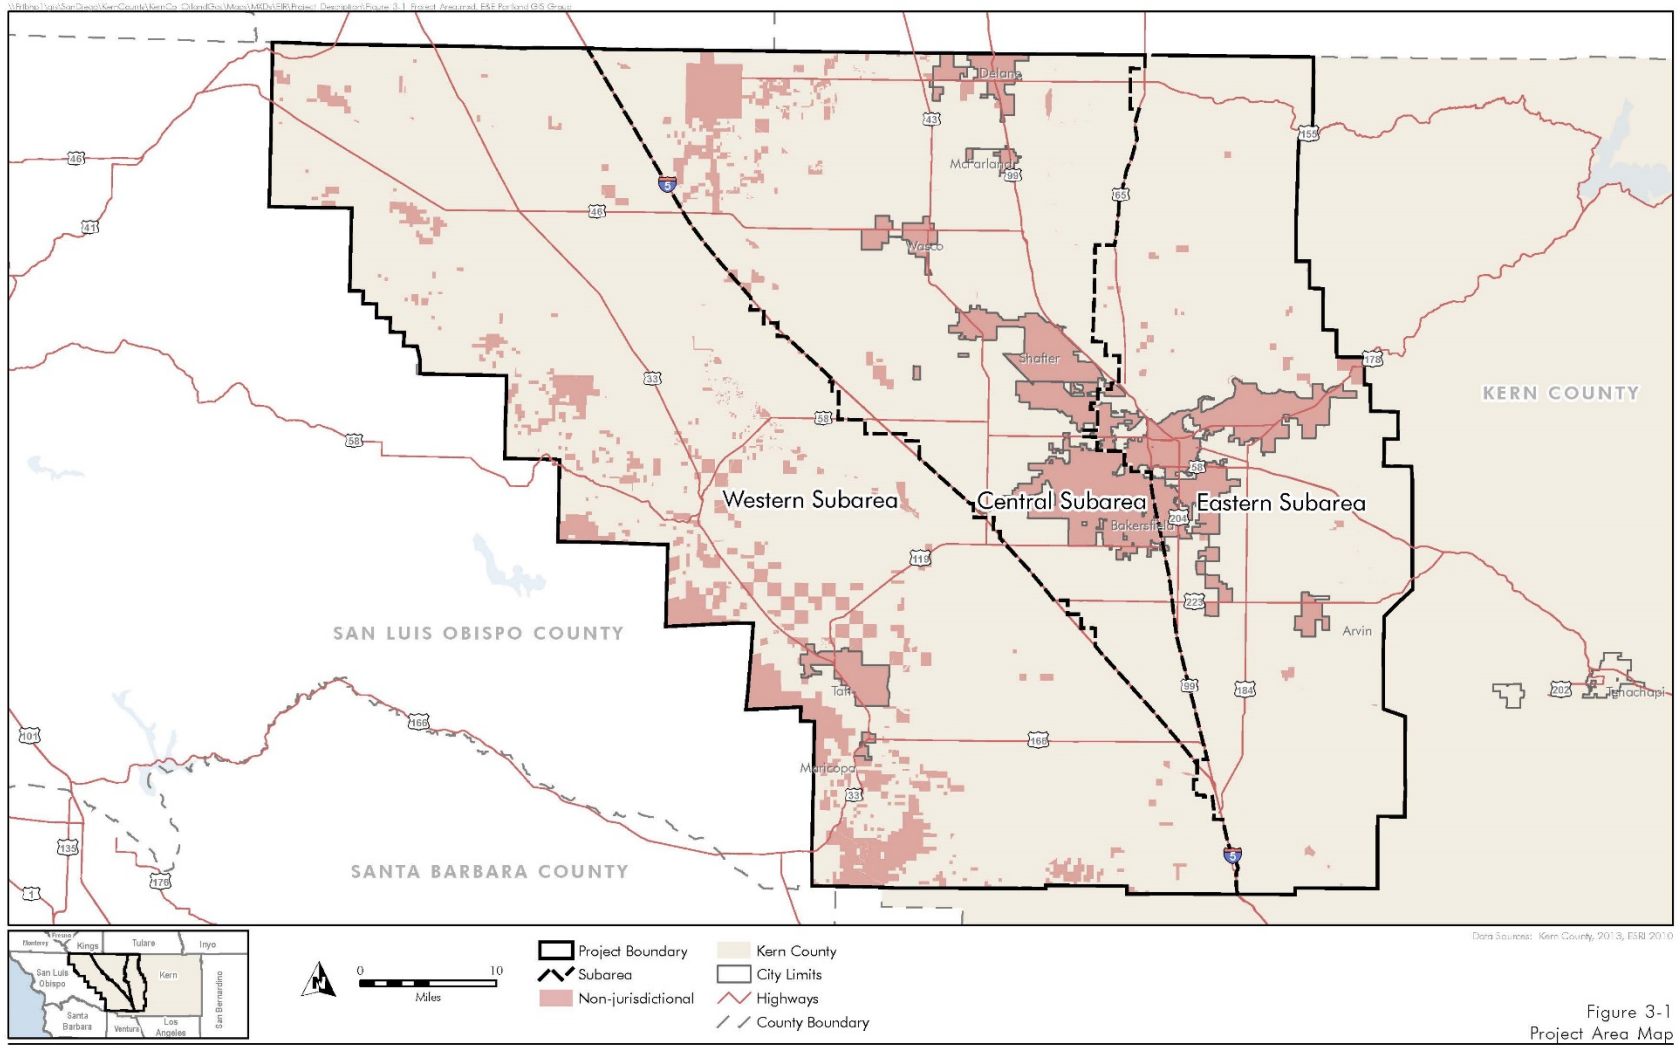

Figure 3-1
Project Area Map

Permitting

- New Tier System for Identifying Lands for Oil and Gas Activities showed as a figure in the ordinance

  - Tier 1 Area – Oil and gas primary land use
  - Tier 2 Area –mixed lands – Ag and Oil
  - Tier 3 Area – historical drilling – not in Tier 1 or 2
  - Tier 4 Area – Needs a Conditional Use Permit
  - Tier 5 Area – Specific Plan areas
  - Non-jurisdictional – Federal, State or Cities

Permitting (Tier Map)

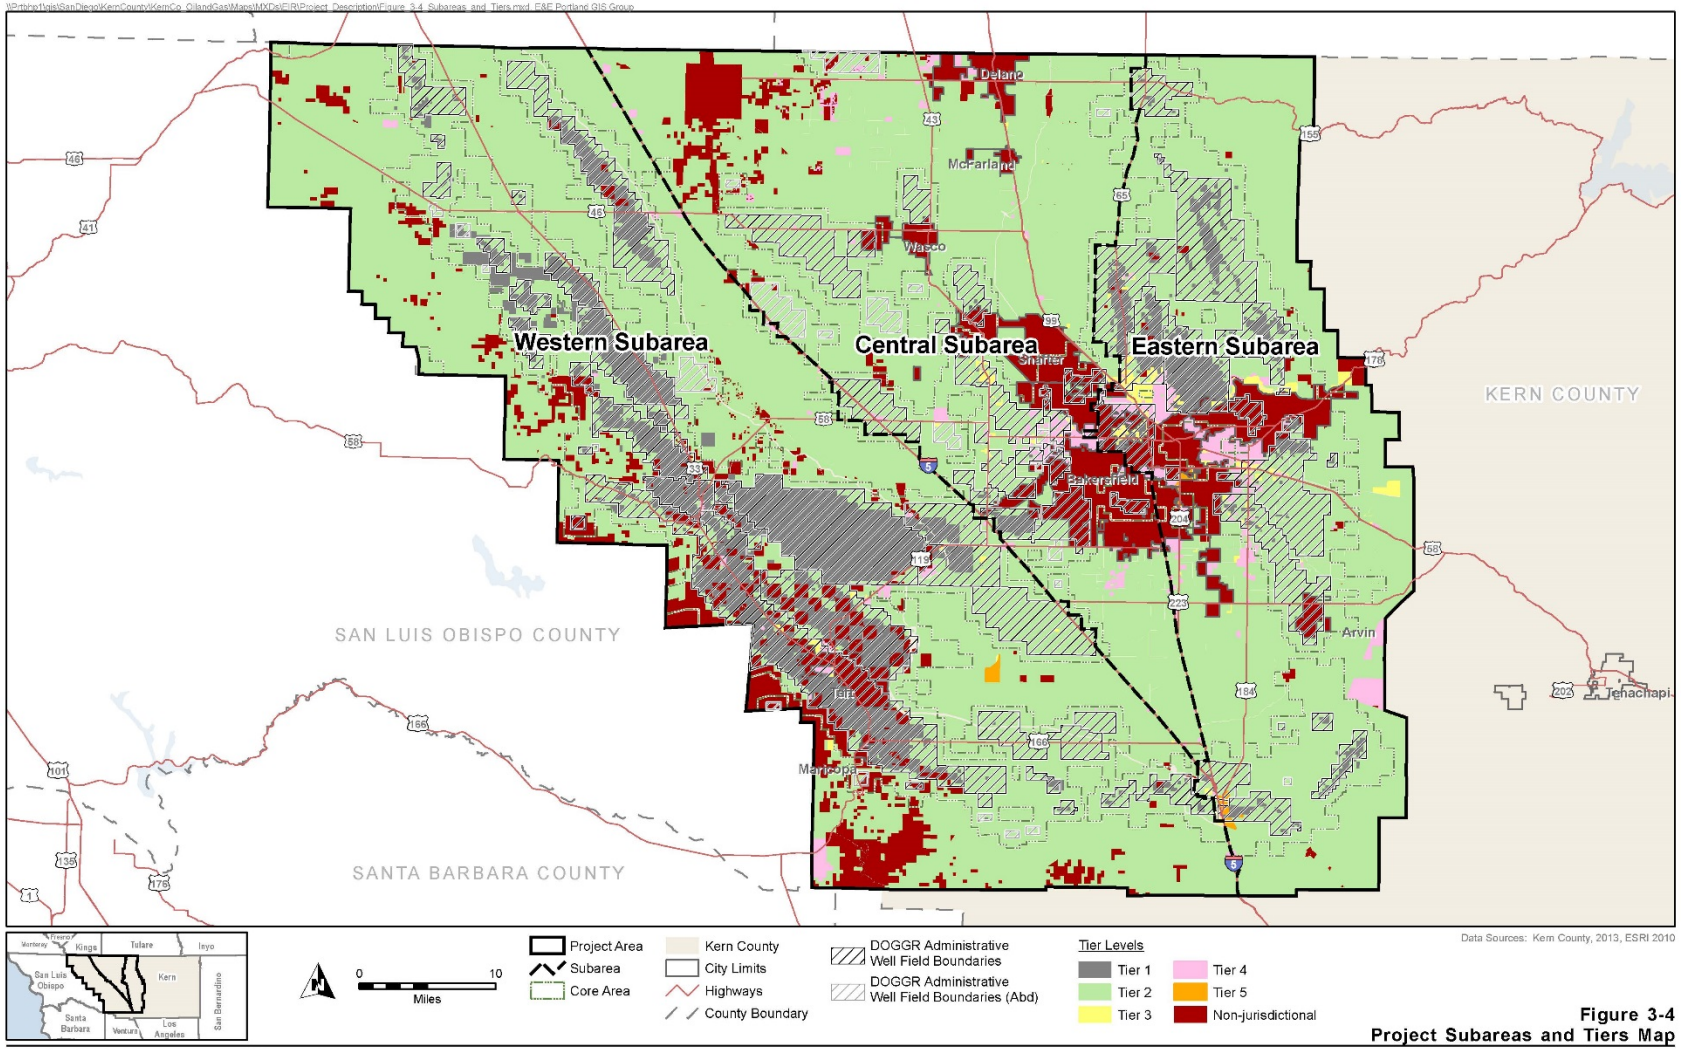

Figure 3-4
Project Subareas and Tiers Map

General Overview

- Oil and Gas Conformity Review
- One Pathway – Tier 1
- Two Pathways – Split Estate – Tier 2,3,5
- Notification of Surface Owner in all pathways
- Signature of Surface Owner required on Site Plan for Tier 2, 3 and 5

Permitting

- Oil and Gas Conformity Review Process
  - with Signature of Surface Owner (7 day + 3 day)
- Oil and Gas Conformity Review Process
  - without Signature of Surface Owner (120 days)
- Minor Activity Review
- Like a Building Permit – Checklist compliance

Split Estate

- Private Land:
  - Surface owner and mineral owner different

Private Land:

Surface owner owns surface down to 500 feet, or

Mineral owner different but does not own surface

Private/Federal Land:

Surface owner owns private surface

Federal government owns minerals (BLM)

Related Programs

- Small Producers Assistance
- Industry Education Workshops
- Surface Owners Education Workshops
- Community Education Workshops
- Legacy Oil Activity Program

California Environmental Quality Act (CEQA)

- TO INFORM Decision makers about significant environmental effects
- TO IDENTIFY ways environmental damage can be avoided
- TO PREVENT avoidable environmental damage
- TO DISCLOSE to the public why a project is approved even if it leads to environmental damage

Process

- Notice of Preparation
  - Circulated on August 30, 2013 – Workshops

Kern County Zoning Ordinance Amendment
Public Workshop Notes

Kern County Administrative Building (July 27, 2015)
City of Shafter Veteran's Hall (August 10, 2015)
City of Taft Veteran's Hall (August 17, 2015)

July 27, 2015

Attendance: Approximately 250

- Concerned about extension of time response
- More than 2 years of work effort to get the document out
- New costly requirements that were not previously in place to obtain a streamlined processing permit structure
- Conservative measures in EIR result in a more proactive mitigation approach as opposed to individual analysis on a case by case basis
- If we say no to hydrologic fracturing, we say no to the future
- Uncertainty in business is a killer
- Government should not make uncertainty worse
- Transparency in the DEIR is important
- Can public sign up to receive upcoming notices
- Not all surface owners have money. Can the County have a program to support these smaller land owners
- Hopefully this plan will provide for the health of the community
- Additional time needed to review the document
- Oil industry has always been responsive and consensus in addressing concerns
- Due to contributions from the oil industry the Grossman Facility was constructed - 3,000 patients
- AIS Cancer Center – Transportation fund started by oil company contributions
- This process is a leap forward in locally controlling our own future
- Measures aggressively protect the environment and the health of the public
- Please discount those who seek to destroy the oil industry
- Hydrocarbons supply everything we use daily in our life
- Industry is at a critical junction
- If oil industry is not drilling, only 20% of workforce is needed
- New fees should be a tax credit
- Industry currently replaces old equipment as part of their project processing. Oil fields are very clean. Incentive to convert to clean fuels
- Water – Important to Kern County. Solar Cycle (drought every 11 years)
- 50,000 local jobs and millions in economic benefits
- Strongest nonprofits in the State are due to the quality of the oil industry representatives who serve on local nonprofit Boards
- Companies & Employees involved in the American Red Cross support many of their programs
- General Fund is very dependent on oil industry. When Oil Industry Gets a Cold, Local Governments get pneumonia
- Kern County is facing an unprecedented challenge and economic opportunity
- 15,000 people have received training from BIA at local training facility
- 12 million private citizens own mineral reserves nation-wide
- Mineral owners can't move their minerals. They rely on leases with producers
- Competing for dollars statewide is always a challenge for Kern County

- Interested in having local monies available to address local concerns
- Legal parameters for local government to participate in the split ownership negotiations
- Permit process must remain ministerial so CEQA does not apply. Local participation could turn the process discretionary.
- County's role is to ensure due process per any adopted ordinance, including enforcement. Substantial upgrade to current process required under law.
- Self-certification should have some protection for the surface owner. Absence of comment does not mean approval and/or agreement
- Maximum cap for wells drilled. How does this document account for variable changes to this cap
- How do we deal with what the responsibilities are when the environment changes and drilling wells are not needed
- What role does our participation play in the larger scheme of things? Can other agencies still deny permits
- Regarding Air District, Millions of $$$ will be required. How do we make sure that Kern County will enjoy the benefits of those dollars and not other jurisdictions
- How will the County treat existing agreements as they relate to new wells

August 10, 2015

Attendance: Approximately 300

- This EIR if approved will provide mitigation to Ag loss, additional mitigation to noise, funding of road maintenance
- DEIR appears fair and balanced to all stakeholders, Local control over oil industry, oil industry helps contribute to Kern County's ranking as #1 to upward mobility, provides light- blue collar jobs
- Oil industry makes up 35% of Kern County's economy, 1 oil job creates up to 17 additional support jobs
- Oil and gas produces critically important hydrocarbons which support our everyday quality of life, even supporting so-called green energy industries
- This DEIR appears scientifically factual, if approved will protect local jobs, if approved will help protect local tax dollars by providing a secure operating environment to the oil industry
- If this EIR is approved this will allow both Oil and Ag industries to work together more effectively
- Oil industry has impacted families in positive ways by providing high paying, good quality jobs
- Having a productive hydrocarbon industry reduces California's dependence on foreign oil, creates tax dollars for the public benefit
- The oil industry already operates in a safe manner but if the EIR is approved it would only improve public confidence
- The changes in the zoning ordinance if approved with provide the oil industry with stability and confidence in a structured permitting process
- If the zone changes are approved would ensure local economic stability, the oil industry would be able to continue to invest in the community, by donating to education programs and job training. Support and open and transparent dialog
- If the zone changes approved it would promote capital investments in local communities, helps ensure process improvements in the oil industry, aids in streamlining the permitting process

- Hydrocarbons are impact everything in our daily live from cars, to homes, to medicine. Hydrocarbons are the foundation of our modern civilization. Without is our modern lives would cease to exist. If we curtail local production we would be more dependent on foreign entities
- The oil and gas industry is a major contributor to kern County
- Hispanic Chamber of Commerce – support Hispanic employees of the oil and gas industry. Jobs for latinos
- Oil and Gas has been a major contributor to Kern County. Board of Supervisors has always been supportive. Need ministerial permitting, Limit CUPs
- Still need unrestricted drilling in oil fields
- Use sound science for mitigation measures
- Leave noticing in Tier 1 for split estate.
- Add another tier for no potable ground water exists, with less monitoring wells. Since no water can be hurt in these areas
- Science is in and fracking is not safe. Governor Just came out with a study. So much beauty in Kern County, it's a shame that short cuts would endanger local citizens. Kern is fabulous, but need an open mind
- There was a great opportunity, but it's been squandered
- EIR makes it easier for Oil and that's a shame
- Not the same as a building permit
- Shame County is continuing this project
- Many health impacts. Example – Criteria pollutants will increase.
- Kern has never been in attainment of clean air act.
- DEIR says local jobs will be created, but most are not high paying jobs. Most Texas license plates.
- Entire EIR is based on jobs and revenue. Quote of EIR "Any link to growth and the project would be speculative"
- Should wait until the EIR is complete before developing regs
- Governor agreed fracking can be done safely and has been for 60 years
- This industry helps CA meet energy needs.
- No one supports getting oil from other countries that suppress women and gays
- Ag mitigation – to protect crops
- Traffic control has to be for county maintained only, not private roads
- EIR will provide stability to the oil companies and service industries
- Want to improve the economy of Kern County
- Oil Industry has invested millions in cleaning up air through changing out engines
- From an agricultural perspective, need a good relationship on split estate
- Not trying to stop you, but because of your size, you need to respect the surface owner
- Under severance deed, ag still has the right as they pay taxes and loss of revenue
- Real challenge of idle wells, issue for the community. 12000 idle wells in Kern County
- Cherry trees died because of an injection well
- Another farmer had to redrill a new water well due to chlorides being too high. DOGGR says it's a legacy issue
- EIR looks to the future, but we don't need to continue to perpetuate these issues
- Modifying the Williamson act is a bad idea, not farmer's choice to lose land to oil wells
- Ag has bad actors as well.
- Oxy did take out an idle well and restore soil, so it can be done
- Farmers are subsidizing oil and gas industry.

- Another farmer has wells that show production on it, but they are really idle
- 20-25 days of power curtailment each year in Shafter because there is not enough power
- Why are we trying to fix something that isn't broke
- Please don't make oil industry put up fences
- Maybe we need a process, but don't put in paved roads or gravel
- Oil and ag are two businesses that need each other
- Governor Brown said we have the most intelligent oil industry in the world
- What doesn't come from here, will come from somewhere else
- This EIR is a pretty throughout process. 2 years isn't greenlighting

August 17, 2015

Attendance: Approximately 300

- Oil prices are not what they once were, this EIR and the suggested mitigation is overreaching and will put a nail in the coffin of local oil production
- The County should produce a reasonable EIR with reasonable mitigation. The way it is currently being proposed local government is overreaching too much
- The existing oil fields should not be subject to
- The Oil Industry is a partner in the quality of life in Taft and Kern County. We should value this community partnership. If the oil industry is hurt by this EIR many County agencies and non-profits will suffer the consequences as well
- This County team has done a wonderful job putting this documents together and we appreciate the hard work.
- Hydrocarbons are the foundation of our modern civilization. Without hydrocarbons our modern lives would cease to exist. Even so called green industries and vehicles require hydrocarbons either to produce or to operate.
- Government should create a business friendly environment for all business to operate in
- This EIR should balance private development needs with stakeholder needs
- Recreation opportunities in Taft are supported by donations from the oil industry, if the oil industry is in decline so with the opportunities for Taft families
- This EIR and its mitigation measure should be able to balance both the needs of the oil industry and the needs of the agriculture industry
- Taft College is supported by the local oil industry, and provides opportunities for students in all courses of study
- The State and this EIR shouldn't try to solve global problems with restrictions focus only on the oil industry which would have a ripple effect on other business that benefits from a strong local economy

Appendix M

Health Risk Assessment Report (July 2015)

Health Risk Assessment
Kern County DEIR –
Proposed Drilling and Oil and Gas Operations

Prepared by:

Environmental Compliance Solutions, Inc.

171 Pier Avenue #337
Santa Monica, CA 90405

June 5, 2015

Table of Contents

1.0 - PROJECT OVERVIEW 2
2.0 - HEALTH RISK ASSESSMENT OVERVIEW 2
3.0 - EXPOSURE ASSESSMENT 6
4.0 - DOSE-RESPONSE 9
5.0 - SIGNIFICANCE THRESHOLDS 10
6.0 - HEALTH RISK ASSESSMENT RESULTS 11
7.0 - REFERENCES 15

1.0 - PROJECT OVERVIEW

This Health Risk Assessment (HRA) was prepared to support the Draft Environmental Impact Report (DEIR) currently being prepared for the proposed Amendment to Title 19 – Kern County Zoning Ordinance – Chapter 19.98 for Oil and Gas Local Permitting.

This HRA evaluates potential calculated cancer risk and acute and chronic health risk from toxic emissions associated with well construction, drilling, and completion as well as oil and gas processing equipment.

Typical well construction phasing and equipment lists were provided as part of our scope of work; along with emission calculations from all well drilling equipment. All well construction emissions were assumed to occur simultaneously for worst case, conservative assumptions.

In March 2015, the state of California released a new HRA guidance document and software. This new program was used to complete this analysis. Use of the new methodology results in calculated risk three to six times higher (300% - 600%) than results for the same emissions profiles using the model previously required for use from 1990 – February 2015.

2.0 - HEALTH RISK ASSESSMENT OVERVIEW

This HRA was performed following the Office of Environmental Health Hazard Assessment (OEHHA), Air Toxics Hot Spots Program Risk Assessment Guidelines (OEHHA, March 2015).

As recommended by the guidelines, the California Air Resources Board (CARB) Hotspots Analysis and Reporting Program, Version 2 (HARP2) (CARB, 2015) was used to perform a refined health risk assessment for potential future drilling and operational emissions. HARP2 includes three modules: a dispersion model, an exposure/dose module and a risk module. The dispersion model incorporates the United States Environmental Protection Agency (USEPA's) AERMOD model and the risk model includes the latest changes made by the State of California to the Risk Assessment inputs.

In general, risk assessments involve four steps:

1) Emissions Estimations of Hazardous Air Pollutants;
2) Exposure Assessments;
3) Dose-response Assessments; and
4) Potential Health Risk Quantification.

Emissions Estimations of Hazardous Air Pollutants

Emission estimates involve identifying and quantifying emissions of potential regulated toxic substances from each source. OEHHA determines the relative toxicity of chemicals regulated by the State of California and determines whether or not they are carcinogenic or possibly

associated with short-term or long-term non-cancer health impacts. Toxic emissions from each source were quantified.

"Hazardous air pollutants" is a term used by the federal Clean Air Act (CAA) that includes a variety of pollutants generated or emitted by industrial production activities. HAPs are also referred to as Toxic Air Contaminants (TACs) under California law (pursuant to the Tanner Act of 1983, codified at Health and Safety Code Section 39650 et. seq.).

California listed diesel exhaust or diesel particulate matter (DPM) as a toxic air contaminant in 1998. The state of California determines the toxicity of each pollutant and assigns each a potency factor. Those factors are built into the HARP2 risk assessment mode.

The diesel particulate matter (DPM) toxicity number incorporates the cumulative health effects of all of the constituents of diesel exhaust into one risk number. Therefore, the only TAC associated with diesel equipment from well construction and completion is DPM. The primary TACs of concern for this project are diesel exhaust associated with construction equipment and drill rigs and benzene (associated with oil processing equipment).

DPM was the only set of toxic emissions analyzed from drilling operations as it accounts for 100 percent of the risk from drilling operations. Benzene accounts for approximately 94 percent of the risk from the oil processing equipment. Although the oil processing equipment scenarios did not result in off-site risk greater than 10 in one million, the risk is attributable to benzene, formaldehyde and polycyclic aromatic hydrocarbons (PAHs). All three are byproducts of natural gas combustion. Potential health effects from these compounds are summarized here.

Diesel Particulate Matter (DPM)

Respirable particles (particulate matter less than about 10 micrometers in diameter [PM_{10}]) can accumulate in the respiratory system and aggravate health problems such as asthma, bronchitis, and other lung diseases. Children, the elderly, exercising adults, and those suffering from asthma are especially vulnerable to adverse health effects of PM_{10} and $PM_{2.5}$. For purposes of this study, all PM2.5 from diesel equipment associated with well drilling (including potential dust and mobile equipment) is conservatively assumed to be toxic diesel particulate matter. DPM represents 100% of the risk associated with well drilling as it is the only TAC expected emitted during construction.

Benzene

The primary risk driver from oil processing equipment is benzene. Benzene is naturally occurring in oil and gas. Approximately 84 percent of the benzene emitted in California comes from motor vehicles, including evaporative leakage and unburned fuel exhaust. Currently, the benzene content of gasoline is less than 1 percent.

Benzene is potentially carcinogenic and naturally occurs throughout California. Benzene also has noncancer health effects. Brief inhalation exposure to high concentrations can cause central nervous system depression. Acute effects include central nervous system symptoms of nausea, tremors, drowsiness, dizziness, headache, intoxication, and unconsciousness.

Neurological symptoms of inhalation exposure to benzene include drowsiness, dizziness, headaches, and unconsciousness in humans. Ingestion of large amounts of benzene may result in vomiting, dizziness, and convulsions in humans. Exposure to liquid and vapor may irritate the skin, eyes, and upper respiratory tract in humans. Redness and blisters may result from dermal exposure to benzene.

Formaldehyde

Formaldehyde is a colorless, flammable, chemical typically used in building materials and many household products such as pressed-wood, particle board, plywood; glues and adhesives. Formaldehyde is also naturally occurring in the environment. It is a by-product of natural gas combustion.

PAHs

The term polycyclic aromatic hydrocarbons (PAHs) refers to a group of several hundred chemically-related, environmentally persistent organic compounds of various structures and varied toxicity. Most of them are formed by a process of thermal decomposition (pyrolysis) and subsequent recombination (pyrosynthesis) of organic molecules. PAHs enter the environment through various routes and are usually found as a mixture containing two or more of these compounds, e.g. soot. They have been shown to cause carcinogenic and mutagenic effects and are potent immunosuppressants. Effects have been documented on immune system development. They are by-products of natural gas combustion.

Well Drilling Emissions

Seven phases of drilling were considered as detailed below. All particulate matter of 2.5 microns (PM2.5) was considered to be toxic diesel particulate matter.

Well depths of 2,000', 5,000' and 10,000' were evaluated. Using a very conservative approach, emissions from all seven phases were assumed to occur simultaneously. An initial year of 2015 was modeled and the final year of 2035 was modeled. For the 10,000' well, 2020 was also evaluated to account for a significant decrease in diesel exhaust emissions from drill rigs and off-road diesel engines as the next CARB regulatory limits become effective. CARB's OFFROAD emissions estimate model was used to calculate emissions from the primarily mobile and off-road diesel equipment. CARB has extensive regulations for diesel equipment with future compliance dates that will result in significant emission reductions of PM2.5 over time. CARB's OFFROAD model can only project emissions to 2029 based on today's available engine technologies. As a result, all emissions between 2029 – 2035 are assumed to be the same.

For this analysis, the following sources were included for evaluation:

- Well drilling (all aspects of construction, well drilling and completion) for a 2,000', 5,000' and 10,000' well.

Each well evaluation consists of the following phases:

- Land Preparation;
- Drilling Survey;
- Well Drilling;
- Well Completion;
- Well Flowline;
- Pump Unit; and
- Electrical.

Numbers and types of equipment associated with each well depth are listed below. An exact equipment list for each of the seven phases and their associated emissions is included as Appendix B.

Both drilling and operational emissions are assumed to occur along a fenceline shared by an oil producer and a private resident.

Table 1 – Equipment Associated with Well Construction, Drilling and Completion*

Depth Feet	Number of Trucks	Off-Road Construction Equip.	Drill Rig HP totals	Drilling Days
10,000	9	45	3 rigs at 1,040HP each	23
5000	9	45	3 rigs at 440HP each	8
2000	9	45	3 rigs at 440HP each	4

*As previously noted, this equipment is for the combined operation of all seven phases of construction, drilling and completion.

Table 2 – Emissions Associated with Well Construction, Drilling and Completion

Depth Feet	Year[1]	Total PM2.5[2] pounds	Annual PM2.5[3] pounds	Days[4]
10,000	2015	516.89	17.23	23
10,000	2018	444.00	14.8	23
10,000	2035	151.83	5.06	23
5000	2015	171.18	5.71	8
5000	2035	35.86	1.20	8
2000	2015	97.12	3.24	4
2000	2035	20.42	0.68	4

[1]2029-2035 emissions are the same.
[2]From Vector Environmental Spreadsheet titled "DRL_EMISSIONS.xlsx", worksheet "EMF".

[3]Total emissions divided by 30 years per OEHHA's HARP2 exposure duration requirements.
[4]From Vector Spreadsheet titled "DRL_EMISSIONS.xlsx", worksheet "MUD".

Operational Equipment Emissions

Maximum daily and annual emissions were also quantified from an oil processing facility and a natural gas combustion facility. The equipment list and parameters was provided as part of our Scope of Work.

Oil Processing Equipment

Emissions from the following equipment were analyzed in the oil processing scenario:

- Two – 1,000 Bbl above-ground tanks;
- One – 3,000 Bbl above-ground tank;
- One 10 MMBtu/hour Flare;
- Truck loading rack;
- Fugitive emissions from valves, flanges, and one underground sump; and
- Thermally enhanced oil recovery (TEOR) equipment.

Natural Gas Combustion Equipment

Emissions from the following natural gas combustion equipment were analyzed in the natural gas scenario:

- One new 100 MMBtu/hour flare;
- One – 8 MMBtu/hour Process Heater;
- One – 10 MMBtu/hour Boiler;
- One – 85 MMBtu/hour Steam Generator; and
- One – 33 MW Cogeneration Plant.

Potential toxic emissions from each of these sources are summarized in Appendix A.

3.0 - EXPOSURE ASSESSMENT

Exposure assessment includes air dispersion modeling, identification of emission exposure routes and estimation of exposure levels. The modeling estimates ground level concentrations based on an emission rate of one gram per second. This rate is then multiplied by the worst case potential emission rate for each substance to obtain ground level concentrations. In addition to inhalation, potential pathways of exposure to offsite receptors include dermal exposure and ingestion.

HARP2 incorporates the USEPA AERMOD (v14134) model. AERMOD predicts resulting cumulative concentrations from various emission sources. The rural setting was selected in AERMOD for this analysis. AERMOD's terrain processor, AERMAP, was used to incorporate

actual terrain elevations for sources and receptors. Five years of meteorological data required for AERMOD was obtained from the San Joaquin Valley Air Pollution Control District (SJVAPCD). Bakersfield station 23155 was used for this analysis.

Three different locations within Kern County were assessed in order to capture various terrain characteristics within Kern County.

These areas were previously determined as being representative of various aspects of the county and were included as part of our Scope of Work: Western, Central and Eastern Kern County.

- Western Subarea – Midway Sunset Oilfield
- Central Subarea – No. Shafter Oilfield
- Eastern Subarea – Kern River Oilfield

Terrain in the Central Subarea is relatively flat, and modeling results would best represent dispersion characteristics with minimal terrain disturbances. More site location and terrain specific influences were observed in the Western Subarea and even more in the Eastern Subarea. Sufficient analysis of different factors that affect dispersion and other modeling inputs were covered by modeling three separate areas within Kern County. The rural setting in AERMOD was selected and the model selects the terrain variability based on real-world conditions.

Table 3 shows the UTM location of the project centers for each selected Subarea.

Table 3 - Modeled Kern County Project Locations[1]

Subarea	Easterly	Northerly
Western	255,000	3918,100
Central	293,650	3934,400
Eastern	319,800	3925,150

[1]Based on Subarea modeling locations provided by Vector dated 2/15/2015 and rounded to the nearest 164 feet. (UTM NAD83, Zone 11)

Source Modeling Parameters

Potential sources were modeled as described in the table below. Both drilling and operational emissions are assumed to occur along a fenceline shared by an oil producer and a private residence.

Table 4 - Modeling Source Characteristics and Release Parameters

Point Sources				
Source Name	Height, ft	Temp, ºF	Velocity, fps	Diameter, ft
10 MMBtu/hr Flare[1]	49.3	1831.7	65.6	1.82
100 MMBtu/hr Flare[1]	68.0	1831.7	65.6	5.76
85 MMBtu/hr Steam Generator[2]	20	200	32.0	2.5
33 MW Cogen	30	991	67.8	10.0
8 mm Btu/hour process heater[2]	15	600	29.9	1.5
1000 bhp Natural Gas Engine[2]	20	850	30	2
10 mm Btu/hour boiler[2]	20	400	23.9	1.5

Area Sources			
Source Name	Release Height, feet	X, feet	Y, feet
Fugitive leaks	3.28	65.5	65.6
Sump	0	30	30
Drilling Mud Sump	0	32.8	32.8
TEOR	0	16.5	16.5

Circular Area Sources		
Source Name	Height, ft	Radius, ft
1000 Bbl Tank	16.0	10.8
1000 Bbl Tank	16.0	10.8
3000 Bbl Tank	24.1	14.9

Volume Sources			
Source Name	Release Height, feet	Initial Lateral Dimension, feet	Initial Vertical Dimension, feet
Drilling	30	16.5	16.5
Vacuum Truck Loading	13.1	1.97	3.05

[1]Adjusted per Ohio EPA methodology.
[2]Per Scope of Work amendment 2-15-2015.
[3]Tank dimensions from tank vendor website.

4.0 - DOSE-RESPONSE

The dose-response assessment describes the quantitative relationship between a human's exposure to a substance (the dose) and the incidence or occurrence of an adverse health impact (the response). For carcinogens, OEHHA has developed cancer potency factors. A cancer potency factor represents the upper bound probability of developing cancer based on a continuous lifetime exposure. The cancer potency factor does not represent a threshold under which a person would not develop cancer, but instead is used to estimate the probability of developing cancer.

For non-carcinogenic chemicals, OEHHA has developed Recommended Exposure Limits (RELs) for acute and chronic impacts. RELS represent concentration thresholds at which no adverse noncancer health effects are anticipated. For chemicals that are not deemed by the State of California as possible carcinogens, but which may pose either short-term (acute) or other non-cancer long-term (chronic) health effects, a Hazard Index (HI) calculation of potential risk is also required by the air district and the state as part of a Health Risk Assessment.

Exposure Pathways

A receptor can be hypothetically exposed to a substance through several different pathways. Typically, the primary environmental exposure pathway in a health risk assessment is direct inhalation of gaseous and particulate air pollutants. However, there is the potential for exposure via non-inhalation pathways due to the deposition of particulate pollutants (diesel particulate matter) in the environment. For this analysis, HARP2 requires assumptions that diesel particulate matter could also be ingested via dermal (skin) absorption, soil ingestion and mother's milk ingestion. PAHs were the only pollutants analyzed for which there is a non-inhalation pathway.

Relative Toxicity

The following table represents the relative toxicity of the compounds which contributed to most of the calculated risk. For example, diesel particulate matter (DPM) (with an inhalation potency factor of 1.1) is approximately 10 times more toxic than benzene (inhalation potency factor of 0.10) and PAHs are almost four times more toxic than DPM.

Table 5 - Chemical Cancer Risk Factors[1]

Chemical	Inhalation Unit Risk[2]	Inhalation Potency Factor[2]	Non-Inhalation Oral Slope Factor
	$(\mu g/m^3)^{-1}$	$(mg/kg\text{-}d)^{-1}$	$(mg/kg\text{-}d)^{-1}$
Diesel Particulate Matter	0.0003	1.1	NA (inhalation only)
Total PAHs[3]	0.001	3.9	12.0
Formaldehyde	0.000006	0.02	NA (inhalation only)
Benzene	0.029	0.10	NA (inhalation only)

[1] May 13, 2015.

[2] Inhalation cancer potency factor: The "unit risk factor" has been replaced in the new risk assessment algorithms by a factor called the "inhalation cancer potency factor". Inhalation cancer potency factors are expressed as units of inverse dose [i.e., (mg/kg-day)-1]. They were derived from unit risk factors [units = (ug/m3)-1] by assuming that a receptor weighs 70 kilograms and breathes 20 cubic meters of air per day. The inhalation potency factor is used to calculate a potential inhalation cancer risk using the new risk assessment algorithms defined in the OEHHA, *Air Toxics Hot Spots Program; Technical Support Document for Exposure Assessment and Stochastic Analysis (August 2012)*.

[3] Polycyclic Aromatic Hydrocarbons (PAHs): (Not including naphthalene.) These substances are PAH or PAH-derivatives that have OEHHA-developed Potency Equivalency Factors (PEFs) which were approved by the Scientific Review Panel in April 1994 (see ARB document entitled *Benzo[a]pyrene as a Toxic Air Contaminant*). PAH inhalation slope factors listed here have been adjusted by the PEFs. See OEHHA's Technical Support Document: Methodologies for Derivation, Listing of Available Values, and Adjustments to Allow for Early Life Exposures (2009) for more information about the scheme. Section 8.2.3 and Appendix G of OEHHA's *The Air Toxics Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments (2003)* also contains information on PAHs.

5.0 - SIGNIFICANCE THRESHOLDS

SJVAPCD publishes CEQA significance thresholds for potential health risk from proposed projects. Currently, risks from a project that are less than the following regulatory thresholds are considered not to be significant and are, therefore, acceptable:

- Cancer risk equal to or less than 10 in one million
- Chronic hazard index equal to or less than 1
- Acute hazard index equal to or less than 1

These metrics are generally applied to the maximally exposed individual (MEI). There are separate MEIs for residential exposure (i.e., residential areas) and for worker exposure (i.e., offsite work places).

Note: SJAPCD is currently planning to increase the risk standard to 20 in one million theoretical excess cancer cases. However, this study is based on the current standard of 10 in one million theoretical excess cancer cases.

6.0 - HEALTH RISK ASSESSMENT RESULTS

A refined health risk assessment was performed using the HARP2 model. As shown, calculated cancer risk from drilling a 10,000' well exceeds a threshold of 10 cases in one million (Table 6). The maximum distances from the shared property boundary (oil company and private resident) are illustrated in Figure 1 below.

The 5,000' well scenario also exceeds 10 in one million in 2015 only. Therefore, after 2015, any well drilled shallower than 5,000' would not result in a risk greater than 10 in one million. (Table 6)

None of the gas fired equipment exceeds a risk of 10 in one million (Table 7).

The scenario in which all of the oil processing equipment operates full time and is located in the exact same location with a shared fenceline to private property results in a 10 in one million risk level from 478 – 701 feet depending on the subarea of Kern County (Table 7).

None of the noncancer hazards for either an oil processing facility or a gas processing facility exceed the regulatory threshold of 1.0 (Tables 9 and 10).

Figure 1 -

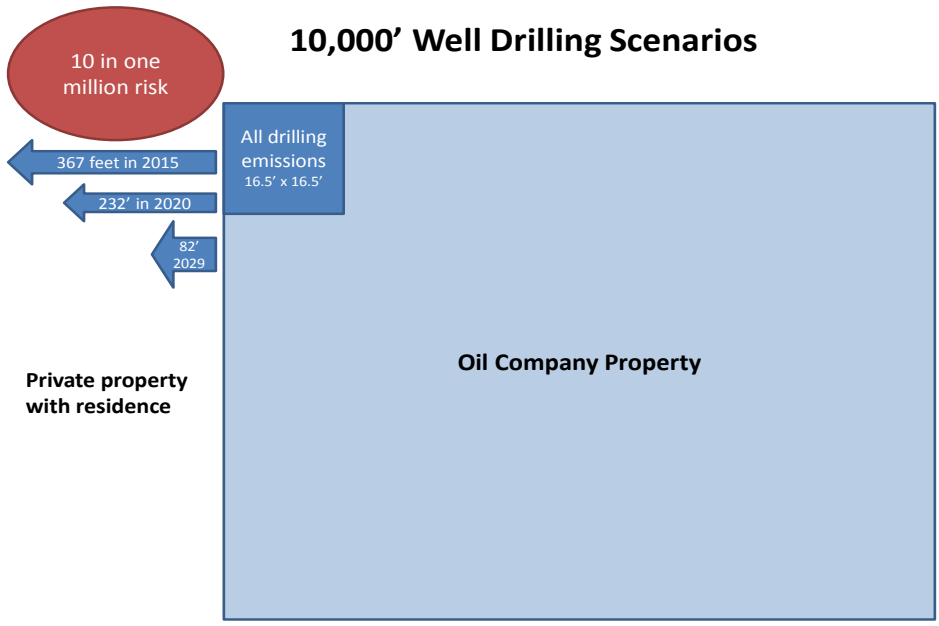

Table 6 –

Potential health risk from well construction, drilling and completion emissions

Well Depth (feet)	Year	Maximum distance from well site and project boundary to 10 in one million calculated risk
Western Subarea		
10,000	2015	367 feet
10,000	2020	232 feet
10,000	2029	82 feet
5000	2015	116 feet
5000	2029	NA*
2000	2015	NA
2000	2029/2035	NA
Central Subarea		
10,000	2015	367 feet
10,000	2020	232 feet
10,000	2029	82 feet
5000	2015	116 feet
5000	2029	NA
2000	2015	NA
2000	2029/2035	NA
Eastern Subarea		
10,000	2015	296 feet
10,000	2019	183 feet
10,000	2029	NA
5000	2015	NA
5000	2029	NA
2000	2015	NA
2000	2029/2035	NA

*NA = no offsite risk greater than 10 in one million.

CONFIDENTIAL DRAFT

Table 7 -

Potential health risks from gas processing equipment

Equipment	Risk greater than 10 in one million?
1000 bhp natural gas ICE	No
100 mmbtu/hr flare	No
85 mmbtu/hour steam generator	No
8 mm btu/hour boiler	No
33 MW cogen	No
TEOR Equipment	No

Table 8 –

Potential health risks from all oil processing equipment

Equipment	Western Subregion Cancer Risk Distance to 10 in one million*	Central Subregion Cancer Risk Distance to 10 in one million*	Eastern Subregion Cancer Risk Distance to 10 in one million*
1,000 bbl oil tank			
1,000 bbl oil tank			
3,000 bbl oil tank			
truck loading rack			
30'x30' sump			
10,000 btu/hour flare			
Fugitive VOCs			
TOTAL CUMULATIVE RISK Distances	701'	625'	478'

*Risk distances assume that all equipment is placed along a shared fence line between the oil site and a private residence.

NOTE: All of this equipment would require SVAPCD air permits. As such, the risk threshold must be complied with or permits cannot be issued. So, in this scenario either less equipment could be used and/or the receptors cannot share a fence line in order for this scenario to be viable.

Equipment and Emissions for Well Depths

2015 Emissions from a 2000 ft. Well

Construction Activity: A1. Land Preparation

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Water Truck	1.0	7.0	8.48	400	3.46
Loader	1.0	4.0	2.5	100	.34
35 Yard Dump Truck	1.0	2 .0	1.00	400	.12
Grader	1.0	4.0	2.5	175	.77
Skip & Scrap (Backhoe)	1.0	1.0	1.0	100	.03
Big Scrapper	1.0	2.0	2.5	362	.47
Dozer (D9R)	1.0	1.0	1.0	255	.08
Low Bed Truck/Trailer	1.0	2.0	.5	400	.06
Dump Truck 10 Wheels	1.0	1.0	.5	400	.03
Backhoe	1.0	2.0	.54	100	.04
Loader	1.0	3.0	2.5	100	.26
Loader	1.0	2.0	1.0	100	.07
Escavator (Backoe/tracks)	1.0	1.0	1.0	163	.03
Dozer (D8T)	1.0	1.0	1.0	255	.08
End Dump Truck & Trailer	1.0	1.0	.50	400	.03
Grader	1.0	1.0	.50	175	.04
Annual Emissions From Offroad Source Activity					5.91

2015 Emissions from a 2000 Ft. Well

Construction Activity: B.1 Drilling Survey

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Rig	1.0	1.0	12.00	100	.58
Cement Truck	1.0	4.0	12.00	400	.70
Annual Emissions From Offroad Source Activity					1.28

2015 Emission from a 2000 Ft. Well

Construction Activity: C.1 Well Drilling

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Crane	1.0	2.0	8.00	230	.81
Port Light Stands	5.0	5.0	12.00	20	2.41
Portable Gen. Hydraulic Power	1.0	5.0	22.00	80	3.66
Portable Gen. DSM/Trailers	2.0	5.0	24.00	100	9.99
Portable Gen. Mud Separator	1.0	4.0	22.00	420	4.65
Rotary Table or Top Drive	1.0	4.0	22.00	135	5.63
Diesel Engine For Hoist	1.0	4.0	22.00	455	6.74
Diesel Engine For Hoist	1.0	4.0	22.0	442	6.55
Diesel Engine for Mud Pump	1.0	4.0	22.00	424	6.28
Annual Emissions From Offroad Source Activity					46.72

2015 Emissions from a 2000 Ft Well

Construction Activity: D.1 Well Completion

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Accumulator Generator	1.0	4.0	24.00	100	4.0
Filter Skid (Pump)	1.0	2.0	3.00	90	.22
Acid Pump #1 (Hydraulic Oil Pump)	1.0	1.0	22.00	175	.85
Acid Pump #2 (Acid Fluid Pumping)	1.0	4.0	22.00	765	2.17
Generator for Doghouse for WO Rig	1.0	4.0	24.00	70	2.8
3 Light Plants for WO Rig	3.0	4.0	12.00	20	1.15
Diesel Engine for COROD or Other	1.0	1.0	22.00	450	1.67
Portable Den. Mud Separator	1.0	4.0	22.00	420	4.65
Rotary Table or Top Drive	1.0	4.0	22.00	135	5.63
Diesel Engine for Hoist	1.0	4.0	22.00	455	6.74
Diesel Engine for Hoist	1.0	3.0	22.00	442	6.55
Diesel Engine for Mud Pump	1.0	4.0	22.00	424	6.28
Annual Emissions From Offroad Source Activity (Lb/Year)					42.71

2015 Emissions from a 2000 Ft. Well

Construction Activity: E.1 Well Flowline

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Side Boom D4/Crawler	1.0	3.0	10.00	520	.92
Backhoe	1.0	3.0	10.00	95	.98
Pipe Fitting or Welders	1.0	3.0	10.00	40	.48
Hydrotest Pump	1.0	1.0	1.00	.08	.01
Forklift	1.0	3.0	10.00	125	.56
Other Equipment/Bending Machine	1.0	3.0	10.00	80	1.12
Annual Emissions From Offroad Source Activity					4.07

2015 Emissions from a 2000 Ft. Well

Construction Activity: F.1 Pump Unit

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Power Generator	1.0	2.0	8.00	10	.06
Backhoe	1.0	2.0	4.00	80	.22
Welder	1.0	2.0	8.00	25	.16
Annual Emissions From Offroad Source Activity					.44

2015 Emissions from a 2000 Ft. Well

Construction Activity: G.1 Electrical

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Line Truck	1.0	4.0	10.00	250	1.73
Bucket Truck	1.0	4.0	10.00	250	1.73
Electrical Service Truck	1.0	4.0	1.00	300	.15
Power Generators	1.0	4.0	1.00	10	.02
Back-Hoe	1.0	1.0	10.00	650	.80
Annual Emissions From Offroad Source Activity					4.43

2015 Emissions from a 5000 ft. Well

Construction Activity: A1. Land Preparation

2015 Emissions from a 5000 Ft. Well

Construction Activity: B.1 Drilling Survey

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Rig	1.0	1.0	12.00	100	.58
Cement Truck	1.0	1.0	12.00	400	.70
Annual Emissions From Offroad Source Activity (Lb/Year					1.28

2015 Emission from a 5000 Ft. Well

Construction Activity: C.1 Well Drilling

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Crane	1.0	2.0	8.00	230	.81
Port Light Stands	5.0	9.0	12.00	20	4.33
Portable Gen. Hydraulic Power	1.0	9.0	22.00	80	6.60
Portable Gen. DSM/Trailers	2.0	9.0	24.00	100	17.99
Portable Gen. Mud Separator	1.0	8.0	22.00	420	9.30
Rotary Table or Top Drive	1.0	8.0	22.00	135	11.26
Diesel Engine For Hoist	1.0	8.0	22.00	455	13.48
Diesel Engine For Hoist	1.0	8.0	22.0	442	13.09
Diesel Engine for Mud Pump	1.0	8.0	22.00	424	12.56
Annual Emissions From Offroad Source Activity					89.42

2015 Emissions from a 5000 Ft Well

Construction Activity: D.1 Well Completion

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Accumulator Generator	1.0	8.0	24.00	100	8.00
Filter Skid (Pump)	1.0	2.0	3.00	90	.22

1.0 - PROJECT OVERVIEW

This Health Risk Assessment (HRA) has been updated to incorporate comments received on the Draft Environmental Impact Report (DEIR) prepared for the proposed Amendment to Title 19 – Kern County Zoning Ordinance – Chapter 19.98 for Oil and Gas Local Permitting.

The HRA completed for the DEIR and this FEIR was based on very conservative assumptions; **one of which was to assume that all receptor locations contain sensitive receptors.**

Sensitive Receptors are defined as people that have an increased sensitivity to air pollution or environmental contaminants are considered to be sensitive receptors. Sensitive receptor locations include schools, parks and playgrounds, day care centers, nursing homes, hospitals, and residential dwelling unit(s). Within each sensitive receptor, it was assumed that children were residing or located at the site. The location of the nearest sensitive receptors to a project site is needed to assess toxic impacts on public health.

California's Office of Environmental Health Hazard Assessment (OEHHA) is tasked with determining the relative toxicity of numerous chemicals and compounds and is also in charge of determining how California's regulatory HRAs will be conducted. HRAs determine the probability that a sensitive receptor may get cancer from a predetermined exposure to certain chemicals, substances or environments.

OEHHA, in conjunction with the California Air Resources Board (ARB), is also responsible for developing guidelines for how an HRA must be conducted. The HRA conducted for the proposed program followed the OEHHA Guidelines as amended in March 2015. The latest version of the Guidance Manual updates the previous version (OEHHA, 2003), and reflects advances in the field of risk assessment along with new more conservative consideration given to infants and children and their associated inhalation rates. The new guidelines are significantly more stringent than the 2003 predecessor and this is the document that was used for the DEIR and FEIR.

The San Joaquin Valley Air Pollution Control District (SJVAPCD) submitted a comment letter on September 11, 2015 regarding the HRA for the DEIR. They requested changes to ensure that the HRA is consistent with their regulatory risk policy which was recently updated. All of the SJVAPCD's recommended changes were incorporated into this revised HRA and are summarized herein:

1) The air district requested that diesel exhaust be modeled as particulate matter of 10 microns or less (PM10) rather than PM2.5 which was previously modeled. This overstates emissions and risk as PM10 includes dust which is not considered to be toxic by OEHHA. This more conservative analysis is included with this revised HRA.
2) The receptor grid spacing has been adjusted per the SJVAPCD's request.
3) Additional meteorological station data were incorporated.
4) One additional modeling location and modeling study was selected in the Western Subarea by the SJVAPCD.
5) They also revised the location of the Eastern subarea location.

6) SJVAPCD suggested referring to the previous Western subarea as Midway Sunset, the new Western subarea location as Derby Acres, the Central subarea as Shafter and the relocated Eastern Subarea as Kern River.
7) Drilling rigs were requested to be modeled as point sources rather than volume sources.
8) Flare emission factor updates were provided by the SJVAPCD and were used in these calculations.
9) The exhaust parameters for the 1,000 horsepower (hp) natural gas-fired internal combustion engine (ICE) were modified by SJVAPCD.
10) SJAPCD utilizes a 70-year residential exposure assumption in HRAs as compared to OEHHA's HARP2 guidelines which require a 30-year residential exposure.
11) The air district requested that the possibility of home-grown food exposure be included in the analysis. This is not part of the State of California guidelines however it has been included in this revised analysis.
12) Finally, SJVAPCD requested that the results be compared against the SJVAPCD CEQA significance threshold for Toxic Air Contaminants of 20 in one million (20×10^{-6}).

This revised HRA evaluates potential calculated cancer risk and acute and chronic health risk from toxic emissions associated with well construction, drilling, and completion as well as oil and gas processing equipment.

None of the equipment assumptions for well drilling or operational activities have changed. Typical well construction phasing and equipment lists were provided as part of our scope of work; along with emission calculations from all well drilling equipment. All well construction emissions were assumed to occur simultaneously for worst case, conservative assumptions.

As stated above, OEHHA released a new HRA guidance document and software in March 2015. This new program was used to complete this analysis. Use of the new methodology results in calculated risk three to six times higher (300% - 600%) than results for the same emissions profiles using the model previously required for use from 1990 through February 2015.

SJVAPCD released its updated risk assessment guidance on May 28, 2015. The Hot Spots Analysis and Reporting Program, Release Version 2 (HARP2) software was revised on June 29, 2015 (Version 15180), and again on July 16, 2015 (Version 15197). Version 15197 was used for this HRA.

2.0 - HEALTH RISK ASSESSMENT OVERVIEW

As recommended by the OEHHA guidelines, HARP2 (CARB, 2015) was used to perform a refined HRA for potential future drilling and operational emissions. HARP2 includes the following three modules: a dispersion model, an exposure/dose module and a risk module. The dispersion model incorporates the United States Environmental Protection Agency (USEPA's) AERMOD model and the risk model includes the latest changes made by OEHHA to the Risk Assessment inputs.

In general, risk assessments involve four steps:

1) Emissions Estimations of Hazardous Air Pollutants;
2) Exposure Assessments;
3) Dose-response Assessments; and
4) Potential Health Risk Quantification.

Emissions Estimations of Hazardous Air Pollutants

Emission estimates involve identifying and quantifying emissions of potential regulated toxic substances from each source. OEHHA guidance regarding whether the pollutants are carcinogenic or possibly associated with short-term or long-term non-cancer health impacts was followed. Toxic emissions from each source were quantified.

"Hazardous air pollutants" is a term used by the federal Clean Air Act (CAA) that includes a variety of pollutants generated or emitted by industrial production activities. HAPs are also referred to as Toxic Air Contaminants (TACs) under the California Clean Air Act of 1988 (CCAA). California listed diesel exhaust or diesel particulate matter (DPM) as a toxic air contaminant in 1998. The state of California determines the toxicity of each pollutant and assigns each a potency factor. Those factors are built into the HARP2 risk assessment mode.

The DPM toxicity number incorporates the cumulative health effects of all of the constituents of diesel exhaust into one risk number. Therefore, the only TAC associated with diesel equipment from well construction and completion is DPM. The primary TACs of concern for this project are diesel exhaust associated with construction equipment and drill rigs and benzene (associated with oil processing equipment).

DPM was analyzed from drilling operations. Drilling operations also include an assumption that a drilling mud sump will be required for each well drilled. Potential fugitive emissions of hydrocarbons (VOCs) can be emitted from drilling mud sumps. Those emissions were also included in both the original HRA and this revised HRA. . Potential health effects from both are summarized here. Although the oil processing equipment scenarios did not result in off-site risk greater than 10 in one million, the risk measured was attributed to benzene, formaldehyde and polycyclic aromatic hydrocarbons (PAHs). All three are byproducts of natural gas combustion.

Diesel Particulate Matter

Respirable particles (particulate matter less than about 10 micrometers in diameter [PM_{10}]) can accumulate in the respiratory system and aggravate health problems such as asthma, bronchitis, and other lung diseases. Children, the elderly, exercising adults, and those suffering from asthma are especially vulnerable to adverse health effects of PM_{10} and $PM_{2.5}$. For purposes of this study, all PM2.5 from diesel equipment associated with well drilling (including

potential dust and mobile equipment) is conservatively assumed to be toxic diesel particulate matter. DPM represents 100% of the risk number associated with well drilling risk as it is the only compound expected to be emitted.

Benzene

The primary risk driver from oil processing equipment is benzene. Benzene is naturally occurring in oil and gas. Approximately 84 percent of the benzene emitted in California comes from motor vehicles, including evaporative leakage and unburned fuel exhaust. Currently, the benzene content of gasoline is less than 1 percent.

Benzene is potentially carcinogenic and naturally occurs throughout California. Benzene also has noncancer health effects. Brief inhalation exposure to high concentrations can cause central nervous system depression. Acute effects include central nervous system symptoms of nausea, tremors, drowsiness, dizziness, headache, intoxication, and unconsciousness.

Neurological symptoms of inhalation exposure to benzene include drowsiness, dizziness, headaches, and unconsciousness in humans. Ingestion of large amounts of benzene may result in vomiting, dizziness, and convulsions in humans. Exposure to liquid and vapor may irritate the skin, eyes, and upper respiratory tract in humans. Redness and blisters may result from dermal exposure to benzene.

Formaldehyde

Formaldehyde is a colorless, flammable, chemical typically used in building materials and many household products such as pressed-wood, particle board, plywood; glues and adhesives. Formaldehyde is also naturally occurring in the environment. It is a by-product of natural gas combustion.

PAHs

The term polycyclic aromatic hydrocarbons (PAHs) refers to a group of several hundred chemically-related, environmentally persistent organic compounds of various structures and varied toxicity. Most of them are formed by a process of thermal decomposition (pyrolysis) and subsequent recombination (pyrosynthesis) of organic molecules. PAHs enter the environment through various routes and are usually found as a mixture containing two or more of these compounds, e.g. soot. They have been shown to cause carcinogenic and mutagenic effects and are potent immunosuppressants. Effects have been documented on immune system development. They are by-products of natural gas combustion.

Well Drilling Emissions

Seven phases of drilling were considered as detailed below. All particulate matter 10 microns (PM10) was considered to be toxic DPM. This significantly overstates true emissions a portion of the PM10 calculated included road dust and other sources of fugitive dust associated with well pad construction, well drilling and completion.

Well depths of 2,000', 5,000', 10,000' and 15,000' were evaluated. Using a very conservative approach, emissions from all seven phases were assumed to occur simultaneously. An initial year of 2015 was modeled and the final year of 2029/2035 was modeled. CARB's OFFROAD emissions estimate model was used to calculate emissions from the primarily mobile and off-road diesel equipment. CARB has extensive regulations for diesel equipment with future compliance dates that will result in significant emission reductions of PM10 over time.

NOTE: CARB's model includes currently adopted diesel regulations designed to reduce emissions from various off-road and on-road engines. No emission reductions are included in future year calculations for potential reductions from proposed or potential additional regulations that may be required in the future.

CARB's OFFROAD model can only project emissions to 2029 based on today's available engine technologies. As a result, all emissions between 2029 – 2035 are calculated to be the same maximum daily amount.

For this analysis, the following sources were included for evaluation:

- Well drilling (all aspects of construction, well drilling and completion) for a 2,000', 5,000', 10,000', and a 15,000' well.

Each well evaluation consists of the following phases:

- Land Preparation;
- Drilling Survey;
- Well Drilling;
- Well Completion;
- Well Flowline;
- Pump Unit; and
- Electrical.

Numbers and types of equipment associated with each well depth are listed below. An exact equipment list for each of the seven phases and their associated emissions is included as Appendix B.

Both drilling and operational emissions are assumed to occur along a fenceline shared by an oil producer and a private resident (i.e., sensitive receptors).

Table 1 – Equipment Associated with Well Construction, Drilling and Completion*

Depth Feet	Number of Trucks	Off-Road Construction Equip.	Drill Rig HP totals	Drilling Days
15,000	10	54	3 rigs at 1,040 HP each	65
10,000	9	45	3 rigs at 1,040 HP each	23
5000	9	45	3 rigs at 440 HP each	8
2000	9	45	3 rigs at 440 HP each	4

*As previously noted, this equipment is for the combined operation of all seven phases of construction, drilling and completion.

Table 2 – Emissions Associated with Well Constriction, Drilling and Completion

Depth Feet	Year[1]	Total PM10[2] pounds	Annual PM10[3] pounds	Days[4]
15,000	2015	1,626.80	23.24	65
10,000	2015	516.89	17.23	23
10,000	2018	444.00	14.8	23
10,000	2035	151.83	5.06	23
5000[5]	2015	171.18	5.71	8
5000	2035	35.86	1.20	8
2000	2015	97.12	3.24	4
2000	2035	20.42	0.68	4

[1]2029-2035 emissions are the same.
[2]From Vector Environmental Spreadsheet titled "DRL_EMISSIONS.xlsx", worksheet "EMF".
[3]Total emissions divided by 30 years per OEHHA's HARP2 exposure duration requirements.
[4]From Vector Spreadsheet titled "DRL_EMISSIONS.xlsx", worksheet "MUD".
[5]Note: 5,000' wells were not re-modeled as part of the revised HRA since previous results were less than 10 in one million.

Operational Equipment Emissions

Maximum daily and annual emissions were also quantified from an oil processing facility and a natural gas combustion facility. The equipment list and parameters was provided as part of our Scope of Work.

Oil and Gas Processing Equipment

Emissions from the following equipment were analyzed in the oil and gas processing HRA scenario:

- Two – 1,000 Bbl above-ground tanks;
- One – 3,000 Bbl above-ground tank;
- One - 10 MMBtu/hour Flare;
- One - Truck loading rack;
- Fugitive emissions from valves, flanges, and one underground sump;
- Thermally enhanced oil recovery (TEOR) equipment;
- One - 100 MMBtu/hour flare;
- One – 8 MMBtu/hour Process Heater;
- One – 10 MMBtu/hour Boiler;
- One – 85 MMBtu/hour Steam Generator; and
- One – 33 MW Cogeneration Plant.

Potential toxic emissions from each of these devices are summarized in Appendix A.

3.0 - EXPOSURE ASSESSMENT

Exposure assessment includes air dispersion modeling, identification of emission exposure routes and estimation of exposure levels. The modeling estimates ground level concentrations based on an emission rate of one gram per second. This rate is then multiplied by the worst case potential emission rate for each substance to obtain ground level concentrations. In addition to inhalation, potential pathways of exposure to offsite receptors include dermal exposure and ingestion.

HARP2 incorporates the USEPA AERMOD (v14134) model. AERMOD predicts resulting cumulative concentrations from various emission sources. The rural setting was selected in AERMOD for this analysis. AERMOD's terrain processor, AERMAP, was used to incorporate actual terrain elevations for sources and receptors. Five years of meteorological data required for AERMOD was obtained from the SJVAPCD. Data from the Bakersfield (Kern River), Fellows (Derby Acres), Missouri Triangle (Midway Sunset) and Wasco (Shafter) Stations were utilized. The USTAR option, a non-regulatory option, was requested by SJVAPCD.

Four different locations within Kern County were assessed in order to capture various terrain characteristics within the County. Two of the four areas: Derby Acres and Kern River were

selected by the air district and two were assessed as being representative of the remaining area of the county.

These areas were previously determined as being representative of various aspects of the county and were included as part of the Scope of Work in the DEIR: Western, Central and Eastern Kern County.

- Western Subarea – Midway Sunset Oilfield
- Central Subarea – No. Shafter Oilfield
- Eastern Subarea – Kern River Oilfield

SJVAPCD added an additional Western Area of complex terrain known as Derby Acres and asked that this area also be modeled. They moved the Midway Sunset previous location over about a mile and they moved the Kern River location to another Kern River location about 8 miles away. The Central Subarea is the exact same location in the original HRA and the revised HRA.

Terrain in the Central Subarea is relatively flat and modeling results would best represent dispersion characteristics with minimal terrain disturbances. More site location and terrain specific influences were observed in the Western Subarea and even more in the Eastern Subarea. Sufficient analysis of different factors that affect dispersion and other modeling inputs were covered by modeling three separate areas within Kern County. The Derby Acres location is a "bowl-type" setting which allows for minimal air dispersion in the immediate vicinity of the selected location.

The rural setting in AERMOD was selected and the model selects the terrain variability based on real-world conditions.

Table 3 shows the UTM location of the project centers for each selected Subarea.

Table 3 - Modeled Kern County Project Locations

Subarea	Easterly	Northerly
Western – Midway Sunset[1]	255,000	3918,100
Central – Shafter[1]	293,650	3934,400
Western – Derby Acres[2]	264,075	3904,580
Eastern – Kern River[2]	320,540	3922,785

[1]Based on Subarea modeling locations provided by Vector dated 2/15/2015 and rounded to the nearest 164 feet. (UTM NAD83, Zone 11)
[2]Provided by SJVAPCD

Source Modeling Parameters

Potential sources were modeled as described in the table below. Both drilling and operational emissions are assumed to occur along a fenceline shared by an oil producer and a private residence (i.e., sensitive receptor).

Table 4 - Modeling Source Characteristics and Release Parameters

Point Sources				
Source Name	Height, meters	Temp, ºK	Velocity, mps	Diameter, meters
Drilling	2.85	761.9	71.2	0.18
10 MMBtu/hr Flare[1]	10.79	1088.7	56.3	0.64
100 MMBtu/hr Flare[1]	13.85	1088.7	56.3	2.03
85 MMBtu/hr Steam Generator[2]	6.10	366.5	21.4	0.76
33 MW Cogen	9.14	806.0	20.7	3.05
8 mm Btu/hour process heater[2]	4.57	588.7	9.11	0.46
1000 bhp Natural Gas Engine[2]	6.78	745.2	3063.9	0.35
10 mm Btu/hour boiler[2]	6.10	477.6	7.3	0.46

Area Sources			
Source Name	Release Height, meters	X, meters	Y, meters
Fugitive leaks	1.00	10.00	10.00
Sump	0	9.14	9.14
Drilling Mud Sump	0	10.00	10.00
TEOR	0	5.00	5.00

Circular Area Sources		
Source Name	Height, meters	Radius, meters
1000 Bbl Tank	4.88	3.28
1000 Bbl Tank	4.88	3.28
3000 Bbl Tank	7.35	4.53

Volume Sources			
Source Name	Release Height, meters	Initial Lateral Dimension, meters	Initial Vertical Dimension, meters
Vacuum Truck Loading	4	0.60	0.93

4.0 - DOSE-RESPONSE

The dose-response assessment describes the quantitative relationship between a human's exposure to a substance (the dose) and the incidence or occurrence of an adverse health impact (the response). For carcinogens, OEHHA has developed cancer potency factors. A cancer potency factor represents the upper bound probability of developing cancer based on a continuous lifetime exposure. The cancer potency factor does not represent a threshold under which a person would not develop cancer, but instead is used to estimate the probability of developing cancer.

For non-carcinogenic chemicals, OEHHA has developed Recommended Exposure Limits (RELs) for acute and chronic impacts. RELS represent concentration thresholds at which no adverse noncancer health effects are anticipated. For chemicals that are not deemed by OEHHA as possible carcinogens but which may pose either short-term (acute) or other non-cancer long-term (chronic) health effects, a Hazard Index (HI) calculation of potential risk is also required by the air district and OEHHA an HRA.

Exposure Pathways

A receptor can be hypothetically exposed to a substance through several different pathways. Typically, the primary environmental exposure pathway in an HRA is direct inhalation of gaseous and particulate air pollutants. However, there is the potential for exposure via non-inhalation pathways due to the deposition of particulate pollutants (diesel particulate matter) in the environment.

For this analysis, HARP2 requires assumptions that diesel particulate matter could also be ingested via dermal (skin) absorption, soil ingestion and mother's milk ingestion. PAHs were the only pollutants analyzed for which there is a non-inhalation pathway.

The following table represents the relative toxicity of the compounds which contributed to most of the calculated risk. For example, DPM (with an inhalation potency factor of 1.1) is approximately 10 times more toxic than benzene (inhalation potency factor of 0.10) and PAHs are almost four times more toxic than DPM.

Table 5 - Chemical Cancer Risk Factors[1]

Chemical	Inhalation Unit Risk[2]	Inhalation Potency Factor[2]	Non-Inhalation Oral Slope Factor
	$(\mu g/m^3)^{-1}$	$(mg/kg\text{-}d)^{-1}$	$(mg/kg\text{-}d)^{-1}$
Diesel Particulate Matter	0.0003	1.1	NA (inhalation only)
Total PAHs[3]	0.001	3.9	12.0
Formaldehyde	0.000006	0.02	NA (inhalation only)
Benzene	0.029	0.10	NA (inhalation only)

[1]May 13, 2015.

[2]Inhalation cancer potency factor: The "unit risk factor" has been replaced in the new risk assessment algorithms by a factor called the "inhalation cancer potency factor". Inhalation cancer potency factors are expressed as units of inverse dose [i.e., (mg/kg-day)-1]. They were derived from unit risk factors [units = (ug/m3)-1] by assuming that a receptor weighs 70 kilograms and breathes 20 cubic meters of air per day. The inhalation potency factor is used to calculate a potential inhalation cancer risk using the new risk assessment algorithms defined in the OEHHA, *Air Toxics Hot Spots Program; Technical Support Document for Exposure Assessment and Stochastic Analysis (August 2012)*.

[3]Polycyclic Aromatic Hydrocarbons (PAHs): (Not including naphthalene.) These substances are PAH or PAH-derivatives that have OEHHA-developed Potency Equivalency Factors (PEFs) which were approved by the Scientific Review Panel in April 1994 (see ARB document entitled *Benzo[a]pyrene as a Toxic Air Contaminant*). PAH inhalation slope factors listed here have been adjusted by the PEFs. See OEHHA's Technical Support Document: Methodologies for Derivation, Listing of Available Values, and Adjustments to Allow for Early Life Exposures (2009) for more information about the scheme. Section 8.2.3 and Appendix G of OEHHA's *The Air Toxics Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments (2003)* also contains information on PAHs.

5.0 - SIGNIFICANCE THRESHOLDS

SJVAPCD publishes CEQA significance thresholds for potential health risk from proposed projects. Currently, risks from a project that are less than the following regulatory thresholds are considered not to be significant and are, therefore, acceptable:

- Cancer risk equal to or less than 20 in one million
- Chronic hazard index equal to or less than 1
- Acute hazard index equal to or less than 1

These metrics are generally applied to the maximally exposed individual (MEI). There are separate MEIs for residential exposure (i.e., residential areas) and for worker exposure (i.e., offsite work places).

6.0 - HEALTH RISK ASSESSMENT RESULTS

None of the modeling scenarios exceed a 20 in one million risk.

A revised refined HRA was performed again using the HARP2 model. As shown, calculated cancer risk from drilling a 15,000' well exceeds a threshold of 10 cases in one million (Table 6) at only one location – the Western Derby Acres site. At a distance of 182 feet, risk is below 10 in one million.

None of the other drilling scenarios exceed a 10 in one million risk.

The scenario in which all of the oil and gas processing equipment operates full time and is located in the exact same location with a shared fenceline to private property results in 20 in one million risk level from 164 – 295 feet depending on the subarea of Kern County (Table 8).

None of the noncancer hazards for either an oil processing facility or a gas processing facility exceed the regulatory threshold of 1.0 (Tables 9 and 10).

Table 6 –

Potential health risk from well construction, drilling and completion emissions

Well Depth (feet)	Year	Maximum distance from well site and project boundary to 10 in one million calculated risk	Maximum distance from well site and project boundary to 20 in one million calculated risk
Western Subarea – Midway Sunset			
15,000	2017	NA*	NA
10,000	2015	NA	NA
10,000	2020	NA	NA
10,000	2029	NA	NA
5000	2015	NA	NA
5000	2029	NA	NA
2000	2015	NA	NA
2000	2029/2035	NA	NA
Central Subarea - Shafter			
15,000	2017	NA	NA
10,000	2015	NA	NA
10,000	2020	NA	NA
10,000	2029	NA	NA
5000	2015	NA	NA
5000	2029	NA	NA
2000	2015	NA	NA
2000	2029/2035	NA	NA
Eastern Subarea – Kern River			
15,000	2017	NA	NA
10,000	2015	NA	NA
10,000	2029	NA	NA
5000	2015	NA	NA
5000	2029	NA	NA
2000	2015	NA	NA
2000	2029/2035	NA	NA
Western Subarea – Derby Acres			
15,000	2017	182 feet	NA

*NA = no offsite risk greater than 10 in one million.

Table 7 –

Potential health risks from all oil processing equipment

Equipment	Western Subregion – Derby Acres Cancer Risk Distances	Western Subregion – Midway Sunset Cancer Risk Distances	Central Subregion Cancer Risk Distances	Eastern Subregion Cancer Risk Distances
1,000 bbl oil tank				
1,000 bbl oil tank				
3,000 bbl oil tank				
truck loading rack				
30'x30' sump				
10,000 btu/hour flare				
Fugitive VOCs				
1,000 bhp natural gas engine				
100 mmbtu/flare				
35 mm btu/hour steam generator				
8 mm btu/hour boiler				
33 mw cogen				
TEOR equipment				
TOTAL CUMULATIVE RISK Distances to 10 in one million	518'	296'	366'	295'
TOTAL CUMULATIVE RISK Distances to 20 in one million	246'	295'	164'	259'

*Risk distances assume that all equipment is placed along a shared fence line between the oil site
and a private residence.

NOTE: All of this equipment would require SJVAPCD air permits. As such, the risk threshold must be complied with or permits cannot be issued. Under this scenario, either less equipment could be used and/or the receptors cannot share a fence line in order to obtain permits.

Table 9
Potential Acute Impacts

Equipment	**Western Subregion *Midway Sunset* Acute Risk**	**Western Subregion *Derby Acres* Acute Risk**	**Central Subregion Acute Risk**	**Eastern Subregion Acute Risk**	**Hazard Index Standard**	**Significant?**
Drilling Emissions 10,000' well	0.0039	0.0018	0.0098	0.0090	1.0	No

Equipment and Emissions for Well Depths

2015 Emissions from a 2000 ft. Well

Construction Activity: A1. Land Preparation

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Water Truck	1.0	7.0	8.48	400	3.46
Loader	1.0	4.0	2.5	100	.34
35 Yard Dump Truck	1.0	2 .0	1.00	400	.12
Grader	1.0	4.0	2.5	175	.77
Skip & Scrap (Backhoe)	1.0	1.0	1.0	100	.03
Big Scrapper	1.0	2.0	2.5	362	.47
Dozer (D9R)	1.0	1.0	1.0	255	.08
Low Bed Truck/Trailer	1.0	2.0	.5	400	.06
Dump Truck 10 Wheels	1.0	1.0	.5	400	.03
Backhoe	1.0	2.0	.54	100	.04
Loader	1.0	3.0	2.5	100	.26
Loader	1.0	2.0	1.0	100	.07
Escavator (Backoe/tracks)	1.0	1.0	1.0	163	.03
Dozer (D8T)	1.0	1.0	1.0	255	.08
End Dump Truck & Trailer	1.0	1.0	.50	400	.03
Grader	1.0	1.0	.50	175	.04
Annual Emissions From Offroad Source Activity					5.91

2015 Emissions from a 2000 Ft. Well

Construction Activity: B.1 Drilling Survey

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Rig	1.0	1.0	12.00	100	.58
Cement Truck	1.0	4.0	12.00	400	.70
Annual Emissions From Offroad Source Activity					1.28

2015 Emission from a 2000 Ft. Well

Construction Activity: C.1 Well Drilling

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Crane	1.0	2.0	8.00	230	.81
Port Light Stands	5.0	5.0	12.00	20	2.41
Portable Gen. Hydraulic Power	1.0	5.0	22.00	80	3.66
Portable Gen. DSM/Trailers	2.0	5.0	24.00	100	9.99
Portable Gen. Mud Separator	1.0	4.0	22.00	420	4.65
Rotary Table or Top Drive	1.0	4.0	22.00	135	5.63
Diesel Engine For Hoist	1.0	4.0	22.00	455	6.74
Diesel Engine For Hoist	1.0	4.0	22.0	442	6.55
Diesel Engine for Mud Pump	1.0	4.0	22.00	424	6.28
Annual Emissions From Offroad Source Activity					46.72

2015 Emissions from a 2000 Ft Well

Construction Activity: D.1 Well Completion

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Accumulator Generator	1.0	4.0	24.00	100	4.0
Filter Skid (Pump)	1.0	2.0	3.00	90	.22
Acid Pump #1 (Hydraulic Oil Pump)	1.0	1.0	22.00	175	.85
Acid Pump #2 (Acid Fluid Pumping)	1.0	4.0	22.00	765	2.17
Generator for Doghouse for WO Rig	1.0	4.0	24.00	70	2.8
3 Light Plants for WO Rig	3.0	4.0	12.00	20	1.15
Diesel Engine for COROD or Other	1.0	1.0	22.00	450	1.67
Portable Den. Mud Separator	1.0	4.0	22.00	420	4.65
Rotary Table or Top Drive	1.0	4.0	22.00	135	5.63
Diesel Engine for Hoist	1.0	4.0	22.00	455	6.74
Diesel Engine for Hoist	1.0	3.0	22.00	442	6.55
Diesel Engine for Mud Pump	1.0	4.0	22.00	424	6.28
Annual Emissions From Offroad Source Activity (Lb/Year)					42.71

2015 Emissions from a 2000 Ft. Well

Construction Activity: E.1 Well Flowline

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Side Boom D4/Crawler	1.0	3.0	10.00	520	.92
Backhoe	1.0	3.0	10.00	95	.98
Pipe Fitting or Welders	1.0	3.0	10.00	40	.48
Hydrotest Pump	1.0	1.0	1.00	.08	.01
Forklift	1.0	3.0	10.00	125	.56
Other Equipment/Bending Machine	1.0	3.0	10.00	80	1.12
Annual Emissions From Offroad Source Activity					4.07

2015 Emissions from a 2000 Ft. Well

Construction Activity: F.1 Pump Unit

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Power Generator	1.0	2.0	8.00	10	.06
Backhoe	1.0	2.0	4.00	80	.22
Welder	1.0	2.0	8.00	25	.16
Annual Emissions From Offroad Source Activity					.44

2015 Emissions from a 2000 Ft. Well

Construction Activity: G.1 Electrical

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Line Truck	1.0	4.0	10.00	250	1.73
Bucket Truck	1.0	4.0	10.00	250	1.73
Electrical Service Truck	1.0	4.0	1.00	300	.15
Power Generators	1.0	4.0	1.00	10	.02
Back-Hoe	1.0	1.0	10.00	650	.80
Annual Emissions From Offroad Source Activity					4.43

2015 Emissions from a 5000 ft. Well

Construction Activity: A1. Land Preparation

2015 Emissions from a 5000 Ft. Well

Construction Activity: B.1 Drilling Survey

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Rig	1.0	1.0	12.00	100	.58
Cement Truck	1.0	1.0	12.00	400	.70
Annual Emissions From Offroad Source Activity (Lb/Year					1.28

2015 Emission from a 5000 Ft. Well

Construction Activity: C.1 Well Drilling

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Portable Crane	1.0	2.0	8.00	230	.81
Port Light Stands	5.0	9.0	12.00	20	4.33
Portable Gen. Hydraulic Power	1.0	9.0	22.00	80	6.60
Portable Gen. DSM/Trailers	2.0	9.0	24.00	100	17.99
Portable Gen. Mud Separator	1.0	8.0	22.00	420	9.30
Rotary Table or Top Drive	1.0	8.0	22.00	135	11.26
Diesel Engine For Hoist	1.0	8.0	22.00	455	13.48
Diesel Engine For Hoist	1.0	8.0	22.0	442	13.09
Diesel Engine for Mud Pump	1.0	8.0	22.00	424	12.56
Annual Emissions From Offroad Source Activity					89.42

2015 Emissions from a 5000 Ft Well

Construction Activity: D.1 Well Completion

Vehicle Category and Use	Equipment		Engine		Emissions from Offroad Mobile Source Equipment (Lb/Well)
Description of Offroad Equipment	Count	Op Days	Hr/Day	HP	PM10
Accumulator Generator	1.0	8.0	24.00	100	8.00
Filter Skid (Pump)	1.0	2.0	3.00	90	.22
Acid Pump #1 (Hydraulic Oil Pump)	1.0	1.0	22.00	175	.85

Pollutants required for toxic reporting: HAPS w/o Risk Factor or Non - HAPs Current as of update date

Name	Oilfield Natural Gas-Fired + Waste Gas Flare			
Applicability	Use this spreadsheet for Natural Gas/Waste Gas-Fired Flares at an Oilfield or Refinery			
Author or updater	Matthew Cegielski	*Last Update*	June 18, 2013	
Facility:	Kern EIR			
ID#:	10 MMBtu/hr Flare			
Project #:				

Inputs	MMscf/hr	MMscf/yr
Flare Rate	1.00E-02	87.60
Specific Gravity of Gas	0.45	
Destruction Efficiency %	98.00	
Methane %	100.00	
	MMscf/hr	MMscf/yr
Flare Gas Methane Rate	0.01	87.60
	MMscf/hr	MMscf/yr
Uncombusted VOCs Rate	2.00E-04	1.75E+00

Formula

Emissions are the result of combustion plus the pass through of uncombusted VOCs. Emissions are determined by the multiplication of each corresponding process Rate and Emission Factor. Enter the Destruction efficiency as a whole number. Default is 98. Enter specific gravity of gas as a decimal. Default is 0.45 Enter the % methane as a whole number. Flare gas assumed to be 100% as a worst case if value is unknown. Waste gas characterization defaults are listed on the Reference tab and can be modified by changing the mole fraction values if so desired.

Diesel Emissions
Well Construction

Diesel Particulate Matter	9901	2.03	18.70

Name	Oilfield Field Gas Turbine - CATEF			
Applicability	Use this spreadsheet for Natural Gas/Waste Gas-Fired Flares at an Oilfield or Refinery			
Author or updater	Matthew Cegielski	*Last Update*	June 18, 2013	
Facility:	Kern EIR			
ID#:	33 MW Field Gas Cogeneration Turbine			
Project #:				

Inputs	MMscf/hr	MMscf/yr
Fuel Rate	2.82E-01	2,470.32
Specific Gravity of Gas	0.45	
Destruction Efficiency %	98.00	
Methane %	100.00	
	MMscf/hr	MMscf/yr
Flare Gas Methane Rate	0.282	2,470.32
	MMscf/hr	MMscf/yr
Uncombusted VOCs Rate	5.64E-03	4.94E+01

Formula

Emissions are the result of combustion plus the pass through of uncombusted VOCs. Emissions are determined by the multiplication of each corresponding process Rate and Emission Factor. 98% Destruction efficiency is assumed. Enter specific gravity of gas as a decimal. Default is 0.45 Enter the % methane as a whole number. Waste gas characterization defaults are listed on the Reference tab and can be modified by changing the mole fraction values if so desired.

Executive Summary

Background

Kern County, located in California's southern San Joaquin Valley, is one of the richest and oldest oil-producing areas in the United States, representing approximately 80 percent of the oil and gas currently produced daily in California. Recently, the California Independent Petroleum Association (CIPA), the Independent Oil Producers' Agency, Inc. (IOPA), and the Western States Petroleum Association (WSPA) requested an amendment to the Kern County Zoning Ordinance to include provisions for local permitting of oil and gas production. Specifically, the amendments are intended establish updated standards and conditions to:

- Address environmental effects of pre-drilling exploration, well drilling, and the operations of wells, including exploration, production, completion, SB 4 regulated well stimulation operations, reworking, injection, monitoring, and plugging.

- Establish a new "Oil and Gas Conformity Review" ministerial permit procedure for county approval of well drilling and operation projects.

- Amend Title 19 of the Kern County zoning ordinance focused on Chapter 19.98 for Oil and Gas Local Permitting.

This amendment requires a project-level Environmental Impact Report (EIR) be prepared under the California Environmental Quality Act (CEQA), with Kern County serving as the lead agency. The intent of the EIR process is to provide economically feasible and environmentally responsible growth of oil and gas production in Kern County while protecting the environmental resources and maintaining the long-term sustainability of those resources.

Objective

The Water Quality Assessment (WQA), described herein, has been prepared to provide technical support to the EIR with respect to water quality in the Project Area from oil and gas operations. The objective of the WQA is to evaluate the potential effects to surface water and groundwater quality from future oil and gas exploration and production operations in the Project Area, defined as the southern end of the San Joaquin Valley, from the valley floor and the gently sloping foothills at the valley's southern edge, to elevations below 2,000 feet.

The WQA provides an assessment of the effects on water quality over the range of possible site locations within the Project Area from current and future oil and gas operations. The WQA describes the project setting, local geology, existing surface and groundwater quality conditions, and oil exploration and production activities conducted in the project area. From this information, the WQA evaluates potential impacts from these activities to surface water bodies and groundwater in the Project Area.

Geologic Setting

The San Joaquin Valley is filled with thousands of feet of marine and continental sediments derived from the surrounding Sierra Nevada and Coast Ranges. The sediment thickness generally increases from the valley margins toward the center, but is thickest along the western side of the valley, where up to 30,000 feet of sediments are found forming an asymmetrical basin. The land surface slopes gently, generally less than four percent, from the foothills along the valley margins to the lower elevation near historical dry lake beds along the northern boundary and west-central portions of the valley. The Project Area has internal drainage that is characterized by several large dry lake beds including the Tulare Lake basin just north of Kern County and Buena Vista Lake and Kern Lake at the southern end of the valley.

Mountains and highlands surround the San Joaquin Valley. The Sierra Nevada Foothills rise up to the east of the Project Area towards the metamorphic and igneous rocks of the Sierra Nevada Batholith exposed to the east. To the west are the faulted and folded Tertiary-aged sediments that comprise the Temblor Range of the Coast Ranges. The Tehachapi Mountains and San Emigdio Mountains rise up from the valley floor to the south. Along the southern boundary, the metamorphic and igneous rocks underlie the Tehachapi Mountains whereas faulted and folded sedimentary rocks underlie the San Emigdio Mountains.

The valley floor is underlain by coalescing Quaternary alluvial fans that have formed along the mountain front, resulting in heterogeneous and discontinuous lenses of gravels and sands with increasing silt and clay towards the center of the basin. The San Joaquin valley is filled with predominantly Late Cretaceous to Pliocene-aged sediments, with organic-rich marine rocks of Late Cretaceous, Eocene, and Miocene age providing the source of most of the oil and gas resources. Significant reservoir rocks include the Point of Rocks member of the Kreyenhagen Formation, the Stevens Sand member in the Monterey Formation, and the Chanac and Kern River Formations. Oil and gas traps in the area are both structural, such as in anticlinal folding or faulting, and stratigraphic where the oil pooled in a reservoir rock is trapped by adjacent impermeable rocks.

Water Resources

The Project Area has been divided into three geographic sub-areas, which include (1) the West sub-area, encompassing the Coast Range hills in western Kern County, (2) the Central sub-area, defined as the largely flat valley floor and gently sloping alluvial sediments that comprise the southern San Joaquin Valley basin, and (3) the East sub-area, which encompasses the western foothill of the Sierra up to an elevation of 1,000 feet.

The Project Area is located in the Tulare Lake Hydrologic Basin. The majority of the surface water supply is derived by the Kings, Kaweah, Tule, and Kern Rivers, which drain the west face of the Sierra Nevada. The Basin is essentially closed, as flood flows during periods of heavy runoff represent the only significant outflows from the Basin. Two lakes in the Basin are supplied by flood water from the major rivers during times of heavy runoff: Buena Vista Lake (located in the Project Area) and Tulare Lake (north of the Project Area).

Of these rivers mentioned above, only portions of the Kern River fall within the Project Area. According to the Water Quality Control Plan for the Tulare Lake Basin (Basin Plan), these

waters are of excellent quality. Besides these main rivers, there are also numerous mountain streams in the Basin, divided into “eastside” and “westside” streams in the Basin Plan using Highway 58 between Bakersfield and Tehachapi.

The primary groundwater aquifers beneath the Project Area include the undifferentiated Plio-Pleistocene sedimentary deposits of the Tulare and Kern River Formations, and unconsolidated Quaternary alluvium consisting of alluvial and terrace deposits. The Tulare Formation contains several thick, regionally extensive clay layers. The most important of these is the Corcoran member of the Tulare Formation, also referred to as the Corcoran Clay, a unit sufficiently thick to create confining conditions below it. The unconfined water-bearing zone above the Corcoran Clay is generally associated with poor-quality groundwater (e.g., impacted by elevated nitrate and total dissolved solids) in comparison to the “main aquifer” characterized by confined, fresh, calcium-bicarbonate/sodium-bicarbonate water at depths of 300 to 800 feet below ground surface. Groundwater production from wells in the Central sub area typically ranges in the 100’s to 1,000’s of gpm and is used for agricultural irrigation, as well as municipal and industrial uses.

Below the production zone is a few hundred feet of aquifer that ranges from about 500 mg/L sodium bicarbonate to about 2,000 mg/L chloride. Few wells are constructed in this layer and it is not considered part of the “main aquifer”. The depth to the base of fresh water varies significantly along the western edge of the valley and is near the surface in some locations. Testing indicates that there is poor hydraulic connection between the transition layer and the main aquifer in that area. A thick high sodium chloride aquifer underlies the transition zone. It consists of reduced black-green, coarse sediments. Salinity grades from about 3,500 mg/l to over 5,000 mg/L. Little is known of the salinity of the deeper regions.

There is a strong regional variation in natural groundwater quality associated with the underlying local geology. In the West sub-area, marine-derived sedimentary materials are present that are relatively easily dissolved, yielding a higher dissolved solids content, and hence poorer quality, groundwater. Consequently, groundwater and surface water in the West sub-area are generally not used as sources of potable water supply. In contrast, groundwater in the Central and East sub-areas is recharged by water initially in contact with igneous and metamorphic rocks of the Sierra. These materials are much less readily dissolved, so the resultant groundwater quality is generally of much better quality in comparison.

Oil and Gas Operations

Water is used in oil and gas production in a variety of capacities, including well drilling, well completion and abandonment, well stimulation, production, enhanced oil recovery, and wastewater storage and disposal. Potential impacts to surface water or groundwater quality can result from the various operations involving the handling of water that is transported to the site or wastewater (e.g., flowback, produced water) or that is generated from the oil and gas-producing wells. Examples include potential impacts to surface soil (residual contaminants adsorbed to soil can impact local surface waters quality through erosion and run-off, as well as shallow groundwater through infiltration), surface water (direct impact from surface releases), shallow groundwater (through infiltration and direct contact from downhole releases), and deep (below the Corcoran Clay and/or below the fresh water interface) groundwater (direct contact from downhole releases).

The activities associated with oil and gas production are already highly regulated. Pertinent regulations that apply to potential releases of water used in these activities to the environment (e.g., land surface, shallow potable aquifer) include,

- At the federal level – under the purview of the Clean Water Act – pertinent regulations include:
    - Spill Prevention (40 CFR Part 112),
    - the National Pollutant Discharge Elimination System Program (40 CFR Part 122 to 129),
    - the National Toxics Rule (40 CFR Part 131),
    - the National Oil and Hazardous Substance Pollution Contingency Plan (NCP) (40 CFR Part 300),
    - Oil and Gas Extraction Point Source Discharge (40 CFR 435),
    - the Oil Pollution Act (33 U.S.C. 2701 et seq.),
    - the Safe Drinking Water Act (42 U.S.C. §300f et seq.),
    - the Resource Conservation and Recovery Act (42 U.S.C. §6921-6992k),
    - the Solid Waste Disposal Act (42 U.S.C. §6901 et seq.),
    - the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) (42 U.S.C. §9601-9662), and
    - the National Environmental Policy Act (NEPA).

- At the state level, pertinent regulations include:
    - the California Environmental Quality Act 14 CCR Division 2, Chapters 2);
    - Oil and Gas Resource Regulations (14 CCR Division 2, Chapters 4), including Section 1722 - Field Rules on Oilfield Spills,
    - the Underground Injection Control Program, and Facility Maintenance Standards (California Assembly Bill 1960);
    - Well Stimulation Treatments (California Senate Bill No. 4, Chapter 313);
    - Hazardous Waste Control Law (22 CCR subsections 66261);
    - the Porter-Cologne Water Quality Control Act (California Water Code [CWC] Sections 13020 et seq.), including Basin Plans and Beneficial Uses (CWC Section 13240), Anti-degradation Policy (23 CCR 2900 – Resolution 68-16),
    - Surface Water Disposal (CWC Section 13260 to 13275),
    - Land Disposal (CWC Section 13260 to 13275);
    - Surface Impoundments, including Siting (27 CCR, Section 20240); and
    - Storm Water Discharge Regulations.

- At the county level, pertinent regulations include:
    - Aboveground Petroleum Storage Act (APSA),
    - the California Accidental Release Program (CalARP) (19 CCR Ch. 4.5, Section 2735.5), and
    - Groundwater Production and Monitoring Wells (County Ordinance Code, Chapter 14.08).

Potential Impacts to Water Resources from Oil and Gas Production

Potential water quality impacts are summarized qualitatively within the WQA, addressing a range of release scenarios. Quantitative impact assessments will necessarily be (1) highly site-specific, and (2) highly dependent upon the scale of any release. Consequently, quantitative impact predictions from posited release events were not undertaken. The intent of the qualitative impacts summary is to provide a comprehensive list of the possible effects to surface water and groundwater quality that could result from intentional or unintentional, direct or indirect, release of water that is used or produced by the oil and gas industry in the Project Area.

The list of impacts presents most reasonably foreseeable potential impacts, although it may not capture every possible impact from unforeseen circumstances. The evaluation of impacts does not include potential effects to groundwater quality or purchased water quality over time from long-term acquisition (i.e., surface or groundwater withdrawal for water supply to oil and gas operations) or resulting disposal.

Section 1: Introduction

Representatives of the oil and gas industry associations, specifically the California Independent Petroleum Association (CIPA), the Independent Oil Producers' Agency, Inc. (IOPA), and the Western States Petroleum Association (WSPA), collectively, "the applicants", have requested an amendment to Chapter 19.98 (Oil and Gas Production) of the Kern County Zoning Ordinance to include provisions for local permitting of oil and gas production. Specifically the amendment will establish updated standards and conditions to:

- Address environmental effects of pre-drilling exploration, well drilling, and the operations of wells, including exploration, production, completion, well stimulation operations, reworking, injection, monitoring, and plugging
- Establish a new "Oil and Gas Conformity Review" ministerial permit procedure for County approval of well drilling and operation projects
- Amend Title 19 of the Kern County zoning ordinance focused on Chapter 19.98 for Oil and Gas Local Permitting

The amendment requires a project level Environmental Impact Report (EIR) be prepared under the California Environmental Quality Act (CEQA), with Kern County as the Lead Agency. The EIR will address oil and gas exploration and production activities and result in development of standards and mitigation measures for oilfield activities (Kern County PCDD 2013). The EIR is being prepared to assess the relative impacts of future oil and gas development and operational activities within Kern County. The purpose of the EIR process is to provide economically feasible and environmentally responsible growth of oil and gas production in Kern County while protecting the environmental resources and maintaining the long-term sustainability of those resources. This Water Quality Assessment (WQA) is prepared in support of the EIR and provides a summary of existing surface water and groundwater quality information and evaluates potential impacts to water quality from oil and gas exploration and production operations.

1.1 Project Location and Setting

Kern County is one of the richest and oldest oil-producing counties in the US and is currently producing about 80 percent of the oil and gas produced daily in California. Kern County is located in California's southern Central Valley area; and is bounded by Kings, Tulare, and Inyo Counties on the north, San Bernardino County on the east, Los Angeles and Ventura Counties on the south, and Santa Barbara and San Luis Obispo Counties on the west. The Project Area includes eight incorporated cities: Arvin, Bakersfield, Delano, Maricopa, McFarland, Shafter, Taft, and Wasco.

The proposed amendment to the Zoning Ordinance will apply to the Project Area (Figure 1-1), which includes most of the valley floor area of Kern County and the lower elevations of the

surrounding mountain ranges, up to 2,000 feet above mean seal level (msl). This area contains geologic deposits that account for numerous oil and gas reservoirs throughout the southern Central Valley. According to the Department of Conservation, Division of Oil, Gas and Geothermal Resources (DOGGR) records, 99 active or abandoned oil fields are located within the Project Area (Figure 1-2), ranging in size from a few hundred acres to more than 65,000 acres.

The Project Area encompasses about 3,700 square miles and generally includes the San Joaquin Valley Floor portion of Kern County up to an elevation of 2,000 feet. Figure 1-1 shows the boundaries of the Project Area and the three oil and gas Sub-Areas (West, Central, and East) that were considered for the purpose of the WQA, based on the boundaries defined by Kern County for the EIR. For the purpose of this report, these two boundaries will be referred to as the Project Area and the three Sub-Areas. The Project Area boundary and Sub-Area boundaries were defined by Kern County based on generally available information regarding areas with potential or confirmed oil and gas resources.

The Project Area is also divided into “Core Areas”, which represent the aerial extent of the 99 active and abandoned oil fields (Figure 1-3), including a buffer zone around each oil field; and land use areas referred to as “Tier” areas. The land use designations for the Tier Areas are defined as:

Tier 1 – oil and gas exploration and production is the primary land use (synonymous with the “Core” areas not including the buffer zones)

Tier 2 – agriculture is the primary land use

Tier 3 – light manufacturing and industrial is the primary land use

Tier 4 – unincorporated cities, airports, industrial, manufacturing, residential, and commercial uses are prevalent

1.2 Objectives

The objective of the WQA is to evaluate the potential effects to surface water and groundwater quality from future oil and gas exploration and production operations in the Project Area. The WQA describes the project setting and local geology, reviews existing surface and groundwater quality conditions, summarizes oil exploration and production activities conducted in the project area, and evaluates potential impacts from these activities to surface water bodies and groundwater in the Project Area.

This WQA also presents Water Management Strategies (WMS) as potential measures to protect and/or improve surface water and groundwater quality in the project area. The WMS summarize typical operations related to oil and gas exploration and production, describe potential impacts to water quality, and propose procedures and best management practices to be implemented to mitigate the potential impacts.

Section 2: Project Area Geology

To provide context for evaluating water quality, this section summarizes the key geological features that relate to both oil and gas reservoirs and groundwater resources.

2.1 Regional Geology

This section on regional geology provides the overall geologic setting and history of the Project Area to describe the geologic variations that occur across the Project Area.

2.1.1 Physical Setting

The Project Area (Figure 1-1) is located at the southern end of the San Joaquin Valley, and is comprised of the valley floor and the gently sloping foothills at the valley's southern edge, to elevations below 2,000 feet. The land surface within the Project Area generally slopes from the foothills along its southern and eastern boundaries to the lower elevation along its northern boundary near historical dry lake beds in the west-central portion of the valley. Grades are generally less than four percent and the topography can generally be characterized as flat. The Tehachapi Mountains and San Emigdio Mountains rise up from the valley floor to the south, while the Temblor Range of the Coast Ranges and the Sierra Nevada Foothills rise up to the west and east of the Project Area. The Project Area has internal drainage that is characterized by several large dry lake beds including the Tulare Lake basin just north of Kern County and Buena Vista Lake and Kern Lake at the southern end of the valley (Bartow and McDougall 1984; Bartow 1991).

2.1.2 Geology

The San Joaquin Valley is filled with thousands of feet of marine and continental sediments of Tertiary and Quaternary age derived from the surrounding Sierra Nevada and Coast Ranges, and their southern extensions. The sediment thickness increases from the valley margins toward the center. The sequence of sediments forming the basin is asymmetrical, with the thickest sediments occurring along the western side of the valley where up to 30,000 feet of sediments are found in the southwest portion of Kern County (Page 1986).

Figure 2-1 provides the general geologic map for the Project Area. Two structural blocks, the Sierra Nevada on the east and the Coast Ranges on the west, have contributed mineralogically-distinct sediments that interfinger in the subsurface (Bartow and McDougall 1984; Bartow 1991; Page 1986; Wood and Dale 1964). The valley floor is underlain by coalescing Quaternary alluvial fans that have formed along the mountain fronts, resulting in heterogeneous and discontinuous lenses of gravels and sands with increasing silt and clay content towards the center of the basin. The metamorphic and igneous rocks of the Sierra Nevada Batholith are exposed to the east. To the west are the faulted and folded Tertiary-aged sediments that comprise the Coast Ranges (shown as Pliocene, Miocene, Oligocene, Eocene and Paleocene sediments on Figure 2-1). Along the southern boundary, the metamorphic and igneous rocks underlie the Tehachapi Mountains (Sierra Nevada block) whereas faulted and folded sedimentary rocks underlie the San Emigdio Mountains (Coast Ranges block).

2.1.3 Geologic History

Basin sedimentation in the southern San Joaquin Valley began in the Jurassic Period, with the erosion of the rising Sierra Nevada in the east. Sediments were deposited onto the shelf edge of a shallow sea. Because the Coast Ranges orogeny had not yet begun, lands to the west were open to the ocean. Deposits accumulated in the deeper water to the west, resulting in the very thick Franciscan Formation that was later uplifted, forming the Coast Ranges. Deposition proceeded throughout the Mesozoic, which is represented by more continuous units and an absence of deformation (Wood and Dale 1964; Croft 1972).

Tectonic activity associated with the uplift of the Coast Ranges began in the Tertiary Period and resulted in folding and faulting of sediments along the west side and a deepening of the valley floor. Thick sequences of marine sediments that were deposited as the Coast Ranges orogeny continued. By the late Tertiary (Pliocene Epoch), the mountains had cut off the connection to the sea and marine waters had been drained from the valley. As deposition continued, non-marine (continental) sediments were deposited across the valley (Bartow and McDougall 1984; Bartow 1991).

The Pleistocene Epoch was dominated by brackish and freshwater lakes resulting in thick deposits of clay, as represented throughout the upper Tulare Formation. These include the widespread Corcoran Clay, which has been mapped over much of the San Joaquin Valley, and its equivalents which have been correlated to clays beneath the Kern and Buena Vista dry lake beds in the southern Project Area as well as the Tulare Lake sediments on the northern boundary of the County (Wood and Dale 1964; Croft 1972). A more detailed description of the Corcoran Clay is provided in Section 2.4.2.

2.1.4 Structural Geology

The San Joaquin Valley is an asymmetrical syncline (Figure 2-1) or trough that runs north-south with the center along the western side of the valley. Although the San Joaquin Valley constitutes part of a discrete geomorphic province, the geology is internally variable in both stratigraphy and style of deformation. Stratigraphically, the greatest variation is the thick section of marine sediments in the southern part of the basin that grades to thinner, non-marine sediments north of Kern County. Structurally, the greatest differences are between the highly-folded sedimentary layers on the west and the little-deformed sedimentary cover on the east side of the valley (Bartow 1991).

The tectonic activity in the area has produced numerous geologic faults, many of which remain active today. Notable faults and folds are shown on Figure 2-1. Figure 2-1 also illustrates the position of the major oil fields in the Project Area relative to major structural features, such as the Bakersfield Arch and the Cenozoic Basin depositional axis. Two generalized west to east cross sections are presented on Figure 2-2 and 2-3 to further illustrate the variability in geology across the Project Area.

The Bakersfield Arch (Figure 2-1) separates the San Joaquin Valley in the Project Area into a northern and southern area. The arch does not have appreciable structural relief, but does have an influence on sedimentation. The thickest sequences of Tertiary sediments of these basins occur approximately coincident with the Pleistocene and Holocene Buena Vista and Kern Lake

basins in the south and the Tulare Lake basin in the north. The Mesozoic and early Tertiary Great Valley sequence, on the other hand, thins southeastward and is apparently absent south of the Bakersfield Arch (Bartow 1991).

The highly-folded western margin of the valley north of the Bakersfield Arch is characterized by Cenozoic folds and faults that trend, for the most part, slightly oblique to the San Andreas Fault on the southwest. The southeast boundary of the fold belt is arbitrarily placed east and south of Elk Hills where the fold trends change from northwest to west (Figure 2-2 and 2-3). The east boundary deviates from the valley syncline axis to include the subdued anticlines that, although lying east of the valley axis, are structurally more akin to the west-side fold belt than to the less-deformed eastern margin (Figure 2-3). The intensity of deformation increases southeastward along the fold belt as well as southwestward across the belt toward the San Andreas Fault. The increased intensity is evidenced by tighter folds and an increased number of reverse and thrust faults (Bartow 1991).

Normal faults along the east side of the valley are concentrated in the area of the Bakersfield Arch. These faults generally trend northwest to north, although a secondary west to west-northwest trend is apparent (Figure 2-2 and 2-3). The net displacement is down to the southwest, although down-to-the-northeast faults are present (Bartow and McDougall 1984; Bartow 1991).

South of the Bakersfield Arch, the structural trends are variable but there is a general west trend along the south margin of the basin (Figure 2-1). The northwest fold trends of the west-side change to west-northwest where that region merges with the deformed belt at the south end of the valley. The northeast-trending White Wolf fault is the dominant structure (Figure 2-1). The White Wolf fault and the smaller Springs fault to the southeast both trend approximately parallel to the Garlock fault, which lies along the southeast side of the Tehachapi Mountains. Both faults, like the Garlock, show some geologic evidence of left-lateral movement. Farther northeast, the northwest- to west-trending Edison fault is an older Tertiary normal fault (Bartow and McDougall 1984; Bartow 1991).

2.1.5 Project Sub-area Characteristics

As described in Section 1, the Project Area has been divided into three geographic sub-areas (Figure 1-1) for the purposes of this water quality evaluation. The sub-areas differ in terms of their physical and geological conditions, which influence the water qualities of local surface and ground waters (described in Section 3: Surface Water and Groundwater Quality). The following is a brief summary of the general characteristics of the three geographic sub-areas.

- ***West Sub-area –*** includes the Coast Range hills in western Kern County and is typified by comparatively poor groundwater quality (relative to the other two sub-areas). Figure 1-1 shows that north of Bakersfield, the East Sub-Area consists of the area west of Interstate 5. Local geology influences the water composition of groundwater and streams draining the area, and is characterized by sedimentary materials that are more easily dissolved, compared to the East sub-area. The Corcoran Clay is present in the eastern portion of this sub-area and separates shallow and deep groundwater zones. The geologic cross-section presented as Figure 2-3 illustrates the occurrence of saline groundwater west of the Lost Hills (generally west of I-5).

- ***Central Sub-area –*** primarily includes the largely flat, gently sloping alluvial sediments that comprise the southern San Joaquin Valley basin in the Project Area. Figure 1-1 shows that north of Bakersfield, the East Sub-Area consists of the area east of Interstate 5 and west of Highway 65. Agricultural land use is predominant in this sub-area. Groundwater production from wells typically ranges in the 100's to 1,000's of gallons per minute and is used for many beneficial uses including agricultural irrigation, municipal water systems and industrial processes. The Corcoran Clay is present throughout much of this sub-area and separates the shallow and deep groundwater zones. The geologic cross section presented as Figure 2-3 illustrates that the groundwater in the upper several hundred to over one thousand feet is relatively fresh, making this the primary aquifer for the region.

- ***East Sub-area –*** includes the West Sierra Foothills, up to an elevation of approximately 1,000 feet msl, and portions of the gently sloping alluvial sediments downslope of the West Sierra Foothills. Figure 1-1 shows that north of Bakersfield, the East Sub-Area consists of the area east of Highway 65. The geologic cross section included as Figure 2-3 illustrates that the sediments thin towards the east as they overlay onto the granitic basin. In the Foothills, the local geology is characterized by tight, poorly draining, low-solubility igneous and metamorphic rocks, which influences the water composition of streams draining the area. Groundwater wells typically have to moderate production (typically in the 10's to 100's gpm) that is used for mostly domestic (i.e., private well) and small community wells. The alluvial areas are similar geologically to the Central Sub-area, but are distinguished from the West and Central sub-areas, in part, by the absence of the Corcoran Clay. Groundwater production from the alluvial areas also is in the range of 100's to 1,000's of gallons per minute that is used for multiple beneficial uses. Groundwater in the East Sub-area generally has good groundwater quality.

2.2 Oil and Gas Field Geology

A typical petroleum-bearing system is comprised of an organic-rich source rock, reservoir rock, an adequate stratigraphic or structural seal, and; favorable timing for petroleum generation, migration, traping, and accumulation. Migration paths from source rocks to the reservoir rock can be complex, and reservoir rocks can be distant, stratigraphically, geographically, and chronologically, from source rocks (Lillis and Magoon 2007).

2.2.1 Reservoirs

Structural features in the southern San Joaquin basin are largely functions of the complex interplay of compression and fault displacement along North America's western margin, as well as regional uplift. The compression and displacement resulting in the folding and faulting strongly influences the locations of hydrocarbon accumulations. A generalized stratigraphic column for the southern San Joaquin Valley is presented on Figure 2-4, and illustrates the key formations that act as oil and gas reservoirs in the Project Area.

Notable reservoir rocks include, for example, the Point of Rocks member of the Kreyenhagen Formation, the Stevens Sand member in the Monterey Formation, and the Chanac and Kern River Formations. In the Project Area, oil and gas are commonly produced from multiple

reservoir formations within the same field, and each formation may produce mainly oil, mainly gas, or both (Hosford Scheirer and Magoon 2007).

Traps may be structural, such as in anticlinal folding or faulting, or stratigraphic where the oil pooled in a reservoir rock is capped by adjacent impermeable rocks (DOGGR 1998). A variety of traps are found in the Kern County fields. Examples of traps are illustrated for each oil field in a series of cross sections presented in Appendix A.

2.2.2 Source Rocks

The San Joaquin valley trough is filled with predominantly Late Cretaceous to Pliocene-aged sediments, with organic-rich marine rocks of Late Cretaceous, Eocene, and Miocene age providing the source of most of the oil and gas (Lillis et al. 2007). Figure 2-5 illustrates the extent of two of the major source rock groups, the older Eocene Kreyenhagen-Tumey and the Miocene Monterey Formations. The Kreyenhagen source rocks are thickest in the west along the basin axis, and the Miocene rocks are more widespread.

The Eocene and younger oils found in California generally contain a great deal of hydrogen sulfide gas and a high carbon-to-hydrogen ratio compared to older oils, making California oils heavier and more viscous. Generally, many California oils are thus more difficult to produce, transport, and refine compared to other oils (DOGGR 1993). Most of California's "heavy" oil (oil exceeding a specific gravity and viscosity) is in Kern County (Guerard 1998). In the Project Area, oils differ in viscosity from field to field. Oil in some fields will flow freely (e.g., the gushers from west side fields) but in others (e.g., the Kern River field) the oil is thick and generally must be heated to be produced.

Lillis and Magoon (2007) describe three broad oil types linked to source rocks in the Kern County area. Oil sourced mainly from the marine shales of the Miocene Monterey Formation, with evidence of terrigenous influence, is found in the eastern and southern parts of the Project Area. Oil sourced from the Eocene Tumey Formation are found in the central and west central part of the Project Area, but are predominantly north of Kern County. Oil sourced from the Eocene Kreyenhagen Formation is widely distributed along the western side of the basin (e.g., Antelope Hills, Antelope Hills North, Belgian Anticline, McKittrick, Paloma fields).

Lillis et al. (2007) describe three general gas types in the Project Area: thermogenic dry gas, thermogenic wet gas, and biogenic gas. Thermogenic gas is generated by the cracking of kerogen or oil at higher temperatures with increasing burial. Thermogenic 'dry' gas is linked to Miocene-age oil-prone source rock. Thermogenic wet gas is linked by Lillis et al. (2007) to the Kreyenhagen and Tumey Formations, whereas Thermogenic 'dry' gas is linked to the Monterey Formation. Biogenic 'dry' gas is produced from shallow reservoirs in the Pliocene San Joaquin Formation, and most likely originated from the microbial decomposition of marine organic matter in the Pliocene San Joaquin formation. Fields with wells completed in the Tulare, San Joaquin, or Etchegoin formations are likely to produce biogenic gas from these formations (Lillis et al. 2007) in addition to thermogenic gas.

2.3 Oil and Gas Fields in Kern County

A regional geologic map including oil fields is presented on Figure 2-1. In general, oil fields are more numerous along the western side of the San Joaquin basin (near the Cenozoic basin's

depositional axis, where sediments are thickest) and along the Bakersfield Arch, but are found throughout the Project Area.

Table 2-1 lists the name, stratigraphic formation and depth for oil and gas pools for each administrative oil field in the Project Area (DOGGR 1998). A geologic cross section for each oil field in the Project Area (DOGGR 1998) is included in Appendix A.

2.4 Groundwater Basin Geology

Groundwater for municipal, industrial and agricultural use is primarily derived from the alluvial deposits in the flat-lying portions of the valley primarily in the Central and East Sub-areas. The following discussion provides information on the occurrence of groundwater in the San Joaquin Valley and its relevance to water quality.

2.4.1 Groundwater Basin Designation

Boundaries for California groundwater basins and sub-basins are designated by California Department of Water Resources (DWR) Bulletin No. 118, California's Groundwater Update (CA DWR 2006). The portion of Kern County that lies within the San Joaquin Valley is designated as the Kern County sub-basin (DWR Groundwater Basin Number: 5-22.14). This sub-basin is located in the part of the San Joaquin Valley Basin known as the Tulare Lake Hydrologic Region.

Historically, the high groundwater levels directly beneath Kern River have established a hydrologic divide, restricting groundwater south of the river from flowing to the north. On the eastern side of the valley, a series of faults effectively prevent significant hydraulic connection between the groundwater in the dissected uplands and in the valley aquifer. Along the western side of the Project Area, a series of southeast-plunging anticlines has uplifted and exposed sediments with poor hydraulic characteristics to the surface. These uplifts appear to be preventing groundwater flow from these western areas to the valley aquifer. The Semitropic and Buttonwillow anticlines are covered by permeable alluvial sediments allowing for groundwater flow over them. In the northern part of the Project Area, clays of the Tulare Lakebed effectively create a groundwater flow barrier to the west and northwest. To the northeast, groundwater does flow between the Kern County sub-basin and the Tule sub-basin and, to a lesser extent, to the Tulare Lake sub-basin. The extent of the interconnection is not certain; however, groundwater elevations and a persistent groundwater depression in northern Kern County indicate that effective groundwater interaction does occur with areas located immediately north of the Kern County boundary (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

2.4.2 Aquifer Stratigraphy

The primary groundwater aquifers beneath the Project Area include the undifferentiated Plio-Pleistocene sedimentary deposits of the Tulare and Kern River Formations, and unconsolidated Quaternary alluvium consisting of older stream and terrace deposits, and more recent flood basin deposits. These formations are underlain by undifferentiated Tertiary sedimentary rocks and a crystalline basement complex. These deeper units are relatively impermeable and occur

at depths that are not economically attractive for groundwater production (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

Unconsolidated continental deposits of late Tertiary and Quaternary age have been mapped on the south and west sides of the valley (in the West Sub-area) at several locations where they overlie and truncate the underlying marine oil-bearing rocks, and are generally assigned to the Tulare Formation (Wood and Dale 1964).

Fresh-water-bearing continental deposits of late Tertiary and Quaternary age, consisting of Continental deposits that are unconformably overlain by alluvium and unconformably overly older marine and continental deposits, occur in the vicinity of the Kern River (located in the Central and Eastern Sub-areas) and are designated as the Kern River Formation (Wood and Dale 1964; Croft 1972).

The Tulare and Kern River Formations are considered to be stratigraphically equivalent units (CA DWR 2006) and their bases effectively define the lower extent of the primary aquifer. The water quality in the western Tulare Formation differs from the Kern River Formation, which is discussed in more detail in Section 2.4.3.

The Tulare Formation occurs beneath the western portion of the Project Area and crops out in the low foothills of the San Emigdio Mountains in the southern portion of the Project Area (Figure 2-3). This formation consists of up to 2,200 feet of interbedded, oxidized to reduced sands, and gypsiferous clays and gravels derived from the Coast Ranges. This formation also includes clay layers equivalent to the Corcoran Clay Member. The Kern River Formation occurs throughout most of the southeastern and eastern portion of the sub-basin (or mainly the Central and Eastern Sub-areas). This Kern River Formation consists of between 500 and 2,000 feet of poorly sorted lenticular deposits of clay, silt, sand, and gravel derived primarily from the Sierra Nevada. Both the Tulare and Kern River Formations are moderately to highly permeable and can yield moderate to large quantities of water to wells (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007). The water quality in the Tulare Formation in the West Sub-area can be poor, however (SWSD 2012), so water production from the two formations is not equivalent (see Section 2.4.3).

The unconsolidated Quaternary alluvium, which comprises the upper portion of the primary aquifer system, is similar in lithology to both the Tulare and Kern River Formations. This alluvium consists of moderately to highly permeable older stream and terrace deposits and younger low permeable flood basin deposits (Wood and Dale 1964). Permeability within the unconsolidated Quaternary alluvium tends to decrease from east to west and is particularly low beneath the beds of Buena Vista and Kern Lakes (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

The Tulare Formation contains several thick, regionally extensive clay layers. The most extensive of the clay layers, the Corcoran member of the Tulare Formation (also referred to as Corcoran Clay or E-clay), is sufficiently thick to create confining conditions below it. Where the E-clay exists, the aquifer below is referred to as the “main” aquifer (with an upper confined zone and a lower confined zone). In the southeast and east part of the District, the E-clay thins, splits as it nears the surface, and becomes hydraulically ineffective as it merges into the “forebay”- the unconfined part of the main aquifer that is hydraulically connected to the main confined aquifer. The distribution of the Corcoran Clay is shown on Figure 2-6. This important hydraulic

connection causes changes in water levels in the forebay and hydraulic head in the main aquifer to affect each other. Were it not for this hydraulic connection, the confined aquifer would receive little recharge.

The other regional clay, the A-clay, further splits the "unconfined" aquifer into a lower confined portion and an upper unconfined portion (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007). Regionally, the unconfined aquifer thins to the east and south, and the lower zones thicken. The dip is generally west-northwest.

Faults that act as barriers to groundwater within the Kern County Sub-basin include the Edison, Pond-Poso, White Wolf, and Springs faults. The White Wolf fault separates a southeastern alluvial subarea from the remainder of the Kern County Sub-basin. The White Wolf fault is a cross-cutting feature that separates the southern end of the valley from a small subarea between the Tehachapi Mountains and Wheeler Ridge (Figure 2-1). A study on groundwater flow in the vicinity of the fault indicates that groundwater levels are disrupted and groundwater flows across the fault only in certain areas and only during conditions of relatively high water levels (Todd Engineers and Kennedy/Jenks Consultants 2007). The Springs fault, located approximately seven miles south and parallel to the White Wolf fault, is a smaller fault that also cross-cuts the southern edge of the valley (Figure 2-1). Groundwater flow is also impeded across the Springs fault. Here, groundwater flowing northward from recharge areas in the Tehachapi Mountains rises along the fault trace and surfaces as springs, providing the fault with its name. Both of these faults have offset aquifer units in the subsurface and impede groundwater flow to the north (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

2.4.3 Aquifers

Public water supply wells in the Kern County Sub-basin as designated by CA DWR (2006) are typically screened at depths between about 300 and 800 feet below ground surface. Water-bearing geologic units occurring in the Sub-basin include the Miocene-age Olcese and Santa Margarita Formations, the Plio-Pleistocene age Tulare and Kern River Formations, and younger sediments (DWR 2006). Groundwater in the Project Area occurs in several different aquifers (SWSD 2012). Five major aquifers or zones are recognized that include the following (SWSD 2012):

- ***Perched Zone –*** A shallow, 5-20 foot-deep, perched aquifer is located along the border of the West and Central Sub-areas in the northern portion of the Project Area. The area affected by perched conditions changes yearly to some extent depending on hydrologic conditions.
- ***Unconfined Zone –*** The upper, unconfined aquifer when compared to the production zone consists of generally poor quality water. The unconfined aquifer lies above the E-clay; the E-clay thickens to the north with proximity to the Tulare Lakebed and is thin and indistinguishable from the sediments of the "main" aquifer in the forebay area along the eastern and southern boundaries of the valley (the Central and East Sub-areas).
- ***Production Zone –*** Beneath the E-clay, the "main" aquifer is characterized as a confined, fresh, calcium-bicarbonate/sodium-bicarbonate aquifer. The production zone is approximately 300-1000 feet thick and consists of oxidized sediments. The sediments

are tan, yellow, olive-gray, and occasionally deep orange, indicating exposure to previous surface weathering. Most sand units are poorly to moderately well sorted sand, the coarsest size being small pebbles. The top and base sediments are thick, fining-upward sands with several discontinuous sands occurring between. The average salinity is estimated at about 300 milligrams per liter (mg/L).

As illustrated on Figure 2-3, the main aquifer of the area is east of Lost Hills, or in the Central Sub-area. West of Lost Hills, in the West Sub-area, the groundwater is saline.

- ***Transition Zone –*** Below the production zone is a few hundred feet of aquifer that ranges from about 500 mg/L sodium bicarbonate to about 2,000 mg/L chloride. Few wells are constructed in this layer and it is not considered part of the "main aquifer". The depth to the base of fresh water varies significantly along the western edge of the valley and is near the surface in some locations (Figure 2-3). Testing indicates that there is poor hydraulic connection between the transition layer and the main aquifer in the northwest part of the Semitropic Water Storage District (SWSD 2012) (the northwest part of the Central Sub-area).
- ***Saline Zone –*** A thick high sodium chloride aquifer underlies the transition zone. It consists primarily of reduced black-green, coarse sediments. Salinity grades from about 3,500 mg/l to over 5,000 mg/L. Little is known of the salinity of the deeper regions. As illustrated on Figure 2-3, the main aquifer of the area is east of Lost Hills, in the Central Sub-area. West of Lost Hills in the West Sub-area the groundwater is saline.

Along the axis of the main valley trough, the interfingered Tulare and Kern River Formations generally form the lower extent of the aquifer; however, the lower portions may contain brackish water that is generally not considered suitable for beneficial use. Poor quality saline groundwater occurs throughout most of the West Sub-area of the Project Area. This poorer water is typical of the lower part of the Tulare Formation, which surfaces on the west side of the valley. To the east, fresh water from the Sierras recharges the Kern River Formation, primarily by the way of infiltration from the Kern River, Poso Creek, Deer Creek, White River, and through extensive leakage from conveyance facilities which parallel the Friant-Kern Canal (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007). Table 2-2 lists the reported base of fresh water for the oilfields in the Project Area, as noted in DOGGR (2013a), or DOGGR (1998) for abandoned fields. The definition of fresh water is context-dependent; DOGGR Field Rules refer to the "base of fresh water" to guide requirements for installation of protective measures (steel casing, cement seals, etc.) in oil wells. These measures are intended to protect fresh water aquifers from the effects of drilling and oil production, such as contamination by saline water, oil, and gas. State Water Resources Control Board Resolution No. 88-63 (CA SWRCB 2006) sets the current limit for suitable or potentially suitable water (water that must be protected) at 3,000 milligrams per liter (mg/L) of total dissolved solids (TDS). This limit is cited in DOGGR's discussion of requirements of Underground Injection and Control (UIC) permitting: "…Operators are required to use every effort and endeavor to protect any underground or surface water suitable for irrigation or domestic purposes from the infiltration of detrimental substances…State Water Resources Control Board Resolution No. 88-63 states that water with total dissolved solids (TDS) of 3,000 mg/L or less is suitable, or potentially suitable, for municipal or domestic use. A minor aquifer exemption may be required for water with TDS between 3,000 and 10,000 mg/L. (40 CFR 146.4.)" (http://www.conservation.ca.gov/dog/general_information/Pages/UICApplicationGuidance.aspx).

In the past, other criteria have been used to map the base of fresh water (for this discussion considered equivalent to 'suitable water'). For example, Page (1973) mapped the base of fresh water in the San Joaquin Valley using the criteria of a maximum electroconductivity (EC) of 3,000 micromhos (umhos)/minimum resistivity of 3.33 ohm-m at 75 degrees Fahrenheit, and maximum TDS concentration of 2,000 mg/l. According to Bryan (1992), Page (1973) used these criteria based upon the work of Olmsted and Davis (1961), who applied the criteria to map the base of fresh water in the Sacramento Valley. Formation water resistivity and EC can be derived from geophysical logs.

The term "fresh water" is further described in Section 3. Based on the information obtained from DOGGR, fresh water is not present in most of the groundwater aquifers in the oilfields in the West sub-area. In contrast, in the Central sub-area the base of fresh water generally ranges in depth from 800 feet below ground surface (bgs) to 5,700 feet bgs. In the East sub-area, the base of fresh water is more variable, ranging from near-ground surface to 2,500 feet bgs.

2.4.4 Groundwater Conditions

Long-term hydrographs indicate that relatively stable groundwater conditions prevailed in the Project Area until the mid-1940s (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007). Subsequently, increased pumping caused water levels to decline at a rate of about 8 feet per year, with seasonal fluctuations approaching 100 feet per year. These declines continued until initiation of surface water deliveries in the mid-1970s. Regional overdraft was first noted in the mid-1940s with the post-WWII expansion in agriculture and irrigation in the basin (Todd Engineers and Kennedy/Jenks Consultants 2007). A myriad of problems associated with declining water levels were documented including:

- loss of well production and well abandonment,
- increasing pumping costs with lifts exceeding 700 feet in some areas,
- drilling of deeper wells that encounter marginal or unsatisfactory water quality,
- land subsidence resulting in well destruction (Todd Engineers and Kennedy/Jenks Consultants 2007).

The shallow alluvial aquifers were essentially dewatered during this time period, resulting in production from deeper and sometimes less permeable aquifers (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007). The commencement of groundwater banking activities in the early 1990s enhanced groundwater recharge. An elliptical, north-to-south groundwater low has formed along the basin in the northern Project Area. Ridges of high groundwater are maintained under the Kern River, however, these ridges appear to break down slightly in critically dry years. Groundwater levels have been relatively stable in recent years up to the current drought, with fluctuations of about 50 feet; declining during "dry" periods, and increasing during "wet" periods (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

DWR posts water level data from select wells (see http://gis.water.ca.gov/app/groundwater/). Most of the wells monitored by DWR are in the Central and East Sub-areas. The DWR monitors fewer wells in the West Sub-area, and those are mainly either just west of I-5 between Highway 119 and Buena Vista Lake Bed, or in the Maricopa Flat area. The length of the monitoring record varies with a few well records extending as far back as the 1940's.

Groundwater levels in wells can be influenced by a myriad of factors, such as pumping rates, surface water allocations, nearby recharge structures, and climate. Groundwater levels in some parts of the Project Area have dropped sharply since the start of the recent drought. Kern County Water Agency (KCWA) reports groundwater level declines of approximately 60 feet from spring 2012 to spring 2013 in some parts of Improvement District 4 (KCWA 2014), in the Central Sub-area (northwest and southeast of Bakersfield) and West Sub-area (southwest of Bakersfield). The water levels in each well behave uniquely but general trends include:

- Declining levels over most of the Central Sub-area, over two feet per year in some cases. The hydrographs commonly show significant declines (followed by recovery) in the early 1980's, early 1990's, 2009-2010, and 2014. In many wells the lowest levels were in 2009-2010.

- Relatively stable or even increasing levels in some parts of the Central Sub-area, and in the East Sub-area that includes the area east of Mettler and near Arvin.

- Relatively stable levels in most of the monitored West Sub-area wells.

2.4.5 Groundwater Recharge

Replenishment of groundwater underlying the Project Area occurs naturally and indirectly through the delivery of available surface water supplies in lieu of pumping groundwater (i.e., such deliveries are to lands that have developed a reliance on pumped groundwater), referred to as *in-lieu* recharge. Additionally, irrigation water not consumed by evapotranspiration of cropped lands percolates to the underlying groundwater, referred to as return flows (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

Recharge to both the confined and semi-confined aquifers occurs principally as subsurface inflow from the semi-confined aquifer forebay, located to the east of where the Corcoran Clay is absent (Figure 2-6). Recharge to the semi-confined aquifer system also includes deep percolation of excess applied irrigation water, and less frequently from surface flows during wet years. Small drainages along the dissected hills also add a small amount of recharge to the valley aquifer. The importation of surface water to the forebay area has been ongoing for decades. Shallow clay layers, particularly in the northwest portion of the Project Area, restrict the percolation of surface water, and have formed areas of perched water (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

The principal component of recharge in "dry" years is seepage from irrigation water, whereas, in "wet" years, intentional surface recharge and in-lieu recharge are the principal components. As the number of groundwater recharge facilities increases over the years, the natural recharge becomes a smaller portion of total recharge. Programs developed throughout Kern County have contributed significantly to basin recharge, and are critical to maintaining groundwater levels and water quality. Groundwater basin management goals for Water Districts in the Project Area reflect the continuing role of these programs in enhancing groundwater recharge to the basin (SWSD 2012; Todd Engineers and Kennedy/Jenks Consultants 2007).

Section 3: Surface Water and Groundwater Quality

This section provides information on existing water quality conditions and concerns in the Project Area, based on a review of published and publicly available data and reports. This information provides a baseline for assessing potential future effects in the Project Area. Availability and age of water quality data varies by location. For surface water, data from 2002 to 2013 was identified and reviewed for the East and Central sub-areas, as well as older data from 1951 to 1991 for the East, Central, and West sub-areas, to determine average water quality for a given surface water body or sub-area. For imported water, data for 2010 to 2013 (Friant-Kern Canal) and 2004 to 2014 (California Aqueduct) was identified and reviewed to determine average water quality. Groundwater quality data reflect U.S. Geological Survey analyses conducted within the past decade, augmented by analyses of data gleaned from California's Groundwater Ambient Monitoring and Assessment Program database (with data reported through 2013).

3.1 Project Area Setting

As described previously, the Project Area includes most of the San Joaquin Valley Floor portion of Kern County up to an elevation of 2,000 feet. It excludes portions of Metropolitan Bakersfield and all other city jurisdictions. The Project Area (Figure 1-1) is located within the Tulare Lake Hydrologic Basin (Basin), which is within the jurisdiction of the Central Valley Regional Water Quality Control Board (CVRWQCB), per Figure 3-1. Although the valley floor in the region once contained the largest block of wetland habitat in California, the local hydrology has been significantly altered to support irrigated agricultural and is now the driest region of the Central Valley.

Historic water quality monitoring studies in the region have focused on the Tulare Lake Hydrologic Basin and/or the Kern County Sub-basin. The location of the Project Area boundary relative to the Tulare Lake Hydrologic Basin is illustrated on Figure 3-2. The Tulare Lake Hydrologic Basin comprises the drainage area of the San Joaquin Valley south of the San Joaquin River and encompasses approximately 16,400 square miles (10.5 million acres). The Project Area roughly coincides with the Kern County Sub-basin (groundwater basin), which is the southern portion of the San Joaquin Valley Groundwater Basin, also illustrated on Figure 3-2.

3.1.1 Local Surface Water

The majority of the surface water supply native to the Tulare Lake Hydrologic Basin (Basin) is provided by the Kings, Kaweah, Tule, and Kern Rivers, which drain the west face of the Sierra Nevada. Of these rivers, portions of only the Kern River fall within the Project Area. According to the Water Quality Control Plan for the Tulare Lake Basin (Basin Plan), these waters are of excellent quality. Besides these main rivers, there are also numerous mountain streams in the Basin, divided into "eastside" and "westside" streams in the Basin Plan using Highway 99 between Bakersfield and Tehachapi. The Basin is essentially a closed basin, as flood flows during periods of heavy runoff represent the only significant outflows from the Basin. Two lakes in the Basin are supplied by flood water from the major rivers during times of heavy runoff:

Buena Vista Lake (located in the Project Area) and Tulare Lake (north of the Project Area). These and other nearby surface waters are referred to in the Basin Plan as valley floor waters (CA RWQCB 2004). Buena Vista Lake is a former freshwater lake that was fed by Kern River and dried up in the mid-20th century when its tributary river waters were impounded for agricultural and municipal water uses.

Surface water supplies together with imported water are inadequate to meet the demand for water for agricultural and other development, and so groundwater is mined within the valley to provide additional supply. Groundwater generated from oil production at the Kern River oilfield is also used for agricultural irrigation supply (CA RWQCB 2004).

The local surface waters that are within the Project Area are shown in Figure 3-3 and include the Kern River downstream of Lake Isabella, Poso Creek, numerous eastside and westside streams (mountain streams), and valley floor waters. The designated beneficial uses of these surface waters are specified in the Basin Plan and summarized in Section 3.4. Manmade water features (e.g., canals) are excluded from Figure 3-3, except the major imported water canals in the Project Area (California Aqueduct and the Friant-Kern Canal). Because the region is very dry, it should be noted that some surface water features indicated on Figure 3-3 may only contain water during the wet season or during wet weather events.

3.1.2 Imported Water

Imported surface supplies enter the Project Area through the San Luis Canal / California Aqueduct and the Friant-Kern Canal. The imported water is considered good quality, although some imported water contains elevated salts. The Basin Plan notes the importance of using high quality imported water in the Basin to protect local groundwater quality, because imported water (and native surface water) that is not consumptively used or lost to evapotranspiration will percolate into valley floor groundwater. The historical increase in salt content in the groundwater basin is attributable, in part, to past low-quality imported surface water supplies (CA RWQCB 2004).

The California Aqueduct delivers water from the State Water Project (SWP), which is the largest state-built, multi-purpose water project in the country. It includes approximately 660 miles of aqueducts and is managed by DWR. The primary water source is the Feather River, a tributary to the Sacramento River in northern California. The majority of the SWP supplies are pumped into the 444-mile long California Aqueduct (Kennedy/Jenks Consultants 2011a). In the Project Area, the California Aqueduct occurs principally in the West sub-area.

Imported water from the Friant-Kern Canal is obtained through the Central Valley Project (CVP). The CVP is a set of federally-owned facilities (canals, pumping stations, supporting operations) that extend from north of Redding to south of Bakersfield. The CVP obtains water from two of California's largest river systems, the Sacramento River and the San Joaquin River. The San Joaquin River flows are diverted south through the Friant-Kern Canal, an approximately 152-mile long canal that carries water south from Millerton Lake (just north of Fresno) to the Kern River intertie (Kennedy/Jenks Consultants 2011a). In the Project Area, the Friant-Kern Canal is situated in the East sub-area (Figure 3-3).

3.1.3 Local Groundwater

The Kern County Sub-basin (Sub-basin) generally receives less than 10 inches of rain per year. Other sources of groundwater recharge include irrigation return flows, artificial groundwater banking operations, and infiltration from ephemeral streams along the edge of the Sub-basin (Burton and Belitz 2012). The locations of groundwater banking operations within the Project Area are illustrated on Figure 3-4. Groundwater banking is so important and prevalent in Kern County that nearly every water district, as well as a few oil companies, participates in some form of water banking (WAKC 2014). Groundwater for municipal use in the Sub-basin is limited to depths above 3,000 feet, with water supply wells typically screened at depths shallower than 1,000 feet (CA DWR 2003). More information on the groundwater conditions, aquifers, and recharge is provided in Section 2.

3.2 Primary Factors Affecting Water Quality

This section provides a general overview of the primary factors affecting water quality in the Project Area. Important local industries to the Basin include agricultural (i.e., growing, processing and packaging) and petroleum production and refining (CA RWQCB 2004). The primary factors that affect surface water and groundwater quality in the San Joaquin-Tulare Basins are climate, local geology, land use, and water use, as described in a U.S. Geological Survey (USGS) study (Gronberg et al. 1998). For surface water, water quality is degraded by evaporative concentration of salts due to the semiarid to arid climate. In the San Joaquin Valley, much of the valley floor is agricultural land. Agricultural water use is the largest nonpoint source of pollution to surface and groundwater in the San Joaquin Valley. Irrigation water can contain elevated concentrations of dissolved solids, nutrients, pesticides, and trace elements. Infiltration of these waters can impact the quality of the shallow groundwater. Additionally, on the west side of the valley, agricultural practices commonly include application of water to crop lands to flush the retained salts out of the root zone, driving the salts downward. High quality surface water bodies (rivers, streams, lakes) can be similarly impacted by runoff from irrigated areas or by discharges from groundwater and subsurface drainage systems.

Nonpoint sources of pathogens and nutrients from household septic systems in the area may also degrade surface waters and shallow groundwater. Near cities, surface waters can be impacted by point source discharges to rivers of effluent from wastewater treatment plants. Stormwater point source runoff carrying elevated concentrations of metals, hydrocarbons and other constituents can also impact surface waters. Point source discharges in the Project Area are summarized in Section 3.3.

Due to the closed nature of the Basin, there is little surface or subsurface outflow. Therefore, salts accumulate in the Basin groundwater from importation of water and evaporation. Imported surface water supplies contribute nearly half the increase of salts occurring within the Basin (CA RWQCB 2004). According to the Basin Plan, the paramount water quality problem in the Basin is the accumulation of salts (CA RWQCB 2004). Additionally, contamination by nitrate is a significant issue (Gronberg et al. 1998). Nitrate contamination of groundwater is not uncommon in California. In 2008 the California State Water Resources Control Board (SWRCB) contracted with the University of California to prepare a report to the Legislature titled *Addressing Nitrate in California's Drinking Water With a Focus on Tulare Lake Basin and Salinas Valley Groundwater* (Harter et al. 2012). Among key findings from this report, agricultural fertilizers and animal

wastes applied to cropland are by far the largest regional sources of nitrate in groundwater, and nitrate problems will likely worsen for several decades. Blending, treatment, and use of alternative water supplies are the most cost effective strategies for minimizing nitrate in drinking water.

Major surface water quality issues that have been identified for the Tulare Lake Hydrologic Basin include salinity, pesticide impacts from agriculture, metals (mercury, selenium, and molybdenum), and impacts related to erosion and sediment. Major groundwater quality issues include salinity, nitrate, 1,2-dibromo-3-chloropropane (DBCP), arsenic, gross alpha particle activity and uranium, hexavalent chromium, and localized contamination by other compounds (CA DWR 2013a). The San Joaquin-Tulare Basins include elevated concentrations of naturally occurring trace elements in shallow groundwater in the Tulare Lake Hydrologic Basin (arsenic, boron, molybdenum, uranium, and vanadium), as well as nitrate in groundwater from sources such as fertilizers, livestock manure, and septic systems (Gronberg et al. 1998).

3.3 Project Area NPDES and WDR Discharges

Locations of permitted discharges within the Project Area regulated under the National Pollutant Discharge Elimination System (NPDES) for protection of surface waters were identified and are listed in Appendix B Table B-1. Figure 3-5 (industrial discharges) and Figure 3-6 (construction-related discharges) show the locations of the permitted discharges as of February 2014. The list of California NPDES discharge locations is available from the California SWRCB (CA SWRCB 2014a). There are 235 sites with active NPDES permits within the Project Area, of which 125 (53%) are noted as "Industrial" or other[1] discharges and 110 (47%) are construction-related. Most of these permitted discharges are related to the release of stormwater. Construction-related stormwater discharges are expected to be of short duration and have minimal impact on groundwater quality.

Waste Discharge Requirements (WDRs) are issued for discharges that can potentially impact groundwater quality. Facilities with WDRs in Kern County[2] are listed in Appendix B Table B-2 (CA SWRCB 2012b). In general, WDRs are issued to individual dischargers (individual WDRs) or for groups of dischargers that meet similar discharge characteristics (general WDRs). There are 167 facilities, 56 regulated by general WDRs and 112 regulated by individual WDRs. The facilities are not mapped due to non-specific address locations for many facilities and the non-point source nature of many WDRs. More information on the regulatory structure for the WDR program is provided in Section 6.3.4.4.

3.4 Designated Beneficial Uses for Water Bodies in the Project Area

The SWRCB protects water quality by setting statewide policy and coordinating the efforts of nine Regional Water Quality Control Boards (RWQCBs) (CA SWRCB 2014d). Each RWQCB

[1] Most of the 125 sites are industrial discharges (likely stormwater); the other program types listed are MNSTW1 (two locations), NPDMUNIOTH (two locations), NPDNONMUNIPRCS, (one location), and Phase II Small MS4 (three locations), according to the SWRCB list.

[2] Table 3-2 is not limited to the Project Area.

has a Water Quality Control Plan, or "Basin Plan". A Basin Plan presents designated beneficial uses to be protected for each surface water and groundwater body, water quality objectives (numerical or narrative) to protect those uses, and an implementation program. Surface and ground waters have many uses and potential uses; hence, there can be many designated beneficial uses for each water body (CA RWQCB 2004).

Abbreviations and definitions for the different types of designated beneficial uses that are applicable in the Project Area are provided in Table 3-1. The surface water and groundwater beneficial uses within the Project Area as listed in Table 3-2 and Table 3-3, respectively, as identified in the Basin Plan. Groundwater and natural surface waters have designated beneficial uses that are protected by appropriate water quality objectives (CA RWQCB 2004). The beneficial uses include one or more of the designations described in Table 3-1.

Among others, constituents for which objectives may be specified include ammonia, regulated drinking water compounds (i.e., having Maximum Contaminant Levels), oil and grease, salinity, suspended material, and turbidity. SWRCB policy requires that whenever the existing quality of the surface water or groundwater is better than the objectives established for those waters, the existing quality must be maintained unless otherwise allowed (CA RWQCB 2004).

For surface waters, Figure 3-3 presents a general map of surface waters located within the Project Area and shows the boundaries of the watershed drainage areas (hydrologic units). Per the Basin Plan Table II-1 and the present report's Table 3-2, eastside streams in the Project Area fall within hydrologic units 554 and 555, westside streams in 556 and 559, and valley floor waters in 557 and 558[3]. The hydrologic unit numbers correspond to designated beneficial uses in Table 3-2. As described in the Basin Plan, the beneficial use of any specifically identified water body generally applies to its tributary streams. It should be noted that the beneficial uses that are indicated in Table 3-2 may not apply to all surface water features that appear in Figure 3-3. Applicability of designated beneficial uses is at the discretion of the CVRWQCB.

For groundwater, the Sub-basin is divided into Detailed Analysis Units (DAUs) for consideration of varying beneficial uses. Figure 3-7 identifies the DAUs for the Sub-basin and Table 3-3 identifies the designated beneficial uses for each DAU. Groundwater is considered a MUN beneficial use, unless exempted by the RWQCB. Groundwater areas with specific beneficial use exemptions adopted into the Basin Plan are footnoted in Table 3-3 and shown on Figure 3-8.

In addition to the exempted areas identified in the Basin Plan, surface water and groundwater can be exempted from the MUN designation for other reasons as outlined in the SWRCB Resolution No. 88-63, Adoption of Policy Entitled "Sources of Drinking Water" (CA SWRCB 2006). Groundwater may also be exempted from beneficial use in accordance with regulations set forth in the 40 CFR, Section 146.4(b), where an aquifer may be exempted if it does not currently serve as a source of drinking water, and either "a" or "b" below apply:

[3] The Project Area map of surface waters (Figure 3-3) is based on more recent information compared to the 1986 Basin Plan Figure II-1, which indicates hydrologic unit boundaries and surface waters in the basin. Hydrologic unit boundaries for Figure 3-3 were obtained from Calwater 2.2.1 (California Interagency Watershed Mapping Committee, California Interagency Watershed Map of 1999, updated May 2004). These hydrologic boundaries differ slightly from that shown in the Basin Plan. The surface waters shown are levels 1 – 11 provided by Esri® Data and Maps from USGS and USEPA, which again differ from that shown in the Basin Plan.

a. It cannot now and will not in the future serve as a source of drinking water because:

    a. It is mineral, hydrocarbon or geothermal energy producing, or can be demonstrated by a permit applicant that it contains minerals or hydrocarbons that, considering their quantity and location, are expected to be commercially producible.

    b. It is situated at a depth or location which makes recovery of water for drinking water purposes economically or technologically impractical;

    c. It is so contaminated that it would be economically or technologically impractical to render that water fit for human consumption;

b. The total dissolved solids content of the ground water is more than 3,000 and less than 10,000 mg/l and it is not reasonably expected to supply a public water system.

In California, the DOGGR has been granted primacy (primary authority) by USEPA to make determinations on aquifer exemptions within oil field boundaries, although final exemption authority lies with USEPA. Aquifer exemptions approved by the DOGGR for the purpose of oilfield production are illustrated on Figure 3-8.

3.5 Section 303(d) Impaired Water Bodies

Section 303(d) of the Clean Water Act requires that States make a list of waters that are not attaining water quality standards after technology-based limits (i.e., best available technology used for pollutant management) are promulgated. For waters on this list, States are required to determine all the sources of the pollutants that cause the water to be listed including contributions from point and non-point sources.

There are no 303(d) impaired water bodies in the Project Area. There is one impaired water body on the 303(d) list in Kern County: Isabella Reservoir, which serves as the source for the Kern River. Isabella Reservoir is included in the 303(d) list for dissolved oxygen and pH (CA SWRCB 2014c; Kennedy/Jenks Consultants 2011b), constituents which will not impact surface water or groundwater in the Project Area.

3.6 Surface Water Quality

Surface water quality for each sub-area of the Project Area is summarized below.

3.6.1 Sources of Information

To identify water quality data, published and publicly available data and reports for the Project Area were reviewed, including:

Databases

- DWR Water Data Library (WDL) (CA DWR 2014)

- California Environmental Data Exchange Network (CEDEN) (CA SWRCB 2012a)
- USGS National Water Information System (NWIS) (USGS 2014b)
- United States Environmental Protection Agency (USEPA) STOrage and RETrieval (STORET) data (EPA 2014), including both the STORET Data Warehouse (more current data) and the STORET Legacy Data Center (data before January 1,1999)

Reports

- USGS reports (Dubrovsky et al. 1998; Gronberg et al. 1998; Gronberg et al. 2004; Kinsey et al. 2005; Kratzer and Shelton 1998; Shelton et al. 2008) obtained from the USGS Publications Warehouse (USGS 2014a)
- Kern Integrated Regional Water Management Plan (IRWMP) for Kern County Water Agency (KCWA) (Kennedy/Jenks Consultants 2011b)
- Urban Water Management Plan (UWMP) for KCWA (Kennedy/Jenks Consultants 2011a)
- KCWA Report on Water Conditions (KCWA 2011; 2012; 2013; 2014)
- Basin Plan for Tulare Lake Basin (CA RWQCB 2004)

3.6.2 Surface Water Quality

Native surface water supplies and imported supplies in the Tulare Lake Hydrologic Basin, which includes the Project Area, are generally of good quality (CA DWR 2013a). Surface water flows from the east side of the Tulare Lake Hydrologic Basin (see Figure 3-2 and Figure 3-3) are considered to be of excellent quality (fed by Sierra snowmelt and granitic bedrock springs). However, flows from the west side are considered to be of comparatively lower quality due to dissolution of naturally occurring constituents (selenium and salinity) (CA DWR 2013a) contained in the soils and sediments. According to the *Tulare Lake Basin Rotational Watershed Monitoring Plan, 2012 – 2016* (CA RWQCB 2012), surface water quality in the upper reaches of the Tulare Lake Hydrologic Basin is not well documented, nor are the spatial or temporal trends within the major river systems in the Basin (Kings, Kaweah, Tule, and Kern Rivers). Of these rivers, portions of only the Kern River fall within the Project Area.

For the present evaluation, water quality data measured between 2002 and 2013 was identified for select sampling stations along the Kern River, Poso Creek, El Paso Creek, and Deer Creek within the Project Area (East and Central sub-areas), and is presented below. Historic data measured from 1951 to 1991 were identified for additional sites over the Project Area, including the West sub-area, and are also presented below. Water quality data were also identified for select canals and tile drains located on the valley floor; these data are excluded from the below summaries, which focus on creek, stream, and river water quality data only, because water quality in canals and tile drains is likely less representative of environmental background conditions. No water quality data was identified in the databases and reports reviewed for other

types of surface waters (i.e., other lakes/ponds that may be present and considered part of the valley floor waters); these surface waters may be seasonal if present.

Figure 3-9 presents a map of all surface water sampling locations that were identified in the Project Area from the SWRCB Surface Water Ambient Monitoring Program (SWAMP), the Central Valley RWQCB Irrigated Lands Regulatory Program (ILRP) (CA SWRCB 2012a), the USGS NWIS (USGS 2014b), and the USEPA STORET Legacy Data Center (EPA 2014), including canals and tile drains. Figure 3-10 presents a map of only the river, creek, or stream sites (excluding canals and tile drains[4]) for which water quality data was compiled. The West sub-area has 11 surface water sampling stations with water quality data, however all of these are USEPA STORET Legacy data sites and therefore the data are older (prior to 1 January 1999). The Central sub-area has three surface water sampling stations of which two appear to be unique and have relatively recent water quality data (Figure 3-10). The East sub-area has 17 surface water sampling stations of which 15 appear to be unique; of these, six sites have recent water quality data (four sites along Kern River) and the remainder are from the USEPA STORET Legacy dataset.

Surface water quality data for Kern River collected by the SWAMP in the East sub-area for four sites is summarized in Table 3-4 (data from CEDEN). The water quality information includes general water quality parameters, some metals, and microbial indicators that were measured between 2002 and 2004. SWAMP water quality data was also identified in select reports for the Tulare Lake Basin (CA RWQCB 2003, 2007) and is included in the CEDEN dataset in Table 3-4. Additional SWAMP monitoring at select Kern River sampling stations is planned for 2015 – 2016 (CA RWQCB 2012), and will include monitoring for dissolved metals, nutrients, general minerals, total suspended solids, and bacteria at sampling stations that include stations within the Project Area.

Water quality information for Kern River is also reported by KCWA for regulated drinking water constituents and other parameters. This information is summarized for the past four years along with KCWA imported water quality in the next section. The Kern River sampling location is assumed to be near Bakersfield.

Surface water quality for four sites along Deer Creek, Poso Creek, and El Paso Creek (see sampling locations in Figure 3-10) collected by the ILRP (data from CEDEN) in the East and Central sub-areas is summarized in Table 3-5. The water quality information includes general water quality parameters, metals, microbial indicators, and pesticides measured between 2009 and 2012. Canals are also monitored as part of the ILRP, and several canal sampling stations are located within the Project Area (see Figure 3-9). The water quality information for canals was excluded from the data summary in Table 3-5.

Data available from the USEPA STORET databases was reviewed to identify any surface water quality information within the Project Area. Surface water quality data for the Project Area was identified in the STORET Legacy Data Center (data before January 1, 1999) for 37 sites (Figure

[4] Also excludes stations for which the location or station name/ID was ambiguous with respect to the type of surface water (e.g., creek vs. canal). These data were excluded from the water quality data summary tables in this section (which focus on rivers, creeks, and streams), except when the station appeared to occur at the location of a mapped creek.

3-9). Based on the sampling station name, 24 sites appear to be for rivers and creeks (Figure 3-10); the remainder may be canals, tile drains, or other features. The water quality data for the 24 river/creek sites is summarized in Appendix C Table C-1. Unique data from the SWAMP (sites in Table 3-4) and ILRP (Table 3-5, Poso Creek only) monitoring programs was identified in the STORET Data Warehouse (i.e., current STORET data) for some sites already summarized above, and was incorporated into these summary tables (Table 3-4 and Table 3-5).

No surface water quality data were found in the California DWR WDL (CA DWR 2014) except for California Aqueduct sampling stations. Some historical monitoring stations on Kern River are available in the DWR WDL but appear to be for flow rate monitoring only.

A limited water quality dataset for nine additional surface water sampling stations in the Project Area was identified in the USGS NWIS database (see Figure 3-9 for sites) (USGS 2014b). The USGS NWIS data is not tabulated for the present evaluation due to limited utility. Except for the "Kern R Nr Bakersfield CA" site, water quality was measured at each site over just one or two sampling events between 1977 to 1986. The "Kern R Nr Bakersfield CA" site was measured more frequently between 1960 and 1980, but the Kern River is well represented in more recent monitoring from SWAMP (Table 3-4).

3.6.3 Surface Water Quality by Sub-Area

Table 3-6 (2002 to 2013) and Table 3-7 (1951 to 1991) present estimated average surface water quality for the project sub-areas (West, Central, East) based on the data available from surface waters that have been monitored[5]. The summary of data is divided into two time periods because the historic data may not represent current conditions. The sites featuring older data (USEPA Legacy) are unique from the sites with the newer data (SWAMP and ILRP), as indicated on the sampling station map (Figure 3-10). West sub-area sites are limited to the historic dataset only.

The historic data (1951 to 1991) is consistent with the general observation that surface water quality is better in the eastern portion of the Basin (CA RWQCB 2004) (East sub-area in the Project Area) compared to the western portion of the Basin (West sub-area). Table 3-7 shows greater concentrations of dissolved salts and general water quality parameters in the West sub-area (i.e., alkalinity, nitrate, hardness, chloride, sodium, specific conductivity, and boron). In the more recent dataset (2002 to 2013 in Table 3-6), the East versus West sub-areas cannot be compared because there are no recent West sub-area sampling stations (Figure 3-10). For both the older and more recent datasets, the water quality between the Central versus East sub-areas is similar (based on dissolved salts and hardness, e.g., chloride, sodium, specific conductivity), with slightly better water quality typically in the East sub-area (i.e., lower dissolved salts and hardness). Using specific conductance and total dissolved solids (TDS) as general indicators of salinity, surface water quality data for salinity is limited in the Project Area (Table

[5] For example, four surface water sampling stations were identified in the Central sub-area that reported ammonia concentration during the 2002 to 2012 period. The average ammonia concentration for each location over its sampling history is tabulated in Table 3-5 and Table 3-8. For the Table 3-6 summary of data, the average ammonia concentration for this area is determined as the average of the four sites' (N = 4) average ammonia concentrations.

3-6 and Table 3-7). Based on the available data, average salinity is below the secondary Maximum Contaminant Limit (MCL) for TDS in drinking water of 500 mg/L (EPA 2013).

This information provides a generalized, baseline understanding of historic and more recent differences in surface water quality across the Project Area; however, this dataset does not include all surface waters present in the area nor are each of the three sub-areas represented equally, due to the availability of data.

3.7 Imported Water Quality

Imported water enters the Project Area through the San Luis Canal / California Aqueduct and the Friant-Kern Canal (see Figure 3-3). Water quality information for imported water from the Friant-Kern Canal is summarized in Table 3-8. The average, median, minimum, and maximum concentrations of various water quality parameters were determined for 2010 to 2013 from data reported by the Kern County Water Agency (KCWA 2011; 2012; 2013; 2014). Water quality information for imported water from the California Aqueduct, as available from the CA DWR Water Data Library is summarized in Table 3-9 (CA DWR 2014).

Using specific conductance and TDS as general indicators of salinity, the imported waters have relatively low salinity levels. Water from the Friant-Kern Canal has an average specific conductance and TDS of approximately 210 microsiemens per centimeter (uS/cm) and 130 mg/L, respectively. California Aqueduct water has slightly higher average levels of 460 uS/cm and 260 mg/L. For reference, the secondary MCL for TDS in drinking water is 500 mg/L (EPA 2013).

3.8 Groundwater Quality

Groundwater quality for each sub-area of the Project Area is summarized below.

3.8.1 Sources of Information

To identify data, published and publicly available data and reports for the Project Area were reviewed, including:

Database

- California SWRCB Groundwater Ambient Monitoring and Assessment (GAMA) database (CA SWRCB 2014b) via the GeoTracker online data retrieval system

Reports

- USGS reports (Dubrovsky et al. 1998; Gronberg et al. 1998; Gronberg et al. 2004; Kinsey et al. 2005; Kratzer and Shelton 1998; Shelton et al. 2008) obtained from the USGS Publications Warehouse available at http://pubs.er.usgs.gov/#home (USGS 2014a)

- KCWA Report on Water Conditions (KCWA 2011; 2012; 2013; 2014)

- Basin Plan for Tulare Lake Basin (CA RWQCB 2004)
- California Water Plan Update 2013 (CA DWR 2013a)
- Draft Environmental Impact Statement/Environmental Impact Reports for the San Joaquin River Restoration Program (USBR 2011) and the Bay Delta Conservation Plan (CA DWR 2013b)
- SWRCB Report to the Legislature on Communities that Rely on Contaminated Groundwater (CA SWRCB 2013a)
- UC Davis Report on Groundwater Nitrate Occurrence With a Focus on Tulare Lake Basin and Salinas Valley Groundwater (Harter et al. 2012)

Site specific groundwater data can also be found in various WDRs for individual dischargers in the Sub-basin and in Groundwater Management Plans for individual water districts. As the objective in this study is to present an overview summary of information, individual WDRs and Groundwater Management Plans were not reviewed.

3.8.2 Groundwater Quality Data

Water quality concerns in the Kern County Sub-basin include elevated TDS, sodium chloride, and sulfate associated with the axial trough of the Sub-basin, elevated arsenic concentrations in some areas associated with lakebed deposits, and elevated nitrate, DBCP, and 1,2-dibromoethane (EDB) concentrations exceeding applicable MCLs in various areas of the Sub-basin (CA DWR 2003, 2006). Additional water quality concerns include gross alpha particle activity and uranium, hexavalent chromium, and localized contamination by organic compounds (benzene, tetrachloroethylene, trichloroethylene and perchlorate) and fluoride (CA DWR 2013a).

According to the California Water Plan Update 2013 (CA DWR 2013a), quality and beneficial uses of deep groundwater (i.e., groundwater beneath the Corcoran Clay layer) remain consistent; however, anthropogenic sources have impacted many shallower (above the Corcoran Clay) zones. Groundwater quality varies from east to west across the basin. In the eastern portion of the Sub-basin (primarily the eastern sub-area), groundwater is predominantly of calcium bicarbonate-type, with the sodium content increasing with greater depth. Bicarbonate ion is replaced by sulfate and, to a lesser extent, chloride, toward the western end of the Sub-basin (CA DWR 2006; Wood and Dale 1964; Wood and Davis 1959; Dale et al. 1966). Overall, the TDS of groundwater in the Sub-basin ranges from 150 mg/l to 5,000 mg/l (KCWA 1998), with generally higher TDS values encountered in the western portion (West sub-area). A generalized map of groundwater TDS concentrations is presented in Figure 3-11 (USBR 2011). The data used to generate the contours in Figure 3-11 were collected between 1934 and 1985, and as such represent “average” values. An evaluation of more recent TDS concentrations, collected between 2007 and 2013, is presented in Section 3.8.3.

Table 3-10 includes a summary of contaminant concentrations for public water systems in the Project Area (2002 to 2010) that rely on groundwater for drinking water and have MCL exceedances. The information presented in Table 3-10 was obtained from the California SWRCB *Report to the Legislature on Communities that Rely on a Contaminated Groundwater*

Source for Drinking Water (CA SWRCB 2013a). Based on the data evaluated in the report, 680 community water systems in California relied on a contaminated groundwater source. Of the 680 community water systems identified, 265 had at least one drinking water MCL violation during the 2002 to 2010 time period.

Another important source of information for groundwater quality in the Project Area is the California GAMA database. Based on analysis of data from this database, the USGS published two comparatively recent summaries of groundwater quality of the Sub-basin (Burton and Belitz 2012; Shelton et al. 2008). The findings from each of these major studies are summarized below.

3.8.2.1 Summary of Findings from 2008 USGS Study (Shelton et al. 2008)

Shelton et al. (2008) selected forty-seven wells within the Sub-basin using a randomized grid-based method to provide a statistical representation of groundwater quality parameters (see Figure 3-12 for a reproduction of the grid). Major water quality parameters (e.g., major cations and anions, iron, and manganese) reported in this study are summarized in Table 3-11. Most of the samples from Sub-basin wells were characterized by concentrations of major elements and TDS below applicable standards, such as the non-enforceable thresholds set for aesthetic concerns.

In addition to major water quality indicators, the GAMA database warehouses data for naturally occurring trace elements, minor ions, and nutrients (e.g., nitrate, nitrite); radioactive constituents; and a large number of anthropogenic constituents, including volatile organic compounds (VOCs), pesticides and their associated degradation products, and constituents of special interest such as perchlorate, *N*-nitrosodimethylamine (NDMA), and 1,2,3-trichloropropane (1,2,3-TCP). Among these data sets, Shelton et al. (2008) observed that detections of most inorganic constituents were below health-based thresholds. Exceptions include nitrate (U.S. EPA's MCL exceeded in two samples), arsenic (U.S. EPA's MCL exceeded in two samples), and vanadium (California notification level exceeded in one sample). VOCs and/or pesticides each were reportedly detected in approximately 60 percent of the grid wells, but detections of all compounds but one were below health-based thresholds (the fumigant DBCP was detected above the USEPA MCL in one sample). Detections of radioactive constituents were reported to be below health-based thresholds, although nine samples were characterized by activities of radon-222 above the lower-proposed USEPA MCL.

A summary of findings for trace element and anthropogenic constituents stemming from the Shelton et al. (2008) study is presented in Table 3-11. A comparison with more recent data extracted for the present evaluation from the GAMA dataset for the Kern County Sub-basin for water samples collected and analyzed between 2007 and 2013 is provided later in Section 3.8.3 (Table 3-12 and Table 3-13).

3.8.2.2 Summary of Findings from 2012 USGS Study (Burton and Belitz 2012)

Burton and Belitz (2012) presented the GAMA data from the Kern County Sub-basin in an alternative format, comparing concentration distributions for individual water quality parameters with various benchmark values. Benchmarks included applicable federal and state regulatory thresholds for protecting human health (e.g., MCLs) or, in their absence, non-regulatory thresholds such as taste and odor standards (e.g., secondary MCLs or SMCLs) or human

health advisory levels. For given parameters, concentrations were correspondingly labeled as "high" if they were greater than the respective benchmark or "moderate" if they were greater than one-half of the benchmark. For organic and special-interest constituents, concentrations were designated as moderate if greater than one-tenth of the respective benchmark. "Low" concentrations included non-detections and values less than moderate concentrations.

Among major water quality indicators assessed by Burton and Belitz (2012) in Kern County Sub-basin wells:

- TDS was listed as present at high concentration across approximately 14 percent of the primary aquifer and at moderate concentration across 17 percent.
- Sulfate was present at high concentrations across approximately eight percent of the primary aquifer and at moderate concentrations across six percent.
- Chloride was reported as present at high concentrations across two percent of the primary aquifer and at moderate concentrations across four percent.
- Iron and/or manganese were present at high concentrations across 13 percent of the primary aquifer and at moderate concentrations across six percent.

Burton and Belitz (2012) reported that trace and/or minor elements are present at high concentrations in 20 percent of the primary aquifer area and at moderate concentrations in another 27 percent. Among minor elements:

- Fluoride was reported as a minor element present at high concentrations across four percent of the primary aquifer and at moderate concentrations in two percent.
- Arsenic, antimony, boron, and vanadium were listed as trace elements occurring at high concentrations across two percent of the primary aquifer.
- Lead, thallium, and selenium were also detected at high concentrations, but across less than two percent of the primary aquifer.

Other findings included:

- Nitrate was found at high concentrations across five percent of the primary aquifer, and at moderate concentrations across another 13 percent. The sources of these elevated concentrations were not distinguished between natural background, applied fertilizer, livestock operations, or septic tank systems.
- Solvents, including carbon tetrachloride and trichloroethene, were reported present at high concentrations across less than one percent of the primary aquifer and at moderate concentrations across four percent.
- Trihalomethanes, potentially attributable to municipal water disinfection and subsequent infiltration of chlorinated landscape irrigation water (Burton and Belitz 2012), were reported present at moderate concentrations across four percent of the primary aquifer.

- Other VOCs (e.g., organic synthesis reagents and gasoline hydrocarbons) were not reported present at high concentrations but were present in moderate concentrations (specifically in the case of benzene) across approximately two percent of the primary aquifer.

- The fumigant DBCP was reported present at high concentrations across some two percent of the primary aquifer. DBCP and other fumigants were reported present at moderate concentrations across four percent of the primary aquifer.

- Perchlorate, an inorganic constituent, and NDMA, a semi-volatile organic compound, were treated as special-interest constituents because of perceived emerging threats to California drinking-water supplies. Within the Kern County Sub-basin, perchlorate was not found at high concentrations in the primary aquifer, but was reported as present at moderate concentrations across six percent of the aquifer. NDMA was not reported at either high or moderate concentrations in the primary aquifer.

- In total, naturally-occurring radioactive constituents – primarily radium and uranium – were reported at high concentrations (according to definitions provided previously) across six percent of the primary aquifer, and at moderate concentrations across 13 percent.

3.8.3 Groundwater Quality by Sub-Area

A review of 2007 to 2013 data from the GAMA database for 490 groundwater wells (e.g., CDPH, environmental) was conducted to evaluate more recent data and compare to the distributions of water quality parameters identified by Shelton et al. (2008). The well locations are shown on Figure 3-13 and the results of this review are summarized in Table 3-12 and Table 3-13. The more recent data generally represents the water quality parameter value distributions reported by Shelton et al. (2008), with differences between the eastern and western portions of the Sub-basin also consistent with historical observations, as noted previously. Concentration data for TDS extracted from the GAMA database are also presented in Figure 3-14 to provide a spatial representation of TDS concentrations in the Sub-basin. As shown in Figure 3-14, TDS concentrations are generally higher on the west side of the Sub-basin than on the east side, consistent with the information presented on Figure 3-11.

Groundwater quality differences among the sub-areas are influenced by geology (Wood and Dale 1964). Streams recharging groundwater in the East sub-area – and, to a large extent, the Central sub-area as well – originate in the Sierra Nevada to the east. Because the streams drain areas that are underlain by low-solubility igneous and metamorphic rocks, the resulting water composition, generally of a calcium-carbonate character, is low in TDS. In contrast, groundwater recharge into the West sub-area stems from the Coast Ranges. These rocks consist of marine-derived sedimentary materials that are more easily dissolved and hence tend to more readily mineralize streams and underlying groundwater (Figure 3-11). For example, sulfate is present at elevated concentrations in some waters in the West sub-basin that have been in contact with gypsum-containing sediments. Also, elevated sodium concentrations are observed in groundwater in some West sub-area locations as a likely result of ion exchange processes (i.e., exchange of calcium and magnesium ions for sodium and potassium ions initially bound to clay minerals in the sediments). For these reasons, groundwater quality in the West sub-area is

generally of poorer quality than the Central and East sub-areas. In the West sub-area, concentrations of many general water quality parameters (e.g., chloride, magnesium, sodium, specific conductivity, and sulfate) are higher in both the shallow and deep groundwater zones, than comparative zones in the Central and East sub-areas (see Tables 3-12 and 3-13; Figures 3-15 and 3-16).

For groundwater, potential effects on water quality in different geographic sub-areas will vary with depth. In particular, the Corcoran Clay (Figure 2-6), present across much of the Central sub-area and a portion of the West sub-area, at depths between 300 and 500 feet, acts as a confining unit that restricts the vertical flow of groundwater. The Corcoran Clay unit is absent from most of the East sub-area. Groundwater encountered above the Corcoran Clay is referred to, herein, as “shallow” groundwater or the shallow aquifer and groundwater below this unit is referred to as “deep” groundwater or the deep aquifer. Where there is no confining clay layer, greater potential exists for shallow groundwater impacts to eventually reach deep groundwater.

3.9 Surface and Groundwater Quality Summary

The sub-area definitions provide a geographic and geologic framework for reviewing and organizing water quality information and evaluating potential impacts to both surface water and groundwater quality within the Project Area

3.9.1 West Sub-area Water Quality

According to the California DWR (CA DWR 2013a), native surface water supplies in the Tulare Lake Hydrologic Basin (which includes the Project Area) are generally of good quality. However, compared to the east side of the Tulare Lake Hydrologic Basin, flows from the west side are considered poor quality due to naturally occurring constituents (e.g., selenium and salinity) (CA DWR 2013a). In general, surface water in the West sub-area is characterized by greater concentrations of dissolved minerals (e.g., alkalinity, nitrate, hardness, chloride, sodium, specific conductivity, and boron) compared to the East sub-area (see Table 3-7 and Table 3-8 and Appendix C, Table C-1).

Similarly, groundwater quality in the West sub-area is generally of poorer quality than the Central and East sub-areas. In the West sub-area, concentrations of many general water quality parameters (e.g., chloride, magnesium, sodium, specific conductivity, and sulfate) are higher in both the shallow and deep groundwater zones, than comparative zones in the Central and East sub-areas (see Tables 3-12 and 3-13; Figures 3-15 and 3-16).

3.9.2 Central Sub-area Water Quality

The Central sub-area includes surface water canals that distribute water for agricultural uses (see Figure 3-3). The Kern River also flows through the Central sub-area before terminating at the West sub-area boundary, where any remaining water is diverted for water supply. Besides this main river, surface waters in the Central sub-area consist of mountain streams flowing from the East sub-area including Poso Creek. Surface water contained in the streams only flows into the Central sub-area during wet months, or wet weather events. The surface water quality in the Central sub-area (when it exists) is similar to the East sub-area (based on dissolved salts and

hardness [e.g., chloride, sodium, specific conductivity]), with slightly better water quality typically in the East sub-area (see Tables 3-5 through 3-8).

Groundwater quality in the Central sub-area is generally of better quality than the West and East sub-areas. In the Central sub-area, concentrations of many general water quality parameters (e.g., chloride, sodium, specific conductivity, and sulfate) are lower in both the shallow and deep groundwater zones, compared to the West and East sub-areas (see Tables 3-12 and 3-13). However, nitrate concentrations in the deep groundwater are highest in the Central sub-area and iron and manganese concentrations in shallow groundwater are significantly higher than the other sub-areas (see Tables 3-12 and 3-13; Figures 3-15 and 3-16).

3.9.3 East Sub-area Water Quality

Surface water flowing from the east side of the Tulare Lake Hydrologic Basin (east of the Project Area) is considered to be excellent quality (CA DWR 2013a). Therefore surface waters in the East sub-area are expected to be of good to excellent quality. The limited data available supports this assessment (see Tables 3-6 and 3-7).

Groundwater quality in the East sub-area is generally of better quality than the West sub-area and poorer quality than the Central sub-area, based on measurements of specific conductivity and distribution and presence of major anions and cations (see Table 3-12; Figures 3-15 and 3-16).

Section 4: Project Area Oil and Gas Production

This section provides background information and the current state of oil and gas production practices in the Project Area. The information presented in this section along with Sections 3 and 5 provide a baseline for evaluating potential impacts to surface and groundwater quality from petroleum exploration and production practices.

4.1 History of Oil and Gas Production in Kern County

Native Americans used asphalt and oil from seeps in the southern San Joaquin Valley for many purposes, such as waterproofing baskets, long before the arrival of Europeans. Spanish explorers also used the asphalt and oil, as did early settlers and travelers (Takahashi and Gautier 2007; DOGGR 1993). As early as 1849 travelers along the western side of the San Joaquin Valley noted the oil seeps and used the material to lubricate wagon wheels (DOGGR 1993).

Settlers found uses for the oil, such as paving, waterproofing, asphalting and refining to produce kerosene and other products. Early developers built pits, quarries, tunnels, and shafts near surface seeps to collect and extract oil and asphalt, such as in the Asphalto and Buena Vista areas (Rintoul 1990). In the late 1800's, shallow wells were drilled with hand tools. Shortly thereafter, deeper wells were drilled with rigs, and society was developing new ways to produce, control, transport, store, and refine the product while innovating ways to increase production. These actions evolved into today's extensive network of activities related to onshore oil and gas production.

DOGGR recognized oil fields in the Project Area are shown on Figure 1-2 and listed in Table 4-1.

4.1.1 Historical Exploration and Production Practices

As noted above, oil production began with pits, quarries, tunnels, and shafts near surface seeps to extract oil and asphalt. This evolved to hand-dug wells in the late 1800s. The first wood derrick for an oil well constructed in Kern County was in 1878 at Reward. The derrick was outfitted to drill an oil well using cable-tool methods (Takahashi and Gautier 2007). Shallow wells were drilled at prospects (commonly near oil seeps) through the area leading to discoveries of the Sunset field in 1887, McKittrick in 1896, Kern River in 1899, and the Midway area of the Sunset field in 1900. Other discoveries followed in the early 20th century, including Elk Hills, Lost Hills, and Belridge South and North (DOGGR, undated). Production from the Kern River field was initially so prolific that it helped vault California to the status of top oil producing state in 1903 (Rintoul 1990).

Cable-tool rigs were outfitted with a steam engine that operated a system of beam, winches, and flywheels. The drill bit, which was basically a large steel chisel suspended from the cable, was dropped repeatedly to pulverize the formation. The chiseling was alternated with bailing to remove the cuttings. Although slow, the method was used for a number of decades.

Rotary drilling largely replaced cable-tool drilling by the 1920s (DOGGR 1993). The rotary system relies on a rotating bit to cut a hole through the rock formation. Drilling fluid circulates down through the drill pipe and out into the open borehole through the face of the bit. The circulating fluid cools the bit and entrains the cuttings, returning them to the surface for removal. The drilling fluid is then recirculated back down the borehole. In this method the entire drill pipe is rotated in order to rotate the drill bit and advance the boring (DOGGR 1993). Modern rotary drills are capable of changing direction, so wells can be drilled at varying angles or horizontal.

Electric well logs were first conducted in 1929. In 1936 the first seismic exploration in California was responsible for discovering the Ten Section field near Bakersfield. Seismic discovery of the productive Paloma and Coles Levee anticlines soon followed (SJGS 2014a).

Some early wells encountered over-pressured formations, which would generate “gushers” of oil and gas that were dangerous or difficult to control, and depleted formation pressures. Early gushers included the 1896 Shamrock well in the McKittrick field, which flowed in at 1,300 barrels per day, and the Lakeview No. 1 gusher, in the Midway-Sunset field in 1910. The Lakeview No. 1 well reached a depth of 2,225 feet when the bailer was blown up through the derrick and a 20-foot wide, 200-foot tall column of oil erupted from the well. The gusher remained uncontrolled for 18 months, spilling more than 8 million barrels of oil onto the ground surface (DOGGR 1993).

Legislation emerged in the late 1800s in California to regulate the industry and protect the resource from water damage and depressurization. The 1903 California Legislature passed a law requiring drillers to seal off water zones between oil-producing zones, and seal a plugged well for at least 100 feet above the producing zone. In 1911 a law was passed to “prevent the wasting of natural gas” (Rintoul 1990). The Department of Petroleum and Gas of the State Mining Bureau was created in 1915, with the duty to supervise petroleum or gas wells in such a manner as to prevent damage to the formations and protect the petroleum resource.

Steps to enhance recovery have a long history in Kern County. Steam flooding had been used successfully on asphalt deposits in the 1800s and on the viscous Kern River oil field in the early 1900s. Experimental bottom hole heating and downhole combustion (“fireflooding”) tests were conducted in the 1950s and 1960s to assess the ability to heat and mobilize viscous oil that was otherwise inaccessible. The experiments indicated that although these methods increased production they were not commercially viable at the time. Much greater success was achieved with hot water or steam injection (Rintoul 1990).

In the 1960s, steam injection became more widely used with the two most common methods being cyclic steam and steam flood. In cyclic steam, steam is introduced into a well for a specified time period, then the injection is stopped and the steam dissipates into the formation. The well is then returned to production, extracting oil and water. This process is completed in cycles throughout the oil field. The cycle times are varied to maximize production. The rate and frequency of steam application can also vary depending on the specific characteristics of the geologic formation. Steam flooding entails continuously adding steam to a specific set of wells to heat and drive the oil to other dedicated extraction wells.

As noted, California led the nation in oil production in 1903. The Kern River, Midway-Sunset, and McKittrick fields accounted for approximately 75% of California’s production; the Kern River field alone produced 17 million barrels. Production increased to a peak during World War II and declined slowly until the early 1970s (SJGS 2014b). Production increased sharply from the early

1970s to a peak in 1985, when Kern County produced 256 million barrels (SJGS 2014a). Production has been steadily declining since 1985.

4.2 Oil and Gas Operations in the Project Area

Oil and gas operations in the Project Area include well installation and completion, well stimulation treatments, production, aboveground fluid separation and processing, water recycling and disposal, and well abandonment. Production includes the extraction of subsurface fluids, in the form of oil, gas and water (referred to as "produced water"). Aboveground processing includes separating the fluids, processing and storing the oil and gas for sale and transportation off of the leasehold, and processing the produced water for use in enhanced oil recovery operations, treating the produced water for beneficial re-use by a third party, or disposal.

4.2.1 Well Installation

Oil and gas production operations begin with drilling wells. The purpose for drilling may be for exploration, field development, or well plugging and abandonment. Exploratory drilling, or wildcatting, is done to assess if oil and gas resources exist in a specific area and if extraction is economically viable, and to investigate the limits of a particular field. Field development consists of step-out drilling and infill drilling and is done to delineate the limits of the field and maximize the recovery of oil and gas within a known field. Development drilling also includes re-drilling and recompleting wells to rejuvenate or maximize the recovery of oil and gas within an existing well (Kern County PCDD 2013).

A summary of the drilling activity from 1995 to 2009 in the Project Area is summarized in Table 4-2 and the number of active producing wells from 1995 to 2009 is summarized in Table 4-3 (DOGGR 2010). A graph showing the number of oil and gas wells drilled, completed, and abandoned from 1995 to 2009 is presented on Figure 4-1. The graph indicates that production well counts peaked in 2002, and well installation/abandonment activities peaked in 2008, and sharply declined in 2009.

Drilling activities occur on a well pad that has been constructed to support the activity (Figure 4-2). Site preparation activities include clearing and grading, and setting containment sumps (temporary pits, operations sumps) and/or portable tanks to store drilling fluids, wellbore cuttings, and waste which result from the drilling process. Portable tanks are also used to mix and store other needed fluids or slurries, such as completion or stimulation fluids.

After the well pad is completed, the drilling rig is set up on the pad (Figure 4-3). Temporary facilities, equipment and materials necessary to support the drilling operation (i.e., water, drilling supplies and materials, crew support trailers, pumps and piping, portable generators, field flares, fuels and lubricants, etc.) are also set up and stored on the well site. Next, a surface casing is set and cemented in place, and blowout prevention equipment is installed at the wellhead and tested.

4.2.1.1 Drilling

Oil wells in the project area are most commonly, but not always, vertical. A small percentage of the wells in the Project Area are advanced at an angle or horizontally, with a process known as directional drilling. Angle borings are commonly drilled when vertical access to the reservoir is not possible, typically as a result of physical constraints at or near the surface. A directionally drilled well starts with a vertical borehole that is extended to a specific point (kickoff point) where the wellbore is curved away from the vertical plane until it intersects the target formation (entry point). At the kickoff point the drill pipe is removed and a hydraulic motor is placed between the drill bit and the drill pipe. The hydraulic motor is powered by the flow of drilling mud down the drill pipe. The motor rotates the drill bit without the need to rotate the entire length of drill pipe between the bit and the surface. This allows the bit to drill a path that deviates from the orientation of the drill pipe. Downhole instruments are used to determine the azimuth and orientation of the drill bit and this information is used by the driller to steer the drill bit (King 2014).

4.2.1.2 Drilling fluid

Drilling fluid, or mud, is typically composed of water, clays (bentonite), fluid loss control additives, density control additives and viscosifiers. Drilling fluids may also have a synthetic chemical base, or even an oil base. The base fluid (typically water), bentonite, and other chemical additives are mixed together in mud mixing tanks and fed into the circulation system. During drilling, the composition and weight of the fluid are altered as needed to suit the changing pressure, temperature, and chemical conditions in the borehole.

The drilling fluid lubricates the bit as it turns, and it carries the drill cuttings back to the surface along the outside of the drill pipe. At the surface, the drilling fluid passes through a screen, which separates out the drill cuttings, and the fluid is circulated back down the drill pipe (DOGGR 1993). Drill cuttings are typically deposited in a reserve pit or sump excavated next to the rig (Kern County PCDD 2013) after they are removed from the drilling mud. The drilling fluid builds a “mud cake” on the walls of the borehole. The mud cake prevents drilling fluids from flowing into porous rock and, together with the weight of the mud column, prevents the hole from caving in. The mud cake also helps seal off the borehole from the surrounding formations (DOGGR 1993).

4.2.1.3 Casing Installation and Cementing

Constructing a typical oil or gas well consists of several cycles of drilling, installing steel casing and cementing the casing in place. The final length of casing, called the production casing, is installed if and when a promising zone has been identified. In each cycle, steel casing of sequentially smaller sizes is installed inside of and below the previous installed casing string. Installing the casing in stages results in multiple layers of protective steel casing and cement in the uppermost portions of the borehole (API 2009).

Before penetrating oil or gas reservoirs, most wells pass through unconsolidated (soil) strata and fresh and/or brackish water-bearing zones (i.e., aquifers - some wells in the West Sub-area do not pass through a freshwater zone before encountering brackish water). The first casing, known as a conductor casing, is placed in the upper portion of the borehole to prevent surface soil from collapsing. For protection of the aquifers and to prevent collapse of the borehole, a

steel casing, known as a surface casing, is installed and cemented into place. The surface casing extends below the base of the fresh water aquifer(s). The “intermediate casing” is set inside the surface casing and typically extends to the top of, or into, the cap rock (the geologic formation that prevents the upward migration of the oil and gas). The last casing installed is the “production casing” and is set, and perforated, in the production zone. Figure 4-4 represents a schematic diagram illustrating the casing and cemented zones of a typical oil or gas well.

Field Rules (DOGGR 2013a) specify casing and cementing depths by field. The rules have been developed over time based on the specific geologic characteristics known by the regulators to exist at the particular field. The conductor casing, surface casing, intermediate, and production casing depth ranges are published along with the annular cement fill depths. Conforming to the Field Rules, and adhering to industry standards of practice for engineering and constructing casing and seals, protects the shallow water-bearing formations from the deep hydrocarbon production zones. DOGGR also requires testing of the cement seals (see Section 6) to assure that they meet certain minimum test pressures, and directs specific corrective measures if a casing or seal fails a pressure test.

The cement slurry design (density, compressive strength, shrinkage, etc.), and the mixing, blending, and pumping of cement is an important factor in establishing the well seal. The design and installation procedures are well established and provided in documents prepared by API (2002) and DOGGR (2013a).

4.2.2 Well Completion

Well completion includes installing production casing, perforation, development, removal of formation damage, installation of production equipment, and production testing. Senate Bill (SB)-4 regulated well stimulation activities (e.g., hydraulic fracturing, acid matrix stimulation) can also be conducted as part of the well completion process. Completion begins once a boring has been drilled to the prescribed depth and drilling mud is removed, and is complete once the well is brought intro production, or used for its’ intended purpose (e.g., injection). Well completion tasks can also be implemented on an existing well to improve performance, or change the production zone (known as recompleting or reworking). A typical production well installation is illustrated on Figure 4-5.

4.2.2.1 Production Casing Installation and Perforation

Once the well has been drilled to its designed depth, typically the bottom of the oil sand or series of oil sands, the production casing is installed in the borehole, and perforated from the bottom of the production zone to a few feet up inside the intermediate casing. The production casing serves as the screened casing for the oil well, allowing oil to enter the well while keeping formation sands out. It is either installed with perforations already made or a blank casing is installed and perforated after installation at the desired depth intervals with a perforating gun (DOGGR 1993).

The steel casing is manufactured to meet requirements of compression, tension, collapse, corrosion resistance, and other factors. Centralizers are used to center the casing in the borehole prior to cementing. The production casing allows hydrocarbons to enter the well and serves as a casing for production tubing and packers that may be inserted into the casing at a

later time. It is cemented in place to isolate the production zone from other formations (API 2009).

After the production casing is installed, a 2-inch to 3.5-inch diameter tubing is installed into the well. The tubing extends from just above the perforated zone to the ground surface, and it is through the tubing that the production fluids are brought to the surface (DOGGR 1993).

4.2.2.2 Well Stimulation

Well stimulation activities (now subject to regulation under SB-4) have been conducted in the Project Area for more than 60 years. Well stimulation is a technique used to increase production by increasing the permeability of the oil-bearing formation through physical or chemical means, thereby improving flow to the well. Well stimulation treatment, as defined in SB-4 includes hydraulic fracturing, acid matrix stimulation, and acid fracturing but excludes uses of acid for routine well cleanout, maintenance and removal of formation damage. Stimulation activities can be conducted on new wells, or as part of reworking an existing well to improve performance. As defined in SB-4, well stimulation "is a short term and non-continual process for the purposes of opening and stimulating channels for the flow of hydrocarbons." SB-4 regulated well stimulation activities do not include steam flooding, water flooding, cyclic steaming, well cleanout work, or routine well maintenance.

SB-4 requires operators to file notices with DOGGR 30 days before conducting a regulated well stimulation treatment. These notices are available to the public on the DOGGR website. Table 4-4 is a summary of the SB-4 regulated well stimulation notices posted for the Project Area since 20 November 2013 (as downloaded on March 3, 2014). The data indicates that hydraulic fracturing treatments represent 85% of the SB-4 regulated well stimulation treatment notices filed between December 2013 and the beginning of March 2014.The data also indicate that the majority of the hydraulic fracturing events were conducted in the Belridge North, Belridge South and Elk Hills oil fields in the West Sub-area.

Hydraulic fracturing in a variety of forms has been widely applied over many decades in California. The vast majority of past and current recorded fracturing activities occur in the North and South Belridge, Lost Hills, and Elk Hills fields, in the Project Area. Contrary to other oil and gas fields in the United States, large-scale application of high-volume hydraulic fracturing has not been widely applied in the Project Area. The majority of the oil produced in the Project Area is not generated from the low-permeability shale source rock (i.e., the Monterey Formation), but rather from geologic formations that have captured oil and gas that migrated from the source rocks. Most of the hydraulically fractured wells in California are vertical or near vertical. These vertical wells are constructed with shorter perforated intervals, compared to long lateral/horizontal wells, and therefore require less fluid for hydraulic fracturing. Therefore, the volumes of water used in hydraulic fracturing in California are much smaller than in oil source rock plays elsewhere.

4.2.2.2.1 Hydraulic fracturing

Hydraulic fracturing (also known as hydrofracturing, "fracking", or "fracing") is the injection of a mixture of water, chemicals, and substances (primarily silica sand) called "proppants" into a well at pressures greater than the fracturing pressure of the formation. Hydraulic fracturing causes microscopic fractures to propagate away from the well/boring, increasing the surface area of the

formation that is in communication with the well. As the injected mixture passes through the fractured formation, the proppants are deposited into the fractures, keeping the fractures open, thereby creating channels through which the oil and/or natural gas can reach the well (DOGGR 2013b). A majority of the wells that are hydraulically fractured in the Project Area are shallow vertical wells installed in the diatomite formations, where permeabilities are extremely low. Data obtained from FracFocus indicate that 830 wells underwent hydraulic fracturing treatment in 2013. Of those 830 wells, only 15 wells were deeper than 2,500 feet bgs. The average hydraulic fracturing job used approximately 127,000 gallons of water. Figure 4-6 illustrates the equipment commonly used on a hydraulic fracturing project in the Project Area.

4.2.2.2.2 Acid Fracturing and Acid Matrix Stimulation

Acid fracturing and acid matrix stimulation are also regulated operations under SB-4. These stimulation operations involve injecting acid into the formation to increase permeability. In the case of acid fracturing, fluids are pumped into the well at pressures exceeding the fracturing pressure of the formation (similar to hydraulic fracturing) in order to fracture the formation, thereby causing or enhancing the production of oil or gas from a well. For acid matrix stimulation, fluids are pumped into the formation at pressures that are lower than the fracturing pressure to achieve the similar results (Robertson and Chilingarian 1989). The DOGGR well stimulation treatment notices reported between the end of November 2013 and the beginning of March 2014 indicate that 15 percent of the notices filed were for acid matrix stimulation treatments.

4.2.2.3 Production Equipment

If the reservoir pressure is sufficient to bring production to the surface without pumping, then a series of valves called a Christmas tree is attached to the tubing at the ground surface, and is used to control the flow. Most wells do not have sufficient reservoir pressure and even flowing wells eventually lose pressure over time, so that a pump must be installed to lift the production to the surface. Reservoirs where heavy oils are present (where steam and water flooding is used to produce the oil) are good examples of this condition.

A rod pump is the most common pumping method for oil wells. A pump mechanism is lowered to the bottom of the tubing and is connected to the surface by a long narrow sucker rod. The top of the sucker rod is attached to a pump jack, which actuates the pump by its constant up and down motion. The pump jack is driven by either a natural gas engine or by electric power, and can either be crank-balanced or air-balanced. Other methods of pumping oil to the surface include submersible pumps and fluid-actuating pumps (DOGGR 1993). Figure 4-5 illustrates a typical production set-up for the Project Area.

4.2.3 Oil Field Production

Oil field production refers to the day-to-day lifting and processing of oil, gas and produced water in the oil fields. As the pump jack operates, production fluids are brought to the surface and transmitted through pipelines that are either above ground or just below ground to a central processing facility called a tank battery. The production fluids arrive at the surface as a mixture of water, oil and gas. The purpose of the tank battery (a number of tanks in series) is to separate the fluids into their respective parts (processing). A typical tank battery is illustrated on

Figure 4-7. Graphs of production and injection data from fields in the Project Area are available on the DOGGR website (DOGGR 2014). Example graphs for production between 1977 and 2013 for the Midway-Sunset and Kern River fields are included as Appendix D.

4.2.3.1 Oil Production

Production fluids from the field are initially fed through a tall cylindrical tank called a separator. Gasses are separated from the fluid and piped out at the top of the separator, while oil and water drain out the bottom. Oil and water then are pumped to a series of vessels designed to separate the fluids based on the viscosity and gravity of the oil. Separation process equipment typically includes free-water knockout vessels, heater treaters and wash tanks (DOGGR 1993). Two chemicals are typically introduced to the production fluid to aid in the separation, an emulsion breaker (to coalesce oil droplets so they can be more effectively removed from the water) and a scale inhibitor (to keep inorganic salts from precipitating on the walls of the tanks and piping).

Oil is skimmed off the top of the separated mixture and piped to stock tanks. Water is drained near the tank bottom. From the stock tanks, the oil is typically piped and metered through a Lease Automated Custody Transfer (LACT) unit. Passing through the LACT unit, the oil is sold and is transported off the lease either by truck or by pipeline. Some tank batteries do not have LACT units. At such facilities the tanks are gauged to determine the volume prior to transport. At this point the oil leaves the production phase and enters the transportation phase.

Oil fields in the Project Area produced a total of 135.4 million barrels (Mbbl) of oil in 2013 (DOGGR 2014). Oil production by field and sub-area for 2013 is summarized in Table 4-5. Table 4-6 summarizes the number of active production and injection wells in each field and sub-area for 2013. Oil production by field is illustrated on Figure 4-8. The data collected from DOGGR indicates the five top oil-producing fields in 2013 were the Midway-Sunset; Belridge, South; Cymric; and Elk Hills fields in the West Sub-area; and the Kern River oilfield in the East Sub-area. Figure 4-9 illustrates the oil production from the top five fields declined an average of 5 percent per year from 2010 to 2013 while production from smaller fields increased by approximately 3 percent per year.

4.2.3.2 Gas Production

Produced gas is a mixture of hydrocarbons including methane, ethane, propane, butane, and natural gasoline. This mixture is also commonly referred to as wet gas. If the field does not produce sufficient gas to process and sell, the gas that is not used to blanket the petroleum in the tanks is sent from the separator to a flare and burned off, used as fuel for steam generators, or sent via pipeline to a gas disposal well. Otherwise, produced gas is piped to a gas plant for processing. The gas plant uses a series of heat treatments to separate the methane, now called dry gas, from the other components, referred to as natural gas liquids (NGLs). The separation process typically uses glycol as a heat transfer fluid. NGLs are drawn off and collected in a tank without further separation. Mercaptans are added to the dry gas to odorize it, and the gas is piped and metered through a LACT unit and sold or consumed on-site. NGLs are also piped through their own, separate, LACT unit. Unwanted component gasses (byproducts) such as hydrogen sulfide are removed by scrubbers using a non-hazardous amine system (Kern County 2013), collected and properly disposed or sold as elemental sulfur.

Oil fields in the Project Area produced a total of 151,402,319 million cubic feet of gas in 2013 (DOGGR 2014) (see Table 4-5). Figure 4-10 illustrates the top gas-producing fields for 2013. Figure 4-11 illustrates that gas production for most fields is relatively steady, except for Kern River which increased sharply from 2012 to 2013.

4.2.3.3 Produced Water

Produced water is usually the largest fraction (commonly greater than 90 percent by volume) of the production fluid in an oilfield in the Project Area. After separation, produced water is typically treated by being passed through an induced gas flotation unit, a sand or walnut shell filter, and an induced air flotation unit (Kern County PCDD 2013). The treated water is then stored in aboveground tanks. Produced water is stored, handled, and disposed or reused depending on the needs of the lease and the quantity and quality of the water. The following are potential options for managing produced water:

- ***Enhanced Oil Recovery Processing –*** Treated as needed (typically this water is softened if being used to generate steam) then pumped to an enhanced recovery system and injected back into the oil producing formation as heated water or steam.

- ***Underground Disposal –*** Pumped to Class II Underground Injection Control (UIC) program wells within the oil field boundary and injected into a deep subsurface formation. The geologic formation receiving the waste fluid is designated by the DOGGER (under authority from the USEPA) to be exempt from meeting water quality standards (referred to as an "exempt aquifer"). This option requires minimal treatment (i.e., filtering) to no treatment.

- ***Land Disposal –*** Treated on-site or transported off the production site, by truck or pipeline, to a wastewater treatment facility or percolation pond. Treated water is pumped to large, permitted, infiltration galleries and allowed to percolate into the subsurface and/or evaporate.

- ***Beneficial Reuse –*** Treated on-site or transported off the lease, by truck or pipeline, to a wastewater treatment facility. Treated water is then provided to a third party for re-use, such as crop irrigation or groundwater recharge (aquifer recharge and storage [ARS] program), wetlands enhancement, etc. (Kern County PCDD 2013).

The DOGGR database indicates that a total of 1,808 Mbbl (75,930 million gallons [Mgal]) of produced water was generated in 2013 (DOGGR 2014), consisting of 1,025 Mbbl from the West Sub-area; 22 Mbbl from the Central Sub-area, 756 Mbbl from the East Sub-area and 5 Mbbl from unspecified fields (Any Field) (Table 4-5). DOGGR data indicate that in the West Sub-area, 90 percent of the produced water is generated by 6 of 44 oil fields (14 percent); in the Central Sub-area 90 percent of the produced water is generated by 8 of 26 oil fields (30 percent); and in the East Sub-area 90 percent of the water is generated by 5 of 20 oil fields (25 percent). The produced water and the ratio of produced water to oil (the "water cut") for 2013 is also summarized in Table 4-5. Figure 4-12 illustrates the percent water produced from the top 15 water-producing fields, relative to the remaining fields. Figures 4-13 and 4-14 illustrate the fields with the highest water cuts (Kern Bluff in the East Sub-area is the highest with 99.4% water to

oil) and the lowest water cuts (Beer Nose in the West Sub-area is the lowest at 6.7% water to oil).

4.2.4 Enhanced Oil Recovery

As reservoirs are depleted and production declines, oil producers seek alternatives to increase efficiency of existing and new wells. Enhanced oil recovery through waterflooding and steam injection has been used in California since the 1950s. Enhanced recovery facilities typically include the same infrastructure as required for oil and gas production, including pipeline distribution, pumps, and compression systems. These systems supply and deliver the water or steam to the reservoir. With thermal enhanced recovery systems, steam is prepared from filtered and softened produced water or sometimes fresh water by onsite gas-fired or solar steam generators or cogeneration facilities. The steam is then delivered via insulated pipelines and injected into wells perforated in the oil-bearing formation (Kern County PCDD 2013). Figure 4-15 presents a photograph of the Kern River Oilfield, showing the network of insulated pipelines that deliver steam to injection wells.

Based on the injection volumes reported in 2013, presented in Table 4-7, water flooding is practiced in all three subareas of Kern County, but is most commonly practiced in the Central subarea where the oil is relatively deep and of low viscosity. Steam flooding and cyclic steam are used in the West and East subareas where the oil tends to be shallow and of higher viscosity.

In 2013, 1,461 Mbbl (61,346 Mgal) of produced water were re-injected into the production zones, in the form of water or steam, to maintain field pressures and optimize production (DOGGR 2014). The amount of water injected as part of field maintenance represents approximately 81 percent of the produced water generated in 2013. Table 4-7 summarizes the steam/water and air injected into formations in 2013, by field. The five oilfields with the largest injection volumes are the South Belridge, Midway-Sunset, Elk Hills and Lost Hills in the West Sub-area, and the Round Mountain oil field in the East subarea. Table 4-8 summarizes the injection volumes for 1995 to 2009 broken down by the method of injection (steamflood, waterflood, etc.) for the Project Area.

The volumes of injected water and steam increased in most fields from 2010 to 2013, as illustrated on Figure 4-16. The largest increase was in Midway-Sunset and the largest decline was in Lost Hills. The general trend is that the volume of fluids being injected is increasing while oil production is declining, gas production is relatively steady, and water production is increasing. For example, for the Midway-Sunset oil field, oil production decreased an average of 5 percent per year between 2010 and 2013, while water production increase approximately 5 percent per year during the same period.

4.2.5 Transportation and Conveyance

Produced oil, gas, and water are generally transported across the oilfields by pipeline or by truck. Pipelines require installation, maintenance, and testing, as well as construction and maintenance of valve stations, compressor stations, and storage tanks. Transportation by truck requires construction and maintenance of roads, support facilities, and storage tanks. Most new pipelines are installed above ground (Kern County PCDD 2013). Transportation of equipment to

and from oil field operations is generally by truck. Access roads are generally maintained by the individual lease operators. Oil and produced water are also transported between the various oil fields and to the refineries via truck and in some cases pipeline. Inter-field movement of water via truck and pipeline is managed and regulated in a similar manner. Inter-field transportation of oil via pipeline is controlled under State Fire Marshall regulations.

4.2.6 Well Abandonment

Well abandonment is performed when a well becomes uneconomical or the producing zone has been depleted. Well abandonment is usually accomplished with a “workover” rig and equipment similar to that used for installation of the production equipment.

Procedures for plugging and abandonment are standardized by the state and special requirements are issued at the field level by way of Field Rules issued by DOGGR. In general, cement plugs are placed across specified intervals to protect oil and gas zones, to prevent degradation of groundwater zones, to protect surface conditions, and for public health and safety. Cement may be mixed with or replaced by other materials with adequate physical properties upon approval by the district DOGGR office (Walker 2011).

An open hole must be plugged with cement from at least 100 feet below the bottom to at least 100 feet above the top of each zone from which oil or gas was produced. A minimum 200-foot thick cement plug must be placed across all fresh-brackish water interfaces or within a thick shale if it separates the fresh water sands from the brackish water sands (Walker 2011).

A cased hole must have all perforations plugged with cement. The cement plug must extend at least 100 feet above the top of the highest perforations, or casing cementing point, or water shut-off holes, or producing zone, whichever is highest for that well. If there is cement outside the casing across the fresh-saltwater interface, a 100-foot cement plug must be placed inside the casing across the interface. If the top of the cement outside the casing is below the top of the highest saltwater sands, pressure cementing is required through perforations to protect the fresh water aquifers. For producing zones in fractured shale or schist, massive sand intervals, depleted productive zones, and multiple producing zones, a cement plug extending from at least 25 feet below the top of the uppermost perforated interval to at least 100 feet above the top of the perforations (or landed liner, or casing cementing point, or water shut-off holes, or producing zone, whichever is highest) is required (Walker, 2011).

At the surface, cement must be placed in at least the top 25 feet inside and outside the casing strings. The district DOGGR office may require that inner casing strings be removed to at least the base of the surface plug prior to placement of the surface plug. All casings must be cut off at least 5 feet but no more than 10 feet below the ground surface. A steel plate must be welded at the top of the casing showing the identification of the well by API well number (Walker 2011).

Well abandonment and plugging operations are required to be permitted by and reported to DOGGR. Table 4-3 summarizes the well abandonment activity from 1995 through 2009 (DOGGR 2010). The records show that well abandonment activity peaked in 2002 with 2,279 wells abandoned and plugged (DOGGR 2010). The number of abandonments appears to have decreased from 1,903 wells in 2005 to 1,176 wells in 2013.

4.3 Future Development Trends

4.3.1 Economic Factors

Oil field development (exploration, enhanced recovery, production, etc.) is driven by the value of the products. Higher prices for oil and gas will generally result in more exploration, more efforts to increase production, and more innovation while lower prices result in the opposite, including the shut-in of currently producing wells, and shut-down of low-yielding fields. The future price of oil and gas cannot be predicted with a reasonable level of certainty; however, it is likely to be sustained at a level to at least support active oil field development for the foreseeable future.

4.3.2 Exploration

Relatively few exploration wells are being drilled in the San Joaquin Valley, which is considered a 'mature' province (Takahashi and Gautier 2007). The most important oil field operators tend to concentrate on developing existing fields. However, as deep and petroliferous as the basin is, undiscovered deposits may exist. Yowlumne field was discovered in 1974, and the Bellevue #1 well in the Lost Hills field tapped into a deep, highly pressured gas zone in the Temblor formation in 1998. Other deposits may yet be found. As such, exploratory wells, within and outside existing oil field boundaries are expected to continue to be drilled in the near future, at a marginal (a few wells per year) rate.

4.3.3 Production

The project applicants estimate that approximately 3,649 wells will be drilled and 2,231 wells will be abandoned each year over the next 20 years in the Project Area, indicating a net gain of 1,418 wells per year. Approximately 2,221 of the 3,649 wells installed annually will be active production wells and 939 will be injection wells. The well count includes 1,029 production wells and 428 injection wells that will be installed annually using SB-4 regulated well stimulation treatments. Recent increases in the volume of produced water suggest that this volume will continue to increase, as oil product decreases. As produced water volumes increase, injection volumes are expected to increase to maintain field pressures. However, the volume of produced water needed for injection will depend on the method of the injection (e.g., waterflood vs. steam injection).

4.3.4 The Monterey Shale

According to the U.S. Energy Information Administration (EIA) Annual Energy Outlook 2014 (EIA 2014), U.S. production of crude oil is projected to increase to 9.6 million barrels (bbl) per day in 2019. Higher production volumes result mainly from increased onshore oil production, predominantly from tight (very-low-permeability) formations.

A report commissioned by EIA (Intek 2011) projected that 15 billion bbl of recoverable, undeveloped oil was available in the "Monterey/Santos" shale in the San Joaquin Valley and Los Angeles areas. However, in May 2014, the estimate for recoverable oils from the Monterey/Santos shale was lowered to 600 million bbl, a 96-percent decrease. The primary

reason cited for the decreased projection was the lack of development to date, based on difficulties in producing oils from the geologically complex formation.

Hughes (2013) states that the Monterey Shale is not comparable to other tight oil plays - it is structurally and stratigraphically complex and thus its depth and thickness are highly variable compared to formations such as the Bakken Shale, in which long horizontal wells are built. The San Joaquin and Santa Maria Basins, where the predominant shale potential lies, have been producing from the Monterey for many decades and Hughes proposes that increases in production are likely to be marginal incremental additions, not a new energy bonanza.

Section 5: Water in Oil and Gas Operations

Water that is needed to explore for and produce oil and gas in the Project Area, including the production of steam for enhanced recovery operations, comes from a variety of sources. Common sources include groundwater (including entitlements as well as purchased), surface water (through various contracts with local purveyors and State Contractors), and produced water (Kern County PCDD 2013). Depending on the proximity of the source to the operation for which it is needed, water is transported by either truck or by pipeline, or both.

Water for oil and gas production may be purchased from local purveyors or pumped from underground sources or produced as part of the oil recovery process. Data collected for calendar year 2012 (WZI 2014) indicates that approximately 96 percent of the water handled in production operations was produced water. Figure 5-1 illustrates the type and volumes of water used for various oil and gas production activities. When the volume of water required to produce oil or gas is less than the cumulative (purchased plus produced) supply, disposal or re-distribution of the excess water is required. Disposal and re-distribution for third-party beneficial reuse occurs under project-specific WDR permits from the RWQCB. Disposal into an administratively exempt aquifer through Class II UIC wells occurs under permits from the DOGGR, under authorization of the USEPA. Table 5-1 summarizes the volume of water disposed to land, pumped into Class II disposal wells, and provided for third-party beneficial re-use in 2012 (Kennedy/Jenks 2015). The following sections present a summary of water quality, quantity and use (handling, transportation, treatment, disposal) as part of the current exploration and production operations in the Project Area, as described in Section 4. Table 5-2 presents summary descriptions of the various water and wastewater handling processes that are part of each operation. Figure 5-2 presents flow diagrams for the various oilfield processes that rely on water.

5.1 Well Drilling, Completion and Abandonment

Well installation, completion and abandonment activities typically use freshwater, obtained from groundwater and surface water sources. The largest volume of drilling-related wastes is used drilling fluid (API 1997). Drilling fluids (drilling mud) contain four basic parts: water; active solids (e.g., clay); inert solids (e.g., barite); and additives. Typical constituents comprising the drilling fluid used in the Project Area are summarized in Table 5-3. Drilling fluids differ based on the zone which is being penetrated. While drilling the upper portion of the borehole (through the fresh water zone), drilling muds are water-based and similar in composition to those used in the water well industry. Once the primary casing is set and sealed, drilling muds more compatible with drilling through the oil-bearing formation are used (commonly oil or synthetic based heavy muds).

As described in Section 4, drill cuttings consist of the inert rock fragments brought to the surface by the fluids. The waste fluid generated from below the fresh water zone typically contains petroleum hydrocarbons, select metals (e.g., boron), and /or high TDS. The USEPA classifies oil and gas wastes and related fluids (e.g., flowback water and produced water) as “special wastes”, which are exempted from classification as a listed hazardous waste. As a result, regulations regarding the handling and disposal of oil-field generated wastes vary from state to

state. Section 6 further describes regulations for characterization, handling and disposal of oilfield wastes in the Project Area.

Drilling and completion of a typical vertical production well in the Project Area uses between 560 and 1,900 bbl of fresh water (dependent on depth and boring diameter), producing an equal amount or more of fluid waste. The forms of the fluid waste commonly include spent drilling muds, cuttings, cement returns, formation (i.e., produced) water and oil. Drilling muds can be stored in aboveground tanks during operations, but are more commonly stored in lined or unlined (where permitted) sumps during drilling. Prior to December 2013, drilling muds and cuttings were typically discharged to surface impoundments after completing drilling operations, where the water was allowed to evaporate, leaving the solid cuttings lining the sump. Prior to December 2013, oilfield practices included removing the free liquid from the sump at the completion of the drilling activities, then mixing the solids with native soils and burying them in-place. Changes in regulations in late 2013 (see Section 6) now require that these solids be removed and appropriately managed.

Well abandonment activities typically use between 850 and 2,950 bbl of fresh water primarily for making cement to seal the well. Handling and disposal of wastes produced during these activities follow those procedures described above.

5.1.1 Well Stimulation

SB-4 well stimulation notices indicate that most of the water used in well stimulation operations consists of fresh water purchased from local water districts. As an example, of the 292,000 bbl (12.3 Mgal) of water used by Chevron for hydraulic fracturing in 2013, 85% (10.8 Mgal) was reportedly purchased freshwater and 15% (1.5 Mgal) was reported to be high-TDS water produced from the Tulare formation. As reported to DOGGR, hydraulic fracturing comprises most of the SB-4 regulated well stimulation activities in the Project Area (Table 5-4). The volume of water injected for hydraulic fracturing projects in 2013 ranged from approximately 3,500 barrels (147,000 gallons) to approximately 11,000 barrels (462,000 gallons) per event. The fresh water used for SB-4 well stimulation activities is typically transported by truck or pipeline to the well site. Proppant and chemical additives are also transported by truck to the well site. Stimulation fluids are mixed with the fresh water at the wellhead, as the mixture is being pumped downhole.

The fracturing fluid utilized is precisely and specifically designed for optimum performance in the specific geologic environment it will be injected. In nearly all instances the fluid is comprised mostly of water, with proppants and a small amount of chemicals added to serve multiple purposes. Chemical additives can include gelling agents, acids, surfactants, biocides, pH stabilizers, gel breakers, clay and iron inhibitors, as well as corrosion and scale inhibitors. Some substances, such as benzene, ethylene glycol, and naphthalene may be included in the additives described above (ALL Consulting 2012). A summary list of chemicals reported in hydraulic fracturing notices for the Project Area is included in Table 5-5 (notices uploaded to DOGGR after November 2013, as reviewed on 13 March 2014). A list of chemicals used in acid fracturing/acid matrix stimulation activities in the Project Area, as obtained from DOGGR, is presented in Table 5-6.

A small amount of the injected hydraulic fracturing fluid is recovered as “flowback” water within a few days of completing the stimulation activities (API 2010). Most of the injected fluid is initially trapped in the production formation and recovered over the long-term as produced water. In the Project Area, SB-4 stimulation notices indicate that flowback water is contained in closed systems (aboveground tanks) at the drill site. Following completion of the stimulation activities, flowback water is transported by truck to a field treatment system (e.g., Elk Hills or Lost Hills), or to a disposal site (e.g., Rose Field). Treated fluid can be re-used (e.g., for enhanced recovery operations in the Elk Hills Field) for other operational processes. Disposal typically occurs by pumping the fluid into Class II UIC wells.

5.1.2 Production

Produced water accounts for the largest volume of water and wastewater that is handled in oil field operations. As summarized in Table 4-5, oilfields in the Project Area generate on average eight to nine barrels of water for every barrel of oil produced. In 2013, 1,808 Mbbl of water (75,930 Mgal) were produced as part of oil production operations (DOGGR 2014). Analyses of produced water from oil fields in the Project Area, principally in the West Sub-area (Mitchell 1989) are summarized in Table 5-7. In general, produced water contains dissolved petroleum hydrocarbons, high TDS concentrations, and elevated metals and semi-metals. The TDS is enriched in sodium and chloride relative to other cations and anions, and relative to shallow groundwater (refer to Section 3). Sulfate concentrations are distinctly low in produced water samples. Elevated boron concentrations (well above the USEPA health advisory concentration of 1 mg/L) are also commonly reported. Produced water is typically transported to field tank batteries through pipes (see Figure 4-14), treated in aboveground tanks (see Figure 4-6), and re-used or disposed.

5.1.3 Enhanced Oil Recovery

Process water for enhanced recovery operations typically consists of treated produced water, with some field also relying on fresh water supplies. Cogeneration plants may use treated produced water or de-mineralized fresh water for evaporative cooling to increase power output when ambient temperatures are high, and untreated fresh water for steam condensation, pump seal flushing and other process uses requiring fresh water. Because treated produced water is used for the majority of enhanced recovery operations, comparatively little purchased fresh water is used in the production of oil and gas (Kern County PCDD 2013). The volume and composition of produced water used for enhanced oil recovery operations is summarized on Table 4-7 and in Section 5.1.2. In 2012, more than 80 percent of the treated produced water was re-used in oilfield operations for water-flooding and steam injection programs (Kern County PCDD 2013).

5.1.4 Wastewater Storage and Disposal

Excess produced water is either disposed or treated and provided to a third party for beneficial re-use (e.g., agricultural irrigation). Disposal practices include injecting produced water into deep subsurface reservoirs using Class II UIC wells, or discharging the water to land (e.g., percolation and evaporation ponds).

Wastewater injection wells are an integral part of California's oil and gas operations. In 2012, there were approximately 10,300 active injection wells operating in the Project Area. Injection wells are classified by the USEPA into six classes according to the type of fluid they inject and where the fluid is injected. Injection wells that are used to inject non-hazardous wastewater associated with oil and natural gas production operations (i.e., produced water) and brine, are designated “Class II” wells. In California, Class II injection wells are regulated by the DOGGR under provisions of the state Public Resources Code and the federal Safe Drinking Water Act. Class II injection wells fall under DOGGR’s UIC program, which is monitored and audited by the USEPA.

The USEPA Region 9 conducted a review and evaluation of the DOGGR UIC Program for compliance with the DOGGR Program Description and Memorandum of Agreement that were submitted in connection with the State of California application for primacy (the Primacy Application) that was approved by EPA in 1983. The review was conducted by Horsley Witten Group, Inc. (HW) under guidance from USEPA Region 9. In general, the USEPA found minor deficiencies in the UIC program and DOGGR prepared a response plan to address the deficiencies. However, the USEPA noted in the report that California regulations require protecting groundwater aquifers containing 3,000 mg/L or less of total dissolved solids, which is a departure from USEPA’s definition of 10,000 mg/L TDS.

Land application of the produced water is regulated under WDRs issued by the CVRWQCB. The CVRWQCB WDR program regulates point source discharges that are exempt under CCR Title 27 and not subject to the Federal Water Pollution Control Act. The discharger must apply to the CVRWQCB for a permit to dispose of the waste, or operate under a General Order if one exists. Discharges are required to submit annual reports summarizing the quality and quantity of water discharged during the preceding year. Land application of produced water requires that the water meet certain quality criteria prior to disposal, which may result in primary treatment of the water to reduce the TDS and/or remove dissolved chemicals. The disposal ponds must be maintained in good condition and operated in accordance with the monitoring program established in the WDR. The ponds may require periodic maintenance to restore their percolation capabilities by dredging out the pond bottoms and restoring the original grade of the ponds (Kern County PCDD 2013). For beneficial re-use the produced water must be treated to meet stringent quality criteria, required by the CVRWQCB as part of the WDR and by the third party receiving the water, to ensure the viability of the crop for which it will be used, including low total dissolved solids and/or metals concentrations.

5.2 Source Water and Produced Water Quality Summary

The following summarizes the general character and sources of different waters and wastewaters used or produced during oil and gas operations, and is a brief summary of the water quality information presented in Section 5.1.

5.2.1 Produced Water Composition

Groundwater contained in oil production zones exhibits some of the characteristics of seawater, including high TDS (often above 10,000 mg/L, and sometimes exceeding 30,000 mg/L) and enrichment in sodium and chloride relative to the concentrations of other major ions. This results in groundwater contained in the oil-bearing formation being geochemically distinct from

shallower groundwater. Oil-zone associated water also appears to be distinctly low in sulfate. In the event of significant mixing of the oil zone (produced) waters and more shallow groundwater as a consequence of oil and gas production operations, the qualitative differences in the composition of oil zone waters and shallow groundwater could allow identification of such an impact through shifts in major ion proportions. However, a comparison of select trace ion data – barium and boron – suggests that trace elements commonly reported for both shallow groundwater and oil-zone waters may not necessarily furnish a means for identifying occurrences when the two are mixed. As indicated on Figures 3-17 and 3-18, both barium and boron are generally present at higher concentrations in produced water and oil zone water samples than ambient shallow groundwater. However, the differences appear to scale with TDS, limiting the value of both trace elements as definitive fingerprint species.

Stable isotopic data pertaining to shallow groundwater and oil-zone produced water were not assessed as part of this study, as such constituents generally do not present regulatory or environmental concerns. However, stable isotope data (e.g., $^{18}O/^{16}O$, $^{2}H/^{1}H$) may be useful for identifying and quantifying mixing of oil-zone produced water with shallow groundwater as a consequence of oil and gas operations.

5.2.2 Well Drilling and Servicing Operations

Well drilling, development and recompletion activities generate used drilling fluid (i.e., drilling mud), consisting of water (typically potable water) mixed with active solids (e.g., clay), inert solids (e.g., barite) and other additives. The additives can be for fluid loss control, density control, and viscosifiers (see Table 5-2). Other waste fluids include cement returns, formation water (high-TDS water from the oil-producing formation), and petroleum products (oil and gas). As of December 4, 2013, drillers using open pit drilling methods must remove drilling fluids and cuttings once the drilling activities are complete. The waste fluids and cuttings must be managed (disposed, recycled, re-used) in accordance with applicable California regulations.

5.2.3 Well Stimulation Operations

SB-4 well stimulation operations (hydraulic fracturing, acid matrix stimulation, and acid fracturing) utilize fresh water mixed with proppants and chemicals additives including acids, surfactants, biocides, pH stabilizers, gel breakers, clay and iron inhibitors, corrosion and scale inhibitors (Table 5-5). Some hazardous substances, such as benzene, ethylene glycol, and naphthalene may also be included in the above additives in small amounts (ALL Consulting 2012). Some of the fluid injected into the formation returns to the well (as flowback water) after the fracturing procedure has been completed. Flowback also includes formation water (high-TDS water from the oil-producing formation), and petroleum products (oil and gas). Of the different SB-4 regulated well stimulation operations, hydraulic fracturing is by far the most common in the Project Area.

5.2.4 Produced Water Handling Operations

Produced water generated during oil and gas extraction accounts for the largest amount (see Figure 5-1) of fluid handled in oilfield operations. Produced water can be treated and reused for enhanced oil recovery operations (waterflooding, steam injection and cyclic steam operations),

treated and provided for beneficial re-use, or disposed (injected into Class II UIC wells or applied to land).

Section 6: Water Quality Regulations

This section describes various regulatory requirements related to water quality protection for oil and gas exploration activities in the Project Area.

6.1 Overview of Regulations and Related Oil Field Activities

Table 6-1 summarizes the various regulations that govern oil and gas exploration and production activities.

6.2 Federal Regulations

This following summarizes various Federal programs and requirements related to water quality protection from oil and gas exploration activities.

6.2.1 The Clean Water Act (CWA) (33 United States Code (U.S.C. §1321 et seq.))

The Clean Water Act regulates the discharge of pollutants into surface waters, and allows for the delegation of authority for implementation to the states. The Clean Water Act is regulated under 40 CFR Chapter 1 Subchapter D, and includes the following programs:

6.2.1.1 Spill Prevention (40 CFR Part 112)

The Spill Prevention Control and Countermeasures (SPCC) rule provides requirements for oil spill prevention, preparedness, and response to prevent oil discharges to navigable waters and adjoining shorelines. The rule requires specific facilities to prepare, amend, and implement SPCC Plans. Any facility capable of storing 1,320 gallons of oil, or more, must prepare an SPCC Plan. Facilities using underground tanks to store oil are exempt from this rule. Underground storage tanks are regulated by the State of California.

6.2.1.2 National Pollutant Discharge Elimination System Program (40 CFR Part 122 to 129)

As authorized by the Clean Water Act, the NPDES permit program regulates point sources that discharge pollutants into waters of the United States. Point sources are discrete conveyances such as pipes or man-made ditches. The State of California administers the NPDES permit program on behalf of the USEPA.

6.2.1.3 National Toxics Rule (40 CFR Part 131)

40 CFR Part 131 describes requirements and procedures for developing and approving water quality standards by States. National Toxics Rule published as Federal Register 57 FR 60848 sets numeric criteria for priority toxic pollutants for inland surface waters. Along with the California Toxics Rule (Section 5.3.4.5 below), it is intended to limit the discharge of “toxics” into

navigable waters. The regulation specifies water quality criteria for 128 priority pollutants based on their toxicity to aquatic species.

The USEPA promulgated the California Toxics Rule (CTR) supplementing the National Toxics Rule (NTR), to limit the discharge of "toxics" into navigable waters. The SWRCB adopted a policy implementing the CTR in 2000 (Resolution 2000-015 as amended by Resolution 2000-30). The CTR specifies water quality criteria for 128 priority pollutants based on their toxicity to aquatic species. These criteria, as presented in the USEPA Federal Register (EPA 2000), are generally lower than NPDES discharge limits based on Basin Plan criteria.

6.2.1.4 The National Oil and Hazardous Substance Pollution Contingency Plan (NCP) (40 CFR Part 300)

The NCP is the United States' blueprint for responding to oil spills and hazardous substance releases. It documents national response capability and is intended to promote overall coordination among the hierarchy of responders and contingency plans.

6.2.1.5 Oil and Gas Extraction Point Source Discharge (40 CFR 435)

This section addresses regulations related to discharges of point source effluents from oil and gas extraction. The water discharged from onshore activities into surface streams should meet the requirements found in 40 CFR 435.30 et seq. and 40 CFR 435.50 et seq.

6.2.1.5.1 40 CFR 435.30 et seq.

This section addresses discharges from the "onshore" subcategory of the oil and gas extraction industry that are located landward of the inner boundary of the territorial seas. Section 435.32 states "there shall be no discharge of waste water pollutants into navigable waters from any source associated with production, field exploration, drilling, well completion, or well treatment" to the west of the 98th meridian. Unless wastewater discharge to the surface waters is subject to other provisions contained in 40 CFR 435, discharge of wastewater directly to navigable waters is not allowed.

6.2.1.5.2 40 CFR 435.50 et seq.

This section addresses onshore facilities "located in the continental United States and west of the 98th meridian for which the produced water has a use in agriculture or wildlife propagation when discharged into navigable waters". The term "use in agricultural or wildlife propagation" is defined in 435.51 to include produced water of sufficient quality to be suitable for agricultural use. Discharge would be subject to the limitations specified in 40 CFR 435.52, namely:

(a) There shall be no discharge of waste pollutants into navigable waters from any source, other than produced water, associated with production, field exploration, drilling, well completion, or well treatment (i.e., drilling muds, drill cuttings, and produced sands).

(b) The produced water does not exceed a daily maximum limitation for oil and grease of 35 mg/L.

In summary, 40 CFR 435 would allow discharge of oilfield produced waters into surface waters in Kern County, if the water quality is in compliance with designated beneficial use requirements and if the oil and grease levels are below 35 mg/L. However, discharge of other oilfield wastes (e.g., drilling muds, drill cuttings, and produced sands) into surface waters is prohibited.

6.2.2 The Oil Pollution Act (33 U.S.C. 2701 et seq.)

The Oil Pollution Act (OPA) of 1990 prescribes a prevention, response, liability and compensation program for oil pollution from vessels, offshore facilities, pipelines, and onshore facilities. Spill contingency plans are required for each facility where an imminent threat of discharges exists. 40 CFR Part 112 requires the development and maintenance of SPCC Plans. All oil production sites storing more than 1,350 gallons are required to maintain a SPCC. In July of 1996, USEPA issued a Spill Prevention and Reporting Compliance Guidance Plan Document which integrated all the various related rules and regulations into one compliance program.

6.2.3 The Safe Drinking Water Act (42 U.S.C. §300f et seq.)

The Safe Drinking Water Act (SDWA) of 1974 regulates the amount of toxic substances allowed in sources of drinking water. The injection of wastes and wastewaters into the subsurface through the UIC Program is regulated under 40 CFR Chapter 1 Subchapter D, Parts 144 to 147 (Section 1424 of the SDWA). The USEPA has provided DOGGR with primary authority (primacy) to implement the UIC Program for Class II disposal wells in California (see below). Class II UIC wells are used for the injection of produced water and other fluids associated with oil and gas production either as a means of either disposal or as an enhanced recovery fluid. The Class II UIC program sets well construction and testing requirements, and regulates the types and composition of fluids that can be injected.

6.2.4 Resource Conservation and Recovery Act (42 U.S.C. §6921-6992k)

RCRA Subtitle C (promulgated in 1976) regulates the generation, storage, treatment, transportation, and disposal of hazardous wastes. RCRA requires the issuance of a permit before hazardous waste may be treated, stored or disposed on a site. Most waste streams from exploration and production operations (such as produced water and drilling fluids) are exempt from RCRA Subtitle C; however, the generator is ultimately responsible for making that decision, in accordance with the regulations.

6.2.5 The Solid Waste Disposal Act (42 U.S.C. §6901 et seq.)

The Solid Waste Disposal Act establishes restrictions on the disposal of solid waste. Hazardous waste characterization of solid wastes, and disposal procedures and methods are regulated under 40 CFR Part 261 et seq. This section provides a definition of solid hazardous wastes and protocols to characterize hazardous wastes. Section 6.3.4 of this report provides additional details for disposal of hazardous wastes in California.

6.2.6 Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA) (42 U.S.C. §9601-9662)

CERCLA addresses the release of hazardous substances and associated remediation. Petroleum is expressly excluded from the definition of hazardous substances under CERCLA. However, wastes containing individual constituents can be designated as a hazardous waste, if certain conditions and concentrations are met.

CERCLA regulations also include reporting requirements for releases of hazardous substances or wastes to the environment. USEPA regulates CERCA under 40 CFR Chapter 1 Subchapter J.

6.2.7 US Army Corps of Engineers 33 CFR 320

The Corps of Engineers is not normally involved in oil and gas exploration projects unless there is direct U.S. Government funding for the construction of a dam, or the project will result in the physical alteration of a navigable waterway. The Corps of Engineers generally relies on the California Department of Dams Safety to oversee construction of dam projects that do not involve federal funding.

6.2.8 National Environmental Policy Act (NEPA)

NEPA (42 U.S.C, Chapter 55, Section 4321) established in 1970, provides the national policy promoting the enhancement of the environment and also established the President's Council on Environmental Quality. The law is applicable to any federal, state, or local project that involves federal funding, work performed by the federal government, or permits issued by a federal agency. The act establishes a multidisciplinary approach to considering environmental effects in federal government agency decision making. The NEPA process consists of evaluating relevant environmental effects of a project or action, including a series of pertinent alternatives. Once a determination of whether or not the proposed action is covered under NEPA is made, there are three levels of analysis that can be undertaken to comply with the law: determination of whether a Categorical Exclusion applies (40 CFR Section 1508.4), preparation of an Environmental Assessment and Finding of No Significant Impact (40 CFR Section 1508.9); or preparation of an Environmental Impact Statement (EIS). The NEPA process could impact exploration and production operations conducted on Federal lands.

6.2.9 Emergency Planning and Community Right to Know (EPCRA)

The Emergency Planning and Community Right-to-Know Act (EPCRA) was passed by Congress in 1986 in response to concerns regarding the environmental and safety hazards posed by the storage and handling of toxic chemicals. The regulations impose requirements for federal, state and local governments, tribes, and industry to provide information about the storage of hazardous chemicals at a facility. These requirements include emergency planning and "Community Right-to-Know" reporting. States and local governments can use the information provided by facilities to improve chemical safety and protect public health and the environment.

Sections 301 to 303 require local governments to prepare chemical emergency response plans, and to review plans at least annually. State governments are required to oversee and coordinate local planning efforts. Facilities that maintain Extremely Hazardous Substances (EHS) on-site in quantities greater than corresponding threshold planning quantities must cooperate in emergency plan preparation.

Section 304 requires facilities to immediately report accidental releases of chemicals and "hazardous substances" in quantities greater than corresponding Reportable Quantities (RQs) defined under the CERCLA to state and local officials. Information about accidental chemical releases must be available to the public.

Sections 311 and 312 require manufacturing, processing, or storage facilities to retain Safety Data Sheets (SDSs) for all hazardous chemicals used / stored on-site. These facilities must also report inventories of on-site hazardous. Information about chemical inventories at facilities and SDSs must be available to the public.

Section 313 requires that facilities storing and/or handling one or more of the chemicals listed on the Toxics Release Inventory list above the applicable threshold quantities submit a toxic chemical release inventory form (Form R) annually.

Section 322 allows facilities to withhold the specific chemical information from the reports filed under sections 303, 311, 312 and 313, if the facility submits a claim with substantiation to EPA.

6.3 State of California Regulations

6.3.1 California Environmental Quality Act (14 CCR Division 2, Chapters 2)

CEQA (California Code of Regulation (CCR), Title 14, Division 2, Chapter 2 (California Public Resources Code §15000 et seq. and §21000 et seq.)) codifies a statewide policy of environmental protection. CEQA requires state and local agencies within California to assess and publically disclose potential environmental impacts from proposed projects and set procedures to mitigate those impacts. CEQA makes environmental protection a mandatory part of every California state and local agency's decision making process. Specifically, for any project under CEQA's jurisdiction, the lead agency must analyze impacts to 18 different environmental resource factors, including “Hydrology and Water Quality”, and for any identified potential significant environmental impacts, must develop mitigation measures or alternatives to reduce or avoid significant impacts if feasible, or make certain findings if mitigation measures or alternatives are not feasible. The analysis and associated mitigation measures are presented in an EIR, or a “Negative Declaration” or “Mitigated Negative Declaration”, and subject to public review and comment.

6.3.2 Oil and Gas Resource Regulations (14 CCR Division 2, Chapter 4)

DOGGR oversees the drilling, operation, maintenance, plugging and abandonment of oil, natural gas and geothermal wells throughout California. CCR, Title 14, Division 2, Chapter 4 (Development, Regulation and Conservation of Oil and Gas Resources) outlines many of the

regulations overseen by DOGGR. In general, these regulations are a guideline for operations to be conducted in accordance with good oil field practices and include:

- Approval of well operations and permits to drill,
- Guidelines for notices of intention to drill, deepen, re-drill, rework, or plug and abandon wells,
- Developing spill contingency plans pursuant to AB-1960 or United States Environmental Protection Agency (USEPA) regulations, and
- Submission of blowout prevention and control plans for certain critical or high pressure wells.

Further, these regulations are supplemented or superseded by “Field Rules”. If Field Rules are established, oil and gas operations shall be performed in accordance with those rules, and overseen by a Field Supervisor.

6.3.2.1 Section 1722 - Field Rules on Oilfield Spills

In August 1998, pursuant to CCR Title 14, Division 2, Chapter 4, Section 1722 (k), DOGGR in conjunction with the SWRCB and the California Department of Fish and Wildlife (CDFW) developed Field Rules that establish volumetric thresholds for reporting discharges of oil to land. The purpose of the Field Rules is to establish reasonable crude oil spill reporting criteria while protecting public health, safety, and the environment. This “Field Rule” (Oil Spill Reporting Criteria) is applicable to Kern County within existing oil and gas fields, as defined by DOGGR. In general, a spill greater than one barrel in volume, occurring on any site without containment, in urban areas, into waters of the United States; or that threatens waters of the United States; or that threatens wildlife or habitat must be reported. However, in areas where a major portion of the oil is highly viscous, with flat terrain and minimal potential impacts to navigable water, habitat or wildlife, operators must report:

1. Spills of five barrels, or more, of crude oil unless the spill occurs within a contained area and is less than ten barrels.
2. Spills of ten barrels or more that occurs within a containment area. (Containment refers to a specific system of dikes or fire walls capable of containing the volume of the largest tank to direct fluids to a preferred collection point.)

Subchapter 1 of Chapter 4, including AB 1960 Amendments, provides requirements related to construction and operation of onshore wells, including the selection of drilling fluids, plugging methods to protect fresh water sources; monitoring and testing requirements during well stimulation treatments; and well closure procedures. This subchapter provides standards for minimizing environmental impacts from potential accidental releases, including guidelines for managing oilfield sumps and open channels, leak detection and testing of aboveground storage tanks, secondary containment around tanks and containment structures, and preparing spill contingency plans.

6.3.2.2 Underground Injection Control Program

The injection of wastes and wastewaters into the subsurface through the UIC Program is regulated under 40 CFR Chapter 1 Subchapter D, Parts 144 to 147 (Section 1424 of the SDWA). In 1981, the USEPA provided DOGGR with primary authority (primacy) to implement the UIC Program for Class II disposal wells in California. In 1983, DOGGR under authority from USEPA, established portions of the groundwater basin as exempt from drinking water standards. The "aquifer exemptions" are based on naturally-occurring elevated concentrations of TDS, and/or the presence of oil in the formation. Since 1983, DOGGR has approved one additional exemption in the project area for the Asphalto oil field. Exempted aquifers are illustrated on Figure 3-8.

Class II UIC wells are used for the injection of produced water and other fluids associated with oil and gas production either as a means of disposal or as an enhanced recovery fluid (e.g., waterflooding, steam flooding, cyclic steaming). The Class II UIC program sets well construction and testing requirements, and regulates the types and composition of fluids that can be injected. It also sets the requirements for permitting and managing waste disposal.

Injection zones are porous and permeable enough to accept injected fluids. The selected zone must be covered by an impermeable formation, like shale, that act as cap rocks, confining injected fluids in the porous beds. The water quality in the injection zone must be designated not suitable for domestic or municipal use; or the aquifer determined not suitable for development as a water supply source.

Injection wells are monitored by DOGGR engineers to ensure the wells are operated properly and have mechanical integrity. Monitoring includes reviewing operational data and running tests like Mechanical Integrity Tests (i.e., spinner, temperature, and pressure tests and tracer surveys).

6.3.2.3 Facility Maintenance Standards (California Assembly Bill 1960)

In 2009, AB 1960 introduced some changes to the regulations (14 CCR, Chapter 4) related to drilling and abandonment of wells, and operation of production facilities. AB 1960 requires DOGGR to prescribe minimum facility maintenance standards for production facilities, including leak detection, corrosion prevention and testing, tank inspection and cleaning, valve and gauge maintenance, and secondary containment maintenance. AB 1960 requires facility operators to:

- notify the supervisor of the construction, alteration, or decommission of a production facility;
- maintain at the production facility's local office all specified production records; and
- provide access to, and copies of, these records to the supervisor.

The regulations also require DOGGR to inspect a production facility to ensure compliance with the standards and issue a cease and desist order to any production facility operating in violation of the prescribed standards.

6.3.3 Well Stimulation Treatments (California Senate Bill No. 4, Chapter 313)

On September 20, 2013, Governor Brown signed into law SB 4, widely considered one of the most comprehensive regulations in the nation governing well stimulation operations. SB 4 requires the DOGGR to consult with the DTSC, California Air Resources Board, SWRCB and various other state and local agencies as it develops its regulations. Formal agreements between the agencies apportioning authority, responsibility and other matters between the agencies are to be entered into by January 1, 2015.

The Bill requires an operator to apply for a permit with the Field Supervisor at least 10 days prior to performing a regulated well stimulation treatment and to record and include all data on acid treatments and hydraulic fracturing treatments, as specified. Also required is disclosure of the composition and disposition of well stimulation fluids, including, but not limited to, hydraulic fracturing fluids and acid stimulation treatment fluids (Section 2, Article 3, 3160). This Bill also requires DOGGR to prepare an EIR to analyze the impacts of well stimulation treatments and adopt rules and regulations specific to well stimulation, including oversight of well construction and full disclosure of the composition and disposition of well stimulation fluids, and authorize the division to allow well stimulation treatments if specific conditions are met (Section 2, Article 3, 3161).

SB 4 requires the SWRCB to develop groundwater monitoring model criteria establishing how to conduct appropriate background groundwater monitoring in the vicinity of individual oil and gas wells subject to a well stimulation treatment. The purpose of the background monitoring program is to establish means and methods for determining impacts to potable water resources, thereby establishing a program for protecting waters designated for beneficial uses. There is a further requirement to report the amount of treatment-generated waste material and identified disposal methods.

SB-4 requires that by January 1, 2015, an independent scientific study be completed on well stimulation treatments, including, but not limited to, hydraulic fracturing and acid well stimulation. The scientific study shall evaluate the potential hazards and risks that well stimulation treatments pose to natural resources and public, occupational, and environmental health and safety. Also, on or before January 1, 2015, the DOGGR is required to enter into formal agreements with the DTSC, the AQMD, the SWRCB, the CVRWQCB, and the Department of Resources Recycling and Recovery to delineate respective authority, responsibility, and notification and reporting requirements associated with well stimulation treatments and related activities.

6.3.4 Hazardous Waste Control Law (22 CCR subsections 66261)

Administered by Department of Toxic Substances Control (DTSC), the regulation sets requirements for generators of hazardous waste.

- Generators must determine if their waste streams are hazardous by characteristic or listing under the program.
- Generators must obtain identification numbers from DTSC for California-only hazardous wastes and from USEPA for RCRA hazardous wastes.

- Generators must follow specific requirements for storing, handling and treating hazardous wastes. The generator is responsible for: (1) determining that a transporter is licensed; (2) that the receiving facility is properly permitted; and (3) the shipping manifest is properly prepared.

Disposal of any hazardous wastes from oil field operations or other activities must be in compliance with DTSC requirements. The DTSC requires that for a waste to be considered non-hazardous, it must be in compliance with 40 CFR 261 and must be in compliance with acute toxicity test (22 CCR subsections 66261.24[a]) criteria:

- the acute oral LD_{50} (the dose causing 50 percent mortality) must be greater than 2,500 milligrams per kilogram (mg/kg)
- the acute dermal LD_{50} must be greater than 4,300 mg/kg
- the acute inhalation LC_{50} must be greater than 10,000 parts per million as gas or vapor
- the acute aquatic 96-hour LC_{50} (lethal concentration causing 50 percent mortality) is greater than 500 mg/L when measured in soft water (total hardness 40 to 48 mg/L of calcium carbonate) with fathead minnows (Pimephales promelas), rainbow trout (Salmo gairdneri) or golden shiners (Notemigonus crysoleucas).

If a waste is found to be hazardous based on the above tests, the end user can submit an application to a local Certified Unifier Program Agency (CUPA) to allow on-site treatment of the waste. The CUPA may provide a conditional authorization for neutralization on a case by case basis. Otherwise, the waste must be disposed off-site at a hazardous waste facility permitted to accept the subject waste.

6.3.5 Porter-Cologne Water Quality Control Act (California Water Code [CWC] Sections 13020 et seq.)

Similar to the Safe Drinking Water Act, the Porter-Cologne Act is the primary statute governing water quality and water protection in California. The authority for the State to regulate wastewater discharges comes from the Porter-Cologne Water Quality Control Act. It established the SWRCB and nine RWQCBs, including the CVRWQCB. The CVRWQCB is the principal regulatory agency responsible for overseeing the discharge of any water that could impact water resources in Kern County. The Porter-Cologne Act gives the SWRCB and the RWQCBs the authority and responsibility to adopt plans and policies, to regulate discharges to surface and groundwater, to regulate waste disposal sites, and to require cleanups of hazardous materials or pollutants.

6.3.5.1 Basin Plans and Beneficial Uses (CWC Section 13240)

The CVRWQCB is responsible for implementing the California Water Code, and has adopted a Water Quality Control Plan for the Tulare Lake Basin (CA RWQCB, 2004). As described in Section 3.4, the “Basin Plan” identifies the beneficial uses of the various existing water resources in the region, including surface and ground water and sets narrative and numerical water quality objectives for designated uses. The beneficial use designations for the water

bodies in Kern County include Municipal and Domestic Water Supply (MUN), Agricultural Water Supply (AGR), Industrial Water Supply (IND), and others.

The Implementation Plan section of the Basin Plan addresses Oil Field Wastewater and presents oil-water separation and use of sumps for controlling discharges. In addition, the Basin Plan defines narrative and numeric criteria for groundwater recharge and agricultural use when the water is not delivered to a surface water body. The CVRWQCB may require that oilfield produced water be treated to meet the applicable narrative and specific numerical water quality objectives identified in the Basin Plan prior to discharge.

Under certain circumstances, the CVRWQCB may provide an exception to the beneficial use designation by applying the criteria in SWRCB Resolution No. 88-63, “Sources of Drinking Water Policy.” The criteria governing those exceptions are:

- "The total dissolved solids (TDS) exceed 3,000 mg/L (5,000 [micromhos per centimeter,] umhos/cm, electrical conductivity) and it is not reasonably expected by the Regional Water Board [for the ground water] to supply a public water system, or

- There is contamination, either by natural processes or by human activity (unrelated to a specific pollution incident), that cannot reasonably be treated for domestic use using either Best Management Practices or best economically achievable treatment practices, or

- The water source does not provide sufficient water to supply a single well capable of producing an average, sustained yield of 200 gallons per day, or

- The aquifer is regulated as a geothermal energy producing source or has been exempted administratively pursuant to 40 CFR, Section 146.4 for the purpose of underground injection of fluids associated with the production of hydrocarbon or geothermal energy, provided that these fluids do not constitute a hazardous waste under 40 CFR Section 261.3."

Per the above exceptions, CRWQCB Basin Plan rules will not be applicable to injection of oil and gas field wastes in oil and gas fields as long as these wastes are not hazardous and are being injected into an exempt aquifer.

6.3.5.2 Anti-degradation Policy (23 CCR 2900 – Resolution 68-16)

The SWRCB adopted an anti-degradation Policy in the late 1960s to maintain the quality of existing water resources. Under this policy (Resolution 68-16), discharges must not cause a degradation of the existing quality of the receiving water unless it has been demonstrated that the change will be consistent with maximum benefit to the people of California, that it will not unreasonably affect the present and anticipated beneficial use of such water, and that it is consistent with other parts of the California Water Code. In addition, the discharger must demonstrate that Best Practicable Treatment or Control (BPTC) will be implemented. The anti-degradation analysis is generally provided by the discharger to CVRWQCB staff before a discharge is authorized.

6.3.5.3 Surface Water Disposal (CWC Section 13260 to 13275)

California regulations for wastewater discharge to surface water are based on the federal Clean Water Act. The USEPA has delegated authority to implement the Clean Water Act and issue discharge permits to the SWRCB and RWQCBs. Authorization from the CVRWQCB is required for any discharge that may have an impact on the region's surface water resources. Authorization is in the form of a NPDES permit or, for discharges not subject to federal NPDES permitting, state Waste Discharge Requirements (WDRs). This permit sets water quality standards for discharges to surface water bodies (navigable waters).

6.3.5.4 Land Disposal (CWC Section 13260 to 13275)

The CVRWQCB issues WDRs to govern non-hazardous waste discharges to the ground surface where no surface water bodies will be directly impacted, or where groundwater will be impacted. The terms in the WDRs are established to protect the beneficial uses of underlying groundwater and implement other requirements of the Basin Plan. Title 22 CCR 66261 establishes the criteria to determine whether a waste is classified as hazardous or non-hazardous. For discharges to land, non-hazardous wastes are further evaluated to determine whether the waste has concentrations of constituents that are higher than the water quality objectives for underlying groundwater or could impact beneficial uses. Based on this evaluation, wastes may be termed "Designated waste" and regulated under Title 27 CCR. Title 27 wastes have additional restrictions regarding siting of discharge locations, construction standards for storage impoundments, monitoring, and other management factors.

The CVRWQCB requires a WDR for beneficial re-use of the produced water when delivered as a beneficial re-use to a qualified end user. The treated water must meet the following water quality criteria:

- Crop water quality requirements
- Water quality requirements of the CVRWQCB Basin Plan

Different requirements exist for waters delivered through an established surface water body or through a fixed delivery system (e.g., piping).

In 1982, the CVRWQCB waived requirements for numerous broad categories of discharges, including the discharge of all types of drilling muds and boring wastes (drilling wastes). In 1999, those waivers became subject to an automatic 5-year termination schedule, which would apply unless the waiver was periodically renewed. In 2003, and again in 2008, the CVRWQCB renewed the drilling waste waiver. In December 2013, the Board passed Resolution R5-2013-0145, approving a waiver of Reports of Waste Discharge (RWDs) and Waste Discharge Requirements (WDRs) for specific types of discharge within the Central Valley Region. The Board reviewed the conditions for the "drilling muds/boring wastes waiver" category (Waiver Category No. 2 included in R5-2008-0182), which applied to wastes generated from both fresh water supply well and oil and gas well drilling. The Board considered potential impacts to water quality based on numerous factors and determined that Waiver Category No. 2 should be renewed only for fresh water supply well wastes; stating that discharge of drilling muds/boring wastes from oil and gas operations will be considered in a separate action. Concequently, drilling wastes associated with oil and gas exploration must be removed from open sumps upon

completion of the drilling activities and managed according to existing handling and disposal regulations.

6.3.6 Surface Impoundments

Due to potential differences in supply and demand for produced water, surface impoundments may be needed to store produced water generated during non-peak demand periods.

6.3.6.1 Siting (27 CCR, Section 20240)

This section provides siting criteria for surface impoundments containing solid or liquid wastes. An exemption from this requirement is available if the waste meets the criteria for an "inert waste" as defined by 15 CCR §2524. An "inert waste" is a subset of waste that does not contain hazardous substances or soluble pollutants at concentrations in excess of applicable water quality objectives and does not contain significant quantities of decomposable waste.

6.3.6.2 Dam Safety (23 CCR, Division 2, Chapter 1)

The Division of Safety of Dams (DSD) would be involved with any project that creates a structure to impound water in a navigable waterway as defined by EPA if the structure is greater than 25 feet high or the impoundment contains more than 50 acre-feet of water. In this role, the DSD would ensure that the structural integrity of any jurisdictional dam (storage structure) is adequate for its intended purpose.

6.3.6.3 Wildlife Protection

Any structure that diverts, obstructs or changes the bed, channel or bank of a waterway would require a streambed alteration permit from the California Department of Fish and Wildlife (CDFW). In addition, CDFW is responsible for ensuring sufficient water flow downstream of any water diversion point at all times in order to protect fish and wildlife resources. (Section 5937, Article 2, Chapter 3, Part 1, Division 6 of the California Fish and Game Code). Approval from the CDFW may be required to obtain water appropriation by an end user.

6.3.7 Storm Water Discharge Regulations

Non-construction-related storm water discharges from oil and gas fields in Kern County are regulated by CVRWQCB. Mostly, these releases are regulated through a the state general industrial storm water permit. Facilities exempted from coverage by the general permit include:

i. those whose storm water discharges are covered by other individual, industry-specific or general NPDES permits,

ii. facilities that a RWQCB believes will potentially impact water quality that may not be appropriately addressed by the General Permit and require an individual permit,

iii. facilities that do not discharge storm water into surface waters (e.g., those facilities that discharge storm water into sanitary sewers), and

iv. discharges from oil and gas facilities composed entirely of flows that are from conveyances or systems of conveyances used for collecting and conveying precipitation runoff and do not come into contact with any overburden, raw materials, intermediate products, finished products, by-products, or waste products located at the facility.

Broadly, the state's General Permit prohibits discharges of material other than storm water (non-storm water discharges) that are not authorized by the General Permit and discharges containing hazardous substances in storm water in excess of reportable quantities established under 40 CFR 117.3 and 40 CFR 302.4. NPDES Permits for storm water discharges must meet all applicable provisions of Sections 301 and 402 of the CWA. These provisions require control of pollutant discharges using best available technology (BAT) that is economically achievable for toxics and non-conventional pollutants, the BACT to prevent and reduce pollutants; as well as any more stringent controls necessary to meet water quality standards. Further, storm water discharges shall not cause or contribute to a violation of an applicable water quality standard of the receiving stream. As part of general permit compliance, all facility operators must prepare, retain on site, and implement a Storm Water Pollution Prevention Plan (SWPPP).

The general permit provides additional details for notification and monitoring requirements, records retention and the operator's compliance responsibilities.

6.3.8 Oil Spills

In June 2014, California passed Senate Bill 861 (SB 861), requiring the Department of Fish and Wildlife Office of Spill Prevention and Response to develop emergency response programs throughout the State to respond to oil spills that could potentially impact the waters of the state. This bill expands the California oil spill contingency plan and the administrator's responsibilities relating to oil spills to cover all waters of the state (inland and coastal). The bill imposes a state-mandated local response program and requires that the California oil spill contingency plan provide for the best achievable protection of all state waters, not solely coastal and marine waters. The bill requires the regulations provide for the best achievable protection of all waters and natural resources of the state. The additional emergency response actions, which a required to be adopted by January 1, 2017, will include activities associated with exploration, transportation (via rail, pipeline, truck, etc.), refining and storage of petroleum products.

6.4 Kern County Regulations

The Kern County Public Health Services Department, Environmental Health Services Department is the CUPA for Kern County. The CUPA administers six specific state hazardous materials programs under one agency. The CUPA for the County of Kern is the Environmental Health Services Department; whereas, the CUPA for the city of Bakersfield is the Bakersfield Fire Department. Under CUPA, site inspections of the six hazardous materials programs (above ground storage tanks, underground storage tanks, hazardous waste treatment, hazardous waste generators, hazardous materials management and response plans, and the California

Fire Code) are consolidated and accomplished by a single entity. The CUPAs also provide emergency response to hazardous materials release events.

6.4.1 Aboveground Petroleum Storage Act (APSA)

The APSA requires development of an SPCC and reporting of any spill or leak in excess of one barrel. The CUPAs are responsible to implement the APSA. Spill reporting is made to the appropriate CUPA, depending on the location of the spill. However, oilfield tanks are exempt from the ASPA since they are regulated by DOGGR, under AB-1960. Each oilfield has a spill response plan to address the issues covered under ASPA.

6.4.2 California Accidental Release Program (CalARP) (19 CCR Ch. 4.5, Section 2735.5)

CalARP is designed to minimize the risk of extremely hazardous substances that potentially cause immediate harm to the public and the environment. CalARP requires owners/operators of businesses handling one or more regulated substance over the State and/or Federal threshold to evaluate and determine potential impacts of an accidental release. Facilities must submit a Risk Management Plan (RMP) to the CUPA. The RMP identifies the potential accidental factors; and preventative measures and safeguards are incorporated into facility operations.

6.4.3 Groundwater Production and Monitoring Wells (County Ordinance Code, Chapter 14.08)

Kern County requires permits to install water monitoring and groundwater production wells. Prior to approving the installation of a new well or using an existing well as a monitoring well, the County will conduct an inspection of the well site to verify that the well meets the specified requirements.

Section 7: Water Quality Impacts Assessment

This section provides an assessment of the potential impacts to local surface and ground water quality resulting from current and future oil and gas operations in the Project Area. The assessment for potential impacts is based on the release mechanism, migration pathways, and the differences in water quality between the released fluid and the receiving water body. The assessments in this section are intended to describe the types of potential impacts and their possible magnitude and likelihood as a technical matter, but does not utilize CEQA thresholds of significance or reach CEQA significance conclusions. This will be determined by Kern County as lead agency based on the technical analyses.

7.1 Water Quality Impacts from Oil and Gas Operations

The following presents potential impacts from oil and gas operations to water quality (surface water and groundwater) resources, including:

- Fresh water - surface water and groundwater that is designated to have a beneficial use and contain less than 3,000 mg/kg TDS.

- Non-fresh water – surface and groundwater bodies containing greater than 3,000 mg/kg TDS, and administratively exempt aquifers, and aquifers that would require significant advanced treatment technologies to meet drinking water quality standards.

Potential impacts to surface water or groundwater quality can result from the various operations involving the handling of fluids at the drill site, as well as oil and wastewater (e.g., flowback, produced water) that are generated from the oil- and gas-producing wells. The water process flow diagram (Figure 5-2), summarizes the major process steps where there is a potential for impact on water quality. The assessment includes potential impacts to surface soil (residual contaminants adsorbed to soil can impact local surface water quality through erosion and run-off, as well as shallow groundwater through infiltration); surface water (direct impact from surface releases), shallow groundwater (through infiltration and direct contact from downhole releases), and deep (below the Corcoran Clay and/or below the fresh water interface) groundwater (direct contact from downhole releases).

Release mechanisms, magnitude, type of release, potential impacts and regulatory controls and best management practices associated with each production operation (process) are summarized in Table 7-1. Additionally, the tables include a “Description of Potential Impact” to characterize the water quality change that may be observed in the event of the release (e.g., elevated concentrations of certain constituents). The listed potential magnitude of any release scenario is a qualitative assessment that is relative to the operation and the potential volume of fluid handled or stored, and is qualitatively evaluated as either small, medium or large. Absolute, quantitative impact assessments are (1) highly site- and activity-specific, and (2) dependent on the scale of oil and gas operations in the future. Consequently, quantitative impact predictions from potential release events were not undertaken.

The intent of the Table 7-1 is to provide a comprehensive list of the possible impacts to surface water and groundwater quality that could result from intentional or unintentional, direct or

indirect, release of fluids that is used or produced by the oil and gas industry in the Project Area. The list of impacts in Table 7-1 presents the reasonably foreseeable potential impacts, although it may not capture every possible impact or every impact from unforeseen circumstances. The evaluation of impacts does not include potential impacts to groundwater quality or purchased water quality over time from long-term acquisition (i.e., surface or groundwater withdrawal for water supply to oil and gas operations) because the volume of fresh water acquired for oil and gas exploration represents only a few percent of the total volume of fresh water used in in the Project Area. Impacts directly related to disposal to land surface or UIC wells are not addressed because these operations is controlled under regulated programs designed to protect groundwater quality.

7.1.1 Potential Impacts from Well Installation

Potential impacts from well installation activities are related to accidental releases during mixing and handling operations, as well as fluid loss during drilling. Chemicals used to create drilling muds can be accidentally released to the surface in dry or liquid form and impact surficial soils. In 2012, well construction operations used between 500 barrels and 1,900 barrels of water (21,000 to 80,000 gallons) on average, which represents a small amount of water when compared to other oilfield activities.

Releases to the surface during drilling activities are likely to occur due to failures in piping, joints or valves, and response to these releases is expected to be quick since the rigs are staffed 24 hours per day and workers are trained in spill response; thereby limiting the volume of fluid lost to the environment to a small quantity. Impact to shallow groundwater, through infiltration, is expected to be minimal because drilling fluids tend to be self-sealing and do not infiltrate far into the formation.

Drilling muds can be lost to the formation when an unexpected highly permeable formation, or fracture, is encountered, resulting in a very localized impact to water contained in the formation. Loss of these fluids is detrimental to the drilling operations; consequently, drilling operators continuously monitor mud volumes and pressures to quickly identify these occurrences and minimize their duration and impact. Additionally, drilling muds, associated chemicals, and fluids from the production zone (oil and produced water) could seep into water bearing formations if the casing seals are improperly set or fail.

7.1.2 Potential Impacts from Well Servicing

Potential impacts from well servicing are similar to those presented for well installation, but with even less impact. Impacts from oil and oily water could occur during removal of well pumps and blow-out equipment. A release of fluids stored in aboveground tanks (during use or associated with treatment prior to disposal) could impact surface soils, nearby surface water bodies and shallow groundwater (through infiltration), and would likely trigger an incident response. In 2012, well rework operations used between 140 barrels and 470 barrels of water (5,900 to 19,800 gallons) on average, which represents a small amount of water when compared to other oilfield activities. Response to surface releases is expected to be quick since crews are on-site at all times while wells are being serviced; thereby limiting the volume of fluid potentially lost to the environment to a small quantity. Impact to shallow groundwater, through infiltration, is expected to be minimal.

7.1.3 Potential Impacts from Well Stimulation

Impacts from SB-4 regulated well stimulation operations include accidental surface releases during chemical mixing or fluid storage (pre- or post-fracturing operations); surface releases related to the sudden failure of a tank, valve, or hose; and subsurface releases during well pressurization. In 2012, SB-4 related well stimulation operations used between 1,900 barrels and 16,200 barrels (80,000 gallons to 680,000 gallons) of water per hydraulic fracturing event, which represents a small amount of water when compared to other oilfield activities.

Responses to incidental surface releases are expected to be quick, resulting in limited volumes of fluids being lost to the environment Sudden releases due to equipment failure (e.g., tank rupture, piping or valve blow-out during pressurization) could be significant and result in impacts to surface soils, nearby surface water bodies, and shallow groundwater (through infiltration). Releases to the surface can also occur during disposal operations, due to equipment failure, with the same results.

Subsurface releases can occur either through the geologic formation, or as a result of well failure. Propagation of fractures beyond the intended lateral (in the case of vertical well fracturing) or vertical (in the case of horizontal well fracturing) limits can result in movement of the fracturing fluids outside the intended geologic formation, and could result in the migration of fluids along a bedding plane or fault to a separate hydrocarbon or water-bearing zone. The likelihood of this type of release is low and the impact is anticipated to be insignificant, due to dilution of the fracturing fluid as it migrates. SB-4 requires that fracture propagation be modeled prior to each project and compared to know geologic features (bedding planes, formation boundaries, faults, etc.) to assess the potential for impact. The assessment is submitted to the DOGGR as part of the permit application. SB-4 also requires that fracture propagation be monitored on every fracturing project to assess the impact relative to the permitted criteria. Additionally, during hydraulic fracturing, fluid and casing annulus pressures are closely monitored and the project is immediately terminated if a sudden decrease in fluid pressure is observed; or if casing annulus pressures exceed certain set points. Therefore, the volume of fluids lost to an uncontrolled subsurface release is expected to be minimal.

A release that results from a well casing rupture would be more significant, depending on the volume of material released and where the casing fails. If the intermediate casing fails, high pressure fluids can be forced up the wellbore and out into the deep groundwater aquifer. This could result in a potentially significant impact to groundwater quality in the immediate vicinity of the well. Again, the volume of fluid being release is expected to be minimal as hydraulic fracturing operations include closely monitoring fluid pressures and terminating operations when a change in pressure, outside the monitoring criteria is observed. Chemicals contained in the hydraulic fracturing fluids (Tables 5-4 and 5-5) could migrate away from the well depending on the volume of materials released, and over the course of several years, nearby surface waters or groundwater wells. Constituents typically contained in hydraulic fracturing fluids include small volumes of acids, biocides, corrosion inhibitors, gels and viscoifiers, scale inhibitors, surfactants and pH adjusting agents. The acids, biocides and gels are typically common chemicals used in water wells and are expected to degrade or attenuate over a short period of time. The surfactants and pH adjustment compounds are common household chemicals and not expected to represent a risk to shallow or deep groundwater aquifers. The corrosion and scale inhibitors, which are common in municipal water well treatment programs, are expected to break down slowly and could impact groundwater for an extended period of time. However, most of the

compounds used in hydraulic fracturing are added to the well in a very dilute concentration. Considering the amount of mixing that would occur if these compounds were released to groundwater, their resulting concentrations are expected to be very low.

7.1.4 Potential Impacts from Handling Produced Water

Impacts from the capture of production fluids and any subsequent treatment, re-use and disposal of produced water include small to very large releases related to equipment failure (e.g., tank, valve, or piping); incidental discharge to the surface or nearby water body; and subsurface releases related to discharge of fluids to land or injection into disposal wells. In 2012, approximately 238,000 acre-feet of produced water was generated within the project area, as a result of oil and gas production activities. Produced water represents approximately 96% of all of the water handled as part of oilfield operations.

Accidental releases of oil, oily water, or produced water within the oilfield operations areas are expected to be small/minor and not result in a significant impact. Most small to medium releases are expected to be contained inside secondary containment areas (AB-1960 requires secondary containment for tanks and some piping, and surface control features for piping that is not secondarily contained) and not have a significant impact to surface water or groundwater quality. Incident response actions will likely include capture and treatment of the spilled fluid as well as remediation of impacted soils. A sudden release from a pipeline could impact a nearby surface water body and/or shallow groundwater (through infiltration), resulting in an incident response, remediation and monitoring.

Releases to the surface may occur during disposal, if operations include land application. Disposal to land is controlled by WDRs that protect surface water and groundwater quality.

Impacts to groundwater can also occur as a result of well failure during the injection/disposal of the produced water. The impact could be minor to significant, depending on the volume of material released and which well casing fails. High pressure fluids can be forced up the well annulus, outside the casing and out into the deep groundwater aquifer. This could result in a significant impact to groundwater quality in the immediate vicinity of the well if the native groundwater is of higher quality than the produced water.

7.2 Salt Loading

A potential water quality-related impact stemming from oil and gas operations includes additional salt loading to shallow groundwater beyond those currently associated with other industrial activities. Compared to the maximum TDS concentrations in the shallow and deep groundwater zones, the long-term loading from untreated produced water represents a relatively small impact. To quantify maximum salt loading rates at the scale of individual oil fields, produced water quality data for selected oil fields (principally in the western region of the study area) and produced water volumes were used to quantify annual mass loading rates for each constituent. These fluxes (kilograms per year, kg/yr) are summarized in Table 7-2. The calculations conservatively assume that 100 percent of produced water is discharged to groundwater, either by design or by accident, without being subject to treatment. For comparison, a second set of constituent-based mass fluxes was calculated assuming evaporation of 99 percent of the produced water (and subsequent removal of precipitated salts)

prior to recharge to groundwater. The brine composition used to quantify this set of mass fluxes was estimated using the USGS PHREEQC geochemical model (Parkhurst and Appelo 2009) and its brine chemistry database; modeled precipitates include calcium and magnesium carbonates, sodium bicarbonate, calcium sulfate, and sodium chloride.

Changes in salt concentrations in shallow groundwater as a result of salt loading were calculated for a subset of four oil fields with specified finite thicknesses of fresh groundwater (Table 7-3). The calculations assume that the salt fluxes specified in Table 7-2 are mixed across a portion of a potable aquifer corresponding to the freshwater zone thickness and the areal extent of the oil field (refer to Section 4, Table 4-5), assuming an average porosity of 0.2. It should be noted that the impact of any release of produced water to a potentially potable shallow aquifer will be scale-dependent. Potable wells in close proximity to a release would be expected to measure the greatest impact, whereas the *spatially-averaged* impact across an aquifer or an entire sub-area as defined in this assessment (e.g., East, Central, or West) may be greatly diluted. The scale of an individual oil field, as used for the analysis in Table 7-3, is intended to represent an intermediate scale, with the data for the four West sub-area example oil fields providing some constraint on the expected magnitude of salt fluxes under the assumed release scenario. As indicated in Table 7-3, the expected increase in TDS concentration in shallow groundwater ranges from less than 0.1 mg/L to 51 mg/L when no water treatment is assumed prior to discharge.

Any salt-loading associated with discharges of untreated or partially-treated process water is only one portion of a much broader, well-recognized salt balance problem affecting groundwater resources in the Central Valley in general. Specifically, the potential contributions of salt mass to potable groundwater resources must be viewed in the context of present and future agricultural practices, demands on groundwater for municipal water supply, and groundwater banking strategies.

7.3 Impacts Summary

The majority of the releases identified in Table 7-1 that could impact water quality can be grouped into three main categories:

- Accidental above-ground spills and leaks to surface water or groundwater (e.g., treated or untreated flowback and produced water, drilling fluids, chemical-water mixtures);
- Accidental releases to groundwater from failed construction or operation of oil and gas wells (e.g., drilling fluids, well stimulation fluids); and
- Accidental releases to groundwater during disposal of the produced water (i.e., infiltration from evaporation ponds, failure of UIC disposal well).

On this basis, impacts to surface waters in the Project Area would generally be limited to accidental above-ground spills and leaks that are significant enough to reach a surface water, if nearby.

Impacts to groundwater in the Project Area can potentially occur from above-ground spills and leaks (through infiltration), failure of well casings (production or disposal) that result in releases

to a different geologic formation than intended, as well as the permitted discharges to groundwater (i.e., land disposal). In Table 7-1, impacts to groundwater are described as potentially influencing either the shallow or deep groundwater within each of the three geographic sub-areas. Where the confining clay unit occurs (in parts of the West and Central sub-areas), “shallow” or “deep” refers to the zones above or below the unit. Where there is no confining clay unit, there is more potential for impacts to shallow groundwater to eventually reach deep groundwater.

Substances that could be released to groundwater through these release scenarios principally include major cations and anions – particularly sodium and chloride – associated with high-TDS oil-zone waters, along with hydrocarbons. Impacts associated with these categories of substances are likely to differ in scale: releases of salts are not likely to appreciably impact groundwater concentrations over existing background levels unless releases are very large and/or are continuous for a long period of time, whereas detections of constituents likely to be directly attributable to oil and gas operations (e.g., hydrocarbons, hydraulic fracturing chemicals) would presumably be associated with smaller releases. In the case of hydraulic fracturing chemicals and substances associated with other enhanced oil recovery operations, predicting future impacts associated with releases from these processes is difficult because the chemicals used change in response to technological developments as well as process economics. Additionally, chemicals may be altered or degraded as they migrate through the subsurface.

Terminology

Aquifer

A saturated body of rock or sediment that is sufficiently porous and permeable to store, transmit, and yield significant or economic quantities of groundwater to wells and springs.

Available water

The amount of water in an aquifer that can be used by an activity, without consideration for other needs or regulatory controls.

Beneficial Use

The description of the ressources, services, and qualities of an aquatic system (surface waters, groundwater, marsh, wetland) that serves as a basis for establishing water quality objectives and discharge prohibitions to attain and protect the established goals.

Beneficial Re-use

The use of treated produced water as a substitute for other water sources, including both internal industrial applications (e.g., enhanced oil recovery, hydraulic stimulation) and external non-industrial applications (e.g., agricultural irrigation, groundwater recharge, habitat enhancement).

Brackish water

Water with a salinity intermediate between seawater and freshwater (containing from 1,000 to 10,000 milligrams per liter of dissolved solids).

Central Valley Project

A large multi-purpose water project operated by the US Bureau of Reclamation. The facilities and service area of the Central Valley Project are generally located in California's Central Valley, with some facilities in the San Francisco Bay Area. Water from the Central Valley Project is delivered to specific entities that hold contracts for the water.

Consumed water / Net consumed water

Water removed from but not returned to the same drainage basin.

Contaminant

Any substance or property preventing the use or reducing the usability of water for ordinary purposes such as drinking, preparing food, bathing, washing, recreation, irrigation, and industrial uses. Any solute or cause of change in physical properties that renders water unfit for a given use. Generally considered synonymous with pollutant.

Cyclic Steam Injection

A method of thermal recovery in which steam in injected into the production reservoir; the injection well is then shut-in and allowed to sit idle for a specified period of time, then subsequently put back into production.

Depletion

Continued withdrawal of water from groundwater or other water body at a rate greater than the rate of replenishment.

Downhole Disposal

Injection of produced water into a subterranean aquifer for the purpose of disposal.

Drainage basin

Area from which direct surface runoff from precipitation drains by gravity into a stream or other water body.

Evapotranspiration

Transfer of water to the atmosphere as a result of evaporation and plant transpiration.

Fossil water

"*Groundwater*" body that has a negligible rate of natural recharge on the human time-scale.

Freshwater

Water that contains less than 1,000 milligrams per liter of dissolved solids.

Groundwater

Water that occurs beneath the land surface and fills the pore spaces of the alluvium, soil, or rock formation in which it is situated. It excludes soil moisture, which refers to water held by capillary forces in the upper unsaturated zones of soil or rock.

Groundwater banking

Storage of water into a groundwater basin for storage and withdrawal/use at a later time.

Groundwater basin

An area underlain by permeable materials capable of furnishing a significant supply of groundwater to wells or storing a significant amount of water. A groundwater basin is three-dimensional and includes both the surface extent and the subsurface fresh water-yielding material.

Groundwater overdraft

The condition of a groundwater basin in which the amount of water withdrawn by pumping exceeds the amount of water that recharges the basin over a period of years during which water supply conditions approximate average conditions. See “Depletion”

Groundwater recharge

The natural or intentional infiltration or pumping of water into the zone of saturation.

Impact

A significant change due to human activity. The change can be positive, negative, relative to the measure applied.

Industrial Water

Water used for industry purposes such as fabricating, processing, washing, diluting, cooling, or transporting a product; incorporating water into a product; or for sanitation needs within a manufacturing facility. Water for industrial use may be supplied by a public source (e.g., municipal water supplier) or be self-supplied; hence it may or may not be potable. The required quality of industrial water is dependent on its intended use.

Municipal Water

Water that has been processed at a central plant to make it potable or "safe to drink", and is then distributed to homes and businesses via a fixed distribution system (i.e., water mains). Either public agencies or private companies can be involved in providing "municipal water."

Potable water

Water that is satisfactory for drinking, culinary and domestic purposes and meets the requirements of the health authority having jurisdiction.

Produced water

Groundwater extracted from an oil reservoir or an oil-bearing formation. Produced water typically contains elevated concentrations of total dissolved solids and select metals; and generally does not have a beneficial use without treatment.

Rainwater

Water that falls to the ground through precipitation.

Rainwater infiltration

The part of precipitation that infiltrates into the ground and recharges groundwater.

Raw Water

Natural water, such as rainwater, groundwater and water from bodies like lakes and rivers that has not undergone any treatment.

Reinjection

The Injection of produced water into a producing reservoir to enhance oil recovery or maintain reservoir pressures.

Return flow

Any flow that is returned to a surface water body or to groundwater after use. Note: the quality, quantity, temperature and point of return to a watershed or aquifer are typically controlled by state regulations.

Receiving water body

A “Water Body” receiving “Return Flow”.

Recycled water

Water that serves more than one use for any industrial, municipal or public program or process, and requires treatment in between uses.

Reused water

Water that serves more than one use for any industrial, municipal or public program or process, but does not require significant treatment in between uses.

Run off

The portion of precipitation that does not infiltrate into the ground but collects in a surface water body (stream, river, lake, reservoir, etc.).

Salinity

The concentration of mineral salts dissolved in water. Typically expressed in terms of concentration or as electrical conductivity. See also total dissolved solids.

State Water Project

A large multi-purpose water project operated by the California Department of Water Resources. The facilities and service area of the State Water Project are located in various parts of California. Water from the State Water Project is delivered to specific entities that hold contracts for the water.

Steam Injection

A method of enhanced oil recovery whereby steam is injected into the production reservoir to reduce the viscosity of the oil, and fluids (oil and water) are extracted at a nearby location.

Supplying water body

Any resource capable of supplying water needed by an activity to meet its process' water requirements.

Surface water

All water in overland flow and storage, excluding seawater.

Total Dissolved Solids

A quantitative measure of the dissolved minerals in a water body or sample. Usually expressed as a concentration and reported in milligrams per liter (mg/L).

Water treatment plant

A facility designed or dedicated to treat and produce water of an acceptable quality for its intended use. The quality of the treated water may or may not meet drinking water criteria depending on its intended use.

Water body

An accumulation of water above or below ground that has definite hydrological, hydrogeologic, physical, and chemical characteristics in a given geographical area.

Water quality

Description of the chemical, physical (e.g. thermal) and biological characteristics of water with respect to its suitability for an intended use.

Water use

Use of water for human activity. Use includes, but is not limited to, direct (drinking water) and indirect (as part of a consumer product) consumption, industrial processes, irrigation, recreation, and other activities necessary to support human existence.

Water withdrawal

Anthropogenic removal of water from any water body or from any drainage basin, either permanently or temporarily.

Wastewater

Excess water requiring discharge or disposal after use, and containing or potentially containing properties or chemicals that can impair its quality.

Wastewater treatment plant

A facility designed or dedicated to treat “Waste Water” prior to being reused (recycled water), discharged to the natural environment, or disposed.

Waterflood

A method of oil recovery whereby hot water is injected into the production reservoir to reduce the viscosity of the oil, maintain reservoir pressures and drive oil towards a nearby production well.

Notes:

(a) Field Names are from DOGGR TR11 *California Oil and Gas Fields* Volume I, downloaded on 12 February 2014.

(b) Area names and Pool names are taken directly from data sheets in DOGGR TR11. Some differences in Area and Pool names may exist between TR11 and monthly/yearly fielc production and injection data reports available from DOGGR.

(c) Producing interval's stratigraphic formation is taken directly as noted on data sheets in DOGGR TR11. Some differences in nomenclature or local/informal usage may occur.

(d) Abd = Abandoned, as designated in DOGGR TR11 or in DOGGR production and injection reports.

Table 2-2: Area and Depth to Fresh Water for Oil and Gas Fields in the Project Area

Sub-area	Administrative Oil Field [a]	Area in Square Miles[b]	Area in Acres	Depth from ground surface to the Base of Fresh Water (feet) [c][d]
West Sub-Area				
Fields Overlying Fresh Water				
West	Belgian Anticline	15.4	9,865	1,200 at west edge of Main area
West	Blackwells Corner	3.6	2,308	600
West	Cal Canal Gas	5.5	3,515	800

Notes:

DOGGR - California Division of Oil, Gas, and Geothermal Resources
(Abd) = Indicates field operations have been abandoned

Footnotes:

(a) Kern County cites California Division of Oil, Gas, and Geothermal Resources (DOGGR) Field Boundaries, 6 March 2013

(b) Field Size in Acres and Square Miles from: Initial Study/Notice of Preparation, Amendment to Title 19 Kern County Zoning Ordinance, focused on

(c) Base of fresh water from 1) Field Rules on DOGGR website http://www.consrv.ca.gov/dog/field_rules/Pages/field_rules_index.aspx#b accessed on 21 February 2014 or 2) If field is abandoned, or field rules were not on DOGGR website, the base of fresh water was taken from DOGGR TR11 (1998)

(d) "No fresh water" is the phrase used in the Field Rules whereas "None" is the phrase used on field data sheets.

(e) DOGGR - Abd: Not shown as Abandoned on NOP, but listed as 'Abandoned' in DOGGR website, accessed 20 February 2014.

(f) ** Field is located on the border of Kern and an adjacent county. Area in Kern County is approximate.

(g) Field overlies both fresh and non-fresh groundwater aquifers

Table 3-1: Definitions for Designated Beneficial Uses of Water Bodies in the Project Area

Abbreviation	Name	Description
MUN	Municipal and Domestic Supply	Uses of water for community, military, or individual water supply systems including drinking water supply
AGR	Agricultural Supply	Uses of water for farming, horticulture, or ranching, including, but not limited to, irrigation, stock watering, or support of vegetation for range grazing
IND	Industrial Service Supply	Uses of water for industrial activities that do not depend primarily on water quality, including mining, cooling water supply, hydraulic conveyance, gravel washing, fire protection, and oil well repressurization
PRO	Industrial Process Supply	Uses of water for industrial activities that depend primarily on water quality
POW	Hydropower Generation	Uses of water for hydropower generation
REC-1	Water Contact Recreation	Uses of water for recreational activities involving body contact with water where ingestion of water is reasonably possible, including swimming, wading, water-skiing, skin and scuba diving, surfing, white-water activities, fishing, and use of natural hot springs
REC-2	Non-Contact Water Recreation	Uses of water for recreational activities involving proximity to water but where there is generally no body contact with water or any likelihood of ingestion of water, including picnicking, sunbathing, hiking, beachcombing, camping, boating, tide pool and marine life study, hunting, sightseeing, and aesthetic enjoyment in conjunction with the above activities
WARM	Warm Freshwater Habitat	Includes support for reproduction and early development of warm water fish
COLD	Cold Freshwater Habitat	Uses of water that support cold water ecosystems, including preservation or enhancement of aquatic habitats, vegetation, fish, and wildlife, including invertebrates
WILD	Wildlife Habitat	Uses of water that support terrestrial or wetland ecosystems, including preservation and enhancement of terrestrial habitats or wetlands, vegetation, wildlife (e.g., mammals, birds, reptiles, amphibians, invertebrates), and wildlife water and food sources
RARE	Rare, Threatened, or Endangered Species	Uses of water that support aquatic habitats necessary, at least in part, for the survival and successful maintenance of plant and animal species established under state or federal law as rare, threatened, or endangered
SPWN	Spawning, Reproduction, and/or Early Development	Uses of water that support high quality aquatic habitats suitable for reproduction and early development of fish (limited to cold water fisheries)

Table 3-1: Definitions for Designated Beneficial Uses of Water Bodies in the Project Area

Abbreviation	Name	Description
GWR	Ground Water Recharge	Uses of water for natural or artificial recharge of groundwater for purposes of future extraction, maintenance of water quality, or halting of saltwater intrusion into freshwater aquifers
FRSH	Freshwater Replenishment	Uses of water for natural or artificial maintenance of surface water quantity or quality

Table 3-2: Surface Water Designated Beneficial Uses in Tulare Lake Basin and the Project Area

Notes: Table is a partial reproduction of the Basin Plan Table II-2 for the Tulare Lake Hydrologic Basin (CA RWQCB 2004).

DAU = detailed analysis unit

(a) Ground water contained in the lower Transition Zone and Santa Margarita formation within 3,000 feet of the Kern Oil and Refining Company proposed injection wells in Section 25, T30S, R28E, MDB&M, is not suitable, or potentially suitable, for municipal or domestic supply (MUN).

(b) Ground water contained in the basal Etchegoin formation, Chanac formation, and Santa Margarita formation within, and extending to one-quarter mile outside the administrative boundary of the Fruitvale Oil Field, as defined by the State of California, Department of Conservation, Division of Oil and Gas in *Application for Primacy in the Regulation of Class II Injection Wells Under Section 1425 of the Safe Drinking Water Act*, dated April 1981, is not suitable, or potentially suitable, for municipal or domestic supply (MUN). However, the upper ground water zone (ground water to a depth of 3,000 feet) retains the MUN beneficial use.

(c) Ground water and spring water within 1/2 mile radius of the McKittrick Waste Treatment (formerly Liquid Waste Management) site in Section 29, T30S, R22E, MDB&M, have no beneficial uses.

(d) Ground water in the San Joaquin, Etchegoin, and Jacalitos Formations within one-half mile of existing surface impoundments P-1, P-2, P-3, P-4, P-4 1/2, P-5, P-6, P-7, P-8, P-9, P-10, P-11, P-12/12A, P-13, P-14, P-15, P-16, P-17, P-18, P- 19, and P-20, and proposed surface impoundments P-21, P-24, P-25, P-27, P-28, and P-29 at the Kettleman Hills Facility (Sections 33 and 34, T22S, R18E, and Section 3, T23S, R18E, MDB&M) of Chemical Waste Management is not a municipal or domestic supply (MUN).

Notes: Source – SWRCB SWAMP, data available from CEDEN (CA SWRCB 2012a) and STORET Data Warehouse (STORET 2014)

N = number of results; ND = not detected above the method reporting limit; SWRCB = State Water Resources Control Board; SWAMP = Surface Water Ambient Monitoring Program

Where "ND", average, median, minimum, and maximum are calculated assuming a value equal to one-half the reporting limit (RL).

(a) Minimum value calculated as the 5th percentile. When one or more result is ND, the minimum is reported as ND.

(b) Maximum value calculated as the 95th percentile.

Table 3-5: Summary of Deer Creek, Poso Creek, and El Paso Creek Water Quality from Central Valley RWQCB ILRP, 2009-2012

Notes: Source – Central Valley RWQCB ILRP, data available from CEDEN (CA SWRCB 2012a) and STORET Data Warehouse (STORET 2014)

N = number of results; ND = not detected above the method reporting limit; RWQCB = Regional Water Quality Control Board; ILRP = Irrigated Lands Regulatory Program

Where "ND", average, median, minimum, and maximum are calculated assuming a value equal to one-half the reporting limit (RL).

(a) Minimum value calculated as the 5th percentile. When one or more result is ND, the minimum is reported as ND.

(b) Maximum value calculated as the 95th percentile.

(c) For Deer Creek at Road 120 and Deer Creek at Road 176, 76 additional pesticides were measured (N = 2 to 9) between 2009 and 2010 and were not detected. For Poso Creek at Zerker Road, 53 additional pesticides were measured (N = 1 to 3) in 2010 and were not detected. No pesticides data is reported for El Paso Creek.

Notes: Source – SWAMP and ILRP monitoring data available from CEDEN database; KCWA (2010, 2011, 2012, 2013)

Statistics are calculated based on the composite historical results for each monitoring location, e.g., AVERAGE(average alkalinity for Station No. 1, average alkalinity for Station No. 2, etc.), MIN(minimum alkalinity for Station No. 1, minimum alkalinity for Station No. 2), etc.

For calculating statistics, ND is assumed to equal 1/2 RL if known or zero if unknown.

Blank cells indicate data is not available.

(a) N is the number of monitoring stations on rivers or creeks in this geographic sub-area that have information on the indicated water quality parameter. In cases where N = 1, the average, median, minimum, and maximum are based on the historic results for the site from multiple sampling events. If N = 1 and there has been only one sampling event at the site, the (single) result is shown in place of the average (with no value for median, min, or max).

(b) Metals concentrations for Kern River reported by KCWA (2010, 2011, 2012, 2013) are assumed to be dissolved metals except arsenic is assumed to be total arsenic (site located in Central Groundwater Basin sub-area).

Notes: Source – USEPA STORET Legacy Data Center (for data before January 1, 1999)

Statistics are calculated based on the composite historical results for each monitoring location, e.g., AVERAGE(average alkalinity for Station No. 1, average alkalinity for Station No. 2, etc.), MIN(minimum alkalinity for Station No. 1, minimum alkalinity for Station No. 2, etc).

Values of "0.0" are as shown in the data source and likely indicate non-detect (ND).

Blank cells indicate data is not available.

(a) N is the number of monitoring stations on rivers or creeks in this geographic sub-area that have information on the indicated water quality parameter. In cases where N = 1, the average, median, minimum, and maximum are based on the historic results for the site from multiple sampling events. If N = 1 and there has been only one sampling event at the site, the (single) result is shown in place of the average (with no value for median, min, or max).

Notes: Source – KCWA (2010; 2011; 2012; 2013)

ND = not detected; MFL = million fibers per liter; mrem/yr = millirems per year; NTU = nephelometric turbidity units; pCi/L = picocuries per liter; SDWA = Safe Drinking Water Act

(a) Statistics calculated based on four years of reported data. Where "ND", average, median, minimum, and maximum assume a concentration of zero (no reporting limit provided by data source).
(b) Minimum values calculated as 5th percentile. When one or more result is ND, the minimum is reported as ND.
(c) Maximum values calculate as 95th percentile.
(d) N = 4 based on four reports (KCWA 2010; 2011; 2012; 2013) that each reported a single value for each parameter. The reports did not indicate whether the result was based on multiple measurements.
(e) 35 compounds were measured and were not detected. Complete list available from KCWA (2010; 2011; 2012; 2013).
(f) 20 compounds were measured and were not detected. Complete list available from KCWA (2010; 2011; 2012; 2013).
(g) Some parameters listed under above categories are also regulated by the SDWA.
(h) 27 compounds were measured and were not detected. Complete list available from KCWA (2010; 2011; 2012; 2013).
(i) 33 compounds were measured and were not detected. Complete list available from KCWA (2010; 2011; 2012; 2013).

Table 3-10: Range of Drinking Water Contaminant Concentrations for Community Water Systems in the Project Area

Notes: Source – Adapted from California SWRCB *Report to the Legislature on Communities that Rely on a Contaminated Groundwater Source for Drinking Water* (CA SWRCB 2013a). Data were collected from the California Department of Public Health (CDPH) Division of Drinking Water and Environmental Management's water quality monitoring database for community water systems for the period 2002 to 2010.

(a) Primary city that is served by the water system. Service areas outside an incorporated area are identified as a Census-designated place (CDP) and a nearby city.
(b) Name of the community water system that provides the water.
(c) Number of groundwater public drinking water supply sources operated by the water system.
(d) The number of groundwater sources (prior to any treatment) with a principal contaminant detection above the MCL in two or more sampling events in the 2002-2010 time period.
(e) Corresponds to the source identification in the California Department of Public Health database.
(f) Chemical detected on two or more sampling events between 2002-2010.
(g) mg/L = milligrams per liter, ug/L = micrograms per liter, pCi/L = picocuries per liter
(h) Date of the most recent detection in the 2002-2010 time period above the drinking water Maximum Contaminant Level (MCL).
(i) Number of samples collected between 2002-2010 with detections above the MCL.
(j) Average concentration in the groundwater source during the 2002-2010 time period.
(k) Maximum concentration detected during the 2002-2010 time period.
(l) Number of samples collected and evaluated from the source during the 2002-2010 time period.
(m) Units erroneously reported in the source publication as mg/L.

Notes: Source – Shelton et al. (2008)

N = number of results (reported for a subset of grid wells as defined by Shelton et al., 2008); ND = not detected above the method reporting limit, refer to Burton and Belitz (2012); pCi/L = picocuries per liter

Where "ND", average, median, minimum, and maximum are calculated assuming a value equal to one-half the reporting limit (RL), or equal to zero if result reported as 0.0, i.e., no detection limit provided.

(a) Minimum value calculated as the 5th percentile. When one or more result is ND, the minimum is reported as ND.
(b) Maximum value calculated as the 95th percentile.
(c) Some parameters listed under above categories are also regulated by the SDWA.

Notes: Source - GAMA Database, Dataset EDF - assumed to be environmental monitoring wells screened above the Corcoran Clay (CA SWRCB 2014b)

ND = not detected above the method reporting limit; pCi/L = picocuries per liter

Where "ND", average, median, minimum, and maximum are calculated assuming a concentration of zero (no reporting limit provided by data source).

(a) Minimum value calculated as the 5th percentile. When one or more result is ND, the minimum is reported as ND.

(b) Maximum value calculated as the 95th percentile.

(c) Some of the constituents and parameters listed above (e.g., General Water Quality) may also be regulated under the SDWA

Table 4-1: Oil and Gas Fields in Project Area

Administrative Oil Field [(a)(b)]	Area in Square Miles	Area in Acres	Field No. in NOP

Notes:

(a) Field Names, Size in Acres and Square Miles from: Initial Study/Notice of Preparation, Amendment to Title 19 Kern County Zoning Ordinance, focused on Chapter 19.98 (Oil and Gas Production) of the Kern County Zoning Ordinance for Oil and Gas Local Permitting. Kern County Planning and Community Development Department. August 2013.

(b) Kern County cites California Division of Oil, Gas, and Geothermal Resources (DOGGR) Field Boundaries, 6 March 2013.

(c) Abd = Abandoned

(d) DOGGR - Abd: Not shown as Abandoned on NOP, but listed as 'Abandoned' in DOGGR website, accessed 20 February 2014.

(e) DOGGR website 20 February 2014 shows no production after 1990, but field is not listed as "Abandoned".

(f) ** Field is located on the border of Kern and an adjacent county. Area in Kern County is approximate.

Table 5-2: Oilfield Fluid Handling Processes

Process	Description
WELL DRILLING OPERATIONS	
Fluid mixing	Trucks deliver fresh water to the drilling site. Water is pumped into a mixing tank and mixed with bentonite clay and a variety of additives to form a drilling fluid or drilling mud. The purposes of the drilling mud are to keep the drill bit cool and clean during drilling, carry out drill cuttings, suspend drill cuttings while drilling is paused, provide hydrostatic pressure in the formation, seal permeable formations, and control corrosion. As downhole conditions change during drilling, other additives are mixed in to adjust the viscosity, density, and pH of the drilling mud. The additives generally include barium sulfate (barite), calcium carbonate (chalk), or hematite. Thickeners may be added such as xanthan gum, guar gum, glycol, carboxymethylcellulose, or starch. Deflocculants may be also used such as polyelectrolytes, polyphosphates, lignosulfonates, or tannic acid derivatives. Other common additives may include lubricants, scale inhibitors, and corrosion inhibitors.
Fluid circulation	The mixed drilling mud is stored at the surface either in steel above ground storage tanks or in a lined earthen pit adjacent to the drilling rig. Pumps, hoses, and pipelines convey the mud to the top of the drill string. The mud travels inside the drill pipe down the drill string and comes out at openings in the drill bit at the bottom of the hole. The mud then travels up the borehole along the backside of the drill pipe. As the mud travels up it carries drill cuttings with it, and it forms a cake on the walls of the open borehole. The mud returns to the surface, passes through a screen to remove drill cuttings, and discharges into the mud pit or tank.
Flowback (comingled with drilling fluid)	Flowback focuses on the return trip of the drilling mud to the surface along the backside of the drill pipe. Along with the drilling mud, the flowback consists of fluids (oil, gas, water) released by the formation . Mudcake on the walls of the open borehole and conductor casings are designed to keep these fluids from entering shallower formations as the drilling mud travels upward to the surface.
Cementing casing	Multiple conductor casings are installed in a telescoping fashion to seal off progressively deeper formations, in accordance with DOGGR field rules. During casing installation, drilling stops at the target depth and the drill string is pulled out of the well. The casing is assembled in segments with a valve assembly at the bottom and is lowered downhole. A calculated quantity of fresh water and cement are mixed at the surface and pumped through the inside of the casing, pushing a lower rubber wiper plug in front of it. When the calculated volume of cement has entered the casing, an upper rubber wiper plug is pushed by drilling fluid behind the plug. When the lower plug, cement column, and upper plug reach the bottom of the hole, the driller applies pressure with drilling fluid. The lower plug seats in the valve assembly, the upper plug is pressed downward, and the cement column is forced through a breakable membrane in the lower plug, out of the casing and up the backside of the casing. A sudden increase in downhole pressure indicates to the driller that the upper plug has reached the lower plug, and all of the cement volume has been pushed into the annulus up to the depth required by DOGGR's field rules. The cement is allowed to cure for 12 to 24 hours before drilling resumes.

Table 5-2: Oilfield Fluid Handling Processes

Process	Description
Treatment and disposal of drilling fluids	Spend drilling mud is generally stored for a period of time in settling tanks or lined settling ponds to allow the water to separate from the clays and other additives. The separation may also be accomplished using a centrifuge. The separated water is decanted off, treated as necessary, and is generally recycled. Solids generated from the separation are generally landfarmed or used as landfill cover.
WELL SERVICING AND FIELD DEVELOPMENT	
Well recompletion using pulling unit	Well recompletion involves mobilizing a drilling rig to the well site. The Christmas tree or pump jack are removed, and the sucker rods and tubing are pulled from the well. The drilling rig seals off the existing producing zones with casing and advances the well into deeper producing zones. During well completion, the same drilling processes are used as in the initial Well Drilling Operations described above.
Mixing and pouring concrete for surface facilities.	Surface facilities would include secondary containments for tank batteries and steam generators, saddles and foundations for tanks, foundations for field offices and outbuildings, and foundations for pump jacks.
Chemical mixing	Trucks deliver fresh water to the completed well site. The christmas tree or pump jack is removed from the wellhead, and sometimes the sucker rod and tubing are pulled from the well. Water is pumped into a mixing tank and mixed with a variety to chemicals to suit the well servicing task at hand, which could include cleaning production casing and tubing, replacing tubing or sucker rods, repairing seals, and reperforating. The chemicals may include corrosion inhibitors, scale inhibitors, lubricants, or surfactants. Alternatively, trucks may arrive on site with chemicals already mixed in the water.
Mix and pump cement downhole to repair casing leaks or seal off unproductive zone	Same procedure as Cementing described above.
Fluid circulation	Fluids mixed at the well site are pumped downhole by a workover rig and may be circulated back to the surface for drilling out plugs, cleaning, or deepening the well.
Pump / remove development fluids	Same procedure as Flowback described above.
Treatment and disposal of development fluids	Same procedure as described in Drilling Operations above.

Table 5-2: Oilfield Fluid Handling Processes

Process	Description
WELL STIMULATION OPERATIONS	
Chemical mixing	The fracturing fluid is a precisely and specifically designed mix of mainly water and proppants, with chemicals added to serve several purposes. Chemical additives include acids, surfactants, biocides, bactericides, pH stabilizers, gel breakers, clay and iron inhibitors, corrosion and scale inhibitors. Some hazardous substances, such as benzene, ethylene glycol, naphthalene may also be added in small amounts
Pressurized fluid injection	To conduct the fracturing, a tool is inserted into the cased well beyond the casing into the open target formation. A device seals the casing against the pressure and the fluid is injected under high pressure into the target formation. The process may be repeated multiple times to extend fractures.
Capture flowback and produced water	Much of the fluid injected into the formation returns to the well after the fracturing procedure has been conducted and the pressure imposed on the fluid is reduced. According to API (2010), the vast majority of injected hydraulic fracturing fluid is recovered within a short time.
Disposal of flowback water	In Kern County, stimulation notices indicate all flowback water is contained in closed systems (tanks) at the drill site. The fluid is transported for treatment in field treatment systems (e.g. Elk Hills or Lost Hills), or "commercial disposal" (e.g. Rose Field). The treated fluid may be re-used (e.g. for enhanced recovery operations in the Elk Hills Field), or injected into permitted Class II wastewater disposal wells.
PRODUCED WATER HANDLING OPERATIONS	
Capture produced water	Production consisting of water, oil, and gas, enters the well through perforations in the production casing or through the liner, and is brought up to the surface through tubing. Under high reservoir pressures, the production will flow naturally up the tubing to the surface, and the pressure and flow will be regulated by a Christmas tree at the wellhead. If reservoir pressures are not sufficient to permit flowing, the production is lifted mechanically using a pump jack at the surface or occasionally a submersible pump at depth. Once it reaches the surface, production is conveyed by above-ground or shallow underground piping to a tank battery.
Oil and gas separation	Production pipelines from the field join at a field header, which conveys the production into the tank battery. The production is initially routed through a tall tank called a stripper, which separates the gas from the oil and water. Oil and water are then routed via pipelines to a series of tanks in which the oil is separated from the water. The separation vessels may include a free-water knockout tank, a heater-treater, or a wash tank, or a combination of these. Emulsion breakers are often added to enhance the separation of the oil from the water. Separated oil is routed to oil stock tanks, and then through a Lease Automated Custody Transfer (LACT) unit, where it is sold and enters the transportation phase via either regional pipelines or trucks.

Table 5-2: Oilfield Fluid Handling Processes

Process	Description
Produced water treatment	After oil/water separation is complete, produced water is routed through a treatment system that usually includes a sand filter and/or an induced gas flotation unit. Chemicals including scale inhibitors and corrosion inhibitors may be added during the treatment. Following treatment, the water is collected in a produced water tank. From the produced water tank, the water may be routed to a disposal well, a waterflood well, or a steam generator; or it may be transported off the lease via pipeline or truck to a produced water disposal facility.
Steam generation	Either treated produced water or fresh water is fed into a steam generator or a cogen. The water is heated to boiling, and the steam is conducted through insulated above-ground pipelines to steam injection wells in the field.
Water flooding / steam injection	In water flooding, treated produced water is conveyed from the produced water tank to waterflood injection wells. The water enters the injection well and is injected into an oil-bearing formation. Because of the well's position in the field, the injected water is intended to migrate downgradient through the formation and push oil and gas to the active production wells in the field. In steam injection, the steam is delivered via insulated pipelines to the well and into an oil-bearing formation. The steam provides both heat, to decrease the viscosity of low-gravity oil and establish flow, and pressure, to push the oil and gas to the production wells in the field.
Disposal of produced water	For onsite disposal, treated produced water is routed to one or more Class II disposal wells, usually located at the downgradient edge of the field. The water enters the disposal well and is injected into the oil-bearing formation whence it came. Because of the disposal well's position in the field, the injected water is not intended to push oil and gas to the production wells in the field. For offsite disposal, treated produced water is metered into a pipeline or to trucks and transported off the lease to a produced water disposal facility. These facilities usually consist of large bermed percolation ponds, evaporation ponds, and a large number of large water tanks.

Total volume of **produced** water to be used as reported on approved notices for well stimulations (bbl): 53,400

Notes:

(a) Notices were viewed at http://maps.conservation.ca.gov/doggr/iwst_index.html on 12-13 March 2014. Notices were posted between 3 December 2013 and 6 March 2014. Each posted notice has a status of "Approved" or "Withdrawn". Only "Approved" notices are counted in this table.

(b) bbl = Barrel. Some notices report "estimated volume" of water for treatment while others report "maximum volume" of water.

(c) If the water volume for the hydraulic fracture of one well (SOSA FOD SB 2086-18) is excluded, the average water volume for well stimulations for this field is 4,800 bbl.

(d) Both "fresh" water and "produced" water are marked for well 72-9G. It is counted with Fresh Water.

Notes:

(a) Chemicals lists were observed on DOGGR Interim Well Stimulation Notices, accessed 13 March 2014. This listing shows chemicals found in a sampling of hydraulic fracture notices from different fields. A chemical is only listed once, even if it shown on multiple notices.

(b) The estimated concentration listed is representative of a "typical" use, based on the information reviewed, and will vary between wells.

Notes:

Data from Mitchell (1989)

(a) TDS = Total Dissolved Solids

(b) *N* = number of analyses reported

(c) ppm = parts per million

Table 6-1: Summary of Regulations Governing Oilfield Activities

Agency	Regulated Activities
Federal Statutes and Regulations	
United States Environmental Protection Agency	
The Clean Water Act	Regulates spill prevention actions; discharge of water to waterways and land; regulates discharges to wastewater treatment plants; establishes the National Oil and Hazardous Substance Pollution Contingency Plan and Onshore Facility Discharge Rule
The Oil Pollution Act	Prescribes a prevention, response, liability and compensation program for oil pollution from vessels, offshore facilities, pipelines, and onshore facilities.
The Safe Drinking Water Act	Regulates the amount of toxic substances in sources of drinking water.
Resource Conservation and Recovery Act	Regulates the generation, storage, treatment, transportation, and disposal of hazardous wastes.
The Solid Waste Disposal Act	Establishes restrictions on the disposal of solid waste.
Comprehensive Environmental Response, Compensation, and Liability Act	Establishes regulations covering the release of hazardous substances and associated remedial actions.
National Environmental Policy Act	Provides the national policy promoting the enhancement of the environment. Applicable to federal, state, and local project that involves federal funding, work performed by the federal government, or permits issued by a federal agency.
United States Army	
US Army Corps of Engineers	Regulates dam construction projects for government funded projects
California Regulations	
California Environmental Quality Act	
Department of Conservation, Division of Oil, Gas and Geothermal Resources	
Oil & Gas Resource Regulations (AB 1960)	Establishes rules and regulations for oil and gas exploration; field rules; oil spill response actions; well construction standards; UIC program rules; discharge of waste water to sumps and surface channels; well stimulation treatments and closure activities
Well Stimulation Treatments	Establishing permitting, notification and reporting requirements; background groundwater monitoring program
Department of Toxic Substances Control	
Hazardous Waste Control Law	Characterization, handling, and disposal of

Table 6-1: Summary of Regulations Governing Oilfield Activities

Agency	Regulated Activities
	hazardous waste.
State Water Resources Control Board	
Porter-Cologne Water Quality Control Act	Primary statute governing water quality and water protection in California. Establishes the SWRCB and RWQCBs; requires development of basin plans; regulates water quality through the anti-degradation policy; regulates disposal to surface water and land.
Surface Impoundments	Regulations controlling siting and construction of surface impoundments, and storage of wastewater and produced water in surface impoundments.
Storm Water Discharge Regulations	Regulates storm water discharges from oil and gas fields, mostly through NPDES permits
Department of Fish and Wildlife	
Wildlife Protection	Regulates receiving stream alterations that could impact fish and wildlife.
Kern County Ordinances	
Environmental Health Services Department	
Groundwater Monitoring Well Permits	Kern County requires permits to install water monitoring and production wells.
Aboveground Petroleum Storage Act	Requirements for reporting of any spill or leak in excess of one barrel.

Table 7-1: Potential Impacts to Water Quality from Oil and Gas Operations

Process[a]	Potential Release	Magnitude of Potential Release[b]	Potentially Impacted Media	Description of Potential Impact	Regulatory Controls	Best Management Practices
WELL DRILLING OPERATIONS						
Drilling mud mixing at surface	Spills/leaks at the surface from ruptured or leaking tanks, pipes, valves, hoses, and other process equipment	Small release, anticipated to be less than a few hundred gallons based on awareness of the crew to shut off releases and contain spills	Surface water	Localized elevated TSS and inorganics	WDR General Order 2003-0003-DWQ AB 1960 (CCR 1722, 1722.9, 1770, 1773.1, 1777.2) DOGGR Field Rules California Accidental Release Program (CalARP)	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized elevated inorganics		
Fluid circulation	Temporary contact of the drilling fluid with aquifer prior to casing the well	Small release, anticipated to be less than a few hundred gallons based on awareness of the crew to recoginze fluid loss	Shallow and deep groundwater	Localized elevated inorganic constituents	WDR General Order 2003-0003-DWQ AB 1960 (CCR 1722, 1722.9, 1770, 1773.1, 1777.2) DOGGR Field Rules	Installation of cemented casing across water bearing zone; use of fresh-water based muds until below base of fresh water; real-time monitoring of fluid pressures and volumes; response plans and training for fluid/circulation loss
Flowback (oil and/or gas comingled with drilling fluid)	Spills/leaks at the surface from ruptured or leaking tanks, pipes, valves, hoses and other process equipment	Small release, anticipated to be less than a few hundred gallons based on awareness of the crew to shut off releases and contain spills	Surface water	Localized elevated TSS, TDS (primarily Na and Cl), hydrocarbons, inorganics	WDR General Order 2003-0003-DWQ AB 1960 (CCR 1722, 1722.9, 1770, 1773.1, 1777.2) DOGGR Field Rules	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized hydrocarbons and inorganics adsorbed to soils		
		Medium release, estimated to be a few hundered to a few thousand gallons, if mud pit is breached or blow-out protection fails	Surface water	Elevated TSS, TDS (primarily Na and Cl), hydrocarbons, inorganics	WDR General Order 2003-0003-DWQ AB 1960 (CCR 1722, 1722.9, 1770, 1773.1, 1777.2) DOGGR Field Rules	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Decrease in soil infiltration characteristics (e.g., residual clay pan); hydrocarbons and inorganics adsorbed to soils		
			Shallow groundwater	Increased TDS (primarily Na and Cl), hydrocarbons, and/or inorganics migrating to shallow groundwater		
	Mixing of flowback with drinking water aquifer from failed or improper casing seal	Small release, anticipated to be less than a few hundred gallons, to aquifer based on restricted flow between casing and borehole wall	Shallow and deep groundwater	Localized increase in TDS (primarily Na and Cl), hydrocarbon and/or inorganic concentrations in shallow and/or deep groundwater	WDR General Order 2003-0003-DWQ AB 1960 (CCR 1722, 1722.9, 1770, 1773.1, 1777.2) DOGGR Field Rules	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for seal design and placment
Cementing *(no potential impacts identified)*						
Treatment and disposal of drilling fluids	Infiltration while stored in evaporation ponds	Small release, estimated to be less than a few hundred gallons, drilling mud expected to soak into and seal permeable soils and prevent signficant migration.	Surface soils	Decrease in soil infiltration characteristics (e.g., residual clay pan); hydrocarbons and inorganics adsorbed to soils	WDR General Order DOGGR Regulation 1775	Maintain and periodically test discharge basins to ensure they meet permitted use conditions. Evaluate groundwater conditions to assess compliance
			Shallow groundwater	Increased TDS (primarily Na and Cl), hydrocarbons, and/or inorganics migrating to shallow groundwater		
WELL SERVICING AND FIELD DEVELOPMENT						
Well recompletion using pulling unit *(see Well Drilling Operations - similar potential releases)*						
Mixing and pouring concrete for surface facilities *(no potential impacts to surface water or groundwater identified)*						
	Spill/release of concentrated chemicals during transfer and mixing	Small release, tens of gallons, based on small volume of chemicals brought on-site	Surface water	Localized impact to surface waters and sediments from release	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) DOGGR Field Rules CalARP	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized adsorption of chemicals onto surface and near-surface soils		

Table 7-1: Potential Impacts to Water Quality from Oil and Gas Operations

Process[a]	Potential Release	Magnitude of Potential Release[b]	Potentially Impacted Media	Description of Potential Impact	Regulatory Controls	Best Management Practices
Chemical mixing	Spills/leaks from tanks, piping, pumps, and other equipment	Small release, less than a few hundred gallons, based on volume of mixed fluid being used and awareness of the crew to contain spills	Surface water	Localized impact to surface waters and sediments from release	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) DOGGR Field Rules CalARP	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized adsorption of chemicals onto surface and near-surface soils		
			Shallow groundwater	Possible increased constituent concentrations in shallow groundwater through vertical migration of spilled fluid		
Mix and pump cement downhole to repair casing leaks or seal off unproductive zone *(no potential impacts identified)*						
Fluid circulation	Leak downhole through failed casing	Small, a few hundered gallons, based on small volume of liquids used in process and awareness of drill crew to note lost circulation and shut down equipment	Shallow and deep groundwater	Localized impact from solutions containing dilute amounts of corrosion inhibitors, scale inhibitors, and surfactants	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) DOGGR Field Rules - well seal placement and testing.	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for seal design and placment
Pump / remove development fluids	Spills/leaks at the surface from ruptured or leaking tanks, pipes, valves, hoses, and other aboveground storage equipment	Small release, tens of gallons to less than a few hundered gallons, based on volume of liquid handled	Surface water	Localized elevated TSS, TDS (primarily Na and Cl), hydrocarbons, inorganics and other constituents used during well development	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) CalARP Aboveground Petroleum Storage Act (APSA) SPCC	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized elevated TDS (primarily Na and Cl), hydrocarbons, inorganics and other constituents used during well development		
			Shallow groundwater	Localized TDS (primarily Na and Cl), hydrocarbons, inorganics and other well development constituents migrating vertically to shallow groundwater		
Treatment and disposal of development fluids	Infiltration while stored in evaporation ponds	Small to medium release, a few hundred to a few thousand gallons, based on volume of liquid recovered during development	Surface soils	Decrease in soil infiltration characteristics (e.g., residual clay pan); TDS (primarily Na and Cl); hydrocarbons and inorganics adsorbed to soils		Maintain and periodically test discharge basins to ensure they meet permitted use conditions. Evaluate groundwater conditions to assess compliance
			Shallow groundwater	Increased TDS (primarily Na and Cl), hydrocarbon and/or inorganic concentrations from vertical migration to shallow groundwater		
	Possible casing or well seal failure during injection into Class II UIC well	Small to medium release, a few hundred to a few thousand gallons, based on volume of liquid recovered during development	Shallow and deep groundwater	Localized increase in TDS (primarily Na and Cl), hydrocarbon and/or inorganic concentrations in shallow and/or deep groundwater	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) DOGGR Field Rules - well seal placement and testing. UIC permit	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for seal design and placment
WELL STIMULATION OPERATIONS						
Chemical mixing	Spill/release of concentrated chemicals during transfer and mixing	Small to medium release, tens to hundreds of gallons, based on volume of indiviual chemicals brought on-site	Surface water	Localized impact to surface waters and sediments from chemicals used in well stimulation process	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) Field Rules CalARP	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized adsorption of process chemicals onto surface and near-surface soils		
	Spills/leaks from tanks, piping, pumps, and other equipment	Medium to large release, hundreds to thousands of gallons, based on volume of fluid storage on-site during operations	Surface water	Localized impact to surface waters and sediments from fluids used in well stimulation process	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) CalARP	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized adsorption of process fluids onto surface and near-surface soils		
			Shallow groundwater	Possible increased constituent concentrations in shallow groundwater through vertical migration of spilled fluid		

Table 7-1: Potential Impacts to Water Quality from Oil and Gas Operations

Process[a]	Potential Release	Magnitude of Potential Release[b]	Potentially Impacted Media	Description of Potential Impact	Regulatory Controls	Best Management Practices
Pressurized fluid injection	Spills/leaks at the surface from ruptured or leaking tanks, pipes, valves, or other process equipment	Small release, anticipated to be less than a few hundred gallons based on awareness of the crew to shut off releases and contain spills	Surface water	Localized impact to surface waters and sediments from fluids used in well stimulation process	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) CalARP SB-4	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized adsorption of process chemicals onto surface and near-surface soils		
			Shallow groundwater	Possible increased constituent concentrations in shallow groundwater through vertical migration of spilled fluid		
	Casing rupture, well seal rupture, bypass of conductor, surface, and intermediate casings and cement seals	Medium to large release, hundreds to thousands of gallons, depending on injection stage, pressure, and awareness of crew to recognize failure	Shallow and deep groundwater	Localized increase in concentration in groundwater of chemicals used in well stimulation process through upward vertical migration of fracturing fluid along borehole wall	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) SB-4	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for high pressure fluid injection; train operations staff; incident response planning and trainiing
	Fracture propagation; seepage along fracture or geologic feature	Small release due to low permeability and diffusion along flow path	Deep groundwater	Localized increased constituent concentrations in groundwater through upward vertical migration of fracking fluid	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) SB-4	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for high pressure fluid injection; train operations staff; incident response planning and trainiing
Capture flowback	Spills/leaks at the surface from ruptured or leaking tanks, pipes, valves, hoses and other process equipment	Minimal flowback from hydraulic fracturing activities in project area. Small surface release based on awareness of crew to shut off pumps and cleanup spills	Surface water	Localized elevated TSS, TDS (primarily Na and Cl), hydrocarbons, inorganics, and chemical constituents contained in well stimulation fluids	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) CalARP APSA SPCC SB-4	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized elevated TDS (primarily Na and Cl), hydrocarbons, inorganics, and well stimulation constituent concentrations adsorbed to soil		
			Shallow groundwater	Localized TDS (primarily Na and Cl), hydrocarbons, inorganics, and well stimulation chemical constituents adsorbed to soil		
Disposal of flowback water	Surface piping failure	Minimal flowback from hydraulic fracturing activities in project area. Small surface release based on awareness of crew to shut off pumps and cleanup spills	Surface water	Localized elevated TSS, TDS (primarily Na and Cl), hydrocarbons, inorganics, and chemical constituents contained in well stimulation fluids	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) CalARP APSA SPCC SB-4	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized elevated TDS (primarily Na and Cl), hydrocarbons, inorganics, and well stimulation constituent concentrations adsorbed to soil		
			Shallow groundwater	Localized elevated TDS (primarily Na and Cl), hydrocarbon and/or inorganic concentrations in shallow groundwater		
	Possible casing or well seal failure during injection into Class II UIC well	Minimal flowback from hydraulic fracturing activities in project area; small release based volume of fluid being disposed	Shallow and deep groundwater	Localized TDS (primarily Na and Cl), hydrocarbons, inorganics, and well stimulation constituent concentrations to shallow and/or deep groundwater	AB 1960 (CCR 1722, 1722.9, 1773.1, 1777.2) UIC SB-4	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for seal design and placment

Table 7-1: Potential Impacts to Water Quality from Oil and Gas Operations

Process[a]	Potential Release	Magnitude of Potential Release[b]	Potentially Impacted Media	Description of Potential Impact	Regulatory Controls	Best Management Practices
PRODUCED WATER HANDLING OPERATIONS						
Capture/storage of produced water	Spills/leaks at the surface from ruptured or leaking tanks, pipes, valves, hoses and other process equipment	Small surface release, less than a few hundred gallons per event, based on awareness of crew to recognize spills and quickly respond.	Surface water	Localized elevated TSS, TDS (primarily Na and Cl), hydrocarbons and inorganics in surface water and sediments	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) APSA SPCC	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized TDS (primarily Na and Cl), hydrocarbons, inorganics adsorbed to soil		
		Medium release, a few hundred to few thousand gallons, if tank or secondary containment failure occurs	Surface water	Elevated TSS, TDS (primarily Na and Cl), hydrocarbons, inorganics in surface waters and sediments	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) APSA SPCC	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Elevated TSS, TDS (primarily Na and Cl), hydrocarbons, inorganics adsorbed to soil		
			Shallow groundwater	Increased TDS (primarily Na and Cl), hydrocarbon and/or inorganic concentrations migrating to shallow groundwater		
Separation of oil and gas from produced water	Oil spill/leak at the surface from leaking tanks, pipes, valves, hoses and other process equipment	Small to medium release, estimate to be less than a few hundred gallons, at surface based on crew awareness to identify release and respond	Surface water	Hydrocarbons (crude oil or natural gas liquids) and inorganics impact surface water and sediments	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) APSA SPCC	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Hydrocarbons (crude oil or natural gas liquids) and inorganics adsorbed to sediments	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) APSA SPCC	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Shallow groundwater	No expected impact due to high viscosity of oils		
Produced water treatment	Discharge of untreated or partially-treated water	Small to medium release, estimate to be less than a few hundred gallons, at surface based on crew awareness to identify release and respond	Surface water	Elevated TDS (primarily Na and Cl), hydrocarbons, inorganics	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) APSA	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized increased TDS (primarily Na and Cl), hydrocarbons, inorganics		
	Spills/leaks from storage tanks and process equipment following treatment	Medium release, estimate to be up to a few thousand gallons, at surface based on crew awareness to identify release and respond	Surface water	Elevated TDS (primarily Na and Cl), minor hydrocarbons, inorganics in surface waters and sediments	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) APSA	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Elevated TDS (primarily Na and Cl), minor hydrocarbons and inorganics adsorbed to soil		
			Shallow groundwater	Localized increased TDS (primarily Na and Cl), inorganics		
Steam generation (enhanced oil recovery) (West and East sub-areas only)	Minor spills during water softening operations or from chemical storage	Small release, up to a few hundred gallons, based on crew ability to respond to and contain spills	Surface water	No expected impact due to containment inside treatment facility		
			Surface soils	No expected impact due to containment inside treatment facility		
Water flooding / Steam injection (enhanced oil recovery)	Surface piping failure	Small to medium release, estimate to be less than a few thousand gallons, at surface based on crew awareness to identify release and respond	Surface water	Localized elevated TDS (primarily Na and Cl) concentrations in surface water	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) Field Rules	Secondary containment, lined sumps, use of spill containment equipment and soil berms, spill reponse planning and training, control site access
			Surface soils	Localized TDS (primarily Na and Cl) adsorbed to soil		
			Shallow groundwater	Localized increase in TDS in Central and East sub-areas due to vertical migration to groundwater. No expected impact in West sub-area as groundwater currently has high TDS concentrations.		

Table 7-1: Potential Impacts to Water Quality from Oil and Gas Operations

Process[(a)]	Potential Release	Magnitude of Potential Release[(b)]	Potentially Impacted Media	Description of Potential Impact	Regulatory Controls	Best Management Practices
	Possible casing or well seal failure during injection	Medium to large release, hundreds to thousands of gallons, based on signficance of casing failure and time lapse prior to identification of failure and response.	Shallow and deep groundwater	Increased TDS (primarily Na and Cl) in shallow and deep groundwater in Central and East sub-areas. No expected impact in West sub-area as groundwater currently has high TDS concentrations.	AB 1960 (CCR 1722, 1722.9, 1773, 1773.1, 1773.2, 1773.3, 1773.4, 1774, 1774.1, 1774.2, 1777, 1777.1, 1777.2) UIC	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for seal design and placment
Disposal of produced water	Infiltration while stored in evaporation ponds	Large release, potentially thousands to millions of gallons, based on the volume of produced water sent to land disposal facilities on a daily basis.	Surface soils	Localized TDS (primarily Na and Cl), minor hydrocarbons adsorbed to soil	WDR	Maintain and periodically test discharge basins to ensure they meet permitted use conditions. Evaluate groundwater conditions to assess compliance
			Shallow groundwater	Localized increase in TDS (primarily Na and Cl), hydrocarbons due to vertical migration to groundwater		
	Possible casing or well seal failure during injection into Class II UIC well	Medium to large release, hundreds to thousands of gallons, based on signficance of casing failure and time lapse prior to identification of failure and response.	Shallow and deep groundwater	Increased TDS (primarily Na and Cl) in shallow and deep groundwater in Central and East sub-areas. No expected impact in West sub-area as groundwater currently has high TDS concentrations.	UIC	Follow API standards and Company SOPs for seal installation; establish and implement QA/QC procedures for seal design and placment

Notes:

BMPs= Best Management Practices

Cl = chloride

DOGGR = Department of Conservation - Division of Oil, Gas and Geohermal Resources

Na = sodium

SOPs = standard operating procedures

SPCC = Spill Prevention, Control and Countermeasures

TDS = toal dissolved solids

TSS = total suspended solids

UIC= Underground Injection Conrol

WDR= Waste Discharge Requirements

Notes:

(a) The 100% discharge assumption corresponds to all produced water being returned to the subsurface.

(b) bbl = barrel of produced water, equivalent to 42 U.S. gallons.

(c) Untreated scenario corresponds to discharge of produced water at the average reported major cation and anion chemistry for the given oil field.

(d) 99% Evaporated scenario corresponds to the residual salt flux after salts (e.g., halite, sodium carbonate, calcite, magnesite, barite, borax) have precipitated from solution after 99% of the water volume has evaporated; estimated using the USGS's PHREEQC geochemical model.

Table 7-3: Changes in Solute Concentration (mg/L) in Fresh Groundwater Underlying Selected Oilfields, Assuming 100% Discharge[(a)]

Field	Area (acres)	Depth of Fresh Water (ft)	Produced Water Volume (bbl[b])	Treatment	Total Dissolved Solids	Sodium	Calcium	Magnes-ium	Barium	Bicarb-onate	Chloride	Sulfate	Boron
Belgian Ant	9,870	1,200	214,000	Untreated	0.2	0.07	0.002	0.001	-	0.02	0.08	0.000	0.001

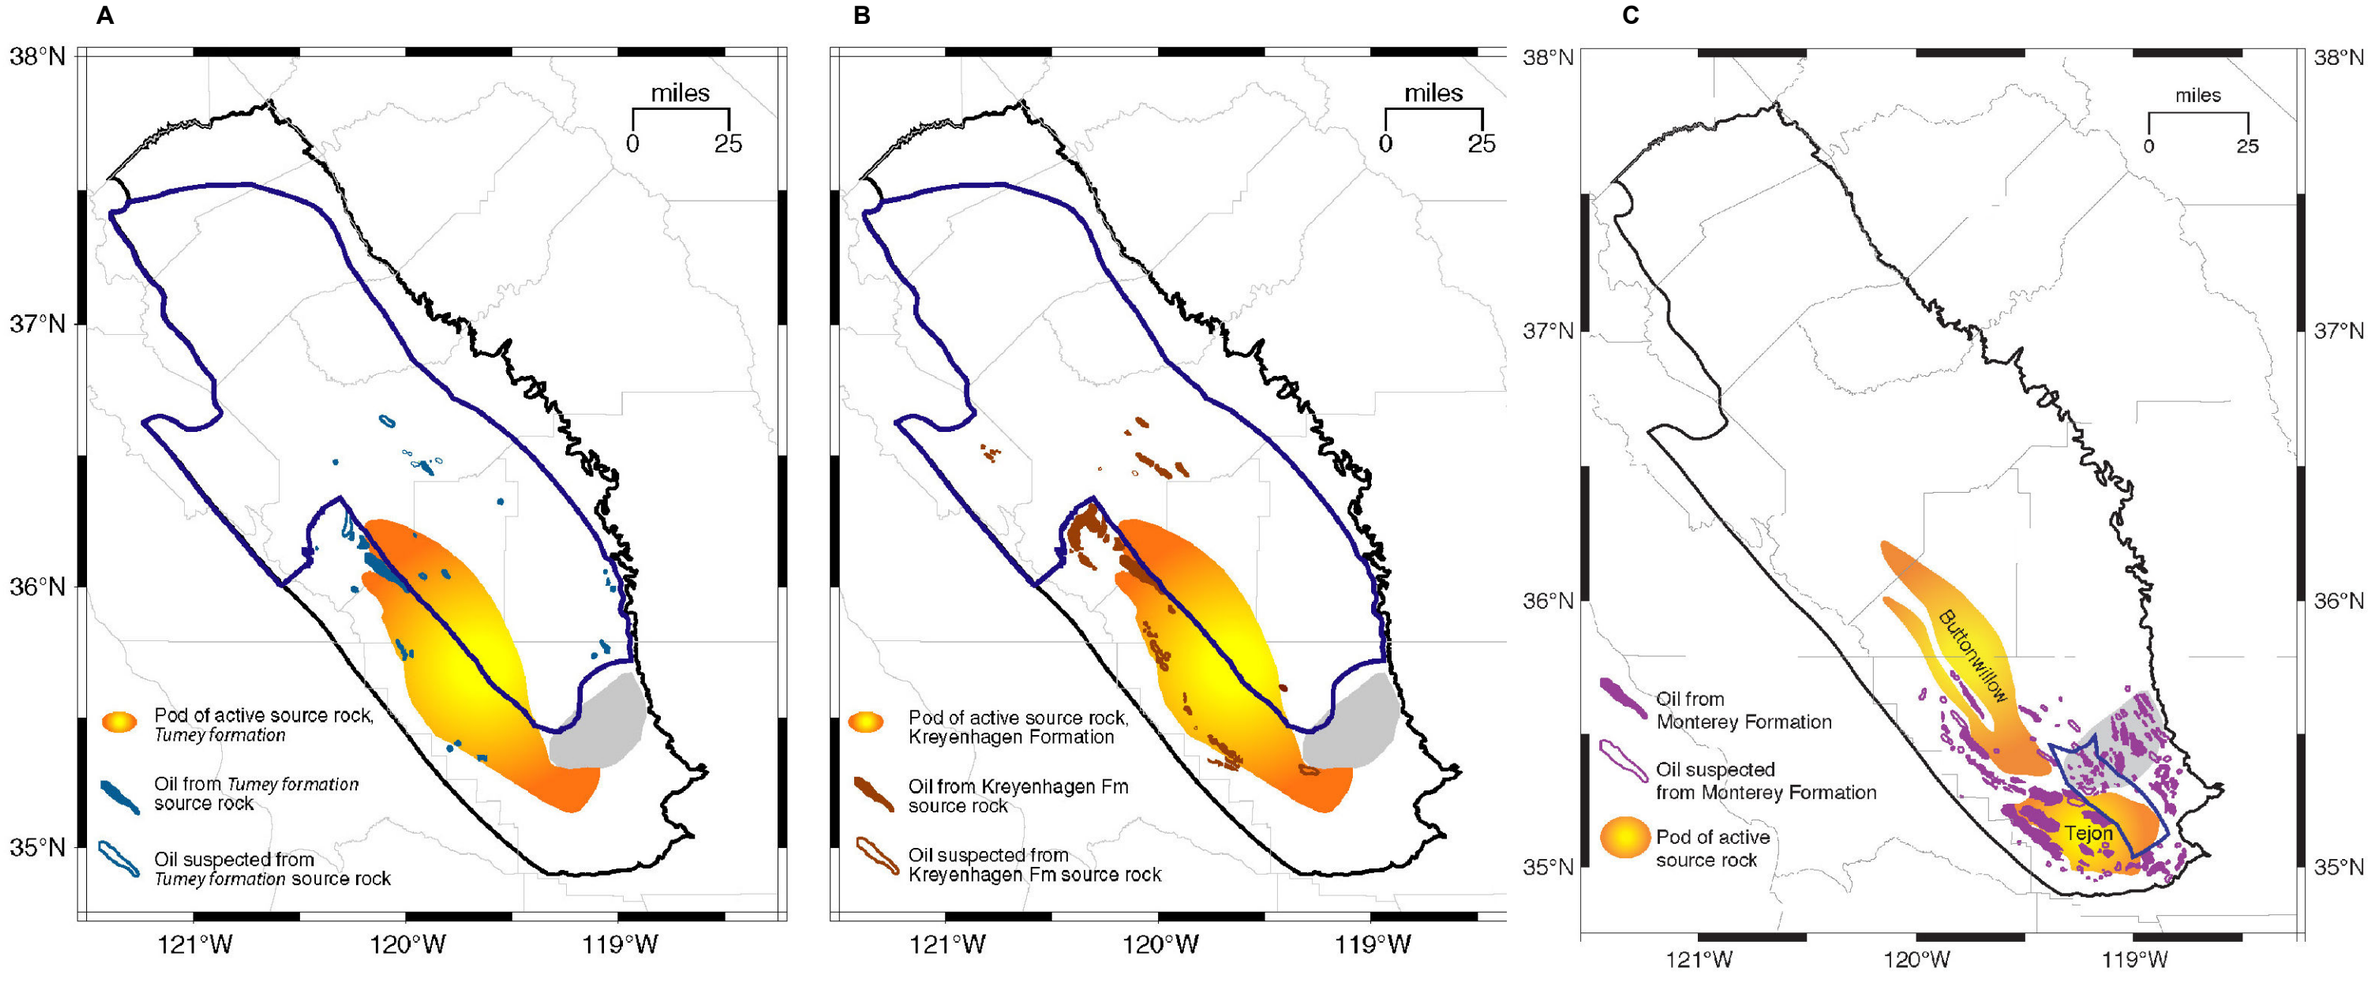
Figure 2-4



On (A) and (B), blue line shows location of North and East of Eocene West Side Fold Belt Assessment Unit with respect to the pods of active source rock of the Tumey formation (A) and Kreyenhagen Formation (B) of the Eocene Total Petroleum System (Peters et al. 2007). Because of a lack of geochemical data, the pod of active source rock for the Tumey formation is assumed to be the same as the pod of active source rock for the Kreyenhagen Formation. The bold line is the San Joaquin Basin Province boundary and thin gray lines are county boundaries. Gray shading shows the location of the Bakersfield Arch.
On (C), blue line shows location of Lower Bakersfield Arch AU with respect to the pods of active source rock of the Miocene Total Petroleum System (Peters et al. 2007). The bold line is the San Joaquin Basin Province boundary and thin gray lines are county boundaries. Gray shading shows the location of the Bakersfield Arch.

Notes:
Groundwater Beneficial Use Exemptions as defined in the Water Quality Control Plan (Basin Plan) for the Tulare Lake Basin (CA RWQCB. 2004. Water Quality Control Plan for the Tulare Lake Basin, Second Edition. California Regional Water Quality Control Board, Central Valley Region (Region 5). [Available at: http://www.waterboards.ca.gov/centralvalley/water_issues/basin_plans/index.shtml, retrieved 18 February 2014]), Table II-2:

1) Groundwater contained in the lower Transition Zone and Santa Margarita formation within 3,000 feet of the Kern Oil and Refining Company proposed injection wells in Section 25, T30S, R28E, MDB&M, is not suitable, or potentially suitable, for municipal or domestic supply (MUN).

2) Ground water contained in the basal Etchegoin formation, Chanac formation, and Santa Margarita formation within, and extending to one-quarter mile outside the administrative boundary of the Fruitvale Oil Field, as defined by the State of California, Department of Conservation, Division of Oil and Gas in Application for Primacy in the Regulation of Class II Injection Wells Under Section 1425 of the Safe Drinking Water Act, dated April 1981, is not suitable, or potentially suitable, for municipal or domestic supply (MUN). However, the upper ground water zone (ground water to a depth of 3,000 feet) retains the MUN beneficial use.

3) Ground water and spring water within 1/2 mile radius of the McKittrick Waste Treatment (formerly Liquid Waste Management) site in Section 29, T30S, R22E, MDB&M, have no beneficial uses.

Section 1: Introduction and Summary

This water supply assessment (WSA) has been prepared in support of the proposed Project that consists of an amendment to the Title 19 Kern County Zoning Ordinance focused on Chapter 19.98 (Oil and Gas Production) related to oil and gas regulations (exploration, extraction, operations, and production activities etc.) in unincorporated Kern County. The amendment of Chapter 19.98 of the Kern County Zoning Ordinance requires environmental review under the California Environmental Quality Act (CEQA). Kern County Planning and Community Development Department (Kern County) is the lead agency for the Environmental Impact Report (EIR).

1.1 Purpose

The purpose of this WSA is to describe current and future water supplies as well as water demands in the Project Area. This WSA presents the water supplies in the Project Area, including imported water, surface water, groundwater, and recycled water. Water supply sources are described in normal, single-dry, and multiple-dry years, in five-year increments from 2015 to 2035, based on existing, publicly available data. Future projections of water supplies are evaluated both for the Project Area and for the three designated oil and gas Sub-Areas, namely West, Central, and East (see Figure 1). As a counterpoint to evaluating supplies this WSA also evaluates current and future demands. Water demands are evaluated in the Project Area and the three designated Sub-Areas in normal, single-dry, and multiple-dry years, in five-year increments from 2010 to 2035, based on existing, publicly available data.

1.2 Major Findings

This WSA uses the best available information. However, many aspects of both the water supply and the water demand involve some level of uncertainty. Among the issues identified, the major data gap is related to groundwater supply and groundwater extraction. It is estimated that groundwater makes up over one-third of total water supplies for Kern County. It is not possible to track extractions as the majority of groundwater extractions are not reported. Groundwater extractions and supply in the Project Area were estimated based on calculations available in published reports. Given the uncertainty with pumping levels, groundwater pumping projections were based on the historical mean of the available records. However, annual groundwater pumping may vary widely from year to year depending on hydrologic year types.

Water supply projections from both the State Water Project (run by the Department of Water Resources) and Central Valley Project (run by the Bureau of Reclamation) also have a great deal of uncertainty. Projections used in this WSA use the most current modeling and data available. However, because 2014 was a historically dry year it is likely projections of supply from these sources will be revised by the Department of Water Resources and Reclamation. Availability of supplies may also be affected by the recently enacted Groundwater Sustainability Act. California Proposition 1, a $7.5 billion general obligation bond measure approved by California voters on November 4, 2014, will further affect supplies in the long-term by funding investments in water projects and programs as part of a statewide, comprehensive water plan for California. On-going litigation over Kern River water may also affect overall supply and/or what part of the Project Area receives the supply.

Project Area and Three Sub-Areas

K/J 1370028.01
March 2014

Figure 1

Water demands are assumed to follow historic trends. However, Governor Jerry Brown's Drought Declaration and new State Water Resources Control Board (SWRCB) regulations may reduce urban demands. New technologies may reduce the oil and gas sector's use of potable water. Changes in crop values and cropping patterns may reduce agricultural demand.

This WSA finds that surplus water is not available in the Project Area. Essentially, any new use of water is taking water away from some other user or results in groundwater overdraft. The Central Sub-Area has the greatest potential shortage. Even in an average year supplies are insufficient to meet demands both currently (2015) and into the future (2035). The Central Sub-Area also has projected shortages in a very dry year as well as a multiple-year drought. The West Sub-Area could experience shortages in a very dry year. The East Sub-Area generally has sufficient supply, but this supply cannot compensate for shortages in the other two subareas.

For the Project Area as a whole, and within each Sub-Area, agriculture represents the greatest demand, followed by urban uses, and then the oil and gas sector. The oil and gas sector reuses water that is a byproduct of hydrocarbon extraction. The use of this "produced water" significantly reduces the oil and gas sector's demand for fresh water.

There are opportunities to enhance supply or reduce demand in the Project Area, including:

- Use of agricultural processing water
- Increased use of recycled water
- Water transfers and exchanges with other regions
- Increased use of produced water in both the oil and gas sector and agricultural sector
- Conservation in all water use sectors

THIS PAGE INTENTIONALLY LEFT BLANK

Section 2: Project Area Description

The Project Area encompasses about 3,700 square miles and generally includes the San Joaquin Valley Floor portion of Kern County up to an elevation of 2,000 feet. Figure 1 shows the boundaries of the Project Area and the three oil and gas Sub-Areas (West, Central, and East) that were considered for the purpose of the WSA, based on the boundaries defined by Kern County for the EIR. For the purpose of this WSA, these two boundaries will be referred to as the Project Area and the three Sub-Areas. The Project Area boundary and Sub-Area boundaries were defined by Kern County based on generally available information regarding areas with potential or confirmed oil and gas resources.

2.1 Climate

Climate in the Project Area is characterized as an "inland Mediterranean climate" with hot and dry summers and cool winters. The climate around the San Joaquin Valley floor is prone to large diurnal fluxes due to its inland location, and is dominated by dry, hot weather throughout the summer months. The Project Area is characterized by low rainfall. The Valley floor receives average precipitation of less than 10 inches per year, most of which falls between November and April. Average temperatures are relatively high, and total evaporation exceeds total precipitation. Winter is generally mild, but an occasional freeze does occur and may cause substantial agricultural damage. Table 1 summarizes the historical range in temperatures and precipitation for the Project Area.

TABLE 1
CLIMATE ON THE SAN JOAQUIN VALLEY FLOOR IN THE KERN REGION

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Monthly Avg. ET (inches)	1.45	2.24	3.90	5.48	7.55	8.60	9.11	8.55	6.17	4.08	2.02	1.41	5.04

2.2 Land Use

Land use in the Project Area is divided among urban and rural areas. Much of the rural area is considered agricultural. Most of the Project Area's population lives within or near the incorporated areas. The largest city in the Project Area is Bakersfield (with a population of over 300,000), followed by the City of Delano (with a population of over 50,000); Shafter, and Wasco; all other cities and communities in the Project Area have populations of less than 10,000 persons. Figure 2 shows a map of the cities and communities within the Project Area.

Land uses within the unincorporated areas are governed by Kern County, and the Kern County General Plan lays out the policies and regulations governing the physical development of the lands under County jurisdiction. Agriculture is an important land use in Kern County and is vital to the local economy. Kern County is the third largest agricultural county in the state in economic value, and produces over 250 different crops, including over 30 types of fruits and

nuts, over 40 types of vegetables, over 20 field crops, lumber, nursery stock, livestock, poultry and dairy products. The total value of these agricultural products annually exceeds $3.5 billion. The average size of farms in Kern County is 1,272 acres and over 98 percent of agricultural lands are irrigated (City-data.com 2009). Figure 3 shows the crop coverage within the Project Area based on the California Department of Water Resources (DWR) land use survey of Kern County (DWR 2014a).

The County has been ranked among California's leading counties in total urbanization and loss of farmland. From 1990 to 2006, the amount of "important" farmland in Kern County decreased by 88,338 acres. Approximately one-third (approximately 29,000 acres) of this decrease was due to urban-related changes (County of Kern 2009). Increasing population raises many land use issues, including urban-rural conflicts and increased competition for resources such as water. Long-term water supply planning is important to ensuring that rural and urban economic growth can be accommodated.

In addition to agriculture, mineral and petroleum resources are fundamental parts of Kern County's economy. In fact, oil and gas properties make up close to 35 percent of the Kern County tax assessment roll (Kern County Assessor Recorder 2014).

2.3 Population

Kern County has a population of over 870,000 and is one of the fastest growing counties in California. As of 2014, Kern County was the 11th most populated county in the state and among the top 15 counties in growth by number (California Department of Finance 2014). Among the areas experiencing the greatest amount of growth within the Project Area is metropolitan Bakersfield. Recent prison construction and corresponding job openings have increased growth rates in the communities of Delano, McFarland, Taft, and Wasco. Population projections indicate that over one million people will reside in Kern County by 2030. If Highway 178 into the Kern Valley is expanded into a four-lane highway (from Bakersfield through Lake Isabella), which according to the California Department of Transportation (CalTrans), may occur in the 2015 to 2020 timeframe, population numbers could be larger than estimated (Kern Integrated Regional Water Management Plan [IRWMP] 2011).

2.4 Agencies in the Project Area

Table 2 lists the wholesale and retail water purveyors and the cities located within the Project Area. The locations of these entities are grouped by the three Sub-Areas.

Figure 2 shows the cities and communities located within the Project Area. Figure 4 shows the boundaries of the water and irrigation districts located within the Project Area and the three Sub-Areas. Water supply conditions associated with the wholesale and retail water purveyors are further described in later sections.

Section 3: Data Sources

This section briefly describes the key data sources that were used as part of the current and future projections of water supply and water demand in the Project Area.

3.1 Water Supply Data Sources

3.1.1 Tulare Lake Basin Portion of Kern County IRWMP

The Tulare Lake Basin Portion of Kern County Region (Kern Region) Integrated Regional Water Management Plan (IRWMP, Kern County IRWMP) covers the entire Project Area and consists of the portion of the Tulare Lake Basin hydrologic region that is within Kern County (Kern Integrated Regional Water Management Plan 2011). The Kern County IRWMP was developed through a collaborative process of many agencies and organizations to manage region-wide water resources and related issues. A wide-range of entities were involved in the development of the IRWMP, including wholesale and retail water purveyors, wastewater agencies, municipalities, special districts, regulatory agencies, and recreational and environmental entities.

The Kern County IRWMP provides relevant information on water resources management and issues in the Project Area that was used in support of the water supply analyses presented in this WSA.

3.1.2 Poso Creek IRWMP

The Poso Creek IRWMP was prepared for the northerly portion of the Kern County and southerly portion of Tulare County (Poso Creek Integrated Regional Water Management Plan 2007; updated in 2014). The Poso Creek IRWMP includes Semitropic Water Storage District (WSD), Cawelo Water District (WD), Delano-Earlimart Irrigation District (ID), Kern-Tulare WD, North Kern WSD, Shafter-Wasco ID, and North West Kern Resource Conservation District (RCD). The purpose of this IRWMP is to provide a framework for coordinating groundwater and surface water management activities and implementing mitigation measures necessary to meet the objectives.

The Kern County IRWMP overlaps the Poso Creek IRWMP. Several entities involved in the development of the Poso Creek IRWMP were also involved in the Kern IRWMP, as presented in Table 2.

3.1.3 State Water Project Draft Delivery Reliability Report

The DWR State Water Project (SWP) Final 2013 Delivery Reliability Report (Final DRR), released in December 2014, includes the most recent published information available by DWR for SWP supply delivery reliability (DWR 2014d); the next update is expected to be released in late spring 2015. Future projections of SWP water supply within the Project Area were estimated based on DWR's projected SWP deliveries as reported in the 2013 Final DRR. This Final DRR updates estimated water delivery by the SWP for current and future conditions through 2035 for a range of hydrologic years. The 2013 Final DRR is the most recent update, and identifies several factors that have the potential to affect the availability and reliability of SWP supplies. It is considered applicable for forecasting SWP supply reliability from future

anticipated SWP operations for the purpose of this water supply assessment as it is deemed per a legal settlement agreement to be the best available information concerning SWP deliveries.

3.1.4 Department of Water Resources California's Groundwater – Bulletin 118

DWR Bulletin 118 (DWR 2003) was used as a source to characterize groundwater conditions in the Project Area, including the subsurface hydrogeology, water bearing formations, and groundwater recharge. The next update to this document is expected to be available in 2015.

3.1.5 2010 Urban Water Management Plans

Current and future projections of water supply were obtained from publicly-available 2010 Urban Water Management Plans (UWMPs). Available 2010 UWMPs include the following: California Water Service Company, East Niles Community Services District, Kern County Water Agency (KCWA) Improvement District No.4 (ID4), North of the River Municipal Water District (MWD), Oildale Mutual Water Company (MWC), Vaughn Water Company (WC), West Kern Water District, City of Bakersfield, City of Delano, City of Shafter, and City of Wasco.

3.1.6 Oilfield Produced Water

Projections of oilfield produced water were based on data from Cawelo Water District. Cawelo Water District has agreements with Chevron USA, Schaefer Oil, and Valley Waste Disposal to receive oilfield produced water. Oilfield produced water received by Cawelo Water District must be in conformance with the Central Valley Regional Water Quality Control Board waste discharge permits. In 2012 Cawelo Water District reports receiving 37,107 AF of oilfield produced water (Cawelo Water District 2014). Hathaway LLC reports delivering 1,551 AFY to agriculture (personal communication Chad Hathaway, Hathaway LLC provided to Jonathan Lilien, Chevron Inc. August 18, 2015). As described further in section 5, year 2012 is considered a representative year for oil and gas operations.

3.2 Water Demand Data Sources

The main data sources that were used as part of the current and future projections of water demands in the Project Area are listed below. Some of these data sources are the same as used for water supply projections described earlier. Below is a brief description these sources:

- Division of Oil, Gas, and Geothermal Resources (DOGGR) database information was compiled and analyzed to estimate the historical and current water use by oil and gas activities in the Project Area. Data also included records of produced water production and wastewater injected during oil and gas operations.

- Kern Council of Governments 2011 Regional Transportation Plan Draft EIR was used to estimate population growth and water demand growth for areas that did not have 2035 water demand projections.

- Tulare Lake Basin Portion of Kern County IRWMP and Poso Creek IRWMP supplemented data in support of the current and future water supply projections in the Project Area.

- Oil and gas water demand projections developed in Section 5 of this WSA.

In addition to the above sources, water management planning documents including Urban Water Management Plans (UWMPs), Agricultural Water Management Plans (AWMPs), and Groundwater Management Plans (GWMPs) were collected and reviewed for 52 different water agencies in the Project Area. The purpose of the review was to identify which agencies accounted for oil and gas sector water use in their planning. The results of the review are summarized in Tables 3 and 4 below.

TABLE 3
AGENCIES IN THE PROJECT AREA WITH URBAN WATER MANAGEMENT PLANS AND AGRICULTURAL WATER MANAGEMENT PLANS WITH INFORMATION ON OIL AND GAS SECTOR WATER USE

UWMP/AWMP	Discuss Water Provided to Oil & Gas?	Quantity (AFY)

Notes: 1.Contract amount is 5,578 AFY but only use 1,600 AFY.

Section 4: Water Supplies

The paragraphs below describe the major water supply sources available in the Project Area. In the Project Area supply sources are used conjunctively to meet demands.

4.1 Kern County Groundwater Subbasin

The Kern County Subbasin (5-22.14) of the San Joaquin Valley Groundwater Basin, covering approximately 1,945,000 acres (3,040 square miles), is the one large basin located within the Project Area. Figure 5 shows the boundary of the Kern County Subbasin and other groundwater basins in the vicinity of the Project Area, including the Walker Basin Creek Valley to the east; Cummings Valley and Brite Valley to the southeast; Cuddy Ranch Area, Cuddy Valley, Mil Potrero Area, and Castac Valley to the south; Cuyama Valley to the southwest; and Carrizo Plain to the west (DWR 2003). Principal rivers and streams in the Kern County Subbasin include the Kern River and Poso Creek.

4.1.1 Subsurface Hydrogeology

The aquifers are generally thick in the San Joaquin Valley subbasins, with groundwater wells commonly exceeding 1,000 feet in depth (DWR 2003). The maximum thickness of freshwater-bearing deposits (4,400 feet) occurs at the southern end of the San Joaquin Valley. Typical well yields in the San Joaquin Valley range from 300 gallons per minute (gpm) to 2,000 gpm with yields of 4,000 gpm possible.

Active faults that affect groundwater movement include the Edison, Pond-Poso, and White Wolf faults. Other barriers to groundwater movement include fold structures such as the Elk Hills and Buena Vista Hills, angular unconformities, and contacts with crystalline and consolidated sedimentary rocks at the subbasin margins (DWR 1977). The Corcoran Clay, a Pleistocene lacustrine deposit, significantly impedes vertical groundwater movement where present (DWR 2003).

4.1.2 Water Bearing Formations

Sediments that comprise shallow to intermediate depth water-bearing deposits in the groundwater subbasin are primarily continental deposits of Tertiary and Quaternary age. From oldest to youngest the deposits include the Olcese and Santa Margarita Formations; the Tulare Formation (western subbasin) and its eastern subbasin equivalent, the Kern River Formation; older alluvium/stream deposits; and younger alluvium and flood basin deposits.

Specific yield values for the unconfined aquifer (Tulare and Kern River Formations and overlying alluvium) range from 5.3 to 19.6 percent and average 11.8 percent for the interval from surface to 300 feet below grade and average 12.4 percent representing an interval thickness of 175 to 2,900 feet. The greatest thickness of unconfined aquifer occurs along the eastern subbasin margin. The highest specific yield values are associated with sediments of the Kern River Fan west of Bakersfield.

Groundwater Basins in the Project Area

K/J 1370028.01
March 2014

Figure 5

Path: \\aims4_data\Projects\KernOilGasEIR\Events\20140312_WS_Report\Fig_05_GroundwaterBasins.mxd

The Tulare Formation includes the Corcoran Clay Member, which is present in the subsurface from the Kern River channel outlet in the west through the Central and much of the East Sub-Area at depths of 300 to 650 feet (Croft 1972). Groundwater beneath the Corcoran Clay is confined. The Kern River Formation includes from 500 to 2,000 feet of poorly sorted, lenticular deposits of clay, silt, sand, and gravel derived from the Sierra Nevada. Both units are moderately to highly permeable and yield moderate to large quantities of water to wells (Hilton and others 1963).

Older alluvium/stream deposits are moderately to highly permeable and yield large quantities of water to wells (Hilton and others 1963; Wood and Davis 1959; Wood and Dale 1964). This sedimentary unit is often indistinguishable from the Tulare and Kern Formations below and together with these underlying formations, forms the principal aquifer body in the Kern County Subbasin. Younger alluvium/flood basin deposits are difficult to distinguish from underlying fine-grained older alluvium and the total thickness of both units may be as much as 1,000 feet (Wood and Dale 1964).

4.1.3 Recharge

Natural recharge occurs primarily in the East and Central Sub-Area and is from stream seepage along the eastern Kern County Subbasin and the Kern River. Average precipitation values range from 5 inches at the subbasin interior to 9 to 13 inches at the subbasin margins to the east, south, and west. Recharge of applied irrigation water, however, is the largest contributor (DWR 1995).

Extensive groundwater recharge and conjunctive use programs are in place in the subbasin, where water districts have recharged several million acre-feet (MAF) for future use. Groundwater recharge programs are intended to ensure that groundwater will continue to be a viable water supply in the future. However, they are highly dependent on the availability of local and imported surface supplies, which serve as sources of recharge water.

4.1.4 Groundwater Levels

Groundwater levels in different portions of the Kern County Subbasin are quite variable. Figure 6 displays historical water level hydrographs for four key areas, based on the data available from KCWA (KCWA 2011a): in the Central Sub-Area the Pond-Poso area and City of Shafter/Rosedale-Rio Bravo WSD area; in the East Sub-Area southwest Bakersfield and the Arvin-Edison WSD area. Each hydrograph represents water levels for a pair of wells – one well is used to monitor shallow groundwater levels, while the other is used to monitor deep groundwater levels (KCWA 2011a).

Overall, the hydrographs demonstrate the variability of groundwater levels in response to hydrologic conditions, with levels declining during dry periods and rebounding during wet periods. In the Pond-Poso area (Central Sub-Area) the unconfined well reflects an upward trend since the 1976-1977 drought, attributed to Central Valley Project (CVP) surface water deliveries via the Friant-Kern Canal. During the 1990-1992 drought there was an increased dependence on groundwater, which is reflected by the decline in water levels during that period. The hydrograph for the confined well shows a variable pattern of water levels from year to year (KCWA 2011a).

Figure 6

The hydrographs for the City of Shafter/Rosedale-Rio Bravo WSD (Central Sub-Area) area show a long-term decline in water levels. These wells are situated close to the Kern River and Rosedale-Rio WSD recharge facilities; thus, the hydrographs show rapid rises in water levels during wet periods (e.g., 1978-1886 and 1993-1998) and declines during drought (e.g., 1987-1992). Recent groundwater level data suggests that no confined aquifer exists east and south of this location, as reflected with annual groundwater levels and fluctuations that are consistent between deep and shallow wells (KCWA 2011a).

The southwest Bakersfield hydrographs (East Sub-Area) show continual declines until 1978. The wet period of 1978-1986 appears as a rise in groundwater levels. The 1987-1992 drought shows another period of decline. Water levels have declined since the beginning of 1999. Similar groundwater levels in both the shallow and deep wells over a long period of time suggest that a confined aquifer may not exist in this area (KCWA 2011a).

The delivery of CVP water to Arvin-Edison WSD (East Sub-Area) in the mid-1970s caused groundwater levels to rise, as seen in the shallow well hydrograph. During the 1976-1977 and 1987-1992 droughts, groundwater levels declined and during recent wet years, water levels rose. The deep well may be in a confined aquifer, since it has shown annual variability in groundwater levels more consistent with the behavior of a confined aquifer. The deep well shows a slight downward trend from 1998 until 2005 when wet conditions returned. With the recurrence of dry hydrologic conditions in 2007, water levels began to drop again. The large difference in groundwater levels between the two wells also suggests that two or more aquifers may exist in this area (KCWA 2011a).

4.1.5 Groundwater Storage

Total water in storage of the subbasin is estimated to be 40 to 50 MAF and dewatered aquifer storage to be 10,000,000 AF (Fryer 2002). It appears that these calculations consider areas of the subbasin that are known to overlie useable groundwater, which are reported to be about 1,000,000 acres (DWR 2003).

4.2 Imported and Local Surface Water Sources

Surface water sources include both imported supplies and local supplies. Sources of imported supplies include the CVP and SWP. CVP water from the Friant Division is conveyed to the Project Area through the Friant-Kern Canal, and SWP water is conveyed through the California Aqueduct. Figure 7 schematically shows the major surface water features and infrastructure system. The Kern River is the primary source of local supply; however, Poso Creek and other minor streams contribute to the locally-available supplies from time to time.

On a long-term average, local surface water supplies (Kern River and other local water) have comprised a little less than one-third of the total water supplies in the Project Area, with the remainder made up of SWP and CVP imported water and groundwater pumping. Kern River water is entirely allocated among parties with long-standing water rights and additional water beyond these allocations is not anticipated.

Figure 7

Path: \\aims4_data\Projects\KernOilGasEIR\Events\20140312_WS_Report\Fig_07_MajorSurfaceWaterFeatures.mxd

SWP and CVP supplies have provided variable amounts of supplies to the Project Area. However, over time, regulatory decisions and court decisions have impacted the availability of imported water supplies in the Project Area. In recent years, environmental and water quality issues surrounding the Sacramento-San Joaquin River Delta (Delta) and the San Joaquin River have limited the ability to export water south of the Delta and into the Friant Division, which has reduced the reliability of SWP and CVP-supplies available to the Project Area.

Based on historical records for the San Joaquin Valley portion of the Kern County, on average groundwater accounts for 37 percent of the total water supply. However, during dry years, it is estimated to be about 60 percent. During the dry years of 2007 and 2008, groundwater pumping made up approximately 69 percent of total supply while it declined to less than 10 percent during the recent wet year of 2011 (KCWA 2011a). During the drought years of 2012-2014 it has transpired that portions of the Project Area have not received any imported water and thus are totally dependent on groundwater. This has negatively impacted groundwater levels in the Project Area.

In the Project Area, irrigated lands rely on the conjunctive use of surface water and groundwater to satisfy irrigation water requirements. While the total irrigated acreage has remained fairly stable over the last 25 years, when surface water supplies are limited, groundwater is used to meet irrigation demand in lands that are largely overlying the usable groundwater basin. Those areas that do not overlie groundwater (mainly in the West Subarea), are almost completely reliant on imported water supplies.

As the main sources of surface water supplies (SWP, CVP, and Kern River) are anticipated to experience reduced reliability, reliance on groundwater pumping in the Project Area will increase over time, with negative impacts to the aquifers. Reduction in water supply reliability is the major water resources management issue for the Project Area.

4.3 Current and Future Water Supplies

This section describes current and future water supplies for the Project Area including imported water, local surface water, groundwater, and recycled water. Water supplies are described both by the Project Area and the three Sub-Areas. Water supplies utilized in the Project Area are the SWP via the California Aqueduct, the CVP via the Friant-Kern Canal, local surface supplies from the Kern River and other local streams, the Kern County Subbasin of the San Joaquin Valley Groundwater Basin and recycled water.

4.3.1 Imported Water Supply from State Water Project

The SWP is the largest state-built, multi-purpose water project in the country. Today, the SWP includes 33 storage facilities, 21 reservoirs and lakes, 24 pumping and generating plants, four hydroelectric power plants, and approximately 660 miles of aqueducts. SWP facilities and deliveries are maintained and operated by DWR. The primary water source for the SWP is the Feather River, a tributary of the Sacramento River. Storage released from Oroville Dam on the Feather River flows down natural river channels to the Delta. While some SWP supplies are pumped from the northern Delta into the North Bay Aqueduct, the vast majority of SWP supplies are pumped from the southern Delta into the 444-mile-long California Aqueduct (Figure 7).

Many of the agencies in the Project Area receive SWP water from turnouts located on the California Aqueduct, and a few also receive SWP water from the Coastal Branch of the California Aqueduct. Several centrally located water districts in the Project Area lie to the east of the California Aqueduct and receive shares of SWP water through the Cross Valley Canal

(CVC), which is also used for many operational exchanges and groundwater banking (Figure 7). Arvin-Edison WSD has a bidirectional intertie to the California Aqueduct at the end of its canal system to facilitate various water management programs.

In the early 1960s, DWR began entering into individual SWP Water Supply Contracts with urban and agricultural water supply agencies located throughout northern, central, and southern California for SWP water supplies. Within the Project Area, KCWA is one of 29 water agencies (commonly referred to as "contractors") that have a Water Supply Contract with DWR for the importation of SWP water (in this case, to Kern County). Individual agencies within Kern County then contracted with KCWA for an imported water supply. Each SWP contractor's SWP Water Supply Contract contains a "Table A," which lists the maximum amount of water an agency may request each year throughout the life of the contract. Table A is used in determining each contractor's proportionate share, or "allocation," of the total SWP water supply DWR determines to be available each year. The total planned annual delivery capability of the SWP and the sum of all contractors' maximum Table A amounts was originally 4.23 million AFY. The initial SWP facilities were designed to meet contractors' water demands in the early years of the SWP, with the construction of additional diversions of coastal rivers, a Peripheral Canal and storage facilities planned as demands increased. However, the Wild and Scenic Rivers Act blocked diversions from coastal rivers, the Peripheral Canal was not authorized by voters, and essentially no additional SWP storage facilities have been constructed since the early 1970s. SWP conveyance facilities were generally designed and have been constructed to deliver maximum Table A amounts to all contractors. After the permanent retirement of some Table A amount by two agricultural contractors in 1996, the maximum Table A amounts of all SWP contractors now total about 4.17 MAF. Currently, KCWA's Table A amount is 982,730 AFY. Table 5 presents the maximum Table A amounts for the individual agencies who have contracts with KWCA to receive SWP water (DWR 2014d). As presented in Table 5, contract amounts are specifically designated for agricultural and municipal and industrial (M&I) use.

TABLE 5
KERN COUNTY WATER AGENCY AND MEMBER UNIT SWP CONTRACT AMOUNTS

District/Agency	Agricultural Contract Amount (AF)	M&I Contract Amount (AF)	Total (AF)
Belridge WSD	121,508		121,508
Berrenda Mesa WD	92,600		92,600

Wheeler Ridge-Maricopa WSD	197,088		197,088
Total	**863,730**	**119,000**	**982,730**

Note: (a) Partially outside of Project Area
(b) Outside of Project Area.

Dudley Ridge WD, located in southernmost Kings County just north of the Project Area, also has a SWP contract. Dudley Ridge WD is a small agricultural water district and lands within the Dudley Ridge WD's service area are mainly agricultural. While some of the landowners within the Dudley Ridge WD transfer or exchange their water with neighboring agricultural growers in Kern County, since the Dudley Ridge WD does not regularly deliver water outside of its service area, its SWP water supply was not considered as a firm water supply for the future SWP water supply projections to the Project Area. It is also noteworthy to mention that any long-term water exchanges with Dudley Ridge WD and agencies within the Project Area would be captured as part of water supplies projected for those agencies within the Project Area.

4.3.1.1 State Water Project Future Supply Reliability

While SWP Table A identifies the maximum annual amount of water an SWP contractor may request, the amount of SWP water actually available and allocated to SWP contractors each year is dependent on a number of factors and can vary significantly from year to year. The primary factors affecting SWP supply availability include hydrology, the amount of water in SWP storage at the beginning of the year, regulatory/biological and operational constraints, and the total amount of water requested by SWP contractors. Urban SWP contractors' requests for SWP water, which were low in the early years of the SWP, have been steadily increasing over time, which increases the competition for limited SWP dry-year supplies. Table 6 presents historical total SWP deliveries to KCWA member units and M&I purveyors.

TABLE 6
HISTORICAL TOTAL SWP DELIVERIES TO KCWA M&I PURVEYORS AND AGRICULTURAL MEMBER UNITS

Year	KCWA Deliveries (AF)
2003	919,424
2004	771,898

2007	716,612
2008	279,334
2009	380,337
2010	469,319
2011	1,083,667
2012	584,589

Sources: DWR 2013 Final Delivery Reliability Report Draft (December 2014d). Data includes deliveries of Table A Amount, Article 21, carryover, and turn back pools.

DWR issued its latest SWP Delivery Reliability Report in December 2014. The report assists SWP contractors in assessing the reliability of the SWP component of their overall supplies. DWR released the first report in 2003 and updated this report most recently in December 2014 (DWR 2014d). In these updates, DWR provides a recommended set of analyses for SWP contractors to use in water supply planning. Recent regulatory and judicial decisions related to endangered species in the Delta have further impacted the reliability of the SWP, due to increased restrictions on pumping from the south Delta. These impacts on the SWP were described in several of the recent Reliability Reports (DWR 2009, 2011a, 2013). It should be noted that the 2013 Delivery Reliability Report represents the best available data as of this Technical Memorandum.

The SWP delivery percentages identified by DWR (2014d) were used as the basis for estimating the SWP supplies projected to be available for delivery to the Project Area. The projected allocation of Table A water for each year was estimated for the 1922-2003 hydrologic period. To determine the projected availability of this supply to the Project Area, these allocations, expressed as percentage, were applied to the maximum Table A amount for KCWA. For the purpose of the WSA, the existing (2013) conditions are assumed to be representative of 2015 and the future (2033) conditions were assumed to be representative of 2020 through 2035 conditions.

Table 7 shows SWP supplies projected to be available to KCWA in average/normal years (based on the average delivery over the study's historical hydrologic period from 1921-2003). Table 7 also summarizes estimated SWP supply availability in a single-dry year (based on a repeat of the worst-case historic hydrologic conditions of 1977) and over a multiple dry year period (based on a repeat of the worst-case historic four-year drought of 1931-1934). The 2013 analyses indicate that the SWP could deliver 58 to 62 percent of the KCWA Table A amount on a long-term average basis. The 2013 analyses also projected that SWP deliveries during multiple-dry year periods could average about 31 percent of the KCWA Table A amount and could possibly be as low as 11 to 12 percent during an unusually single-dry year.

TABLE 7
KCWA WHOLESALE SUPPLY RELIABILITY (AF)

Wholesaler (Supply Source)	2015	2020	2025	2030	2035[b]

KCWA Table A Supply	293,700	293,700	293,700	293,700	293,700
% of Table A Amount[a]	31%	31%	31%	31%	31%

Note: (a) Percentages of Table A amount based on DWR 2013 SWP Final Delivery Reliability Report. Assumes Table A contract amount of 982,730 AFY. The majority of Tejon-Castac WD is located outside of the Project Area; thus their contract amount of 5,278 AF was excluded from future projections. A small portion of Tehachapi-Cummings County Water District (about 5%) is within the Project Area; thus, 5% of its contract amount (equivalent to 1,035 AFY) was included for future projections.

(b) The SWP Final Delivery Reliability Report contains projections through 2033. For the purposes of this WSA 2035 is assumed to be the same as 2033.

Table 8 presents the SWP supply projections breakdown by the three Sub-Areas in average/normal years, a single-dry year, and multiple dry years. The future projections of the SWP supplies by the Sub-Areas were based on the assumption that the percent of Table A amount (both Agricultural and M&I) of the individual districts that have contracts with KCWA is

distributed by each Sub-Area proportional to each district's service area within each Sub-Area[1]. This should be considered only an approximation, to represent how future SWP supply projections might vary between the three Sub-Areas, which are not subdivisions of the KCWA service area.

TABLE 8
KCWA WHOLESALE SUPPLY RELIABILITY BY SUB-AREAS (AF)

East	46,000	46,000	46,000	46,000	46,000
West	157,300	157,300	157,300	157,300	157,300
Total	***293,700***	***293,700***	***293,700***	***293,700***	***293,700***
% of Table A Amount	31%	31%	31%	31%	31%

Note: (a) The majority of Tejon Castac WD is located outside of the Project Area; thus its contract amount of 5,278 AF was excluded from future projections. A small portion of Tehachapi-Cummings County Water District (about 5%) is within the Project Area; thus, 5% of its contract amount (equivalent to 1,035 AFY) was included for future projections.

(b) The SWP Final Delivery Reliability Report only has projections through 2033. For the purposes of this WSA 2035 and 2040 are assumed to be the same as 2033.

While the primary supply of water available from the SWP is allocated Table A supply, SWP supplies in addition to Table A water are periodically available, including "Article 21" water, Turnback Pool water, and DWR dry-year purchases. However, the availability of these sources is uncertain and dependent on hydrology; therefore, these sources are not included as a firm supply as part of the overall WSA. They are briefly described but not evaluated quantitatively in this WSA.

Article 21 water (which refers to the SWP contract provision defining this supply) is water that may be made available by DWR when excess flows are available in the Delta (i.e., when Delta outflow requirements have been met, SWP storage south of the Delta is full, and conveyance capacity is available beyond that being used for SWP operations and delivery of allocated and scheduled Table A supplies). Article 21 water is made available on an unscheduled and

[1] The geographic location and the purposes for which water from the SWP can be used are prescribed by water contracts with the California Department of Water Resources. To use water outside the place of use specified by a water supply contract requires approval by the water supply entity (DWR) as well as the State Water Resources Control Board. The water supply contracts also have some provisions as to the purpose of the types of use. This water supply assessment describes all supplies available in the Project Area but the reader should be aware that these water supplies are not available throughout the Project Area or subarea and that not all water supplies can be used for all purposes. The terms of the contracts can be modified, but only after appropriate review by the water supply entity following completion of contractually-required administrative protocols and necessary environmental documentation.

interruptible basis and is typically available only in average to wet years, generally only for a limited time in the late winter. However, recent regulatory and judicial decisions will have significant impacts on the future availability of Article 21 water, since excess flows that normally make up the bulk of this supply may now be used to meet new flow requirements for Delta fish species.

The Turnback Pool is a program wherein contractors with allocated Table A supplies in excess of their service area needs in a given year may turn back that excess supply for purchase by other contractors that need additional supplies that year. The Turnback Pool can make water available in all types of hydrologic conditions, although generally less excess water is turned back in dry years. As urban contractor demands have increased through time, the amount of water turned back and available for purchase has diminished.

In critically dry years, DWR has formed Dry Year Water Purchase Programs for contractors needing additional supplies. Through these programs, water is purchased by DWR from willing sellers in areas that have available supplies and is then sold by DWR to contractors willing to purchase those supplies.

4.3.2 Imported Water Supply from the Central Valley Project

The CVP is a set of federal facilities that extend generally from north of Redding to areas near Bakersfield, as well as the South Bay Area. The CVP encompasses two of California's largest river systems, the Sacramento River, which flows southward toward the Delta and the San Joaquin River, which flows north into the Delta. Friant Dam stores San Joaquin River flows in Millerton Lake and diverts this water southward through the Friant-Kern Canal (and north in the Madera Canal, though that facility does not serve the Project Area). The Friant-Kern Canal is 151.8 miles long and carries water south from Millerton Lake just northeast of Fresno and terminates into the Kern River infrastructure complex in southwest Bakersfield (Figure 7). The Friant-Kern Canal has a maximum capacity of 5,000 cubic feet per second (cfs), which decreases to 2,000 cfs at its terminus. Deliveries are dependent upon Class 1 (firm) and Class 2 (non-firm, hydrology dependent) contract percent allocations determined by the U.S. Bureau of Reclamation (USBR), however the USBR may also provide surplus water (Section 215 contracts) to non-long term contractors. An average of 318,877 AF of CVP water is delivered through the Friant-Kern Canal annually to the Project Area for agricultural and municipal and irrigation uses. Table 9 provides a summary of the historical deliveries to the Project Area.

The CVP contractors in the Project Area include Arvin-Edison WSD, Delano-Earlimart ID, Kern-Tulare WD, Shafter-Wasco ID, and Southern San Joaquin WSD. Exchanges have allowed non-CVP contractors (KCWA, Kern Delta WD, North Kern WSD, Rosedale-Rio Bravo WSD, and Semitropic WSD) to receive water from the CVP, as presented in Table 9. Since 2003, deliveries of CVP water to the districts within the Project Area have ranged from 260,000 AF (2007) to 800,000 (2005), as presented in Table 9.

Through various agreements, at times the California Aqueduct can deliver CVP supplies from the Delta, which are typically sold to districts with California Aqueduct access or exchanged with Friant districts such as Arvin-Edison WSD. For example, Arvin-Edison WSD's Friant water can be delivered to upstream Friant reaches while Arvin-Edison WSD takes delivery of SWP supplies delivered via the California Aqueduct and/or the Cross Valley Canal.

Dudley Ridge WD, located to the north of the Project Area, also has a CVP contract. Landowners within the Dudley Ridge WD can transfer or exchange their water with neighboring agricultural growers in the Kern County. However, since the Dudley Ridge WD does not

regularly deliver water outside of its service area, its CVP water supply was not considered as a firm water supply as part of the future CVP water supply projections to the Project Area. It is also noteworthy to mention that any long-term water exchanges with Dudley Ridge WD and agencies within the Project Area would be captured as part of water supplies projected for those agencies.

4.3.2.1 Central Valley Project Future Supply Reliability

Future CVP supplies in the Project Area are subject to an ongoing restoration effort on the San Joaquin River. The restoration effort is a direct result of a Settlement reached in September 2006 (after an 18-year lawsuit) by the U.S. Departments of the Interior and Commerce, the Natural Resources Defense Council, and the Friant Water Users Authority (now Friant Water Authority), to provide sufficient fish habitat in the San Joaquin River below Friant Dam. The Settlement received Federal court approval in October 2006 and required specific legislation, which passed in 2009. With the 2006 Settlement, some of the flows that historically would have been diverted to CVP Friant contractors will (in the future) be discharged to the river channel below Friant Dam (Poso Creek IRWMP 2014).

Table 10 presents the tentative release schedule through February 2014. As of February 1, 2014, flows released from Friant Dam were decreased to 360 cfs to begin ceasing restoration flows due to the critical low water year beginning March 1, 2014. Unless conditions improve, the Program will not receive any restoration flows until March 2015.

TABLE 10
TENTATIVE INTERIM FLOW RELEASE SCHEDULE FOR FRIANT DAM

Interim Flow Start Date / Duration	Estimated Riparian Release (cfs)	Estimated Interim Flow Release (cfs)	Total Release from Friant Dam (cfs)
June 10 – June 30	190	160	350
July 1 – August 31	230	120	350
September 1 – September 30	210	140	350
October 1 – October 31	160	190	350
November 1 – November 10	130	570	700
November 11 – December 31	120	230	350
January 1 – February 28, 2014	100	250	350

Note: This represents the release schedule at the time of this WSA preparation. The table is subject to change and the release schedule for flows after February 2014 has not been determined at this time. Future CVP supply forecasts reflect what is currently best known about the flow release schedule from Friant Dam.

Source :USBR San Joaquin River Restoration Program.

Full Restoration Flows starting in 2014 will generally range from 350 cfs to over 4,000 cfs, depending on hydrology and time of year, with reduced flows in critically dry years. Total Restoration Flow releases in excess of current water rights requirements as defined in the Settlement will range from approximately 71,000 AF in critical dry years (except a repeat of 1977 when there would be no Restoration Flow releases) to approximately 556,000 AF (San Joaquin River Restoration Program 2009*).* The Interim and Restoration flows will have a priority over existing contracts.

Interim and Restoration flows will result in reductions to water supply deliveries to CVP Friant Division contractors. Depending on which assumptions are used regarding use of buffer flows and reductions in Section 215 water (surplus flows), modeling results based on historical hydrology indicate that total annual deliveries to the Friant Division water service area during the Interim Flow period would be reduced by approximately 175,000 to over 200,000 AF on average, corresponding to an approximate 13 to 15 percent reduction in average annual deliveries from Friant. These flows, however, could potentially be recaptured and recirculated by CVP Friant Division contractors downstream from Friant

Dam, such as at existing CVP and SWP export facilities, subject to environmental and other regulations and no material adverse water supply impacts to third parties.

These flows could affect the future flows to the Project Area provided in Tables 11 and 12. Arvin-Edison WSD, has estimated that impacts to its CVP supplies will average 30,000 to 40,000 AFY. Additionally, it has been estimated that CVP supplies to Kern County will be further reduced by an average of 30,000 to 40,000 AFY due to reductions in Section 215 water. These averages assume full Restoration flows, which have been temporarily reduced due to capacity restraints and seepage impacts. In the future, this impact could be reduced by proposed mitigation measures.

Future deliveries of the CVP water to the agencies in the Project Area were evaluated based on Class 1 (firm) supplies. As a conservative approach, Class 2 supplies are not accounted for as part of the future supply projections since they are not "firm" supplies. The future reliability of the CVP supplies was based on the analysis conducted during the development of the 2006 San Joaquin River Settlement Agreement.

Hydrologic modeling of the 1922-1994 period was conducted during the development of the settlement to evaluate the terms of the settlement and to help estimate the water supply expected to be available during various hydrologic conditions (Poso Creek IRWMP 2014). This modeling of post-settlement operations was used as the basis for projections of future CVP-Friant supplies of Class 1 water. According to the 2006 San Joaquin River Post-Settlement Conditions, water year types were developed and simulated for the contracts in the Friant Division of the CVP.

To determine the projected availability of Class 1 water supply to the Project Area, the Class 1 percent allocations were simply applied to the Class 1 contract amounts for the CVP-Friant contractors in the Project Area. This results in a projected long-term average availability of 305,600 AFY. Table 11 summarizes the CVP water deliveries allocated to the five agencies that have CVP contracts for agricultural use and illustrates the reduction in reliability of these supplies under the San Joaquin River Settlement. Based on modeling, the CVP could deliver 91 percent of Class 1 water on a long-term average basis. CVP deliveries could average about 23 percent during a single-dry year (based on a repeat of the worst-case historic hydrologic conditions of 1977) and about 68 percent during multiple-dry year periods (based on a repeat of the worst-case historic four-year drought of 1931-1934).

Overall, future CVP deliveries are anticipated to be below the average historical deliveries. Due to the San Joaquin River Restoration Program (see Table 11 below), Friant Division contractors as well as Section 215 contract water available to Kern Region are expected to experience a reduction in deliveries.

TABLE 11
PROJECTED CENTRAL VALLEY PROJECT SUPPLY DELIVERIES (AF)

CVP Water Supply Reliability	Delano – Earlimart ID	Shafter-Wasco ID	Southern San Joaquin MUD	Arvin-Edison WSD	Kern-Tulare WD	Total

Notes:
(a) Includes Class 1 allocations from a portion of Arvin-Edison WSD (2%).
(b) Includes Class 1 allocations from the following agencies: Delano-Earlimart ID, Shafter-Wasco ID, Southern San Joaquin MUD, a portion of Arvin-Edison WSD (4%), and a portion of Kern-Tulare WD (77%).
(c) Includes Class 1 allocations from the following agencies: a portion of Arvin-Edison WSD (93%) and a portion of Kern-Tulare WD (23%).

Table 12 presents the CVP future supplies breakdown by the three Sub-Areas in average/normal years, a single-dry year, and multiple-dry years. The future projections of CVP supplies by the Sub-Areas were based on the assumption that the percentage of Class 1 water for an individual agency is distributed by each Sub-Area proportional to the agency's area within each Sub-Area. This is similar to the approach taken for evaluating the SWP supply reliability and considered as an approximation to represent how the future CVP supply projections would vary between the three Sub-Areas[2].

[2] The geographic location and the purposes for which water from the CVP can be used are prescribed by water contracts with the USBR. To use water outside the place of use specified by a water supply contract requires approval by the water supply entity (USBR) as well as the State Water Resources Control Board. The water supply contracts also have some provisions as to the purpose of the types of use. This water supply assessment describes all supplies available in the project area but the reader should be aware that these water supplies are not available throughout the project area and that not all water supplies

4.3.3 Local Surface Water

The most important source of naturally occurring surface water in the Project Area is the Kern River, which is regulated by the Isabella Dam and Reservoir, operated by the U.S. Army Corps of Engineers (COE) and the Kern River Watermaster. Local minor streams, many of which are ephemeral, provide additional local surface water in the Project Area. A very small percentage of minor stream runoff is collected and used as irrigation for agriculture; the majority of these irregularly-occurring flows serve to recharge local groundwater basins. It is estimated that roughly 95 percent of local runoff percolates into the underlying aquifers and contributes to groundwater levels near the Kern Lake Bed, Arvin-Edison WSD/Kern Delta WD boundaries, and the Kern National Wildlife Refuge (KNWR).

4.3.3.1 Kern River

The Kern River is approximately 164 miles long and is fed by annual snowmelt from the southern Sierra Nevada. Figure 7 depicts the Kern River and the other major surface water features in the Project Area. Table 13 provides a summary of the natural and regulated flows for the Kern River.

TABLE 13
HISTORIC KERN RIVER FLOWS (AF)

Year	Natural (AF)	Regulated (AF)	Year	Natural (AF)	Regulated (AF)
1980	1,639,957	1,560,652	1996	1,038,261	968,036

Source: Kern County IRWMP and KCWA Water Supply Report 2011.

The Kern River originates high in the Sierra Nevada near Mt. Whitney and drains approximately 2,100 square miles of watershed area above Isabella Reservoir, another 300 square miles of the foothills below Isabella Reservoir, and about 600 square miles of alluvial fan in the Kern River Canyon (County of Kern 1985). The main branch of the river (also called the North Fork Kern) joins the South Fork Kern River just upstream of Isabella Reservoir. Minor tributaries are Erksine, Bodfish, Clear, and Cottonwood creeks, which join the river downstream of Isabella Reservoir. With the exception of the small valley in which

can be used for all purposes. The terms of the contracts can be modified after appropriate review by the water supply entity following completion of contractually-required administrative protocols and appropriate environmental documentation.

Isabella Reservoir is located, the Kern River and its principal tributaries flow in steep, narrow canyons from their headwaters to the mouth of Kern Canyon, where it enters the Valley floor. Beyond the mouth of the Canyon, the River channel is deeply entrenched in an alluvial fan that extends westward to the main valley trough where the channel is controlled by levees to prevent flood flows from spreading to adjacent lands (City of Bakersfield and County of Kern 2007).

The Kern River had an unregulated flow until 1954, when the Isabella Dam and Reservoir were constructed by the U.S. Army Corps of Engineers (COE). The primary purpose of the dam is flood control. Isabella Reservoir was designed to store approximately 570,000 AF of water; however, since 2006 due to seepage and earthquake concerns, water storage in the Lake has been limited to approximately 60 percent of capacity, 20 feet below the spillway, or 340,860 total AF. The COE is undertaking studies at Isabella Dam with the intent of restoring reservoir capacity (COE 2009).

The Kern River Watermaster represents entities with water rights downstream of Isabella Reservoir. The Watermaster identifies the daily water releases to be made from the reservoir by the COE. The Watermaster also keeps records of Kern River flow. With the exception of very wet years, there is no river flow downstream of Bakersfield due to upstream canal diversions by water rights holders. The River encounters its first diversion into a canal when it first exits the Kern River Canyon and encounters another diversion when it reaches the east side of Bakersfield, near Hart Park. The Beardsley and Rocky Point weirs are the first two of seven diversion weirs in Bakersfield. From there, canal water travels north and south to irrigate farmlands. In total, the River is diverted into seven canals that pass through the City of Bakersfield. During very wet years, the river flows southwest to the Buena Vista Lake Bed and then north toward the Tulare Lake Bed, or into the California Aqueduct Intertie near Tupman (City of Bakersfield and County of Kern 2007), and is delivered to southern California.

Since the late 19th century, Kern River water has been primarily diverted for irrigation and to recharge groundwater. In 1989 the SWRCB declared that the Kern River, from the Buena Vista Lake bed upstream (including all tributaries) was fully appropriated year-round. The "fully appropriated" status of the Kern River means the SWRCB will not accept new applications for diversions from the Kern River. Six petitions have been filed with the SWRCB challenging the fully appropriated status of the Kern River. The entities filing petitions are:

- North Kern WSD and City of Shafter
- City of Bakersfield
- Buena Vista WSD
- Kern Water Bank Authority
- KCWA
- Rosedale Rio Bravo WSD

Along with the petitions to revise the Kern River's fully appropriated status, these entities have filed applications to appropriate water from the Kern River. Depending on the outcome of the fully appropriated streams status and any subsequent water rights decisions, water diversions from the Kern River may be altered.

The City of Bakersfield is planning the Kern River Flow and Municipal Water Program whereby the City will use Kern River water for additional groundwater recharge. This additional recharge may mean less diversion by some entities from the Kern River and less Kern River flow. Aspects of this program are under litigation.

4.3.3.2 Minor Streams

Local minor streams are the second-largest source of local surface water for the Project Area, particularly the Central and East Sub-Areas. Streams with measurable runoff are grouped into four separate watershed areas, based on hydrologic similarity of the watersheds: Poso, Caliente, El Paso, and San Emigdio. Streams with the largest historical flows, including Poso and Tehachapi Creeks, are equipped with flow meters to record actual data while flow rates of smaller streams are estimated by statistical methods based on historical watershed, precipitation, and runoff data. The mean stream flow of these minor streams is 98,900 AF. Historical minor stream runoff is summarized in Table 14.

TABLE 14
HISTORICAL MINOR STREAM RUNOFF (AF)

Year	Annual Stream Flow (AF)	Year	Annual Stream Flow (AF)
1980	70,300	1996	79,500
1981	45,100	1997	103,000
1982	93,600	1998	709,500
1983	503,300	1999	40,100
1984	46,500	2000	27,700
1985	37,800	2001	37,200
1986	52,400	2002	22,800
1987	70,900	2003	55,900
1988	29,900	2004	30,700
1989	27,800	2005	89,900
1990	17,500	2006	54,100
1991	41,900	2007	20,500
1992	87,300	2008	60,300
1993	110,900	2009	40,870
1994	37,400	2010	72,525
1995	426,400	2011	149,722

Source: Kern IRWMP and KCWA Water Supply Report 2011.

Small creeks and streams drain local mountain ranges. The majority are ephemeral and flows quickly infiltrate once reaching the valley floor. However, under certain hydrologic conditions, some of these streams carry very large flows that can be quite damaging. Examples include flooding in the Kelso Creek area, and in the area around the cities of Arvin and Lamont. Regional efforts to address flooding and to better manage such flow events have been initiated among various parties in the Project Area, including County of Kern, KCWA and the affected areas.

A very small percentage of runoff from local minor streams is collected and used as irrigation for agriculture located in the North Kern WSD and the Semitropic WSD. Much of the remaining water percolates into the underlying aquifer. Some of this recharge probably contributes to shallow groundwater in the Kern Lake Bed area and near the KNWR (KCWA 2011a). Because only a small percentage of local minor streams are used, this source is not further considered within this WSA.

4.3.3.3 Local Surface Water Supply Available in Project Area and Sub-Areas

As described earlier, the Kern River is the topic of ongoing litigation. As a simplifying assumption, this WSA assumes future local surface water supply from the Kern River is approximate to past surface water diversions. Allowable diversions from the Kern River have been set by time of year and a particular instant diversion rate (for example, it is allowable to take 10 cfs for 40 days in summer and 20 cfs for 60 days in fall). On average, from 1970 to 2011 the average total diversion from the Kern River has been 764,400 AFY (KCWA 2011a). In 1977, the driest year for which data is available, diversions were only 197,000 AF (KCWA 2011a). During the multi-dry period from 1987 to 1991 the average diversion was 335,500 AF (KCWA 2011a). As a second simplifying assumption, it is assumed that all water of the Kern River is used in the East Sub-Area, though in very wet years the river may flow to the other Sub-Areas.

TABLE 15
ESTIMATED LOCAL SURFACE WATER SUPPLY 2015 T0 2030 BASED ON HISTORIC USE

Water Year Type	Project Area (AF)	West Sub-Area (AF)	Central Sub-Area (AF)	East Sub-Area (AF)
Average Water Year (based on average diversions 1970 to 2011)	764,400	--	--	764,400
Single-Dry Water Year (based on diversions 1977)	197,000	--	--	197,000
Multiple Dry Year (based on average diversions 1987 to 1991)	335,500	--	--	335,500

4.3.4 Groundwater

The San Joaquin Valley Groundwater Basin (DWR Groundwater Basin 5-22.14) covers the majority of the managed resources in the Project Area (Figure 5).

With less than 10 inches per year of average rainfall, groundwater is necessary to maintain a sufficient water supply in the semi-desert climate of the Project Area. It is estimated that on average, groundwater accounts for 37 percent of total water supply to the Project Area; however, it is estimated to be as much as 60 percent during dry years.

The main sources of groundwater recharge in the Project Area are applied irrigation water, surplus SWP/CVP water (Article 21 and Section 215 type as well as large allocations of Table A and Class 2 water) and the Kern River. In the Kern River bed are 500 to 2,000-foot thick poorly sorted deposits of silt, sand, rock, and clay that originated from the Sierra Nevada, and that provide moderate to high permeability through the river bed. This

phenomenon is also seen in some of the unlined canals which branch off from the river. Major water banking and conjunctive use projects also contribute large amounts of recharge to the underlying groundwater basin.

4.3.4.1 Groundwater Extractions

Agriculture, M&I users, and groundwater banking operations all draw upon local groundwater resources. Agriculture is estimated to be the largest user of groundwater. The majority of groundwater extractions in the Project Area are not recorded; thus obtaining an accurate assessment of groundwater extractions is difficult. In the past, agricultural and urban power records were matched with calculations to estimate groundwater production. However, because water agencies are not required to record the amount of groundwater extracted, since 2001 groundwater extractions have been estimated based on trends in groundwater storage (Table 16) and/or assessment of crop water requirements.

TABLE 16
HISTORICAL TOTAL GROUNDWATER EXTRACTIONS BY PURVEYORS

Year	Extractions (AF)	Year	Extractions (AF)
1980	977,000	1996	1,609,600

1993	987,700	2009	1,212,400
1994	1,897,700	2010	230,400
1995	1,242,800	2011	419,000
		Mean [(a)]	**1,319,000**

Note: (a) Mean of the historical records is rounded off to the nearest hundred.
Source: Kern IRWMP and KCWA Water Supply Report 2011.

Groundwater management in the Project Area depends on the sustained delivery of surface water from the three major sources described above: SWP, CVP, and Kern River. Any reduction in one supply, unless accompanied by an increase in another, can have a negative impact on groundwater. Surface water supplies to the Project Area have generally stabilized groundwater levels over recent history. It is reasonable to expect that this relatively balanced condition will continue if deliveries of surface water supplies remain the same as recent historical conditions. However, as discussed above, and reported in the recently completed Kern and Poso IRWMPs, the three principal sources of surface water are projected to decrease in the future relative to the historical conditions. As reliability of surface water decreases, it is apparent that entities in the Project Area will make additional use of the groundwater basin. As a result, any reduction in historically available water supplies will translate to a decline in groundwater levels. While future pumping levels could potentially exceed historical conditions, given the uncertainty with groundwater pumping, the

historical mean of 1,319,000 AFY was assumed as a reasonable estimate for future projections of groundwater extractions, as presented in Table 16.

The historical mean extraction value used in this WSA analysis (and specifically in Tables 16 and 17) does not represent the safe or sustainable yield for the Project Area. This assessment does not consider or identify a safe or sustainable yield for the Project Area. The Project Area basins are subject to the most stringent requirements under the new Sustainable Groundwater Management Act, which requires the development of a Groundwater Sustainability Plan (GSP). The GSP will identify the sustainable or safe yield that will avoid unsustainable extraction rates that could yield "undesirable results". The projected groundwater extracted use in this assessment is not intended to represent the safe yield for the Project Area. Rather, it uses an historical mean extraction value for analysis purposes as the best available information prior to the implementation of the GSP for the basin.

4.3.4.2 Groundwater Banking and Recharge

Groundwater banking is the recharge of excess water supplies into aquifer storage during wet periods for later withdrawal/recovery for use during dry periods.

The extensive use of groundwater in the San Joaquin Valley has historically caused subsidence broadly throughout the floor of the San Joaquin Valley (LSCE, Borchers and Carpenter 2014). Between 1926 and 1970, groundwater extraction in the groundwater basin resulted in more than eight feet of subsidence in the north-central portion of the basin, and approximately nine feet in the south-central area (Ireland et al. 1984). Since 2007 there has been up to 1.5 feet of subsidence along the western edge of Kern County, west of Highway 33, south of Highway 46 and north of Highway 58 in the West Sub-Area, as well as approximately 1 foot of subsidence in an area east of the City of Taft (also in the West Sub-Area) (LSCE, Borchers and Carpenter 2014).

Historically, during wet periods, imported water (SWP and CVP) in the Project Area have been substantial enough to satisfy irrigation and urban water needs and excess water has been recharged to groundwater aquifers. CVP water is recharged in spreading ponds operated by Arvin-Edison WSD or in the channels of the Kern River and Poso Creek, as well as in recharge facilities on the Kern River Alluvial Fan. SWP water is recharged by KCWA, KWBA and several water districts in the Kern River channel (via the CVC), in unlined irrigation canals and in various district-operated recharge sites. Kern River water is also recharged by a combination of deliberate spreading in recharge areas, by losses in unlined canals or by percolation in the Kern River channel (KCWA 2011a). The groundwater is then pumped out through the many private and publicly owned wells located throughout the Project Area during dry periods when local or imported surface water supplies are insufficient.

Groundwater banking was initiated in the subbasin in 1978 (DWR 2003). Groundwater banking programs are now widely used in the Project Area. Many notable groundwater storage programs exist, including those operated by Arvin-Edison WSD, Semitropic WSD, North Kern WSD, the City of Bakersfield, Rosedale-Rio Bravo WSD, and various other districts. The Kern Water Bank Authority (KWBA) is responsible for the largest water banking program in the world and has contributed over 2 MAF of water into storage since the program began operations in 1995. It is estimated that there are over 30,000 acres of

groundwater recharge ponds in the Project Area. Groundwater banking programs in the Project Area:

- Arvin-Edison Water Storage District Water Management Program
- Berrenda Mesa Property Joint Water Banking Project
- Buena Vista Water Storage District Water Management Program
- Buena Vista Water Storage District/West Kern Water District Water Supply Project
- Cawelo Water District/Dudley Ridge Water District Conjunctive Use Program
- Cawelo Water District Modified Famoso Water Banking Project
- City of Bakersfield 2800 Acre Groundwater Recharge Facility
- Kern Delta Water District's Groundwater Banking Program
- Kern Water Bank
- North Kern Water District Groundwater Storage Project
- Thomas N. Clark Recharge and Banking Project (KCWA)
- Pioneer Banking Project (KCWA)
- Rosedale-Rio Bravo Water Storage District and Improvement District No. 4 Joint Use Groundwater Recovery Project
- Rosedale-Rio Bravo Water Storage District's Groundwater Banking Program
- Semitropic Groundwater Banking Project
- West Kern Water District Groundwater Banking Program

Among these, the Kern Water Bank is the largest groundwater banking project with a storage capacity of nearly one MAF. KCWA also manages the Pioneer and Berrenda Mesa Banking projects. In total, maximum annual recharge capacity in the Project Area is estimated at 1.5 MAF with maximum annual recovery estimated at 900,000 AF. In January 2008, KCWA estimated that total storage capacity for the Kern Region is approximately 50 MAF. Currently, approximately 10 MAF of that storage has been dewatered and, therefore, is available for conjunctive use and groundwater banking operations. There is approximately 5.4 MAF of water in managed groundwater storage in the Kern Region.

4.3.4.3 Groundwater Supply Available in Project Area and Sub-Areas

As described in the previous paragraphs, groundwater supply and demand is not fully defined in the Project Area. The WSA assumes groundwater supply is approximate to past known groundwater use. In a normal year groundwater supply is assumed to be the historic average groundwater use; in a dry year the groundwater supply is assumed to be the historic use during dry and critical years and the groundwater supply during a multiple dry year period is assumed to be 1987 to 1992. Table 17 describes estimated groundwater supply in the Project area and three Sub-Areas.

TABLE 17
ESTIMATED GROUNDWATER SUPPLY FOR 2015 TO 2035 BASED ON HISTORIC EXTRACTIONS

	Project Area (AF)	West Sub-Area (AF)	Central Sub-Area (AF)	East Sub-Area (AF)
Average Water Year (based on average extractions 1980-2011)	1,319,000	659,500	237,400	422,100
Single-Dry Water Year (based on average of dry and critical years of extractions 1980-2011)	1,673,000	836,500	301,100	535,400
Multiple Dry Year (based on average extractions 1987-1992)	1,635,000	817,450	294,300	523,200

Note: Groundwater extractions by the Sub-Areas were estimated based on the simplifying assumption that groundwater extractions would be proportional to the estimated agricultural demand within the Sub-Areas. This does not imply that groundwater supplies are available for all uses.

4.3.5 Recycled Water

Recycled water is important in the Kern Region due to the fact that the Tulare Lake hydrologic region mainly consists of a "closed basin," that is, supplies entering the basin have no natural outlet. Because there is no natural outflow all effluent must be treated and disposed of within the basin. Agriculture, which accounts for the majority of total water use in Kern County, does not require water treated to potable water standards. The large amount of agriculture in the region has meant that nearly all wastewater effluent produced by the various wastewater treatment facilities located in the Project Area can be applied to salt tolerant non-human consumption crop irrigation and environmental habitat restoration. Recycled water is also used to irrigate and flood certain areas of the KNWR.

Currently, there are 14 active wastewater treatment plants (WWTPs) in the San Joaquin Valley portion of Kern County. These plants provide secondary and tertiary treated effluent. In 2011, approximately 54,000 AF of effluent was recycled. It is estimated that approximately 49,000 AF of this recycled water was used by agriculture (KCWA 2011a). Table 18 provides a summary of the historical volumes of recycled water in the Project Area.

In addition to treatment plant effluent, another source of reusable wastewater results from agricultural tailwater return systems. Many farming operations have installed these systems to intercept water that would normally run off fields during irrigation. This recovered water is either transported back to the main irrigation system or is applied on an adjacent field (from the foot of one field to the head of another). Tailwater return systems are widely used on fields that are furrow or border irrigated. Their efficiency lies in saving the energy required to recover the water from wells or by reducing the need to import additional surface supplies.

TABLE 18
HISTORICAL RECYCLED WATER USE

Year	Deliveries (AF)	Year	Deliveries (AF)
1980	32,800	1996	51,300
1981	34,100	1997	50,800
1982	32,100	1998	48,800
1983	35,300	1999	48,533
1984	35,800	2000	49,970
1985	34,200	2001	51,035
1986	58,000	2002	51,600
1987	39,200	2003	56,600
1988	44,200	2004	54,800
1989	44,000	2005	55,200
1990	42,500	2006	56,800
1991	45,200	2007	59,000
1992	46,100	2008	51,900
1993	47,600	2009	50,800
1994	49,700	2010	53,400
1995	49,700	2011	53,900

Note: Historical record above does not include deliveries from five WWTP's in the Tehachapi area (CCI WWTP, City of Tehachapi WWTP, Golden Hills Sanitation Company WWTP, Bear Valley WWTP, and Stallion Springs WWTP. According to the 2010 Tehachapi Regional Urban Water Management Plan, these five facilities produce approximately 2,000 AF of recycled water annually, but are located outside of the Project Area.

Source: Kern IRWMP and KCWA Water Supply Report 2011.

For future projections of recycled water flows, 77,000 AFY was assumed, based on the estimate provided in the Kern IRWMP (Kern IRWMP 2011). This water supply is available in all water year types. This is a conservative number because multiple entities in the region are examining the possibility of increasing production and use of recycled water. Increased use of recycled water for irrigated agriculture as well as landscape irrigation in the M&I sector could help lower dependence on high quality SWP and CVP water and will provide an additional water source during drought or periods of regulatory restrictions when imported potable water quantities are reduced. In addition, waste discharges will be greatly reduced and the high quality imported water can be applied towards best use. Wastewater effluent is regulated by the California Code of Federal Regulations (CFR) as well as the State Water Resources Control Board Division of Drinking Water. Municipal treatment facilities producing effluent for introduction into irrigation canals must disinfect to a minimum of 23 most probable number (MPN) of coliform per 100 ml of discharge.

4.3.6 Oilfield-Produced Water

Unlike treated municipal effluent or tailwater, oilfield-produced waters are a true addition to the hydrologic system, being drawn from deep, connate waters that are intermixed with oil deposits. From 2003 to 2013 the amount of produced water increased from 180,000 AFY to 232,000 AFY. Of this amount, oil and gas operations reuse a significant portion, some is disposed, and the remainder is sent for beneficial reuse by agriculture.

4.3.6.1 Produced Water Use by Oil and Gas

As described further in section 5, it is estimated that as of year 2015, oil and gas will reuse approximately 93,100 AFY of the produced water generated. Based on projections of future

oil and gas activities (see section 5) oil and gas use of produced water will go up to approximately 121,400 AFY by 2035. This is not including agricultural use of produced water which is discussed in section 4.3.6.2.

4.3.6.2 Agricultural Use of Produced Water

The Kern River Oilfield located just north of the City of Bakersfield is the third largest oilfield in California and the fifth largest field in the country. In the Kern River oilfield, substantial quantities of water are removed with each barrel of oil. With minimal treatment, the chemical quality of this water is generally within acceptable limits for agriculture.

In the past, the water released during oil extraction was discharged into the Kern River, but following implementation of more stringent environmental protection measures, companies began reusing the water in the form of steam to accelerate oil extraction. Beginning in 1980, Cawelo Water District began receiving oilfield-produced water for recharge and irrigation purposes. In 2012 Cawelo Water District reports receiving 37,107 AF of oilfield produced water (Cawelo Water District 2014). Hathaway LLC reports delivering 1,551 AFY to agriculture (personal communication Chad Hathaway, Hathaway LLC provided to Jonathan Lilien, Chevron Inc. August 18, 2015). For future projections of oil-field produced water used by agriculture, 38,658 AFY was assumed for all water year types (average, single-dry, and multiple-dry year).

4.3.6.3 Oilfield Produced Water as Water Supply

Like recycled water, oilfield produced water is only a supply to the extent that it is delivered for beneficial use. Table 19 documents current and future estimates of produced water supply in the Project Area.

4.3.7 Other Water Supply Opportunities

In addition to the available water supplies, other water supplies in the Project Area include agricultural processing wastewater and transfers and exchanges, as explained in the following sections.

4.3.7.1 Agricultural Processing Wastewater

In addition to treated wastewater effluent, effluent from plants processing crops harvested from the field and those preparing processed food potentially provide a source of additional water supply opportunities. Currently, effluent from agricultural processing facilities is being recycled for irrigation use and is being evaluated for use in groundwater recharge programs.

Multiple-Dry Year	131,764	138,840	145,916	152,992	160,070

4.3.7.2 Transfers and Exchanges

As described above, multiple water sources are available in the Project Area, including the SWP, CVP, groundwater, Kern River, and minor local streams. Because of these multiple sources the Kern Region has developed a complex and interconnected water distribution system. This network of canals and pipelines makes it possible to “wheel” or convey water from one area to another, both regionally and statewide. Local agencies have agreements in place that allow agencies to call on available supplies when another supply source is experiencing shortage, and for other reasons to reduce costs, conserve energy, and/or improve water quality. For example, the KCWA ID4 has transfer and exchange agreements in place with North Kern WSD, Buena Vista WSD and Kern Delta WD that allow KCWA ID4 to increase its use of Kern River water in years when SWP supplies are limited. Arvin-Edison WSD also has assisted districts with transfers and exchanges given its CVP contract and facility infrastructure interconnections with all major conveyance systems (Kern River, CVP/Friant-Kern Canal, SWP/California Aqueduct, CVC, and interconnections with Kern Delta WD).

This distribution network makes it possible to store excess water in a given year or period and then recover and deliver that water in another year or later in a year. Several of the water banks have agreements to store surface water from agencies outside the Kern Region. These agreements allow imported supplies that belong to out-of-region banking participants to be delivered to banking programs within the Kern Region, usually via the California Aqueduct or Friant-Kern Canal. The water is either percolated into the groundwater basin and stored, or utilized by local agencies in-lieu of groundwater pumping, thus allowing water levels in the groundwater basin to be maintained or improved. During water-short periods, the stored water can either be pumped and delivered directly (if the banking participant is physically located south of the Project Area), or arrangements can be

made to use out-of-region banked water locally, in exchange for the use of KCWA's Table A amount or Arvin-Edison WSD's contract amount (if the banking participant is physically located north of the Project Area).

4.4 Estimated Current and Future Water Supply

Table 20 summarizes the water supply projections through 2035 for the Project Area, including SWP and CVP imported water, groundwater pumping, Kern River water, recycled water, and oilfield-produced water. Table 21 presents a summary of the water supply projections through 2035 for the same water supply sources by sub-area. The assumptions and approach used to divide up the water sources by the Sub-Areas are described earlier in this WSA and additional notes are provided in Table 21.

TABLE 20
SUMMARY OF WATER SUPPLIES 2015 TO 2035 FOR PROJECT AREA

	Average (AF)	Single-Dry Year (AF)	Multiple Dry Year (AF)
Current (2015)[a]			
SWP Imported Water	565,900	105,500	293,800
CVP Imported Water	305,600	77,200	228,400
Groundwater Pumping	1,319,000	1,673,000	1,635,000
Kern River	764,400	197,000	335,500
Recycled Water [c]	77,000	77,000	77,000
Oil Produced Water [d]	125,887	125,887	125,887
Sub-Total	*3,157,777*	*2,255,577*	*2,695,477*
Future (2035)			
SWP Imported Water	565,900	105,500	293,800
CVP Imported Water	305,600	77,200	228,400
Groundwater Pumping	1,319,000	1,673,000	1,635,000
Kern River	764,400	197,000	335,500
Recycled Water [b]	77,000	77,000	77,000
Oil Produced Water [c]	154,182	154,182	154,182
Sub-Total	*3,186,083*	*2,283,883*	*2,723,883*

Notes:
(a) Table 20 summarizes available supplies without taking account of the additional 5,887 acre-feet of treated produced water available for agricultural irrigation in the eastern subarea as shown in Table 19 and Table 28 or the pro-rata reduction in agricultural demand for other irrigation water sources as a result of the additional use of treated produced water. For ease of reference, these adjustments are shown in Table 39 and carried forward in the regional supply and demand analyses for average, single dry and multiple dry years in Tables 41 through 43
(b) Recycled water by Sub-Area was estimated approximately based on the location of the entity producing the recycled water.
(c) Oilfield-produced water supply provided to Cawelo Water District was assumed to come from the East Sub-Area based on data provided by WZI.

Figure 8 graphically depicts both the current and future water supplies anticipated in the Project Area.

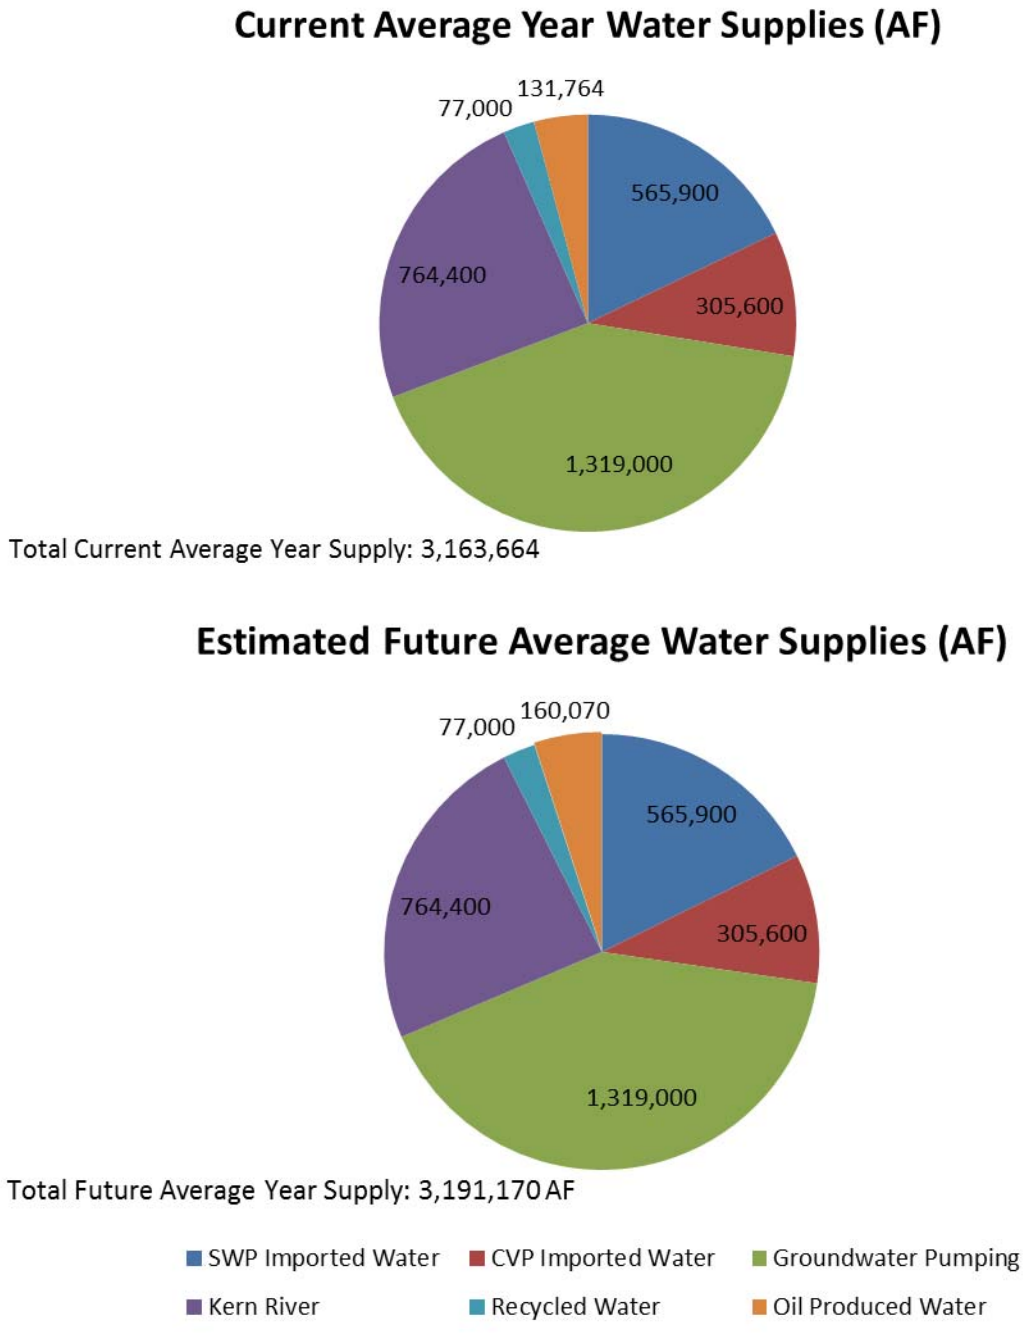

Figure 8. Current and Future Water Supplies in Project Area

Total	**2,695,681**	**2,702,937**	**2,710,193**	**2,717,449**	**2,724,704**

Notes:

(a) Recycled water by the Sub-Areas was estimated approximately based on the location of the entity producing the recycled water. The additional available oilfield produced water supply for agricultural irrigation, as shown on Table 28, and the pro-rata decrease in water demand s addressed in Table 39, and is not included in the above table for ease of reference.

(b) Table 21 summarizes available supplies without taking account of the additional 5,887 acre-feet of treated produced water available for agricultural irrigation in the eastern subarea as shown in Table 19 and Table 28 or the pro-rata reduction in agricultural demand for other irrigation water sources as a result of the additional use of treated produced water. For ease of reference, these adjustments are shown in Table 39 and carried forward in the regional supply and demand analyses for average, single dry and multiple dry years in Tables 41 through 43.

(c) Oilfield-produced water supply provided to Cawelo Water District was assumed to come from the East Sub-Area based on data provided by WZI.

4.5 Water Supply Data Gaps and Limitations

As with most hydrologic studies, data is limited. Table 22 describes data limitations of this study as well as the approach used by the WSA to address the various limitations and uncertainty. Among the issues identified, the major data gap is the uncertainty related to groundwater supply and groundwater extraction. It is estimated that groundwater makes up over one-third of total water supplies and up to 60 percent in dry years. It is not possible to track extractions as the majority of groundwater extractions are not reported. Groundwater extractions and supply in the Project Area were estimated based on calculations available in published reports (KCWA 2011a). In addition, given the uncertainty with pumping levels, groundwater pumping projections were based on the historical mean of the available records. However, annual groundwater pumping may vary widely from year to year depending on hydrologic year types.

TABLE 22
APPROACH TO DATA LIMITATIONS AND UNCERTAINTY

Data Type	Approach to Data Limitation/Uncertainty
Groundwater Extraction	Pumping records unavailable. Reported data are based on estimated calculations from published KCWA reports.
Groundwater Pumping Projections	Assumed to be based on historical mean, but annual pumping may vary widely depending on hydrologic conditions.
SWP Future Projections	SWP future projections are based on the DWR 2013 Draft Delivery Reliability Report for long-term planning of water supply sources and they are not intended to capture year-to-year hydrologic variations.
CVP Future Projections	CVP future projections are based on the San Joaquin River Settlement for long-term planning of water supplies under different hydrological year types and they are not intended to capture year-to-year hydrologic variations.
CVP Deliveries - Flow Release Schedule from Friant Dam	Flow release schedule from Friant Dam are based on the currently available tentative interim flows. These flows are subject to change and the release schedule for flows after February 2014 has not been determined at the time of the WSA preparation.
Kern River Flow and Use	Kern River water is currently under litigation. Supply assumed to be similar to historic supplies. Assumed to be available on a consistent basis only in the East Sub-Area.

Section 5: Oil and Gas Water Demand

This section briefly summarizes the activities that use, generate and dispose of water during oil and gas production. The objectives of this section are to: i) provide an overview of historic water use, produced water generation and water disposal in the Project Area, ii) provide a water balance estimate for the year 2012 which is indicated as "representative year" for current and future water related activities for Kern County oil and gas production (WZI 2014), and iii) provide an estimate of fresh water (referred to as Municipal and Industrial [M&I] water) use in the Project Area.

Broadly, activities consuming water during oilfield operations include well drilling, development, maintenance, injection (water or steam) for oil extraction, well stimulation, and well closure. Next, depending on the age, characteristics of the formation and the type of production operation, various amounts of formation and injected waters (produced water) are extracted during oil production. Finally, produced water that is not re-used for oilfield operations and waste streams generated (e.g. drilling wastewater) are disposed of via deep injection wells or land disposal (via permit) or offsite reuse. The water use, production and disposal estimates are summarized for each of the three Sub-Areas (see Figure 1).

5.1 Data Sources

The following data sources were used for water balance evaluation in the project area.

- Various DOGGR Databases (Downloaded in March 2014): Historic data on annual well drilling, number and type of wells in operation, number of wells plugged or abandoned, injection water use for various oil production operations, produced water generation, waste disposal, and types of oil production in various oilfields.

- WZI Inc., 2014, Water Impact Factors, Kern County Oil and Gas EIR, prepared for Western States Petroleum Association [WSPA]). In this report WZI identified water use and disposition for different oil and gas activities (i.e. well construction, well maintenance, oil production). The report used a material balance approach to identify the water use ("impact factor") for the various activities. The material balance requires that the volume of water produced and purchased must equal the volume of water injected (for any purpose) or disposed to land or reused for agricultural irrigation. For the purpose of the WZI analysis, the year 2012 was selected as representative based on a review of the DOGGR data from 1993 to 2012. Impact factors (i.e. M&I or produced water use, production and disposal normalized to the number of certain type of wells) developed by WZI for various oilfield water related activities were used in the water balance evaluation.

5.2 Data Evaluation Procedures

Two types of data evaluations were conducted as part of this WSA. First, historic trends in water related activities were identified using information from DOGGR database. Water used for injection, produced water and disposal information were developed for the three Sub-Areas. These evaluations were performed to identify broader trends related to water use during oil and gas production in the past several years.

Secondly, water demand estimates for the next 20 years were estimated using water use data developed by WZI. The WZI report indicated that while annual water use, production and disposal varied from year to year, 2012 data were more representative of the average oil and gas operation with respect to water estimates for the Project Area. These data were used in conjunction with the data from DOGGR database to develop water balance estimates for 2012.

5.3 Oilfields and Types of Oil Production Operations

5.3.1 Oilfields in Project Sub-Areas

Table 23 shows the list of oilfields in each of the three sub-areas of the Project Area. There are 36, 18 and 19 oilfields, respectively, in the West, Central and East sub-areas.

TABLE 23
OIL-FIELDS BY PROJECT SUB-AREAS

West		Central	East
Antelope Hills, North	Los Lobos	Bellevue	Ant Hill
Asphalto	Lost Hills	Bellevue, West	Comanche Point
Beer Nose	Lost Hills, Northwest	Bowerbank	Dyer Creek
Belgian Anticline	McDonald Anticline	Calders Corner	Edison
Belridge, North	McKittrick	Canal	Edison, Northeast
Belridge, South	Midway-Sunset	Canfield Ranch	Fruitvale
Blackwells Corner	Monument Junction	Greeley	Jasmin
Buena Vista	Paloma	Rio Bravo	Kern Bluff
Cal Canal Gas	Pioneer	Rose	Kern Front
Carneros Creek	Pleito	Rosedale	Kern River
Chico-Martinez	Railroad Gap	Rosedale Ranch	Mount Poso
Cienega Canyon	Rio Viejo	Semitropic	Mountain View
Coles Levee, North	San Emidio Nose	Seventh Standard	Poso Creek
Coles Levee, South	Temblor Ranch	Shafter, North	Round Mountain
Cymric	Welcome Valley	Stockdale	Tejon
Devils Den	Wheeler Ridge	Strand	Tejon Hills
Elk Hills	White Wolf	Ten Section	Tejon North
Landslide	Yowlumne	Wasco	Union Avenue, Valpredo

5.3.2 Types of Enhanced Oil Recovery Operations

The oil and gas industry in Kern County uses three major types of operations for enhanced oil recovery (EOR) that consume some form of water (water or steam). They include steam flooding, water flooding and cyclic steam. In addition, oil is also produced from some wells without any water or steam injection. The water demand and produced water during the three types of operations vary with the type of operation and other local conditions. Table 24 shows the number of oilfields involved in each type of oil production in 2012 and 2013. In the West Sub-Area a total of 29 and 28 oilfields were involved in oil production in the years 2012 and 2013 respectively, using these three types of oil production. One oilfield in the

Central Sub-Area produced oil by water flooding. Twenty (20) oilfields in the East Sub-Area used a combination of cyclical steam, steam flooding, and water flooding in 2012 and 2013.

TABLE 24
NUMBER OF OILFIELDS INVOLVED IN VARIOUS TYPES OF OIL PRODUCTION ACTIVITIES IN PROJECT SUB-AREAS DURING 2012 AND 2013

Sub-Area	Cyclic Steam		Steam Flooding		Water Flooding		Total	
	2012	2013	2012	2013	2012	2013	2012	2013
West	9	8	9	9	11	11	29	28
Central	0	0	0	0	1	1	1	1
East	6	6	7	7	7	7	20	20

5.4 Historic Water Injection for Oil Production

Figures 9 to 11 show the historical trends in water used for various types of EOR operations. The water use shown includes both M&I water and treated oilfield produced water. In Kern County, the total annual water injection increased from approximately 79,000 AF in 1995 to approximately 105,000 AF in 2013 (Figure 9). Total water use for steam flooding operations gradually decreased from approximately 49,000 AF in year 2000 to approximately 39,000 AF in 2013. However, the water use for water flooding operations increased from 21,000 AF in 2000 to 47,000 AF in 2013. Water use for cyclic steam operations increased from 15,000 to 19,000 AF during this period. Figures 9 to 11 rely on data from WZI as a breakdown of water use from these different sources is not included in the DOGGR database.

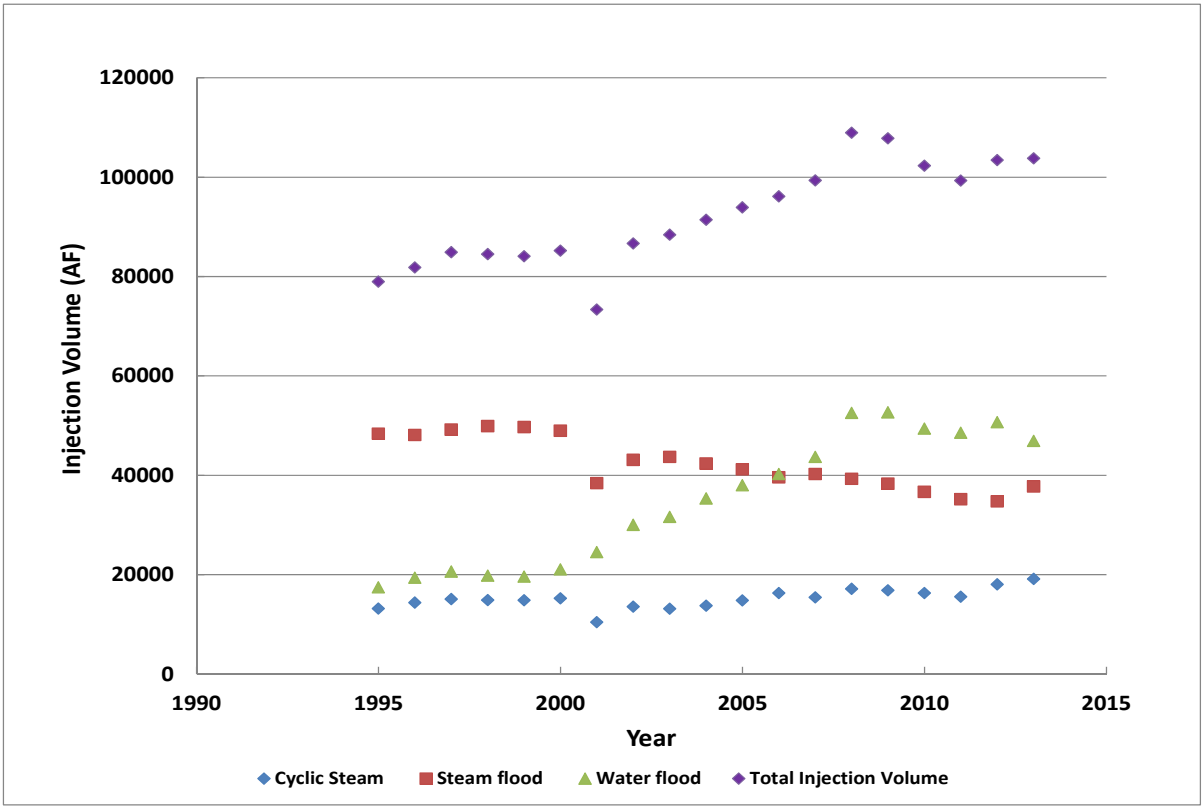

Figure 9. Historic Injection Volume for Oil and Gas Production in Kern County

The amount of water use and the trends in the three sub-areas varied during the past several years. Figure 10 shows the water use trends for EOR in the West Sub-Area from years 2003 to 2013. The water use for water flooding operations increased by 45 percent, from approximately 31,300 AF in 2003, to 45,500 AF, in 2013. The water use for steam flooding decreased by about 16 percent, from approximately 29,200 AF in 2003 to 24,600 AF in 2013. The water use for cyclic steam increased nearly 50 percent from approximately 11,500 AF in 2003 to 17,500 AF in 2013. The total water use for EOR in the West Sub-Area in 2013 is approximately 87,600 AF.

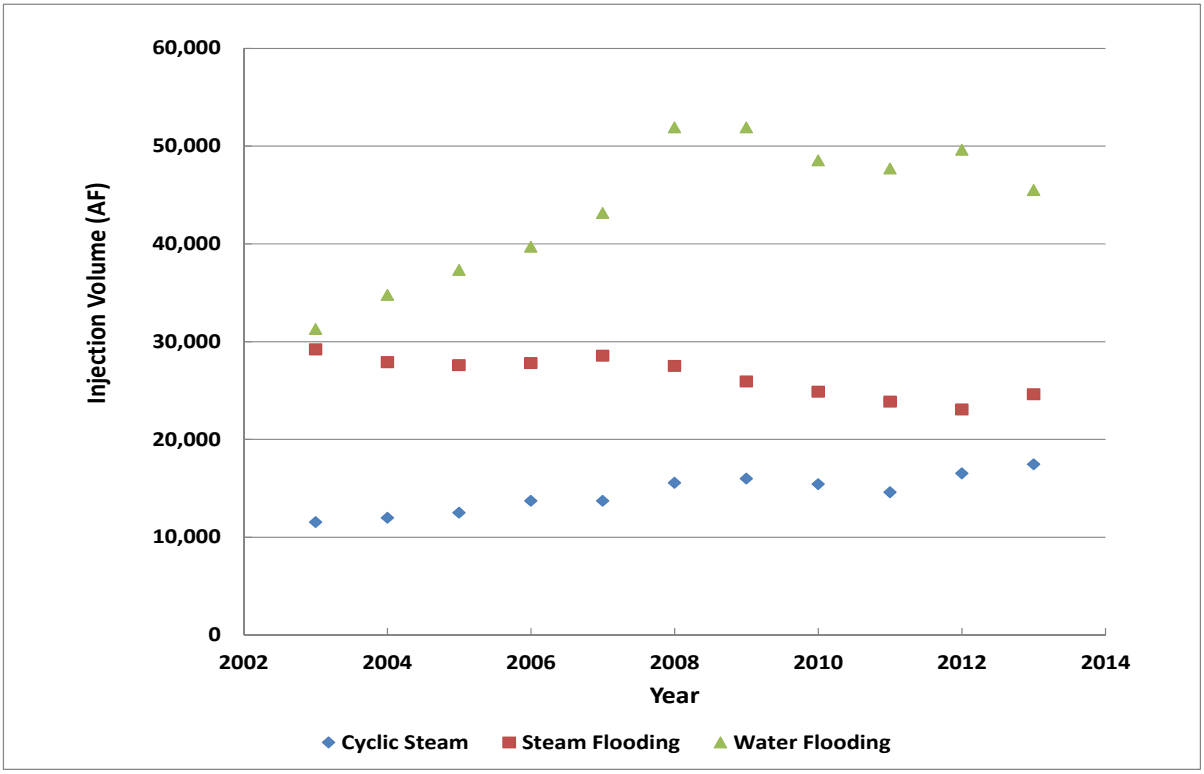

Figure 10. Historic Injection Volume for Oil and Gas Production in West Sub-Area

Figure 11 shows the water trends for oil production in the Central Sub-Area from 2003 to 2013. The water use for water flooding increased ten–fold, from approximately 0.13 AF in 2004 to approximately 14 AF in 2013. The annual water use for steam flooding and steam injection operations was less than 0.05 AF throughout this period. The total water use for oil production in the Central Sub-Area in 2013 is approximately 14.2 AF.

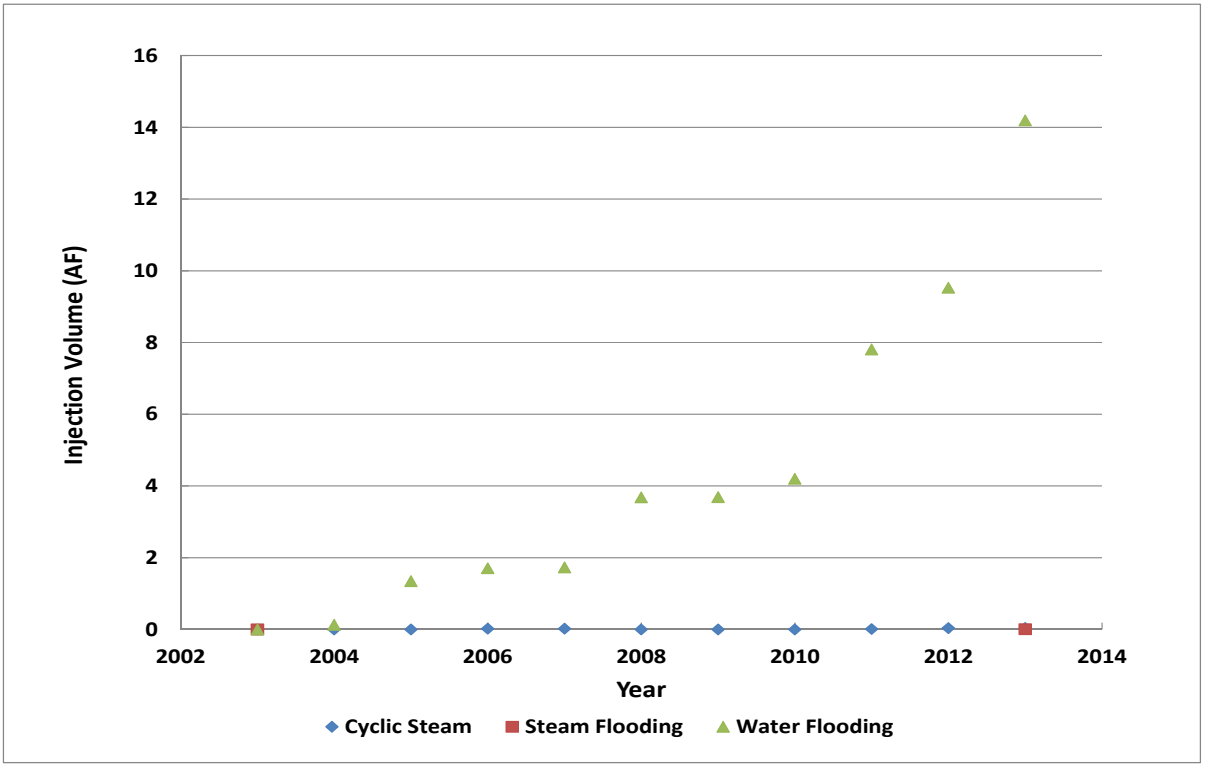

Figure 11. Historic Injection Volume for Oil and Gas Production in Central Sub-Area

Figure 12 shows the water trends for oil production in the East Sub-Area from 2003 to 2013. The distribution of the type of oil production and thus, the water use trends in the East Sub-Area are significantly different than those in the West and Central sub-areas. Approximately 85 percent of the water injection for EOR in the East Sub-Area is associated with steam flooding. The water use for steam flooding decreased by approximately 10 percent from approximately 14,500 AF in 2003 to approximately 13,000 AF in 2013. The water use for water flooding increased two fold, from approximately 340 AF in 2003 to 747 AF in 2013. The water use for cyclic steam was approximately remained about the same at 1,600 AF between 2003 and 2013. The total water use for EOR in the East Sub-Area in 2013 was approximately 15,400 AF.

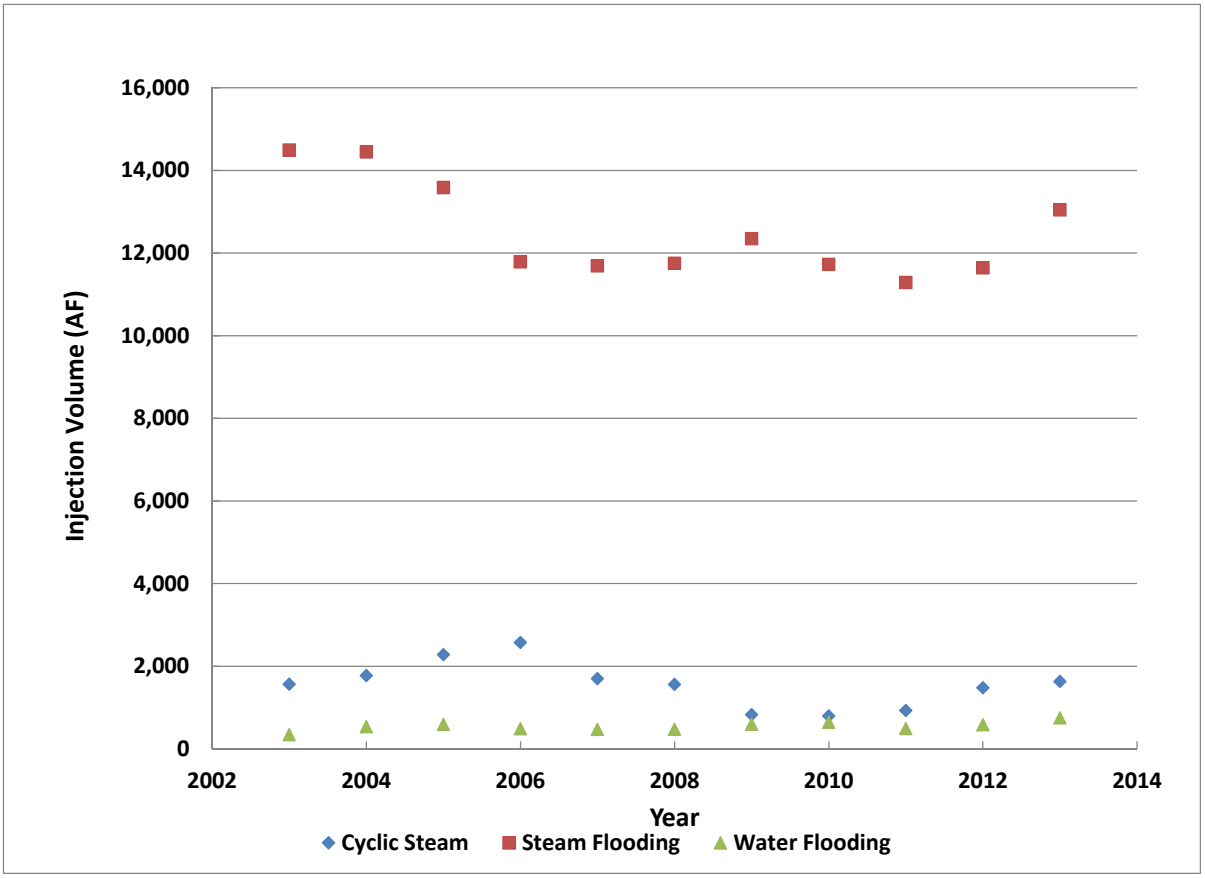

Figure 12. Historic Injection Volume for Oil and Gas Production in East Sub-Area

5.5 Water Use for Well Drilling, Stimulation, and Abandonment

The DOGGR data base provides the number of wells drilled, stimulated and abandoned each year. Figure 13 shows the number of wells drilled in Kern County from 2003 to 2009. The amount of water used exclusively for well drilling is not available in the DOGGR database. The WZI report provides an impact factor for well drilling where the water use is normalized to the number of active production wells in the sub-area and provides an estimate of water used for well drilling, stimulation, and abandonment in 2012.

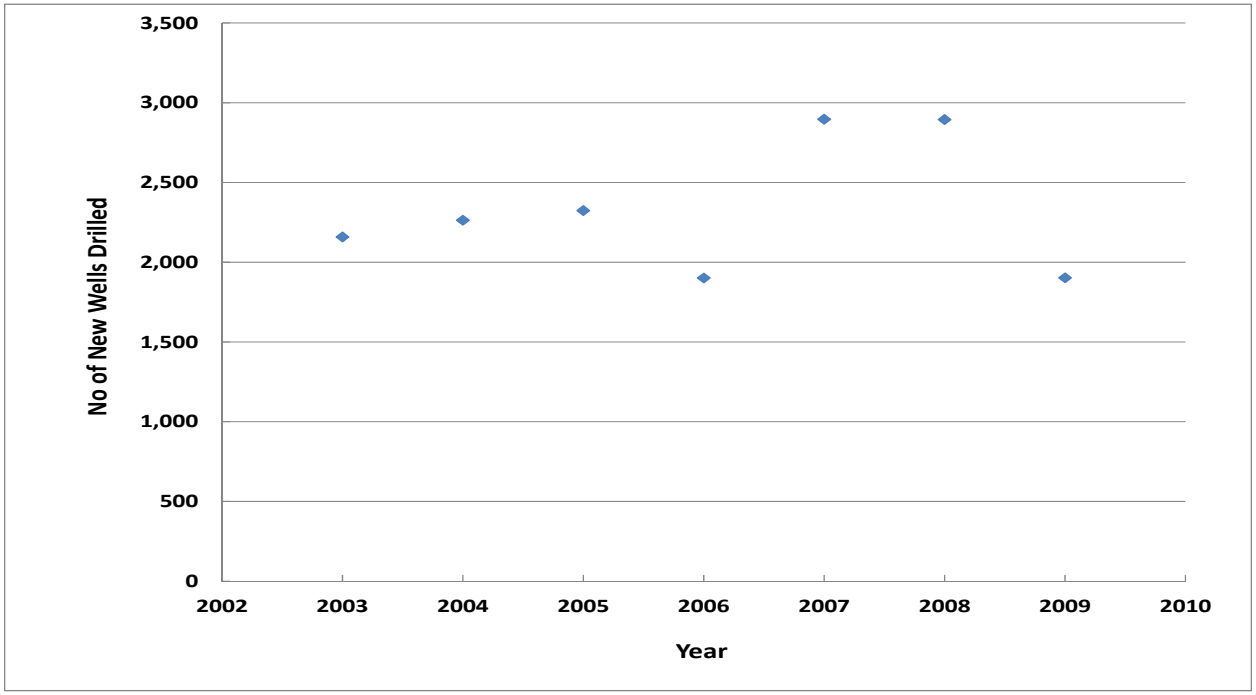

Figure 13. Number of Wells Drilled in the Project Area

5.6 Produced Water Generation

Figure 14 shows historic produced water generation in the Project Area. From 2003 to 2013 the amount of produced water generated increased from 180,000 AF to 232,000 AF. Approximately 57 percent of the produced water is generated in West Sub-Area and 42 percent from the East Sub-Area and 1 percent from the Central Sub-Area.

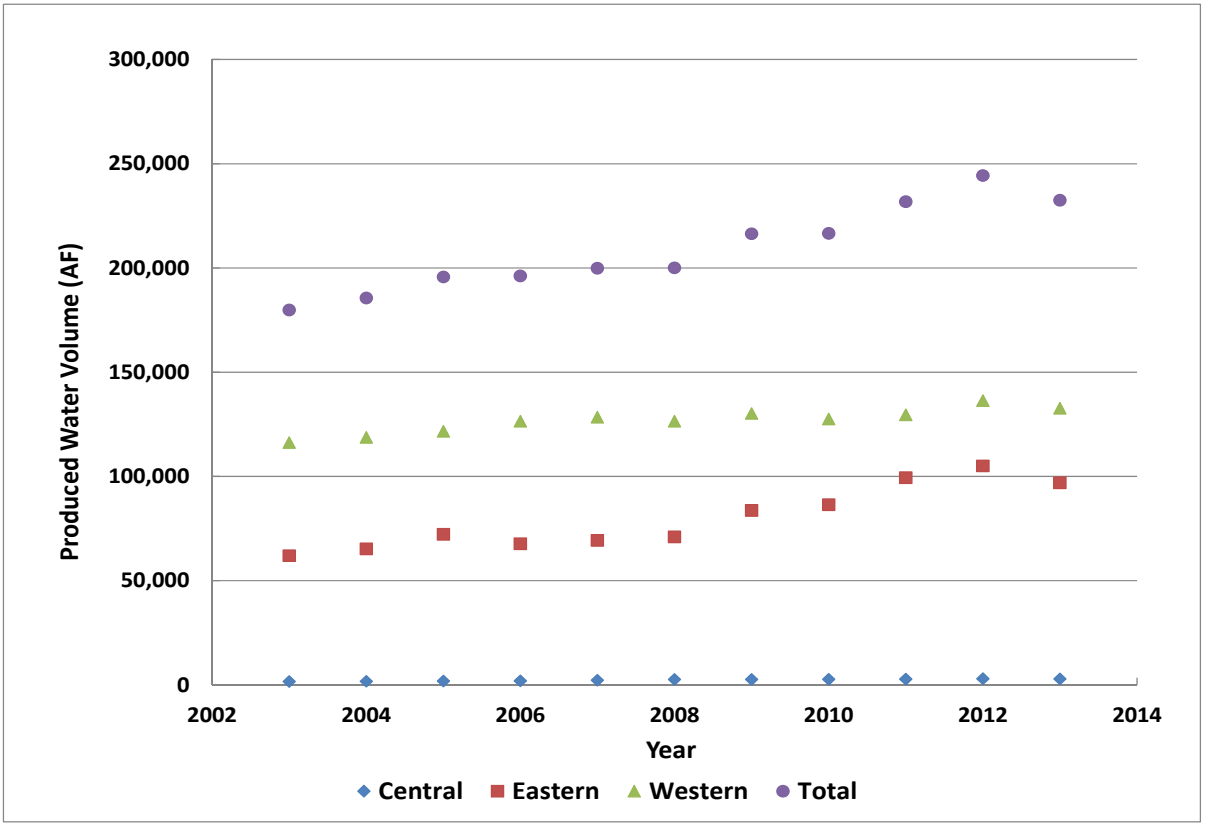

Figure 14. Historic Produced Water in the Project Area

5.7 Estimates of Produced Water Disposal as Waste by Deep Well Injection

Depending on water quality characteristics and other considerations the produced water generated is either reused for enhanced oil recovery, various oilfield construction and maintenance activities, or disposed as waste through deep well injection or by surface means. Historical use of produced water for EOR is shown in Figures 10 through 12. Figure 15 provides the historical volume of water disposed as waste through deep well injection during oil and gas production in Kern County. Approximately 41,100 AF of water was disposed of through injection wells in 1995. This volume decreased to approximately 29,600 AF in 2000. The waste injection volume then gradually increased to approximately 84,500 AF in 2013. Table 25 provides the number of waste disposal wells and volume disposed in each sub-Area in 2013.

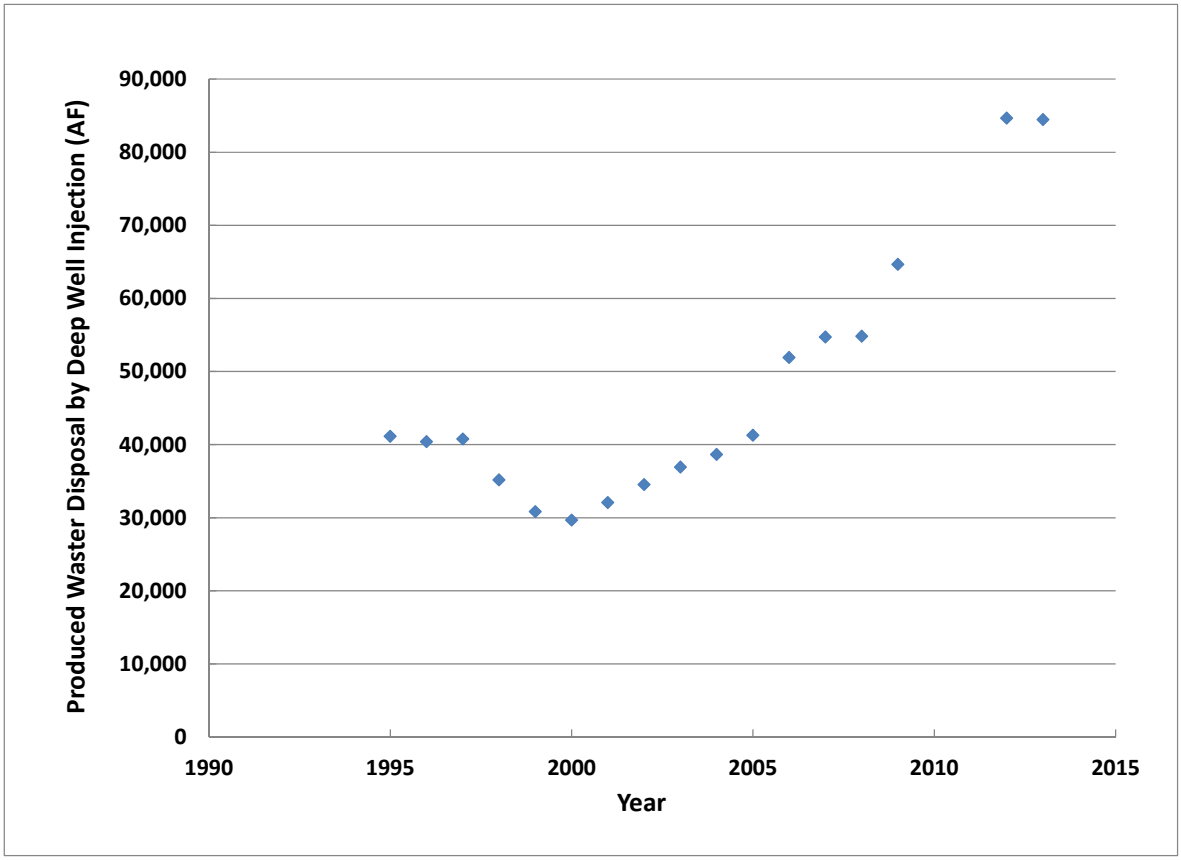

Figure 15. Historic Disposal Volume by Injection in the Project Area

TABLE 25
WASTE DISPOSAL WELLS AND VOLUME DISPOSED IN 2013 BY DEEP WELL INJECTION

Project Sub-area	No. of Wells	Waste Disposal Volume (AF)
East	438	42,320
Central	99	2,000
West	876	40,070
Any Field	9	74
Total	1,422	84,464

5.8 Kern County Oil and Gas Water Balance in 2012

As described in Section 5.1 WZI developed impact factors for water use, production and disposal activities in the project area. Tables 26 and 27 summarize the impact factors developed by WZI.

TABLE 26
IMPACT FACTOR FOR M&I WATER FOR THE THREE SUB-AREAS (WZI 2014)

Component	Unit Demand (bbl)[(a)]			Basis
	West	Central	East	
I. Water Use for New Well Construction				
Drilling Mud	563	1,856	538	Per producing Well
Cementing	422	1,391	403	Per producing Well
SB4 Activities	1,903	1,6125	0	Per producing Well
II. Water Use for Maintenance and Abandonment Activities				
Mud Service	141	466	135	Per Reworked Well
Cementing	211	696	201	Per Reworked Well
Acidizing Wells	128	128	128	Per new producing well
Coiled Tubing[(b)]	83	274.5	79.5	Per new producing well
Well Abandonment Water	891	2,939	851	Per abandoned well
Domestic Water	85.3	85.07	85.3	Per producing Well
III. Water Use for Oil Production				
Steam Production	1,566	0	0	Per producing Well

Notes: (a) bbl – barrels (42 gallons)

(b) The values represent 50% of the coil tubing water demand. WZI report indicates that the reminder of the water demand will be met using oilfield produced water.

TABLE 27
IMPACT FACTOR FOR OILFIELD PRODUCED WATER FOR THE THREE SUB-AREAS (WZI 2014)

(Unit Demand bbl)

Activity	West	Central	East	Basis
Steam injection from Treated Produced Water[(a)]	6,264	0	5,407	Per producing Well
Pressure Maintenance from Treated Produced Water	11	0	0	Per producing Well
Water Flooding from Treated Produced Water	9,803	5,540	223	Per producing Well
Coiled Tubing	83	274.5	79.5	Per new producing well
Well Pulling	126	415	120	Per producing Well
Water for dust control	240	240	240	Per "new reworked' well
Water for surface Facility Construction	17	17	17	Per new well

Notes: (a) Includes cyclic steam and steam flooding operations

This WSA primarily relies on data provided by WZI to determine potential oil and gas water demand. In addition, as a cross-check, a review of DOGGR data was included to evaluate produced water generation, injection disposal and groundwater extraction within oilfields, as well as various construction, maintenance, abandonment, land disposal, and agricultural use. Evaluation of DOGGR data in conjunction with WZI data indicated convergence (approximately >95%) of the water balance for the three sub-areas. Table 28 provides a summary of water balance thus estimated.

In Table 28 oil and gas demand is divided into M&I and non-M&I water use. Table 28 illustrates that a significant portion of oil and gas demand is met with produced water. However, M&I water use is the important demand for the purposes of this WSA, since M&I water is water that could be used for other uses besides oil and gas operations.

TABLE 28
WATER BALANCE ESTIMATES (WZI 2014)[1]

	Region			
Water Requirements by Activity (AF/yr)	**West**	**Central**	**East**	**Total**
Water Demand

1. This Table is intended to i) provide a general overview of water balance in the project area, and ii) to compare data obtained from WZI with other sources (e.g. DOGGER 2012 database). Hence, some values in this Table may slightly differ from those in Figures 16 to 24 shown in the following Sections, where the data are derived primarily from WZI database. However, the overall water balance differed by approximately 3% or less due to these minor discrepancies. Footnotes 2 through 5 provide additional details on the differences in the values shown in this Table and in Figures 16 to 24 in this report.
2. The values shown are estimated from DOGGER 2012 report for Kern County oilfields. These values differ from the values of 132,022 AF, 2,873 AF and 102,923 AF for West, Central and East sub-areas reported by WZI by 0.2 to 0.5%. WZI reported values are primarily used for Figures 16 through 24 in this report.
3. The values include approximately 37,107 AF AF used by Cawelo Water District in 2012 (Agricultural Water Master Plan, 2014) 1,460 AF used by Jasmine Fields and 91 AF used by Concordia Fields for agriculture (Personal communication Chad Hathaway, Hathaway LLC provided to Jonathan Lilien, Chevron Inc. August 18, 2015). WZI (2014) reported agricultural use of produced water as 32,771 AF in 2012. The data in Cawelo AWMP (Feb 2014, Table 30) indicate that the average annual deliveries of "Oilfield Produced" water to Cawelo Water District averaged 32,233 AF (2 year average - 2011 and 2012), 32,535 AF (3 year average 2010 to 2012) and 32,326 (4 year average, 2009 to 2012).

Sections 5.8.1 and 5.8.2, provide a detailed breakdown of produced water and M&I water balance in the project area in 2012.

5.8.1 2012 Produced Water Balance in Kern County

This section presents the produced water balance for the total project area as well as the three sub-areas, developed using the impact factors provided by WZI for 2012. Figure 16 shows the amount of produced water generated in the project area in 2012. Of the approximately 238,000 AF generated in the Project Area, approximately 132,000, 2,800 and 103,000 AF (56%, 1% and 43%) were produced in West, Central and East sub-areas, respectively. In 2012, approximately 216 and 242 AF of produced water generated in the Central Sub-Area were transferred to the West and East sub-areas, respectively for beneficial reuse or disposal as waste.

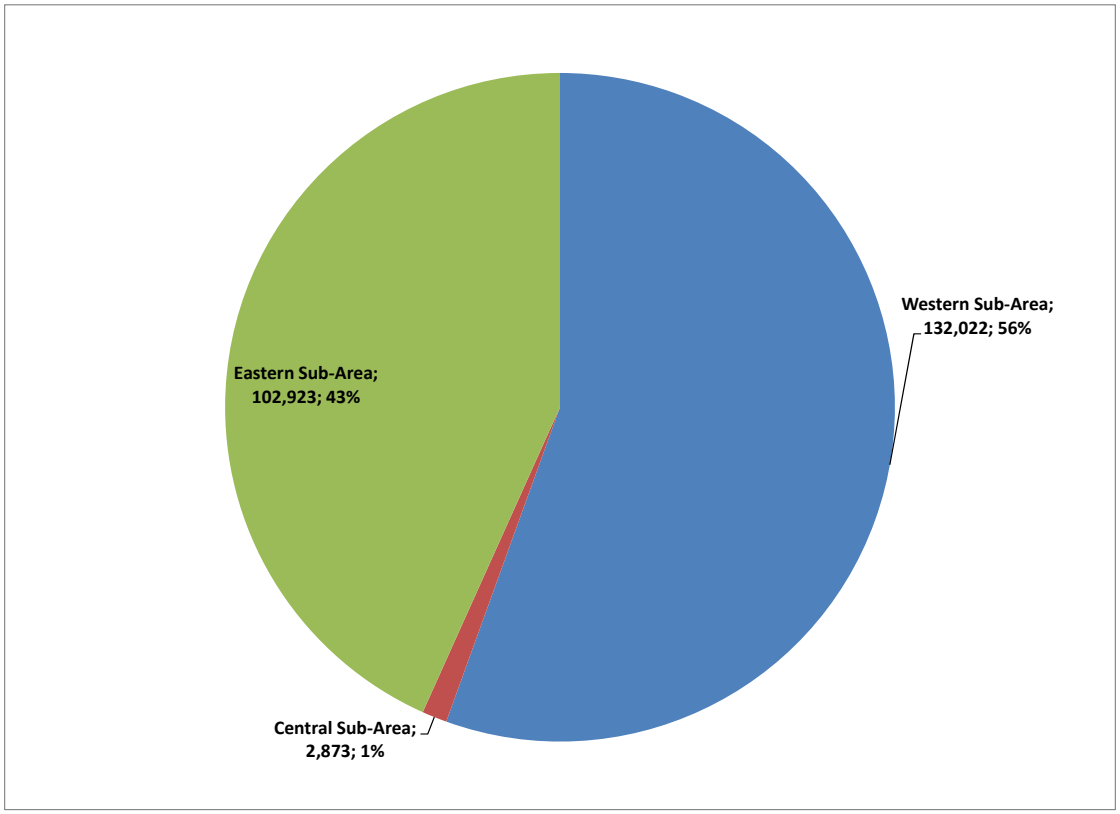

Figure 16. Estimate of Produced Water Generated in the Project Area in 2012 (AF)[1]
1.Some values shown in the Figure differs from those in Table 28 by 0.2 to 0.5% for different sub-areas due to the differences in data source. Refer to notes 1 and 2 in Table 28.

Figure 17 shows the produced water balance for the total Project Area in 2012. The solid areas in the pie chart shows the amount of produced water beneficially used in the project area and the cross-hatched areas show the amount of produced water disposed as waste through deep well injection or by surface disposal.

Approximately 32 percent (75,400 AF) of the produced water generated in the project area was used for EOR in the West Sub-Area, and nearly 20 percent (46,900 AF) was used for EOR and other beneficial uses in the East Sub-Area. A small amount (<1%, 380 AF) of produced water was used for beneficial uses, including EOR in the Central Sub-Area. Approximately 24 percent of the produced water was disposed as waste in the West Sub-Area either through deep well injection (16%) or surface disposal (8%). Approximately 16% was disposed as waste in the

East Sub-Area. Approximately 1 percent of the produced water was disposed as waste in the Central Sub-Area. Overall, approximately 54 percent of the produced water generated in the Project Area was used for beneficial uses, and the rest was disposed by deep well injection or by surface discharge.

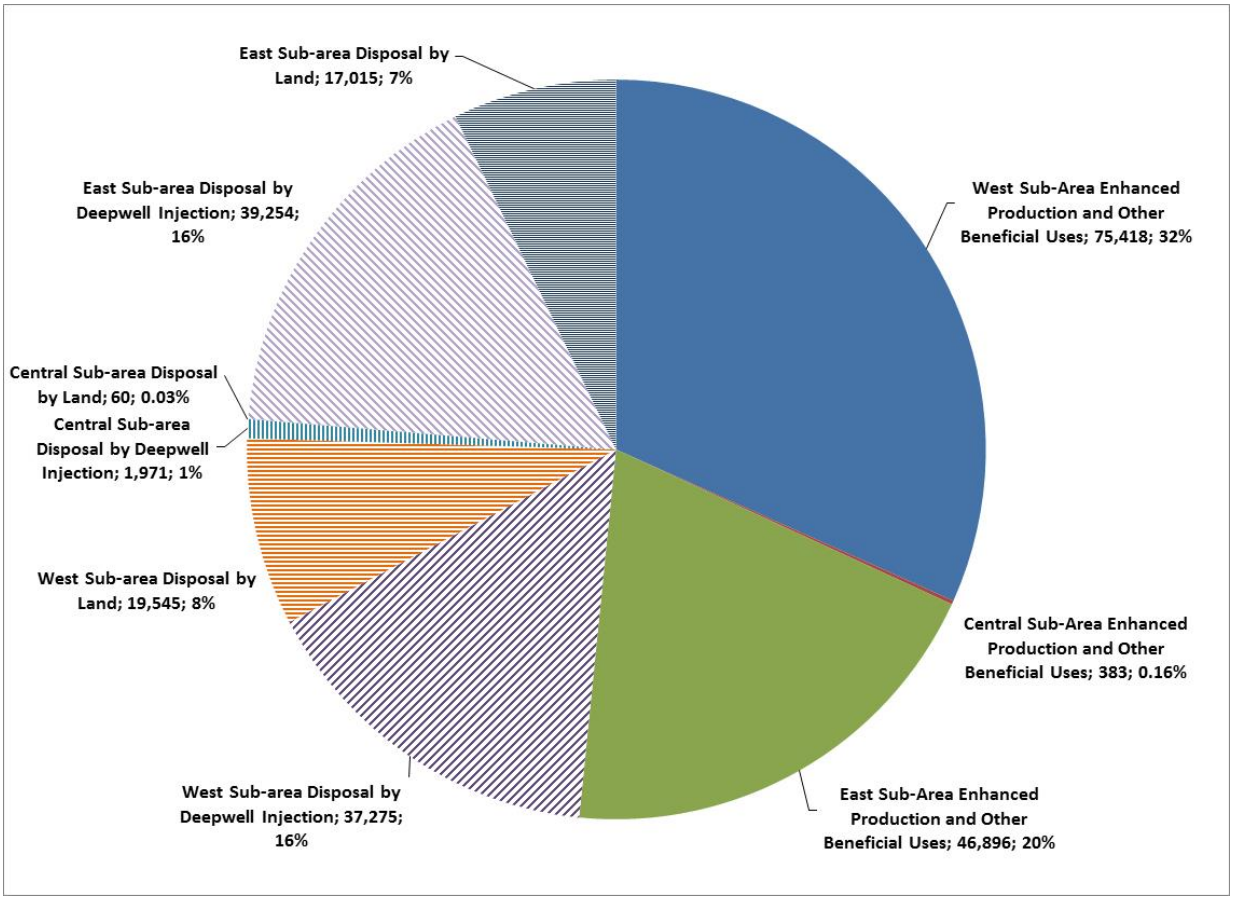

Figure 17. Estimated Produced Water Use and Disposal in the Project Area in 2012 (AF)[1]

1.Some values shown in the Figure differ from those in Table 28 due to the differences in data source and assumptions of M&I water use and resulting land applied water estimates. Refer to notes 1 and 2 in Table 28.

Figure 18 shows the produced water balance for the West Sub-Area. The solid legends in the pie chart shows the amount of produced water beneficially used in the Project Area and the hashed legends show the amount of produced water disposed as waste through deep well injection or by surface disposal.

The water balance for West Sub-Area also includes 216 AF transferred from the Central Sub-Area. Approximately 35 percent (~45,600 AF) of the produced water generated or otherwise received was used for EOR by water flooding operations. Approximately 9 and 13 percent of the produced water were used for EOR by cyclic steam and steam flooding operations. A small amount of produced water (~ 600 AF) was beneficially used for oilfield construction and other maintenance activities. Approximately, 28 and 15 percent of the produced water were disposed as waste through deep well injection and by surface means, respectively. Overall, nearly 57 percent of the produced water in the West Sub-Area was beneficially used for various applications, and 43 percent of the produced water was disposed as waste.

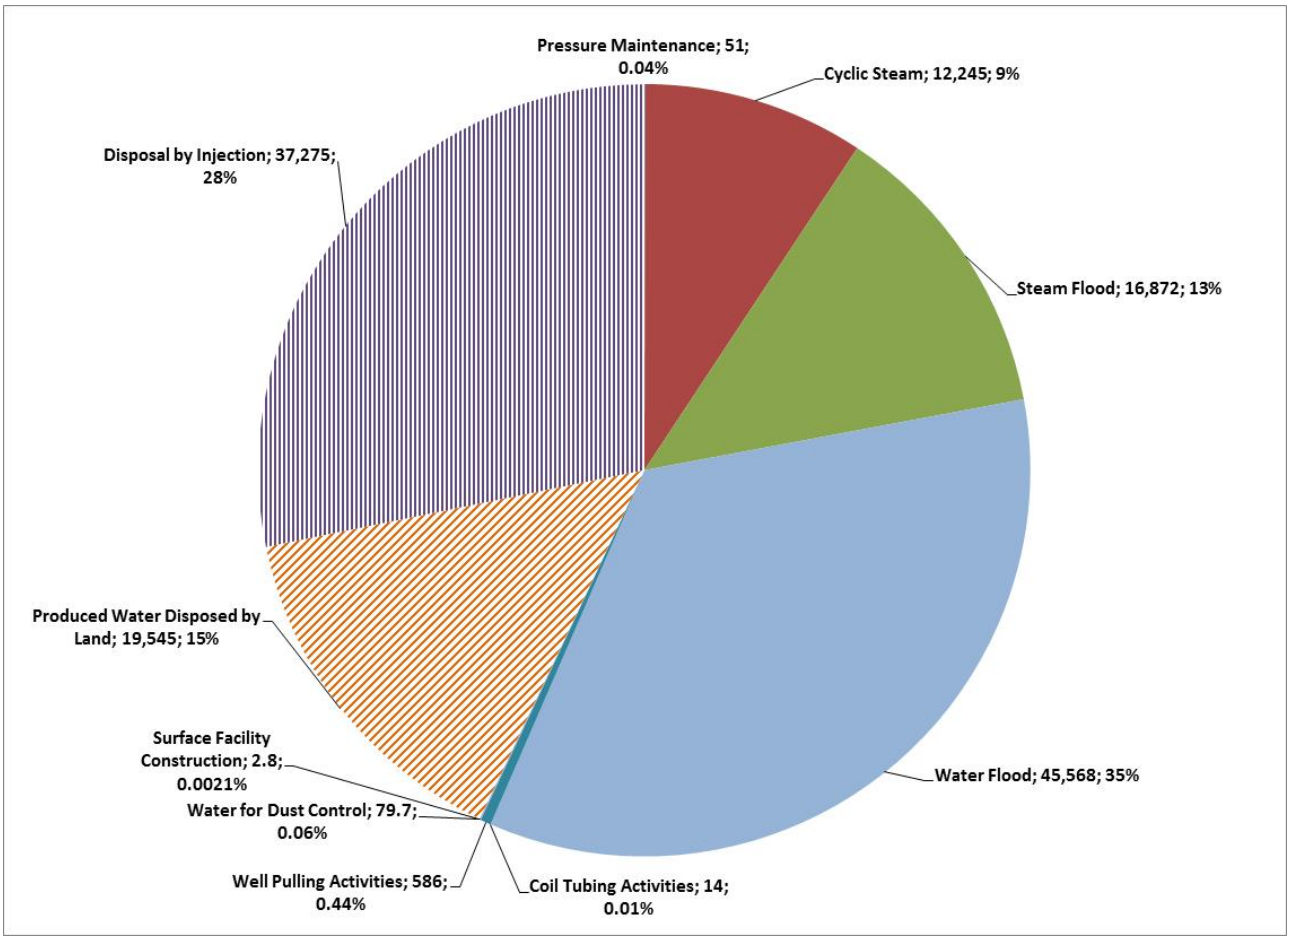

Figure 18. Estimated Produced Water Use and Disposal in the West Sub-Area in 2012 (AF)[1]

1.Some values shown in the Figure differ from those in Table 28 due to the differences in data source and assumptions of M&I water use and resulting land applied water estimates. Refer to notes 1 and 2 in Table 28.

Figure 19 shows the produced water balance for the Central Sub-Area. The solid areas in the pie chart shows the amount of produced water beneficially used in the Project Area (or transferred to other sub-Areas for beneficial use or disposal), and the crosshatched areas show the amount of produced water disposed as waste through deep well injection or by surface disposal.

Out of the 2,873 AF of produced water generated in the Central Sub-Area, approximately 12.4 percent (~355 AF) was used for EOR by water flooding operations. A small amount of produced water (~28 AF) was beneficially used for oilfield construction and other maintenance activities. Approximately 16 percent of the produced water was transferred to the West and East sub-areas for beneficial use or disposal. Approximately, 69 percent of the produced water was disposed as waste through deep well injection and 2 percent through surface discharge.

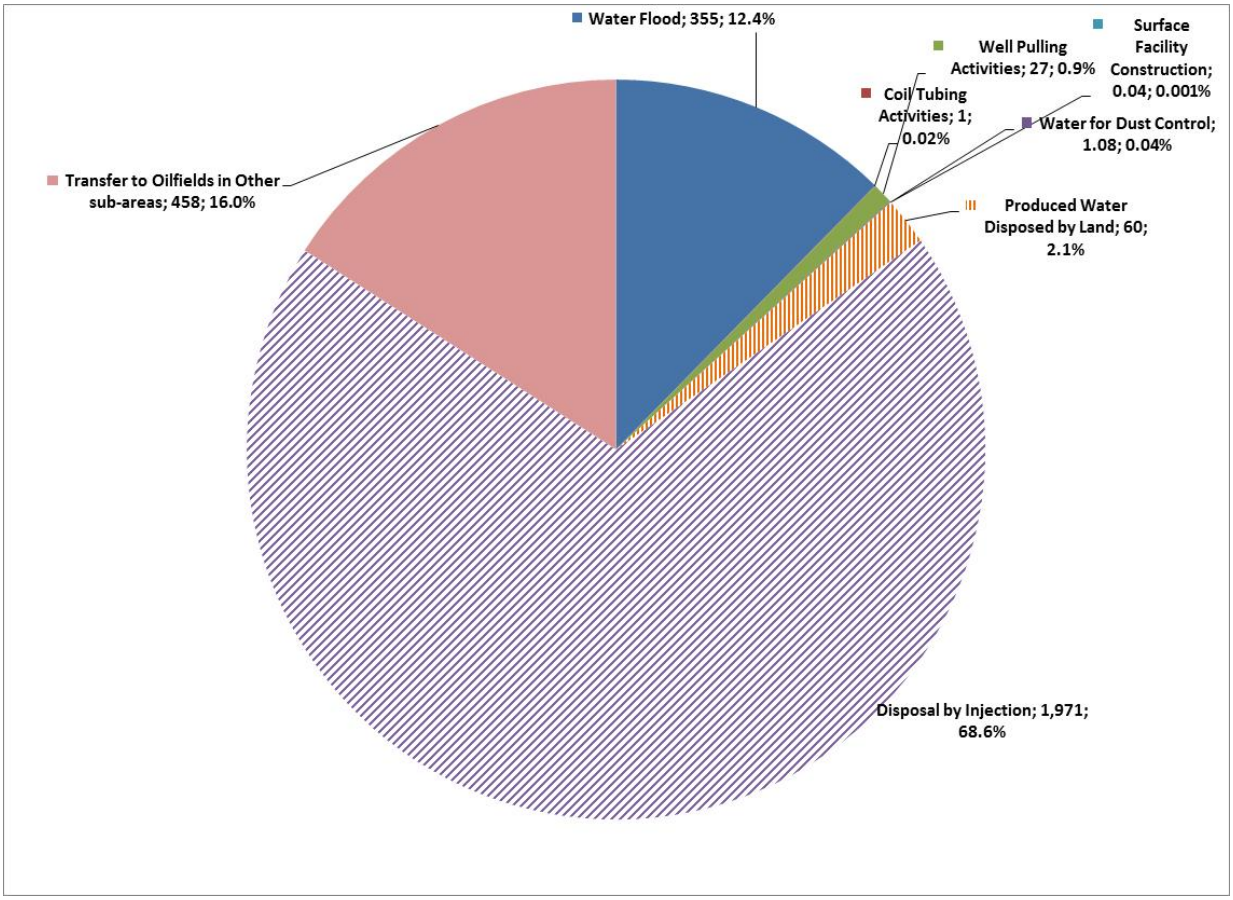

Figure 19. Estimated Produced Water Use and Disposal in the Central Sub-Area in 2012 (AF)[1]

1.Some values shown in the Figure differ from those in Table 28 due to the differences in data source and assumptions of M&I water use and resulting land applied water estimates. Refer to notes 1 and 2 in Table 28.

Figure 20 shows the produced water balance for the East Sub-Area. The solid areas in the pie chart shows the amount of produced water beneficially used in the Project Area and the cross hatched areas show the amount of produced water disposed as waste through deep well injection or by surface disposal.

The water balance for East Sub-Area also includes the 242 AF transferred from the Central Sub-Area. A key beneficial use of produced water from East Sub-Area is its use for agriculture by Cawelo Water District. Approximately 36 percent (~37,000 AF) of the produced water generated or otherwise received in the East Sub-Area is used by Cawelo Water District for agriculture. Additionally, about 1,500 AF of produced water is used for agriculture in Jasmine Mutual Water Company and Concordia Ranch. Approximately 10 percent (~10,400 AF) of the produced water was used for EOR by steam flooding operations. About 2 percent of the produced water was used for EOR by cyclic steam and water flooding operations and other oilfield construction and maintenance activities. Approximately, 38 and 17 percent of the produced water was disposed as waste through deep well injection and by surface means, respectively. Overall, approximately 50 percent of the produced water in the East Sub-Area was beneficially used for various applications, and 50 percent of the produced water was disposed as waste.

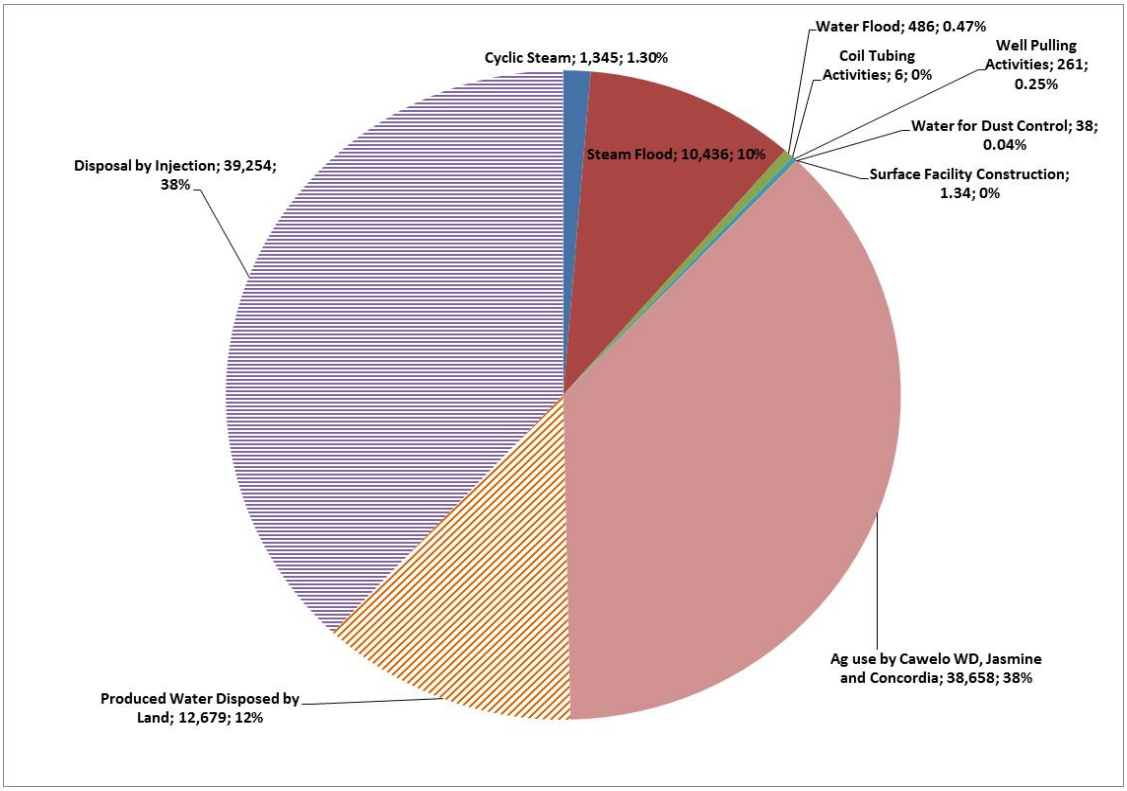

Figure 20. Estimated Produced Water Use and Disposal in the East Sub-Area in 2012 (AF)[1]

1.Some values shown in the Figure differ from those in Table 28 due to the differences in data source and assumptions of M&I water use and resulting land applied water estimates. Refer to notes 2 and 3 in Table 28.

5.8.2 2012 M&I Water Balance in Kern County

Figure 21 shows estimated M&I water use for various oil and gas applications in the Project Area. The total estimated oil and gas M&I water use in the Project Area is approximately 8,778 AF for 2012. Approximately 95 percent (8,358 AF) was used in the West Sub-Area for various activities. The oil and gas M&I water use in the Central and East sub-areas are approximately 1 percent (63 AF) and 4 percent (357 AF), respectively. The estimated total oil and gas M&I water use of 8,778 AF is approximately 3.4 percent of produced water (256,070 AF) beneficially used in the Project Area in 2012.

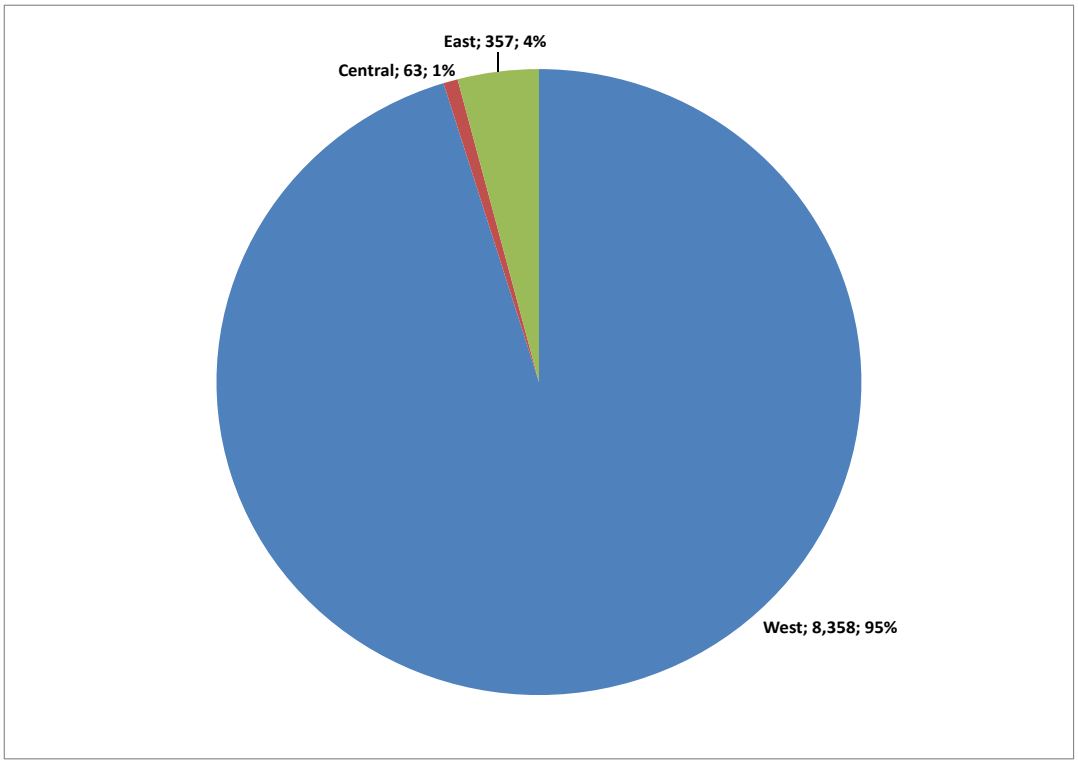

Figure 21. Estimated M&I Water Use in the Project Area in 2012 (AF)

Figure 22 shows the estimated oil and gas M&I water use for various activities in the West Sub-Area in 2012. The major oil and gas M&I water use include steam production for EOR (87%), domestic water use (5%) and SB-4 activities (4%).

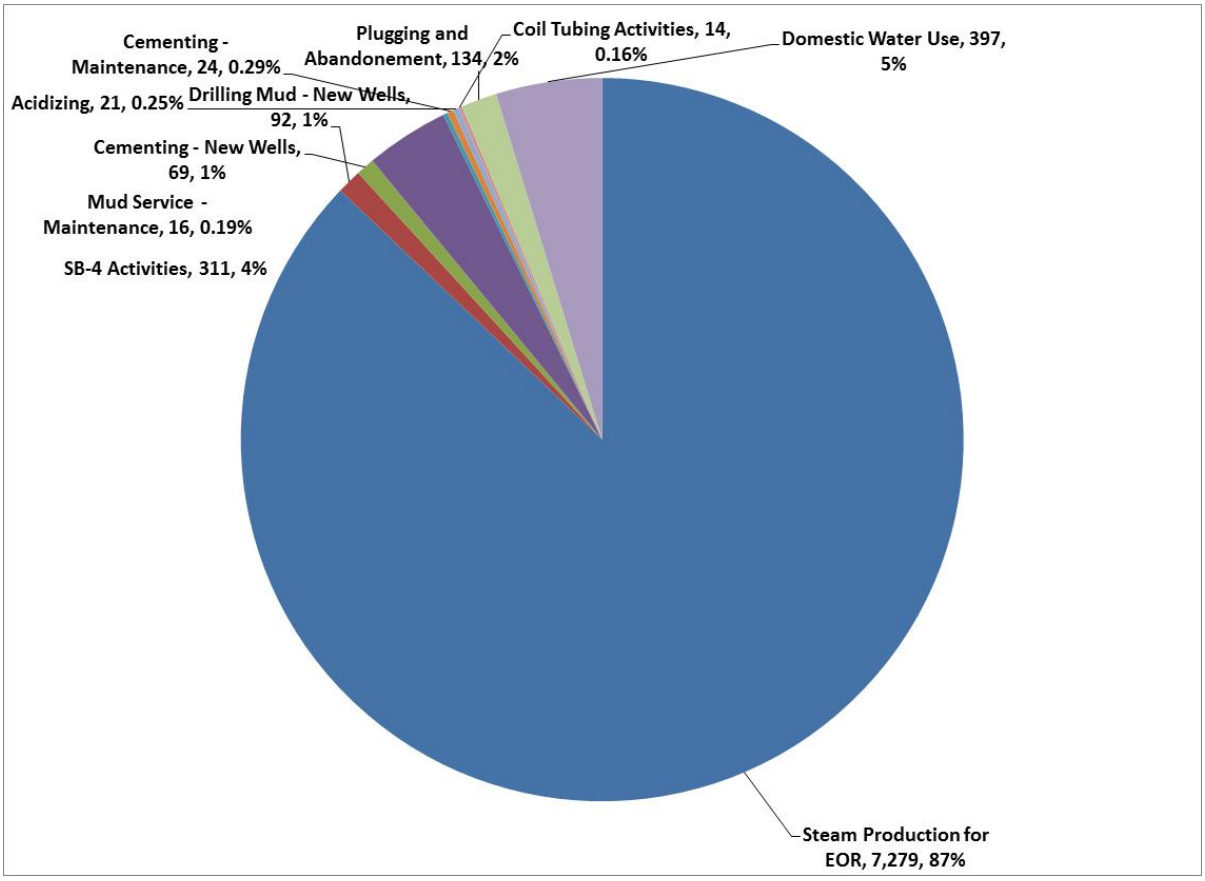

Figure 22. Estimated M&I Water Use in the West Sub-Area in 2012 (AF)

Figure 23 shows the estimated oil and gas M&I water use for various activities in the Central Sub-Area in 2012. The major oil and gas activities that require M&I water include, SB-4 activities (56%) water, domestic water use (18%) and drilling mud for new well construction (6%).

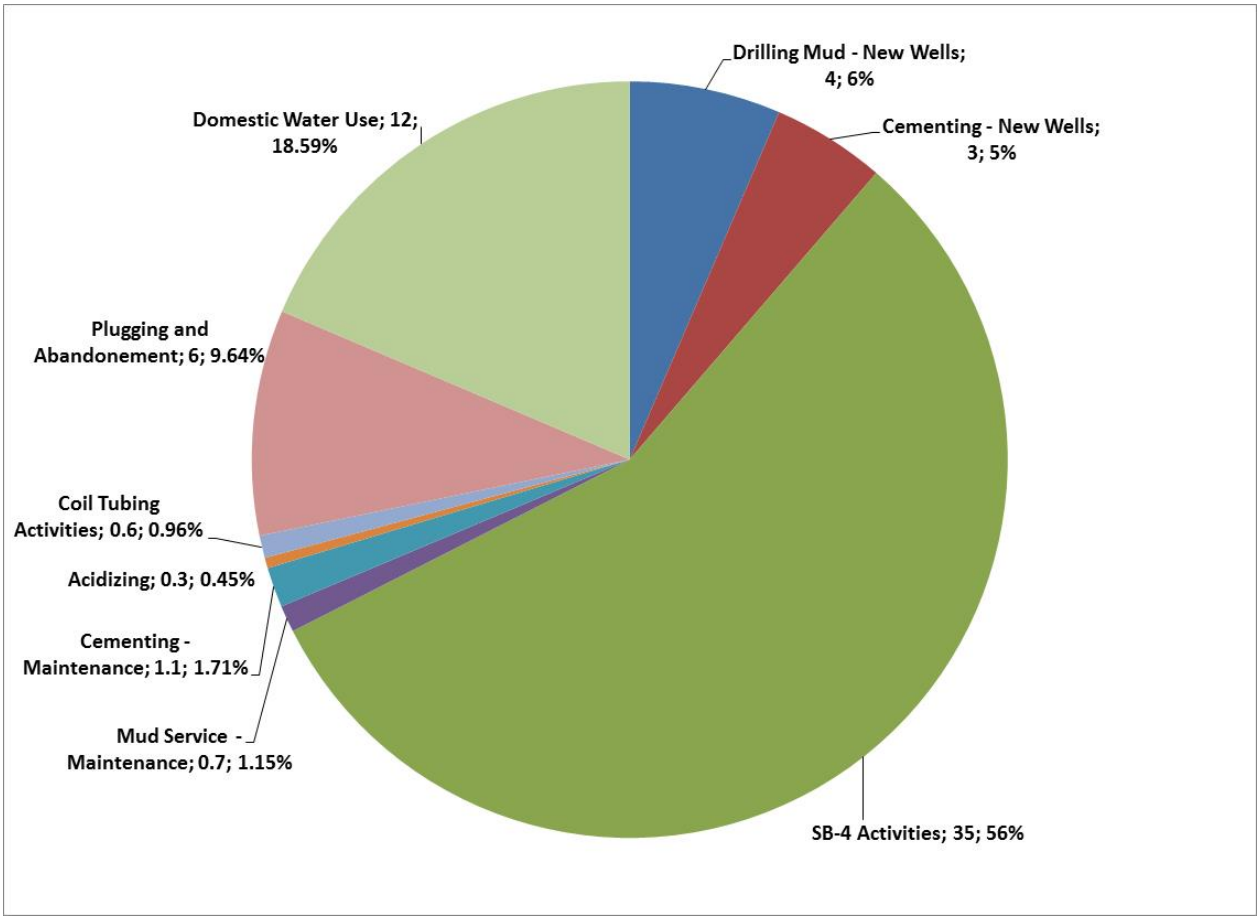

Figure 23. Estimated M&I Water Use in the Central Sub-Area in 2012 (AF)

Figure 24 shows the estimated oil and gas M&I water use for various activities in the East Sub-Area in 2012. The major oil and gas activities that require M&I water include, domestic water use (52%), plugging and abandonment (17%) and drilling mud for new wells (12%).

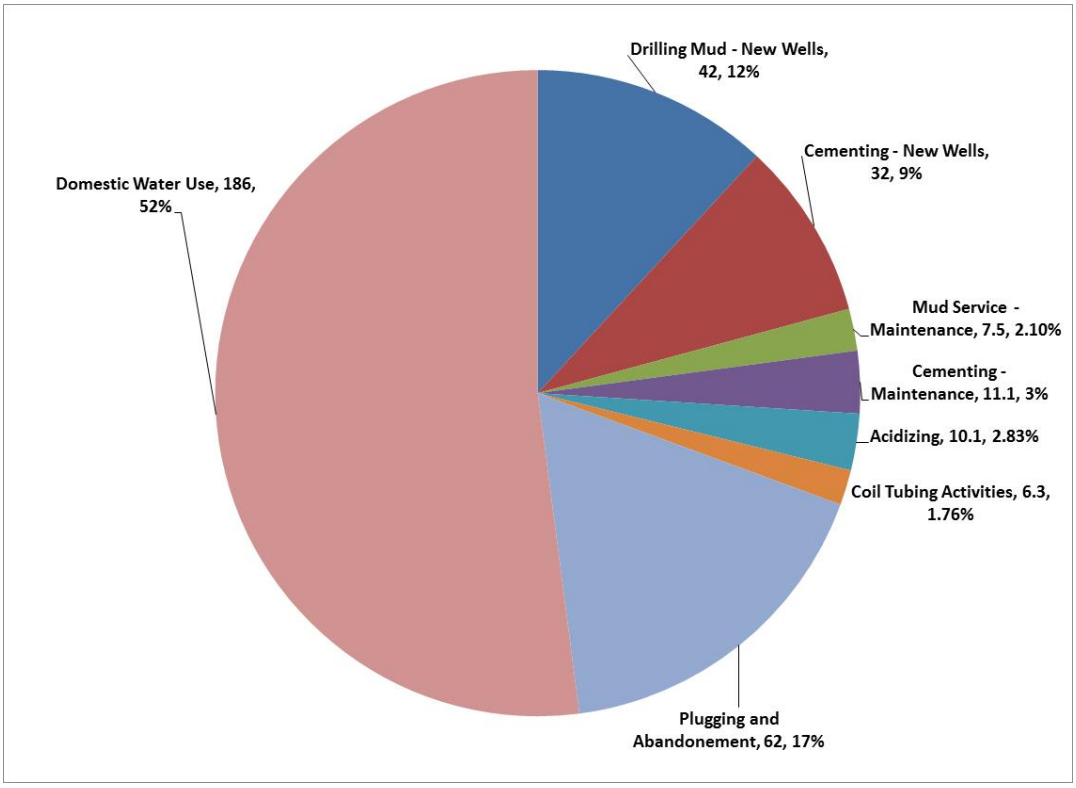

Figure 24. Estimated M&I Water Use in the East Sub-Area in 2012 (AF)

5.9 Oil and Gas Water Demand

Based on WZI evaluations, in 2012 oil and gas water demands were:

- 8,778 AF M&I water and 88,812 AF produced water for the Project Area
- 8,358 AF M&I water and 75,418 AF produced water for the West Sub-Area
- 63 AF M&I water and 820 AF produced water for the Central Sub-Area
- 357 AF M&I water and 12,574 AF produced water for the East Sub-Area (does not include produced water delivered to Cawelo Water District, Jasmine Mutual Water Company and Concordia Ranch for agriculture)

5.10 Future Oil and Gas Water Demand

Future oil and gas water demand was estimated using the impact factors for various well construction, oil & gas production, maintenance and abandonment activities developed by WZI (see Tables 28 and 29). These impact factors were used in conjunction with the projections for number of wells estimated to be drilled and abandoned in future years provided by WZI (Table 29). Table 29 provides the breakdown of various types of wells to be drilled or abandoned in the three sub-areas in future. The assumptions used in the well projections are also shown. In addition, the number of "reworked" wells in each sub-area was estimated using the ratio of reworked well to total wells in 2012 and the total estimated wells in a given year.

TABLE 29
PROJECTIONS FOR FUTURE WELL OPERATION, CONSTRUCTION, AND ABANDONMENTS

Activity	West	Central	East	Total
New Producing Wells. (Active, New, Idle and Blank)	1730	131	836	2,697
Total Wells: Active, New, Idle and Blank	2,447	162	1040	3,649
Hydraulic Stimulation (SB-4)	680	131	2	763
Plugging & Abandonment[(a)]	1,803	74	354	2,231

Notes: (a) The number of abandoned producing and non-producing wells were estimated using the ratio of new producing and non-producing wells drilled in each sub-area

Figure 25 show the projected water demand for the oil and gas sector estimated using the above projections and assumptions for the three sub-Areas. The total projected oil and gas sector produced water demand increases from approximately 128,000 AF in 2012 to approximately 161,000 AF in 2035.

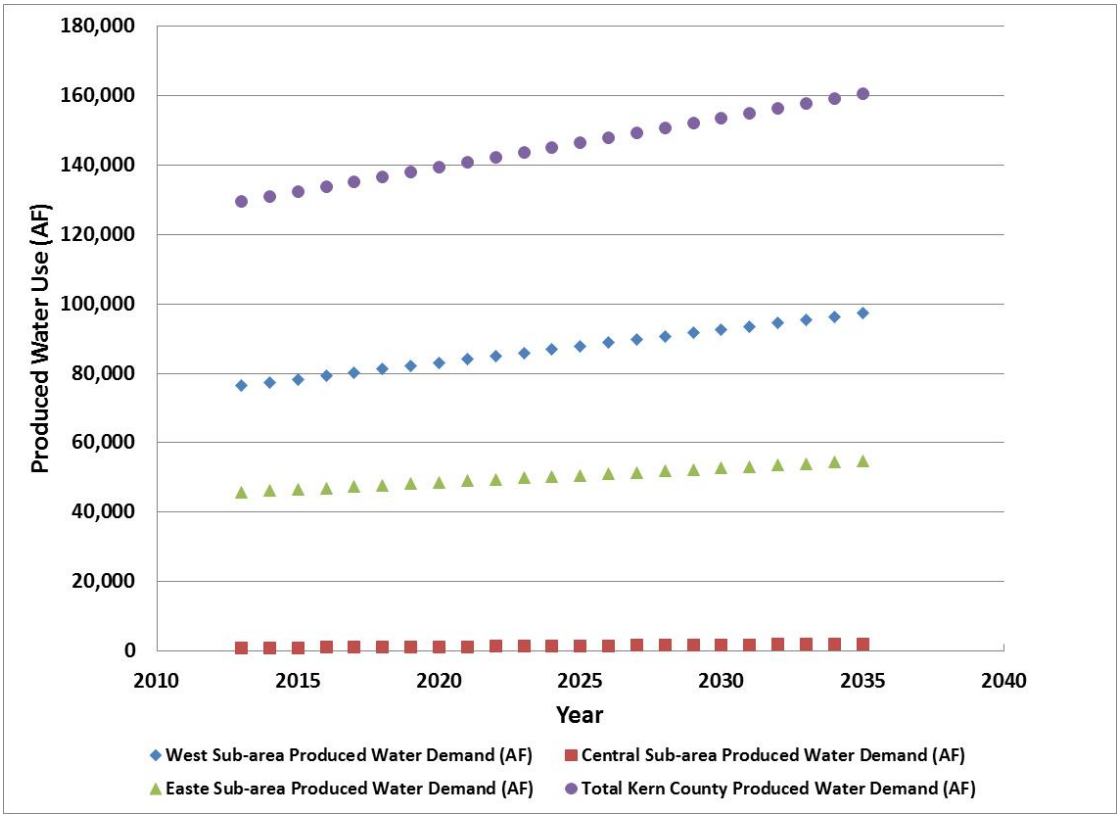

Figure 25. Projected Beneficial Produced Water Demand in the Project Area from 2015 to 2035

Table 30 and Figure 26 show the M&I water demand for the oil and gas sector estimated using the above projections and assumptions for the three sub-areas. For the West Sub-Area, the projected M&I water demand increases from 8,700 AF in 2013 to 10,850 AF in 2035. For the

Central Sub-Area the projected M&I water demand increases from 375 AF to 395 AF in 2035. For the East Sub-Area the projected M&I water demand increases from 374 AF to 515 AF in 2035. The total projected oil and gas sector M&I water demand increases from 9,450 AF in 2013 to 11,760 AF in 2035, an approximately 34 percent increase from the 2012 M&I water demand. The West Sub-Area projected M&I water demand is approximately 92 percent of the total projected M&I water demand. Figure 26 shows the trends in projected M&I water demands for the oil and gas sector Project Area.

In Table 30 the left column for each sub-area is based on projections. However, in Table 30 to be conservative, a 10 percent contingency has been added to cover any annual variations.

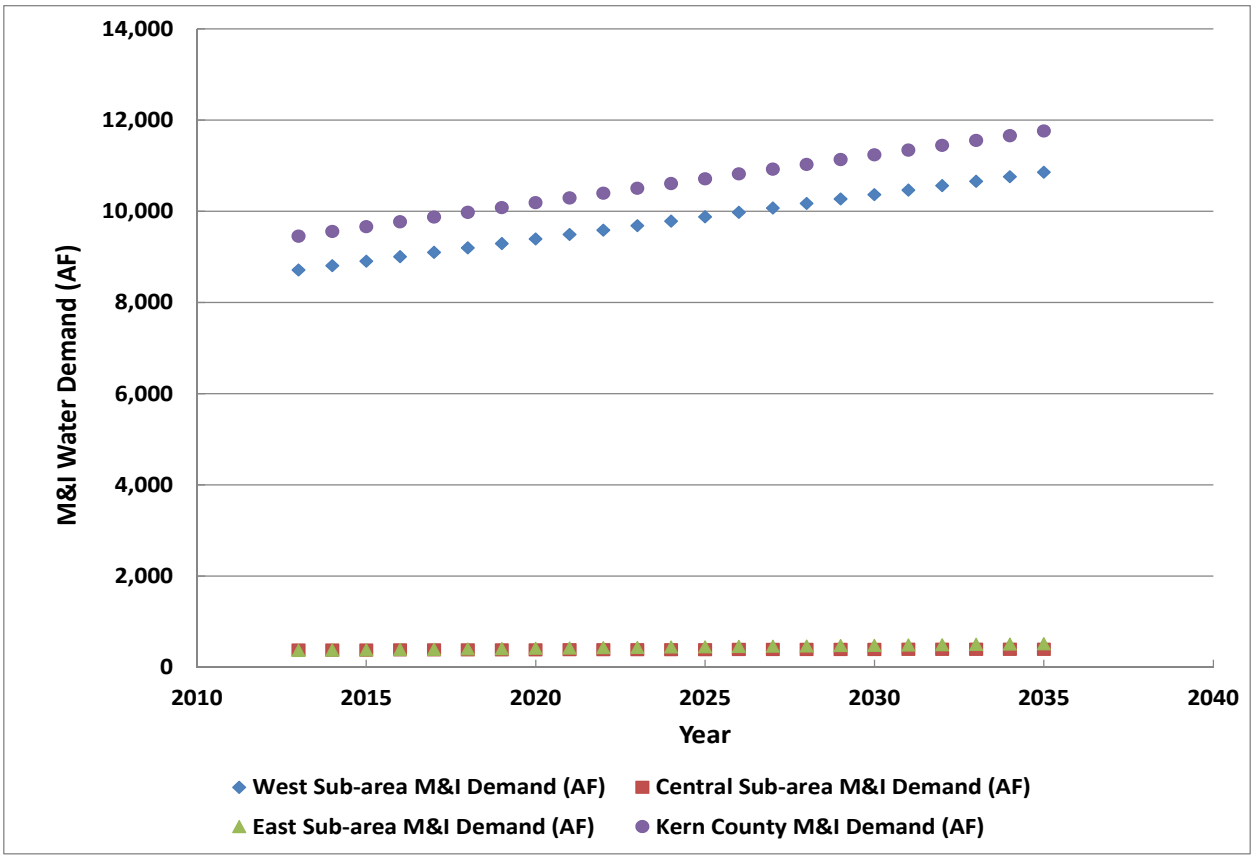

Figure 26. Projected M&I Water Demand for Oil and Gas Activities

TABLE 30
OIL AND GAS SECTOR M&I WATER DEMAND PROJECTION PLUS 10% CONTINGENCY

Year	West Sub-Area		Central Sub-Area		East Sub-Area		Total for Project Area

2035	10,851	11,936	395	434	515	566	11,760	12,936

Section 6: Project Area Water Demand

In addition to evaluating supplies, a WSA must also evaluate current and future demands. This WSA evaluates the water demands in the Project Area and the three designated oil and gas Sub-Areas, West, Central, and East. Future water demand projections are described in normal, single-dry, and multiple-dry years, in five-year increments from 2010 to 2035, based on existing, publicly available data.

6.1 Overview of Water Demand

Water demands within the Kern Region are serviced by a variety of water purveyors, including the large wholesale agency, KCWA, its member districts, irrigation and water storage districts, investor-owned water companies, mutual water companies, municipalities and private well owners. The locations of the water purveyors and communities in the Project Area are described in section 2.4 of this WSA.

The current water demand in the Project Area includes urban (M&I), agricultural, and oil and gas sectors. Water districts in the Project Area conjunctively use surface water (both imported and local), groundwater, recycled water, and oilfield produced water to meet their water demand requirements.

The total current demand for the urban, agriculture, and oil and gas sectors in the Project Area is estimated to be approximately 3,008,480. The combined urban and agricultural demand for the current conditions is estimated to be approximately 2,905,700 AF annually. Of all demands (ag, urban, oil and gas), agriculture is by far the largest water use, accounting more than 88%. The current water demand by the oil and gas sector is estimated to be approximately 102,800 AF, making up less approximately 4% of the total Project Area demand.

The total water demand for all sectors is projected to be a little more than 3,103,500 AF by 2035. This represents a 3.2% increase in demand from the current conditions. The urban demand would reach about 302,000 AF by 2035, an increase of approximately 27% from 2015 conditions. Although some changes to agricultural land use is anticipated to occur in the future, as a conservative assumption, agricultural demand was assumed to stay at the same level as current conditions.

Urban demand is anticipated to vary by hydrological year types (normal, single-dry, and multiple-dry years), but the change in demand through time would be greater than the variations due to hydrological conditions. Compared to the 2035 normal demand projections (302,000 AF), urban demand would be slightly lower during a single-dry year (300,000 AF) and slightly higher during multiple dry years (306,000 AF).

Oil and gas demand is assumed to be controlled primarily by future operations, and not affected by hydrological conditions; thus, demand for this sector was assumed to be independent from hydrological year types.

6.1.1 Current and Future Water Demand

This section presents the current and future projections of water demand for the Project Area and the three Sub-Areas. The water demand projections were estimated separately for the urban, agricultural, and oil and gas sectors and described in the following sections.

6.1.1.1 Urban Demand

Urban demand projections were evaluated in normal, single-dry, and multiple-dry years in five-year increments from 2010 to 2035, based on existing, publicly available data. Data were compiled primarily from the water purveyors with UWMPs in the Project Area, the Tulare Lake Basin Portion of Kern County IRWMP, and the Poso Creek IRWMP. Water supplies utilized in the Project Area to meet urban demand are the SWP via the California Aqueduct, the CVP via the Friant-Kern Canal, local surface supplies from the Kern River and other local streams, groundwater pumping from the Kern County Subbasin of the San Joaquin Valley Groundwater Basin, recycled water, and oilfield produced water. Urban water demands reported by the agencies typically include M&I customers (residential, commercial/industrial/institutional, and landscape) and other water use types (e.g., fire and water losses). Purveyors supplying water to M&I customers include the followings:

- Arvin CSD
- Buttonwillow CWD
- California Water Service
- Casa Loma WC
- City of Bakersfield
- City of Delano
- City of Shafter
- City of Tehachapi
- City of Wasco
- East Niles CSD
- Greenfield CWD
- KCWA ID4
- Lamont PUD
- Lost Hills UD
- McFarland MWC
- Mettler CWD
- North of the River MWD
- Oildale MWC
- Stockdale MWC
- Vaughn WC
- Victory MWC
- West Kern WD

6.1.1.2 Urban Demand for Project Area

Table 31 provides a summary of current and projected urban water demands for the Project Area for normal water year from 2010 to 2035. Tables 32 and 33 present urban water demand projections during a single-dry year and multiple-dry years, respectively. Overall, the water demand in the Project Area is projected to increase by 2035. During normal years, water demand would increase from approximately 237,000 AF in 2015 to 302,000 AF in 2035. Water demand projections are estimated to be slightly lower for a single-dry year and slightly higher for multiple-dry years compared to normal year projections. Water demand would increase from approximately 235,000 AF in 2015 to 300,000 AF in 2035 during a single-dry year and from 240,000 AF in 2015 to 306,000 TAF in 2035 during multiple-dry years.

The current and future demand projections were not readily available for Casa Loma WC and Mettler CWD, which are both located in the Central Sub-Area. Casa Loma WC is a privately held company located in Bakersfield within the KCWA ID4 service area, but serves its customers local groundwater. The source of Mettler CWD's water supply is unknown, but is assumed to be small.

For agencies without published 2035 demand projections, demand was assumed to grow at the same rate as population. The 2035 demand projections were estimated based on the average annual population growth rate of 1.8% for Kern Country from 2030 to 2035 based on the population forecast reported by the Kern Council of Governments Draft 2014 Regional Transportation Plan/Sustainable Communities Strategy (Kern Council of Governments 2014).

(i) Vaughn WC 2010 UWMP for 2010 and 2030 water demand projections (Table 32).
(j) West Kern WD 2010 UWMP for 2010 through 2035 water demand projections (Table 6-6).
(k) City of Delano 2010 UWMP (Table 5-15).
(l) City of Shafter 2010 UWMP (Table 28).
(m) City of Wasco 2010 UWMP (Tables 5-11, 5-14, 5-17, 5-20, and 5-23).
(n) A small portion of the Tehachapi-Cummings CWD (about 5 percent) is within the Project Area; thus, only 5 percent of the demand is included.

In an effort to segregate any reporting of agricultural water demand from urban demand, water demand projections for specific water sectors, in particular the agricultural sector, was identified from UWMPs. Data reviewed suggest that urban water demand projections reported by the agencies primarily represent M&I customers and do not typically account for water deliveries to large agriculture farmlands. Data also suggest that some agencies report water use for agricultural within their service area, but agricultural demand was reported to be supplied mainly by recycled water where agencies typically use agricultural lands to discharge the treated wastewater from wastewater treatment plants (WWTPs). With the exception of East Niles CSD that reported a small amount of water delivery to agricultural sector (about 20 AFY) as part of their urban water use, information from UWMPs indicates that urban water demand as reported in UWMPs excludes agricultural water use. In the case of East Niles CSD, urban water demand projections were adjusted to exclude the 20 AFY of agricultural demand from total demand. Tables 31, 32, and 33 reflect this adjustment for East Niles CSD.

6.1.2 Urban Demand by Sub-Areas

Urban water demand projections by the three Sub-Areas are presented for normal/average years, a single-dry year, and multiple-dry years in Tables 34, 35, and 36, respectively. The future projections of water demand by the Sub-Areas were based on the assumption that water demand for an individual agency is distributed by each Sub-Area proportional to the agency's area within each Sub-Area. This is a similar approach taken for evaluating the water supply reliability by the Sub-Areas as described earlier in this WSA. This approach was used as an approximation to illustrate how the future demand projections would vary between the three Sub-Areas.

Similar to the trends seen for the Project Area, water demand by the Sub-Areas would increase over time in a normal year and water demand would vary slightly by the hydrological year types. The highest urban demand would be experienced in the East Sub-Area, accounting for about 50 percent of the total urban water demand. The Central Sub-Area accounts for the next largest share of urban demand and the remaining 15 percent of total demand is estimated in the West Sub-Area.

6.1.3 Agricultural Demand

Kern County ranks among the leading five counties in the US in the value of its agricultural products. The gross value of all agricultural products from the County in 2012 exceeded $6.2 billion according to the Kern County Crop Report (Department of Agriculture and Measurement Standard, 2013).

Water supplies utilized in the Project Area to meet agricultural demand include surface water (both imported and local), groundwater, recycled water, and oil-field produced water. In the Project Area, detailed records of the exact amount of water and the source of water used by individual agencies on agricultural lands are not available. This differs from urban demand projections where the agencies with UWMPs report their water use by different sectors both for current and future conditions. To provide a basis for quantitative analysis, agricultural demand for the Project Area was developed from the irrigated acreage based on the latest land use data for Kern County and an average consumptive water use of 2.87 AF per acre as reported in the Tulare Lake Basin Portion of Kern County IRWMP. This is considered a reasonable approach commonly applied to estimate the agricultural water demand in the absence of actual data. Figure 3 shows the land use data used based on the latest available land use database from DWR. DWR's land use data for Kern County reflect 2006 conditions (DWR 2006).

In general, the region relies heavily on imported water supplies to support the irrigated agricultural economy. It is anticipated that to the extent that surface water supplies are inadequate to meet irrigation water requirements, groundwater will be used to make up the shortfall. Therefore, uncertainties with the reliability of imported surface water and long-term sustainability of groundwater resources will continue to be high priority concerns for the region.

The following water districts located in the Project Area supply water to agricultural customers:

- Arvin-Edison WSD
- Belridge WSD
- Berrenda Mesa WD
- Buena Vista WSD
- Buttonwillow ID
- Cawelo WD
- Delano-Earlimart ID
- Henry Miller WD
- KCWA
- Kern Delta WD
- Kern-Tulare WD
- Lost Hills WSD
- North Kern WSD
- Rio Bravo Ranch
- Pond Poso ID
- Rag Gulch WD
- Rosedale Ranch ID
- Rosedale-Rio Bravo WSD
- Semitropic WSD
- Shafter Wasco ID
- Southern San Joaquin MUD
- Tehachapi-Cummings CWD
- West Kern WD
- Wheeler Ridge-Maricopa WSD

6.1.3.1 Agricultural Demand for Project Area

Table 37 provides a breakdown of the acreage by crop type in the Project Area and water demand by each crop. The total irrigated land is estimated to be approximately 885,828 acres. Nearly 40 percent of the irrigated land (or about 346,540 acres) is located in the Poso Creek area which is predominantly agricultural land.

The total agricultural demand in the Project Area is estimated to be approximately 2.669 MAF, as presented in Table 37. Historically the trend of agricultural water use has been decreasing, this is confirmed by review of Kern County Agricultural Crop Reports for 2000 to 2013. This analysis relies on 2006 crop data from DWR. The amount of land used for agriculture has not been greater than the acreage in 2006 in any year since 2006. For the purposes of this analysis future agricultural water demands were assumed to remain the same as 2006 levels, at 2.669 MAF. This is a conservative assumption given the conversion from agricultural to urban use in the region.

6.1.3.2 Agricultural Demand by Sub-Areas

Table 38 presents the irrigated acreage and corresponding agricultural water demand by the three Sub-Areas. As shown in Table 38, the agricultural water demand is highest in the Central Sub-Area that comprises about 50 percent of the total demand. The West Sub-Area accounts for the next largest agricultural demand, making up about 32 percent of total demand while the East Sub-Area accounts for the remaining 18 percent.

Similar to the approach used for the Project Area demand projections, future agricultural water demands by the Sub-Areas were assumed to stay at the same levels as the current conditions.

TABLE 37
SUMMARY OF AGRICULTURAL WATER DEMAND (AFY)

Crop Type	Irrigated Acreage[(a)]	Consumptive Water Use (AF/acre)[(b)]	Agricultural Water Demand (AFY)
Alfalfa and alfalfa mixtures	90,129	4.10	369,529
Almonds	171,273	3.28	561,776
Apples, Pears, Plums	3,958	3.45	13,655
Apricots, Nectarines, Peaches	4,890	3.35	16,383
Beans (dry and green)	3,811	2.11	8,041
Carrots	24,684	2.55	62,944
Citrus(grapes, lemons, oranges)	60,566	3.37	204,108
Corn, Grain Sorghum	26,659	2.95	78,644
Cotton	103,302	2.71	279,949

6.3 Water Demand Data Gaps and Limitations

As with most hydrologic studies, there are inherent data limitations. Table 40 describes data limitations of this study as well as the approach used by the WSA to address the various limitations and uncertainty. Among the issues identified, the major data gap is the uncertainty related to agricultural groundwater demand. It is not possible to track detailed records of agricultural groundwater pumping within individual agency service areas, as the majority of water used for agriculture has not been reported. Agricultural demand in the Project Area was estimated based on land use acreages and crop consumptive use. Recent legislation requires the reporting of groundwater pumping in the future.

TABLE 40
APPROACH TO DATA LIMITATIONS AND UNCERTAINTY

Data Type	Approach to Data Limitation/Uncertainty
Agricultural Demand	Detailed records by individual agencies unavailable. Reported data are based on estimated calculations from land use acreages and crop consumptive use. The land use reflects 2006 conditions based on the latest DWR survey data for Kern County.
Future Projections of Agricultural Demand	While some changes in the land use could occur in the future, agricultural land use has been mostly stable; thus, future agricultural demand was assumed to be the same as the current estimate of agricultural demand.
2035 Urban Water Demand Projections	2035 demand projections were unavailable for some agencies with UWMPs and other smaller entities without UWMPs. Urban demand was projected from 2030 to 2035 based on the assumption that urban demand is the same as population growth rate.
Single-Dry Year and Multiple-Dry Year Urban Water Demand Projections	Single-dry year and multiple-dry year demand projections unavailable for agencies without UWMPs. As an assumption, normal year demands were assumed.
DOGGR Dataset Well Locations	Some inconsistencies were encountered with well locations in the DOGGR dataset. Wells were identified in the production/injection database listed as “Kern County” and specific well fields, but their spatial coordinates were well outside of Kern County or outside of the US boundary. Wells with inaccurate well locations were excluded from the dataset and analysis. This affected about 244 wells with minor injection volumes out of approximately 134,819 wells included in the database.

Section 7: Comparison of Supplies and Demands

This WSA compares total projected water use with the projected water supply over the next twenty years and beyond in 5 year increments and includes an assessment for a normal/average year, a single-dry year and a multiple-dry year period.

7.1 Normal/Average Water Year

Table 21 provides information on Sub-Area and Project Area water supplies during a normal year. Table 41 provides information on total demand for the Sub-Area and Project Areas. Table 41 provides a comparison of regional water supplies and demands for these sources. Table 41 demonstrates that adequate regional supplies are anticipated for 2015 to 2035 under normal/average conditions. However, Table 41 does illustrate the fact that supplies in the Central Sub-Area are insufficient, meaning that demands in the Central Sub-Area could be served by bringing in supplies from the other Sub-Areas or pumping groundwater (which may result in potentially unsustainable levels).

TABLE 41
COMPARISON OF SUPPLIES AND DEMANDS, NORMAL YEAR 2015 TO 2035 (AF)

Sub-Area	2015	2020	2025	2030	2035
West					
Supplies	1,041,993	1,047,065	1,052,136	1,057,208	1,062,279

Supplies	3,157,881	3,165,137	3,172,393	3,179,649	3,186,904
Demands	3,008,482	3,016,310	3,043,669	3,073,050	3,103,596
Difference (supplies - demands)	*149,399*	*148,827*	*128,724*	*106,599*	*83,308*

7.2 Single-Dry Water Year

The single-dry year is generally the lowest annual runoff for a watershed since the water-year beginning in 1903 (DWR 2011b). The single-dry year may differ for various sources. This section summarizes regional water supplies available to meet demands over the 25-year planning period during a single-dry year and compares them to demands for the same period. Table 42 anticipates inadequate regional water supplies for the period 2015 to 2035 under single-dry year conditions. This means that in a single-dry year, some demands cannot be met with available supplies, and may require taking water out of water banks, and/or pumping groundwater at potentially unsustainable levels.

TABLE 42
COMPARISON OF SUPPLIES AND DEMANDS, SINGLE-DRY YEAR
2015 TO 2035 (AF)

Sub-Area	2015	2020	2025	2030	2035

Project Area					
Supplies	2,255,681	2,262,937	2,270,193	2,277,449	2,284,704
Demands	3,006,391	3,015,514	3,042,583	3,071,672	3,101,831
Difference (supplies - demands)	*-750,710*	*-752,577*	*-772,390*	*-794,223*	*-817,127*

7.3 Multiple-Dry Water Year

A multiple-dry year period is generally the lowest average runoff for a consecutive period of three or more years (DWR 2011b). The multiple-dry year period may differ for various sources. This section summarizes regional water supplies available to meet demands over the 25-year planning period during a multiple-dry year period and compares them to demands for the same time frame. Table 43 anticipates inadequate regional supplies for the period 2015 to 2035 under multiple-dry year conditions. While supplies in a multiple-dry year period are sufficient in the West and East sub-areas, the shortage is severe in the Central Sub-Area, meaning that in a multiple-dry year period some demands cannot be met with available supplies, which may require recovering water from water banks, and/or pumping groundwater at potentially unsustainable levels.

TABLE 43
COMPARISON OF SUPPLIES AND DEMANDS, MULTIPLE-DRY YEARS
2015 TO 2035 (AF)

Section 8: Findings

Assessment of the documents reviewed as part of this WSA establishes that there is no surplus water in the Project Area. Other studies have also come to similar conclusions. A summary of other references documenting potential water supply shortage in the Project Area follows.

8.1 California Water Plan Update 2013

In July 2014, DWR released the California Water Plan (CWP) Update 2013. In Volume 2 - Regional Reports for the Tulare Lake Hydrologic Region, the following is stated:

> *During years of normal or above normal precipitation, or during periods of low groundwater extraction, aquifer systems tend to recharge and respond with rising groundwater levels. As groundwater levels rise, they reconnect to surface water systems, contributing to surface water baseflow or wetlands, seeps, and springs. However, for much of the Tulare Lake Hydrologic Region, due to extensive pumping over the years the groundwater table has been disconnected from the surface water system for decades and provides no contribution to baseflow.*

CWP Volume 2 continues with that assessment stating that "in 1980, DWR Bulletin 118-80 (DWR 1980) identified five of the seven southern San Joaquin Valley groundwater subbasins (Kings, Kaweah, Tulare Lake, Tule, and Kern County) as being subject to conditions of critical overdraft. Thirty years later, things do not appear to have changed much. Although efforts have been made by local groundwater management agencies to reduce overdraft conditions in the region, a number of the groundwater management plans and more recent studies of these five key groundwater subbasins acknowledge that groundwater overdraft continues."

Figure 27 shows an overall decline in groundwater levels for much of the region. Isolated locations showing 40- to 50-foot increases in 2005-2010 groundwater levels largely correspond to nearby recharge basins within the Kaweah and Tule subbasins. The largest decline in groundwater levels is along the axis of the valley, in the western Kings, Kaweah, Tule, and Kern County subbasins. The maximum decline in 2005-2010 groundwater levels in these areas ranges from 40 to 90 feet (CWP Update 2013 Volume 2 Tulare Lake Hydrologic Region 2014).

Groundwater levels in wells can be influenced by myriad factors, such as pumping rates, surface water allocations, nearby recharge structures, and climate. Groundwater levels in some parts of the Project Area have dropped sharply since the start of the most recent drought. KCWA reports groundwater level declines of approximately 60 feet from spring 2012 to spring 2013 in some parts of ID4 (KCWA 2014), in the Central Sub-area (northwest and southeast of Bakersfield) and West Sub-area (southwest of Bakersfield). The water levels in each well behave uniquely but general trends include:

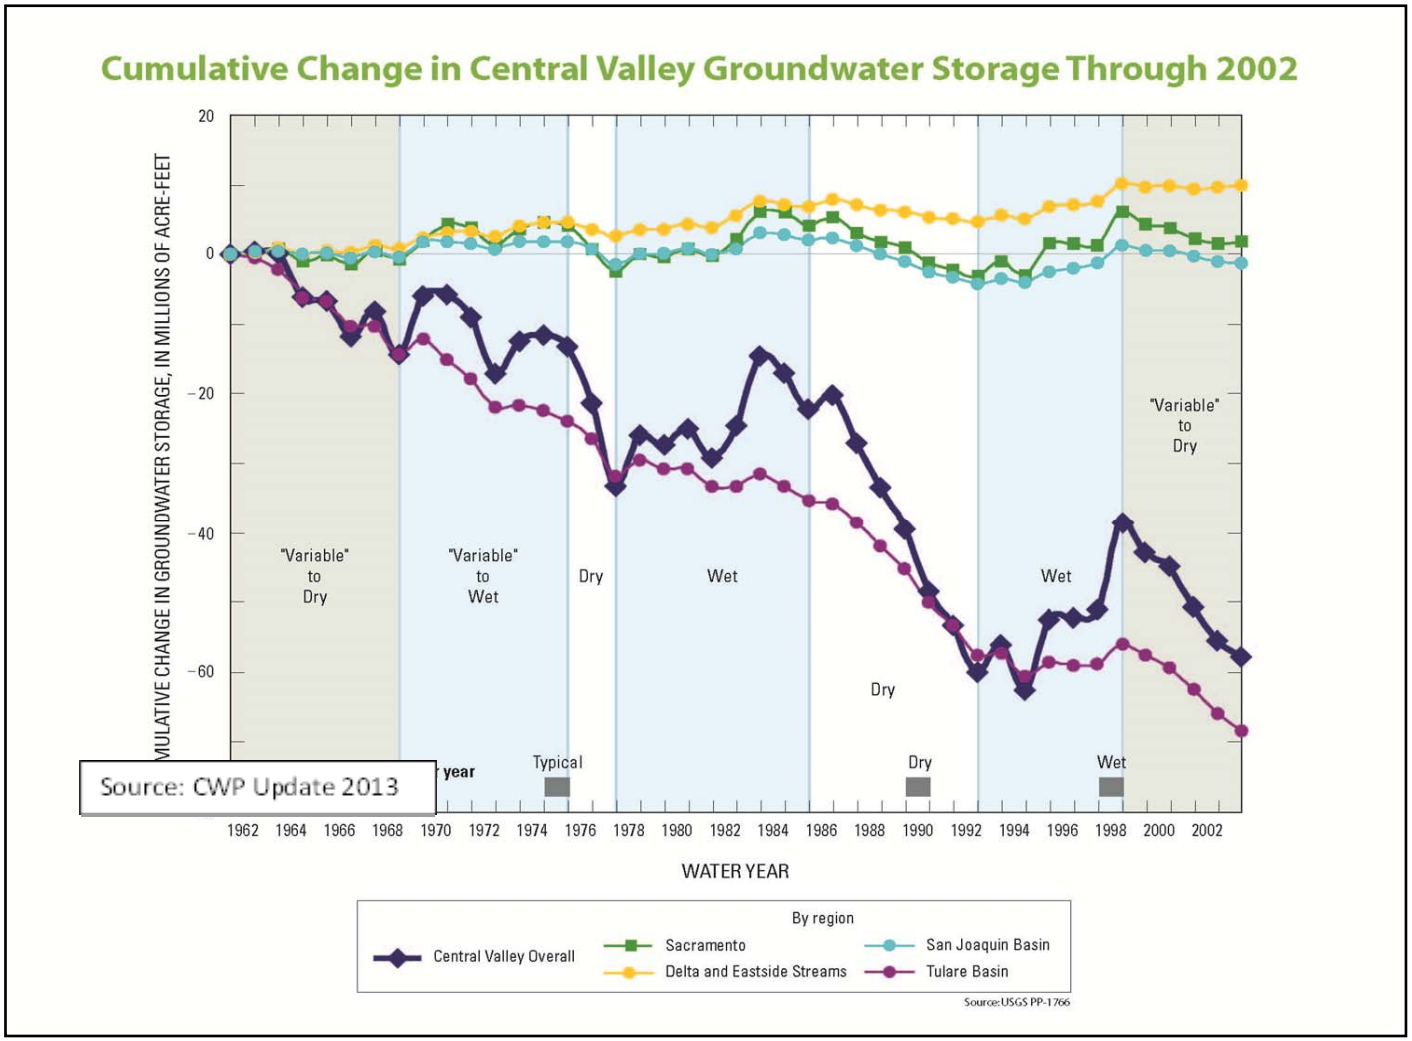

Figure 27. Central Valley Groundwater Storage Change

- Declining levels in most of the Central Sub-area, over two feet per year in some cases. The hydrographs commonly show significant declines (followed by recovery) in the early 1980s, early 1990s, 2009-2010, and 2014. In many wells the lowest levels were reached in 2009-2010.
- Relatively stable or even increasing levels in some parts of the Central Sub-area, and in the East Sub-area that includes the area east of Mettler and near Arvin.
- Relatively stable levels in most of the monitored West Sub-area wells

8.2 Groundwater Basin Prioritization

DWR implemented the California Statewide Groundwater Elevation Monitoring (CASGEM) Program in response to legislation enacted in California's 2009 Comprehensive Water package. As part of the CASGEM Program and pursuant to the California Water Code (CWC §10933), DWR is required to prioritize California groundwater basins, so as to help identify, evaluate, and determine the need for additional groundwater level monitoring.

The CWC requires a statewide prioritization of California's groundwater basins using the following eight criteria:

1. Overlying population;
2. Projected growth of overlying population;
3. Public supply wells;
4. Total wells;
5. Overlying irrigated acreage;
6. Reliance on groundwater as the primary source of water;
7. Impacts on the groundwater; including overdraft, subsidence, saline intrusion, and other water quality degradation; and
8. Any other information determined to be relevant by the Department.

The CASGEM Groundwater Basin Prioritization (Basin Prioritization) is a statewide ranking of groundwater basin importance that incorporates groundwater reliance and focuses on basins producing greater than 90% of California's annual groundwater.

According to the new DWR CASGEM basin prioritization, two “high priority” basins in the Kern Region are listed below:

Hydrologic Region	Sub Basin	Basin Number
Tulare Lake	Kern County	5-22.14
Tulare Lake	Tulare Lake	5-22.12

Notes: Source: DWR California Statewide Groundwater Elevation Monitoring (CASGEM).

DWR also prepared the “Public Update for Drought Response, Groundwater Basins with Potential Water Shortages and Gaps in Groundwater Monitoring” report as required by Governor's January 17, 2014 Emergency Drought Proclamation (Order Action Number 11).

The proclamation required that DWR describe basins with potential water shortages and gaps in groundwater monitoring.

Figure 28 presents data for an observation well in the Kern County Subbasin (San Joaquin Valley) near the Friant-Kern Canal in northern Kern County. Due to increased surface water deliveries from the Friant-Kern Canal and reduced demand on groundwater, water levels generally increased from the mid-1960s. Water levels declined slightly during 1977 and 1978 and then increased more than 30 feet during the wet years of the mid-1980s. From 1990 to 2006, the water levels remained relatively stable. Water levels declined in 2008 and 2009 then stabilized during the above average water years of 2010 and 2011; however, between 2007 and 2013, water levels declined a total of almost 60 feet.

8.3 IRWM Plans

The 2011 Tulare Lake Basin Portion of Kern County IRWM Plan included the following statement on the Tulare Lake Basin Portion of Kern County groundwater overdraft:

> *One of the longest-standing issues in the Kern Region is groundwater overdraft. Groundwater pumping in the Region has been high since the area was settled in the late 1800s, and today groundwater provides approximately 39 percent of local water needs. Certain portions of the groundwater basin underlying the Region have experienced overdraft conditions. According to DWR Bulletin 118, the basin generally underlying the Region experiences a net loss to storage of approximately 325,000 AFY. Key components to recovering from overdrafted conditions are the many conjunctive use and groundwater recharge and banking programs in the Region. However, as urban demand increases and imported water supplies decrease, the ability of these programs to successfully ameliorate groundwater overdraft will be challenged.*

In an effort to eliminate the potential for overdraft conditions in the Greater Bakersfield subregion, surface water was made available to former groundwater users via the Friant-Kern Canal and the SWP. As is well known to the Region, recharge of groundwater supplies is very dependent on surface water. The sources of surface water available to Greater Bakersfield are the Kern River, the SWP and the CVP. Also, the wet period/dry period cycle can have a significant impact on recharge, with groundwater banking being the most noticeably impacted source of recharge (page 3-9, Kern County IRWM Plan).

The 2014 Poso Creek IRWM Plan does not use the term “overdraft,” but it does present the following: “The present utilization of water supplies in the southern San Joaquin Valley is predominantly for irrigated agriculture, which is also true for the Poso Creek Regional Water Management Group (RWMG). Most of the lands in the Poso Creek RWMG are underlain by useable groundwater and, as a result, most of the irrigated agriculture was developed in reliance on pumped groundwater and some lands continue to rely exclusively on pumped groundwater. Accordingly, to the extent that surface water supplies are inadequate to meet irrigation water requirements, groundwater is used to make up the shortfall.”

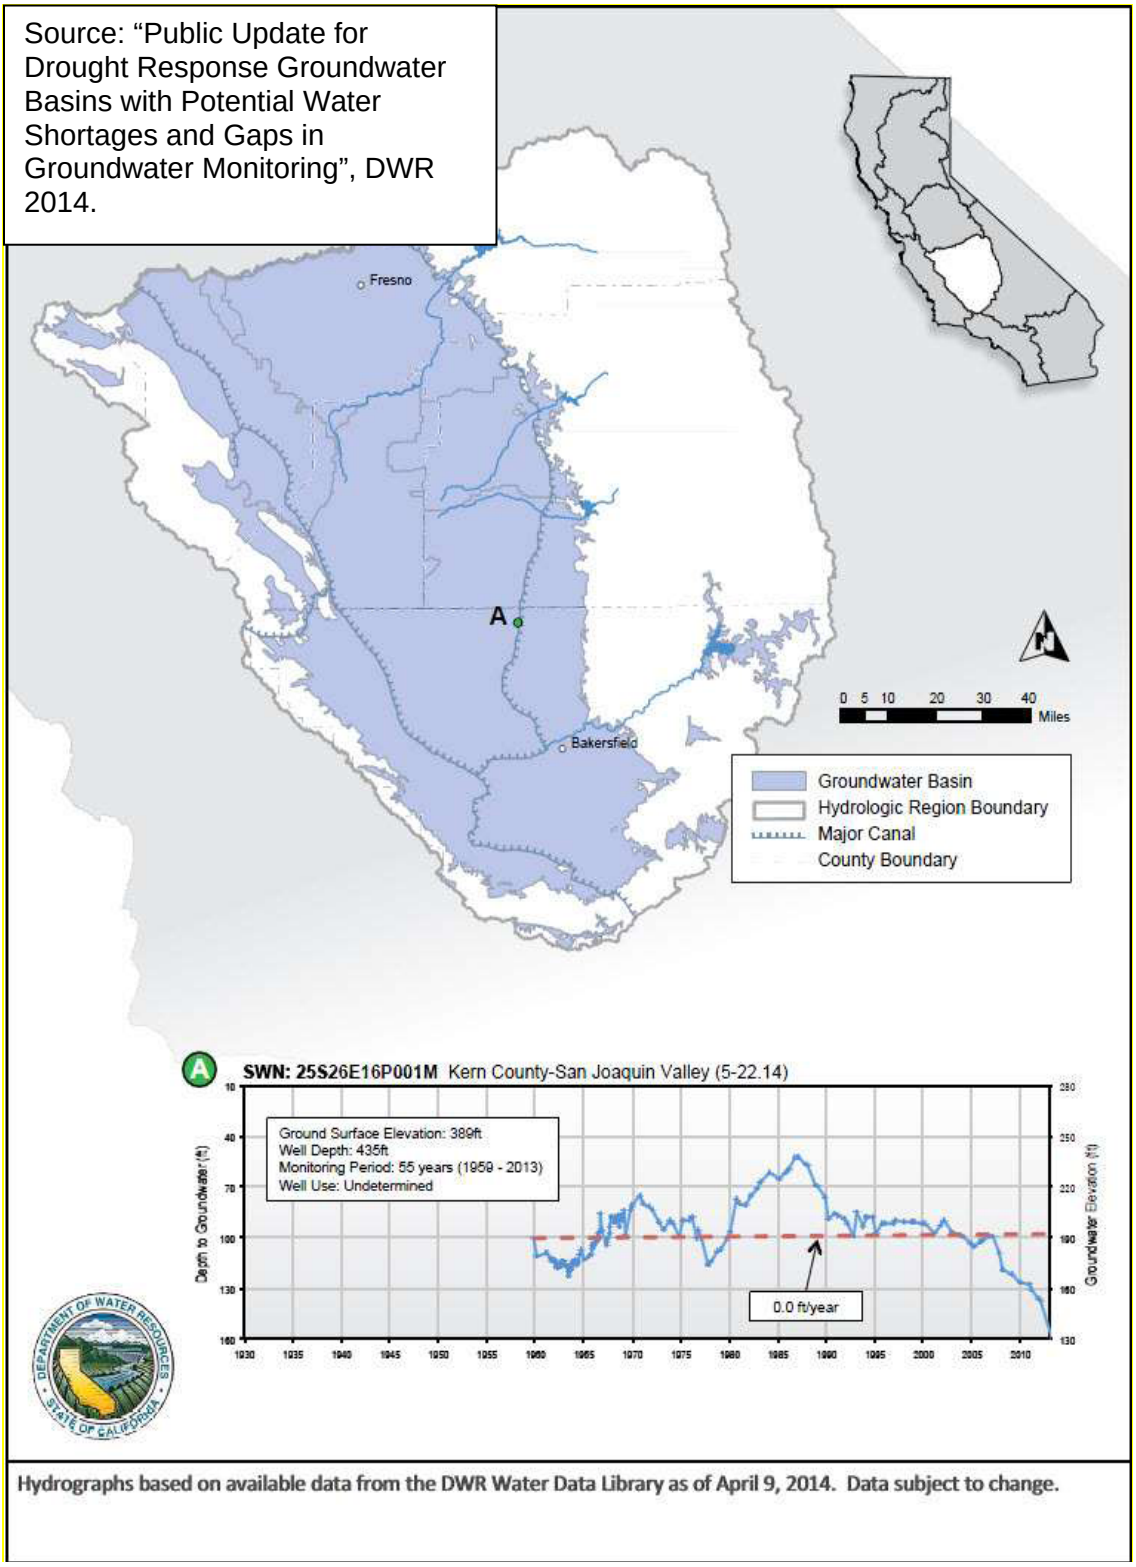

Figure 28. Selected Hydrographs – Tulare Lake Hydrologic Region

8.4 NASA Mapping

New observations from space reveal that since October 2003, the aquifers for California's primary agricultural region - the Central Valley - and its major mountain water source - the Sierra Nevada - have lost nearly enough water combined to fill Lake Mead, America's largest reservoir. The findings, based on data from the NASA/German Aerospace Center Gravity Recovery and Climate Experiment (GRACE), reflect California's extended drought and increased rates of groundwater being pumped for human uses, such as irrigation (NASA 2009).

In short, it can be extremely difficult to compile an accurate picture of groundwater storage changes from ground-based well data alone. In 2009, the University of California Center For Hydrologic Modeling completed a report, “Water Storage Changes in California’s Sacramento and San Joaquin River Basins, Including Groundwater Depletion in the Central Valley” using GRACE and supplementary data from 2003 to 2009. Following are some published results from the report:

- In the 66 month period analyzed, the water stored in the combined Sacramento-San Joaquin River Basin decreased by over 31 km^3 (7.4 $miles^3$), or nearly the volume of Lake Mead.
- Nearly two-thirds of this, or roughly 20 km^3 (4.8 $miles^3$), came from changes in groundwater storage, primarily from the Central Valley.
- Preliminary analyses suggest that as much as 75% of the groundwater loss is occurring in the San Joaquin River Basin, including the Tulare Lake basin, which is consistent with ground-based observations and other studies.
- Drought conditions since 2006 have minimized groundwater recharge and have resulted in constraints on surface water allocations to the Central Valley, triggering a reliance on groundwater resources, particularly in the San Joaquin Valley.
- Groundwater is being used for irrigation at unsustainable rates, leading to declining water tables, decreasing crop sizes and continued land subsidence.
- In the long term, continued reliance on groundwater will deplete critical reserves that buffer cuts to surface water allocations. Continued depletions pose significant threats to food production in the US and the state’s economy.
- Note that the trends are for the specified time period (October, 2003-March, 2009). This time period was selected because it maximized the overlap with the other datasets used in the study (University of California Center For Hydrologic Modeling, 2009).

ENVIRONMENTAL NOISE ASSESSMENT

OIL AND GAS DEVELOPMENT EIR
KERN COUNTY, CALIFORNIA

BBA Report No. 14-057

PREPARED BY

BROWN-BUNTIN ASSOCIATES, INC.
VISALIA, CALIFORNIA

SEPTEMBER 4, 2015

113 North Church Street, Suite 203 · Visalia, CA 93291 · (559) 627-4923

INTRODUCTION

Project Description:

This is a noise analysis of oil and gas exploration, extraction, operations, and production activities in unincorporated Kern County and includes recommendations to update development standards and conditions to address environmental impacts of pre-drilling exploration, well drilling, and the operation of wells, including the exploration, production, completion, stimulation, reworking, injection, monitoring, plugging and abandonment.

Location:

The project area generally includes the unincorporated areas of Kern County, California where oil and gas development and production has historically occurred or is likely to occur in the future. The project area has been subdivided into three sub-areas as shown by Figure 1.

Environmental Noise Assessment:

This environmental noise assessment has been prepared by Brown-Buntin Associates, Inc. (BBA) to determine if significant noise impacts would occur as a result of the project and to describe mitigation measures for noise if significant impacts are determined.

Appendix A provides definitions of the acoustical terminology used in this report. Unless otherwise stated, all sound levels reported in this analysis are A-weighted sound pressure levels in decibels (dB). A-weighting de-emphasizes the very low and very high frequencies of sound in a manner similar to the human ear. Most community noise standards utilize A-weighted sound levels, as they correlate well with public reaction to noise.

REGULATORY SETTING

Appendix G (Environmental Checklist Form) of the CEQA Guidelines indicates that significant noise impacts may be assumed to occur when a project will expose people to noise levels in excess of standards established in local noise ordinances or general plans, or causes a substantial permanent or temporary increase in noise levels above levels existing without the project.

Noise Level Standards:

The project area does not include incorporated cities within Kern County. However, project-related activity results are relevant to the incorporated cities within the County if such activities occur near or adjacent to incorporated city boundaries. The project area also includes land that is under the jurisdiction of the U.S. Bureau of Land Management (BLM). Noise standards for the County, certain cities within the project area and the BLM are therefore addressed by this study.

It is noted that most jurisdictions within Kern County and the BLM utilize the Day-Night Average Level (DNL) or Community Noise Equivalent Level (CNEL) to describe noise exposure for noise compatibility planning purposes. Both the DNL and CNEL represent the time-weighted energy average noise level for a 24-hour day, with a 10 dB penalty added to noise levels occurring during the nighttime hours (10:00 p.m.-7:00 a.m.). The CNEL includes an

additional penalty of 5 dB (technically 4.77 dB) that is added to noise levels occurring during the evening hours between 7:00 p.m. and 10:00 p.m. The CNEL is utilized to describe aircraft noise exposure as required by the State of California. Both the DNL and CNEL represent cumulative exposure to noise over an extended period of time and are therefore calculated based upon *annual average* conditions. The DNL and CNEL are considered to be equivalent descriptors of the community noise environment for the purposes of this study.

Some jurisdictions also apply hourly standards to noise from non-transportation sources that are not preempted from local regulation by existing state or federal standards. Transportation noise sources include traffic on public roadways, railroads and aircraft. Non-transportation (or stationary) noise sources generally include commercial and industrial activities.

Kern County

The Kern County Noise Element of General Plan[1] (2004) establishes a land use compatibility criterion of 65 dB DNL for exterior noise levels in outdoor activity areas of residential uses. Outdoor activity areas generally include backyards of single-family residences and individual patios or decks of multi-family developments. The intent of the exterior noise level requirement is to provide an acceptable noise environment for outdoor activities and recreation.

The noise element also requires that interior noise levels attributable to exterior noise sources not exceed 45 dB DNL. The intent of the interior noise level standard is to provide an acceptable noise environment for indoor communication and sleep.

City of Delano

The City of Delano General Plan (2005) contains noise level standards applicable to transportation and non-transportation sources. For noise-sensitive uses exposed to noise from transportation noise sources, the exterior noise level standard (Table 7-2 of the noise element) is 65 dB DNL/CNEL. The interior noise level standard for noise-sensitive uses is 45 dB DNL/CNEL.

For non-transportation sources, the noise element establishes hourly noise level standards in terms of the equivalent sound level (L_{eq}) and maximum noise level (L_{max}) descriptors. The standards are more restrictive during the nighttime hours between 10:00 p.m. and 7:00 a.m. The hourly L_{eq} standards are 55 dB during the day and 50 dB during the night. The hourly L_{max} standards are 75 dB during the day and 70 dB during the night.

City of McFarland

The City of McFarland has adopted by reference the Noise Element of the Kern County General Plan. The exterior noise level standard is therefore 65 dB DNL for noise levels in outdoor activity areas of residential and other noise-sensitive uses. The interior noise level standard is 45 dB DNL within interior living spaces or other noise-sensitive interior spaces.

City of Wasco

The City of Wasco General Plan (2002) utilizes the same noise level standards as Kern County. The exterior noise level standard is 65 dB DNL for noise levels in outdoor activity areas of residential and other noise-sensitive uses. The interior noise level standard is 45 dB DNL within interior living spaces or other noise-sensitive interior spaces.

City of Shafter

The City of Shafter General Plan (2005) establishes noise objectives for different land uses in terms of the CNEL. The general plan noise objective for rear yards of single-family dwellings and open areas within multi-family developments is 60-65 dB CNEL. For school classrooms and play areas, the noise objectives are 60 dB and 70 dB CNEL, respectively. The noise objective for the interior of hospitals and libraries is 60 dB CNEL. For commercial and industrial uses the noise objective is 65-70 dB CNEL at the front setback. The general plan does not specifically establish an interior noise level standard for residential uses. However, the general plan makes reference to enforcing the California Noise Insulation Standards which require an interior noise exposure of 45 dB DNL/CNEL for new multi-family dwellings and transient lodging.

City of Arvin

The City of Arvin General Plan (1989) utilizes the same noise level standards as Kern County. The exterior noise level standard is therefore 65 dB DNL for noise levels in outdoor activity areas of residential and other noise-sensitive uses. The general plan does not specifically establish an interior noise level standard for residential uses. However, the general plan makes reference to enforcing the California Noise Insulation Standards which require an interior noise exposure of 45 dB DNL/CNEL for new multi-family dwellings and transient lodging.

City of Bakersfield

The Metropolitan Bakersfield General Plan (2002) establishes noise level standards for transportation and non-transportation sources. For transportation sources, the noise element sets a standard of 65 dB CNEL at the exterior of noise-sensitive uses. Noise-sensitive uses include residences, schools, hospitals and recreational areas. An interior noise standard of 45 dB CNEL applies within interior living spaces.

For non-transportation noise sources, the noise element applies hourly noise level performance standards at residential and other noise-sensitive uses. Table 1 summarizes the applicable hourly noise level standards.

TABLE I

HOURLY NOISE LEVEL PERFORMANCE STANDARDS
STATIONARY NOISE SOURCES
METROPOLITAN BAKERSFIELD GENERAL PLAN

Maximum Acceptable Noise Level, dB		
Min./Hr. (L_n)	**Day (7a-10p)**	**Night (10p-7a)**
30 (L_{50})	55	50
15 (L_{25})	60	55
5 ($L_{8.3}$)	65	60
1 ($L_{1.7}$)	70	65
0 (L_{max})	75	70

Note: L_n means the percentage of time the noise level is exceeded during an hour. L_{50} means the level exceed 50% of the hour (30 minutes), L_{25} is the level exceed 25% of the hour (15 minutes), etc.

Source: Metropolitan Bakersfield General Plan

City of Taft

The City of Taft General Plan (2009) contains a land use compatibility chart (Table 8.0-1) that specifies acceptable noise exposure for various land uses. The acceptable exterior noise exposure for noise-sensitive uses, including residential, transient lodging, mixed use, schools, libraries, churches, hospitals and nursing homes, is 65 dB DNL/CNEL. For playgrounds, neighborhood parks, office buildings and commercial buildings, the acceptable exterior noise exposure is 70 dB DNL/CNEL. For industrial, manufacturing and agricultural uses, the acceptable exterior noise exposure is 75 dB DNL/CNEL. The noise element also specifies an acceptable interior noise exposure for the above-described noise-sensitive uses of 45 dB DNL/CNEL or below.

City of Maricopa

The City of Maricopa noise standards are contained within its zoning ordinance. The standards are the same as those contained within the County's noise element. The exterior noise level standard is therefore 65 dB DNL for noise levels in outdoor activity areas of residential and other noise-sensitive uses. The interior noise level standard is 45 dB DNL within interior living spaces or other noise-sensitive interior spaces.

State of California

There are no known state noise standards that are applicable to the project.

Federal Noise Standards

The U.S. Department of the Interior, Bureau of Land Management (BLM) has jurisdiction over part of the land within the project area. The BLM does not employ specific noise level standards but historically has referred to guidelines contained with U.S. Environmental Protection Agency (EPA) document entitled "Information on Levels of Environmental Noise Requisite to Protect

the Public Health and Welfare with an Adequate Margin of Safety"[2] (1974 EPA Levels Document).

One of the purposes of the 1974 EPA Levels Document was to provide information for use by state and local governments in developing their own noise standards. It was intended that such information be utilized along with other factors such as the balance between costs and benefits when establishing noise level standards. Information contained within the document was taken into consideration by the State of California when it published guidelines for developing local general plan noise elements. The noise level standards of Kern County and its incorporated cities are based upon those guidelines.

The 1974 EPA Levels Document identified an exterior noise exposure of 55 dB DNL and an interior noise exposure of 45 dB DNL as sufficient to *prevent* activity interference and annoyance. As noted above, such recommendations do not take into account the balance between cost and benefit. The noise level standards adopted by Kern County and its incorporated cities are intended as a compromise to protect the public health and welfare while allowing for reasonable development and commerce.

Other federal standards that could be considered applicable to the project include the U.S. Department of Housing and Urban Development (HUD) standards. The HUD standards are the same as those of Kern County with an exterior noise standard of 65 dB DNL and an interior standard of 45 dB DNL. The HUD standards come into play when federal funds may be used for housing development projects.

Substantial Noise Increases:

CEQA does not define what constitutes a substantial increase in noise levels. Some guidance is provided by the 1992 findings of the Federal Interagency Committee on Noise (FICON) [3], which assessed changes in ambient noise levels resulting from transportation noise sources. The FICON recommendations are based upon studies that relate aircraft and traffic noise levels to the percentage of persons highly annoyed by the noise. The rationale for the FICON recommendations is that it is possible to consistently describe the annoyance of people exposed to transportation noise in terms of the DNL (or CNEL). Annoyance is a summary measure of the general adverse reaction of people to noise that results in speech interference, sleep disturbance, or interference with other daily activities.

Although the FICON recommendations were specifically developed to address transportation noise impacts, they are used in this analysis for all noise sources that are described in terms of cumulative noise exposure metrics such as the DNL or CNEL. Table II summarizes the FICON recommendations.

TABLE II

MEASURES OF SUBSTANTIAL NOISE INCREASE FOR TRANSPORTATION SOURCES

Ambient Noise Level Without Project (DNL/CNEL)	Significant Impact Assumed to Occur if the Project Increases Ambient Noise Levels By:
<60 dB	+ 5 dB or more
60-65 dB	+3 dB or more
>65 dB	+1.5 dB or more

Source: FICON, 1992, as applied by Brown-Buntin Associates, Inc.

Construction Noise and Vibration:

There are no known state or federal standards that specifically address construction noise or vibration.

Kern County does not specifically limit hours during which construction may occur. However, it is a common practice to limit hours of construction to minimize construction noise impacts in areas where sensitive uses are located during the early morning and late evening hours, and on weekends and holidays. Although not specifically stated in the noise element, it is also a standard requirement of many jurisdictions that all construction equipment be properly maintained and muffled to minimize noise generation at the source.

Kern County does not have regulations that define acceptable levels of vibration. One of the most recent references suggesting vibration guidelines is the California Department of Transportation (Caltrans) Transportation and Construction Vibration Guidance Manual[4]. The Manual provides guidance for determining annoyance potential criteria and damage potential threshold criteria. These criteria are provided below in Table III and Table IV, and are presented in terms of peak particle velocity (PPV) in inches per second (in/sec).

TABLE III

GUIDELINE VIBRATION ANNOYANCE POTENTIAL CRITERIA

Human Response	Maximum PPV (in/sec)	
	Transient Sources	Continuous/Frequent Intermittent Sources
Barely Perceptible	0.04	0.01
Distinctly Perceptible	0.25	0.04

EXISTING NOISE ENVIRONMENT

Major noise sources in the project area include state highways, railroads, airports and existing commercial/industrial operations including oil and gas production facilities. Existing ambient noise levels within the project area vary considerably depending upon distance from major noise sources and the noise generation characteristics of contributing noise sources at any given location. The noise environment in the project area has been characterized by conducting ambient noise level measurements at various locations within the project area and quantifying typical noise levels from the major sources that affect the project area.

Ambient Noise Level Measurements:

Ambient noise level measurements were conducted at eighteen (18) locations within the project area. Noise monitoring sites were selected to represent acoustic settings within the project area where project-related activities either occur or could occur in the future with the project. Noise monitoring was conducted using unattended automated equipment that measured ambient noise levels continuously for a minimum period of 24 hours at each site. Ambient noise monitoring was conducted during January 2015. Noise monitoring sites are shown in Figure 2.

Noise monitoring equipment consisted of Larson-Davis Laboratories Model LDL 820 sound level analyzers equipped with Bruel & Kjaer (B&K) Type 4176 ½'' microphones. Microphones were located on tripods at approximately five (5) feet above the ground and were equipped with random incidence correctors so that noise levels from sources in all directions could be accurately measured. The monitors were calibrated with a B&K Type 4230 acoustical calibrator to ensure the accuracy of the measurements. The equipment complies with applicable specifications of the American National Standards Institute (ANSI) for Type 1 sound measurement systems.

Table V summarizes ambient noise monitoring results. Noise measurement data are described in terms of the equivalent energy (L_{eq}), maximum (L_{max}) and L_{90} noise level descriptors. The L_{eq} and L_{max} describe energy average and maximum noise levels measured during each hour of the sample periods, respectively. The L_{90} describes the noise level exceeded 90 percent of the time

during each hour, which is generally considered to represent the residual (or background) noise level in the absence of identifiable single noise events from traffic, aircraft and other local noise sources. The measured DNL for each of the 18 ambient noise monitoring sites is also included in Table V for comparison with the Kern County 65 dB DNL standard.

Reported maximum noise levels were most likely caused by localized activities near the microphone, agricultural, commercial or industrial activities, occasional aircraft over-flights or roadway traffic at the long-term sites. Since hourly L_{eq} values represent energy average noise levels, they can be significantly affected by occasional noise events in the vicinity of the monitoring site. Measured DNL values ranged from 44.8-67.8 dB at the ambient noise monitoring sites with an average of 54.7 dB. Generally, the highest ambient noise levels occurred at sites that were located relatively close to major transportation sources or commercial/industrial activities.

Appendix B provides a detailed description of the noise monitoring sites, aerial photographs showing the site locations, noise sources affecting the site and measured noise levels. An hourly noise level chart is included for each site that graphically depicts measured noise levels at the site over the 24-hour monitoring period.

TABLE V

MEASURED AMBIENT NOISE LEVELS
KERN COUNTY OIL AND GAS PRODUCTION EIR PROJECT AREA
JANUARY 2015

Measurement Site	Range of Hourly Noise Levels, dB			DNL, dB
	L_{eq}	L_{max}	L_{90}	
Site 1	42.9-58.4	54.8-76.5	34.2-39.4	58.5

Traffic Noise Levels:

There are many roadways within the project area. It was beyond the scope of the study to calculate noise from traffic on every such roadway. Noise levels were therefore calculated for US 5 and all state highways within the project area to provide a representative sampling of the range of traffic-related noise levels along major roadways within the project area.

Traffic noise levels along state highways were calculated using the FHWA Highway Traffic Noise Prediction Model[5]. The FHWA Model is a standard methodology for traffic noise prediction. Annual average traffic volumes used in the noise modeling process were determined by reference to the Caltrans website for 2013 traffic conditions. Other inputs into the FHWA Model were estimated based upon studies completed by BBA for other projects along similar roadways within the project area. Appendix C summarizes traffic data used for noise modeling.

Table VI summarizes existing annual average traffic noise exposure in terms of the distances from the center of the roadway to the 60 and 65 dB DNL contours for each roadway analyzed. A total of 270 roadways segments were analyzed for existing traffic noise exposure. Traffic noise exposure described in Table VI represents the segment with the highest calculated noise level for each individual roadway. Appendix D provides traffic noise exposure data for each of the 270 analyzed roadways segments. The reported distances are generalized in that they do not take into account local terrain, sound walls, buildings or other site-specific factors that could influence noise levels at a given location.

Railroad Noise Levels:

There are three railroads that currently serve the project area. The Union Pacific Railroad (UPRR) and Burlington Northern Santa Fe Railway (BNSF) mainlines traverse the project area in a generally north-south direction. The UPRR generally follows the alignment of SR 99 north of Bakersfield and SR 58 east of Bakersfield. The BNSF generally follows the SR 43 alignment north of Bakersfield and has track-age rights over the UPRR east of Bakersfield. Amtrak operates passenger trains over the BNSF north of Bakersfield. The San Joaquin Valley Railroad SJVRR operates low-speed branch-line railroads from Bakersfield to the community of Oildale, City of Arvin, community of Buttonwillow, and to industrial facilities east of Taft.

Table VII summarizes railroad operational data as obtained from the Federal Railroad Administration (FRA) website. The noise levels generated by the UPRR and BNSF are similar in that the locomotives and rail cars utilized and maximum track speeds are comparable. The primary difference is that Amtrak operates 12 passenger trains per day over the BNSF mainline north of Bakersfield.

Noise levels generated by railroad operations were calculated based upon noise levels measured by Brown-Buntin Associates, Inc. (BBA) for various development projects in Kern County over the past few years. Since train engineers are required to sound the warning horn when approaching an at-grade roadway crossing, noise levels are higher in the proximity of a grade crossing. For high-speed mainlines, such as the UPRR and BNSF, engineers generally start sounding the warning horn when within approximately 1,000 feet of the crossing. For low-speed branch-line operations, the warning horn is typically sounded relatively close to the crossing. Calculated distances from the center of the track to the DNL 65 dB contours are summarized in Table VII for each railroad. The reported distances are generalized in that they do not take into account local terrain, sound walls, buildings or other site-specific factors that could influence noise levels at a given location.

TABLE VII

RAILROAD OPERATIONS DATA AND NOISE EXPOSURE
KERN COUNTY OIL AND GAS PRODUCTION EIR PROJECT AREA

Railroad	Route	Average # Daily Trains	Maximum Speed (mph)	Distance (feet) to 65 dB DNL Contour	
				Within 1,000 feet of Crossings	More than 1,000 feet from Crossings

Aircraft Noise Levels:

There are a number of private and public use airports within the study area. Noise level and aircraft operations information are available for public use airports in the Kern County Airport Land Use Compatibility Plan[6] adopted in 2012. The public use airports addressed by the plan that are within the project area include Meadows Field, Bakersfield Municipal, Delano Municipal, Elk Hills-Buttonwillow, Poso Kern County, Taft Kern County, Shafter-Minter Field, Wasco Kern County and Lost Hills Airports.

With the exception of Meadows Field in Bakersfield, aircraft operations at airports within the project area consist of relatively infrequent flights by small general aviation propeller aircraft. There are occasional corporate jet aircraft operations at the Bakersfield Municipal, Delano Municipal and Shafter-Minter Field Airports. Meadows Field is an air carrier airport with scheduled airline service by turboprop and jet aircraft and relatively frequent operations by general aviation propeller and jet aircraft.

The 65 dB CNEL contours for airports within the project area are confined to the airport property with the exception of Bakersfield Municipal Airport and Meadows Field where the 65 dB CNEL contours extend slightly to the northwest of airport property.

High Speed Rail Noise Levels:

Although the high speed train (HST) line proposed by the California High Speed Rail Authority (CHSRA) has not yet been constructed, it is reasonable to assume that HST operations could eventually be a major source of noise in portions of the project area.

The final alignment of the proposed HST line has not yet been determined. However, most of the alternative alignments under consideration by CHSRA generally follow the existing alignment of the BNSF Railway north of Bakersfield and the existing alignment of the UPRR east of Bakersfield. According to the Revised DEIR/Supplemental DEIS (DEIR/SDEIS)[7] for the Fresno-Bakersfield section of the HST project, the HST will use electrically powered trains capable of operating up to 220 mph over a fully grade-separated, dedicated track alignment. The HST line passing through the project area would consist of a double track on a ballasted roadbed 5-6 feet higher than the surrounding terrain. The HST line would be elevated in some areas and would utilize grade-separated crossings with roadways.

There are three major sources of noise associated with HST movements. At speeds up to 160 mph, the electric propulsion system and wheel/rail interaction are the predominant sources. At speeds above 160 mph, aerodynamic sound produced by the airflow moving past the train becomes the dominant source. The DEIR/SDEIS analyzed potential noise and vibration impacts from the HST line using the Federal Railroad Administration (FRA) *High-Speed Ground Transportation Noise and Vibration Impact Assessment Report* prepared in 2005 (FRA Guidance Manual). The FRA Guidance Manual is based upon comprehensive noise and vibration measurements conducted in Asia and Europe. The DEIR/SDEIS presents a series of tables that summarize projected HST noise levels along the proposed line in terms of the Day-Night Average Level (DNL).

The DEIR/SDEIS assumed that there would be 188 trains per day during the daytime hours (7:00 a.m.-10:00 p.m.) and 37 trains during the nighttime hours (10:00 p.m.-7:00 a.m.). For the section of the HST line that would pass through the project area, the projected DNL is 72 dB at distance of 150 feet from the center of the tracks. Noise from the HST line would be expected to decrease with distance from the tracks at the rate of 3.0-4.5 dB for each doubling of distance. That means that the 65 dB DNL contour could be located in the range of 400-750 feet from the center of the tracks.

PROJECT-RELATED NOISE IMPACTS AND MITIGATION

Thresholds of Significance:

The existing noise level standards of Kern County and its incorporated cities within the project area have been developed based upon guidelines established by the State of California and research conducted by the federal government (EPA) on how excessive noise exposure may adversely affect people. The standards are intended to protect the health and well-being of local citizens without being overly restrictive and thereby inhibiting reasonable commerce.

As previously noted, the project area does not include incorporated cities within Kern County. However, project-related activities could affect certain incorporated cities within the County if such activities occur near or adjacent to incorporated city boundaries. For that reason, existing noise standards for certain cities within the project area have also been considered by this study for comparison purposes. The noise level standards adopted by the County and its incorporated cities within the project area are summarized in Table VIII.

TABLE VIII

SUMMARY OF NOISE LEVEL STANDARDS
KERN COUNTY OIL AND GAS PRODUCTION EIR PROJECT AREA

Jurisdiction	DNL/CNEL		Hourly Noise Standards (Exterior)[1]			
			Leq, dB		Lmax, dB	
	Exterior[1]	Interior[1]	7a-10p	10p-7a	7a-10p	10p-7a
Kern County	65	45	---	---	---	---
Delano	65	45	55	50	75	70
McFarland	65	45	---	---	---	---
Wasco	65	45	---	---	---	---
Shafter	65	45	---	---	---	---
Bakersfield	65	45	55[2]	50[2]	75	70
Arvin	65	45	---	---	---	---
Taft	65	45	---	---	---	---
Maricopa	65	45	---	---	---	---

[1]Standards are for noise-sensitive receiving properties such as residential uses, schools, libraries, hospitals, churches and long-term care facilities. Some jurisdictions also have less-restrictive standards for receiving uses not considered noise-sensitive.

[2]The Bakersfield hourly noise standards are based upon the statistical distribution of noise over time. The L_{50} descriptor (30 minutes/hour) is comparable to the L_{eq} for most noise sources.

Source: Brown-Buntin Associates, Inc.

From Table VIII it may be determined that Kern County and its incorporated cities within the project area all apply an exterior noise level standard of 65 dB DNL/CNEL for noise-sensitive receptors and an interior noise level standard of 45 dB DNL/CNEL for interior spaces of noise-sensitive buildings. Table VIII also shows that the cities of Bakersfield and Delano have hourly noise level standards. Such standards are only applicable to non-transportation (or stationary) noise sources that may be regulated by a local jurisdiction. Stationary noise sources include most project-related activities that could affect nearby noise-sensitive uses.

The precedent for using cumulative noise exposure metrics such as the DNL and CNEL has been well established for land use compatibility planning purposes. However, from a CEQA standpoint, it has been successfully argued that the DNL or CNEL do not by themselves adequately define the potential noise impacts resulting from intermittent sources of noise that may occur at different times of the day or night. For that reason, hourly noise level standards are recommended to determine if a project-related activity will result in a significant impact and the need for noise mitigation.

For consistency with local jurisdictions in Kern County and elsewhere in the San Joaquin Valley, hourly equivalent sound level (Leq) standards of 55 dB during the daytime hours (7:00 a.m.-10:00 p.m.) and 50 dB during the nighttime hours (10:00 p.m.-7:00 a.m.) are applied. Additionally, hourly maximum noise level (L_{max}) standards of 75 dB during the daytime hours and 70 dB during the nighttime hours are applied.

Compliance with the above-described hourly noise level standards will ensure compliance with the 65 dB DNL standard that has been adopted by Kern County, even if the source were to operate 24 hours per day. A constant noise level of 50 dB for 24 hours per day would result in a DNL/CNEL of approximately 57 dB. A constant noise level of 55 dB for 24 hours per day would result in a DNL/CNEL of approximately 62 dB.

Noise levels generated by the project are considered a significant impact if any of the following conditions would be expected to occur:

1. The project will cause noise levels exterior to any existing or planned noise-sensitive receptor to exceed 65 dB DNL. Noise-sensitive uses include residential, transient lodging, churches and other places of worship, schools, libraries, hospitals, long-term care facilities, and any other use deemed noise-sensitive by Kern County.

2. The project will cause noise levels exterior to any existing or planned noise-sensitive receptor to exceed an hourly equivalent sound level (L_{eq}) of 55 dB during the daytime hours (7:00 a.m.-10:00 p.m.) or 50 dB during the nighttime hours (10:00 p.m.-7:00 a.m.).

3. The project will cause noise levels exterior to any existing or planned noise-sensitive receptor to exceed an hourly maximum sound level (L_{max}) of 75 dB during the daytime hours (7:00 a.m.-10:00 p.m.) or 70 dB during the nighttime hours (10:00 p.m.-7:00 a.m.).

4. The project will cause a 5 dB or greater increase in the ambient noise level, as defined by the annual average DNL, at the location of any existing or planned noise-sensitive receptor. The annual average DNL may be estimated from noise exposure information

contained within the general plan of the affected jurisdiction, or from the findings of a project-specific noise analysis performed by a qualified individual.

Project-Related Noise Impacts:

Noise levels associated with various oil and gas production activities were measured at several locations throughout Kern County in December, 2014 and January, 2015. For each activity, noise level measurements were taken in a minimum of four different directions from the activity to document the loudest direction of noise. The activities measured included production well drilling (during both well advancement and pulling out of the borehole), exploratory well drilling, hydraulic fracturing, well workover activities and active production wells (both electric and diesel powered).

Noise measurements were conducted using a Larson Davis Model 824 Sound Level Meter to document the spectral (frequency) components of each source. The meter was calibrated prior to use with a Larson Davis CA250 calibrator to ensure the accuracy of the measurements. A windscreen was used over the microphone to avoid interference resulting from wind sources during outdoor measurements.

Project-related noise levels were calculated using the SoundPLAN noise model. SoundPLAN utilizes measured spectral sound power levels to determine noise exposure from a noise source. Inputs to the model include noise source spectral sound power levels, topography, atmospheric conditions, ground absorption factors, shielding from existing walls or buildings, noise source height and receiver height. Since this analysis is not site specific, some assumptions and generalities were made in order to calculate potential project-related noise levels. Table IX summarizes the assumptions used for the model. These assumptions represent a worst-case assessment in regards to noise propagation from individual sources.

TABLE IX

NOISE MODELING ASSUMPTIONS
KERN COUNTY OIL AND GAS PRODUCTION EIR

Topography	Flat
Ground Absorption Factor	0.5 (a mixture of hard ground, water, vegetation, loose soils, etc.)
Shielding	None
Temperature	40° Fahrenheit
Relative Humidity	50%
Receiver Height	5 feet
Noise Source Height	10 feet

Source: BBA

The oil production activities calculated using SoundPLAN are described briefly below. For each modeled activity, the loudest observed measurement was utilized as a basis for modeling potential project-related noise exposure for future activities.

Well Drilling: Well drilling is the process by which a machine (drill rig) is used to drill a well bore. Major components of a drill rig include the mud tanks, mud pumps, rig mast, rotary table, drillstring and power generation equipment. Drill rigs can vary widely in size and configuration. BBA staff conducted noise measurements of multiple types of drill rigs. Measurements were conducted from multiple directions in order to document the loudest level produced while operating. Typically, the loudest source of noise associated with a drill rig is the power generation equipment, which is typically a diesel powered internal combustion engine.

Additionally, BBA staff conducted measurements of Kenai Drilling's Rig #7. The Kenai rig is one of the largest operating drill rigs in the United States, and is used for exploratory drilling at depths up to 25,000 feet below surface elevation. Noise levels produced by such drill rigs are substantially higher than those produced by "typical" rigs utilized in the project area. It is not expected that a rig of this size would be commonly used within the project area; however, noise exposure related to the Kenai #7 is presented in this analysis.

Well Workover: Well workover involves repair or maintenance of an existing production well for the purpose of restoring, prolonging or enhancing the production of the well. Well workover includes the process of performing maintenance or remedial treatments on an oil or gas well. In some cases well workover includes the removal and replacement of the well casing. Typically, the loudest source of noise associated with a drill rig is the power generation equipment, which is typically a diesel powered internal combustion engine.

Hydraulic Fracturing: Hydraulic fracturing is the stimulation treatment commonly performed on oil and gas wells that have been established in regions of lower permeability substrates. Fluids are pumped at high pressures into the reservoir. Grains of sand are mixed with the treatment fluid to keep the fracture open after the process has occurred. The process is intended to increase production of existing wells. Typically, the loudest source of noise associated with hydraulic fracturing is the power generation equipment, which is typically a diesel powered internal combustion engine. Hydraulic fracturing operations utilize several different pieces of equipment simultaneously, and noise level measurements obtained included noise from multiple equipment sources. Noise levels utilized for this study were the loudest observed measurements during the monitoring period, and therefore represent a worst-case assessment of typical hydraulic fracturing activities.

Oil Well Operation: Oil well operation is the ongoing production of a well for extraction purposes. Operating oil wells are typically powered by either electricity and less frequently by a diesel powered internal combustion engine. Electric powered wells produce significantly less noise than a diesel powered well. BBA conducted noise measurements of each.

Using the noise levels measured of the above-described activities as well as the assumptions provided in Table IX, distances from individual project-related noise sources to the 50 dB 55 dB Leq contours were calculated using SoundPLAN. The results of the calculations are provided in Table X. It should be noted that at increased distances from a modeled noise source (distances greater than 1000 feet), the modeled results should be considered with tolerance limitations of +/- 5 dB. At such distances from the noise source variables such as atmospheric conditions (including wind speeds and direction), topography and ground absorption could cause modeled results to vary significantly from modeled results.

TABLE X

PROJECT-RELATED NOISE EXPOSURE
KERN COUNTY OIL AND GAS PRODUCTION EIR
SHORT-TERM Leq LEVEL

Activity	Distance (feet) to Leq Contour	
	50 dB	**55 dB**
Drilling (Well Advancement)	3,550	2,270
Drilling (Pull Out Of Well/Borehole)	2,130	1,300
Large-Scale Exploratory Drilling[1]	7,250	4,750
Well Workover	2,150	1,350
Hydraulic Fracturing	2,700	1,650
Well Production (Electric Power)	180	110
Well Production (Diesel Power)	580	330

[1]Kenai Drill Rig #7. This rig is not typically used in Kern County.

Source: Brown-Buntin Associates, Inc.

Table XI provides the distances to the 60 dB DNL and 65 dB DNL contours for individual project-related noise sources. The distances were calculated based upon modeled noise levels that represent not only the loudest direction from the equipment, but also while each piece of equipment was being operated at a maximum noise level. Over any given period of time, noise levels from drilling operations can vary widely. Noise levels are typically at a maximum during active well advancement. Noise levels reduce while additional lengths of drill pipe are added, the drillstring is being retracted, or during times of rig maintenance. Because the contour distances provided in Table XI are based upon measurements obtained at the loudest location during the loudest periods of operation, they should be considered a worst-case assessment of actual DNL noise levels. The contour distances assume maximum noise levels, continuously, over a 24-hour period.

TABLE XI

PROJECT-RELATED NOISE EXPOSURE
KERN COUNTY OIL AND GAS PRODUCTION EIR
DAY-NIGHT AVERAGE SOUND LEVEL (DNL)

Activity	Distance (feet) to DNL Contour	
	60 dB	**65 dB**
Drilling (Well Advancement)	2500	**1550**
Drilling (Pull Out Of Well/Borehole)	1320	**820**

Prescriptive Noise Mitigation Measures

Tables X and XI summarize the project-related activities that have been analyzed and provide distances from each activity to various noise levels for the L_{eq} and DNL metrics. Table X provides the distances between the activity and a noise-sensitive use where an applicable threshold of significance will not be exceeded (50 and 55 dB Leq contours) such as in the cities of Delano and Bakersfield. The distances provided in Table X can be used when statistical (L_{eq} or L_{50}) standards are applicable.

Table XI provides the distances between the activity and noise-sensitive uses that must be achieved when DNL noise level standards are applicable. The Noise Element of the Kern County General Plan establishes a land use compatibility criterion of 65 dB DNL for exterior noise levels in outdoor activity areas of residential uses. Additionally, the 65 dB DNL exterior noise level criterion is commonly applied throughout incorporated areas of Kern County, and therefore should be used to determine project compliance in most instances.

Compliance with the distances summarized by Table X and Table XI should be interpreted to mean that a significant noise impact would not be expected as a result of the project and additional noise mitigation will not be required. However, determination of whether the project could result in a 5 dB or greater increase in the existing annual average DNL will require that noise exposure information for the project site be analyzed by reference to appropriate documents or a site-specific analysis be conducted.

Additionally, if more than one of the above-described activities are occurring in close proximity to each other, the distances to the contours described in Tables X and XI would likely increase. Tables X and XI do not address the additive nature of multiple noise sources. Decibels are logarithmic units that cannot be added linearly. For example, if two identical noise sources are added together, noise levels would increase by 3 dB over the individual source levels (65 dB + 65 dB=68 dB). It is not possible to quantify or describe every potential scenario of combinations.

It should be noted; distances described in Tables X and XI for "Large-Scale Exploratory Drilling" should not be applied to common or typical drilling operations performed in Kern County. The Kenai Drill Rig #7 (and similar large-scale exploratory drill rigs), utilized for reference noise measurements and noise modeling are used very infrequently in Kern County, and are not typically used in proximity to noise-sensitive uses. Noise setback analysis distances described in Tables X and XI for "Drilling (Well Advancement)" represent noise levels that are to be expected from commonly used drill rigs throughout the county.

It is recognized that there may be instances where the noise level data and distances presented in Tables X and XI may not adequately define the potential for significant noise impacts. The determination of such circumstances should be made by Kern County. Factors that should be considered in making such a determination should include the noise generation potential of the project due to modified or specialized equipment or processes that were not analyzed as a part of this study, the topographical relationship between the source and affected noise-sensitive receptors, the duration and proposed hours of operation of the project, and the potentially unique

character of the receiving land use or existing ambient noise levels. Under such circumstances, an acoustical analysis may be required to determine project-related noise levels and required mitigation measures. Potential additional noise mitigation measures are described below.

1. Limits on hours of operation: Since the hourly noise level standards are 5 dB more restrictive at night between the hours of 10:00 p.m. and 7:00 a.m., a particular activity could occur closer to a sensitive receiver if hours of operation were restricted to the daytime hours between 7:00 a.m. and 10:00 p.m.

2. Temporary or permanent noise barriers: Depending upon site-specific conditions, noise barriers could be used to reduce project-related noise levels at nearby sensitive receivers. For projects that could operate for an extended period of time, sound walls or earthen berms may be an effective form of mitigation. Temporary noise barriers, such as sound blankets, plywood or other portable materials, could be used to mitigate noise from temporary sources or construction activities. Most temporary noise barriers are effective noise reduction if properly positioned without gaps that could create sound flanking paths.

3. Use of "quiet technology" equipment: If equipment is modified or equipment with special sound reduction capabilities is utilized, and it may be demonstrated that such equipment is quieter than the equipment analyzed for this study, potential significant noise impacts may be mitigated. Examples of such measures include use of electric motors in place of internal combustion engines and the use of equipment with special sound attenuation equipment.

4. Implementation of a quiet mode drilling plan or other sound reduction technology or practices.

5. Arranging for temporary relocation of sensitive receptors during the high noise period.

6. Or other methods that prevent or reduce noise exposure to sensitive receptors.

Construction Noise Impacts:

Construction noise could occur at various locations within the project area. During construction, noise from construction activities could potentially impact noise-sensitive land uses if such uses are located in the immediate area. Activities involved in construction would generate noise levels at 50 and 100 feet as indicated by Table XII.

TABLE XII

TYPICAL CONSTRUCTION EQUIPMENT
MAXIMUM NOISE LEVELS, dBA

Type of Equipment	50 Ft.	100 Ft.
Backhoe	80	72
Concrete Saw	90	84
Crane	85	79
Excavator	85	79
Front End Loader	80	73
Jackhammer	85	79
Paver	85	79
Pneumatic Tools	85	79
Dozer	85	79
Rollers	85	79
Trucks	84	78
Pile Drivers	95	89
Rock Drills	85	79
Pumps	77	71
Scrapers	85	79
Portable Generators	82	76
Front Loader	80	73
Backhoe	80	73
Excavator	85	79
Grader	85	79

Construction Noise Mitigation

Construction noise is not usually considered to be a significant impact if construction occurring near noise-sensitive land uses is limited to the daytime hours, extraordinary noise-producing activities (e.g., pile driving) are not anticipated, and construction equipment is adequately maintained and muffled. It is therefore recommended that construction activities be limited to the daytime hours and that nearby residents be notified prior to construction activities that could produce abnormally high noise levels.

Construction Vibration Impacts:

Vibration from construction activities could be detected if there are sensitive uses located near a construction site. Typical vibration levels at a reference distance of 100 feet are summarized by Table XIII. The vibration levels described below at a distance of 100 feet are below the thresholds of annoyance or damage, as described in Table III and Table IV.

TABLE XIII

TYPICAL VIBRATION LEVELS DURING CONSTRUCTION

	PPV (in/sec)
Equipment	**@ 100´**
Bulldozer (Large)	0.011
Bulldozer (Small)	0.0004
Loaded Truck	0.01
Jackhammer	0.005
Vibratory Roller	.03
Caisson Drilling	.01
Source: *Caltrans*	

Construction Vibration Mitigation

Construction vibration is usually not considered to be significant for the same reasons as construction noise. However, it is recommended that construction activities be limited to the daytime hours and that nearby residents be notified prior to construction activities that could produce abnormally high vibration levels.

FIGURE 1: PROPOSED PROJECT SUB-AREAS

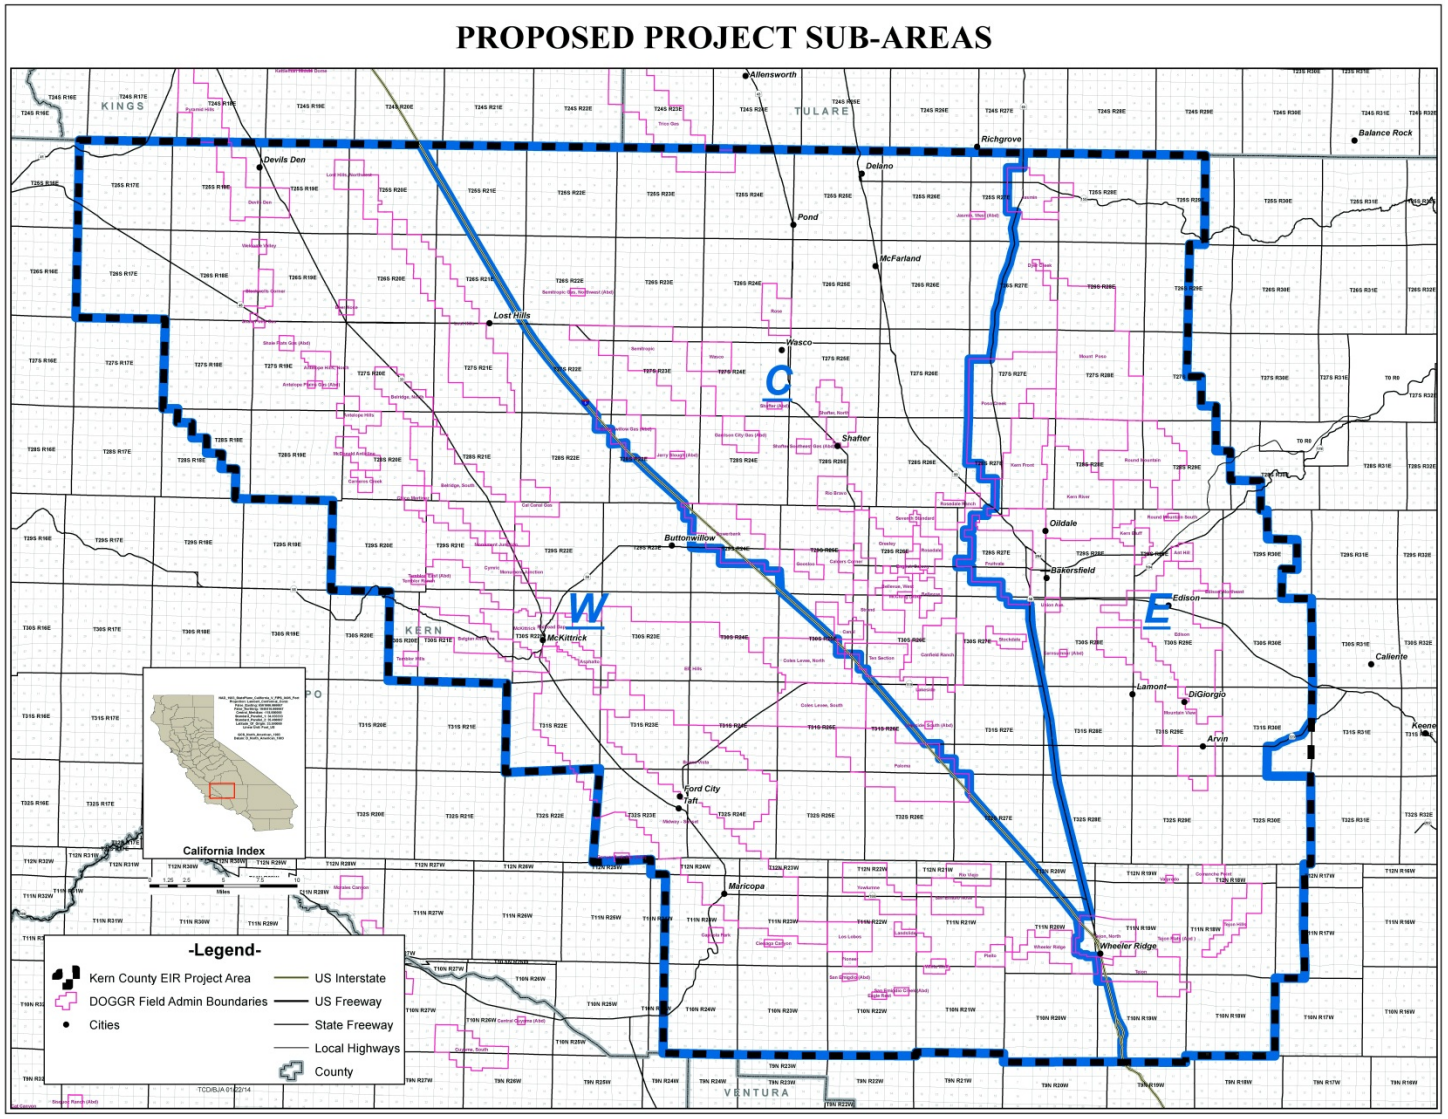

FIGURE 2: AMBIENT NOISE MONITORING SITE LOCATIONS

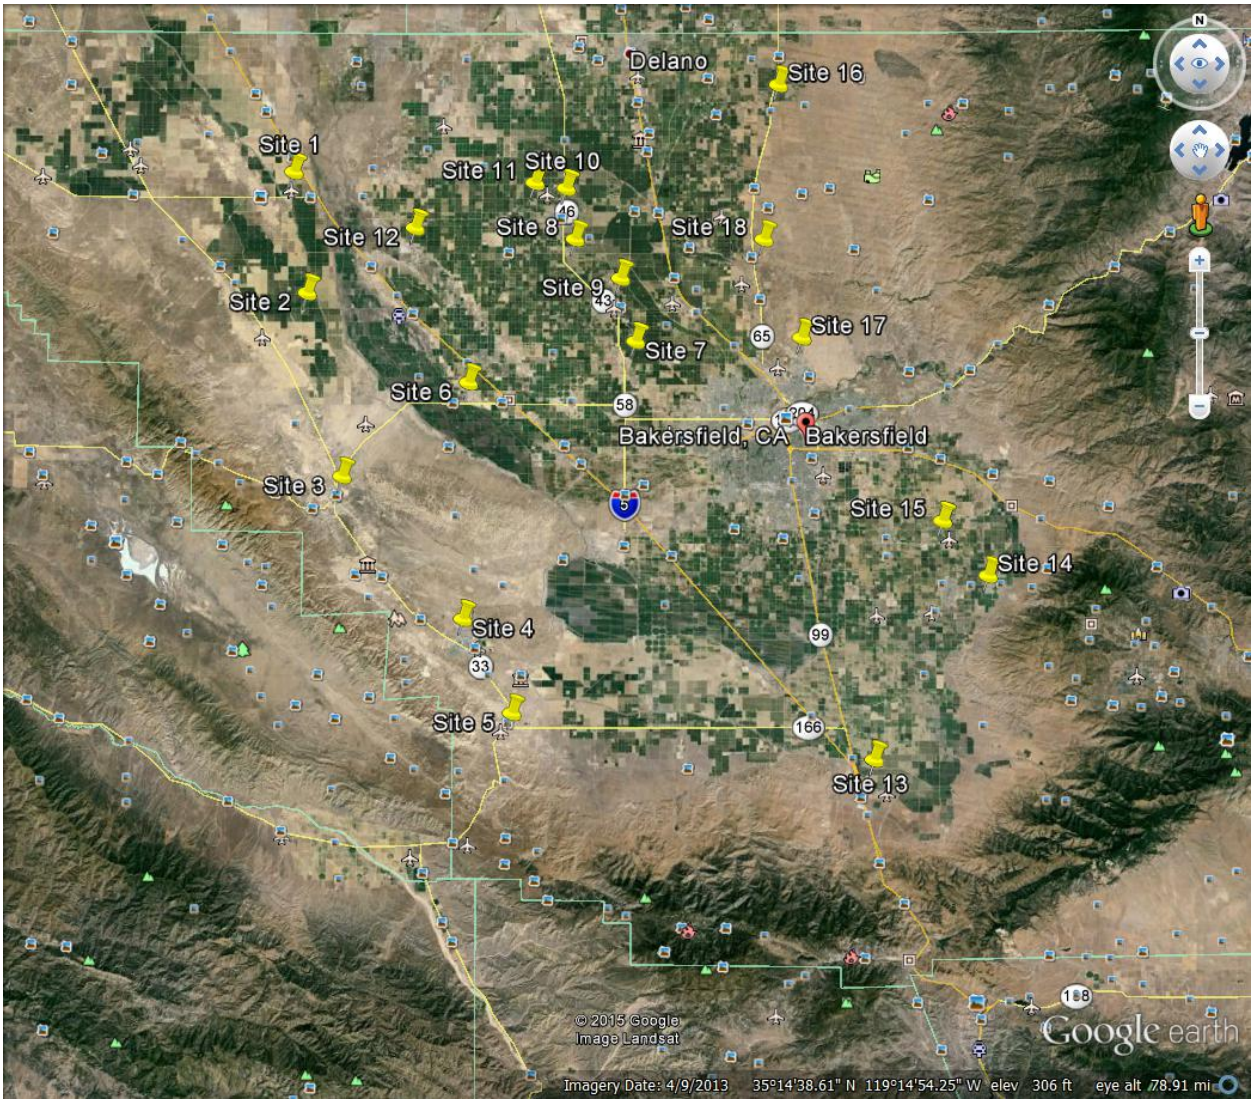


APPENDIX A

ACOUSTICAL TERMINOLOGY

AMBIENT NOISE LEVEL: The composite of noise from all sources near and far. In this context, the ambient noise level constitutes the normal or existing level of environmental noise at a given location.

CNEL: Community Noise Equivalent Level. The average equivalent sound level during a 24-hour day, obtained after addition of approximately five decibels to sound levels in the evening from 7:00 p.m. to 10:00 p.m. and ten decibels to sound levels in the night before 7:00 a.m. and after 10:00 p.m.

DECIBEL, dB: A unit for describing the amplitude of sound, equal to 20 times the logarithm to the base 10 of the ratio of the pressure of the sound measured to the reference pressure, which is 20 micropascals (20 micronewtons per square meter).

DNL/L_{dn}: Day/Night Average Sound Level. The average equivalent sound level during a 24-hour day, obtained after addition of ten decibels to sound levels in the night after 10:00 p.m. and before 7:00 a.m.

L_{eq}: Equivalent Sound Level. The sound level containing the same total energy as a time varying signal over a given sample period. L_{eq} is typically computed over 1, 8 and 24-hour sample periods.

NOTE: The CNEL and DNL represent daily levels of noise exposure averaged on an annual basis, while L_{eq} represents the average noise exposure for a shorter time period, typically one hour.

L_{max}: The maximum noise level recorded during a noise event.

L_n: The sound level exceeded "n" percent of the time during a sample interval (L_{90}, L_{50}, L_{10}, etc.). For example, L_{10} equals the level exceeded 10 percent of the time.

APPENDIX A (concluded)

ACOUSTICAL TERMINOLOGY

NOISE EXPOSURE CONTOURS: Lines drawn about a noise source indicating constant levels of noise exposure. CNEL and DNL contours are frequently utilized to describe community exposure to noise.

NOISE LEVEL REDUCTION (NLR): The noise reduction between indoor and outdoor environments or between two rooms that is the numerical difference, in decibels, of the average sound pressure levels in those areas or rooms. A measurement of "noise level reduction" combines the effect of the transmission loss performance of the structure plus the effect of acoustic absorption present in the receiving room.

SEL or SENEL: Sound Exposure Level or Single Event Noise Exposure Level. The level of noise accumulated during a single noise event, such as an aircraft overflight, with reference to a duration of one second. More specifically, it is the time-integrated A-weighted squared sound pressure for a stated time interval or event, based on a reference pressure of 20 micropascals and a reference duration of one second.

SOUND LEVEL: The sound pressure level in decibels as measured on a sound level meter using the A-weighting filter network. The A-weighting filter de-emphasizes the very low and very high frequency components of the sound in a manner similar to the response of the human ear and gives good correlation with subjective reactions to noise.

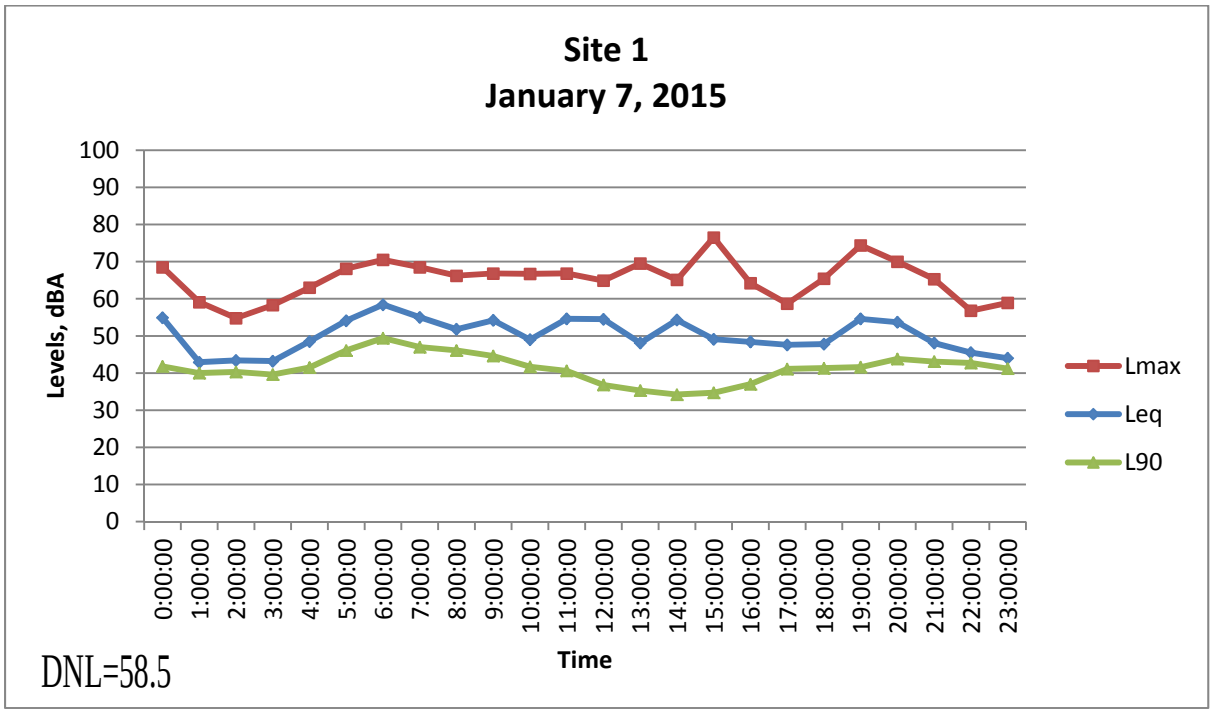
SOUND TRANSMISSION CLASS (STC): The single-number rating of sound transmission loss for a construction element (window, door, etc.) over a frequency range where speech intelligibility largely occurs.

APPENDIX B

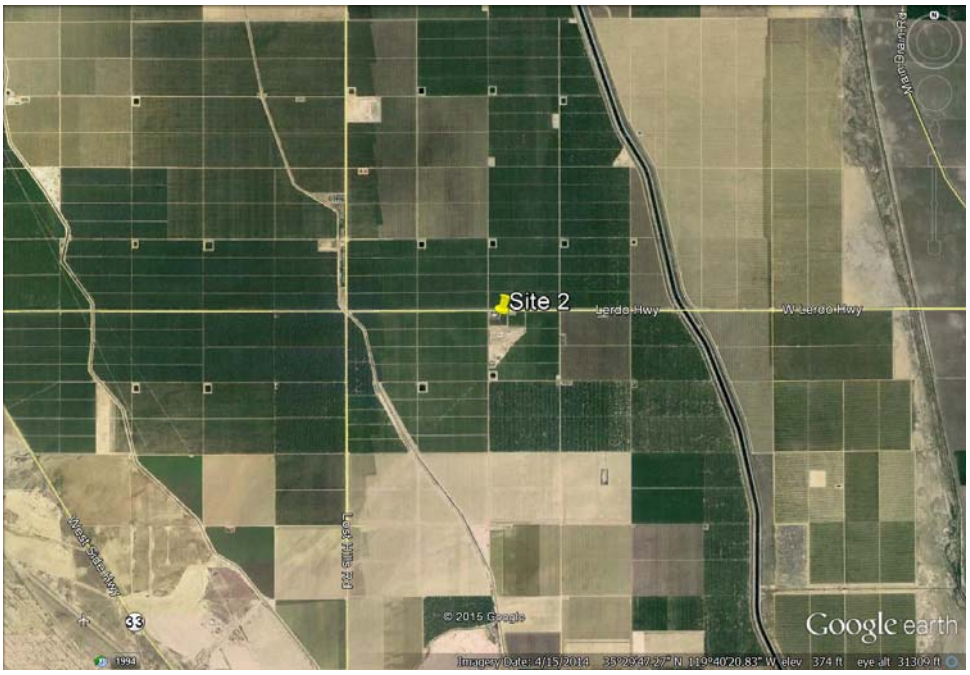
AMBIENT NOISE MONITORING SITES

Site 1

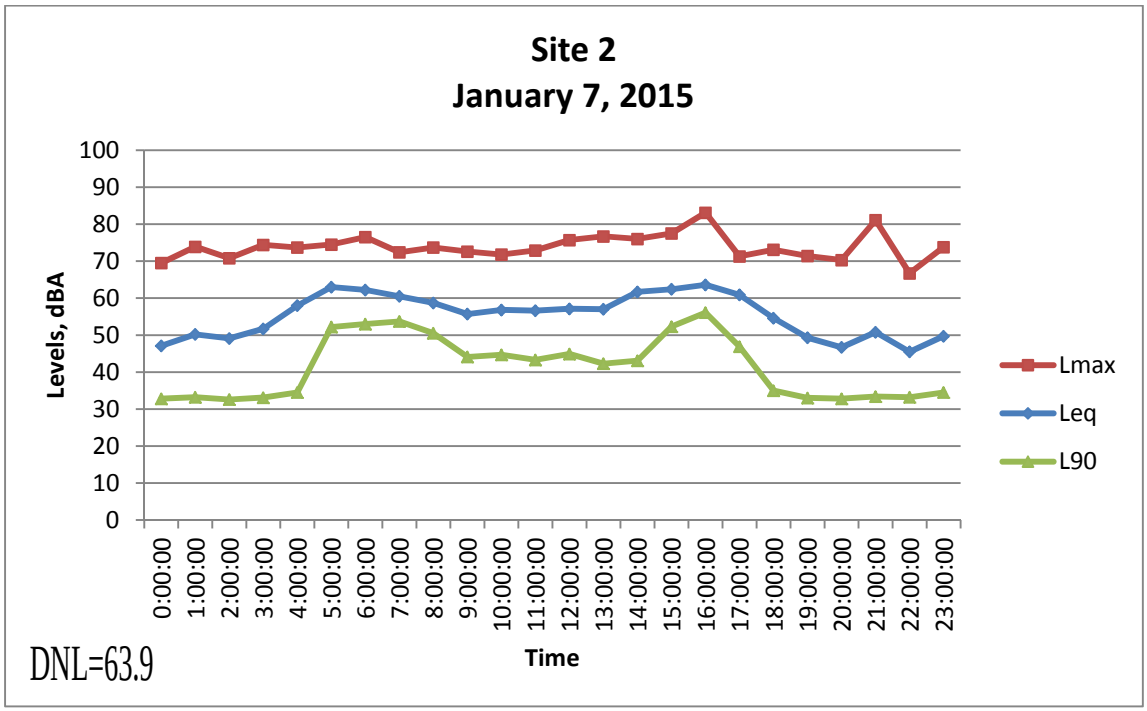
Site 1 was located north of the community of Lost Hills. The noise monitor was located in an open field west of Lost Hills Road. Audible sources of noise at Site 1 included traffic on Lost Hills Road, nearby commercial activities and birds. Noise measurements were taken over a 24-hour period on January 7, 2015. The measured DNL value for the 24-hour monitoring period was 58.5 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 42.9 dB to 58.4 dB. Measured hourly maximum (L_{max}) values ranged from 54.8 dB to 76.5 dB. Measured hourly L_{90} values ranged from 34.2 dB to 39.4 dB.



Site 2

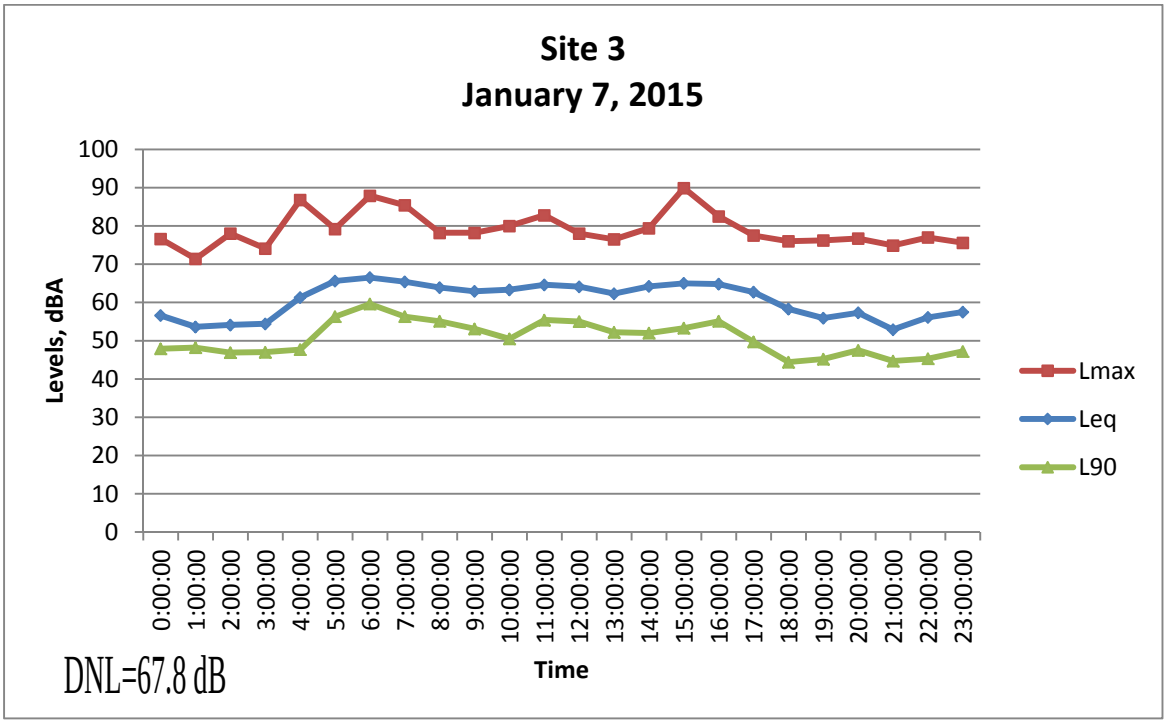


Site 2 was located approximately 1 mile east of the intersection of Lerdo Highway and Lost Hills Road. The noise monitor was located along the east side of an agricultural office facility, at a distance of approximately 250 feet from Lerdo Highway. Audible sources of noise at Site 2 included traffic on Lerdo Highway, nearby agricultural activities and birds. Long-term noise measurements were taken over a 24-hour period on January 7, 2015. The measured DNL value for the 24-hour monitoring period was 63.9 dB. The chart below shows hourly noise monitoring data during the study period. Measured hourly L_{eq} values ranged from 45.5 dB to 63.6 dB. Measured hourly maximum (L_{max}) values ranged from 66.7 dB to 83.1 dB. Measured hourly L_{90} values ranged from 32.6 dB to 56.1 dB.



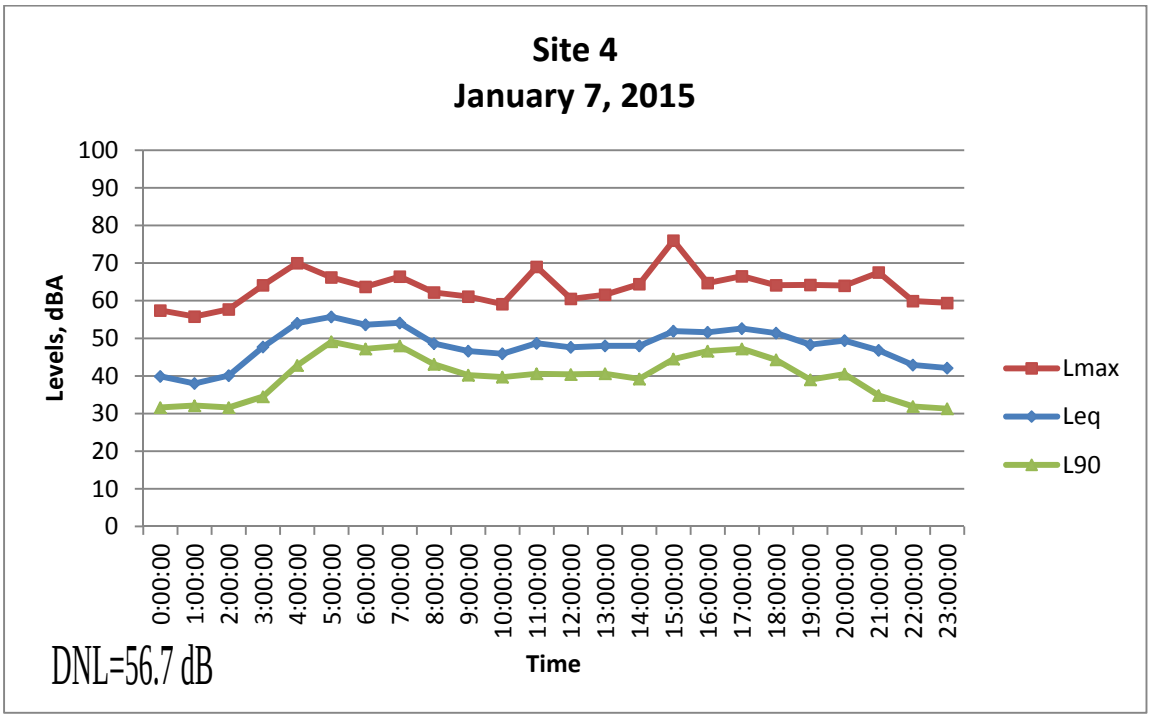
Site 3

Site 3 was located within the community of McKittrick, near the intersection of Reward Road and 2nd Street. The noise monitor was located in an open field behind 33 & E Market. Audible sources of noise at Site 3 included traffic on Reward Road and 2nd Street, voices from nearby commercial activities and activities associated with nearby residential land uses. Noise measurements were taken over a 24-hour period on January 7, 2015. The measured DNL value for the 24-hour monitoring period was 67.8 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 52.9 dB to 66.5 dB. Measured hourly maximum (L_{max}) values ranged from 71.4 dB to 89.9 dB. Measured hourly L_{90} values ranged from 44.4 dB to 59.6 dB.

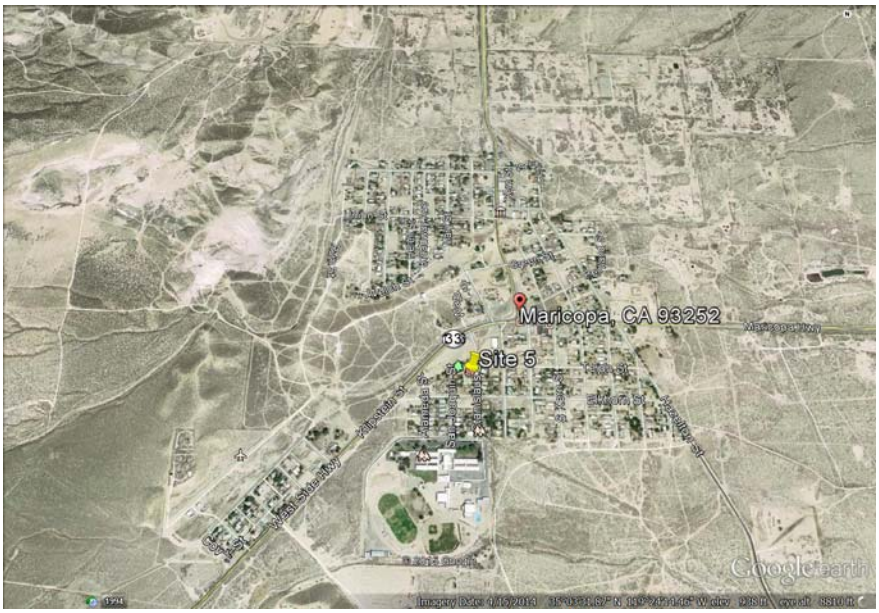


Site 4

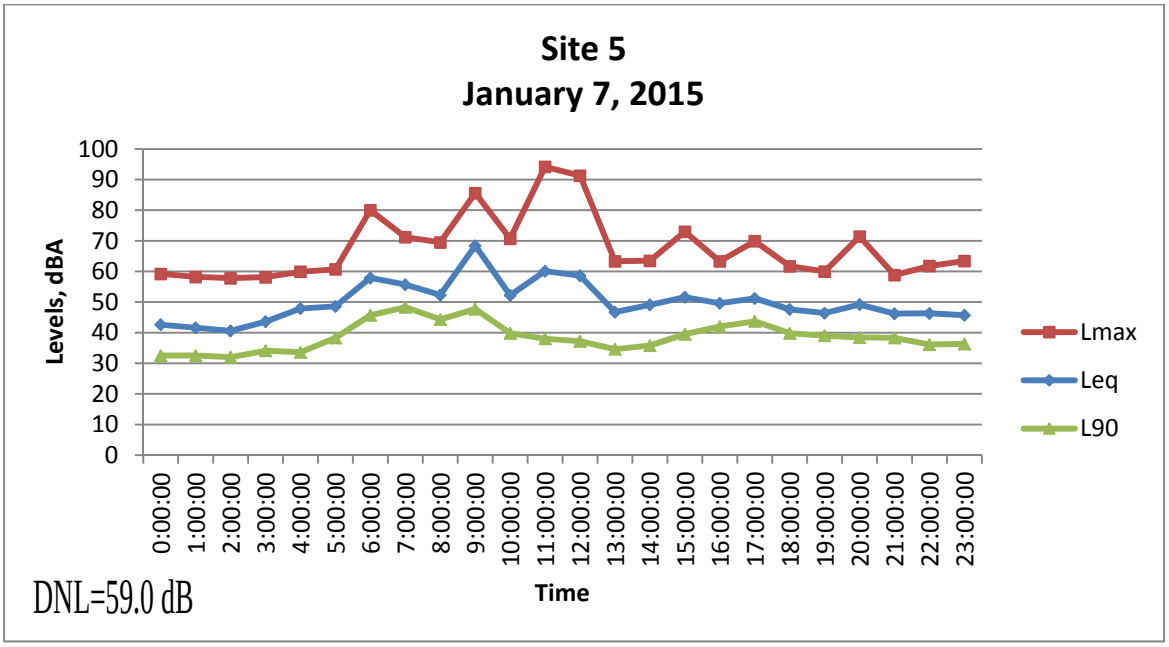
Site 4 was located along Division Street, north of Cedar Street, northwest of the City of Taft. The noise monitor was located in an open field behind the Kern County Sheriff's substation office, at a distance of approximately 500 feet from Division Street. Audible sources of noise at Site 4 included traffic on Lerdo Highway Road, nearby agricultural activities and birds. Noise measurements were taken over a 24-hour period on January 7, 2015. The measured DNL value for the 24-hour monitoring period was 56.7 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 38.0 dB to 55.7 dB. Measured hourly maximum (L_{max}) values ranged from 55.8 dB to 76.0 dB. Measured hourly L_{90} values ranged from 31.3 dB to 49.1 dB.



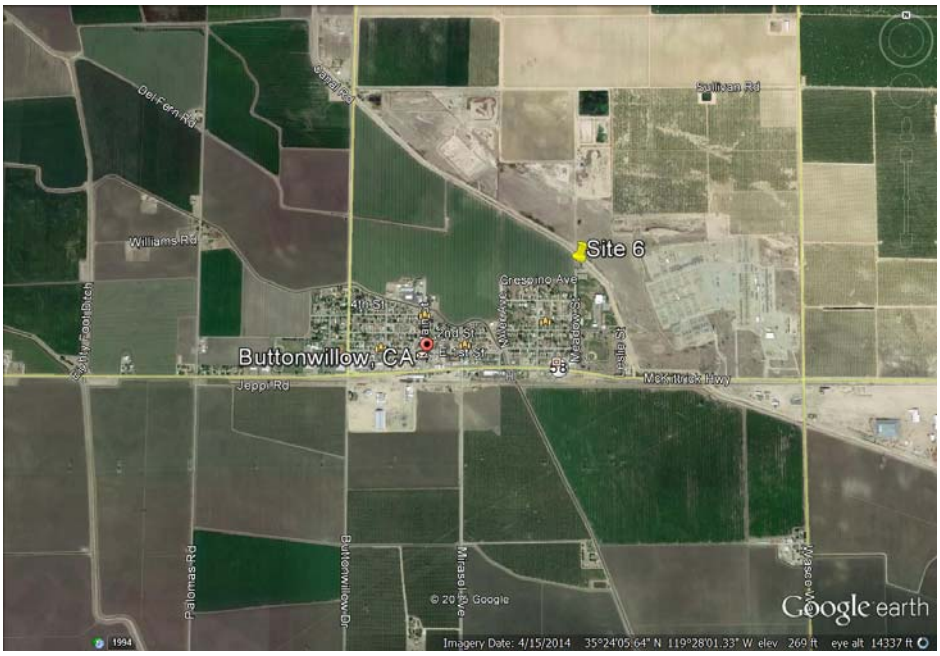
Site 5



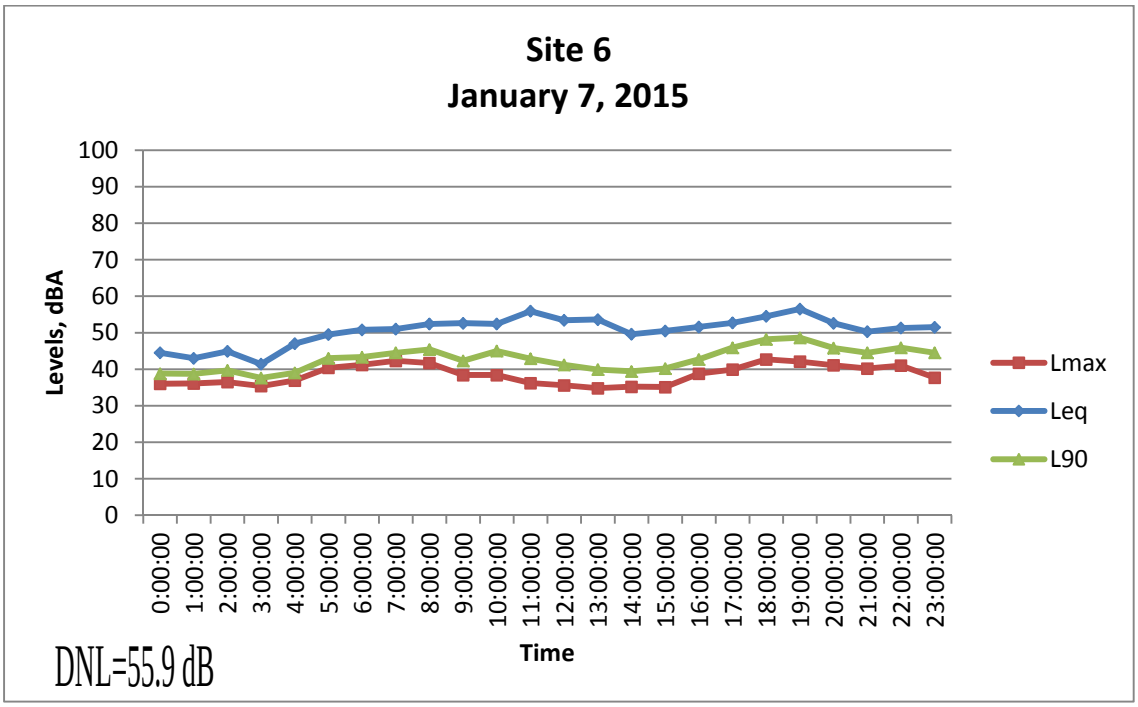
Site 5 was located near the City of Maricopa, approximately 500 feet from State Route 33. The noise monitor was located in the rear area of the Kern County Fire Department station. Audible sources of noise at Site 5 included traffic on SR 33, traffic on other local roadways and birds. Although not observed at the time of set up or take down of the equipment, it is expected that maximum levels measured at Site 5 were the result of sirens from fire station activities. Noise measurements were taken over a 24-hour period on January 7, 2015. The measured DNL value for the 24-hour monitoring period was 59.0 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 40.6 dB to 68.4 dB. Measured hourly maximum (L_{max}) values ranged from 57.8 dB to 94.2 dB. Measured hourly L_{90} values ranged from 32.0 dB to 48.3 dB.



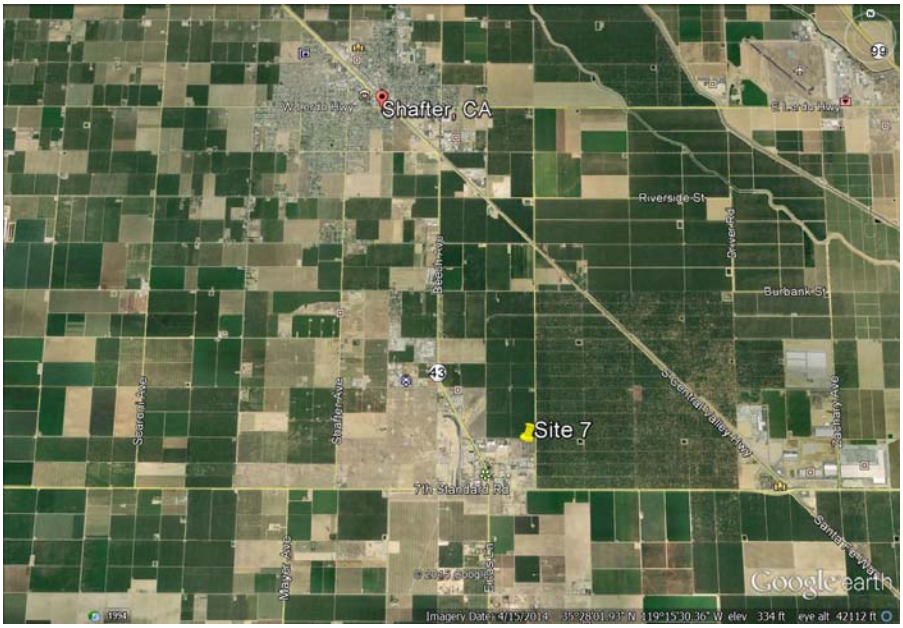
Site 6



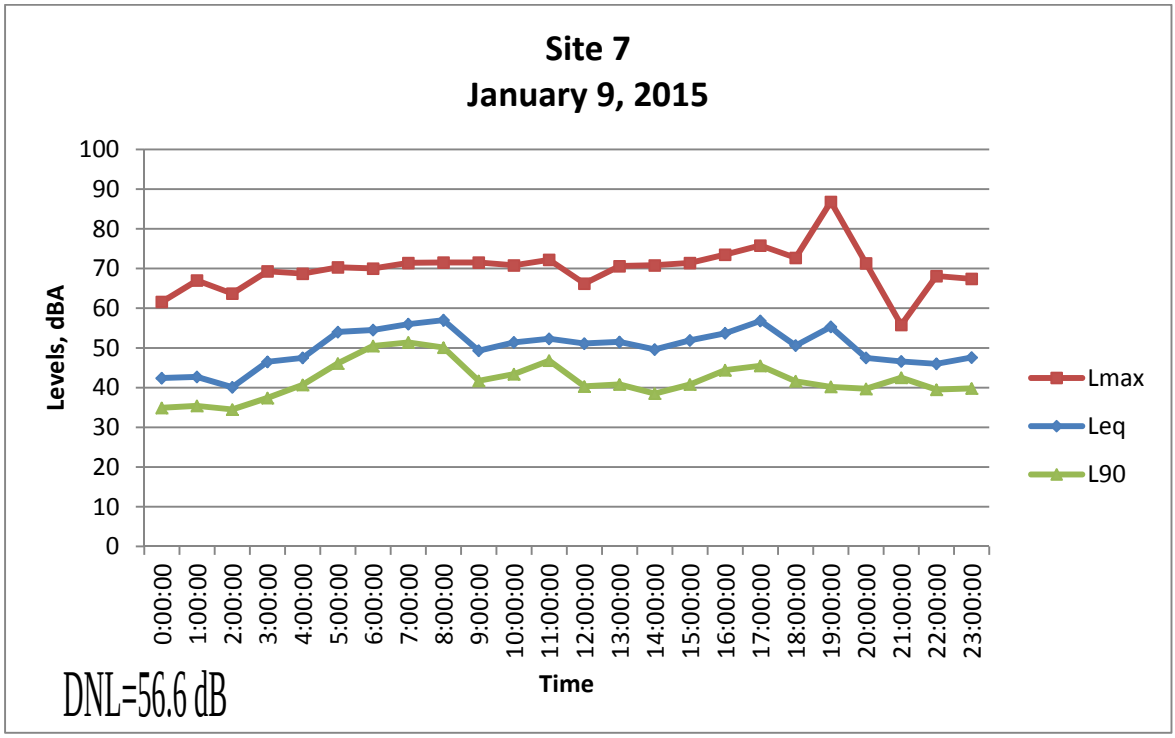
Site 6 was located near the community of Buttonwillow, near the northern Terminus of Meadow Street. The noise monitor was located near open agricultural land along an irrigation ditch. Audible sources of noise at Site 6 included traffic from local roadways, noise related to nearby residential land uses, agricultural activities and birds. Long-term noise measurements were taken over a 24-hour period on January 7, 2015. The measured DNL value for the 24-hour monitoring period was 55.9 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 41.4 dB to 56.5 dB. Measured hourly maximum (L_{max}) values ranged from 57.6 dB to 76.5 dB. Measured hourly L_{90} values ranged from 37.6 dB to 48.6 dB.



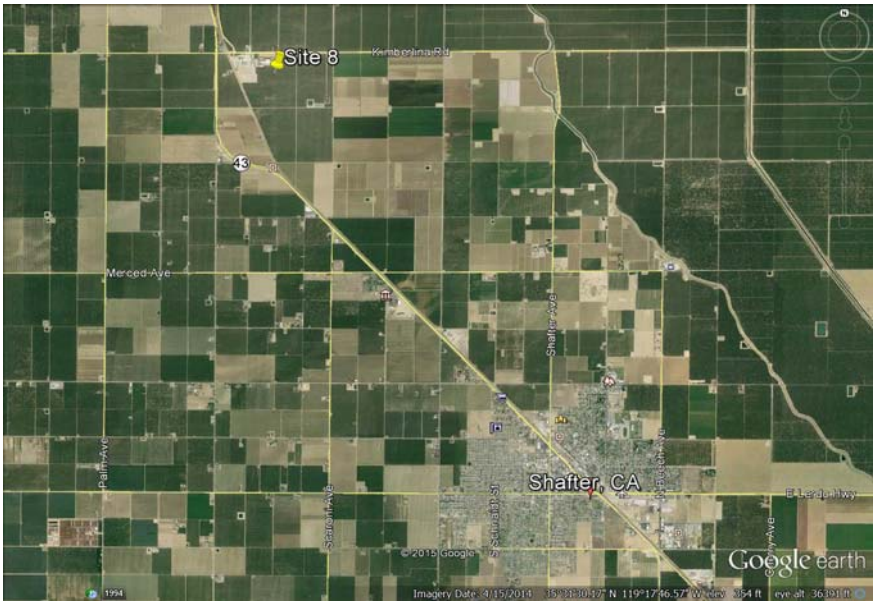
Site 7



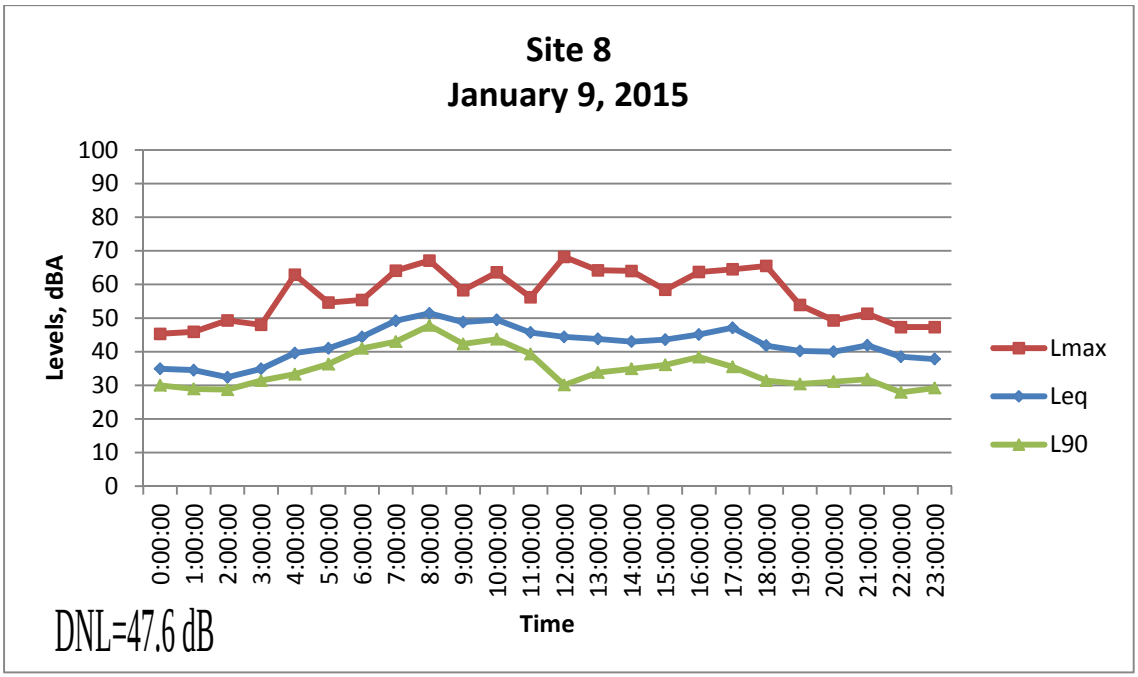
Site 7 was located south of the City of Shafter, approximately ½ mile northeast of the intersection of 7th Standard Road and Enos Lane. The noise monitor was located in an open field. Audible sources of noise at Site 7 included traffic on local roadways, noise from nearby commercial and industrial activities, and noise related to nearby agricultural activities. Noise measurements were taken over a 24-hour period on January 9, 2015. The measured DNL value for the 24-hour monitoring period was 56.6 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 40.1 dB to 57.0 dB. Measured hourly maximum (L_{max}) values ranged from 55.8 dB to 86.8 dB. Measured hourly L_{90} values ranged from 34.5 dB to 51.4 dB.



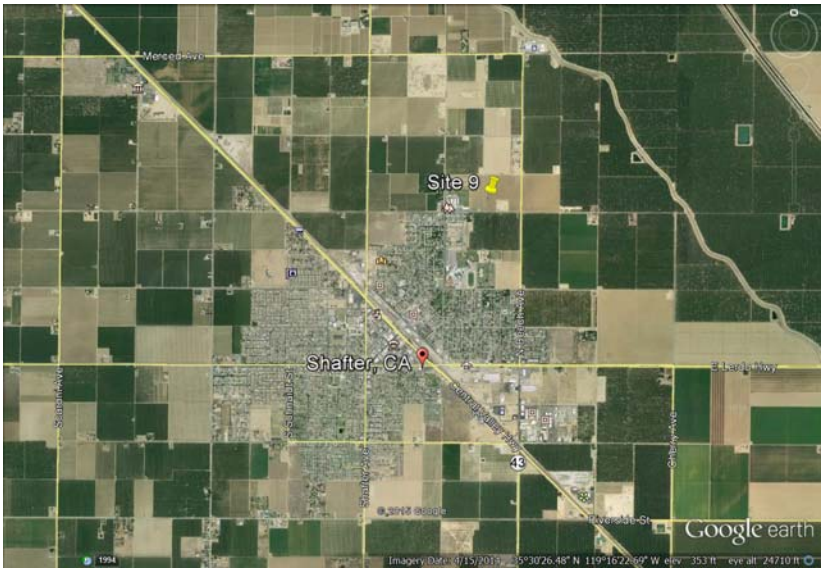
Site 8



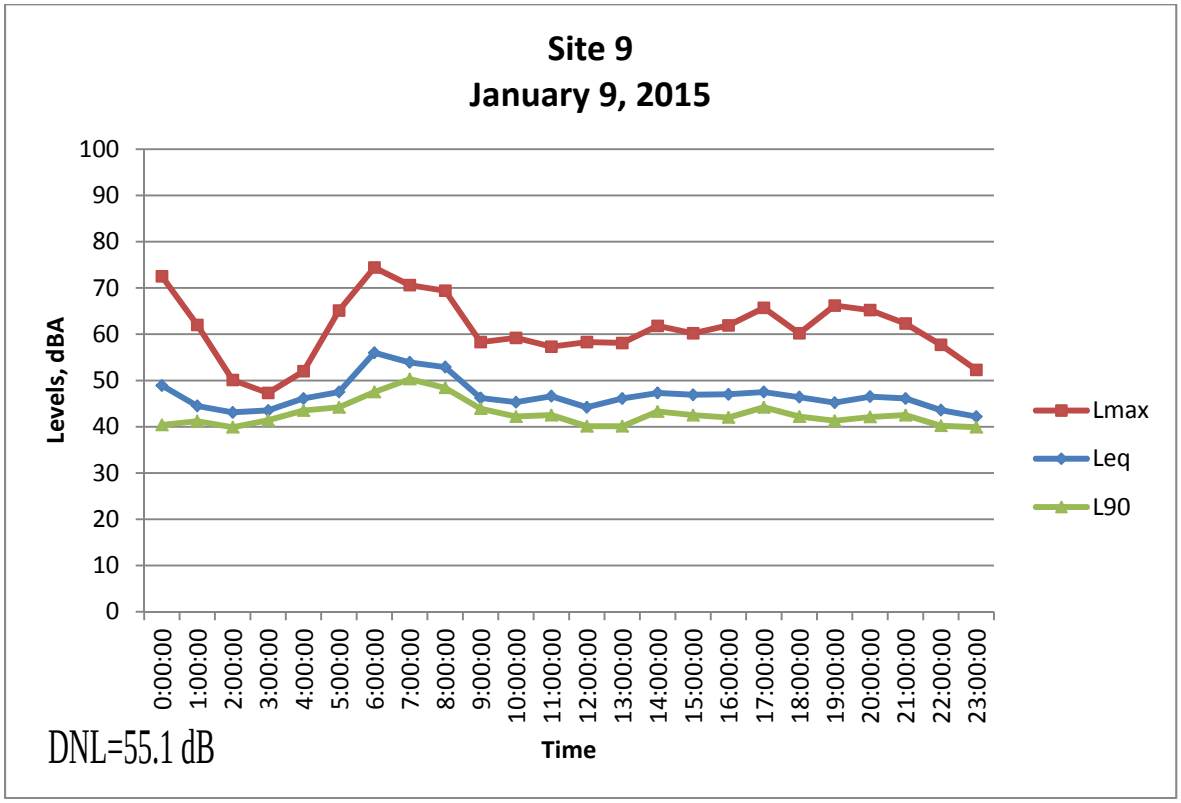
Site 8 was located between the City of Wasco and City of Shafter. The noise monitor was located in a field. Audible sources of noise at Site 8 included traffic from local roadways, noise related to agricultural activities and birds. Noise measurements were taken over a 24-hour period on January 9, 2015. The measured DNL value for the 24-hour monitoring period was 47.6 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 32.4 dB to 51.4 dB. Measured hourly maximum (L_{max}) values ranged from 45.3 dB to 68.2 dB. Measured hourly L_{90} values ranged from 27.9 dB to 47.8 dB.



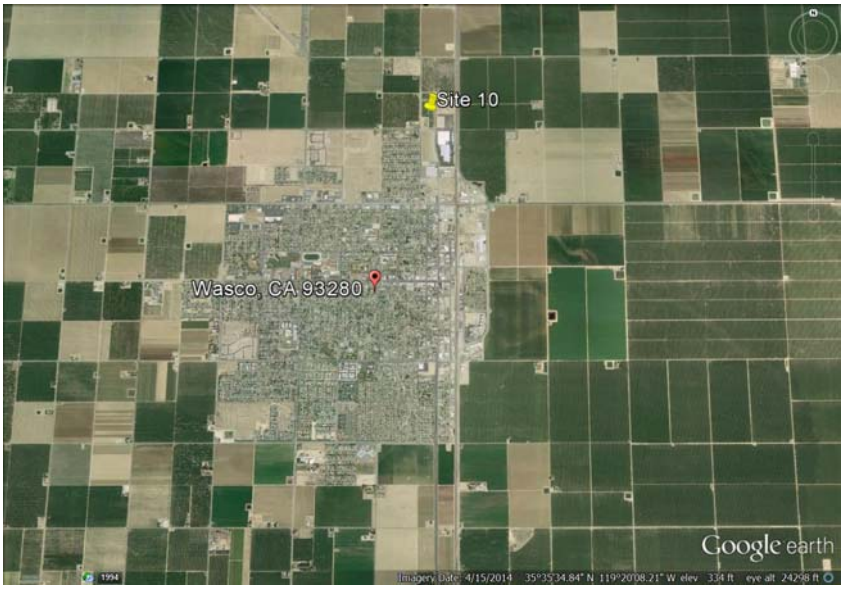
Site 9



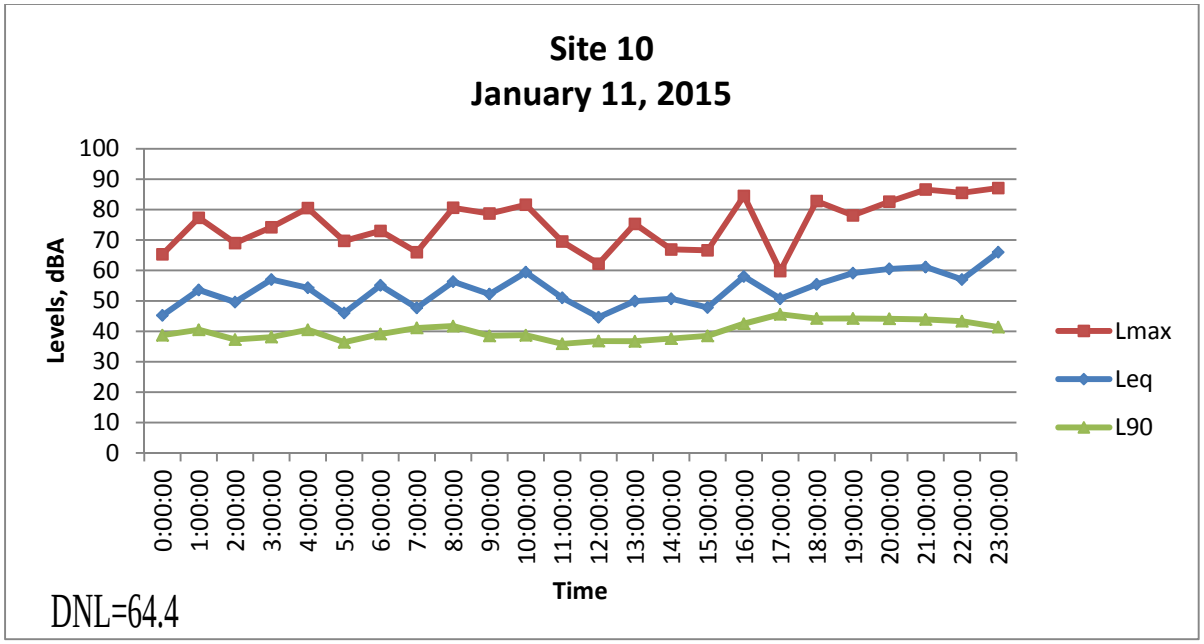
Site 9 was located northeast of City of Shafter, near Sequoia Elementary School. The noise monitor was located in an open field near an existing oil well. Audible sources of noise at Site 9 included traffic on local roadways, noise from nearby agricultural activities and noise from the nearby oil well. Noise measurements were taken over a 24-hour period on January 9, 2015. The measured DNL value for the 24-hour monitoring period was 55.1 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 42.2 dB to 56.0 dB. Measured hourly maximum (L_{max}) values ranged from 47.3 dB to 74.4 dB. Measured hourly L_{90} values ranged from 39.9 dB to 50.3 dB.



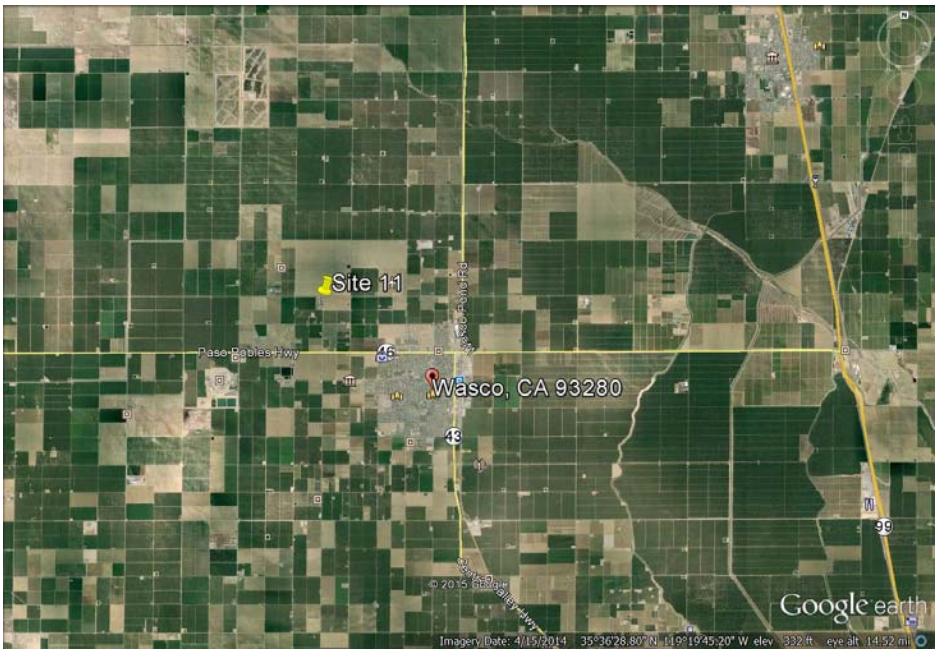
Site 10



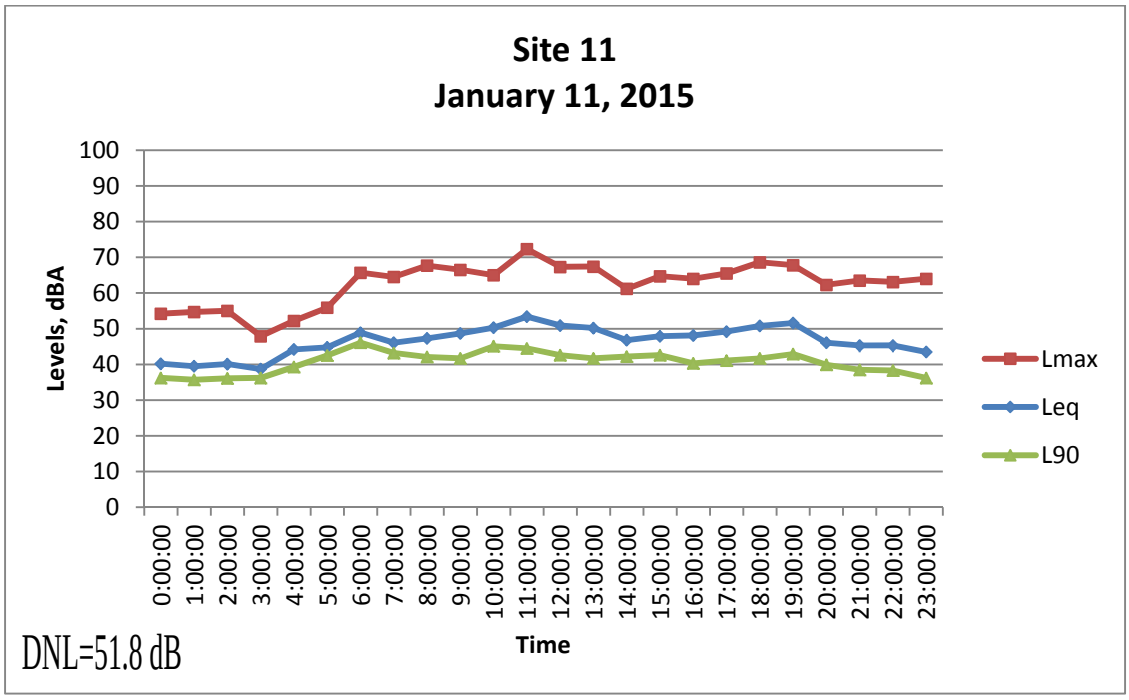
Site 10 was located northeast of the City of Wasco. The noise monitor was located in a public park. Audible sources of noise at Site 10 included traffic from local roadways, noise related to agricultural activities and noise from trains along the BNSF Railway line. Noise measurements were taken over a 24-hour period on January 11, 2015. The measured DNL value for the 24-hour monitoring period was 64.4 dB. Hourly average and maximum noise levels at Site 10 were greatly influenced by train noise along the BNSF Railway line. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 44.6 dB to 66.0 dB. Measured hourly maximum (L_{max}) values ranged from 59.8 dB to 87.1 dB. Measured hourly L_{90} values ranged from 35.9 dB to 45.6 dB.



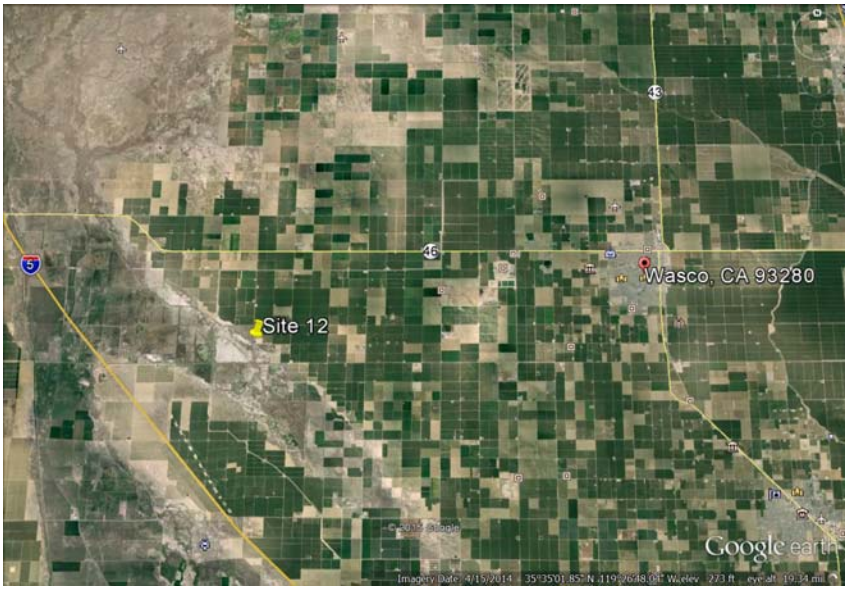
Site 11



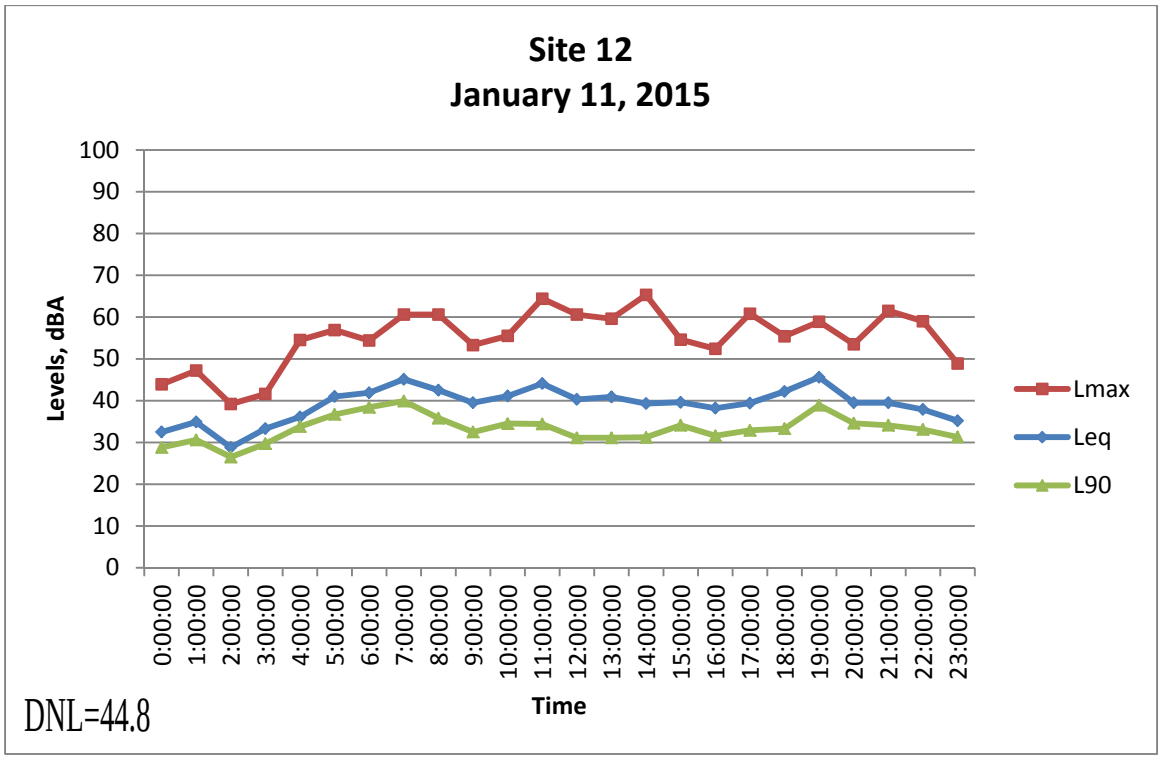
Site 11 was located northwest of City of Wasco, southwest of the intersection of McCombs Road and Western Avenue. The noise monitor was located in an open field behind rural residential land use. Audible sources of noise at Site 11 included traffic on local roadways and noise from nearby agricultural activities. Noise measurements were taken over a 24-hour period on January 11, 2015. The measured DNL value for the 24-hour monitoring period was 51.8 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 38.7 dB to 53.4 dB. Measured hourly maximum (L_{max}) values ranged from 47.9 dB to 72.3 dB. Measured hourly L_{90} values ranged from 35.7 dB to 46.1 dB.



Site 12

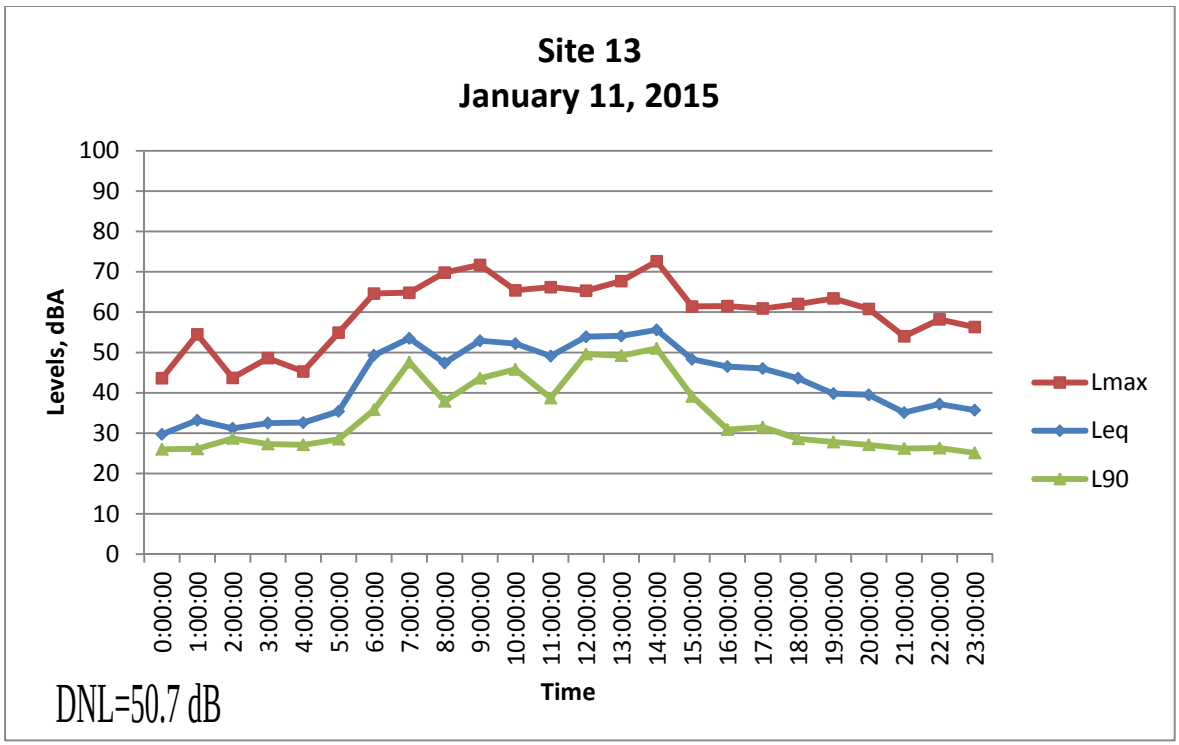


Site 12 was located in a rural area approximately 5 miles east of Interstate 5 and 2 miles south of State Road 46. The noise monitor was located in an a field near a retaining pond. Audible sources of noise at Site 12 included noise related to agricultural activities, birds and wind. The noise measurements were taken over a 24-hour period on January 11, 2015. The measured DNL value for the 24-hour monitoring period was 44.8 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 28.8 dB to 45.6 dB. Measured hourly maximum (L_{max}) values ranged from 39.2 dB to 65.3 dB. Measured hourly L_{90} values ranged from 26.5 dB to 39.9 dB.



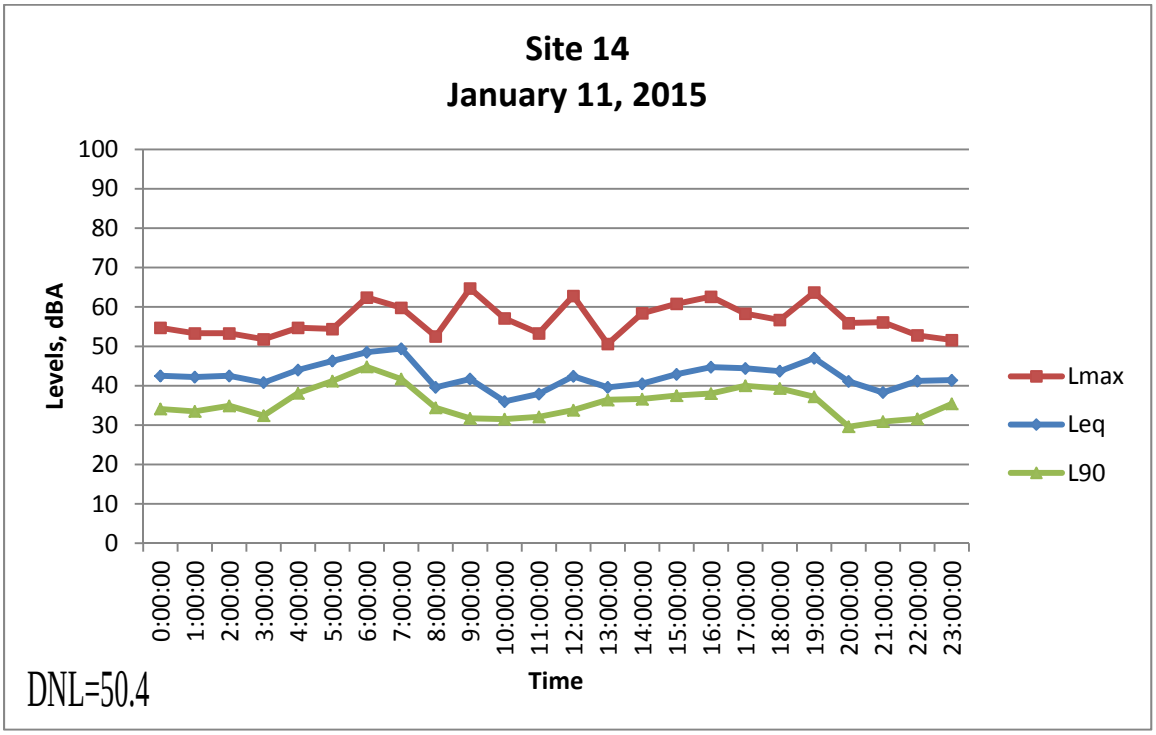
Site 13

Site 13 was located approximately 1 mile east of the junction of Interstate 5 and State Route 99. The noise monitor was located in an orchard. Audible sources of noise at Site 13 included traffic on I-5/SR 99 and noise related to agricultural activities. The noise measurements were taken over a 24-hour period on January 11, 2015. The measured DNL value for the 24-hour monitoring period was 50.7 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 29.7 dB to 55.6 dB. Measured hourly maximum (L_{max}) values ranged from 43.6 dB to 72.6 dB. Measured hourly L_{90} values ranged from 25.1 dB to 51.0 dB.



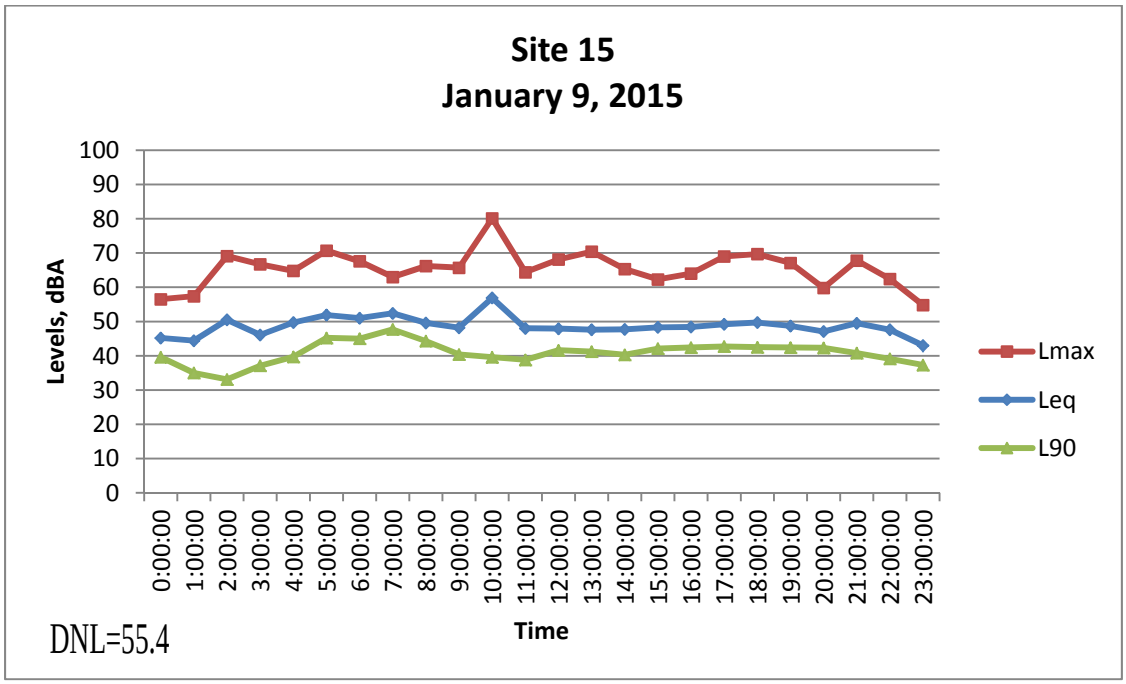
Site 14

Site 14 was located east of the City of Arvin, approximately ¼ south of Bear Mountain Boulevard. The noise monitor was located in a field near a retaining pond. Audible sources of noise at Site 14 included traffic noise from Bear Mountain Boulevard, noise related to agricultural activities, birds, and wind. The noise measurements were taken over a 24-hour period on January 11, 2015. The measured DNL value for the 24-hour monitoring period was 50.4 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 36.0 dB to 49.4 dB. Measured hourly maximum (L_{max}) values ranged from 50.6 dB to 64.7 dB. Measured hourly L_{90} values ranged from 29.6 dB to 44.8 dB.

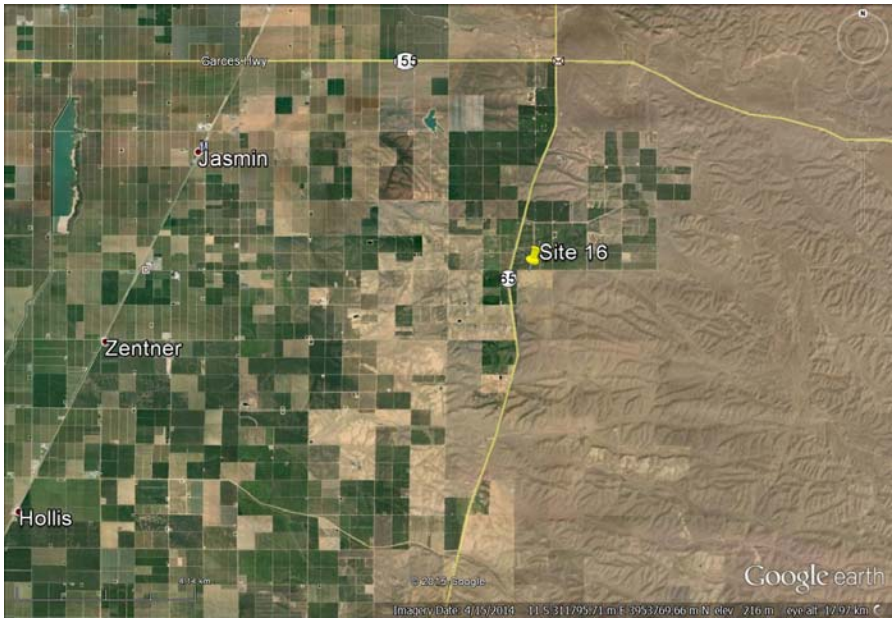


Site 15

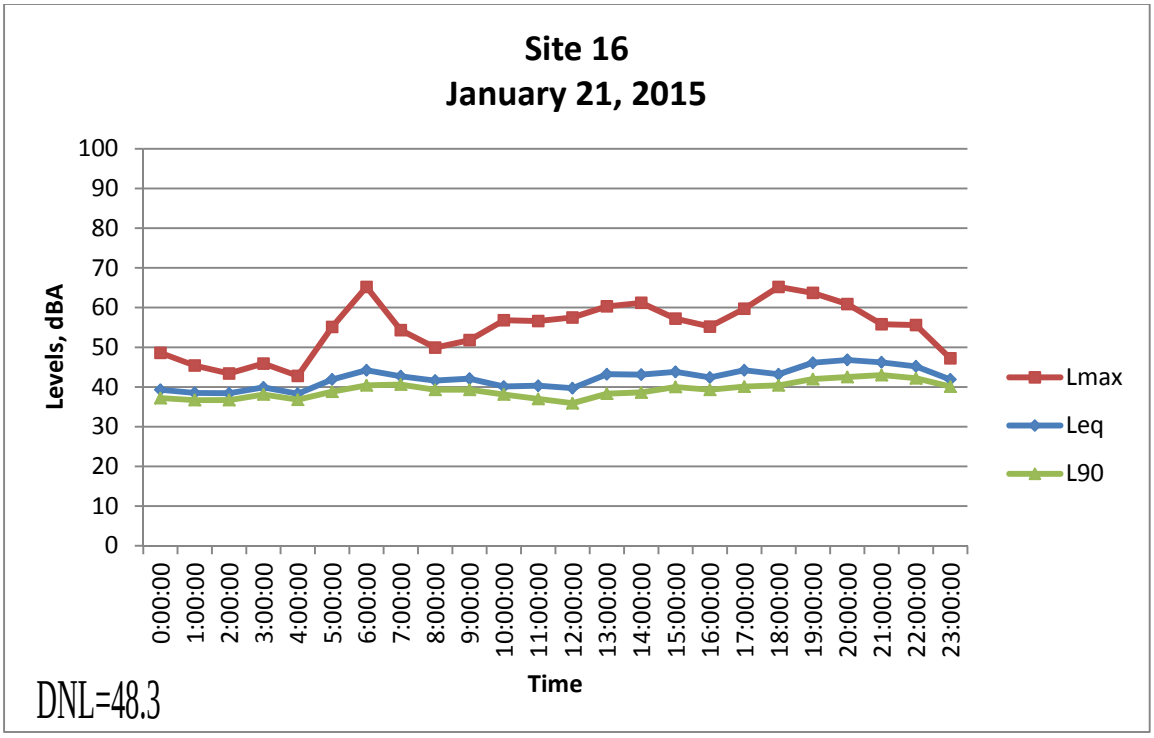
Site 15 was located approximately 3 miles east of the community of Lamont. The noise monitor was located in a field near agricultural land uses. Audible sources of noise at Site 15 included traffic on local roadways and noise related to agricultural activities. Noise measurements were taken over a 24-hour period on January 9, 2015. The measured DNL value for the 24-hour monitoring period was 55.4 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 43.0 dB to 56.9 dB. Measured hourly maximum (L_{max}) values ranged from 54.8 dB to 80.1 dB. Measured hourly L_{90} values ranged from 33.1 dB to 47.7 dB.



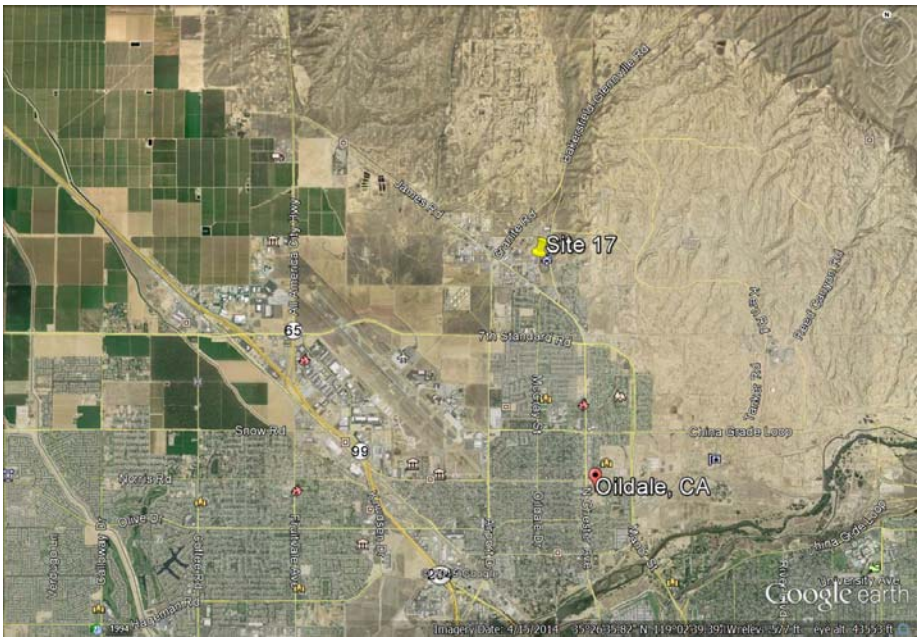
Site 16



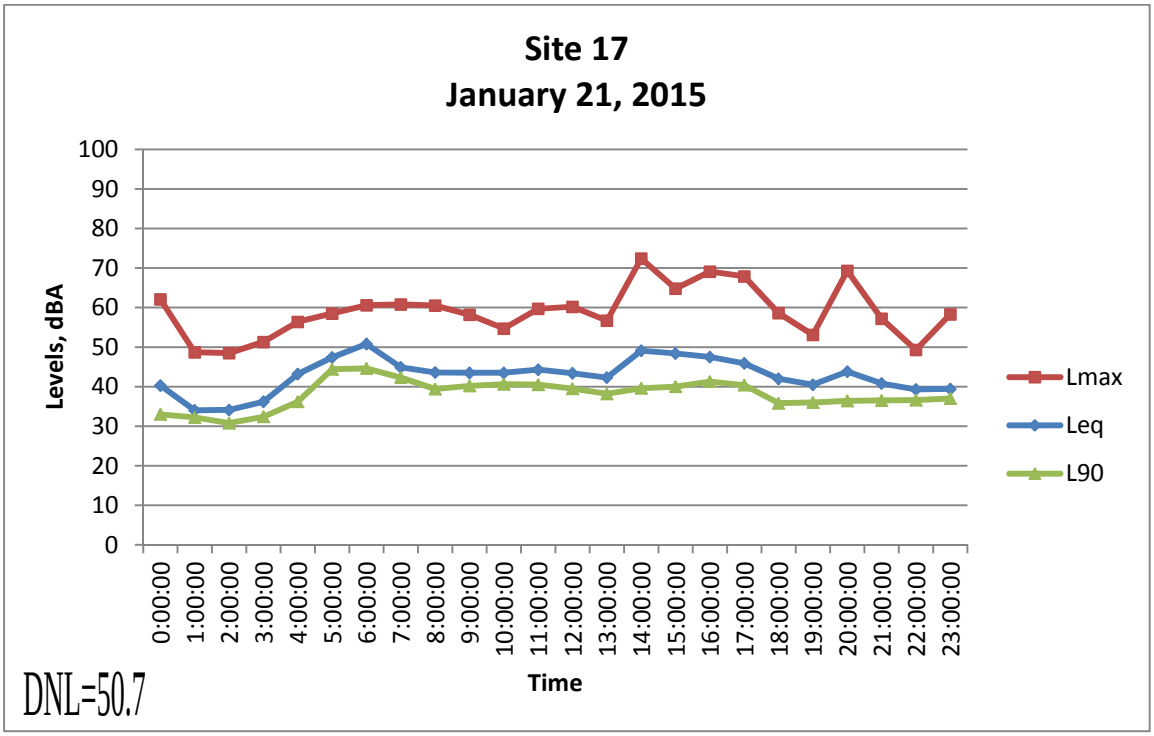
Site 16 was located east of the City of Arvin, approximately ¼ mile east of State Route 65. The noise monitor was located in an open field near agricultural land uses. Audible sources of noise at Site 16 included traffic noise from SR 65, noise related to agricultural activities, birds, and wind. Noise measurements were taken over a 24-hour period on January 21, 2015. The measured DNL value for the 24-hour monitoring period was 48.3 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 38.3 dB to 46.8 dB. Measured hourly maximum (L_{max}) values ranged from 42.8 dB to 65.2 dB. Measured hourly L_{90} values ranged from 35.9 dB to 43.0 dB.



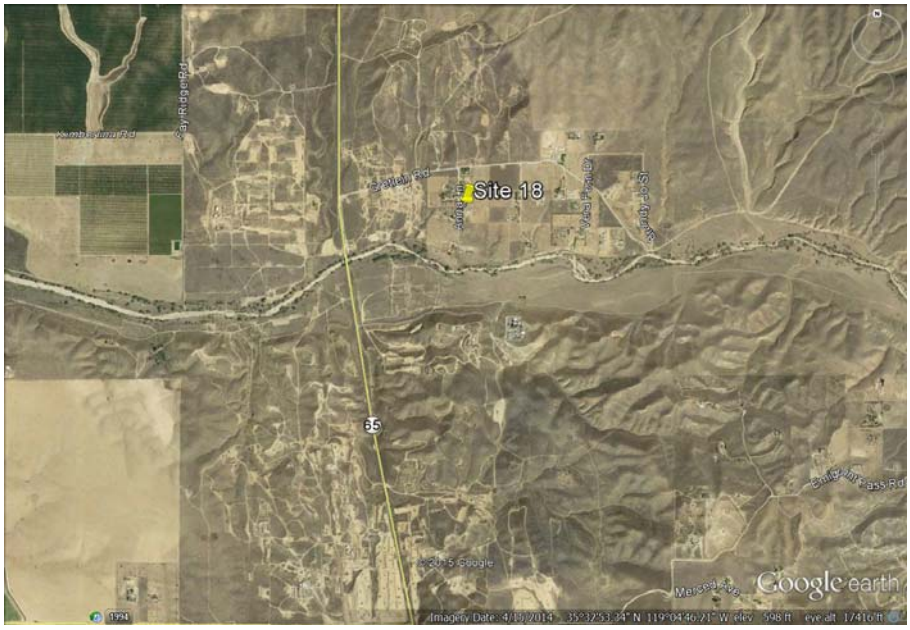
Site 17



Site 17 was located north of the community of Oildale. The noise monitor was located in a storage lot located at the rear of a mobile home complex. Audible sources of noise at Site 17 included noise related to the mobile home complex and noise from nearby commercial activities. Noise measurements were taken over a 24-hour period on January 21, 2015. The measured DNL value for the 24-hour monitoring period was 50.7 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 34.0 dB to 50.8 dB. Measured hourly maximum (L_{max}) values ranged from 48.5 dB to 72.4 dB. Measured hourly L_{90} values ranged from 30.8 dB to 44.6 dB.



Site 18



Site 18 was located on a residential property along Anna Lane. Audible sources of noise at Site 18 included local traffic on public roadways, noise related to nearby oil operations, birds and wind. Noise measurements were taken over a 24-hour period on January 21, 2015. The measured DNL value for the 24-hour monitoring period was 46.9 dB. The chart below shows hourly noise monitoring data during the monitoring period. Measured hourly L_{eq} values ranged from 34.8 dB to 45.9 dB. Measured hourly maximum (L_{max}) values ranged from 43.2 dB to 66.8 dB. Measured hourly L_{90} values ranged from 31.2 dB to 41.5 dB.

APPENDIX D

TRAFFIC NOISE EXPOSURE

Brown-Buntin Associates, Inc
FHWA-RD-77-108
Calculation Sheets
February 16, 2015

Project #: 14-057
Description: Kern Oil and Gas
Ldn/Cnel: Ldn
Site Type: Soft

			Distance to Traffic Noise Contours			
Segment	**Roadway Name**	**Segment Description**	**60.0**	**65.0**	**70.0**	**75.0**

CALIFORNIA RESOURCES CORPORATION

September 19, 2015

Chris Mynk
Supervising Planner – Permit Assistance Center
Planning and Community Development Department
County of Kern
2700 M Street
Bakersfield, CA 93301

Re: Geophysical Surveys and Vibration

Dear Mr. Mynk:

Your question regarding vibration from energy sources used in geophysical surveys was referred to me. This letter will explain the types of technology used in conducting the surveys, how we choose which technology to use, and how we manage the surveys to avoid damage to structures or annoyance to people.

By way of background, I am the Chief Geophysicist for California Resources Corporation. In this and previous capacities, I have been responsible for designing, conducting and interpreting the results of geophysical surveys for nearly 35 years. Over the past nine years this effort has been entirely in California where I've been involved with the project management of approximately 1200 square miles of three-dimensional geophysical surveys and another 115 miles of two-dimensional geophysical surveys in Kern County and other parts of the Central Valley. My previous 25 years of experience include similar work in West Texas, New Mexico, Utah, Oklahoma, Wyoming, each with diverse terrains and special situations. Attachment 1 is a copy of my resume.

Purpose of Geophysical Surveys

Oil is found underground in a limited number of rock types. It is usually trapped by geologic formations such as faults or anticlines comprised of impermeable cap rock. The oil bearing formations are typically thousands of feet beneath the surface, so studying surface geology gives very limited information about the oil-bearing potential of an area. Geophysical surveys are used to provide a picture of the geological structuring and layering. This information helps a geologist determine the potential extent of natural gas and oil reserves present, and whether such resources warrant development of additional production.

Geophysical Survey Technologies

Geophysical surveys use low-frequency sound waves. The sound waves are generated by one of two primary means, Vibroseis or shot hole.

The Vibroseis technique utilizes truck-mounted machines to generate vibrations. The Vibroseis trucks are positioned at the source-generation point, a steel plate is lowered from the undercarriage of the vehicle until it rests on the ground, the weight of the vehicle is shifted to the steel plate, and then a vibratory pulse is transmitted through the it to the Earth in order to generate the sound waves. Typically four trucks are utilized in line. The Vibroseis units weigh 63,000 lbs. The drive level refers to the percentage of the weight of the truck that is resting on the steel plate, 70% being a maximum. Less weight generates less force.

For the shot hole method, an explosive charge is detonated at the bottom of a hole. The explosive material is specially designed and manufactured for the geophysical industry. Shot holes are drilled with a rotary drill in areas inaccessible to the Vibroseis trucks such as mountainous or hilly back-country or cultivated farmland. Shot holes vary in depth from 30-50 feet, typically with a diameter of 4 inches, although this can vary slightly depending on drill type. Explosive charges are placed at the bottom of the holes, back-filled with cuttings and bentonite, and detonated during recording to generate seismic waves directed down into the Earth. Typically, the size of the charge ranges from 5 to 20 pounds. The shot holes are typically 110 to 1320 feet apart.

While the Vibroseis and shot hole methods provide the source of energy to generate seismic waves, both methods require the deployment of geophones to record the minute reflected energy that bounces off the deep formations

thousands of feet below the surface. These geophones are positioned in a grid over the survey area. Geophones are increasingly self-contained units that not only detect the seismic reflections coming from deep below, but also record and store the data. These self-contained units are called nodes and require no cables or recording trucks. Older recording systems use small geophones connected by cables, much like strings of Christmas lights that eventually plug into a recording truck (seismograph). The seismic waves travel through the rock and eventually some of the energy bounces back. The grid of geophone detectors receive and record this energy from many hundreds of thousands of subsurface points. How the seismic waves are reflected back to the surface varies depending on the type of rock and its depth and structural position, i.e. if it's steeply dipping, faulted, or flat-lying. The data is processed to generate a three dimensional image of the earth typically from about 1,000 to 20,000 feet deep, and the geoscience team interprets the data to determine the underlying geology.

Regardless of which method is used, the sounds waves are generated for only brief periods. A Vibroseis unit typically operates for only two to five minutes at a location, and during this time the unit alternates between signal generation and listening. For the shot hole method, the detonation of charges is nearly instantaneous.

Vibration, also called ground motion, is measured as peak particle velocity (PPV, inches/second). Because geophysical surveys are designed to create vibrational or impulsive energy for the purpose of obtaining reflections from deep rock layers, the energy sources for both Vibroseis and shot hole methods are designed to direct energy downward rather than up and out. In fact, energy that goes up or out interferes with collection and interpretation of the reflection data from deeper geology. Accordingly, geophysical surveys are designed to result in relatively low PPV levels even at reasonably close surface proximity.

Selection of Geophysical Survey Technology for a Particular Site

The Vibroseis method is preferred, however it may be infeasible or inappropriate in certain circumstances. The shot hole method is required in areas of steep terrain where the specialized Vibroseis-equipped truck cannot operate safely. Also, in agricultural areas, farmers may indicate a preference for the shot hole method, for example, in orchards where low branches cannot accommodate Vibroseis units, or in tilled fields where the truck tires and pads would crush crops or disturb furrows.

Regulatory and Industry Standards

Geophysical surveys are conducted in a vast array of environments from tropical jungles to the Arctic, from deep sea to transitional coastal environments. In the United States, operators generally rely on the U.S. Bureau of Mines (USBM) in Report of Investigations 8507 (November 1980) and the Blasting Guidance Manual (1987) of the U.S. Department of Interior Office of Surface Mining Reclamation and Enforcement in determining the charges to be used in proximity to different receptors and structures. Geophysical surveys for oil and gas development are not directly regulated by the Bureau of Mines or the Office of Surface Mining Reclamation and Enforcement. However, operators routinely refer to the research done by these agencies in designing geophysical surveys, and use the Blasting Guidance Manual to determine stand-off distances. (The stand-off distance means the buffer distance between the source generating the sound wave and a structure or other item - e.g., a water well - in the vicinity that will ensure the structure is not damaged by the vibration.)

According to the Blasting Guidance Manual, velocities as low as 0.50 in/sec may cause threshold damage to brittle materials such as lath and plaster that may be found in older structures, while threshold damage may occur to newer construction materials such as drywall used in interior walls starting at PPV of 0.75 in/sec. Threshold damage is defined by the Bureau of Mines as the loosening of paint, small plaster cracks at joints between construction elements or the lengthening of old plaster cracks. The load bearing or other structural portions of a house normally can experience considerably higher velocities without damage. Similar thresholds are summarized in the California Department of Transportation Vibration Guidance Manual, September 2013.

The Bureau of Mines and Office of Surface Mining Reclamation and Enforcement testing and conclusions are summarized in Attachment 2, which is a report by Matheson Mining Consultants entitled *Utilizing Peak Particle Velocities to Develop Seismic Offset Distances*, published in the Denver Geological Society's monthly publication,

explained above, California Resources Corporation would not use these standoff distances. When working around engineered structures we follow the USBM and OSMRE guidelines.

For the purpose of the Environmental Impact Report and the vibration level for ministerial permitting purposes, I would recommend using the following minimum PPV tolerance limits or stand-off distances:

Energy Source	**Protected Structures**	**PPV Not to Exceed at Protected Structure**	**Stand-off Distance**
Vibroseis	Occupied buildings, water wells, sewer systems, septic tanks, etc.	0.50 in/sec.	150 feet
Shothole	Occupied buildings, water wells, sewer systems, septic tanks, etc.	0.50 in/sec.	300 feet

In response to the comment letter from Pacific Ag Management, dated September 11, 2015: The recommended stand-off distances in the table above **should not** be understood to state that the PPV value is 0.5 in/sec. at 150 ft for Vibroseis or 300 ft for shot-hole. In fact, the PPV values for these energy sources at these stand-off distances are considerably lower and can be derived from the attached reports. We use these stand-off distances because they provide an extra level of protection **above and beyond the USBM and OSMRE guidelines**, and because these are specific numbers that would protect in all situations required for ministerial permitting purposes.

Sincerely,

Cynthia E. Black, Chief Geophysicist

RESUME

CYNTHIA E. BLACK
11524 Indian Hawthorne St.
Bakersfield, CA 93311
Work: (661)412-5036 Cell: (661)343-7328 Email: cynthia.black@crc.com

34 years of successfully managing all phases of geophysical projects from acquisition, processing to final interpretation within exploration, production and exploitation settings in various basins and plays: San Joaquin, Sacramento, Los Angeles, Permian, Anadarko, Paradox, Rockies Overthrust Belt; Geophysical prospector and technical lead

Strengths & Skills

- Seismic Acquisition field management in difficult acquisition and permitting scenarios
- Solid interpretation skills with 2D, 3D, VSP geophysical data & well logs
- Solid geological background
- Peak particle motion studies acquisition, management, and interpretation
- Downhole microseismic – frac mapping and reservoir monitoring
- Interpretation of a variety of structural styles from seismic & wells
- Sequence stratigraphy-based interpretation & close integration of well control
- 2D zero-offset modeling to characterize reservoir problems
- Seismic attribute analysis to evaluate reservoir character (primarily, but not exclusively, amplitude)
- Play analysis, risking of plays and prospects using probabilistic techniques, e.g. Pete Rose
- Workstation interpretation software experience: Landmark suite products, and others
- Many years of working with paper sections 2D CDP and single fold
- Deal-screening; asset evaluation; deal selling
- Strong presentation and communication skills
- Strong people skills
- Industry network & many years working with local SEG-affiliated geophysical societies

Employment & Education History

2014 Dec – date	**California Resources Corporation**, Chief Geophysicist, California (Oxy spin-off)
2009 Sep - 2014	**Occidental Oil & Gas Corp.**, Chief Geophysicist, California
2007 Jan – 2009	**Occidental of Elk Hills, Inc**., Chief Geophysicist, Elk Hills
2005 Feb - 2007	**Oxy Permian** (Occidental Petroleum Corp.), Sr. Geophysical Advisor
2001 Mar - 2005	**Digital Prospectors**, Geophysicist/**Consultant (multiple clients)**
1998 Feb - 2001	**Burlington Resources, Inc.**, Mid-Continent Div., Midland, TX, Geophysical Advisor
1995 Sep - 1998	**Arco Permian**, Midland, TX, Sr. Staff Geophysicist
1987 Aug - 1995	**Exxon Co., U.S.A**., Production Department, Midland, TX, Sr. Petroleum Geophysicist
1982 Dec - 1987	**Exxon Co., U.S.A**., Exploration Department, Midland, TX, Sr. Geophysicist
1981 - 1982	**M.Sc. (Geology) – Texas A&M University** – Prof. Robert R. Berg, advisor (thesis: Environment of Deposition and Reservoir Facies of the Taylor "B" Sandstone, Cotton Valley Group (U. Jurassic), Kildare Field, Cass Co., TX (cores & logs)
1981 – 1982	**Texas A&M University** – Teaching Assistantship for undergraduate Mineralogy & Microscopy; Field Camp
1977 - 1980	**B.Sc. (Hons., I, Geology & Mineralogy) – Aberdeen University**, Scotland
1979 - 1980	**British Geological Survey** – combined 3 months summer work over 2 years – geochemical sampling & site description
1978 – 1980	**Aberdeen University**, Scotland – Demonstrator in numerous 1st, 2nd, and 3rd year labs for Introductory, Intermediate and Advanced Historical, Mineralogy, Igneous, Metamorphic and Sedimentary Petrology Fall 1978 through Spring 1980
1975 - 1977	**Temple University**, Philadelphia (**Geology major**)
1983 – date	Numerous continuing education courses within Exxon, Arco, BR, Oxy, as well as annual symposia for AAPG, SEG, GCAGS (published thesis), PBGS, and minor publications

Work Highlights

9/09 – date **California – San Joaquin Basin/Elk Hills, VPC, THUMS/LBU**

- Rio Lobo 3D (Kettleman North Dome) – 200 mi2 – project management, i.e. planning, approval, contracts, field coordination, permit compliance, processing, etc. (2014-2015)

- Re-vamp 3D in Long Beach – reprocess Thums and 3DVSP, License Signal Hill's 3D over Townlot and Pico; interpret
- Tulainyo 2D – 115 mi – project management
- Antelope Valley 3D – 113 mi2 – project management
- Jacalito 3D – 512 mi2 - project management 09/09 – 06/11
- Belgian Anticline 3D – 65 mi2 – coordinate with operating partner (2010)
- Moco 3D – 96 mi2 – project management & partner coordination 08/09 – 06/11
- Numerous processing & reprocessing projects in extremely difficult data – QC
- Mentoring younger geophysicists and interns
- Oversight various smaller projects; foster geophysical community through regular Geophysical Round Tables
- Project definition, resource allocation, negotiating contracts, working with Supply Chain, Land, Regulatory, Legal
- Budget management
- Some, but not enough interpretation

1/07 – 9/09 **California – San Joaquin Basin/Elk Hills, THUMS/LBU**

- Mentoring/training young career geophysicists and/or interpreters
- Geophysical resource allocation
- Prospecting & interpretation in/around Elk Hills Field
- Passive microseismic reservoir monitoring (Monterey Shale during CO2 injection)
- Zero-offset VSP Acquisition & Interpretation
- Planning & managing 200 mi2 Buena Vista 3D acquisition

3/01 – 1/07 **Permian Basin 3D projects** (consulting for many operators, esp. Oxy, CrownQuest)

- Prospecting throughout Oxy acreage in Delaware (Texas) and Midland basins generating numerous prospects
- Would Have (Clearfork) – Inversion work to image porosity in Clearfork limestone detrital play (used to pick key updip location)
- Howard Co. Canyon play – active exploration/prospect generation
- Winkler Co. – Keystone South (picked #441 location), Flying W, Jasper area
- SE New Mexico: Morrow play; deep structural work on platform edge Pecos Valley/Southern Platform: Detrital chert play in Canyon
- NW Shelf: Clearfork play; Fusselman play; Horseshoe Atoll/Scurry Reef (Diamond M Unit)
- Delaware Basin: Wolfcamp detrital play (Reeves Co.)
- Central Basin Platform: Clearfork detrital play; Wolfcamp reef play
- Midland Basin/Eastern Shelf: Clearfork/Wolfcamp/Pennsylvanian plays
- Tatum Basin, Trinity Field – Wolfcamp play – stratigraphic detection of porosity: use RAVE to correlate seismic attributes to PhiH – 100% success rate in finding porosity and oil

Maverick Basin 3D project (consulting for Conoco)

- Rodessa reef play (Glen Rose); Pearsall Shale

Anadarko Basin/Texas Panhandle (consulting for numerous operators)

- Structural/stratigraphic work in Arbuckle & Granite Washes adjacent to Panhandle Field

2/98 – 2/01 **Anadarko Basin** (for Burlington Resources)

- Washita & Beckham Co.'s, OK - Springer/Morrow, Atoka, Redfork, Granite Wash; multiple prospects generated, one exploratory success in the Atoka, numerous in-field proposals within Elk City Field (basin-centered deep gas) & exploitation prospects generated (one became a major discovery by another operator)
- 250 mi2 of 3D seismic interpreted along with about 1000 mi. of 2D; responsible for project management of 150 mi2 of 3D acquisition (BR's Cordell Anticline 3D)
- Play analysis (Pete Rose techniques/software) and asset evaluation

9/95 – 1/98 **Permian Basin – Valverde basin, southern Central Basin Platform, Delaware basin, Eastern Shelf** for Arco Permian (primarily 3D work; scattered 2D work)

- Prospect generation throughout the southern Midland Basin with detailed work within the Brown Bassett, Benedum, Coyanosa, Waha fields. Extensive experience in Wolfcamp and Strawn plays in Upton and Crockett Co.'s; horizontal Devonian play in Midland Co., and the Parks-Pegasus area; Strawn, Montoya, Devonian and Delaware horizontal plays; Fusselman, Ellenburger, Wolfcamp gas plays; early involvement in Montoya fracture play at Waha field
- Project management of acquisition through interpretation of a number of 3D surveys as well as reprocessing of numerous other vintage 3D's

8/87 – 9/95 **Wyoming Overthrust Trend, Powder River, Williston, Denver, Paradox, & Permian Basins (3D & 2D work) – with Exxon Co., USA Production Department**

- Cordona Lake (Devonian subcrop) field – project management of 3D; initial interpretation to optimize CO2 flood and primary drilling and production
- Collett Creek and Bridger Fork fields in Wyoming Overthrust (Bighorn) – remapping a complex subthrust "pillow" play and identifying reservoir heterogeneity using stratigraphic modeling – using 2D – managed 2D acquisition
- Silo field, Wyoming (horizontal Niobrara) – guiding horizontal drill wells w/ 2D – partnered for new 2D acquisition
- Cane Creek play (horizontal Cane Creek), Paradox Basin, Utah: identifying drilling opportunities, guiding horizontal drill wells; and specifically picked location for the Kane Springs Fed. 1-10 (IP >700 BOPD), completed for 325 BO/.8 MMCF per day; managed 2D acquisition
- Williston, Wind River and Powder River basins; Delaware basin fields such as Gomez, Haley Ut., SE New Mexico

12/82 – 8/87 **Exploration (2D only) – with Exxon Co., USA**

- SE New Mexico (Morrow, Delaware)
- Andrews Co., Texas (detailed structural mapping)
- Midland Basin (stratigraphic work)

Scholarships/Awards

1977	Recipient of Andrew Mutch Scholarship for one-year's study in Scotland presented by the St. Andrews Society of Philadelphia
1979	Recipient of Andrew Carnegie Scholarship at Aberdeen (merit-based)
1981	Recipient of ARCO Scholarship to cover all graduate studies at A&M University

Society Memberships & Activity

2004-2005	President – Permian Basin Geophysical Society
2003-2004	President-Elect - Permian Basin Geophysical Society (but worked as President)
2002-2003	Vice-President – Permian Basin Geophysical Society
1999-2003	Secretary/Newsletter editor – Permian Basin Geophysical Society
1983-date	West Texas Geological Society – Member
2007-date	San Joaquin Geological Society – Member
2007-date	Pacific Coast Section – SEG - Member
1989-date	Society of Exploration Geophysicists – Active member (#014431)
1982-date	American Association of Petroleum Geologists – Active Member (#38113-1)

Other Interests

Travel – Scotland (1977-1980; 1984), Spain (1998), Ireland (2006)

Family - Son US Army Reserve/student, BS Computer Science, Texas State University; Daughter, MS in progress, University of AK, Fairbanks, BS Wildlife Biology, University of Montana Missoula, Blue – 14 year old Catahoula, Zoe – 11 year old Pomeranian, Taiga – 2 yr old Husky/Shepherd mix

Cycling, hill-walking, camping, reading/writing, Alaska, New Mexico, travel, music

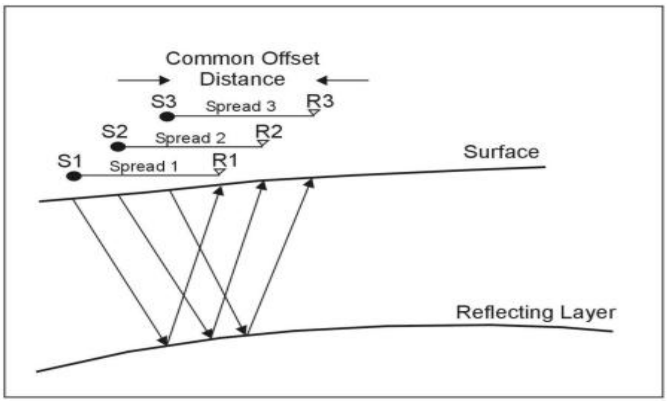
For The Record:

Draconian Rule?

Commentary
By Steve Jensen
DGS Editor

I am relinquishing my normal article this month to make room for an important report on seismic offset distances. It seems the state of Colorado is about to introduce draconian new rules on seismic offset distances from cultural objects. The following report from Mark Burgus at Matheson Mining Consultants tries to put some science behind reasonable seismic acquisition setbacks.



I encourage all geophysicists, oil companies, and seismic contractors to voice their opinion about this very important subject. We can't let others in the state or outside our state attempt to dictate our ability to collect seismic data in Colorado.

Please read Mark's report on seismic offset distances. We need to discuss this in the geophysical community as soon as possible. After we come together on this as a professional group, we can help advise Colorado on reasonable offset distances when collecting seismic data.

SPECIAL REPORT:
Geophysical Survey Standoff Recommendations

Commentary

By Mark L. Burgus, P.G.

UTILYZING PEAK PARTICLE VELOCITIES TO DEVELOP SEISMIC OFFSET DISTANCES

Matheson Mining Consultants (MMC) would like to propose offset distances for various points of concern (locations of sensitive resource objects) for shot hole and Vibroseis geophysical exploration based on statistical peak particle velocity (PPV) ground motion studies and accepted vibration limits obtained from US Bureau of Mines (USBM) and other research papers. MMC has performed well over a hundred ground motion attenuation studies throughout the western United States. A shot hole analysis was run on 1366 shot hole data points taken from 42 different studies. A Vibroseis analysis was run on 459 data pairs from 12 studies that all used four 60,000 pound or higher peak force vibrators operating at 70% or higher drive levels. Data was taken from studies performed in California, Utah, Wyoming, Montana, Colorado, New Mexico, Texas, and Oklahoma.

The geophysical exploration industry has often used the offset tables found in the BLM 3150 Handbook, Illustration 16, 1/9/2007. These tables have been widely used for recommended offset distances on federal projects. Stock ponds, springs and wetland/riparian areas have recently been analyzed for potential impacts. Since very little research exists on the effects of ground motion on stock ponds, springs and riparian/wetland areas, PPVs/Offsets could not be developed for these Objects at this time. Some existing Object categories have been re-evaluated and/or re-grouped into categories with similar impact protection standards. Results from the summary shot hole and Vibroseis analyses were used in developing these updated geophysical survey offset tables.

BACKGROUND ON GROUND MOTION ATTENUATION STUDIES

Ground motion attenuation studies are performed in accordance with Federal Code of Regulations guidelines. Although these guidelines specify +95% confidence level equations be used, an additional set of tables is presented using +99.9% confidence levels. The ground motion attenuation study is designed to statistically predict (with a confidence level of 95%) safe surface stand-off distances from points of concern (such as residences, businesses, water wells, and oil and gas wells and pipelines) within the survey area. Particle velocity data acquired in the field are input into a least squares linear regression analysis program. This program has been approved by the United States Office of Surface Mining and Reclamation Enforcement (OSMRE) and is defined in 30 CFR 816.67(d)(3)(ii). The regression analysis yields a site-specific attenuation formula in the form:

$$PPV = H(SD)^{-B}$$

Where,

H = the velocity (y axis intercept) at a scaled distance of one,

B = the slope of the curve,

PPV = the peak particle velocity in inches per second, and

SD = Scaled Distance = Distance from shot to recorder divided by the square root of the charge weight = Distance for Vibroseis studies

The program also yields the correlation coefficient (goodness of fit), , with 1.0 being perfect. Thirty data points are required for statistical validity.

Once the equation for the ground motion has been defined, shot hole predictions may be made for PPV, charge weight, or offset distance by manipulating the equation and holding two of the variables constant and for Vibroseis, predictions may be made for PPV or distance by manipulating the equation and by holding one of the variables constant.

SPECIAL REPORT:
Geophysical Survey Standoff Recommendations

– continued from previous page –

For Vibroseis studies, a complete statistical data set is acquired for each set of parameters the Vibroseis are expected to operate under. The data presented below is from studies using four vibrators with at least 60,000 pound peak force operating at high force (70% or higher drive levels).

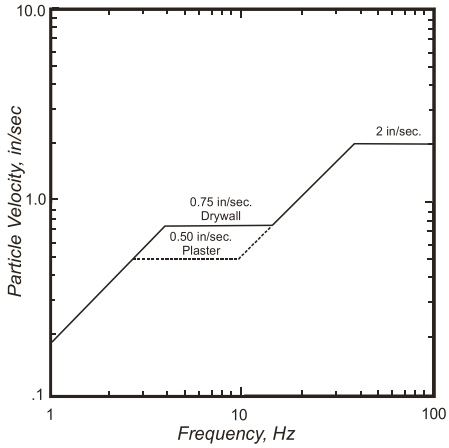
Vibration measurements are taken perpendicular to the Vibroseis array from the center vibrator base plate (experience, azimuthal studies around the vibrator array, and research dictate this is the direction of highest surface ground motion). In order to effectively establish the end points of the curve, data is acquired at distances of less than 10 feet from the vibrator base plate to perhaps 250 feet or more (until readings of <0.05 inches per second (ips) are obtained).

For individual shot hole studies, typically, from six to eight test holes are drilled in a line on 25-foot centers. In order to achieve a good correlation coefficient, test holes were drilled to the same depth for each study and were loaded with sufficiently large charges to provide a good signal at the recording locations (usually 2.2 pounds or greater). Shot holes are typically stemmed with bentonite and cuttings and are allowed to "sleep" for over a day to ensure no blow outs occur. Shot holes are individually detonated. Recording locations are placed in a logarithmic manner. The summary study uses data from 0.5, 1.1, 2.2, 3.3, 4.4, 5.5, 10, 11, and 20 pound charge sizes in hole depths ranging from seven to one hundred twenty feet.

The studies are designed to be conservative in nature. They are located in representative areas of each survey area that will provide worst-case results; topographically flat and in an area with near surface water saturation. Vibroseis PPV measurements are typically much less during production that during studies due to changes in the vibrator array with respect to the point of concern.

RECOMMENDED VIBRATION LIMITS

MMC recommends adherence with USBM and/or OSMRE (US Office of Surface Mining and Reclamation Enforcement) Variable Frequency versus Particle Velocity criteria. Adherence to these criteria provides a maximum level of protection. Documented cases of structural damage have never been observed in any structure, historic, exceptionally fragile, residential, or commercial, at particle velocities less than those recommended in the USBM and OSMRE standards.



USBM Criteria from RI-8507, November 1980

Under typical circumstances ground vibrations need to exceed the USBM recommendations or the OSMRE regulations by a considerable amount in order to produce threshold damage such as plaster or drywall cracking or paint flaking. Applying a peak vibration limit of 0.50 ips provides a high degree of protection for engineered structures and is the threshold level for possible damage to plaster-on-lath, considered the most fragile of modern construction materials. The threshold of human perception is around 0.03 ips and complaints rise when residents experience levels over about 0.25 ips.

SPECIAL REPORT:

Geophysical Survey Standoff Recommendations

– continued from previous page –

Bell Labs states that a limit of 4.00 ips is safe for fiber optic cable. The USBM states that 4.92 ips is a safe level for all buried pipelines, regardless of material, age, or pressurization, and that this limit is also applicable to wells. Railroad tracks and main paved roads experience high vibration levels when trains or traffic are present and a limit of 4.00 ips is conservative. Vibroseis operations in urban areas cause no damage when they are directly on pavement or concrete.

Much of the western U.S. has experienced light earthquakes (instrumental intensity IV). Instrumental intensity is an instrumentally-derived, estimated Modified Mercalli Intensity scale. These have not caused damage to stock ponds, springs or riparian and wetland areas. According to the USGS, this equates to peak ground velocities of up to 1.34 ips. Detonation of shot holes and vibrator production induce short duration events, whereas earthquakes typically are of much higher intensity, longer duration and are of much lower frequency. Thus, seismic source generation should not pose the risk of soil liquefaction that earthquakes do, since it is of low intensity and short signal duration. In riparian and wetland areas, wet or hydric soils do not structurally or biologically need an offset buffer as shot hole detonation and vibrators can be (and are commonly) used directly in these environments. Potential rutting would be of more concern than source generation offsets/buffers.

The following table from the USGS relates perceived shaking, potential damage, peak acceleration, peak ground velocity (in cm/sec) and instrumental intensity:

Perceived Shaking	Not felt	Weak	Light	Moderate	Strong	Very Strong	Severe	Violent	Extreme
Potential Damage	none	none	none	Very light	Light	Moderate	Moderate/Heavy	Heavy	Very Heavy
Peak ACC (%g)	<.17	.17-1.4	1.4-3.9	3.9-9.2	9.2-18	18-34	34-65	65-124	>124
Peak Vel (in/s)	<.04	0.04-0.43	0.43-1.34	1.34-3.19	3.19-6.30	6.30-12.20	12.20-23.62	23.62-45.70	>45.70
Instrumental Intensity	I	II-III	IV	V	VI	VII	VIII	IX	X+

MMC has experience monitoring pictographs and petroglyphs. Pictographs in Montana near a large scale surface coal mine have been monitored for over 14 years. The highest reading was 3.4 ips with around a 1.0 ips level measured approximately 40 times. Blasting has occurred about once per day. The pictographs are on massive sandstone and no degradation to the pictographs has occurred to date.

In another major project for railroad construction in Abo Canyon in New Mexico, dozens of shots were measured at pictographs and petroglyphs sites on massive sandstones. Levels as high as 1.13 ips were measured with no degradation observed.

In yet another project, MMC monitored Vibroseis production at pictographs on massive sandstone in Nine Mile Canyon outside of Price, Utah. An imposed limit of 0.75 ips was never exceeded and road construction induced higher vibration levels near the rock art than the Vibroseis production. No degradation occurred.

The massive rock layers experience large environmental stresses due to diurnal temperature changes. These stresses can equate to high particle velocities on the order of inches per second. However, due to the sensitive and valuable nature of these cultural resources, MMC recommends a plaster limit of 0.50 ips.

The following tables, from Illustration 16 in the BLM 3150 Handbook, 1/9/2007, have been adapted using conservative MMC ground motion attenuation study results. A column of PPV limits has been added. Point of concern categories (Objects) have been added for springs, riparian areas, stock ponds, high risk earthen dams, and pictograph and petroglyph panels. Water well, building, and pipeline categories have been re-combined in similar groups for resource protection analysis purposes. The Vibroseis table has been changed to reflect the same categories as in the shot hole table. Offset distances derived from the +95% confidence level

Additional considerations may be necessary for selecting offset distances for sensitive points of concern, that are not solely based on scientific data. In addition, considerations for human perception may need to be taken into account. The use of a plaster limit (0.50ips) in these situations is appropriate.

A Western US Shot Hole Summary and Summary of Western US Vibroseis Studies analyses for both +95% and +99.9% confidence levels are attached.

The shot hole analysis used values generated by +95% and +99.9% confidence level tables of particle velocity vs. distance for 0.5, 1, 2, 3, 5, 10, 15, and 20 pound charges. The correlation coefficient is 0.809, which indicates a good fit of the data.

The Vibroseis analysis includes +95% confidence level tables of particle velocity vs. distance covering two different ranges of data. The correlation coefficient is 0.784, which indicates an average fit of the data. Data scatter is largely attributed to different operating parameters, such as differing frequency ranges, sweep tapers, sweep durations, and sweep boost.

Sincerely,

Mark L. Burgus, P.G.

RECOMMENDED VIBRATION LIMITS

The U.S. Bureau of Mines (USBM) in Report of Investigations 8507 (November 1980) recommends a Variable Particle Velocity versus Frequency standard for assuring non-damage to all structures (see Figure 1). The Office of Surface Mining, Reclamation and Enforcement (OSMRE) regulations, as outlined in their Blasting Guidance Manual, employ a similar variable particle velocity versus frequency limit, the least restrictive and most accurate of their four compliance options. These two standards are the most often quoted limits for ground vibration from blasting or other ground motion producing operations and are very conservative. Under typical circumstances ground vibrations need to exceed the USBM recommendations or the OSMRE regulations by a considerable amount in order to cause threshold damage such as plaster or drywall cracking, or paint flaking. Engineered structures such as pipelines and wells are able to withstand significantly greater peak vibration levels. Human response is often the limiting factor in determining a reasonable ground vibration limit.

Matheson Mining Consultants, Inc. recommends adherence with USBM and/or OSMRE Variable Frequency versus Particle Velocity criteria. Adherence to these criteria provides a maximum level of liability protection and is the least restrictive in allowing the highest particle velocities at close distance. Documented cases of structural damage have never been observed in any structure (historic, exceptionally fragile, residential, or commercial) at particle velocities less than or equal to those recommended in the USBM and OSMRE standards.

More restrictive ground vibration standards exist internationally, notably the German vibration standards (DIN 4150) and Australian standard (CA 23-1967). These restrictive standards are based on prevention of annoyance, not for any technical or damage related justification.

RESIDENTIAL STRUCTURES

Seismological research by the U.S. Bureau of Mines, foreign investigative groups, and individual seismologists has established criteria relating the occurrence of structural damage to certain frequencies and levels of ground motion.

USBM Report of Investigations 8507, "Structure Response and Damage Produced by Ground Vibration From Surface Mine Blasting,"[1] states that residential structures are most prone to damage as a result of vibration energy within the frequency range of 4-12 hertz. Within this range, a 0.5-inch per second maximum particle velocity is recommended to preclude 'threshold' damage to the plaster-on-wood lathe interior portions of older structures. The line that separates real from alleged

[1] Siskind, D.E., M.S. Stagg, J.W. Kopp, and C.H. Dowding. Structure Response and Damage Produced by Ground Vibration From Surface Mine Blasting. U.S. Bureau of Mines Report of Investigations 8507, 1980, p. 1.

or imagined damage is ill defined. Therefore, it is common to talk in terms of probability or possibility of damage.

In general, very high particle velocities are necessary to cause any damage. Ground motion blast vibration damage is well documented, and the points at which threshold damage can occur are well defined. "Failure can occur to brittle materials such as plaster at particle velocities less than one inch per second at very low frequencies (1.5 to 10 Hz). The majority of failures will not begin to occur, however, until vibration levels exceed 3 to 4 inches per second."[2]

In addition to the threshold level of damage being dependent on peak particle velocity and frequency, it is also dependent on other factors such as: the geography and type of terrain the structure sits on, the type of structure, the height of the structure, the natural frequency of the structure, and the state of repair, or disrepair, of the structure. "…Some of these conditions may combine so that even if actual damage is unlikely below 2 or 3 inches per second, it is nevertheless possible that threshold damage might occur under some conditions at velocities as low as 0.50 to 0.70 inches per second…the (government) regulations are designed to provide positive protection against damage to private and public property."[2] Therefore, these regulations are as conservative as possible.

Threshold damage is defined by the USBM as the loosening of paint, small plaster cracks at joints between construction elements or the lengthening of old plaster cracks. A maximum of 0.75 inch per second is recommended for the protection of modern drywall interior construction. The damage threshold is normally considerably higher for load bearing or other structural portions of a house.

Above 12 hertz, the allowable vibration increases as the frequency increases, up to 40 hertz. Above 40 hertz, a constant 2.0 inches per second level is recommended to protect the interior walls and ceilings of structures, regardless of construction material. A graphic representation of the USBM recommended criteria is shown in Figure 1.[1]

All buildings are characterized by a single natural fundamental frequency. This means that, as with a pendulum or a tuning fork, there is one dominant frequency to which a particular building will respond. The structures fundamental frequency depends primarily upon its height. Tall buildings are more flexible and respond to low frequencies. Low-rise structures, being stiffer, respond to higher frequencies.

[1] Ibid, p. 7.

UNITED STATES BUREAU OF MINES CRITERIA
(From Report RI-8507, November, 1980)

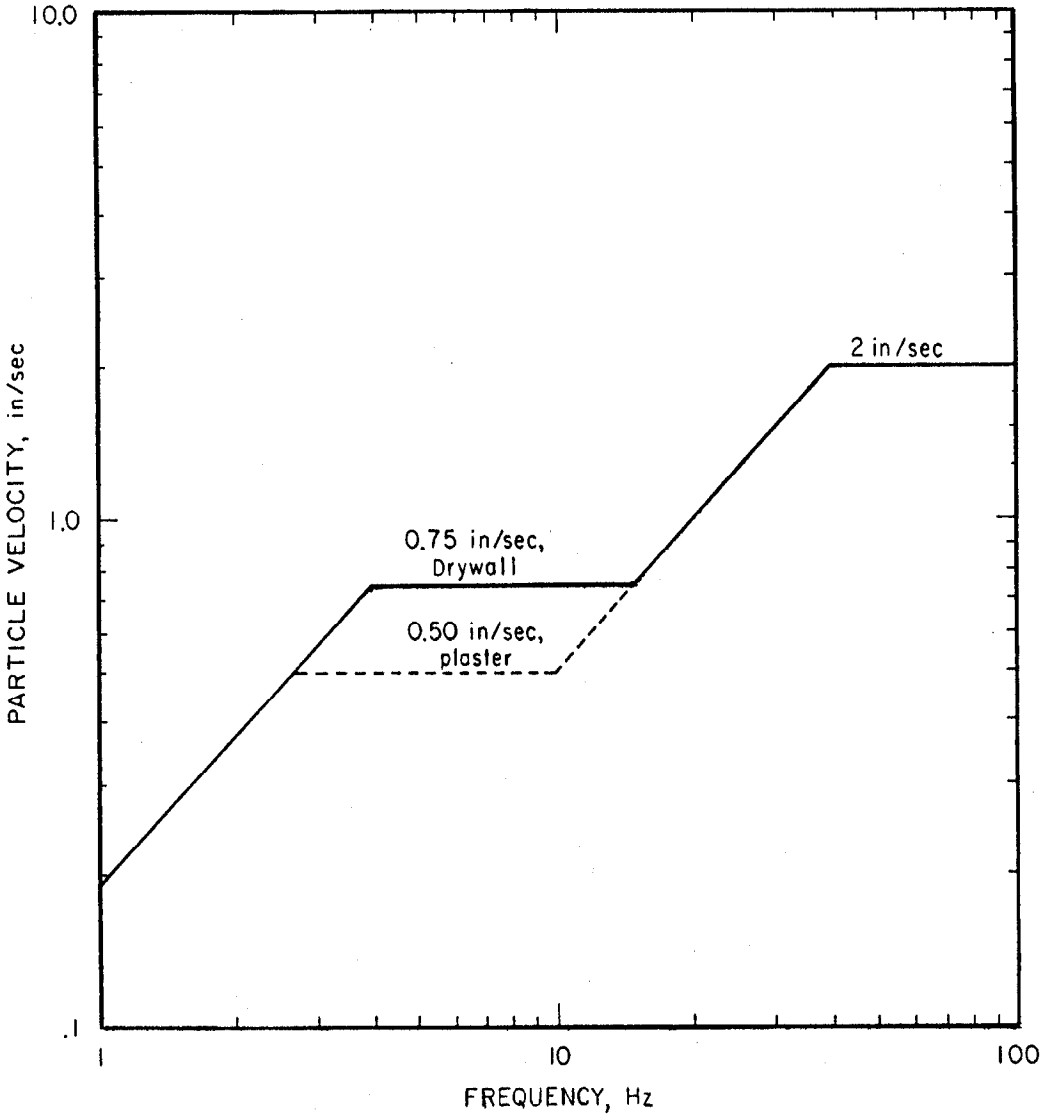

Figure 1: USBM Criteria from RI-8507, November 1980

CONCRETE DAMAGE

In order for damage to occur to a concrete pad, the supporting soil must fail. It is therefore nearly impossible to damage concrete with elastic ground vibrations. Nearly all concrete has suffered some form of environmental damage. This is due primarily to initial curing shrinkage and thermal expansion and contraction. Expansive soils (such as clays), erosion, and settlement are also common causes of concrete damage. The peak displacement associated with most surface vibrations is of no consequence to concrete. For example, a shot recently measured by MMC at 1.20 inches per second had a peak displacement of only 0.0146 inches. "Typical deflections in bridge deck, building floors, and highway slabs are often greater by up to a factor of ten…The only known cause of damage to concrete slabs from typical external industrial and construction sources of vibrations comes from very close or intense sources that can directly rupture the concrete, as in the crater zone of a blast,"[3]

ENVIRONMENTAL FORCES

Environmental forces that act on structures include both internal and external stresses. Internal stresses include: changes in moisture, changes in temperature, curing of lumber, drying and curing of plaster, stucco, concrete, or adobe; changes in application of internal heat, aging, the loss of coulomb friction, and gravity. External sources include: poorly compacted or expansive soils, poor drainage, water damage, wind, freeze/thaw cycle, and vegetation. Environmental forces are generally static (non-vibratory).

Most environment forces act silently. Therefore, most people are unaware of the large stresses and large strains induced in structures and materials. Many people who feel they have incurred damage from a ground vibration find it difficult to believe the silent environmental forces cause more stress than the vibration they felt and heard. Environmental forces are responsible for on going, time-dependent damage and deterioration to all structures and materials. "A careful study of buildings shows that cracks continue to increase in size and number as the building ages."[3]

Figure 2 shows typical environmental stresses and equivalent ground vibrations. This table is taken from Vibroseis Operations in an Urban Environment by L.L. Oriard. This was derived from information in USBM R.I. 8896, Effects of Repeated Blasting on a Wood-Frame House (Stagg, 1984)[3]. Environmental forces may induce equivalent ground vibrations as high as eight inches per second in a structure.

[3] Ibid, p. 356.

[3] Ibid, p. 358.

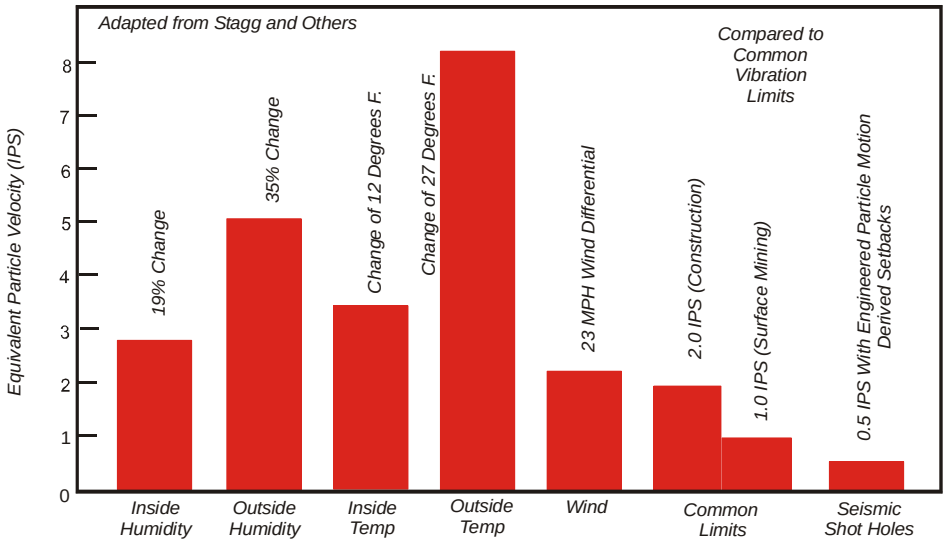

Figure 2: Typical Environmental Stresses & Equivalent Ground Vibrations

EVERYDAY ACTIVITIES

Stresses are also induced in structures as a result of human activities, traffic, and industrial activities. Human activities include door slams, walking, jumping, pounding nails into a wall, etc… These stresses are not as intense as environmentally induced stresses but nevertheless may produce equivalent ground vibrations as high as 2 inches per second. These stresses often account for hairline cracks in plaster and sheetrock around doorways and window frames. Figure 3 shows vibrations from everyday activities and equivalent ground motions and is taken from Vibroseis Operations in an Urban Environment by L.L. Oriard and was also adapted from USBM R.I. 8896, Nicholls, 1971, and others.[3]

[3] Ibid, p. 359.

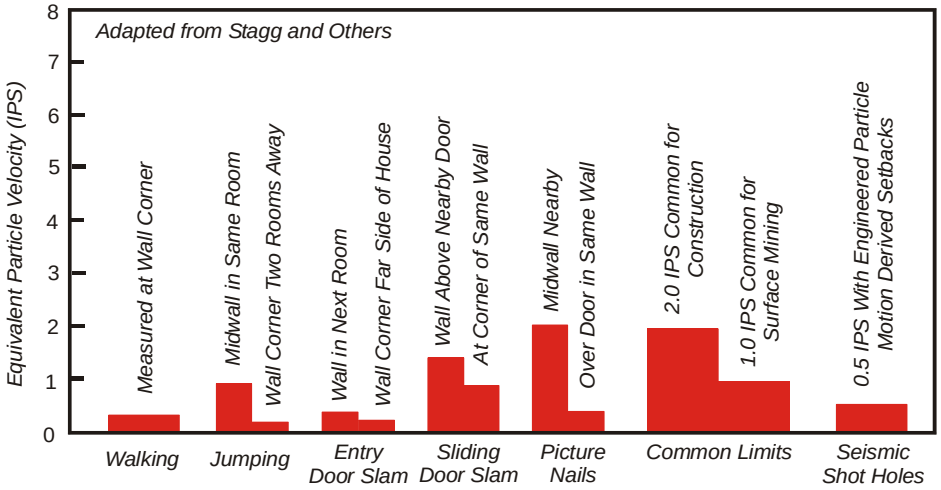

Figure 3: Vibrations for Everyday Activities

CYCLE FATIGUE

There is often a misapprehension by property owners that repeated blasting has a cumulative effect on the structure. USBM study R.I. 8896, Effects of Repeated Blasting on a Wood-frame House is an investigation of this concept. In this study, the USBM built a wood-frame test house in the path of advancing surface coal mining. Structural fatigue and damage were assessed over a two-year period.

The house was subjected to vibrations from 587 production blasts with particle velocities that varied from 0.10 to 6.94 inches per second. Later, the entire house was shaken mechanically to produce fatigue cracking. Failure strain characteristics of construction materials were evaluated as a basis for comparing strains induced by blasting and shaker loading to those induced by weather and household activities.

Cosmetic or hairline cracks 0.01 to .010 mm wide occurred during construction of the house and also during periods when no blasts were detonated. The formation of cosmetic cracks increased from 0.3 to 1.0 cracks per week when ground motions exceeded 1.0 in/s. Human activity and changes in temperature and humidity cause strains in walls that were equivalent to those produced by ground motions up to 1.2 in/s. When the entire structure was mechanically shaken, the first crack appeared after 56,000 cycles, the equivalent of 28 years of shaking by blast-generated ground motions of 0.5 in/s twice a day.[4]

[4] Stagg, M.S., D.E. Siskind, M.G. Stevens, and C.H. Dowding. Effects of Repeated Blasting on a Wood Frame House. U.S. Bureau of Mines, Report of Investigations 8896, 1984, p. 1.

HUMAN RESPONSE TO GROUND MOTION

"Vibration levels that are completely safe for structures are annoying and even uncomfortable when viewed subjectively by people."[5] Figure 4 was taken from Bulletin 656 and shows subjective response of the human body to vibratory motion. These limits were based on empirical results for sinusoidal vibration.

According to the Office of Surface Mining Reclamation and Enforcement's (OSMRE) Blasting Guidance Manual, "Most researchers agree that the threshold of human perception of ground motion is around 0.03 inches per second. Depending on activity, sensitivity, and whether or not the subject knows when the event is to occur, a few humans can sense ground motion…to about 0.01 inches per second.

Although complaints can occur at any level perceptible to humans, they are unusual below 0.08 inches per second or so…At, say, 0.25 inches per second, a level that is eminently safe, and well within OSMRE limits, except below 2 Hz, complaints can be expected."[1] Human reactions to ground motion from blasting can be the limiting factor. Vibration levels can be felt that are considerably lower than those required to produce damage. "Particle velocities of 0.5 in/sec…should be tolerable to about 95% of the people perceiving it as 'distinctly perceptible.'"[1]

What is annoying to one person may not be annoying to another. Each person perceives movement differently. Factors that can influence how human beings perceive blasting are:

- The frequency content of the blast events.
- The number of events per day or week.
- The time of day. The structure response.
- The condition of the property.
- The degree of activity of the person.
- The state of health of the person.
- The state of mind of the individual.
- The position and attitude of the person, i.e., in bed, working, sitting, inside or outside, etc…
- The local perception of the operation.
- The history of local damage claim payments (including "good neighbor" payments related to damage claims where liability was denied.

In some cases, regardless of the levels of ground motion experienced, complaints may still arise. "No amount of objective data will convince a person who "feels" strong vibrations that the vibration level as measured was barely perceptible-similarly with noises and air blasts. Personal

contact and strong efforts in public relations help alleviate the problem but convince few."[5] In this event, pre-survey inspections, a monitoring program, and good record keeping can be invaluable should matters proceed to the legal arena. In extreme cases, dishonest individuals may see this as an opportunity for repairs or new water well.

WATER WELLS AND AQUIFERS

Water wells and aquifers exhibit a constrained response when subject to ground vibration. That is to say, they move in concert with the geologic material that surrounds them. In general, this geologic material surrounding the well must be disrupted to cause damage to a water well. In the case of the aquifer, a change in its structure (permeability) would be the necessary affect for it to have undergone changes as a result of blast vibration. Furthermore, the amplitude of the ground motion greatly decreases with depth. Following is general information on hydrology as well as information from studies on shothole geophysical exploration and surface mine blasting effects on water wells and aquifers.

Hydrology

A groundwater system is a dynamic system where water moves down-gradient from a recharge area to a discharge area (ie., a spring). Normally, ground water moves slowly, the rate ranging from a fraction of an inch per year to a few feet per day. The geology determines the rate of ground-water recharge and movement. Most sedimentary aquifers consist of sandstone, limestone, Tertiary sediments, Recent alluvium, or coal seams. Aquifers can also exist in fractured metamorphic rocks and igneous rocks. Hydraulic characteristics of aquifers include porosity, permeability, transmissivity, and the coefficient of storage. These characteristics differ greatly among different rock types.

Porosity is the volume of void space in a unit volume of material (this space can be occupied by water). Permeability is a measure of the capability of a geologic material to transmit water through a unit area. Transmissivity is defined as the permeability times the vertical thickness of the material, usually an aquifer. Coefficient of storage is defined as the volume of water that an aquifer can release from or take into storage per unit surface area, per unit change in head in a line normal to that surface.

Shot-Hole Geophysical Exploration

In "A Study of the Influence of Seismic Shotholes on Groundwater and Aquifers in Eastern Montana,"[6] five widely distributed sites in eastern Montana were chosen and monitored: (1) a 25 pound charge at a 197 foot depth, 150 feet away from the 150 foot deep test well, (2) a 25 pound charge at a 197 foot depth, a 165 foot distance away from the 90 foot deep test well, (3) a 80 pound charge at a 200 foot depth, 400 feet away from an 80 foot deep test well and a 25 pound charge at a depth of 150 feet, 150 feet away from the same test well, (4) a 25 pound charge at a 200 foot depth, 150 feet away from a test well with a 22 foot depth and a test well with a 96 foot depth, and (5) a 25 pound charge at a 200 foot depth, 150 feet away from a 135 foot deep test well and a 207 foot deep test well.

[6] Bond, E.W., A Study of the Influence of Seismic Shotholes on Groundwater and Aquifers in Eastern Montana, State of Montana - Montana Bureau of Mines and Geology, Special Publication 67, 1975.

> Pumping tests of existing water wells and specially drilled observation wells, before and at several times after the firing of a seismic shot, revealed no detectable change in the physical properties of the aquifers. Analyses of water samples collected from water wells, observation wells, and test holes, at frequent intervals throughout the study period, showed only the random minor variations expectable in water from shallow aquifers. A few water samples from shotholes showed minor temporary increases in some chemical constituents, but these were not enough to affect the use of the water. Water-level measurements during the pumping tests showed that most of the shotholes were virtually sealed through the aquifer within a few months, at most, but tests could not be repeated over a long enough period to determine the final sealing date of all shotholes.
>
> Any mechanical change in aquifer structure as a result of seismic shooting should be indicated by change in permeability of the aquifer material. None of the aquifer tests conducted at the five test sites showed any change in aquifer structure, although poor efficiency of common well construction was evident…A change in aquifer permeability would require either a change in the packing arrangement of the aquifer material or an alteration of the cement holding the aquifer material together.
>
> Because drill holes for seismic programs average only about 200 feet in depth, multiple aquifers would have relatively small differences in hydrostatic head, and the quality of the waters would probably be similar.[6]

This indicates minimal interflow between aquifers.

In "The Effects of Seismic Blasting on Shallow Water Wells and Aquifers in Western North Dakota,"[7] the results of a literature search, a preliminary investigation, a field investigation, and an experimental investigation are presented. The preliminary investigation involved sending questionnaires to federal, state, county, and city agencies, certified water well contractors, as well as, grazing and environmental groups.

The questionnaires along with a news release, resulted in numerous personal letters alleging effects during and after seismic testing. A third of these wells were field investigated. Both old and new wells were investigated. Eighteen wells were less than twenty years old and twenty five wells were more than twenty years old. This indicates the problem is not restricted to older wells. Effects that were described by owners include long term decline in water quality (over a several year period), an abrupt (over several hours) decline in water quality, and 53 of 76 questionnaires cited decreased yield. In some instances these wells were not pumped wells, but rather were flowing wells. A gradual decline in a flowing well (or spring) is a naturally occurring result of usage.

Few instances of legal action were found during the study's preliminary search. Few people have good or complete records of their wells with respect to production and water quality. This causes difficulties when defending their position. A few respondents claimed to have replaced wells and

---

7 Beaver, F.W. The Effects of Seismic Blasting on Shallow Water Wells and Aquifers in Western North Dakota, Master's Thesis Submittal, University of North Dakota, 1984.

equipment at their own expense. Also, because of the lack of background information on the wells, it is difficult to draw definitive conclusions regarding changes in water quality and production.

> Pumping tests conducted in a sand a coal aquifer system showed no apparent physical effects when shots were detonated one quarter mile away from the pumping wells. Shots 500 feet distant resulted in to permanent effects. Shots 100 feet or closer increased the yield from wells finished in the sand aquifer and decreased the yield from the coal aquifer. Fracturing of the poorly indurated sandstone aquifer is suggested as the mechanism for the increase. Collapse of the fractures is suggested as the failure mechanism in the coal aquifer. Well casings remained intact after 25 pound charges were detonated as close as 10 feet from a well screen…
>
> During the pumping tests, no significant long term chemical or mineralogical equilibrium changes were observed which could be attributed to the blasting.[6]

Surface Mining

The source of these comments is the U.S. Bureau of Mines (USBM) study "Survey of Blasting Effects on Ground Water Supplies in Appalachia."[8] This study relates to coal mine blasting where large per delay explosive weights exceeding 5000 pounds are common. The USBM study included four test sites chosen for geographic and geologic diversity. Maximum resultant particle velocities of up to 5.44 inches per second were recorded at the surface next to the wells.

> No direct evidence of change in water quality or well performance was produced by blast vibrations, but removal of downslope support by excavation does cause lateral stress relief which permits the water-bearing fractures to become more open. This additional storage capacity causes the static water level to drop and for well-bore permeability to improve. Static water level recovers if sufficient recharge is available and well performance is improved.
>
> The well continues to perform in the same manner although blast induced round vibrations at the surface may approximate 2.0 inches per second maximum resultant particle velocity, until surface mining approaches to within about 300 feet of the water well.
>
> State agencies and coal companies in Appalachia were contacted to develop a list of reportedly blast damaged wells. Of 36 wells so reported, 24 were investigated in the field but there was no clear evidence that the problem was blast related. In most cases, it was evident that other factors were responsible for changes in well behavior.
>
> Maximum ground vibration levels at the four test wells, measured as close as practical to the well heads, were 2.2, 5.44, 2.14, and .84 inches per second resultant particle velocity.

---

8 Robertson, D.A., Gould, J.A., Straw, J.A., and Dayton, M.A., Survey of Blasting Effects on Ground Water Supplies in Appalachia, U.S. Bureau of Mines Contract J-0285029, prepared by Philip R. Berger & Associates, 1980.

> Based on observable change in well conditions immediately after a blast, there was no direct evidence of any significant change as a result of blasting. At three sites, when mining approached within a distance of approximately 300 feet, a fairly abrupt drop in static water level occurred followed by a significant improvement in well performance as indicated by specific capacity. At the fourth site, there was no change.
>
> Measurements made at the bottoms of wells indicated that vibrations were considerably attenuated at depths of 140 to 160 feet.[7]

This study found the vibrations at the bottom of an observation well to be between 14 to 68 % as strong as those at the surface (approximately 150 feet deep). The largest effects on vibration attenuation with depth are the geometric relationship between the charge location and the well and the degree of confinement of the shot.

This study quotes another study, "Water Well Design for Earthquake Induced Motions,"[9] a survey of published reports describing the conditions of numerous water wells during and after three major earthquakes. This study involved 350 wells in areas where severe damage to structures occurred. Almost all wells reported to be permanently damaged were in regions of permanent displacement of the surrounding earth, primarily landsliding. Eight wells were destroyed, four were inoperable but reparable, and forty five wells were damage but operable. The intensity of the earthquakes in the study were modified Mercalli scale magnitudes VIII, IX, and X (impossible for a person to stand, furniture broken, partial to total collapse of structures, general destruction, landslides, soil failure).

PIPELINE RESPONSE

Five pipeline sections were studied by the U.S. Bureau of Mines in conjunction with the State of Indiana and AMAX Coal and its consultants in the advance of coal mine overburden blasting (USBM R.I. 9523).[10] These tests were conducted on the highwall of the Minnehaha Mine near Sullivan, Indiana and were designed for testing to failure.

All five pipeline sections were 76 m (249 ft) long. Four sections were welded steel pipe and one section was PVC. The pipeline sections were laid parallel to one another, 3 m (9.8 ft) apart, with 1 m (3.3 ft) depths of burial. They were buried in a clay soil. Each pipeline had three uprights for pressurization and gage access. Following is a summary of the pipeline attributes:

Outside Diameter, cm, (in)	Wall Thickness, mm, (in)	Fill Material	Age	Material Type
Steel:				
16.8, (6.6)	4.78, (.188)	Gas	Used	X-42
32.4, (12.8)	6.35, (.250)	Gas	Used	Grade B
32.4, (12.8)	6.35, (.250)	Gas	New	X-42
50.8, (20.0)	6.63, (.261)	Water	Used	X-56
PVC:				
21.9, (8.6)	8.43, (.332)	Water	Used	SDR26

Steel Pipelines: Initial pressurization 6.2 MPa (900 psi).
PVC Pipeline: Initial pressurization 0.62 MPa (90 psi).

The pipelines were monitored for vibration, strain, and pressure for a period of 6 months while production advanced up to a point 15 m (49 ft) away. 29 productions blasts were measured. The blasts used maximum charge weights per delay of up to 950 kg (2090 pounds) in 31 cm (12.25 inch) diameter holes.

Following the production blasts, a single row of four blast holes was drilled between the pipelines to complete the destructive test. The explosive charge was below the pipes at 5 to 6 m (16.4 to 19.7 ft) distances. The vibration level measured was greater than 900 mm/s (35.43 in/s), however, this was non-elastic response. The result of the destructive test on each pipeline is as follows: 1) 16.8 cm (6.6 in) diameter steel pipe - severely bent but unbroken, 2) new 32.4 cm (12.8 in) diameter steel pipe - bowed, but unbroken, 3) used 32.4 cm (12.8 in) diameter steel pipe - cleanly broken at the risers, 4) water filled 50.8 cm (20.0 in) diameter steel pipe - uplifted, parted, fell back down, and 5) 22 cm (8.6 in) diameter PVC pipe - came apart at O-rings, but unbroken.

[10] Siskind, D.E., M.S. Stagg, J.E. Wiegand, and D.L. Schulz. Surface Mine Blasting Near Pressurized Transmission Pipelines. U.S. Bureau of Mines, Report of Investigations 9523, 1994, 51 pp.

The results of the closest production blast (15 m (49.2 ft) distant from the closest pipeline) resulted in a 635 mm/s (25.00 in/s) measurement at the surface and 234 to 274 mm/s (9.21 to 9.84 in/s) on two instrumented pipelines.

> Analysis found low pipe responses, strains, and calculated stresses from even large blasts. Ground vibration of 120 to 250 mm/s (4.72 to 9.84 in/s) produced worst case strains that were about 25% of the strains resulting from normal pipeline operations and calculated stresses of only about 10% to 18% of the ultimate tensile strength. No pressurization failures or permanent strains occurred even at vibration amplitudes of 600 mm/s (23.62 in/s)…
>
> …Although particle velocities of over 600 mm/s (23.62 in/s) were sustained without loss of pipe integrity, it is recommended that 125 mm/s (4.92 in/s) measured at the surface is a safe-level criterion for large surface mine blasts for Grade B or better steel pipelines. The same criterion is recommended for SDR 26 or better PVC pipe…Also, no adjustment is believed needed for pipeline age, assuming the protective coating is intact, unless the pipeline is known to be at higher risk from previous damage or other causes. The same safe-level criterion also appears applicable, at a minimum, to vertical wells and telephone lines.[10]

The primary blasting risk to pipelines appears to be from block motion or from having the pipeline in the actual crater zone. In both cases, permanent strain has occurred in the surrounding geologic material, which is weaker than the pipe.

In the early 1960's work was undertaken by the American Gas Association Pipeline Research Committee to establish limits for charge size (pounds per delay) and distance from a blast to high-pressure gas transmission pipelines. The primary research found that there had been no reported case of pipeline failure due to normal blasting activities. Only when explosives were detonated directly adjacent to a pipeline, were failures recorded.

Sincerely,

APPENDIX III

BACKGROUND ON GROUND MOTION STUDIES

The ground motion is measured in terms of peak particle velocity and is a combination of body and surface waves (Figure 1)[1]. The body waves attenuate more rapidly with distance from the shot (or Vibroseis) than the surface waves. Body waves spread spherically, whereas the surface waves expand in two dimensions. The principal cause of ground motion attenuation with distance is due to simple geometric spreading. As the ground motion wave train spreads outwards from the energy source, the medium's individual particles are set in retrograde elliptical motion about their rest positions. The wave is generated as each particle transmits energy to the next particle. Some energy loss occurs with each transmission of energy from one particle to the next, which is also a cause of ground motion attenuation with distance. The ground motion is a complex wave train consisting of many different wave types (Figure 2)[1]. As the body waves impinge upon the surface, they are converted to surface waves. Body waves may also be reflected and refracted to the surface to become converted to surface waves. As the surface wave spreads out, the various components of the wave train have different particle motions, travel at different velocities, and have different geometric constraints.

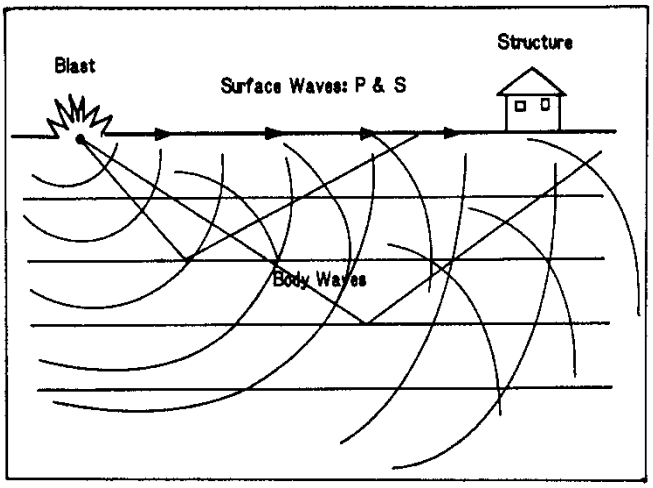

Figure 1 - Surface and Body Waves

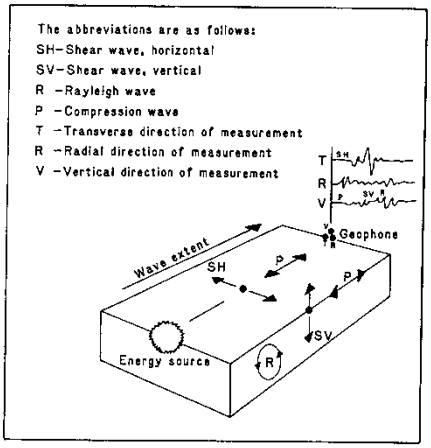

Figure 2 - Types of Ground Motion Waves

Particle velocity has been determined to be the most significant single parameter, in terms of the potential for damage (as opposed to acceleration or displacement). Furthermore, the peak particle velocity found on any of the three geophone channels is the parameter used, rather than the resultant vector sum particle velocity. All research has been done and all regulations have been written in terms of peak particle velocity (PPV). Using the PPV instead of the vector sum allows for easier, more consistent comparison of values. A true resultant velocity could be calculated from

[1] Rosenthal, M.F., and G.L. Morlock. Blasting Guidance Manual. U.S. Department of the Interior, Office of Surface Mining Reclamation and Enforcement, March, 1987, p.11.

[1] Ibid., p. 12.

the peak measurements for all three components if they occurred at the same instant of time. In addition, there is variability in how different seismograph manufacturers calculate the vector sum. Some actually calculate a pseudo resultant sum. These models take the peak levels on all three channels, regardless of where they individually occurred in time, to calculate the vector sum.

Since the 1920's or earlier, ground vibrations have been studied extensively to determine their potential for damage to various structures and construction materials. Blasting activities are among the most common sources of ground motion, have therefore been studied the most, and have thus prompted the ordinances and regulations that are in place. At the present time, the only federal regulation that pertains to ground motion is from the Office of Surface Mining and Reclamation Enforcement (OSMRE). This regulation was written to protect residential structures. Complaints of damage to residences were, and are, the most common form of complaint resulting from the perception of ground motion.

The ground motion attenuation study is designed to statistically predict safe surface standoff distances from residences and other points of concern. Particle velocity data acquired in the field are input into a least squares linear regression analysis program. This program has been approved by the United States Office of Surface Mining and Reclamation Enforcement (OSMRE). The regression analysis yields a site-specific attenuation formula in the form:

$$PPV = H(SD)^{-B}$$

Where:
H = the velocity (y axis intercept) at a scaled distance of one,
B = the slope of the curve,
PPV = the peak particle velocity in inches per second, and
SD = scaled distance = distance from shot to recorder divided by the square root of the charge weight = distance for Vibroseis studies.

The program also yields the correlation coefficient (goodness of fit), r^2. 1.0 is perfect.

Once the equation for the ground motion is defined, predictions may be made for PPV or distance (or scaled distance for the shot hole studies) by manipulating the equation and by holding one of the variables constant. Thirty data points for each study are desired for statistical validity.

OCCIDENTAL OF ELK HILLS – BUENA VISTA 3D
SUMMARY OF VIBROSEIS GROUND MOTION ATTENUATION STUDY

Matheson Mining Consultants, Inc. (MMC) was asked to perform a low force (60% drive) Vibroseis ground motion attenuation study in the Buena Vista 3D survey area in order to recommend safe stand-off distances from points of concern that primarily include residences, oil and gas pipelines and wells, water wells, and irrigation structures. Data was acquired on October 31, 2009 for a low force study with four 62,000 pound peak force Vibrators operating under the following parameters: sweep duration of 6 seconds from 2 to 64 Hz, linear array and sweep, with a 0.6 second start taper and a 0.4 second end taper. A complete report will follow.

The study was designed to be as conservative in nature as possible. The area chosen for the survey was flat and the Vibroseis were parked in the same position for the entire study. Data was taken in a perpendicular direction from the number two Vibrator (experience and research dictate this is the direction of highest ground motion).

Recommended Vibration Limits

The U.S. Bureau of Mines (USBM) in Report of Investigations 8507 (November 1980) recommends a Variable Particle Velocity versus Frequency standard for assuring non-damage to all structures (see Figure 1). The Office of Surface Mining, Reclamation and Enforcement (OSMRE) regulations, as outlined in their Blasting Guidance Manual, employ a similar variable particle velocity versus frequency limit. These two standards are the most often quoted limits for ground vibration from blasting operations and are very conservative. Under typical circumstances ground vibrations need to exceed the USBM recommendations or the OSMRE regulations by a considerable amount in order to observe threshold damage such as plaster or drywall cracking or paint flaking. Engineered structures such as pipelines and wells are able to withstand significantly greater peak vibration levels. Human response is often the limiting factor in determining a reasonable ground vibration limit.

Matheson Mining Consultants, Inc. recommends adherence with USBM and/or OSMRE Variable Frequency versus Particle Velocity criteria. Adherence to these criteria provides a maximum level of liability protection and is the least restrictive in allowing the highest particle velocities at close distance. Documented cases of structural damage have never been observed in any structure, historic, exceptionally fragile, residential, or commercial, at particle velocities less than those recommended in the USBM and OSMRE standards.

The OSMRE Variable Particle Velocity versus Frequency standard states that from 4-12 hertz (Hz), a 0.50 inches per second (ips) maximum particle velocity is recommended to preclude "threshold" damage to plaster-on-lath, the most fragile of construction materials. Above 12 hertz, the allowable vibration increases as the frequency increases, up to 40 hertz. Above 40 hertz, a constant 2.0 inches per second level is recommended to protect the interior walls and ceilings of structures, regardless of construction material. A graphic representation of the USBM recommended criteria is shown in Figure 1.

Applying a peak vibration limit of 0.50 inches per second (ips) provides a high degree of protection for engineered structures (the threshold level for possible damage to plaster-on-lath construction). However, complaints from residents often begin at levels of 0.25 ips of less. Oil and gas wells, pipelines, and fiber optic cables can withstand significantly higher levels and a level of 2.00 ips is conservative. For example, Bell Labs states that a limit of 4.00 ips is safe for their fiber optic cable and the U.S. Bureau of Mines states that a limit of 4.92 ips is safe for a variety of pipeline materials and ages.

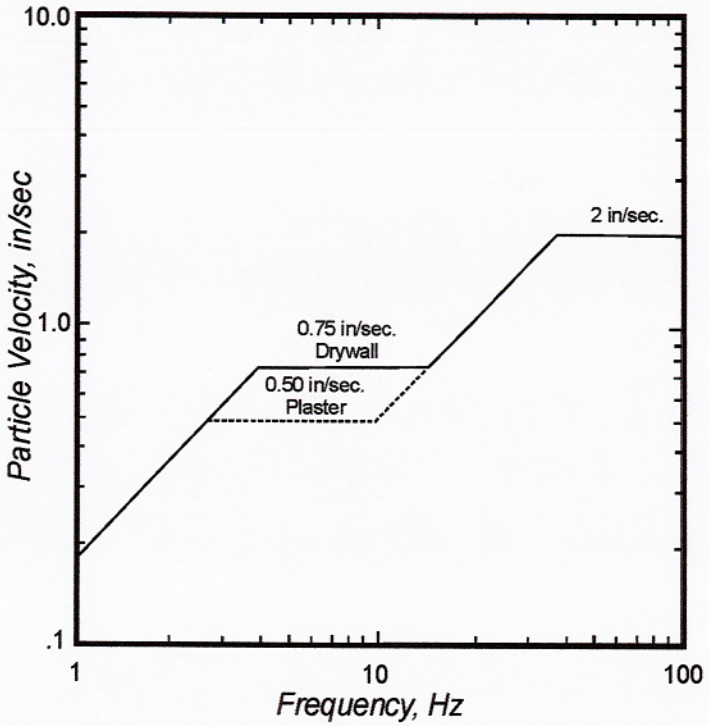

Figure 1: USBM Criteria from RI-8507, November 1980

Following is the regression curve and table of recommended stand-off distances to not exceed various particle velocities based on the derived +95% confidence level equation for the high force study.

The study has an excellent correlation coefficient ($r^2 = 0.962$).

95% Confidence Equation: PPV= 8.10 x (D)^-0.651 -- R^2 = 0.962

Particle Velocity vs. Distance

Particle Velocity (in/s)	Distance (ft)
0.10	854.38
0.20	294.64
0.25	209.14
0.50	**72.13**
0.75	38.69
1.00	24.87
1.50	13.34
2.00	8.58
4.00	2.96

Conclusions

Applying limits for plaster-on-lath (the most fragile of modern construction materials) will also provide a large factor of safety for any engineered structures that may exist within the survey area (pipelines, wells, fiberoptic cable...). In order to not exceed 0.50 ips with 4 Vibroseis at 60% drive (the parameters used in and around towns), the offset distance is 72 feet. This study was very conservative. During production, particle velocities will typically be lower than those measured during the study due to a more virgin earth surface, a reduced number of sweeps per location, and changes in the Vibroseis array orientation with respect to the point of concern.

Sincerely,

Mark L. Burgus

VINTAGE PRODUCTION CALIFORNIA, LLC
RIO LOBO 3D

SUMMARY OF VIBROSEIS GROUND MOTION ATTENUATION STUDIES

July 31, 2014
Fresno County, California

Matheson Mining Consultants, Inc. (MMC) acquired Vibroseis data in two locations within the Rio Lobo 3D survey area in order to recommend safe offset distances from points of concern. Site 1 was located near staging and Site 2 was located off of the Skyline Drive Road. At each location, both high (70% drive) and low (40% drive) force data sets were acquired. Four 63,000 pound I/O AHV-IV vibrators parked in a linear array were employed for the studies. Sweep parameters were: 12 second duration, 2-70 Hz, linear boost, and a 800 ms start taper and 400 ms end taper. A complete report will follow.

Additional analyses were performed grouping high force data for both sites and low force data for both sites.

The ground motion attenuation study is designed to statistically predict safe surface standoff distances from residences, pipelines, wells and other points of concern. Particle velocity data acquired in the field are input into a least squares linear regression analysis program. This program has been approved by the United States Office of Surface Mining and Reclamation Enforcement (OSMRE). The regression analysis yields a site-specific attenuation formula in the form:

$$PPV = H(SD)^{-B}$$

Where:
H = the velocity (y axis intercept) at a scaled distance of one,
B = the slope of the curve,
PPV = the peak particle velocity in inches per second, and
SD = scaled distance = distance (feet) from shot to recorder divided by the square root of the charge weight (pounds) = **Distance for Vibroseis studies**

The program also yields the correlation coefficient (goodness of fit), r^2. 1.0 is perfect.

The regression analysis yields a site-specific attenuation formula. Once the equation is derived, it can be solved to predict peak particle velocities based on fixed distances or it can be solved to predict distances for fixed peak particle velocities.

Recommended Vibration Limits

The U.S. Bureau of Mines (USBM) in Report of Investigations 8507 (November 1980) recommends a Variable Particle Velocity versus Frequency standard for assuring non-damage to all structures (see Figure 1). The Office of Surface Mining, Reclamation and Enforcement (OSMRE) regulations, as outlined in their Blasting Guidance Manual, employ a similar variable particle velocity versus frequency limit. These two standards are the most often quoted limits for ground vibration from blasting operations and are very conservative. Under typical circumstances ground vibrations need to exceed the USBM recommendations or the OSMRE regulations by a considerable amount in order to observe threshold damage such as plaster or drywall cracking or paint flaking. Engineered structures such as pipelines and wells are able to withstand significantly greater peak vibration levels. Human response is often the limiting factor in determining a reasonable ground vibration limit.

Matheson Mining Consultants, Inc. recommends adherence with USBM and/or OSMRE Variable Frequency versus Particle Velocity criteria. Adherence to these criteria provides a maximum level of liability protection and is the least restrictive in allowing the highest particle velocities at close distance. Documented cases of structural damage have never been observed in any structure, historic, exceptionally fragile, residential, or commercial, at particle velocities less than those recommended in the USBM and OSMRE standards.

The OSMRE Variable Particle Velocity versus Frequency standard states that from 4-12 hertz (Hz), a 0.50 inches per second (ips) maximum particle velocity is recommended to preclude "threshold" damage to plaster-on-lath, the most fragile of construction materials. Above 12 hertz, the allowable vibration increases as the frequency increases, up to 40 hertz. Above 40 hertz, a constant 2.0 inches per second level is recommended to protect the interior walls and ceilings of structures, regardless of construction material. A graphic representation of the USBM recommended criteria is shown in Figure 1.

Applying a peak vibration limit of 0.50 inches per second (ips) provides a high degree of protection for engineered structures (the threshold level for possible damage to plaster-on-lath construction). However, complaints from residents often begin at levels of 0.25 ips of less. Oil and gas wells, pipelines, and fiber optic cables can withstand significantly higher levels and a level of 2.00 ips is conservative. For example, Bell Labs states that a limit of 4.00 ips is safe for their fiber optic cable and the U.S. Bureau of Mines states that a limit of 4.92 ips is safe for a variety of pipeline materials and ages and wells.

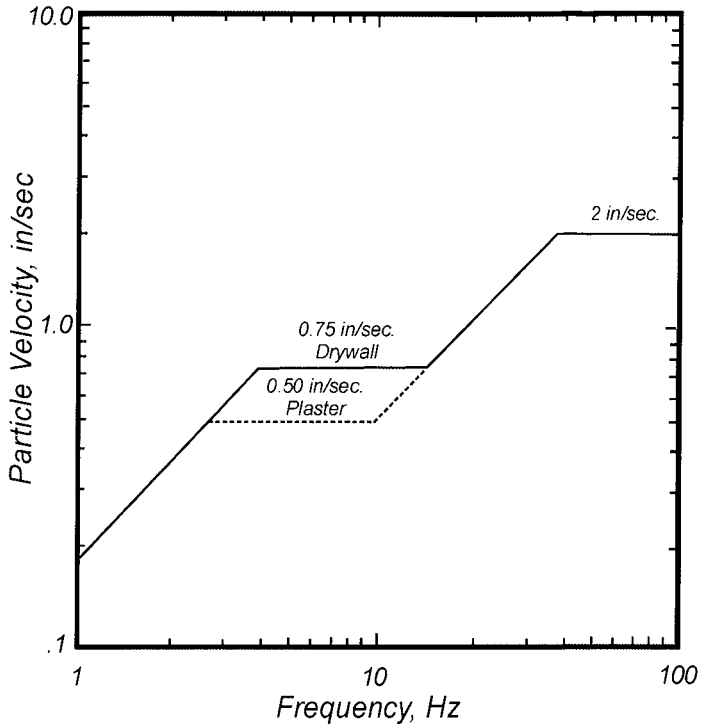

Figure 1: USBM Criteria from RI-8507, November 1980

Results

The following table summarizes the coefficients of determination, the number of data pairs, and the +95% confidence formula derived for each of the analyses. All six analyses showed excellent fits of data. Attached to this summary are the curves and tables of Peak Particle Velocity vs. Distance. All graphs and tables are based on the +95% confidence level equation derived from each analysis.

Summary of Shot Hole Analyses Results

Analysis	Derived Formula	Coefficient of Determination	Number of Data Pairs
Site 1, 70% Drive	$PPV = 41.88(D)^{-1.02}$	0.940	35
Site 1, 40% Drive	$PPV = 10.72(D)^{-0.83}$	0.926	34
Site 2, 70% Drive	$PPV = 40.69(D)^{-0.99}$	0.943	35
Site 2, 40% Drive	$PPV = 10.81(D)^{-0.84}$	0.918	31
Sites 1 & 2, 70% Drive	$PPV = 41.80(D)^{-1.01}$	0.939	70
Sites 1 & 2, 40% Drive	$PPV = 10.74(D)^{-0.83}$	0.923	65

Conclusions

Applying limits for plaster-on-lath (the most fragile of modern construction materials) will also provide a large factor of safety for any engineered structures that may exist within the survey area (pipelines, wells, fiber optic cable...). Results for both areas are very similar. The following table summarizes stand-off distances for recommended vibration limits for each of the analyses.

+95% Confidence Level Stand-off Distances for Fixed Particle Velocities and Charge Weights

Analysis	0.25 ips (approx. human annoyance limit)	0.50 ips (plaster-on-lath limit)	0.75 ips (sheetrock limit)	2.00 ips (conservative, water well, well, pipeline limit)	4.92 ips (pipeline limit)
Site 1, 70% Drive	149'	76'	51'	20'	8'
Site 1, 40% Drive	94'	41'	25'	8'	3'
Site 2, 70% Drive	170'	84'	56'	21'	8'

RIO LOBO 3D

SUMMARY OF SHOT HOLE GROUND MOTION ATTENUATION STUDIES

July 31, 2014
Fresno County, California

Matheson Mining Consultants, Inc. (MMC) acquired data in two locations within the Rio Lobo 3D survey area in order to recommend safe offset distances from points of concern. Site 1 was located near staging and Site 2 was located off of the Skyline Drive Road. At each location, three test holes were drilled and loaded, one with a 5.5 pound charge, one with an 11 pound charge, and one with a 13.2 pound charge of dBX. The 5.5 pound charges were placed in 30 foot deep holes and the 11 and 13.2 pound charges were placed in 50 foot deep holes. The test holes were 4 inch diameter and each charge was stemmed with a bag of bentonite, a hole plug was placed, and then the rest of the hole was stemmed with native cuttings. Each set of three test holes was monitored with six seismographs. A complete report will follow.

Although 30 data points are desired for statistical validity, additional analyses were performed for: Site 1 – All Data, Site 2 – All Data, All 5.5 pound Data, All 11 pound Data, and All 13.2 pound Data. These analyses all exhibited clear trends and good coefficients of determination.

The ground motion attenuation study is designed to statistically predict safe surface standoff distances from residences, pipelines, wells and other points of concern. Particle velocity data acquired in the field are input into a least squares linear regression analysis program. This program has been approved by the United States Office of Surface Mining and Reclamation Enforcement (OSMRE). The regression analysis yields a site-specific attenuation formula in the form:

$$PPV = H(SD)^{-B}$$

Where:
H = the velocity (y axis intercept) at a scaled distance of one,
B = the slope of the curve,
PPV = the peak particle velocity in inches per second, and
SD = scaled distance = distance (feet) from shot to recorder divided by the square root of the charge weight (pounds)

The program also yields the correlation coefficient (goodness of fit), r^2. 1.0 is perfect.

The regression analysis yields a site-specific attenuation formula. Once the equation is derived, it can be solved to predict peak particle velocities based on fixed distances and fixed charge weights or it can be solved to predict distances for fixed peak particle velocities and fixed charge weights.

Recommended Vibration Limits

The U.S. Bureau of Mines (USBM) in Report of Investigations 8507 (November 1980) recommends a Variable Particle Velocity versus Frequency standard for assuring non-damage to all structures (see Figure 1). The Office of Surface Mining, Reclamation and Enforcement (OSMRE) regulations, as outlined in their Blasting Guidance Manual, employ a similar variable particle velocity versus frequency limit. These two standards are the most often quoted limits for ground vibration from blasting operations and are very conservative. Under typical circumstances ground vibrations need to exceed the USBM recommendations or the OSMRE regulations by a considerable amount in order to observe threshold damage such as plaster or drywall cracking or paint flaking. Engineered structures such as pipelines and wells are able to withstand significantly greater peak vibration levels. Human response is often the limiting factor in determining a reasonable ground vibration limit.

Matheson Mining Consultants, Inc. recommends adherence with USBM and/or OSMRE Variable Frequency versus Particle Velocity criteria. Adherence to these criteria provides a maximum level of liability protection and is the least restrictive in allowing the highest particle velocities at close distance. Documented cases of structural damage have never been observed in any structure, historic, exceptionally fragile, residential, or commercial, at particle velocities less than those recommended in the USBM and OSMRE standards.

The OSMRE Variable Particle Velocity versus Frequency standard states that from 4-12 hertz (Hz), a 0.50 inches per second (ips) maximum particle velocity is recommended to preclude "threshold" damage to plaster-on-lath, the most fragile of construction materials. Above 12 hertz, the allowable vibration increases as the frequency increases, up to 40 hertz. Above 40 hertz, a constant 2.0 inches per second level is recommended to protect the interior walls and ceilings of structures, regardless of construction material. A graphic representation of the USBM recommended criteria is shown in Figure 1.

Applying a peak vibration limit of 0.50 inches per second (ips) provides a high degree of protection for engineered structures (the threshold level for possible damage to plaster-on-lath construction). However, complaints from residents often begin at levels of 0.25 ips of less. Oil and gas wells, pipelines, and fiber optic cables can withstand significantly higher levels and a level of 2.00 ips is conservative. For example, Bell Labs states that a limit of 4.00 ips is safe for their fiber optic cable and the U.S. Bureau of Mines states that a limit of 4.92 ips is safe for a variety of pipeline materials and ages and wells.

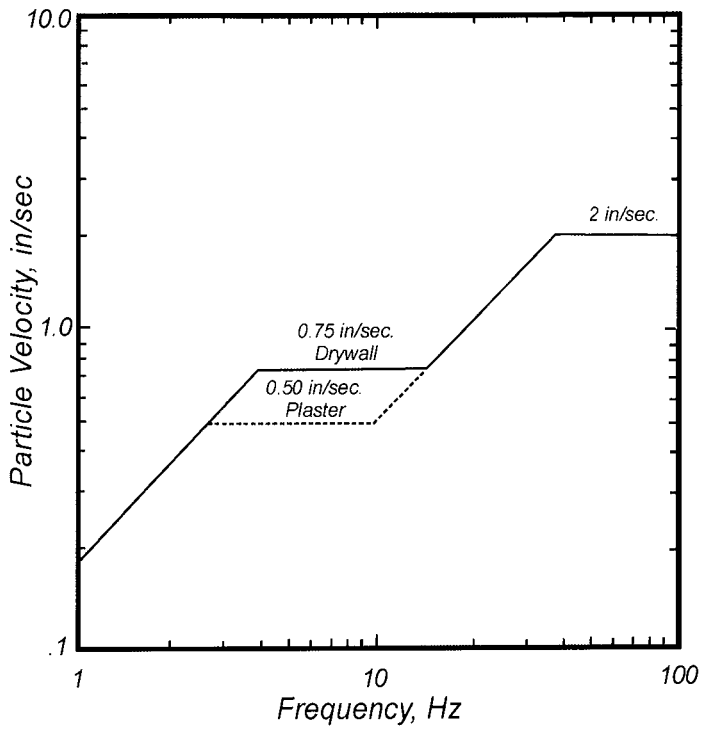

Figure 1: USBM Criteria from RI-8507, November 1980

Results

The following table summarizes the coefficients of determination, the number of data pairs, and the +95% confidence formula derived for each of the analyses. All six analyses showed good fits of data. Attached to this summary are the curve and tables of Peak Particle Velocity vs. Distance for 5.5, 11, and 13.2 pound charges for each of the six analyses. All graphs and tables are based on the +95% confidence level equation derived from each analysis.

Summary of Shot Hole Analyses Results

Analysis	Derived Formula	Coefficient of Determination	Number of Data Pairs
Sites 1 & 2, All Data	$PPV = 499.58(SD)^{-1.63}$	0.823	36
Site 1, All Data	$PPV = 419.48(SD)^{-1.70}$	0.870	18
Site 2, All Data	$PPV = 435.11(SD)^{-1.57}$	0.873	18
All 5.5 # Data	$PPV = 335.89(SD)^{-1.54}$	0.920	12
All 11 # Data	$PPV = 503.35(SD)^{-1.75}$	0.894	12
All 13.2 # Data	$PPV = 1157.51(SD)^{-1.96}$	0.883	12

Conclusions

Applying limits for plaster-on-lath (the most fragile of modern construction materials) will also provide a large factor of safety for any engineered structures that may exist within the survey area (pipelines, wells, fiber optic cable…). The following table summarizes stand-off distances for recommended vibration limits for each of the analyses.

+95% Confidence Level Stand-off Distances for Fixed Particle Velocities and Charge Weights

Analysis	Charge Weight (lbs)	0.25 ips (approx. human annoyance limit)	0.50 ips (plaster-on-lath limit)	0.75 ips (sheetrock limit)	2.00 ips (conservative, water well, well, pipeline limit)	4.92 ips (pipeline limit)
Sites 1&2, All Data	5.5	251'	164'	128'	70'	40'
