All Rights Reserved

EXECUTIVE SUMMARY

ES.1 Introduction

The Yuba County Water Agency (Yuba Water) operates the Yuba River Development Project (YRDP) and the Narrows Hydroelectric Project (Narrows Project), both of which are hydroelectric projects that operate pursuant to licenses issued by the Federal Energy Regulatory Commission (FERC) under the Federal Power Act (FPA). Yuba Water is seeking renewal of the FERC licenses to continue its operations and maintenance (O&M) of both projects. As the lead agency under the California Environmental Quality Act (CEQA), Yuba Water has elected to prepare a joint environmental impact report (EIR) for the FERC license renewals for both the YRDP and the Narrows Project. This Draft EIR (DEIR) evaluates the potential environmental impacts of the proposed renewal of FERC licenses for both the YRDP (Proposed YRDP Project) and the Narrows Project (Proposed Narrows Project), hereinafter also referred to jointly as the Proposed Projects.

ES.2 Project Background

The Project Area is located mainly in northeastern Yuba County, along with a portion of Sierra County and bordering Nevada County. The YRDP is shown in **Figure ES-1**. The existing YRDP includes three developments – New Colgate, New Bullards Bar Minimum Flow, and Narrows 2. The first two developments are primarily centered around New Bullards Bar Dam and Reservoir in northeastern Yuba County. The New Colgate Development includes two diversion dams (Our House and Log Cabin), two diversion tunnels (Lohman Ridge and Camptonville), one storage reservoir (New Bullards Bar), one power tunnel and penstock (New Colgate) and one powerhouse (New Colgate). The New Bullards Bar Minimum Flow Development consists of one penstock, one powerhouse, one transformer, and one streamflow gage. The third development, Narrows 2, is located downstream of Englebright Dam, which is owned and operated by the U.S. Army Corps of Engineers (USACE). The Narrows 2 Development consists of one penstock, one powerhouse and switchyard, and both a full and a partial bypass. The YRDP also includes 16 developed recreation facilities, located at New Bullards Bar Reservoir. These consist of seven campgrounds, two day use/picnic sites, three boat launches/boat access sites, two observation sites, and two trails. Undeveloped recreation sites are located at the Log Cabin Diversion Dam and the Our House Diversion Dam impoundments.

The existing Narrows Project is located in Nevada County and consists of one development (Figure ES-2). The Narrows Project was formerly owned and operated by the private utility Pacific Gas & Electric (PG&E), but it is now owned and operated by Yuba Water, and the Narrows Project is operated in coordination with the YRDP Narrows 2 Development. Similar to the Narrows 2 Development, the Narrows 1 Powerhouse and related facilities are located downstream of Englebright Dam. These facilities include one tunnel, one penstock and standpipe, one powerhouse, and one powerhouse access tram. The Narrows Project has no recreation facilities.

Figure ES-1. YRDP and Project Vicinity.

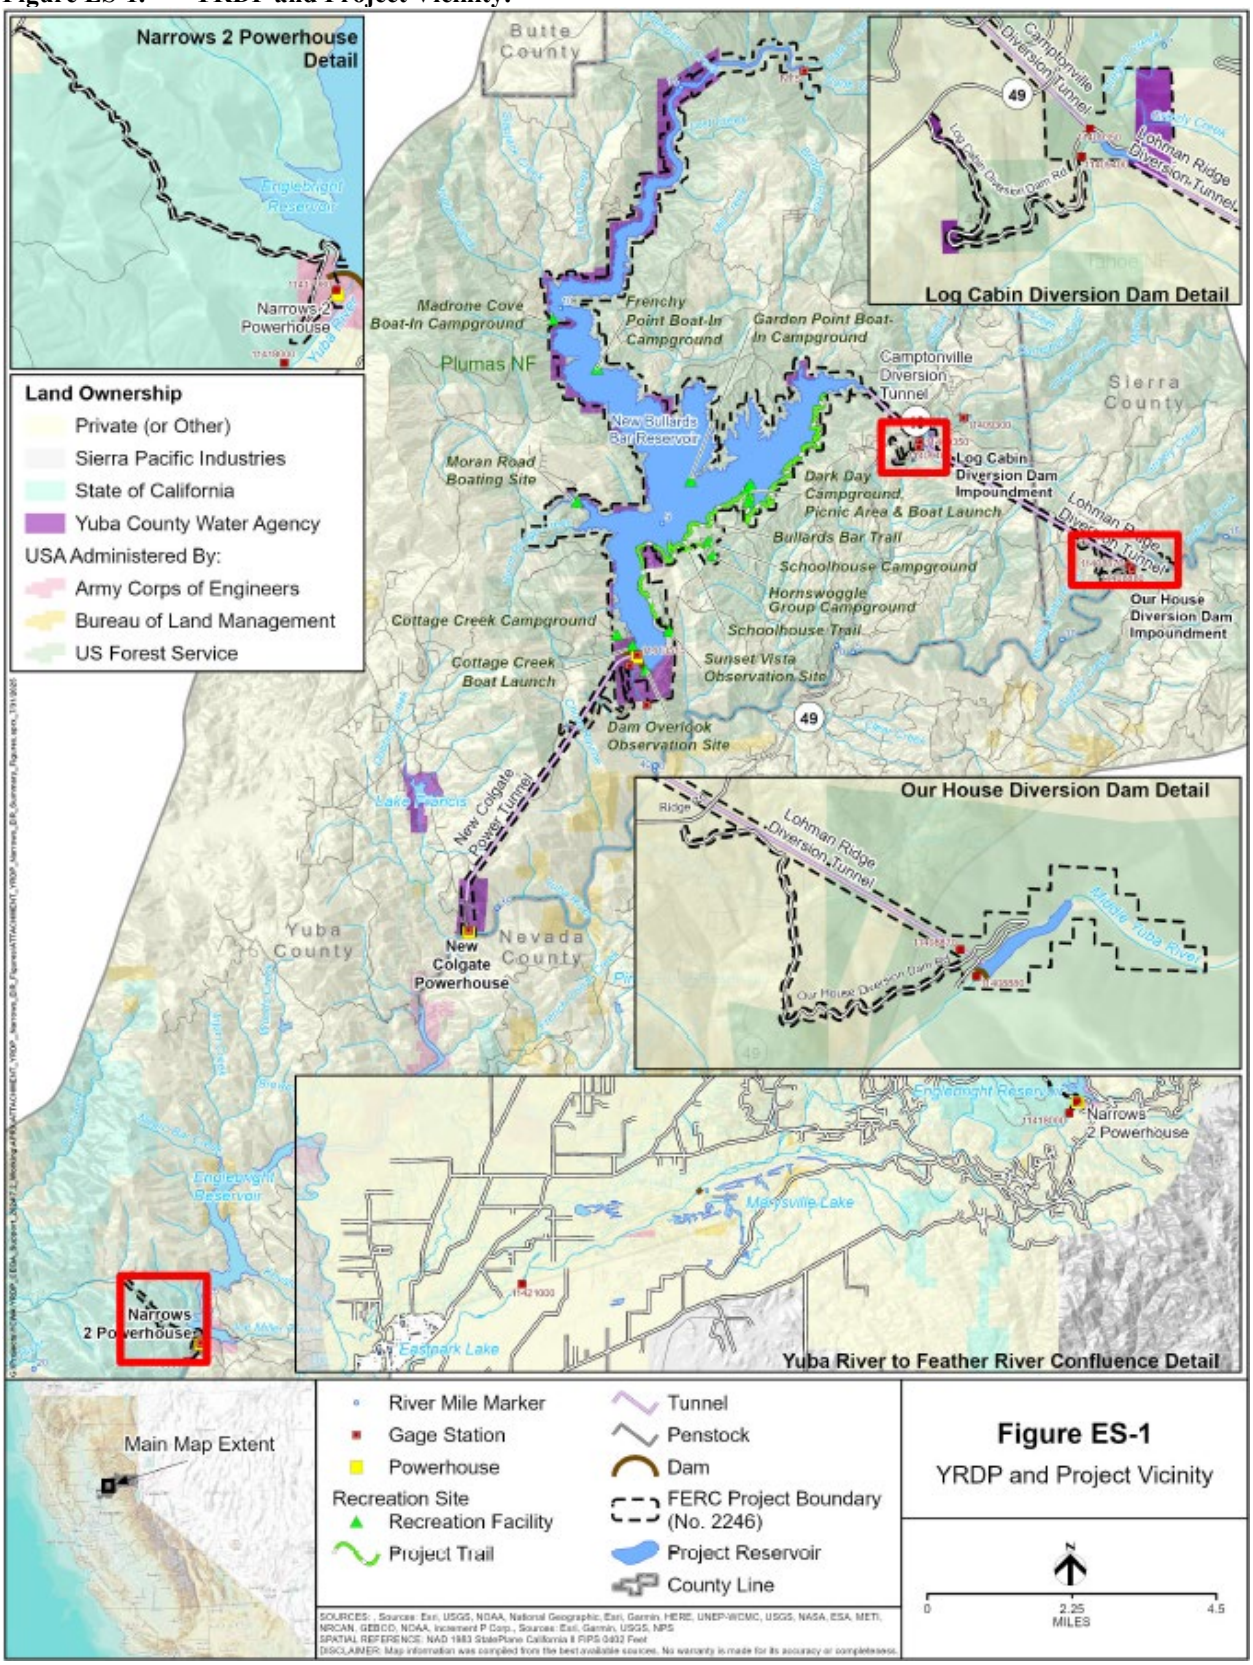

Figure ES-2. Narrows Project and Project Vicinity.

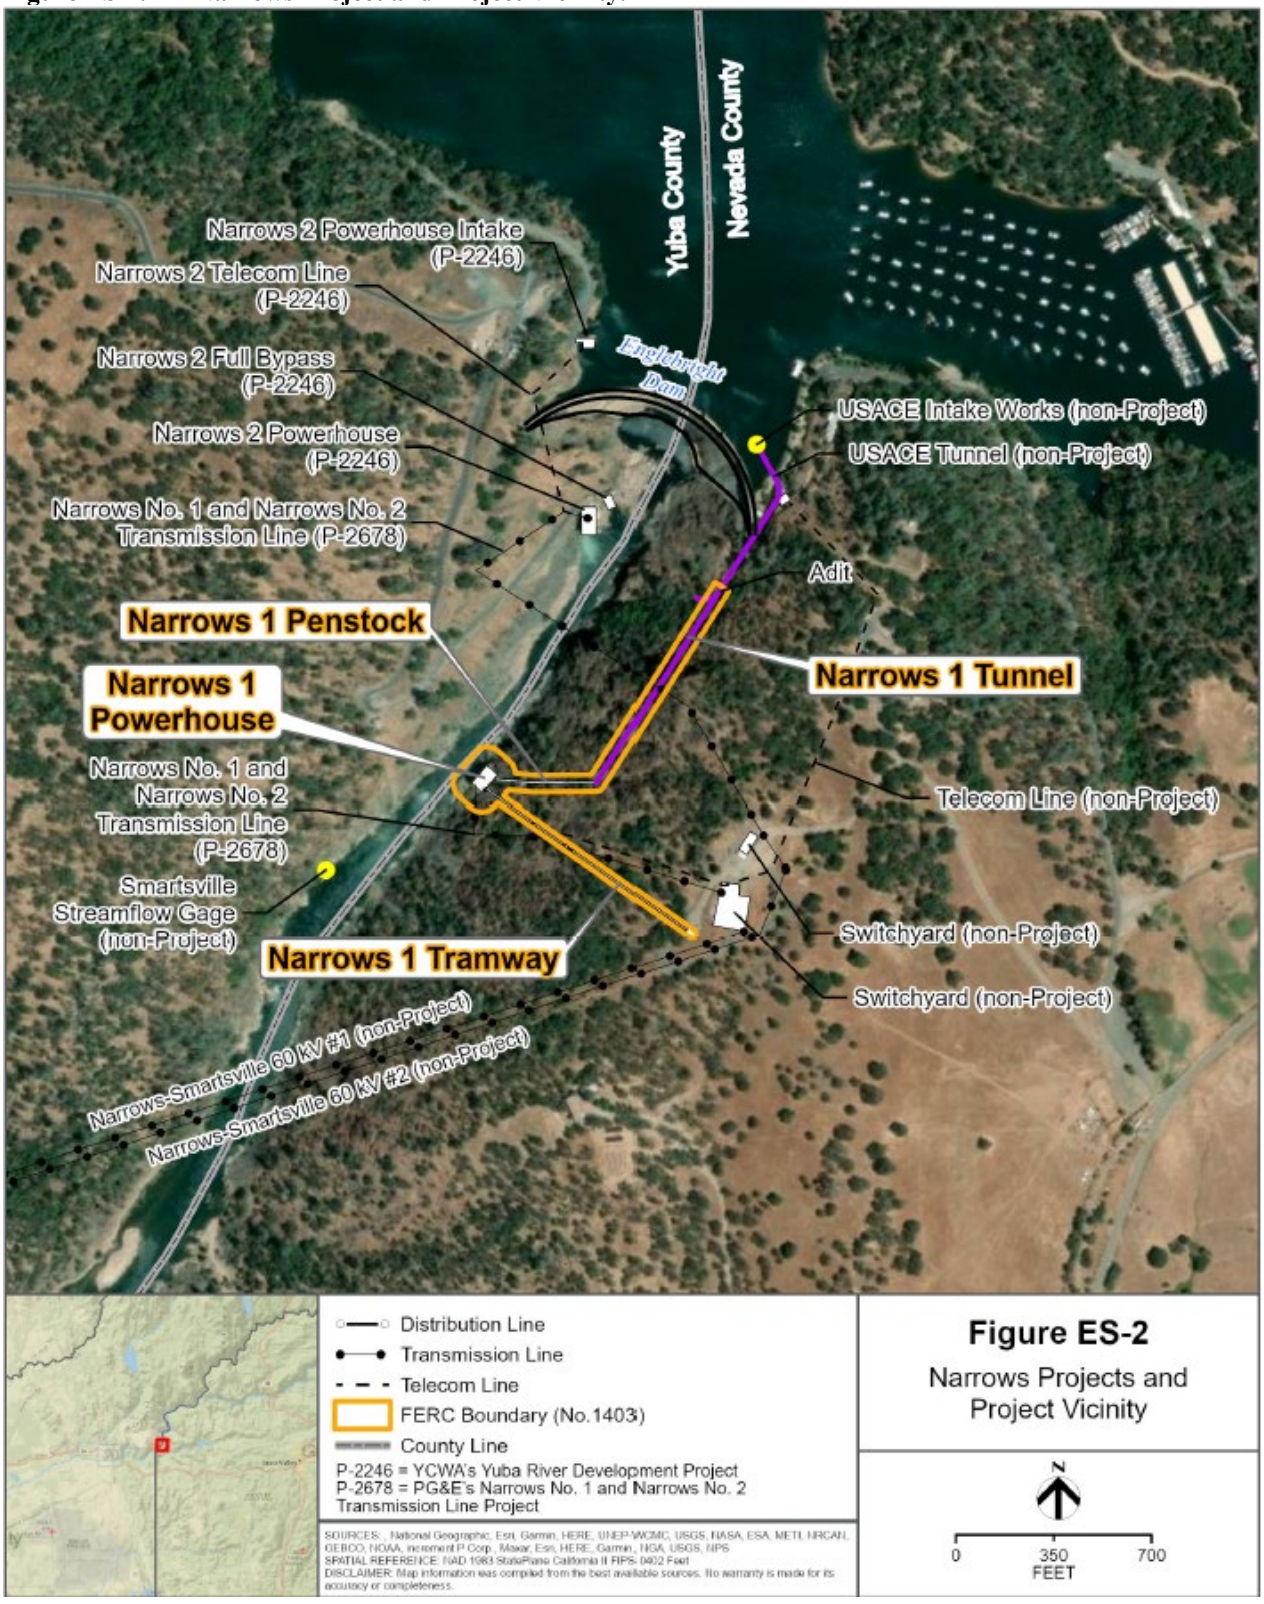

The YRDP (FERC Project No. 2246) currently operates under a 50-year license that was originally issued on May 16, 1963 by the Federal Power Commission, FERC's predecessor. The Federal Power Commission's May 6, 1966, Order Amending License changed the license's effective date to May 1, 1966, for a term ending on April 30, 2016. Since the existing license expired in 2016, FERC has issued Yuba Water an automatically renewing annual license that allows operation of the project under existing license terms and conditions until FERC issues the new FPA license with updated terms and conditions.

On April 28, 2014, Yuba Water filed an application for a new 50-year license with FERC to continue to operate and maintain the YRDP (Docket No. P-2246). On June 5, 2017, Yuba Water filed an amended license application (errata filed July 21, September 15, and November 1, 2017) for the YRDP. Yuba Water has requested a new 50-year license for the YRDP because Yuba Water anticipates incurring substantial expenses during the next license term for modifications to its generation facility, the addition of a flood control outlet, and implementing protection, mitigation, and enhancement measures, including constructing and refurbishing recreation facilities and access roads thereto.

The Federal Power Commission also issued an original license for the Narrows Project (FERC Project No. 1403) to the Pacific Gas and Electric Company (PG&E) on August 1, 1941. FERC issued a new project license to PG&E on February 11, 1993, stating that the new license would be effective for the period from February 1, 1993, through January 31, 2023. On January 26, 2018, FERC approved PG&E's request to extend the license term to January 31, 2026. On May 2, 2019, FERC approved the transfer of the license from PG&E to Yuba Water.

On November 14, 2023, Yuba Water filed an application for a new FPA license with FERC to continue to operate and maintain the Narrows Project (Docket No. P-1403). Yuba Water has requested a new license term of 50 years for the Narrows Project that would end concurrently with the term of the FPA license issued for the YRDP. Although Yuba Water is not proposing changes to the Narrows Project that would ordinarily justify a 50-year license term, it is in the public interest, and consistent with FERC's 2017 Policy Statement (82 FR 49501) on establishing license terms, to relicense the two projects at the same time in the future. As described in this DEIR, the Narrows Project and the YRDP Narrows 2 Development are co-located at Englebright Dam and have coordinated operations. Accordingly, Yuba Water determined that it would be most appropriate to address the environmental impacts of relicensing both the YRDP and the Narrows Project in the same CEQA document.

Compliance with the National Environmental Policy Act (NEPA) of 1969 must be demonstrated prior to FERC undertaking a federal action, including issuance of new FPA licenses to Yuba Water for continued O&M of the YRDP and the Narrows Project. In 2019, FERC, along with the USACE as a cooperating agency, issued a Final Environmental Impact Statement (FEIS) for Hydropower License, Yuba River Development Project, Project No. 2246-065 – California (FEIS) in accordance with NEPA and FERC regulations. Subsequently, FERC sent Yuba Water an Additional Information Request (AIR) on March 8, 2021 to inform FERC staff's analysis in a Supplemental EIS (SEIS) for the YRDP.

When a project action requires compliance with both CEQA and NEPA, state and local agencies are encouraged to use the NEPA document rather than preparing an independent CEQA document. However, if the NEPA document does not fully meet all the requirements of CEQA, those points of analysis missing from the NEPA document must be added, supplemented, or identified. Yuba Water previously issued a Notice of Intent to rely on the 2019 FERC FEIS for the YRDP Relicensing, in combination with a Supplemental Analysis to satisfy CEQA requirements. Subsequently, FERC informed Yuba Water of its plans to prepare a SEIS and a revised biological assessment (BA). FERC explained that the SEIS will address new information in the administrative record and may revise FERC staff's preferred project alternative. To date, FERC has not yet issued either the SEIS for the YRDP or a NEPA environmental compliance document for the Narrows Project, and the timing of these pending federal actions is unknown. As a result, Yuba Water no longer intends to rely on the FEIS and a CEQA Supplemental Analysis; instead, it has prepared this stand-alone EIR for the Proposed Projects.

ES.3 Project Purpose and Objectives

When FERC issues new licenses for the YRDP and the Narrows Project under the FPA, Yuba Water will be required to decide whether or not to accept each one of the new licenses. The project objectives provide the reasons that Yuba Water is seeking renewal of FERC licenses for the YRDP and the Narrows Project, respectively.

The project objectives for the YRDP Relicensing are the following:

1. Obtain a new FERC license for the YRDP under which Yuba Water can generate sufficient revenues to support its continued use, operation, and maintenance of the YRDP facilities to advance its missions established by the Legislature in the Yuba County Water Agency Act (Agency Act).
2. Obtain a new FERC license for the YRDP under which Yuba Water can generate sufficient revenues to maintain and operate Yuba Water's existing flood control facilities, and implement new flood risk reduction projects in Yuba County.
3. Obtain a FERC license for the YRDP under which Yuba Water can operate the YRDP to provide adequate and reliable agricultural surface water supplies within Yuba County and to maintain sustainable conditions in the North Yuba and South Yuba groundwater basins for all beneficial uses, consistent with the Sustainable Groundwater Management Act (Water Code sections 10720-10738).
4. Operate the YRDP to provide streamflow and water temperature benefits for sensitive fish species in the lower Yuba River, downstream of the YRDP's facilities, consistent with the benefits the YRDP has provided for those beneficial uses.
5. Consistent with FERC's March 2021 AIR, implement any additional protections for ESA-listed fish species in the lower Yuba River in a way that both:

(a) improves Yuba River water temperatures for those species and their designated critical habitat; and

(b) equitably allocates protective activities such that no entity is disproportionately burdened with a responsibility to mitigate impacts on those species caused by other entities.

6. Continue to generate long-term, predictable revenue for Yuba Water's programs to support Yuba County's disadvantaged communities consistent with Yuba Water's mission.
7. Continue to support California's power requirements by providing carbon-free hydropower generation to:

   (a) meet resource diversity and capacity needs within the Sierra Local Capacity Area consistent with the Agency Act, California Energy Commission (CEC) regulations and California Independent System Operator (CAISO) energy markets.

   (b) To respond to requests from CAISO to provide additional power during power emergencies (e.g., heat-related shortages) to support statewide electrical grid systems.

8. Continue to generate long-term, predictable revenue for Yuba Water's fisheries and aquatic habitat enhancement projects on the lower Yuba River.
9. Obtain stability and predictability in long-term YRDP operations to generate sufficient funds to allow Yuba Water to comply with the YRDP license conditions, and to justify substantial upfront investments by Yuba Water for modifications to its generation facilities, the addition of the flood control outlet, and implementing protection, enhancement, and mitigation measures (PM&Es), including constructing and refurbishing recreation facilities and access roads thereto during the next license term.
10. Consistent with state policies favoring water transfers stated in Water Code sections 109 and 475, continue to support statewide water supply reliability through continued Lower Yuba River Accord transfers to contractors of the Central Valley Project (CVP) and the State Water Project (SWP), and potentially others, under the Lower Yuba River Accord Water Purchase Agreement.

FERC's issuance of a new license for the YRDP would allow Yuba Water to continue to use water available to Yuba Water to generate electricity at the YRDP facilities for the term of a new FERC license, consistent with the above objectives.

The project objectives for the Narrows Project Relicensing include the following:

1. Continue to support Yuba Water's coordinated operations of the Narrows Project with the YRDP to advance and implement Yuba Water's core flood-control and water-supply missions established by the Legislature in the Agency Act.
2. Obtain a new FERC license for the Narrows Project to generate revenues to continue to fund operation and maintenance of the Narrows Project facilities as part of Yuba Water's flood-control and water-supply missions under the Agency Act.
3. Continue to generate long-term, predictable revenue for Yuba Water's programs to support Yuba County's disadvantaged communities.

4. Continue to generate long-term, predictable revenue for Yuba Water's fisheries and aquatic habitat enhancement projects on the lower Yuba River.
5. Continue to support California's power requirements by providing renewable hydropower generation to meet resource diversity and capacity needs consistent with the Yuba County Water Agency Act, CEC regulations and CAISO energy markets.
6. Obtain stability and predictability in long-term Narrows Project operations to generate funds to allow Yuba Water to comply with the Narrows Project license conditions.
7. Continue to provide stability and reliability in long-term YRDP and Narrows Project coordinated operations by obtaining a new FERC license for the Narrows Project that will run concurrently with the term of a new FERC license for the YRDP.

FERC's issuance of a new license for the Narrows Project would allow Yuba Water to continue to use public waters to generate electricity at the Narrows Project facilities for the term of the new FERC license, making electrical power from a renewable resource available for transmission to its customers, consistent with the above objectives.

ES.4 Description of Proposed Projects

The YRDP component of the Proposed Projects is shown in **Figure ES-1**, while the Narrows Project component is shown in **Figure ES-2**.

ES.4.1 YRDP

Yuba Water is seeking renewal of the FERC license for the YRDP to continue to provide a source of hydroelectric power and flood control and serve as a water supply for both domestic and irrigation purposes. Project benefits include water supply, flood control, recreation, fish and wildlife habitat, and power generation. The latter is a significant source of revenue for Yuba Water; these revenues finance the YRDP generally and enable Yuba Water to implement all its statutory missions, to make substantial water-related investments to support Yuba County's disadvantaged communities, and to continue to fund significant environmental projects. Yuba Water is also proposing the project, in part, because the YRDP provides low-cost power that displaces generation from non-renewable resources (i.e., fossil-fuel generation).

In addition to the continued O&M of the existing YRDP facilities described in Section 2.3 of the EIR, the YRDP Relicensing Project includes:

1. Project-related changes proposed by Yuba Water and accepted by FERC staff in the FEIS;
2. FERC staff-recommended modifications of Yuba Water's proposal and additional measures;
3. Implementation of the USFS's December 2, 2022 Revised Final FPA Section 4(e) Terms and Conditions for the YRDP (Section 4(e) Conditions);

4. Implementation of Yuba Water's recommended findings for 2025 CWA Section 401 Water Quality Certification (WQC) Conditions for the new YRDP FERC license that were submitted for consideration to the SWRCB on December 30, 2024;

5. FERC Form L-5 Terms and Conditions of License for Constructed Major Project Affecting Navigable Waters and Lands of the United States; and

6. Implementation of protective measures for ESA-listed species under the jurisdictional authority of the USFWS, as described in the USFWS's June 21, 2018 letter of concurrence.

Also, as described in Chapter 2, Project Description, the YRDP Relicensing Project would involve:

- Modifications to existing YRDP facilities, including recreation facilities.
- Adjustments to the FERC Project Boundary.
- Protection, mitigation, and enhancement (PM&E) measures proposed by Yuba Water.
- All mandatory terms and conditions.

ES.4.1.1 Proposed YRDP Facilities

ES.4.1.1.1 Power Generation Facilities

Yuba Water proposes to add to the YRDP a new Tailwater Depression System (TDS) at the New Colgate Powerhouse. The proposed TDS would introduce compressed air into the turbine discharge chamber to lower the tailwater elevation to a level that does not interfere with turbine operation, thereby allowing continued turbine operation during high flows. The proposed TDS would only operate during high flow events, when the combined releases from New Bullards Bar Dam and flows from the Middle Yuba River would otherwise preclude New Colgate Powerhouse operations. The anticipated total duration of the construction would be 5 months.

ES.4.1.1.2 Non-Generation Facilities

New Bullards Bar Dam Auxiliary Flood Control Outlet (i.e., ARC Spillway)

The ARC Spillway project, while considered part of the YRDP, was analyzed for its environmental impacts in a separate EIR certified in 2024. However, ARC Spillway operations are being considered as part of the YRDP Relicensing Project that is characterized in this DEIR because it was addressed in FERC's FEIS and it is expected to be a component of the long-term operation of the YRDP that is described in the new FERC license. Releases from the ARC Spillway would be made in anticipation of large storms to provide increased evacuated storage capacity in New Bullards Bar Reservoir prior to and during high-precipitation events and large storm peak inflows to reduce the peak outflow. The ARC Spillway would operate conjunctively with the New Bullards Bar Dam Primary Spillway and the New Colgate Powerhouse to meet the overall target releases of the dam. Once completed, the ARC Spillway and associated facilities/areas would be incorporated into the YRDP under FERC's jurisdiction and regulated under the FPA.

Modifications to Our House Diversion Dam and Log Cabin Diversion Dam Fish Release Outlets

Yuba Water proposes to change minimum flows on the Middle Yuba River downstream of Our House Diversion Dam from the requirement in the existing license of 30 - 50 cubic feet per second (cfs) to 40 - 120 cfs, and to change minimum flows on Oregon Creek downstream of Log Cabin Diversion Dam from the requirement in the existing license of between 8 - 12 cfs to 6 - 43 cfs. Furthermore, Yuba Water proposes to include in the new license a requirement to control spill at Our House Diversion Dam by releasing up to 600 cfs and to control spill at Log Cabin Diversion Dam by releasing up to 100 cfs. To accomplish this, because the proposed flows would exceed the capabilities of the existing fish release outlets, a 68-inch diameter outlet pipe with control valve is proposed to be installed at Our House Diversion Dam and a 38-inch diameter outlet pipe with control valve is proposed to be installed at Log Cabin Diversion Dam. The existing fish release outlets at Our House and Log Cabin diversion dams would remain in place and be able to release at the existing capacities (i.e., 59 and 18 cfs, respectively). The new low-level outlets would not affect the existing low-level outlets at the dams and would only be used for controlled releases from the dams in excess of the existing fish release valves; the modifications would not result in added power generation. Actual field construction for each proposed facility would take no more than six months.

Modifications to Lohman Ridge Diversion Tunnel Intake

Yuba Water proposes to periodically close the Lohman Ridge Diversion Tunnel on the Middle Yuba River during wetter water years and when there is sufficient storage in New Bullards Bar Reservoir to meet water management objectives. To do this, Yuba Water proposes to replace an existing gate on the tunnel intake with a more efficient gate structure involving the addition of a new regulating gate and the relocation of the existing bulkhead gate. Actual field construction would take no more than six months.

ES.4.1.1.4 Recreation Facilities

Yuba Water proposes several enhancements to the existing YRDP recreation facilities, along with the construction of new facilities, all at New Bullards Bar Reservoir. When constructing new YRDP recreation facilities, Yuba Water would obtain all necessary permits and approval for survey work, facility design and on-site resource evaluations, including U.S. Forest Service permits for work on National Forest System (NFS) land.

Existing facilities that would be improved would include Schoolhouse Campground, Dark Day Campground, and Hornswoggle Group Campground. These would involve primarily utility and restroom improvements, although additional campsites would be provided at Schoolhouse and Hornswoggle Campgrounds, and a 50-person capacity amphitheater is proposed at Schoolhouse Campground. The existing Cottage Creek Picnic Area would have four additional campsites and utility improvements, and the Dark Day Picnic Area would have additional picnic sites and other amenities. Yuba Water also proposes rehabilitation of the Garden Point and Madrone Cove Boat-in Campgrounds, while decommissioning the existing Frenchy Point Boat-in Campground. The Sunset Vista Observation Site is proposed for rehabilitation and the Dam Overlook Observation Sites would be enhanced. The Cottage Creek and Dark Day Boat Launches would be rehabilitated, along with the Moran Road Boating Site. The existing water treatment and delivery system serving

the campgrounds would undergo major rehabilitation and expansion. Additionally, recreation wastewater systems also are proposed for rehabilitation.

New recreation facilities that are proposed include the Kelly Ridge Campground, which would have 27 campsites with showers and restrooms. The Shadow Ridge Campground, which would replace the former Burnt Bridge Campground, would have 18 campsites, along with restrooms and a 30-person capacity amphitheater. A new Cottage Creek Picnic Site with 10 picnic sites would be constructed. A West Shoreline Trail would be installed along the western shoreline of New Bullards Bar Reservoir, connecting the Cottage Creek and Shadow Ridge recreation complexes.

The Bullards Bar and Schoolhouse recreation trails are proposed for enhancements. Yuba Water is proposing to add 0.23 miles of new Recreation Roads. Yuba Water also proposes to withdraw 0.77 miles of Recreation Roads.

Yuba Water's *Recreation Facilities Plan* includes a detailed implementation schedule for major rehabilitation, near-term rehabilitation and enhancements at each existing recreation facility and for new recreation facilities extending from License Year 1 through 20. The majority of the work on NFS lands would occur within the first eleven years of the new license, with some work on Yuba Water facilities occurring in Years 14 through 20.

ES.4.1.1.5 Other Facilities

Yuba Water's *Transportation System Management Plan* provides guidance for the rehabilitation and maintenance of Primary Project Roads and Trails, which are non-general use roads and trails that are primarily used for the YRDP. Approximately 12.47 miles of non-recreational Primary Project Roads and Trails are proposed for rehabilitation, along with approximately 5.59 miles of new roads. Approximately 4.07 miles of recreational Primary Project Roads and Trails are proposed for rehabilitation, along with approximately one mile of new roads.

ES.4.1.2 Proposed FERC Boundary

Yuba Water proposes several changes to the FERC Project Boundary for the YRDP to more accurately define lands necessary for the safe O&M of the YRDP and other purposes, such as recreation, shoreline control, and protection of environmental resources. There are two categories of proposed project boundary changes:

- Category 1 - Corrections to the existing FERC Project Boundary to: (1) add lands currently utilized with a preponderance of use related to the YRDP O&M; (2) add lands associated with proposed new recreation facilities under Yuba Water's proposed resource management measures; or (3) remove lands from the Project Boundary that do not have YRDP Facilities and are not used or necessary for YRDP O&M. These proposed changes are essentially making corrections to the FERC Project Boundary.
- Category 2 - Proposed changes to the existing FERC Project Boundary around the YRDP reservoir and impoundments from surveyed coordinates to a contour located above the normal maximum water surface elevation (NMWSE).

In total, the proposed changes would decrease the area within the YRDP FERC Project Boundary by 1,591.8 acres, including 1,003.4 acres of land managed by the USFS and 5.0 acres of land managed by USACE.

ES.4.1.3 Proposed Changes to Conditions in the Existing YDRP FERC License

Yuba Water developed 41 proposed conditions for the YRDP, including associated implementation plans, for the new license in collaboration with Relicensing Participants. In particular, 12 of Yuba Water's YRDP proposed conditions would modify flow requirements in the existing FERC license and, thereby, affect future YRDP operations.

- Water year types (WYTs) for Conditions Pertaining to New Bullards Bar Dam, Our House Diversion Dam, and Log Cabin Diversion Dam (Yuba Water's YRDP Proposed Condition WR2)

- WYTs for Conditions Pertaining to Narrows 2 Powerhouse and Narrows 2 Full Bypass (Yuba Water's YRDP Proposed Condition WR3)

- Minimum Flows in the Middle Yuba River Downstream of Our House Diversion Dam and Log Cabin Diversion Dam (Yuba Water's YRDP Proposed Condition AR1)

- Minimum Flows in the North Yuba River Flow Downstream of New Bullards Bar Dam (Yuba Water's YRDP Proposed Condition AR10)

- Control Project Spills at Our House Diversion Dam (Yuba Water's YRDP Proposed Condition AR2)

- Control Project Spills at Log Cabin Diversion Dam (Yuba Water's YRDP Proposed Condition AR12)

- Periodically Close Lohman Ridge Diversion Tunnel (Yuba Water's YRDP Proposed Condition AR11)

- Provide Whitewater Boating Below Our House Diversion Dam (Yuba Water's YRDP Proposed Condition RR3)

- Minimum Flows on the Yuba River Downstream of the Narrows 2 Powerhouse and Narrows 2 Full Bypass (Yuba Water's YRDP Proposed Condition AR3)

- Control Project Ramping and Flow Fluctuation Downstream of Englebright Dam (Yuba Water's YRDP Proposed Condition AR9)

- Control Project Spills at New Bullards Bar Dam (Yuba Water's YRDP Proposed Condition AR4)

- Implement Log Cabin and Our House Diversion Dams Sediment Management Plan (Yuba Water's YRDP Proposed Condition GS2)

ES.4.1.4 FERC Staff Alternative Modifications to YRDP Proposal

FERC's FEIS analyzed the potential effects of continued YRDP operation and recommended conditions for any new license that may be issued by FERC for the YRDP. In addition to Yuba Water's proposal, FERC considered several alternatives and selected the FERC Staff Alternative as the NEPA preferred alternative. The FERC Staff Alternative included several recommended modifications of Yuba Water's proposal, as well as some additional measures identified by FERC staff:

Water Quantity:

- Modify Yuba Water's proposed Drought Management Plan (YRDP Proposed Condition WR9).

Aquatic Resources:

- Maintain summer water temperatures in the lower Yuba River in Schedule 6 years.
- Modify Yuba Water's proposed Aquatic Invasive Species Management Plan (YRDP Proposed Condition AR5).
- Modify Yuba Water's proposed New Bullards Bar Reservoir Fish Stocking Plan (YRDP Proposed Condition AR6).
- Modify Yuba Water's proposed Lower Yuba River Aquatic Monitoring Plan (YRDP Proposed Condition AR8).
- Develop a Narrows Reach Fish Stranding Prevention Plan for the lower Yuba River, downstream of the Narrows 1 and Narrows 2 Powerhouses.
- Revise minimum streamflows below New Bullards Bar Dam (YRDP Proposed Condition AR10).
- Develop a comprehensive Large Woody Material (LWM) enhancement plan.

Terrestrial Resources:

- Modify Yuba Water's proposed Integrated Vegetation Management Plan (YRDP Proposed Condition TR1).
- Develop a lower Yuba River riparian restoration plan, in consultation with USFWS, CDFW, NMFS, and the South Yuba River Citizen's League (SYRCL).
- Modify Yuba Water's proposed Bald Eagle and American Peregrine Falcon Management Plan (TR2).
- Monitor water temperature continuously from April 1 through September 15 for 3 years at two foothill yellow-legged frog breeding sites in the Middle Yuba River downstream from Our House Diversion Dam and at two sites in Oregon Creek downstream of Log Cabin Diversion Dam.

- Ensure procedures for decontaminating field equipment to prevent the spread of aquatic pests and disease between waterbodies, as described in Yuba Water's proposed Aquatic Invasive Species Monitoring Plan, are applied for activities where equipment is transported from one body of water to another.

Cultural Resources:

- Revise Yuba Water's Historic Properties Management Plan (HPMP).

ES.4.1.5 Summary of FERC-Approved YRDP Implementation Plans

During the FERC relicensing process, Yuba Water, other agencies, and other stakeholders reached collaborative agreement on more than 30 measures, many of which include detailed implementation plans. Although the agreed-upon measures and associated plans are intended to improve existing conditions and provide benefits overall, some plans do involve construction and operations-related activities that could have the potential to impact environmental resources. Because these collaboratively agreed-upon measures and associated plans are important components of the YRDP Proposed Project, they are listed below:

- Aquatic Invasive Species Management Plan (2019)
- Bald Eagle and American Peregrine Falcon Management Plan (2019)
- Bat Management Plan (2016)
- Drought Management Plan (2017)
- Erosion and Sediment Control Plan (2016)
- Fire Prevention and Response Plan (2017)
- Hazardous Materials Management Plan (2019)
- Historic Properties Management Plan (2017)
- Integrated Vegetation Management Plan (2019)
- Lower Yuba River Aquatic Monitoring Plan (2016)
- New Bullards Bar Reservoir Fish Stocking Plan (2019)
- Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan (2018)
- Log Cabin and Our House Diversion Dams Sediment Management Plan (2018)
- Recreation Facilities Plan (2022)
- Ringtail Management Plan (2016)

- Streamflow and Reservoir Level Compliance Monitoring Plan (2017)
- Transportation System Management Plan (2017)
- Upper Yuba River Aquatic Monitoring Plan (2017)
- Visual Resources Management Plan (2016)
- Water Quality Monitoring Plan (2016)
- Water Temperature Monitoring Plan (2016)

In addition to implementing the activities described in the implementation plans discussed above, the FERC Staff Alternative and FERC's draft license articles in Appendix C of the FEIS recommended that Yuba Water also develop and implement three new plans and revise five existing plans at such time as a new FERC license is issued. The implementation plans that are to be developed or revised when a new FERC license for the YRDP is issued include the following:

New Plans:

- Narrows Reach Fish Stranding Prevention Plan (FERC Article 409)
- Large Woody Material Management Plan (FERC Article 410)
- Lower Yuba River Riparian Restoration Plan (FERC Article 412)

Revised Plans:

- Bald Eagle and American Peregrine Falcon Management Plan (FERC Article 413)
- Drought Management Plan (USFS 4(e) Condition 53)
- Historic Properties Management Plan (FERC Article 415)
- Integrated Vegetation Management Plan (FERC Article 411)
- New Bullards Bar Reservoir Fish Stocking Plan (FERC Article 406)

ES.4.1.6 YRDP Federal Power Act Section 4(e) Conditions

Section 4(e) of the FPA (16 U.S.C. § 797(e)) provides that any license issued by FERC "for a project within a federal reservation shall be subject to and contain such conditions as the Secretary of the responsible federal land management agency deems necessary for the adequate protection and use of the reservation." In accordance with Section 4(e) of the FPA and 18 CFR 5.25(d), the USFS filed with FERC Revised Final FPA Section 4(e) Terms and Conditions for the YRDP on December 2, 2022. The USFS's December 2, 2022 filing of Revised Final Section 4(e) Terms and Conditions was comprised of two parts. Part I included 27 administrative conditions deemed necessary for the administration of NFS lands. Part II included 26 specific resource conditions for protection and utilization of NFS lands, such as special-status species, vegetation management, visual resources, and historic properties among others. They also include conditions specific to the following YRDP facilities:

- Condition No. 33 - Control Project Spills at Our House Diversion Dam
- Condition No. 34 - Control Project Spills at Log Cabin Diversion Dam
- Condition No. 35 - Periodically Close Lohman Ridge Diversion Tunnel
- Condition No. 37 – Log Cabin and Our House Diversion Dams Sediment Management Plan
- Condition No. 38 – Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan

ES.4.2 Narrows Project

In addition to the continued O&M of the existing Narrows Project facilities described in Section 2.3 of this EIR, the Narrows Relicensing Project includes:

1. Project-related changes proposed by Yuba Water;
2. Protective measures proposed by Yuba Water;
3. FERC-recommended modifications of Yuba Water's proposal and additional measures (if any); and
4. All mandatory terms and conditions (if any).

To date, no FERC-recommended modifications or additional measures to Yuba Water's proposal have been identified, and no FPA Section 4(e) Conditions have been recommended by the USFS or others.

Yuba Water does not propose any changes to the existing Narrows Project works or facilities. Yuba Water proposes to continue to operate the Narrows Project in substantial conformance with existing operations, with minor modifications. Yuba Water does not propose any changes to the existing FERC Project Boundary for the Narrows Project.

ES.4.2.1 Proposed Changes to Conditions in the Narrows Project FERC License

For the Narrows Project, Yuba Water proposes to include, with some updates, the following four conditions in the new license that would replace Articles 402 and 411, 405, 403 and 410 in the current license:

- Yuba Water's Narrows Project Proposed Condition 1, Supplemental Flows. This condition would continue the requirements of Article 402 and 411 where Yuba Water shall coordinate with the YRDP to develop a Water Release Plan to define how the two projects would coordinate operations and provide flows to the lower Yuba River.

- Yuba Water's Narrows Project Proposed Condition 2, Ramping Rates. This condition would continue the requirements of Article 405 where Yuba Water's releases from the Narrows 1 Powerhouse shall not result in a rate of change in streamflow greater than flow fluctuation limits required at USGS gage station 11418000, *Yuba River Below Englebright Dam Near Smartsville, CA*, in the license for the YRDP.
- Yuba Water's Narrows Project Proposed Condition 3, Fish Stocking. This condition would continue the requirement of Article 403 where Yuba Water shall provide annually up to 5,000 rainbow trout (half pound each) to be stocked in Englebright Reservoir.
- Yuba Water's Narrows Project Proposed Condition 4, Consult with SHPO and Affiliated Native American Tribes. This condition would continue the requirement in Article 410 where Yuba Water, before starting any land clearing, land-disturbing, or spoil-producing activities in areas in which Yuba Water has not previously conducted a cultural resources survey and consulted with SHPO and affiliated Native American Tribes, shall consult with SHPO and affiliated Native American Tribes and conduct a cultural resources survey of the affected areas.

In addition to the above four conditions that would replace existing conditions, Yuba Water proposes to include the following three new conditions:

- Yuba Water's Narrows Project Proposed Condition 5, Water Surface Elevation in Englebright Reservoir. Yuba Water's operation of the Narrows Project within its reasonable control shall not cause Englebright Reservoir's water surface elevation to be lower than an elevation of 514.0 ft unless necessary for the temporary protection of life, health, property or environmental resources.

- Yuba Water's Narrows Project Proposed Condition 6, Nesting Peregrine Falcon Protection. To the greatest extent feasible, Yuba Water would schedule Narrows Project vegetation clearing, ground-disturbing and loud noise-generating activities outside of the nesting bird season of January 1 through August 15 to avoid take of nesting American peregrine falcons (*Falco peregrinus*).

- Yuba Water's Narrows Project Proposed Condition 7, Bat Management. Yuba Water would, in the first full calendar year after license issuance, document bat roosts and openings large enough to admit bats within the Narrows 1 Powerhouse and tram building. If bats, signs of roosting, or openings are present where staff have a routine presence (i.e., at least daily or weekly), Yuba Water would, where feasible, place humane exclusion devices to prevent occupation of the structure by bats.

ES.5 Agency Roles and Responsibilities

Yuba Water, as the CEQA lead agency, has the principal responsibility for approving and carrying out the Proposed Projects and for ensuring that CEQA requirements and all other applicable regulations are met. The following responsible and trustee state agencies are anticipated to have jurisdiction or permitting authority over some aspects of the Proposed Projects:

- California Department of Fish and Wildlife (CDFW)
- California Department of Water Resources (DWR)
- State Office of Historic Preservation
- State Water Resources Control Board (SWRCB)
- Central Valley Regional Water Quality Control Board (RWQCB)
- California Department of Forestry and Fire Protection (CALFIRE)
- California Department of Transportation
- California Department of Industrial Relations, Division of Occupational Safety and Health

The following regional and local agencies are also potential responsible agencies under CEQA:

- Feather River Air Quality Management District (FRAQMD)
- Northern Sierra Air Quality Management District (NSAQMD)
- Yuba County
- Sierra County
- Nevada County

Additionally, the following Federal agencies are anticipated to have permitting or review authority over portions of the Proposed Projects:

- FERC
- USACE
- USFS
- National Marine Fisheries Service (NMFS)
- U.S. Fish and Wildlife Service (USFWS)

ES.6 Alternatives

CEQA requires an EIR to describe and evaluate a range of reasonable alternatives to the project or to the location of a project that could feasibly attain most of the basic project objectives and would avoid or substantially lessen significant project impacts. The alternatives analysis must include the "No Project Alternative" as a point of comparison. Chapter 3 of this DEIR describes three alternatives to the Proposed Projects, which are analyzed along with the Proposed Projects in Chapters 5 through 24 of this DEIR. In addition to the No Project Alternative, the alternatives considered in this DEIR were developed based on information gathered during the preliminary project design and are summarized below.

ES.6.1 No Project Alternative

The analysis of the No Project Alternative addresses two potential No Project scenarios: (1) Yuba Water would not accept new licenses for either the YRDP or the Narrows Project; and (2) Yuba

Water would not accept a new license for the Narrows Project but would accept the new FERC license for the YRDP. Related to the first potential scenario, Yuba Water also would not be able to obtain one-year FERC licenses for either the YRDP or the Narrows Project under the No Project Alternative. The potential circumstances that could occur under the No Project Alternative with respect to Yuba Water's non-acceptance of the pending new FPA licenses to be issued by FERC are:

(1) Yuba Water could decide not to accept the conditions associated with a new FPA license for both the YRDP and the Narrows Project. In the absence of a hydropower license from FERC, the YRDP and the Narrows Project would discontinue hydropower generation operations. Yuba Water would continue to operate the YRDP and Narrows Project facilities, excluding the power generating facilities, outside of FERC jurisdiction as water supply facilities (i.e., no electricity generation facilities) and for flood management purposes. No new environmental PM&E measures would be implemented. Upstream of USACE's Englebright Reservoir, flow and water temperature conditions generally would be similar to those that occur under the CEQA Baseline (Existing Condition), except that there would be reduced fluctuations of Yuba River inflows into Englebright Reservoir and in Englebright Reservoir water surface elevations. Also, weekly fluctuations in reservoir storage would not occur. Downstream of Englebright Reservoir, flow and water temperature conditions in the lower Yuba River would be the same as flows and water temperatures under the CEQA Baseline (Existing Condition).

(2) Yuba Water could decide to accept the conditions associated with a new FPA license for the YRDP, but not for the Narrows Project. Under these circumstances, Yuba Water would be able to meet specified regulatory requirements regarding lower Yuba River instream flows and continue to achieve various components of the agency's mission to provide a source of hydroelectric power, flood risk reduction, and water supplies for both domestic and irrigation purposes, as well as providing benefits for recreation, fish and wildlife habitat. Operations under this scenario would be similar to Proposed Projects operations. The full release capacity of the Narrows Project tunnel and outlet works might still be used to coordinate with the YRDP, augment flows from the Narrows 2 Powerhouse and provide release capabilities to meet required downstream flows if the Narrows 2 Powerhouse and bypasses were not available, such as a tunnel outage. There are a range of options for releases of water from the remaining facilities of the Narrows Project, but all the most likely options would be either no reduction or relatively small reductions in release capacity and a change in release point. The only major change would be a loss of qualifying small hydropower renewable power sold by Yuba Water, as the Narrows Project is classified as a renewable energy small hydropower facility under the state's Renewables Standard Portfolio.

ES.6.2 Alternative 1 (Yuba Water's October 31, 2022 Offer of Settlement for the YRDP)

FERC's March 8, 2021 AIR Item 3 requested that Yuba Water evaluate options for the equitable allocation of water to provide cooler water temperatures in the lower Yuba River at times by consulting with PG&E (Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310) and Lower Drum Hydroelectric Project (FERC Project No. 14530)) and Nevada Irrigation District (NID) (Yuba-Bear Hydroelectric Project (FERC Project No. 2266) and Deer Creek Hydroelectric Project (FERC Project No. 14531)) and develop an agreed-upon analysis of the amount of additional water from either storage or transfers necessary in Dry and/or Critically Dry years (or

combination of dry type years) to maintain cooler water in the lower Yuba River for federally listed species protection from July through November. FERC also sent coordinated AIRs to NID and PG&E on March 8, 2021. Yuba Water developed its Offer of Settlement in response to FERC's AIR Item 3 within the context of FERC's coordinated request to Yuba Water, NID and PG&E.

Alternative 1 includes an integrated suite of measures to be implemented by Yuba Water, PG&E, and NID, in coordination with each other. Yuba Water developed Alternative 1 as a proposal for the YRDP and upstream projects to equitably allocate water to provide cooler water temperatures in the lower Yuba River for federally listed species protection from July through November. Alternative 1 proposes to reoperate the release of 15,600 acre-feet of additional flow from the Yuba-Bear/Drum-Spaulding (YB/DS) projects, during Dry and Critically Dry years. This reoperation would only be possible if water is made available by the YB/DS projects, which is subject to approval of a new license term by FERC. Because Yuba Water cannot impose operational changes on PG&E's and NID's upstream projects, Alternative 1 is a conditional alternative that is subject to FERC's acceptance and implementation.

Alternative 1 would include all non-flow components of the YRDP and all Narrows Project operations under the Proposed Projects, as described in DEIR Chapter 2, Project Description. Compared to the Proposed Projects, Alternative 1 includes modifications to YRDP operations and additional non-flow measures.

Specifically, Alternative 1 includes two non-flow components and two flow components, to be implemented as an integrated suite of actions by Yuba Water in coordination with PG&E and NID, consistent with proposed license conditions in new licenses issued by FERC. These are described below.

- Yuba Water would use the upper intake at New Bullards Bar Dam during the spring (March, April, and May) and the lower intake the remainder of the year. To implement this non-flow action (referred to as the NBBD Dual Intake), Alternative 1 would include a new proposed license condition for the YRDP (see Chapter 3).
- Yuba Water would manage flows into and out of Englebright Reservoir to increase the target water surface elevation from 519 ft msl to 525 ft msl from August 25 through September 10, maintaining the target elevation of 525 ft msl through October 15, and implementing an October 16-31 ramp-down. To implement this non-flow action, Alternative 1 would include a new proposed license condition for the YRDP (see Chapter 3).
- The YB/DS projects would collectively release an additional 15,600 acre-feet of water in Dry or Critically Dry years, for reregulation and release by Yuba Water into the lower Yuba River during September 1 through October 15. NID and PG&E would decide among themselves how to allocate responsibility for the additional 15,600 acre-feet. To implement this flow action, Alternative 1 would include a new proposed license condition for the YB/DS (see Chapter 3).

- As noted above, the Yuba-Bear and Drum-Spaulding Projects would collectively provide 15,600 acre-ft of water during April and early May of Dry and Critically Dry years. Yuba Water would release this water to provide increased flows of 175 cfs to the lower Yuba River from September 1 through October 15 during Dry and Critically Dry years. To implement this non-flow action, Alternative 1 would include a new proposed license condition for the YRDP (see Chapter 3).

ES.6.3 Alternative 2 - SWRCB Draft Bay-Delta Plan Update Regulatory Pathway Scenario

Yuba Water developed Alternative 2 in response to comments from the SWRCB on the Notice of Preparation (NOP) for this DEIR. For many years, the SWRCB has been considering potential amendments to the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Watershed. On October 25, 2024, the SWRCB issued a draft of this plan, called the Draft Bay-Delta Plan Update. According to the SWRCB, the Draft Bay-Delta Plan Update "regulatory pathway" is ultimately intended to provide benefits to the Sacramento-San Joaquin Delta (Delta) by providing higher flows to support a connected and functioning ecosystem and to benefit native fish in the Sacramento Valley and the Delta. Relative to the Proposed Projects, the SWRCB Draft Bay-Delta Plan Update involves an entirely separate process that is not specific to the FERC relicensing of the YRDP or the Narrows Project, or the issuance of new FPA licenses by FERC. However, because Yuba Water has been and remains involved in supporting the Draft Bay-Delta Plan Update process, this DEIR includes an analysis of Alternative 2 to provide insight into the potential impacts associated with a possible future "regulatory pathway" SWRCB Draft Bay-Delta Plan Update.

The SWRCB proposes a regulatory pathway that involves a 55% unimpaired flow requirement for the Bay-Delta Plan Update. If a 55% unimpaired flow requirement were adopted, it would be reasonable to expect that all of the FERC relicensing projects (i.e., YRDP, Narrows Project and the YB/DS projects) would be required (through WQCs) to operate in accordance with the conditions of the new FERC licenses that would be in effect, and conduct operations necessary to comply with a 55% unimpaired flow requirement.

Alternative 2 would include all non-flow components of the Proposed Projects. Similarly, Alternative 2 includes the same modeled operational assumptions as the Proposed Projects, including FERC's (2019) FEIS flow requirements in the North Yuba, Middle Yuba, and Yuba rivers that will become part of a new license for the YRDP and use of the variable-elevation intake for the New Colgate Powerhouse.

Compared to the Proposed Projects, Alternative 2 includes modifications to YRDP and Narrows Project operations, as well as similar operational changes to the upstream YB/DS projects under new FERC licenses, to comply with the following additional regulatory requirements under the SWRCB Draft Bay-Delta Plan Update:

- A requirement to provide 55% of the unimpaired Middle Yuba River
- A requirement to provide 55% of the unimpaired South Yuba River flow

- A requirement to provide 55% of the unimpaired Yuba River flow at its confluence with the Feather River
- A minimum end-of-September New Bullards Bar Reservoir storage of 600 TAF in Wet, Above Normal, and Below Normal years
- A minimum end-of-September New Bullards Bar Reservoir storage of 400 TAF in Dry and Critical years

Alternative 2 includes a representative operational scenario that could be implemented in response to the SWRCB Draft Bay-Delta Plan Update. Among other components, this scenario includes curtailment of agricultural surface water supply deliveries, as necessary, to meet the 600 TAF carryover storage requirement in New Bullards Bar Reservoir in Wet, Above Normal, and Below Normal years. In Dry and Critical years, Yuba Water would continue to curtail agricultural surface water deliveries, as necessary, to meet its existing carryover storage requirement of 440 TAF in the first dry or critical year of a sequence, and 400 TAF in subsequent dry or critical years. Agricultural surface water supplies also would be curtailed, as necessary, to meet the 55% of the unimpaired flow at the Marysville Gage.

ES.6.4 Comparison of Alternatives and Environmentally Superior Alternative

DEIR Chapter 25, Other CEQA Considerations, contains a comparison of the potential environmental impacts of the Proposed Projects and the alternatives, including the No Project Alternative, along with a comparison of consistency with the Proposed Projects objectives described in Section ES.3. The No Project Alternative would avoid the environmental impacts associated with proposed YRDP construction activities and new YRDP facilities that would occur under the Proposed Projects and Alternatives 1 and 2. However, the No Project Alternative would have significant and unavoidable individual and cumulative impacts related to power production and greenhouse gas emissions due to the complete loss of hydropower generation.

Alternatives 1 and 2 would include the same YRDP construction activities and non-flow YRDP and Narrows Project operations activities as the Proposed Projects; therefore, they would have the same environmental impacts associated with those activities. Impacts related to flow-based operations would generally be similar under the Proposed Projects and Alternative 1, though Alternative 1 would provide additional environmental benefits, while Alternative 2 would have more severe environmental impacts. Alternative 2 would result in more frequent and more severe surface water supply shortages that would lead to increased groundwater pumping such that groundwater levels would fall below local management levels. Additionally, Alternative 2 would result in significant losses in hydropower generation, which would in turn result in substantially higher indirect GHG emissions compared to the Proposed Projects and Alternative 1. When comparing the alternatives to the Proposed Projects objectives, Alternative 1 would meet all objectives and the Proposed Projects would meet most objectives. By contrast, Alternative 2 and the No Project Alternative would not meet a number of the Proposed Projects objectives.

As described in DEIR Chapter 25, CEQA Guidelines Section 15126(e)(2) requires identification of an "environmentally superior alternative." Based on the comparison of relevant impacts of the

alternatives, as described in Chapter 25, Alternative 1 is considered the environmentally superior alternative.

ES.7 Areas of Controversy and Issues to Be Resolved

Areas of controversy have been identified for the Proposed Projects, based on input provided as part of the FERC relicensing process for the YRDP and through comments provided during both the 2022 and 2024 CEQA scoping processes. Regarding the YRDP, the following areas of controversy have been identified to date:

- **Alternatives Analysis** – A total of ten alternatives were suggested by various parties, along with requests to evaluate each of these alternatives in the DEIR. In a number of cases, the suggested alternative was found to be (1) not feasible; (2) not warranted or justifiable under the FPA (as determined by FERC); (3) not protective or beneficial to fisheries resources; or (4) incongruous with Yuba Water's mission and because it would not achieve most of Yuba Water's project objectives. Chapter 3, Alternatives, presents the alternatives that were analyzed, which are summarized in Section ES.6 above. Chapter 3 also has additional information and supporting rationale regarding why specific alternatives were not evaluated in detail.
- **Clean Water Act Section 401 Compliance Issues -** The uncertainty of future CWA regulatory constraints imposed by the SWRCB's WQC Conditions that will be issued for the YRDP and the Narrows Project is an issue of concern with respect to potential changes to YRDP operations, and resultant changes in reservoir storage, flow release patterns, and water temperature regimes in the lower Yuba River.
- **Bay-Delta Water Quality Control Plan Update -** The uncertainty of future regulatory constraints associated with the SWRCB's Updates to the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary for the Sacramento River and its Tributaries, Delta Eastside Tributaries, and Delta (Bay-Delta Plan Update), and the potential for such regulatory constraints to adversely affect YRDP operations within the Yuba River Watershed, as well as flow and water temperature throughout the Central Valley, are of concern due to the potential for direct and redirected impacts on fisheries resources, water supply, water quality, and potentially other environmental resources.
- **Suggested Mitigation Measures -** Some commenters suggested that the DEIR should consider mitigation for YRDP impacts related to Large Woody Material (LWM) and sediment management on the North Yuba River below New Bullards Bar Dam that were not addressed in the FERC FEIS. Some commenters also suggested that that EIR should consider implementation of lower Yuba River floodplain restoration activities to accompany the riparian vegetation planning that was recommended by FERC in the 2019 FEIS.

Although this EIR evaluates multiple alternatives to the Proposed YRDP Project, Yuba Water ultimately only has discretion to accept the license that FERC issues for the YRDP, subject to any additional regulatory constraints issued by the SWRCB, or decline the license (evaluated as the No Project Alternative). Implementing Alternatives 1 and 2 would require action by entities other than Yuba Water, but those alternatives are evaluated in this EIR to inform those entities' decisions

during the relicensing process. To date, no specific areas of controversy or issues to be resolved have been identified for the Narrows Project.

ES.8 Public Review and Final EIR

This DEIR is being distributed to responsible and other potentially interested agencies, stakeholder organizations, and individuals for a 45-day review period. This distribution ensures that interested parties have an opportunity to express their views regarding the project's environmental impacts and ensures that information pertinent to permits and approvals is provided to decision makers and CEQA responsible and trustee agencies by the lead agency.

Yuba Water expects that the SWRCB will be a CEQA responsible agency. Yuba Water also expects that CDFW will be involved in the CEQA process because it is both a trustee agency for the state's fish and wildlife resources and a responsible agency for administering the California Endangered Species Act (CESA) and other provisions of the California Fish and Game Code that afford protection to the state's fish and wildlife public resources.

A Notice of Completion for this DEIR has been filed with the State Clearinghouse, in accordance with CEQA Guidelines Section 15085, and a Notice of Availability of this DEIR has been posted in accordance with CEQA Guidelines Section 15087. A public notice was sent to the Marysville Appeal-Democrat, the Mountain Messenger, and the Union on and to all previous commenters that have requested information regarding the proposed project. A list of Agencies and Tribes to which notice is distributed is available in Appendix ES-1.

Copies of this Draft EIR are also available to review at the Yuba Water office any business day between the hours of 9:00 a.m. and 4:00 p.m. at the address below or on the project website at: https://www.yubawater.org/.

Yuba County Water Agency
1220 F Street
Marysville, CA 95901

Copies of the Draft EIR are also available at the county offices of Yuba, Nevada, and Sierra Counties, and at the Yuba County Library in Marysville and the Nevada County Library in Grass Valley. The public review period for providing comments on this DEIR is from August 1, 2025 until close of business at 5:00 p.m. on September 15, 2025. Written comments or questions concerning the DEIR must be directed to the name and address below via postal mail or email by no later than 4:00 p.m. on September 15, 2025:

John James
Yuba County Water Agency
1220 F Street
Marysville, CA 95901
jjames@yubawater.org

After the 45-day public review period, comments regarding environmental issues received in response to the DEIR will be addressed in a response to comments document, which, together with

the DEIR and any changes to the text made in response to comments, or initiated by staff, will constitute the Final EIR (FEIR). After a public hearing on the proposed project, Yuba Water will review the FEIR, staff recommendations, and public testimony prior to certifying the FEIR and deciding whether to approve or deny the proposed project. Should Yuba Water approve the project even if the FEIR identifies significant impacts that cannot be mitigated, Yuba Water must state in writing the reasons for its actions. In accordance with CEQA Guidelines Section 15093(c), a Statement of Overriding Considerations must be included in the record of the project approval and mentioned in the Notice of Determination (NOD). The NOD shall be filed within five working days of approval with the State Clearinghouse and with the County Clerks of Yuba, Sierra, and Nevada Counties.

ES.9 Summary of Potential Impacts and Mitigation

CEQA requires that the environmental analysis contained in the DEIR also include a summary of a proposed project and its consequences, including an identification of each potentially significant impact of the project and its level of impact, proposed mitigation measures if applicable, and the level of impact after any mitigation measures are implemented. **Table ES-1** presents a summary of the impacts and mitigation measures identified for the Proposed Projects. A full description of each impact and mitigation measure is found in the appropriate technical EIR chapters, from Chapter 5 to Chapter 24.

ES.9.1 Mitigation Measures

The Proposed Narrows Project would not result in any potentially significant impacts. For impacts of the Proposed YRDP Project determined to be significant or potentially significant, the DEIR has identified feasible mitigation measures that would avoid or reduce most of these impacts to a level that would be less than significant. **Table ES-1** includes these mitigation measures, which were identified for the following environmental issues:

- Non-Fisheries Biological Resources – Special-status species, sensitive natural communities, and conflict with local biological resource ordinances (MM-BIO-1 through MM-BIO-16)
- Visual Resources – Light and glare during construction (MM-VIS-1)
- Air Quality – Conflicts with applicable air quality plans; cumulatively considerable net increases in criteria pollutants; other emissions (MM-AQ-1, MM-AQ-2)
- Wildfire – Emergency evacuations; exposure of people or structures to wildland fire risk (MM-WF-1)
- Noise – Noise from construction activities (MM-NOISE-1, MM-NOISE-2)
- Utilities - Relocation or Construction of New or Expanded Infrastructure (MM-UTIL-1)

ES.9.2 Significant and Unavoidable Impacts

Under CEQA, an EIR shall discuss any significant effect on the environment that cannot be avoided if a project is implemented. CEQA Guidelines § 15126.2(c) further specifies that

significant and unavoidable effects include those that can be mitigated but not reduced to a level of insignificance.

Significant and unavoidable impacts were described within each technical chapter of the DEIR, where appropriate. **Table 25.3-1** in Chapter 25, Other CEQA Issues, summarizes the significant and unavoidable impacts identified under the Proposed Projects and the alternatives. The Proposed Narrows Project would not result in any significant and unavoidable impacts. For the proposed YRDP Project, significant and unavoidable impacts were identified for the following environmental issues:

- Air Quality and Greenhouse Gas Emissions
- Transportation

These significant and unavoidable YRDP impacts would also occur under Alternative 1 and Alternative 2. In addition, the YRDP under Alternative 2 would have significant or potentially significant and unavoidable impacts on Surface Water Resources, Groundwater Resources, Energy, Surface Water Quality, Fisheries Resources, and Recreation, and the Narrows Project under Alternative 2 would have significant and unavoidable impacts on Energy. Under the No Project Alternative, the YRDP and the Narrows Project would have significant or potentially significant and unavoidable impacts on Energy and Air Quality and Greenhouse Gas Emissions.

ES.9.3 Cumulative Impacts

This DEIR provides an analysis of cumulative impacts of the Proposed Projects taken together with other past, present, and probable future projects producing related impacts, as required by CEQA Guidelines Section 15130. Cumulative impacts are defined in CEQA Guidelines Section 15355 as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts." A cumulative impact occurs from the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects.

Each resource chapter of this DEIR discusses whether there would be a potentially cumulative significant environmental impact from the Proposed Projects' effects in combination with those of closely related past, present, and reasonably foreseeable probable future projects and determines whether the Proposed Projects or a Project Alternative could make a cumulatively considerable contribution to any cumulatively significant impacts. "Cumulatively considerable", as defined in CEQA Guidelines Section 15130, means that the incremental effects of the individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects.

Each resource chapter in this DEIR contains a Cumulative Impact Assessment that describes the cumulative condition with the Proposed Projects and the alternatives, then assesses the cumulative contribution of the Proposed Projects and alternatives. **Tables 25.5-1** and **25.5-2** in Chapter 25, Other CEQA Issues, summarize the significance of the cumulative impacts under the Proposed Projects and the alternatives for the YRDP and Narrows Project, respectively, for each environmental issue analyzed in this DEIR. The proposed Narrows Project would not result in any potentially significant cumulative impacts. For the proposed YRDP Project, significant cumulative impacts were identified for the following environmental issues:

- Air Quality and Greenhouse Gas Emissions
- Transportation

Table ES-1. Summary of Impacts and Mitigation Measures, Proposed Projects.

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
Chapter 5 - Surface Water Resources			
EXISTING CONDITION			
YRDP Impact SW-PP-1: Rate or Amount of Surface Runoff from YRDP Operations	LTS	None required.	--
YRDP Impact SW-PP-2: Impede or Redirect Flood Flows	LTS/PB	None required.	--

Chapter 10 - Non-Fisheries Biological Resources			
EXISTING CONDITION – AREAS UPSTREAM OF ENGLEBRIGHT DAM			
YRDP Impact BIO-PP-1: Proposed YRDP Construction Impacts on Special-Status Species	S	**MM-BIO-1:** Project Footprint constrains work to the minimum required to get the work done and directs as much as possible to occur in previously disturbed locations, as well as flagging the bounds of work to keep construction activities from wandering outside the boundaries. This will minimize loss of habitat and individuals of the species. **MM-BIO-2:** Garbage and Trash keeps work areas free of garbage, including microtrash, which can damage habitat, especially if it spreads outside of the work areas to surrounding habitats. Some species may also eat garbage, which can make them sick or even kill them. Alternatively, species feeding on garbage may become dependent on or too socialized to humans, which can make them pests and/or unable to exist in the wild. **MM-BIO-3:** Vehicular Best Management Practices will keep vehicles on established roads and other areas for driving and fueling/maintenance, as well as restrain the speed of the vehicles. This will limit destruction of habitat from crushing and fuel spills, as well as collisions that can cause injury or death of species on or near roads and other construction areas. **MM-BIO-4:** Clean Fill will minimize the use of imported fill, and if needed, imported fill will be from clean sites and weed-free. This will limit secondary impacts to work areas and the species that inhabit them by preventing the introduction of non-native species and/or contaminated fill which would degrade sites. **MM-BIO-5:** Worker Environmental Awareness Program will provide all workers on projects with information on the special-status species that may be on or near the work area and the requirements for their protection. This training assists in the implementation of required protective measures, such that they are effective in protecting species and habitat, as required by the CEQA document (as well as license measures, management plans and other permits). **MM-BIO-6:** Flagging Sensitive Resources would mark for avoidance any sensitive resources that need to be retained in or near work areas to keep equipment and workers out of known occurrences of special-status species (such as special-status plants), sensitive habitats (such as milkweed occurrences) or other sensitive areas (such as wetlands or riparian vegetation) during project activities. This will prevent direct harm to species, such as death or injury, and indirect, such as damage to habitat or disturbance by vibrations or dust.	LTSM

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
		MM-BIO-7: Minimization of Vegetation Removal would limit any removal or disturbance of vegetation to the minimum necessary, preventing destruction or damage to special-status species habitat by project activities. Additionally, oaks with a diameter at breast height (DBH) of 6 inches or greater and native trees with a DBH of 30 inches or greater will be avoided, as well as other sensitive habitats. This would include flagging/fencing of riparian habitat, other sensitive habitats, and larger oaks and native trees. **MM-BIO-8:** Special-Status Semi-Aquatic Species Protection requires clearance surveys of appropriate habitats for semi-aquatic species. For work under the Sediment Management Plan, species will be relocated. For all other work, species will be allowed to leave the area of their own volition, per **MM-BIO-13**. These sweeps prevent direct harm to species via trampling, crushing or other injury, as well as limiting non-flow-related indirect harm by pausing work until species clear the work area. **MM-BIO-9:** Avoid Work in Flowing Water would prevent equipment, except pumps, from being used in flowing water. This protects fouling of both work areas and downstream habitats by sediment or other materials that would be stirred up by equipment. Sensitive aquatic and semi-aquatic species may be harmed or their habitat damaged by sediment or other plumes of material, as well as leakage or sloughing of materials off equipment in flowing water. **MM-BIO-10:** Migratory Bird and Raptor Surveys requires any clearing and/or construction activities taking place between February 1 and August 31 have nesting bird surveys occur no more than a week prior to start. If active nests are located a protective buffer will be established for the duration of the work or until the nest is inactive. Construction activities can directly remove or destroy nests, but may also cause nest abandonment or lower chick success due to disturbance. **MM-BIO-11:** No Net Loss of Sensitive Habitat mandates that any permanent loss of sensitive communities, as identified in this document, would be mitigated for at a 1:1 ratio. This prevents permanent destruction of already rare habitat, such as wetlands and riparian communities, which often serves as the habitat for special-status plants and wildlife, as well. **MM-BIO-12:** Pre-construction Surveys will identify occurrences of special-status species or their habitats in areas that have not been surveyed recently, such that impacts to species and habitat may be more accurately determined and required avoidance and mitigation measures properly employed prior to and during activities. **MM-BIO-13:** Special-status Wildlife Species - If special-status wildlife enters a work area, they will be allowed to move out on their own and work will be paused in the area of the species, which will protect the species from death or injury from workers and equipment and other impacts of the work, such as noise, dust or vibrations.	

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
		MM-BIO-14: Excavations require that unattended excavations are covered, surrounded by exclusionary fencing, or have an escape ramp such that wildlife does not get trapped in an excavation. Excavations would also be checked prior to the start of excavations. These actions prevent small wildlife from being killed or injured during excavation activities. **MM-BIO-15:** Avoidance of Aquatic Habitat requires that all impacts to delineated aquatic resources would be limited to the amount necessary for completion of work activities. This prevents death or injury of species within these areas, as well as destruction or damage to their aquatic habitat, which is also a sensitive resource. **MM-BIO-16:** Bat Protections requires that Project facilities will be surveyed for bats (if they have not been already) and humane exclusionary devices put in place between November 1 and February 28.

EXISTING CONDITION			
YRDP Impact TCR-PP-1: Project Impacts That May Cause a Substantial Adverse Change in the Significance of a TCR Listed or Eligible for Listing in the CRHR, or in a Local Register of Historical Resources	LTS	None required.	--
YRDP Cumulative Impact TCR-PP-1: Project Impacts That May Cause a Substantial Adverse Change in the Significance of a TCR Listed or Eligible for Listing in the CRHR, or in a Local Register of Historical Resources	LTS	--	--
Chapter 15 - Air Quality and Greenhouse Gas Emissions			
EXISTING CONDITION			
YRDP Impact AQ-PP-1: Conflicts with Applicable Air Quality Plan from Construction Activities	S	**MM-AQ-1:** Implement Best Management Practices to Reduce Emissions during Construction Standard conditions and best management practices from applicable state regulations or the local air district are listed below. • Haul trucks would be compliant with CARB's Truck and Bus Regulation, which mandates that nearly all trucks will be required to have 2010 or newer model year engines to reduce particulate matter and oxides of nitrogen emissions. • In accordance with the In-Use Off-Road Diesel Fueled Fleet Regulation, renewable diesel is required to be used. • A dust control plan would be required per NSAQMD Rule 226 Dust Control. This would be required by the air district and not considered a mitigation. The construction emissions calculated incorporate twice daily watering, which is a standard condition of dust control plans and would achieve a default PM10 and PM2.5 reduction of 61 percent. Other standard dust controls include limiting speeds to 15 mph on unpaved roads, suspending construction when winds exceed 20 mph, street sweeping/washing, seeding, and maintaining a minimum 6 inches of freeboard in the bed of a transport vehicle (NSAQMD 2024). • The FRAQMD recommends standard mitigation measures (for projects that do not exceed the construction thresholds of significance) and best available mitigation measures (for projects that do exceed the construction thresholds of significance) for construction as described below (FRAQMD 2024). Both standard and best available mitigation measures would be required. <u>Standard mitigation measures:</u> 1. Implement the Fugitive Dust Control Plan 2. Construction equipment exhaust emissions shall not exceed FRAQMD Regulation III, Rule 3.0, Visible Emissions limitations (40 percent opacity or Ringelmann 2.0).	LTSM

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
		3. The contractor shall be responsible to ensure that all construction equipment is properly tuned and maintained prior to and for the duration of onsite operation. 4. Limiting idling time to 5 minutes – saves fuel and reduces emissions. (State idling rule: commercial diesel vehicles-13 CCR Chapter 10 § 2485 effective 02/01/2005; off road diesel vehicles- 13 CCR Chapter 9 Article 4.8 § 2449 effective 05/01/2008) 5. Utilize existing power sources (e.g. power poles) or clean fuel generators rather than temporary power generators. 6. Develop a traffic plan to minimize traffic flow interference from construction activities. The plan may include advance public notice of routing, use of public transportation, and satellite parking areas with a shuttle service. Schedule operations affecting traffic for off-peak hours. Minimize obstruction of through-traffic lanes. Provide a flag person to guide traffic properly and ensure safety at construction sites. 7. Portable engines and portable engine-driven equipment units used at the Project work site, with the exception of on-road and off-road motor vehicles, may require California Air Resources Board Portable Equipment Registration with the State or a local district permit. The owner/operator shall be responsible for arranging appropriate consultations with the ARB or the District to determine registration and permitting requirements prior to equipment operation at the site. <u>Best available mitigation measures</u> 1. All grading operations on a Project should be suspended when winds exceed 20 mph or when winds carry dust beyond the property line despite implementation of all feasible dust control measures. 2. Construction sites shall be watered as directed by the Department of Public Works or Air Quality Management District and as necessary to prevent fugitive dust violations. 3. An operational water truck should be available at all times. Apply water to control dust as needed to prevent visible emissions violations and offsite dust impacts. 4. Onsite dirt piles or other stockpiled particulate matter should be covered, wind breaks installed, and water and/or soil stabilizers employed to reduce wind blown dust emissions. Incorporate the use of approved non-toxic soil stabilizers according to manufacturer's specifications to all inactive construction areas.	

		5. All transfer processes involving a free fall of soil or other particulate matter shall be operated in such a manner as to minimize the free fall distance and fugitive dust emissions. 6. Apply approved chemical soil stabilizers according to the manufacturers' specifications, to all-inactive construction areas (previously graded areas that remain inactive for 96 hours) including unpaved roads and employee/equipment parking areas. 7. To prevent track-out, wheel washers should be installed where Project vehicles and/or equipment exit onto paved streets from unpaved roads. Vehicles and/or equipment shall be washed prior to each trip. Alternatively, a gravel bed may be installed as appropriate at vehicle/equipment site exit points to effectively remove soil buildup on tires and tracks to prevent/diminish track-out. 8. Paved streets shall be swept frequently (water sweeper with reclaimed water recommended; wet broom) if soil material has been carried onto adjacent paved, public thoroughfares from the Project site. 9. Provide temporary traffic control as needed during all phases of construction to improve traffic flow, as deemed appropriate by the Department of Public Works and/or Caltrans and to reduce vehicle dust emissions. An effective measure is to enforce vehicle traffic speeds at or below 15 mph. 10. Reduce traffic speeds on all unpaved surfaces to 15 miles per hour or less and reduce unnecessary vehicle traffic by restricting access. Provide appropriate training, onsite enforcement, and signage. 11. Reestablish ground cover on the construction site as soon as possible and prior to final occupancy, through seeding and watering. 12. Disposal by Burning: Open burning is yet another source of fugitive gas and particulate emissions and shall be prohibited at the Project site. No open burning of vegetative waste (natural plant growth wastes) or other legal or illegal burn materials (trash, demolition debris, et. al.) may be conducted at the Project site. Vegetative wastes should be chipped or delivered to waste to energy facilities (permitted biomass facilities), mulched, composted, or used for firewood. It is unlawful to haul waste materials offsite for disposal by open burning. **MM-AQ-2:** Implementation of Emission Reducing Equipment and Develop Equipment and Vehicle Inventory Yuba Water will require contractors to include the use of Tier 4 final or other emission reducing equipment, where feasible, into engineering plans and bid documents. Yuba Water will require its contractor to prepare a comprehensive inventory list (i.e., make, model, engine year, horsepower, emission rates) of all heavy-duty (equal to or greater than 50 horsepower) off-road (portable and mobile) equipment that will be	

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
		used an aggregate of 40 or more hours for the construction Project including owned, leased, and subcontractor vehicles). The contractor will calculate the emissions as compared to FRAQMD and NSAQMD thresholds of significance for air quality and submit their findings to the appropriate air district prior to commencing construction. Estimated emissions will be shown to be below the thresholds for ROG, NOx, and PM or will need re-evaluation and coordination with the appropriate air district to achieve compliance with the thresholds. The Project will provide a monthly summary of heavy-duty off-road equipment usage to FRAQMD and NSAQMD, as appropriate, throughout Project construction. A final summary at the end of construction for each major construction activity will be submitted to FRAQMD and NSAQMD, as appropriate, within 60 days of completion. Data to be collected includes construction equipment (number of pieces of each equipment type, model year, engine horsepower and tier, hours of operation for each type), haul trucks (number of heavy-duty haul truck trips, on-road and off-road distance for haul truck trips), number of construction workers per day, and total volume of cut/fill.	
YRDP Impact AQ-PP-2: Conflicts with Applicable Air Quality Plan from Operations	SU	None feasible.	--

Chapter 17 - Hazards and Hazardous Materials			
EXISTING CONDITION			
YRDP Impact HAZ-PP-1: Construction of proposed YRDP facilities, or operations of existing YRDP facilities, that would create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials.	LTS	None required.	--
YRDP Impact HAZ-PP-2: Construction of proposed YRDP facilities, or operations of existing YRDP facilities, that would create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.	LTS	None required.	--
YRDP Impact HAZ-PP-3: Construction of proposed YRDP facilities, or operations of existing YRDP facilities, that would impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan	LTS	None required.	--
Narrows Impact HAZ-PP-1: Operations of existing Narrows Project facilities that would create a significant hazard to the public or the	LTS	None required.	--

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
environment through the routine transport, use, or disposal of hazardous materials.			
Narrows Impact HAZ-PP-2: Operations of existing Narrows Project facilities that would create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment	LTS	None required.	--
Narrows Impact HAZ-PP-3: Operations of existing Narrows Project facilities that would impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan	NI	None required.	--
YRDP Cumulative Impact HAZ-PP-1: Potential for significant cumulative hazards and hazardous materials impacts resulting from the construction or operation of YRDP facilities.	LTS	--	--
Narrows Cumulative Impact HAZ-PP-2: Potential for significant hazards and hazardous materials impacts resulting from the operations of Narrows facilities.	LTS	--	--
Chapter 18 - Wildfire			
EXISTING CONDITION			
YRDP Impact WF-PP-1: Construction Impacts on Emergency Response Plans or Emergency Evacuation Plans	LTS	None required.	--
YRDP Impact WF-PP-2: Operational Impacts on Emergency Response Plans or Emergency Evacuation Plans	PS	**MM-WF-1.** Yuba Water, in coordination with the Yuba County Office of Emergency Services and the Yuba Watershed and Fire Safe Council, shall prepare a plan to be implemented in the event that visitors to Yuba Water recreation facilities and Yuba Water employees and contractors cannot be safely evacuated from a wildfire that spreads to the Project Area and vicinity. This plan may include, but is not limited to, shelter-in-place procedures and designation of temporary refuge areas, which may include but are not limited to parking lots and outdoor gathering areas. This plan is to be implemented as a last resort and in no way shall be interpreted as to allow Yuba Water visitors, employees, and contractors to ignore evacuation notices, whether advisory or mandatory.	LTSM
YRDP Impact WF-PP-3: Construction Impacts on Exposure of Project Occupants to Pollutant Concentrations or Uncontrolled Spread of Wildfire	LTS	None required.	--
YRDP Impact WF-PP-4: Operational Impacts on Exposure of Project Occupants to Pollutant Concentrations or Uncontrolled Spread of Wildfire	LTS	None required.	--
YRDP Impact WF-PP-5: Construction Impacts Related to Installation or Maintenance of Associated Infrastructure	LTS	None required.	--
YRDP Impact WF-PP-6: Operational Impacts Related to Installation or Maintenance of Associated Infrastructure	LTS	None required.	--
YRDP Impact WF-PP-7: Construction Impacts on Exposure of People or Structures to Significant Risks Resulting from Runoff, Post-fire Slope Instability, or Drainage Changes.	LTS	None required.	--

Narrows Cumulative Impact TRANS-PP-1: Potential for significant cumulative transportation resulting from the Narrows Project.	NI	--	--

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
Chapter 20 - Noise			
EXISTING CONDITION – AREAS UPSTREAM OF ENGLEBRIGHT DAM			
YRDP Impact NOISE-PP-1: Construction Impacts on Ambient Noise	S	**MM-NOISE-1.** Yuba Water will require its primary contractor(s) for engineering design and construction to implement the following measures to avoid and minimize construction noise effects on sensitive receptors. Measures that will be used to limit noise will include, but not be limited to, the measures listed below. • No construction will be performed within 1,000 feet of an occupied dwelling unit on Sundays, legal holidays, or between the hours of 10:00 p.m. and 7:00 a.m. on other days without the approval of the Yuba Water construction project manager. • All equipment used will have sound-control devices no less effective than those provided on the original equipment. No equipment will have unmuffled exhaust. All equipment will comply with pertinent equipment EPA noise standards. • All construction activities shall not exceed the maximum noise standards set forth in the Yuba County General Plan for non-transportation noise sources at noise-sensitive land uses, as required by Yuba County Code § 11.26.050. This shall also include any recreation facilities open in the area during any construction work in the open season (April 15 – October 15), The contractor shall implement any noise-reduction measures to achieve the Yuba County General Plan standards, including but not limited to noise barriers and use of electric equipment. These measures shall be incorporated within final construction specifications. These measures need not be applied during the time the recreation facilities are regularly closed, or if the contractor can demonstrate that non-recreation noise-sensitive land uses would not be exposed to noise levels exceeding Yuba County General Plan standards. • Construction and haul routes will be planned to minimize construction and traffic during nighttime hours, and route haul traffic away from residential receptors to the extent feasible and practicable. • A disturbance coordinator will be designated. The disturbance coordinator's phone number will be conspicuously posted around the construction site, in adjacent public spaces, and in construction notifications. The disturbance coordinator will be responsible for responding to any complaints about construction activities. The disturbance coordinator will receive all public complaints about construction disturbances and be responsible for determining the cause of the complaint and implement any feasible measures to alleviate the complaint.	LTSM

Impact	Significance Before Mitigation	Mitigation Measure	Significance After Mitigation
		The disturbance coordinator will have the authority to halt noise-generating activity, if necessary and feasible, to protect public health. **MM-NOISE-2.** The following measures will be implemented to notify nearby residences and recreationists of construction work activities: • Signage will be posted at the Emerald Cove Marina and nearby recreation areas such as the Yuba Rim Trail, New Bullards Bar Trail, Cottage Creek boat launch, and the Dark Day boat launch notifying people that excessive noise generation from construction activities will occur at times. • Prior to implementing any nighttime (10:00 p.m. – 7:00 a.m.) construction work that is approved by the Yuba Water construction project manager per Mitigation Measure MM-NOISE-1, residences within a 0.75-mile radius of the construction site will be notified in writing (email or letter) at least 48 hours in advance of any potential or planned nighttime construction work with the estimated schedule (dates) for such nighttime work. In addition, the same notification of potential nighttime construction work will be posted at the Emerald Cove Marina.

Narrows Cumulative Impact PS-PP-1: Potential for significant cumulative public service impacts resulting from the Narrows Project.	NI	--	--
Chapter 24 - Utilities and Service Systems			
EXISTING CONDITION			
YRDP Impact UTIL-PP-1: Relocation or Construction of New or Expanded Infrastructure	PS	**MM UTIL-1.** Prior to start of construction, Yuba Water will implement the following measures to avoid and minimize potential damage to utilities and infrastructure: • Coordinate with applicable utility and service providers to implement orderly relocation of utilities that need to be removed or relocated. • Provide notification of any potential interruptions in service to the appropriate agencies and affected landowners. • Verify through field surveys and Underground Service Alert service the locations of buried utilities on the construction site, including but not limited to electrical and water lines. Any buried utility lines will be clearly marked in the construction area (e.g., in the field) and on the construction specifications in advance of any earthmoving activities. • Prepare and implement a response plan that addresses potential accidental damage to a utility line. The plan will identify chain-of-command rules for notification of authorities and appropriate actions and responsibilities regarding the safety of the public and workers. A component of the response plan will include worker training on responses to accidental damage. • Stage utility relocations prior to and during construction to minimize interruptions in service. • Coordinate with PG&E to relocate electrical and other transmission lines and associated infrastructure such as power poles.	LTSM

CHAPTER 1

INTRODUCTION

The Yuba County Water Agency (Yuba Water) was established by State legislation in 1959 to reduce flood risk and to provide a sustainable water supply for the people of Yuba County. Yuba Water owns and operates the Yuba River Development Project (YRDP) and the Narrows Hydroelectric Project (Narrows Project), both of which are hydroelectric projects that operate separately pursuant to individual licenses issued by the Federal Energy Regulatory Commission (FERC) under the Federal Power Act (FPA). Yuba Water is seeking renewal of its two FERC licenses to continue operation and maintenance (O&M) of both projects. Yuba Water is the lead agency under the California Environmental Quality Act (CEQA) for environmental consideration of acceptance of the FERC license renewals for both projects. Yuba Water has elected to prepare a joint environmental impact report (EIR) for the YRDP and the Narrows Project relicensings. This Draft EIR (DEIR) evaluates the potential environmental impacts of the proposed renewals of the FERC licenses for the YRDP and the Narrows Project, respectively.

The YRDP (FERC Project No. 2246) currently operates under a 50-year license that was originally issued on May 16, 1963 by the Federal Power Commission, predecessor of FERC, for the period from May 1, 1963 through April 30, 2013. The Federal Power Commission's May 6, 1966, Order Amending License changed the license's effective date to May 1, 1966, for a term ending on April 30, 2016. Since the existing license expired in 2016, FERC has issued Yuba Water an automatically renewing annual license that allows operation of the YRDP under the existing license until FERC issues the new license with updated terms and conditions. On April 28, 2014, Yuba Water filed an application for a new 50-year license with FERC to continue to operate and maintain the YRDP.[1] On June 5, 2017, Yuba Water filed an amended license application (errata filed July 21, September 15, and November 1, 2017) for the YRDP.[2] Yuba Water has requested a new 50-year license for the YRDP because Yuba Water anticipates incurring substantial expenses during the remainder of the existing license and under the new license term for modifications to its generation facility, the addition of a flood control outlet, and implementing protection, mitigation, and enhancement (PM&E) measures, including constructing and refurbishing recreation facilities and access roads thereto.

Similarly, the Federal Power Commission issued an original license for the Narrows Project (FERC Project No. 1403) to the Pacific Gas and Electric Company (PG&E) on August 1, 1941,[3] and FERC issued a new project license to PG&E on February 11, 1993, for the period from February 1, 1993 through January 31, 2023. On January 26, 2018, FERC approved PG&E's request to extend the license term to January 31, 2026. On May 2, 2019, FERC approved the transfer of the license from PG&E to Yuba Water. On November 14, 2023, Yuba Water filed an application for a new license with FERC to continue to operate and maintain the Narrows Project. Yuba Water has requested a new license term of 50 years for the Narrows Project that would end concurrently with the term of the new license that FERC issues for the YRDP. Although Yuba Water is not proposing changes to the Narrows Project that would ordinarily justify a new 50-year

[1] Available in FERC's eLibrary at Accession No. 20140428-5072 (Filed on April 28, 2014).

[3] 62 FERC ¶ 62,093 (1993). FERC's predecessor, the Federal Power Commission, issued an original license for the Narrows Project in 1941. 2 F.P.C. 892 (1941).

license term, it is in the public interest, and consistent with FERC's 2017 Policy Statement (82 FR 49501) on establishing license terms to coordinate license terms for projects located in the same river basin. As described in this DEIR, the Narrows Project and the YRDP's Narrows 2 Development are co-located at the U.S. Army Corps of Engineers (USACE) Englebright Dam and have coordinated operations. Accordingly, Yuba Water determined that it would be most appropriate to address the environmental impacts of relicensing both the YRDP and the Narrows Project in the same CEQA document.

1.1 Type and Purpose of this CEQA Document

Pursuant to the National Environmental Policy Act (NEPA) of 1969, FERC must consider the environmental impacts of proposed major Federal actions as part of its decision-making process, including issuance of new FERC licenses to Yuba Water for continued O&M of the YRDP and the Narrows Project. In 2019, FERC, along with the USACE as a cooperating agency, issued a Final Environmental Impact (FEIS) Statement for Hydropower License, YRDP, Project No. 2246-065 – California in accordance with NEPA and FERC regulations (Title 18 Code of Federal Regulations Part 380). The FERC and USACE (2019) FEIS[4] included detailed environmental analyses of the YRDP, including licensee-proposed PM&E measures recommended for inclusion in the new license for continued operation of the YRDP. Subsequently, FERC sent Yuba Water an Additional Information Request (AIR)[5] on March 8, 2021 to further inform FERC staff's analysis in a forthcoming supplemental EIS (SEIS) for the YRDP (FERC 2021). To date, FERC has not issued a NEPA environmental compliance document for the Narrows Project. However, as a step forward, FERC issued a "*Notice of Application Ready for Environmental Analysis* [REA] *and Soliciting Comments, Recommendations, Terms and Conditions, and Prescriptions*" for the Narrows Project on February 26, 2025, which included a 60-day comment period scheduled to end on April 28, 2025.

Similarly, CEQA (Pub. Res. Code §§21000-21189.3) requires state and local government agencies to follow specified procedures to identify any significant environmental impacts of their proposed actions and to avoid or mitigate those impacts whenever feasible. CEQA applies to all discretionary activities proposed to be undertaken or approved by California state agencies, such as the State Water Resources Control Board (SWRCB) and the California Department of Fish and Wildlife (CDFW), or local government agencies such as Yuba Water. Compliance with CEQA is necessary to inform the future discretionary action of Yuba Water's Board of Directors to accept the new FERC licenses issued by FERC. Issuance of the new licenses by FERC would allow Yuba Water to continue to generate electricity at the 361.9-megawatt (MW) capacity YRDP and at the 12-MW capacity Narrows Project for the term of the new licenses (default license terms are for 40 years, but FERC may issue the license for up to 50 years).

Yuba Water previously issued a Notice of Intent (NOI) to rely on the 2019 FERC FEIS, in combination with a Supplemental Analysis, to satisfy CEQA for the YRDP Relicensing (State Clearinghouse Number 2022110118) and held CEQA public scoping meetings during the NOI

[4] As described above, it is recognized that the 2019 FEIS for the YRDP was prepared by both FERC and the USACE (as a cooperating agency under NEPA). For ease of use throughout this document, the 2019 FEIS is generally referred to as "FERC (2019)" or "FERC's FEIS" from this point forward in this document because: (1) the most substantive decision-making will be made by FERC; and (2) FERC was the lead author of the FEIS.

[5] Available in FERC's eLibrary at Accession No. 20210308-3037 (Filed on March 8, 2021).

public comment period. FERC informed Yuba Water of its plans to prepare a SEIS and a revised biological assessment (BA) (see additional discussion below under Section 1.2.1). FERC explained that the SEIS will address new information in the administrative record and may revise FERC staff's preferred project alternative. To date, FERC has not yet issued the SEIS for the YRDP or a NEPA environmental compliance document for the Narrows Project, and the timing of these pending federal actions is unknown. As a result, Yuba Water no longer intends to rely on the FEIS and a Supplemental Analysis for CEQA compliance for the YRDP Relicensing.

Because FERC is preparing a supplement to the 2019 FEIS for the YRDP and has not yet issued a NEPA environmental compliance document for the Narrows Project, Yuba Water has elected to prepare a new, standalone EIR for both the YRDP and the Narrows Project relicensings to comply with CEQA. This DEIR evaluates the potential environmental impacts of the proposed renewal of Yuba Water's FERC licenses for both the YRDP and the Narrows Project.

As the local governmental agency with the authority to accept the new FERC licenses, Yuba Water is the lead agency for the CEQA process for the YRDP and Narrows Project relicensings and expects that the SWRCB will be a CEQA responsible agency. Yuba Water also expects that CDFW will be involved in the CEQA process because it is both a trustee agency for the state's fish and wildlife resources and a responsible agency for administering the California Endangered Species Act (CESA) and other provisions of the California Fish and Game Code that afford protection to the state's fish and wildlife public resources (CEQA Guidelines § 21070 and 21069).

This DEIR has been prepared in accordance with CEQA (Public Resources Code, § 21000 et seq.) and the CEQA Guidelines (Cal. Code Regs. Title 14, § 15000 et seq.), consistent with Public Resources Code Section 21083.5 and Cal. Code Regs. Title 14, § 15221.

1.2 Project Background and History

1.2.1 Yuba Water's Mission and its Relationship to the YRDP

Yuba Water is seeking renewal of its FERC license for the YRDP to continue to provide a source of hydroelectric power, in addition to providing flood control and serving as a water supply for both domestic and irrigation purposes. Project benefits include water supply, flood control, recreation, fish and wildlife habitat, and power generation (YCWA 2010).

The project purpose and objectives (see Chapter 2) depend on the broader purposes of Yuba Water and, therefore, the YRDP. In 1955, a devastating flood on the Feather River killed 38 people, left more than 4,000 injured and forced the evacuation of 40,000 residents from their homes. The cost of the damage was reported to amount to $100 million, equivalent to $3.4 billion in 2024 (Villarreal 2024; YCWA 2024a). In addition, due to the presence of the 15,000 acres of hydraulic mining debris located immediately south of the Yuba River in the Yuba Goldfields, farmers in south Yuba County were unable to access water from the Yuba River, and the resulting groundwater pumping created a long-term overdraft in the area (YCWA 2019).

In 1959, the Legislature created Yuba Water by enacting the Yuba County Water Agency Act. (Cal. Stats. 1959, ch. 788, §§ 1-28, pp. 2780-2798.) The Legislature found that the special creation of Yuba Water was necessary as follows:

> The Legislature hereby finds that water problems in the County of Yuba require countywide water conservation, flood control and development of water resources; that all land within the county will be benefited thereby; that the solution of these problems lies within and is peculiar to the area to be included in the Yuba County Water Agency; that the county for many years has made investigations and engineering surveys of the county's water resources by private, public and United States engineers; that county water districts, municipalities, irrigation districts and reclamation districts now exist within portions of the county, have acquired property and works, developed a limited water supply, and have incurred indebtedness, but have been and are unable alone to economically develop an adequate water supply and control the floods of said county, and for such reason it is necessary to have a political entity at least coextensive with the geographical limits of the entire county. It is therefore hereby declared that a general law cannot be made applicable to said county, and that the enactment of this special law is necessary for the conservation, development, control and use of said water for the public good and for the protection of life and property therein (Cal. Stats., ch. 788, § 26, p. 2798.).

The Legislature authorized Yuba Water "*to do any and every lawful act necessary in order that sufficient water may be available for any present or future beneficial use or uses of the lands or inhabitants within the agency*." (Cal. Stats. 1959, ch. 788, § 4, p. 2783.) More specifically, and recognizing that hydroelectric generation was likely to be a significant source of revenue for Yuba Water, the Legislature authorized Yuba Water to develop hydroelectric generation, enter into related contracts for terms not to exceed 50 years, and "*to pledge the revenue therefrom for the payment of principal and interest on revenue bonds*." (Cal. Stats. 1959, ch. 788, § 4.1, p. 2783; see also Cal. Stats. 1959, ch. 788, §§ 4.7, 4.11, pp. 2784-2785 (authorizing Yuba Water to take other acts concerning hydroelectric power)).

Events following the Legislature's creation of Yuba Water have demonstrated the critical importance of the YRDP's operations to Yuba County's people. In 1964, before Yuba Water was able to build the YRDP, another deadly flood struck Yuba County (USGS 2014). In 1969, however, Yuba Water was able to operate the partially constructed YRDP to reduce Yuba River flood flows (Perini News 1969). In the mid-1980s, Yuba Water began providing Yuba River water made available by the YRDP to farms in south Yuba County and the groundwater in that area has recovered to levels that are sustainable for the long term (YCWA 2019).

As anticipated by the Legislature's authorization of Yuba Water to not only generate hydroelectric power, but also to rely on the resulting revenues to finance the YRDP generally, those revenues have been, and remain, critical for Yuba Water in implementing its statutory missions as assigned by the Legislature. Under Yuba Water's current FERC license, it contracted with PG&E to sell all the electricity that the YRDP generated to PG&E, with PG&E's payments to Yuba Water then providing the revenues necessary for Yuba Water to repay the bonds that financed the YRDP's

construction. Revenue generated by sales of the YRDP's electrical generation are critical for Yuba Water to implement its statutory missions.

Because Yuba Water no longer operates the YRDP under an agreement with PG&E, Yuba Water will be solely responsible under the new license for costs associated with YRDP's ongoing operations and any capital improvements necessary to achieve Yuba Water's flood-control and water-supply missions. For example, Yuba Water has proposed to construct and operate an Atmospheric River Control (ARC) Spillway at the YRDP's New Bullards Bar Dam in order to improve downstream flood control (YCWA 2023b). The ARC Spillway's estimated cost (2023 dollars) is about $210,570,000 million (YCWA 2023c). To the extent that federal and state funds are not available to support the ARC Spillway's construction, Yuba Water will need to fund the construction of the ARC Spillway, and revenues from the YRDP's hydroelectric generation would be the primary source of such funding. Similarly, Yuba Water will rely on revenue from YRDP sales to maintain the YRDP facilities over the term of the new license and beyond. This will be a very significant financial obligation for Yuba Water. For example, the YRDP's New Bullards Bar Dam is now 55 years old and is a 675-foot-high concrete arch dam. Its maintenance will be critical to sustain the flood-control and water-supply benefits it provides to Yuba County and to ensure its indefinite structural integrity.

Revenue from the YRDP also enables Yuba Water to make substantial water-related investments to support Yuba County's disadvantaged communities (DACs). Yuba County is one of the most economically disadvantaged counties in California, with the majority of its population living in DACs as identified by the State of California (SCDD 2024). Since 2016, when the power purchase agreement between PG&E and Yuba Water ended, Yuba Water has been able to make over $92.9 million in substantial investments in water-related programs and improvements throughout Yuba County to improve conditions in the County's DACs. Given Yuba County's general economic condition, Yuba Water is the only source of local funding for such programs and improvements. For example, Yuba Water is the only available source of funds to make the local match that is often required for federal and state grants for water-related projects. Since 2016, Yuba Water has provided grant funding to support various initiatives, including the agency's core mission areas of flood risk reduction ($66.4 million) and water supply management ($14.9 million), as well as forest health and water resilience ($6.5 million).

The continuation of revenues from the YRDP's hydroelectric generation under a new license also will be critical for Yuba Water to continue to fund significant environmental projects that will continue Yuba Water's efforts to address the long-term damage to conditions for sensitive fish—including Chinook salmon, steelhead and green sturgeon—in the lower Yuba River caused by hydraulic mining and facilities owned by others. Hydraulic mining in the 1800s obliterated the Yuba River's original channel by releasing an amount of earth and other debris that was more than three times the amount of earth excavated to build the Panama Canal (Gilbert 1917) as cited in Yoshiyama et al. (2001). In an effort to control this debris, the federal government built several facilities in the lower Yuba River that, among other things, still block or impede migration of salmonids and other fish through the lower Yuba River. It is well-documented that, before Yuba Water constructed and began operating the YRDP in the late 1960s, conditions in the lower Yuba River were extremely detrimental for fish (Wooster 1963; Wooster & Wickwire 1970). For example, in 1960, CDFW built a barrier across the mouth of the lower Yuba River to prevent salmon from migrating upstream into the river until later in the year, when more stable streamflows

would be available (Wooster & Wickwire 1970). It also is well-documented that the YRDP's operations significantly improve conditions for fish in the lower Yuba River by providing more stable, and much cooler, streamflows during the summer and fall, relative to conditions that existed, and would exist, without the YRDP (YCWA 2017a; YCWA 2017b; YCWA et al 2007).

To maximize the value of these YRDP benefits, Yuba Water has used its hydroelectric revenues, in combination with other funds, to improve physical habitat and fish passage in the lower Yuba River. For example, Yuba Water spent $3 million of its revenues to support construction of the Hallwood Side Channel and Floodplain Restoration Project[6] (Hydro Review 2023). That project was completed in 2023 (YCWA 2024a). Similarly, under a memorandum of understanding with CDFW and the National Marine Fisheries Service (NMFS) signed at a May 2023 event involving Governor Gavin Newsom, Yuba Water is working to design, construct and operate a Nature-Like Fishway that would enable volitional passage of Chinook salmon, steelhead, green sturgeon and other fish around USACE's Daguerre Point Dam on the lower Yuba River (YCWA 2023d). On February 18, 2025, Yuba Water's Board of Directors adopted Resolution No. 2025-05 finding that the Daguerre Point NLF Project is within the scope of the Statewide Restoration General Order Program EIR (SWRCB 2022), approved the NLF project and authorized execution of the Yuba River Resilience Initiative Agreement. Yuba Water anticipates that its share of this project's cost will be at least $30 million and anticipates using its hydroelectric revenues to support this commitment.

In addition to supporting Yuba Water's implementation of its statutory missions within Yuba County, the YRDP's hydroelectric generation provides significant benefits to the region's and to California's electrical grid. The YRDP has an installed capacity of 361.9 MW and generates approximately 1,418,044 MWh per year under existing conditions since the Lower Yuba River Accord (Yuba Accord) was approved.[7] Yuba Water currently sells all of the electrical output from the YRDP into the California Independent System Operator (CAISO) daily and real-time energy markets, and receives payment from the CAISO pursuant to the CAISO daily and real-time energy market payment rules. Generally, electrical generation scheduling is driven by water throughput requirements to meet regulatory flow requirements, consumptive demands, and flood control objectives.

The North American Electric Reliability Corporation (NERC) annually forecasts electrical supply and demand nationally and regionally for a 10-year period. The YRDP is located in the California/Mexico area of the Western Electricity Coordinating Council (WECC) region of NERC. According to NERC's 2023 forecast, net internal demand for the California/Mexico area is expected to increase from 56,349 MW to 64,566 MW over the period 2024 to 2033 (NERC 2023). NERC predicts that anticipated resource capacity will decline[8] over the same period; however, adequate reserve capacity would still be available. Beginning in the summer of 2024 onwards, the

[6] Various other grants (about $4.5 million) and in-kind contributions (about $45 million from Teichert) also supported the Hallwood Project.

[7] Yuba Water first implemented flows associated with the Yuba Accord in 2006 when it started a pilot project to study the effects of changes in flow on environmental resources. Yuba Water and stakeholders signed the Yuba Accord in 2007 and the SWRCB incorporated the terms of the Yuba Accord into the Yuba Water water right permits in 2008.

[8] The total capacity of traditional baseload generation fuel-types will continue to decline as older generators retire. For example, anticipated reductions will partially be due to 2.8 giga-watts (GW) of natural gas planned for retirement by the end of 2023, 1.2 GW of coal in 2025, and 2.3 GW of nuclear by the end of 2030) (NERC 2023).

California/Mexico subregion is anticipated to show a shortfall of electricity transfers, meaning that imports may be necessary if new resources were to be significantly delayed (NERC 2023).

Hydroelectricity generated from the YRDP would help meet a need for power in the California/Mexico subregion in both the short- and long-term. According to the California Energy Commission (CEC), electricity consumption statewide is projected to grow at an annual average compounded rate of 1.7% annually through 2040 (CEC 2023). The peak hour demand for the California/Mexico subregion occurs during the summer, and long-term demand in the subregion is expected to increase slightly (1.52% annualized average rate) since the previous forecast (NERC 2023). Yuba Water's proposed project would continue to meet part of existing load requirements within the system, which is in need of resources (NERC 2023).

Yuba Water is also proposing the project, in part, because the YRDP provides low-cost power that displaces generation from non-renewable resources (i.e., fossil-fired generation). Displacing the operation of non-renewable facilities may avoid some power plant emissions, thus creating an environmental benefit. New Colgate Powerhouse is a source of firm, dispatchable generation, which is useful for providing both peak summertime regional demands for energy and for providing ancillary services to the regional grid (e.g., spinning reserve). These ancillary services will likely have increasing importance as other non-dispatchable sources of intermittent power generation (e.g., wind and solar generation) are incorporated into the regional grid to help meet renewable portfolio standard requirements.

In addition to these benefits, YRDP hydroelectric generation also provides critical reliability benefits to the northern California electrical grid. The YRDP's New Colgate Powerhouse is a 340-MW facility and is a source of firm, dispatchable generation. The New Colgate Powerhouse is able to ramp from a no-generation operation to maximum generation within eight minutes. This extreme flexibility makes the New Colgate Powerhouse one of the most critical electrical sources in northern California for generating to meet both peak summertime energy demand and Automatic Generation Control response to ensure reliability of the CAISO grid. For example, during the most recent heat emergencies declared by Governor Newsom in August 2020 and September 2022, Yuba Water, at the request of the CAISO, increased generation output to assist the state in meeting extreme electrical demands and to avoid widespread blackouts (State of California 2020; 2022). The New Colgate Powerhouse's extremely flexible generation will likely have increasing importance as other non-dispatchable sources of intermittent power generation (e.g., wind and solar generation) are incorporated into the regional grid to help meet renewable portfolio standard requirements.

The YRDP's existing FERC license expired in 2016, but the YRDP continues to operate under annual licenses issued by FERC. As the above discussion demonstrates, obtaining a new license from FERC for the YRDP's generation of hydroelectricity is critical for Yuba Water to maintain the revenue sources that enable it to implement its statutory missions as assigned by the Legislature and to continue to provide critical support for the stability of the northern California electrical grid. If Yuba Water were unable to obtain, or accept, a new FERC license for the YRDP, the YRDP would be unable to continue to serve these purposes.

In addition to Yuba County-specific benefits, and broader electrical benefits that the YRDP produces, since the late 1980s, Yuba Water has been able to operate the YRDP to produce water supplies that Yuba Water has transferred to communities and water agencies in areas of California with significant unmet water demands, consistent with state policy enacted by the Legislature.[9] Since 1987, Yuba Water has operated the YRDP to transfer more than two million acre-feet of stored water to areas of need. In particular, since 2008 under the Yuba Accord, Yuba Water has transferred a reliable supply to contractors of the Central Valley Project (CVP), the State Water Project (SWP), and others in a total that has exceeded one million acre-feet as of 2022 (YCWA 2024c). These transfers occur under Yuba Water's Yuba Accord Water Purchase Agreement (Yuba Accord Water Purchase Agreement) with the state Department of Water Resources. The Yuba Accord's long-term implementation began in 2008 because the SWRCB, in its Corrected Order WR 2008-0014, incorporated Yuba Accord-based minimum streamflow requirements into Yuba Water's consumptive water-right permits for the YRDP and approved long-term Yuba Accord transfers through 2025 (SWRCB 2008).[10] Yuba Water's *Amended Application for a New License for Major Project – Existing Dam* (AFLA) submitted to FERC in 2017 for a new license for the YRDP incorporates, and is based on, the Yuba Accord minimum streamflow requirements.

The terms of a new license for the YRDP will be a critical factor determining whether Yuba Water is able to continue making water transfers to areas of need consistent with its last several decades of operation. Yuba Accord transfers depend on Yuba Water's implementation of the Yuba Accord minimum streamflow requirements. Transferable water is an increment of water that Yuba Water releases under the Accord requirements. In addition, significant changes to the Accord requirements could significantly impair, or eliminate, the volumes of water that Yuba Water can transfer because those changes could impact the water supplies that Yuba Water can deliver within Yuba County and any transfer water must be surplus to Yuba County's needs. Under the Yuba Accord Fisheries Agreement and the SWRCB's Corrected Order WR 2008-0014, the YRDP's new license will supersede the Yuba Accord's minimum streamflow requirements and therefore will determine whether Yuba Water is able to transfer water during the term of the new license.

As lead agency under CEQA, Yuba Water has developed this DEIR to inform: (1) the decision of Yuba Water's Board of Directors regarding the future discretionary action of accepting a new FERC license for the YRDP; and (2) decisions by state agencies with discretionary approval over some portion of the YRDP relicensing, including the SWRCB (issuance of a Clean Water Act (CWA) Section 401 Water Quality Certification (WQC) for the project) and CDFW (e.g., Streambed Alteration Agreement).

---

[9] Water Code section 109(a) states, "*It is hereby declared to be the established policy of this state to facilitate the voluntary transfer of water and water rights where consistent with the public welfare of the place of export and the place of import*." Water Code section 475 states, "*The Legislature hereby finds and declares that voluntary water transfers between water users can result in a more efficient use of water, benefiting both the buyer and the seller.* [¶] *The Legislature further finds and declares that transfers of surplus water on an intermittent basis can help alleviate water shortages, save capital outlay development costs, and conserved water and energy.*" In enacting statutes to govern the wheeling of water through conveyance facilities in 1986, the Legislature stated, "*It is the policy of the state to facilitate the voluntary sale, lease, or exchange of water or water rights in order to promote efficient use*." (Cal. Stats. 1986, ch. 918, § 1, p. 3171.)

[10] Under Water Code sections 386 and 1736, Yuba Water has filed a water-right petition to the SWRCB for authorization to continue Yuba Accord transfers through 2050 (SWRCB 2024; YCWA 2024b).

1.2.2 Yuba Water's Mission and its Relationship to the Narrows Project

Yuba Water is also seeking renewal of the FERC license for the Narrows Project to continue to provide a source of renewable, non-flexible base load energy as a hydroelectric generation facility (PG&E 2019). The Federal Power Commission issued an original license for the Narrows Project to PG&E on August 1, 1941,[11] and FERC issued a new license to PG&E on February 11, 1993,[12] effective for the period from February 1, 1993 through January 31, 2023. On January 26, 2018, FERC approved PG&E's request to extend the license term to January 31, 2026. On May 2, 2019, FERC approved the transfer of the license from PG&E to Yuba Water.

On November 14, 2023, Yuba Water filed an application for a new license with FERC to continue to operate and maintain the Narrows Project. Yuba Water has requested a new license term of 50 years for the Narrows Project that would end concurrent with the term of the new FERC license for the YRDP. Yuba Water's request for a 50-year license term is in the public interest and is consistent with FERC's 2017 Policy Statement (82 FR 49501) on establishing license terms to coordinate license terms for projects located in the same river basin. The Narrows Project and the YRDP's Narrows 2 Development[13] are co-located at the USACE's Englebright Dam and have coordinated operations.

Since the YRDP's construction, the YRDP and the Narrows Project have operated in coordination. The Narrows Project is unique in that it operates in coordination with Yuba Water's YRDP and the YRDP's Narrows 2 Development to provide flows to the lower Yuba River. In particular, coordinated operation of the Narrows 1 and Narrows 2 powerhouses have been critical for the protection of Chinook salmon, steelhead, and other fish in the lower Yuba River because the two powerhouses provide the only controllable means of releasing water to the lower Yuba River from behind USACE's Englebright Dam.[14] Additionally, the Narrows Project directly supports the proposed PM&E measures that are part of the FERC Staff Alternative for the YRDP that are being analyzed through FERC's ongoing NEPA analysis of the YRDP Project. As cited in FERC's (2019) FEIS for the YRDP, the Narrows 1 and Narrows 2 powerhouses both release water from the USACE's Englebright Dam and Reservoir and are operated collectively to provide the measures (e.g., downstream flows) analyzed in FERC's (2019) FEIS for the YRDP. It is due to this unique coordination and co-location of the Narrows 1 and Narrows 2 powerhouses that the studies, as well as the NEPA analysis performed in support of the ongoing YRDP relicensing, are directly applicable to the Narrows Project relicensing.

Although Narrows 1 and Narrows 2 operate in a coordinated manner, unlike the YRDP's operation, no water is withdrawn from Narrows Project facilities for irrigation, domestic water supply, steam-electric plant, industrial, or other consumptive purposes (YCWA 2023a). As presented throughout this DEIR, Yuba Water is not proposing any operational or structural

[11] 2 F.P.C. 892 (1941).

[12] 62 FERC ¶ 62,093 (1993).

[13] The Narrows 2 Development is a part of the YRDP that is located on the main stem of the lower Yuba River immediately downstream of USACE's Englebright Dam. The development includes the following features: (1) Narrows 2 Powerhouse Penstock; (2) Narrows 2 Full Bypass; (3) Narrows 2 Powerhouse and Switchyard; (4) Narrows 2 Partial Bypass; and (5) about 2.27 miles of existing project roads. The Narrows 2 Development does not include any recreation facilities or recreation roads.

[14] The United States built Englebright Dam to impound hydraulic mining debris, so it has no low-level outlet and, other than through the Narrows 1 and Narrows 2 powerhouses, the only means of releasing water from behind the dam is through spills over it.

modifications to the Narrows Project, and thus, consistent with the Narrows Project's existing license, Yuba Water proposes to operate the Narrows 1 Powerhouse in a manner that supports the measures that are the subject of the ongoing YRDP relicensing. Accordingly, Yuba Water has determined that it would be appropriate to jointly address the environmental impacts of relicensing both the YRDP and the Narrows Project in this DEIR.

1.2.3 Status of NEPA Compliance for the FERC Relicensing Process

Any new FERC licenses for the YRDP and the Narrows Project are subject to numerous requirements under the FPA and additional applicable statutes, including NEPA. A summary of the NEPA-related activities that have been undertaken by FERC is provided below.

1.2.3.1 YRDP

Under the provisions of the FPA, FERC must decide whether to issue a license to Yuba Water for the YRDP and what conditions should be placed on the new license. To issue a license for the YRDP, FERC must determine that the YRDP will be best adapted to implement a comprehensive plan for improving or developing the waterway. In addition to the power and developmental purposes for which licenses are issued (e.g., flood control, irrigation, and water supply), FERC must give equal consideration to: (1) the purposes of energy conservation; (2) the PM&E of fish and wildlife, including related spawning grounds and habitat; (3) the provision of recreational opportunities; and (4) the preservation of other aspects of environmental quality.

In anticipation of the 2016 expiration of the original license for the YRDP, Yuba Water initiated the relicensing process by conducting environmental studies and preparing and filing with FERC an Application for a New License Major Project – Existing Dam (FLA) for the YRDP in April 2014. In June 2017, Yuba Water filed with FERC an AFLA, with errata filed July 21, September 15, and November 1, 2017.

In January 2019, FERC, along with the USACE as a cooperating agency, issued a *Final Environmental Impact Statement for Hydropower License, Yuba River Development Project, Project No. 2246-065 – California* (the FEIS) pursuant to NEPA. As documented in Section 1.4 of the FEIS (FERC 2019), FERC issued a DEIS for the relicensing of the YRDP on May 30, 2018, and held two public meetings on July 10, 2018 in Marysville, California, to receive public comments on the DEIS. Statements made at the meetings were recorded by a court reporter and incorporated into FERC's public record for the proceeding.[15] Written comments on the DEIS were due July 30, 2018. Appendix B of the FEIS (FERC 2019) documents the comments that FERC received and provides FERC's responses to those comments and indicates, where appropriate, how it modified the text of the FEIS. A copy of the FEIS (FERC 2019) is available to the public at Yuba Water's offices, 1220 F Street, Marysville, CA, as well as from Yuba Water's relicensing website at: https://www.yubawater.org/217/Yuba-River-Development-Project-Relicensi.

In the FEIS, FERC assessed the potential environmental and economic effects of continuing to operate the YRDP: (1) as proposed by the applicant (i.e., Yuba Water); (2) with FERC's

[15] See transcripts of the July 10, 2018, scoping meetings and associated errata, FERC eLibrary Accession Nos. 20180815-4001, 20180815-4002, 20180815-4003, 20180815-4004, and 20180905-4002.

recommended measures; and (3) with any mandatory conditions prescribed by state and Federal agencies. The 2019 FEIS also evaluated the potential impacts associated with operations of the YRDP and alternatives to the proposed project. It also includes recommendations to FERC on whether to issue a new license, and if so, includes recommended terms and conditions to become a part of any new license. FERC also considered the effects of the No Action Alternative.[16] Important issues that were identified and addressed in FERC's 2019 FEIS included the effects of continued project operation on instream flows, shoreline erosion and sediment transport, water quality, fishery resources and fish passage, terrestrial resources, threatened and endangered species, recreation and land use, and cultural resources.

On September 18, 2020, FERC issued a BA for the YRDP under the federal Endangered Species Act (ESA) and requested initiation of formal ESA consultation with NMFS. NMFS responded to FERC on October 16, 2020, and asserted that the BA did not provide all the information needed to initiate consultation.

In a letter to Yuba Water dated March 8, 2021, FERC announced its plans to prepare an SEIS for the YRDP and a revised BA. FERC explained that the SEIS will address new information in the administrative record, including Section 401 WQC conditions, and may revise FERC staff's preferred licensing alternative (FERC 2021). FERC's March 8, 2021 AIR requested that Yuba Water evaluate options for the equitable allocation of water to provide cooler water temperatures in the lower Yuba River at times by consulting with PG&E (Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310) and Lower Drum Hydroelectric Project (FERC Project No. 14530)) and Nevada Irrigation District (NID) (Yuba-Bear Hydroelectric Project (FERC Project No. 2266) and Deer Creek Hydroelectric Project (FERC Project No. 14531)) and developing an agreed-upon analysis of the amount of additional water from either storage or transfers necessary in Dry and/or Critically Dry years (or combination of dry-type years) to maintain cooler water in the lower Yuba River for federally listed species protection from July through November. Preparation of FERC's SEIS is currently in progress.

Following completion of the SEIS and the revised BA, FERC will re-initiate ESA consultation with NMFS, and NMFS then is expected to prepare a biological opinion. Following ESA consultation, FERC is expected to issue a new YRDP license so that Yuba Water may continue to operate and maintain the YRDP, subject to the terms and conditions as described in the new FERC license.

1.2.3.2 Narrows Project

As with the YRDP relicensing, FERC must evaluate the potential environmental effects of relicensing the Narrows Project, and it must consider reasonable alternatives to the licensee's proposed action in compliance with NEPA, FERC regulations, and other applicable laws. The decision on whether to prepare an environmental assessment (EA) or an environmental impact statement (EIS) will be made once FERC determines the scope of effects and measures under

[16] Under the No Action Alternative, FERC stated that the project would continue to operate as it has in the past. None of Yuba Water's proposed measures or the resource agencies' recommendations and mandatory conditions would be required. None of the FERC staff-recommended measures would be implemented, including measures to enhance environmental conditions for fish and wildlife within the Project Area, measures to improve flow conditions downstream of the project for salmonids, and measures that would expand and improve recreation opportunities (FERC 2019, p. xlvii).

consideration. FERC's scoping process will help determine the required level of analysis and satisfy the NEPA scoping requirements, irrespective of whether FERC prepares an EA or an EIS.

Given that the relicensing for YRDP, as well as the other upper Yuba River Watershed relicensings[17] for NID's Yuba-Bear Hydroelectric Project (FERC Project No. 2266) and PG&E's Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310), Lower Drum Hydroelectric Project (FERC Project No. 14531) and Deer Creek Hydroelectric Project (FERC Project No. 14531) are ongoing with FERC's intent to issue a SEIS for those five projects, Yuba Water believes there would be significant advantages to aligning the Narrows Project's post-application relicensing activities with the relicensing activities for those projects; in particular, FERC's NEPA analysis and Section 7 ESA consultation. The advantages would include cost and time savings to FERC, Yuba Water, resource agencies, and other stakeholders, as well as ensuring a comprehensive analysis of the interrelated operations of all the watershed projects. Yuba Water intends to work with FERC and interested parties to ensure that the SEIS's basin-wide analyses adequately consider the Narrows Project.

Pursuant to NEPA, FERC staff will prepare either an EA or an EIS that will be used by FERC to determine whether, and under what conditions, to issue a new license for the Narrows Project. On June 7, 2024, FERC circulated Scoping Document 1 (SD1) to advise relicensing participants on the proposed scope of FERC's NEPA document for the Narrows Project and to seek additional information pertinent to that analysis (FERC 2024a). FERC's comment period on the NEPA scoping document for the Narrows Project closed on August 6, 2024. On December 4, 2024, FERC issued Scoping Document 2 (SD2) to identify issues to be analyzed in the NEPA document (FERC 2024a). Based on comments received during FERC's scoping process, FERC updated SD1 to reflect its current view of the issues to be considered in the NEPA document for the Narrows Project. Key changes from SD1 to SD2 included the following.

- FERC staff modified the upstream extent of the geographic scope of the Narrows Project to include Englebright Dam and Reservoir.
- For water and aquatic resources, FERC staff modified the geographic scope of the cumulative effects analysis to include Englebright Dam and Reservoir and downstream through the lower Yuba River to the confluence with the Feather River, the lower Feather River, the lower Sacramento River, and through the Sacramento-San Joaquin Delta to the San Francisco Bay.[18]
- FERC staff will conduct an analysis of shot rock (riprap) in the Narrows Dam Reach.
- FERC identified cumulative effects from the Narrows Project as having the potential to affect geology, soils, fisheries, and aquatic resources.

[17] This DEIR uses the term "YB/DS projects" to refer to four other FERC relicensing projects located in the upper Yuba River Watershed, which include: (1) NID's Yuba-Bear Hydroelectric Project (FERC Project No. 2266); and (2) PG&E's Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310), Lower Drum Hydroelectric Project (FERC Project No. 14531) and Deer Creek Hydroelectric Project (FERC Project No. 14531).

[18] FERC (2024a) acknowledged that: (1) the geographic scope of the cumulative effects analysis is not the same as the geographic scope of needed studies for the Narrows Project relicensing; and (2) the expanded geographic scope does not imply that Narrows Project-related effects extend significantly beyond the Yuba River downstream of Englebright Dam but rather that actions occurring downstream to the San Francisco Bay affect the same anadromous fish populations and essential fish habitat that may be cumulatively affected by the Narrows Project.

FERC's SD1 (2024a) and SD2 (2024b) for the Narrows Project identified a preliminary list of environmental issues[19] to be addressed for NEPA compliance purposes. FERC (2024a; 2024b) has indicated that the issues identified by an asterisk (*) in the list of environmental resources to be evaluated (see below) in FERC's NEPA document for the Narrows Project will be analyzed for both cumulative and site-specific effects. On February 26, 2025, FERC issued a "*Notice of Application Ready for Environmental Analysis and Soliciting Comments, Recommendations, Terms and Conditions, and Prescriptions"* for the Narrows Project. No new environmental issues were identified in FERC's 2025 REA notice.

- ***Fisheries and Aquatic Resources***
    - Effects of continued Narrows Project operation on water quantity and water quality*
    - Effects of continued Narrows Project O&M on aquatic habitat and fishery resources*
- ***Terrestrial Resources***
    - Effects of continued Narrows Project O&M, including vegetation management, on botanical and wildlife species, including any special-status species and nesting birds occurring in the Project Area
    - Effects of non-native, invasive plant species potentially introduced and spread as a result of Narrows Project operations
- ***Threatened and Endangered Species***
    - Effects of continued Narrows Project O&M on: (1) the Federally threatened California red-legged frog, valley elderberry longhorn beetle, and vernal pool fairy shrimp; and (2) the proposed threatened northwestern pond turtle, western spadefoot, and monarch butterfly
    - Effects of continued Narrows Project O&M on Federally listed species and their habitat, including the threatened Central Valley spring-run Chinook salmon, California Central Valley steelhead Distinct Population Segment (DPS), and North American green sturgeon Southern DPS*
- ***Geology and Soils***
    - Effects of bank erosion on the south bank of the lower Yuba River*
    - Effects of hillslope erosion within the bypassed reach*
    - Effects of continued Narrows Project O&M on turbidity, shoreline erosion, and suspended sediment loads*
    - Effects of sediment movement on or within the Narrows Project shorelines and streambanks along the project impoundment
    - Effects of shot rock (riprap) within the river channel in the vicinity of the Narrows 1 and Narrows 2 powerhouses (e.g., Englebright Dam Reach)

[19] The list is not intended to be exhaustive or final, but contains those issues raised to date that could have substantial effects.

- ***Recreation, Land Use, and Aesthetics***
    - Effects of continued Narrows Project O&M on recreational resources in the Project Area
    - Effects of continued Narrows Project O&M on land use and aesthetic resources in the Project Area
- ***Cultural Resources***
    - Effects of continued Narrows Project O&M on historic and archaeological resources, or traditional cultural properties that may be eligible for inclusion in the National Register of Historic Places
- ***Developmental Resources***
    - Effects of proposed or recommended PM&E measures[20] on project economics, hydropower generation and economics, and continued Narrows Project O&M on local and regional economies

The 60-day comment period on FERC's REA notice closed on April 28, 2025. Parties that filed comments with FERC included the SWRCB, CDFW, U.S. Fish and Wildlife Service (USFWS), NMFS, and various non-governmental organizations (NGOs). According to the FERC relicensing process, Yuba Water has until June 11, 2025 to submit responses to the REA comments to FERC. In consideration of the comments and responses received in response to the REA notice, FERC will evaluate Yuba Water's license application for the Narrows Project to determine how it will be processed. Because FERC must comply with NEPA, it will further identify the issues and level of analysis required for its licensing action and prepare a NEPA document, which also will be subject to public review when it becomes available. FERC initiated the NEPA process by issuing a *Notice of Intent to Prepare an Environmental Assessment* (EA) for the Narrows Project on May 12, 2025.[21] Based on information in the FERC record, including comments filed on FERC's REA Notice, FERC staff do not anticipate that relicensing the Narrows Project would constitute a major federal action significantly affecting the quality of the human environment (FERC 2025a). Consequently, FERC (2025a) states that the EA[22] will be issued for a 45-day comment period, which is anticipated to occur during November 2025.

Although the evaluation of potential impacts resulting from the Narrows Project in this DEIR is conducted independently of FERC's NEPA process, the environmental resource areas and associated issues identified by FERC for NEPA purposes are generally consistent with those identified in this DEIR for CEQA review and compliance purposes. Therefore, even though FERC has not yet issued a NEPA document, the identification and evaluation of environmental resource issues for the Narrows Project in this DEIR addresses the issues that are of concern to Narrows Project relicensing participants, including those parties that are also CEQA responsible agencies

[20] SD2 (FERC 2024b) does not address recommendations for FERC license conditions, such as PM&E measures (e.g., settlement agreement conditions, resource management plans) because such recommendations will be addressed in the NEPA document, or any license order issued for the Narrows Project. FERC's February 26, 2025 REA notice requested terms and comments, recommendations, terms and conditions, and prescriptions that will be considered by FERC during the NEPA process.

[21] Available in FERC's eLibrary at Accession No. 20250512-3018 (Filed on May 12, 2025).

[22] For tracking purposes under NEPA, the unique identification number for documents relating to FERC's environmental review of the Narrows Project is EAXX-019-20-000-1747040730 (FERC 2025a).

(e.g., SWRCB, CDFW) who will need to rely upon this DEIR as part of their decision-making process for the Narrows Project relicensing.

1.2.4 Status of Federal ESA Section 7 Consultation for the FERC Relicensing Process

1.2.4.1 YRDP

On May 31, 2018, as part of its ESA consultation, FERC requested concurrence from the USFWS regarding FERC's finding that the YRDP may affect, but is not likely to adversely affect, certain species. On June 22, 2018, USFWS concurred with FERC's determination, completing FERC's ESA consultation with USFWS (**Appendix 2D**). Following completion of FERC's SEIS, there may be a need for FERC to reconsult with the USFWS if there are changes to FERC's proposed action that could result in new adverse effects or have the potential to alter USFWS's previous conclusions.

On September 18, 2020, FERC issued a BA under the ESA and requested initiation of formal ESA consultation with NMFS. NMFS responded to FERC on October 16, 2020, asserting that the BA did not provide all the information needed to initiate consultation. In a letter dated March 8, 2021, FERC announced its plans to prepare a SEIS and revised BA to provide the information requested by NMFS. FERC explained that the SEIS will address new information in the administrative record and may revise FERC staff's preferred project alternative. Following completion of the SEIS and a revised BA, FERC will request reinitiation of ESA consultation with NMFS, after which NMFS is expected to prepare a biological opinion. Given the ongoing relicensing processes of YRDP, NID's Yuba-Bear Hydroelectric Project, and PG&E's Upper Drum-Spaulding Hydroelectric Project, Lower Drum Hydroelectric Project and Deer Creek Hydroelectric Project and consistent with FERC's intent to issue a single SEIS for those three projects, it is anticipated that FERC would reinitiate Section 7 ESA consultation on all three projects. Following completion of the SEIS and ESA consultation process, FERC is expected to issue a new YRDP license so that Yuba Water may continue to operate and maintain the YRDP, subject to the terms and conditions as described in the new FERC license.

1.2.4.2 Narrows Project

Similar to the other FERC relicensing processes that are ongoing within the Yuba River Watershed, it is anticipated that the Narrows Project would be included as part of the proposed action that is described and evaluated in FERC's revised BA that would be used to support a Section 7 ESA consultation with NMFS. At this time, FERC has stated that it is unclear whether the Narrows Project would result in potentially adverse effects to ESA-listed species and critical habitat under the jurisdiction of the USFWS. Using information contained within Yuba Water's FLA for the Narrows Project and potentially informed by the NEPA process, it is anticipated that FERC will determine whether a separate ESA consultation with the USFWS is warranted.

Following completion of the SEIS and ESA consultation process, FERC is expected to issue a new license for the Narrows Project so that Yuba Water may continue to operate and maintain the Narrows Project subject to the terms and conditions as described in the new FERC license.

1.3 Agency Coordination and Public Involvement Processes

1.3.1 YRDP FERC Relicensing Process

FERC's regulations (18 Code of Federal Regulations [C.F.R.], sections 5.1–5.16) require that applicants consult with appropriate resource agencies, Native American tribes, and other entities before filing an application for a license. This consultation is the first step in complying with the Fish and Wildlife Coordination Act, the ESA, the National Historic Preservation Act (NHPA), and other Federal statutes.

To support development of the EIS, FERC conducted scoping to determine what issues and alternatives should be addressed. A NEPA SD1 was issued by FERC on January 4, 2011, and an environmental site review of the YRDP was held on February 1, 2011. Two scoping meetings, both advertised in the Appeal Democrat, The Union, and The Mountain Messenger, were held on February 2, 2011, in Marysville, California, to request oral comments on the project. A court reporter recorded all comments and statements made at the scoping meetings, and these are part of FERC's public record for the project. The afternoon meeting was attended by individuals representing NGOs and public agencies, including the United States Department of Agriculture, Forest Service (USFS), USFWS, NMFS, SWRCB, and CDFW. The evening meeting was attended by tribal and NGO representatives and members of the public. In addition to comments provided at the scoping meetings, over 30 entities provided written comments pertaining to SD1, the preliminary application document, and additional study needs. Based on comments at the public meetings and written comments FERC received on SD1 by March 7, 2011, FERC issued a revised SD2 on March 18, 2011.

Following Yuba Water's filing of its application for a new license in 2014 and AFLA in 2017, FERC solicited and received written comments on the application from more than 80 entities. On June 26, 2017, FERC issued a notice that Yuba Water's application was accepted. The notice also stated that the application was REA and solicited comments, recommendations, preliminary terms and conditions, and preliminary fishway prescriptions.

FERC distributed the Notice of Availability (NOA) of the DEIS for the YRDP on May 30, 2018. The notice included a deadline of July 30, 2018 for submission of written comments on the DEIS (60 days). FERC staff also held a second round of public outreach for the purpose of receiving comments on the DEIS,[23] which included afternoon and evening public meetings in Marysville, California on July 10, 2018. The meetings were announced in local newspapers and in the Federal Register. In addition, FERC held a meeting with Federal and state fish and wildlife agencies to discuss those agencies' FPA section 10(j) recommended fish and wildlife conditions on August 29, 2018, in Sacramento, California. The meeting was announced in local newspapers and in the Federal Register. On January 2, 2019, FERC distributed the NOA of the FEIS for the YRDP.[24]

[23] FERC's 2018 DEIS for the YRDP is available on FERC's eLibrary under the YRDP docket at accession number 20180530-3011 (Filed on May 30, 2018).

[24] FERC's 2019 FEIS for the YRDP is available on FERC's eLibrary under the YRDP docket at accession number 20190102-3000 (Filed on January 2, 2019).

During the relicensing process, Yuba Water collaborated with Federal and state resource agencies, Native American tribes, NGOs, and members of the public (collectively, the relicensing participants) to develop proposed new license conditions. Yuba Water held more than 150 meetings with interested parties, including the SWRCB's representatives, to discuss issues and to collaboratively develop conditions to be included in the new FERC license. The FERC Staff Alternative presented in the FEIS, in combination with resource agency terms and conditions (see Chapter 2, Project Description), reflects the result of collaborative efforts between Yuba Water and the YRDP relicensing participants. The relicensing website for the YRDP provides information about the relicensing process, access to public documents, and details about the Project, public participation, communication plans, and meetings. The website can be accessed at: https://www.yubawater.org/217/Yuba-River-Development-Project-Relicensi.

1.3.2 Narrows Project FERC Relicensing Process

On January 28, 2021, Yuba Water filed with FERC a NOI to File an Application for a New License, a Pre-Application Document (PAD) and a request to use FERC's traditional licensing process (TLP) for the Narrows Project. The NOI stated Yuba Water's intent to file an application for a new license no later than January 31, 2024. On June 6, 2023, Yuba Water filed with FERC a *Draft Application for a New License Major Project – Existing Dam for YCWA's Narrows Hydroelectric Project, FERC Project Number 1403 (DLA)*, and initiated a 90-day public comment period that closed on September 4, 2023. Following consideration of comments received on the DLA, Yuba Water filed its *Final Application for a New License Major Project – Existing Dam for YCWA's Narrows Hydroelectric Project (Project), FERC Project Number 1403 (FLA)* with FERC on November 14, 2023. Yuba Water proposes to continue operating the Narrows Project with no modification to existing Narrows Project facilities, Project Boundary, or operations, and the adoption of the resource management measures described in its November 2023 FLA.

Yuba Water distributed notices of the availability of the 2021 PAD (letter dated January 28, 2021), the June 2023 DLA (letter dated June 6, 2023), and the November 2023 FLA (letter dated November 14, 2023) to ten Federal agencies, nine state agencies, two local agencies, as well as numerous businesses, NGOs, and members of the public in the expectation that these parties may be interested in the Narrows Project relicensing. FERC also initiated consultation with Native American tribes potentially affected by the relicensing of the Narrows Project.

Yuba Water made a copy of the Application for New License available to these parties or their designee. The relicensing website for the Narrows Project provides information about the relicensing process, access to public documents, and details about the Project, public participation, communication plans, and meetings. The website can be accessed at: https://www.yubawater.org/357/Narrows-Relicensing.

1.3.2.1 Outreach with Native American Tribes Regarding Notice of Opportunity to Consult Under Assembly Bill 52

Federally recognized Indian tribes and other Native Americans that may be affected by the relicensing of the Narrows Project were identified based on information provided to Yuba Water by the Native American Heritage Commission (NAHC) on May 4, 2020. The identified organizations included:

- United Auburn Indian Community of the Auburn Rancheria
- Colfax-Todds Valley Consolidated Tribe
- Tsi Akim Maidu
- Enterprise Rancheria of Maidu Indians
- Mooretown Rancheria of Maidu Indians

As part of reinitiating the AB 52 process for the YRDP relicensing with simultaneous review of the Narrows Project relicensing, Yuba Water sent emails to each potentially interested California Native American Tribe on October 18, 2024, regarding an early engagement opportunity to discuss the Proposed Projects prior to formal AB 52 consultation notification. Yuba Water formally re-initiated the CEQA and AB52 processes and procedures for the YRDP relicensing along with the Narrows Project relicensing by sending letters on October 31, 2024, via email and United States Postal Service of the opportunity to consult to Native American tribes that requested formal notification, and courtesy notification to other potentially interested California Native American tribes identified by the NAHC. United Auburn Indian Community (UAIC) and Enterprise Rancheria Estom Yumeka Maidu (Enterprise Rancheria) have each requested consultation for the proposed Project in response to the notice of opportunity. Consultation with Enterprise Rancheria and UAIC is in progress.

1.3.3 CEQA Process for the YRDP and Narrows Project

1.3.3.1 November 7, 2022 Notice of Intent and CEQA Public Scoping Process

On November 7, 2022, Yuba Water issued a *Notice of Intent to Rely on FERC/USACE Final Environmental Impact Statement, in Combination with a Supplemental Analysis, to Satisfy CEQA for the Yuba River Development Project Relicensing and Notice of CEQA Scoping Meetings.* The 45-day period to comment on the NOI extended to December 22, 2022. Yuba Water held two CEQA public scoping meetings during the NOI public comment period to discuss and receive input on the issues that are not addressed in FERC's FEIS, but should be addressed in Yuba Water's CEQA Supplemental Analysis. The public scoping meetings were undertaken in an open house format and allowed agencies and individuals an opportunity to submit written comments to Yuba Water for consideration in the development of the CEQA Supplement. Yuba Water and their consultants were available during the open house to discuss proposed project physical footprint and features, proposed operations, CEQA process, and respond to public questions, as possible. Participants of the open house were requested to document comments or questions on the proposed project and submit during the scoping meeting, or via mail or email by the end of the public scoping period to Yuba Water.

Overall, a total of 15 individual commenters submitted a total of 57 comments via five letters during the public comment period (see **Appendix 1A**, 2022 CEQA Scoping Report). No comments were submitted during the public meetings.

1.3.3.2 2021 Outreach with Native American Tribes Regarding Notice of Opportunity to Consult Under Assembly Bill 52

Pursuant to Public Resources Code Section 21080.3.1(d) and Assembly Bill No. 52 (AB 52),[25] Yuba Water reached out to local Native American tribes and extended a formal invitation to consult with Yuba Water on the proposed YRDP relicensing project. In 2021, letters were sent to the following Native American tribes and several individuals, including:

- UAIC
- Colfax-Todds Valley Consolidated Tribe
- Greenville Rancheria Tribe of Maidu
- Mooretown Rancheria of Maidu Indians
- Pakan'yani Maidu of Strawberry Valley Rancheria
- Mechoopda Indian Tribe of Chico Ranch
- Washoe Tribe of Nevada and California
- Shingle Springs Band of Miwok Indians
- Enterprise Rancheria
- Nevada City Rancheria
- Tsi Akim Maidu

Yuba Water received one response from UAIC on the initial letter. On October 3, 2022, Yuba Water sent a follow-up letter to UAIC indicating that it was re-initiating work on the CEQA document and would like to reinitiate consultation with the UAIC under AB 52. Yuba Water requested that UAIC respond within 30 days if the UAIC was interested in reinitiating the consultation, but a response was not received. Since the initial distribution in 2021, the Shingle Springs Band of Miwok Indians and the Enterprise Rancheria have requested to be added to Yuba Water's AB 52 list.

1.3.3.3 October 28, 2024 Notice of Preparation and CEQA Public Scoping Process

Because FERC is preparing a supplement to its 2019 FEIS for the YRDP and has not yet issued a NEPA environmental compliance document for the Narrows Project, Yuba Water ultimately elected not to prepare a CEQA Supplement but instead to prepare a new, stand-alone EIR for both the YRDP and the Narrows Project to comply with CEQA.

On October 28, 2024, Yuba Water released a *Notice of Preparation of a Draft Environmental Impact Report and Notice of Public Scoping Meetings for the Yuba River Development Project FERC Relicensing (Project No. 2246) and the Narrows Hydroelectric Project FERC Relicensing (Project No. 1403)* (see Appendix 1B, CEQA Scoping Report and Attachment 1-2, for a copy of the October 28, 2024 Notice of Preparation [NOP]). The NOP informed responsible and trustee agencies and other interested parties about Yuba Water's change in CEQA compliance approach for the FERC relicensings and its intention to prepare a joint EIR and hold additional scoping

[25] AB 52 requires public agencies to consult with Native American tribes during the CEQA process. For additional information, see https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=201320140AB52&search_keywords=

meetings for both the YRDP and Narrows Project (CEQA Guidelines section 15165). The NOP was circulated for a 30-day review and comment period from November 1, 2024 through December 2, 2024.

To further supplement the extensive scoping that has occurred during the FERC relicensing process, Yuba Water held two CEQA public scoping meetings during the NOP public comment period at the following locations.

Date	***Time***	***Location***
November 13, 2024	2:00 to 4:00 PM	Yuba Water Agency 1220 F Street Marysville, California 95901
November 14, 2024	5:00 to 7:00 PM	Gold Miners Inn 121 Bank Street Grass Valley, California 95945

The public scoping meetings were undertaken in an open house format and allowed agencies and individuals an opportunity to submit written comments to Yuba Water for consideration in the development of this DEIR. Yuba Water and their consultants were available during the open house to discuss the Proposed Projects' physical footprint and features, proposed operations, CEQA process, and respond to public questions, as possible. Participants of the open house were requested to document comments or questions on the Proposed Projects and submit them during the scoping meeting, or via mail or email by the end of the public scoping period to Yuba Water.

Four commenters submitted letters during the public comment period (see **Appendix 1B**, 2024 CEQA Scoping Report). No comments were submitted during the public meetings.

1.4 Areas of Known Controversy

Pursuant to CEQA Guidelines Section 15123(b)(2), a lead agency is required to include areas of controversy raised by agencies and the public in an EIR. Areas of controversy have been identified for the Proposed Projects based on input provided as part of the FERC relicensing process for the YRDP and Narrows Project, and through comments provided during the CEQA scoping process (including the 2022 NOI and the 2024 NOP).

1.4.1 YRDP

The following areas of controversy have been identified to date.

- **Alternatives Analysis**
    - Over the 15-year duration of the ongoing FERC relicensing process for the YRDP, various operational scenarios for the YRDP have been proposed by several FERC relicensing participants, and the resultant effects of those alternative operational proposals on flow and water temperature conditions in the lower Yuba River have

been the subject of considerable discussion and analyses. Chapter 3 (Alternatives) of this DEIR presents additional information about the alternatives evaluated in this DEIR, as well as other alternatives that Yuba Water declined to consider further.

- **CWA Section 401 Compliance Issues**
    - The uncertainty of future CWA regulatory terms imposed by the SWRCB's WQCs that will be issued for the YRDP and the Narrows Project is an issue of concern with respect to potential changes to YRDP operations, and resultant changes in reservoir storage, flow release patterns and water temperature regimes in the lower Yuba River. The hydrologic changes that may be imposed by conditions in the WQCs have the potential to result in direct and/or redirected impacts on fisheries resources, water supply, water quality, and other environmental resources.
- **Bay-Delta Water Quality Control Plan Update**
    - Future regulatory constraints associated with the SWRCB's Updates to the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary for the Sacramento River and its Tributaries, Delta Eastside Tributaries, and Delta (Bay-Delta Plan Update) and the potential for such regulatory constraints to adversely affect YRDP operations within the Yuba River Watershed, as well as flow and water temperature throughout the Central Valley, are of concern due to the potential for direct and redirected impacts on fisheries resources, water supply, water quality, and other environmental resources.
- **Suggested Mitigation Measures**
    - Some commenters suggested that the EIR should consider mitigation for YRDP impacts related to Large Woody Material (LWM) and sediment management on the North Yuba River below New Bullards Bar Dam that were not addressed in the FERC (2019) FEIS.
    - Some commenters also suggested that the EIR should consider implementation of lower Yuba River floodplain restoration activities to accompany the riparian vegetation planning that was recommended by FERC in the 2019 FEIS.

1.4.2 Narrows Project

To date, no specific areas of controversy or issues to be resolved for the Narrows Project have been identified. To the extent that Narrows Project operations pertain to the coordinated operations of the YRDP, the issues discussed above in Section 1.4.1 may also be applicable to the Narrows Project.

1.5 Background Regarding Required Project Permits and Approvals

As noted, given that the FERC relicensing for the YRDP and additional FERC relicensings in the Yuba River Watershed are ongoing, Yuba Water believes there would be significant advantages to aligning the Narrows Project's post-application relicensing activities (e.g., FERC's NEPA analysis and Section 7 ESA consultation) with the ongoing and future YRDP relicensing activities.

These would include cost and time savings to FERC, Yuba Water, resource agencies and other stakeholders, as well as ensuring a comprehensive analysis of the interrelated operations of both projects. Following the filing of the 2017 AFLA for the YRDP and the 2023 FLA for the Narrows Project, Yuba Water has continued to work with FERC and the other parties to align relicensing activities that will support the timely issuance of both licenses.

1.5.1 Status of Clean Water Act Section 401 Compliance

Section 401 of the federal CWA authorizes a state to issue a WQC with conditions on a federal license for a hydroelectric project to ensure that the project complies with state water quality standards. The WQC-issuing agency in California is the SWRCB. With respect to both the YRDP and the Narrows Project, Yuba Water is acting as the CEQA Lead Agency for each relicensing project, and the SWRCB is a Responsible Agency in the CEQA process.

A CWA Section 401 WQC confirms that a project complies with all applicable water quality standards, limitations and restrictions, and is required prior to issuance of the FERC license. WQCs for FERC's relicensing of the YRDP and the Narrows Project require an analysis of those projects' overall effects on water quality, including whether the designated beneficial uses identified in a Basin Plan (in this case, the SWRCB's Bay-Delta Plan, as well as the Central Valley Regional Water Quality Control Board (CVRWQCB) Water Quality Control Plan for the Sacramento and San Joaquin River Basins)[26] are adequately protected. While the SWRCB is a formal participant in the FERC relicensing process, including input and review throughout the FERC EIS process, it will also use this DEIR to complete its review of the YRDP and Narrows Project's effects consistent with CEQA.

Federal law provides that the SWRCB must act on a WQC application within a reasonable period of time (not to exceed one year), or else the WQC is considered waived with respect to the application. This DEIR serves as an informational source for the SWRCB's own decision-making regarding CEQA and FERC relicensing.

1.5.1.1 YRDP

On December 30, 2024, Yuba Water filed an application for a WQC with the SWRCB in support of its application for a new FERC license for the YRDP. In anticipation of filing the WQC application, Yuba Water and the SWRCB participated in a pre-filing meeting on October 10, 2024 consistent with the regulatory requirements described in 40 C.F.R. §121.4. A copy of Yuba Water's WQC application was also filed with FERC.[27] As stated in FERC's December 31, 2024 acknowledgement,[28] if the SWRCB fails or refuses to act on the YRDP WQC request on or before December 30, 2025, then the certifying authority is deemed waived pursuant to Section 401(a)(1) of the CWA, 33 U.S.C. § 1341(a)(1). The WQC application package for the YRDP that Yuba Water submitted to the SWRCB included background information and recommended findings for the WQC (Appendix 2E), which are included as part of the YRDP Proposed Project that is evaluated in this DEIR.

[26] Water Quality Control Plan for the California Regional Water Quality Control Board Central Valley Region for the Sacramento River Basin and the San Joaquin River Basin. Fifth Edition. Revised February 2019 (with Approved Amendments).

[27] Available in FERC's eLibrary at Accession No. 20241230-5127 (Filed on December 30, 2024).

[28] Available in FERC's eLibrary at Accession No. 20241231-3020 (Filed on December 31, 2024).

1.5.1.2 Narrows Project

As previously discussed, FERC issued a REA notice on February 26, 2025, which included a 60-day deadline for filing comments, recommendations, terms and conditions, and prescriptions that closed on April 28, 2025. In compliance with 18 C.F.R. §4.34(b)(5), Yuba Water filed proof of submittal of a WQC application for the Narrows Project with FERC on December 30, 2024.[29] As stated in FERC's January 3, 2025 acknowledgement,[30] if the SWRCB fails or refuses to act on the Narrows Project WQC request on or before December 30, 2025, then the certifying authority is deemed waived pursuant to Section 401(a)(1) of the CWA, 33 U.S.C. § 1341(a)(1).

The WQC application package for the Narrows Project that Yuba Water submitted to the SWRCB included background information and recommended findings for the WQC (**Appendix 2G**), which are included as part of the Narrows Proposed Project that is evaluated in this DEIR.

1.5.2 Other Permits

The new proposed FERC license conditions for the YRDP and the Narrows Project include construction and maintenance activities that will likely require permits from other entities. Yuba Water will obtain all required regulatory permits, prior to undertaking these activities. The required permits may include the following:

- USACE CWA Section 404 Permit
- USFS Road Use Permit and Special Use Permits
- State Historic Preservation Officer NHPA Section 106 consultation
- CESA Incidental Take Permit (ITP)
- CDFW Section 1600 Streambed Alteration Agreement
- CVRWQCB Waste Discharge Requirement
- National Pollution Discharge Elimination System (NPDES) Permit[31]
- CALFIRE and/or Air Quality Management District (AQMD) Burn Permit
- AQMD Authority to Construct / Permit to Operate
- State of California Construction General Permit
- Caltrans Transportation Permit (Oversize/Overweight Vehicles)
- California Department of Industrial Relations, Division of Occupational Safety and Health Permit to Operate Air Pressure Tank

[29] Available in FERC's eLibrary at Accession No. 20241230-5125 (Filed on December 30, 2024).

[30] Available in FERC's eLibrary at Accession No. 20250103-3006 (Filed on January 3, 2025).

[31] The SWRCB adopted a general NPDES permit for stormwater discharges associated with construction activity (Construction Stormwater General Permit) in Order No. 2022-0057-DWQ/NPDES Permit CAS000002, which became effective on September 1, 2023. Construction activities that disturb one or more acre of land are required to obtain coverage under the Construction Stormwater General Permit, which involves filing of a NOI and preparation and implementation of a stormwater pollution prevention plan (SWPPP).

- County Permits (e.g., annual environmental health permit for hazardous materials storage, grading, etc.)

1.5.3 Other Intended Uses of the DEIR

This DEIR has been prepared in compliance with the requirements of CEQA. Several agencies have responsibility for issuing permits or approvals for the YRDP and the Narrows Project or for resources that may be affected by the two FERC relicensing projects. Before the selection and approval of an alternative is considered, the lead agency must comply with the necessary state environmental review requirements. This DEIR is intended to provide sufficient CEQA support for approval, if appropriate, for the project and related decisions by Yuba Water, trustee agencies, and responsible agencies. The roles and responsibilities of some of these agencies are summarized below.

Under CEQA, a ***responsible agency*** is a public agency, other than the lead agency, which has responsibility for carrying out or approving a project (Public Resources Code § 21069). In most circumstances, CEQA requires a responsible agency to use the lead agency's CEQA document to support its own decision-making process (CEQA Guidelines § 15096). A ***trustee agency*** is a state agency that has jurisdiction by law over natural resources that are held in trust for the people of the State of California that may be affected by a project (Public Resources Code § 21070). Trustee agencies must be consulted when the lead agency is preparing a CEQA document with potential project effects on those resources. Additionally, state or other California public agencies may contribute to and rely on information prepared as part of the environmental compliance process, including the certified CEQA document and supporting materials.

1.5.3.1 State Water Resources Control Board

As previously discussed in this chapter, the SWRCB is a responsible agency under CEQA that would be undertaking a discretionary action regarding the issuance or denial of a water quality certification under Section 401 of the CWA. As part of the WQC process, the SWRCB is responsible for reviewing projects to ensure compliance with relevant water quality control plans, in this case the SWRCB's Bay-Delta Plan and the Water Quality Control Plan for the Sacramento River and San Joaquin River Basins (Basin Plan) (CVRWQCB 2019). For additional details on the WQC process, see Section 1.2.3 above.

1.5.3.2 California Department of Fish and Wildlife

CDFW is both a responsible agency and a trustee agency under CEQA (CEQA Guidelines §§ 15381 and 15386(a)). CDFW has discretionary authorities under various sections of the California Fish and Game Code and has trustee authorities with regard to the fish and wildlife of the state, to designated rare or endangered native plants, and to game refuges, ecological reserves, and other areas administered by the department.

1.5.3.2.1 California Fish and Game Code Section 2081(b)

CDFW administers and enforces CESA, which prohibits the import, export, take, possession, purchase, or sale of species listed by the state as endangered, threatened, or in specific cases,

candidate species (Fish & Game Code §§ 2080, 2081.1). "*Take"* under CESA is defined as any action or attempt "*to hunt, pursue, catch, capture, or kill*" (Fish & Game Code § 86). As provided by Section 2081(b) of the Fish & Game Code, CDFW may authorize take that is otherwise prohibited by Section 2080 with an ITP. CESA allows CDFW to issue an ITP for a state-listed threatened and endangered species only if specific criteria are met (14 Cal. Code Regs. § 783.4 (a) and (b)). Incidental take of endangered, threatened, or candidate species may be authorized if an applicant demonstrates, among other things, that the effects of the proposed take will be minimized and fully mitigated (Fish & Game Code § 2081(b)(2)).

1.5.3.2.2 California Fish and Game Code Section 1600 et seq.

Section 1602 of the Fish & Game Code requires any person, state, or local government agency to provide advance written notification to CDFW prior to initiating any activity that would do the following.

- Substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake.
- Deposit or dispose of debris, waste, or other material into any river, stream, or lake.

Certain actions that would be implemented under the new YRDP FERC license may trigger the need to provide notice under Section 1602. CDFW would review notifications of actions to determine if the aspects of the project triggering notification would substantially adversely affect existing fish and wildlife resources that are directly dependent on a lake, river, or stream. If CDFW determines that the project action may substantially adversely affect an existing fish and wildlife resource, it could require, as part of a Lake and Streambed Alteration Agreement, reasonable measures if necessary to protect the fish and wildlife resource (Fish and Game Code §1603(a)).

1.6 Organization of the YRDP and Narrows Project Joint DEIR

This DEIR begins with several introductory chapters that provide important foundations for analyses. The early chapters provide detail about the history and purpose of the YRDP and the Narrows Project, the intended uses of this document (Chapter 1 – Introduction), a description of the Proposed Projects (Chapter 2 - Project Description), and a description of the alternatives considered (Chapter 3 - Alternatives). Chapter 4 describes the format and approach of the CEQA analysis. After these introductory chapters are 19 chapters that discuss specific environmental resources and the potential impacts of the Proposed Projects on these areas. These chapters are where most of the CEQA analysis occurs.

After the resource chapters, this DEIR concludes with a chapter that discusses the additional issues required to be considered in an EIR by CEQA. These issues include growth-inducing impacts, significant environmental effects that cannot be avoided, and significant irreversible environmental changes that would occur should the Proposed Projects be implemented (CEQA Guidelines Section 15126). This DEIR also includes a discussion of climate change and its impacts on the Proposed Projects. The discussion of climate change in Chapter 25, Other CEQA Considerations, is limited to impacts of climate change on the Proposed Projects and alternatives, but not the projects' GHG emissions and potential impacts on climate change, which are addressed

in Chapter 15, Air Quality and Greenhouse Gas Emissions. Information about climate change and how it may affect YRDP and Narrows Project operations in the future is presented for informational purposes only in the interest of disclosure. The climate change discussion does not apply CEQA thresholds of significance, nor does it make resource-specific impact conclusions or propose mitigation. This DEIR also contains a suite of appendices that provide additional details about the YRDP and the Narrows Project, as well as additional information and supporting documentation related to the analytical foundations and applicable resource chapters.

CHAPTER 2

PROJECT DESCRIPTION

The Proposed Projects analyzed in this DEIR are the continued O&M of the YRDP (FERC Project No. 2246) and the Narrows Project (FERC Project No. 1403) under new FERC licenses.

This chapter summarizes the existing facilities and power operations of both projects, and the changes to facilities and operations that would be associated with renewal of both licenses, and also summarizes the environmental measures (proposed by Yuba Water, by FERC Staff, and by other public agencies) that would be implemented under the new licenses. Descriptions of existing facilities and modifications and conditions associated with the new license for the YRDP are largely summarized or excerpted from the 2019 FERC FEIS, Section 2.0, Proposed Action and Alternatives, and from Yuba Water's AFLA (errata filed July 21, September 15, and November 1, 2017) for the YRDP filed with FERC on June 5, 2017 (errata filed July 21, September 15, and November 1, 2017).[1] Descriptions of existing facilities and modifications and conditions associated with the new license for the Narrows Project are largely summarized or excerpted from the Yuba Water's FLA license application filed with FERC on November 14, 2023.[2]

The new FERC license for the YRDP would consist of: (1) modifications to existing YRDP facilities (see Section 2.2.1); (2) adjustment of the YRDP FERC Project Boundary (see Section 2.3.1); (3) protection, mitigation, and enhancement (PM&E) measures proposed by Yuba Water; (4) FERC Staff recommended modifications of Yuba Water's proposal and additional measures; and (5) all mandatory terms and conditions. Mandatory terms and conditions are those required by the USFS and the U.S. Department of the Interior (Interior) under the FPA. Additionally, the SWRCB[3] can require conditions under the CWA (USFS 2018). The YRDP license also would include reasonable and prudent measures required in any biological opinion for the Project under the ESA. Together, these components will comprise the new obligations and Project modifications expected to be implemented under a new FERC license for the YRDP.[4]

The new FERC license for the Narrows Project would consist of: (1) project-related changes proposed by Yuba Water (see Section 2.2.3); (2) PM&E measures proposed by Yuba Water; (3) FERC Staff recommended modifications of Yuba Water's proposal and additional measures (if

[1] Available in FERC's eLibrary at Accession No. 20170605-5050 (Filed on June 5, 2017).

[2] Available in FERC's eLibrary at Accession No. 20231114-5136 (Filed on November 14, 2023).

[3] The SWRCB has not yet acted on Yuba Water's request for a CWA Section 401(a)(1) WQC, which was submitted to the SWRCB on December 30, 2024 and filed with FERC (Available in FERC's eLibrary at Accession No. 20241230-5127 (Filed on December 30, 2024)).

[4] For the YRDP FERC relicensing process, several exhibits were developed by Yuba Water and filed with FERC as part of Yuba Water's 2017 AFLA. YRDP-related exhibits that are relevant to characterizing the CEQA Baseline (Existing Condition) and the YRDP Proposed Project are attached to this DEIR in **Appendix 2A**, and include: (1) AFLA Exhibit A – Project Description; (2) AFLA Exhibit B – Project Operations and Resource Utilization; (3) AFLA Exhibit C – Construction History and Proposed Construction Schedule; (4) AFLA Exhibit D – Statement of Costs and Financing; and (5) AFLA Exhibit G – Project Maps. All exhibits related to the YRDP AFLA are available in FERC's eLibrary at Accession No. 20170605-5050 (Filed on June 6, 2017).

any); and (4) mandatory terms and conditions (if any).[5] Together, these components will comprise the new obligations and Project modifications expected to be implemented under a new FERC license for the Narrows Project.[6]

2.1 Project Purpose and Objectives

CEQA requires that an EIR contain a "*statement of the objectives sought by the proposed project*." "[A] *clearly written statement of objectives will help the lead agency develop a reasonable range of alternatives to evaluate in the EIR and will aid the decision makers in preparing findings or a statement of overriding considerations. The statement of objectives should include the underlying purpose of the project and may discuss the project benefits*" (CEQA Guidelines § 15124(b)).

When FERC issues new licenses for the YRDP and the Narrows Project under the FPA, Yuba Water will be required to decide whether or not to accept each one of the new licenses.[7] The project objectives provide the reasons that Yuba Water is seeking renewal of FERC licenses for the YRDP and the Narrows Project, respectively.

2.1.1 YRDP

The project objectives for the YRDP Relicensing are the following:

1. Obtain a new FERC license for the YRDP under which Yuba Water can generate sufficient revenues to support its continued use, operation, and maintenance of the YRDP facilities to advance its missions established by the Legislature in the Yuba County Water Agency Act (Agency Act).[8]
2. Obtain a new FERC license for the YRDP under which Yuba Water can generate sufficient revenues to maintain and operate Yuba Water's existing flood control facilities, and implement new flood risk reduction projects in Yuba County.
3. Obtain a FERC license for the YRDP under which Yuba Water can operate the YRDP to provide adequate and reliable agricultural surface water supplies within Yuba County and to maintain sustainable conditions in the North Yuba and South Yuba groundwater basins

[5] To date, no FERC-recommended modifications or additional measures to Yuba Water's proposal for the Narrows Project have been identified, and no FPA Section 4(e) Conditions have been recommended by the USFS or others. The SWRCB has not yet acted on Yuba Water's request for a WQC that was submitted to the SWRCB on December 30, 2024 and filed with FERC (Available in FERC's eLibrary at Accession No. 20241230-5125 (Filed on December 30, 2024)). Yuba Water will evaluate whether any measures or conditions included in the license require further environmental review as required by CEQA before considering accepting the license.

[6] Several exhibits were developed by Yuba Water for the Narrows Project FERC relicensing process and filed with FERC as part of Yuba Water's 2023 FLA. Narrows-related exhibits that are relevant to characterizing the CEQA Baseline (Existing Condition) and the Narrows Proposed Project are presented in **Appendix 2F**, and include: (1) Narrows Exhibit A – Project Description; (2) Narrows Exhibit B – Project Operations and Resource Utilization; (3) Narrows Exhibit C – Construction History and Proposed Construction Schedule; (4) Narrows Exhibit D – Statement of Costs and Financing; and (5) Narrows Exhibit G – Project Maps. All exhibits related to the Narrows Project FLA are available in FERC's eLibrary at Accession No. 20231114-5136 (Filed on November 14, 2023).

[7] A licensee's failure to file a request for rehearing of FERC's license order within 30 days constitutes the licensee's acceptance of the new license.

[8] Section 4.1 of the Agency Act (West's California Water Code App. § 84-4.1) authorizes Yuba Water to develop hydroelectric power in connection with Yuba Water's projects. For additional information regarding Yuba Water, refer to Yuba Water's website at https://www.yubawater.org/.

for all beneficial uses, consistent with the Sustainable Groundwater Management Act (Water Code sections 10720-10738).

4. Operate the YRDP to provide streamflow and water temperature benefits for sensitive fish species in the lower Yuba River, downstream of the YRDP's facilities, consistent with the benefits the YRDP has provided for those beneficial uses.
5. Consistent with FERC's March 2021 Additional Information Request (AIR), implement any additional protections for ESA-listed fish species in the lower Yuba River in a way that both:
    (a) improves Yuba River water temperatures for those species and their designated critical habitat; and
    (b) equitably allocates protective activities such that no entity is disproportionately burdened with a responsibility to mitigate impacts on those species caused by other entities.
6. Continue to generate long-term, predictable revenue for Yuba Water's programs to support Yuba County's disadvantaged communities consistent with Yuba Water's mission.
7. Continue to support California's power requirements by providing carbon-free hydropower generation to:
    (a) meet resource diversity and capacity needs within the Sierra Local Capacity Area consistent with the Agency Act, CEC regulations and CAISO energy markets.
    (b) To respond to requests from CAISO to provide additional power during power emergencies (e.g., heat-related shortages) to support statewide electrical grid systems.
8. Continue to generate long-term, predictable revenue for Yuba Water's fisheries and aquatic habitat enhancement projects on the lower Yuba River.
9. Obtain stability and predictability in long-term YRDP operations to generate sufficient funds to allow Yuba Water to comply with the YRDP license conditions, and to justify substantial upfront investments by Yuba Water for modifications to its generation facilities, the addition of the flood control outlet, and implementing PM&Es, including constructing and refurbishing recreation facilities and access roads thereto during the next license term.
10. Consistent with state policies favoring water transfers stated in Water Code sections 109 and 475, continue to support statewide water supply reliability through continued Lower Yuba River Accord transfers to contractors of the CVP and the SWP, and potentially others, under the Lower Yuba River Accord Water Purchase Agreement.

As described in FERC's (2019) FEIS, FERC's issuance of a new license for the YRDP would allow Yuba Water to continue to use water available to Yuba Water to generate electricity at the YRDP facilities for the term of a new FERC license, consistent with the above objectives.

2.1.2 Narrows Project

The project objectives for the Narrows Project Relicensing include the following:

1. Continue to support Yuba Water's coordinated operations of the Narrows Project with the YRDP to advance and implement Yuba Water's core flood-control and water-supply missions established by the Legislature in the Agency Act.
2. Obtain a new FERC license for the Narrows Project to generate revenues to continue to fund operation and maintenance of the Narrows Project facilities as part of Yuba Water's flood-control and water-supply missions under the Agency Act.
3. Continue to generate long-term, predictable revenue for Yuba Water's programs to support Yuba County's disadvantaged communities.
4. Continue to generate long-term, predictable revenue for Yuba Water's fisheries and aquatic habitat enhancement projects on the lower Yuba River.
5. Continue to support California's power requirements by providing renewable hydropower generation to meet resource diversity and capacity needs consistent with the Agency Act, CEC regulations and CAISO energy markets.
6. Obtain stability and predictability in long-term Narrows Project operations to generate funds to allow Yuba Water to comply with the Narrows Project license conditions.
7. Continue to provide stability and reliability in long-term YRDP and Narrows Project coordinated operations by obtaining a new FERC license for the Narrows Project that will run concurrently with the term of a new FERC license for the YRDP.

FERC's issuance of a new license for the Narrows Project would allow Yuba Water to continue to use public waters to generate electricity at the Narrows Project facilities for the term of the new FERC license, making electrical power from a renewable resource available for transmission to its customers, consistent with the above objectives.

2.2 Project Location

The YRDP and Narrows Project are both located in the Yuba River Watershed, which has a drainage area of approximately 1,108 square miles (sq mi) at Englebright Dam[9] and 1,339 sq mi at its confluence with the Feather River. Figure 2.2-1 shows the general regional location of the Yuba River Watershed.

[9] The Harry L. Englebright Dam (Englebright Dam) and Reservoir, a federally owned facility administered and operated by the USACE, is located upstream of the YRDP's and Narrows powerhouse facilities. Both the YRDP and the Narrows Project take advantage of water received from USACE's Englebright Reservoir. Englebright Dam, which is about 260 ft high and forms Englebright Reservoir, was constructed by the California Debris Commission in 1941. Englebright Dam and the surrounding land are owned by the United States. When the California Debris Commission was decommissioned in 1986, administration of Englebright Dam and Reservoir passed to the USACE.

2.2.1 YRDP

The YRDP is located in Yuba, Sierra and Nevada counties, California, on the main stems of the Yuba River, the North Yuba River and the Middle Yuba River, and on Oregon Creek, a tributary to the Middle Yuba River. The Yuba River is a tributary to the Feather River and is part of the Sacramento River Basin, which drains into San Francisco Bay. The YRDP currently occupies 4,432.8 acres (ac) of Federal land, consisting of 4,416.7 ac within the Tahoe National Forest (TNF) and the Plumas National Forest (PNF) associated with the New Colgate Development, which is administered by the USFS, and 16.1 ac associated with the Narrows 2 Development, which is administered by USACE. Figure 2.2-2 shows the Project Vicinity,[10] including the existing FERC Project Boundary for the YRDP (dashed black line). The YRDP area ranges in elevation from 290 feet (ft) to 2,030 ft above mean sea level (msl).

[10] For the purposes of this document, "Project Vicinity" refers to the area surrounding the proposed YRDP Relicensing Project on the order of United States Geological Survey (USGS) 1:24,000 quadrangles.

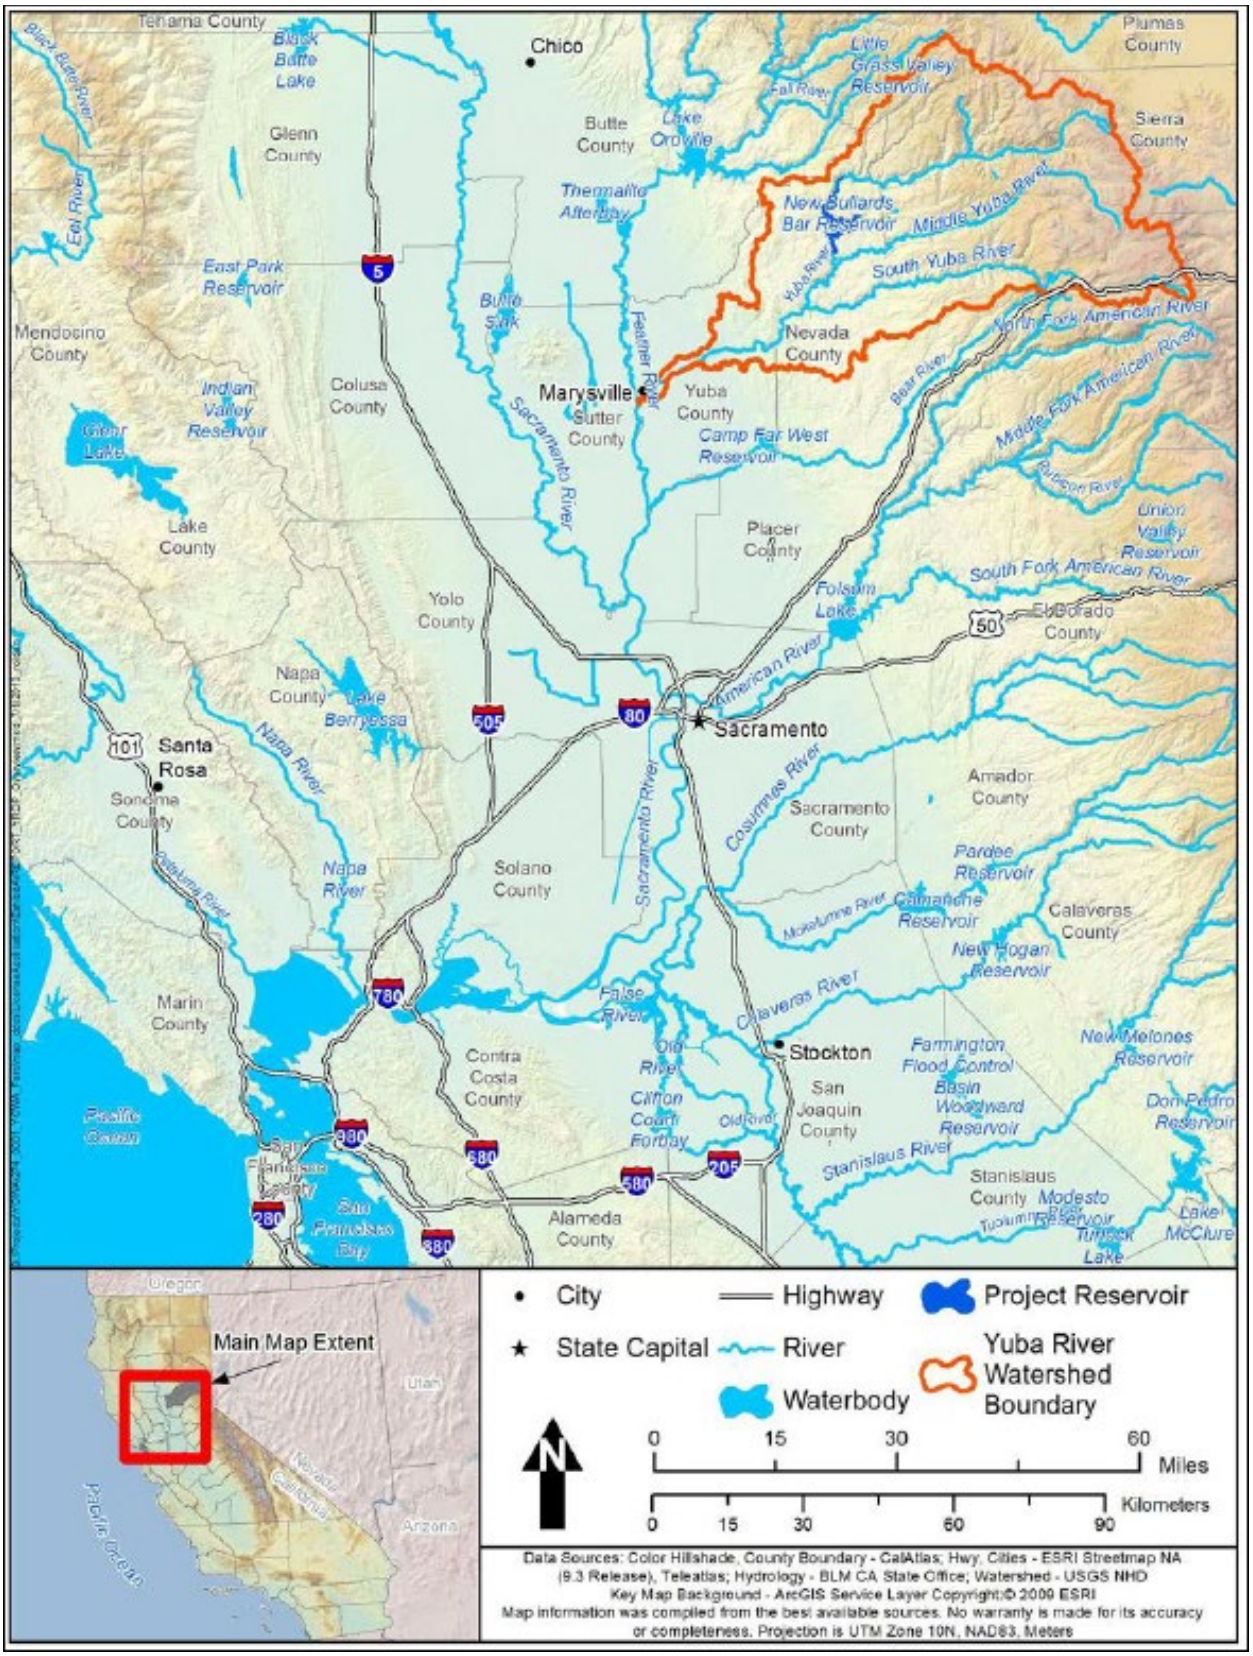

Figure 2.2-1. Yuba River Watershed in relation to the Feather River and other tributaries of the Sacramento River.

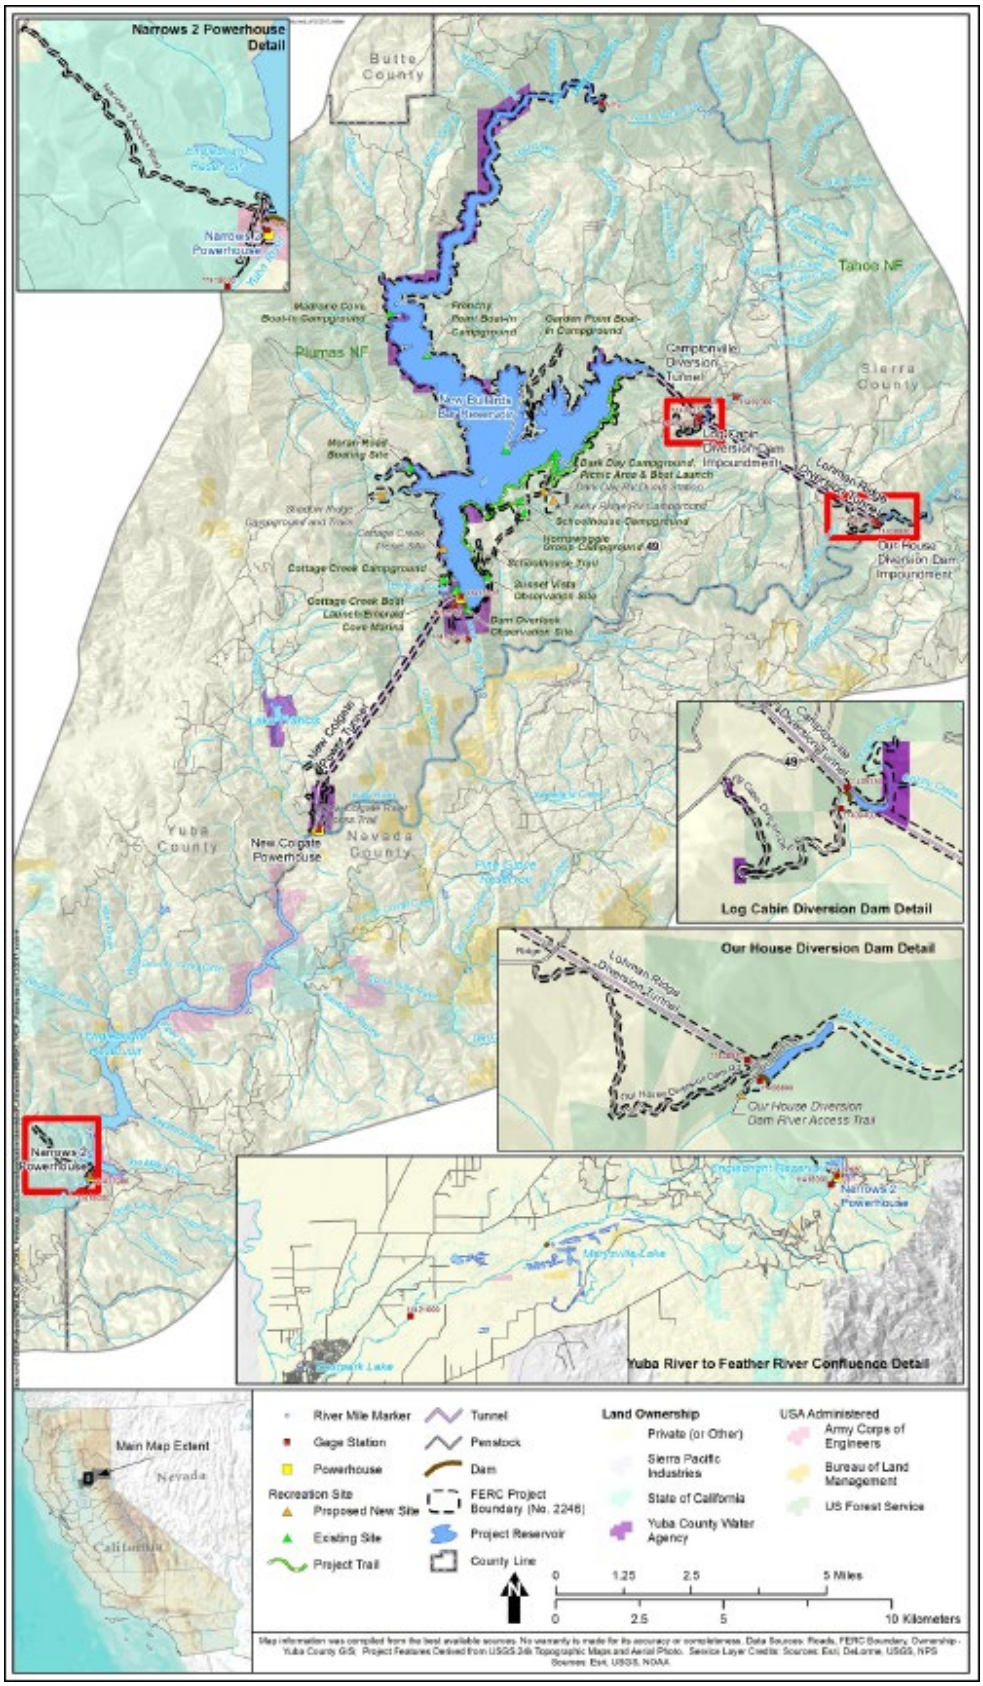

Figure 2.2-2. Yuba Water's YRDP and Project Vicinity.

2.2.2 Narrows Project

The Narrows Project is located along the lower Yuba River in Nevada County, California, approximately 23 miles northeast of the City of Marysville. The Narrows Project works are located on the south bank of the lower Yuba River extending approximately 0.2-mile downstream of USACE's Englebright Dam (Figure 2.2-3). The FERC Project Boundary includes a total of 2.92-ac, including 2.37 ac of Yuba Water-owned lands, which include all lands on which above-ground Project facilities and features are located, and 0.55-ac of federal lands, which are above the Narrows Tunnel (i.e., no surface facilities on federal lands) and are administered by the USACE (YCWA 2021). The Narrows Project area ranges in elevation from 300 ft to 849 ft above msl.

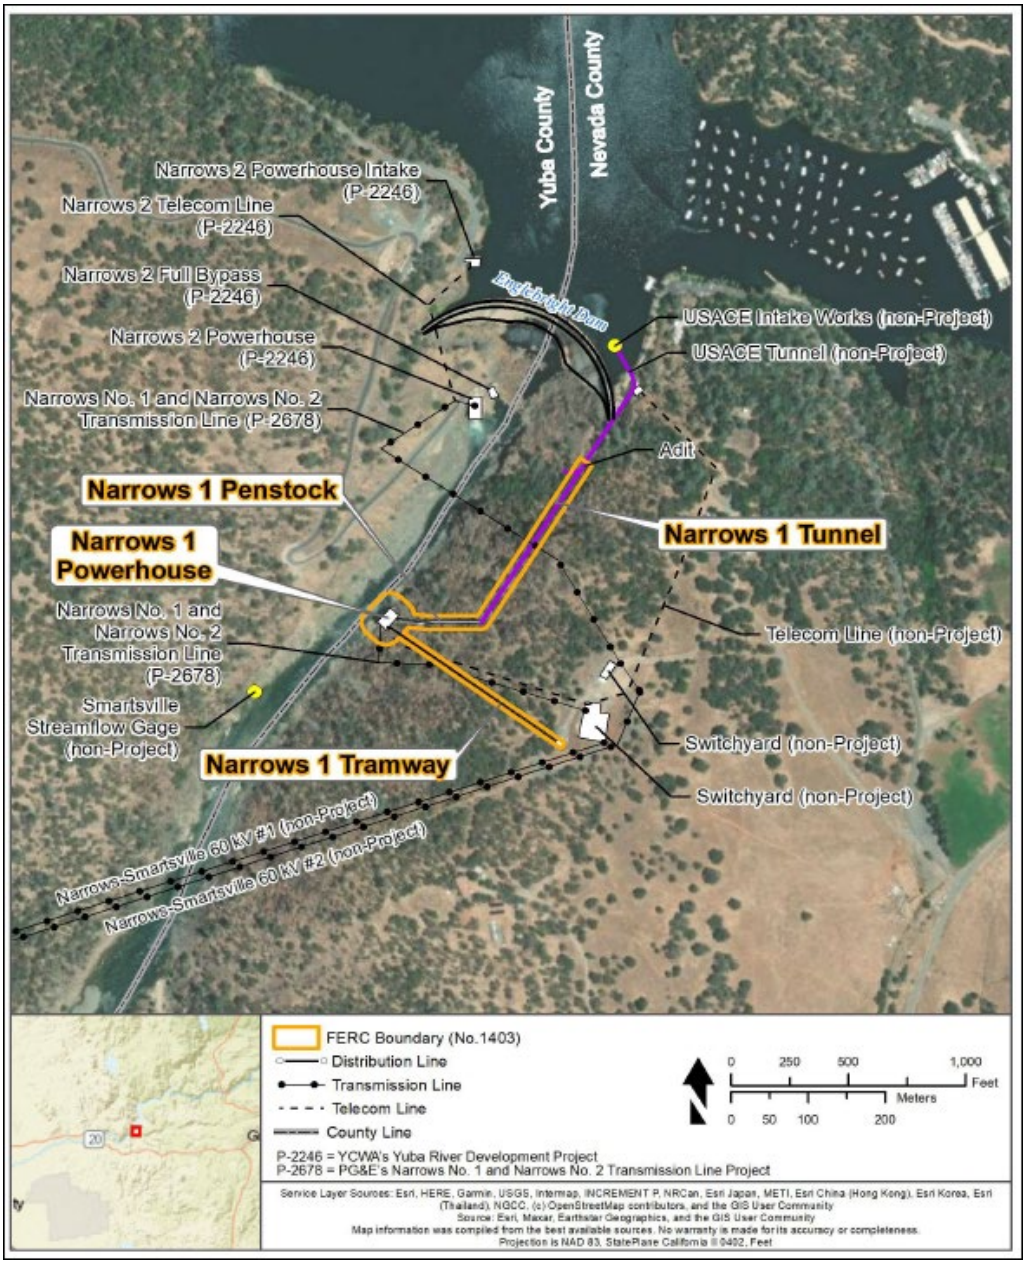

Figure 2.2-3. Yuba Water's Narrows Project and nearby non-YRDP facilities and features.

From the Narrows 1 Powerhouse, the lower Yuba River flows approximately 24.1 miles to its confluence with the Feather River, which is part of the Sacramento River Basin and drains into the Sacramento River and subsequently into San Francisco Bay.

2.3 Existing Projects

For both the YRDP and the Narrows Project, provided below is a description of: (1) existing facilities; (2) existing FERC Project Boundary; (3) current operations; (4) maintenance activities; (5) existing recreation facilities; and (6) conditions in the existing FERC license and other agreements and contracts that affect existing operations.

2.3.1 Existing YRDP

2.3.1.1 Existing YRDP Facilities

The existing YRDP includes three developments[11] – New Colgate, New Bullards Bar Minimum Flow, and Narrows 2 – each of which is described below. Existing YRDP facilities are shown in Figure 2.2-2. From 2008 through 2024, the YRDP generated an average of 1,188,624 MWh of power annually. The YRDP's total installed capacity under the existing license is 361.9 MW and Yuba Water's calculated dependable capacity is 247,331 kilowatts (kW). Table 2.3-1 summarizes key information for YRDP powerhouses.

Table 2.3-1. Key information regarding YRDP powerhouses.

Powerhouse	Unit	Turbine Type	Rated Head (ft)	Rated Hydraulic Capacity (cfs)		Generation Capacity (kW)		Average Annual Energy (MWh/yr)
				Minimum	Maximum	Nameplate Rating[1]	Dependable[2]	
New Colgate	1	Pelton	1,306	0	1,715	157,500	247,261	1,082,762
New Colgate	2	Pelton	1,306	0	1,715	157,500		
New Bullards Minimum Flow	1	Pelton	561	0	5	150	0	984
Narrows 2	1	Francis	236	600	3,400	46,750	70	161,441
Total	**4**	**--**	**--**	**--**	**--**	**361,900**	**247,331**	**1,245,187**

Notes: cfs = cubic feet per second; kW = kilowatt; MWh/yr = megawatt-hours/year

[1] From Table 5.2-6 in Exhibit D of Yuba Water's 2017 AFLA (see Appendix 2A-4).

[2] From Table 5.2-7 in Exhibit D (i.e., historical dependable capacity) of Yuba Water's 2017 AFLA (see Appendix 2A-4).

The existing YRDP can store approximately 966,473 acre-feet (ac-ft) of water in gross storage. Table 2.3-2 summarizes key information for YRDP reservoirs.

[11] A "hydropower development" refers to the process of building and constructing a facility that harnesses the power of flowing water to generate electricity, essentially creating a hydropower plant at a specific location, which typically involves building a dam or diversion structure to control the water flow and drive turbines to produce electricity. "Developments" are project facilities that are situated immediately upstream of a powerhouse, which are not part of another development. "Developments" may include the part of a project comprising an impoundment and its associated dams, forebays, water conveyance facilities, power plants, and other appurtenant facilities. A project may comprise one or more developments (18 C.F.R. 12.3(b)(7)).

Table 2.3-2. Key information regarding YRDP reservoirs and impoundments.

Project Reservoir	NMWSE[1] (ft)	Gross Storage[2] (ac-ft)	Usable Storage (ac-ft)	Surface Area[2] (ac)	Maximum Depth[2] (ft)	Shoreline Length[2] (mile)	Drainage Area[3] sq mi)
Our House Diversion Dam Impoundment	2,030	280	None	14	65	0.7	144.8
Log Cabin Diversion Dam Impoundment	1,970	90	None	5	40	0.4	29.1
New Bullards Bar Reservoir	1,956	966,103	961,103	4,790	636	71.9	466.6
Total	**--**	**966,473**	**961,103**	**4,809**	**--**	**--**	**--**

[1] NMWSE = Normal Maximum Water Surface Elevation
[2] Storage between NMWSE and the invert of the 72-in. hollow jet low level outlet.
[3] At the dam, and drainage areas are not additive.

2.3.1.1.1 New Colgate Development

The New Colgate Development is located on the main stems of the North Yuba River, Middle Yuba River, Yuba River, and Oregon Creek, a tributary to the Middle Yuba River. The development includes two diversion dams (Our House and Log Cabin), two diversion tunnels (Lohman Ridge and Camptonville), one storage reservoir (New Bullards Bar), one power tunnel and penstock (New Colgate) and one powerhouse (New Colgate). Representative photographs of the non-recreation facilities and features are provided in Appendix 2A, Exhibit A**.** Additionally, Figure 2.0-2 in Exhibit A to Appendix 2A shows all of these YRDP features on a map.

The New Colgate Development consists of the following features:

1. Our House Diversion Dam is a 130-ft radius, double curvature, concrete arch dam located in Sierra County on the Middle Yuba River 12.6 miles upstream of its confluence with the North Yuba River. The dam is 70 ft high with a crest length of 368 ft and a crest elevation of 2,030 ft, and has a drainage area of 144.8 sq mi. The dam has a spillway, a fish release outlet valve used for releasing minimum flow requirements in the existing FERC license, and a low-level (5-ft diameter) outlet valve (Figure 2.3-1).[12] The spillway, with an invert elevation of 2,030 ft, is ungated and has a maximum capacity of 60,000 cubic feet per second (cfs). The fish release outlet valve has an invert elevation of 1,990 ft, and an engineer's estimated maximum capacity of 59 cfs when the pool is at the invert (2,015 ft) of the Lohman Ridge Diversion Tunnel. The fish release outlet is controlled by a hand-operated 24-inch (in.) valve on the downstream end of the outlet. The low-level outlet has an invert elevation of 1,987 ft, and an engineer's estimated maximum capacity of 463 cfs when the pool is at the invert of the Lohman Ridge

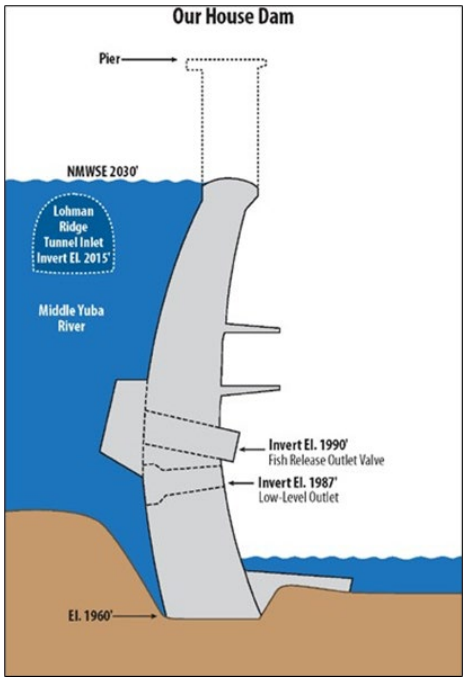

Figure 2.3-1. Our House Diversion Dam features.

[12] For the purpose of Yuba Water's FERC application, the slide gate that controls the Our House Diversion Dam low-level outlet is referred to as a "valve."

Diversion Tunnel. The low-level outlet is controlled by a slide gate, which is operated by a two-person portable gasoline powered engine, on the upstream face of the dam.

2. Our House Diversion Dam Impoundment, a 280 ac-ft impoundment formed by Our House Diversion Dam.

3. Lohman Ridge Diversion Tunnel, a 12.5-ft high by 12.5-ft wide tunnel that conveys a maximum flow of 860 cfs through its 19,410-ft (90% unlined and 10% lined) length from the Middle Yuba River to Oregon Creek. The invert of the tunnel intake is at elevation 2,015 ft, which is 15 ft below the Normal Maximum Water Surface Elevation (NMWSE) for Our House Dam (i.e., water can only be diverted through the tunnel when the impoundment's water surface elevation (WSE) is 2,015 ft or greater).

4. Log Cabin Diversion Dam, is a 105-ft radius, concrete arch dam located in Yuba County on Oregon Creek 4.3 miles upstream of the confluence with the Middle Yuba River. The dam is 42.5 ft high with a crest length of 300 ft, a crest elevation of 1,970 ft, and a drainage area of 29.1 sq mi. The dam has a spillway, a fish release outlet valve used for releasing minimum flow requirements in the existing FERC license, and a low-level (5-ft diameter) outlet valve (Figure 2.3-2).[13] The spillway, with an invert elevation of 1,970 ft, is ungated and has a maximum capacity of 12,000 cfs. The fish release outlet valve has an invert elevation of 1,947 ft and an engineer's estimated maximum capacity of 18 cfs when the pool is at the invert (1,952 ft) of the Camptonville Diversion Tunnel. The outlet is controlled by a hand-operated valve on the downstream end of the outlet. The low-level outlet has an invert elevation of 1,935 ft, and an engineer's estimated maximum capacity of 348 cfs when the pool is at the invert of the Camptonville Diversion Tunnel. The low-level outlet is controlled by a slide gate, which is operated by a two-person portable gasoline powered engine, on the upstream face of the dam.

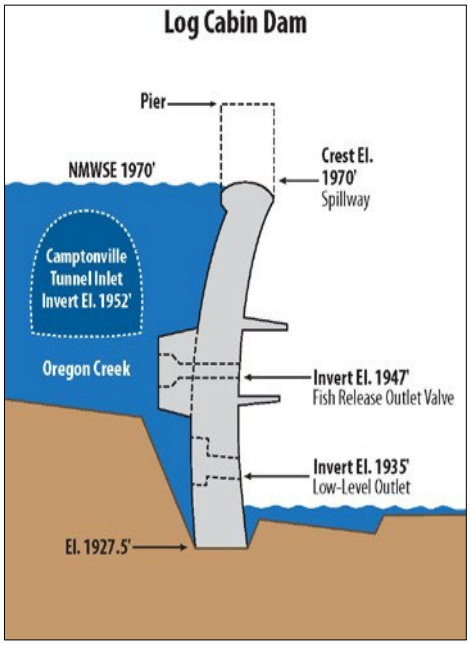

Figure 2.3-2. Log Cabin Diversion Dam features.

5. Log Cabin Diversion Dam Impoundment, a 90 ac-ft impoundment formed by Log Cabin Diversion Dam.

6. Camptonville Diversion Tunnel, a 6,107-ft long tunnel that has the capacity to convey 1,100 cfs of water from Oregon Creek to New Bullards Bar Reservoir on the North Yuba River. The first 4,275 ft of the conduit is an unlined, horseshoe-shaped tunnel 14.5 ft wide by 14.5 ft high, which (for the last 1,832 ft) becomes a lined, horseshoe-shaped tunnel 11.7 ft wide by 13 ft high. The tunnel invert elevation is 1,952 ft, which is 18 ft below the

[13] For the purpose of Yuba Water's FERC application, the slide gate that controls the Log Cabin Diversion Dam low-level (5-ft diameter) outlet is referred to as a "valve."

NMWSE for Log Cabin Diversion Dam (i.e., water can only be diverted through the tunnel when the impoundment's WSE is greater than 1,952 ft).

7. New Bullards Bar Dam, a 1,110-ft radius, double curvature, concrete arch dam located on the North Yuba River about 2.4 miles upstream of its confluence with the Middle Yuba River. The dam is 645 ft high with a maximum elevation of 1,965 ft. The dam includes one low-level outlet – a 72-in. Hollow Jet Valve (invert elevation 1,444.5 ft) with a maximum design capacity of about 3,500 cfs at full reservoir pool, and an actual capacity of 1,250 cfs (i.e., actual release capacity is limited to 1,250 cfs because of valve vibrations at higher release rates). The dam includes an overflow-type spillway with a width of 106 ft and a crest elevation of 1,902 ft. Control gates on the spillway consist of three Tainter Gates measuring 30 ft wide and 54 ft tall and hoisted by 10 horsepower drum hoists. The maximum design capacity of the spillway is 160,000 cfs. Figure 2.3-3 provides a longitudinal schematic of New Bullards Bar Dam.
8. New Bullards Bar Reservoir, a storage reservoir on the North Yuba River formed by New Bullards Bar Dam. At NMWSE (1,956 ft), New Bullards Bar Reservoir extends about 15.3 river miles upstream on the North Yuba River, has an estimated gross storage capacity of 966,103 ac-ft, a surface area of 4,790 ac, a shoreline of about 71.9 miles, and a drainage area of 488.6 sq mi.
9. New Colgate Power Tunnel Intake, a structure on the upstream face of New Bullards Bar Dam composed of a curtain wall, trash rack and two intakes, one with an invert elevation of 1,808 ft and the other with an invert elevation of 1,627.5 ft. The upper intake is not used per the direction of CDFW (Figure 2.3-3).
10. New Colgate Power Tunnel and Penstock, a 5.2-mile-long conveyance facility composed of four different types of conveyance structures: an unlined horseshoe-shaped tunnel 26 ft square; a lined horseshoe-shaped tunnel 20 ft wide and 14.5 ft high; a lined circular tunnel 14 ft in diameter; and 2,809 ft of steel penstock with a diameter ranging from 9 ft to 14.5 ft. The tunnel and penstock have a maximum flow capacity of 3,500 cfs (Figure 2.3-3).

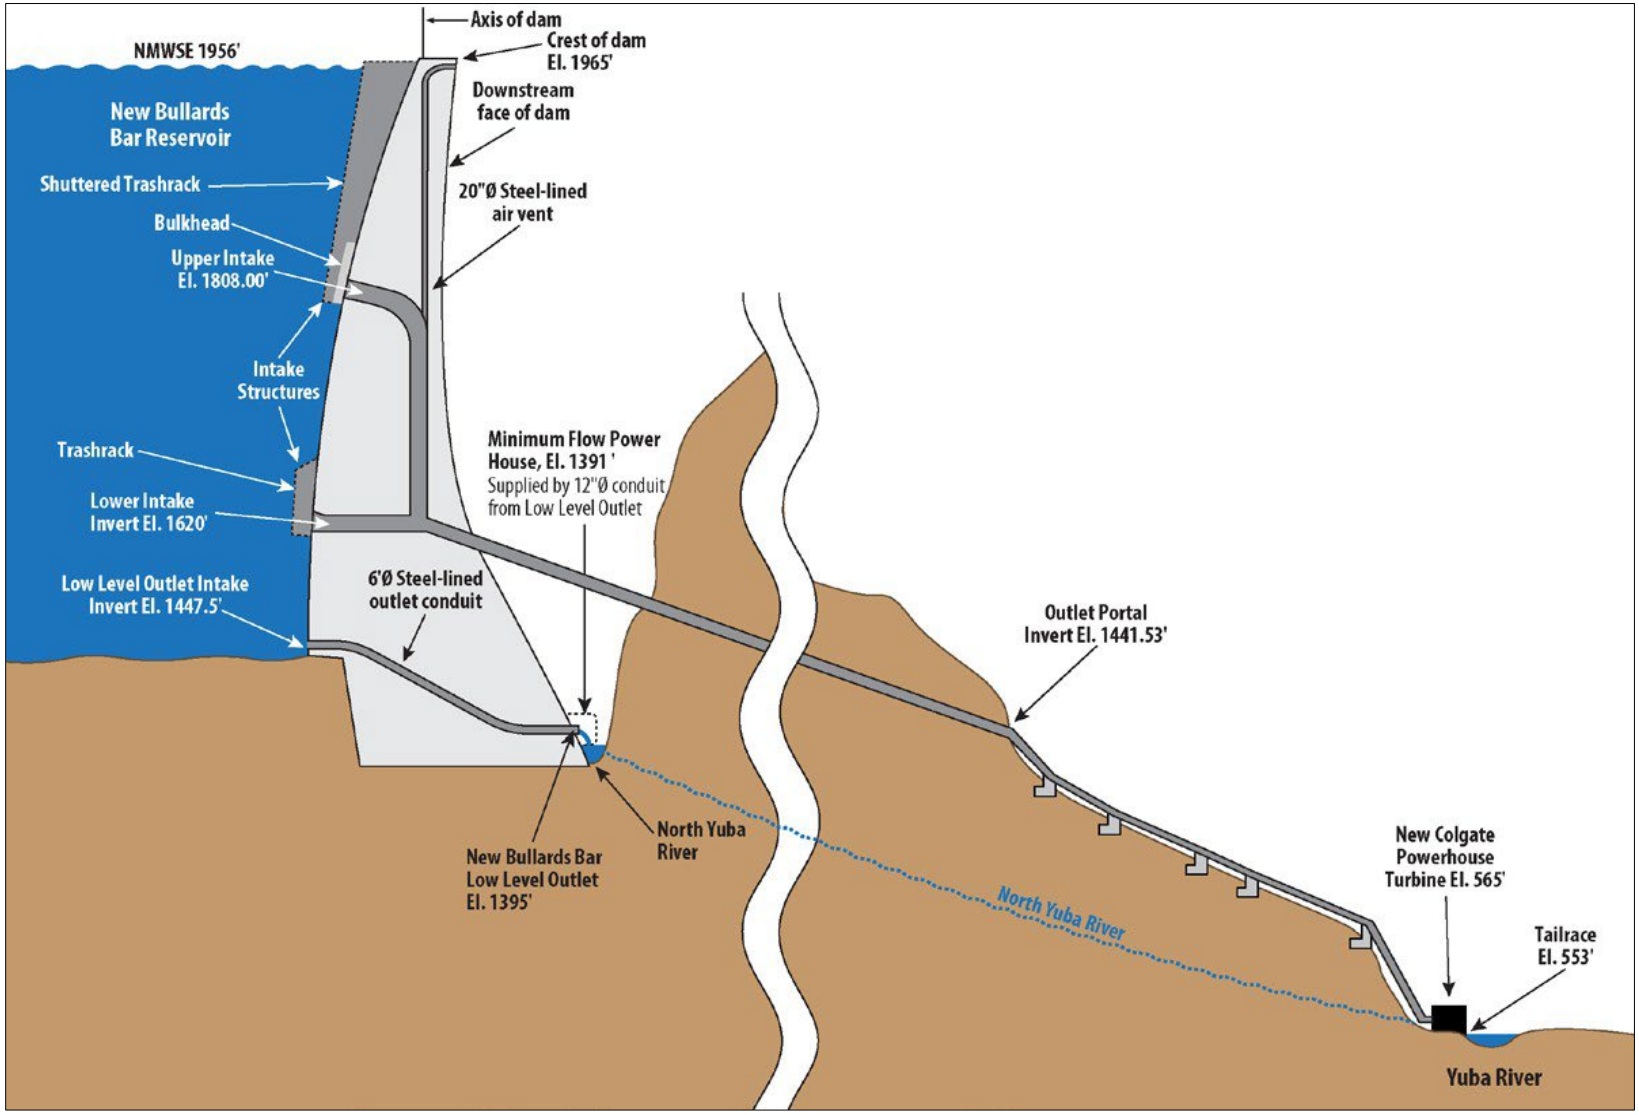

Figure 2.3-3. Longitudinal schematic of New Bullards Bar Dam on the North Yuba River and New Colgate Power Tunnel and Powerhouse on the Yuba River.

11. New Colgate Powerhouse and Switchyard, a mostly underground, steel reinforced, concrete powerhouse located adjacent to the Yuba River. The powerhouse contains two vertical-shaft Voith Siemens Pelton type turbines with a total actual measured capacity of 340 MW under a design head of 1,306 ft and a measured flow of 3,430 cfs. The New Colgate Switchyard is located adjacent to New Colgate Powerhouse (Figure 2.3-3).
12. New Bullards Bar Reservoir Recreation Facilities, 16 recreation facilities, which are: (1) Hornswoggle Group Campground; (2) Schoolhouse Campground; (3) Dark Day Campground; (4) Cottage Creek Campground; (5) Garden Point Boat-in Campground; (6) Madrone Cove Boat-in Campground; (7) Frenchy Point Boat-in Campground; (8) Dark Day Picnic Area; (9) Sunset Vista Point; Dam Overlook; (10) Moran Road Day Use Area; (11) Cottage Creek Boat Launch; (12) Dark Day Boat Launch; (13) Schoolhouse Trail; (14) Bullards Bar Trail; and (15) floating comfort stations. All of the recreation facilities are located on National Forest System (NFS) land, with the exception of the Dam Overlook, Cottage Creek Boat Launch and small portions of the Bullards Bar Trail, which are located on land owned by Yuba Water. All of the developed recreation facilities are located within the existing FERC Project Boundary, except for a few short segments of the Bullards Bar Trail to the east of the Dark Day Boat Launch.
13. Streamflow Gages, two streamflow gages, one each located downstream of Our House Diversion Dam (USGS Gage 11408880) and downstream of Log Cabin Diversion Dam (USGS Gage 11409400).
14. Roads, 15 existing Primary Project Road segments for a total length of 4.61 miles, and 12 recreation-related road segments for a total length of 3.84 miles (Appendix 2A, Exhibit A).

2.3.1.1.2 New Bullards Bar Minimum Flow Development

The New Bullards Bar Minimum Flow Development consists of the following facilities and features:

1. New Bullards Minimum Flow Powerhouse Penstock, a 70-ft long, 12-in. diameter steel penstock with a maximum flow capacity of 6 cfs (Figure 2.3-3). The penstock bifurcates off the New Bullards Bar Dam low-level outlet upstream of the 72-in. Hollow Jet Valve.
2. New Bullards Minimum Flow Powerhouse, a single Pelton turbine with a capacity of 150 kW at a flow of 5 cfs (Figure 2.3-3).
3. New Bullards Minimum Flow Transformer, a transformer located adjacent to the New Bullards Minimum Flow Powerhouse.
4. Streamflow Gages, one streamflow gages, located downstream of New Bullards Bar Dam (USGS Gage 11413517).

The New Bullards Bar Minimum Flow Development does not include any recreation facilities, Primary Project Roads, or Recreation Roads.

2.3.1.1.3 Narrows 2 Development

The YRDP Narrows 2 Development consists of the following features:

1. Narrows 2 Powerhouse Penstock, a tunnel that is 20 ft in diameter and concrete lined in the upper 376 ft, and 14 ft in diameter and steel lined for the final 371.5 ft. The penstock has a maximum flow capacity of 3,400 cfs. The penstock bifurcates above the spiral case. One branch conveys water to the Narrows 2 Full Bypass, which is described below. The other branch conveys water to the Narrows 2 Powerhouse and Partial Bypass, which are described below. Figure 2.3-4 provides a longitudinal schematic of the Narrows 2 Powerhouse Penstock and Powerhouse.

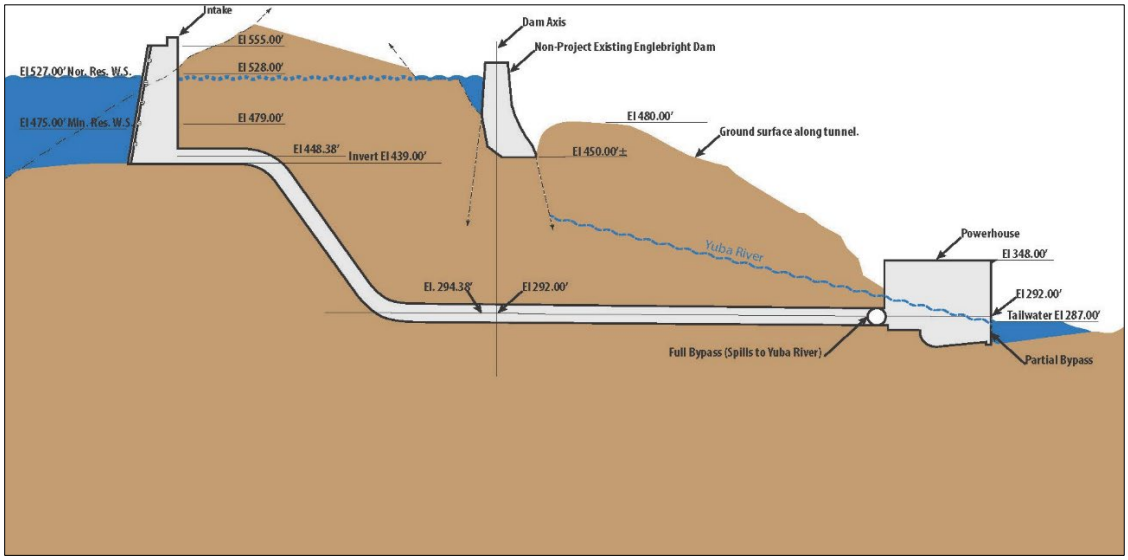

Figure 2.3-4. Longitudinal schematic of YRDP Narrows 2 Powerhouse Penstock and Powerhouse.

1. Narrows 2 Full Bypass (Full Bypass), a valve and penstock branch off the Narrows 2 Penstock, which can discharge[14] up to 3,000 cfs of water at full head into the Yuba River immediately upstream of the Narrows 2 Powerhouse through a 72-in. diameter fixed-cone valve in a concrete structure. The full bypass was installed in 2008 to maintain minimum flows during times of full shutdown of the Narrows 2 Powerhouse and is also used during flow transitions between the Narrows 2 Powerhouse and the Narrows Project (FERC No. 1403) Narrows 1 Powerhouse (Figure 2.3-4).
2. Narrows 2 Powerhouse and Switchyard, an indoor powerhouse located about 200 ft downstream of Englebright Dam. The powerhouse consists of one vertical axis Francis turbine with a capacity of 55 MW at a head of 236 ft and flow of 3,400 cfs. Releases from the powerhouse draft tube are subsurface. The Narrows 2 Powerhouse Switchyard is located adjacent to the powerhouse.
3. Narrows 2 Partial Bypass (Partial Bypass), includes a pipe off the Narrows 2 Powerhouse turbine scroll case, which can discharge up to 650 cfs of water at full head into the Yuba River through a 36-in. valve located on the downstream face of the powerhouse above the

[14] For the purpose of the FERC relicensing process and this DEIR, "discharge" means the estimated flow through a facility at a designated location in terms of cfs. A discharge may be measured or estimated, and may also be referred to as a "release."

draft tube outlet. The Partial Bypass was built as part of the original design when the Narrows 2 Powerhouse was constructed.

4. Streamflow Gages, none.[15]
5. Roads, four existing Primary Project Road segments for a total length of 2.27 miles.

The YRDP Narrows 2 Development does not include any recreation facilities or recreation roads.

2.3.1.2 Existing YRDP FERC Project Boundary

The FERC Project Boundary consists of all lands necessary for the safe O&M of the YRDP and other purposes, such as recreation, shoreline control, and protection of environmental resources. For the YRDP, the existing Project Boundary encompasses 7,815.2 ac of land in Yuba, Nevada and Sierra counties, California. The existing FERC Project Boundary (Figure 2.2-2) includes a zone of area that encloses all YRDP facilities and features. The width of the zone around a facility or feature varies depending on the type of YRDP facility or feature and the activities associated with it.

A total of 56.5 percent of the land (4,416.7 ac) within the FERC Project Boundary is NFS lands, and 0.2 percent (16.1 ac) is USACE lands. The state of California owns 0.3 percent of the land (20.1 ac). Yuba Water owns 40.3 percent of the land (3,149.3 ac). The remaining 2.7 percent of the land (213.0 ac) within the existing FERC Project Boundary is in private ownership. The existing FERC Project Boundary for the YRDP (dashed black line) is shown on Figure 2.2-2, and more detailed maps of the existing FERC Project Boundary for the YRDP are provided in **Appendix 2A-5**.

2.3.1.3 Existing YRDP Operations

One of Yuba Water's major considerations each year is anticipated water availability. Yuba Water begins estimating water availability each year in January and continually updates the estimate throughout the spring runoff period. When estimating available water supply, Yuba Water considers current reservoir storage and California Department of Water Resources (DWR) Bulletin 120 forecasts of unimpaired flow at the Smartsville Gage on the lower Yuba River and the Goodyears Bar Gage on the North Yuba River. Estimates of available water supply and other water needs are compared to estimates of required releases, consumptive demands within Yuba Water, and target levels for fall carryover storage in New Bullards Bar Reservoir.

Typically, Yuba Water operates New Bullards Bar Reservoir by capturing winter and spring runoff from rain and snowmelt. The North Yuba River inflow to New Bullards Bar Reservoir is augmented by diversions from the Middle Yuba River to Oregon Creek through the Lohman Ridge Tunnel, and by diversions from the Lohman Ridge Tunnel and Oregon Creek into the reservoir

[15] The YRDP Narrows 2 Development does not include any streamflow gages. Yuba Water uses two non-project gages to monitor compliance with streamflow requirements. These gages are: USGS Gage 11418000, *Yuba River Below Englebright Dam, Near Smartsville*, and USGS Gage 1142100, *Yuba River Near Marysville*. The Smartsville Gage is owned, operated, and maintained by PG&E. The Marysville Gage is owned by Yuba Water and operated by USGS.

through the Camptonville Tunnel.[16] Consequently, New Bullards Bar Reservoir normally reaches its peak storage at the end of the spring runoff season, and then is gradually drawn down until its lowest elevation in early to mid-winter. The reservoir does not undergo significant daily changes in elevation.

New Bullards Bar Reservoir has mandatory reserved flood storage space criteria from mid-September through the end of May that limit maximum authorized storage (see Section 2.1.5.1; see also 33 Code of Federal Regulations [C.F.R.] section 208.11(e)). The Our House and Log Cabin diversion dam impoundments have no appreciable storage, and Yuba Water operates them exclusively to divert water to New Bullards Bar Reservoir in the winter and spring during high flow periods.

During the spring of each year, Yuba Water determines the anticipated runoff into New Bullards Bar Reservoir, relying upon snow course measurements and forecasts of runoff provided by DWR. Yuba Water also makes estimates of water needs for local water deliveries and for releases to meet required instream flows for the current WY. Based on these forecasts, an end-of-September storage is estimated. If the forecasted end-of-September storage is higher than a pre-determined target used for Yuba Accord operations (650,000 ac-ft),[17] releases are increased above the required flows to draw reservoir storage down to the target level. The target storage is an operational measure used to drive releases in relatively wet years and supports water releases for out-of-basin transfers under the Yuba Accord.

In addition to the target storage, there is a minimum storage at the end-of-water year to provide carryover storage requirement for drought protection purposes. If forecasted end-of-September storage falls below an end-of-September carryover storage target of 440,000 ac-ft for the first year of a drought, or 400,000 ac-ft for subsequent years, agricultural deliveries may be reduced to ensure adequate water supply for the following year. Reservoir carryover storage is used to make up the difference between the available surface water supply provided by the current year's runoff and system demands (e.g., diversion demands, instream flow requirements, and system operational losses) under drought conditions. During wetter years, Yuba Water operates New Bullards Bar Reservoir to an end-of-September target storage level for the Yuba Accord of 650,000 ac-ft, as well as other target storage levels for various times in mid-winter and spring that are parts of power generation operations and flood control operations.

The New Bullards Bar Minimum Flow Powerhouse is operated as a "base load" facility, where flows are set at a constant rate to provide the required instream flows downstream of New Bullards Bar Dam. In contrast, the New Colgate Powerhouse is a highly versatile facility and is used for a combination of peaking and base generation. Depending upon energy demand, the New Colgate Powerhouse generation can be fluctuated in less than 10 minutes from a minimum of 2 MW with only one unit operating to maximum load of 340 MW with both units operating if both units are ramped up at the same time. This ability to rapidly fluctuate generation, along with substantial

[16] The average total inflows to New Bullards Bar Reservoir from the North Yuba River and diversions from the Middle Yuba River and Oregon Creek are about 1,200,000 ac-ft per year, and annual inflow has ranged from a low of 163,000 ac-ft in 1977 to a high of 2,800,000 ac-ft in 1982.

[17] An end-of-September storage of 650,000 ac-ft would ensure adequate storage to meet full irrigation demands and dry-year flow requirements for a 90 percent exceedance drought in the following year.

storage available in New Bullards Bar Reservoir and its central geographical location, makes the New Colgate Powerhouse important and unique to the Northern California power grid.

For most of the year, New Colgate Powerhouse is operated as a peaking facility, or to provide ancillary services such as spinning reserves or regulation. Under peaking operations, releases through the powerhouse are concentrated to hours of the day when power is most valuable or when power demand is higher, such as weekdays from mid-morning through early evening that largely correspond to warmer times of the day and peak workday and early evening hours. Under ancillary services operations, the generating station is ramped upwards or downwards quickly to respond to power system load changes on a near-real-time basis, and generating the station output and flows may vary substantially minute-to-minute. The New Colgate Powerhouse also often operates under a combined peaking/ancillary service protocol, with one unit operating in peaking mode and the other unit responding to ancillary service requirements. During some of the late 1990s and early 2000s, New Colgate Powerhouse operations were focused on weekday peak generation. More recently, power generation has shifted to a schedule driven by a balance of peak period generation and providing ancillary services to the region.

At many times, New Colgate Powerhouse provides a significant percentage of the required ancillary service for grid regulation, as dispatched by the CAISO, the entity responsible for maintaining grid reliability in California. Peaking operations dominate power generation operations at New Colgate Powerhouse. However, under high flow conditions, some or all of the available capacity is used for base load generation, generating inexpensive power while excess water must be moved through the system anyway.

2.3.1.3.1 Narrows 2 – Flow Transitions[18]

The existing YRDP FERC license requires Yuba Water to coordinate releases from the Project's Narrows 2 Powerhouse, Partial Bypass and Full Bypass and the Narrows Project in accordance with specified streamflow requirements.

Except for flow transitions, Yuba Water does not operate the Full or Partial bypasses when Narrows 2 Powerhouse is operating (i.e., water is passing through the turbine and generating electricity) and, except in very rare instances, does not operate both bypasses at the same time. The transition between Narrows 2 Powerhouse and the Full Bypass can be performed in response to an emergency when a forced outage occurs or during normal operations as part of shutdown of the powerhouse. Since installation of the Full Bypass in January 2007, use of the Partial Bypass has been significantly reduced.

Many factors contribute to how the YRDP and the Narrows Project are operated in tandem at any given time, including equipment outages, storm flows and reliability of continuous water supply conveyance. Discharge can occur from the Narrows 1 and Narrows 2 powerhouses based on:

1. Water demand;
2. Market conditions;

[18] For the purpose of this DEIR, a "transition" or "change-over" refers to decreasing or increasing the discharge from one facility in coordination with decreasing or increasing flows in another facility. A transition may include a shutdown of one facility.

3. Capacity and condition of the turbines, generators and bypasses;
4. Transmission line conditions; and
5. A desire to maintain Englebright Reservoir elevations within a limited range and Yuba River flow fluctuations for the protection of fisheries and other reasons.

There are many diverse combinations of conditions that influence these operations. Yuba Water currently operates these facilities with a fair amount of flexibility that enables the agency to rely on its experience and familiarity with the equipment, safety, and protection of environmental resources. However, Table 2.3-3 provides a rough summary of the typical historical flow ranges through the Narrows 2 Powerhouse, the Partial Bypass, the Full Bypass and the Narrows 1 Powerhouse.

Table 2.3-3. Typical distribution of flows under normal operations (i.e., excluding brief transition periods) among Narrows 2 Powerhouse (generation only), Partial Bypass, Full Bypass and Narrows 1 Powerhouse.

Range of Flow Releases to Yuba River (cfs)	Narrows 2 Powerhouse Release (generation)[1] (cfs)	Partial Bypass Release[1] (cfs)	Full Bypass Release[1] (cfs)	Narrows 1 Powerhouse Release[2] (cfs)
Up to 150	0	Up to 150	0	0
150 - 730	0	Typically not used	Typically not used	150 - 730
730 – 900	0	Up to 170	Typically not used	730
900 – 1,080	350	Typically not used	Used When Narrows 2 Powerhouse not available	550 - 730
1,080 - 4,130	350 - 3,400	Typically not used	Used When Narrows 2 Powerhouse not available	730
> 4,130	3,400	Typically not used	Used When Narrows 2 Powerhouse not available	730

[1] The typical operating flow ranges of Narrows 2 facilities are limited by long-term reliability considerations, such as vibration and cavitation of the runner; and are as follows: the Narrows 2 Powerhouse between 350 and 3,400 cfs; the Partial Bypass between 0 and 230 cfs (with physical capacity to release as high as 650 cfs); and the Full Bypass between 150 and 3,000 cfs.

[2] The use of the Narrows 1 Powerhouse is prioritized due to Narrows 1 Powerhouse being classified as a renewable energy source, and the economic value that accompanies the classification.

2.3.1.4 Existing YRDP Maintenance Activities

All YRDP facilities are maintained to ensure safe and reliable operation. Each YRDP facility is visited at least several times weekly by Yuba Water's personnel who are experienced and familiar with the facilities. Potential problems are identified and corrected, or scheduled for repair as they are discovered, in order of the severity of the potential problems. YRDP operations personnel are on duty seven days a week, and maintenance personnel are on duty Monday through Friday. Additionally, remote operation and monitoring of the YRDP facilities is automatically controlled by a supervisory control and data acquisition (SCADA) system from the YRDP's Colgate Powerhouse, which is staffed 24 hours a day 7 days a week. Stream gages and power facilities are continuously monitored, and any parameters out of the normal operating ranges are brought to the Colgate Powerhouse operator's attention with alarms. The operator evaluates and determines further action, including call-out of O&M personnel.

Ongoing YRDP maintenance includes testing gates and valves at the dams and intakes throughout the year when impact to YRDP operations can be minimized. Spill gates are operated during the spring and fall, consistent with the Division of Safety of Dams gate operation certificates. FERC requires annual testing of the gates and valve-testing every 5 years, but Yuba Water also operates

gates and valves at least once every 3 years for water rights purposes at each location and Yuba Water tests their large valves annually.

Yuba Water typically conducts annual maintenance on the powerhouses during the fall (September through November), when consumptive water and power demands are generally low. Each powerhouse is taken out of service for approximately 1 to 3 weeks on staggered schedule. Maintenance includes inspections of equipment in the powerhouse and switchyard and may include replacing parts and calibrating components. Annual maintenance does not typically require a reservoir drawdown, but downstream YRDP operations can be affected by certain outages.

The only YRDP spillway gates are located at New Bullards Bar Dam. The New Bullards Bar Dam spillway gates are inspected annually to check items including functionality and structural integrity. Functional checks are conducted annually, while inspections take place in the summer, after flood season use, and in the fall prior to flood season use. New Bullards Bar Dam's spillway can be accessed by various means throughout the year.

2.3.1.5 Existing YRDP Recreation Facilities

YRDP recreation facilities are located in the North Yuba and Middle Yuba River Watersheds. Developed and undeveloped recreation opportunities occur at New Bullards Bar Reservoir and the Our House and Log Cabin Diversion Dam impoundments.

The YRDP's developed recreation facilities (16 total) are located at New Bullards Bar Reservoir and include overnight camping, picnicking, trails, and boat launching facilities. Thirteen of the recreation facilities are located on NFS land, and three facilities are located on land owned by Yuba Water. All existing YRDP project trails are located within the existing FERC Project Boundary, except for a few short sections of the Bullards Bar Trail to the east of Dark Day Boat Launch. The YRDP also includes two undeveloped recreation sites at Our House and Log Cabin Diversion Dams located on NFS land within the existing FERC Project Boundary. Campgrounds with vehicle and boat-in access typically include vault restrooms, picnic tables, pedestal grills/fire rings, and food lockers. Campgrounds with vehicle access have group, single- and multi-family sites for tent and RV camping that may have paved or gravel-surfaced parking spurs, flush restrooms, and potable water spigots throughout the campground. Picnic areas may have vault restrooms, potable water, parking areas, picnic tables, and pedestal grills. Boat launches have parking areas, surfaced launch lane(s), courtesy docks, and restrooms. Existing YRDP recreation resources, facilities, land ownership, condition, accessibility and current and projected use levels are described in **Appendix 2B-14** (Recreation Facilities Plan). Additional information about the existing YRDP recreation facilities is provided in FERC (2019) and YCWA (2017a) AFLA.

2.3.1.6 Existing YRDP Environmental Measures

The existing FERC license for the YRDP includes 60 articles. Of these, Yuba Water considers 19 articles (Articles 28, 29, 30, 35, 36, 41, 42, 43, 44, 48, 50, 51, 52, 58, 60, 62, 65, 66, and 67), "completed" because each pertains to completion of a construction activity, a filing related to a construction activity, or another activity. As a result, the existing license contains 41 "active" articles. Complete descriptions of the articles in the current FERC license for the YRDP are

available on Yuba Water's relicensing website (https://www.yubawater.org/217/Yuba-River-Development-Project-Relicensi).

2.3.2 Existing Narrows Project

2.3.2.1 Existing Narrows Project Facilities

The existing Narrows Project consists of one development that includes: one tunnel, one penstock and standpipe, one powerhouse, and one powerhouse access tram. Yuba Water owns, operates and maintains these Narrows Project works. The Narrows Project works do not include any dams, intakes, reservoirs, open water conveyance facilities, switchyards or transmission lines,[19] roads,[20] recreation facilities, or active borrow or spoil areas. In addition, the USACE-owned portion of the tunnel (see Section 2.4.3.1 below) is not a Narrows Project facility. Existing Narrows Project works, which are shown in Figure 2.2-3 in Chapter 2, include:

- Narrows Tunnel - a 1,077-ft-long tunnel that connects to the USACE tunnel and to the Narrows Penstock. The first 1,000 ft of the Narrows Project tunnel is irregularly shaped and gunite-lined, with an average height of 11 ft, 9 in and an average width of 11 ft, 6 in. The next 77 ft of the tunnel consists of an 8-ft diameter, gunite-lined circular section. The Narrows Project includes an adit portal[21] located on the southeastern wall of the Yuba River canyon, which connects to the Narrows Project tunnel near the upstream end. The adit portal is the point of delineation between the USACE-owned tunnel and the downstream portion of the tunnel that is part of the Narrows Project works. The Narrows Project does not include a control gate at the upstream end of the tunnel. The USACE tunnel intake has the ability to fully open or close its tunnel and, thereby, the Narrows Project's Narrows Tunnel.

- Narrows Penstock - a 266-ft-long steel pipe that connects the Narrows Tunnel to the Narrows 1 Powerhouse. The penstock exits the tunnel part way up the steep south bank of the Yuba River canyon at an elevation of 436 ft. The penstock is exposed for 165 ft between the upper and lower anchor blocks, where it is inclined down the slope at an angle of 55 degrees. The steel pipe has welded longitudinal seams and riveted circumferential butt joints. The penstock pipe plate thickness varies from 7/16 to 1/2 in. The first 260 ft are 8 ft inside diameter, and the last 6 ft taper from 8 ft to 7.6 ft inside diameter. The majority of the penstock pipe is above ground, supported on the hillside by two anchors and three piers. A standpipe for pressure relief is attached to the upper end of the penstock and extends further up the slope above the penstock. The surge structure is a 227-ft-long, 24 in. steel standpipe.

- Narrows 1 Powerhouse - a reinforced concrete structure, 82 ft, 6 in. by 43 ft, 8 in. and a total height of approximately 92 ft. The powerhouse contains a main floor, basement, and sub-basement. The powerhouse was constructed in 1941 and 1942 and began commercial operation on December 29, 1942. The turbine within the powerhouse consists of a single

[19] The Narrows 1 Powerhouse is connected to the power grid via PG&E's Narrows No. 1 and Narrows No. 2 Transmission Line Project (FERC Project No. 2678), which is composed of a 1,100-ft-long, three-phase 11-kilovolt (kV) transmission line from the Narrows 1 Powerhouse to a substation that interconnects with the electric grid. Therefore, the Narrows Project does not have a primary transmission line.

[20] Access to the Narrows Project is entirely over public roads.

[21] See Section 2.4.3.1, below.

vertical "I.P. Morris" Francis turbine designed for 13,500 horsepower at 235 ft of head and is capable of passing up to 730 cfs. The turbine is equipped with a Pelton Water Wheel Company 100 percent relief valve with a 60-in. inlet and a 48-in. outlet. A 90-in. butterfly valve is located in the penstock at the turbine inlet. Control of the unit is accomplished with a Pelton hydraulic controller, which is a combination hydraulic cylinder and motor-driven jack screw functioning in place of a servomotor.

The generator is a 3 phase, 60 Hertz, 11,000 volt (V), 300 revolutions per minute (rpm) 12,000 kilovolt-amperes (kVA), 0.85 power factor vertical Westinghouse Electric and Manufacturing Company unit. The generator is directly connected to the turbine and to the 250 V, 100 kVA direct current exciter. The exciter field is energized from the 125 V storage battery and charging set. The generator is provided with a closed system of air cooling, and the bearings are water cooled. Additional generator protection is provided for overload, overvoltage, overspeed, and temperature. Once water has been utilized by the turbine to generate electricity, it exits the powerhouse and discharges directly into the Yuba River. A 48-in.-diameter bypass pipe with a 48-in.-diameter butterfly valve and a 48-in. by 36-in. "Larner Johnson" needle valve is located on the penstock side of the penstock butterfly valve for the purpose of bypassing water to the Yuba River when the unit is shut down. Maximum hydraulic capacity through the bypass pipe is 550 cfs. Yuba Water reports flow through the powerhouse via the USGS Gage 11417970, Narrows No. 1 Powerhouse at Englebright Dam. The FERC-authorized installed capacity of the unit, calculated in accordance with 18 C.F.R. 11.1(i), is 12,000 kW (i.e., generator limited).

- Powerhouse Access Tram - a car running on a set of steel tracks from elevation 849 ft to the main generator floor elevation of 332 ft. The tramcar is cable-hoisted from an electrically operated drum located at the top of the tramway. When not in use, the tramcar is stored in a wood-framed structure containing the hoist and electronics for the hoist controls. The structure has plan dimensions of approximately 20 ft by 32 ft. The foundation of the hoist, motors, and tram house is constructed of reinforced concrete.

Yuba Water conducts annual mechanical and electrical inspections and maintenance at Narrows 1 Powerhouse to verify the structural and/or functional integrity of the works and to identify conditions that might disrupt operations. This activity typically occurs in June or July and extends for approximately two weeks but can be longer or shorter depending on the planned maintenance activities to occur during the outage.

2.3.2.2 Existing Narrows FERC Project Boundary

The FERC Project Boundary for the Narrows Project (shown on Figure 2.2-3) consists of all lands necessary for Yuba Water's safe O&M of the project. The existing FERC Project Boundary for the Narrows Project includes 2.92 ac, including 2.37 ac on which above-ground Narrows Project works are located, and 0.55-ac of USACE lands overlying the Narrows Tunnel (i.e., there are no above-ground works on federal lands). Along the tunnel alignment, the FERC Project Boundary begins at the adit portal[22] located on the southeastern wall of the Yuba River canyon. The Project

[22] The 1994 O&M Agreement between PG&E and USACE for the Narrows Project describes ownership (i.e., title) of Narrows Project facilities, including a description of the tunnel adit plug (formerly owned by PG&E and now owned by Yuba Water), steel lining and dished head, which if abandoned or no longer needed, would pass back to the USACE.

Boundary includes 30 ft on either side of centerline along the Narrows Tunnel and Narrows Penstock (i.e., a 60-ft corridor), 15 ft on either side of the centerline of the Powerhouse Access Tram (i.e., a 30-ft corridor), and 65 ft from the Narrows 1 Powerhouse outside wall. More detailed maps of the existing FERC Project Boundary for the Narrows Project are provided in **Appendix 2F-5**.

2.3.2.3 Existing Narrows Project Operations

2.3.2.3.1 Automatic Operations

Typically, Yuba Water remotely operates and monitors Narrows Project works from Yuba Water's New Colgate Powerhouse Operations Center, which is staffed at all times. In addition, the Narrows Project can be manually operated on site. Yuba Water personnel visit the Narrows Project facilities several times a week.

2.3.2.3.2 Coordinated Operations Between Narrows 1 and YRDP's Narrows 2

Yuba Water began operating the Narrows Project in April 2020. Before that, Yuba Water and the previous licensee (PG&E) for the Narrows Project coordinated YRDP and Narrows Project operations pursuant to a coordinated operations agreement. Many factors contribute to how the YRDP and the Narrows Project are operated in tandem at any given time to meet the downstream water demands, instream flow requirements and power generation, including equipment outages, storm flows and reliability of continuous water supply conveyance. However, generally, the Narrows 1 Powerhouse is operated in conjunction with the Narrows 2 Powerhouse and/or the Narrows 2 Full Bypass as follows:

- If required releases are less than the Narrows 1 Powerhouse capacity at the time, only the Narrows 1 Powerhouse is operated.
- If required releases are greater than the Narrows 1 Powerhouse capacity at the time and range up to about 900 cfs, the Narrows 1 Powerhouse is operated and the remainder of the required release is released from the Narrows 2 Full or Partial bypasses, thereby superseding the fourth change described and noted above.
- If required releases are greater than 900 cfs, either the Narrows 2 Powerhouse is operated alone or the Narrows 1 and Narrows 2 powerhouses are operated together, mainly depending upon the electric market and the specific required release rate.
- If the Narrows 2 Powerhouse is operating and the Narrows 1 Powerhouse is not operating but is to be brought online, the Narrows 1 Powerhouse is synchronized to the electric grid while reducing the flow through the Narrows 2 Powerhouse to compensate for the increased releases from the Narrows 1 Powerhouse. As the Narrows 1 Powerhouse load is increased, releases from the Narrows 2 Powerhouse are decreased to a level needed to supplement the Narrows 1 Powerhouse release. The transition could take between 10 and 30 minutes to reach the full flow of the Narrows 1 Powerhouse.
- If the Narrows 1 Powerhouse is operating and the Narrows 2 Powerhouse is not operating but is to be brought online, the process described above is reversed.

Due to the above operational changes, some of them being relatively recent, historical flows in the lower Yuba River near the Narrows Project and historical Narrows Project operations information do not reflect the amount of water available to the Narrows Project under current conditions.

2.3.2.3.3 Narrows 1 Powerhouse Operations

The Narrows 1 Powerhouse contains a single vertical "I.P. Morris" Francis turbine designed for 13,500 horsepower at 235 ft effective head and capable of passing up to 730 cfs. Table 2.3-4 shows from WY 2020 through WY 2024, the Narrows Project gross annual generation, plant capability and plant factor.

Table 2.3-4. Narrows Project historical annual gross generation, plant capability and plant factor for WYs 2020 through 2024.

Water Year	Gross Annual Generation (KWh)	Plant Capability (kW)	Plant Factor (%)
2020	4,011,659[1]	105,120,000	4%
2021	75,380,293	105,120,000	72%
2022	69,872,734	105,120,000	66%
2023	69,573,536	105,120,000	66%
2024	81,958,092	105,120,000	78%
Average Annual	**67,380,249**	**105,120,000**	**57%**
Average Annual Excluding WY 2020	**74,196,163**	**105,120,000**	**71%**

Source: Yuba Water's annual filings with FERC.

[1] WY 2020 generation impacted by prolonged outage related to a standpipe replacement project.

Plant factor is calculated by dividing the amount of generation that occurred in the WY by the amount of generation that would have occurred if the powerhouse operated at maximum capability for the entire year. Yuba Water began operating the Narrows Project in April 2020. Yuba Water estimates that, on average, less than one kW of Narrows Project power is used on site to serve the Narrows 1 Powerhouse.

The dependable capacity of a generating facility is defined as "*the generating capacity that the plant can deliver under the most adverse water supply conditions to meet the needs of an electric power system with a given maximum demand*" (Elliott et al. 1997). One of the critical parameters for defining dependable capacity is the period over which the capacity must be provided. Traditionally, a year or season from time of maximum storage to minimum storage is used for the time period by which capacity is calculated. Because Englebright Reservoir storage is maintained within a relatively narrow range, the Narrows 1 Powerhouse generation capacity is flow-limited, rather than head-limited. Furthermore, because releases from Englebright Reservoir are required at all times to provide flow in the lower Yuba River downstream of Englebright Reservoir, and the Narrows 1 Powerhouse can be operated for lower flows than the Narrows 2 Powerhouse, the dependable capacity at the Narrows 1 Powerhouse is determined based on the period with the lowest historical flow at the Smartsville Gage.

For the Narrows Project, Yuba Water used September 24, 1977, when the total historical flow at the Smartsville Gage was 140 cfs and assumed the lowest operational head on the Narrows 1 Powerhouse (217 ft) to determine the historical dependable capacity. Under these conditions, the historical dependable capacity of the Narrows 1 Powerhouse is 1,390 kW. Under simulated conditions, the lowest total flow at the Smartsville Gage of 392 cfs occurred on August 30, 1977; assuming the lowest operational head on the Narrows 1 Powerhouse as described above, the simulated dependable capacity of the Narrows 1 Powerhouse is 6,245 kW.

2.3.2.4 Existing Narrows Project Maintenance Activities

All Narrows Project facilities are maintained to ensure safe and reliable operation. Each Narrows Project facility is visited at least several times weekly by Yuba Water's personnel who are experienced and familiar with the facilities. Potential problems are identified and corrected, or scheduled for repair as they are discovered, in order of the severity of the potential problems. Narrows Project operations personnel are on duty seven days a week, and maintenance personnel are on duty Monday through Friday. Additionally, remote operation and monitoring of the Narrows Project facilities is automatically controlled by the SCADA system from the YRDP's Colgate Powerhouse, which is staffed 24 hours a day 7 days a week. As with the YRDP, stream gages and power facilities are continuously monitored, and any parameters out of the normal operating ranges are brought to the Colgate Powerhouse operator's attention with alarms. The operator evaluates and determines further action, including call-out of O&M personnel.

Yuba Water also conducts annual mechanical and electrical inspections and maintenance at Narrows 1 Powerhouse to verify the structural and/or functional integrity of the works and to identify conditions that might disrupt operations. This activity typically occurs in June or July and extends for approximately two weeks but can be longer or shorter depending on the planned maintenance activities to occur during the outage. During planned outages, the unit hydraulic energy is controlled using either the 90-in. penstock butterfly valve or by dewatering the tunnel and penstock by requesting the USACE close its intake gates. During an unplanned outage, such as when the unit trips offline, water flows to the penstock bypass pipe. Depending on maintenance work needed on the penstock, it can be dewatered by closing the USACE's intake gates. Air is expelled through the penstock standpipe when refilling or draining the penstock. The turbine shutoff valve at the powerhouse is operated at least annually to verify integrity. Maintenance on the penstock is implemented on an as-needed basis. The bypass pipe/system is tested annually.

Yuba Water implements routine maintenance activities within the FERC Project Boundary to ensure safe and reliable operation of Narrows Project facilities and to protect worker and public health and safety and environmental resources. Activities include re-painting the exterior of the powerhouse, penstocks, surge chamber (i.e., standpipe), tram house, and tram as needed. Vegetation management, primarily trimming by hand and using herbicides, is implemented by Yuba Water at Narrows Project works, as needed. Vegetation management is implemented within the area necessary to reduce fire hazard, to provide adequate Narrows Project facility access and inspection, to protect Narrows Project works, and to provide for worker health and safety. These management activities are conducted as needed in conjunction with facility inspections.

Yuba Water uses herbicides and surfactants in addition to manual vegetation management activities on as needed basis at Narrows Project works on Yuba Water lands, along with USACE lands if Yuba Water has obtained permission from USACE to use herbicides on its lands. All herbicide applications occur under the direction of a licensed Pest Control Advisor (PCA). Prior to applying herbicides, Yuba Water establishes protocols that require individuals applying herbicides to complete training on general application procedures and precautions. In addition, the PCA prepares Pest Control Recommendations (PCR) for each site prescribing specific application direction and associated precautions that must be strictly followed. Herbicides used near the water's edge are only those certified for use in or near water. In general, herbicides are applied

using backpack sprayers or small hand-held sprayers, and all herbicides are applied in accordance with label instructions and PCR.

Few hazard trees, generally defined as dead or dying trees or trees with defects that may result in failure and have the potential to cause property damage, personal injury, or death, are near Narrows Project facilities. However, if a hazard tree is identified, removal is conducted with a chainsaw, handheld saw, or other equipment. Smaller diameter debris from felled hazard trees is either chipped or lopped and scattered. Downed logs are typically left onsite and only moved if needed for safety. If moving logs is necessary, it may be completed by hand or machine depending on the situation. If the tree is on USACE-administered lands, USACE permission would be obtained prior to removal.

Yuba Water implements rodent control as needed in facility interiors using non-restricted rodenticides (e.g., D-Con®), which are applied in accordance with the label instructions. Rodent control occurs within the Narrows 1 Powerhouse as well as other Narrows Project facilities and is only applied on USACE-administered lands with the approval of USACE.

2.3.2.5 Existing Narrows Project Recreation Facilities

There are no existing developed or undeveloped recreation facilities associated with the Narrows Project.

2.3.2.6 Existing Narrows Project Environmental Measures

The existing FERC license for the Narrows Project includes 50 articles. Of the 50 articles in the existing FERC license, Yuba Water considers 10 articles (articles 14, 27, 28, 203, 401, 404, 406, 407, 408, and 409), "completed" because the article pertains to an activity that either has been completed or is no longer relevant to the Narrows Project. As a result, the existing license contains 40 articles that Yuba Water considers "active". Complete descriptions of the articles in the current FERC license for the Narrows Project are presented in Exhibit B of Yuba Water's (2023) FLA, which is available on Yuba Water's relicensing website (https://www.yubawater.org/357/Narrows-Relicensing).

2.3.3 Existing Non-Yuba Facilities

In addition to the existing YRDP and Narrows Project facilities identified above, there are various other existing hydroelectric facilities in the region that are not involved in the Proposed Projects, but may be affected by the Proposed Projects or contribute to environmental effects along with the Proposed Projects.[23]

2.3.3.1 Englebright Dam and Reservoir

Englebright Dam and Reservoir and associated facilities are owned and operated by the USACE and are not subject to FERC's jurisdiction or in the FERC-designated Project Boundary for either the YRDP or the Narrows Project. Englebright Dam is a concrete constant angle arch structure, with a

[23] The non-Yuba facilities (and their resultant operations) described in this section have the potential to affect inflows into Englebright Reservoir and hydrologic conditions (e.g., flows and water temperatures) in the lower Yuba River.

crest length of 1,142 ft and a maximum height of 260 ft. Englebright Reservoir is about 9 miles long and has about 24 miles of shoreline and a surface area of about 815 ac at its NMWSE of 527 ft[24] (i.e., spillway crest elevation).

The primary purpose of USACE's Englebright Dam is to capture sediment and debris derived from extensive historical hydraulic mining that occurred in the upper Yuba River Watershed (YCWA 2017a). At the time of construction, Englebright Reservoir had a gross storage capacity of approximately 70,000 ac-ft. Although hydraulic mining no longer occurs in the upper reaches of the Yuba River, Englebright Dam continues to capture hydraulic mining debris from the upstream areas. The current reservoir's gross storage capacity is estimated to be approximately 50,000 ac-ft. The surface water elevation of the reservoir typically fluctuates between 517 ft and 525 ft, with a normal maximum of 527 ft.

The existing FERC license for the Narrows Project states that the O&M of Narrows Project works that, in the judgment of USACE, may affect the structural integrity of operation of the USACE's Englebright Dam are subject to periodic or continuous inspections by the USACE. Consequently, the Narrows Project intake structure, trash rack, and the first 700 ft of the conduit are regularly inspected on a 5-year cycle by the USACE, as these three components are owned and maintained by the USACE (USACE 2013). These three components extend to the structure known as the "adit."[25] The remaining portion of the conduit, extending from the adit to the Narrows 1 power plant and its appurtenances, is owned and maintained by Yuba Water. Yuba Water cooperates with USACE in conducting any requested inspections, and no deficiencies or difficulties have been identified to date (YCWA 2023a). Yuba Water conducts separate inspections of its Narrows 1 facility for hydropower purposes.

2.3.3.2 Other FERC Relicensing Projects in the Upper Yuba River Watershed

Upstream of USACE's Englebright Dam and Reservoir, there are five other hydroelectric projects in the Yuba River Watershed that are currently in the relicensing process, which include:

- Yuba-Bear Hydroelectric Project (FERC Project No. 2266-102)
- Drum-Spaulding Hydroelectric Project (Project No. 2310)[26]
    - Lower Drum Hydroelectric Project (FERC Project No. 14531-000)
    - Deer Creek Hydroelectric Project (FERC Project No. 14530-000)

[24] Elevation data are in U.S. Department of Commerce, National Oceanic and Atmospheric Association, National Geodetic Survey Vertical Datum of 1929 (NGVD 29), unless otherwise stated.

[25] FERC approved PG&E's O&M Agreement fulfilling Articles 101 and 102 on November 18, 1994, and on March 31, 2020, the agreement was transferred to Yuba Water as the new licensee for the Narrows Project. The agreement states that if the outlet facilities are no longer needed for the Narrows Project, "*title to the concrete tunnel adit plug, steel lining and dished head will pass to the Corps*." Yuba Water shall also grant the USACE free and unrestricted access to, through and across Narrows Project lands. The USACE reserves the right to direct Yuba Water to cease operation of the Narrows Project if it is deemed detrimental to water quality or water control objectives, public safety, or other events that may threaten structural integrity (YCWA 2023a).

[26] PG&E's current proposal to FERC includes splitting the existing Drum Spaulding Hydroelectric Project into three separate new licensed projects that would include: (1) the Lower Drum Project; (2) Deer Creek Project; and (3) the remaining Drum-Spaulding Project (referred to as the Upper Drum-Spaulding Project) (FERC 2014).

    - Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310-193)
- South Feather Power Project (FERC Project No. 2088-068)

The Yuba-Bear Hydroelectric Project (Yuba-Bear Project) is located in Sierra, Nevada, and Placer Counties, California. In 2011, NID filed an application with FERC for a new major license to operate and maintain the Yuba-Bear Project that would increase its licensed capacity from 79.32 MW to 90.72 MW. An amended application was filed on June 18, 2012. The Yuba-Bear Project includes four developments located on the Middle Yuba River, the South Yuba River, and the Bear River. The Yuba-Bear Project's developments include Bowman (3.6-MW installed capacity), Dutch Flat No. 2 (24.6-MW installed capacity), Chicago Park (39 MW installed capacity), and Rollins (12.2-MW installed capacity) (FERC 2014).

The Drum-Spaulding Hydroelectric Project (Project No. 2310) is located on the South Yuba River, the Bear River, South Fork of Deer Creek, and the North Fork of the North Fork American River in Nevada and Placer Counties, California. In 2011, PG&E filed an application with FERC for a new major license to operate and maintain the Drum-Spaulding Project and to retire its Alta Powerhouse Unit 2 that would reduce the project's licensed capacity from 192.5 MW to 191.5 MW. All project facilities in the Yuba River Basin are located in the headwaters of the South Yuba River and are upstream of Englebright Reservoir (a non-project facility). The Drum Spaulding Project consists of 10 developments, including: Spaulding No. 3, Spaulding No. 1 and No. 2, Deer Creek, Alta, Drum No. 1 and No. 2, Dutch Flat No. 1, Halsey, Wise, Wise No. 2, and Newcastle. In 2013, PG&E amended its proposal to split the currently licensed Drum-Spaulding Project into three new licensed projects: (1) the Lower Drum Project; (2) Deer Creek Project; and (3) the remaining Drum-Spaulding Project (referred to as the Upper Drum-Spaulding Project) (FERC 2014).

- ***Lower Drum Project*** – Includes the following developments: Halsey (11-MW installed capacity), Wise (14-MW installed capacity), Wise No. 2 (3.2-MW installed capacity), and Newcastle (11.5-MW installed capacity). Among the four developments, there are 3 reservoirs, 4 canals, 4 powerhouses, 1 distribution line, 1 transmission line, and appurtenant facilities and structures, including recreation facilities. The project diverts water from the Bear River at the Bear River canal diversion dam below the Yuba-Bear Project's Rollins Dam. Water diverted from the Bear River moves through the Lower Drum Project for power generation and delivery at various locations for consumptive water use by NID and the Placer County Water Agency. The Lower Drum Project facilities affect flows in Dry Creek below Halsey Afterbay, Rock Creek below Rock Creek Reservoir, Auburn Ravine below South Canal, and Mormon Ravine below Newcastle Powerhouse (FERC 2014).
- ***Deer Creek Project*** – The 5.7-MW Deer Creek development includes: (1) the South Yuba canal and Chalk Bluff canal; (2) Deer Creek forebay; (3) Deer Creek powerhouse penstock; (4) Deer Creek powerhouse; (4) Deer Creek–Drum transmission line; and (5) appurtenant facilities and structures, including one recreation facility. The Deer Creek Project diverts water at the Spaulding No. 2 Powerhouse via the South Yuba canal to the Chalk Bluff canal, and from there to the Deer Creek powerhouse which discharges to the South Fork of Deer Creek.

- ***Upper Drum-Spaulding Project*** – Includes the following developments: Spaulding No. 3 (5.8-MW installed capacity), Spaulding No. 1 and No. 2 (11.4-MW installed capacity), Alta (2-MW installed capacity), Drum No. 1 and No. 2 (105.9-MW installed capacity), and Dutch Flat No. 1 (22-MW installed capacity). Among the five developments, there are 26 reservoirs, 4 water conduits, 6 powerhouses, 4 transmission lines, and appurtenant facilities and structures, including recreation facilities. The project's larger reservoirs (Fordyce Lake, Lake Spaulding, and Lake Valley Reservoir) operate as storage reservoirs to capture precipitation during the spring and are slowly drawn down through summer and fall months, releasing water for power generation, irrigation, and domestic consumption purposes (FERC 2014).

Water rights held by both NID and PG&E are exercised through within-basin diversions and out-of-basin water transfers. Yuba-Bear/Drum-Spaulding (YB/DS) dams on the Middle Yuba and South Yuba rivers collectively divert significant amounts of water from the upper Yuba River Watershed and transfer that water out of the watershed. In 2014, FERC prepared a FEIS that evaluated the impacts of PG&E's Upper-Drum-Spaulding, Lower Drum, and Deer Creek Projects and NID's Yuba-Bear Project. FERC (2014) reported that those projects' average combined diversion of about 410,000 ac-ft of water annually from the Yuba River to the Bear River watershed accounts for about 17 percent of the natural unimpaired discharge from the upper Yuba watershed (North Yuba, Middle Yuba, and South Yuba rivers), but stated that it is difficult to determine the relative influence of the Upper Drum-Spaulding, Lower Drum, Deer Creek, and Yuba-Bear Projects diversions on anadromous salmonid habitat conditions in the lower Yuba River downstream of Englebright Dam given existing flow management operations.

More recently, in response to FERC's 2021 AIR, Yuba Water's (2022) analysis demonstrated that flows in the lower Yuba River are cumulatively affected by the out of basin water transfers resulting from operations of the YB/DS projects.[27] These out-of-basin transfers significantly deplete water supply that otherwise potentially would be available to benefit ESA-listed fish species and their habitat in the lower Yuba River. For the Water Year (WY) 1990 to WY 2016 period, total exports by NID and PG&E ranged from about 265 thousand acre-feet (TAF) (30% of average annual unimpaired watershed runoff) in Critically Dry WYs and 316 TAF (28% of average annual unimpaired watershed runoff) in Dry WYs to about 498 TAF (13% of average annual unimpaired watershed runoff) in Wet WYs (YCWA 2022a).

In contrast to the YB/DS projects, water that the YRDP diverts stays in the Yuba River Watershed. Yuba Water's hydroelectric diversions involve power generation exclusively within the watershed. Yuba Water's consumptive diversions divert about 260 TAF per year from the lower Yuba River at Daguerre Point Dam. Because Daguerre Point Dam is located downstream of the most heavily utilized salmonid spawning and rearing habitat in the lower Yuba River, the YRDP's consumptive diversions provide significant flow and water temperature benefits in that habitat during the summer and fall. In addition, Yuba Water's transfers involve water that flows through the entirety of the lower Yuba River before being diverted by other users downstream (i.e., outside of the Yuba River Watershed). For additional information on YB/DS flow-related operations, see Section

[27] This DEIR uses the term "YB/DS projects" to refer to the following other FERC relicensing projects located in the upper Yuba River Watershed, which include: (1) NID's Yuba-Bear Hydroelectric Project (FERC Project No. 2266); and (2) PG&E's Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310), Lower Drum Hydroelectric Project (FERC Project No. 14531) and Deer Creek Hydroelectric Project (FERC Project No. 14530).

4.3.3.1.4, Technical Considerations and Rationale Supporting the "Dual Baseline" Approach of this DEIR.

In 2007, the South Feather Water and Power Agency (South Feather), submitted an application to FERC to relicense its 117.3-MW South Feather Power Project (Project No. 2088-068), which is located on the South Fork Feather River, Lost Creek, and Slate Creek in Butte, Yuba, and Plumas Counties, California. Slate Creek, a tributary to the North Yuba River, extends from the Slate Creek Diversion Dam to the confluence with the North Yuba River. The lower section of Slate Creek contains migratory species from New Bullards Bar Reservoir (e.g., kokanee) which could migrate up to a natural upstream migration barrier located approximately 4.6 miles upstream of the North Yuba River confluence. Diversion of water from Slate Creek by South Feather reduces the volume of water that is contributed to the North Yuba River via Slate Creek. In 2023, FERC issued a draft SEIS for the South Feather Power Project, which analyzed the environmental measures in the SWRCB's WQC, the USFS's Revised Final FPA Section 4(e) Conditions, and the South Feather Settlement Agreement (FERC 2023). Because the YRDP is located downstream of Slate Creek, Yuba Water recommended that FERC reserve authority to require South Feather to make reasonable provisions for modifying project facilities or operations as necessary to mitigate or avoid cumulative effects identified in any environmental analysis of the YRDP. Yuba Water indicated that this reservation would be applicable in the context of any relicensing or license amendment proceeding involving the downstream YRDP (FERC 2023).

2.3.3.3 Measures in Other Licenses, Agreements and Contracts that Affect YRDP and Narrows Project Operations

In addition to the current FERC license requirements, various applicable licenses, agreements and contracts include various streamflow-related requirements, which are summarized below. These licenses, agreements and contracts, and the terms and conditions in them, affect both YRDP and Narrows Project operations, but are not part of the existing FERC licenses.

2.3.3.3.1 Lower Yuba River Accord and SWRCB Corrected Order Water Right 2008-0014 (No Expiration Date)

The Yuba Accord was developed by a multi-agency resource team, including representatives from Yuba Water, NMFS, USFWS, CDFW, and a group of NGOs. It originally consisted of the following four agreements that were executed in 2007:

- The Lower Yuba River Fisheries Agreement, which specifies the Yuba Accord's lower Yuba River minimum streamflows and creates a detailed fisheries monitoring and evaluation program;
    - The Water Purchase Agreement, under which DWR purchases water from Yuba Water, some of which is provided by the Yuba Accord's minimum streamflows, for

California Bay-Delta Program (CALFED)'s[28] Environmental Water Account (EWA) and SWP and CVP contractors;

- The Conjunctive Use Agreements with seven of Yuba Water's Member Units,[29] which specify the terms of the Yuba Accord's groundwater conjunctive- use program; and
    - Amendments to the 1966 Power Purchase Contract between Yuba Water and PG&E.[30]

The SWRCB approved modifications to Yuba Water's consumptive water-right permits, and authorized related water transfers, in its Corrected Order WR 2008-0014. Since 2008, Yuba Water has been operating the YRDP to implement the Yuba Accord according to the authorizations and requirements in that corrected order. Subsequent to the SWRCB approval process in 2008, the Cordua Irrigation District (CID), one of the Member Units, also joined the Yuba Accord.

The Yuba Accord includes a specific set of flow schedules for the Yuba River. Flow schedules 1 and 2 were developed to optimize habitat conditions for anadromous fish during high flow years. Schedule 6 flow schedules were developed to create the best habitat conditions for these fish that are possible during very low flow years, considering available water supplies and competing demands. Flow schedules 3, 4 and 5 then were developed by the resource team by using available water supplies to create habitat conditions during the months when additional flows (over Schedule 6 amounts) will provide the greatest benefits. The Yuba Accord also specifies requirements for "Conference Years," which are the very driest years, and are predicted to occur approximately one percent of the time. The flow schedule that is in effect at any particular time is determined by the North Yuba Index (NYI), a hydrologic index that was developed as a part of the Yuba Accord. The flow schedules are listed in Table 2.3-5. The NYI is shown in Figure 2.3-5**.**

[28] CALFED was initiated in 1995 as a cooperative state-federal planning effort between water, environmental, state and Federal officials to resolve water resources conflicts in the Sacramento/San Joaquin Rivers Delta and San Francisco Bay (Bay-Delta) in California. The program planning effort focused on developing a plan to address three main problem areas in the Bay-Delta, including: ecosystem health, water quality, and water supply reliability. This joint federal and California program is administered by the California Bay-Delta Authority, a department within the government of California, administered under the California Resources Agency.

[29] As described in Yuba Water et al. (2007), a Member Unit is any municipality, town, or district wholly or partially within or contiguous to Yuba Water that is empowered to appropriate and deliver water and which contracts with the agency for payment of construction costs or for delivery of water, as defined in Section 2(g) of the Agency Act. Yuba Water provides surface water to eight Member Units, including: Brophy Water District, Browns Valley Irrigation District, Cordua Irrigation District, Dry Creek Mutual Water Company, Hallwood Irrigation Company, Ramirez Water District, South Yuba Water District, and Wheatland Water District.

[30] The Power Purchase Contract, as amended, was in force for 50 years and terminated in April 2016. Yuba Water now operates the YRDP's power operations and contracts with a scheduler to sell generation and other ancillary services from the YRDP to the California power market.

Table 2.3-5. Yuba Accord flow schedules.

A	700	700	700	700	700	700	700	700	--	--	--	--	--	--	--	700	--
B	600	600	600	550	550	550	550	600	--	--	--	--	--	--	--	500	--

Notes:
Marysville Gage flows represent average volumes for the specified period. Actual flows may vary from the indicated flows according to established criteria. Marysville Gage Schedule 6 flows do not include an additional 30,000 ac-ft that SWRCB Corrected Order WR 2008-0014 requires Yuba Water to make available through groundwater substitution transfers. These additional flows will be allocated during Schedule 6 years. Smartsville Gage Schedule A is used with Marysville Schedules 1, 2, 3, and 4. Smartsville Gage Schedule B is used with Marysville Schedules 5 and 6.

During Conference Years, which are defined as years when the NYI is less than 500,000 ac-ft, and which are expected to occur approximately 1 percent of the time, Yuba Water is required to: (1) maintain minimum instream flows in the Yuba River pursuant to Article 33 of Yuba Water's existing FERC license; (2) release any supplemental flows recommended by the Lower Yuba Accord River Management Team (RMT) and approved by the SWRCB's Deputy Director for Water Rights or, if no such recommended flows are effective by April 11 of such a Conference Year, then to release any supplemental flows ordered by the SWRCB, after a hearing under California Code of Regulations (CCR), title 23, section 767; and (3) limit total water supply diversions at Daguerre Point Dam to 250,000 ac-ft.

Yuba Water is proposing to extend the Yuba Accord Water Transfer Program beyond its current expiration date of December 31, 2025 and has prepared a supplemental environmental impact report (SEIR) (supplement to the original EIR prepared for the Yuba Accord in 2007) to satisfy the requirements of CEQA. The Accord Extension does not involve the minimum flow requirements established by the Fisheries Agreement, which will not expire at the same time as the other components of the Yuba Accord. The CEQA process for the Extension of the Lower Yuba River Accord Water Transfer Program is separate from this DEIR and the CEQA process for the YRDP and Narrows Project FERC relicensings.

FLOW SCHEDULE YEAR TYPES
BASED ON THE NORTH YUBA INDEX
FOR ESTABLISHING REQUIRED FLOWS IN THE LOWER YUBA RIVER FISHERIES AGREEMENT

The water year hydrologic classification for the Yuba River to determine the flow requirements of Yuba County Water Agency's water right permits shall be based on the North Yuba Index. Determinations of a year's flow schedule year type shall be made in February, March, April, and May and for any subsequent updates.

Flow Schedule Year Type	North Yuba Index Thousand Acre-Feet (TAF)
Schedule 1	Equal to or greater than 1400
Schedule 2	Equal to or greater than 1040 and less than 1400
Schedule 3	Equal to or greater than 920 and less than 1040
Schedule 4	Equal to or greater than 820 and less than 920
Schedule 5	Equal to or greater than 693 and less than 820
Schedule 6	Equal to or greater than 500 and less than 693
Conference Year	Less than 500

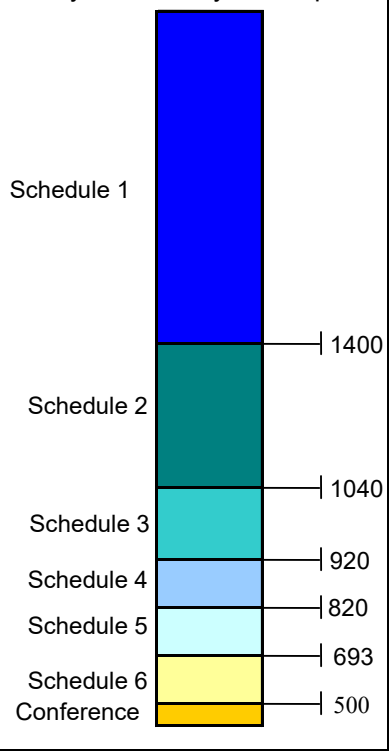

Figure 2.3-5. Yuba Accord North Yuba Water Year Type (WYT) Index.

2.3.3.3.2 Yuba Water's Water Rights for Power (No Expiration Date) for the YRDP and Narrows Project

Yuba Water holds pre-1914 appropriative rights dating from 1897 and post-1914 appropriative water rights confirmed by water right licenses, for the purposes of operating the YRDP for hydroelectric power generation. Table 2.3-6 lists the post-1914 appropriative water right licenses held by Yuba Water for power generation.

Table 2.3-6. Water right licenses held by Yuba Water for operation of the YRDP for power generation.

Priority (date)	SWRCB Designation (application)	SWRCB Designation (license)	Source (Waterbody)	Amount & Place of Diversion or Storage (amount & place)		Season (period)		Place of Beneficial Use (powerhouse)
2/11/1921	2197	435	North Yuba River	700 cfs at New Bullards Bar Dam		1/1 - 12/31		New Colgate Powerhouse
				5,000 ac-ft/yr at New Bullards Bar Dam		about 12/15 to about 7/15		
9/7/1922	3026	436	North Yuba River	10,000 ac-ft/yr at New Bullards Bar Dam		about 12/15 to about 7/15		New Colgate Powerhouse
4/30/1926	5004	777	North Yuba River	15,000 ac-ft/yr at New Bullards Bar Dam		about 12/15 to about 7/15		New Colgate Powerhouse
7/30/1927	5631	11565	Middle Yuba River	810 cfs at Our House Dam	490,000 ac-ft/yr storage in New Bullards Bar Res	1/1-12/31 (dir. div.)	10/15 to 6/30 (stor.)	New Colgate Powerhouse and Narrows 2 Powerhouse
			Oregon Creek	240 cfs at Log Cabin Dam		1/1-12/31 (dir. div.)		
			North Yuba River	1,800 cfs at New Bullards Bar Dam		11/1-7/31 (dir. div.)		
			Yuba River	1,800 cfs at USACE's Englebright Dam		1/1- 12/31		
3/1/1939	9516	3050	North Yuba River	100 cfs at New Bullards Bar Dam		1/1 - 12/31		New Colgate Powerhouse
9/12/1941	10282	5544	North Yuba River	5,335 ac-ft/yr at New Bullards Bar Dam		about 10/1 to about 3/1		New Colgate Powerhouse
								Narrows 2 Powerhouse
2/20/1953	15205	11566	Middle Yuba River	3,200 ac-ft/yr at Log Cabin Dam; storage in New Bullards Bar Res.		5/1- 6/30		New Colgate Powerhouse and Narrows 2 Powerhouse
			North Yuba River	245 cfs and 700 ac-ft/yr at New Bullards Bar Dam		3/15- 6/15 (dir. div.); 5/1- 6/30 (stor.)		
			Yuba River	800 cfs at USACE's Englebright Dam		11/1-7/15		
10/2/1953	15563	11567	Middle Yuba River	30,000 ac-ft/yr at Our House Dam	all storage in New Bullards Bar Res.	10/15 - 6/30		New Colgate Powerhouse and Narrows 2 Powerhouse
			Oregon Creek	1,400 ac-ft/yr at Log Cabin Dam		10/15 - 6/30		
			North Yuba River	146,000 ac-ft/yr at New Bullards Bar Dam		10/15 - 6/30		
			Yuba River	910 cfs at USACE's Englebright Dam		11/1 - 6/30		

Yuba Water operates the YRDP consistent with the terms and conditions of the above water rights.

Yuba Water holds all necessary water rights to operate the Narrows Project at its full capacity. These include a 1936-priority water-right license, and a water right permit issued by the State of California on July 7, 1961, that confirms the priority/first use of the right dated September 21, 1936. As the holder of License No. 6388 (Application No. 8794) issued by the SWRCB, Yuba Water has the right to appropriate water from the Yuba River for the purpose of generating electric energy at Narrows 1 Powerhouse, as provided in Table 2.3-7 below. These water rights are supplemented by riparian

rights gained through ownership of riparian land (see Statement of Water Diversion and Use No. 10838).

Table 2.3-7. Water right licenses held by Yuba Water for operation of the Narrows Project for power generation.

Priority (date)	Statement of Water Diversion and Use (Riparian)	SWRCB Designation (license)	Source (waterbody)	Direct Diversion and Amount & Place of Diversion Storage	Season (period)	Place of Beneficial Use (powerhouse)
2/21/1936	--	6388	Yuba River	700 cfs	1/1 – 12/31	Narrows 1 Powerhouse
				Englebright Reservoir 45,000 ac-ft	10/1 – 3/1	
1942	10838	--	Yuba River	740 cfs	--	Narrows Powerhouse

2.3.3.3.3 USACE and Yuba Water Use of Outlet Facilities and Storage Space Agreement and Operations and Maintenance Agreement

In compliance with Articles 101 and 102 of the original FERC license for the Narrows Project, PG&E entered into a Use of Outlet Facilities and Storage Space Agreement and an O&M Agreement with the USACE in November 1994. The agreements were fully transferred to Yuba Water in 2020.

2.3.3.3.4 Water Supply Deliveries

Within the YRDP project area, Yuba Water pumps some water directly from New Bullards Bar Reservoir to supply water to the Cottage Creek Water Treatment Plant for domestic and recreational uses adjacent to the reservoir. The amount of this pumping averages approximately 6 ac-ft per year, which does not affect YRDP operations. Yuba Water anticipates that pumping of this small amount of water will continue during the period of the new license.

Downstream of the YRDP and the Narrows Project, water is diverted under Yuba Water's consumptive-use water right permits to eight water users, which are collectively referred to as the Yuba Water Member Units. In 2016, new agreements were signed that changed some of the volumes, timing, and conditions for providing water supplies from the YRDP. Water supply is provided under Yuba Water's consumptive-use water-right permits to eight water users, which are collectively referred to as the Yuba Water Member Units. The places of water delivery to Yuba Water's Member Units are listed in Table 2.3-8. The Yuba Water Member Unit service areas are shown in Figure 2.3-6.

Table 2.3-8. Yuba Water's annual contract amounts and place of delivery.

Member Unit	Water Right Based Supply (ac-ft)	Project Based Supply (ac-ft)	Total Contract (ac-ft)
BROWNS VALLEY IRRIGATION DISTRICT PUMPLINE DIVERSION FACILITY[1]			
Browns Valley Irrigation District	24,505	9,500	34,005
YUBA MAIN CANAL[2]			
Brophy Water District	--	86,870	86,870
South Yuba Water District	--	54,307	54,307
Dry Creek Mutual Water Company	--	17,751	17,751
Wheatland Water District	--	40,230	40,230
HALLWOOD-CORDUA CANAL[3]			
Cordua Irrigation District	60,000	24,000	84,000
Hallwood Irrigation Company	78,000	11,208	89,208
Ramirez Water District	--	30,389	30,389
Total	**162,505**	**274,255**	**436,760**

Notes: BVID=Browns Valley Irrigation District, BWD=Brophy Water District, CID=Cordua Irrigation District, DCMWC=Dry Creek Mutual Water Company, HID=Hallwood Irrigation District, RWD=Ramirez Water District, SYWD=South Yuba Water District, WWD=Wheatland Water District.

[1] BVID receives water at the Pumpline Diversion Facility, located 1 mile upstream of USACE's Daguerre Point Dam.

[2] BWD, SYWD, DCMWC and WWD receive water from the Yuba Main Canal (South Canal), which begins on the south side of the Yuba River slightly upstream of the south abutment of USACE's Daguerre Point Dam.

[3] CID, HID and RWD receive water through the Hallwood-Cordua Canal (North Canal), located on the north abutment of USACE's Daguerre Point Dam.

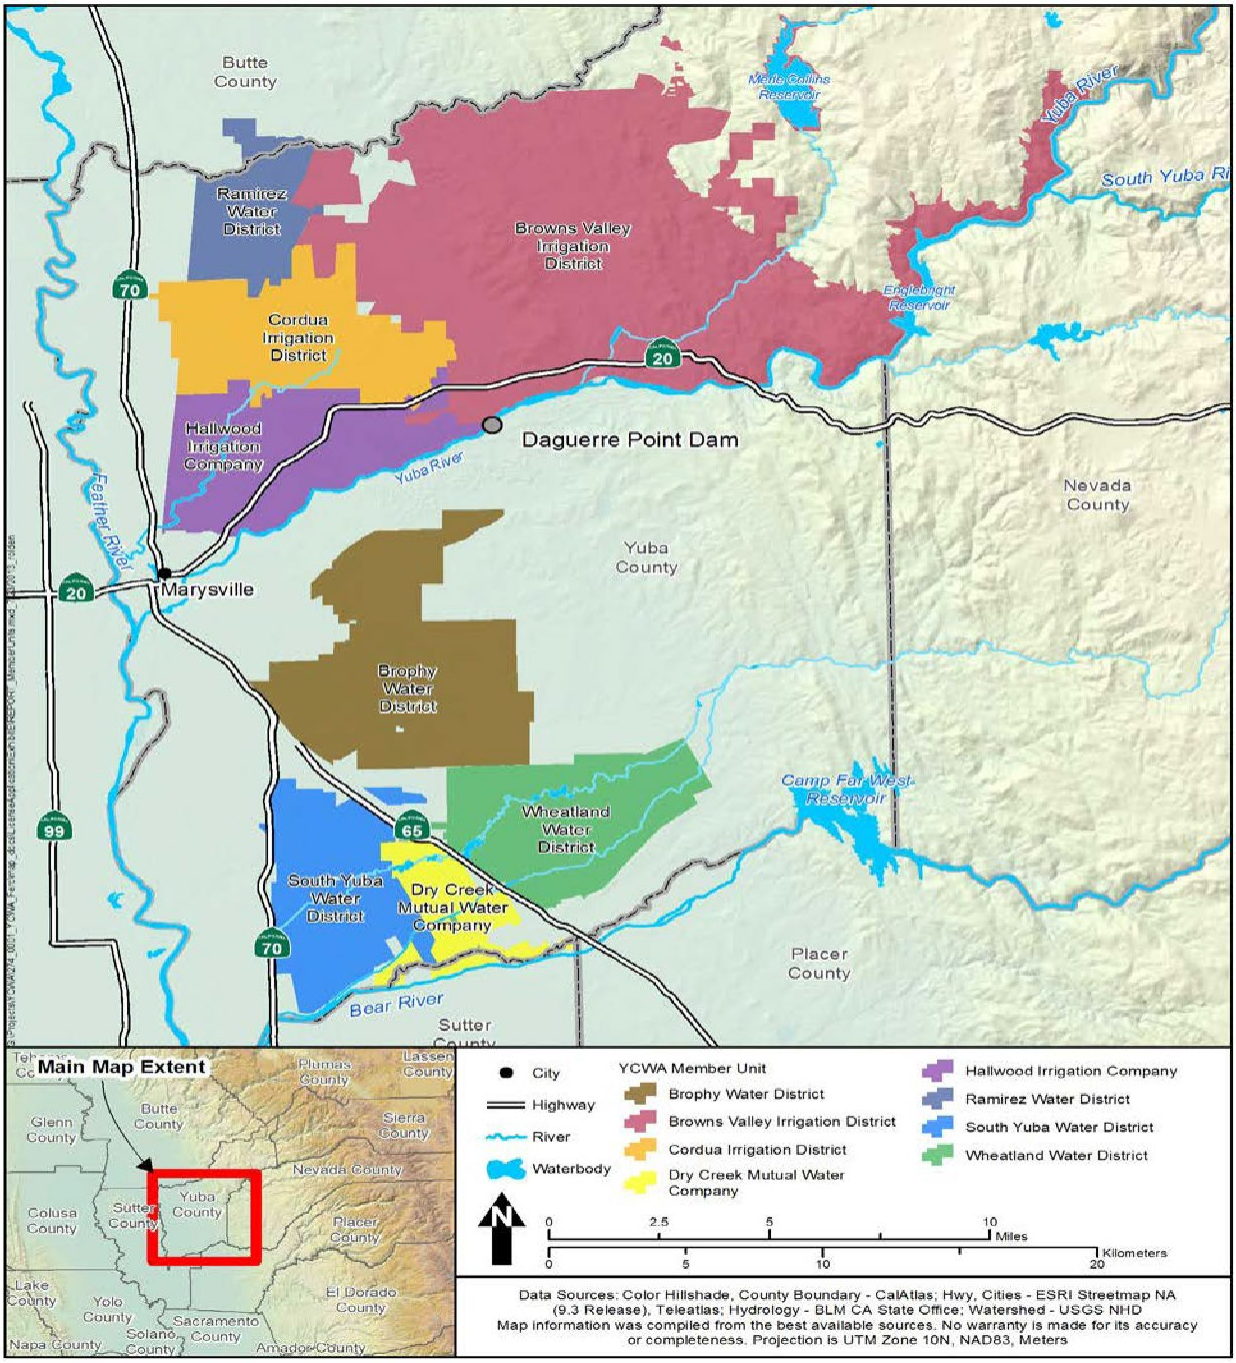

Figure 2.3-6. Yuba Water's Member Unit service areas.

Browns Valley Irrigation District (BVID) receives water at the Pumpline Diversion Facility, located 1 mile upstream of Daguerre Point Dam. Brophy Water District (BWD), South Yuba Water District (SYWD), Dry Creek Mutual Water Company (DCMWC), and Wheatland Water District (WWD) receive water from the Yuba Main Canal (South Canal), which begins on the south side of the Yuba River slightly upstream of the south abutment of Daguerre Point Dam. CID, Hallwood Irrigation Company (HIC), and Ramirez Water District (RWD) receive water through

the Hallwood-Cordua Canal (North Canal), located on the north abutment of Daguerre Point Dam. None of these facilities are under FERC's jurisdiction.

All eight of the Member Units receive contracted YRDP water supplies that are not based on their own water rights and are provided under Yuba Water's water rights. BVID, CID, and HIC have their own water rights on the Yuba River. Under water supply agreements with Yuba Water, CID and HIC receive surface water supplies as part of YRDP operations that are based on these Member Units' water rights. Dry year deficiency criteria in these contracts are different from the deficiency criteria in Yuba Water's contracts with other Member Units. Provisions in Yuba Water's water supply agreements preclude deficiencies in water right based supplies unless DWR's April forecast of unimpaired runoff as measured at the Smartsville Gage is less than 40 percent of average. No deficiencies in such deliveries may be imposed on BVID. Contract shortage provisions are presented in Table 2.3-9. Yuba Water's contract volumes are based on the gross acreage served by each Member Unit.

Table 2.3-9. Yuba Water's water supply contract shortage provisions.

Category	Trigger for Reduced Contract Allocation[1]	Percentage of Settlement/ Contract Allocation Available
PRE-1914 RIGHTS SETTLEMENT WATER RIGHT BASED SUPPLY		
Browns Valley Irrigation District	All	100%
Cordua Irrigation District	$f \geq 40\%$	100%
Hallwood Irrigation Company	$f < 40\%$	80%
YUBA WATER CONTRACT SUPPLY		
Base Project Water for Other Member Units	$f > 85\%$	100%
	$40\% < f \leq 85\%$	75%
	$f < 40\%$	Determined annually by Yuba Water in its reasonable discretion considering forecasted runoff and operational conditions.

[1] April 1 DWR forecast of unimpaired Yuba River runoff near Smartsville in percentage of 50-year average.

In 2009, Yuba Water started providing water to the WWD under a water service contract. Until then, water users within WWD relied solely on groundwater for irrigation. The Wheatland Project now conveys surface water, diverted by Yuba Water at Daguerre Point Dam, to WWD through the South Canal system.

2.3.3.3.5 Yuba Water's Water Transfers

Water transfers are an important component of Yuba Water's YRDP operations. Details of individual transfers are presented in Table 2.3-10. Stored water transfers listed in the table were made by Yuba Water from storage releases from New Bullards Bar Reservoir to meet the Yuba Accord required flows or to meet an end of September Accord target storage in New Bullards Bar Reservoir of 650,000 ac-ft. Groundwater substitution transfers are made by Yuba Water in coordination with its Member Units.

Table 2.3-10. Yuba Water historical sales from 2007 to 2022 (YCWA 2024a).

Year	WYT Sacramento Valley 40-30-30 Index	Buyer	Stored Water Transfer (ac-ft)	Groundwater Substitution Transfer (ac-ft)
2007	Dry	Yuba Accord Water Purchase Participants	65,000[1,2,3,4]	--
2008	Critical	Yuba Accord Water Purchase Participants	117,212[1]	48,875
2009	Dry	Yuba Accord Water Purchase Participants	91,100[1,2]	88,900[5]
2010	Below Normal	Yuba Accord Water Purchase Participants	74,179[1,2]	66,211
2012	Below Normal	Yuba Accord Water Purchase Participants	86,618[1,2]	--
2013	Dry	Yuba Accord Water Purchase Participants	112,544[1,2]	64,730[7]
2014	Critical	Yuba Accord Water Purchase Participants	104,663[1,2]	56,984[7]
2015	Critical	Yuba Accord Water Purchase Participants	59,131	30,000
2016	Below Normal	Yuba Accord Water Purchase Participants	60,000	--
2018	Below Normal	Yuba Accord Water Purchase Participants	76,576	16,411
2020	Dry	Yuba Accord Water Purchase Participants	43,538	77,000
2021	Critical	Yuba Accord Water Purchase Participants	130,090	--
2022	Critical	Yuba Accord Water Purchase Participants	15,077	62,400
		Total	**1,096,596**	**511,511**
		Average per Year	**78,328**	**56,835**

[1] In 2007, 2008, 2009, 2010, 2012, 2013, 2014, and 2015 BVID transferred an additional 3,100 ac-ft to the Santa Clara Valley Water District through conservation.

[2] Transfers to the Yuba Accord Water Purchase Participants include 60,000 ac-ft of stored water for the EWA.

[3] The 2007 transfer was under Yuba Accord Pilot Program. It also included 60,000 ac-ft of transfer to the EWA purchased in 2006.

[4] Sacramento Valley Index as defined in SWRCB RD-1641.

[5] In 2009, CID transferred an additional 8,322 ac-ft of groundwater substitution transfer to the DWR Drought Water Bank.

[6] In 2013, CID transferred an additional 7,774 ac-ft of groundwater substitution transfer to the DWR Drought Water Bank.

[7] In 2014, CID transferred an additional 1,976 ac-ft of groundwater substitution transfer to the DWR Drought Water Bank.

For cross-Delta water transfers to service areas south of the Delta, the Delta must be in balanced water conditions[31] and available conveyance capacity must exist at the SWP's Harvey O. Banks Pumping Plant or the CVP's C.W. "Bill" Jones Pumping Plant, both located near Tracy, CA, to convey the transfer water to willing buyers. Water transfer exports from the Delta currently may occur from July through November (YCWA 2004; NMFS 2019). Under the Yuba Accord, transfer releases can occur throughout the year as part of the releases to meet the Yuba Accord flow schedules and end- of-September target storage in New Bullards Bar Reservoir, but transfer water is generally conveyed across the Delta during the summer months.

2.3.3.3.6 Power Marketing Contracts

Yuba Water markets the electrical energy output of the YRDP and Narrows Project by scheduling the energy output of both projects into the CAISO energy markets. Yuba Water markets the capacity products of the YRDP and Narrows Project (including Resource Adequacy and Renewable Energy Credits) to Shell Energy North America through the terms of an energy marketing agreement and a standard-form (Edison Electric Institute) Master Power Purchase and Sale Agreement. All the electrical output from the Narrows Project is sold at the interconnect with the PG&E grid just outside of the Narrows 1 Powerhouse.

[31] Balanced water conditions are periods when it is agreed that releases from upstream reservoirs plus unregulated flows approximately equal the water supply needed to meet Sacramento Valley in-basin uses plus required Bay-Delta outflows and exports (USBR and DWR 1986).

2.4 Description of Yuba Water's Proposed Projects under New FERC Licenses

2.4.1 Proposed YRDP under New FERC License

In addition to the continued O&M of the existing YRDP facilities described in Section 2.3, the YRDP Relicensing Project includes:

1. Project-related changes proposed by Yuba Water and accepted by FERC staff in the FEIS;

2. FERC staff-recommended modifications of Yuba Water's proposal and additional measures;

3. Implementation of the USFS's December 2, 2022 Revised Final FPA Section 4(e) Terms and Conditions for the YRDP (Section 4(e) Conditions);

4. Implementation of Yuba Water's recommended findings for 2025 CWA Section 401 WQC Conditions for the new YRDP FERC license that were submitted for consideration to the SWRCB on December 30, 2024;

5. FERC Form L-5 Terms and Conditions of License for Constructed Major Project Affecting Navigable Waters and Lands of the United States; and

6. Implementation of protective measures for ESA-listed species under the jurisdictional authority of the USFWS, as described in the USFWS's June 21, 2018 letter of concurrence.

This section describes: (1) the proposed YRDP facilities (Section 2.5.5.1.1); (2) the proposed FERC Project Boundary for the YRDP (Section 2.5.5.1.2); (3) proposed Yuba Water changes to conditions in the existing FERC license for the YRDP (Section 2.5.5.1.3); (4) FERC Staff Alternative modifications to Yuba Water's proposal (Section 2.5.5.1.4); (5) FPA Section 4(e) Conditions (Section 2.5.5.1.5); (6) FERC Form L-5 Terms and Conditions (Section 2.5.5.1.6); (7) ESA Section 7 consultation status (Section 2.5.5.1.7); (8) Yuba Water's proposed WQC conditions for the YRDP (Section 2.5.5.1.8); and (9) a summary of the YRDP's proposed implementation plans that were developed during the FERC relicensing process (Section 2.5.5.1.9).

2.4.1.1 Proposed YRDP Facilities

Yuba Water does not propose to add to the YRDP any previously constructed, unlicensed water power structures or facilities.

2.4.1.1.1 Power Generation Facilities

New Colgate Powerhouse New Tailwater Depression System

Proposed Facilities

Yuba Water proposes to add to the YRDP a new Tailwater Depression System (TDS) at the New Colgate Powerhouse.

The New Colgate Powerhouse generators are driven by six-jet, vertical-shaft Pelton wheel turbines. The turbine runners rotate in the air of the turbine discharge chambers where water can fall freely off the turbine buckets. When the water level in the turbine discharge chamber rises, the foam and backsplash cause uneven resistance to free rotation with resulting vibration. Consequently, the rate of water release must be reduced, and at high stages, the operation of the turbines must cease.

The water level in the turbine discharge chambers rises as the water level in the Yuba River rises during flood events. The flood runoff can come from spillway releases at New Bullards Bar Dam, unregulated flow downstream of the dam, and the Middle Yuba River. Above certain water levels at the powerhouse, when Yuba River flow upstream of the New Colgate Powerhouse reaches approximately 17,000 cfs, which corresponds to a WSE of about 558.5 ft, the New Colgate Powerhouse must be shutdown, and at flows as low as 11,000 cfs the New Colgate Powerhouse releases must be reduced to prevent excessive vibration. Besides affecting generation, this reduces the ability to move water, which could encroach upon the available flood storage space in the reservoir. For example, if the New Colgate Powerhouse were totally shut down for 72 hours prior to and during a period of peak flood inflow to New Bullards Bar Reservoir, there would be a loss of over 20,000 ac-ft of useable storage.[32]

The proposed TDS would introduce compressed air into the turbine discharge chamber to lower the tailwater elevation to a level that does not interfere with turbine operation, thereby allowing continued turbine operation during high flows. The TDS would thus enhance the ability to regulate flood releases from New Bullards Bar Reservoir and increase the production of energy.

Proposed Operations

The proposed TDS would only operate during high flow events, when the combined releases from New Bullards Bar Dam and flows from the Middle Yuba River would otherwise preclude New Colgate Powerhouse operations. When the WSE of flows in the New Colgate Powerhouse tailrace rises to an elevation of 555 ft, which corresponds to approximately 11,000 cfs of flow upstream of the New Colgate Powerhouse, the first compressor would be started, and would be modulated to fully open as needed. The second compressor would be started when the WSE in the tailrace reaches an elevation of 556 ft (having been lowered by the first compressor startup) and would be modulated to fully open, as needed. If necessary, the third compressor would be started when water level inside the tailrace conduit again reaches an elevation of 556 ft. Modulation of each compressor would maintain a WSE in the tailrace within a range of 554 ft and 556 ft. If only one unit is running, compressed air will still be discharged into both units. If the tailwater elevation

[32] The outlet into New Colgate Tunnel is below the level of the spillway lip, which allows for releases in advance of any limits in flood operation regulations.

continues to rise above elevation 556 ft with all three compressors operating at maximum pressure, plant operators would either reduce unit load or shut the units down. As the tailwater recedes, the compressors would be shut down in reverse sequence to their startup, as the tailrace elevation drops to elevations below 556 ft. Typical duration of operation of the proposed TDS is expected to be less than or equal to the historical duration of spills at New Bullards Bar Dam, which occurs an average of approximately 21 days per year.

The compressors have been sized to allow the plant to operate under flows similar to those observed in the January 1997 flood event where the maximum river stage at the New Colgate Powerhouse was at an elevation of 578 ft. The powerhouse has been assessed as being "flood proof" for a maximum tailwater elevation of 583 ft (YCWA 2004). There were 16 generation curtailment events between 1971 and 2016 (YCWA 2002) that would have benefited from the TDS. The cumulative loss of power generation during these 16 events was nearly 250,000 MWh, or approximately 5,560 MWh per year.

Addition of the proposed TDS would have an effect on New Bullards Bar Reservoir operations during flood operations. The proposed TDS would increase New Bullards Bar Reservoir release capacity during flood events when spillway capacity is limited by allowing the New Colgate Powerhouse to continue to operate during high flow events through the injection of compressed air into the New Colgate Powerhouse tailrace when the stage of the Yuba River would otherwise prevent generation. Operating the proposed TDS throughout a flood event would allow for increased releases from New Bullards Bar Reservoir, thus reducing New Bullards Bar Reservoir storage during the flood event, and ultimately reducing the peak flood release. Other than allowing the New Colgate Powerhouse to operate during high flow events, the proposed TDS would not affect YRDP operations.

The proposed TDS would include oil containment structures around the base of the air compressors capable of capturing the entire volume of oil in the system, and a condensation system for removing oil mist from the compressed air before it is introduced into the turbine chamber.

Proposed Construction

The anticipated total duration of the construction would be 5 months, commencing after issuance of a new license from FERC, detailed design, approval of detailed construction plans and acquisition of any additional required permits. It is anticipated that the work would not require a separate outage and could be accomplished during planned outages. Key activities would include the following:

- Site preparation at powerhouse yard and deck, including construction of equipment foundations and relocation of the New Colgate Powerhouse pedestrian bypass
- Installation of blowers, pipe supports, roofing, air piping and valves
- Installation of power supply, including the tap of the 13.8-kv isolated phase bus, transformer, switchgear and cables to the blowers
- Procurement and installation of turbine shaft seals
- Curtain wall modifications
- Installation of bulkhead shaft seal

- Installation of instrumentation and controls
- System testing and startup including construction and removal of temporary test barrier. All work would occur within the proposed FERC Project Boundary for the YRDP.

The construction labor force is estimated to average about 12 persons over the total construction period. Equipment would be transported to the powerhouse via Highway 20, Marysville Road, and Lake Francis Road, all of which are paved and suitable for the anticipated loads. It is anticipated that not more than 30 trailer ("low boy") truck roundtrips would be required to bring the blower skids, transformer, other electrical gear, pipe, structural steel and other heavy materials and equipment. About 15 to 20 truckloads of ready-mixed concrete may be needed for equipment pads, foundations and curbs. No changes in road conditions are anticipated as a result of the work.

At the site, typical heavy construction equipment would include an excavator (backhoe), an air compressor, one or two trucks, two truck-mounted cranes, pickup trucks, a construction office trailer and miscellaneous equipment. Smaller equipment would include hoists and platforms, concrete placing and drilling equipment, a welding machine, pipe fitting equipment, and other miscellaneous equipment customary to the electrical, mechanical and structural crafts.

No borrow areas are anticipated to be required because the work does not entail significant earthwork. It is expected that the available space within the fenced plant area would be sufficient for laydown and staging of materials and equipment. All work would be confined to the powerhouse, yard and immediate vicinity. No undisturbed areas are anticipated to be disturbed as a result of the work.

2.4.1.1.2 Non-Generation Facilities

New Bullards Bar Dam Auxiliary Flood Control Outlet (i.e., ARC Spillway)

As described in Yuba Water's Application for New License (YCWA 2014), the 2017 AFLA and FERC's (2019) FEIS, Yuba Water proposes to construct, operate and maintain a new auxiliary flood control outlet (now renamed the ARC Spillway) that would allow releases from New Bullards Bar Dam to occur when the WSE in New Bullards Bar Reservoir is below the existing New Bullards Bar spillway in anticipation of large storm events. The new auxiliary flood control outlet would increase the existing release capacity of New Bullards Bar Dam during high-flow events to improve flood management and to enhance public safety for Yuba and Sutter counties. Once constructed, the ARC Spillway and its related flood control operations will be a new operational component of the new FERC license that has not historically been part of the YRDP and is not part of the existing FERC license (unless FERC decides to issue an amendment order adding the ARC Spillway to the existing license in response to Yuba Water's 2025 application for a non-capacity amendment,[33] which could occur sooner than waiting until the new FERC license for the YRDP Relicensing is issued).

When Yuba Water submitted the 2014 FLA and subsequent 2017 AFLA to FERC, Yuba Water expected and planned that FERC would have issued a new license for the YRDP by the time that Yuba Water was ready to construct the ARC Spillway. Therefore, construction and operation of

[33] Available in FERC's eLibrary at Accession No. 20250131-5499 (Filed on January 31, 2025).

the ARC Spillway were included in the FERC license application. Since the FERC (2019) FEIS was completed, pre-construction design and permitting work on the ARC Spillway has progressed, some of the construction- and operations-related components have changed, and Yuba Water is ready to proceed with the ARC Spillway Project. Because the ARC Spillway would provide significant public benefits and because of the uncertainty regarding when the new license for the YRDP Relicensing Project will be issued, Yuba Water proposes to add the new ARC Spillway under the existing FERC license rather than wait until the new FERC license is issued. It has become apparent that the schedule of events planned in 2014/2017 have not occurred as expected, Yuba Water determined that it was necessary for the ARC Spillway Project to proceed ahead of relicensing. Because the ARC Spillway will be part of the YRDP, the project construction and operation of the ARC Spillway requires FERC approval.

In consideration of the substantial public benefit that the ARC Spillway would have and because of the uncertainty regarding when FERC will issue a new license for the YRDP, on January 31, 2025, Yuba Water filed an application for non-capacity related amendment to the existing FERC license to authorize the ARC Spillway Project. Even though FERC (and USACE) evaluated a new secondary spillway in the 2019 FEIS, FERC staff requested that Yuba Water include in its Application for Amendment an applicant-prepared draft environmental assessment (APDEA) that focused solely on the new ARC Spillway and anticipated changes under the existing FERC license. In response, Yuba Water prepared and included an APDEA in its Application for Amendment.

Yuba Water also undertook a separate process of complying with CEQA for the ARC Spillway Project. On December 17, 2024, Yuba Water certified a Final EIR for the ARC Spillway Project (YCWA 2024b) that fully analyzed construction-related and O&M impacts of the ARC Spillway.[34]

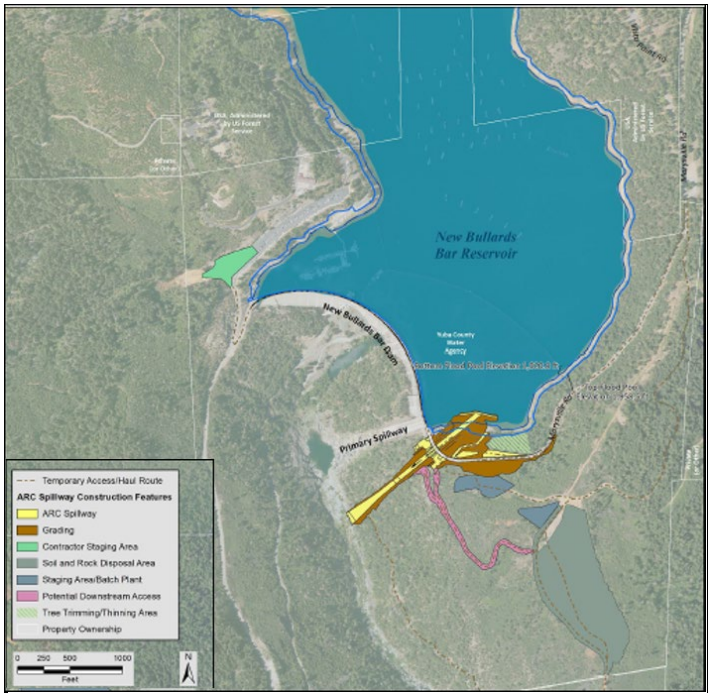

Figure 2.4-1. ARC Spillway proposed construction areas and access (YCWA 2023b).

Figure 2.4-1 shows an overview of the ARC Spillway components. For the ARC Spillway, a new approximately 0.35-mile access road to the spillway chute would be constructed necessitating the addition of approximately 1.2 ac to the FERC Project Boundary for the YRDP (YCWA 2025).

As described and evaluated in the ARC Spillway Project DEIR (YCWA 2023b), releases from the ARC Spillway would be made in anticipation of large storms to provide increased evacuated storage capacity in New Bullard's Bar Reservoir prior to and during high-precipitation events and large storm peak inflows to reduce the peak outflow. The ARC

[34] https://ceqanet.opr.ca.gov/2020110163/6

Spillway would operate conjunctively with the Primary Spillway and New Colgate Powerhouse to meet New Bullards Bar Dam overall target releases. Yuba Water's (2023b) analysis of the ARC Spillway determined that the addition of the ARC Spillway to the YRDP would have no effect on flow requirements in the existing FERC license, nor would it have any effect on the flow requirements that are anticipated to be in the new license (YCWA 2023b). Yuba Water previously identified and adopted mitigation measures (including one mitigation measure requested by the SWRCB) to reduce the water quality impacts associated with ARC Spillway operations to less than significant. These previously adopted mitigation measures for ARC Spillway operations have been incorporated into the YRDP Relicensing Project, and will continue to apply to ARC Spillway operations under the Proposed Projects.

ARC Spillway operations are being considered as part of the YRDP Relicensing Project that is characterized in this DEIR because it was addressed in FERC's (2019) FEIS and it is expected to be a component of the long-term operation of the YRDP that is described in the new FERC license. As described in the ARC Spillway Project DEIR (YCWA 2023b), "*it is assumed that all requirements that apply to YRDP-licensed facilities under the existing FERC license would apply to operation and maintenance of the ARC Spillway, including all requirements and management plans (e.g., Erosion Control, Integrated Vegetation, etc.)*." Anticipated flood management operations associated with the ARC Spillway have been incorporated, as appropriate, into the assumptions that are used to characterize the cumulative hydrologic modeling simulations[35] that represent the Proposed Projects that are evaluated in this DEIR. Once completed, the ARC Spillway and associated facilities/areas would be incorporated into the YRDP under FERC's jurisdiction and regulated by under the FPA.

Modifications to Our House Diversion Dam and Log Cabin Diversion Dam Fish Release Outlets

Proposed Facilities

Yuba Water proposes to change minimum flows on the Middle Yuba River downstream of Our House Diversion Dam from the requirement in the existing license of 30 - 50 cfs to 40 - 120 cfs, and to change minimum flows on Oregon Creek downstream of Log Cabin Diversion Dam from the requirement in the existing license of between 8 - 12 cfs to 6 - 43 cfs (YRDP Proposed Condition AR1, *Maintain Minimum Streamflows Below Our House Diversion Dam and Log Cabin Diversion Dam)* (YCWA 2017a). Further, Yuba Water proposes to include in the new license a requirement to control spill at Our House Diversion Dam by releasing up to 600 cfs (YRDP Proposed Condition AR2, *Control Project Spills at Our House Diversion Dam)* (YCWA 2017a), and to control spill at Log Cabin Diversion Dam by releasing up to 100 cfs (YRDP Proposed

[35] Yuba Water flood management operations of anticipatory releases through the ARC Spillway or flood management-related releases when storage is below the USACE flood reservation space are included in modeling of the cumulative condition. Future operations of the ARC Spillway were determined based on a number of real-time factors, including upstream snow-pack and forecasted storm intensity that are not included in the Operations Model. Modeling of the YRDP to augment the existing New Bullards Bar Dam spillway capacity indicates the ARC Spillway could be used each time New Bullards Bar Reservoir spill operations are needed, but the existing capacity is adequate for all low-to-medium intensity storm events so the release from the dam can be made through either outlet. The cumulative condition modeling results show that the ARC Spillway additional release capacity and release capacity at a lower water-surface elevation would only be needed during very large storm events, or in roughly 12 out of 52 years. Any pre-emptive releases associated with the Forecast-Informed Reservoir Operations (FIRO) program would likely be made using the ARC Spillway in even fewer occurrences than the 12 in 52 years. Other than reducing the peak flow rate during storms, or shifting the peak release to an earlier time, the ARC Spillway would not affect YRDP operations.

Condition AR12, *Control Project Spills at Log Cabin Diversion Dam)* (YCWA 2017a). The proposed flows would exceed the capabilities of the existing fish release outlets (i.e., maximum existing valve capacities are 59 cfs at Our House Diversion Dam and 18 cfs at Log Cabin Diversion Dam). Yuba Water proposes to increase the capacity at each of these outlets to accommodate the new requirements.

At Our House Diversion Dam, a 68-in. diameter outlet pipe with control valve is proposed to be installed at the same invert elevation as the existing fish release outlet. At Log Cabin Diversion Dam, a 38-in. diameter outlet pipe with control valve is proposed to be installed at the same invert elevation as the existing fish release outlet. The new 68-in. diameter outlet at Our House Diversion Dam is expected to result in an outlet capacity of 611 cfs at minimum head (i.e., upstream water level at tunnel invert elevation of 2015.0 ft); the new 38-in. diameter outlet at Log Cabin Diversion Dam is expected to result in an outlet capacity of 106 cfs at minimum head (i.e., upstream water level at tunnel invert elevation of 1952.0 ft). The existing fish release outlets at Our House and Log Cabin diversion dams would remain in place and be able to release at the existing capacities (i.e., 59 and 18 cfs, respectively). The new fish release outlets at the dams would not affect the existing low-level outlets at the dams.

Proposed Operations

Yuba Water anticipates that the new low-level outlets would only be used to provide for controlled releases from the dams in excess of the existing fish release valves. The modifications would not result in added power generation to the YRDP. YRDP Proposed Condition AR1 includes new flow requirements for the Middle Yuba River downstream of Our House Diversion Dam and for Oregon Creek downstream of Log Cabin Diversion Dam. The required flow would be determined by the applicable Smartsville Hydrologic Index WYT. Table 2.4-1 and Table 2.4-2 show the proposed monthly required flows for the Middle Yuba River and Oregon Creek, by WYT, as included in YRDP Proposed Condition AR1. As required by USGS (Article 8 of FERC's Form L-5, Standard Articles), Yuba Water also would record streamflow at all of the gages listed in Table 2.4-1 and Table 2.4-2.

Proposed Construction

All work would occur within the proposed FERC Project Boundary, where temporary facilities and laydown/staging locations are available adjacent to each site. The work would occur during late summer when the minimum flow release from each dam is generally low and equal to inflow into the impoundment. Yuba Water would open the low-level outlet to allow the WSE in the impoundment to drop below the intake to the fish release outlet. A crane would be brought on-site and used to install temporary construction platforms and needed formwork for concrete modifications and installation of the new civil work. A new upsized fish release pipe and associated valve system would be installed at each facility, with the centerline of the new pipe at the same centerline elevation as the existing fish release outlet (i.e., no disturbance to the existing fish release outlet). The concrete facilities needed at the inlets and outlets of the new fish release outlets would be similar to those for the existing fish release outlets, upsized for the larger pipes accordingly. The penetration through the dams for the new fish release outlets would be achieved by coring multiple small diameter overlapping bores through the dam to form a circular opening large enough to accommodate the new outlet pipe and associated localized structural reinforcement

rebar and plating. At the new fish release inlets, conical transition and stop-log slots would be installed; at the outlets, valve support platforms and valve stem guides would be constructed.

The construction labor force is estimated to average about 10 persons over the total construction period. Equipment would be transported to the diversion tunnel via Highway 20, Marysville Road, and Highway 49, all of which are paved and suitable for the anticipated loads. It is anticipated that not more than 10 trailer ("low boy") truck roundtrips would be required to bring the mechanical, electrical and other heavy materials and equipment to the project site. No more than 20 truckloads of ready-mixed concrete may be needed for equipment supports and foundations. No changes in road conditions are anticipated as a result of the work.

At the sites, typical heavy construction equipment would include a crane, a concrete coring machine, air compressors, dump trucks, heavy-duty trucks, a floating barge, and miscellaneous equipment. Smaller equipment would include hoists and platforms, scaffolding, concrete placing and drilling equipment, a welding machine, and other miscellaneous equipment customary to the electrical, mechanical and structural crafts.

No borrow areas are anticipated to be required because the work does not entail significant earthwork. For construction at the Log Cabin Dam, it is expected that the available space on the access roads to the dam areas would be sufficient for laydown and staging of materials and equipment. For construction at the Our House Dam, it is expected that the available space to the northeast, adjacent to the river-right abutment to the dam would be sufficient for laydown and staging of materials and equipment. For both sites, all work would be confined to the dam outlet area and immediate vicinity. No undisturbed areas are anticipated to be disturbed as a result of the work at either site.

It is currently anticipated that environmental compliance and permitting would take a total of 6 months for each diversion dam and the design would occur concurrently with permitting. Actual field construction would take no more than six months. While each site can be modified concurrently, the total time for these two activities is estimated to be two years. Additional information about construction is described in **Appendix 2A-3**.

Modifications to Lohman Ridge Diversion Tunnel Intake

Proposed Facilities

Yuba Water proposes to periodically close the Lohman Ridge Diversion Tunnel on the Middle Yuba River (YRDP Proposed Condition AR11, *Periodically Close Lohman Ridge Diversion Tunnel)* (YCWA 2017a). There is an existing gate on the tunnel intake, but it is not appropriate for closing and opening the tunnel during high flows. Yuba Water proposes to replace the gate with a more efficient gate structure.

Inlet modifications necessary to add a new regulating gate and relocate the existing bulkhead gate would require the following activities:

- Extending the deck and approach walls of the existing inlet upstream 4 to 5 ft
- Constructing a hoist deck to achieve gate and bulkhead lift clearances

- Modifying the existing bulkhead slot to accommodate a regulating gate
- Constructing a new bulkhead slot within the new inlet extension
- Constructing a new trash rack and debris rake at the front of the extended inlet

The inlet extension would be constructed much like the existing inlet (i.e., made of concrete). Based on using a screw-drive for regulating the gate and a wire rope hoist for the bulkhead gate, both hoists would be located on a raised platform approximately 17 ft above the inlet deck elevation or approximately 5 to 6 ft above the current upper access road elevation. Locating the hoists at this elevation allows for both gates to be lifted fully above the current deck for maintenance and inspection. A debris rake would be added to the inlet deck just above the trash rack.

Proposed Operations

Yuba Water proposes to periodically close the Lohman Ridge Diversion Tunnel (YRDP Proposed Condition AR11) during wetter water years and when there is sufficient storage in New Bullards Bar Reservoir to meet water management objectives. Yuba Water anticipates that the new Lohman Ridge Diversion Tunnel Intake Gage would be used to open or close the Lohman Ridge Diversion Tunnel from October 1 through 31 if the water year is wet, above normal, or below normal and New Bullards Bar Reservoir storage is 600,000 ac-ft or more. All water would flow down the Middle Yuba River during closures. If May is a wet, above normal or below normal water year (defined in YRDP Proposed Condition WR2) and the subsequent end-of-September New Bullards Bar Reservoir storage is 600,000 ac-ft or greater, Yuba Water would fully close the Lohman Ridge Diversion Tunnel from October 1 through December 31 of that calendar year.

Yuba Water would also close the Lohman Ridge Diversion Tunnel if the forecast for a wet water year and storage at New Bullards Bar Reservoir storage is 775,000 ac-ft or more at the end of March. If the end-of-March New Bullards Bar Reservoir storage is 775,000 ac-ft or greater and the subsequent April is a wet water year (defined in Yuba Water's YRDP Proposed Condition WR2), Yuba Water would close the Lohman Ridge Diversion Tunnel within two business days of publication of DWR's April Bulletin 120, and it would remain fully closed through September 30 of that calendar year. Concurrent with the Lohman Ridge Diversion Tunnel closure, Yuba Water would open the low-level outlet and fish release valve at Log Cabin Diversion Dam, but it may leave the Camptonville Diversion Tunnel fully open (FERC 2019).

Proposed Construction

All work would occur within the proposed FERC Project Boundary, where temporary facilities and laydown/staging locations are available adjacent to the site. The work would occur during late summer when the minimum flow releases are low and equal to inflow into the impoundment. Yuba Water would open the low-level outlet to allow the WSE in the impoundment to drop below the intake to the diversion tunnel. A crane would be brought on-site and used to install temporary construction platforms and needed formwork for concrete modifications and installation of the new civil work. A new inlet control gate and debris rake would be installed. Penetrations through the existing tunnel inlet deck for the new gate and debris rack would be developed using concrete drilling and cutting tools. Mechanical and electrical control devices would be installed on the tunnel inlet deck.

The construction labor force is estimated to average about eight persons over the total construction period. Equipment would be transported to the diversion tunnel via Highway 20, Marysville Road, and Highway 49, all of which are paved and suitable for the anticipated loads. It is anticipated that not more than 10 trailer ("low boy") truck roundtrips would be required to bring the mechanical, electrical and other heavy materials and equipment to the project site. No more than five truckloads of ready-mixed concrete may be needed for equipment pads and foundations. No changes in road conditions are anticipated as a result of the work.

At the site, typical heavy construction equipment would include an excavator (backhoe), an air compressor, a heavy-duty truck, a truck-mounted crane and miscellaneous equipment. Smaller equipment would include hoists and platforms, concrete placing and drilling equipment, a welding machine, and other miscellaneous equipment customary to the electrical, mechanical, and structural crafts.

No borrow areas are anticipated to be required because the work does not entail significant earthwork. It is expected that the available space within the tunnel intake area would be sufficient for laydown and staging of materials and equipment. All work would be confined to the tunnel intake and immediate vicinity. No undisturbed areas are anticipated to be disturbed as a result of the work.

It is currently anticipated that environmental compliance and permitting would take a total of six months and the design would occur concurrently with permitting. Actual field construction would take no more than six months. The total time for these activities is estimated to be no longer than 18 months.

2.4.1.1.3 YRDP Recreation Facilities

YRDP recreation facilities include existing facilities and new facilities that either are, or would be, part of the YDRP and would be part of the new FERC license, as described in Yuba Water's YRDP Proposed Condition RR1, *Recreation Facilities Plan* (YCWA 2017a). Yuba Water proposes several enhancements to the existing YRDP recreation facilities. When constructing new YRDP recreation facilities, Yuba Water would obtain all necessary permits and approval for survey work, facility design and on-site resource evaluations, including USFS permits for work on NFS land.

A summary of these enhancements is provided below. Additional details may be found in the following appendices to this DEIR:

- Site-specific characterization of existing campgrounds and other recreation facilities, including representative photographs (Appendix 2A-1).
- Existing campground and recreation facility locations are identified on various YRDP relicensing maps (Appendix 2A-5).

- Site plans for existing facilities are provided in the Recreation Facilities Plan (Appendix 2B-14).
- Construction schedules for recreation facilities and for roads are described in the Recreation Facilities Plan and in the Transportation System Management Plan (Appendix 2B-17).

Campgrounds

Schoolhouse Campground (NFS Lands)
This facility is scheduled for major rehabilitation[36] in License Year 10. Yuba Water would provide the following enhancements:

- A standardized four-panel entrance station kiosk (License Year 1).[37]
- Appropriate trailhead signage on the facility entrance sign (License Year 1).
- Replacement of existing vault and flush restroom buildings with new restroom buildings, including septic systems (License Year 2).
- Conversion of all the double and triple campsites into single campsites, except for campsite #9 (double site), which would be separated into two single sites (for a total of 57 sites) (License Year 10).
- Expand and formalize the existing overflow parking area to provide a single, paved and striped parking area with 10 vehicle plus trailer spaces and 15 single vehicle spaces that would serve both campground overflow and trailhead parking needs (License Year 10).
- Construct native surface, non-motorized, multi-use connector trail to Schoolhouse Trail from the trailhead parking area (License Year 10).
- Construct a 50-person capacity amphitheater across the road from the campground overflow and trailhead parking area with bench seating, a large group fire ring and an electrical hookup (License Year 10).
- Install electricity at the entrance station, host site, and each restroom (License Year 10).
- Upgrade the host site with water and electric hookups and a holding tank (License Year 10).
- Install a shower building or buildings with a total of four shower stalls (License Year 10).
- Upgrade the campsite vehicle spurs to accommodate recreational vehicles (RVs) as outlined in Table 3.3-1 of Yuba Water's *Recreation Facilities Plan* (see Appendix 2B-14) (License Year 10).

[36] Information on design standards and guidance for activities associated with major rehabilitation of recreation facilities is provided in Section 3.2 of Yuba Water's Recreation Facilities Plan (see Appendix 2B-14).

[37] The scheduling (years) in Yuba Water's Recreation Facilities Plan (see Appendix 2B-14) use "License Years," with "License Year 1" designating the first full calendar year in which the new license is effective.

- Install RV hookups (water and electric only) at 10 existing campsites (License Year 10).
- Upgrade the existing campground circulation roads to accommodate RVs up to 45 ft in length as outlined in Table 3.3-2 of the Recreation Facilities Plan (see Appendix 2B-14). These upgrades would only be completed if they do not require significant re-designing of the existing circulation roads and do not reduce the total number of existing campsites (License Year 10).

Dark Day Campground (NFS Lands)
This facility is scheduled for major rehabilitation in License Year 6. Yuba Water would provide the following enhancements:

- Install a standardized four-panel entrance station kiosk (License Year 1).
- Replace the two-unit vault restroom building that serves Campsites 5 through 10 with a new vault restroom (License Year 2).
- Maintain facility for tent camping only (License Year 7).
- Provide vegetative screening between campsites (License Year 7).
- Improve each campsite that does not comply with current accessibility standards and guidelines (License Year 7).
- Install a one-unit vault restroom at Campsite #4 (License Year 7).
- Replace the two-unit vault restroom building that serves double campsites (Sites #1 through #3) with an efficient two-unit flush model if the site terrain allows for a leach field. If a flush model is not feasible, then replace with a vault model (License Year 7).

Hornswoggle Group Campground (NFS Lands)
This facility is scheduled for major rehabilitation in License Year 11. Yuba Water would provide the following enhancements:

- Install a standardized four-panel entrance station kiosk (License Year 1).
- Replace the existing four-unit flush restroom buildings at the Manzanita and Madrone campsites with efficient two-unit flush models including appropriate septic systems (License Year 2).
- Replace the existing two-unit vault restroom at the Sugarpine campsite with a one-unit vault model (License Year 2).
- Replace the existing two-unit vault restroom at the Douglas Fir campsite with an efficient one-unit flush model (including appropriate septic system) (License Year 5).
- Install efficient one-unit flush restroom buildings including appropriate septic system at Dogwood and Ponderosa campsites (1 each where restroom buildings do not currently exist) (License Year 5).
- Install a shower building or buildings with a total of 4 shower stalls (License Year 5).

- Reconfigure turning radii of each existing group campsite spur road to accommodate RVs up to 45-ft-long at all the group campsites, except Site No. 4 (Ponderosa). Site No. 4 (Ponderosa) would be designated with an RV size limit (exact limit to be determined), which includes signage at the campsite and the facility entrance information kiosk, as well as a disclosure about the size limit at this particular site through the USFS reservation system at the time of reservation (License Year 5).
- Improved turning radii of each existing group campsite spur road to accommodate RVs up to 45-ft-long at all the group campsites, except Site No. 4 (Ponderosa), where an RV size limit would be implemented (License Year 5).
- Expand the capacity by one group campsite (25-person capacity), including a paved parking area, one-unit vault restroom, and group camping area with picnic tables, food lockers, fire ring and a pedestal grill (License Year 5).
- Provide electricity at the entrance kiosk/information board and each restroom (License Year 5).

Cottage Creek Picnic Area (NFS and Yuba Water Land)

Yuba Water would complete the second phase of the facility reconstruction on the eastern portion of the campground that was severely burned in the 2010 fire once the area has been sufficiently re-vegetated, based on an average tree height of 20 ft for trees in the replanted area). For planning purposes, Yuba Water scheduled the second phase of development in License Year 2 unless the work was completed under the existing license or Yuba Water and the USFS determine that development is premature due to the re-vegetation status. The development would consist of four additional small group campsites with the following specifications:

- A total of four additional campsites, including two double campsites and two triple campsites each with a paved vehicle spur and a living space and the following additional specifications:
    - Double campsites would consist of a paved vehicle spur with 2 single vehicle spaces and 2 RV camping spaces; and a living space with 1 group-sized fire ring, 2 food lockers, 2 picnic tables and 2 tent pads.
    - Triple campsites would consist of a paved vehicle spur with 3 single vehicle spaces and 3 RV camping spaces; and a living space with 1 group-sized fire ring, 3 food lockers, 3 picnic tables and 3 tent pads.
- A potable water system extension from the existing system consisting of underground distribution and water hydrants.
- A two-unit vault restroom building.
- A paved circulation road with vehicle barriers.
- Trash facilities, including a dumpster and recycling receptacles.

- A standardized four-panel entrance station kiosk, if not installed under the first phase (initial license).
- A two-panel interpretive display at a location with the best view down canyon within the facility.

Garden Point Boat-in Campground (NFS Lands)
This facility is scheduled for major rehabilitation in License Year 11. Yuba Water would provide the following enhancements:

- Install a standardized four-panel entrance station kiosk (License Year 1).
- Install a one-panel interpretive display that includes information about the gold mining history in the Yuba River drainage and the North Yuba River/Bullards Bar area (License Year 1).
- Install animal-resistant food lockers (at least 30 ft^3) at each site if not done prior to new license (License Year 1).
- Replace the existing (2) one-unit and (1) two-unit vault restroom buildings with new vault models with the most efficient configuration of one- and/or two-unit restroom buildings based on campsite locations (License Year 2).
- Expand the site capacity by at least seven new single campsites to replace lost capacity with the closure of Frenchy Point Campground (License Year 11).
- Install additional restroom building(s) to meet the needs of the final number of new campsites developed with the most efficient configuration of one- and/or two-unit restroom buildings based on campsite locations (License Year 11).
- Provide solar-powered lighting at the entrance station kiosk (License Year 11).
- Remove Klamath stove facilities and concrete bases (License Year 11).

Madrone Cove Boat-in Campground (NFS Lands)
This facility is scheduled for major rehabilitation in License Year 11. Yuba Water would provide the following enhancements:

- Install a standardized four-panel entrance station kiosk (License Year 1).
- Install a one-panel interpretive display that includes information about the gold mining history in the Yuba River drainage and the North Yuba River/Bullards Bar area (License Year 1).
- Install animal-resistant food lockers (at least 30 ft^3) at each site if not done prior to new license (License Year 1).
- Replace the existing vault restroom with a new vault model – evaluate the size, design and location of the new vault toilet (License Year 2).
- Improve the facility to meet the needs of the users (e.g., redevelopment from a family campground to a group campground) (License Year 11).

- Replace campsite retaining walls with durable materials (License Year 11).
- Provide solar-powered lighting at the entrance station kiosk (License Year 11).
- Remove old Klamath stove facilities and concrete bases (License Year 11).

Frenchy Point Boat-in Campground (NFS Lands)
During License Year 1, Yuba Water would decommission the facility due to low use caused by difficult (very steep) access conditions. Yuba Water would remove the remaining site facilities and restore the site to conditions satisfactory to the USFS. Once decommissioned, the site would no longer be used as a dispersed shoreline camping area.

Day Use Facilities

Dark Day Picnic Area (NFS Lands)
This facility is scheduled for major rehabilitation in License Year 6, and Yuba Water would provide the following enhancements:

- Install a standardized three-panel entrance station kiosk (License Year 1).
- During License Year 6, concurrent with major rehabilitation of the facility:
    - At the western picnic site cluster:
- Provide a total of 10 picnic sites near the NMWSE – each with a picnic table and a concrete grill with self-contained ash box.
- Remove any existing, remnant picnic sites and amenities (tables and grills); and restore the sites to conditions satisfactory to the USFS.
- Remove the existing Klamath stoves at each picnic site.
- Install signage to direct users from the parking area to the re-located picnic sites via the new outdoor recreation access routes (ORARs).
- Where practical, enhanced reservoir views at the re-located picnic sites through selective vegetation management.
- Yuba Water would apply to Yuba County for an ordinance establishing a non-motorized boating only zone on the reservoir adjacent to the western picnic site cluster.
    - At the northern/peninsula picnic site cluster:
- Provide a total of five picnic sites near the end of the peninsula – each with a picnic table and a concrete grill with self-contained ash box.
- Remove any existing, remnant picnic sites and amenities (tables and grills) beyond the 5 proposed new/improved picnic sites; and restore the sites to conditions satisfactory to the USFS.
- Remove the Klamath stoves at each picnic site.
- Install signage to direct users from the parking area to the re-located picnic sites via improved ORARs.

- Where practical, enhance reservoir views at the re-located picnic sites through selective vegetation management.
    - Replace and relocate the existing four-unit vault restroom with a new four-unit vault model. The restroom would be located to provide for more efficient maintenance and provide the opportunity for expanded parking where the existing restroom is located.
    - Provide a total parking capacity of 34 single vehicle spaces by:
- Re-configuring the existing parking area to maximize the parking capacity, including utilizing the existing island and peripheral areas, as practical; and
- Expanding the parking area to meet the total parking capacity of 34 single spaces.
    - Install trailhead signage for the Bullards Bar Trail, as follows:
- At the parking area, install: (1) a trailhead identification sign; (2) a 1-panel information board with trail information and a map; (3) trailhead identification signs where the Bullards Bar Trail intersects the parking area; and
- On Marysville Road at Dark Day Road junction, install a trailhead identification sign.

Sunset Vista Observation Site (NFS Land)

This facility is scheduled for major rehabilitation during License Year 2. Yuba Water would provide the following enhancements:

- Install a standardized three-panel entrance station kiosk (License Year 1).
- Install two additional picnic sites, each with a picnic table and a concrete grill with self-contained ash box. Note: the site design, vegetation management measures and visual enhancement measures at the new picnic sites should aim to provide shade through existing trees, but in the event that shading via existing trees would not be adequate, then at the time of design and/or construction the installation of shade structures (e.g., ramadas) may be utilized to provide shading (License Year 2).
- Install a water hydrant near the new picnic sites (License Year 2).
- Upgrade the existing picnic site by replacing the picnic table and installing a concrete grill with self-contained ash box (License Year 2).
- Enhance the vistas of the reservoir from each picnic site by selectively clearing vegetation per the guidelines in Yuba Water's *Visual Resources Management Plan* (**Appendix 2B-19**) (License Year 2).
- Replace the existing four-unit vault restroom with a new two-unit vault model (License Year 2).
- Pave and delineate the parking spaces/areas on the shoreline side for the vista/picnic visitors and trailhead users (License Year 2).

- Install a trailhead sign at the start of the Bullards Bar Trail (License Year 2).
- Install a one-panel interpretive display at the picnic sites. The interpretive panel would be approx. 3-ft by 4-ft in size and would contain key historical information about the YRDP, particularly the dam and associated facilities; and the primary purposes of Yuba Water and the YRDP (e.g., flood control, downstream water supply, recreation, fisheries enhancement, hydroelectric generation) (License Year 2).

Dam Overlook Observation Site (Yuba Water Land)[38]
Yuba Water would provide the following enhancements:

- Grade, gravel and install vehicle barriers at the existing parking area for a total parking capacity of 10 single vehicle spaces (License Year 7).
- Install a standardized 3-panel entrance station kiosk (License Year 7).
- Install a one-panel interpretive display. The interpretive panel would be approximately 3-ft by 4-ft in size and would contain key historical information about the YRDP, particularly the dam and associated facilities; and the primary purposes of Yuba Water and the YRDP (e.g., flood control, downstream water supply, recreation, fisheries enhancement, hydroelectric generation) (License Year 7).

Boat Launch Facilities

Cottage Creek Boat Launch (Yuba Water Land)
This facility is scheduled for major rehabilitation in License Year 18, and Yuba Water would provide the following enhancements:

- Install a standardized four-panel entrance station kiosk (License Year 1).

Dark Day Boat Launch (NFS Lands)
This facility is scheduled for major rehabilitation in License Year 4, excluding the overflow boat ramp parking area (constructed in 2004), which is scheduled for major rehabilitation in License Year 10. Yuba Water would provide the following enhancements:

- Overflow Parking Area
    - Improve the switchback trail by conducting basic trail maintenance on the trail connecting the overflow parking area to the boat ramp, including brush cutting, rock and root removal, slough and berm removal, and switchback maintenance (License Year 1).

[38] This facility is scheduled for major rehabilitation during License Year 7. However, as described in YCWA (2023b), the existing location of the Dam Overlook Observation Site is needed to construct the ARC Spillway and the Overlook Site will be relocated approximately 500 ft to the east of the existing site along a relocated segment of the Marysville Road. The relocated Overlook Site will occupy an area that is now partially occupied by Marysville Road but would become available once the road is relocated to the south over the new control structure (YCWA 2023b). It would have a similar surface area to the existing Overlook Site and will be surfaced with aggregate base and asphalt concrete (the former road pavement). The new Overlook Site is planned to have space for 10 vehicles. If the ARC Spillway is constructed, then Yuba Water would alternatively complete the recreation facility major rehabilitation and improvements described below within two years of completion of the ARC Spillway Project.

- Decommission the adjacent, user-created, non-switchback trail (License Year 1).
- Install trail signage at the start and end of the trail (License Year 1).
- Install lighting at the existing restroom (License Year 1).
- Install a standardized four-panel entrance station kiosk (License Year 1).

- Main Parking Area and Boat Ramp
  - A standardized four-panel entrance station kiosk (License Year 1).
  - Install trailhead signage at the parking area (License Year 1).
  - Upgrade the existing launch ramp in consultation with the USFS and the California Division of Boating and Waterways (CDBW) staff that meets: (1) Division of Boating and Waterways ramp design standards; and (2) the goals of straightening widening and extending the boat ramp, minimizing ramp-side erosion[39] and providing a fully functional/accessible floating courtesy dock (License Year 4).
  - Install lighting at the restroom, top of the launch ramp and in the parking area (License Year 4).
  - Replace the existing four-unit vault restroom with a new four-unit vault model (if not done sooner as part of parking area re-organization work under the initial license) (License Year 4).
  - Repave and stripe the existing parking area (if not done sooner as part of parking area reorganization work under the initial license) (License Year 4).
  - Removal of the accessible loading ramp (if not done sooner as part of parking area reorganization work under the initial license) (License Year 4).

- Future Parking Area Expansion
  - Yuba Water would evaluate the need to provide additional boat launch parking at the Dark Day Boat Launch facility based on site-specific monitoring at the Dark Day and Cottage Creek boat launch designated parking areas and overflow parking outside of designated parking areas.

<u>Moran Road Boating Site (NFS Lands)</u>
This facility is scheduled for major rehabilitation in License Year 5, and Yuba Water would provide the following enhancements:

- Install a standardized four-panel entrance station kiosk (License Year 1).
- Closure of Moran boat ramp (at existing gate on boat ramp beyond parking area/restrooms), annually from October 15 to May 1, to protect the California red-legged frog from vehicle mortality (License Year 1).

[39] The Dark Day Boat Launch ramp has a functionality issue at an approximate WSE of 1,856 ft due to slope instability in the upslope side of the ramp, where at times, the slope erodes depositing sediment on the boat ramp – typically during the non-peak season (January up to Memorial Day weekend and after Labor Day through December). The accumulation of sediment impacts the functionality of the boat ramp, making the boat ramp impassable by vehicles backing down boat trailers; and the sediment impedes or damages the function of the boat dock rail and roller system requiring that the dock be removed.

- Replace the gravel on the existing boat ramp (License Year 5).
- Improve each of the three existing turnarounds along the car-top boat ramp (License Year 5) as follows:
    - Widen to meet turning radius standards at the time of design for a large pickup truck.
    - Installing gravel on the turnaround surface, vehicle barriers and appropriate signage.
    - Installing vehicle barrier and signage at the end of the ramp/third turnout to prevent vehicle access beyond.
- Expand the existing parking area by five new single spaces (License Year 5).[40]

Our House Diversion Dam Impoundment Facilities

This site does not have any recreation facilities and, thus, is not scheduled for major rehabilitation. Yuba Water would provide the following enhancements:

- Install a standardized three-panel entrance station kiosk (License Year 1).
- Provide a temporary restroom (1 unit) every year from October 1 through June 30 (License Year 1).
- Construct a "beach access" trail downstream of the diversion dam and weir. The beach access route would be designed to accommodate whitewater boaters transporting rafts, inflatable kayaks and hardshell kayaks from the end of the existing maintenance road below the diversion dam down the slope to the granite bench near the river's edge (License Year 4).
- Provide a wheeled cart designed for carrying whitewater rafts behind the existing locked gate at the parking area (License Year 4).

Other Facilities

Recreational Trails (Bullards Bar and Schoolhouse Trails)

The Bullards Bar and Schoolhouse trails are not scheduled for major rehabilitation. Yuba Water would provide the following enhancements:

- Install a trailhead symbol or sign at all facility entrance signs located along Marysville Road that provide access to YRDP trails and at YRDP trailhead parking areas (License Year 1).
- Install consistent directional signage at all YRDP trail junctions (License Year 1).

[40] Expansion of the parking area may require relocating the existing one-unit vault restroom to provide the 5 additional single vehicle parking spaces.

Recreation Water and Wastewater Systems

- Water Delivery System
    - This facility is scheduled for major rehabilitation in two phases in License Year 3 and 6.
- Replace the first segment of underground water distribution system from the water treatment facility at Cottage Creek Boat Launch, across the dam, along Marysville Road and terminating at the Dark Day Road, including the above-ground span of piping across the dam (License Year 3).
- Replace the underground water distribution system from the end of the first segment above to the Dark Day Campground, Picnic Area and Boat Launch complex (License Year 6).
    - Note: The underground water distribution lines (off the main line) and hydrants within each recreation facility would be replaced as part of the major rehabilitation of each facility and not specifically as part of the main line rehabilitation.
- Water Treatment Facility
    - This facility is scheduled for major rehabilitation in License Year 20. No specific improvements to the water treatment facility and storage tanks are planned at this time. However, as Yuba Water prepares to construct additional recreational facilities as scheduled in the Recreation Facilities Plan, then Yuba Water would rehabilitate, improve and upgrade the capacity of the water treatment facility as needed to meet the water system demands of the existing and new recreation facilities. As noted above, Yuba Water would be replacing and upgrading the water delivery system piping in the first three years of the new license, which Yuba Water expects would improve the overall water system supply. Thus, at a minimum, Yuba Water would wait to see the impacts that the delivery system upgrades have on the overall system supply before addressing any further treatment facility upgrades. In the meantime, Yuba Water would continue to maintain and operate the water treatment facility with the current layout and capacity.
- Water Storage Tanks
    - This facility is scheduled for major rehabilitation in License Year 10. No specific improvements to the water storage tanks near Sunset Vista Observation Site and at the Cottage Creek Boat Launch maintenance yard are planned at this time. However, as Yuba Water prepares to construct additional recreational facilities as scheduled in the Recreation Facilities Plan (Appendix 2B-14), then Yuba Water would rehabilitate, improve and upgrade the storage tanks as needed to meet the water system demands of the existing and new recreation facilities.
- Recreational Wastewater Systems (Septic and Leach Fields)
    - The existing wastewater systems are scheduled for major rehabilitation in License Year 2. No specific improvements to the recreational wastewater systems are planned at this time.

- Floating Comfort Stations
    - This facility is scheduled for major rehabilitation as needed, but no later than License Year 20. When each floating comfort station is replaced during major rehabilitation, Yuba Water would install a station that meets applicable accessibility standards and guidelines.

Proposed New YRDP Recreation Facilities

In addition to the improvements to the existing YRDP recreation facilities, Yuba Water proposes several new YRDP recreation facilities. A description of these new facilities is provided below.

Kelly Ridge Campground (NFS Lands)

Yuba Water would construct a new campground designed to accommodate small groups (double and triple sites) and RVs on Kelly Road off Marysville Road in License Year 9. This is a new recreation site that is proposed to be added to the FERC Project Boundary. The facility would include two discrete camping areas (a conceptual layout is shown in Appendix 2B-14) separated by Kelly Road, and would have the following specific facilities, features and configurations:

- A total of 27 campsites (22 double campsites and 5 triple campsites), each with a paved vehicle spur, RV hookups, and a living space.
    - The double campsites would consist of a paved vehicle spur with 2 single vehicle spaces and 2 RV camping spaces; 2 water and electric RV hookups (no septic); a living space with 1 group-sized fire ring, 2 food lockers, 2 picnic tables and 2 tent pads.
    - The triple campsites would consist of a paved vehicle spur with 3 single vehicle spaces and 3 RV camping spaces; 3 water and electric RV hookups (no septic); a living space with 1 group-sized fire ring, 3 food lockers, 3 picnic tables and 3 tent pads.
- A host site designed for an RV with a 20-ft-wide by 60-ft-long vehicle spur, and RV hookup with water and electric connections, and a septic holding tank.
- A potable water source and delivery system.
- A shower building with 4 shower stalls, 4 flush restroom stalls and a parking area.
- Restroom buildings including (2) two-unit vault buildings and the remainder would be flush buildings.
- Paved circulation roads with vehicle barriers and gates.
- Install a standardized four panel entrance station kiosk and directional signage.

Shadow Ridge Campground (NFS Lands)

Yuba Water would construct a new campground designed to accommodate single families at the former Burnt Bridge Campground site in License Year 5. Work would involve a rebuild of an older decommissioned site (i.e., Burnt Bridge Campground), which is located within the existing FERC Project Boundary. Yuba Water is proposing to retain only those lands that are located within the existing boundary that are necessary for O&M of the Shadow Ridge camping site and

associated trails. The facility would include a campground, trailhead parking area, non-motorized shoreline loop trail, a non-motorized interpretive trail and a reservoir overlook (conceptual layouts are shown in Appendix 2B-14). The facility would have the following specific facilities, features and configurations:

Camping Facilities

- A total of 18 single campsites each with a paved vehicle spur and a living space (1 fire ring, food locker, picnic table and two tent pads).
- A host site designed for an RV (20-ft-wide by 60-ft-long vehicle spur) with water and a septic holding tank.
- A potable water system, including source (well), underground distribution and water hydrants dispersed throughout the campground.
- 2 two-unit restroom buildings (1 flush and 1 vault model).
- Paved circulation roads.
- A 30-person capacity amphitheater with bench seating and a large group fire ring.
- Install a standardized four-panel entrance station kiosk.

Trailhead, Trails and Overlook Facilities

A trailhead parking area consisting of:

- Gravel parking area (10 vehicles) with vehicle barriers.
- Standardized four-panel entrance station kiosk.
- Two-panel interpretive display with information about local wildlife.

A non-motorized shoreline loop trail (at least 48 in. wide) around the Shadow Ridge peninsula.

A non-motorized interpretive trail, with at least a 48-in. wide tread and a native surface, from the trailhead along the existing road to the top of the Shadow Ridge peninsula. The interpretation would include 8–10 interpretive display stations each with a one-panel interpretive display (12 in. by 18 in.) identifying specific local wildlife, vegetation and any other relevant site-specific information.

A reservoir overlook atop the peninsula along the interpretive trail consisting of:

- A picnic area with 3 to 5 picnic sites (tables only).
- A two-panel interpretive display.

Appropriate vegetation management and clearing to enhance the views of the reservoir (Moran Cove).

Future YRDP Campground Expansion

Yuba Water would expand the campground by an additional 10 single campsites based upon the site-specific monitoring detailed in the Recreation Facilities Plan (see Appendix 2B-14). If the monitoring triggers are met, then Yuba Water would expand the campground with the following facilities and amenities.

10 single campsites each with a paved vehicle spur and a living space with 1 fire ring, 1 food locker, 1 picnic table and 2 tent pads).

An extension of the potable water system constructed during the initial development, including underground distribution and water hydrants dispersed throughout the campsites.

A two-unit vault restroom building.

Paved circulation roads.

Cottage Creek Picnic Site (Yuba Water/NFS/Private Lands)

Pending access easements from the private landowners along the access road to the site, Yuba Water would construct a new picnic site (refer to the conceptual layouts in Appendix 2B-14) with the following facilities and features during License Year 2.

Parking Area

Develop a gravel parking area for 15 single vehicles with vehicle barriers.

Install a two-unit vault restroom.

Install a facility identification sign and directional signage at the parking area, and along Yuba County Road 169 at the intersection with the facility access road (USFS Road 18N15).

Install a standardized three-panel entrance station kiosk.

Shoreline Day-Use Area

Develop 10 picnic sites each with a picnic table.

Develop a beach access route (approximately 200 ft to 300 ft) to the NMWSE from the picnic site to the cove southwest of the picnic site.

Yuba Water would apply to Yuba County for an ordinance establishing a non-motorized boating only zone in the cove accessed by the accessible shoreline trail; and install buoys at the mouth of the cove stating non-motorized watercraft only in the cove.

Install a one-panel interpretive display with information about the history of the valley.

Access Road

Provide basic improvements[41] to the existing access road (Forest Service Road 18N15) from the intersection with Yuba County Road 169 to the new parking area. Anticipated road improvements may include: (1) maintaining a native surface road; (2) removing the old asphalt pavement segments; (3) installing spot gravel where road surface needs repair; (4) installing a new culvert plus shoulder drainage improvements where the creek intersects the road; (5) installing vehicle pullouts periodically along the road to allow two-way vehicle passing; and (6) installing signage along the road stating, "No Vehicular Access off Designated Road."

Install vehicle barriers (e.g., gate, boulders, etc.) to prevent vehicle access beyond the road and the parking area.

Install a gate: (1) near the junction with County Road 169; and (2) immediately after the parking area to prevent vehicles from accessing private property beyond the parking area.

Because the road crosses private property, and as a condition of the easement across the private property, the access road may be closed periodically: (1) due to road conditions/safety, until the condition is fixed, which would be Yuba Water's responsibility; and (2) potentially during private logging activity or other potentially dangerous forest management activities on private lands nearby the picnic site.

The Cottage Creek Picnic Site would be open during the same period that the Cottage Creek Campground is open (approximately April 15 to October 15) because the Operating Staff at Cottage Creek Campground (facility located at the start of the day-use facility access road) would be responsible for closing and opening the gate daily. When the Cottage Creek Campground closes, the picnic facility would be closed as well, including signage indicating the facility is closed for the season.

<u>Dark Day RV Dump Station (NFS Lands)</u>
Yuba Water would construct a sanitary dump station for RVs on Dark Day Road in License Year 9. The facility would include the following facilities and features.

A one-lane dump station with an 8,000-gallon holding tank, potable water hydrant, non- potable water tower for cleaning, an overhead light and trash facilities.

A one-way (15-ft-wide) paved circulation road with an RV-sized pullout after the dump station.

A turning lane on Dark Day Road for vehicles coming from the Marysville Road direction.

Install a standardized three-panel entrance station kiosk and facility identification signs.

<u>New Colgate Powerhouse River Access (Yuba Water Land)</u>
Immediately downstream of the New Colgate Powerhouse, Yuba Water would complete the following river access improvements (refer to the conceptual layouts in Appendix 2B-14) in

[41] It is expected that the existing road alignment and width is adequate for the new facility needs.

License Year 2.

Construct a non-motorized river access trail, with 36-in-wide tread and native surface) from the shoulder of Lake Francis Road (Yuba County Road 139) to the river's edge.

Install a standardized three-panel entrance station kiosk.

Install directional signage indicating where parking is permitted/not permitted along the shoulder of Lake Francis Road (Yuba County Road 139).

West Shoreline Trail (Yuba Water/NFS Lands)

Yuba Water would develop a shoreline trail (Figure 2.4-2) and appropriate signage on the west shoreline of New Bullards Bar Reservoir connecting the Cottage Creek recreation complex (boat launch, campground and picnic site) and the Shadow Ridge recreation complex (campground and trails). The trail would be "Class 3" trail designed for non-motorized uses (pedestrian, mountain biking and equestrian uses) with a 48-in-wide native surface tread and a 36-in-wide vegetation clearance on each side of the tread. Yuba Water would install footbridges over stream crossings, and signs to make users aware of the sensitive nature of California red-legged frog habitat along the West Shoreline Trail. Yuba Water would complete this trail construction in two phases, as described below.

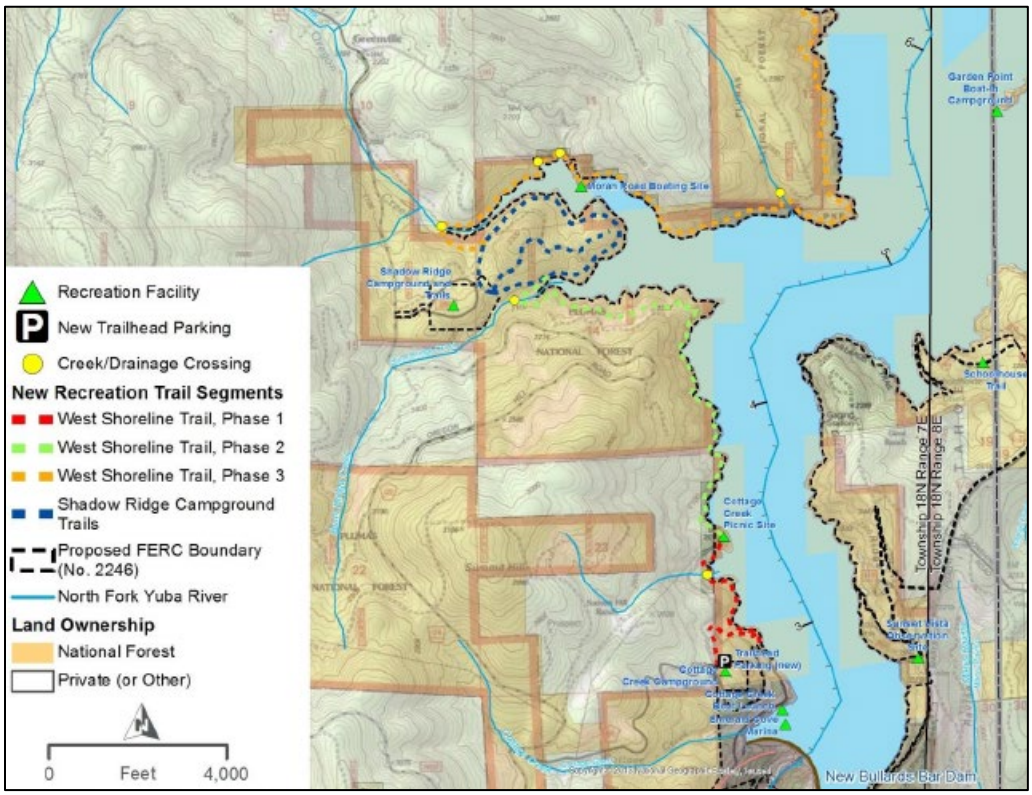

Figure 2.4-2. General alignment for the three phases of the West Shoreline Trail.

Phase 1 Segment: Cottage Creek Boat Launch to Cottage Creek Campground and Cottage Creek Picnic Site

In License Year 2, concurrent with the development of Cottage Creek Picnic Site (new facility to be constructed), Yuba Water would construct an approximately 1.1-mile trail that connects the three adjacent Cottage Creek Facilities – boat launch, campground and picnic site. Trailhead parking areas for this trail segment would utilize the existing parking areas at the Cottage Creek Boat Launch and Cottage Creek Picnic Site. In addition, because the Cottage Creek Campground lacks a suitable parking area to accommodate trailhead parking, Yuba Water would provide a native surface parking area adjacent to the campground alongside USFS Road 18N15 for 10 single vehicles with vehicle barriers and appropriate signage.

Phase 2 Segment: Cottage Creek Picnic Site to Shadow Ridge Campground

In License Year 6, Yuba Water would construct an approximately 4.5-mile trail that connects the Cottage Creek Picnic Site to the trailhead at Shadow Ridge Campground. Notably, Shadow Ridge Campground is a new facility scheduled for construction by Year 5 that would include trails and a trailhead parking area, which would serve as the trailhead for this new trail segment as well.

Phase 3 Segment (Future Expansion): Shadow Ridge Campground to Madrone Cove Boat-in Campground

Yuba Water would develop a third trail segment from Shadow Ridge Campground to Madrone Cove Boat-in Campground based upon the site-specific monitoring detailed in the Recreation Facilities Plan (see Appendix 2B-14).

2.4.1.1.4 YRDP Recreation Facility Operating Season

YRDP recreation facilities would remain open with all services to be provided under the responsibility of Yuba Water according to the schedules by type of facility shown in Table 2.4-3.

Table 2.4-3. Operating season for each type of YRDP recreation facility.

Type of Facility	Operating Season		Conditions
	Open	Close	
All Campgrounds	April 15	October 15	Once outside the peak season (Memorial Day to Labor Day), partial closures of the camping facilities may occur due to reduced use.
Dark Day and Cottage Creek Picnic Sites	April 15	October 15	Access to Cottage Creek Picnic Site occurs over private lands where private timber activities may require temporary closures.
All Other Day-use Facilities	January 1	December 31	Some Facilities may be closed during winter months due to very low use (e.g., close restroom buildings, trash facilities, water, etc.)
Boat Ramps	January 1	December 31	As conditions permit. If ramps are out of the water, ramp may be closed or remain open but with appropriate warning signs.
Recreational Trails	January 1	December 31	Whole or sections of trail may need to be closed temporarily due to weather or other site conditions.

Outside of the operating season, necessary closing and opening preparations, and any additional maintenance and repairs that were not possible during the operating season, would be the responsibility of Yuba Water. When YRDP recreation facilities are closed, Yuba Water would post information in a conspicuous location at the facilities and on Yuba Water's website to advise the public that the facilities are closed and provide the information to the USFS for electronic posting on the USFS website. Major rehabilitation/reconstruction of YRDP recreation facilities or

unforeseen damage to facilities may require Yuba Water to close facilities until construction or repairs are complete and the facility is in safe working order.

2.4.1.1.5 Proposed Construction of YRDP Recreation Facilities

Yuba Water's YRDP Proposed Condition RR1 (Recreation Facilities Plan) includes a detailed implementation schedule for major rehabilitation, near-term rehabilitation and enhancements at each existing recreation facility and for new recreation facilities extending from License Year 1 through 20. The majority of the work on NFS lands would occur within the first eleven years of the new license, with some work on Yuba Water facilities occurring in Years 14 through 20. After Year 20, the need for replacement and/or redevelopment of facilities would be discussed and planned during annual coordination meetings with the USFS, as described in Yuba Water's *Recreation Facilities Plan* (Appendix 2B-14).

As described in the Recreation Facilities Plan (see Appendix 2B-14), major recreation rehabilitation and improvement work generally involves a three-step planning and implementation process. Steps in this process include: (1) preparation of a Site Plan (Design Narrative and Site Concept Plan); (2) preparation of a Site Development and Construction Plan; and (3) contracting and construction for each facility. In addition, for all sites located on NFS lands, reconstruction plans and minor recreation rehabilitation or improvements would meet current USFS standards, and each step would require approval by the USFS. It is also recognized that variances may occur because of the complexity or simplicity of the rehabilitation or improvement work. As a rule, construction (Step 3) would not occur until all environmental and permitting work is complete. However, the timing and scope of the environmental review and permitting work would vary between major rehabilitation of existing recreation facilities as compared to the construction of new facilities (YCWA 2022b).

The *Recreation Facilities Plan* further states "*For major rehabilitation of existing Facilities, YCWA anticipates the FERC relicensing EIS* [and this DEIR] *will cover the environmental analysis and the permitting scope of work will be well-known, well-defined and will begin after 100 percent design (Step 2) is complete. In comparison, for the construction of new Facilities, YCWA expects an increased level of environmental review and permitting to occur overall and earlier on in the three-step planning process (often starting in Step 1 compared to after Step 2 for major rehabilitation). YCWA expects that environmental studies and analysis will be needed, particularly where new Facilities are located outside the existing FERC Project boundary; and these studies may be necessary to inform the design process (e.g., avoidance of sensitive resources) in Step 2 (Site Development Plan and Construction Plan)*."

2.4.1.1.6 YRDP Proposed Primary Project Roads

Yuba Water's YRDP Proposed Condition LU1, *Transportation System Management Plan*, provides guidance for the rehabilitation and maintenance of Primary Project Roads and Trails, which are non-general use roads and trails that are primarily used for the YRDP. A "Primary Project Road" or "Primary Project Trail" is a road or trail that is identified in the FERC license as a YRDP facility, is used almost exclusively to access the YRDP, is entirely within the FERC Project Boundary (and therefore will be under FERC's jurisdiction for the YRDP Proposed Project) and is maintained exclusively by Yuba Water as a YRDP project feature. General Access

Roads are general use roads that are outside the FERC Project Boundary. Yuba Water has consulted with the USFS to determine which roads on NFS land are Primary Project Roads and which are General Access Roads. In addition, if a road providing primary access to YRDP facilities is a County Road, it is included in a Road Maintenance Agreement between Yuba Water and Yuba County. The Road Maintenance Agreement is for maintenance of County Road segments that provide primary access to YRDP facilities, including "driveway" entrances to YRDP Recreation Roads that fall within a County Road right-of-way. This agreement is not jurisdictional to the FERC license and is intended to remain as a separate agreement between Yuba Water and Yuba County that generally addresses shared responsibilities and funding. Yuba Water renews the Road Maintenance Agreement with Yuba County on an annual basis, and it is consistent with the Primary Project Roads and Trails list.

Yuba Water proposes the following Primary YRDP Project Roads and Trails (Table 2.4-4) and Recreation Roads[42] (Table 2.4-5). Additional details are available in Yuba Water's Transportation System Management Plan (see **Appendix 2B-17**), which presents more specific information on YRDP roads and trails, general road maintenance activities and standards, recommended rehabilitation of roads in poor condition, and the scope of improvements needed for design, construction, O&M, signage and rehabilitation, with emphasis on Primary Project Roads and Trails and Recreation Roads on NFS land.

Table 2.4-4. Primary YRDP Project Roads and Trails (non-recreation roads and trails).

Road Name	Begin	End	Land Ownership	Mile Marker-Start	Mile Marker-End	Total Length (mile)
Our House Diversion Dam Road (TNF Rd 0180-Our House)	Ridge Road	Our House Diversion Dam	Private	0	0.79	0.79

New Bullards Bar Dam Road Spur	New Bullards Bar Dam Road	New Bullards Bar Dam	Private	0	0.11	0.11

[42] For the purposes of Yuba Water's YRDP Transportation System Management Plan, a "Recreation Road" or "Recreation Trail" is a road or trail that provides access to YRDP-related recreation facilities and is within the FERC Project Boundary. Recreation Roads typically extend from a Primary Project Road or a county or state road to and within a YRDP recreation facility. A Recreation Road includes all roadways and parking areas within a YRDP recreation facility, so is part of the YRDP facility identified in the FERC license. A Recreation Trail provides foot access from one YRDP facility to another YRDP facility or along a YRDP facility (e.g., a reservoir). Recreation Roads and Recreation Trails are maintained exclusively by Yuba Water.

Table 2.4-4. (Continued).

Road Name	Begin	End	Land Ownership	Mile Marker-Start	Mile Marker-End	Total Length (mile)

Total	**13 road segments**						**4.07 miles**

[1] Yuba County has confirmed the first 0.33-mile is County Road 181.

The roads listed above in Table 2.4-4 and Table 2.4-5 are inclusive of all YRDP Project Roads for O&M of the YRDP.[43] For clarity regarding proposed changes to the YRDP, Yuba Water's proposed modifications to the existing Primary Project Roads and Trails and Recreation Roads are listed below. Table 2.4-6 shows YRDP Primary Project Roads and Trails that have been added, and Table 2.4-7 shows Recreation Roads added and removed. The YRDP Proposed Project only includes proposed additions to, and withdrawals of, Recreation Roads associated with the YRDP New Colgate Development. Yuba Water does not propose any changes to Recreation Roads and Trails associated with the YRDP New Bullards Bar Minimum Flow Development or the YRDP Narrows 2 Development.

Table 2.4-6. Proposed additions to Primary Project Roads and Trails (non-recreation roads and trails) included in the YRDP, by Development.

[43] Yuba Water's responsibilities as they relate to specific non-YRDP, general access roads in Yuba County are to be addressed in a Road Maintenance Agreement between Yuba Water and Yuba County, which is outside of the FERC relicensing process. Yuba Water's responsibilities as they relate to specific non-YRDP, general access roads on NFS land may be addressed in a Road Maintenance Agreement between Yuba Water and the USFS, which is also outside of the FERC relicensing process. In addition, the Road Maintenance Agreement between Yuba Water and Yuba County will address maintenance of County Road segments that provide primary access to YRDP facilities, including "driveway" entrances to YRDP Recreation Roads that fall within a County Road right-of-way. General access roads are maintained jointly and are not a YRDP facility or feature.

Table 2.4-7. Proposed additions to and withdrawals of Recreation Roads associated with the YRDP New Colgate Development.

Road Name	Associated Recreation Facility	Begin	End	Land Ownership (FS Road #, if applicable)	Mile Marker-Start	Mile Marker-End	Total Length (mile)

2.4.1.2 Proposed Changes to the YRDP FERC Project Boundary

Yuba Water proposes several changes to the FERC Project Boundary for the YRDP to more accurately define lands necessary for the safe O&M of the YRDP and other purposes, such as recreation, shoreline control, and protection of environmental resources. There are two categories of proposed Project Boundary changes:

- Category 1 - Corrections to the existing FERC Project Boundary to: (1) add lands currently utilized with a preponderance of use related to the YRDP O&M; (2) add lands associated with proposed new recreation facilities under Yuba Water's proposed resource management measures; or (3) remove lands from the Project Boundary that do not have YRDP Facilities and are not used or necessary for YRDP O&M. These proposed changes are essentially making corrections to the FERC Project Boundary.
- Category 2 - Proposed changes to the existing FERC Project Boundary around the YRDP reservoir and impoundments from surveyed coordinates to a contour located above the NMWSE. These changes are proposed, consistent with the preferred method of defining new project boundaries as outlined in the FERC Drawing Guide (FERC 2014, as cited in FERC 2019), as it is a better representation of lands required for O&M around the YRDP reservoirs.

Proposed changes are discussed by YRDP development below. Additional details regarding proposed changes are shown in maps provided in Appendix 2A-5. Since 2019, additional changes to the YRDP FERC Project Boundary related to the proposed inclusion of the ARC Spillway[44] have been identified, which are displayed on Figure 2.4-3.

[44] For CEQA compliance purposes, Yuba Water's ARC Spillway is a separate project with independent utility that was fully analyzed in a separate environmental review process, which included the preparation of a DEIR (YCWA 2023b) and Final EIR (YCWA 2024b). For completeness, the ARC Spillway is included in the YRDP Proposed Project because: (1) it was included as part of Yuba Water's proposed (2017) AFLA; (2) it was included as part of the FERC Staff Alternative that was evaluated in FERC's (2019) FEIS; and (3) the ARC Spillway facilities and operations will be included as part of the new license for the YRDP that is issued by FERC.

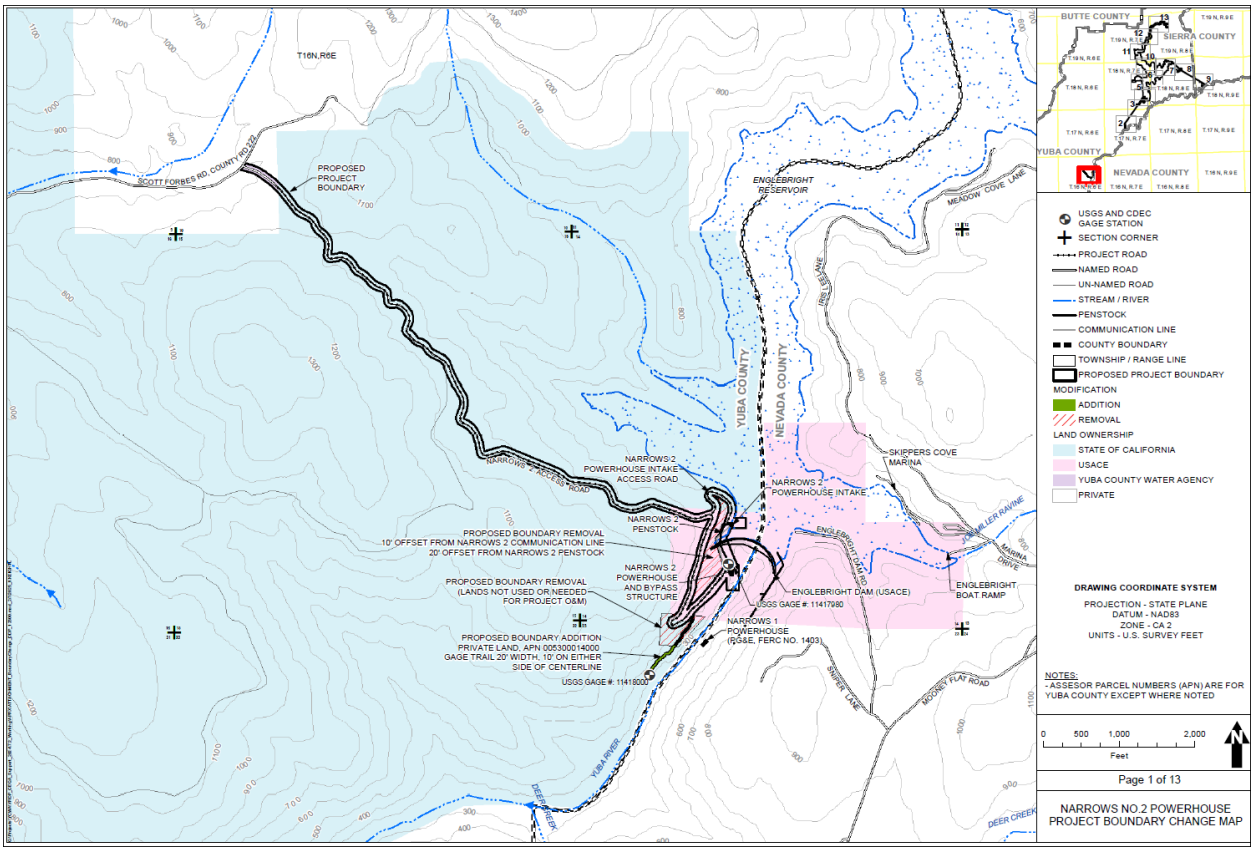

Figure 2.4-3. Proposed changes to the existing YRDP FERC Project Boundary related to the proposed inclusion of the ARC Spillway as part of a new FERC license for the YRDP.

2.4.1.2.1 YRDP New Colgate Development

For the New Colgate Development, Yuba Water proposes the following changes under the category of corrections to the existing Project Boundary:

- Add the areas that encompass 100-ft rights-of-way (i.e., 50 ft on either side of centerline) of nine separate Primary Project Roads used to access and maintain the New Colgate Surge Chamber, New Colgate Powerhouse Penstock and New Colgate Powerhouse. Lands in these proposed additions are owned by private landowners and by Yuba Water.
- Remove land owned by PG&E to the east of New Colgate Powerhouse (Yuba County Assessor's Parcel Number 048270011000). This land is not used or needed for YRDP O&M. PG&E owns and uses the land to maintain PG&E facilities located within the boundaries of that parcel.
- Add the area that encompasses USGS Gage 11413517 (located at the Old Colgate Diversion Dam) and the Primary Project Trail used to access the gage for YRDP O&M purposes. Yuba Water owns the land in this proposed addition.
- Remove lands that encompass a section of Marysville Road (County Road 8) that is in the existing Project Boundary. Marysville Road is commonly used for many purposes not related to the YRDP and as such it is not considered a Primary Project Road. Land in this proposed removal area is owned by private landowners and by Yuba Water.

- Remove the area north of a 50-ft offset from centerline of Cottage Creek Campground Access Road to the proposed boundary near New Bullards Bar Reservoir's edge, except the area surrounding the Cottage Creek Campground. Land parcels in this region are not currently used for YRDP O&M. Land in this proposed removal area is a combination of lands owned by Yuba Water and federal land managed by the USFS as part of the PNF.
- Add the area that encompasses a 100-ft right-of-way (i.e., 50 ft on either side of centerline) of the section of road that connects the Cottage Creek Campground Access Road to Cottage Creek Campground. Yuba Water and private landowners own the land in this proposed addition.
- Remove the area that encompasses the Administration Site located north of the Sunset Vista Observation Site that is used for non-YRDP related activities by the USFS with the exception of the water supply system that provides water to YRDP recreation sites, which includes a 25-ft offset from water distribution tanks and 20-ft right-of-way (i.e., 10 ft on either side of centerline) of water distribution pipe alignments. Also included in the exception is a short segment of a 100-ft right-of-way (i.e., 50 ft on either side of centerline) of the section of road that provides access to the water storage tanks from the Administration Site. The USFS manages this federal land as part of the TNF.
- Add the area that encompasses a 20-ft right-of-way (i.e., 10 ft on either side of centerline) around the YRDP portion of the Bullards Bar Trail that follows along the southeast side of the New Bullards Bar Reservoir. Land in this proposed addition is a combination of federal land managed by the USFS as part of the TNF and land owned by Yuba Water.
- Add the area that encompasses a 20-ft right-of-way (i.e., 10 ft on either side of centerline) around the Schoolhouse Trail that provides access to the Bullards Bar Trail from Schoolhouse Campground. Land in this proposed addition is a combination of federal land managed by the USFS as part of the TNF, Yuba County road right-of-way, and private landowners.
- Add the area that encompasses a 20-ft right-of-way (i.e., 10 ft on either side of centerline) around the water distribution pipe alignments that parallel both Marysville Road (County Road 8) and Dark Day Road. The water distribution system provides water to YRDP recreation sites and is considered a YRDP facility. Land in this proposed addition is federal land managed by the USFS as part of the TNF.
- Add the area that encompasses the leach field that is a part of the Hornswoggle Group Campground. Land in this proposed addition is federal land managed by the USFS as part of the TNF.
- Add the area that encompasses a 100-ft right-of-way (i.e., 50 ft on either side of centerline) of the non-county-maintained portion of the Dark Day Access Road which provides access to Dark Day Boat Launch, Picnic Area, and Campground. The non-county-maintained road starts approximately 0.33-mile from Marysville Road. Land in this proposed addition is federal land managed by the USFS as part of the TNF.
- Add the area that encompasses a 100-ft right-of-way (i.e., 50 ft on either side of centerline) of the non-county-maintained portion of Garden Valley Road, which provides YRDP maintenance access for the annual removal of debris and maintenance access to Garden

Point Boat-In Campground. The non-county-maintained road begins just past the gate located approximately at the road's intersection with the Township Line common between Section 5, T18N, R8E, and Section 32, T19N, R8E. Land in this proposed addition is federal land managed by the USFS as part of the TNF.

- Add the area that encompasses a 100-ft right-of-way (i.e., 50 ft on either side of centerline) around the Primary Project Road that is used to access USGS Gage 11408880 located downstream from Our House Diversion Dam. Land in this proposed addition is federal land managed by the USFS as part of the TNF.
- Remove lands around the former Burnt Bridge Campground site with the exception of the lands proposed to be utilized for the construction of the proposed new Shadow Ridge Campground access road and facilities. The lands proposed to remain within the Project Boundary include the newly proposed trails associated with the proposed new Shadow Ridge Campground. Lands in this proposed removal are federal lands managed by the USFS as part of the PNF.

For the New Colgate Development, Yuba Water proposes the following changes under the category of expanding the existing FERC Project Boundary in anticipation of proposed new recreation facilities:

- Add the area that encompasses the proposed new Kelly Ridge Campground. Land in this proposed addition is federal land managed by the USFS as part of the TNF.
- Add the area that encompasses both the proposed new Dark Day RV Dump Station and the proposed Dark Day Entrance Station. Land in this proposed addition is federal land managed by the USFS as part of the TNF.
- Add the area that encompasses a 20-ft right-of-way (i.e., 10 ft on either side of centerline) around the proposed new Our House Diversion Dam River Access Trail. Land in this proposed addition is federal land managed by the USFS as part of the TNF.

For the New Colgate Development, Yuba Water proposes the following changes under the category of redefining the boundary around the YRDP reservoir and impoundments from surveyed coordinates to a contour located above the NMWSE. A contour 30 ft above NMWSE or 200 horizontal ft from the NMWSE was chosen to define the proposed boundary for each of the three YRDP impoundments in areas where the boundary is not already defined to encompass YRDP facilities and recreation sites. The proposed boundary would encompass between 50 and 200 horizontal ft from the reservoir NMSWE except where slopes exceed 60 percent, in which case the boundary would encompass less than 50 horizontal ft. As such, the proposed boundary would provide shoreline access from the reservoir of at least 50 ft for all areas where slopes are unsafe (FERC 2019).

- Add and remove land such that the Project Boundary around New Bullards Bar Reservoir where the Project Boundary is not encompassing YRDP facilities or proposed YRDP facilities is defined by the lesser (closer to reservoir NMWSE) of either the topographic contour of 1,985 ft, which is 30 ft above the NMWSE, or 200 horizontal ft from the NMWSE. Lands in this proposed change are a combination of lands owned by private landowners and Yuba Water, and federal lands managed by the USFS as part of the PNF and the TNF.
- Add and remove lands such that the Project Boundary around Log Cabin Diversion Dam impoundment where the Project Boundary is not encompassing YRDP facilities is defined by the topographic contour of 2,000 ft, which is 30 ft above the NMWSE. Lands in these proposed changes are a combination of federal lands managed by the USFS as part of the TNF, lands owned by Yuba Water, and a small area within a Yuba County road right-of-way.
- Add and remove lands such that the Project Boundary around Our House Diversion Dam impoundment where the Project Boundary does not encompass YRDP facilities is defined by the topographic contour of 2,060 ft, which is 30 ft above the NMWSE. Lands in these proposed changes are a combination of federal lands managed by the USFS as part of the TNF, and land owned by private landowners.

2.4.1.2.2 YRDP New Bullards Bar Minimum Flow Development

For the New Bullards Bar Minimum Flow Development, Yuba Water proposes the following changes under the category of corrections to the existing FERC Project Boundary.

- Add the area that encompasses a 20-ft right-of-way (i.e., 10 ft on either side of centerline) around the Primary Project Trail that is used to access USGS Gage 11413517 downstream of the New Bullards Bar Minimum Flow Powerhouse. Yuba Water owns the land in this proposed addition.

2.4.1.2.3 YRDP Narrows 2 Development

For the Narrows 2 Development, Yuba Water proposes the following changes under the category of corrections to the existing Project Boundary.

- Add the area that encompasses a 20-ft right-of-way (i.e., 10 ft on either side of centerline) around the Primary Project Trail that is used to access USGS Gage 11418000 located downstream of the Narrows 2 Powerhouse and the gage building itself. Land in this proposed addition is owned by and managed by the State of California.

- Remove the area that extends south beyond a 100-ft right-of-way (i.e., 50 ft on either side of centerline) along the Narrows 2 Powerhouse Access Road, which is a Project Road. This land is not used for YRDP O&M and does not have any YRDP facilities. Lands in this proposed removal area are a combination of federal land managed by USACE, land owned and managed by the State of California, and land owned by private landowners.
- Remove the area that is between a 50-ft offset from the centerline of Narrows 2 Powerhouse Access Road, 50-ft offset from the centerline of Narrows 2 Powerhouse Intake Access Road, and a 10-ft offset from westernmost extent of either the communication line between the Narrows 2 Powerhouse and Powerhouse Intake Structure or the Narrows 2 Powerhouse Penstock. These land parcels are not used for YRDP O&M and do not have any YRDP facilities. Land in the proposed removal is federal land managed by USACE.

2.4.1.2.4 Other Areas

Based on FERC staff recommendations in the Draft EIS (FERC 2018) and in the FEIS (FERC 2019),[45] Yuba Water has proposed to modify the proposed FERC Project Boundary for the YRDP to include lands adjacent to New Bullards Bar Dam necessary for operating and maintaining the proposed ARC Spillway (Figure 2.4-2), and lands necessary for the construction of the proposed trail along the west shoreline of New Bullards Bar Reservoir between Cottage Creek Campground and Madrone Cove Boat-in Campground.

As previously discussed in Section 2.1.2.1.1, separate from the YRDP relicensing process and this DEIR, Yuba Water has filed a non-capacity amendment of the existing FERC license for the YRDP to add the ARC Spillway to the Project. As part of Yuba Water's application for a non-capacity amendment (YCWA 2025) for the ARC Spillway Project, Yuba Water identified the enlargement of the FERC Project Boundary by approximately 12.8 ac to encompass a new access road to the spillway chute and an existing but overgrown Forest Service access road to the discharge channel. Even though a new secondary spillway was addressed in FERC's (2019) FEIS, FERC staff requested that Yuba Water include in its application for non-capacity amendment an APDEA that

[45] FERC (2019) concluded that, in general, Yuba Water's proposed changes to the FERC Project Boundary for the YRDP reflect lands needed to fulfill YRDP purposes, with two exceptions. Around New Bullards Bar Reservoir, the proposed reduction in land within the FERC Project Boundary would continue to provide sufficient shoreline access and be consistent with FERC guidelines that the Project Boundary should not extend more than 200 ft upslope from the NMWSE. Comparing the proposed Project Boundary, as shown on Appendix 2, Exhibit G maps, and the proposed West Shoreline Trail alignment, as shown in the proposed Recreation Facilities Plan (RR1), the proposed Project Boundary would remove at least some YRDP lands where this trail would be constructed. The trail would be part of Yuba Water's recreation facilities that support public access to the YRDP, and FERC recommend that the Project Boundary include the trail in any new license issued for the YRDP. Additionally, FERC (2019) concluded that the proposed FERC Project Boundary does not appear to include sufficient land for operating and maintaining the New Bullards Bar Dam auxiliary flood control outlet (i.e., ARC Spillway). FERC recognized that: (1) the proposed ARC Spillway would require an access road, borrow sites, and disposal areas that appear to be located outside the proposed FERC Project Boundary; and (2) Yuba Water would likely need to periodically use the access road after construction to perform maintenance at outlet works (e.g., remove vegetation, repairs). Similarly, borrow and disposal sites would likely require ongoing monitoring and treatment to address erosion and visual effects. Accordingly, these lands would be necessary for the construction and maintenance of the auxiliary flood control outlet, and therefore, should be enclosed within the FERC Project Boundary for the YRDP. For these reasons, FERC recommended that Yuba Water modify the proposed FERC Project Boundary to enclose project land in the vicinity of: (1) Marysville Road and New Bullards Bar Dam access road; and (2) the west shoreline of New Bullards Bar Reservoir between Cottage Creek Campground and Madrone Cove Boat-in Campground. Because these lands are already part of the existing FERC Project Boundary of the current license, there is no cost (relative to existing conditions) to enclose these lands within the project Boundary. In response to the FERC staff recommendation in the Draft EIS, Yuba Water (July 30, 2018 comments on the Draft EIS) proposed to modify the FERC Project Boundary consistent with the FERC staff recommendation (FERC 2019).

focused solely on the new ARC Spillway and anticipated changes under the existing FERC license (YCWA 2025). Although the timing of when (and if) FERC may approve Yuba Water's request and amend the existing FERC license for the YRDP to add the ARC Spillway is uncertain, it is assumed that the amendment of the license potentially could be completed in advance of completing the CEQA process for the YRDP relicensing.

The modifications to the FERC Project Boundary described above would reduce the amount of federal land administered by the USFS by 1,003.4 ac (from 4,445.6 ac to 3,442.2 ac) and would reduce the amount of federal land administered by USACE by 4.9 ac (from 16.1 ac to 11.2 ac). In total, the proposed changes would decrease the total area within the Project Boundary by 1,591.8 ac, including 1,003.4 ac of land managed by the USFS and 5.0 ac of land managed by USACE.

The resulting changes in the FERC Project Boundary for the YRDP are shown in Table 2.4-8.

Table 2.4-8. Summary of land ownership within the proposed FERC Project Boundary, by YRDP Development, and difference as compared to existing FERC Project Boundary for the YRDP.

YRDP Development	USFS (acres)	USACE (acres)	State of California (acres)	Yuba Water (acres)	Other Private (acres)	Total

2.4.1.3 Yuba Water Proposed Changes to Conditions in the Existing YRDP FERC License

Yuba Water developed proposed conditions for the YRDP, including associated implementation plans, for the new license in collaboration with Relicensing Participants. Table 1.4-5 in Exhibit E of the AFLA (YCWA 2017a) presented a comprehensive list of Yuba Water's YRDP Proposed Conditions and Yuba Water's understanding of agreement on each of the 41 conditions that were proposed by Yuba Water.

In particular, 12 of Yuba Water's YRDP Proposed Conditions would modify flow requirements in the existing FERC license and, thereby, affect future YRDP operations. Each of these 12 proposed conditions is summarized below.

2.4.1.3.1 WYTs for Conditions Pertaining to New Bullards Bar Dam, Our House Diversion Dam, and Log Cabin Diversion Dam (Yuba Water's YRDP Proposed Condition WR2)

Yuba Water's YRDP Proposed Condition WR2 includes the definition of a new hydrologic index, the "Smartsville Hydrological Index," and associated WYTs that are used to determine minimum required flows on the North Yuba River downstream of New Bullards Bar Dam, the Middle Yuba River downstream of Our House Diversion Dam, and on Oregon Creek downstream of Log Cabin Dam These hydrologic year types are defined by published forecasts of annual unimpaired Yuba

River flow near Smartsville and computed unimpaired flows for previous months. DWR publishes forecasts of annual volumes of unimpaired Yuba River flow near Smartsville in its Bulletin 120, Water Conditions in California, every year in early February, March, April and May. After the end of the WY (i.e., beginning of October), Yuba Water would use the actual annual volume of unimpaired Yuba River flow near Smartsville for the previous WY to determine the WYT used until the next forecast is released (i.e., in early February). Table 2.4-9 shows the Smartsville Hydrological Index thresholds and associated WYTs.

Table 2.4-9. Smartsville Hydrological Index WYTs and associated thresholds (YCWA 2017a).

WYT	Forecast of Total Unimpaired Runoff in the Yuba River at Smartsville in Thousand Acre-Feet or DWR Full Natural Flow Near Smartsville for the Water Year in Thousand Acre-Feet[1]
Wet	Greater than 3,240
Above Normal	2,191 to 3,240
Below Normal	1,461 to 2,190
Dry	901 to 1,460
Critically Dry	616 to 900

1 DWR rounds the Bulletin 120 forecast to the nearest thousand acre-feet. The Full Natural Flow is provided to the nearest ac-ft, and Yuba Water would round DWR's Full Natural Flow to the nearest thousand ac-ft.

2.4.1.3.2 WYTs for Conditions Pertaining to Narrows 2 Powerhouse and Narrows 2 Full Bypass (Yuba Water's YRDP Proposed Condition WR3)

Yuba Water's YRDP Proposed Condition WR3 defines the calculation of the NYI, to be used to identify the required flow schedule at the Smartsville and at Marysville gages. The schedules in this proposed condition are the same as the schedules described in Exhibits 2, 4 and 5 of the Lower Yuba River Fisheries Agreement. Table 2.4-10 shows the NYI thresholds and associated WYTs.

Table 2.4-10. North Yuba Index Schedules and associated thresholds (YCWA 2017a).

WYT	Thousands of Acre-Feet
Schedule 1	Equal to or greater than 1,400
Schedule 2	Equal to or greater than 1,040 and less than 1,400
Schedule 3	Equal to or greater than 920 and less than 1,040
Schedule 4	Equal to or greater than 820 and less than 920
Schedule 5	Equal to or greater than 693 and less than 820
Schedule 6	Equal to or greater than 500 and less than 693
Conference Year	Less than 500

The NYI is calculated as the active storage in New Bullards Bar Reservoir on September 30 of the previous WY plus New Bullards Bar Reservoir inflow to date plus forecasted inflow[46] through September 30 of the current WY.

2.4.1.3.3 Minimum Flows in the Middle Yuba River Downstream of Our House Diversion Dam and Log Cabin Diversion Dam (Yuba Water's YRDP Proposed Condition AR1)

Under Yuba Water's YRDP Proposed Condition AR1, there would be new flow requirements for the Middle Yuba River downstream of Our House Diversion Dam. The required flow would be determined based on the applicable Smartsville Hydrological Index WYT. Table 2.4-11 shows the

[46] Based on DWR-published Bulletin 120 in each of the months of February, March, April and May, and then thereafter whenever DWR issues an update to the Bulletin 120.

proposed monthly required flows for the Middle Yuba River downstream of Our House Diversion Dam by WYT, as included in YRDP Proposed Condition AR1.

Table 2.4-11. Proposed YRDP flow requirements for the Middle Yuba River downstream of Our House Diversion Dam by Smartsville Hydrological Index WYT.

Month	Wet Water Year (cfs)[1]	Above Normal Water Year (cfs)[1]	Below Normal Water Year (cfs)[1]	Dry Water Year (cfs)[1]	Critically Dry Water Year (cfs)[1]
October 1 – 30	60	60	55	50	40
November 1-30	60	60	55	50	40
December 1 – 31	70	60	55	50	40
January 1 – 31	90	75	70	50	40
February 1- 29	90	75	70	50	40
March 1 – 31	100	90	80	55	45
April 1 – 30	120	100	90	70	60
May 1- 31	120	100	90	70	60
June 1 – 30	120	100	90	70	60
July 1 – 31	100	80	70	60	45
August 1 – 31	80	70	60	50	45
September 1- 30	70	60	55	50	45

[1] Or natural inflow if natural inflow is less.

In addition, YRDP Proposed Condition AR1 would establish new flow requirements for Oregon Creek downstream of Log Cabin Diversion Dam. The required flow would be determined based on the applicable Smartsville Hydrological Index WYT. Table 2.4-12 shows the monthly required flows for Oregon Creek downstream of Log Cabin Diversion Dam by WYT, as included in YRDP Proposed Condition AR1.

Table 2.4-12. Proposed YRDP flow requirements for Oregon Creek downstream of Log Cabin Diversion Dam by Smartsville Hydrological Index WYT.

Month	Wet Water Year (cfs)[1]	Above Normal Water Year (cfs)[1]	Below Normal Water Year (cfs)[1]	Dry Water Year (cfs)[1]	Critically Dry Water Year (cfs)[1]
October 1 – 30	8	8	6	6	6

September 1- 30	13	10	8	6	6

[1] Or natural inflow if natural inflow is less.

2.4.1.3.4 Minimum Flows in the North Yuba River Flow Downstream of New Bullards Bar Dam (Yuba Water's YRDP Proposed Condition AR10)

Yuba Water's YRDP Proposed Condition AR10 would require new flow requirements for the North Yuba River downstream of New Bullards Bar Dam. The required flow would be determined based on the applicable Smartsville Hydrological Index WYT. Table 2.4-13 shows the monthly required flows for the North Yuba River downstream of New Bullards Bar Dam by WYT, as included in YRDP Proposed Condition AR10.

Table 2.4-13. Proposed YRDP Flow Requirements for the North Yuba River downstream of New Bullards Bar Dam by Smartsville Hydrological Index WYT (YCWA 2017a).

Month	Wet Water Year (cfs)	Above Normal Water Year (cfs)	Below Normal Water Year (cfs)	Dry Water Year (cfs)	Critically Dry Water Year (cfs)
October 1 - 30	13	13	13	13	7
November 1-30	13	13	13	13	7
December 1 - 31	13	13	13	13	7
January 1 - 31	13	13	13	13	7
February 1- 29	13	13	13	13	7

June 1 - 30	5	5	5	5	5
July 1 - 31	11	12	13	13	7
August 1 - 31	11	12	13	13	7
September 1- 30	11	12	13	13	7

2.4.1.3.5 Control Project Spills at Our House Diversion Dam (Yuba Water's YRDP Proposed Condition AR2)

YRDP Proposed Condition AR2 would require Yuba Water to control the rate of spill cessation for flows over Our House Diversion Dam in non-tunnel-closure years. This condition indicates the spill cessation measure would affect flows over Our House Diversion Dam of 600 cfs or less between April 1 and July 31 in Below Normal, Dry and Critically Dry WYs, and between May 1 and July 31 in Wet and Above Normal WYs (WR2). Under these conditions, the Our House Diversion Dam low-level outlet would be used to regulate Middle Yuba River flows downstream of Our House Diversion. The low-level outlet valve would be used to reduce flows by a maximum of 100 cfs every two days for spills between 200 cfs and 600 cfs, and by a maximum of 50 cfs for spills less than 200 cfs.

2.4.1.3.6 Control Project Spills at Log Cabin Diversion Dam (Yuba Water's YRDP Proposed Condition AR12)

The YRDP Proposed Project includes Condition AR12 that would control the rate of spill cessation for flows over Log Cabin Diversion Dam. This condition, AR12, indicates the spill cessation measure would affect flows over Log Cabin Diversion Dam between 100 cfs or less between April 1 and July 31. Under these conditions, the Log Cabin Diversion Dam low-level outlet would be used to regulate Oregon Creek flows downstream of Log Cabin Diversion Dam. The low-level outlet valve would be used to reduce flows by a maximum of 20 cfs every four days.

2.4.1.3.7 Periodically Close Lohman Ridge Diversion Tunnel (Yuba Water's YRDP Proposed Condition AR11)

Under Yuba Water's YRDP Proposed Condition AR11, if DWR's May Bulletin 120 forecast is a Wet, Above Normal or Below Normal WY, as defined in YRDP Proposed Condition WR2, and the subsequent end-of-September New Bullards Bar Reservoir storage is 600,000 ac-ft or greater, the Lohman Ridge Diversion Tunnel would close from October 1 through December 31.

In addition, the condition requires that the Lohman Diversion Tunnel would be closed within 2 business days of when DWR publishes its April Bulletin 120 through September 30 if the Bulletin 120 April Forecast is for a Wet WY, as defined in YRDP Proposed Condition WR2, and the end-

of-March New Bullards Bar Reservoir storage is 775,000 ac-ft or greater. Concurrent with the Lohman Ridge Diversion Tunnel closure, the low-level outlet and fish release valve at Log Cabin Diversion Dam would be fully opened.

2.4.1.3.8 Provide Whitewater Boating Below Our House Diversion Dam (Yuba Water's YRDP Proposed Condition RR3)

Under Yuba Water's YRDP Proposed Condition RR3, Yuba Water would provide weekend boating days from October 1 and March 31 between 600 cfs and 2,000 cfs, as measured at USGS Gage 11408880, according to the schedule given in Table 2.4-14**.**

Table 2.4-14. Proposed YRDP whitewater boating flows below Our House Diversion Dam.

WYT as Defined in YRDP Proposed Condition WR2			Number of Weekend Whitewater Boating Days from October 1 through March 31
DWR's Full Natural Flow at Smartsville for the Full Water Year that Ended on September 30	DWR's Bulletin 120 February Forecast	DWR's Bulletin 120 March Forecast	
Wet, Above Normal, Below Normal or Dry	Any WYT	Wet	8
Wet, Above Normal, Below Normal or Dry	Any WYT	Above Normal	6
Wet, Above Normal, Below Normal or Dry	Any WYT	Below Normal, Dry, or Critically Dry	4
Critically Dry	Wet or Above Normal	Any WYT	2
Critically Dry	Below Normal, Dry, or Critically Dry	Any WYT	0

2.4.1.3.9 Minimum Flows on the Yuba River Downstream of the Narrows 2 Powerhouse and Narrows 2 Full Bypass (Yuba Water's YRDP Proposed Condition AR3)

Under Yuba Water's YRDP Proposed Condition AR3, the required conference year flows for the Yuba River near Smartsville and near Marysville are slightly modified from the Yuba Accord in Conference Years. Table 2.4-15 shows the proposed required flows for the Yuba River near Smartsville and Marysville, based on the WYT schedules defined in YRDP Proposed Condition WR3.

Table 2.4-15. Proposed YRDP flow requirements for the Yuba River downstream of Narrows 2 Powerhouse and Narrows 2 full flow bypass by North Yuba Index Flow Schedule.

Month	Schedule 1 (cfs)	Schedule 2 (cfs)	Schedule 3 (cfs)	Schedule 4 (cfs)	Schedule 5 (cfs)	Schedule 6 (cfs)	Conference Year (cfs)
YUBA RIVER - BELOW NARROWS 2 POWERHOUSE/NARROWS 2 FULL BYPASS (Compliance Point: USGS Streamflow Gage 11418000)

* Modified by the FERC (2019) as part of the FERC Staff Alternative.

2.4.1.3.10 Control Project Ramping and Flow Fluctuation Downstream of Englebright Dam (Yuba Water's YRDP Proposed Condition AR9)

Under Yuba Water's YRDP Proposed Condition AR9, Yuba Water would operate New Bullards Bar Reservoir and Project facilities downstream of Englebright Dam and coordinate on the operations of the Narrows 1 Powerhouse to avoid fluctuations in flow of the Yuba River downstream of Englebright Dam at the Smartsville Gage and daily changes in YRDP operations affecting releases or bypasses of flow downstream of Englebright Dam at the Smartsville Gage. Changes in Yuba River flow downstream of Englebright Dam would not increase at a rate of greater than 500 cfs per hour, nor decrease at a rate in excess of 200 cfs per hour at any point in the year. Also, at no point in the year would flows change, either up or down, by more than 15 percent of the average daily flow once they have been established at a base rate, nor would they be reduced by more than 30 percent of the previous day's flow.

In addition, between September 1 and December 31, and between January 1 and May 31, flow reductions under normal operations (i.e., non-spill management) would be limited according to the flows in Table 2.4-16 and Table 2.4-17. In the two tables, "Base Flow" means the flows other than flows related to emergencies, required by USACE flood control criteria, required to maintain a flood control buffer or for other flood control purposes, bypasses of uncontrolled flows into Englebright Reservoir, uncontrolled spilling, or uncontrolled flows of tributary streams downstream of Englebright Dam.

Table 2.4-16. Maximum flow reductions corresponding to the maximum 5-day average release (Base Flow) that has occurred during the period extending from September 1 through December 31.

Base Flow Range (cfs)	Maximum Allowable Flow Reduction (cfs)
450 – 549	200
550 - 849	250
850 – 1,049	300
1,050 – 1,349	350
1,350 – 1,599	400
1,600 – 1,849	450
1,850 – 2,199	500
2,200 – 2,549	550
2,550 – 2,899	600
2,900 – 3,199	650
3,200 – 3,549	700
3,550 – 4,130	750

Table 2.4-17. Maximum flow reductions corresponding to the maximum 5-day average release (Base Flow) that has occurred during the period extending from January 1 through May 31.

Base Flow Range (cfs)	Maximum Allowable Flow Reduction (cfs)
450 - 499	200
500 - 549	250
550 - 649	300
650 - 849	350
850 – 1,199	400
1,200 – 1,449	450
1,450 – 1,699	500
1,700 – 1,899	550
1,900 – 2,149	600
2,150 – 2,399	650
2,400 – 2,699	700
2,700 – 2,949	750
2,950 – 3,199	800
3,200 – 3,449	850
3,450 – 3,899	900
3,900 – 4,130	950

In addition, between April 1 through July 15, flow reductions under normal operations (i.e., non-spill management) would be limited according to the flows in Table 2.4-18. The previous day's average flow would be based on USGS Gage 11418000.

Table 2.4-18. Maximum flow reductions corresponding to the preceding day average flow that has occurred during the period extending from April 1 through July 15.

Previous Day Average Flow Range (cfs)	Maximum Flow Reduction (cfs)
400-999	79
1000-1999	150
2000-4200	200

2.4.1.3.11 Control Project Spills at New Bullards Bar Dam (Yuba Water's YRDP Proposed Condition AR4)

Under Yuba Water's YRDP Proposed Condition AR4, Yuba Water would implement a spill cessation operation, where spills of 2,000 cfs or less from New Bullards Bar Dam from May 1 through July 31 would be reduced at a rate of 250 cfs per day until spill has ceased.

2.4.1.3.12 Implement Log Cabin and Our House Diversion Dams Sediment Management Plan (Yuba Water's YRDP Proposed Condition GS2)[47]

Under Yuba Water's YRDP Proposed Condition GS2, Yuba Water would operate the low-level outlet valves at Our House and Log Cabin diversion dams during high flow events between October 1 and March 21 to move sediment trapped behind the diversion dams to the Middle Yuba River and Oregon Creek, respectively. These actions would be tied to events when inflows exceed 3,000 cfs at Our House Diversion Dam and 1,000 cfs at Log Cabin Diversion Dam. The low-level outlet at each diversion dam would be opened fully for 9 days, closed halfway on the 10th day, and then fully closed on the 11th day. The low-level outlet can be closed during the 11-day period if flow into the impoundment drops below the capacity of the low-level outlet, which is assumed to be 600 cfs for Our House Diversion Dam and 540 cfs for Log Cabin Diversion Dam.

2.4.1.4 FERC Staff Alternative Modifications to Yuba Water's YRDP Proposal

FERC's (2019) FEIS analyzed the potential effects of continued YRDP operation and recommended conditions for any new license that may be issued by FERC for the YRDP. In addition to Yuba Water's proposal (described above), FERC considered several alternatives and selected the FERC Staff Alternative as the NEPA preferred alternative. FERC chose the Staff Alternative as its preferred alternative because:

1. Issuing a new license for the YRDP would allow Yuba Water to operate the YRDP as an economically beneficial and dependable source of electrical energy for the region (1,374,003 MWh annually);
2. The 361.9 MW of electric capacity comes from a renewable resource that does not contribute to atmospheric pollution, including greenhouse gases;
3. The public benefits of the FERC Staff Alternative would exceed those of the NEPA No Action Alternative; and
4. The environmental measures proposed by Yuba Water and/or modified or recommended by FERC staff would protect and enhance fish and wildlife resources and improve recreation opportunities provided by the YRDP (FERC 2019).

[47] The Log Cabin and Our House Diversion Dams Sediment Management Plan was initially drafted in 2014 and approved by the FERC on September 23, 2014 (148 FERC ¶ 62,227) and amended on March 4, 2016 (154 FERC ¶ 62,158). On August 10, 2018, and supplemented January 29, 2020, and September 18, 2020, Yuba Water filed a revised Plan, which was approved by the FERC on November 10, 2020 (173 FERC ¶ 62,069). A separate CEQA Initial Study/Mitigated Negative Declaration (YCWA 2020) was developed, and mitigation measures were identified, for the revised Plan. The revised Plan (including the previously adopted mitigation measures) is currently being implemented and would remain in effect under the Proposed YRDP Relicensing Project pursuant to YRDP Proposed Condition GS2.

As described in the FEIS (FERC 2019, p. 2-38), "*Under the staff alternative, the project would include most of YCWA's proposed measures…as part of any license issued for the project*." The FERC Staff Alternative (FERC 2019) also included several recommended modifications of Yuba Water's proposal, as well as some additional measures identified by FERC staff, which are briefly described below.

FERC staff recommendations for conditions for any new FERC license for the YRDP are based on the analysis presented in the FEIS (FERC 2019). Appendix C of the FEIS contains draft license articles (specifying measures/conditions, as appropriate) to be included in a new FERC license based upon FERC's analysis in the FEIS. The draft license articles include, or reference, the various environmental measures (or conditions) that were either proposed by Yuba Water and adopted by FERC without modification, proposed by Yuba Water and modified by FERC, or newly identified by FERC as part of the FERC Staff Alternative in the FEIS (FERC 2019).

For this DEIR, FERC's draft license articles are presented in **Appendix 2C** (Yuba Water Expected Conditions in New FERC License). A summary of Yuba Water's 21 proposed implementation plans that are either part of, or referenced in, FERC's draft license articles is provided in Section 2.4.1.5 below, and copies of each implementation plan are provided in Appendix 2B.

2.4.1.4.1 Water Quantity

Modify Yuba Water's proposed Drought Management Plan (YRDP Proposed Condition WR9) to change the condition of drought conditions based on available data specific to the YRDP rather than basing plan implementation on state-wide conditions.

2.4.1.4.2 Aquatic Resources

Maintain summer water temperatures in the lower Yuba River in Schedule 6 years by modifying Yuba Water's proposed minimum flows from the Narrows 2 Powerhouse and the Narrows 2 full bypass (AR3) to include minimum flows of 350 cfs, from June 1 through August 31.

Modify Yuba Water's proposed Aquatic Invasive Species Management Plan (YRDP Proposed Condition AR5) to include monitoring Asian clams at Cottage Creek, Dark Day Boat Launch, and Emerald Cove.

Modify Yuba Water's proposed New Bullards Bar Reservoir Fish Stocking Plan (YRDP Proposed Condition AR6) to include annual consultation with CDFW to determine species of fish appropriate for stocking for recreational purposes.

Modify Yuba Water's proposed Lower Yuba River Aquatic Monitoring Plan (YRDP Proposed Condition AR8) to remove: (1) benthic macroinvertebrate monitoring in the lower river; (2) upstream fish passage monitoring at Daguerre Point Dam; (3) weekly Chinook salmon and steelhead spawning surveys in the lower river; and (4) general monitoring of riparian vegetation cover and community structure.

Develop a Narrows Reach Fish Stranding Prevention Plan for the lower Yuba River, downstream of the Narrows 1 and Narrows 2 Powerhouses, to include conducting fish rescues when stranding is observed, reporting estimates of the number and species of fish stranded and the number of fish

rescued, recording any evidence of harm caused by YRDP facilities or operation, identifying potential operational and/or structural measures that could be implemented to reduce stranding, and reporting requirements for unplanned flow reductions.

Revise minimum streamflows below New Bullards Bar Dam (YRDP Proposed Condition AR10) to use Yuba Water flows in October through May and agency flow recommendations in June through September as listed in CDFW "Recommended Conditions for Fish and Wildlife Protection, Mitigation, and Enhancement," Table 2.4-1 dated August 25, 2017 and shown in Table 2.4-19 below.

Table 2.4-19. Minimum streamflows in cfs in the North Yuba River downstream of New Bullards Bar Dam by month and Water Year Type, the latter of which is defined in Yuba Water's YRDP Proposed Condition WR2.

Month	Wet Water Year	Above Normal Water Year	Below Normal Water Year	Dry Water Year	Critically Dry Water Year
NORTH YUBA RIVER - BELOW NEW BULLARDS BAR DAM (COMPLIANCE POINT: USGS STREAMFLOW GAGE 11413517)					
October 1 - 30	13	13	13	13	7
November 1-30	13	13	13	13	7
December 1 - 31	13	13	13	13	7
January 1 - 31	13	13	13	13	7
February 1- 29	13	13	13	13	7
March 1 - 31	11	12	13	13	7
April 1 - 30	5	5	5	5	5
May 1- 31	5	5	5	5	5
June 1 - 30	60	60	60	60	60
July 1 – 31	40	40	40	40	40
August 1 - 31	40	40	40	40	40
September 1- 30	30	30	30	30	30

Develop a comprehensive LWM enhancement plan that: (1) identifies sources of LWM in the project reservoirs; (2) includes provisions for storing and transporting collected LWM; (3) identifies suitable LWM size classes for placement; (4) identifies locations for placement in the lower Yuba River; (5) details a consultation process to determine LWM placement that includes relevant agencies and whitewater boating interests; and (6) contains a monitoring and mapping process to provide an indication of the stability of these enhancements and inform the need for future placement activities.

2.4.1.4.3 Terrestrial Resources

Modify Yuba Water's proposed Integrated Vegetation Management Plan (YRDP Proposed Condition TR1) to: (1) include treatment and monitoring plans for target non-native invasive species on all lands in the YRDP FERC Project Boundary; (2) apply revegetation measures (Sections 4.1 through 4.5 of the plan) to all lands in the Project Boundary; (3) implement best management practices (BMPs) to protect foothill yellow-legged frog and California red-legged frog habitat when vegetation management activities occur within 300 ft of streams; (4) define BMPs for any pesticide use that is deemed necessary within the YRDP FERC Project Boundary and within 500 ft of known locations of foothill yellow-legged frogs that avoid adverse effects on individuals and their habitats; (5) prohibit the use of pesticides within a 260-ft buffer around the mean high-water mark of aquatic features, unless necessary to ensure project safety; (6) avoid stockpiling and subsequent removal of any fuels, slash, or debris related to hazard tree removal within 1,000 ft of wetlands or aquatic features; and (7) prior to any activities that would result in

vegetation disturbance, conduct surveys for elderberry plants within 165 ft of the activity area and consult with USFWS if elderberry plants are found to determine if additional protective measures are necessary.

Develop a lower Yuba River riparian restoration plan, in consultation with USFWS, CDFW, NMFS, and the South Yuba River Citizen's League (SYRCL) that includes: (1) planting riparian vegetation on 100 ac of floodplain in the lower Yuba River, including no fewer than four separate planting sites; (2) a species list for plantings that includes, at a minimum, cottonwood and willow species; (3) a description of planting methods consistent with methods used at the Hammon Bar restoration site, including planting to ground water depth; (4) success criteria based on survivorship of plantings; (5) monitoring methods and a schedule for determining success; (6) provisions for additional plantings if success criteria are not met; (7) a process and schedule for identifying planting sites; and (8) a reporting schedule.

Modify Yuba Water's proposed Bald Eagle and American Peregrine Falcon Management Plan (TR2) to include surveys for American peregrine falcon eyries every year or until a new eyrie is documented.

Monitor water temperature continuously from April 1 through September 15 for 3 years at two foothill yellow-legged frog breeding sites in the Middle Yuba River downstream from Our House Diversion Dam and at two sites in Oregon Creek downstream of Log Cabin Diversion Dam. Monitoring sites should be selected to represent the upstream and downstream limit of breeding sites in each reach. After 3 years, file a summary report that: (1) summarizes the results of the temperature monitoring; (2) evaluates how often water temperatures fall below 16 degrees Celsius (ºC) during the tadpole development period; and (3) describes any changes in flow releases from Our House and Log Cabin Diversion Dams that may be warranted to address adverse effects on foothill yellow-legged frog reproduction.

Ensure procedures for decontaminating field equipment to prevent the spread of aquatic pests and disease between waterbodies, as described in Yuba Water's proposed Aquatic Invasive Species Monitoring Plan, are applied for activities where equipment is transported from one body of water to another.

2.4.1.4.4 Cultural Resources

Revise Yuba Water's Historic Properties Management Plan (HPMP) (CR1) included in the YRDP AFLA (YCWA 2017a) to include: (1) cultural resources information and consultation results developed after preparation of the 2016 Draft HPMP; (2) updated determinations of National Register of Historic Places (National Register) eligibility of six historic sites (CA-YUB-1751H, CA-YUB-1760H, CA-YUB-1762H, CA-YUB-1768H, CA-YUB-1770H and CA-YUB-1736H) and the New Colgate Penstock; (3) clarification of the description of site CA-SIE-1849H (previously CA-YUB-1733H); and (4) the results of Yuba Water's final supplemental Traditional Cultural Property (TCP) report.

2.4.1.5 Summary of FERC-Approved YRDP Implementation Plans

During the FERC relicensing process, Yuba Water, other agencies, and other stakeholders reached collaborative agreement on more than 30 measures, many of which include detailed

implementation plans. As discussed above, FERC staff recommended modifications to some of the implementation plans as environmental measures were refined through FERC's (2019) NEPA process. Similarly, additional refinements to certain implementation plans have been identified in response to the USFS's 2018 Final FPA Section 4(e) Terms and Conditions, the USFS's 2022 Revised Final FPA Section 4(e) Terms and Conditions, and the Section 7 ESA consultation process between FERC and USFWS (see Sections 2.4.1.6 and 2.4.2.9 above).

Although the agreed-upon measures and associated plans are intended to improve existing conditions and provide benefits overall, some plans do involve construction and operations-related activities that could have the potential to impact environmental resources. Because these collaboratively agreed-upon measures and associated plans are important components of the YRDP Proposed Project, they are listed below.

- Aquatic Invasive Species Management Plan (YCWA 2019a)
- Bald Eagle and American Peregrine Falcon Management Plan (YCWA 2019b)
- Bat Management Plan (YCWA 2016a)
- Drought Management Plan (YCWA 2017b)
- Erosion and Sediment Control Plan (YCWA 2016b)
- Fire Prevention and Response Plan (YCWA 2017c)
- Hazardous Materials Management Plan (YCWA 2019c)
- Historic Properties Management Plan (YCWA 2017d)
- Integrated Vegetation Management Plan (YCWA 2019d)
- Lower Yuba River Aquatic Monitoring Plan (YCWA 2016c)
- New Bullards Bar Reservoir Fish Stocking Plan (YCWA 2019e)
- Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan (YCWA 2018b)
- Log Cabin and Our House Diversion Dams Sediment Management Plan (YCWA 2018c)
- Recreation Facilities Plan (YCWA 2022b)
- Ringtail Management Plan (YCWA 2016d)
- Streamflow and Reservoir Level Compliance Monitoring Plan (YCWA 2017e)
- Transportation System Management Plan (YCWA 2017f)
- Upper Yuba River Aquatic Monitoring Plan (YCWA 2017g)
- Visual Resources Management Plan (YCWA 2016e)
- Water Quality Monitoring Plan (YCWA 2016f)
- Water Temperature Monitoring Plan (YCWA 2016g)

Each of the implementation plans are briefly summarized in Table 2.4-20 to provide context regarding the plan's association with specific measures/conditions, the purpose of the plan, and the types of activities that would be conducted to implement each plan. Copies of each of the 21 implementation plans are included in **Appendix 2B** of this DEIR.

In addition to implementing the activities described in the implementation plans discussed above, the FERC Staff Alternative and FERC's draft license articles in Appendix C of the FEIS (FERC 2019) recommended that Yuba Water also develop and implement three new plans and revise four existing plans at such time as a new FERC license is issued. The implementation plans that are to be developed or revised when a new FERC license for the YRDP is issued include the following.

2.4.1.5.1 New Plans to be Developed when FERC Issues a New License for the YRDP

- Narrows Reach Fish Stranding Prevention Plan (FERC Article 409)
    - Develop new plan to be filed with FERC within 6 months of license issuance.
    - Action – Identify potential operational and/or structural measures (or other actions) that could be implemented to reduce fish stranding in the lower Yuba River from immediately below Englebright Dam to the Narrows 1 Powerhouse.
- Large Woody Material Management Plan (FERC Article 410)
    - Develop new plan to be filed with FERC within one year of license issuance.
    - Action – Place LWM in the lower Yuba River (quantity and location unspecified by FERC).
- Lower Yuba River Riparian Restoration Plan (FERC Article 412)
    - Develop new plan to be filed with FERC within 6 months of license issuance or at least 90 days prior to the start of any ground-disturbing activity, whichever comes first.
    - Action - Plant riparian vegetation on 100 ac of floodplain in the lower Yuba River, including no fewer than four separate planting sites.

Page Left Blank

Table 2.4-20. Summary of proposed measures/conditions and FERC-approved implementation plans for the YRDP.

Category	Measures/Conditions*		Purpose/Synopsis	Implementation Plan Summary of Activities	FERC 2019 FEIS				USFS 2022 Revised Final FPA Section 4(e) Conditions
	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
Aquatic Resources	AR1	Maintain Minimum Streamflows below Our House Diversion Dam and Log Cabin Diversion Dam	Provide minimum flows in the Middle Yuba River from Our House Diversion Dam and Log Cabin Diversion Dam based on the WYT (see USFS Condition 31).	N/A			**X**		Condition 32
Aquatic Resources	AR2	Control Project Spills at Our House Diversion Dam	Gradually reduce spills at Our House Diversion Dam by closing the low-level outlet valve or fish valve. Provide annual report of valve adjustments. (NOTE: This measure would require modifications to the Our House Diversion Dam fish release outlet.)	N/A		**X**			Condition 33
Aquatic Resources	AR3	Maintain Minimum Streamflows at Narrows 2 Powerhouse and Narrows 2 Full Bypass	Make minor modifications to the flow downstream of Englebright Dam during very dry years (referred to as conference years in the Yuba Accord) to maintain summer water temperatures.	N/A			**X**		
Aquatic Resources	AR4	Control Project Spills at New Bullards Bar Dam	Implement a spill cessation operation at New Bullards Bar Dam (NBBD), where spills of 2,000 cfs or less from May 1 through July 31 would be reduced at a rate of 250 cfs per day to protect resident fish populations until the spill has ceased. For spill events greater than approximately 2,000 cfs, when the spill has receded to approximately 2,000, Yuba Water would reduce the spill at a target rate of approximately 250 cfs per day until the spill has ceased (i.e., releases from NBBD are equal to the minimum flow requirement at that time). If a spill of less than approximately 2,000 cfs occurs, Yuba Water would reduce the peak spill at a target rate of approximately 250 cfs per day or a slower rate until the spill has ceased and releases from NBBD are being made to provide flows within 20 percent of the minimum flow requirement downstream of NBBD.	N/A		**X**			
Aquatic Resources	AR5	Implement Aquatic Invasive Species Management Plan	The purpose of the plan (AR5) is to: (1) implement activities to minimize and prevent the introduction and spread of aquatic invasive species (AIS) into and throughout YRDP-affected waters; (2) provide education and outreach to ensure public awareness of AIS effects and management throughout YRDP-affected waters; (3) implement monitoring programs to ensure early detection of AIS; and (4) ensure all YRDP AIS management activities comply with federal and State of California laws, regulations, policies, and management plans, and with USFS directives and orders regarding AIS (see FERC's draft license Article 405 in Appendix C of FERC 2019).	Plan implementation would involve: (1) Implement Public Education Program with signage. (2) Conduct houseboat inspections. (3) Develop BMPs for YRDP O&M and construction. (4) Monitor for quagga and zebra mussels and Asian clams at YRDP reservoirs twice per year. Record incidental observations during fieldwork for other monitoring efforts. Report immediate observations of quagga and zebra mussels and hydrilla to CDFW, USFWS, SWRCB, USFS; 30 days for other invasive species. (5) If detected, implement control/eradication measures for invasive mollusks in coordination with CDFW, USFS, USFWS and SWRCB. (6) Conduct bullfrog population suppression (via hand/net removal) around Moran Cove to protect California red legged frog during the first 5 years of the license. (7) Conduct annual employee training. Revise and update plan as warranted by new information.			**X**		Condition 39
Aquatic Resources	AR5	Aquatic Invasive Species Management Plan - Add Decontamination Protocols	FERC's draft license Article 408 (FERC 2019, Appendix C) states that Yuba Water must implement procedures for decontaminating field equipment to prevent the spread of aquatic pests and disease between waterbodies, as described in the Aquatic Invasive Species Management Plan, are applied to all activities where equipment is transported from one body of water to another.	CDFW's Aquatic Invasive Species Decontamination Protocol was added to the plan as Attachment D. Methods are described for equipment and watercraft decontamination.			**X**	Ensure procedures for decontaminating field equipment to prevent spread of aquatic pests and disease between waterbodies are applied to all activities where equipment is transported from one body of water to another.	

Table 2.4-20. (Continued)

Category	Measures/Conditions*		Purpose/Synopsis	Implementation Plan Summary of Activities	FERC 2019 FEIS				USFS 2022 Revised Final FPA Section 4(e) Conditions
	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
Aquatic Resources	AR6	Implement New Bullards Bar Reservoir Fish Stocking Plan	The purpose of the plan (AR6) is to establish the fish stocking process, procedures, targets and creel (i.e., angler) surveys that Yuba Water would follow when stocking fish in New Bullards Bar Reservoir (see FERC's draft license Article 406 in Appendix C of FERC 2019).	Plan implementation would involve: (1) Annual stocking of 65,000 fingerling kokanee and 3,000 catchable rainbow trout - stocking would occur in 2 to 4 events between 3/1 and 10/31 each year, and fish would be acquired from sources that would maintain genetic diversity. (2) Conduct creel surveys (from Jun 1 thru Sep 30) at New Bullards Bar Reservoir during License Years 1-3 and every 6 years thereafter. Target species are kokanee and rainbow trout. (3) Evaluate the success of the stocking program in consultation with CDFW. (4) Yuba Water reserves the right to charge a fee to offset fish stocking costs. (5) Prepare and provide annual report to FERC, USFS, CDFW and USFWS. (6) Conduct periodic reviews of stocking numbers and data with USFS, CDFW and USFWS for use in informing the need for potential plan revisions.			**X**	Revise the Reservoir Fish Stocking Plan (filed 12/2/2016) in consultation with CDFW	
Aquatic Resources	AR7	Implement Upper Yuba River Aquatic Monitoring Plan	The purpose of the plan (AR7) is to develop information regarding aquatic resources in the upper Yuba River area (e.g., North Yuba River, Middle Yuba River, mainstem Yuba River and Oregon Creek) in response to changes in flow conditions from the initial FERC license to the new license.	Monitoring activities in the upper Yuba River area would focus on the distribution, abundance, and condition of stream fish (especially rainbow trout), benthic macroinvertebrates (BMI), foothill yellow-legged frogs (FYLF), western pond turtle (WPT), sedimentation at Our House and Log Cabin diversion dam impoundments, stream channel morphology, riparian vegetation, and LWM. For specific details regarding each of the various monitoring activities listed above, including locations, frequency, reporting requirements, etc., see the Upper Yuba River Aquatic Monitoring Plan.	**X**				Condition 43
Aquatic Resources	AR8	Implement Lower Yuba River Aquatic Monitoring Plan	The purpose of the plan (AR8) is to develop information about aquatic resources in the lower Yuba River in response to changes in flow conditions from the initial FERC license to the new license.	Monitoring activities related to anadromous salmonids would include: (1) fish passage at Daguerre Point Dam; (2) annual spawning population abundance; (3) temporal and spatial distributions and use of spawning habitat; (4) abundance, size and timing of emigration; and (5) interactions of anadromous fish with Narrows 2 facilities and operations. Other monitoring activities pertain to riparian vegetation cover and community structure, channel substrate and LWM, and benthic macroinvertebrate (BMI) community structure. See the Lower Yuba River Aquatic Monitoring Plan for specific details regarding each of the various monitoring activities listed above, including locations, frequency, reporting requirements, etc.			**X**		
Aquatic Resources	AR9	Control Project Ramping and Flow Fluctuations Downstream of Englebright Dam	Yuba Water would manage fluctuations in the flow of the lower Yuba River downstream of USACE's Englebright Dam by coordinating operations with the Narrows 1 Powerhouse. Changes in flow would not increase at a rate of more than 500 cfs per hour, or decrease at a rate in excess of 200 cfs per hour. Also, Yuba Water would cap daily flow change to 15 percent of the average daily flow.	N/A		**X**			
Aquatic Resources	AR10	Maintain Minimum Streamflow below New Bullards Bar Dam	Minimum continuous flows in North Yuba River: 60 cfs (6/1-6/30); 40 cfs (7/1-8/31); 30 cfs (9/1-9/30). Shift flows during 3-day periods (6/1-6/3 and 9/28-9/31). Minimum flow in the lower Yuba River during Schedule 6 Water Years of 350 cfs (see FERC's draft license Article 407 in Appendix C of FERC 2019).	N/A			**X**		
Aquatic Resources	AR11	Periodically Close Lohman Ridge Diversion Tunnel	Depending on the WYT (USFS Condition 31) and New Bullards Bar Reservoir water surface elevation, close the tunnel and use the low-level outlet and fish release valves at Log Cabin Diversion Dam.	N/A		**X**			Condition 35
Aquatic Resources	AR12	Control Project Spills at Log Cabin Diversion Dam	Gradually reduce spills at Log Cabin Diversion Dam by closing the low-level outlet valve or fish valve. Provide annual report of valve adjustments. (NOTE: This measure would require modification of the Log Cabin Diversion Dam fish release outlet.)	N/A		**X**			Condition 34
Aquatic Resources		Log Cabin Diversion Dam Fish Release Outlet Modification	Modify the Log Cabin Diversion Dam fish release outlet to allow higher minimum flows from the current range of 8 to 12 cfs to a range of 6 to 43 cfs and install a 38-in. diameter outlet pipe with control valve at same invert elevation as the existing fish release outlet.	N/A			**X**		
Aquatic Resources		Lohman Ridge Diversion Tunnel Intake Modification	Modify the Lohman Ridge Diversion Tunnel intake to allow it to be opened and closed during high flows on the Middle Yuba River to decrease fish entrainment.	N/A					

Table 2.4-20. (Continued)

Category	Measures/Conditions*		Purpose/Synopsis	Implementation Plan Summary of Activities	FERC 2019 FEIS				USFS 2022 Revised Final FPA Section 4(e) Conditions
	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
Aquatic Resources		Our House Diversion Dam Fish Release Outlet Modification	Modify the Our House Diversion Dam fish release outlet to allow higher minimum flows from the current range of 30 to 50 cfs to a range of 40 to 120 cfs and install a 68-in. diameter outlet pipe with control valve at the same invert elevation as the existing fish release outlet.	N/A		**X**			
Aquatic Resources		Tailwater Depression System at New Colgate Powerhouse	Install tailwater depression system at the New Colgate Powerhouse that would inject air into the turbine discharge chamber to lower the tailwater and allow turbine operation during high flows.	N/A					
Aquatic Resources		Develop and implement a new Narrows Reach Fish Stranding Prevention Plan (FERC Article 409)	FERC's draft license Article 409 (FERC 2019, Appendix C) states that Yuba Water is to develop a new Narrows Reach Fish Stranding Prevention Plan to help reduce the potential for fish stranding following shutdowns of the YRDP Narrows 2 Powerhouse facilities within 6 months of issuance of a new license by FERC.	The new plan must include: (1) potential operational and/or structural measures (or other action) to reduce fish stranding; and (2) procedures for reporting potential fish stranding events to CDFW, NMFS and USFWS if a flow reduction > 500 cfs occurs for more than five minutes.				Develop a new plan for the reach of the lower Yuba River downstream of Englebright Dam to the Narrows 1 Powerhouse	
Aquatic Resources		Develop and implement a new Lower Yuba River Riparian Restoration Plan (FERC Article 412)	FERC's draft license Article 412 (FERC 2019, Appendix C) states that Yuba Water is to develop a new Lower Yuba River Riparian Restoration Plan In consultation with CDFW, NMFS, USFWS and SYRCL within 6 months of issuance of a new license by FERC.	The new plan is to: (1) plant at least 100 acres of riparian vegetation on the floodplain of the lower Yuba River (no fewer than 4 sites); (2) include cottonwood and willow species; (3) describe the planting methods; (4) identify success criteria; (5) describe monitoring methods; (6) provisions for additional plantings (if success criteria not met); (7) reporting schedule; and (8) implementation schedule.				Develop and implement a new lower Yuba River riparian restoration plan	
Aquatic Resources		Develop and implement a new comprehensive Large Woody Material Enhancement Plan for the lower Yuba River (FERC Article 410)	FERC's draft license Article 410 (FERC 2019, Appendix C) states that Yuba Water is to develop and implement a new LWM enhancement plan when a new license is issued by FERC.	In addition to the plan (GS3) for the upper Yuba that was approved in Article 403, a new plan is to be developed for the lower Yuba River including: (1) identify sources LWM; (2) store and transport LWM collected at New Bullards Bar Reservoir downstream to the lower Yuba River; (3) identify suitable size classes of LWM for placement; (4) identify LWM placement locations in the lower Yuba River; (5) consult with agencies and American whitewater on placement plan; and (6) develop a monitoring and mapping process to indicate the stability of these and future enhancements.				Develop and implement a new Large Woody Material enhancement plan	
Aquatic Resources		Reservation of Authority to Prescribe Fishways	FERC may require that Yuba Water construct, operate and maintain fishways in the future (see FERC's draft license Article 402 in Appendix C of FERC 2019).	N/A				FERC may require fishways in the future	
Aquatic Resources		Modifications of 4(e) Conditions in the event of anadromous fish re-introduction	The USFS reserves the right to modify its 4(e) Conditions to respond to any reintroduction of ESA-listed Chinook salmon or steelhead to streams that are on or may have effects on USFS lands.	N/A					Condition 27
Cultural Resources	CR1	Implement Historic Properties Management Plan (HPMP)	Contact Monica Ruth for more information.	Contact Monica Ruth for more information.			**X**	Implement Programmatic Agreement; revise and implement HPMP (see FERC's draft license Article 415 in Appendix C of FERC 2019).	Condition 50
Geology & Soils	GS1	Implement the Erosion and Sediment Control Plan	The plan describes existing Yuba Water and USFS BMPs to control site-specific erosion and sedimentation impacts during routing O&M, new construction and reconstruction of YRDP facilities, and includes emergency erosion control measures/protocols to control sedimentation during severe storm events. The plan would be implemented in coordination with the Integrated Vegetation Management Plan and the Transportation System Management Plan.	Plan implementation would involve: (1) Use of erosion and sediment control BMPs. (2) Develop and implement Stormwater Pollution Prevention Plans (SWPPP). (3) Use USFS BMPs on USFS lands. (4) Monitor New Bullards Bar Reservoir shoreline stability in License Year 1, then every 5 years. Consult with USFS about erosion areas and treatment. (5) Consult with the USFS annually about USFS lands.		**X**			Condition 51

Table 2.4-20. (Continued)

Category	Measures/Conditions*		Purpose/Synopsis	Implementation Plan Summary of Activities	FERC 2019 FEIS				USFS 2022 Revised Final FPA Section 4(e) Conditions
	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
Geology & Soils	GS2	Implement Log Cabin and Our House Diversion Dams Sediment Management Plan	The purpose of the plan (GS2) is to prescribe procedures for the management of sediment behind Log Cabin Diversion Dam and Our House Diversion Dam to: (1) provide for dam safety and proper functioning of YRDP facilities, especially the fish release and low level outlet valves; and (2) maintain the health of the aquatic environment downstream of the dams by allowing the passage of sediments that occur behind the dams.	Plan implementation would involve: (1) Opening the low-level outlet valve (between Oct 1 and Mar 21) for 9+ days to allow sediment to pass downstream. (2) Implement remedial actions if the fish release valves and/or low-level outlet valves become partially or fully blocked by sediment. (3) Implement planned mechanical removal of sediment (summer/early fall) during low flow periods. (4) Conduct testing of sediment for metals prior to removal. (5) Implement sediment-related BMPs and biological monitoring. (6) Equipment mobilization. (7) Temporary diversion/control or pumping of water to route away from planned excavation of sediment. (8) Removal, disposal of sediment and stockpile stabilization. (9) Equipment demobilization. (10) Emergency mechanical removal of sediment. (11) Conduct monitoring (see Upper Yuba River Aquatic Monitoring Plan). (12) Provide annual reports to FERC, USACE, CDFW, USFS, USFWS, SWRCB and RWQCB. Update plan as warranted in consultation with agencies following License Year 3 effectiveness review.		**X**			Condition 37
Geology & Soils	GS3	Implement Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan	The purpose of the plan (GS3) is to provide guidance (including coordination with USFS) for: (1) Yuba Water's passage of woody material at Our House Diversion Dam on the Middle Yuba River and at Log Cabin Diversion Dam on Oregon Creek; and (2) Yuba Water's annual collection, storage and disposal of woody material in New Bullards Bar Reservoir on the North Yuba River.	Plan implementation would involve: (1) All sizes of LWM > 8 in. in diameter and up to 36 ft in length shall be allowed to pass downstream past the dams. (2) NBBR LWM collection procedures, LWM storage (at Primary Burn Site and Secondary Burn Site), and disposal procedures. (3) Protective measures for special-status wildlife. (4) Reporting requirements.		**X**			Condition 38
Land Use	LU1	Implement Transportation System Management Plan	The purpose of the plan (LU1) is to provide guidance for the rehabilitation and maintenance of YRDP Primary Project Roads (17), Primary Project Trails (2) and Project Recreation Roads (9), with special emphasis on Primary Project Roads and Trails and Project Recreation Roads on NFS land. Numerous road, ditch, and culvert improvements are to be implemented during License Years 1, 3, and 5. In addition to describing road maintenance and management standards that are acceptable to the USFS, the plan also would minimize erosion and damage to natural resources, and provide for traffic safety. USFS revised final 4(e) Condition 19 requires that Yuba Water would be responsible for all maintenance of Project Roads identified in the plan.	The plan describes the scope of improvements needed for YRDP Primary Project Roads (about 12 miles) and Recreation Roads (4.07 miles) design, signage, construction and maintenance, with special emphasis on Primary Project Roads and Trails and Recreation Roads on NFS land. More specifically, the plan: (1) describes rehabilitation actions to bring existing roads up to standards by the end of the fifth full calendar year after license issuance; (2) includes measures to protect sensitive resources; (3) defines applicable road and trail maintenance activities (including frequency) and standards for performing maintenance; and (4) specifies reporting and consultation requirements with the USFS for roads located on NFS land. The plan also addresses maintenance of YRDP roads that are not located on NFS-managed lands and describes mapping and inventory Yuba Water would accomplish, sign placement and maintenance, pavement surface monitoring, and emergency repair procedures. See the YRDP Transportation System Management Plan (LU1) for details on specific road locations, engineering features, site plans, maps and implementation schedule.		**X**			Condition 19
Land Use	LU2	Implement the Fire Prevention and Response Plan	The purpose of the plan (LU2) is to provide: (1) a mechanism for preventing and reporting wildfires to appropriate agencies; (2) information on fire ignition sources in the YRDP project area; and (3) cooperation between Yuba Water and appropriate agencies for investigating fires that may be related to YRDP O&M. The plan describes fire prevention procedures, reporting and safe fire practices for Yuba Water personnel and contractors responsible for conducting O&M of the YRDP, with emphasis on NFS land.	Plan implementation would involve: (1) Obtain written permits prior to blasting, storing explosives, burning, air pollution, fires, welding and cutting. (2) Provide a communication system with USFS and California Department of Forestry and Fire Protection (CALFIRE). (3) Emergency response preparedness (equip Yuba Water/contractor vehicles with axes, saws, shovels, backpack water pump, fire extinguisher, radio, etc.), have water trailer during fire precautionary periods. (4) Consult with USFS TNF and PNF to determine YRDP Project Activity Level during Fire Precautionary Periods. (5) Use Very High fire rating restrictions for emergency repairs involving cutting or welding. (6) Report all fires by calling 911, and cooperate with authorities on wildfire investigations. (7) Consult with USFS annually. Modify plan in consultation with USFS and others.		**X**			Condition 53
Land Use		Land Use and Occupancy	Article 417 specifies the types of non-YRDP activities that Yuba Water can approve in the FERC Project Boundary and the process for seeking FERC approval.	N/A				Implement standard land use article (see FERC's draft license Article 417 in Appendix C of FERC 2019).	

Table 2.4-20. (Continued)

Category	Measures/Conditions*		Purpose/Synopsis	Implementation Plan Summary of Activities	FERC 2019 FEIS				USFS 2022 Revised Final FPA Section 4(e) Conditions
	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
Recreation	RR1	Implement Recreation Facilities Plan	The plan (RR1) guides the management of public recreation use of the YRDP's existing and new facilities over the term of the new license, and minimizes recreation use impacts to natural, historic and cultural resources.	The plan (RR1) describes Yuba Water's responsibilities regarding routine O&M of recreation facilities, rehabilitation/improvement of existing recreation facilities and construction of new recreation facilities. Numerous enhancements to existing recreation facilities (campgrounds, picnic areas, parking areas, boat launches, overlooks, etc.) are planned, as well as construction of several new facilities, including: Kelly Ridge and Shadow Ridge Campgrounds, Cottage Creek Picnic Site, Dark Day RV Dump Station and Entrance Station, New Colgate Powerhouse Access, and West Shoreline Trail. Other improvements address the potable water supply system, the wastewater system (e.g., restrooms, septic, floating comfort stations, etc.), recreation trails, circulation and spur roads, and signage, among other features. See the Recreation Facilities Plan for site-specific details and the master implementation schedule.		**X**			Condition 46
Recreation	RR2	Provide Recreation Flow Information	Provide forecasts for flows at least monthly in Middle Yuba River downstream of Our House Diversion Dam, in Oregon Creek downstream of Log Cabin Diversion Dam, North Yuba River downstream of New Bullards Bar Dam, Yuba River at Smartsville.	N/A			**X**	Include flow forecasts (see FERC's draft license Article 414 in Appendix C of FERC 2019).	Condition 47
Recreation	RR3	Provide Whitewater Boating Below Our House Diversion Dam	Provide weekend whitewater boating flows (600 -2,000 cfs) for October through March based on WYT (Condition 31). Notify FERC annually of compliance with requirements. If the Lohman Ridge Diversion Tunnel must be modified to provide flows, seek approval for modification and modify by License Year 2.	N/A		**X**			Condition 48
Recreation		Safety Plan and Construction Inspections (USFS lands)	Develop and implement Safety During Construction Plans for work on USFS land. Inspect construction sites daily. Inspect structural improvements regularly.	N/A					Condition 24
Terrestrial Resources	GEN2	Annual Review of Special-Status Species Lists and Assessment of New Species on NFS Lands	Annually review special status species in consultation with the USFS.	N/A	**X**				Condition 30
Terrestrial Resources	GEN3	Provide Environmental Awareness Training to Employees	Provide annual environmental and cultural resource awareness training to employees.	N/A	**X**				Condition 28
Terrestrial Resources	TR1	Implement Integrated Vegetation Management Plan	The plan provides guidance for the management of vegetation (with the exception of aquatic invasive plants) and hazard reduction activities related to YRDP O&M, as well as non-native invasive plants (NNIP), revegetation and vegetation management in sensitive areas within the FERC Project Boundary (see FERC's draft license Article 411 in Appendix C of FERC 2019).	Specific activities described in the plan include: (1) management and monitoring actions to prevent the introduction, and establishment and spread of NNIP into new areas; (2) control and localized eradication of known infestations of NNIP; (3) the restoration of native vegetation in areas disturbed by YRDP activities; (4) the protection of sensitive areas; and (5) implementation of YRDP-related vegetation management and hazard reduction activities using BMPs. YRDP O&M actions address routine maintenance, fuels management, road right-of-way management, recreation area management, pesticide use, and revegetation procedures.The 2019 plan (TR1) includes protections for California red-legged frog, foothill yellow-legged frog, VELB, and aquatic resources. See the Integrated Vegetation Management Plan for details.			**X**		Condition 40
Terrestrial Resources	TR2	Implement Bald Eagle and American Peregrine Falcon Management Plan	The purpose of the plan (TR2) is to establish and implement protective guidelines and activities that would ensure that YRDP O&M, as well as YRDP recreation activities, do not result in "take" of bald eagles and American peregrine falcons (including eggs and nests) (see FERC's draft license Article 413 in Appendix C of FERC 2019).	Plan implementation would involve: (1) Conduct annual surveys of bald eagle roosts and nests. Conduct annual surveys of peregrine falcon eyries. (2) Establish buffer zones around active nests/eyries and restrict activities in those buffers during nesting periods. Install water (buoys/signage) and land (fencing/signage) barriers around known occupied nests to prevent disturbance. (3) Record presence of other special-status raptors during annual surveys. (4) Conduct annual employee awareness training. (5) Revise and update plan as warranted by new information.			**X**	Revise to include annual survey for falcon eyries.	Condition 41
Terrestrial Resources	TR3	Implement Ringtail Management Plan	The plan (TR3) is intended to provide for the protection of ringtail at YRDP facilities (e.g., New Colgate Powerhouse, switchyard and administrative building adjacent to the New Colgate Powerhouse, Narrows 2 Powerhouse) where ringtail have been observed to ensure that YRDP O&M is consistent with the "Fully Protected" status of this species.	Plan implementation would involve: (1) Install protective devices at the New Colgate Powerhouse and Narrows 2 powerhouse switchyards to protect ringtail from electrocution. (2) Install ringtail exclusion devices at YRDP structures and inspect quarterly or biannually. (3) Limit access to ringtail attractants in YRDP facilities. (4) Conduct annual employee awareness training on plan requirements. (5) Prepare and provide annual report to CDFW.		**X**			

Table 2.4-20. (Continued)

	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
Terrestrial Resources	TR4	Implement Bat Management Plan	Provide guidance for the protection of bats at YRDP structures (e.g., powerhouses, storage buildings, valve houses, and dams), recreation facilities, or other structures where Yuba Water staff has a routine presence that may be used as a roosting structure by bats.	Plan implementation would involve: (1) Conduct survey to identify bats, roosts and/or signs of roosting at YRDP facilities. Year 1: daytime visual assessment and nighttime emergence survey of YRDP structures (July 1 – August 31). (2) Install humane exclusion devices/screens in YRDP buildings with frequent human use (November 1 – February 28); inspect devices after 6 months and then annually. (3) Inspect facilities every 2 years after installation to ensure no new roosts. (4) Inspect recreation facilities restrooms annually for bat use. (5) Conduct annual employee awareness training. (6) Provide annual report to CDFW, USFS, USFWS. Update plan as warranted in consultation with CDFW, USFS, USFWS.		**X**			Condition 42
Terrestrial Resources		Pesticide-Use Restrictions USFS lands	Obtain USFS approval for pesticide and herbicide use on USFS land.	N/A					Condition 23
Terrestrial Resources		Unattended Construction Equipment (USFS lands)	Do not leave unattended construction equipment on USFS land without USFS approval.	N/A					Condition 25
Visual Resources	VR1	Implement Visual Resource Management Plan	The plan (VR1) provides guidance for the management of visual resources within the FERC Project Boundary, with special emphasis on visual resources on NFS land. The plan describes how to bring YRDP facilities into compliance with USFS Visual Quality Objectives (VQOs) and uses mitigation and enhancement measures to better meet USFS objectives and integrate YRDP facilities into the visual environment on NFS land.	Measures identified by Yuba Water and USFS to be completed within three years after license issuance include: (1) Emerald Cove Marina fuel storage tanks - paint gray/green or brown to blend with surrounding. (2) Gate controls and housings on New Bullards Bar Dam - paint them green or similar. (3) Sunset Vista Point - manage vegetation to maintain view from site. (4) Implement a visual review process for projects with the USFS and develop Visual Resource Protection Plans for future modification(s) of YRDP facilities on NFS land. (5) Consult with USFS annually on visual quality activities on NFS land within the FERC Project Boundary. (6) Consider plan revisions with USFS, as needed, when significant changes in the existing conditions occur.		**X**			Condition 49
Water Quantity		Auxiliary Flood Control Outlet (i.e., ARC Spillway)	Install a new flood control outlet at New Bullards Bar Dam to improve flood management.	N/A					
Water Resources	WR1	Implement the Hazardous Materials Management Plan	The plan addresses the storage, use, transport and disposal of hazardous materials that would be used within the FERC Project Boundary for O&M purposes, with emphasis on NFS land, and describes how Yuba Water would manage hazardous materials. The plan provides a description, by location, of hazardous materials that may be used, stored or transported for routine YRDP O&M.	Plan implementation would involve: (1) Train Yuba Water staff on procedures to reduce risk and respond to spills. (2) Maintain powerhouse oil sumps. (3) Implement BMPs including: (1) refueling vehicles and equipment in areas where spills cannot enter lakes and streams; and (2) storing potentially hazardous materials away from waterways. (4) Implement spill prevention measures during maintenance work and new construction. (5) Meet with USFS annually. Modify plan in consultation with USFS and others.		**X**			Condition 22
Water Resources	WR2	Determine WYTs for Conditions Pertaining to Our House Diversion Dam, Log Cabin Diversion Dam and New Bullards Bar Dam	Classify WYTs based on flows in the Middle Yuba River during months of February, March, April, May, and October.	N/A		**X**			Condition 31
Water Resources	WR3	Determine WYTs for Conditions Pertaining to Narrows 2 Powerhouse and Narrows 2 Full Bypass	Determine WYTs for related measures pertaining to Narrows 2 Powerhouse and Narrows 2 full bypass using the North Yuba Index.	N/A		**X**			
Water Resources	WR4	Implement Streamflow and Reservoir Level Compliance Monitoring Plan	The purpose of the plan (WR4) is to describe how Yuba Water documents compliance with streamflow and reservoir level requirements in the new FERC license. The plan describes the locations where Yuba Water monitors compliance, the equipment used (including deployment, data collection frequency, operation and calibration), data retrieval, QA/QC procedures, and data storage processes.	Plan implementation would involve: (1) Maintain 10 USGS gages to monitor project releases, reservoir elevations, Lohman Ridge Diversion Tunnel and Camptonville Diversion Tunnel flows. (2) Estimate and report New Bullards Bar Dam primary spillway releases. (3) Modify three USGS gages to accommodate new license flows. (4) Change the method for reporting releases from New Bullards Bar Reservoir. (5) Prepare and provide annual reports to FERC. (6) As needed, review, update, and/or revise the Plan in consultation with USFS, USGS, DOI, USFWS, CDFW, and the SWRCB.		**X**			Condition 36
Water Resources	WR5	Maintain New Bullards Bar Reservoir Minimum Pool Elevation	Maintain a minimum pool elevation in New Bullards Bar Reservoir at 1,730 ft or higher (see FERC's draft license Article 404 in Appendix C of FERC 2019).	N/A		**X**			

Table 2.4-20. (Continued)

Category	Measures/Conditions*		Purpose/Synopsis	Implementation Plan Summary of Activities	FERC 2019 FEIS				USFS 2022 Revised Final FPA Section 4(e) Conditions
	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
Water Resources	WR6	Operate New Bullards Bar Reservoir for Flood Control	Yuba Water would operate YRDP reservoirs (e.g., New Bullards Bar Reservoir) for flood control in accordance with rules prescribed by USACE.	N/A		**X**			
Water Resources	WR7	Implement Water Temperature Monitoring Plan	The purpose of the plan (WR7) is to describe the water temperature monitoring to be conducted in YRDP reservoirs, YRDP impoundments and YRDP-affected stream reaches of the North, Middle, and mainstem Yuba rivers, and in Oregon Creek.	The plan describes the methods that would be used to monitor and analyze water temperature, which would then be used to compare post-license water temperature information with pre-license issuance information. For specific details regarding the 23 monitoring sites, sampling locations, frequency, reporting, etc., see the Water Temperature Monitoring Plan.	**X**				Condition 44
Water Resources	WR8	Implement Water Quality Monitoring Plan	The purpose of the plan (WR8) is to describe the water quality monitoring activities to be conducted in YRDP reservoirs and impoundments and in YRDP-affected reaches of the North, Middle, and mainstream Yuba rivers, and in Oregon Creek.	The plan focuses on four general water quality parameters, including: (1) *in situ* (i.e., direct monitoring in water); (2) general water chemistry (e.g., samples collected for laboratory analysis); (3) recreation-related water quality monitoring (e.g., total coliform, fecal coliform, *e coli*, oil & grease, etc.); and (4) bioaccumulation (i.e., metals accumulation in fish (e.g., rainbow trout, bass)). For specific details regarding monitoring activities, locations, frequency, etc., see the Water Quality Monitoring Plan.	**X**				Condition 45
Water Resources	WR9	Implement Drought Management Plan	The purpose of the plan (WR9) is to facilitate approval of variances to FERC license conditions so that drought management measures that require a variance to license conditions may be implemented in a timely, efficient and effective manner. Implementation of the Drought Management Plan by Yuba Water is discretionary and would be determined based upon specific considerations described in Section 2.1 of the plan.	Drought management options that may require a variance to one or more FERC license conditions include relief from minimum flow requirements (AR3), flow fluctuation criteria (AR9), control of YRDP spills at Our House and Log Cabin diversion dams (AR2), NBBR minimum pool operations (WR5), relief from whitewater boating recreation flows (RR3), among others. Drought management options would be determined based on specific conditions.FERC would require modification of the plan in consultation with various agencies (CDFW, USFWS, NMFS, USFS, SWRCB) regarding drought triggers, consultation with agencies during droughts, and the specific license requirements that could have variances.			**X**		Condition 53
General		Modify the FERC Project Boundary to better represent lands required for O&M around YRDP reservoirs	Change the existing FERC Project Boundary around the YRDP reservoir and impoundments from the surveyed coordinates to a contour located above the normal water surface elevation. Specific changes to the existing Project Boundary would reduce the shoreline buffer along YRDP impoundments to 30 ft where YRDP infrastructure and recreation facilities are not located along the shoreline.	N/A		**X**			
General		Modify the FERC Project Boundary to make corrections to the existing Project Boundary	Specific changes to the existing Project Boundary would: (1) include additional lands necessary for current and future YRDP O&M and recreation development; and (2) remove lands that do not have YRDP facilities and where there are no YRDP-related uses necessary for O&M.	N/A		**X**			
General		USFS Reservation of Authority, Resource Plan Modification and Variance Requests	Allows the USFS to modify its conditions. Requires Yuba Water to consult for non-emergency variances from conditions.	N/A					Condition 1
General	GEN1	Organize Ecological Group and Host Meetings	Establish Ecological Group with agencies and others. Meet with group at least annually to review license compliance, environmental studies and reports for previous year, anticipated reports/studies for the upcoming year.	N/A	**X**				Condition 3
General	GEN4	Develop and Implement a Coordinated Operations Plan to Assure Licensee Compliance with the New License for the YRDP	Develop and Implement a Coordinated Operations Plan to Assure Licensee's Compliance with the New License for the YRDP.		**X**				
General	GEN5	Special-Status Species on NFS Lands	Prepare a biological evaluation for USFS special status species, and critical habitat prior to construction of new YRDP facilities on USFS land.		**X**				Condition 29
General	LU1	Use of National Forest System Roads for Project Access	USFS Condition 19 states that Yuba Water must implement the Transportation System Management Plan for locations on, or directly affecting NFS lands (including implementation of numerous road, ditch, culvert improvements in License Years 1, 3, 5 described in the plan).						Condition 19
General		Access (USFS lands)	The USFS can use, or allow the use of, its lands for any purpose that does not conflict with the Federal Power Act or license.						Condition 14

Table 2.4-20. (Continued)

Category	Measures/Conditions*		Purpose/Synopsis	Implementation Plan Summary of Activities	FERC 2019 FEIS				USFS 2022 Revised Final FPA Section 4(e) Conditions
	Yuba Water Designation	Name/Description			Measure Rejected	Measure Retained	Measure Modified	New Measure (FERC Staff Recommended)	
General		Access by the United States (USFS)	The United States has unrestricted use of any road over which Yuba Water has control within the YRDP project area in connection with the protection, administration, management, and utilization of Federal lands or resources.						Condition 20
General		Compliance with Regulations (USFS lands)	Comply with all federal, state, local, and USFS regulations.						Condition 8
General		Crossings (USFS lands)	Yuba Water must maintain USFS crossings for roads and trails that intersect the right-of-way occupied by linear YRDP features (powerline, penstock, ditch and pipeline).						Condition 15
General		Damage to Land, Property, and Interests of the United States (USFS lands)	Protect land, property, and interests of the United States from damage, including fire associated with operation of the YRDP.						Condition 12
General		Existing Claims (USFS lands)	The United States is not subject to claims/rights affecting the License.						Condition 7
General		Ground Disturbing Activities (USFS lands)	Yuba Water must consult per NEPA prior to ground-disturbing activities.						Condition 18
General		Indemnification (USFS lands)	Indemnify the United States for claims against Yuba Water associated with the YRDP.						Condition 11
General		Maintenance of Improvements on or affecting National Forest System Lands	Maintain YRDP facilities and lands consistent with USFS standards.						Condition 6
General		Protection of United States Property (USFS lands)	Protect United States property from damage.						Condition 10
General		Risks and Hazards on National Forest System Lands	Report risks and hazards on USFS lands to USFS and consult with USFS to resolve issues.						Condition 13
General		Road Use (USFS lands)	Yuba Water would restrict vehicle use to roads and designated access routes (see Transportation System Management Plan).						Condition 21
General		Signs (USFS lands)	Yuba Water must obtain USFS approval of public safety signage and sign locations.						Condition 17
General		Review of Improvements on National Forest System Lands	If YRDP project use expands to include additional USFS land outside of the current Project Boundary, obtain a special use permit.						Condition 26
General		Surrender of License or Transfer of Ownership (USFS lands)	If the license is surrendered, restore USFS lands. If the license is transferred, ensure transferee could restore lands if need be.						Condition 9
General		Surveys, Land Corners (USFS lands)	Yuba Water would avoid disturbance and damage to public land survey monuments, private property corners, and USFS boundary markers.						Condition 16
General		USFS Annual Consultation	Meet with the USFS annually and invite other agencies to attend. Provide annual O&M plan, report on compliance with conditions.						Condition 2
General		USFS Approval of Changes	Obtain approval from USFS for changes to existing facilities on USFS land.						Condition 5
General		USFS Approval of Final Designs	Obtain approval from USFS for design plans for facilities on USFS land.						Condition 4
General	GEN6	Review of Improvements on NFS Lands	Obtain approval from USFS for changes to existing facilities on USFS land.		**X**				Condition 26

For the purposes of this table, cells in the column titled "Yuba Water Designation" are blank of a measure/condition was proposed by a party (e.g., FERC, USFS) other than Yuba Water.

2.4.1.5.2 Existing Plans to be Revised when FERC Issues New License for the YRDP

Bald Eagle and American Peregrine Falcon Management Plan (FERC Article 413)

- Revise existing plan and file with FERC within 6 months of license issuance.

Drought Management Plan (USFS 4(e) Condition 53)

- For the protection of USFS resources, finalize the plan in consultation with USFS, SWRCB, other government agencies and interested parties and file with FERC within one year of license issuance. Implement plan after USFS approval and other approvals, if necessary.

Historic Properties Management Plan (FERC Article 415)

- Revise existing plan and file with FERC within 6 months of license issuance.

Integrated Vegetation Management Plan (FERC Article 411)

- Revise existing plan and file with FERC within 6 months of license issuance, or at least 90 days prior to the start of any ground-disturbing activity, whichever comes first.

New Bullards Bar Reservoir Fish Stocking Plan (FERC Article 406)

- Revise existing plan and file with FERC within 6 months of license issuance.

For the purposes of this DEIR, although these are part of the YRDP Relicensing Project, it is not possible to ascertain the specific activities that could be identified for implementation or the resultant potential impacts from each of these seven new and revised plans. Thus, additional CEQA compliance may be required in the future, after a new FERC license is issued and the respective plans are developed/revised and approved by FERC.

Developing a lower Yuba River riparian restoration plan, as FERC staff recommend, would include provisions for planting of cottonwood and willow on 100 ac of currently unvegetated floodplains at a minimum of four different locations. These riparian planting efforts would create additional habitat complexity and diversity, and provide increases in canopy structure, sediment retention, organic input into the lower Yuba River, and seed sources for further expansion of riparian vegetation species (FERC 2019). Riparian enhancement also would increase the extent of riparian vegetation on the lower Yuba River, providing for increased wetland habitat to benefit waterfowl, amphibians, and other terrestrial wildlife.

To accomplish riparian planting that meets FERC's goal of 100 ac, or some portion thereof, Yuba Water plans to address some component of FERC's riparian plan by adding additional riparian vegetation and placing LWM in areas that are either within or adjacent to habitat enhancement projects on the lower Yuba River that are currently in the planning stages or are in progress. Examples of potential Yuba River habitat enhancement projects that could be expanded to address a component of FERC's plan include: (1) the Yuba River Canyon Restoration Project (USFWS and Yuba County 2016); (2) the Hammon Bar Riparian Enhancement Project (SYRCL 2013); (3) Yuba Water's Narrows 2 Large Woody Material Mitigation Project (YCWA 2018a; YCWA 2022c); (4) the Hallwood Side Channel and Floodplain Restoration Project (YCWA 2022d; NMFS

2017); (5) the Lower Long Bar Habitat Enhancement Project (USFWS and Yuba County 2021); and (6) the Upper Long Bar Habitat Enhancement Project (USFWS and Yuba County 2021). Because Yuba Water is already identified as a partner on several of these habitat enhancement initiatives, the potential exists for building upon the habitat enhancement work that is currently occurring along the river by identifying opportunities for creating an expansion of cottonwood and willow habitat that could be provided by a Lower Yuba River Riparian Planting Plan.

Consistent with FERC's (2019) conclusions, implementation of a riparian planting plan would provide overall beneficial impacts to various aquatic resources (e.g., fisheries, amphibians, wildlife, etc.). However, it is also recognized that there may be some degree of potential temporary and localized construction-related impacts, including disturbance of staging areas, creation of transport roads and/or river access, as well as increases in turbidity, among others. For the purposes of this DEIR, potential impact considerations related to LWM placement and riparian planting evaluated in the aforementioned projects and NMFS BOs (e.g., NMFS 2020; NMFS 2017; NMFS 2014) (which likely would be representative of the activities to be conducted as part of a Lower Yuba River Riparian Restoration Plan and a Large Woody Material Management Plan) are incorporated into the appropriate resource-specific analyses of the YRDP Proposed Project, to the extent feasible.

2.4.1.6 YRDP Federal Power Act Section 4(e) Conditions

Section 4(e) of the FPA (16 U.S.C. § 797(e)) authorizes FERC to issue hydropower licenses and sets forth some basic parameters for the application and review process, including a requirement that the Chief of Engineers and the Secretary of the Army approve plans for any hydropower project "*affecting the navigable capacity of any navigable waters of the United States*" prior to issuance of the license. Section 4(e) of the FPA provides that any license issued by FERC "*for a project within a federal reservation shall be subject to and contain such conditions as the Secretary of the responsible federal land management agency deems necessary for the adequate protection and use of the reservation*." According to these provisions, USACE and USFS can issue 4(e) Conditions that meet the requirements of the law and must be included in any license issued by FERC, regardless of whether FERC includes the condition in its staff alternative (FERC 2019).

In accordance with Section 4(e) of the FPA and 18 C.F.R. 5.25(d), the USFS filed with FERC Revised Final FPA Section 4(e) Terms and Conditions for the YRDP on December 2, 2022. The USFS previously filed Final FPA Terms and Conditions and Recommendations on September 27, 2018. A subsequent January 31, 2020 FERC filing confirmed USFS approval of updates of five resource management plans filed by Yuba Water in November 2019. The USFS's December 2, 2022 revised terms and conditions directly incorporated references to those revised resource management plans (e.g., Recreation Facilities Plan, New Bullards Bar Fish Stocking Plan) along with updated standardized language for both Administrative and Resource Conditions. The USFS's December 2, 2022 filing included the Revised Final Section 4(e) terms and conditions to be included in the new FERC license and found to be necessary for the protection and utilization of the TNF and the PNF.

USFS's December 2, 2022 filing of Revised Final Section 4(e) Terms and Conditions was comprised of two parts. Part I included administrative conditions deemed necessary for the administration of NFS lands. Part II included specific resource requirements for protection and

utilization of NFS lands. The USFS's FPA Revised Final Section 4(e) Terms and Conditions are listed below. Additional details about each of the 53 USFS 4(e) Conditions are provided in Appendix 2C (Yuba Water Expected Conditions in New FERC License) of this DEIR.

- Part I: Administrative Conditions
    - Condition No. 1 – Reservation of Authority, Resource Plan Modification, and Variance Requests
    - Condition No. 2 – Consultation
    - Condition No. 3 – Organize Ecological Group and Host Meetings
    - Condition No. 4 - Forest Service Approval of Final Design
    - Condition No. 5 – Approval of Changes
    - Condition No. 6 – Maintenance of Improvements on or Affecting National Forest System Lands
    - Condition No. 7 – Existing Claims
    - Condition No. 8 – Compliance with Regulations
    - Condition No. 9 – Surrender of License or Transfer of Ownership
    - Condition No. 10 – Protection of United States Property
    - Condition No. 11 – Indemnification
    - Condition No. 12 – Damage to Land, Property, and Interests of the United States
    - Condition No. 13 – Risks and Hazards on National Forest System Lands
    - Condition No. 14 – Access
    - Condition No. 15 – Crossings
    - Condition No. 16 – Surveys, Land Corners
    - Condition No. 17 – Signs
    - Condition No. 18 – Ground Disturbing Activities
    - Condition No. 19 – Use of National Forest System Roads for Project Access
    - Condition No. 20 – Access by the United States
    - Condition No. 21 – Road Use
    - Condition No. 22 – Hazardous Materials Management Plan
    - Condition No. 23 – Pesticide-Use Restrictions on National Forest System Lands
    - Condition No. 24 – Safety Plan and Construction Inspections
    - Condition No. 25 – Unattended Construction Equipment

- Condition No. 26 – Review of Improvements on National Forest System Lands
- Condition No. 27 – Modifications of 4(e) Conditions in the Event of Anadromous Fish Re-introduction

- Part II: Resource Conditions
  - Condition No. 28 – Environmental Awareness Training to Employees
  - Condition No. 29 – Special-Status Species
  - Condition No. 30 – Annual Review of Special-Status Species Lists and Assessment of New Species on Federal Land
  - Condition No. 31 – Water Year Types for the Middle Yuba River and Oregon Creek
  - Condition No. 32 – Minimum Streamflows for the Middle Yuba River and Oregon Creek
  - Condition No. 33 – Control Project Spills at Our House Diversion Dam
  - Condition No. 34 – Control Project Spills at Log Cabin Diversion Dam
  - Condition No. 35 – Periodically Close Lohman Ridge Diversion Tunnel
  - Condition No. 36 – Streamflow and Reservoir Level Compliance Monitoring Plan
  - Condition No. 37 – Log Cabin and Our House Diversion Dams Sediment Management Plan
  - Condition No. 38 – Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan
  - Condition No. 39 – Aquatic Invasive Species Management Plan
  - Condition No. 40 – Integrated Vegetation Management Plan
  - Condition No. 41 – Bald Eagle and American Peregrine Falcon Management Plan
  - Condition No. 42 – Bat Management Plan
  - Condition No. 43 – Upper Yuba River Aquatic Monitoring Plan
  - Condition No. 44 – Water Temperature Monitoring Plan
  - Condition No. 45 – Water Quality Monitoring Plan
  - Condition No. 46 – Recreation Facilities Plan
  - Condition No. 47 – Recreation Flow Information
  - Condition No. 48 – Whitewater Boating Below Our House Diversion Dam
  - Condition No. 49 – Visual Resource Management Plan
  - Condition No. 50 – Historic Properties Management Plan
  - Condition No. 51 – Erosion and Sediment Control Plan
  - Condition No. 52 – Fire Prevention and Response Plan
  - Condition No. 53 – Drought Management Plan

2.4.1.7 Section 18 of the Federal Power Act

New licenses for the YRDP and Narrows Project would be subject to numerous requirements under the FPA, including Section 18. Section 18 of the FPA states that FERC must require construction, operation, and maintenance by a licensee of such fishways as may be prescribed by the Secretaries of Commerce or the Interior. Interior, by letter filed with FERC on August 25, 2017, requested that a reservation of authority to prescribe fishways under Section 18 be included in any license issued for the YRDP.

2.4.1.8 Recommended CWA Section 401 Certification Conditions for New YRDP FERC License

On December 30, 2024, Yuba Water filed an application for a WQC with the SWRCB in support of Yuba Water's application for a new FERC license for the YRDP. After filing the request, Yuba Water received a confirmation email from the SWRCB that the application was received. In anticipation of filing the WQC application, Yuba Water and the SWRCB participated in a pre-filing meeting on October 10, 2024 consistent with the regulatory requirements in 40 C.F.R. § 121.4.

Between October 2024 and January 2025, SWRCB staff participated in a series of coordination meetings where Yuba Water, CDFW, and NMFS presented a suite of recommended Section 401 WQC Conditions for the new YRDP FERC License (**Appendix 2E**). The proposed WQC Conditions address multiple operations-related considerations, including water year type classification, minimum instream flows, ramping rates to protect anadromous salmonids and riparian seedling recruitment, spill reduction, drought management, coordinated operations with the Narrows Project and operation of the New Colgate Powerhouse intakes,[48] among others. Other proposed WQC Conditions address riparian restoration, water quality (e.g., mercury management) and water temperature monitoring, aquatic invasive species management, LWM management, sediment management, and recreation facilities management and whitewater boating.

The proposed WQC Conditions presented in Appendix 2E were collaboratively developed by Yuba Water in coordination with CDFW and NMFS as recommended Section 401 WQC Conditions,[49] with the exception of the modification provisions in proposed WQC Conditions 1(D), 12 and 24. *NMFS and CDFW do not take a position on modification provisions in Conditions 1(D), 12 and 24, which they believe should be developed by the State Water Board and YWA.* NMFS and CDFW support Yuba Water's recommendation that the SWRCB adopt these conditions for the new YRDP FERC License and acknowledge that Yuba Water and the SWRCB may engage in further discussions to develop appropriate modification provisions.

The suite of recommended Section 401 WQC Conditions for the new YRDP FERC License are included as part of the YRDP Relicensing Project that is evaluated in this DEIR.

[48] Proposed WQC Condition 7 (Operation of New Colgate Powerhouse Intakes) would require the use of the New Bullards Bar Dam (NBBD) Upper Intake during spring (March, April and May) and the Lower Intake for the remainder of the year. This specific operation of the New Colgate Powerhouse Intakes also is included under Alternative 1.

[49] Other than the proposed modification provisions, the initial basis of the proposed WQC conditions was derived from the conditions that the SWRCB developed for the July 2020 WQC, which the SWRCB set aside in 2024.

2.4.1.9 FERC's Form L-5 Terms and Conditions of License for Constructed Major Project Affecting Navigable Waters and Lands of the United States

FERC's Form L-5 Terms and Conditions of License for Constructed Major Project Affecting Navigable Waters and Lands of the United States[50] includes 37 standard terms and conditions used by FERC in licenses for constructed projects affecting navigable waters and lands of the United States. Specific details about each of the 37 Form L-5 Terms and Conditions are provided in Appendix 2C (Yuba Water Expected Conditions in New FERC License) of this DEIR and would be expected to be applicable to both the YRDP and the Narrows Project.

2.4.1.10 YRDP Endangered Species Act Section 7 Consultation

2.4.1.10.1 USFWS

On May 31, 2018, FERC submitted a letter to the USFWS requesting concurrence with FERC's determination that the proposed action (i.e., relicensing the YRDP), as proposed with FERC staff-recommended measures and mandatory conditions, *"may affect, but is not likely to adversely affect"* the valley elderberry longhorn beetle *(Desmocerus californicus dimorphus)* and the California red-legged frog *(Rana draytonii),* as well as designated critical habitat for the California red-legged frog under the federal ESA.

On June 21, 2018, the USFWS responded to FERC's request and concurred with FERC's determination that the YRDP may affect, but is not likely to adversely affect, valley elderberry longhorn beetle and California red-legged frog. USFWS also concluded that the YRDP is not likely to adversely affect the primary constituent elements of critical habitat for the California red-legged frog (USFWS 2018). The USFWS concurrence letter for the YRDP does not authorize take of listed species. As described in the June 21, 2018 letter, over the course of the FERC relicensing process, the USFWS has worked collaboratively and provided ongoing technical assistance to Yuba Water and to FERC to identify conservation measures that should be implemented with a new license to avoid or minimize impacts to federally-listed species and their critical habitat. The specific measures that were identified by USFWS in their June 21, 2018 letter of concurrence as being protective of listed species and critical habitat are summarized below.

- Valley Elderberry Longhorn Beetle
    - Implement Yuba Water's proposed Integrated Vegetation Management Plan (TR1) that includes measures for controlling non-native plant species, protecting special-status species, and revegetating disturbed areas, with a modification that prior to any activities that would result in vegetation disturbance, conduct surveys for elderberry plants within 165 ft of the activity area and consult with USFWS if elderberry plants areas are found in order to determine if additional protective measures are necessary.

[50] Issued by FERC in October 1975.

- California Red-legged Frog
    - Implement Yuba Water's proposed Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan (GS3) filed on April 12, 2018 that includes measures for the collection, storage, and disposal of woody material from project reservoirs and prevents wood stockpiling and/or burning in California red-legged frog critical habitat.
    - Implement Yuba Water's proposed Integrated Vegetation Management Plan (TR1) that includes measures for controlling non-native plant species, protecting special-status species, and revegetating disturbed areas, with modifications to*:" ... (3) implement BMPs to protect foothill yellow-legged frog and California red-legged frog habitat when vegetation management activities occur within 300 feet of streams; (4) define protocols for any pesticide use that is deemed necessary within the project boundary and within 500 feet of known locations of foothill yellow-legged frog that avoid adverse effects on individuals and their habitats; (5) prohibit the use of pesticides within a 260-foot buffer around the mean high water mark of aquatic features; (6) avoid stockpiling and subsequent removal of any fuels, slash, or debris related to hazard tree removal within 1,000 feet of wetlands or aquatic features*."
    - Implement Yuba Water's proposed Recreation Facilities Plan (RFl), with modifications to: " ... (3) include footbridges over stream crossings and signs to make users aware of the sensitive nature of California red-legged frog habitat along the West Shoreline Trail; and (4) continue closure of Moran Road from October 15 to May 1 to protect the California red-legged frog from vehicle mortality."
    - Implement Yuba Water's proposed Aquatic Invasive Species Monitoring Plan (AR5) that includes measures for bullfrog suppression efforts in Moran Cove, which is located in California red-legged frog critical habitat. FERC included modifications to ensure procedures for decontaminating field equipment to prevent the spread of aquatic pests and disease, including chytrid, are applied to all activities where equipment is transported from one body of water to another.

Additional information about the ESA consultation process that has occurred between FERC and USFWS is provided in **Appendix 2D** of this DEIR.

2.4.1.10.2 NMFS

To date, FERC has not completed consultation with NMFS under Section 7 of the ESA for the YRDP. On September 18, 2020, FERC sent a letter to NMFS requesting initiation of formal consultation and submitted a BA that analyzed the potential effects of relicensing the Upper Drum Spaulding Hydroelectric Project, the Lower Drum Spaulding Hydroelectric Project, Deer Creek Hydroelectric Project, Yuba-Bear Hydroelectric Project, and the YRDP on California Central Valley (CCV) spring-run Chinook salmon, Central Valley (CV) steelhead, and the Southern DPS of North American green sturgeon, their designated critical habitat, and essential fish habitat

(EFH). FERC's 2020 BA did not include consideration of the Southern Resident Killer Whale (SRKW) DPS (see additional discussion below in Section 2.5.2.6).

NMFS responded to FERC on October 16, 2020 indicating that the materials submitted with FERC's consultation request did not adequately describe the proposed action with sufficient detail to assess the effects of the action on listed species and critical habitat consistent with the nature and scope of the proposed action and, thus, did not provide all information necessary to initiate formal consultation under the ESA. NMFS's letter stated that the YRDP and the YB/DS projects were identified as two of ten FERC-licensed projects in the CV that have the potential to affect salmon in the Bay-Delta. Consequently, NMFS contended that the action area described in FERC's BA excluded significant portions of the West Placer County Streams as well as the lower Feather River, lower Sacramento River, and the Sacramento-San Joaquin Delta where effects associated with all five relicensing projects may occur. NMFS also recognized that the SWRCB had not issued final CWA Section 401 WQCs for the Upper Drum-Spaulding (P-2310), Lower Drum (P-14530), and Deer Creek (P-14531) projects. Because the terms and conditions of the SWRCB's final WQCs are mandatory and will be incorporated into the final FERC licenses, NMFS (2020) stated that the WQCs must be included as a part of the proposed action. Without the SWRCB's final WQC terms and conditions, NMFS (2020) stated that there is significant uncertainty in the proposed action and the effects of the proposed action to listed species and critical habitat.

In a letter dated March 8, 2021, FERC requested from Yuba Water additional information to support FERC's preparation of a SEIS and a revised BA to complete FERC's ESA Section 7 consultation with NMFS for the YRDP. FERC is continuing to work on both the SEIS and revised BA, which presumably will address the potential effects of all five FERC relicensings in the upper Yuba River Watershed.

2.4.2 Proposed Narrows Project under New FERC License

In addition to the continued O&M of the existing Narrows Project facilities described in Section 2.3, the Narrows Relicensing Project includes:

1. Project-related changes proposed by Yuba Water;
2. Protective measures proposed by Yuba Water;
3. FERC-recommended modifications of Yuba Water's proposal and additional measures (if any); and
4. All mandatory terms and conditions (if any).

To date, no FERC-recommended modifications or additional measures to Yuba Water's proposal have been identified, and no FPA Section 4(e) Conditions have been recommended by the USFS or others.

This section describes: (1) the proposed Narrows Project facilities; (2) the proposed FERC Project Boundary for the Narrows Project; and (3) proposed Yuba Water changes to conditions in the existing FERC license for the Narrows Project. To date, no implementation plans have been proposed for the Narrows Project through the FERC relicensing process.

2.4.2.1 Proposed Narrows Project Facilities

Yuba Water does not propose any changes to existing Narrows Project works or facilities. Yuba Water proposes to continue to operate the Narrows Project in substantial conformance with existing operations, with minor modifications (see Section 2.4.2.3).

2.4.2.2 Proposed Narrows Project FERC Project Boundary

Yuba Water does not propose any changes to the existing FERC Project Boundary for the Narrows Project.

2.4.2.3 Proposed Yuba Water Changes to Conditions in the Narrows Project FERC License

As described in Section 2.3.2.6, the current FERC license for the Narrows Project includes 50 articles, of which Yuba Water considers Articles 14, 27, 28, 203, 401, 402, 404, 406, 407, 408, and 409 to be out-of-date. Yuba Water does not propose to include these, or articles similar to them, in the new license. Of the remaining articles in the current license, Articles 1 through 13, 15 through 26, 29 through 32, 201 through 204, are legal or administrative in nature. Yuba Water does not propose these but assumes that FERC would include them, or similar articles, if it chooses to do so in the Narrows Project's new license.

Articles 101 through 104 are USACE FPA Section 4(e) Conditions in the current license. Yuba Water does not propose them for the new license but expects FERC to include a standard article for existing projects at USACE dams requiring the licensee to enter into a Memorandum of Agreement with the USACE describing the detailed operation of the power facilities acceptable to the USACE.

For the Narrows Project, Yuba Water proposes to include, with some updates, the following four articles in the current license that replace Articles 402 and 411, 405, 403 and 410, respectively:

- Yuba Water's Narrows Project Proposed Condition 1, Supplemental Flows. This condition would continue the requirements of Article 402 and 411 where Yuba Water shall coordinate with the YRDP to develop a Water Release Plan to define how the two projects would coordinate operations and provide flows to the lower Yuba River. The Water Release Plan shall include a provision that releases from the Narrows Project Powerhouse up to 730 cfs, the maximum release capacity of the powerhouse, would be provided to assist YRDP meet the minimum flow requirements at USGS gage station 11418000, Yuba River Below Englebright Dam Near Smartsville, CA, as specified in the YRDP FERC license.
- Yuba Water's Narrows Project Proposed Condition 2, Ramping Rates. This condition would continue the requirements of Article 405 where Yuba Water's releases from the Narrows 1 Powerhouse shall not result in a rate of change in streamflow greater than flow fluctuation limits required at USGS gage station 11418000, *Yuba River Below Englebright Dam Near Smartsville, CA*, in the license for the YRDP. When Englebright Dam is spilling, no ramping rate shall apply to releases from the Narrows 1 Powerhouse.

- Yuba Water's Narrows Project Proposed Condition 3, Fish Stocking. This condition would continue the requirement of Article 403 where Yuba Water shall provide annually up to 5,000 rainbow trout (half pound each) to be stocked in Englebright Reservoir. The number of fish to be stocked and timing and location of fish stocking shall be coordinated with CDFW.
- Yuba Water's Narrows Project Proposed Condition 4, Consult with SHPO and Affiliated Native American Tribes. This condition would continue the requirement in Article 410 where Yuba Water, before starting any land clearing, land-disturbing, or spoil-producing activities in areas in which Yuba Water has not previously conducted a cultural resources survey and consulted with SHPO and affiliated Native American Tribes, shall consult with SHPO and affiliated Native American Tribes and conduct a cultural resources survey of the affected areas.

In addition to the above four existing measures that Yuba Water proposes be included in the new license, Yuba Water proposes to include the following three new measures:

- Yuba Water's Narrows Project Proposed Condition 5, Water Surface Elevation in Englebright Reservoir. Yuba Water's operation of the Narrows Project within its reasonable control shall not cause Englebright Reservoir's WSE to be lower than an elevation of 514.0 ft unless necessary for the temporary protection of life, health, property or environmental resources. If Yuba Water's normal operations or direction from the USACE result in an Englebright Reservoir's WSE lower than 514.0 ft, Yuba Water shall notify the Commission as soon as possible but no later than 10 days after the variance occurs. Yuba Water's notification shall include the reason for and expected duration of the temporary variance.

- Yuba Water's Narrows Project Proposed Condition 6, Nesting Peregrine Falcon Protection. To the greatest extent feasible, Yuba Water would schedule Narrows Project vegetation clearing, ground-disturbing and loud noise-generating activities outside of the nesting bird season of January 1 through August 15 to avoid take of nesting American peregrine falcons (*Falco peregrinus*). If these activities cannot be avoided during the nesting bird season, Yuba Water would conduct an occupancy survey for the American peregrine falcon nest site located adjacent to the Narrows Project in the cliff complex below Englebright Dam across from and approximately 575-600 ft south-southeast of the Narrows 2 Powerhouse. Surveys would be conducted as described in *Protocols for Observing Known and Potential Peregrine Falcon Eyries in the Pacific Northwest* (Pagel 1992).

  Yuba Water would perform an initial visit of at least four continuous hours to the survey area to determine occupancy. If no evidence of occupancy is found during the survey, work may proceed. A determination that a potential nest site is not occupied can only be made after at least two visits are completed consisting of observation periods of four hours or more during each visit. Yuba Water would conduct a second visit (i.e., 25 to 30 days after the first visit) to confirm whether the potential nest site is occupied. If the nest is occupied, work would be postponed until the end of the nesting season, or when the nest is confirmed as abandoned or successful (per 14-day fledged period concluded). Work may continue if additional nest surveys demonstrate that the young have fledged, and the 14-day post fledge period has concluded.

- Yuba Water's Narrows Project Proposed Condition 7, Bat Management. Yuba Water would, in the first full calendar year after license issuance, document bat roosts and openings large enough to admit bats within the Narrows 1 Powerhouse and tram building. If bats, signs of roosting, or openings are present where staff have a routine presence (i.e., at least daily or weekly), Yuba Water would, where feasible, place humane exclusion devices to prevent occupation of the structure by bats.[51] Humane exclusion devices would be placed when bats are absent from the facility, generally between November 1 and February 28. If overwintering bats are present during the inspection, installation of humane exclusion measures shall be delayed. Prior to installation of the humane exclusion devices, Yuba Water shall perform an inspection of the facility to ensure that overwintering bats would not be trapped. When a new exclusion device is installed, the device would be inspected 6 months later to confirm effectiveness (i.e., no evidence of bat presence). All exclusion devices would be inspected on a biannual basis, and the facilities would be reevaluated for roosting bats and openings every 5 years to check that no new roosts or entry points have been established.

Refer to Appendix E2 in Exhibit E of Yuba Water's (2023a) FLA[52] for the complete text and rationale for each of the conditions Yuba Water proposes to include in the new license for the Narrows Project (YCWA 2023a).

None of Yuba Water's proposed conditions, if included in the new license, would materially alter Narrows Project operations that are summarized above and fully described in Exhibit B of Yuba Water's (2023a) FLA.[53] Therefore, the plots and descriptions of Narrows Project operations under Yuba Water's proposed conditions are not repeated here. Under the new license, Yuba Water would continue to market the electrical energy output of the Narrows Project by scheduling the energy output of the Narrows Project into the CAISO and market the capacity products, including Resource Adequacy and Renewable Energy Credits.

Yuba Water does not propose any changes to its current facility maintenance activities described in Section 2.3.2.4. Yuba Water also has no plans to change the period (typically 3 weeks during June or July) when planned annual outages are taken for maintenance purposes but may do so as long as the outage is not in conflict with any license terms or applicable laws or regulations.

2.4.2.4 FERC Staff Alternative Modifications, Section 4(e) Conditions, and Form L-5 Terms and Conditions for Narrows Project

To date, FERC has not recommended conditions for any new license that may be issued for the Narrows Project. Additionally, no FPA Section 4(e) terms and conditions for the Narrows Project have been identified by the USACE or USFS, or provided to FERC. If FPA Section 4(e) Conditions are provided to FERC by USACE and/or USFS, such mandatory conditions would become part of the new FERC license for the Narrows Project. As noted in Section 2.4.0.7, FERC's Form L-5 standard Terms and Conditions, specified in Appendix 2C, would be expected to be applicable to the Narrows Project as well as the YRDP.

[51] Bats will not be excluded from roosts discovered on the exterior of Narrows Project facilities.

2.4.2.5 Recommended CWA Section 401 Certification Conditions for New Narrows Project FERC License

On December 30, 2024, Yuba Water filed an application for a WQC with the SWRCB in support of Yuba Water's application for a new FERC license for the Narrows Project. After filing the request, Yuba Water received a confirmation email from the SWRCB that the application was received. In anticipation of filing the WQC application, Yuba Water and the SWRCB participated in a pre-filing meeting on October 10, 2024 consistent with the regulatory requirements in 40 C.F.R. §121.4.

The WQC application package for the Narrows Project that Yuba Water submitted to the SWRCB included background information and recommended findings for the WQC (**Appendix 2G**), which are included as part of the Narrows Relicensing Project that is evaluated in this DEIR.

2.4.2.6 Narrows Project Endangered Species Act Section 7 Consultation

To support the development of Yuba Water's FLA for the Narrows Project, Yuba Water searched several informational sources (e.g., the California Native Plant Society's (CNPS) database, CDFW's California Natural Diversity Database (CNDDB), USFWS's and NMFS's online database and recovery plans) to identify ESA-listed species that may be present in the project vicinity that could be affected by the Narrows Project. Based on these searches, Yuba Water identified a total of eleven ESA-listed species. The Narrows Project was visited on May 1 and May 21, 2020, for a focused plant survey and habitat assessment. No ESA-listed species were observed during either visit. Based on the May 2020 surveys and assessment, Yuba Water determined that the relicensing proposal for the Narrows Project would have no effect on most of the identified ESA-listed species.

As a result, Yuba Water concluded that only three ESA-listed species have a potential to be affected by Yuba Water's relicensing proposal for the Narrows Project, including spring-run Chinook salmon, steelhead, and the Southern DPS of North American green sturgeon. For both the Narrows Project and the YRDP relicensings, Yuba Water determined that the SRKW DPS would not be affected, as discussed below (YCWA 2023a).

According to NMFS (2024), potential impacts on the SRKW DPS may occur as a result of changes in the availability of SRKW preferred prey (i.e., Chinook salmon) in coastal waters where SRKWs may encounter Chinook salmon from the CCV. NMFS (2024) recognizes that available data and analyses do not currently support an analytical approach that statistically quantifies the effects of changes in Chinook salmon abundance to SRKW survival and recovery (i.e., mortality and reproduction). In the absence of a predictive analytical tool to evaluate this relationship, NMFS (2024) uses a weight-of-evidence approach to consider all of the information available to assess impacts on SRKW. Applying a similar approach, the SRKW DPS was dismissed from consideration in this DEIR for the following reasons.

- Although Chinook salmon reportedly make up approximately 20% of the SRKW diet from February through April, the contribution varies by stock and proportion in each of those months. The vast majority of Chinook salmon in the CV are non-ESA listed fall-run Chinook salmon and, to a lesser degree, non-ESA-listed late fall-run Chinook salmon and ESA-listed populations of CV spring-run Chinook salmon (NMFS 2024).

- For long-term operation of the CVP and SWP, relative to current CVP/SWP operations, NMFS (2024) reports that the change in Chinook salmon abundance in the ocean is estimated to be relatively small (less than 1% median estimate).

- Although there is reportedly a declining trend in Chinook salmon productivity in the CV, which is of concern to the long-term outlook for available prey resources for SRKWs, the overall productivity of the system currently depends heavily on modified hatchery release practices to minimize impacts from long-term CVP/SWP operations and other factors in the CV (NMFS 2024).

- NMFS (2024) concluded that long-term operation of the CVP and SWP will add further, albeit slight, reductions in adult ESA-listed and non-ESA-listed Chinook salmon available as prey to SRKWs to the declining trend. However, NMFS (2024) concluded that long-term operation of the CVP and SWP is not likely to appreciably reduce the likelihood of both the survival and recovery of the SRKW DPS. NMFS (2024) also determined that the effects of long-term CVP/SWP operations would not appreciably diminish the value of the critical habitat for the conservation of SRKWs.

As supported by the analyses conducted in Chapter 9 (Fisheries Resources) of this DEIR, neither YRDP relicensing operations nor Narrows Project relicensing operations would result in significant (or potentially significant) impacts to any run of Chinook salmon. Consequently, because the Proposed Projects would not affect the SRKW prey base, this DEIR does not further consider potential impacts to SRKW or its critical habitat. As previously discussed, the Narrows Project is unique in that it operates in coordination with the YRDP to provide flows to the lower Yuba River. In particular, the Narrows Project directly supports the PM&Es that were proposed for the YRDP that are being analyzed through FERC's ESA consultation with NMFS. It is due to this unique coordination and co-location of the Narrows 1 and Narrows 2 powerhouses that the studies, as well as the ESA consultation performed in support of the ongoing YRDP relicensing, are directly applicable to the Narrows Project FERC relicensing. For these reasons, Yuba Water believes there would be significant advantages to aligning post-application relicensing activities (in particular, FERC's NEPA analysis and Section 7 ESA consultation) for the Narrows Project with the relicensing activities for the YRDP. Because FERC has not yet completed consultation with USFWS or NMFS under Section 7 of the ESA for the Narrows Project, it is unknown whether additional ESA-related regulatory requirements will be identified for implementation of the Narrows Project as part of a new FERC license.

CHAPTER 3

ALTERNATIVES

This chapter provides a description of the alternatives considered in this DEIR, which are analyzed in each of the individual resource chapters (see Chapters 5-24) at a level that provides sufficient information about the environmental effects of each alternative for comparative purposes and to allow for informed decision-making. Chapter 25 provides a summary of the overall environmental impacts of the alternatives, compares how well the alternatives meet the YRDP and Narrows Project objectives, and identifies the environmentally superior alternative. Several other alternatives were considered, but because they were rejected from further consideration (see Section 3.6) they are not included in the comparison of alternatives.

3.1 Introduction

The California Code of Regulations (C.C.R.) Section 15126.6(a) (State CEQA Guidelines) requires EIRs to describe *"… a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives. An EIR need not consider every conceivable alternative to a project. Rather, it must consider a range of potentially feasible alternatives that will avoid or substantially lessen the significant adverse impacts of a project, and foster informed decision making and public participation. An EIR is not required to consider alternatives that are infeasible. The lead agency is responsible for selecting a range of project alternatives for examination and must publicly disclose its reasoning for selecting those alternatives. There is no ironclad rule governing the nature or scope of the alternatives to be discussed other than the rule of reason*." This section of the State CEQA Guidelines also provides guidance regarding what the alternatives analysis should consider. Subsection (b) further states the purpose of the alternatives analysis is as follows:

> Because an EIR must identify ways to mitigate or avoid the significant effects that a project may have on the environment (Public Resources Code [PRC] Section 21002.1), the discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives, or would be more costly.

The State CEQA Guidelines require that the EIR include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the Proposed Projects. If an alternative would cause one or more significant effects in addition to those that would be caused by the project as proposed, the significant effects of the alternative must be discussed, but in less detail than the significant effects of the project as proposed (C.C.R. Section 15126.6[d]).

The State CEQA Guidelines further require that a "no project" alternative be considered (C.C.R. Section 15126.6[e]). The purpose of describing and analyzing a no project alternative is to allow decision makers to compare the impacts of approving Proposed Projects with the impacts of not approving the Proposed Projects. If the no project alternative is the environmentally superior

alternative, CEQA requires that the EIR "…*shall also identify an environmentally superior alternative among the other alternatives*." (C.C.R. Section 15126.6[e][2]).

In defining "feasibility" (e.g., "… feasibly attain most of the basic objectives of the project …"), C.C.R. Section 15126.6(f) (1) states, in part:

> Among the factors that may be taken into account when addressing the feasibility of alternatives are site suitability, economic viability, availability of infrastructure, general plan consistency, other plans or regulatory limitations, jurisdictional boundaries (projects with a regionally significant impact should consider the regional context), and whether the proponent can reasonably acquire, control or otherwise have access to the alternative site (or the site is already owned by the proponent). No one of these factors establishes a fixed limit on the scope of reasonable alternatives.

In determining what alternatives should be considered in the EIR, it is important to consider the objectives of the project, the project's significant effects, and unique project considerations. These factors are crucial to the development of alternatives that meet the criteria specified in Section 15126.6(a). Although, as noted above, EIRs must contain a discussion of "potentially feasible" alternatives, the ultimate determination as to whether an alternative is feasible or infeasible is made by the lead agency's decision-making body—here, the Yuba Water Board of Directors (See PRC Sections 21081.5, 21081[a] [3]).

3.2 Alternatives Development Process

The range of alternatives considered and evaluated in this DEIR are the product of an extensive FERC relicensing process conducted for the YRDP (FERC 2019) that has included considerable public input and involvement. The FERC relicensing process for the YRDP has spanned over a decade and involved multiple studies and resource planning efforts. The planning efforts considered a wide variety of factors, including the feasibility of implementation and opportunities for reducing potentially significant environmental impacts while meeting the Proposed Projects' CEQA objectives. As described in Chapter 2, the Proposed Projects include a suite of PM&Es (including the 21 YRDP implementation plans) that were pro-actively developed and agreed upon by FERC, Yuba Water and other Relicensing Participants to address concerns about potential environmental impacts of the Proposed Projects that were raised during the FERC relicensing process. Therefore, the YRDP and Narrows Project relicensings are generally improving conditions, relative to the Existing Condition. Nevertheless, due to the nature of the Proposed Projects, the potential does exist for potentially significant impacts to occur. For this reason, as well as to provide additional information that has been requested to help inform the decision-making processes of FERC and the SWRCB, this DEIR identifies and evaluates several alternatives to the Proposed Projects.

3.2.1 Alternatives Overview

This DEIR evaluates three alternatives to the Proposed Projects:

- No Project Alternative
- Alternative 1 – Yuba Water's October 31, 2022 Offer of Settlement for the YRDP
- Alternative 2 – SWRCB Draft Bay-Delta Plan Update Regulatory Pathway Scenario

The analysis of the No Project Alternative addresses two potential No Project scenarios: (1) Yuba Water does not accept new licenses for either the YRDP or the Narrows Project; and (2) Yuba Water does not accept a new license for the Narrows Project. Additional information about the No Project Alternative is provided in Section 3.5 below.

Both Alternative 1 and Alternative 2 include operational changes for the YRDP specifically; however, because YRDP and Narrow Project operations are coordinated, the analysis of these alternatives also is relevant for both Proposed Projects.

3.3 Alternative 1 (Yuba Water's October 31, 2022 Offer of Settlement for the YRDP)

Yuba Water developed Alternative 1 as a proposal for the YRDP and upstream projects to equitably allocate water to provide cooler water temperatures in the lower Yuba River for federally listed species protection from July through November. Alternative 1 proposes to reoperate the release of 15,600 acre-ft of additional flow from the YB/DS projects[1] during Dry and Critically Dry years, but this reoperation would only be possible if water is made available by the YB/DS projects – which is subject to approval of a new license term by FERC.

On March 8, 2021, FERC sent Yuba Water an Additional Information Request (AIR) to inform FERC staff's analysis in a supplemental EIS and to prepare a revised biological assessment for Yuba Water's YRDP (FERC Project No. 2246) (FERC 2021). The AIR's Item 3 requested that Yuba Water evaluate options for the equitable allocation of water to provide cooler water temperatures in the lower Yuba River at times by consulting with the Pacific Gas & Electric Company (PG&E) (Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310) and Lower Drum Hydroelectric Project (FERC Project No. 14530)) and Nevada Irrigation District (NID) (Yuba-Bear Hydroelectric Project (FERC Project No. 2266) and Deer Creek Hydroelectric Project (FERC Project No. 14531)) and developing an agreed-upon analysis of the amount of additional water from either storage or transfers necessary in Dry and/or Critically Dry years (or combination of dry type years) to maintain cooler water in the lower Yuba River for federally listed species protection from July through November. FERC also sent coordinated AIRs to NID and PG&E on March 8, 2021. Yuba Water developed its Offer of Settlement in response to FERC's AIR Item 3 within the context of FERC's coordinated request to Yuba Water, NID and PG&E.

To identify potential actions to address FERC's goal of providing cooler water temperatures from July to November in the lower Yuba River during Dry and Critically Dry years, a multi-step process was undertaken by Yuba Water (2022). One of these steps was an examination of the

[1] This DEIR uses the term "YB/DS projects" to refer to four other FERC relicensing projects located in the upper Yuba River Watershed, which include: (1) NID's Yuba-Bear Hydroelectric Project (FERC Project No. 2266); and (2) PG&E's Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310), Lower Drum Hydroelectric Project (FERC Project No. 14531) and Deer Creek Hydroelectric Project (FERC Project No. 14530).

magnitude and frequency of occurrence of water temperatures in the lower Yuba River over the July to November period. Based on evaluations of water temperature exceedance distributions for the Proposed YRDP Project (FERC Staff Alternative) with operations to the 4(e) flows for NID and PG&E's YB/DS projects, and Base Case scenarios for the 48-year period of simulation used in the AIR analysis, as well as separately for the 15 Dry and Critically Dry water years, the identification and development of actions to improve water temperatures in the lower Yuba River primarily focused on reducing water temperatures during the early portion of the spring-run Chinook salmon spawning and incubation period (i.e., September and October), and secondarily focused on the remaining portion of the July through November period.

Another of the steps undertaken in the process of identifying water temperature enhancement actions was examination of mechanisms driving water temperatures in the lower Yuba River. This step, in particular, led Yuba Water to identify non-flow actions that directly address identified mechanisms affecting water temperatures in the lower Yuba River. Consequently, both non-flow and flow actions were included in Yuba Water's proposed Offer of Settlement to FERC, which is presented in this DEIR as Alternative 1. These non-flow and flow actions are an integrated suite that, when collectively implemented, would achieve a water temperature regime that is protective of ESA-listed fish species.

On October 31, 2022, Yuba Water submitted a Technical Memorandum (TM) to FERC along with this proposed "Offer of Settlement." This TM, which provides additional information about this process and history and documents Yuba Water's previous determination that the proposal would equitably benefit ESA-listed fish and their critical habitat, is included in **Appendix 3A** of this DEIR.

Alternative 1 includes an integrated suite of measures to be implemented by Yuba Water, PG&E, and NID, in coordination with each other, for Yuba Water's YRDP, PG&E's Upper Drum-Spaulding Project, Lower Drum Project, and Deer Creek Project, and for NID's Yuba-Bear Project. Alternative 1 proposes to reoperate the release of 15,600 acre-ft of additional flow from the YB/DS projects during Dry and Critically Dry years, but this reoperation would only be possible if water is made available by the YB/DS projects – which is subject to approval of a new license term by FERC. Because Yuba Water cannot impose operational changes on PG&E's and NID's upstream projects, Alternative 1 is a conditional alternative that is subject to FERC's acceptance and implementation.

Alternative 1 would include all non-flow components of the Proposed Projects and all Narrows Project operations under the Proposed Projects. These are described in Section 2.5.1 (Proposed YRDP under New FERC License) and Section 2.5.2 (Proposed Narrows Project under New FERC License) of Chapter 2 and are not repeated here. Compared to the Proposed Projects, Alternative 1 includes modifications to YRDP operations and additional non-flow measures.

Specifically, Alternative 1 includes two non-flow components and two flow components, to be implemented as an integrated suite of actions by Yuba Water in coordination with PG&E and NID, consistent with proposed license conditions in new licenses issued by FERC. These are described below.

- **New Bullards Bar Dam (NBBD) Dual Intake (Yuba Water Proposed Measure AIR-1):** Yuba Water would use the upper intake at NBBD during the spring (March, April, and May) and NBBD's lower intake the remainder of the year. To implement this non-flow action (referred to as the NBBD Dual Intake), Alternative 1 would include the following proposed license condition for the YRDP:

  Beginning the first full calendar year of the new license term, Licensee shall open the upper intake for New Colgate Powerhouse and close the lower intake within the first five days of March. The upper intake will remain open during the months of March, April and May, and the upper intake will be closed and the lower intake will be opened at a time determined by Licensee during the last five days of May. The upper intake will remain closed until the following March. The schedule will be repeated each year unless the water surface elevation of New Bullards Bar Reservoir falls below elevation 1881.0 ft msl (648,800 acre-feet) between March and May, at which time the upper intake will not be used. In consultation with CDFW and NMFS, Licensee may propose to delay the starting date and implement an earlier ending date for utilization of the upper intake for improving water temperature conditions in the lower Yuba River. If supported by CDFW and NMFS, Licensee may adjust the period for use of the upper intake. The shutter system covering the upper intake at the face of New Bullards Bar Dam will not be used for this operation.

- **Englebright Variable Water Surface Elevation (WSE) (Yuba Water Proposed Measure AIR-2):** Yuba Water would manage flows into and out of USACE's Englebright Reservoir to increase the target water surface elevation from 519 ft msl to 525 ft msl from August 25 through September 10, maintaining the target elevation of 525 ft. msl through October 15, and implementing an October 16-31 ramp-down. To implement this non-flow action, Alternative 1 would include the following proposed license condition for the YRDP:

  Beginning the first full calendar year of the new license term, in Dry or Critically Dry year types as defined by the Smartsville Index, Licensee shall increase the targeted water surface elevation of Englebright Reservoir from the normal operating range of 516 to 523 ft. msl to a target elevation of 525 ft msl by gradually increasing the target range starting August 25 and achieving the target elevation of 525 ft. msl by September 10, maintaining a target elevation of 525 ft msl until October 15, and then ramping down from October 16 to October 31. For this condition, targeting an Englebright Reservoir elevation of 525 ft. msl means making a reasonable attempt to hold the water surface elevation above 523 ft msl, and not exceeding 526.5 ft msl. The target elevation will not apply any time that: (1) a California Independent System Operator Energy Emergency is in effect; (2) a similar emergency is declared by an entity with responsibility for management of northern California's electrical grid; or (3) an electrical or grid emergency proclamation of the Governor of California is in effect.

  During years that are not Dry or Critically Dry, but Licensee determines that mean daily water temperatures as measured at the Smartsville Gage (USGS

stream gage 11418000) may exceed 56 degrees Fahrenheit anytime during September or October, Licensee in consultation with CDFW and NMFS may use the target water surface elevation of 525 ft. msl described in this condition to improve water temperature conditions in the lower Yuba River.

- **Upstream Flow Contribution for Water Temperature Improvement for ESA-Listed Species in the Lower Yuba River (YB/DS Proposed Measure):** The YB/DS projects would collectively release an additional 15,600 acre-feet of water in Dry or Critically Dry years, for reregulation and release by Yuba Water into the lower Yuba River during September 1 through October 15. NID and PG&E would decide among themselves how to allocate responsibility for the additional 15,600 acre-feet. To implement this flow action, Alternative 1 would include the following proposed license condition for the YB/DS projects:

  For the purpose of improving water temperatures in the lower Yuba River for fish listed under the Endangered Species Act, Licensees of Projects Nos. P-2266, P-2310, P-14530 and P-14531 collectively shall release 15,600 acre-feet during Dry or Critically Dry water years (that are not extreme Critically Dry years) as defined by water year types of the Yuba-Bear and Drum-Spaulding Projects that is above the minimum streamflows of these projects' licenses. Licensees shall release that water at as even a rate as possible over about 30 days, but not extending past May 10, starting immediately after the California Department of Water Resources or a successor agency releases its April version of its Bulletin 120 (or a successor hydrologic forecast) that identifies the relevant year as a Dry or Critically Dry year. As expeditiously as possible during each Dry or Critically Dry Year, Licensees shall inform Yuba County Water Agency, the licensee for Project No. 2246, of the rate at which they will make their releases and the locations from which they will make their releases. Licensees of Projects Nos. P-2266, P-2310, P-14530 and P-14531 shall consult with one another as frequently as necessary to determine how to operate their respective projects to satisfy this license term and shall inform the Commission promptly of how they will allocate responsibility among themselves for meeting this term. The Licensees may determine their respective responsibilities under this license term on an annual or multi-year basis as they collectively deem appropriate.

- **175 cfs Flow Action (Yuba Water Proposed Measure AIR-3):** As noted above, the Yuba-Bear and Drum-Spaulding Projects would collectively provide 15,600 acre-ft of water during April and early May of Dry and Critically Dry years. Yuba Water would release this water to provide increased flows of 175 cfs to the lower Yuba River from September 1 through October 15 during those year types. To implement this flow action, Alternative 1 would include the following proposed license condition for the YRDP:

  Beginning the first full calendar year of the new license term, in Dry or Critically Dry year types that are not Extreme Critically Dry years as defined by water year types of the Yuba-Bear and Drum-Spaulding Projects, Licensee shall determine the additional volume of flow released during April 1 through

May 10 by the Yuba-Bear Project and the Drum Spaulding Project licensees for the purpose of lower Yuba River temperature reduction, not to exceed a total volume of 15,600 acre-feet that is above the minimum streamflows of those licensees. Licensee will operate Project No. 2246 so that, in order to improve water temperatures for listed fish, it releases an equivalent amount of water over the period of September 1 to October 15 as an increase in the minimum streamflow downstream of Narrows 2 Powerhouse as measured at the Smartsville Gage (USGS stream gage 11418000) and Marysville Gage (USGS stream gage 11421000).

Within 90 days of issuance of a new license, Licensee shall submit a plan defining how Licensee will calculate the amount of additional volume released by the upstream licensees for this condition.

As stated above, Alternative 1 is a conditional alternative that would require FERC's acceptance and implementation, including the license amendments proposed for the other FERC projects. All of the Yuba Water and non-Yuba Water components of Alternative 1 are included in this DEIR because each component is a necessary part of the integrated suite of proposed actions. At this time, Yuba Water cannot forecast whether or not FERC will accept the Offer of Settlement, or whether FERC would include the "YB/DS Proposed Measure" described as part of new licenses for the YB/DS projects. Moreover, Yuba Water cannot impose the operations described in the "YB/DS Proposed Measure" on any other party (i.e., the YB/DS projects).

For these reasons, this DEIR evaluates indirect impacts of Alternative 1 associated with the flow contributions from the YB/DS projects at a programmatic level, based on the information that is currently available to Yuba Water and reasonably foreseeable assumptions about how those non-Yuba Water operations would occur to meet Federal and California regulatory requirements. The YB/DS relicensings are also subject to their own CEQA review process. To the extent that YB/DS operations under new FERC licenses would have impacts that are outside the scope of those disclosed in this EIR or in the CEQA document(s) prepared by NID or PG&E for the new YB/DS FERC licenses, those impacts will need to be addressed through subsequent project-level CEQA review before NID and PG&E accept the new licenses. That CEQA review may incorporate information from this EIR and other relevant CEQA documents, as appropriate.

This DEIR fully evaluates the impacts of Alternative 1; however, at this time, Yuba Water cannot forecast whether FERC would approve Alternative 1 and include the above proposed conditions in new licenses for the YRDP and the YB/DS projects.

3.4 Alternative 2 - SWRCB Draft Bay-Delta Plan Update Regulatory Pathway Scenario

Yuba Water developed Alternative 2 in response to comments from the SWRCB on the NOP for this DEIR (see Appendix 1B).

For many years, the SWRCB has been considering potential amendments to the Water Quality Control Plan (WQCP) for the San Francisco Bay/Sacramento-San Joaquin Delta Watershed. For example, in July 2018, the SWRCB staff released a "*Framework for the Sacramento/Delta Update to the Bay-Delta Plan*" (SWRCB 2018) which included, among other proposals, proposed water

quality objectives under which: (1) the minimum streamflows in all Sacramento River basin tributaries of the Delta would be required to be in an "adaptive range between 45% and 65% of unimpaired flow," with a default standard of 55% of unimpaired flow; and (2) those tributaries also would need to be managed to "*maintain stream flows and reservoir storage . . . to protect cold water habitat for sensitive fish species, including Chinook salmon, steelhead and sturgeon*."[2] In September 2023, the SWRCB released a draft staff report (DSR) as a draft substitute environmental document (SED) under CEQA to analyze the environmental and economic effects of, among other things, the implementation of the 2018 framework's proposed water quality objectives.[3,4] In keeping with these documents, in its December 2, 2024 comments on Yuba Water's NOP for this DEIR, the SWRCB requested representing implementation of the Draft Bay-Delta Plan Update "regulatory pathway" in the Yuba River Watershed.

On October 25, 2024, the SWRCB issued a draft of the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Watershed (Draft Bay-Delta Plan Update) consistent with its 2018 framework and 2023 DSR.[5] According to the SWRCB, the Draft Bay-Delta Plan Update "regulatory pathway" is ultimately intended to provide benefits to the Sacramento-San Joaquin Delta (Delta). The DSR (SWRCB 2023) asserted that, by providing higher flows to support a connected and functioning ecosystem and benefit native fish in the Sacramento Valley and the Delta, the Draft Bay-Delta Plan Update would be expected to improve conditions for native fish and wildlife in the Sacramento Valley and the Delta over time.[6]

Relative to the Proposed Projects, the SWRCB Draft Bay-Delta Plan Update involves an entirely separate process that affects the entire Central Valley of California and is not specific to the FERC relicensing of the YRDP or the Narrows Project, or the issuance of new FPA licenses by FERC. For that reason, Alternative 2, which evaluates Yuba Water's compliance with a possible future "regulatory pathway" Draft Bay-Delta Plan Update (as opposed to Yuba Water's attempts to accomplish the objectives for the Proposed Projects discussed in Chapter 2), is not the type of alternative to the Proposed Projects that CEQA would ordinarily require. However, because Yuba Water has been and remains involved in supporting the Draft Bay-Delta Plan Update process, this DEIR includes an analysis of Alternative 2 to provide insight into the potential impacts associated with a possible future "regulatory pathway" SWRCB Draft Bay-Delta Plan Update.

If the SWRCB adopts a "regulatory pathway" that involves a 55% unimpaired flow requirement for the Bay-Delta Plan Update, then it is anticipated that the SWRCB would seek implementation of the 55% unimpaired flow requirement through the WQCs that would be issued for the FERC relicensings that are occurring in the upper Yuba River Watershed. FERC has stated that it will be conducting the YRDP, Narrows, and YB/DS relicensings as a basin-wide proceeding. Therefore, if a 55% unimpaired flow requirement were part of the "regulatory pathway" adopted by the

4 https://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/docs/2024/drft-sacdelta-bdplan-updates.pdf

5 https://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/docs/2024/drft-sacdelta-bdplan-updates.pdf

6 In January 2024, Yuba Water and many others submitted comments on the DSR that, among other things, documented that the unimpaired flow-based minimum streamflow standards proposed by the 2018 framework and discussed in the DSR would be unlikely to actually benefit many native fish species due to, among other impacts, their impacts on water temperatures.

SWRCB as part of the Bay-Delta Plan Update, it would be reasonable to expect that all of the FERC relicensing projects (i.e., YRDP, Narrows Project and the YB/DS projects) would be required to operate in accordance with the conditions of the new FERC licenses (including the 4(e) flow requirements) that would be in effect, and conduct operations necessary to comply with a 55% unimpaired flow requirement.

Moreover, because implementation of the SWRCB Draft Bay-Delta Plan Update would apply not only to Yuba Water, but also to many other entities throughout the Sacramento Valley (including those that manage the CVP and the SWP), it would be speculative to make operational assumptions about how the SWRCB Draft Bay-Delta Plan Update could be implemented throughout the system (e.g., Feather River, Sacramento River, Delta). Since 2019, only two approaches to modeling how the SWRCB Draft Bay-Delta Plan Update could be implemented have been undertaken by the state. More recently, many conditions have changed and the SWRCB Draft Bay-Delta Plan Update continues to evolve as a result of the SWRCB's ongoing process (SWRCB 2025). Thus, while this DEIR explores how changed YRDP operations as part of the SWRCB Draft Bay-Delta Plan Update would be expected to affect flows in the lower Yuba River, the analysis does not speculate about how the SWRCB Draft Bay-Delta Plan Update might be implemented at the statewide level.

For the above reasons, this DEIR's inclusion of Alternative 2 differs from the more typical CEQA approach of evaluating only those alternatives to a proposed project that could feasibly attain most of the basic project objectives while also avoiding or substantially lessening potentially significant project impacts. During the scoping process, Yuba Water determined that Alternative 2 would not meet either of these criteria. Nevertheless, this DEIR identifies and evaluates Alternative 2 for the sole purpose of providing additional information requested by the SWRCB.

Alternative 2 would include all non-flow components of the Proposed Projects. Similarly, Alternative 2 includes the same modeled operational assumptions as the Proposed Projects, including FERC's (2019) FEIS flow requirements in the North Yuba, Middle Yuba, and Yuba rivers that will become part of a new license for the YRDP and use of the variable-elevation intake for the New Colgate Powerhouse. These are described in Chapter 2 and are not repeated here. The YRDP and Narrows Project would be operated in a manner consistent with all applicable requirements of the current Bay-Delta water quality control plan (Bay-Delta WQCP) (CVRWQCB 2019).

Compared to the Proposed Projects, Alternative 2 includes modifications to YRDP and Narrows Project operations (as well as similar operational changes to the upstream YB/DS projects under new FERC licenses) to comply with the following additional regulatory requirements under the SWRCB Draft Bay-Delta Plan Update:

- A requirement to provide 55% of the unimpaired Middle Yuba River[7]
- A requirement to provide 55% of the unimpaired South Yuba River flow[8]

[7] The Draft Bay-Delta Plan Update does not specify where the compliance location is to be located on the Middle Yuba River or the South Yuba River except for a general note that states where available existing stream gage locations would be used. The Middle Yuba River does not have a stream gage near the confluence with the Yuba River, but for modeling purposes the confluence is used.

[8] The compliance location for the South Yuba River is assumed to be located at the USGS Jones Bar stream gage location.

- A requirement to provide 55% of the unimpaired Yuba River flow at its confluence with the Feather River
- A minimum end-of-September New Bullards Bar Reservoir storage of 600 TAF in Wet, Above Normal, and Below Normal years
- A minimum end-of-September New Bullards Bar Reservoir storage of 400 TAF in Dry and Critical years

Given the lack of operational specificity in the SWRCB Draft Bay-Delta Plan Update regulatory pathway, Alternative 2 includes a representative operational scenario that could be implemented in response to the SWRCB Draft Bay-Delta Plan Update. This scenario includes the following:

- NID operations to provide the greater of 55% of unimpaired Middle Yuba River flows above Our House Dam on a daily basis or the YB project's FERC 4(e) requirements.
- Yuba Water operations to provide 55% of unimpaired Middle Yuba River flow at its confluence with the North Yuba River. Yuba Water would bypass flows at Our House Dam, as needed, to ensure 55% of the total Middle Yuba River watershed unimpaired flow reaches its mouth on a 21-day rolling average.[9]
- NID and PG&E operations of the YB/DS projects to provide the greater of 55% of the unimpaired South Yuba River flow at Jones Bar on a daily basis or their respective FERC 4(e) requirements.
- Yuba Water operations to provide the greater of 55% of the total Yuba River unimpaired flows at the Marysville gage on a 21-day rolling average[10] or the FERC (2019) FEIS-evaluated flows that will be part of a new license for the YRDP, whichever is greater. Yuba Water would not induce spills at New Bullards Bar Dam to meet the 55% unimpaired flow requirement, but it would spill Englebright Dam, if necessary and within its capability. Agricultural surface water supplies would be curtailed, as necessary, to meet the 55% of the unimpaired flow at the Marysville Gage.

[9] The SWRCB Draft Bay-Delta Plan Update regulatory pathway default implementation includes a requirement "r*equiring a year-round minimum flow level of 55 percent of unimpaired flow on a minimum 7-day running average*" (SWRCB 2024, p. 51). Yuba Water has previously provided comments to the SWRCB in response to the Draft Bay-Delta Plan Update stating the requirement for a 7-day running average is not operationally achievable. The Draft Bay-Delta Plan Update also includes an adaptive implementation provision to "o*ptimize flows to benefit native fish and wildlife while also minimizing water supply impacts*" (SWRCB 2024, p. 54). For simulation of Alternative 2, a 21-day running average was selected as an adaptive implementation to simulate compliance while attempting to minimize flow fluctuations that could impact fish and to minimize short term, high flow requirements that would require limiting water supply deliveries due to limited release capacity at New Colgate Powerhouse.

[10] See previous footnote.

- Yuba Water would curtail agricultural surface water supply deliveries, as necessary, to meet the 600 TAF carryover storage requirement in New Bullards Bar Reservoir in Wet, Above Normal, and Below Normal years, as defined by the SWRCB's Decision 1641 Sacramento Valley Index (SVI).
- In SVI Dry and Critical years, Yuba Water would continue curtail agricultural surface water deliveries, as necessary, to meet its existing carryover storage requirement of 440 TAF in the first dry or critical year of a sequence, and 400 TAF in subsequent dry or critical years.

Because the only differences between the Proposed Projects and Alternative 2 are flow-related, the narrative characterization of Alternative 2 above focuses on the flow-related operational changes that would occur under Alternative 2. This characterization informs the hydrologic modeling scenarios used to quantitatively evaluate Alternative 2 in this DEIR. For additional information, see Chapter 4, Framework for the Environmental Analysis.

3.5 No Project Alternative

As described in Section 15126.6(e)(2) of the CEQA Guidelines, the No Project Alternative shall discuss the existing conditions at the time the NOP is published, or if no NOP is published, at the time environmental analysis is commenced, as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services.

Under the No Project Alternative, there are two variants of how potential future conditions could be characterized: (1) Yuba Water would not accept the new 50-year FERC licenses for the YRDP and the Narrows Project; or (2) Yuba Water would not accept the new FERC license for the Narrows Project, but would accept the new FERC license for the YRDP. Operations under the second potential scenario would be similar to Proposed Projects operations. Related to the first potential scenario, Yuba Water also would not be able to obtain one-year FERC licenses for either the YRDP or the Narrows Project under the No Project Alternative. Yuba Water would continue to operate the YRDP and Narrows Project facilities, excluding the power generating facilities, outside of FERC jurisdiction as water supply facilities (i.e., no electricity generation facilities) and for flood management purposes. No new environmental PM&E measures would be implemented. Anticipated YRDP and Narrows Project operations under the No Project Alternative would be as follows.

Areas Upstream of Englebright Reservoir

Upstream of USACE's Englebright Reservoir, flow and water temperature conditions under the No Project Alternative generally would be similar to those that occur under the CEQA Baseline (Existing Condition) with the following exceptions:

- In the absence of power generation under the No Project Alternative, there would be no peaking operations at the YRDP's Colgate Powerhouse. Because YRDP operations under the No Project Alternative would not include Colgate Powerhouse peaking operations, this would result in reduced fluctuations of Yuba River inflows into Englebright Reservoir and Englebright Reservoir water surface elevations, relative to the CEQA Baseline (Existing Condition).
- The only difference in operations relative to the CEQA Baseline (Existing Condition) would be minor hourly and intraday variation releases from the Colgate Powerhouse into the Yuba River reach that flows into Englebright Reservoir. However, these small flow and water temperature changes would be equalized in Englebright Reservoir and would not result in changes downstream in the lower Yuba River.[11]
- Without peaking at the YRDP's Colgate Powerhouse, there would essentially be a constant flow of water into Englebright Reservoir, so the weekly fluctuations in reservoir storage (normally about 8 ft with peaking occurring) would not occur under the No Project Alternative.

Lower Yuba River

Downstream of USACE's Englebright Reservoir, flow and water temperature conditions in the lower Yuba River under the No Project Alternative would be the same as flows and water temperatures under the CEQA Baseline (Existing Condition). As described above, changes in flow and water temperature conditions upstream of USACE's Englebright Reservoir would not occur except for relatively minor intra-day variation in releases between New Colgate Powerhouse and Englebright Reservoir. Downstream of USACE's Englebright Dam, conditions in the lower Yuba River under the No Project Alternative would be identical to the CEQA Baseline (Existing Condition). For these reasons, the No Project Alternative is not quantitatively evaluated as a modeled comparative scenario in this DEIR. For certain resources, potential effects of the No Project Alternative compared to the CEQA Baseline (Existing Condition) are qualitatively discussed, as appropriate.

Other Considerations

Hydropower Generation

In the absence of a hydropower license from FERC under the No Project Alternative, the YRDP and the Narrows Project would discontinue hydropower generation operations. Thus, these projects would no longer be able to provide hydroelectric generation to meet part of California's power requirements, resource diversity, and capacity needs. Consequently, the non-operation of YRDP and the Narrows Project facilities for hydropower generation purposes, particularly the YRDP's New Colgate Powerhouse, would result in a reduction in available power supplied to the California grid, as well as a reduction in the operational flexibility of the grid by CAISO.

[11] The changes described above for the No Project Alternative are not reflected in the flow and water temperature modeling due to differences in the routing of water not being represented in the modeling outputs (e.g., essentially the same flows result in the lower Yuba River). However, the changes anticipated under the No Project Alternative are discussed qualitatively in Chapter 5 (Surface Water Resources).

The elimination of YRDP and Narrows Project energy generation capabilities[12] would also eliminate Yuba Water's ability to market power and obtain hydropower revenues that have historically been reinvested back into Yuba County to improve flood management, water supply reliability and overall economic conditions, as well as funding important community-based initiatives (e.g., Community Impact Grant and Loan Program, Watershed Resilience and Forest Health Projects), watershed education programs, recreational opportunities and environmental restoration projects in the lower Yuba River. Because Yuba Water would no longer benefit from the revenue generated from power sales, Yuba Water's water customers also would likely be affected. Furthermore, Yuba Water's debt that is being used to fund the FERC relicensing efforts is secured with hydropower revenue. If revenue could not be obtained from the Proposed Projects, this would also be expected to put a financial burden on Yuba Water's water customers.

Federal Power Act License Acceptance – Alternative Characterizations of the No Project Alternative

Although the description of the No Project Alternative provided above assumes that Yuba Water would not accept new FPA licenses issued by FERC for both the YRDP and the Narrows Project, the potential does exist for other circumstances in which Yuba Water may choose to accept a new FPA license for one FERC project but not for the other FERC project. The potential circumstances that could occur under the No Project Alternative with respect to Yuba Water's non-acceptance of the pending new FPA licenses to be issued by FERC are discussed below.

- **No Project Alternative (FPA Scenario A) – Yuba Water accepts the conditions associated with a new FPA license for the YRDP, but not for the Narrows Project.**

  Under this characterization of the No Project Alternative, Yuba Water could decide to accept the conditions associated with a new FPA license for the YRDP, but not for the Narrows Project. Under these circumstances, Yuba Water would be able to meet specified regulatory requirements regarding lower Yuba River instream flows and continue to achieve various components of the agency's mission to provide a source of hydroelectric power, flood risk reduction, and water supplies for both domestic and irrigation purposes, as well as providing benefits for recreation, fish and wildlife habitat.

  Under a No Project Alternative where Yuba Water decides to accept the conditions associated with a new FPA license for the YRDP, but not for the Narrows Project, the full release capacity of the Narrows Project tunnel and outlet works might still be used to coordinate with the YRDP, augment flows from the Narrows 2 Powerhouse and provide release capabilities to meet required downstream flows if the Narrows 2 Powerhouse and bypasses were not available, such as a tunnel outage. The release capacity at the Narrows Project might also be slightly lowered to only the bypass capacity of 530 cfs versus the full capacity of the Narrows Project of 730 cfs. There are a range of options for releases of water from the remaining facilities of the Narrows Project if Yuba Water decided not to accept a new license for the Narrows Project, but all the most likely options would be either no reduction, or relatively small reductions in release capacity and a change in release point. Any water that would have been released from the Narrows Project operations would

[12] Details regarding the potential environmental consequences resulting from the elimination of energy and revenue generation under the No Project Alternative are discussed in each of the individual resource chapters, as appropriate.

be released instead through Narrows 2 Powerhouse, or bypasses, or spilled at Englebright Dam. Flows to the lower Yuba River, release temperatures from Englebright Reservoir or storage levels in Englebright Reservoir would not materially change. The only major change would be a loss of qualifying small hydropower renewable power sold by Yuba Water as the Narrows Project is classified as a renewable energy small hydropower facility.

- **No Project Alternative (FPA Scenario B) – Yuba Water accepts the conditions associated with a new FPA license for the Narrows Project, but not for the YRDP.**

  Under this characterization of the No Project Alternative, Yuba Water could decide to accept the conditions associated with a new FPA license for the Narrows Project, but not for the YRDP. Under these circumstances, however, it would not be feasible for Yuba Water to continue to meet many of its core responsibilities associated with the agency's mission (see Section 1.2.1). Although operational coordination between the Narrows Project and the YRDP would continue, the resultant environmental consequences under this type of a scenario (i.e., a FPA license for the Narrows Project but not for the YRDP) would be the same as the conditions that would be anticipated if Yuba Water could not accept new 50-year FERC licenses for both the YRDP and the Narrows Project. For example, the hydropower revenues generated by the Narrows Project alone would not be sufficient to maintain the existing infrastructure of Yuba Water facilities, nor would they be sufficient to continue to support all of the other Yuba Water activities that have historically been supported by revenues from the YRDP, including benefits provided to recreation and for environmental purposes. Many other community-based activities (e.g., infrastructure expansion, education and workforce development, tourism and visitor services, community improvement grants, regional technology improvements, etc.) that Yuba Water actively supports would no longer be fiscally possible. Consequently, this version of a No Project Alternative scenario is not feasible because such a construct would make it impossible for Yuba Water to fulfill many of the core commitments described in its mission statement – primarily to provide sustainable management of water resources in support of the environment and quality of life for Yuba Water's communities.

3.6 Alternatives Considered but Eliminated from Detailed Analysis

One of the purposes of this DEIR is to identify and analyze a reasonable range of alternatives that could feasibly achieve most of the basic project objectives but avoid or substantially lessen any of the significant impacts of the Proposed Projects. Each of the alternatives considered below was eliminated from further consideration in this DEIR for the reasons described below.

3.6.1 YRDP Alternatives Considered but Eliminated by FERC

For NEPA compliance purposes, FERC considered the following two alternatives to Yuba Water's proposal in the 2019 FEIS but eliminated them from further analysis because FERC determined that they "*are not reasonable in the circumstances of this case*" (FERC 2019, p. 2-42).

- Issue a Non-Power License[13] - FERC (2019, p. 2-42 to 2-43) stated "*A non-power license is a temporary license that the Commission will terminate when it determines that another governmental agency [not Yuba Water] will assume regulatory authority and supervision over the lands and facilities covered by the non-power license. At this point, no agency has suggested a willingness or ability to do so. No party has sought a non-power license and we have no basis for concluding that the project should no longer be used to produce power. Thus, we do not consider issuing a non-power license a reasonable alternative to relicensing in this circumstance*."
- Retire the Project - FERC (2019, p. 2-43) stated that "*Project retirement could be accomplished with or without dam removal. Either alterative would involve denial of the relicense application and surrender or termination of the existing license with appropriate conditions. No participant has suggested that dam removal would be appropriate in this case, and we have no basis for recommending it. The project dams are used for hydroelectric power generation and provide critical flood-control and water supply functions, as well as important environmental (coldwater pool) and recreation opportunities. Thus, dam removal is not a reasonable alternative to relicensing the project with appropriate protection, mitigation and enhancement measures. The second project retirement alternative would involve retaining the dam and disabling or removing equipment used to generate power. Project works would remain in place and would be used for historical flood-control, consumptive-use, environmental and recreational water management, or other purposes. This would require us to identify another government agency with authority to assume regulatory control and supervision of the remaining facilities. No agency has stepped forward, and no participant has advocated this alternative. Nor have we any basis for recommending it. Because the power supplied by the project is needed, replacement power from some other source, providing comparable ancillary benefits without adding air pollutants would have to be provided. In these circumstances, we do not consider removal of the electric generating equipment to be a reasonable alternative*."

In addition to the rationale provided in FERC (2019), which has been incorporated by reference here for disclosure purposes, alternatives involving the issuance of a non-power license and the retirement of the YRDP are not evaluated in this DEIR because Yuba Water has determined that such alternatives would not feasibly attain many of the basic project objectives identified for the YRDP, particularly those related to: (1) the ability to support California's power requirements and needs by providing renewable hydropower generation; (2) the ability to generate sufficient long-term, predictable revenue for Yuba Water's various projects and programs; (3) the continuing ability to meet regulatory flow requirements; and (4) the ability to obtain continued stability and predictability in long-term YRDP operations to provide water supply reliability support and to justify Yuba Water investments for modifications and improvements to its infrastructure. Although it would be speculative to make assumptions as to what specific actions (e.g., issue a non-power license to another government agency, remove electric generating equipment, etc.) FERC would or would not take under the scenarios described above, it is assumed that resultant impacts from such activities could be similar to those described for the No Project Alternative that is being

[13] A non-power license may be issued by FERC for purposes of transferring regulatory authority to a State, municipality, interstate agency, or another federal agency that is authorized and willing to assume regulatory supervision of the lands and facilities included under the non-power license (FERC 2004).

evaluated in this DEIR. Due to similarities between FERC's eliminated action alternatives and the No Project Alternative, considerations related to potential resultant activities that could occur in the absence of new FERC licenses for the YRDP and the Narrows Project relicensings are addressed in this DEIR as part of the analysis of the No Project Alternative.

3.6.2 Narrows Project Alternatives Considered but Eliminated by FERC

As described in FERC's (2024a; 2024b) scoping documents for the Narrows Project, FERC eliminated the following alternatives from detailed evaluation in its NEPA document for the reasons discussed below.

- Federal Government Takeover - FERC (2024a) stated that it does not consider federal takeover to be a reasonable alternative for the Narrows Project - "*In accordance with §16.14 of the Commission's regulations, a federal department or agency may file a recommendation that the United States exercise its right to take over a hydroelectric power project with a license that is subject to Sections 14 and 15 of the FPA.*[14] *We do not consider federal takeover to be a reasonable alternative. Federal takeover of the project would require congressional approval. While that fact alone would not preclude further consideration of this alternative, there is currently no evidence showing that federal takeover should be recommended to Congress. No party has suggested that federal takeover would be appropriate, and no federal agency has expressed interest in operating the project"* (FERC 2024a).[15]
- Issue a Non-Power License[16] - "*A non-power license is a temporary license the Commission would terminate whenever it determines that another governmental agency [not Yuba Water] is authorized and willing to assume regulatory authority and supervision over the lands and facilities covered by the non-power license. At this time, no governmental agency has suggested a willingness or ability to take over the project. No party has sought a non-power license, and we have no basis for concluding that the Narrows Project should no longer be used to produce power. Thus, we do not consider a non-power license a reasonable alternative to relicensing the project*."
- Narrows Project Decommissioning - "*As the Commission has previously held, decommissioning is not a reasonable alternative to relicensing in most cases.*[17] *Decommissioning can be accomplished in different ways depending on the project, its environment, and the particular resource needs.*[18] *For these reasons, the Commission does not speculate about possible decommissioning measures at the time of relicensing, but rather waits until an applicant actually proposes to decommission a project, or a*

[14] 16 U.S.C. §§ 807-808.

[15] In addition, the federal takeover provisions in the FPA are inapplicable to projects owned by a state or municipality such as Yuba Water. See Pub. L. No. 278, 67 Stat. 587 (1953) and 16 U.S.C. § 828.

[16] A non-power license may be issued by FERC for purposes of transferring regulatory authority to a State, municipality, interstate agency, or another federal agency that is authorized and willing to assume regulatory supervision of the lands and facilities included under the non-power license (FERC 2004).

[17] *See, e.g.*, *Eagle Crest Energy Co.,* 153 FERC ¶ 61,058, at P 67 (2015); *Public Utility District No. 1 of Pend Oreille County*, 112 FERC ¶ 61,055, at P 82 (2005); *Midwest Hydro, Inc.*, 111 FERC ¶ 61,327, at PP 35-38 (2005).

[18] In the unlikely event that FERC denies relicensing a project or a licensee decides to surrender an existing project, FERC must approve a surrender "*upon such conditions with respect to the disposition of such works as may be determined by the Commission.*" 18 C.F.R. § 6.2 (2023). This can include simply shutting down the power operations, removing all or parts of the project (including the dam), or restoring the site to its pre-project condition.

participant in a relicensing proceeding demonstrates that there are serious resource concerns that cannot be addressed with appropriate license measures and that make decommissioning a reasonable alternative.[19] [Yuba Water] *does not propose decommissioning, nor does the record to date demonstrate there are serious resource concerns that cannot be mitigated if the project is relicensed; as such, there is no reason, at this time, to include decommissioning as a reasonable alternative to be evaluated and studied as part of* [FERC] *staff's NEPA analysis*."

In addition to the rationale provided by FERC (2024a; 2024b), alternatives involving federal government takeover, issuance of a non-power license to a non-Yuba entity, and decommissioning of the Narrows Project are not evaluated in this DEIR because Yuba Water has determined that such alternatives would not feasibly attain many of the basic project objectives identified for the Narrows Project, particularly those related to Yuba Water's ability to: (1) support California's power requirements and needs by providing renewable hydropower generation; (2) support long-term coordinated operations between the YRDP and the Narrows Project used to meet regulatory flow requirements; (3) generate sufficient long-term, predictable revenue for Yuba Water's various projects and programs; and (4) obtain stability and predictability in long-term coordinated operations between the YRDP and the Narrows Project to provide water supply reliability support and to justify Yuba Water investments for modifications and improvements to its infrastructure.

3.6.3 Alternatives Suggested During the CEQA Public Scoping Process

3.6.3.1 SWRCB 2020 Water Quality Certification for the YRDP

As discussed in Chapter 1, since the SWRCB issued its WQC for the YRDP in 2020, there have been several legal, regulatory and technical changes that have occurred, which relate to both the YRDP and the Narrows Project. On September 18, 2024, the SWRCB adopted State Water Board Order WQ 2024-0083 and set aside the 2020 WQC certification for the relicensing of the YRDP. State Water Board Order WQ 2024-0083 also dismissed the pending petitions for reconsideration of this certification.

During December 2024, Yuba Water filed new WQC applications for the YRDP and the Narrows Project with the SWRCB. As described in Chapter 2, proposed recommended WQC conditions for the YRDP[20] and separate proposed recommended WQC conditions for the Narrows Project[21] are included as part of the Proposed Projects evaluated in this DEIR.

---

[19] *See generally Project Decommissioning at Relicensing; Policy Statement*, FERC Stats. & Regs., Regulations Preambles (1991-1996), ¶ 31,011 (1994); *see also City of Tacoma, Washington*, 110 FERC ¶ 61,140 (2005) (finding that unless and until FERC has a specific decommissioning proposal, any further environmental analysis of the effects of project decommissioning would be both premature and speculative).

[20] The proposed WQC Conditions presented in Appendix 2E were collaboratively developed by Yuba Water in coordination with CDFW and NMFS as recommended Section 401 WQC Conditions, with the exception of the modification provisions in proposed WQC Conditions 1(D), 12 and 24. NMFS and DFW do not take a position on these modification provisions because they believe they should be developed by the State Water Board and YWA. Other than the proposed modification provisions, the initial basis of the proposed WQC conditions was derived from the conditions that the SWRCB developed for the July 2020 WQC.

[21] Similar to the proposed WQC conditions developed for the YRDP Relicensing Project, Yuba Water has proposed WQC conditions for the Narrows Project Relicensing. The proposed WQC conditions are generally consistent with the proposed conditions presented in Exhibit 2A of the FLA and are commensurate with the scope of the Narrows Project.

3.6.3.1.1 Characterization of Alternative Considered

Condition 1 of the SWRCB's 2020 WQC contained recommendations for modifications of the minimum flow requirements described in FERC's (2019) FEIS for relicensing of Yuba Water's YRDP. The 2020 WQC's Condition 1(D) would have authorized the SWRCB's Deputy Director for Water Rights to order Yuba Water to comply with whatever new lower Yuba River streamflow standards he or she chose to adopt. The 2020 WQC also contained other terms[22] under which the Deputy Director could modify the YRDP's streamflow requirements to implement future Bay-Delta water quality control plan amendments and for other reasons.

3.6.3.1.2 Rationale for Elimination

At the time that the 2020 WQC was issued, Yuba Water had not yet initiated the CEQA process or conducted an evaluation of the FERC-relicensing changes being proposed for the YRDP in compliance with CEQA requirements. Although the SWRCB is a responsible agency under CEQA, no analysis was conducted by the SWRCB to demonstrate that the 2020 WQC requirements were in compliance with CEQA prior to issuance of the 2020 WQC. Since 2020, Yuba Water is not aware of any CEQA compliance documentation prepared by the SWRCB that demonstrates that the requirements that would be imposed by the 2020 WQC would be beneficial and would not result in adverse significant impacts to environmental resources under CEQA.

Previous analyses[23,24] of the 2020 WQC conducted by Yuba Water for purposes other than CEQA have demonstrated that the new streamflow requirements identified in the 2020 WQC: (1) could significantly reduce Yuba Water's hydroelectric generation and agricultural water supplies, including supplies that are used in areas that were in a state of significant overdraft before Yuba Water's water deliveries began; and (2) adversely affect Yuba Water's implementation of measures to benefit lower Yuba River salmon and steelhead by compelling Yuba Water to operate its facilities in a manner that would, among other things, significantly reduce reservoir storage and consequently increase the river's water temperatures at sensitive times for those fish species. In consideration of Yuba Water's previous analytical results and conclusions; the fact that potential impacts associated with the 2020 WQC have not been evaluated for CEQA compliance purposes; the fact that the Fresno County Superior Court has invalidated the 2020 WQC and the SWRCB set it aside in Order WQ 2024-0083; and the fact Yuba Water and the SWRCB are now consulting on a new WQC, a detailed analysis of the 2020 WQC in this DEIR would not appropriately reflect the potential conditions under which FERC might relicense the YRDP and potentially could be misleading. In addition, in Alternative 2 and at the SWRCB's request, this DEIR analyzes a potential relicensing scenario in which the YRDP and the Narrows project would be required to comply with minimum streamflow requirements based on 55% of unimpaired flows, consistent with documents the SWRCB has produced in the Bay-Delta water quality planning process.

As discussed in Chapter 1, since the SWRCB issued its WQC for the YRDP in 2020, there have been several legal, regulatory and technical changes that have occurred, which relate to both the YRDP and the Narrows Project. On September 18, 2024, the SWRCB adopted State Water Board Order WQ 2024-0083 and set aside the 2020 WQC certification for the relicensing of the YRDP.

---

22 See SWRCB (2020), pp. 56-57 (Conditions 26, 28, 30-32).

24 https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/yubariver_ferc2246.html

State Water Board Order WQ 2024-0083 also dismissed the pending petitions for reconsideration of this certification.

During December 2024, Yuba Water filed new WQC applications for the YRDP and the Narrows Project with the SWRCB. As described in Chapter 2, proposed recommended WQC conditions for the YRDP[25] and separate proposed recommended WQC conditions for the Narrows Project[26] are included as part of the Proposed Projects evaluated in this DEIR.

3.6.3.2 CDFW-FWS-FWN Floodplain and FPA Section 10(j) Flow Recommendations Alternative

During the public scoping process for this DEIR, it was suggested that Yuba Water should consider an alternative that analyzes the CDFW-FWS-FWN floodplain and FPA Section 10(j) flow recommendations that were submitted to FERC.

3.6.3.2.1 Characterization of Alternative Considered

As described in FERC (2018), under the CDFW and USFWS recommended FPA Section 10(j) flow regime, minimum flows in the lower Yuba River would be the same as those proposed by Yuba Water except during the spring (March 23 to May 31), when they would be substantially higher than Yuba Water's during schedule 1 and 2 water years (and slightly higher during schedule 3, 5, 6, and conference years). Flows would also be significantly higher for February 1 to 6 of schedule 5, 6, and conference years, if higher flows had not already occurred during the previous December 1 through February 1 period. CDFW and USFWS suggest that the increased 10(j) flows were intended to mimic the natural hydrograph more closely in the lower Yuba River to promote floodplain inundation, the transport, storage, deposition, and recruitment of substrates and organic matter (such as woody materials), and the development, recruitment, and persistence of riparian vegetation. They are also designed to facilitate salmon and steelhead reproduction and outmigration, increase the amount of important off-channel rearing habitat, and enhance riparian seedling recruitment (FERC 2018).

CDFW, USFWS and FWN also asserted that YRDP operations impaired floodplain inundation and the establishment of riparian vegetation in the lower Yuba River. They suggested riparian restoration actions (e.g., floodplain lowering) to achieve greater floodplain inundation that would increase the extent of riparian vegetation on the lower Yuba River, providing for increased wetland habitat to benefit waterfowl, amphibians, and other terrestrial wildlife (FERC 2018).

[25] The proposed WQC Conditions presented in Appendix 2E were collaboratively developed by Yuba Water in coordination with CDFW and NMFS as recommended Section 401 WQC Conditions, with the exception of the modification provisions in proposed WQC Conditions 1(D), 12 and 24. *NMFS and DFW do not take a position on these modification provisions because they believe they should be developed by the State Water Board and YWA.* Other than the proposed modification provisions, the initial basis of the proposed WQC conditions was derived from the conditions that the SWRCB developed for the July 2020 WQC.

[26] Similar to the proposed WQC conditions developed for the YRDP Relicensing Project, Yuba Water has proposed WQC conditions for the Narrows Relicensing Project. The proposed WQC conditions are generally consistent with the proposed conditions presented in Exhibit 2A of the FLA and are commensurate with the scope of the Narrows Project.

3.6.3.2.2 Rationale for Elimination

Issues related to YRDP operations and potential effects on lower Yuba River instream flows, floodplain inundation, and fisheries resources have been extensively studied for over 30 years. Two of the most intensive and substantial environmental study processes were the Yuba Accord and the YRDP FERC relicensing process.

- **Lower Yuba River Accord**[27] - From 2002 through 2005, Yuba Water, CDFW, NMFS, USFWS, and several NGOs negotiated a set of minimum flow requirements (flow schedules) for the lower Yuba River downstream of Englebright Dam. These parties carefully considered the water supplies that would be available in different types of water years, ranked the stressors in the lower Yuba River that apply to each species or run of salmonids, and considered all relevant biological factors as they developed these flow schedules. From 2005 through 2007, Yuba Water conducted a comprehensive CEQA/NEPA process that analyzed the environmental effects of the Yuba Accord. In 2008, the SWRCB adopted its Corrected Order WR 2008-0014, which amended Yuba Water's water right permits to incorporate the Yuba Accord flow schedules. In 2024, Yuba Water approved a supplemental EIR to extend the Yuba Accord Long-term Water Transfer Program. As a component of the Yuba Accord, Yuba Water established the River Management Team (RMT), which evaluated the effects of implementing the Yuba Accord on anadromous fish in the lower Yuba River. The RMT collected field data to develop an instream flow model from June 2006 through June 2010, and a hydraulic model was developed from October 2010 through June 2012 (FERC 2018). Much of the work conducted by the RMT was used to directly inform the YRDP FERC relicensing process.
- **YRDP FERC Relicensing Process**[28] – Initiated in 2010, the relicensing process undertook an extensive effort to conduct numerous studies (e.g., hydrology, channel morphology, water operations, water quality, instream flows and fisheries resources, riparian habitat, ESA-listed species, among others) to investigate the potential effects of YRDP operations on instream flows, floodplain inundation, riparian habitat and fisheries resources, among other issues. Issues pertaining to the CDFW-FWS-FWN floodplain and flow recommendations were extensively examined at several points during the relicensing process, including:
    - YRDP Study Plan Development and Implementation[29]
    - FERC's Study Plan Dispute Resolution Process for the YRDP[30]
    - Preparation of Yuba Water's 2017 AFLA for the YRDP[31]

[31] Available in FERC's eLibrary at Accession No. 20170605-5050 (Filed on June 2, 2017)

- FERC's Notice of Application Accepted for Filing, Soliciting Motions to Intervene and Protests, Ready for Environmental Analysis (REA), and Soliciting Comments, Recommendations, Preliminary Terms and Conditions, and Preliminary Fishway Prescriptions [32]
- Yuba Water's Petition for Reconsideration of the SWRCB's 2020 WQC for the YRDP[33]

- The data collected and analyses conducted for the activities listed above are in the FERC record for the project and were used to inform and support FERC's Draft EIS (2018) and Final EIS (2019), as well as this DEIR.

During FERC's REA process, CDFW, FWS and FWN made a number of non-flow recommendations for the lower Yuba River. The most significant and far-reaching of these was the recommendation to develop a plan for extensive physical habitat modifications[34] in the lower Yuba River, including lowering of floodplain surfaces, planting of riparian vegetation, and installation of LWM. However, as described in various sources of relicensing documentation (e.g., YCWA 2017a; 2017b), Yuba Water's YRDP is not responsible for the geomorphic and riparian conditions of the lower Yuba River, which have been severely degraded as a result of hydraulic mining during the Gold Rush era, dam building by the federal government for sediment control, and flood control channelization. Because the recommended habitat improvement measures cannot change the fundamental reshaping of the geomorphic and riparian conditions in lower Yuba River that occurred as a result of these historical influences, any improvements would be transitory at best (YCWA 2017b). Moreover, the costs of the habitat modifications proposed by the CDFW-FWS-FWN recommendations were estimated to be approximately $300,000,000 (in 2017 dollars) over 30 years.

Yuba Water modeled and analyzed the environmental, recreation, and cost impacts of resource agency and other stakeholder recommendations, including the CDFW-FWS-FWN proposed flow recommendations. Yuba Water provided the results of its modeling, analyses and technical reports to FERC, and made them available to the Relicensing Participants, CDFW,USFWS and other stakeholders.[35,36,37] On the lower Yuba River, Yuba Water (2017a) demonstrated that the CDFW-FWS-FWN proposal would upset the careful balance of the Yuba Accord flow schedules by recommending spring floodplain inundation flows, as well as spring and winter pulse flows. In

[32] Available in FERC's eLibrary at Accession No. 20170626-3039 (Filed on June 26, 2017)
[33] https://www.yubawater.org/DocumentCenter/View/4658/Petition-for-Reconsideration-searchable?bidId=
[34] The FPA Section 10(j) recommendations proposed by CDFW, FWS and FWN involved extensive removal of floodplain sediments to lower 340 acres of floodplain currently inundated at 5,000 cfs to be accessible to flows between 1,500 and 3,000 cfs. As part of the CDFW-FWS-FWN recommendations, Yuba Water also would have been required to vegetate (with native riparian plants) these acres and an additional 251 acres of floodplain currently inundated at flows between 3,000 and 21,000 cfs. Although CDFW, FWS and FWN did not conduct any assessment of potential environmental impacts, Yuba Water's (2017b) technical analysis found that an increase of 340 acres in terraced areas wetted between 1,500 and 3,000 cfs would result in an increase of over 40% in bankfull wetted area; thus over 40% of the entire area most proximate to the flowing river would be potentially impacted by wholesale grading operations. Yuba Water (2017a) estimated that if 680 acres would need to be disturbed in order to construct these terraces, then a total of 40% of the entire floodplain area of the length of the lower Yuba River would need to be disturbed in order to implement this recommendation. For terraforming of 340 acres of river channel, feathering the lowered areas into the remaining banks, and constructing haul and spoil areas, a simplistic estimate of grading volume would total about 4,000,000 yds^3 of coarse sediment (YCWA 2017b).

[37] Available in FERC's eLibrary at Accession No. 20171013-0006 (Filed on October 12, 2017)

their proposal, CDFW, FWS and FWN provided no evidence that additional flows are needed or would provide any significant benefits. In addition, Yuba Water's (2017a) modeling and analysis demonstrated that these flow recommendations would not provide significant benefits and would result in a substantial cost in lost power and water supply.

The CDFW-FWS-FWN proposal also included restrictions on project ramping and flow fluctuations downstream of Englebright Dam for protection of riparian seedlings. Yuba Water's analysis showed that the additional operational restrictions would not provide significant benefits and would result in less suitable water temperatures for numerous life stages of federal ESA-listed anadromous salmonids and would jeopardize the YRDP's ability to provide stable flows for spring-run Chinook salmon spawning. In addition, the restrictions would seriously impair the YRDP's flexibility in providing water supply when needed (YCWA 2017b).

Based on Yuba Water's (2017a) analysis, the CDFW-FWS-FWN proposal has a variety of flaws ranging from failure to support their recommendations with evidence of nexus to a YRDP project effect, failure to provide evidence of a problem that needs to be mitigated, failure to provide evidence that their recommendations will result in significant environmental benefits, failure to recognize that in many cases the recommendations would have redirected adverse environmental impacts, and failure to show that the environmental benefits, if any, outweigh the substantial costs that Yuba Water would incur to implement them as well as the loss of water supply to the water users who Yuba Water serves.

Based on FERC's analysis of the documentation submitted by various Relicensing Participants as part of the REA process and its analysis conducted for the 2019 FEIS, FERC determined that the floodplain and 10(j) flow recommendations proposed by CDFW-FWS-FWN did not have merit and should not be adopted.

Based upon: (1) the extensive amount of historical literature and previously conducted analyses on lower Yuba River instream flows, floodplain inundation, and fisheries resources that are available in the record; and (2) the fact that no nexus has been established between YRDP operations and adverse effects to floodplain inundation and fisheries resources in the lower Yuba River, a detailed analysis of the CDFW-FWS-FWN floodplain and flow recommendations as a distinct CEQA alternative in this DEIR is not warranted.

Moreover, the analyses conducted to date demonstrate that a "CDFW-FWS-FWN floodplain and flow recommendations alternative" would not feasibly attain most of the basic project objectives identified for the Proposed Projects, including those related to Yuba Water's ability to implement protections for lower Yuba River fisheries resources in a way that: (1) improves or provides additional protections for ESA-listed fish species and their designated critical habitat in the lower Yuba River; and also (2) fairly allocates protective activities such that no entity is disproportionately burdened with a responsibility to mitigate watershed impacts caused by other entities. A "CDFW-FWS-FWN floodplain and flow recommendations alternative" also would not meet other project objectives including the ability to: (1) support California's power requirements and needs by providing renewable hydropower generation; (2) continue to provide the existing level of water supply reliability support throughout the state consistent with the Lower Yuba River Accord Water Purchase Agreement; (3) generate sufficient long-term, predictable revenue for Yuba Water's various projects and programs; and (4) obtain stability and predictability in long-

term YRDP and Narrows Project coordinated operations to justify Yuba Water investments for modifications and improvements to its infrastructure. In addition, an alternative comprised of the CDFW-FWS-FWN floodplain and FPA Section 10(j) flow recommendations would not avoid or substantially reduce potentially significant impacts of the Proposed Projects. Accordingly, this alternative was eliminated from further consideration not only because it would not meet most of the project objectives but also because it would not eliminate or reduce the Proposed Projects' significant impacts.

3.6.3.3 Reduced Water Transfer Exports Alternative

During the public scoping process for this DEIR, it was suggested that Yuba Water should consider a "Reduced Water Transfer Exports Alternative" that analyzes reduced water transfers under Yuba Water's water transfer program.

In 2024, Yuba Water prepared a Supplemental EIR (SEIR),[38] a supplement to the 2007 Yuba Accord EIR, to evaluate the Extension of the Yuba Accord Long-Term Water Transfer Program (Accord Extension) - which was a separate project independent of the Proposed Projects being evaluated in this DEIR. The Accord Extension Final SEIR was certified by Yuba Water in September 2024. During the public comment period on the Accord Extension Draft SEIR, a "Reduced Water Transfer Exports Alternative" was suggested as an alternative to the Proposed Accord Extension. The summary rationale explaining why a "Reduced Water Transfer Exports Alternative" is not evaluated in this DEIR was taken from Yuba Water's Final SEIR (2024a, pp. 2-79 to 2-81) response to Comment O1-7, which is incorporated by reference. Yuba Water's Final SEIR (2024a) is available at https://www.yubawater.org/157/Lower-Yuba-River-Accord.

3.6.3.3.1 Characterization of Alternative Considered

Commentors suggested that a "Reduced Water Transfer Exports Alternative" would reduce out of basin water exports in anticipation of climate change impacts and the SWRCB's adoption of the Bay-Delta Plan Update. The comment stated that a reduced transfers alternative is reasonably foreseeable because Yuba Water may have less water available for transfer in the future due to proposed updates to the Bay-Delta Plan. The comment further indicates that a reduced transfers alternative would result in fewer impacts, relative to Yuba Water's extension of the Yuba Accord Long-Term Water Transfer Program (Accord Extension) that was evaluated in a separate SEIR (YCWA 2024a; 2024b).

3.6.3.3.2 Rationale for Elimination

The discussion provided below was taken from Yuba Water's Accord Extension SEIR (YCWA 2024a; 2024b) and appropriately explains why a "Reduced Water Transfer Exports Alternative" was not carried forward in that SEIR, as well as why it is not carried forward for detailed evaluation in this DEIR.

Yuba Water's (2024b) Draft SEIR for the Accord Extension was not required to consider alternatives to the project proposed in that SEIR, including a commenter's proposed "Reduced

[38] California State Clearinghouse Number 2005062111 (https://ceqanet.opr.ca.gov/Project/2005062111).

Transfers" alternative, because there would be no significant impacts to avoid or lessen through implementation of alternatives. Additionally, CEQA does not require that a lead agency identify and analyze alternatives based on hypothetical future conditions. As explained in the Draft SEIR (YCWA 2024a):

> Future changes to the watershed may occur due to the Voluntary Agreements, the future adoption of an updated Bay-Delta Water Quality Control Plan (Bay-Delta Plan), the outcome of the Biological Opinions (BOs) for the Long-Term Operations of the CVP and SWP, and the anticipated terms of a FERC license renewal and associated Water Quality Control Plan conditions. ***Each of these long-term processes are currently incomplete, with timelines for resolution that are wholly uncertain, and likely years away. Each process is related to some extent to the Yuba Accord, but at this point have only hypothetical outcomes that could resolve in myriad unknown ways.*** Therefore, incorporating these processes into the baseline would require speculation… ***Emphasis added.***

Regardless, substantial evidence demonstrated that a "Reduced Transfers" alternative would neither achieve the Accord Extension's project objectives nor be the environmentally superior alternative (YCWA 2024a). As Yuba Water previously demonstrated in its technical comments on the SWRCB's (2023) Draft Staff Report (DSR), the potential unimpaired flow-based requirements cited by the Accord Extension commenter would result in highly adverse impacts to the lower Yuba River's sensitive fish due to changes in water temperatures.

Although the comment on the Accord Extension suggested, without evidence, that it would be feasible for Yuba Water to implement a "Reduced Transfers" alternative in the event that SWRCB adopts unimpaired flow-based requirements, substantial evidence suggests otherwise. In January 2024, Yuba Water submitted extensive comments on the 2023 DSR to the SWRCB. As Yuba Water explained on pages 53 to 56 of those comments and in Technical Memorandum #2 that Yuba Water submitted with those comments, the SWRCB's imposition of unimpaired flow-based requirements on Yuba Water as proposed in the 2023 DSR likely would terminate all Yuba Accord transfers.[39] Yuba Water's comments and Technical Memorandum #2 provide an expert hydrological review of the SACWAM hydrologic modeling on which the DSR is based and concludes that operation of Yuba Water's YRDP, according to the DSR's SACWAM modeling, would eliminate Yuba Accord water transfers, and thereby eliminate a significant source of statewide water supply in droughts.

Because substantial evidence demonstrates that the new unimpaired flow-based requirements described in the 2023 DSR likely would terminate all Yuba Accord water transfers, the comment's premise that its proposed "Reduced Transfers alternative could achieve the project objectives" of the Accord Extension SEIR was incorrect. That premise was not supported by any information or data submitted with the comment or otherwise available. Yuba Water's comments on the 2023 DSR demonstrate that exactly the opposite would likely be the case. Specifically, the SWRCB's implementation of unimpaired flow-based requirements as discussed in the 2023 DSR likely would preclude *any* of the Accord Extension's project objectives from being met (YCWA 2024a).

[39] Yuba Water included its comments on the DSR, and Technical Memorandum #2 that it submitted with those comments, in the administrative record for the Accord Extension SEIR (YCWA 2024b). Those comments are publicly available from the SWRCB via a request sent to SacDeltaComments@waterboards.ca.gov (SWRCB 2024).

Likewise, because several of the objectives identified for the Proposed Projects in this DEIR are similar to those of the Accord Extension, Yuba Water's comments on the 2023 DSR also support the fact that a "Reduced Transfers" alternative would not align with the FERC relicensing process being considered in this DEIR.

Moreover, to the extent that a "Reduced Transfers" alternative might be implemented outside of a situation in which the SWRCB had adopted unimpaired flow-based requirements as discussed in the 2023 DSR, the comment appears to assume that other water users, including the U.S. Bureau of Reclamation (Reclamation) and DWR as the operators of the CVP and the SWP, respectively, would desist from exercising their own water rights with points of diversion downstream of the Yuba River to divert water that would be transferred under the Accord Extension. There is no basis for such an assumption. Nothing in the Accord Extension would involve the SWRCB acting to prevent the CVP and the SWP from exercising their own water rights to divert water Yuba Water would otherwise releases as part of the continuing elements of the Yuba Accord, but would be precluded from transferring in a "Reduced Transfers" alternative. The only water-right petition involved in the Accord Extension involves Yuba Water's water rights (See YCWA 2024b, p. 2-7.) Contrary to the assumption that a "Reduced Transfers" alternative would involve "*some of the water that is transferred under current operations would instead become Delta outflow*," the CVP and the SWP likely would simply divert that water, only without compensating Yuba Water.

In this scenario, the effect of a "Reduced Transfers" alternative would be to limit only Yuba Water's ability to transfer Yuba River water released under the Yuba Accord and would not be to limit other water users' ability to divert that water under their downstream water rights. Any such water therefore likely would be diverted by one or more of the many downstream water-right holders (who would not compensate Yuba Water). As explained in Yuba Water (2024a), the most likely outcome would be that the CVP and the SWP would divert that water as part of their project supplies. The proposed alternative therefore would not reduce any alleged environmental effects in the south Delta as the Accord Extension comment suggests. Yuba Water (2024b) concluded that a "Reduced Transfers" alternative therefore is either infeasible (in the event that the SWRCB adopts unimpaired flow-based requirements discussed in the 2023 DSR) or is unlikely to actually reduce south Delta diversions or significantly reduce any existing environmental impacts, assuming the SWRCB does not adopt unimpaired flow-based requirements as discussed in the DSR (SWRCB 2023).

Finally, because the Accord Extension commenters' proposed "Reduced Transfers" alternative was premised on the SWRCB's adoption of unimpaired flow-based requirements as discussed in the DSR, it would be associated with lower Yuba River water temperatures that would be highly adverse for the river's fish. As pages 26 through 29 of Yuba Water's comments on the DSR explained, technical analyses that Yuba Water previously had submitted to FERC demonstrated that implementing unimpaired flow-based requirements like those discussed in the DSR would increase the lower Yuba River's water temperatures up to 13° Fahrenheit (°F) during the summer and increase temperatures at other times to levels that would be highly adverse for lower Yuba

River salmon and steelhead.[40] Accordingly, implementation of the SWRCB's proposals that are the premise for a "Reduced Transfers" alternative would have significantly worse impacts on the lower Yuba River's sensitive fish compared to the Accord Extension (YCWA 2024b). A "Reduced Transfers" alternative therefore would not be an environmentally superior alternative, as the commentor suggests, or even an appropriate alternative under CEQA (California Code of Regulations, Title 14, Section 15126.6[a], [c], [f].). Accordingly, this alternative was eliminated from further consideration in the Accord Extension SEIR (YCWA 2024b) not only because it would not meet most of the project objectives but also because it would not eliminate or reduce the project's significant impacts.

For the reasons described above, a "Reduced Transfers alternative" would not feasibly attain the basic project objectives identified for the Proposed Projects, including those related to Yuba Water's ability to implement protections for lower Yuba River fisheries resources in a way that improves or provides additional protections for ESA-listed fish species and their designated critical habitat in the lower Yuba River. A "Reduced Transfers alternative" also would not meet other project objectives including the ability to: (1) continue to provide the existing level of water supply reliability support throughout the state consistent with the Lower Yuba River Accord Water Purchase Agreement; and (2) generate sufficient long-term, predictable revenue for Yuba Water's various projects and programs. In addition, a "Reduced Transfers alternative" would not avoid or substantially reduce potentially significant impacts of the Proposed Projects. Accordingly, this alternative was eliminated from further consideration not only because it would not meet most of the project objectives but also because it would not eliminate or reduce the Proposed Projects' significant impacts.

3.6.3.4 Narrows 1 or Narrows 2 Powerhouse Intake Extension Considerations and Rationale for not Advancing the Extension

Over the course of the FERC relicensing process for the YRDP and during the public scoping process for this DEIR, it has been suggested that Yuba Water should consider an intake extension that would be constructed at either the YRDP's Narrows 2 Powerhouse or the Narrows 1 Powerhouse.

Given the interest expressed in considering potential intake extensions at the Narrows 1 and/or Narrows 2 powerhouses to further enhance water temperatures in the lower Yuba River, Yuba Water prepared a technical analysis (**Appendix 3B**) that analyzed intake extension and temperature control projects at its Narrows 1 and 2 powerhouses in response to comments filed by FERC Relicensing Participants in connection with FERC's March 2021 AIR. Yuba Water's analysis utilized a series of modeled scenarios to demonstrate whether intake extensions and temperature control projects as suggested by these other parties would achieve lower water temperatures in the lower Yuba River during the late summer and early fall of dry and critically-dry years to benefit listed fish species. The conclusions presented in Yuba Water's (2023b)

[40] Yuba Water submitted with its comments to the SWRCB the relevant technical memoranda that it previously had submitted to FERC. Those memoranda were Exhibits G and H and are included in the administrative record for the Accord Extension SEIR (YCWA 2024a). Those memoranda also are present in FERC's eLibrary at Accession Numbers 20211207-5175 and 20220307-5273. The commenters are parties to FERC's proceeding for the YRDP's relicensing and therefore should have received notice of Yuba Water's submission of those memoranda to FERC at the time of their submission. In addition, as discussed above, the SWRCB makes publicly available all comments on the DSR.

technical report are supported by a series of future operating and intake extension scenarios that have been modeled by Yuba Water and filed with FERC.

3.6.3.4.1 Lower Yuba River Water Temperatures

To investigate the efficacy of non-flow actions to lower water temperatures in the lower Yuba River, Yuba Water previously evaluated a Narrows 1 Powerhouse intake extension. A Narrows 1 intake extension would involve modifications at the USACE's Narrows 1 intake in Englebright Reservoir. Narrows 1 was selected as the powerhouse for further analysis of an intake extension rather than Narrows 2 for the following reasons.

- The target time identified for further temperature reduction of September and early October is the time when the Narrows 2 Powerhouse is shut down for maintenance. This is the only time when planned flows are low enough each year to meet downstream requirements with the Narrows 1 Powerhouse.
- The typical flow release rate below Englebright Dam during the September and October period in Dry and Critically Dry years ranges from 500 to 900 cfs, averaging 770 cfs. The Narrows 1 Powerhouse capacity is 730 cfs while the Narrows 2 Powerhouse capacity is 3,400 cfs. Because the September-October period is the period with which FERC is concerned for temperature management and because flow releases during that period are within the Narrows 1 Powerhouse's release capacity during that period and Yuba Water therefore conducts annual maintenance on the Narrows 2 Powerhouse then, constructing an intake extension at the 3,400-cfs Narrows 2 Powerhouse for operation during September and early October would not make sense and likely would result in an inappropriate expenditure of tens of millions of dollars of public funds for no benefit greater than could be achieved at the Narrows 1 Powerhouse.
- Initial modeling identified that the intake extension flows would need to be blended with flows from the existing intake to provide suitable water temperatures for the greatest duration, which was only about 28 days. The maximum flow rate through the intake extension would be 30% of the total flow to the intake, or a flow averaging about 230 cfs, less than 7% of the capacity of the Narrows 2 Powerhouse Intake. Achieving these low flow levels for mixing at Narrows 2 would be difficult to achieve because the Narrows 2 intake capacity is over 3,400 cfs.

Initial modeling of a Narrows 1 Powerhouse intake extension showed that a water temperature benefit could only be provided for a limited period of about 28 days. To provide reduced water temperatures, a gradual ramping of intake extension flows would be needed to initiate use of the intake. The limited duration is a result of Englebright Reservoir containing a small cold water pool that would be exhausted quickly. Once the small cold water pool is exhausted, no additional benefit can be derived and release water temperatures would be higher than without use of an intake extension. The need to blend the flow of water through the intake extension with flow from the existing intake at variable rates would require a complex intake structure and controls. The analysis also showed that with existing accumulated sedimentation in Englebright Reservoir and continued sedimentation, the volume of cold water in Englebright available in the fall continues to reduce and further limits the small amount of temperature reduction an intake extension would achieve. In the future sedimentation will all but eliminate a cold water pool in Englebright Reservoir.

3.6.3.4.2 Engineering and Environmental Feasibility Considerations

Yuba Water's (2023a) assessment also demonstrated that there would be significant limitations, uncertain benefits, and large costs of implementing an action involving an intake extension.

First, any major structural modification of a federally owned dam (i.e., Englebright Dam) would likely require Congressional approval.

Second, because of uncontrolled flow into Englebright Reservoir and the need to continuously provide flow to the lower Yuba River to maintain cooler temperatures, the reservoir could not be de-watered to construct the intake extension facilities and construction would have to be completed underwater at depths up to 150 ft below the normal operating pool water surface elevation. An intake extension project would have to include a temperature control device (TCD) with a tower extending well above the flood flow elevation, which would have to be constructed into the lakebed below substantial sediment deposits, and would have to withstand the force of major flood flows.

Third, because a conceptual design has not been developed and would take extensive investigation, a rough estimate of cost for an intake extension was not developed, but would likely be very expensive (e.g., in excess of $77 million) based on costs incurred for water temperature control devices at other reservoirs (see Reclamation (2020) report titled "Review of Temperature Control Options for Reservoir Release Flows").

Fourth, in addition to several unique engineering challenges associated with Englebright Dam and Reservoir[41], the greatest challenge, and potential fatal flaw in attempting to construct an intake extension facility at Englebright Dam and Reservoir is the documented existence of contaminated sediments at depths where the deeper intakes would have to be located. It is well documented by the USGS that sediments at the bottom of Englebright Reservoir are substantial in volume and are heavily laden with mercury, as well as other metals (USGS 2006). The USGS cautioned about the hazard of releasing this material into the water column which would be transported downstream "*The environmental risk associated with release of fine-grained sediment containing an elevated concentration of mercury is related to the potential for the mercury to be converted to the more toxic form of methylmercury if conditions are favorable"* (USGS 2006, p. 4).

Given the significant potential for downstream contamination due to release of mercury in its various forms, including methylmercury during construction, extensive measures would have to be employed to implement an intake extension facility. Even with such measures, it would likely be impossible to completely contain the construction site to avoid dispersing contaminated sediments to the reservoir and downstream. Because of the presence of mercury in the Englebright Reservoir sediments and because construction of a TCD tower would require extensive disturbance of these sediments to construct a foundation, environmental impacts due to the release of mercury into the water column would be a significant concern for this type of project. Any intake extension project would have to attempt to mitigate the release of mercury and other sediment constituents into the water column that would then flow downstream. The cost of such mitigation activities is unknown at this time but would be large and significantly increase the project's costs. Given all these factors, and excluding the potential cost of sediment control, an order of magnitude estimate

[41] See Section 9 (TCD Design Concepts) of Yuba Water's (2023b) report.

of total project cost is estimated to be at least $80 million to $120 million or more, in 2023 dollars (YCWA 2023). Given the minimal temperature benefit an intake extension would produce, it would not be an economically feasible or reasonable alternative.

3.6.3.4.3 Intake Extension Summary Conclusions

In summary, Yuba Water investigated the possibility of an intake extension at both Narrows 1 and Narrows 2. For the reasons discussed above, an intake extension at Narrows 1 would have the capacity to release almost all flows in the September-October period and is the logical powerhouse for a facility of this type given the September-October period with which FERC is concerned and how Yuba Water must operate during that period. As to Narrows 1, the investigation demonstrated that a Narrows 1 intake extension would: (1) be complex and expensive; (2) involve modification to a USACE facility that is not part of either the YRDP or the Narrows Project; (3) require disturbing mercury laden sediments in the reservoir to construct an intake extension and (4) provide only a small temperature reduction benefit.

As detailed in Yuba Water (2023b), neither a Narrows 1 nor a Narrows 2 intake extension or a TCD for either powerhouse intake is a viable option for providing cooler temperatures to the lower Yuba River. This conclusion is based on the fundamental mechanisms of the temperature regime of Englebright Reservoir, the small and diminishing volume of the reservoir and its cold water pool, complexities of structures needed to attempt to blend cold water with upper intake releases that would be needed to extend the duration of any colder releases, the substantial costs of the environmental and structural challenges of constructing such extension, and ultimately the limited uncertain cold water benefits that can be achieved. In addition, 2048 was estimated as the time needed to obtain a new FERC license, conduct engineering and planning, and obtain all other necessary permits and approvals and complete the construction of a TCD at Narrows 1 or Narrows 2. Given this timing, a TCD has a major disadvantage over Yuba Water's Offer of Settlement measures which could be implemented immediately upon FERC's issuance of a new license.

Consistent with Englebright Dam's intended design and purpose as a debris collection dam, there is ongoing sediment accumulation within Englebright Reservoir, including accumulation of mercury contamination within the reservoir sediments. The current and projected accumulation of this material presents significant problems for the construction and operation of an "intake extension." The "intake extension" conceptually proposed in 2000 would provide minimal water temperature benefit, and the potential suggested alternative of a TCD also would be difficult to construct and provide little benefit, particularly in comparison with its likely very high cost. Additionally, any construction within Englebright Reservoir would take many years to implement, which would delay any of the likely marginal benefits for ESA-list fish in the lower Yuba River. As discussed above, Yuba Water's February 27, 2023 filing[42] with FERC provided additional details regarding the limitations and challenges of constructing and operating a TCD within Englebright Reservoir for the purposes of protecting and enhancing ESA-listed species and their designated critical habitat in the lower Yuba River.

In addition to the technical analysis and rationale discussed above, an alternative involving an intake extension at either the YRDP Narrows 2 Powerhouse or the Narrows Project is not evaluated

[42] Available in FERC's eLibrary at Accession No. 20230227-5265 (Filed on February 27, 2023)

in this DEIR because such an alternative would not feasibly attain most of the basic project objectives identified for the YRDP and the Narrows Project, including those related to Yuba Water's ability to implement protections for lower Yuba River fisheries resources in a way that: (1) improves Yuba River water temperatures to protect ESA-listed fish species and their designated critical habitat; but also (2) fairly allocates protective activities such that no entity is disproportionately burdened with a responsibility to mitigate watershed impacts caused by other entities. As presented in Yuba Water's (2023b) technical report, an extension of the Narrows 1 intake or the Narrows 2 intake would not provide a sustainable strategy for lower Yuba River water temperature enhancement for the anticipated terms of the YRDP or Narrows Project FERC licenses. Accordingly, this alternative was eliminated from further consideration not only because it would not meet most of the project objectives but also because it would not eliminate or reduce the Proposed Projects' significant impacts.

3.6.4 Other Alternatives Considered

3.6.4.1 Implement Fish Passage into the Upper Yuba River Watershed

Over the course of the FERC relicensing process for the YRDP, some Relicensing Participants have suggested that anadromous fish passage into the upper Yuba River Watershed should be considered as an alternative for the YRDP Relicensing Project.

Since its construction in 1941, USACE's Englebright Dam has restricted salmon and steelhead to the lower 24 miles of the Yuba River, and it is currently the upstream limit of salmon and steelhead migration. Because Englebright Dam was built without fish passage facilities, it is a complete barrier to upstream fish passage (FERC 2018; 2019). While a variety of fishways have been used in California, Oregon, and Washington and have successfully transported salmon past dams for many years, fish passage into the upper watershed above USACE's Englebright Dam has not been provided on the Yuba River. In its 2014 Recovery Plan, NMFS identified Englebright Dam as one of the dams where fish passage would contribute to recovery of the Central Valley spring-run Chinook salmon ESU and the Central Valley steelhead DPS.

FERC's September 30, 2011 Study Plan Determination[43] did not require anadromous fish passage studies related to YRDP facilities above Englebright Dam because of the lack of nexus between those facilities and impacts to anadromous fish. FERC (2011) recognized that the Narrows 2 facilities that are part of the YRDP were not constructed until after USACE's Englebright Dam was erected, and that anadromous fish have not occurred upstream of Englebright Dam since construction was completed in 1941. USACE's Englebright Dam blocked upstream fish passage for almost 25 years before the development of the Narrows 2 Powerhouse. Furthermore, FERC (2011) stated that it was unaware of any hydroelectric generating facility that serves as a passage route for upstream migrating fish. The Narrows 2 Powerhouse is located nearly 400 feet downstream from the Englebright Dam. Therefore, potential project effects on upstream fish passage are limited to the 400 feet between the Narrows 2 Powerhouse outlet and Englebright Dam, which is the next barrier for upstream fish passage. Due to the failure of Relicensing Participants to demonstrate a nexus between studying anadromous fish passage upstream of Englebright Dam and the Narrows 2 Powerhouse, FERC did not adopt requests to study fish

[43] Available in FERC's eLibrary at Accession No. 20110930-3051 (Filed on September 30, 2011)

passage above Englebright Dam and concluded that fish passage studies into the upper watershed were not necessary (FERC 2011).[44] The Study Plan Determination (FERC 2011) concluded that the required studies for the YRDP relicensing, along with studies being conducted by the RMT, would provide the information necessary to conduct an analysis of project effects on federally listed salmonids in the lower Yuba River (downstream of Englebright Dam) and Essential Fish Habitat (EFH) in all project-affected stream reaches.

FERC's December 28, 2011 Formal Study Dispute Resolution Determination[45] for the YRDP reaffirmed FERC's agreement with the Study Plan Determination that there is no nexus between project effects and anadromous fish upstream of Englebright Dam because anadromous fish are not present above the dam and therefore there is no need to study fish passage at facilities above Englebright Dam.

FERC's (2018) Draft EIS[46] appropriately contained separate discussions of the existing blockage of upstream anadromous fish passage by Englebright Dam and potential future projects to transport anadromous salmonids between the lower Yuba River and the North Yuba River. Specifically, FERC (2018, p. 3-54 and p. 3-203) clearly explained the historical and ongoing impacts of USACE's Englebright Dam on fisheries and aquatic resources. Some Relicensing Participants recommended that a placeholder be reserved in any new FERC license to implement any future fish passage actions for Daguerre Point and Englebright dams. As discussed in FERC's (2019) FEIS,[47] FERC licenses already include a standard fish and wildlife reopener article that could be used to assess the need for any additional fish and wildlife measures during a license term.

An alternative involving fish passage into the upper watershed could require Yuba Water to spend hundreds of millions of dollars to move anadromous fish upstream of the federal government's Englebright Dam – which was built in the early 1940s to contain hydraulic mining debris. Such an alternative would present a dangerous financial risk[48] to Yuba Water by potentially increasing annual expenses, and decreasing hydroelectric and water-sale annual revenues, by many millions of dollars in each direction. Facing such a serious financial constraint, Yuba Water would be forced to reduce its expenditures on flood damage reduction projects, habitat and watershed restoration, recreation, and community grants. Such an outcome also would further burden vulnerable populations in Yuba County's disadvantaged communities.

---

[44] FERC's (2011) decision was also based upon the fact that, although there have been several efforts to study anadromous fish passage into the upper Yuba River Watershed, no fish passage plans have been developed, approved, or funded. Accordingly, it is unknown when fish passage might occur, how fish passage would be accomplished, or which part of the watershed would be targeted.

[45] Available in FERC's eLibrary at Accession No. 20111228-3031 (Filed on December 28, 2011)

[46] Available in FERC's eLibrary at Accession No. 20180530-3011 (Filed on May 30, 2018)

[47] Available in FERC's eLibrary at Accession No. 20190102-3000 (Filed on January 2, 2019).

[48] Concept-level cost estimates of several fish passage facility options were developed for the Yuba Salmon Partnership (YSP), which included Yuba Water, NMFS, CDFW, American Rivers, and the California Sport Fishing Protection Alliance. Each facility cost estimate was bounded by a "low" and "high" cost estimate to reflect the uncertainties in design at such an early planning stage. Cost estimates included: (a) the Opinion of Probable Construction Cost (OPCC) for various fish passage program facilities (in 2015 dollars); and (b) the Net Present Value (NPV) for construction and operation of potential fish passage program facilities over a 50 year period, using the OPCC cost estimates for construction costs. Construction-only costs were estimated at $380 million based on established design parameters, biological constraints, and challenging site conditions. Additionally, O&M and monitoring were estimated to cost about $4.1 million per year in 2016 dollars. Total nominal costs for a full-scale implementation over a 50-year time period were estimated at $1.19 billion and NPV costs were $630 million with low (-35%) and high (+50%) bounds around those numbers.

For the reasons discussed above (i.e., lack of project nexus), Yuba Water does not propose any alternatives that would provide upstream or downstream fish passage for the Proposed Projects. An alternative involving fish passage would not avoid or reduce potential impacts of the YRDP or the Narrows Project under CEQA. In addition, under California Fish & Game Code sections 5900, 5931 and 5938, the obligation for fish passage associated with a federal dam is with the United States. Under those statutes, the fact that someone else has attached a facility to a dam does not make it the dam's "owner." For example, in a 2015 decision, the California Court of Appeal decided that CDFW's modification of a dam owned by a city by, among other things, installing a fish ladder, did not make CDFW an "owner" of the dam.[49] Accordingly, this alternative was eliminated from further consideration because it would not eliminate or reduce the Proposed Projects' significant impacts.

3.6.4.2 Federal Agency Takeover of the YRDP

Similar to the Narrows Project, federal takeover of the YRDP is not a reasonably foreseeable alternative. Although not specifically addressed in FERC's (2019) FEIS, federal takeover and operation of the YRDP would require Congressional approval. While that fact alone would not preclude further consideration of such an alternative, there is no evidence to indicate that federal takeover should be recommended to Congress. Similar to the Narrows Project, no Relicensing Participant or other party has suggested federal takeover of the YRDP would be appropriate, and no federal agency has expressed an interest in operating the YRDP. Therefore, federal takeover of the YRDP is not a reasonably foreseeable alternative.[50]

In addition to the rationale provided above, an alternative involving the federal government takeover of the YRDP is not evaluated in this DEIR because such an alternative would not feasibly attain many of the basic project objectives identified for the YRDP, particularly those related to Yuba Water's ability to: (1) support California's power requirements and needs by providing renewable hydropower generation; (2) generate sufficient long-term, predictable revenue for Yuba Water's various projects and programs; and (3) obtain stability and predictability in long-term YRDP operations to justify Yuba Water investments for modifications and improvements to its infrastructure. Accordingly, this alternative was eliminated from further consideration not only because it would not meet most of the project objectives but also because it would not eliminate or reduce the Proposed Projects' significant impacts.

CHAPTER 4.0

FRAMEWORK FOR THE ENVIRONMENTAL ANALYSIS

4.1 Introduction

The intent of this chapter is to describe the scope and extent of the environmental resource impact evaluations that are presented in this DEIR, particularly with respect to the key elements and analytical framework that is common among the respective resource analyses. The analytical framework described in this chapter provides readers of this DEIR with context to aid them during review of the document. Specifically, this chapter presents an overview of the following.

- The overall organization and content of the resource-specific analyses in the DEIR that meet CEQA (Pub. Resources Code § 21000 et seq.) content requirements.
- The environmental resources that are evaluated in this DEIR, as well as any significance criteria (or portions thereof) for resources that are not applicable to the evaluation of the Proposed Action and alternatives, and the rationale why some resources have been dismissed from detailed evaluation.
- Assumptions about the environmental setting/existing condition.
- The analytical approach used to support: (1) how the resource-specific analyses address environmental setting information; (2) the project areas for analysis; (3) baseline assumptions for comparing the Proposed Projects and the alternatives to determine the magnitude of impact; (4) construction, operational, and maintenance impacts; (5) determination of whether the magnitude of the impact is significant; (6) alternative comparisons; and (7) mitigation measures where a potential impact is determined to be significant.
- Assumptions about the analyses' level of detail.
- Assumptions regarding the use and integration of previously conducted analyses from the ongoing FERC relicensing processes for the YRDP and Narrows Project to support the CEQA analyses.
- Approach to evaluating potential cumulative effects and climate change effects.

Resource-specific information about the analytical approach and methodology for evaluating the Proposed Projects and the alternatives considered is provided in the respective individual resource chapters included in this DEIR.

4.2 Organization of the DEIR

This DEIR begins with several introductory chapters and contains appendices that provide important foundations for analyses. The early chapters provide detail about the history and purpose of the YRDP and Narrows Projects (Chapter 1 – Introduction), a description of the Proposed

Projects (Chapter 2 - Project Description), a description of the alternatives considered (Chapter 3 - Alternatives), and the intended uses of this document (Chapter 1).

This DEIR includes analytical sections for the following resource categories: surface water resources, groundwater resources, power production and energy consumption, surface water quality, fisheries resources, biological resources (terrestrial and wildlife), recreation, visual resources, cultural resources, tribal cultural resources, air quality, greenhouse gas emissions, geology/soils, hazards and hazardous materials, wildfire, transportation, noise, agriculture and forest resources, land use/planning, public services, utilities and service systems, and other CEQA considerations (e.g., growth inducement, climate change). Chapters 5 through 25 each contain the following required CEQA components for these resource categories, which are generally organized into the sections described below.

- **Environmental Setting/Existing Condition**. This section of each resource chapter describes existing conditions at the time that the NOP was issued (i.e., October 28, 2024) for each resource in the Project Area where potential impacts may occur. The geographic scope of the environmental setting may vary for each resource depending on impact mechanisms and the extent of the area in which impacts are expected to occur for a resource. The environmental setting section in each resource chapter identifies and characterizes existing conditions for the resource and describes historical changes and trends affecting the resource based on the best available information. Unless otherwise noted, the existing conditions described in the Environmental Setting section are used as the CEQA baseline when comparing alternatives to determine the magnitude of impact.
- **Regulatory Setting**. The applicable laws, regulations, and programs considered in the assessment of potential project impacts are provided in this section of each resource chapter, as appropriate. Applicable laws, regulations, and programs associated with state and federal agencies that have a review or potential approval responsibility have also been considered in the development of CEQA impact thresholds or are otherwise considered in the assessment of environmental impacts. A listing of some of the agencies and their respective potential review and approval responsibilities, in addition to those under CEQA, is provided in Chapter 1.
- **Impact Assessment Methodology.** This section of each resource chapter describes the resource-specific methodology used to identify and assess potential environmental impacts that may result from implementing the Proposed Projects or an alternative.
- **Impact Indicators and Significance Criteria.** This section of each resource chapter describes the impact indicators and a threshold(s) of significance as an identifiable qualitative, quantitative, or performance-level threshold, where exceedance of the threshold would be determined to be a significant environmental impact, and being under the threshold would likely be considered a less-than-significant impact.
- **Environmental Impact Analysis.** This section of each resource chapter describes the direct, indirect, and cumulative environmental impacts associated with a particular resource that may result from construction, operation, or maintenance of the Proposed Projects (or an alternative) and is organized into subsections, as described below. This section of each resource chapter: (1) describes direct and reasonably foreseeable indirect environmental impacts associated with the No Project Alternative (as applicable to both

the YRDP and the Narrows Project), the Proposed Projects, and alternatives; (2) explains the CEQA significance conclusions; and (3) identifies mitigation measures (if any) that could be used to reduce or avoid potentially significant environmental impacts. For each resource, specific measures are proposed when feasible and necessary to avoid, reduce, minimize, or compensate for potentially significant environmental impacts of the Proposed Projects. This is consistent with CEQA's specific requirement that, whenever possible, agency decision makers adopt feasible mitigation to reduce a project's significant impacts to a less than significant level (CEQA Guidelines § 15126.4). For each resource, the potentially significant environmental impacts (if any) associated with mitigation measures are discussed and analyzed. This section further evaluates whether the proposed mitigation measures would result in reducing the potential impact to a less than significant level, as well as whether the measure(s) are technically and economically feasible to implement, thus demonstrating that the mitigation measures will meaningfully lessen the potential negative effects on the environment.

- **Cumulative Impact Assessment.** This section of each resource chapter discusses whether there would be a potentially cumulative significant environmental impact from the Proposed Projects' effects in combination with those of closely related past, present, and reasonably foreseeable probable future projects and determines whether the Proposed Projects (or a Project Alternative) could make a cumulatively considerable contribution to any cumulatively significant impacts. Cumulatively considerable means that "*the incremental effects of the individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects*" (CEQA Guidelines § 15130(a)). This section further identifies feasible mitigation measures (if any) that could be used to reduce or avoid any potentially significant cumulative impacts of the Proposed Projects (or a Project Alternative).

4.2.1 Environmental Resources Not Evaluated in Detail

During preparation of this DEIR, it became evident that some environmental resources are present in the Project Area, but no impact on these resources was identified that could potentially occur as a result of the Proposed Projects and alternatives. Based upon a review of the CEQA Appendix G Environmental Checklist, the scope of this DEIR has been focused on those environmental resources that potentially would be significantly affected by implementation of the Proposed Projects, and the following environmental topics have been eliminated from detailed consideration in this DEIR. These topics were dismissed from further analysis, for the reasons summarized below and discussed in more detail in **Appendix 4A**.

- **Mineral Resources** - The Proposed Projects do not involve the extraction of any mineral resources and would not: (1) result in the loss of availability of a known mineral resource that would be a value to the region and the residents of the state; or (2) result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.
- **Population and Housing** - The Proposed Projects do not involve the construction of new homes or businesses (or the substantial expansion of roads and infrastructure) that could result in growth-inducing effects. Therefore, the Proposed Projects would not induce substantial unplanned population growth in an area, either directly (for example, by

proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure). The Proposed Projects also would not displace substantial numbers of existing people or housing, necessitating the construction of replacement housing elsewhere. Water provided by the Proposed Projects would be used to fill existing needs, not to support new, unplanned growth. Therefore, the Proposed Projects would not result in growth-inducing impacts, cause or remove an obstacle to growth, or result in growth-inducing impacts associated with changes in water deliveries.

4.3 Approach to the CEQA Analysis

CEQA requires the preparation of an EIR when there is substantial evidence in light of the entire record that supports a fair argument that a project, such as approval and implementation of the Proposed Projects here, may have a significant impact on the environment. This DEIR discloses and presents analysis of the potential environmental impacts of the Proposed Projects and alternatives and describes ways to mitigate or avoid potentially significant effects. Pursuant to CEQA Guidelines Section 15126.6(a), this DEIR describes a range of reasonable alternatives that would feasibly attain all or most of the basic project objectives and, where possible, avoid or substantially lessen significant environmental impacts.

4.3.1 Geographic Extent of the Environmental Setting

4.3.1.1 YRDP

The geographic area (aka Project Area) that could be affected by the YRDP and that has been identified for this DEIR includes the Yuba River Watershed and the streams, waterbodies, groundwater basins, and facilities that could be particularly affected by changes in Yuba River outflow to the Feather River. These areas (Figure 4.3-1) include:

- New Bullards Bar (NBB) Reservoir.
- North Yuba River below NBBD to the confluence with the Middle Yuba River.
- Our House Diversion Dam (OHDD) Impoundment on the Middle Yuba River.
- Middle Yuba River (i.e., OHDD Reach) from OHDD to the confluence with the North Yuba River.
- Oregon Creek (Log Cabin Diversion Dam Reach) downstream to the confluence with Middle Yuba River.
- Englebright Reservoir.
- Lower Yuba River to the confluence with the Feather River.
- North Yuba and South Yuba Groundwater Subbasins (Yuba Subbasins) of the Sacramento Valley Groundwater Basin (see Chapter 6).

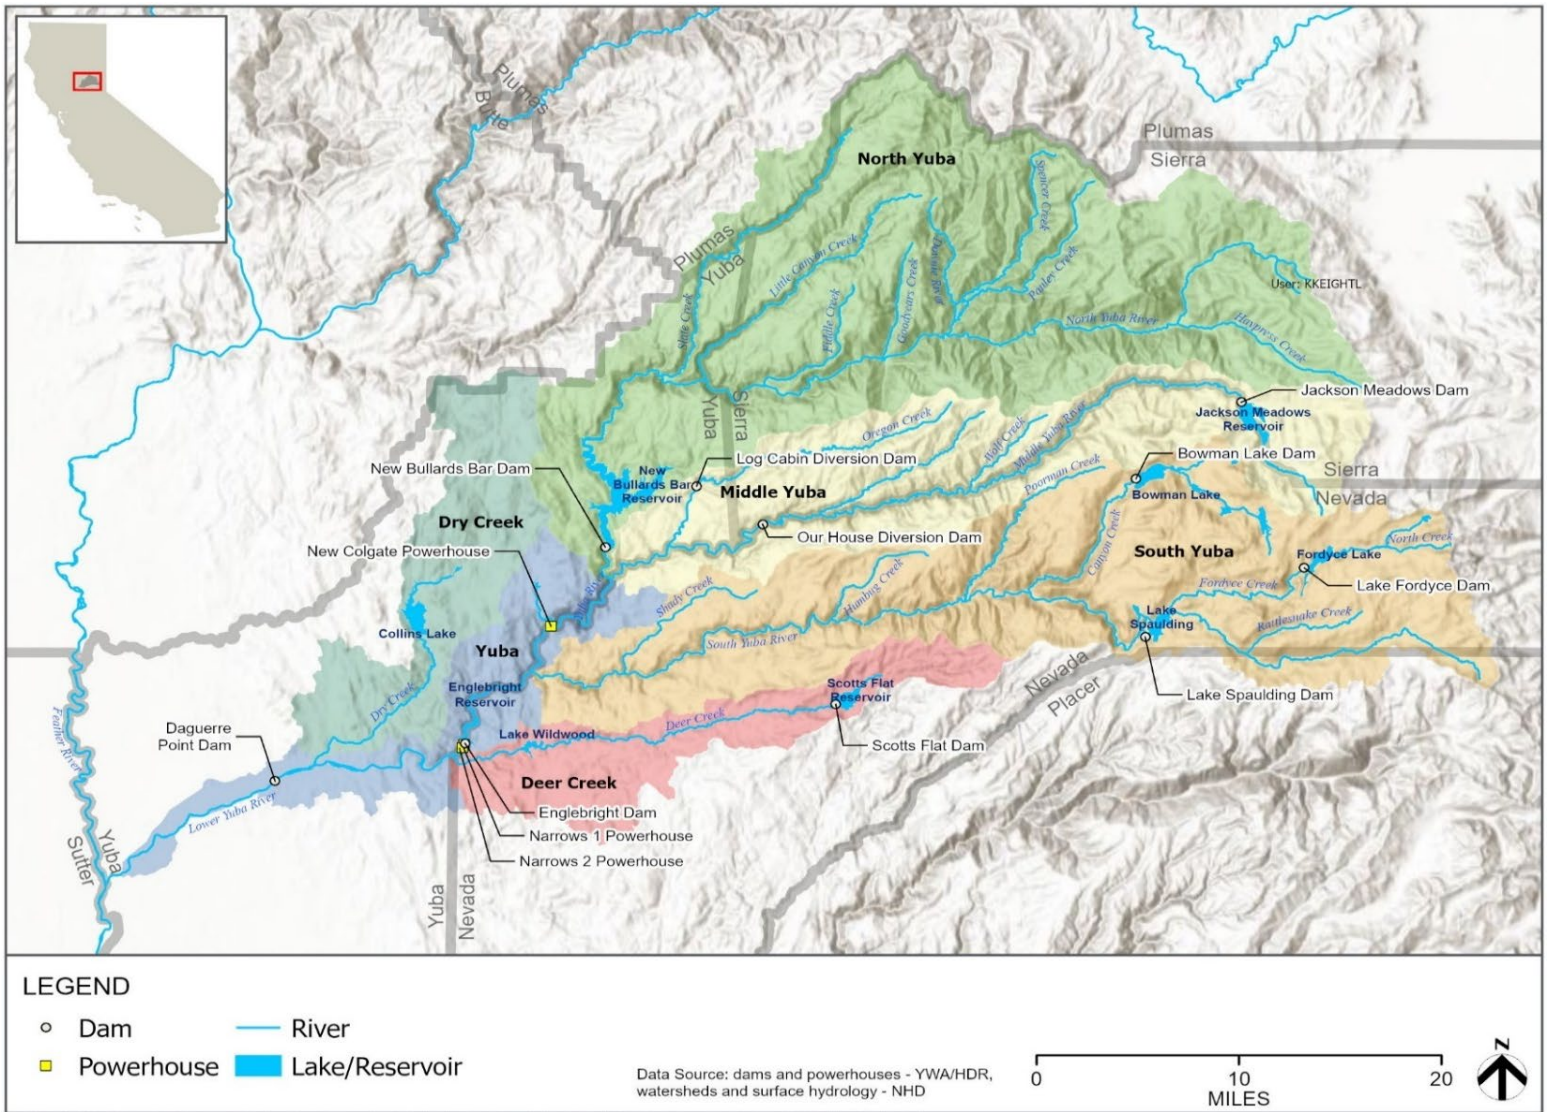

Figure 4.3-1. Geographic extent of the Project Area for the YRDP.[1]

[1] NOTE: For a limited number of water-related resources (i.e., surface water resources, surface water quality and fisheries), the potential exists for changes in Yuba River outflow to also affect hydrologic conditions in the lower Feather River, the lower Sacramento River and the Delta.

Due to the potential for indirect impacts and indirect cumulative impacts that may occur as a result of potential YB/DS operational changes associated with the provision of 15.6 TAF under Alternative 1 (see Chapter 3 of this DEIR), the following additional areas are included in the Project Area for certain environmental resources (i.e., surface water resources, surface water quality and fisheries).

- Jackson Meadows Reservoir.
- Middle Yuba River below Jackson Meadows Dam and Milton Diversion Dam to the OHDD Impoundment.
- Bowman Lake.
- Canyon Creek below Bowman Lake and Bowman-Spaulding Diversion Dam to its confluence with the South Yuba River.
- Fordyce Lake.
- Fordyce Creek from Fordyce Lake to Lake Spaulding.
- Lake Spaulding.
- South Yuba River below Lake Spaulding to Englebright Reservoir.

In addition, for a limited number of water-related resources (i.e., surface water resources, surface water quality and fisheries), the potential also exists for changes in Yuba River outflow to affect hydrologic conditions in the lower Feather River, the lower Sacramento River and the Delta (see discussion below).

4.3.1.2 Narrows Project

The geographic area that could be affected by the Narrows Project and that has been identified for this DEIR includes the lower Yuba River and facilities that could be affected by changes in Yuba River outflow to the Feather River. These areas include:

- Lower Yuba River to the confluence with the Feather River.

For the Narrows Project, the geographic extent of the lower Yuba River extending from Englebright Dam downstream to the confluence with the Feather River also is shown in Figure 4.3-1. In addition, for a limited number of water-related resources (i.e., surface water resources, water quality and fisheries), the potential also exists for changes in Yuba River outflow to affect hydrologic conditions in the lower Feather River, the lower Sacramento River and the Delta (see discussion below).

4.3.1.3 Downstream Extent of the Project Area

Consistent with FERC's (2019; 2024a) analyses conducted for both the YRDP and the Narrows Project, it is generally not anticipated that direct, indirect or cumulative effects on environmental resources would occur downstream of the mouth of the lower Yuba River (i.e., in the lower Feather River or Sacramento River). YCWA's March 2022 response to FERC's March 2021 AIR item

2(c) included a sensitivity analysis to determine whether hydrological changes associated with the YRDP could have the potential to change flow and water temperature conditions downstream in the Feather River. To support the determination of geographic extent of the Project Area for this DEIR, Yuba Water's sensitivity analysis was updated to incorporate operations of both the YRDP and the Narrows Project, as well as recent updates to the modeling tools and applications (e.g., period of simulation) that are described in Chapter 5 of this DEIR. As discussed below, the updated sensitivity analysis reaffirms that it is generally appropriate to identify the confluence of the lower Yuba River and the Feather River as the downstream extent of the Project Area.

Flow Considerations

To investigate whether Yuba River flows under the Proposed Projects or alternatives could result in measurable changes in lower Feather River aquatic habitat conditions, the following analysis was conducted consistent with Yuba Water's March 2022 FERC AIR analysis of the potential effect of changes in Yuba River flows on the Feather River.

- Step 1. Modeled daily flows in the lower Yuba River at Marysville were averaged to obtain monthly average flows under the Proposed Projects scenario and the Base Case (Existing Condition) scenario.
- Step 2. Historical average daily flows in the Feather River near Gridley for the period of October 1, 1969 through September 30, 2021 were obtained from the DWR Water Data Library.
- Step 3. For the portion of the period of record of October 1, 1969 through September 30, 2021, the daily average flows in the lower Yuba River at Marysville under the Proposed Projects scenario and the Existing Condition were modeled, and then added to the daily average flows in the Feather River below Gridley to determine a representative Feather River flow below the Yuba River.
- Step 4. Monthly averages for the full period of record were computed based on the daily average synthetic Feather River flow below the Yuba River.
- Step 5. The percent changes in monthly average flows in the Feather River immediately downstream of the Yuba River were evaluated to investigate whether changes in lower Yuba River flows at Marysville resulting from the Proposed Projects have the potential to result in detectible changes in lower Feather River flows downstream of the confluence with the lower Yuba River.

Over the 624 months of the period evaluated (Oct 1969-Sep 2021), the average difference in monthly average flow for the Proposed Projects compared to the Existing Condition is 0.11 percent (11 one-hundredths of 1 percent). Consequently, the Proposed Projects scenario, relative to the Existing Condition, would not result in detectable changes in Feather River flows immediately downstream of the Yuba River, and changes in aquatic habitat conditions downstream of the mouth of the Yuba River would not be measurable. Similarly, the average difference in flow for Alternative 1 compared to the Future Baseline is 0.36 percent (36 one-hundredths of 1 percent) and Alternative 1 would not result in detectable changes in Feather River flows relative to the Future Baseline and changes in aquatic habitat conditions downstream of the mouth of the Yuba River would not be measurable.

Moreover, operations of DWR's SWP control relatively large flows in the lower Feather River. Thus, even if measurable changes to flows in the Yuba River were to occur, it would not be practicable to attempt to segregate potential changes in lower Feather River flow downstream of the Yuba River associated with potential changes in Yuba River outflow. This conclusion is consistent with previous analyses, as when NMFS (2016) excluded the Sacramento River downstream from the Feather River from the action area for its BO on DWR and FERC's activities at the Oroville Facilities Hydroelectric Project (FERC Project No. 2100-134), stating "*While operations of Oroville Facilities do influence flows downstream of the confluence of the Feather River and the Sacramento River, through the Delta, San Pablo and San Francisco Bays to the ocean, these flows are mixed with natural flows and those related to the operation of the CVP, so that the effects are not easily segregated. The broader effects of the Oroville Facilities as part of the coordinated operations of the CVP and SWP are analyzed in the CVP/SWP BO. These include the effects of the co-mingled flows of the CVP and SWP in the lower Sacramento River, downstream from the confluence of the Feather River with the Sacramento River, through the Sacramento-San Joaquin River Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and westward to the Pacific Ocean. Therefore, …we do not consider the downstream effects of the proposed action in terms of how the Feather River flows influence the Sacramento River and fish downstream of the Feather River…"* By contrast to most other environmental resources considered in this DEIR, the potential effects of co-mingled flows would primarily affect fisheries resources. Similar to the approach taken by NMFS (2016), considerations regarding system-wide effects of coordinated CVP/SWP operations in the Feather River, the Sacramento River and the Delta are indirectly taken into account within the context of describing the status of the species (e.g., the Central Valley spring-run Chinook salmon ESU, the California Central Valley steelhead DPS and the Southern DPS of North American green sturgeon) under the environmental setting in Chapter 9 of this DEIR.

With respect to Alternative 2 – which is included as requested by the SWRCB and others for the purpose of including an alternative representing implementation of the SWRCB's "regulatory pathway" in the draft Water Quality Control Plan for the Draft Bay-Delta Plan Update – it is recognized that the Draft Bay-Delta Plan Update is ultimately intended to provide benefits to the Delta. In 2023, the SWRCB issued its DSR, which the SWRCB stated was a draft SED under its certified regulatory program for the purposes of CEQA to analyze the environmental impacts of adopting and implementing possible Draft Bay-Delta Plan Update alternatives (SWRCB 2023). The SED was prepared prior to the release of the most recent Draft Bay-Delta Plan Update and did not include a specific proposal for moving forward with the Bay-Delta Plan (SWRCB 2023a; 2023b). In the DSR, the SWRCB's draft analysis stated that, by providing higher flows to support a connected and functioning ecosystem and benefit native fish in the Sacramento Valley and the Delta, the Draft Bay-Delta Plan Update's proposed "regulatory pathway" scenario involving unimpaired flows would be expected to improve conditions for native fish and wildlife in the Sacramento Valley and the Delta over time. The DSR, however, does not contain water temperature modeling for the Yuba River and instead only states an assumption that higher streamflows generally will lower water temperatures. Yuba Water's 2022 responses to FERC's March 2021 AIR demonstrates, however, that at least some scenarios involving increased streamflow requirements would result in significant water temperature increases that would be adverse for Chinook salmon, among other species.

Because flows exiting the lower Yuba River under Alternative 2 must pass through the lower Feather River and the lower Sacramento River before entering the Delta, a discussion of potential impacts associated with Alternative 2 must consider these downstream areas. Using a similar methodology as was used for the Proposed Projects and Alternative 1, the change in Feather River flows under Alternative 2 would be 6.61% (relative to the Existing Condition) and 6.11% (relative to the Future Baseline). However, as described above, the Feather River would likely be similarly compelled to release 55% of unimpaired flows, so any quantified evaluation of the effect of flows from the Yuba River is not possible. Because implementation of the SWRCB's Draft Bay-Delta Plan Update (i.e., the unimpaired flows identified in a "regulatory pathway" scenario) would not only apply to Yuba Water, but to many other entities (including those that manage the CVP and the SWP), it would be speculative to make operational assumptions about how the SWRCB's Draft Bay-Delta Plan Update could be implemented throughout the Sacramento Valley (e.g., Feather River, Sacramento River, Delta) for modeling purposes. Since 2019, only two approaches to modeling how the SWRCB's Draft Bay-Delta Plan Update could be implemented have been undertaken by the state. More recently, many conditions have changed and a SWRCB Draft Bay-Delta Plan Update potential "regulatory pathway" scenario continues to evolve as a result of comments that the SWRCB has received on its DSR (SWRCB 2023), comments on its *October 2024 Draft Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Watershed* (SWRCB 2024), comments from SWRCB workshops held during 2024 and working meetings that are ongoing (SWRCB 2025).

Although Yuba Water has not speculated about how the SWRCB's Draft Bay-Delta Plan Update "regulatory pathway" could be implemented at the state-wide level, Yuba Water has investigated how changed YRDP operations as part of the SWRCB's Draft Bay-Delta Plan Update would be expected to affect flows in the lower Yuba River. Yuba Water's modeling conducted to evaluate Alternative 2 suggests that flow changes in the lower Yuba River associated with the regulatory pathway represented by the SWRCB's Draft Bay-Delta Plan Update would generally occur within the same range of hydrologic conditions that resulted over the 624 months of the period (Oct 1969-Sep 2021) evaluated for the sensitivity analysis described in the fourth paragraph above.

Water Temperature Considerations

Because Yuba Water's Relicensing Water Temperature Model (Temp Model) does not simulate changes in lower Feather River water temperatures, it is not possible to make a direct comparison of modeled daily water temperature changes at Marysville in the lower Yuba River with potential daily water temperature changes downstream in the lower Feather River. Therefore, to investigate whether changes in Yuba River water temperatures under the Proposed Projects could result in measurable changes in lower Feather River aquatic habitat conditions, the following analysis was conducted consistent with Yuba Water's March 2022 FERC AIR analysis of the potential effect of changes in Yuba River flows on the Feather River.

- Step 1. Modeled daily water temperatures in the lower Yuba River at Marysville were averaged to obtain monthly average water temperatures under the Proposed Projects scenario and the Base Case (Existing Condition) scenario.

- Step 2. The weighted daily average water temperature downstream from the Yuba River was computed by comparing the flow and water temperature at the mouth of the Yuba River with that from the Feather River upstream of the Yuba River. Flows were determined using the analysis described in Section 4.3.1.1.1. Water temperatures in the Feather River were developed based on the approach described in Yuba Water's March 2022 FERC AIR response using historically-measured flow and temperature data in the Feather River at Gridley.
- Step 3. For the portion of the period of record that is common between the modeling and historical data, which extends from October 28, 1980 through September 30, 2021, the flow-weighted daily average water temperature in the Feather River below its confluence with the Yuba River was computed using each day's average water temperature and flow for the Yuba River at its confluence with the Feather River, and average flow and water temperature on the Feather River upstream from the Yuba River.
- Step 4. Monthly averages for the full period of record were computed based on the daily average synthetic Feather River temperatures below the Yuba River.
- Step 5. The percent change in monthly average water temperatures in the Feather River near the confluence with the Yuba River was evaluated to investigate whether changes in lower Yuba River water temperatures at Marysville have the potential to result in detectible changes in lower Feather River water temperatures.

The period of interest for this water temperature evaluation extends from May through November. Over the 211 months of the period evaluated (November 1989-September 2021), the average difference in monthly average water temperature is 0.31 percent (31 one-hundredths of 1 percent). Consequently, the Proposed Projects, relative to the Existing Condition, would not result in detectable changes in Feather River water temperatures immediately downstream of the Yuba River, and changes in aquatic habitat conditions downstream of the mouth of the Yuba River would not be measurable. Similarly, the average difference in monthly average water temperature for Alternative 1 compared to the Future Baseline is 0.14 percent (14 one-hundredths of 1 percent) and Alternative 1 would not result in detectable changes in Feather River water temperatures immediately downstream from the mouth of the Yuba River and changes in aquatic habitat conditions downstream of the mouth of the Yuba River would not be measurable.

Therefore, based on these flow and water temperature considerations associated with the Proposed Projects, this DEIR does not include the lower Feather River or other downstream areas as part of the geographic scope of the analysis for most environmental resources. However, the SWRCB states that the Draft Bay-Delta Plan Update "regulatory pathway" (represented as Alternative 2 in this DEIR) is intended to provide benefits to the Delta. As such, certain water-related resources (i.e., surface water resources, water quality and fisheries) in this DEIR give consideration to the potential for changed conditions (both beneficial and/or adverse) that may be expected to result in areas downstream (e.g., the lower Feather River, lower Sacramento River and Delta) – these considerations are addressed in a qualitative manner.

4.3.2 CEQA Baseline (Existing Condition)

Section 15125 of the CEQA Guidelines states "*An EIR must include a description of the physical environmental conditions in the vicinity of the project. This environmental setting will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant."*

The CEQA Guidelines further explain that the baseline physical condition (CEQA Baseline) often reflects the "*physical environmental conditions as they exist at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced*…." In some cases, however, "*[w]here existing conditions change or fluctuate over time, and where necessary to provide the most accurate picture practically possible of the project's impacts,*" the CEQA Baseline may appropriately reflect "*historic conditions, or conditions expected when the project becomes operational, or both, that are supported with substantial evidence.*" Similarly, "*a lead agency may also use baselines consisting of both existing conditions and projected future conditions that are supported by reliable projections based on substantial evidence in the record*."

The CEQA Baseline employed in this DEIR is consistent with the principles outlined above. Because FERC is preparing a supplement to the 2019 FEIS for the YRDP and has not yet issued a NEPA environmental compliance document for the Narrows Project, Yuba Water has elected to prepare a new, standalone EIR for both the YRDP and the Narrows Project to comply with CEQA. On October 28, 2024, Yuba Water released a NOP to prepare an EIR for the YRDP and the Narrows Project (refer to Appendix 1A and 1B, Project Scoping Summary Reports and attachments for copies of the November 7, 2022 NOI and the October 28, 2024 NOP).

Consistent with the considerations of the CEQA Baseline discussed above, the existing condition for this DEIR includes the O&M activities of the YRDP and the Narrows Project in effect in 2024. Assumptions for the existing condition related to operations of the YRDP include actions required by: (1) the existing FERC license for the YRDP; (2) the minimum-flow and other flow-related actions that are part of the Lower Yuba River Accord (no expiration date in SWRCB Corrected Order WR 2008-0014); (3) Yuba Water's water rights for power described in Section 2.4.3.3.2 of Chapter 2; and (4) other existing agreements and contracts (e.g., water supply deliveries, Yuba Water's water transfers) that are described in Section 2.4.3.3 of Chapter 2. Assumptions for the existing condition related to operations of the Narrows Project include actions required by: (1) the existing FPA license for the Narrows Project; and (2) existing Yuba Water's YRDP operations. Details regarding the existing YRDP and Narrows Project facilities and operations under the CEQA Baseline (Existing Condition) are described in Chapter 2, Section 2.3 (Existing Projects).

Under the CEQA Baseline (Existing Condition), both of the FERC Proposed Projects would continue to operate into the future as they have operated since the YRDP's original FERC license ended in 2016, and no new environmental PM&E measures would be implemented. For modeling purposes, the Existing Condition is characterized as the continuation of annual 1-year FERC licenses for the YRDP, consistent with conditions occurring since 2016. Additional information on the assumptions used to characterize the Exiting Condition for modeling purposes are available in Chapter 5 and the related modeling appendices (**Appendices 5A to 5E)**.

4.3.3 Other Baseline Assumptions Used in this DEIR

To support the impact analyses conducted as part of this DEIR, Yuba Water has decided to apply a "dual baseline" approach, which involves the characterization and use of a future baseline in addition to the use of the typical Existing Condition basis of comparison under CEQA. The section below has been prepared to explain why a future baseline is being considered, and why it is appropriate to also use a future baseline as part of the analysis to be conducted for the YRDP and Narrows Project in this DEIR.

4.3.3.1 Characterization of the Future Baseline (for modeling purposes only)

As noted above Section 15125 of the CEQA Guidelines states the use of a both existing and future baselines is permissible for analytical purposes if they are supported by reliable projections based on substantial evidence in the record (Cal. Code Regs. Tit. 14, § 15125). Use of both existing and future baselines is permissible and consistent with CEQA requirements here as explained below.

Both the YRDP and the Narrows Project are seeking new 50-year licenses from FERC. As discussed above in Section 4.3.2.3 (Existing Non-Project Facilities), several other FERC projects also are currently undergoing relicensing in the upper Yuba River Watershed including: (1) PG&E's Upper Drum-Spaulding Hydroelectric Project (FERC Project No. 2310), Lower Drum Hydroelectric Project (FERC Project No. 14530) and Deer Creek Hydroelectric Project (FERC Project No. 14530); and (2) NID's Yuba-Bear Hydroelectric Project (FERC Project No. 2266). Unlike many projects that are evaluated for CEQA purposes, there are unique aspects associated with the circumstances and surrounding conditions that are in place with having multiple ongoing FERC relicensing projects in the Yuba River Watershed.

Alternative 1 (Yuba Water's Offer of Settlement) includes a contribution of 15.6 TAF of water from the YB/DS projects that would be provided under new FERC licenses for those projects. Alternative 2 also includes new FERC licenses for the upstream YB/DS projects but not the contribution of 15.6 TAF of water. Because new FERC licenses for the YB/DS projects would necessarily include upstream mandatory 4(e) flow conditions regardless of whether either Alternative was approved, comparing these alternatives to the Existing Condition (which does not include upstream 4(e) conditions) could misinform and mislead the analysis by incorrectly attributing some differences in flows and water temperatures caused by the upstream 4(e) conditions to the alternatives. Thus, an accurate assessment of the effects of Alternatives 1 and 2 requires using a baseline that includes the YB/DS mandatory 4(e) flow requirements to isolate the potential impacts associated with each alternative. This DEIR refers to that baseline condition, which assumes a new FERC license for the YD/DS projects and associated mandatory 4(e) flow requirements, as the "Future Baseline."

This DEIR evaluates the potential impacts of Alternatives 1 and 2, relative to the Existing Condition, for informational purposes only. Because these comparisons are misleading, as explained above, the DEIR does not use the Existing Condition to draw significance conclusions for impacts resulting from Alternatives 1 and 2. All significance conclusions for Alternatives 1 and 2 are based on the comparisons between those alternatives and the Future Baseline.

By contrast, and as explained previously, the appropriate baseline for evaluating the impacts of the Proposed Projects and the No Project Alternative is the Existing Condition. To enable a useful comparison (i.e., one that is not misleadingly influenced by the upstream 4(e) requirements) between the Proposed Projects and Alternatives 1 and 2, however, this DEIR evaluates the impacts of the Proposed Projects relative to both the Existing Condition and the Future Baseline. This "dual baseline" approach allows Yuba Water to (i) draw significance conclusions using appropriate baselines for the Proposed Projects and all alternatives, (ii) meaningfully evaluate the relative benefits of the Proposed Projects and all alternatives, and (iii) disclose complete modeling results for informational purposes only, while recognizing the limitations inherent in results from unrealistic or misleading scenarios (e.g., Alternatives 1 and 2 compared to the Existing Condition). This approach satisfies CEQA's purposes of allowing the public and decisionmakers to compare the potential environmental effects of the Proposed Projects and alternatives.

Use of a Future Baseline for Project-Specific Application in this DEIR

To provide a complete analysis that satisfies the regulatory requirements of CEQA and that most accurately presents and analyzes potential impacts, the environmental resource analyses that rely on hydrologic modeling in this DEIR use a "dual baseline" approach that includes the following two scenarios as bases of comparison.

- **Existing Condition** – Includes the existing operations of all four FERC relicensing projects (i.e., YRDP, the Narrows Project and YB/DS projects).
- **Future Baseline** – Includes existing operations of the YRDP and the Narrows Project, and the future operations of the YB/DS projects operating at FERC 4(e) flows.

For additional information about the modeling assumptions related to each of the bases of comparison scenarios listed above, (see Chapter 5 - Surface Water Resources) and related appendices.

4.4 Overview of Impact Analysis Framework

For this DEIR, each resource chapter provides comprehensive analyses of construction and O&M impacts associated with the Proposed Projects depending on specific impact mechanisms relevant to each resource topic. The analysis provided in each chapter is specific to the environmental resource being evaluated, the data available, and the impact mechanisms expected as a result of the YRDP and Narrows Relicensing Projects. Project elements that are not expected to have impacts on a given resource are not discussed at the same level of detail as project elements that are expected to have environmental impacts. Because construction-related impacts related to Alternative 1 and Alternative 2 are identical to those discussed for the Proposed Projects, they are not repeated in the subsequent discussion of potential impacts related to those alternatives.

For resource topics that could be affected by changes (e.g., flows, water temperatures) associated with operating the YRDP and Narrows Project facilities, modeled hydrology results were used to compare Project Alternatives. The impact analysis compares modeling outputs from one modeling scenario with outputs from another scenario to determine the potential for changes in hydrologic and environmental conditions. Parameters represented by the modeling outputs include reservoir

storages and water surface elevations, river flows, and river water temperatures. The analyses are organized to present the Proposed Projects scenarios first in each resource impact section followed by analyses of the alternatives and then the No Project Alternative.[2]

In each resource chapter of the DEIR, the subsection describing the anticipated environmental impacts and consequences discusses the potential impacts associated with the following comparisons, in the following order:

- Proposed Projects compared to the Existing Condition.
- Proposed Projects compared to the Future Baseline (water-related modeled resources only, to enable a useful comparison to Alternatives 1 and 2).
- Alternative 1 compared to the Existing Condition (as this comparison is misleading for water-related modeled resources, it is provided for those resources for informational purposes only).
- Alternative 1 compared to the Future Baseline (water-related modeled resources only).
- Alternative 2 compared to the Existing Condition (as this comparison is misleading for water-related modeled resources, it is provided for those resources for informational purposes only).
- Alternative 2 compared to the Future Baseline (water-related modeled resources only).
- No Project Alternative compared to the Existing Condition.
- Cumulative Condition (Proposed Projects) compared to the Existing Condition.
- Cumulative Condition (Alternative 1) compared to the Existing Condition.
- Cumulative Condition (Alternative 2) compared to the Existing Condition.

Modeling scenarios were developed to represent existing and future hydrologic conditions with and without implementation of the Proposed Projects and alternatives to enable an evaluation of potential environmental impacts for water-related resource. These scenarios include: (1) Existing Condition; (2) Future Baseline (water-related modeled resources only); (3) No Project Alternative; (4) Proposed Projects; (5) Alternative 1; (6) Alternative 2; (7) Cumulative Condition (Proposed Projects); (8) Cumulative Condition (Alternative 1); and (9) Cumulative Condition (Alternative 2). The hydrologic modeling and related post-processing of outputs is used to simulate Yuba Water's project operations associated with implementation of the YRDP and Narrows Relicensing Projects.

For evaluations of the Proposed Projects and alternatives that involve potential flow-related impacts on environmental resources, the Future Baseline is used as the analytical basis of

[2] As discussed in Chapter 3, the potential hypothetically exists for the following circumstances to occur under the No Project Alternative: (1) Yuba Water does not accept new FERC licenses for either the YRDP or the Narrows Project; (2) Yuba Water accepts a new FERC license for the YRDP, but not the Narrows Project; or (3) Yuba Water accepts a new FERC license for the Narrows Project, but not the YRDP. For the reasons explained in Chapter 3, there is no possibility that circumstance #3 (accept a new license for Narrows but not the YRDP) would occur. As also explained in Chapter 3, activities resulting from circumstance #2 would be very similar to those that would occur as a result of circumstance #1. For this reason, the assumptions used to characterize the No Project Alternative for quantitative analysis purposes assume the conditions that would be expected to occur if Yuba Water does not accept new FERC licenses for either the YRDP or the Narrows Project.

comparison for significance determination. Although not all environmental resource analyses may use the detailed model output results involving the Future Baseline, those resources that specifically rely upon modeling to support impact conclusions include surface water resources, surface water quality, fisheries resources, biological resources, recreation, visual resources and to a lesser extent, cultural resources.

As discussed above, this DEIR evaluates the potential impacts of Alternatives 1 and 2, relative to the Existing Condition, for informational purposes only. Because these comparisons are misleading for the reasons explained above, the DEIR does not use the Existing Condition to draw significance conclusions for impacts resulting from Alternatives 1 and 2. Significance conclusions for Alternatives 1 and 2 that pertain to simulated changes in hydrology rely upon evaluation comparisons that use the Future Baseline as the basis of comparison.

The evaluation of potential indirect impacts is only conducted for the "Alternative 1 relative to Existing Condition" and the "Alternative 1 relative to the Future Baseline" comparisons because only Alternative 1 would involve changes to hydrologic conditions in the Middle Yuba River upstream of the YRDP's OHDD and in the South Yuba River in response to the provision of 15.6 TAF from the YB/DS projects. With respect to impact determinations associated with potential indirect impacts under Alternative 1, the Future Baseline is the appropriate basis of comparison. Because the Future Baseline includes the existing operations of the YRDP and the Narrows Project, and the future operations of the YB/DS projects operating at FERC 4(e) flows, this comparison allows for meaningful comparison that isolates changes specifically due to the provision of the 15.6 TAF. As explained in Chapter 3, Alternatives, this DEIR analyzes the potential indirect impacts resulting from YB/DS operations upstream of the YRDP under Alternative 1 on a programmatic level based on the information that is currently available to Yuba Water and reasonably foreseeable assumptions about how those non-Yuba Water operations would occur to meet Federal and California regulatory requirements. To the extent that YB/DS operations under new FERC licenses would have impacts that are outside the scope of those disclosed in this EIR or in the CEQA document(s) prepared by NID or PG&E for the new YB/DS FERC licenses, those impacts will need to be addressed through subsequent project-level CEQA review before NID and PG&E accept the new licenses.

For the "Alternative 2 relative to the Existing Condition" scenario, Yuba Water determined that it is not reasonable to evaluate potential indirect impacts associated with Alternative 2 and the YB/DS projects in the upper Yuba River Watershed for the following reason. If the SWRCB adopts a "regulatory pathway" that includes a 55% unimpaired flow requirement for the Bay-Delta Plan Update, then it is anticipated that the SWRCB would seek implementation of the 55% unimpaired flow requirement through the WQCs that would be issued for the FERC relicensings that are occurring in the Yuba River Watershed. As described for Alternative 2 in Chapter 3, FERC has stated that it will be conducting the YRDP, Narrows, and YB/DS relicensings as a basin-wide proceeding. Therefore, if a 55% unimpaired flow requirement were part of the "regulatory pathway" adopted by the SWRCB as part of the Bay-Delta Plan Update, it would be reasonable to expect that all of the FERC relicensing projects (i.e., YRDP, Narrows Project and the YB/DS projects) would be required to operate in accordance with the conditions of the new FERC licenses (including the 4(e) flow requirements) that would be in effect, as well as operations necessary to comply with a 55% unimpaired flow requirement.

Comparison of model results for the different scenarios is used in the discussions of environmental effects in the following resource chapters of the DEIR:

- Chapter 5 - Surface Water Resources (Hydrology, Water Supply and Management)
- Chapter 6 - Groundwater Resources
- Chapter 7 - Power Production and Energy Consumption
- Chapter 8 - Surface Water Quality
- Chapter 9 - Fisheries Resources
- Chapter 10 - Biological (Terrestrial) Resources
- Chapter 11 - Recreation
- Chapter 12 - Visual Resources
- Chapter 13 - Cultural Resources
- Chapter 14 - Tribal Cultural Resources

4.5 Models Used for the Impact Analysis

The information provided in this Section 4.5 describes the hydrologic modeling tools that were used to support the environmental resources impact evaluations conducted in this DEIR. It provides an overview of the modeling tools, primary modeling assumptions, model inputs, and methodologies that are used to evaluate potential effects on reservoir operations, stream flow, water quality, and water temperature under the various scenarios that are analyzed in the DEIR.

4.5.1 YRDP Water Balance/Operations Model

As part of the YRDP FERC relicensing process, Yuba Water developed an operations model of the YRDP to simulate current and future operations of the YRDP using historical hydrology to define a representative range of hydrological conditions, and to output resulting flows, reservoir storage and water-surface elevations, and power generation for use by Yuba Water and the Relicensing Participants during the relicensing process. Operations for Narrows Project also are represented in the Yuba River Development Project Model (YRDPM). The YRDPM is intended to be used as a comparative model rather than a predictive one to eliminate any biases or inconsistencies in upstream operations. Potential changes in operations are measured as the relative difference in model output as it compares to a basis of comparison.

Yuba Water's YRDP AFLA model scenarios evaluated in FERC's (2019) FEIS were simulated using a hydrological period of record of WY 1970 through 2010 (41 years). Subsequent to the AFLA, the period of record was extended to a 52-year period of record (WY 1970-2021). Several updates also were made to the YRDPM to address FERC's 2021 AIR direction that the Yuba Water and the YB/DS licensees consult and develop an agreed-upon analysis of the amount of additional water from either storage or transfers to provide the necessary flow in dry and/or critically dry years (or combination of dry type years) to maintain cooler water in the Yuba River from July through November. While the YRDPM is essentially the same as the model used in previous Yuba

Water FERC-related analyses, several updates were made to enable the model to represent potential water temperature management actions in Yuba Water's CEQA alternatives. Updates to the YRDPM are described below.

4.5.1.1 Englebright Reservoir Variable Water Surface Elevation

Alternative 1 includes a variable Englebright Reservoir water surface elevation during Dry and Critical years. To simulate operations for an increased Englebright Reservoir water surface elevation, a time series for target elevations was added to the YRDPM to replace the static value previously used. Because the model operates the New Colgate Powerhouse to maintain storage at the target elevation, no further action would be needed to trigger increased New Colgate Powerhouse releases for an increased elevation. The YRDPM also includes an Englebright Reservoir water surface elevation trigger, at which point the full Narrows 1 and 2 powerhouse release capacity would be used to return storage to the target elevation. This value was changed from a single value to a time series in the YRDPM update. These two new time series would work in concert to operate the New Colgate and Narrows 1 and 2 powerhouses to maintain water surface elevation in Englebright Reservoir.

For purposes of evaluating the benefits of raising the Englebright Reservoir water surface elevation, a target elevation of 519 feet above mean sea level (ft-msl) was used for November 1 through August 25, and an elevation of 525 ft-msl was used for September 9 through October 15. The water surface elevation would be gradually increased between August 26 and September 8, and gradually decreased between October 16 and October 31. The elevation trigger for maximum Narrows 1 and 2 powerhouse releases was 523 ft-msl from November 1 through August 25, and 526 ft-msl from September 9 through October 15. The trigger elevation increased and decreased during the same times as the target elevations.

4.5.1.2 Increases in Flows in the Yuba River below Englebright Dam

Alternative 1 also includes increased flows below Englebright Dam during Dry and Critical years, based on the Smartsville Index year-type definitions. Yuba Water added logic to allow the user to specify the flow rate and the Smartsville Index trigger for the additional block of water, and the start and end dates for the release.

Alternative 1 includes an additional 175 cfs between September 1 and October 15 when the Smartsville Index indicated the WY type was Dry (Smartsville Index <=1,460 TAF) or drier. The additional flow requirement was added to the Yuba River flow requirement at the Smartsville and Marysville gages.

4.5.1.3 Narrows Project Model Updates

To better describe the "base case" (Existing Condition) for the Narrows Project FERC relicensing (in progress as a separate FERC relicensing) Yuba Water used the newly updated YRDPM. As discussed above, the YRDPM was updated to simulate operation of the YB/DS projects that affect flows on the Middle Yuba River and South Yuba River upstream of the YRDP and to be consistent with models used for the upstream YB/DS relicensing projects. For the Narrows Project relicensing, Yuba Water made three changes to the YRDPM: (1) Yuba Water updated the logic to

reflect the current approach for allocating flows between the Narrows 1 and Narrows 2 powerhouses; (2) Yuba Water added the annual Narrows 1 and 2 Powerhouse outage periods; and (3) Yuba Water updated the approach used to compute Narrows 1 Powerhouse generation to better reflect the results of a 1941 flow test performed by PG&E. The period of record for the YRDPM used for the Narrows Project relicensing includes representative dry, wet, and normal periods, and is consistent with the updated period of simulation used in the YRDP AIR response simulations.

For this DEIR, Yuba Water's current YRDPM simulates YRDP and Narrows Project operations on a daily timestep for a 52-year period of record (WY 1970 through 2021). Additional details about the YRDPM are provided in **Appendix 5A** (Water Operations Model TM), and a full description of the updates to the YRDP hydrology model are provided in Technical Memorandum – Modeling Approach (YCWA 2021),[3] which was submitted to FERC on December 7, 2021 as part of Yuba Water's response to FERC's AIR.

4.5.1.4 Operations to Meet a 55% Unimpaired Flow Requirement on the Middle Yuba River

Alternative 2 includes requirements to provide 55% of the unimpaired flow on the Middle Yuba River at its confluence with the North Yuba River. Under this analysis, NID's releases from the Milton Diversion Dam would be to meet their 4(e) requirements, and the 55% unimpaired flow at the mouth of the Middle Yuba River would be met through a combination of accretions between the Milton Diversion Dam and OHDD, accretions between Our House and Log Cabin Diversion Dams and the confluence of the Middle Yuba and North Yuba rivers, and Lohman Ridge Tunnel closures. Accretions between the Our House and Log Cabin diversion dams and the Middle Yuba River's confluence with the North Yuba River are added to computed unimpaired Middle Yuba River flow above OHDD to determine the total unimpaired Middle Yuba River flow at its confluence with the North Yuba River. Daily accretions below the Our House and Log Cabin Diversion dams are subtracted from 55% of the 21-day average unimpaired flow to compute the release requirement from OHDD, which is used in the model as a flow requirement below the OHDD.

4.5.1.5 Operations to Meet a 55% Unimpaired Flow Requirement on the Yuba River

The unimpaired flow requirement on the South Yuba River would be met through increased releases from Bowman and Spaulding dams and accretions upstream from Jones Bar. Yuba Water used its Upstream Project Model (Mini-Model, described in Chapter 5) to simulate operations of the YB/DS projects to meet a 55% unimpaired flow requirement on a daily basis on the South Yuba River Jones Bar. The division between Bowman and Spaulding Dams is based on their respective portion of unimpaired flows upstream from the dams. The Mini-Model used its standard reservoir storage targets to determine if the 55% unimpaired flow requirement was met from storage withdrawals or reductions in out-of-basin diversions.

[3] Available in FERC's eLibrary at Accession No. 20211207-5175 (Filed on December 7, 2021).

4.5.1.6 Operations to meet a 600 TAF Carryover Storage Requirement in Wet, Above Normal, and Below Normal Years

Alternative 2 includes requirements to provide 55% of the unimpaired flow of the whole Yuba River Watershed at the Marysville Gage, which represents the watershed's mouth at the Feather River. To represent operations to provide 55% of unimpaired flow at the mouth of the Yuba River, the cumulative unimpaired flows on the Middle Yuba and South Yuba rivers are added to the cumulative inflows from the North Yuba River, Oregon Creek, Deer Creek, and accretions to NBB and Englebright reservoirs and along the Yuba River downstream from Englebright Dam to compute the total unimpaired flow at the mouth of the Yuba River. 55% of the 21-day average total unimpaired flow is included as a requirement at the Marysville gage in addition to the FERC FEIS minimum flow. While NBB Reservoir releases were allowed to use the full New Colgate Powerhouse capacity, no increased releases through the NBB spillway or through the NBB low-level outlet to meet the 55% unimpaired flow requirement were included; the SWRCB has stated its intent is not to increase flood releases from storage reservoirs. Furthermore, releases from the spillway would be unreliable since they would only be possible when NBB storage was high enough to reach the spillway sill. In the cases that there was inadequate inflow to and releases from Englebright Reservoir to meet both agricultural water supply deliveries and the 55% unimpaired flow requirement, delivery shortages were allowed to go as high as 99% of the total demand on a daily basis to meet the flow requirement.

4.5.2 YRDP Water Temperature Model

Yuba Water also developed a Temp Model as part of the YRDP FERC relicensing process to simulate reservoir and stream water temperatures resulting from historical meteorology, inflow hydrology, and YRDP O&M for use by Yuba Water and the Relicensing Participants during the relicensing process. The three components of the Temp Model include: (1) Upstream of Englebright Reservoir (i.e., Upper Temp Model); (2) Englebright Reservoir (i.e., Englebright Temp Model); and (3) Downstream from Englebright Dam (i.e., Lower Temp Model). The Temp Model accurately reproduces observed reservoir and stream water temperatures, within acceptable calibration standards over a range of hydrologic and meteorological conditions to serve as a modeling platform and tool to simulate existing and potential future operations (YCWA 2013a).

The Temp Model simulation areas includes: (1) the Middle Yuba River from and including OHDD impoundment to the confluence with the North Yuba River; (2) Oregon Creek from and including the Log Cabin Diversion Dam impoundment to the confluence with the Middle Yuba River; (3) the North Yuba River from and including NBB Dam Reservoir to the confluence with the Middle Yuba River; and (4) the portion of the Yuba River from the confluence of the North and Middle Yuba rivers to the Feather River, including USACE's Englebright Reservoir.

The Temp Model applied in this evaluation is an updated version of the Yuba River Watershed Temp Model developed by YCWA (2017a), which simulates daily water temperatures for a period of record matching that of the updated YRDPM (WY 1970 through 2021). Yuba Water has undertaken extensive efforts to re-calibrate the water temperature model to reflect a greater range of conditions observed since the original calibration (circa 2013) using more recent data. Simulated daily flows and storages output from the YRDPM were used as inputs to the Temp Model. Yuba

Water relicensing Technical Memorandum 2-6 (Temp Model)[4] provides a detailed description of the various modeling platforms used in the development of the Temp Model.

The Temp Model applied in this evaluation is essentially the same one used in previous FERC-related analyses, although some other updates were made to address FERC's 2021 AIR, including: (1) representation of dual-level intakes to Colgate Powerhouse; and (2) updates to the YRDP Upper Project Spreadsheet Model. A full description of the updates to the Temp Model are provided in Technical Memorandum – Modeling Approach (YCWA 2021),[5] which was submitted to FERC on December 7, 2021, as part of Yuba Water's response to FERC's AIR. Additional details about the Temp Model are provided in **Appendix 5B** (Temp Model TM).

4.5.3 Modeled Scenarios and Comparisons

Table 4.5-1 identifies each model scenario developed for evaluation in this DEIR, including abbreviated nomenclature for ease of reference in the model output data, and the basis for development of each scenario.

Table 4.5-1. Model scenario nomenclature.

Scenario Number	CEQA Scenario Name	Abbreviated Name for Modeling Purposes
1	Existing Condition	Existing Condition
2	Future Baseline *	Future Baseline
3	No Project Alternative	No Proj
4	Proposed Projects (existing YB/DS without 4(e) Conditions)	Prop Proj (existing)
5	Proposed Projects (future YB/DS with 4(e) Conditions) *	Prop Proj (future)
6	Alternative 1	Alt 1
7	Alternative 2	Alt 2
8	Cumulative Condition (Proposed Projects)	Cumulative (Prop Proj)
9	Cumulative Condition (Alternative 1) *	Cumulative (Alt 1)
10	Cumulative Condition (Alternative 2) *	Cumulative (Alt 2)

* Includes Yuba-Bear/Drum-Spaulding (YB/DS) FERC 4(e) flow conditions.

4.5.4 Model Applications and Limitations

Although computer-based modeling tools assist in projecting physical, biological, and other factors related to potential impacts on environmental resources for comparative purposes, the modeling tools and analytical methods used in the impact analyses have limitations. Model assumptions and results are generally believed to be more reliable for comparative purposes than for absolute predictions of conditions. Results from a single simulation may not necessarily correspond to actual system operations for a specific month or year, but are representative of general conditions. Model results are best interpreted using various statistical measures such as long-term and year-type average, and probability of exceedance.

Yuba Water has voluntarily chosen to conduct a sensitivity analysis to investigate potential effects of climate change and how such climate change-related effects may potentially influence future YRDP and Narrows Project operations in the Yuba River Watershed under the Proposed Projects and alternatives (see Chapter 25 – Other CEQA Considerations). It should be recognized that potential changed conditions related to anticipated climate change and the future operation of the Proposed Projects in consideration of climate change are also highly uncertain. One source of

[4] Available in FERC's eLibrary at Accession No. 20140429-4062 (Filed on April 29, 2014).
[5] Available in FERC's eLibrary at Accession No. 20211207-5175 (Filed on December 7, 2021).

uncertainty in climate projections is the fact that different climate models may produce different outcomes (Cal-Adapt 2024). Over 30 global climate models have been developed by various climate modeling centers, and they have different ways of representing the climate system. In addition, some aspects of the climate system are less well understood than others, and scientists are constantly working to improve theories about the climate system and its representation in climate models (Cal-Adapt 2024). When sources of uncertainty in climate models are discussed (see Appendix 5E - Yuba River Development Project Model Climate Change Hydrology Report), it is to acknowledge that there could be a range in possible future outcomes. Uncertainties exist in the extent to which the climate will change in the future, the rate of future climate change, and precisely how the changes will affect natural and human systems (Cal-Adapt 2024).

4.5.5 Model Output Results for Environmental Resources

Each model scenario was simulated using hydrologic, hydraulic and water temperature modeling over a 52-year period of record (WY 1970-2021) to evaluate potential flow- and water temperature-related changes under each alternative scenario relative to a basis of comparison. For water-related environmental resources evaluated in this DEIR, Yuba Water utilized post-processed model output results to determine whether, and to what degree, each alternative comparative scenario could result in a potentially significant impact (or benefit), relative to the basis of comparison.

The results of these comparisons are evaluated to describe the potential changes in hydrologic parameters (e.g., instream flows, reservoir elevations, end-of-month reservoir storage, water temperatures) that would be expected to occur in the Project Area under the Proposed Projects and alternatives, relative to the basis of comparison. The evaluations of environmental impacts are made by comparing the differences in model outputs that are calculated in each of these comparisons over the 52-year period of hydrologic record to the impact indicators and significance criteria that were developed for each resource area. These evaluations are presented in the individual resource chapters (Chapters 5-14).

For each comparative scenario, a suite of model outputs at various locations in the Yuba River Watershed are available to support the environmental resource impact evaluations. A high-level summary of modeled flows and water temperatures for the YRDP reaches in all scenario comparisons is provided in **Appendix 4B** (Summary of Changes in Modeled Riverine Flows and Water Temperatures). More detailed scenario-specific model output results are presented in **Appendix 4C** (Flow and Water Temperature Data Products) and were used to inform the scope of the resource-specific analyses.

Although this DEIR does not present detailed, quantitative analyses of resource-specific impacts for the No Project Alternative compared to the Existing Condition (showing no changes), the model output results are presented in Appendix 4B for disclosure purposes.

4.6 Overview of the Types of Potential Impacts Considered

In the analysis conducted for this DEIR, mechanisms that could cause potential impacts are discussed for each environmental resource. General categories of impact mechanisms are construction, and O&M. Project-related impacts are categorized as follows and as appropriate, to

describe the intensity or duration of the impact:

- A temporary or short-term impact would generally occur only during project construction. Construction impacts would occur during the defined construction period (which would vary by facility and in some cases could extend several years) and include all activities that would occur to construct each project facility. Construction disturbance areas include the project facility footprint plus the land area around that footprint that would be used for materials laydown, soil stockpiling, equipment storage, construction vehicle parking, equipment/vehicle maintenance, spoil disposal, construction debris, batch plants, materials delivery, access roads, actual construction activity disturbance, and any other activity conducted during the construction period for a project purpose that would cease after the project facilities are built.
- A long-term or permanent impact would occur after the completion of project construction. In some cases, a long-term impact could be a permanent impact. Project O&M impacts include activities that must occur to operate and maintain each project facility. These activities and their associated impacts are long-term and permanent. Operation activities include those related to the movement of water (such as reservoir level fluctuations, or the intake or release of water), the generation/transmission of electricity, the use of roads during O&M activities, and the recreation activities that would be associated with operation of the project.
- A ***direct impact*** is an impact that would be caused by an action and would occur at the same time and place as the action.
- An ***indirect impact*** is an impact that would be caused by an action but would occur later in time or farther removed in distance, but are still reasonably foreseeable.

4.7 Assessment of Impacts

For the purposes of the analyses conducted in this DEIR, a combination of the CEQA Appendix G Environmental Checklist Form criteria are used, along with professional judgment that considers current regulations, standards, knowledge of the area, and the context and intensity of the environmental effects. The specific criteria for determining impacts will be listed in each resource chapter and used to develop one consistent impact conclusion by impact type.

For the environmental resource discussions presented in Chapters 5 through 24, separate impact statements are presented for the YRDP Relicensing Project and the Narrows Relicensing Project. Each identified impact statement has been formatted to include reference to the environmental resource and the scenario (or alternative) being evaluated. Table 4.7-1 presents an example of the naming convention format being used in the impact statements, using fisheries resources as an example. Included in each impact discussion is the reasoning indicating whether and why there would be an impact and the level of significance of each impact, when compared to the relevant bases of comparison.

Table 4.7-1. Example of Impact Statement Naming Conventions.

Environmental Resource Area	Impact Statement Numbering*
Fisheries Resources	YRDP Impact FISH-PP-#:
	Narrows Impact FISH-PP-#:
	YRDP Impact FISH-Alt1-#:
	Narrows Impact FISH-Alt1-#:
	YRDP Impact FISH-Alt2-#:
	Narrows Impact FISH-Alt2-#:

* Each resource impact is numbered, with the first impact numbered "1."

The level of significance of potential impacts described in the DEIR may be classified based on the following impact definitions:

- ***Beneficial Impact***: A beneficial impact would result in an improvement to the environment regardless of the threshold of significance. No mitigation is required.
- ***No Impact***: No change in the environment would result from implementing the Proposed Projects or an alternative. No mitigation is required.
- ***Less Than Significant Impact***: A less than significant impact would cause no substantial adverse change in the environment from implementing the Proposed Projects or an alternative. No mitigation is required.
- ***Less Than Significant with Mitigation Incorporated***: A potentially significant impact that is reduced to a less than significant impact with mitigation incorporated, which would cause no substantial adverse change in the environment from implementing the Proposed Projects or an alternative.
- ***Potentially Significant Impact***: A potentially significant impact may cause a substantial adverse change in the environment based on the evaluation of project effects using significance criteria specific to each resource. However, additional information is needed regarding the extent of the impact. A potentially significant impact is treated as a significant impact unless additional information indicates that the impact will not be significant. Mitigation measures are proposed, when feasible, to reduce potential impacts on the environment.
- ***Significant Impact***: A significant impact would cause a substantial adverse change in the physical conditions of the environment. Significant impacts are identified by the evaluation of project effects using significant criteria specific to each resource. Mitigation measures and/or Project Alternatives are identified to reduce project effects to the environment.
- ***Significant Unavoidable Impact***: A significant unavoidable impact would result in a substantial change in the environment that cannot be avoided or mitigated to a less than significant level if the project is implemented.

4.8 Analysis Level of Detail

According to CEQA Guidelines Section 15151, "[a]*n EIR should be prepared with a sufficient degree of analysis to provide decision makers with information which enables them to make a decision which intelligently takes account of environmental impacts. An evaluation of the environmental effects of a project need not be exhaustive, but the sufficiency of an EIR is to be reviewed in light of what is reasonably feasible*." CEQA Guidelines Section 15204 explains that

what is "reasonably feasible" inevitably varies from project to project, based on factors such as (1) the magnitude of the project at issue; (2) the severity of potential environmental impacts; and (3) the geographic scope of the project. Thus, for complex projects such as the YRDP and Narrows Project, what is reasonably feasible is different than what could be reasonably accomplished for smaller projects with relatively simple analysis. The degree of specificity required in an EIR depends on the type of project being analyzed (CEQA Guidelines § 15146). Project elements are analyzed at a degree of specificity that corresponds to the degree of specificity involved in the underlying activity that is described in the DEIR (CEQA Guidelines § 15146).

The analysis of potential construction-related impacts on environmental resources focuses on areas upstream of Englebright Dam because: (1) construction activities associated with the YRDP Relicensing Project are limited to areas upstream of Englebright Reservoir and would not occur along the lower Yuba River; and (2) no construction activities are proposed for the Narrows Project relicensing (see Chapter 2 - Project Description, Section 2.7.2, "Proposed Narrows Project under New License"). Because no new facilities are proposed for the Narrows Project, there would be no construction impacts on environmental resources related to this project.

4.8.1 YRDP Construction Schedules

As described in Chapter 2, YCWA's (2017a) AFLA proposes seven general changes to existing YRDP facilities, including: (1) modification to the OHDD fish release outlet; (2) modification to the Log Cabin Diversion Dam fish release outlet; (3) modification to the Lohman Ridge Diversion Tunnel Intake; (4) modifications to recreation facilities at NBB Reservoir; (5) addition of a TDS at New Colgate Powerhouse; (6) addition of a new auxiliary flood control outlet (aka ARC Spillway)[6] at NBB Reservoir; and (7) modifications to YRDP roads.

Chapter 2 summarizes the YRDP proposed construction activities and provides general information about the proposed schedule for construction of key facilities to provide an understanding of the estimated overall 1- to 20-year[7] facility construction period. Exhibit C of YCWA's 2017 AFLA (see Appendix 2A of this DEIR) describes Yuba Water's construction methods and schedule for the above changes, with the exception of recreation facilities and roads. The construction schedules (including sequencing and duration) for recreation facilities and for roads are described in Yuba Water's proposed Condition RR1 (Implement Recreation Facilities Plan) and proposed Condition LU1 (Implement Transportation System Management Plan), which are included in Appendix 2B of this DEIR. Where available and appropriate, resource impact analyses use the detailed construction schedule and sequencing information available to estimate potential impacts (e.g., air quality).

Recreation-related construction activities are scheduled to extend over the duration of the new FERC license, and the implementation schedule for the major rehabilitation and improvements at

[6] For CEQA compliance purposes, Yuba Water's proposed ARC Spillway is a separate project with independent utility that was fully analyzed in a separate environmental review process, which included the preparation of a DEIR (Yuba Water 2023b) and Final EIR (Yuba Water 2024). For completeness, the ARC Spillway is included in the YRDP Proposed Project because: (1) it was included as part of Yuba Water's proposed (2017a) AFLA; (2) it was included as part of the FERC Staff Alternative that was evaluated in FERC's (2019) FEIS; and (3) the ARC Spillway facilities and operations will be included as part of the new license for the YRDP that is issued by FERC. Where appropriate, the resource-specific analyses of the ARC Spillway presented in Yuba Water's (2023b; 2024) EIR is incorporated by reference into this DEIR.

[7] Most construction work would not begin the first full calendar year (i.e., "Year 1") of the new FERC license.

each existing recreation facility (covering new License Years 1 through 20) is described in proposed Condition RR1 (Implement Recreation Facilities Plan) (see Appendix 2B). The implementation schedule for new recreation facilities (i.e., improvements) also is described in the Recreation Plan. As shown in the implementation schedule, construction work at individual recreation facilities is generally planned to be conducted in phases (e.g., License Year 1, License Years 6-10, License Years 10-15, etc.). The majority of work on National Forest System (NFS) lands will occur within the first eleven years of the new license, with some work on Yuba Water facilities occurring during License Years 14 through 20. After Year 20, the need for replacement and/or redevelopment of facilities will be discussed and determined at annual coordination meetings with the USFS, as described in the Recreation Facilities Plan (YCWA 2022a).

Yuba Water's Transportation System Management Plan includes two components with regards to timing of road maintenance activities: (1) short-term maintenance;[8] and (2) long-term maintenance.[9] Long-term road repairs have historically occurred on average about every 7-10 years and are undertaken in addition to the short-term (annual) road maintenance. Specific rehabilitation actions (including stabilizing and revegetating areas affected by road-related drainage or erosion) for YRDP roads are summarized in Attachment A of the Transportation System Management Plan (see Appendix 2B of this DEIR). Additional rehabilitation detail and a timeframe for implementation are provided in Attachment F of the Transportation System Management Plan for specific primary project roads and recreation road features (e.g., culverts, erosion sites, landslide sites, pavement, safety and signs).

When resource impacts are isolated at specific construction sites, the duration and phasing for construction of that facility is generally identified in the Recreation Plan and/or the Transportation System Management Plan for use in estimating the potential impact durations. This information is intended to accurately characterize the impact at a construction location and to help readers understand the temporal extent of an impact at a proposed facility or construction site.

4.8.2 Maintenance-related Activities

Maintenance-related activities pertaining to the Proposed Projects and alternatives would be expected to be relatively standard (e.g., equipment inspections, assessing structural integrity of facilities, testing functionality of facility gates, valves and intakes, etc.) or similar in nature to the types of activities (e.g., cleaning, making minor repairs, vegetation management, hazard tree removal, etc.) that could be conducted as part of YRDP construction, but to a lesser extent (i.e., lower frequency and smaller magnitude). Potential impacts related to maintenance activities (if any) are addressed on a resource-by-resource basis depending upon whether the potential exists for maintenance-related activities to affect a particular environmental resource. Impact statements associated with maintenance-related activities are only included in resource chapters where activities have the potential to affect that particular resource.

[8] Short-term road maintenance is defined as routine annual maintenance for localized and seasonal repairs to address normal wear and tear during road use under typical annual weather conditions.

[9] Long-term maintenance is defined as repairs that are scheduled around specific events that impact the overall integrity of a given road, such as heavy-haul events or unusually heavy storm events – events that typically require road repairs that are beyond the scope and budget of the annual (short-term) road maintenance procedures.

4.8.3 Concurrent Project Effects

The impact analyses presented in this DEIR have been designed to address the whole of both the YRDP and Narrows Project FERC Relicensings (and Alternatives 1 & 2), and YRDP construction-related activities are evaluated for each resource topic in a synthesized manner. Because of the large scale of the YRDP's proposed activities, project construction activities are expected to occur at multiple YRDP facility sites simultaneously, as well as during various phases of project implementation over the period of a new FERC license. The collective environmental impacts on each resource are considered and evaluated to describe the aggregated effect on certain resources (e.g., fisheries, cultural resources) over time. For other resource topics, such as air quality and transportation, assumptions were made regarding a comprehensive project schedule with estimates

of construction vehicle and equipment use was used to estimate the peak effects on these resources when multiple construction sites (and phases of implementation) are expected to occur.

4.8.4 Environmental Commitments and Mitigation Measure Development

The CEQA Guidelines instruct lead agencies to "*distinguish between the measures which are proposed by project proponents to be included in the project and other measures proposed by the lead, responsible or trustee agency or other persons*" in their EIRs (CEQA Guidelines 29 § 15126.4(a)(1)(A)).

As used in this DEIR, there are many environmental commitments[10], including best BMPs[11] and PM&Es that have been identified through the FERC relicensing process, including FERC-approved implementation plans that are already incorporated into the project design and construction, either as a result of: (1) Yuba Water's proposal described in the 2017 AFLA for the YRDP; (2) FERC's (2019) analysis of the FERC Staff Alternative in the FEIS for the YRDP; or (3) USFS's 2022 Revised Final Section 4(e) Conditions for the YRDP (see Chapter 2 – Project Description). For the YRDP relicensing, Yuba Water has committed that PM&Es and BMPs would be incorporated into the Mitigation Monitoring and Reporting Plan (MMRP) and implemented if Yuba Water accepts a new FERC license for the YRDP as described in this DEIR. For the Narrows Project, no PM&Es or BMPs have been identified through the FERC relicensing process to date.

In addition to the environmental commitments (e.g., BMPs, PM&Es) that have been identified through the FERC relicensing process and are part of the Proposed Projects, if new significant impacts are identified as a result of the resource-specific CEQA analysis conducted for this DEIR, then additional mitigation measures may be identified to minimize or avoid those potentially significant impacts. If "potentially significant" impacts are identified, mitigation measures will be formulated to eliminate or reduce the intensity of the impacts and focus on the protection of sensitive resources to the extent feasible. If a mitigation measure would cause one or more significant impacts in addition to those that would be caused by the Proposed Projects, the impact(s) of the mitigation measure also is discussed but, in less detail, than the significant impacts

[10] Environmental commitments, including PM&Es, are intended to anticipate and possibly avoid or minimize environmental impacts.

[11] BMPs are well-established, generally applicable practices or requirements that are incorporated into a project's engineering, design, and construction process.

of the Proposed Projects. Implementation of more than one mitigation measure may be needed to reduce an impact below a level of significance.

Under CEQA, the effectiveness of a mitigation measure will be determined by evaluating the impact remaining after the application of the mitigation, and reaching one of two conclusions, including: (1) the mitigation reduced the impact to a less-than-significant level; or (2) no feasible mitigation exists to reduce the impact to a "less-than-significant level" and, therefore, the impact is determined to be "significant and unavoidable." No mitigation measures are needed or proposed when an impact is determined to be "less than significant." To aid readers of this DEIR, each mitigation measure is identified numerically to correspond with the number of the impact being mitigated by the measure. The mitigation measures (if any) proposed in this DEIR are identified within each resource chapter (Chapters 5 through 25). If new mitigation measures are identified, such measures will be incorporated into the MMRPs, as appropriate, for the YRDP and the Narrows Project, respectively, and implemented if the projects are approved.

4.8.5 Reliance on Other Available Sources of Information

For the YRDP, the extensive FERC relicensing process that has been conducted over the past decade has resulted in the development of many studies, analyses and reports that may provide relevant and useful information to help inform the content of this DEIR. Some of the key sources of information include:

- YCWA's (2010) PAD for the YRDP.
- YCWA's (2013b) DLA for the YRDP.
- YCWA's (2014) FLA for the YRDP.
- YCWA's (2017a) AFLA for the YRDP.
- YCWA's (2017b) Response to FERC's Notice of Application Accepted for Filing, Soliciting Motions to Intervene and Protests, REA, and Soliciting Comments, Recommendation, Preliminary Terms and Conditions, and Preliminary Fishway Prescriptions.
- FERC's (2018) DEIS for the YRDP.
- FERC's (2019) Final EIS for the YRDP.
- YCWA's (2022b) FERC Filings in Response to FERC's March 8, 2021 AIR.
- YCWA's (2023a) DEIR for the ARC Spillway Project.

For the Narrows Project, although the FERC relicensing process has been initiated more recently, previously developed information also is available to help inform the content of this DEIR, including:

- YCWA's (2021) PAD for the Narrows Project.
- YCWA's (2023) DLA for the Narrows Project.

- YCWA's (2023b) FLA for the Narrows Project.
- FERC's (2024a) Scoping Document 1 for the Narrows Project.

Where appropriate, and in accordance with CEQA Guidelines §15150, some sections (e.g., environmental setting) of this DEIR have incorporated by reference portions of the documents listed above. Incorporation by reference is generally "*most appropriate for including long, descriptive, or technical materials that provide general background but do not contribute directly to the analysis of the problem at hand*" (CEQA Guidelines, § 15150, subd. (f)). All of the documents listed above are publicly available on FERC's eLibrary website (https://www.ferc.gov/ferc-online/elibrary). Documents that have been filed with FERC and are cited in FERC's eLibrary that have either been incorporated by reference or are simply cited in this DEIR are included as part of Yuba Water's administrative record for the Proposed Projects.

4.9 Introduction to the Cumulative Analysis

This DEIR provides an analysis of cumulative impacts of the Proposed Projects taken together with other past, present, and probable future projects producing related impacts, as required by Section 15130 of the State CEQA Guidelines. The goal of such an exercise is twofold: first, to determine whether the overall long-term impacts of all such projects would be cumulatively significant; and second, to determine whether the incremental contribution to any such cumulatively significant impacts by the project would be "cumulatively considerable" (and thus significant). (See State CEQA Guidelines Sections 15130[a]–[b], Section 15355[b], Section 15064[h], and Section 15065[c]; and *Communities for a Better Environment v. California Resources Agency* (2002)103 Cal. App. 4th 98, 120.) In other words, the required analysis intends first to create a broad context in which to assess cumulative impacts, viewed on a geographic scale beyond the project site itself, and then to determine whether the project's incremental contribution to any significant cumulative impacts from all projects is itself significant (i.e., "cumulatively considerable").

Cumulative impacts are defined in State CEQA Guidelines Section 15355 as "*two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts*." A cumulative impact occurs from "the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time" (State CEQA Guidelines Section 15355[b]).

Consistent with State CEQA Guidelines Section 15130, the discussion of cumulative impacts in this DEIR focuses on significant and potentially significant cumulative impacts. Section 15130(b) of the State CEQA Guidelines provides, in part, the following:

> [t]he discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion should be guided by the standards of practicality and reasonableness, and should focus on

the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact.

The DEIR analyzes potentially significant impacts that could result from the Proposed Projects and alternatives, in combination with related past, present, and future projects. The Proposed Projects and alternatives would have a significant impact if: (1) a significant cumulative impact exists or would occur, and (2) the incremental contribution of the Proposed Projects or alternatives to such an impact would be cumulatively considerable. Because the YRDP and the Narrows Project are distinct FERC hydropower projects, separate analyses of potential cumulative impacts related to the YRDP and related to the Narrows Project are presented in the DEIR. If potentially significant impacts are identified for the YRDP, the cumulative analysis will evaluate whether the incremental contribution of any such cumulatively significant impacts of the YRDP would be "cumulatively considerable" (and thus significant). Similarly, if potentially significant impacts are identified for the Narrows Project, the cumulative analysis will evaluate whether the incremental contribution of any such cumulatively significant impacts of the Narrows Project would be "cumulatively considerable" (and thus significant).

4.9.1 Cumulative Context and Approach

4.9.1.1 Geographic Scope

For most environmental resources, the geographic area that could be affected by the Proposed Projects (or an alternative) and is appropriate for a cumulative impact analysis includes the Yuba River Watershed and the streams, water bodies, groundwater basins, and facilities that could be affected by changes in Yuba River outflow to the Feather River. These areas potentially include:

- NBB Reservoir.
- NBB Dam Reach, including the North Yuba River and the Yuba River downstream of NBB Dam to the confluence of the North Yuba River with the Middle Yuba River.
- OHDD Impoundment on the Middle Yuba River.
- Middle Yuba River from Jackson Meadows Reservoir downstream to the Milton Diversion Dam and OHDD Impoundments.[12]
- Middle Yuba River (i.e., OHDD Reach) from OHDD to the confluence with the North Yuba River.
- Oregon Creek (Log Cabin Diversion Dam Reach) downstream to the confluence with the Middle Yuba River.
- Fordyce Lake.
- Fordyce Creek below Fordyce Lake Dam to Lake Spaulding.
- South Yuba River from upstream reservoirs (e.g., Bowman Lake, Lake Spaulding) downstream to Englebright Reservoir, including tributaries (e.g., Canyon Creek).[13]

[12] With respect to potential indirect cumulative impacts only.
[13] With respect to potential indirect cumulative impacts only.

- Englebright Reservoir.
- Lower Yuba River to the confluence with the Feather River.
- Yuba Subbasins of the Sacramento Valley Groundwater Basin.

For the reasons described above in Section 4.3.1.3 (Downstream Extent of the Project Area), the geographic extent considered for the cumulative analyses conducted for certain water-related resources (i.e., surface water resources, water quality and fisheries) extends downstream of the lower Yuba River and includes the lower Feather River, the lower Sacramento River and the Delta. As discussed in Section 4.3.1.3, it would be speculative to make operational assumptions about how the SWRCB's Draft Bay-Delta Plan Update "regulatory pathway" could be implemented by the various involved entities throughout the Sacramento Valley (e.g., Feather River, Sacramento River, Delta) for modeling purposes. Attempts to characterize such assumptions for modeling purposes also would be speculative in consideration of ongoing uncertainties and the evolving status of the SWRCB Draft Bay-Delta Plan Update "regulatory pathway" as demonstrated by the suite of public comments (e.g., DSR (SWRCB 2023), 2024 public workshops, 2025 working meetings, etc.) that have been provided to the SWRCB.

The approach taken for characterizing the geographic extent of the cumulative impact analysis in this DEIR is also consistent with the approach taken by FERC. FERC (2019; 2024b) defined the geographic scope of analysis for cumulatively affected resources by the physical limits or boundaries of: (1) the FERC proposed action's effect on the resources, and (2) contributing effects from other hydropower and non-hydropower activities. For both the YRDP and the Narrows Project, FERC (2019; 2024b) determined that the cumulative geographic scope for most resources extended downstream to the mixing zone of the Yuba River and the Feather River. However, for the YRDP, FERC (2019) extended the cumulative geographic scope for anadromous fish downstream to the confluence with the Feather River, the lower Feather River to the lower Sacramento River, and through the Sacramento-San Joaquin Delta to the San Francisco Bay. For the Narrows Project, FERC (2024b) extended the geographic scope for water and aquatic resources downstream through the lower Yuba River watershed to the confluence with the Feather River, the lower Feather River, the lower Sacramento River, and through the Sacramento-San Joaquin Delta to the San Francisco Bay.

For the reasons above, the cumulative analyses for certain water-related resources (i.e., surface water resources, water quality and fisheries) in this DEIR includes consideration of potential changed conditions that may occur in areas (e.g., the lower Feather River, lower Sacramento River and Delta) downstream of the lower Yuba River, and these potential cumulative impact considerations are addressed in a qualitative manner.

4.9.1.2 Related Projects

Section 15130(b)(1) of the State CEQA Guidelines identifies two approaches to analyzing cumulative impacts. The first is a summary approach (also known as the "plan" approach), wherein the relevant projections, as contained in an adopted planning document that evaluates regional or area-wide conditions, are summarized. The second is the "list" approach, by which a defined set of past, present, and reasonably anticipated future projects producing related or cumulative impacts is considered for analysis.

The cumulative analysis in this DEIR uses the "list" approach. The list of projects for the cumulative impact analysis was developed by first identifying projects proposed by Yuba Water and others at NBB Dam and Reservoir, within the Yuba River Watershed, and along the North Yuba River, the Middle Yuba River, the South Yuba River and the Yuba River downstream of NBB Dam to the confluence of the Lower Yuba River with the Feather River.

Table 4.9-1 shows known past, present, and reasonably foreseeable future projects that may affect similar environmental resources as the Proposed Projects, the impacts of which may combine with impacts from the Proposed Projects to cause cumulative impacts. The table is organized by geographic region and includes the name of the project, the project status (i.e., past, present, or future), lead agency(ies), and summary descriptions of the scope of the project. The projects listed in Table 4.9-1 serve as the foundational information for conducting the cumulative impact assessments for the resources addressed in the DEIR.

Not all of the projects included in Table 4.9-1 are considered for the cumulative assessment of each resource topic analyzed in the DEIR. For each resource topic, the geographic and temporal context for cumulative analysis was considered, and the list of projects in Table 4.9-1 was screened against these contexts to identify only those projects that have the potential to combine with impacts from the Proposed Projects (or an alternative) to cause a cumulative impact.

Page Left Blank

Table 4.9-1. Cumulative Project List.

Project	Status	Primary Agencies	Description
Upper Yuba River Watershed			
North Yuba Forest Partnership	In Progress	YCWA, USFS, SYRCL, The Nature Conservancy (TNC), Camptonville Community Partnership, The Nisenan, National Forest Foundation, Sierra County, Blue Forest	This is a partnership effort of nine agencies, including YCWA, working together to implement forest restoration across 275,000 acres through ecological thinning and prescribed fire. Treatment areas have been identified including north and east of NBB Reservoir. No treatment areas are located at the project site or immediate vicinity.
Yuba Foothills Healthy Forest Project	In Progress	YCWA, USFS, Yuba Watershed Protection and Fire Safe Council, private timber companies and landowners	The project supports significant biomass removal treatments on 5,375 acres in the Yuba County foothills, all of which are adjacent to communities with limited resources for fire risk reduction efforts, including Oregon House, Dobbins, Brownsville, Challenge and Rackerby. Treatment activities include wildland-urban interface fuel reduction/break, ecological restoration treatments, prescribed burning, mechanical/manual treatments, and herbicide use. These treatments will improve forest health and reduce the risk of a catastrophic wildfire within a "Project Impact Zone" that spans more than 71,000 acres and includes an estimated 2,721 structures. CEQA environmental compliance was completed by Yuba County in 2020. Project implementation began in 2020 and completion is expected in 2024.
Upper Yuba Headwaters Forest Restoration Project	In Progress	Sierra Nevada Conservancy (SNC), NID	The project serves to reduce fire risk in the Middle and South Yuba watersheds near Jackson Meadows Reservoir by mechanically treating approximately 400 acres of hazardous-fire fuels adjacent to a critical water storage reservoir and associated infrastructure, which will complement other NID restoration and enhancement projects. The region has been prioritized for fire fuels reduction and hazard-tree removal. Activities will be a combination of hazard tree removal, mastication, and hand crew understory thinning. The project aims to reduce fire risk, support water quality, and enhance forest health with factors such as reduced resource composition, enhanced carbon sequestration, increased hydrologic activity, and increased resilience to pests and climatic disturbances. Project implementation is to occur between July and November over a 4-year period (2023-2027). NID proposes to implement treatments at a rate of 100 acres per year.
Inimim Forest Restoration Project	Phases 1 & 2 completed; Phase 3 In Progress	Yuba Watershed Institute (YWI), SNC, CalFire, BLM	The project purpose is to increase forest ecosystem resilience to forest disturbances anticipated to occur over the next 100 years. The project aims to help restore the 'Inimim Forest to an old-growth condition, manage its timber based on ecologically sustainable yields, protect its wildlife, and protect its cultural, historical, recreational, educational, and scenic values. Vegetation management activities involved three phases. Phases 1 and 2 involved treatments of hazard tree removal, hand-thinning, mastication and prescribed burning of over 850 acres. Phase 3 (initiated in 2023) included mastication, biomass harvest, and hand thinning treatments on about 279 additional acres.
Yuba Roadside Fuel Treatment Project	In Progress / Reasonably Foreseeable	Yuba Watershed Protection and Fire Safe Council, YCWA	The project serves to reduce fire fuels and fire risk along 555 miles of County Service Area roads and private roads in the Yuba Foothills. Mechanical and manual treatments, herbicide applications, and pile burning will be utilized to create shaded fuel breaks within a 150-foot buffer on each side of County roads and a 30-foot buffer on each side of CSA and private roads. Protections for wildlife, rare plants, watercourses, water quality, and soils will be implemented. Fuel reduction efforts began during spring 2023, with additional treatments planned in the fall and winter of 2023 and 2024. Retreatment would be dependent on regrowth conditions and would differ by location. However, retreatment is anticipated to occur between five and 10 years.
Camptonville Biomass Plant	Reasonably Foreseeable	Camptonville Community Partnership, YCWA	A 5 megawatt conventional direct combustion, forest biomass to renewable energy project, located in Camptonville. The proposed plant will have the capacity to process 40,000 bone dry tons of woody material per year. This project will provide a means to dispose of excess forest biomass, reduce fire hazard, revitalize Camptonville's former sawmill site and boost the local economy, reduce regional air emissions from open pile burning, promote forest health in and around Camptonville and neighboring communities, maintain the region's water quality, quantity and reliability for local and downstream users, and produce renewable energy.
Yuba-Bear Hydroelectric Project (Yuba-Bear Project) FERC Project No. 2266 Relicensing, Upper Drum-Spaulding Hydroelectric Projects (FERC No. 2310), Lower Drum Hydroelectric Project (FERC No. 14531), and Deer Creek Hydroelectric Project (FERC Project No. 14530) Relicensing	Reasonably Foreseeable	FERC, NID, PG&E	NID is applying for a new license for the Yuba-Bear Project (FERC Project No. 2266), and PG&E is applying for the Drum-Spaulding Project (FERC Project Nos. 2310 and 14531). The Yuba-Bear Project is located on the Middle and South Yuba rivers, Bear River, and Jackson and Canyon creeks. Concurrently, PG&E is applying for a license renewal for the Drum-Spaulding Project. The Upper Drum-Spaulding Project is located in Nevada and Placer counties, and consists of 24 dams and reservoirs, 7 powerhouses, 4 overhead transmission lines, 1 diversion dam, and various water conduits, recreation facilities, and other associated facilities and structures. The Upper Drum-Spaulding Hydroelectric Project's dams are located on the South Yuba River, Bear River, Fordyce Creek, North Fork of the North Fork American River, and associated tributaries. The Lower Drum Project facilities are in Placer County and consist of 5 dams and reservoirs, 4 powerhouses, and various water conduits, recreation facilities, and other associated facilities and structures. The Lower Drum Project dams are located on the Bear River, Dry Creek, Rock Creek, Auburn Ravine, Mormon Ravine, and associated tributaries. PG&E closely coordinates the operations of the Drum-Spaulding Project with NID's Yuba-Bear Project. The proposed 5.7-MW Deer Creek Project would include the existing Deer Creek development with the exception of the upper 1.57 miles of the South Yuba Canal, which would be part of the Upper Drum-Spaulding Project. The two projects overlap in part in the Yuba River and Bear River basins, and many of the facilities are hydraulically interconnected, including facilities that are used to meet water supply demands in Nevada and Placer counties. The FERC relicensing processes for these projects is underway. Final WQC for PG&E's Upper Drum-Spaulding and Lower Drum Projects were issued by SWRCB in 2021. NID and PG&E are awaiting the FERC license renewal.
Lower Yuba River			
Yuba River Resilience Initiative	Reasonably Foreseeable	YCWA, CDFW, NMFS	In May 2023, YCWA, CDFW, and NMFS signed a term sheet to partner on an extension program to implement habitat restoration measures on the lower Yuba River and the North Yuba River. The Term Sheet sets forth a framework for a Settlement Agreement to implement certain restoration measures, including the potential for construction of a new fishway and modernized water diversion at Daguerre Point and initiation of a comprehensive program to reintroduce spring-run Chinook salmon to the North Yuba River. At the time this Final EIR was prepared, negotiations for implementation of the Term Sheet have been progressing and the parties involved are seeking to resolve the remaining issues, complete CEQA review as discussed below, and execute the agreement by the end of 2024. YCWA anticipates relying on the SWRCB's General Order for Clean Water Act Section 401 WQC and Waste Discharge Requirements for Restoration Projects Statewide (SRGO), which provides a programmatic authorization for qualifying restoration projects, for construction, operation, and maintenance of the Nature-Like Fishway component of the Restoration Plan. YCWA evaluated the project's consistency with the SRGO and the SWRCB's 2022 Program EIR (PEIR) (State Clearinghouse No. 2019100230) for the SRGO to determine the appropriate CEQA document for the project. In February 2025, Yuba Agency adopted a CEQA analysis memorandum and determined that the project is within the scope of the SWRCB's SRGO PEIR. The memorandum also serves as an addendum (YCWA 2025). YCWA also authorized execution of the Yuba River Resilience Initiative Agreement, which includes the Lower Yuba River at Daguerre Point Nature-Like Fishway as a component in February 2025.
Lower Yuba River Accord Water Transfer Program Extension	In Progress	YCWA	In 2008, YCWA implemented the Lower Yuba River Accord (Yuba Accord), which is a comprehensive settlement resolving issues related to instream flow requirements for the lower Yuba River, water transfers, conjunctive use of surface water and groundwater, and fisheries management. The Yuba Accord involves three sets of related agreements: (1) fisheries agreement between YCWA, CDFW and certain non-governmental organizations; (2) conjunctive use agreements between YCWA, Member Units, and local water and irrigation districts and companies; and (3) water purchase agreement between YCWA and DWR. The Yuba Accord was implemented through a SWRCB WR order (Corrected Order WR 2008-0014). YCWA prepared and certified a Final EIR for the Yuba Accord in 2007. The fisheries agreement established new minimum instream flow requirements during specified periods of the year and a monitoring and evaluation program for the fisheries resources in the lower Yuba River. The conjunctive use agreements enable the Member Units to participate in the Yuba Accord Groundwater Substitution Water Transfer Program. Under this program, the member districts pump groundwater as a substitute supply for YCWA surface water deliveries during certain dry years, which allows surface water to remain in the lower Yuba River during those years. The water purchase agreement allows YCWA to sell and transfer to DWR and others the water that is being released by YCWA for instream flows and water made available through groundwater substitutions by the Member Units, in accordance with agreed-upon accounting principles. The Yuba Accord water purchase agreement, conjunctive use agreements, and long-term water transfer authorization in SWRCB Corrected Order WR 2008-0014 expire on December 31, 2025. YCWA plans to extend the Yuba Accord water transfer program before this expiration date. Extension of the Yuba Accord water transfer program will involve three principal components: (1) a new or extended DWR water purchase agreement; (2) new or extended conjunctive use agreements; and (3) a SWRCB water right change petition and SWRCB approval. YCWA has approved a Yuba Accord water transfer program extension without significant substantive changes. The Proposed Extension would not result in any changes to reservoir storage levels (e.g., NBB Reservoir, Englebright Reservoir) or to flow releases into the lower Yuba River, relative to the range of operations that may occur under CEQA baseline (i.e., existing conditions). On January 12, 2023, YCWA released its NOP of a Draft SEIR and Notice of Scoping Meetings for Extension of the Lower Yuba River Accord Water Transfer Program. On April 5, 2024, YCWA issued the Draft SEIR, which had a 45-day public review and comment period that closed on May 20, 2024. On May 29, 2024, YCWA filed the water right petition to the SWRCB, which is currently considering that petition. YCWA completed and certified the Final SEIR in September 2024.

Table 4.9-1. (Continued).

Project	Status	Primary Agencies	Description
Lower Yuba River (cont.)			
ARC Spillway Project	Reasonably Foreseeable	YCWA	YCWA proposes to construct, operate, and maintain a second spillway (i.e., the ARC Spillway) at NBB Dam. Releases from the ARC Spillway would be made in anticipation of large storms to provide increased evacuated storage capacity in New Bullard's Bar Reservoir prior to and during high-precipitation events and large storm peak inflows to reduce the peak outflow. The ARC Spillway Project would be operated conjunctively with the existing Primary Spillway at the dam and New Colgate Powerhouse to meet NBDD overall target releases and to efficiently release flows downstream, including earlier passage of flows during large storm events. The existing concrete dam and Primary Spillway would not be altered by the ARC Spillway Project. Flood control in the Yuba River is mainly provided by 170,000 AF of seasonally dedicated storage in NBB Reservoir. YCWA provides overall reservoir operations although USACE flood management operations are directed through its 1959 Master Manual of Reservoir Regulation, Sacramento River Basin, California, and, specifically, by the NBB Reservoir Water Control Manual (WCM) (USACE 1972). Operational flood rules dictate the amount of variable flood space made available seasonally. No flood space is required from June 1 to September 15. During the peak flood season (November 1 – March 31), the flood control space is a USACE-mandated 170,000 AF. The primary benefit of the ARC Spillway Project is operational flexibility for managing outflow at the dam, significantly reducing flood risk downstream at Marysville and the Feather-Yuba River confluence and providing public safety benefits. Because the ARC Spillway would provide significant public benefits and because of the uncertainty regarding when the new license for the YRDP Relicensing Project will be issued, YCWA proposes to add the new ARC Spillway under the existing FERC license rather than wait until the new FERC license is issued. As discussed in Chapter 2, because the schedule of events planned has not occurred as expected, YCWA determined that it was necessary for the ARC Spillway Project to proceed ahead of FERC relicensing for the YRDP. Once constructed, the ARC Spillway and its related flood control operations will be a new operational component of the new FERC license that has not historically been part of the YRDP and is not part of the existing FERC license (unless FERC decides to issue an amendment order adding the ARC Spillway to the existing license in response to YCWA's 2025 application for a non-capacity amendment, which could occur sooner than waiting until the new FERC license for the YRDP Relicensing is issued). However, because the ARC Spillway ultimately will be part of the YRDP, project construction and operation of the ARC Spillway also requires FERC approval. YCWA undertook a separate process of complying with CEQA for the ARC Spillway Project. YCWA released a DEIR for the ARC Spillway Project for a 60-day public review period that closed on August 20, 2023. YCWA then issued the Final EIR (YCWA 2024) and approved the project in December 2024. In January 2025, YCWA filed a Final Non-Capacity License Amendment for the ARC Spillway with FERC. YCWA's (2023a) analysis of the ARC Spillway determined that the addition of the ARC Spillway to the YRDP would have no effect on flow requirements in the existing FERC license, nor would it have any effect on the flow requirements that are anticipated to be in the new license (YCWA 2023a). It is anticipated that construction of the ARC Spillway would occur in advance of other YRDP relicensing-related construction activities that would not be initiated until after FERC issues a new license. Thus, it is unlikely that the timing of ARC Spillway construction would occur simultaneously with construction activities of the YRDP Relicensing Project. Moreover, many of the recreation-related construction activities associated with the YRDP Relicensing Project would be phased over the duration of the new license term.
USACE NBB Dam and Reservoir WCM Update	Reasonably Foreseeable	USACE	Flood management operations in the Yuba River Watershed are controlled by USACE's 1959 Master Manual of Reservoir Regulation, Sacramento River Basin, California, and, more specifically, by the NBB Reservoir WCM (USACE 1972). As discussed above, YCWA manages water releases from NBB (NBB) Dam and Reservoir during flood-related operations according to the WCM, which includes a guide curve (or rule curve) that governs the water storage and release schedule based on past weather patterns. USACE is in the process of updating the NBB WCM to reflect changed circumstances, new technology, and improved practices. The updated NBB WCM is expected to implement FIRO, which is a flexible water management approach that uses watershed monitoring data and improved weather forecasting to help water managers selectively retain or release water from a reservoir for increased resilience to droughts and floods and to better manage releases before and during a storm. When the revised WCM is completed (anticipated 2026), it will govern water releases during, and in anticipation of, floods, major storms, and high-water events.
500-year Flood Protection Project	Reasonably Foreseeable	TRLIA	Three Rivers Levee Improvement Authority (TRLIA) is improving the Reclamation District 784 urban levee system to provide 500-year flood protection to southwest Yuba County. The project would reduce flood risk, ensure the system is adaptable to climate change, and address differing flood protection levels resulting from incremental construction and improvement of the system. Project components include improving 10 miles of existing levees south of the Yuba River, east of the Feather River, north of the Bear River, west of the Western Pacific Interceptor Canal (WPIC) and southeast of the Olivehurst Detention Basin. Approximately 3 miles of new levee would be constructed on the west edge of the Yuba Goldfields and to extend the WPIC West Levee to the north.
Marysville Ring Levee	In Progress	USACE, YCWA, CVFPB, Marysville Levee District	This project reinforces the 7.5-mile-long Marysville Ring Levee, slated for completion by 2026. The levee system reduces flood risk for the historic City of Marysville including from flooding along the lower Yuba River. Once completed, the levee system is anticipated to reduce flood risk for the City of Marysville by providing close to a 200-year level of protection.
Yuba River North Training Wall (NTW) Project	Phase 1 completed; Phase 2 in progress	TRLIA	TRLIA is reshaping the existing Yuba River NTW and constructing a new embankment to extend the wall upstream to meet high ground and provide 100-year flood protection to the community of Hallwood. The project components include a tie-in embankment and potential habitat restoration areas. The total project footprint will be up to approximately 100 acres and extend approximately 1,000 feet upstream from the east end of the existing NTW embankment to connect the NTW to high ground and provide a complete, stable embankment. The embankment crest will be 5 feet above the 200-year design water surface elevation.
Yuba Subbasins Water Management Plan: A Groundwater Sustainability Plan (GSP) Implementation	Present	YCWA, CID, City of Marysville	In 2014, the State of California enacted the Sustainable Groundwater Management Act (SGMA) to provide local and regional agencies the authority to sustainably manage groundwater. SGMA required the preparation of a GSP for medium- or high-priority basins/subbasins to reach sustainability within 20 years of implementing their sustainability plans. DWR, which oversees SGMA, approved the GSP for the North and South Yuba groundwater subbasins in 2021. Sustainable groundwater management criteria were developed with measurable objectives that allow for changes in the subbasin to the extent they are not significant and unreasonable. The components of the GSP are focused on the four sustainability indicators defined through SGMA that are relevant to the Yuba Subbasin, including: (1) chronic lowering of groundwater levels; (2) depletion of interconnected surface water; (3) significant and unreasonable degraded water quality; and (4) significant and unreasonable land subsidence. The GSP concluded that because the Yuba Subbasins are sustainable under historical, current, and projected conditions (including incorporating the effects of climate change), no projects or management actions are required to achieve sustainability. However, even with the existing sustainable conditions, the GSP includes projects and management actions to assist in enhancing management capability and improve the understanding of the groundwater system. Further, an adaptive management approach was developed to allow for response to unanticipated conditions (YCWA 2019).
Cordua Groundwater Monitoring Well	Reasonably Foreseeable	CID	Cordua regularly participated in Groundwater Substitution Transfers in coordination with DWR and YCWA and as of 2020 has signed a Yuba Accord Conjunctive Use agreement with YCWA. New requirements set by DWR for the 2020 transfer required that all participating transfer wells have a corresponding monitoring well within a 2-mile radius. The monitoring well must not be used for the transfer and must have the same depth as the related transfer wells. The district has been monitoring 50+ wells since 1991 and the accumulation of data is used to monitor groundwater conditions over time and prevent any third-party impacts to surrounding water users. CID is proposing the installation of a new monitoring well to improve the accuracy and reliability of its monitoring well network (YCRWMG 2023)
WWD In-Lieu Recharge Project	Present	WWD, YCWA	The Wheatland Project was implemented in the mid 2000's with the construction of canals and pumping stations to deliver surface water to WWD. The project was a Proposition 13 Conjunctive Use Storage Project, with 50% of the cost of construction funded through a Proposition 13 grant. This project was funded to improve basin storage in the area, providing greater conjunctive use opportunities and increasing the volume of GWS transfers from the Yuba Subbasins. The Wheatland Project is described in Chapter 6 - Groundwater Resources of this DEIR.

Table 4.9-1. (Continued).

Project	Status	Primary Agencies	Description
			Lower Yuba River (cont.)
Yuba County Integrated Regional Water Management Plan (IRWMP) Implementation	Present	Yuba County, YCWA, Regional Water Management Group (RWMG)	In 2002, the State Legislature passed the IRWM Planning Act (SB 1672) to encourage local entities to improve water quality and water supply reliability to meet the state's agricultural, domestic, industrial and environmental water needs. The Yuba County IRWM region encompasses Yuba County and extends from the Sierra Nevada foothills to the confluence of the lower Yuba River and the Feather River near Marysville. The Yuba County IRWMP was initially developed and adopted by 12 agencies in Yuba County in 2008. The IRWMP was updated in 2015 and again in 2018. The 2018 Update identifies seven goals: • Ensure adequate and reliable water supply that meets the diverse needs of the region • Protect, restore, and enhance water quality for water users and in support of healthy watersheds • Preserve and restore watershed health and promote environmental stewardship • Enhance regional economic development • Support efforts to improve public safety • Address climate vulnerabilities and reduce greenhouse gas emissions • Promote equitable distribution of resources to disadvantaged communities and Tribes across the region. The Yuba County IRWMP has developed objectives that include both quantitative or qualitative measures, as required by DWR's guidelines. The RWMG is responsible for evaluating IRWMP implementation actions and performance (YCRWMG 2018).
Narrows 2 LWM Mitigation Plan	Completed	YCWA	As mitigation for a 2015 Narrows 2 temporary flow deviation event, YCWA installed 30 pieces of LWM distributed among three locations along the lower Yuba River (RM 20, RM18.4) during September 2019. Each of the locations were selected based on their suitability to retain LWM and ability to provide benefits to a variety of salmonid lifestages.
USACE Authorized Operations and Maintenance of Existing Fish Passage Facilities at Daguerre Point Dam on the Lower Yuba River	In Progress	USACE	USACE's authorized O&M activities associated with Daguerre Point Dam include limited discretionary actions related to the existing fish passage facilities and implementation of voluntary and protective conservation measures for anadromous fish and habitat enhancement purposes, including ongoing gravel augmentation in the Englebright Dam Reach and a LWM placement program.
Hallwood Side Channel and Floodplain Restoration Project	Completed	YCWA, Yuba County, USFWS, SYRCL, CNRA Wildlife Conservation Board, Teichert, Western Aggregates	The Hallwood Project is designed to enhance habitat in the lower Yuba River by increasing the extent and duration during which juvenile Chinook salmon and steelhead are able to access the floodplain over a range of flows, as well as create and enhance perennial and seasonal side channel habitat. Project improvements have enhanced up to 157 acres of seasonally inundated riparian floodplain, approximately 1.7 miles of perennial side channels, and approximately 6.1 miles of seasonally inundated side channels, alcoves, and swales. Enhancements were made through land surface changes (e.g., removal of the Middle Training Wall), riparian planting, and placement of LWM embedded to simulate a more natural river channel at key locations. The project also reduces flood risk by improving the lower Yuba River's ability to withstand floods. About 3.2 million cubic yards of sediment were removed throughout the Project Area, reducing flood risk for local communities by lowering water surface elevations during large storms. Project construction was completed in November 2023.
Yuba River Canyon Salmon Habitat Restoration Project	Completed	USFWS, Yuba County	Funded by the Anadromous Fish Restoration Program (AFRP), the project was designed to improve about 8.5 acres of anadromous salmonid spawning habitat and juvenile rearing habitat. The project is located in the lower Yuba River at the lower end of the Englebright Dam Reach, just above the confluence with Deer Creek. The restoration approach was to excavate, grade and sort the alluvial bar and enhance existing in-river topography, while reducing the amount of armoring on the adjacent alluvial bar. Construction was completed in the fall of 2018 (USFWS and Yuba County 2016). The States Land Commission approved a 10-year General Lease - Public Agency Use to the USFWS through August 16, 2027.
Timbuctoo Acquisition and Restoration Project	Reasonably Foreseeable	BYLT	The project includes protection of three miles of the lower Yuba River containing Chinook salmon and steelhead spawning habitat and 700 acres of surrounding lands with intact blue oak woodlands. The property is currently privately owned and under threat of subdivision and conversion to a housing development project. BYLT is seeking funding to cover part of the property acquisition and to passively restore three miles of lower Yuba River for aquatic habitat through revegetation. This project supports the Yuba IRWMP by encouraging groundwater recharge and protecting existing groundwater levels through preventing home construction and well drilling on 700-acres. It will protect surface water quality of tributaries flowing directly into the lower Yuba River and protect river flows and river surface water quality. It also supports the Lower Yuba River Accord through protection of Chinook salmon and steelhead spawning areas and habitat improvements along the lower Yuba River. In addition to salmonid species, the federally-listed foothill yellow legged frog is also documented in this reach of the river. Public access to the property will likely be limited, however, there will still be opportunities for education and recreation (YCRWMG 2023).
Upper Long Bar Habitat Restoration Project	In Progress	USFWS, SYRCL	The project will restore at least 40 acres of floodplain habitat and nearly one mile of off-channel habitat at the downstream end of Long Bar in the Parks Bar to Marysville section of the lower Yuba River. The habitat enhancements will include floodplain lowering, side channel enhancement, riparian planting, and LWM placement. The completed Upper Long Bar project will reconnect flood flows with restored floodplains. Lateral reconnection will increase habitat availability as well as enhanced hydraulic complexity and quality of available flow for the benefit of spring- and fall-run Chinook salmon and steelhead. Additionally, this project supports the population doubling goals of the USFWS' Anadromous Fish Restoration Program (YCRWMG 2023). The project is funded by the California Wildlife Conservation Board's 2020 (Prop 1) Stream Flow Enhancement Program.
Lower Long Bar Restoration Project	Completed	USFWS, SYRCL, other parties	The project involved the restoration of 42 acres along the lower Yuba River. Efforts included removing approximately 350,000 yards of hydraulic mining debris, lowering floodplains, designing channels, and planting vegetation. Since project completion, naturalized side channels, vegetation recruitment, and extended rearing of juvenile salmonoids have been observed.
Upper Rose Bar Habitat Restoration Project	In Progress	YCWA, SYRCL, Yuba County, USFWS, and Wildlife Conservation Board	Located about 9 miles downstream of Englebright Dam, the project will restore about 43 acres to increase Chinook salmon and steelhead spawning habitat (about 5 acres), create backwater habitat and reduce bank erosion on the lower Yuba River. The project is intended to: • Increase the amount of high-quality spawning habitat by modifying hydraulic (i.e., depth and velocity) and substrate conditions to within the ranges preferred by Chinook salmon and steelhead during typical spawning periods. • Create a design that mimics natural morphological features (e.g., riffle, pool) that would not erode significantly through typical non-flood control related operations. Reduce bank erosion that may be contributing mercury contaminated soil to the Yuba River. Land-side construction began in 2023, and in-water work was initiated 2024.
Hallwood/Cordua Canal – Fish Screen Return Line Replacement	Reasonably Foreseeable	HIC, CID	HIC and CID have a canal that diverts water from the lower Yuba River near Daguerre Point Dam for irrigating their districts along with the Ramirez Water District. The diversion is the main source of irrigation for 24,500 acres of prime farmland. A fish screen was installed downstream in the district canal and a 24" return line that transports fish back to the lower Yuba River. However, the return line to the river has had issues over the years due to extreme flows changing the river alignment and depth of the riverbed. These conditions have made maintaining the flow in the line for fish returning to the river difficult. The return line has become deep in the current river channel and becomes blocked by large rocks and debris during high water events. The districts cannot divert water from the river without this return line. The districts' fish screen return pipe is being inundated with large amounts of gravel and the districts are collaborating to replace the pipe at a straighter alignment to the river. This new alignment would allow for better flow and maintenance as well as a secondary discharge point during high water events (YCRWMG 2023).
South Canal Diversion Water Supply and Fish Passage Enhancement Annual Maintenance Project	In Progress	YCWA	River alluvium is annually excavated from the south channel of the lower Yuba River to allow for additional water flow into the south channel and subsequently enhance fish passage for Chinook salmon and steelhead in the YCWA South Canal Diversion. Annual maintenance (2023-2027) involves removing sediment from an 800-foot-long reach of the south channel of the lower Yuba River between the south channel/main channel junction and the entrance to the South Canal Diversion. The project additionally involves installing a temporary access ramp, constructing temporary berms, spreading excavated river alluvium on the adjacent gravel bar, installing cobble lining and root wad, and conducting site clean-up.

Table 4.9-1. (Continued).

Project	Status	Primary Agencies	Description
Lower Yuba River (cont.)			
Yuba City Boat Ramp Sediment Removal Project	Phase 1 complete; Phase 2 In Progress	Sutter Butte Flood Control Agency	Sediment buildup in portions of the Feather River, exacerbated by the Oroville Dam Spillway incident of 2017, created dangerous conditions for recreational users, made some boat launch facilities nearly unusable, and hampered public safety as it has affected emergency vessel launching capabilities. The project will remove sediment for safety purposes, restore recreation access to the Feather River, and to restore fish passage at the confluence of the Feather and Yuba Rivers. Phase 1 was completed in 2021 and involved dredging approximately 65,000 cubic yards of sediment at the confluence of the Feather River and Yuba River. Phase 2 would involve dredging an additional 250,000 cubic yards of sediment if additional funding becomes available, for a total of 315,600 cubic yards. The timing of Phase 2 will depend on availability of funding. Overall, the project aims to restore safe recreational access to the Feather River and to restore fish passage at the confluence of the Feather and Yuba Rivers.
Pumpline Solar Project	In Progress	BVID	BVID proposes to install solar infrastructure to supplement the cost of lifting Yuba River water 35 feet to the head of its Pumpline Canal, which provides water to support about 4,500 acres of production agriculture (rice, tree crops, etc.). The project would protect against predicted PG&E rate increases, improve resiliency against Public Safety Power Shutoff events, help to maintain agricultural operations functioning, and increase fire prevention and protection.
Various Water Supply Improvement Projects	Reasonably Foreseeable	HIC, CID, Camptonville Community Services District Linda County Water District, North YCWA District, City of Wheatland, City of Marysville, Yuba County, and YCWA	The identified agencies are proposing various water supply improvement projects, including diversion structure replacements, ditch lining, ditch undergrounding to pipelines, flume capacity expansions, groundwater well replacement, new groundwater monitoring well installation, SCADA system upgrades, and other water infrastructure upgrades to allow for remote operation, provide real-time flow rate data acquisition and automated data sharing, achieve more precise water application, reduce seepage and overtopping losses, improve water supply reliability, and enable "smarter" operation to increase overall water use efficiency. The water savings and resiliency would also allow for continued avoidance of "deficit pumping." Furthermore, the water savings from these projects would improve water supply conditions that would allow the Yuba Subbasins water suppliers to implement their groundwater substitution transfer program which provides benefits during dry years to water suppliers throughout the state (YCRWMG 2023).
Areas Downstream of the Lower Yuba River[14]			
Oroville Facilities Hydroelectric Project FERC Relicensing (FERC Project No. 2100)	Present	FERC, DWR	The Oroville Facilities Hydropower Project is a 762 MW project owned by DWR and is a key component of the SWP. The project includes the Oroville Wildlife Recreation Area, numerous other recreational facilities, and three main FERC developments: (1) Oroville (including Oroville Dam, containing the Hyatt Pumping and Generation Plant (PGP)); (2) Thermalito (including the Thermalito Dam/Diversion Pool, Power Canal, and Thermalito Dam PGP, Thermalito Forebay/Dam, Thermalito Forebay Dam's PGP, and Thermalito Afterbay and Dam); and (3) the Feather River Fish Hatchery (including the Fish Barrier Dam, which directs anadromous fish into the FRFH and its appurtenant facilities). As part of the SWP, the Oroville Facilities are operated for flood management, power generation, water quality improvement in the Delta, recreation, and fish and wildlife enhancement. The objective of the relicensing process is to continue O&M of the Oroville facilities for electric power generation, along with implementation of any terms and conditions to be considered for inclusion in a new FERC hydroelectric license. The initial FERC license for the Oroville Facilities, issued on February 11, 1957, expired on January 31, 2007. A settlement agreement was finalized in 2006. DWR published a Final EIR and NOD in 2008. The final WQC was issued by SWRCB in 2010. NMFS issued a BO in 2016. DWR is awaiting the FERC license renewal.
South Feather Power Project FERC Relicensing (FERC Project No. 2088)	Present	FERC, South Feather Water and Power Agency (SFWPA)	The South Feather Power Project is a water supply/power project composed of four hydroelectric developments (Sly Creek, Woodleaf, Forbestown, and Kelly Ridge) located on the South Fork Feather River, Lost Creek (tributary to the South Fork Feather River), and Slate Creek (tributary to the North Yuba River). The project stores 171,986 AF of water and generates an average of 514.1 gigawatt hours of power annually. In 2012, SFWPA, DWR, and the State Water Contractors entered into the settlement agreement that allows DWR to request that SFWPA temporarily cease discharges from the Kelly Ridge Powerhouse into the Thermalito Diversion Pool and release an equivalent amount of water into Oroville Reservoir. The final WQC was issued by SWRCB in 2018. In 2023, FERC staff prepared a draft SEIS to supplement the 2009 FEIS in accordance with FERC filings made subsequent to the issuance of the FEIS, including the settlement agreement, the WQC, and revised final conditions filed by the USFS under section 4(e) of the FPA. The draft SEIS also informed ongoing consultation with USFWS under the ESA and addresses several newly listed species. SFWPA is awaiting the FERC license renewal.
Coordinated Long-term Operation of the CVP and the SWP	Past and Present	Reclamation, DWR, USFWS, NMFS	Reclamation and DWR reinitiated consultation under Section 7 of the ESA, as amended, on the Coordinated Long-Term Operation of the CVP and SWP in 2021. Reclamation completed a biological assessment in 2023 to support reinitiation of consultation, which documented the potential effects of its proposed action on federally listed endangered and threatened species that have the potential to occur in the CVP/SWP project area and critical habitat for these species. The USFWS (2024) and NMFS (2024) issued BO that contain Reasonable and Prudent Actions that limit the operations of the CVP and SWP for protecting federally listed endangered and threatened species.
CVP and SWP 1986 Coordinated Operations Agreement (COA), including 2018 Addendum	Past and Present	Reclamation and DWR	Reclamation and DWR operate their respective facilities in accordance with the COA, which defines the rights and responsibilities of the CVP and SWP with respect to in-basin water needs and provides a mechanism to account for those rights and responsibilities. Congress, through Public Law 99-546, authorized and directed the Secretary of the Interior to execute and implement the COA in 1986. The COA defines the project facilities and their water supplies, sets forth procedures for coordinating operations, and identifies formulas for sharing joint responsibilities for meeting Delta standards and other legal uses of water in a manner that meets Sacramento Valley and Delta needs while maintaining their respective water supplies. The COA further identifies how un-stored flow is shared, sets up a framework for exchange of water and services between the projects, and provides for periodic review of the agreement. In 2018, Reclamation and DWR amended four key elements of the COA to address changes since the COA originally was signed: (1) in-basin uses; (2) export restrictions; (3) CVP use of Banks Pumping Plant up to 195,000 AFY; and (4) periodic review. The COA sharing percentages for meeting Sacramento Valley in-basin uses now vary from 80% responsibility of the CVP and 20% responsibility of the SWP in wet year types to 60% responsibility of the CVP and 40% responsibility of the SWP in critical year types.
Long-term and Short-term Water Transfers	Present	Reclamation, San Luis and Delta–Mendota Water Authority (SLDMWA), Biggs–West Gridley Water District, BVID	These projects provide water to municipal, agricultural, and ecosystem water users, including wildlife refuges with programs that transfer water from Northern California to the San Joaquin Valley and Southern California across the Delta (Reclamation and SLDMWA 2019; Biggs–West Gridley Water District 2021; BVID 2009).
Sites Reservoir Project	Present and Future	Reclamation, Sites Project Authority	The Sites Reservoir Project would involve the construction and operation of an off-stream surface water reservoir to provide direct and real benefits to instream flows, the Delta ecosystem, and water supply reliability. The reservoir inundation area would be in rural, unincorporated areas of Glenn and Colusa Counties, and project components would be located in Tehama County, Glenn County, Colusa County, and Yolo County. The project would use existing infrastructure to divert unregulated and unappropriated flow from the Sacramento River at Red Bluff and Hamilton City and convey the water to a new off-stream reservoir west of the community of Maxwell, California. New and existing facilities would move water into and out of the reservoir, with ultimate release back to the Sacramento River system via existing canals and a new pipeline located near Dunnigan. Water released from Sites Reservoir would be used to benefit local, state, and federal water use needs, including public water agencies, anadromous fish species in the Sacramento River Watershed, wildlife refuges and habitats, and the Yolo Bypass to help supply food for delta smelt. A Final EIR/EIS and NOD was published in 2023.
Delta Conveyance Project	Future	DWR, Delta Conveyance Design and Construction Authority	The project would develop a new diversion and conveyance facilities in the Delta to restore and protect the reliability of SWP water deliveries, and potentially CVP water deliveries south of the Delta, consistent with the state's Water Resilience Portfolio. It would modernize the state's water infrastructure to: (1) capture and move more water during wet seasons to better endure dry seasons; (2) minimize future losses from climate-driven weather extremes; (3) protect against earthquakes disrupting water supplies; and (4) continue meeting regulatory water quality and fishery requirements, and add new operating rules for further fishery protections, among others (DWR 2023). DWR selected the Bethany Reservoir alignment at 6,000 cfs conveyance capacity as the proposed project. The Bethany Reservoir alignment consists of the construction, operation, and maintenance of new SWP water diversion and conveyance facilities in the Delta that would be operated in coordination with the existing SWP facilities. The new water conveyance facilities would divert up to 6,000 cfs of water from two new north Delta intakes through state-of-the-art fish screens and convey it via a single tunnel on an eastern alignment directly to a new pumping plant and aqueduct complex between Byron Highway and Mountain House Road near Mountain House in the south Delta, discharging it to the Bethany Reservoir for delivery to existing SWP export facilities. A Draft EIR was issued by DWR in 2022 and a certified Final EIR was issued in 2023. A Draft EIS was issued by USACE in 2022 and a Final EIS has not yet been issued (USACE 2023).

[14] As explained in Chapter 4 and in this chapter above, for most environmental resources, the geographic area that could be affected by the Proposed Projects and is appropriate for a cumulative impact analysis includes the Yuba River Watershed and the streams, water bodies, groundwater basins, and facilities that could be affected by changes in Yuba River outflow to the Feather River. However, the geographic extent considered for the cumulative analyses conducted for surface water resources, surface water quality and fisheries resources extends downstream of the lower Yuba River and includes the lower Feather River, the lower Sacramento River and the Delta (see rationale in Section 4.9.1.1).

Table 4.9-1. (Continued).

Project	Status	Primary Agencies	Description
			Lower Yuba River (cont.)
Bay-Delta Water Quality Control Plan Update	Past, Present, and Future	SWRCB, CVRWQCB, San Francisco RWQCB	Water quality and flow objectives to meet water quality criteria are included in the Water Quality Control Plan for the San Francisco Bay/Sacramento–San Joaquin Delta Estuary (Bay-Delta Plan) (SWRCB 2006). The SWRCB is actively engaged in the process of updating the Bay-Delta Plan through two separate processes (Plan amendments) – first (Phase 1) efforts focusing on the lower San Joaquin River flows and Southern Delta salinity, and later (Phase 2) efforts focusing on the Sacramento River and its tributaries, Delta eastside tributaries, Delta outflows, and interior Delta inflows. In 2018, the SWRCB completed the Phase 1 efforts by adopting Bay-Delta Plan amendments focused on flows in the Lower San Joaquin River and its three major tributaries (the Stanislaus, Tuolumne, and Merced Rivers) for the protection of fish and wildlife, and establishing a new salinity objective for the reasonable protection of agricultural uses in the southern Delta. The SWRCB initiated Phase 2 to evaluate updating portions of the Bay-Delta Plan including criteria for Delta outflow, Sacramento and non-San Joaquin River tributaries inflow, Suisun Marsh salinity, Delta Cross Channel Gate closure, Delta export limits, and reverse flows in Old and Middle River. In 2016, the SWRCB issued a working Draft Scientific Basis Report, which was finalized during October 2017, to evaluate possible Sacramento/Delta updates to the Bay-Delta Plan. Subsequently in July 2018, the SWRCB released the *Framework for the Sacramento/Delta Updates to the Bay-Delta Plan* (Framework). The SWRCB's 2018 Framework proposed new inflow objectives that included both a narrative and numeric component. The numeric component included maintaining inflows from the Sacramento/Delta tributaries at 55% of unimpaired flow, within an allowed adaptive range between 45 and 65% of unimpaired flow. The SWRCB's 2018 Framework also suggested that it may be possible for "Voluntary Agreements" (VAs) to be reached that provide for both flow and habitat restoration actions that could achieve the same benefits as 55% of unimpaired flow or more with a lower water supply cost. In December 2018, CDFW, DWR and other parties submitted to the SWRCB a *Framework Proposal for Voluntary Agreements to Update and Implement the Bay-Delta Water Quality Control Plan,* which proposed to improve conditions for fish through targeted river flows and a suite of habitat-enhancing projects, including floodplain inundation and physical improvement of spawning and rearing areas. In 2022, the SWRCB received a Memorandum of Understanding (MOU) signed by CNRA, California EPA, DWR, and CDFW proposing VAs as an alternative to updating and implementing the Bay-Delta Plan (CNRA 2025). If the SWRCB adopts a "regulatory pathway" that involves an unimpaired flow requirement for the Bay-Delta Plan Update, it is anticipated that the SWRCB would seek implementation of those unimpaired flow requirements through the WQCs that would be issued for the FERC relicensings that are occurring in the Yuba River Watershed. As described for Alternative 2 in Chapter 3, FERC has stated that it will be conducting the YRDP, Narrows, and YB/DS relicensings as a basin-wide proceeding. Therefore, if unimpaired flow requirements were part of the "regulatory pathway" adopted by the SWRCB as part of the Bay-Delta Plan Update, it would be reasonable to expect that all of the FERC relicensing projects (i.e., YRDP, Narrows Project and the YB/DS projects) would be required to operate in accordance with the conditions of the new FERC licenses (including the 4(e) flow requirements) that would be in effect, as well as operations necessary to comply with an unimpaired flow requirement.
Healthy Rivers and Landscapes (HR&L) Program	Reasonably Foreseeable	SWRCB	During September 2023, the SWRCB released the DSR for potential Sacramento/Delta updates to the Bay-Delta Plan for public review and comment. The DSR (SWRCB 2023) also included a Final Draft Scientific Basis Report Supplement in support of the proposed VAs (now referred to as the HR&L Program). The DSR stated that it served as a draft SED for CEQA compliance, and it evaluated potential economic, environmental, and other impacts, and associated mitigation measures, of a range of alternatives for updating the Bay-Delta Plan. Those alternatives included: (1) an alternative based on the SWRCB's 2018 Framework that states that the SWRCB's staff would make many discretionary future decisions about how the 2018 Framework's water quality objectives would actually be implemented; (2) an alternative that would implement the proposed HR&L Program (formerly referred to as the proposed VAs); and (3) several "modular" alternatives that might be implemented with either the SWRCB's 2018 Framework-based alternative or the HR&L-based alternative. YCWA, as one of the HR&L Parties, has developed a proposed HR&L project for the Yuba River consisting of a proposed flow contribution and construction of habitat enhancements. The flow contribution includes two components of water to be dedicated to Delta outflow. First, all Yuba Accord Released Transfer Water (as that term is defined in the Yuba Accord Water Purchase Agreement), from stored water releases that occurs during April, May, and June in Above Normal, Below Normal, and Dry years that DWR cannot export or back into Oroville Reservoir would be contributed to the HR&L Program (Component A). The second component (Component B) is an additional release of stored water from NBB Reservoir, reducing end of WY (September 30) storage by as much as 50,000 acre-ft, to be released during the months of April, May, or June in Above Normal, Below Normal, Dry years. Along with the other elements of the HR&L Program, it is reasonably possible to qualitatively evaluate how YCWA's HR&L proposal would be implemented and therefore to analyze its environmental effects as a cumulative project. With respect to the cumulative analysis for Alternative 2 in this DEIR, it is noted that the HR&L Program and a 55% unimpaired flow requirement under Alternative 2 are mutually exclusive because it would not be possible to implement both operations at the same time.

4.9.1.3 Cumulative Impact Assessment Methodology

Each environmental resource chapter in this DEIR includes a section that addresses potential cumulative effects anticipated from implementation of the Proposed Projects (or an alternative), together with related projects in the Yuba River Watershed and downstream waterbodies and facilities. Potential cumulative impacts associated with the Proposed Projects and alternatives are analyzed both quantitatively and qualitatively in this DEIR. The CEQA alternatives comparisons that are evaluated in this EIR for cumulative effects purposes are:

- Cumulative Condition (Proposed Projects) compared to the Existing Condition
- Cumulative Condition (Alternative 1) compared to the Existing Condition
- Cumulative Condition (Alternative 2) compared to the Existing Condition
- Cumulative Condition (No Project Alternative) compared to the Existing Condition

The purpose of the comparisons identified above is to determine whether the incremental effects of the Proposed Projects and alternatives would be expected to be "cumulatively considerable" when viewed in connection with the effects of past projects, the other current projects, and probable future projects (PRC Section 21083, subdivision (b)(2)). "*The [proposed] project must make some contribution to the impact; otherwise it cannot be characterized as a cumulative impact of that project*" (Sierra Club v. West Side Irrigation Dist. (2005) 128 Cal.App.4th 690, 700). Thus, "[t]*he mere existence of significant cumulative impacts caused by other projects alone shall not constitute substantial evidence that the proposed project's incremental effects are cumulatively considerable*" (CEQA Guidelines, Section 15064, subd. (h)(4)). Also, even if the Proposed Projects and alternatives will not have an incremental effect that is "cumulatively considerable," the lead agencies still are required to briefly describe the basis for reaching this conclusion in the EIR (CEQA Guidelines, Section 15130(a)).

Applying these rules to the cumulative analysis conducted for this DEIR, the resource-specific findings in each of the DEIR chapters may conclude that the Proposed Projects or an alternative would not result in any significant cumulative impacts on a resource category, if the analysis concludes that the Proposed Projects or an alternative would not have any impacts on that resource category. For resource categories where these comparisons show no impacts, it is appropriate for the discussion in the respective DEIR chapter to state that conclusion and then explain that, for this reason, the Proposed Projects or an alternative would not have any cumulative impacts on the resource category.

The cumulative analysis also considers a cumulative condition under the No Project Alternative, which was evaluated because of the potential for future environmental conditions resulting from the No Project Alternative to be different from the Existing Condition. For most resources considered in this DEIR, however, the No Project Alternative would not substantially differ from the Existing Condition because Yuba Water would continue its existing YRDP and Narrows Project operations, except for hydropower generation, outside of FERC jurisdiction. By contrast, because halting all YRDP and Narrows Project hydropower operations under the No Project Alternative would reflect a significant departure from the Existing Condition in terms of power production and energy consumption, as well as air quality and greenhouse gas emissions, the

impact analyses in Chapter 7 (Power Production and Energy Consumption) and Chapter 15 (Air Quality and Greenhouse Gas Emissions) include a discussion of potential cumulative impacts related to the No Project Alternative. Because no potentially significant cumulative impacts associated with the No Project Alternative are anticipated to occur to any other resource categories, and there is little to no possibility of the No Project Alternative resulting in a cumulatively considerable incremental impact to the cumulative condition to any other resource categories, no other chapters include cumulative impact discussions for the No Project Alternative. As discussed in other chapters of this DEIR, model output was used to demonstrate whether hydrologic changes associated with the Proposed Projects or an alternative would be expected to directly result in resource-specific impacts. Building on this approach, model output also was used as a tool in the cumulative impact assessment to help demonstrate not only whether hydrologic changes associated with the Proposed Projects or alternative would be expected to directly result in a significant impact, but also to determine whether it would be likely that such hydrologic changes would or would not be expected to result in an incremental contribution to potentially significant cumulative impacts.

To quantitatively evaluate changes in hydrologic conditions that may be caused by projects, they must be well-defined and reasonably foreseeable. Therefore, only those projects that have been adequately defined (i.e., in recent project-level environmental documents or modeling) and that have the potential to contribute to cumulative impacts are included in the quantitative assessment. This quantitative analysis focuses largely on water-related issues because the anticipated future cumulative conditions have been established through the modeling process. To the extent possible, cumulative impacts related to resources such as surface water resources, hydropower, surface water quality, fisheries and aquatic resources, terrestrial resources, recreation, visual resources, and cultural resources are evaluated quantitatively utilizing model output to provide an indication of the potential incremental contributions of the Proposed Projects and alternatives to cumulative impacts. However, to fully address cumulative impacts, these analyses also may be supplemented with an accompanying qualitative analysis.

The qualitative analysis of cumulative effects takes into account the other projects that are being discussed by various entities but which are either not able to be characterized in the modeling or not yet sufficiently defined for modeling purposes. Cumulative impacts related to resources such as groundwater, air quality, and land use generally are evaluated qualitatively.

The analysis of resource-specific cumulative impacts is presented in each resource chapter of this DEIR. For cumulative impacts assessment purposes, the tools, approach, impact indicators, and significance criteria used to determine the environmental impacts of hydrologic changes are the same as those used in the resource-specific impact analysis. The level of detail associated with the cumulative analysis may vary by resource, and is dependent upon whether the Proposed Projects or an alternative would result in any potential impacts to the resource. To assess the incremental contribution of the Proposed Projects (and alternatives) to cumulative impacts, the future with-project conditions are compared to the future without-project conditions. By comparing the potential impacts of the Proposed Projects (and alternatives) against the future without-project cumulative conditions, the incremental contributions of the YRDP and Narrows Projects to overall cumulative impacts can be determined. The approach for addressing potential cumulative impacts associated with other future actions that cannot be defined quantitatively at this time are discussed below.

The qualitative analysis of cumulative impacts considers "reasonably foreseeable" projects that are in the planning stage or that are being developed by various entities, but that have not been sufficiently defined to be evaluated in a quantifiable manner. Projects that are not yet quantifiable using modeled simulations, but that could have an effect on various resources, are addressed qualitatively to provide as much information on potential cumulative impacts as possible. For some resources including surface water resources, surface water quality, and fisheries resources, this qualitative analysis complements the discussion that is based on a quantitative evaluation, and provides additional qualitative context of potential future cumulative impacts and benefits of the Proposed Projects (and alternatives). All other resource topics that are not dependent on hydrology, water level, or water quality or that are not effectively evaluated using hydrologic modeling (i.e., groundwater, air quality, land use) are assessed in a qualitative manner only.

Reasonably foreseeable projects to be included in the resources-specific qualitative analyses were identified through a collaborative, multi-step process that included input provided by the lead agency and application of several decision-making criteria. The criteria used to identify individual projects for consideration in the cumulative analysis included the following: (1) whether the project is under active consideration by a project proponent and/or lead agency; (2) whether the project would be operational or completed within the timeframe being considered for the Proposed Projects and alternatives; and (3) whether the project, in combination with the Proposed Projects and alternatives, has the potential to affect the same resources. Projects determined to meet all three of the above criteria are considered to be reasonably foreseeable and within the planning horizon for the Proposed Projects (and alternatives) and, thus, were selected for inclusion in the qualitative cumulative analysis presented in each of the resource-specific chapters of this DEIR (Table 4.9-1).

4.9.1.4 Analysis of Potential Cumulative Impacts in this EIR

The DEIR's analysis conforms with Section 15130(b) of the State CEQA Guidelines, which specifies that the "discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the Proposed Projects alone. The discussion should be guided by the standards of practicality and reasonableness and should focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact."

To be consistent with CEQA requirements, there are four different possible impact statement outcomes for the cumulative effects analysis:

1. There would be no significant cumulative impact. This conclusion is appropriate when the combined effects of the project and closely related past, present, and reasonably foreseeable probable future projects would be less than significant. This requires a discussion providing evidence to support the conclusion.
2. There is an existing significant cumulative impact, but the project's incremental contribution would not be considerable. This conclusion is appropriate when the combined effects of closely related past, present, and reasonably foreseeable probable future projects would be cumulatively significant, but the project's incremental contribution to the significant cumulative impact would not be considerable. This requires a discussion of why

the project's incremental contribution would not be significant or cumulatively considerable. For example, there may be mitigation measures implemented to reduce/avoid/minimize the impacts of the project, or the magnitude of the incremental effect of the project may be very small, demonstrating that the project's contribution to any significant cumulative effects would be less than significant.

3. There is an existing significant cumulative impact, and the project's incremental contribution would be considerable. This conclusion is appropriate when the combined effects of closely related past, present, and reasonably foreseeable probable future projects are already cumulatively significant, and the project's incremental contribution to the significant cumulative impact would be cumulatively considerable. This requires a discussion of all feasible mitigation measures that could reduce/avoid/minimize the project's contribution to the significant cumulative effect. If no feasible mitigation measures are available, the project's contribution to the impact would remain cumulatively considerable (significant and unavoidable).
4. There would be a new significant cumulative impact because the project's incremental contribution would be substantial when considered with other related projects. This conclusion is appropriate when the combined effects of closely related past, present, and reasonably foreseeable probable future projects are not significant, but the project's incremental contribution is substantial enough that when added to the cumulative effects of related projects, would result in a new significant cumulative impact. This requires a discussion of all feasible mitigation measures that could reduce/avoid/minimize the project's contribution to the significant cumulative effect. If no feasible mitigation measures are available, the project's contribution to the impact would remain cumulatively considerable (significant and unavoidable).

The standards used herein to determine a considerable contribution are that either the incremental contribution to the impact by the Proposed Projects (and alternatives): (1) must be substantial (i.e., it would cause an otherwise less-than-significant cumulative impact to become significant, or it would substantially increase the severity of an existing significant cumulative impact); or (2) must exceed an established threshold of significance.

This cumulative analysis assumes that the Proposed Projects' protective measures and environmental commitments (see Chapter 2 – Project Description) are implemented. The analysis herein analyzes whether, after implementation of such measures and commitments, the residual impacts of the Proposed Projects would cause a significant cumulative impact or would contribute considerably to existing/anticipated (without the Proposed Projects) significant cumulative effects. If the analysis finds that the Proposed Projects could result in a cumulatively considerable impact(s), then mitigation measures have been identified to reduce the significant incremental impact(s) of the Proposed Projects to the extent feasible when considered alongside the impacts of past, present, and reasonably foreseeable future projects in the area, aiming to lessen the combined impact on the environment by addressing the Proposed Project's incremental contribution to the cumulative effect.

CHAPTER 5

SURFACE WATER RESOURCES

5.1 Introduction

This chapter describes the environmental setting and regulatory framework for surface water resources of the Yuba River watershed, and it identifies direct, indirect and cumulative impacts of the Proposed Projects and alternatives during construction and O&M. focusing on areas affected by the Proposed Projects operations, particularly water supply and flood management.

5.2 Environmental Setting

The YRDP and Narrows Project are located in the Yuba River watershed which drains approximately 1,339 square miles of the western slope of the Sierra Nevada Mountains, including portions of Sierra, Placer, Yuba, and Nevada Counties. The Yuba River is a tributary of the Feather River, which in turn is a tributary of the Sacramento River. The watershed rises from an elevation of about 88 feet to about 8,590 feet. In general, watershed runoff is nearly equally divided between runoff from rainfall during October through March and runoff from snowmelt during April through September. Figure 5.2-1 shows the Yuba River watershed and major infrastructure. Unless otherwise indicated, facilities shown within the Yuba River watershed are owned and operated by Yuba Water.

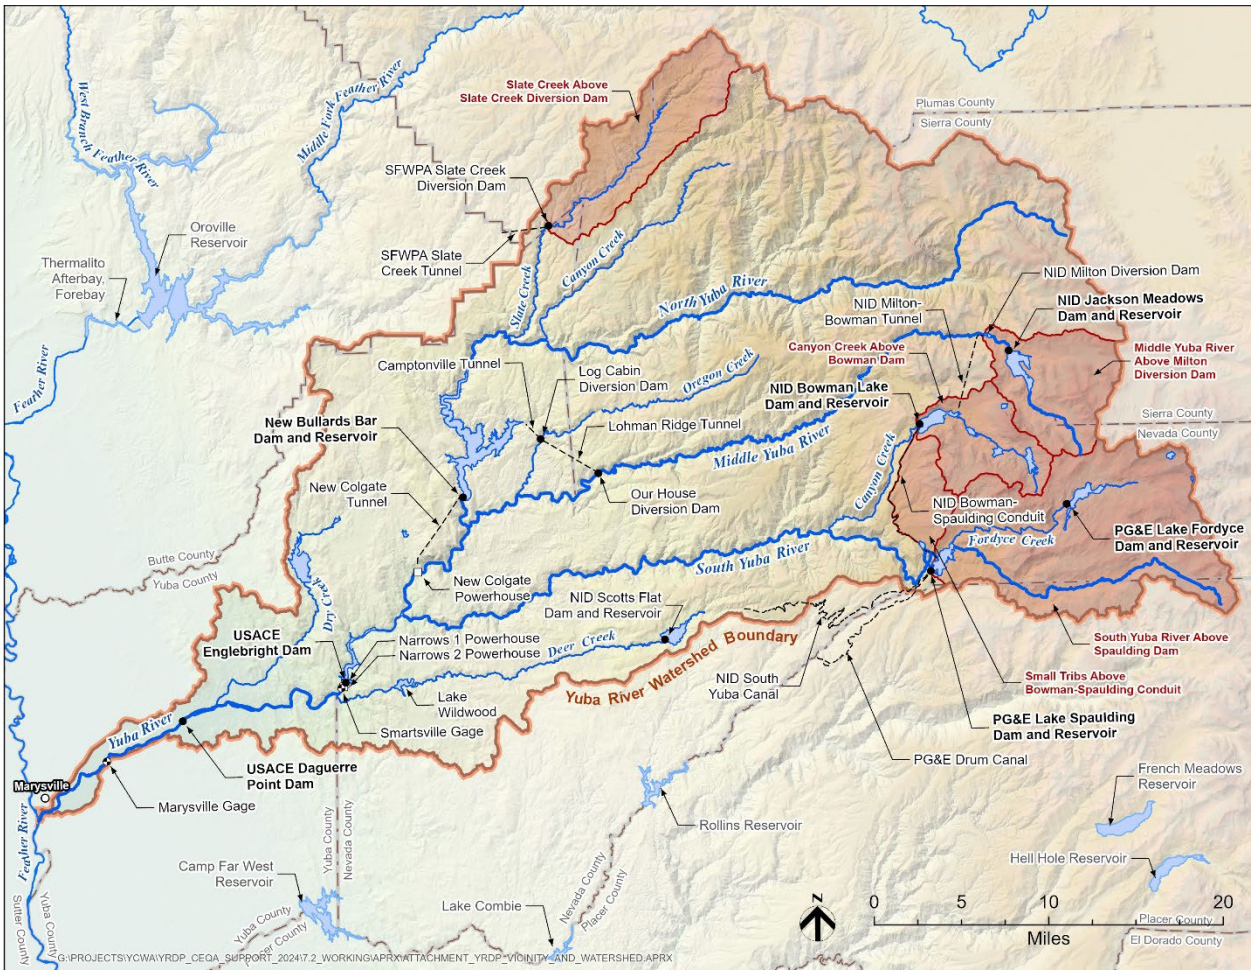

Figure 5.2-1. The Yuba River Watershed and Major Infrastructure. Red areas denote portions of the watershed under other Agencies' regulation.

5.2.1 Areas Upstream of Englebright Dam

The following section describes Yuba River surface water resources upstream from Englebright Dam, including on the North, Middle, and South Yuba rivers, Oregon and Slate creeks, and New Bullards Bar Dam and Reservoir.

5.2.1.1 Surface Water Hydrology

Upstream of Englebright Dam are the North, Middle, and South Yuba rivers, and Slate and Oregon creeks. Each tributary is described below.

5.2.1.1.1 North Yuba River

The upper extent of the North Yuba River is at Yuba Pass (elevation 6,701 feet msl) near State Route (SR) 49 in Sierra County. The river flows parallel to SR 49 as far as Downieville, where it diverges from the highway and flows westward into Yuba Water's New Bullards Bar Reservoir. The North Yuba River terminates at its confluence with the Middle Yuba River, approximately 2 miles downstream from New Bullards Bar Dam, at which point the combined flow of the two

rivers becomes the Yuba River. The total area of the North Yuba River watershed is approximately 491 square miles and includes portions of Yuba, Sierra, and Plumas counties. The record of daily flow data from the primary gage in the watershed, Goodyears Bar (USGS Gage 11413000) at approximately 2,453 feet msl, extends from October 1, 1930 through the present and represents drainage from a watershed area of approximately 250 square miles. There are no impairments on the North Yuba River above Goodyears Bar that substantially affect river flow.

The North Yuba River subbasin is a predominantly snowmelt-fed stream, with peak flows occurring from March through May. On a long-term average basis, North Yuba River flows are lowest from August through October. Canyon Creek, an ungaged tributary to the North Yuba River, with a subbasin of approximately 61 square miles, flows into the North Yuba River approximately 8 miles downstream from Goodyears Bar. Similar to the North Yuba River subbasin above Goodyears Bar, the Canyon Creek subbasin is predominantly snowmelt-fed and has no upstream impairments.

5.2.1.1.2 Slate Creek

Slate Creek originates near the town of La Porte, in the northern portion of the Yuba River watershed. The Slate Creek subbasin is approximately 61 square miles. The South Feather Water and Power Agency (SFWPA) diverts flows from Slate Creek into the Feather River Basin near Strawberry Valley via the Slate Creek Tunnel at approximately 3,500 feet msl as part of their South Feather Power Project (FERC Project 2088-068). Approximately 49 square miles of the Slate Creek subbasin is above the Slate Creek Tunnel. The Slate Creek Tunnel has a maximum capacity of 848 cubic feet per second (cfs), and its flow has been measured at USGS Gage 11413250 since October 1, 1962. Slate Creek joins the North Yuba River approximately 0.5 miles upstream from the normal high-water mark of NBB and approximately 12 miles below the Goodyears Bar gage. Slate Creek flows have been continuously gaged below the Slate Creek Tunnel by USGS Gage 11413300 since October 1, 1960.

5.2.1.1.3 Middle Yuba River

Flows in the Middle Yuba originate from snowmelt and rainfall runoffs above the largest upper watershed impoundment, NID's Yuba-Bear Project's (FERC Project No. 2266) Jackson Meadows Reservoir, with a dam crest of elevation 6,044.5 feet msl, in Sierra County. NID's Milton Diversion Dam, located just downstream from Jackson Meadows Dam at river mile 44.4, diverts a portion of the Middle Yuba River flow into the Milton-Bowman Tunnel, which discharges in Bowman Reservoir in the South Yuba Watershed. Below the Milton Diversion Dam, most of the upper Middle Yuba River is confined by narrow, steep canyons which continue downstream to Yuba Water's 75-foot-high Our House Diversion Dam, the upper extent of the YRDP on the Middle Yuba River, located southwest of Camptonville near the Sierra/Nevada County line. A portion of the Middle Yuba River's flow can be diverted into Yuba Water's Lohman Ridge Tunnel at the Our House Diversion Dam. Approximately 12 miles below Our House Diversion Dam, the Middle Yuba River joins the North Yuba River to form the Yuba River.

5.2.1.1.4 Oregon Creek

Oregon Creek is entirely contained within the Middle Yuba River watershed and originates near elevation 4,455 feet msl. Yuba Water's Log Cabin Diversion Dam, a 55-foot-high dam, diverts flows from Oregon Creek to NBB through Yuba Water's Camptonville Tunnel. Yuba Water's Log Cabin Diversion Dam is approximately 4 miles upstream from Oregon Creek's confluence with the Middle Yuba River. Oregon Creek flow above the Log Cabin Diversion Dam is a combination of outflow from the Lohman Ridge Tunnel, originating at Our House Dam on the Middle Yuba River, and Oregon Creek flow. Above the outfall of the Lohman Ridge Tunnel, Oregon Creek is free of impairments. Of the approximately 35 square miles of the Oregon Creek watershed, about 6 square miles lie below Log Cabin Dam.

5.2.1.1.5 South Yuba River

The headwaters of the South Yuba River originate at elevation of 9,000 feet msl in Placer County near Castle Peak and Donner Lake. The South Yuba River is subject to multiple upstream impairments before it joins the Yuba River in Englebright Reservoir. Primary upstream impairments are NID's Yuba-Bear Project, and PG&E's Drum-Spaulding Project (FERC Project No. 2310). A portion of Canyon Creek flow, including inflow from the Milton Bowman-Tunnel, are diverted from NID's Bowman Reservoir, located at river mile 10.4 on Canyon Creek, through the Bowman-Spaulding Tunnel to PG&E's Lake Spaulding at river mile 40.8 on the South Yuba River. Releases from Lake Spaulding are diverted into the Bear and American river basins via the Drum Canal and South Yuba Canal.

Diversions from the Drum and South Yuba canals provide water supply to NID and Placer County Water Agency[1] (PCWA) customers. In addition to water supplies from the Yuba River watershed, NID water users receive water supplies from the Bear River and Deer Creek under NID water rights and a contract with PG&E[2] (NID 2021). In addition to purchases from PG&E, PCWA water users receive water supplies from PCWA's Middle Fork Project (FERC Project 2079) and groundwater.

Remaining South Yuba River flow below Spaulding Dam combines with remaining Canyon Creek flow, and joins the Yuba River in Englebright Reservoir 32.4 miles downstream from the Canyon Creek-South Yuba River confluence. Flows on the lower South Yuba River have been continuously measured at Jones Bar gage (USGS Gage 11417500), located approximately 7 miles upstream from the confluence of the Yuba River and South Yuba River, since April 1, 1959. Of the approximately 352-square-mile South Yuba River watershed, approximately 42 square miles lie below Jones Bar gage.

[1] Placer County Water Agency has two water supply contracts that allow for purchase of up to 125,400 acre-feet of water annually from PG&E: 100,400 ac-ft annually for Zone 1, and 25,000 ac-ft for Zone 3 (PCWA 2006);

[2] NID has a water purchase contract with PG&E to purchase up to 54,361 AF, however purchase is only available in monthly allotments in which many of the months are during the winter. For planning purposes, NID assumes 7,500 AF is available on an average basis.

5.2.1.2 Reservoirs

5.2.1.2.1 New Bullards Bar Reservoir

New Bullards Bar Reservoir is the principal storage facility for the YRDP. The reservoir has a gross storage capacity of 966,103 ac-ft (i.e., storage at the normal maximum water surface elevation) and a regulatory minimum pool of 1,730 ft, as required by Yuba Water's FERC license, which equates to a storage of approximately 230,000 ac-ft. Thus, the reservoir's operable capacity is 736,103 ac-ft. This is not to be confused with usable storage, which is 961,103 ac-ft, and is the volume of water in the reservoir between NMWSE and the elevation of the invert of the 72-inch hollow jet low level outlet (i.e., El. 1,395 ft). A portion of the operable capacity - 170,000 ac-ft - must be held empty from November 1 through March 31 for flood management; the full pool of the reservoir is available for storage between June 1 and September 15. The required storage volume is linearly interpolated between these two quantities on other dates.

Releases from New Bullards Bar Reservoir are made through the New Colgate Power Tunnel to the New Colgate Powerhouse on the Yuba River; the New Bullards Bar Minimum Flow Powerhouse at the base of the dam; the dam's low level outlet; or the gated spillway. The New Colgate Power Tunnel is approximately 5.2 mi long and has a maximum flow capacity of 3,400 cfs. The New Bullards Bar Minimum Flow Powerhouse has a maximum flow capacity of 5 cfs. The low-level outlet at the base of New Bullards Bar Dam has a maximum capacity of 1,250 cfs with an invert elevation of 1,395 ft, but it is rarely used. The New Bullards Bar Dam Spillway has a crest elevation of 1,902 ft and a maximum capacity of 124,000 cfs at full pool. Minimum flow on the North Yuba River downstream of New Bullards Bar Dam is met through a combination of releases from the New Bullards Bar Minimum Flow Powerhouse and seepage from the New Bullards Bar Dam. Any additional non-spill releases are made through the New Colgate Powerhouse. The spillway is only used during flood management operations.

New Bullards Bar Reservoir typically reaches its usable storage capacity of 966,103 acre-feet at the end of the spring runoff season and is gradually drawn down to its minimum operating elevation of 1,730 feet in early to mid-winter. The reservoir does not undergo significant daily changes in elevation. Historical storage in New Bullards Bar Reservoir has been recorded at the New Bullards Bar Reservoir gage (USGS 11413515) from January 14, 1969 through September 30, 2023. Yuba Water typically manages New Bullards Bar Reservoir storage to balance flows in the Yuba River below Englebright Reservoir for fisheries benefits while maintaining storage in case of a subsequent year drought. Table 5.2-1 shows generalized end-of-month target storages based on discussions with YRDP operators for New Bullards Bar Reservoir.

Table 5.2-1. General End-of-Month New Bullards Bar Reservoir Target Storages.

Location	Average[1] End-of-Month Storage (TAF)											
	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep
New Bullards Bar Reservoir[2]	750	750	750	780	780	790	890	966	966	845	735	650

5.2.1.2.2 Englebright Reservoir

USACE's 260-ft-high Englebright Dam was constructed by the United States in 1941 at Yuba River RM 24.0, forming Englebright Reservoir to trap sediment derived from hydraulic mining operations in the Yuba River watershed. USACE's Englebright Reservoir is about 9 miles long and has a gross storage capacity of about 70,000 acre-feet. In addition to its role as a debris-management structure, Englebright Reservoir functions as an afterbay for the New Colgate Powerhouse; releases to the Yuba River below Englebright Dam are held relatively consistent, while storage in Englebright Reservoir fluctuates according to New Colgate Powerhouse releases. Inflow to Englebright Reservoir comes from multiple sources: releases from the New Colgate Powerhouse, releases from New Bullards Bar Dam, releases from Our House and Log Cabin diversion dams, inflow from the South Yuba River, and local inflows to Oregon Creek and the Middle Yuba, North Yuba, and Yuba rivers downstream from the upstream impairments.

Englebright Reservoir elevations are held above 516 feet above mean sea level according to an agreement with local marina operators. Englebright Dam has a passive spillway at 527.0 feet above mean sea level. There is approximately 7,000 acre-feet of storage between 516 feet and 527 feet above mean sea level. As a result of normal Yuba Water operations, Englebright Reservoir water surface levels generally are between approximately 517 feet above mean sea level and 523 feet above mean sea level, but levels can fluctuate according to inflows. For analytical purposes, Yuba Water used a target elevation of 519 feet above mean sea level to define normal Englebright Reservoir water surface elevation.

5.2.1.3 Water Quantity & Historical Delivery

The Nevada Irrigation District and PG&E export approximately 410,000 acre-feet per year from the Yuba River Basin to the Bear River and American River Basins (NMFS 2012). This is sourced from the Middle Yuba and South Yuba Rivers and associated diversion facilities which have a total storage capacity of 307,000 acre-feet. In addition, the South Feather Water and Power Agency exports an average of about 70,000 acre-feet per year from Slate Creek (a tributary to the North Yuba River) to the Feather River Basin. While these upper basins lie outside the Project Area, their operations can significantly reduce the water supply available to the Proposed Projects, particularly during dry and critically dry water years.

Within the Project Area above Englebright Dam, Yuba Water pumps an average of 6 acre-feet per year from New Bullards Bar Reservoir to supply water to the Cottage Creek Treatment Plant for domestic and recreational uses adjacent to the reservoir. Diversions downstream are discussed below.

Although the area on the west side of the New Bullards Bar Reservoir and North Yuba River is located within the boundaries of the North Yuba Water District, the North Yuba Water District obtains most of its water supply from the South Fork Feather River Project and does not divert adjacent to the YRDP site.

5.2.1.4 Flood Management

The Yuba River upstream of the Englebright Dam is mapped by FEMA[3] as flood Zone A (areas with a 1% annual chance of flooding). Similarly, the South Yuba River is also mapped as being Zone A. Upstream of the junction with the Dobbins Creek, the Yuba River is mapped as being Zone X (areas outside of the 0.2% annual chance flood). The flood risk along the Middle Yuba River has not been determined.

According to the USACE National Levee Database, there are no Federal levees upstream of the Englebright Dam.[4] In the event of a spillway failure on the New Bullards Bar Dam, the North Yuba River and downstream communities are identified as being in the "Extremely High" downstream inundation hazard zone.[5]

The Middle and South Yuba Rivers are virtually unprotected by flood control systems.

New Bullards Bar Reservoir acts as the main flood control facility for the Yuba River watershed with 170,000 acre-feet of usable capacity held in reserve for flood storage from October through April. The reservoir controls about half of the flood flows of the Yuba River watershed, with the remainder of the runoff left largely uncontrolled. In accordance with a contract between Yuba Water and the USACE, a portion of the usable capacity, 170,000 acre-feet, must be available for flood management from November 1 through March 31, with lesser amounts of flood storage required during September, April, and May. The seasonal flood storage space allocation schedule is presented in Table 5.2-2.

Table 5.2-2. New Bullards Bar Reservoir Flood Reservation Storage.

	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep
End of Month Storage Allocation (TAF)	170	170	170	170	170	170	70	0	0	0	0	56
End of Month Maximum Allowable Storage (TAF)	796	796	796	796	796	796	896	966	966	966	966	910

Source: United States Army Corps of Engineers, New Bullards Bar Reservoir, Reservoir Regulation for Flood Control, June 1972
Key: TAF = Thousands of acre-feet

In addition to reservation of flood control space in New Bullards Bar Reservoir, flood management regulations include rules governing ramping rates as well as target maximum flows in the Yuba River and the Feather River below the confluence with the Yuba River (USACE 1970; USACE 1972). New Bullards Bar Reservoir is operated for the following maximum flows:

- 50,000 cfs on the North Yuba River below New Bullards Bar Dam
- 120,000 cfs on the Yuba River at Marysville
- 300,000 cfs on the Feather River below the Yuba River
- 320,000 cfs on the Feather River below the Bear River

[3] FEMA Flood Map Service Center. Accessed October 2024. FEMA Flood Map Service Center | Search By Address
[4] National Levee Database. Map View. Accessed October 2024. National Levee Database (army.mil)
[5] Dam Breach Inundation Map. Accessed October 2024. Dam Breach Inundation Map Web Publisher (ca.gov)

Releases from New Bullards Bar Reservoir are made through the New Colgate Powerhouse on the Yuba River, the New Bullards Bar Minimum Flow Powerhouse at the base of the dam, a low-level outlet at the base of the dam, and/or the gated spillway. Based on Yuba Water operational records, New Bullards Bar Dam has historically spilled in 29 out of the last 54 water years between 1970 and 2023. Historically, peak monthly spill volumes have occurred in January 1970 (410 TAF), February 1986 (406 TAF), January 1997 (577 TAF) and February 2017 (621 TAF). The maximum daily average spill of 53,633 cfs occurred on January 2, 1997.

Yuba Water is pursuing the addition of an Atmospheric River Control Spillway (ARC Spillway) at New Bullards Bar Dam that would allow for increased spill releases from New Bullards Bar Reservoir at lower elevations. The proposed ARC Spillway is described and analyzed in detail in a separate EIR by Yuba Water (State Clearinghouse No. 2020110163).[6]

5.2.2 Lower Yuba River

The following section describes surface water resources on the Yuba River downstream from Englebright Dam, also known as the lower Yuba River, to its confluence with the Feather River.

5.2.2.1 Surface Water Hydrology

The Lower Yuba River extends 24.3 miles from Englebright Dam to the river's confluence with the Feather River, which flows into the Sacramento River, and then subsequently flows into the Sacramento - San Joaquin River Delta. Deer Creek (RM 23.4) and Dry Creek (RM 13.9) contribute flow to the lower Yuba River draining areas of 89 square miles and 108 square miles, respectively. Diversions for irrigation throughout this portion of the Yuba River are common. The Yuba River at its confluence with the Feather River has a drainage area of 1,339 square miles.

USGS gage 11418000 (Yuba River below Englebright Dam near Smartsville, California) captures a drainage area of 1,108 square miles. The gage measures flow in the Yuba River downstream from both the Narrows 1 and Narrows 2 Powerhouses, described in detail in Chapter 2, which are located immediately downstream of the Englebright Dam, and includes both spills from the dam and powerhouse releases. USGS gage 11421000 (Yuba River near Marysville, California), is located 6.2 miles upstream from the Yuba River's confluence with the Feather River and captures a drainage area of 1,339 square miles.

5.2.2.2 Reservoirs and Impoundments

Flows on the Yuba River are restricted by Daguerre Point Dam, constructed by the United States in 1906 downstream of Englebright Dam at RM 11.6 to prevent hydraulic mining debris from the Yuba River watershed from flowing into the Feather and Sacramento rivers downstream. This dam is only 25 feet high and has no appreciable storage capacity. Daguerre Point Dam provides elevation control for diversion into the Hallwood-Cordua Canal on the north side of the dam, and

[6] The analysis of ARC Spillway operations from the ARC Spillway EIR is incorporated by reference and is available at https://www.yubawater.org/252/ARC-Spillway-at-New-Bullards-Bar-Dam . The ARC Spillway EIR found that operation of the ARC Spillway would not result in any unmitigated significant impacts to surface water resources, and would have a beneficial impact related to reservoir storage, downstream flows, and flood risk. While the ARC Spillway EIR evaluated ARC Spillway operations under Yuba Water's existing FERC license for the YRDP, those operations would not significantly change under a new FERC license. As a result, ARC Spillway operations under the Proposed Projects would not have new or worse impacts compared to those previously disclosed in the ARC Spillway EIR.

the Yuba Main Canal on the south side. There are existing fish ladders on each end. Yuba Water is pursuing a Nature-Like Fishway that would replace the south fish ladder and the diversion structure for the Yuba Main Canal.

5.2.2.3 Water Quantity & Historical Delivery

Yuba Water is a major water-right holder on the Yuba River. Yuba Water holds pre-1914 appropriative rights dating from 1897 and post-1914 appropriative water rights confirmed by water-right licenses. Yuba Water diverts water for consumptive uses under several permits that authorize direct diversion up to a total rate of 1,593 cfs from the lower Yuba River from September 1 to June 30 for irrigation and other uses, and up to 1,250,000 ac-ft from October 1 to June 30 to storage in the New Bullards Bar Reservoir[7]. In most years, water supply for irrigation after June 30 is provided from storage.

As described in Section 2.4.3.3.4, eight water districts, irrigation districts, and mutual water companies, also known as member units, have water supply contracts with Yuba Water for delivery of water. Figure 5.2-2 shows a map of Yuba Water's member units' service areas.

[7] Yuba Water Agency. Yuba County Integrated Regional Water Management Plan. Accessed October 2024. CONTENTS (yubawater.org)

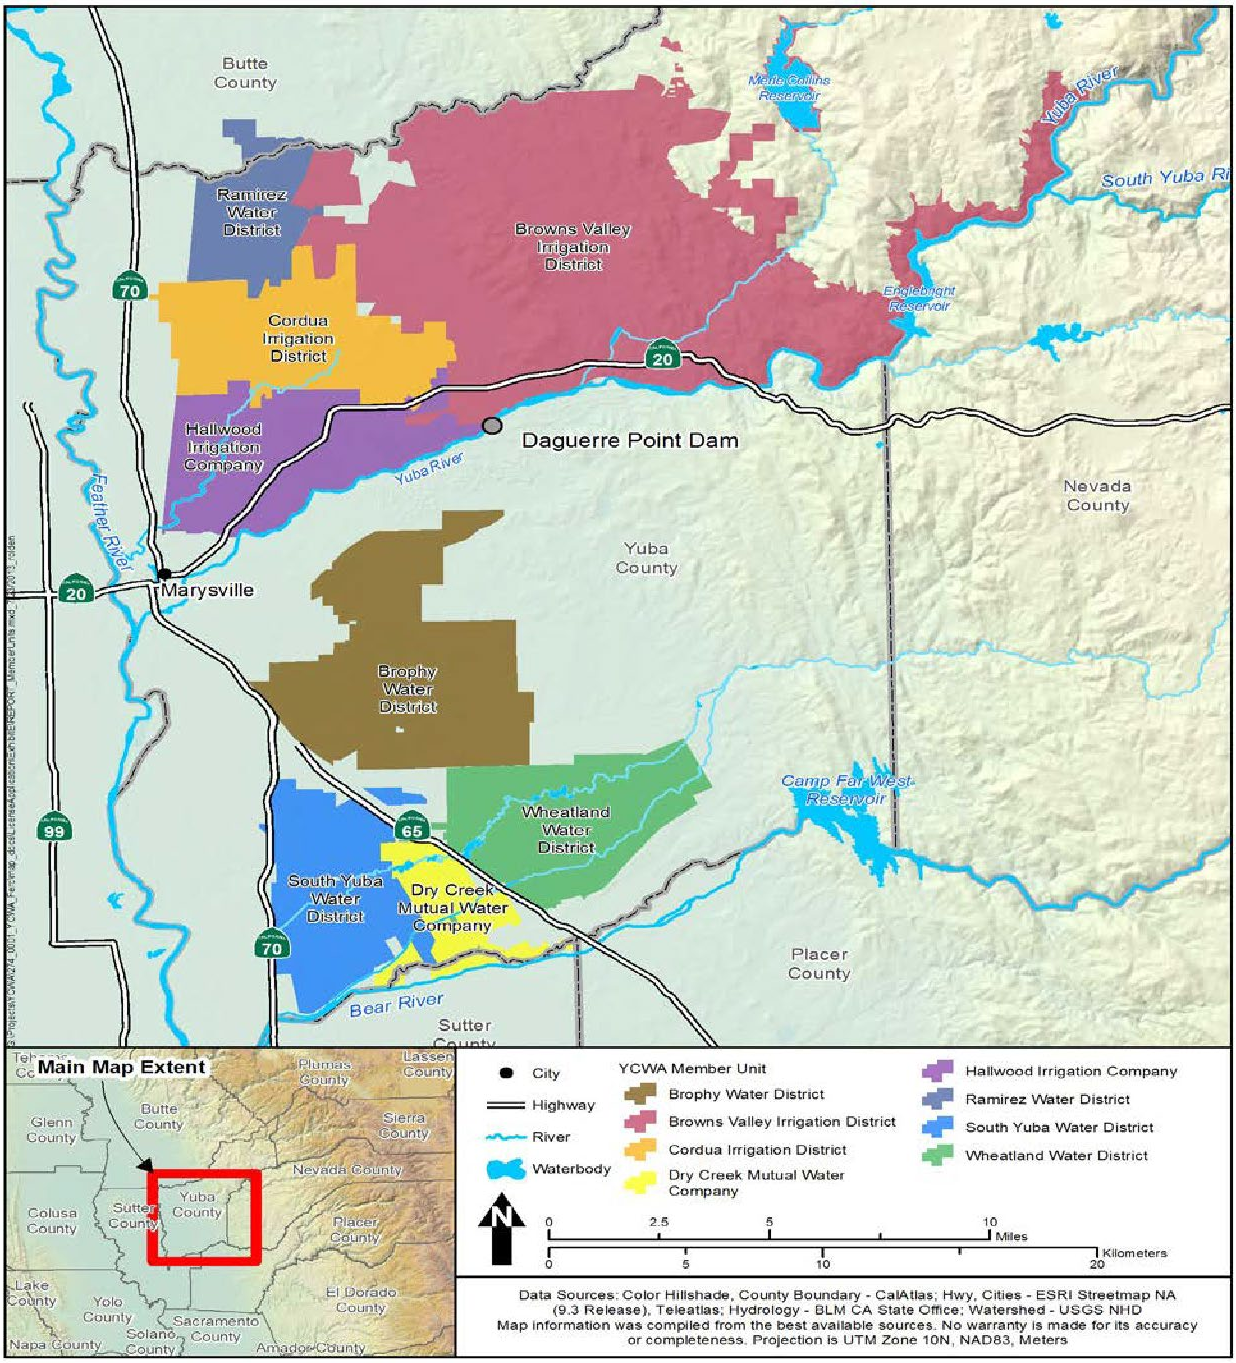

Figure 5.2-2. Yuba Water's Member Unit service areas.

In 2016, new agreements were signed that changed some of the volumes, timing, and conditions for providing water supplies from the YRDP. Yuba Water provides water supplies under Yuba Water's consumptive-use water-right permits to its eight Member Units. The places of water delivery to Yuba Water's Member Units are listed in Table 5.2-3.

Table 5.2-3. Yuba Water's Annual Contract Amounts and Place of Delivery.

Member Unit	Water Right Based Supply (acre-feet)	Project Based Supply (acre-feet)	Total Contract (acre-feet)
Browns Valley Irrigation District Pumpline Diversion Facility[1]			
Browns Valley Irrigation District	24,505	9,500	34,005
Yuba Main Canal[2]			
Brophy Water District	--	86,870	86,870
South Yuba Water District	--	54,307	54,307
Dry Creek Mutual Water Company	--	17,751	17,751
Wheatland Water District	--	40,230	40,230
Hallwood-Cordua Canal[3]			
Cordua Irrigation District	60,000	24,000	84,000
Hallwood Irrigation Company	78,000	11,208	89,208
Ramirez Water District	--	30,389	30,389
Total	162,505	274,255	436,760

[1] BVID receives water at the Pumpline Diversion Facility, located 1 mile upstream of United States Army Corps of Engineers' (USACE) Daguerre Point Dam.

[2] BWD, SYWD, DCMWC and WWD receive water from the Yuba Main Canal (South Canal), which begins on the south side of the Yuba River slightly upstream of the south abutment of USACE's Daguerre Point Dam.

[3] CID, HIC and RWD receive water through the Hallwood-Cordua Canal (North Canal), located on the north abutment of USACE's Daguerre Point Dam.

Browns Valley Irrigation District (BVID), Cordua Irrigation District (CID), and Hallwood Irrigation Company (HIC) have their own water rights on the Yuba River. Under water supply agreements with Yuba Water, CID and HIC receive surface water supplies as part of YRDP operations that are based on these Member Units' water rights. All eight of the Member Units receive some of their water as contracted supplies that are based on Yuba Water's water rights. Dry year deficiency criteria in BVID, CID, and HIC contracts are different from the deficiency criteria in Yuba Water's contracts with other Member Units. Provisions in Yuba Water's water supply agreements preclude deficiencies in water-right based supplies unless DWR April forecast of unimpaired runoff as measured at the Smartsville Gage is less than 40 percent of average. Contract shortage provisions are presented in Table 5.2-4.

Table 5.2-4. Yuba Water's water supply contract shortage provisions.

Category	Unimpaired Runoff Forecast (f) [1]	Percentage of Water Supply/ Contract Allocation Available[2]
PRE-1914 RIGHTS AGREEMENTS		
Browns Valley Irrigation District[3]	All	100%
Cordua Irrigation District	$f \geq 40\%$	100%
Hallwood Irrigation Company	$f < 40\%$	80%
YUBA WATER SUPPLY CONTRACTS		
Base Project Water for Other Member Units	f > 85%	100%
	$40\% \leq f \leq 85\%$	75%
	$f < 40\%$	50%

[1] April 1 DWR forecast of unimpaired Yuba River runoff near Smartsville in percentage of 50-year average.

[2] Based on water availability; if insufficient water is available for delivery, contract allocations could be lower than listed values.

[3] When the unimpaired runoff forecast is less than 40%, BVID's water rights give it the first 47.2 cfs of North Yuba River flow.

Current agricultural surface water supply demand includes only lands irrigable by existing infrastructure, demand in below normal, dry, and critical years is approximately 305 TAF, 145 TAF of which is for pre-1914 water right holders, and 160 TAF of which is for Yuba Water Supply Contract holders; demand in wet and above normal years, when precipitation contributes more for irrigation water supply, is estimated to be 291 TAF, 137 TAF of which is for pre-1914 water right holders, and 154 TAF of which is for Yuba Water Supply Contract holders. Historical cumulative annual surface water deliveries are shown in Figure 5.2-3.

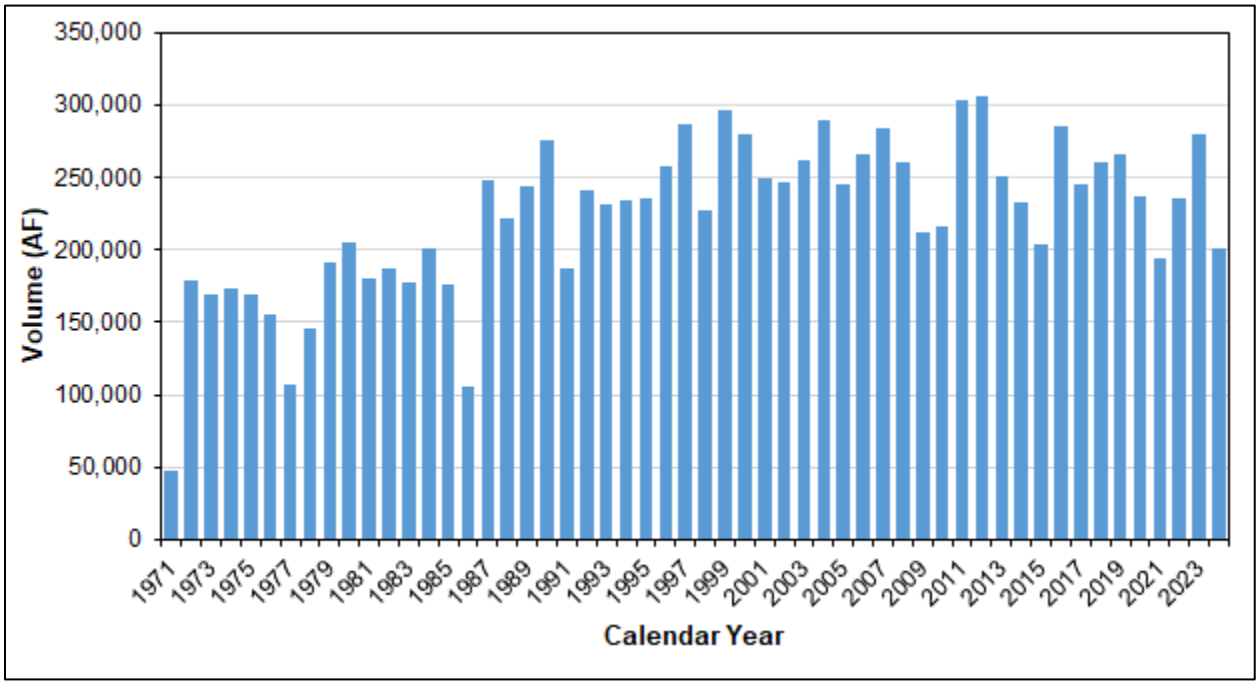

Figure 5.2-3. Historical Annual Yuba County Water Agency Member Unit Surface Water Deliveries.
Source: Yuba Water Surface Water Delivery Records

Since it began delivering water supply from the YRDP, Yuba Water has delivered full surface water supply requests to its contractors in all but four years: 2013, 2014, 2015, and 2021. These shortages have been due to hydrology reducing New Bullards Bar Reservoir storage below Yuba Water's end-of-September carryover storage threshold of 440,000 AF for the first year of a drought and 400,000 AF in subsequent drought years. Yuba Water imposes shortages to maintain storage in New Bullards Bar Reservoir for water supply in subsequent drought years. Approximate shortage volumes in those years are shown in Table 5.2-5.

Table 5.2-5. Estimated Historical Annual Member Unit Surface Water Delivery Shortage Volumes.

Calendar Year	Estimated Surface Water Shortage Volume (AF)
2013	14,500
2014	5,500
2015	55,000
2021	80,000

Notes:
[1] Period of Record: 10/1/1969 through 9/30/2023
[2] Yuba Water Operations Records
Key: AF = Acre-feet

In case of shortages, the member units effectively have three options: (1) pump groundwater to replace the reduction in surface water; (2) fallow land; or (3) do a combination of groundwater pumping and land fallowing. The decision about which of these options to take is made by individual farmers based on a multitude of factors including the value of the crop, the cost of groundwater pumping, and the availability of groundwater.

5.2.2.4 Flood Management

Both structural and non-structural elements are used to manage flood risk in Yuba County. Structural elements include upstream reservoirs with active flood control space, levees along major watercourses, flood channels, and drainage facilities that pump interior runoff and seepage into the flood control channels. Non-structural elements address the components of risk that cannot be mitigated through structural elements. These include public education, forecasting and warning systems, development regulation and management, reservoir operations, emergency operations, and other activities. A description of structural elements in Yuba County's flood risk management system are described below.

5.2.2.4.1 Structural Elements

Yuba County's flood management system is part of a much larger system of multi-purpose reservoirs, leveed stream channels, weirs, and overflow structures constructed to reduce flooding in the Sacramento Valley over the past 170 years. Together, these facilities comprise the State Plan of Flood Control (SPFC) for the Sacramento River Basin. Structural elements specific to the Yuba River below Englebright Dam include levees and training walls, both of which are described below.

Levees

Levees provide structural flood risk reduction to communities in the southwestern portion of Yuba County, which lies within the Central Valley. The SPFC levees along the Yuba River are described in Table 5.2-6

Table 5.2-6. SPFC Levees along the Yuba River.

LMA	System/ Unit	Location	Length (mi)
Marysville Ring Levee (City of Marysville)			
Marysville Levee Commission	Unit 3	Yuba River north bank	3.0
City of Marysville System 2			
Marysville Levee Commission, State	NE Extension	Yuba River north bank	1.8
Plumas Lakes Basin (Olivehurst, Linda, Arboga, Plumas Lake)			
RD 784	Unit 1	Yuba River south bank	2.2
	Unit 7	Yuba River south bank	3.8
	N/A	Goldfields Embankment*	2.5

Sources: USACE 2021; T. Engler, personal communication, January 22, 2022.
Notes:
*The Goldfields Embankment is not a federal project but will be incorporated into the SPFC upon completion.

Yuba River Training Walls

At the turn of the 20th century, cobble tailings were used to construct embankments along the lower Yuba River to confine flow and convey mining debris downstream. The Middle Training Wall is a two-mile long embankment that divides flow into the main channel of the Yuba River and a perennial side channel to the north; the North Training Wall runs along the north bank of the perennial side channel, and South Training Wall runs in parallel on the south bank of the Yuba River.

A substantial portion of the training walls' mass has eroded since their original construction, and they are subject to breaching. Yuba Water and the Three Rivers Levee Improvement Agency (TRLIA) recently partnered on a project to fix the North Training Wall geometry and erosion issues in order to secure 100-year accreditation from FEMA and provide improved protection to the community of Hallwood. The Middle Training Wall is no longer needed for flood control, and the Hallwood Side Channel and Floodplain Restoration Project, funded partially by Yuba Water and completed in 2023, removed large portions of the embankment to lower flood stages and to restore and enhance riparian floodplain habitat in the lower Yuba River downstream from Daguerre Point Dam.

5.2.2.5 Areas Downstream of the Yuba River

The following section describes surface water resources for potentially affected areas downstream from the Yuba River.

5.2.2.5.1 Water Supply

At its downstream end, the Yuba River flows into the Feather River near the cities of Marysville and Yuba City. The Feather River flows around 28 miles before it reaches its confluence with the Sacramento River near Verona. The Sacramento River flows 36 miles before it reaches Freeport, just south of Sacramento, and another 49 miles before flowing out into the San Francisco Bay. Agricultural and municipal water users take diversions from the Feather and Sacramento rivers, and the San Joaquin-Sacramento River Delta (Delta) at numerous points downstream from the Yuba River under water rights and contracts with the California Department of Water Resources'

(DWR) State Water Project (SWP) or with the U.S. Bureau of Reclamation's Central Valley Project (CVP).

Yuba Water transfers a portion of its releases to meet lower Yuba River minimum flows under the Yuba River Accord (Yuba Accord). Yuba Water has frequently transferred Yuba Accord water in this way since 2007. An extension of the Yuba Accord transfers is currently under SWRCB review.

The SWP and CVP have a shared responsibility for water quality, water level, and flow requirements in the Delta. The two projects have an agreement that details their respective responsibilities for meeting those requirements (DWR and Reclamation 2018), and how they can divide non-CVP and non-SWP flows, like those from the Yuba River. Any non-transferrable Yuba River outflow becomes subject to this agreement.

5.2.2.5.2 Flood Management

The Feather River downstream of its confluence with the Yuba River is mapped by FEMA as a Special Flood Hazard Area (Zone AE), with areas of the floodplain mapped as Zone X (areas with reduced flood risk due to levees). As identified in the USACE National Levee Database, there is an extensive network of levees along the Feather River both upstream and downstream of the Feather River-Yuba River confluence. Feather River levees downstream from the Yuba River are maintained by the Three Rivers Levee Improvement Agency (TRLIA) along the east bank and the Sutter-Butte Flood Control Agency (SBFCA) along the west bank.

As described below, New Bullards Bar Reservoir is operated cooperatively with the California Department of Water Resources' Oroville Reservoir to meet common flow objectives on the Feather River below the Yuba River and below the Bear River.

5.3 Regulatory Setting

Operations of the YRDP and the Narrows Project are regulated through a series of agreements, contracts, and laws. The primary focus of these regulations is water resource management operations subject to control by these various documents.

5.3.1 Federal Plans, Policies, Regulations, and Laws

5.3.1.1 Flood Control Act of 1944

The Flood Control Act of 1944 (P.L. 78–534) authorized the construction of numerous public works on rivers and harbors for flood control, and for other purposes. Per Section 7 of the Flood Control Act of 1944, the US Army Corps of Engineers (USACE) is responsible for prescribing regulations for the use of storage allocated for flood control or navigation at all reservoirs constructed wholly or in part with Federal funds provided for those purposes.

5.3.1.2 USACE Water Control Manual

The USACE Master Manual of Reservoir Regulation, Sacramento River Basin, California (Master Manual), describes hydrologic and flood management conditions and systemwide operating procedures in the Sacramento River Basin in accordance with USACE Engineer Regulation 1110-

2-240 and Engineer Manual 1110-2-3600, which detail USACE responsibilities for prescribing flood control and navigation regulations for certain reservoir projects constructed or operated by other Federal, non-Federal, or private agencies.[8] Each major river in the region is governed by operating rules as described in various appendices to the Master Manual. Appendix V to the Master Manual governs operations at New Bullards Bar Dam and Reservoir. According to the Master Manual, New Bullards Bar Reservoir is required to maintain Yuba River flows at Marysville not to exceed 120,000 cfs (180,000 cfs when the Feather River is low) but limited to 50,000 cfs unless inflows during the current flood have exceeded 50,000 cfs. If inflow to New Bullards Bar Reservoir has exceeded 50,000 cfs, water can be released at rates up to the maximum rate of inflow, given that downstream flow criteria are met.[9] The USACE and Yuba Water are currently reviewing and updating the New Bullards Bar Dam and Reservoir Water Control Manual.

5.3.1.3 FERC License No. 1403 for the Narrows Project

The Narrows 1 Powerhouse is part of the Narrows 1 Project, a hydroelectric project operated by Yuba Water pursuant to License No. 1403 issued by FERC. While the existing Narrows 1 FERC license includes flow requirements in the Yuba River downstream from Englebright Dam, those flow requirements are less than those required by the Yuba Accord, and as a result do not affect operations. As previously discussed, Narrows 1 Powerhouse operations are coordinated with the Narrows 2 Powerhouse to meet Yuba Water flow and water supply obligations in the Yuba River downstream from Englebright Dam.

5.3.1.4 FERC License No. 2246 for the Yuba River Development Project

The New Bullards Bar Dam and Reservoir are part of the YRDP, a hydroelectric project operated by Yuba Water pursuant to License No. 2246 issued by FERC.

The FERC license states requirements for operation of the YRDP under a series of articles which govern all aspects of the construction, operation, maintenance, and access to the project. Article 6 requires Yuba Water to construct and operate a series of stream gages to monitor and regulate water flow diverted for the operation of the YRDP works, the amount of water held in and withdrawn from reservoir storage, and the effective head (pressure) on the power-generating turbines. Article 33 includes minimum streamflow schedules for maintenance of fish life in several locations. Required flows on the Middle Yuba River, Oregon Creek, and North Yuba River from Article 33 are shown in Table 5.3-1.

[8] U.S. Army Corps of Engineers (USACE). 1959 (March) Master Manual of Reservoir Regulation, Sacramento River Basin, California; 2016 (May) Engineer Regulation 1110-2-240, Engineering and Design WATER CONTROL MANAGEMENT; and EM 1110-2-3600, Management of Water Control Systems. USACE Publications - Engineer Regulations (army.mil)

[9] U.S. Army Corps of Engineers (USACE). 1959 (March) Master Manual of Reservoir Regulation, Sacramento River Basin, California; and 1972 (June) Reservoir Regulation for Flood Control, New Bullards Bar Reservoir, North Yuba River, California. Appendix V to Master Manual of Reservoir Regulation, Sacramento River Basin, California.

Table 5.3-1. Article 33 Existing FERC-Required Flows on the Middle Yuba River, Oregon Creek, and North Yuba River.

Stream	Flow (cfs)[1,2]	
	April 15 to June 15	June 16 to April 14
Middle Yuba (downstream of Hour House Diversion)	50	30
Oregon Creek (downstream of Log Cabin Diversion)	12	8
North Yuba (downstream of New Colgate Diversion)	5	5

[1] Or natural flow, whichever is less. Maximum 24-hour fluctuations of plus or minus 10 percent are permitted for flows in Middle Yuba downstream of Hour House Diversion and in Oregon Creek downstream of Log Cabin Diversion.

[2] Water releases shall be subject to the following reduction in any critical dry year, defined as a water year for which the April 1 forecast of the California Department of Water Resources predicts that streamflow in the Yuba River at Smartsville be 50 percent or less of normal: 50% or normal allows for 15% reduction in releases; 45% of normal allows for 20% reduction; 40% or less allows for 30% reduction

Article 33 also includes flow requirements on the Yuba River downstream from Englebright Dam. Table 5.3-2 shows Article 33-required flows by month on the Yuba River downstream from Englebright Dam.

Table 5.3-2. Article 33 Existing FERC-Required Flows on the Yuba River downstream from Englebright Dam.

Period	Flow Below Englebright Dam (cfs)[1,2]	Flow Below Daguerre Point Dam (cfs)[3]
October 1-October 15	0	400
October 16-October 31	600-1,050	400
November 1-November 30	600-700	400
December 1-December 31	600-1,400	400
January 1-January 15	1,000-1,850	245
January 16-March 31	600	245
April 1- June 30	0	245
July 1-September 30	0	70

Notes:

[1] Variations from this schedule are permissible during emergencies, uncontrollable flood flows, and critical dry year curtailments.

[2] With the exception of emergencies, releases required by U.S. Army Corps of Engineers flood control criteria, releases required to maintain a flood control buffer or for other flood control purposes, bypasses of uncontrolled flows into Englebright Reservoir, uncontrolled spilling, or uncontrolled flows of tributary streams downstream of Englebright Dam, Licensee shall make reasonable efforts to operate New Bullards Bar Reservoir and Englebright Reservoir to avoid fluctuations in the flow of the lower Yuba River downstream of Englebright Dam, and daily changes in project operations affecting releases or bypasses of flow from Englebright Dam shall be continuously measured at the United States Geological Survey gage at Smartsville, and shall be made in accordance with the following conditions:

i. Project releases or bypasses that increase streamflow downstream of Englebright Dam shall not exceed a rate of change of more than 500 cubic feet per second (cfs) per hour.

ii. Project releases or bypasses that reduce streamflow downstream of Englebright Dam shall be gradual and, over the course of any 24-hour period, shall not be reduced below 70 percent of the prior day's average flow release or bypass flow.

iii. Once the daily project release or bypass level is achieved, fluctuations in the streamflow level downstream of Englebright Dam due to changes in project operations shall not vary up or down by more than 15 percent of the average daily flow.

iv. During the period from September 15 to October 31, the licensee shall not reduce the flow downstream of Englebright Dam to less than 55 percent of the maximum five-day average release or bypass level that has occurred during that September 15 to October 31 period or the minimum streamflow requirement that would otherwise apply, whichever is greater.

v. During the period from November 1 to March 31, the licensee shall not reduce the flow downstream of Englebright Dam to less than the minimum streamflow release or bypass established under (iv) above; or 65 percent of the maximum five-day average flow release or bypass that has occurred during that November 1 to March 31 period; or the minimum streamflow requirement that would otherwise apply, whichever is greater.

[3] Water releases shall be subject to the following reduction in any critical dry year, defined as a water yar for which the April 1 forecast of the California Department of Water Resources predicts that streamflow in the Yuba River at Smartsville be 50 percent or less of normal: 50% or normal allows for 15% reduction in releases; 45% of normal allows for 20% reduction; 40% or less allows for 30% reduction. However, in no event shall releases for fish life below Daguerre Point Dam be reduced to less than 70 cfs. The critical dry year provisions herein shall be effective from the time the aforesaid forecast is available until the April 1 forecast of the following year.

Article 34 specifies that the minimum pool for New Bullards Bar Reservoir is at elevation 1,730 feet, corresponding to approximately 230,000 acre-feet of storage. Article 46 specifies that Yuba Water would follow the USACE New Bullards Bar Dam and Reservoir Water Control Manual, described above.

5.3.1.5 FEMA National Flood Insurance Program

The Federal Emergency Management Agency (FEMA) conducts mapping of flood zones and levee certifications to support the National Flood Insurance Program. Areas mapped into certain flood zones may be eligible for flood insurance. FEMA-mapped flood hazard areas and levee certifications also affect flood repair reimbursement for post-disaster relief and repairs.

5.3.1.6 PL 84-99.

Public Law (PL) 84-99 (1955) authorized the USACE Rehabilitation and Inspection Program (RIP) for federal flood control works, among other programs. Although PL 84-99 is voluntary, it is desirable for State Plan of Flood Control (SPFC) levees to meet PL 84-99 design and O&M standards in order to maintain eligibility for federal funding for repairs after a qualifying flood event. To remain active in the program, levees must be maintained to meet certain geometry and O&M standards and pass rigorous USACE inspections. Unacceptable encroachments, vegetation, geometry, or maintenance regimes may result in an "Unacceptable" overall system rating and inactive status. Levee systems with inactive status are not eligible for rehabilitation assistance under PL 84-99. USACE allows Local Maintaining Agencies (LMAs) with "Unacceptable" system ratings to prepare Systemwide Improvement Framework (SWIF) plans in order to maintain PL 84-99 eligibility while planning and implementing repairs and improvements needed to correct unacceptable inspection items. LMAs must prepare a Letter of Intent (LOI) that is accepted by USACE prior to preparing a SWIF.

5.3.1.7 FEMA 100-Year Accreditation.

FEMA recognizes levee systems that protect against floods that have a one percent or greater chance of occurring each year (more commonly known as a 100-year flood). To be accredited, the levee must meet certain design criteria, including but not limited to three feet of freeboard above the flood stage of the 100-year flood (the base flood elevation or BFE) (44 C.F.R. Part 65.10). Accreditation also requires levee systems to have formal O&M plans that meet specified criteria. Accreditation is desirable because it removes leveed areas from the regulatory floodplain (except for areas of interior drainage flooding) such that property owners are no longer required to purchase and maintain flood insurance. Provisional accreditation may be granted to levees that formerly met accreditation standards, while FEMA is awaiting or processing compliance documentation. Landside areas protected by provisionally accredited levees (PAL) are also excluded from the regulatory floodplain.

5.3.2 State

5.3.2.1 1965 Yuba County Water Agency and California Department of Fish and Game Streamflow Release Agreement

Instream flow requirements for the Yuba Project were originally specified in the September 2, 1965 agreement between Yuba Water and the California Department of Fish and Game (CDFG). These requirements were later incorporated into the 1966 FERC license.

5.3.2.2 Lower Yuba River Accord in SWRCB Corrected Order Water Right 2008-0014)

In 2005, Yuba Water and 16 other interested parties signed memoranda of understanding that specify the terms of the Yuba Accord, a comprehensive, consensus-based program to protect and enhance aquatic habitat in the Yuba River downstream of Englebright Dam. Following environmental review, Yuba Water and parties executed the following four agreements in 2007, which together comprise the Yuba Accord: 1) the Lower Yuba River Fisheries Agreement, which specifies the Yuba Accord's lower Yuba River minimum streamflows and creates a detailed fisheries monitoring and evaluation program; 2) the Water Purchase Agreement, under which DWR purchases water from Yuba Water, some of which is provided by the Yuba Accord's minimum streamflows, for SWP and CVP contractors; 3) the Conjunctive Use Agreements with seven[10] of Yuba Water's member units, which specify the terms of the Yuba Accord's groundwater conjunctive-use program; and 4) amendments to the 1966 Power Purchase Contract between Yuba Water and PG&E. Since the expiration of the 1966 Power Purchase Contract and Yuba Water's subsequent acquisition of the Narrows Project, the amendments to Yuba Water's contract with PG&E are no longer relevant.

Yuba Water has been operating the YRDP to implement the Yuba Accord since 2006. The 2006, 2007, and early 2008 operations were under 1-year pilot programs that were approved by the SWRCB through its Orders Water Right (WR) 2006-0009, WR 2006-0010, WR 2007-0002 and WR 2007-0012-DWR. Since 2008, Yuba Water has been operating the YRDP to implement the Yuba Accord according to the authorizations and requirements in SWRCB Corrected Order WR 2008-0014 (SWRCB 2008).

The Yuba Accord includes a specific set of flow schedules for the Yuba River. The flow schedule that is in effect at any particular time is determined by the North Yuba Index (NYI), a hydrologic index that was developed as a part of the Yuba Accord. The flow schedules are listed in Table 5.3-3.

[10] Cordua Irrigation District was not originally a signatory to Conjunctive Use Agreement, but later signed the Conjunctive Use Agreement in January 2021.

Table 5.3-3. Yuba Accord flow schedules.

Schedule	Oct 1-15	Oct 16-30	Nov 1-30	Dec 1-31	Jan 1-31	Feb 1-29	Mar 1-31	Apr 1-15	Apr 16-30	May 1-15	May 16-31	Jun 1-15	Jun 16-30	Jul 1-31	Aug 1-31	Sep 1-30	Total Annual Vol. (ac-ft)

Notes:
Marysville Gage flows represent average volumes for the specified period. Actual flows may vary from the indicated flows according to established criteria.
Compliance with the Yuba Accord flow schedules is measured by a 5-day running average of average daily streamflows; with instantaneous flows never less than 90 percent of the specified requirement. Instantaneous flows will not be less than the applicable requirement for more than 48 consecutive hours.
Marysville Gage Schedule 6 flows do not include an additional 30,000 acre-feet that State Water Resources Control Board Corrected Order Water Right 2008-0014 requires Yuba Water to make available through groundwater substitution pumping. These additional flows will be allocated during Schedule 6 years.

DRAFT

The WY hydrologic classification for the Yuba River to determine the flow requirements of Yuba Water's water-right permits shall be based on the North Yuba Index. Determinations of a year's flow schedule year type shall be made in February, March, April, and May, and for any subsequent updates after the May forecast. Table 5.3-4 shows the North Yuba Index schedule year-types.

Table 5.3-4. North Yuba River Index Schedule Year Types.

Flow Schedule Year Type	North Yuba Index Value (thousand ac-ft)
Schedule 1	Greater than or equal to 1,400
Schedule 2	Greater than or equal to 1,040 and less than 1,400
Schedule 3	Greater than or equal to 920, and less than 1,040
Schedule 4	Greater than or equal to 820 and less than 920
Schedule 5	Greater than or equal to 693 and less than 820
Schedule 6	Greater than or equal to 500 and less than 693
Conference Year	Less than 500

During Conference Years, which are defined as years when the NYI is less than 500,000 ac-ft, and which are expected to occur approximately 1 percent of the time, Yuba Water is required: 1) to maintain minimum instream flows in the Yuba River at the levels specified in Article 33 of Yuba Water's existing FERC license without the reductions authorized by subsections (c) and (d) of that article; 2) to release any supplemental flows recommended by the Lower Yuba Accord River Management Team and approved by the SWRCB's Deputy Director for Water Rights or, if no such recommended flows are effective by April 11 of such a Conference Year, then to release any supplemental flows ordered by the SWRCB, after a hearing under California Code of Regulations, title 23, section 767; and 3) to limit total water supply diversions at Daguerre Point Dam to 250,000 ac-ft.

As part of the Yuba Accord, a portion of the Yuba River flow at Marysville is considered transferrable based on comparison against a hypothetical Baseline operation, defined in the Yuba Accord Water Purchase Agreement. Under the Yuba Accord, operations of the YRDP and Narrows Projects would be to meet required flows described in Table 5.3-3 above at the Marysville and Smartsville gages. If operations to meet required flows would result in an end-of-September New Bullards Bar Reservoir storage greater than 650,000 ac-ft, Yuba Water would increase releases from New Bullards Bar Reservoir in order to achieve an end-of-September storage of 650,000 acre-feet. Under the hypothetical Baseline operations, Yuba Water would operate according to the Interim minimum flow requirements stated in the SWRCB's Revised Decision –1644 (SWRCB 2003), which were in place at the time Yuba Accord implementation began, or an end-of-September storage of 705,000 acre-feet. Transferable flows are the difference between the Yuba Accord and Baseline operations.

In addition to Yuba Water's releases of water under the Yuba Accord described above, Yuba Accord water transfers can come from groundwater substitution transfers, where Yuba Water member units forgo surface water deliveries and pump groundwater instead. Historical transfers conducted under the Yuba Accord are presented in Table 5.3-5.

Table 5.3-5. Historical Yuba Water Transfers under the Yuba Accord (YCWA 2024a).

Year	WYT Sacramento Valley 40-30-30 Index	Buyer	Stored Water Transfer (ac-ft)	Groundwater Substitution Transfer (ac-ft)
2007	Dry	Yuba Accord Water Purchase Participants	125,000[1,2,3]	--
2008	Critical	Yuba Accord Water Purchase Participants	117,212[1]	48,875
2009	Dry	Yuba Accord Water Purchase Participants	91,100[1,2]	88,900[5]
2010	Below Normal	Yuba Accord Water Purchase Participants	74,179[1,2]	66,211
2011	Wet	None		
2012	Below Normal	Yuba Accord Water Purchase Participants	81,681[2]	--
2013	Dry	Yuba Accord Water Purchase Participants	112,544[1,2]	64,730[7]
2014	Critical	Yuba Accord Water Purchase Participants	104,663[1,2]	56,984[7]
2015	Critical	Yuba Accord Water Purchase Participants	59,131	30,000
2016	Below Normal	Yuba Accord Water Purchase Participants	60,000	--
2017	Wet	None		
2018	Below Normal	Yuba Accord Water Purchase Participants	76,576	16,411

2020	Dry	Yuba Accord Water Purchase Participants	43,538	77,000
2021	Critical	Yuba Accord Water Purchase Participants	130,090	--
2022	Critical	Yuba Accord Water Purchase Participants	15,077	62,400
2023	Wet	None		
2024	Above Normal	None		
		Total of Transfers	**1,035,728**	**511,511**
		Average of Transfers In Years with Transfers	**79,671**	**56,835**
		Average of Transfers in Dry and Critical Years	**109,494**	**72,942**

Notes:

[1] In 2007, 2008, 2009, 2010, 2012, 2013, 2014, and 2015 BVID transferred an additional 3,100 acre-feet to the Santa Clara Valley Water District through conservation.

[2] Transfers to the Yuba Accord Water Purchase Participants include 60,000 acre-feet of stored water for the Environmental Water Account (EWA).

[3] The 2007 transfer was under Yuba Accord Pilot Program. It also included 60,000 acre-feet of transfer to the EWA purchased in 2006.

[4] Sacramento Valley Index as defined in SWRCB RD-1641.

[5] In 2009, CID transferred an additional 8,322 acre-feet of groundwater substitution transfer to the DWR Drought Water Bank.

[6] In 2013, CID transferred an additional 7,774 acre-feet of groundwater substitution transfer to the DWR Drought Water Bank.

[7] In 2014, CID transferred an additional 1,976 acre-feet of groundwater substitution transfer to the DWR Drought Water Bank.

As stated above, Yuba Water has operated the YRDP in compliance with the Yuba Accord since 2006. Yuba Water has certified a supplemental EIR for an extension of the Yuba Accord water transfers, and is awaiting approval by the SWRCB. This transfer extension will not affect Yuba Water operations of the YRDP or Narrows Project.

5.3.2.3 Forecast-Coordinated Operations

Within the Yuba-Feather basin, there is a program called the Yuba-Feather Forecast-Coordinated Operations (F-CO) which formalizes the mechanism for exchange of information (hydrologic forecasts, as well as weather data and operation information) among DWR, Yuba Water, USACE, and the California-Nevada River Forecast Center (CNRFC) of the National Weather Service. With F-CO, forecasters provide estimates of inflow and downstream unregulated flows into the reservoirs, and, in turn, reservoir operators provide anticipated releases based on these flows. To

enhance the sharing of information among operating agencies, and with the cooperation of all the agencies involved, the State of California funded the design, development, and deployment of a decision support system (DSS) that facilitates F-CO for the Yuba-Feather system.

5.3.2.4 Urban Levee Design Criteria (ULDC).

Levee systems in California that protect urban communities of more than 10,000 people (or urbanizing communities expected to grow to 10,000 people) must meet State ULDC. ULDC geometry standards require 3 feet of freeboard over the 0.5 percent annual chance flood elevation (200-year flood elevation). Exceptions and deviations from this standard are permitted depending on the method and certainty by which the 200-year flood elevation was modeled.

5.3.2.5 CVFPB Designated Floodways

The Central Valley Flood Protection Board (CVFPB) has the authority to study, designate, and regulate uses within Designated Floodways in the Central Valley. The CVFPB defines a Designated Floodway as either the channel of the stream and that portion of the adjoining floodplain reasonably required to provide for the passage of a design flood as indicated by floodway encroachment lines on an adopted map, or the floodway between existing levees as adopted by the board or the Legislature (23 Cal. Code Regs § 4[i]). Designated Floodways have different boundaries than the regulatory floodways delineated on FEMA Flood Insurance Rate Maps (FIRMs) and are used to implement a separate regulatory process at the State level. Digital maps of the CVFPB Designated Floodways are hosted on DWR Best Available Map (BAM).

CVFPB regulations reduce risk by limiting exposure within Designated Floodways. Under CVFPB regulations (23 Cal. Code Regs § 107), the only uses permitted in the Designated Floodway are:

(a) Open space uses not requiring a closed building, such as agricultural croplands, orchards, livestock feeding and grazing, or public and private recreation areas.

(b) Fences, fills, walls, or other appurtenances which do not create an obstruction or debris-catching obstacle to the passage of floodwaters.

(c) Storage yards for equipment and material, if the equipment and material can be either securely anchored or removed upon notice.

(d) Railroads, streets, bridges, and public utility wires and pipelines for transmission and local distribution.

(e) Commercial excavation of materials from pits, strips, or pools provided that no stockpiling of materials, products, or overburden creates an obstruction to the passage of flood flows.

(f) Improvements in stream channel alignment, cross-section, and capacity.

(g) Structures that are designed to have a minimum effect upon the flow of water and are firmly anchored to prevent the structure from flotation, provided that normally no structures for human habitation will be permitted.

(h) Recreational vehicles and related service facilities that are either floodproofed or are removed during the flood season of the particular stream involved.

(i) Other uses which are not appreciably damaged by floodwaters.

Encroachments in the floodway require review and approval from the CVFPB.

5.3.2.6 Sacramento River Basin and San Joaquin River Basin Water Quality Control Plan

The preparation and adoption of water quality control plans (Basin Plans) is required by the California Water Code (Section 13240) and supported by the Federal Clean Water Act. Section 303 of the Clean Water Act requires states to adopt water quality standards which "consist of the designated uses of the navigable waters involved and the water quality criteria for such waters based upon such uses." According to Section 13050 of the California Water Code, Basin Plans consist of a designation or establishment for the waters within a specified area of beneficial uses to be protected, water quality objectives to protect those uses, and a program of implementation needed for achieving the objectives. State law also requires that Basin Plans conform to the policies set forth in the Water Code beginning with Section 13000 and any state policy for water quality control. Since beneficial uses, together with their corresponding water quality objectives, can be defined per federal regulations as water quality standards, the Basin Plans are regulatory references for meeting the state and federal requirements for water quality control (40 C.F.R. 131.20).

Beneficial uses are critical to water quality management in California. State law defines beneficial uses of California's waters that may be protected against quality degradation to include (and not be limited to) "...domestic; municipal; agricultural and industrial supply; power generation; recreation; aesthetic enjoyment; navigation; and preservation and enhancement of fish, wildlife, and other aquatic resources or preserves" (Water Code Section 13050(f)). Protection and enhancement of existing and potential beneficial uses are primary goals of water quality planning.

The Basin Plan divides the Yuba River watershed into two regions: Sources to Englebright Reservoir and Englebright Dam to the Feather River. Existing beneficial uses for Sources to Englebright Reservoir are listed as the following:

- Municipal and Domestic Supply;
- Irrigation;
- Stock Watering;
- Power;
- Contact Recreation;
- Canoeing and Rafting;
- Other Non-Contact;
- Cold Freshwater Habitat;

- Cold Spawning; and
- Wildlife Habitat.

Existing beneficial uses for Englebright Dam to Feather are listed as the following:

- Irrigation;
- Stock Watering;
- Power
- Contact Recreation
- Canoeing and Rafting;
- Other Noncontact Recreation;
- Warm Freshwater Habitat;
- Cold Freshwater Habitat
- Warm Spawning;
- Cold Spawning; and
- Wildlife Habitat.

5.3.3 Local

5.3.3.1 Water Supply Uses

Within the Project Area, Yuba Water pumps some water directly from New Bullards Bar Reservoir to supply water to the Cottage Creek Water Treatment Plant for domestic and recreational uses adjacent to the reservoir. The amount of this pumping averages approximately 6 ac-ft per year, which does not affect overall New Bullards Bar Reservoir operations. Yuba Water anticipates that pumping of this small amount of water will continue during the period of the new license.

Yuba Water also provides water supply to its member units, as described in detail in Section 5.2.2.3.

5.3.3.2 Local General Plan

All cities and counties in California are required to prepare general plans to guide future growth and development in a manner consistent with State law. General plans inform the types of land uses and development standards permitted within a city or county and serve as the legal basis for local zoning and permitting decisions. California statute mandates that local agencies consider flood protection in the safety element of their local general plans. Senate Bill 397 (2015) added a requirement that the safety element be updated to include a climate change vulnerability assessment, and adaptation and resiliency strategies to address those vulnerabilities (Cal. Gov. Code § 65302).

Both Yuba County and the City of Marysville updated the safety elements of their respective general plans in 2021 to meet the requirements of SB 397 and incorporated the 2021 Local Hazard Mitigation Plan (LHMP) by reference (City of Marysville 2022, Yuba County 2021a). The City

of Wheatland has identified the need to update its safety element and incorporate the LHMP (Yuba County 2021b) and is seeking funding to complete this action. Each local agency's safety element identifies goals and policies to reduce flood risk, described below under Hazard Mitigation Planning.

5.3.3.3 Yuba County Development Code Title XI

Yuba County Development Code (Title XI) includes provisions to comply with the 2007 California Senate Bill-5 (SB 5) which required 200-year urban level of flood protection for urban areas in the California Central Valley. Title XI applies to areas within the 200-year floodplain as delineated on the most current available maps from the State of California or as adopted by the County. Title XI requires that the County find that there is an urban level of flood protection for urban/urbanizing areas, or a FEMA-standard level of protection for non-urban areas, prior to approving a tentative map or parcel map located within a flood hazard zone.

5.3.3.4 Hazard Mitigation Planning

Hazard mitigation planning reduces flood risk by identifying actions to reduce flood risk and making local agencies eligible for State and federal funding to implement mitigation actions. The Disaster Mitigation Act of 2000 outlined requirements for State and local hazard mitigation plans (SHMPs and LHMPs, respectively) to be developed and updated every five years as a condition of eligibility for certain federal mitigation and disaster recovery funding. California's SHMP outlines tools, resources, and strategies for addressing hazards at the local level. Assembly Bill 2140 (2006) provides financial incentives to local agencies to prepare LHMPs and adopt them by reference as part of the safety element of their local general plan. Yuba County prepared an update to its multi-jurisdictional LHMP in 2021 (Yuba County 2021b), covering the County, the City of Marysville, the City of Wheatland, Yuba Water, all five reclamation districts, and other special districts within the County.

Yuba County's HMP includes goals and actions around climate change, dam failure, drought and water shortage, floods, and levee failure, among others. HMP goals associated with water resources include the following:

> **GOAL 1**: Minimize risk and vulnerability of Yuba County to natural hazards, including climate change considerations, and prevent injuries, loss of life, and damage to property, economy and the environment
>
> **GOAL 2**: Provide protection for critical facilities, infrastructure, and utilities; and create redundancy and reliability to minimize loss and facilitate recovery
>
> **GOAL 3**: Promote public awareness, education, and understanding of natural hazards and the risks they present to quality of life, property and the economy; and encourage individual responsibility to minimize impacts to natural hazards

GOAL 4: Enhance the ability of Yuba County and participating jurisdictions to be prepared for, respond to, and recover from the effects of hazards on people, property, economy, and the environment; including expanded use of technology and shared resources

GOAL 5: Continue to support partnerships with private and public sector agencies, businesses, and organizations to further comprehensive planning and implementation of mitigation measures

GOAL 6: Maintain FEMA eligibility and position Yuba County and participating jurisdictions for grant funding through continued compliance with the Disaster Mitigation Act of 2000 and the National Flood Insurance Program

HMP actions associated with water resources include the following

Yuba County Action 1: Integrate Local Hazard Mitigation Plan into Safety Element of General Plan

Yuba County Action 2. Enhance Public Education and Awareness of Natural Hazards and Public Understanding of Disaster Preparedness

Yuba County Action 5. Climate Change Vulnerability Analysis

Yuba County Actions 6 through 12. Local drainage improvements

City of Marysville Action 1. Enhance Public Education and Awareness of Natural Hazards and Public Understanding of Disaster Preparedness

City of Marysville Action 2. General Plan Safety Element Update

City of Marysville Action 3. Dam Failure Mitigation

City of Marysville Action 4. Update Safety Element Policies and Implement Drought and Water Shortage Policies

City of Marysville Action 5. Update Safety Element Flood Policies and Implement Flood Policies

City of Marysville Action 6. Levee Upgrades by the Army Corps

City of Wheatland Action 1. Integrate Local Hazard Mitigation Plan into Safety Element of General Plan

City of Wheatland Action 2. Enhance Public Education and Awareness of Natural Hazards and Public Understanding of Disaster Preparedness

City of Wheatland Action 4. Annual Coordination with Dam Owner

City of Wheatland Action 5. Annual Storm Drain and Storm Ditches Cleaning

City of Wheatland Action 8. Comprehensive Drinking Water Project - Phase 1

City of Wheatland Action 9. Comprehensive Drinking Water Project - Phase 2

Browns Valley Irrigation District Action 3. Sicard Flat Ditch with Pipeline

Browns Valley Irrigation District Action 4. Replace Remaining Wood Flume with Metal Flume during Regular Maintenance

Browns Valley Irrigation District Action 5. Relocate Bypass Channel that Supplies Yuba River Water to BVID Fish Screen/Pump Station

Marysville Levee Commission Action 1. Eliminate Openings in Levees

Marysville Levee Commission Action 2. Addressed Levee Underseepage

Reclamation District 10 Action 1. Implement Feather River Levee Improvement Projects - Seepage and Stability Mitigation (Feather River Levee Improvement Projects) – (To consider combination of seepage/stability berms and/or cutoff walls) Implementation of the RD 10 Toe Access Corridor Project for Flood Fight Access, Monitoring, and Operations and Maintenance

Reclamation District 10 Action 2. Implementation of the RD 10 Toe Access Corridor Project for Flood Fight Access, Monitoring, and Operations and Maintenance

Reclamation District 10 Action 3. Implement: Pipe Replacement Projects and Pump Improvement Projects

Reclamation District 784 Action 1. Dam Failure Mitigation

Reclamation District 784 Action 2. Drought & Water Shortage Mitigation

Reclamation District 784 Action 4. Floods: Localized Stormwater Mitigation

Reclamation District 784 Action 5. Flood Mitigation

Reclamation District 784 Action 7. Severe Weather Mitigation

Reclamation District 2103 Action 1. Implement improvements recommended in Dry Creek and Small Communities Flood Risk Reduction Feasibility Studies

Reclamation District 2103 Action 2. Repair and certify Grasshopper Slough Levee

Reclamation District 2103 Action 3. Develop a USACE System-Wide Improvement Framework Plan

South Sutter Water District Action 1. Auxiliary Spillway

Three Rivers Levee Improvement Authority Action 1. Yuba River North Training Wall Project

Three Rivers Levee Improvement Authority Action 2. Yuba River Goldfields 500 yr Project

Yuba County Water Agency Action 1. New Bullards Bar Dam Secondary Spillway

5.4 Impact Assessment Methodology

This section presents the assessment methods used to analyze the effects on surface water supply, the thresholds of significance that determine the significance of effects, and the potential environmental consequences as they relate to the Proposed Projects and their alternatives.

For purposes of this evaluation, the primary study area is the portion of the Yuba River watershed directly affected by operations of the YRDP and Narrows Project for the Proposed Projects and alternatives. More specifically, this area is the Middle Yuba River downstream from the Our House Diversion Dam; Oregon Creek downstream from the Log Cabin Diversion Dam; the North Yuba

River, including New Bullards Bar Reservoir downstream from the high water mark of the reservoir; and the Yuba River to its confluence with the Feather River.

The secondary study area is portion of the Yuba River watershed indirectly affected by operations of the YRDP and Narrows Project for the Proposed Projects and alternatives, and the portions of the Delta watershed indirectly affected by operations of the YRDP and Narrows Project for the Proposed Projects and alternatives. More specifically, this area includes NID and PG&E's Yuba-Bear and Drum-Spaulding projects, but only as their operations for water supply are indirectly affected by Yuba Water's Alternative 1; their operations to meet other regulatory requirements are outside the scope of Yuba Water's analysis.

5.4.1 Impact Analysis Methodology

This analysis addresses impacts relating to surface water resources, specifically water supply and flood management, that could result from operation activities at the Projects sites, as well as project-related changes to reservoir operations (e.g. reservoir releases to meet different flow requirements) and resulting downstream hydrology.

5.4.1.1 Construction

None of the construction-related activities associated with the Proposed Projects or alternatives affect New Bullards Bar Reservoir's ability to make releases through the New Colgate Powerhouse, nor would any construction activities affect releases from Englebright Reservoir, or agricultural diversion structures near Daguerre Point Dam. Accordingly, there would be no construction-related impacts from the Proposed Projects or their alternatives on water supplies. Because of this, construction impacts associated with water supply will not be analyzed in this chapter.

Construction activities, particularly associated with the Our House and Log Cabin diversion dams have the potential to affect high-flow operations at those facilities. Construction activities within the New Bullards Bar Reservoir area would not affect New Bullards Bar Dam's ability to regulate high flows. Potential impacts associated with construction activities around these facilities are discussed below.

5.4.1.2 Operations

The operations analysis evaluates impacts related to hydrologic changes from the Proposed Projects and alternatives, including changes in flows downstream from New Bullards Bar Dam and changes in surface water supply availability to Yuba Water member units.

Potential impacts are assessed based on model results from Yuba Water's Yuba River Development Project Model (YRDPM). The YRDPM includes representation of a long-term period of record of hydrology (water year 1970 through 2021), member unit water supply demands, current and proposed facilities, and current and proposed operational requirements. Changes in simulated flows and water supply deliveries as a result of each alternative, relative to the bases of comparison, are used to determine potential impacts. More information about the

YRDPM, including assumptions, inputs, and model limitations, are further described in Appendix 5A, Yuba Water Operations Model Technical Memorandum.

Yuba Water's analysis also relied on the "Mini-Model" described in Appendix 5E, Yuba Water Mini Model Technical Memorandum, to simulate operations of NID's Yuba-Bear Project and PG&E's Drum-Spaulding Project under various regulatory regimes including their existing and proposed FERC license requirements. Yuba Water developed the Mini-Model to provide a reasonable representation of inflows to the YRDP and Narrows Project for use in evaluating the effects of changes in Yuba-Bear and Drum-Spaulding projects' flow regimes on YRDP and Narrows Project resource areas. The intent was to provide a reasonable representation of the general timing and magnitude of inflows above Our House Diversion Dam and Englebright Reservoir.

While the Mini-Model includes information about changes in storage in Yuba-Bear and Drum-Spaulding reservoirs and associated water supply deliveries, the model is limited in its representation of many of the Yuba-Bear and Drum-Spaulding projects' operations, including flow ramping, recreational flows, and spill cessations. The Mini-Model does not include specific demands for NID and PG&E customers, it instead diverts available water up to the Milton-Bowman, South Yuba, and Drum canals' respective capacities. A more refined water-supply analysis would need to incorporate, among other things, the measures that water suppliers that receive water conveyed through the various canals state that they take in dry years in, among other documents, their urban water management plan. For purposes of the programmatic analysis of indirect impacts upstream of the YRDP resulting from YB/DS operations under Alternative 1, reductions in flows in those canals are treated as conservatively representative of a potential reduction in water supply. However, NID, PG&E and other water suppliers that use water exported from the Yuba River watershed via the Yuba-Bear and Drum-Spaulding projects would have various water management measures available to them, potentially in consultation with FERC and the resource agencies.

The programmatic analysis assumes that the upstream operations would incorporate reasonably foreseeable measures to avoid or reduce water supply impacts. As explained in Chapter 3, the YB/DS relicensings are subject to their own CEQA process. To the extent that YB/DS operations under new FERC licenses would have impacts that are beyond the scope of those disclosed in this EIR or other CEQA documents, those impacts may need to be addressed through subsequent project-level CEQA review as more concrete information about those operations becomes available.

5.4.1.2.1 Methodology for Determining Changes in Flow

Changes in simulated daily river flows as a result of each alternative's assumptions (including those of the Proposed Projects) are compared to the appropriate basis of comparison to determine changes in river flow resulting from each alternative. Table 5.4-1 shows the appropriate basis of comparison for each alternative. Table 5.4-2 below shows the summary of model scenarios for YRDP and Narrows Project analyses. A comprehensive description of the bases of comparison is included in Section 2.6, the Proposed Projects is described in Section 2.7, Alternative 1 is described in Section 3.3, and Alternative 2 is described in Section 3.4. The intent of each comparison is described in Section 4.4.

Table 5.4-1. Summary of Scenario Comparisons.

Alternative Scenario Number	Alternative Scenario Name	Basis of Comparison Number	Basis of Comparison Name
3	No Project	1	Existing Condition
4	Proposed Projects	1	Existing Condition
5	Proposed Projects (Future)	2	Future Baseline
6	Alternative 1	1	Existing Condition
6	Alternative 1	2	Future Baseline
9	Alternative 2	1	Existing Condition
9	Alternative 2	2	Future Baseline
7	Proposed Projects Cumulative Condition	1	Existing Condition
8	Alternative 1 Cumulative Condition	1	Existing Condition
10	Alternative 2 Cumulative Condition	1	Existing Condition

The No Project Alternative is functionally equivalent to the Existing Condition from a flow and water supply perspective because, in the No Project Alternative, Yuba Water would continue to operate at least the YRDP and Narrows Project's facilities to achieve Yuba Water's flood-control and water-supply missions as defined by the Legislature in the Yuba County Water Agency Act. Accordingly, no quantitative analysis is included for the No Project Alternative in this section.

5.4.1.2.2 Methodology for Determining Changes in Surface Water Supplies

The YRDP and Narrows Project are operated to provide water supply to agricultural water users within Yuba County, which is defined in the Basin Plan as an existing beneficial use of water within the watershed. As described above, the YRDPM includes representation of daily water supply deliveries to Yuba Water's Member Units for the full period of record. The YRDPM will impose surface water supply shortages on Yuba Water's Member Units when New Bullards Bar Reservoir storage would otherwise drop below a carryover storage target of 440,000 acre-feet at the end of September, with a maximum potential shortage of 50% of daily combined water supply demand. Shortages are applied to member units without pre-1914 water rights first to maintain storage above 440,000 acre-feet; if additional shortages are necessary to meet flow requirements and no water is available from New Bullards Bar Reservoir storage (i.e., New Bullards Bar Reservoir is at minimum storage), pre-1914 water right holders would be subject to shortages as well. Under Alternative 2, the SWRCB's thresholds of 600,000 acre-feet for wet, above normal, and below normal years, and 400,000 acre-feet for dry and critical years are used instead of New Bullards Bar Reservoir minimum storage[11].

Re-operation of the YRDP under each alternative could result in different volumes of shortages. The YRDPM assumes shortages in surface water supply deliveries would be made up from groundwater pumping. As evaluated and discussed in Chapter 6 Groundwater Resources, the associated impacts on groundwater may be significant, but this chapter focuses on surface-water resources. The YRDPM also assumes that Yuba Water member units would pump 30,000 acre-feet of groundwater in NYI Schedule 6 years under the two bases of comparison rather than taking surface water diversions, and 30,000 acre-feet of surface water would be released to the Yuba River below Englebright Reservoir above the required flow. Under the Proposed Project, NYI

[11] Described in the SWRCB Program of Implementation (POI) in Chapter 4 of the October 2024 draft of the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Watershed (SWRCB 2024).

Schedule 6-required flows at Marysville are increased to a rate that they would effectively otherwise have been with groundwater substitution transfers. These required flows could be met by releases from New Bullards Bar Reservoir storage, or with groundwater substitution transfers. Accordingly, neither the Proposed Projects nor their alternatives include the assumption that Yuba Water member units would pump groundwater rather than take surface water deliveries in NYI Schedule 6 years.

Yuba Accord water transfers play an important role in statewide water supply. Yuba Water transfers are measured at the Marysville gage relative to a defined baseline operation. Those transfers therefore generally involve an increment of water that Yuba Water releases to meet minimum Yuba River flows, rather than an additional release specifically for transfers. Accounting for transfers includes a determination of the baseline flow and the accounting for refill of New Bullards Bar Reservoir after the transfer. This accounting is typically conducted in real-time and includes consideration of SWP and CVP operations. For purposes of this analysis, companion Baseline operations are simulated using the YRDPM to represent operations under similar hydrological conditions, but according to Baseline operations defined in the Yuba Accord Water Purchase Agreement (Yuba Water and DWR 2007). Modeling conducted by the California Department of Water Resources (DWR) for its 2023 Delivery Capability Report (2023 DCR) (DWR 2024a) is used to define periods when the CVP and SWP could take the Yuba Accord transfers. Yuba Accord transfers have historically contributed to statewide water supplies. Changes in Marysville flow during balanced conditions[12] in July through October are generally considered directly transferrable in the Delta. As a result, simulated increases in Yuba River flow at Marysville during July through October, compared to the transfer Baseline operations, when the Sacramento River-San Joaquin River Delta is in balanced condition, will be used to represent potential Yuba Accord water transfers, and changes in agricultural water supply shortages will be used as a surrogate for changes in ability to provide groundwater substitution transfers.

Since the Mini-Model's representation of NID and PG&E operations is relatively coarse, diversions to PG&E's Drum Canal and NID's South Yuba Canal are aggregated into a single value, the "Spaulding Canals". For purposes of the programmatic analysis, a reduction in diversions to the Spaulding Canals could result in potential reductions in water supplies for NID and PCWA users if reasonably foreseeable operational measures are not available to avoid or mitigate the potential reductions.

Using the comparisons described in Table 5.4-1, differences in shortages in surface water supply deliveries for each alternative and basis of comparison will be evaluated to determine if an alternative has an impact on water supply deliveries.

[12] Sacramento River-San Joaquin River Delta balanced conditions is defined in the December 12, 2018, Addendum to the Agreement between the United States of American and The Department of Water Resources of the State of California for Coordinated Operation of the Central Valley Project and the State Water Project (DWR and Reclamation 2018).

5.4.2.1 Impact Indicators

5.4.2.1.1 Water Supplies

Three different parameters are analyzed to evaluate any water-supply impacts, specifically: (1) shortages in Yuba Water's water supply deliveries to its Member Units; (2) Yuba Water's transfers to buyers downstream of the lower Yuba River; and (3) exports out of the Yuba River watershed by NID and PG&E through their Yuba-Bear Project and Drum-Spaulding Projects, respectively.

Yuba Water imposes shortages to maintain storage in New Bullards Bar Reservoir for water supply in subsequent drought years. Yuba Water's member unit contracts apply shortages first to member units without senior water rights (Brophy Irrigation District, Dry Creek Mutual Water Company, Ramirez Water District, and South Yuba Water District, and the Wheatland Water District), all of which except Ramirez WD are located south of the Yuba River.

Reoperation of the YRDP under the Proposed Projects and their alternatives may result in reduced surface water deliveries by Yuba Water to its Member Units in some years. In reporting simulated model results, the focus is on both the volume of shortages in surface water supply to Yuba Water member units resulting from changes in water supply availability and the frequency of shortages. Changes in shortage volumes, computed as the difference between total annual demand and total annual surface water supply deliveries, between the Proposed Projects and alternatives and the bases of comparison will be used to evaluate effects on water supply. When faced with shortages, the member units effectively have three options: (1) pump groundwater to replace the reduction in surface water; (2) fallow land; or (3) do a combination of groundwater pumping and land fallowing. The decision about which of these options to take is made by individual farmers based on a multitude of factors including the value of the crop, the cost of groundwater pumping, and the availability of groundwater. For purposes of this analysis, Yuba Water assumes reductions in surface water deliveries to the member units would be made up by groundwater pumping. An increase in the frequency of shortages in water supply deliveries within the period of record to Yuba Water member units could imply one of the existing beneficial uses of water within the watershed is not being met.

Similarly, reoperation of the YRDP under the Proposed Projects and their alternatives could affect Yuba Accord water transfer volumes due to changes in flow requirements or New Bullards Bar Reservoir storage. The Yuba Accord water transfers are one of the few long-term transfer programs available to State Water Project (SWP) and Central Valley Project (CVP) agricultural water service contractors. During the 2014 drought, Yuba Water transferred a total of 104,663 acre-feet (AF) of water, split evenly between the SWP and CVP, with each receiving 50,823 AF. That year, SWP contractors received 474,421 AF of their Table A contract supplies, which was only about 11% of the total contracted amount (4,172,786 AF in 2023). Similarly, south-of-Delta CVP agricultural contractors had a 0% allocation of their contract amount (1,951,217 AF in 2023) and received no CVP contract deliveries. The Yuba Accord transfers accounted for over 10% of many SWP and CVP contractors' total water supply, highlighting their importance during drought conditions. Although not every dry year is as severe as 2014, reducing Yuba Accord transfers in such years

would substantially impact water supply reliability to SWP and CVP contractors. As shown in Table 5.3-5, the historical average annual transfer volume in dry and critical years has been 109,494 AF. DWR Table A deliveries in dry and critical years since 2007 have averaged 907,630 AF (DWR 2012a, 2012b, 2013, 2015, 2016, 2017, 2024b); a 20% reduction in transfers would mean a loss of almost 11,000 AF each to SWP and CVP contractors which would be about 1% of the total SWP Table A deliveries in dry and critical years; in those years, even a 1% reduction in SWP water supply is meaningful.

Operations under Alternative 1 could lead to reductions in diversions by NID and PG&E through PG&E's Drum Canal and NID's South Yuba Canal, combined in modeling as Spaulding Canals. This programmatic analysis assumes that NID's and PG&E's diversions during dry and critical years would provide water supply to NID and PCWA water users. Consequently, reductions in Spaulding Canals' diversions during these years could indicate reductions in water supply deliveries.

5.4.2.1.2 Flood Protection

Reoperation of the YRDP under the Proposed Projects or the alternatives may result in changes in flow throughout the Yuba River. Increases in high flows could damage downstream infrastructure, or subject populations to increased flood risk. Changes in flood risk will be represented by changes in New Bullards Bar Reservoir releases beyond those permitted by the USACE WCM, or a reduction in flood protection performance from New Bullards Bar Dam.

5.4.2.2 Significance Criteria

5.4.2.2.1 Flood Protection

For flood protection, impact indicators and significance criteria rely upon the CEQA Guidelines Appendix G: Environmental Checklist Form. Under CEQA Guidelines Appendix G, New Bullards Bar Reservoir spills, the Proposed Projects or the alternatives would have a significant impact on flooding if it would:

- **Impact SW-1:** Substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-site; or
- **Impact SW-2:** Impede or redirect flood flows.

5.4.2.2.2 Water Supplies

Impact indicators and significance criteria provided in the CEQA Guidelines Appendix G: Environmental Checklist Form do not provide specific guidance for evaluating potential surface water supply-related impacts that could result from the Proposed Projects or alternatives, so indicators aligned with the potential effects of the Proposed Projects and alternatives have been defined. For surface water supplies, the Proposed Projects or the alternatives would have a significant impact, relative to the appropriate basis of comparison, if it would result in:

- **Impact SW-3:** A reduction in surface water deliveries to Yuba Water Member Units, relative to the appropriate bases of comparison shown in Table 5.4-1, as a result of

decreases in annual water supply availability or increases in flow requirements in the Yuba River below Englebright Dam, at an increased frequency and magnitude that, assuming the Yuba Water Member Units elected to pump a similar volume groundwater to replace the reduced surface water delivery, would result in groundwater levels below the local management levels defined in the Yuba Groundwater Sustainability Plan (Yuba Water 2024b), would be considered significant. Effects of increases in groundwater pumping are evaluated in Chapter 6, Groundwater Resources.

- **Impact SW-4:** Yuba Accord water transfers provide water supply value to water users outside of the Yuba River watershed, particularly in Dry and Critical[13] years. While there is substantial variation in year-to-year transfers, reductions in Yuba Accord transfers greater than 20% in Dry or Critical years would represent a meaningful reduction in water supply reliability to CVP and SWP water contractors and would be considered potentially significant.
- **Impact SW-5**: Alternative 1 has the ability to affect diversions from NID and PG&E's Yuba-Bear and Drum-Spaulding projects to the Drum and South Yuba Canals (combined in modeling as Spaulding Canals). For purposes of the programmatic analysis of this impact, a significant impact would occur if these changes in diversions cause additional water supply shortages for NID and PCWA water users.

5.5 Environmental Impact Analysis

5.5.1 Hydrologic Effects of Alternatives

The following discussion provides a narrative discussion of how the YRDP and Narrows Project operate under each of the scenarios to provide a context for potential impacts associated with operations of the projects. Operational requirements for the Existing Condition and the Proposed Projects are described in detail in Chapter 2, and for the alternatives in Chapter 3.

5.5.1.1 Existing Conditions

Under the Existing Conditions scenario, the YRDP and Narrows Project are operated to meet the existing requirements.

5.5.1.1.1 Areas Upstream of Englebright Dam

Our House and Log Cabin Diversion Dams

On the Middle Yuba River, all inflow above the required flow below the Our House Diversion Dam is diverted into the Lohman Ridge Tunnel up to its physical capacity. The Lohman Ridge Tunnel directs the flow into Oregon Creek above the Log Cabin Diversion Dam. Similar to operations at the Our House Diversion Dam, flows greater than the requirement for below the Log Cabin Diversion Dam are diverted into the Camptonville Tunnel and subsequently released directly into New Bullards Bar Reservoir. Flows below Our House and Log Cabin diversion dams

[13] As defined in SWRCB Decision 1641 in the Matter of: Implementation of Water Quality Objectives for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (SWRCB 2000).

combine in the Middle Yuba River and subsequently combine with the North Yuba River to form the headwaters of the Yuba River.

New Bullards Bar Dam and Reservoir

New Bullards Bar Reservoir receives inflow from the North Yuba River and from the Camptonville Tunnel. New Bullards Bar Reservoir is generally operated in three modes: (1) to meet the requirements of the USACE water control manual (WCM); (2) to meet flow requirements and agricultural water supply demand in the Yuba River below Englebright Dam; and (3) to manage storage throughout the year to reach an end-of-September storage target of 650,000 acre-feet. Releases are made from the dam's base to meet the required North Yuba River flow below New Bullards Bar Dam via the Minimum Flow Powerhouse and from dam seepage. Any additional releases for the three modes are first made through the New Colgate Powerhouse up to its capacity. The only condition under which flows would be made from the New Bullards Bar Dam spillway would be if additional releases beyond the capacity of the New Colgate Powerhouse and Minimum Flow Powerhouse were needed to meet the USACE WCM storage restrictions described in Section 5.2.1.4.

If operations to meet minimum flows and agricultural water supply deliveries below Englebright Dam would result in end-of-September New Bullards Bar Reservoir storage greater than 650,000 acre-feet, releases from New Bullards Bar Dam would be increased, and Englebright Dam releases would reflect New Bullards Bar Dam releases plus inflows from the Middle Yuba and South Yuba rivers, potentially above the flows needed to meet lower Yuba River flow requirements and agricultural water supply deliveries.

If operations to meet flow requirements and agricultural water supply deliveries would result in an end-of-September storage of less than 440,000 acre-feet in the first year of a drought or 400,000 acre-feet in subsequent drought years, Yuba Water would reduce water supply deliveries to a level that would ensure at least 440,000 acre-feet or 400,000 acre-feet, whichever is appropriate, at the end of September with a maximum shortage of 50% of total demand. New Bullards Bar Reservoir storage would be drawn down potentially all the way to the minimum pool (230,000 acre-feet), if a 50% reduction in water supply deliveries was insufficient to meet required flows in the lower Yuba River at all times. If Yuba Water reduces water supply deliveries to meet an end-of-September storage of 440,000 acre-feet or 400,000 acre-feet, the member units would pump an equivalent volume of groundwater to meet their agricultural water supply demands.

5.5.1.1.2 Lower Yuba River

Englebright Dam and Reservoir

Releases from Englebright Reservoir are made through three outlets: (1) the Narrows 1 Powerhouse; (2) the Narrows 2 Powerhouse; and (3) the Englebright Dam spillway. The Englebright Dam spillway is generally not used unless both powerhouses are operating at their maximum capacity, and since the New Colgate Powerhouse release capacity is less than the combined capacity of the two powerhouses, Englebright spills would not occur unless New Bullards Bar Dam is spilling or inflows from the Middle Yuba and South Yuba rivers were relatively high, or a combination of both factors. The decision process to divide Englebright Dam

releases between the Narrows 1 and Narrows 2 powerhouses is described in detail in Section 2.4.1.3.

Non-spill releases from Englebright Dam are made for two purposes: (1) to meet flow requirements and agricultural diversion demands in the lower Yuba River, and (2) to maintain the water surface elevation in Englebright Reservoir around 519 feet above mean sea level. Releases for flow requirements and agricultural water supply are determined based on the greater of the Smartsville flow requirement or the Marysville flow requirement plus agricultural diversions from Daguerre Point Dam less intervening accretions. Releases from New Bullards Bar Reservoir, through the New Colgate Powerhouse, are used to supplement inflows from the Middle Yuba and South Yuba rivers, if needed, to meet the lower Yuba River minimum flows and agricultural diversions.

Lower Yuba River Flows

As described above, flows in the Yuba River downstream from Englebright Dam under the Existing Condition are driven by operations to meet flow requirements at the Smartsville and Marysville gages and to provide agricultural water supply deliveries to diversion points near the Daguerre Point Dam. If New Bullards Bar Reservoir is operating for storage management or inflows to the Yuba River and Englebright Reservoir downstream from New Bullards Bar Dam are relatively high, flows in the lower Yuba River would be above the required flows, but under no circumstance would flows be less than the required flows.

Agricultural Water Supply Deliveries

Yuba Water provides water supplies at three locations along the lower Yuba River: (1) BVID's Pumpline Diversion just upstream from Daguerre Point Dam; (2) the Hallwood-Cordua Canal at the north end of the Daguerre Point Dam; and (3) the Yuba Main Canal, also known as the South Canal, at the south end of the Daguerre Point Dam. These agricultural water supplies are described in detail in Section 5.2.2.3 above. Shortages in agricultural water supplies only occur when New Bullards Bar Reservoir's storage is forecasted to fall below 440,000 acre-feet at the end of September in the first year of a drought, or below 400,000 acre-feet after the first year of a drought. Shortages under the Existing Condition are limited to a maximum of 50% of total annual demand. Groundwater would be pumped, up to the region's pumping capacity, to make up any shortages in surface water deliveries.

Yuba Accord Transfers

Under the Yuba Accord water transfer program, Yuba Water would potentially provide transferable Yuba River outflow through three methods: (1) the primary method of operating to meet required flows, a portion of the required flow at the Marysville gage could be potentially transferable; (2) when operating for an end-of-September storage of 650,000 acre-feet, a portion of the releases above the minimum flows could be potentially transferable; and (3) through groundwater substitution transfers. Under both methods (1) and (2), the portion of the flow considered potentially transferable is based on measured flows at the Marysville gage above a computed baseline flow.

Transfer Baseline operations would be based on the same inflows to the YRDP and Narrows Project as the Existing Conditions, but with operations to meet the Transfer Baseline operations,

as defined in the Yuba Accord Water Purchase Agreement. In addition to transfers from water released from New Bullards Bar Reservoir, the Yuba Accord provides an opportunity for member units to pump groundwater rather than taking surface water deliveries, also known as a groundwater substitution transfer. Yuba Water stores the undelivered water supply in New Bullards Bar Reservoir and makes it available to the buyers downstream of the lower Yuba River at a time they can take it. Any groundwater pumping in response to surface water supply shortages would reduce member units' ability to provide groundwater substitution transfers. In NYI Schedule 6 years, the member units have agreed to pump 30,000 acre-feet of groundwater substitution, regardless of the buyers' ability to take the water.

Yuba Accord water transfers provide valuable supplemental water supplies to CVP and SWP water users, particularly in dry and critical years when CVP and SWP water users' supplies from other sources become more scarce.

Downstream from Yuba River

The Yuba River joins the Feather River near Marysville, the Feather River flows into the Sacramento River near Vernona, and the Sacramento River flows into the Delta. DWR operates Oroville Reservoir on the Feather River upstream from the Yuba River; New Bullards Bar and Oroville dams operate cooperatively during flood events through the F-CO Program to ensure flows below the Yuba and Bear rivers remain below thresholds defined in the two dams' USACE WCMs. While Existing Condition flows are relatively small compared to those in the Feather and Sacramento rivers, Yuba River flows contribute towards CVP and SWP's operations to meet Delta water quality and flow requirements. Portions of Yuba River outflow that are not transferable are available to downstream water right holders, including DWR and Reclamation.

5.5.1.2 Future Baseline

Under the Future Baseline, operations would be essentially identical as those under Existing Conditions, except NID and PG&E would operate their respective projects to meet their proposed FERC 4(e) flow requirements, which are higher than their existing FERC requirements, and thus their releases would be increased when operations are driven by minimum flows, and flows in the Middle Yuba River above Our House Diversion Dam and the South Yuba River above Englebright would be similarly increased. These increased inflows would result in lower releases from the New Colgate Powerhouse when the YRDP and Narrows Project were operating to meet lower Yuba River flow requirements and water supply deliveries, but would potentially increase New Bullards Bar Reservoir releases when it was in a storage management mode due to potentially higher flows in the Lohman Ridge and Camptonville tunnels.

Baseline operations for Future Baseline would be based on the same inflows to the YRDP and Narrows Project as the Future Baseline, but with operations to meet the Baseline operations, as defined in the Yuba Accord Water Purchase Agreement.

5.5.1.3 Proposed Project

Under the Proposed Projects, the YRDP and Narrows Project would be operated similarly to the Existing Conditions and the Future Baseline, but to meet the YRDP FERC FEIS license conditions described in Chapter 2.

5.5.1.3.1 Areas Upstream of Englebright Dam

Our House and Log Cabin Diversion Dams

Operations at the Our House Diversion Dam would change the most under the YRDP FERC FEIS conditions. In addition to higher flow requirements downstream from the dam included in the FERC FEIS, the spill cessation, sediment transport, and recreational flow requirements would also necessitate increased releases at times. Lastly, FERC FEIS license conditions would require the closure of the Lohman Ridge Tunnel at times. Each of these actions would reduce the volume of Yuba Water's diversions from the Middle Yuba River into Oregon Creek and New Bullards Bar Reservoir, and increase flows from the Middle Yuba River into Englebright Reservoir.

The Log Cabin Diversion Dam on Oregon Creek has similar increases in flow requirements downstream from the dam, along with sediment transport and spill cessation measures, each of which would increase flows in Oregon Creek and subsequently the Middle Yuba River, while reducing diversions through the Camptonville Tunnel to New Bullards Bar Reservoir.

New Bullards Bar Dam and Reservoir

The FERC FEIS includes similar increases in required flows in the North Yuba River downstream from New Bullards Bar Dam, along with a spill cessation measure that will increase New Bullards Bar Dam releases to the North Yuba River. When combined with the increased flows in the Middle Yuba River and Oregon Creek and decreased Lohman Ridge and Camptonville Tunnel flows, there would be a reduction in New Colgate Powerhouse releases. The increased flows from the Middle Yuba River and Oregon Creek as a result of Yuba Water's FERC FEIS license conditions on Our House and Log Cabin diversion dams would displace releases from the New Colgate Powerhouse towards the lower Yuba River flow requirements and agricultural water supply deliveries. With less tunnel flows, there would be a small reduction in New Bullards Bar Reservoir storage management releases. Operations for flood management would continue to be governed by the USACE WCM. The ARC Spillway, if constructed, would improve Yuba Water's flexibility for operating during high-flow events by increasing the release capacity from New Bullards Bar Dam near the bottom of the flood reservation space. This increased capacity would be used to make larger releases at the beginnings of flood events and reducing the peak flows at the height of the flood events.

5.5.1.3.2 Lower Yuba River

Englebright Dam and Reservoir

Englebright Dam and Reservoir would be operated similarly as under the Existing Conditions, with similar overall priorities. Reservoir elevations would be managed to similar levels, and release decisions through the Narrows 1 and Narrows 2 powerhouses would be the same.

Lower Yuba River Flows

While required flows would be different, the YRDP and Narrows Project would operate for the Proposed Projects as described for the Existing Condition scenario, with similar overall priorities. While there might be slight differences in end-of-September storage, relative to the Existing Condition, the NYI would not consistently be higher or lower than under the Existing Condition. These changes in end-of-September storage could precipitate changes in the following year's NYI,

described in Section 5.3.2.2. If the end-of-September storage were reduced enough to trigger a higher NYI schedule, the following year's flow requirements would be reduced relative to the Existing Conditions.

Flow requirements in the lower Yuba River are very similar to those under Existing Conditions. The Schedule 6 flow requirements in June through August have been increased, but due to the required groundwater substitution transfers under Existing Conditions, flows in the river would not be substantially different. Yuba Water could elect to meet the Schedule 6 FERC FEIS flow requirements through groundwater substitution transfers or through storage releases from New Bullards Bar Reservoir. The FERC FEIS Englebright Dam-release flow fluctuation and ramping requirements will slightly extend releases during relatively wet years, particularly during New Bullards Bar Reservoir storage management operations, but will not significantly affect operations in relatively dry years when operations are generally governed by flow requirements.

Agricultural Water Supply Deliveries

Operations to provide agricultural water supply deliveries would be the same under the Proposed Projects as under Existing Conditions. Differences in shortages would be a result of a change in New Bullards Bar Reservoir storage and changes in NYI schedules and the associated flow requirements.

Yuba Accord Transfers

The portion of the Proposed Projects flow considered potentially transferable is based on measured flows at the Marysville gage above the Transfer Baseline flow. Transfer Baseline operations for the Proposed Projects would be based on the same inflows to the YRDP and Narrows Project as the Existing Conditions, but with operations for the Transfer Baseline requirements, as defined in the Yuba Accord Water Purchase Agreement (Yuba Water and Reclamation 2007), rather than for the Proposed Projects' requirements. Operations to provide Yuba Accord transfers would be unaffected by the Proposed Project.

Downstream from Yuba River

Under the Proposed Projects, flows in the Feather and Sacramento rivers and Delta would essentially be the same as those under Existing Conditions and the effect of the Proposed Projects on downstream resources would effectively be the same as under Existing Conditions.

5.5.1.4 Proposed Projects Future Conditions

Under Proposed Projects future conditions, with NID's Yuba-Bear Project and PG&E's Drum-Spaulding Project both operating for their proposed FERC 4(e) license requirements, there would be additional inflows to the YRDP and Narrows Project on the Middle Yuba and South Yuba rivers. However, the relative effect of the Proposed Projects Future Condition compared to the Future Baseline would be similar to the Proposed Projects compared to the Existing Conditions. New Bullards Bar Reservoir releases would be for either flood management, to meet flow requirements and water supply deliveries, or to manage storage for an end-of-September storage target. Flows in the lower Yuba River and throughout the YRDP and Narrows project's area would be essentially the same or slightly higher as the YRDP and Narrows Projects re-operate in response to slight increases in inflows from the Middle Yuba and South Yuba rivers.

The YRDP and Narrows Project would operate for the Proposed Projects Future Conditions similarly as in the Proposed Projects scenario, with similar overall priorities. Operations for agricultural water supplies would be essentially the same under the Proposed Projects Future Conditions as under the Future Baseline.

The portion of the Proposed Projects Future Conditions flow considered potentially transferable is based on measured flows at the Marysville gage above the Baseline flow. Baseline operations for the Proposed Projects Future Conditions would be based on the same inflows to the YRDP and Narrows Project as the Future Baseline, but with operations to meet the Baseline operations, as defined in the Yuba Accord Water Purchase Agreement.

Similarly, operations for flood management would continue to be governed by the USACE WCM.

5.5.1.5 Alternative 1

Yuba Water's basic operations in Alternative 1 would be the same as under the Proposed Projects Future Conditions. Alternative 1 includes all of the Proposed Projects requirements and features, but includes several additional elements.

5.5.1.5.1 Areas Upstream of Englebright Dam

Alternative 1 assumes FERC would require 15,600 acre-feet of additional releases from the upstream projects above their respective proposed FERC 4(e) license requirements in the spring of dry and critical years. While Yuba Water has modeled these operations with 5,000 acre-feet on the Middle Yuba River and 10,600 acre-feet from the South Yuba River as a block of flow on top of minimum flows in April to provide a reasonable representation of inflows to the YRDP and Narrows Project for use in evaluating the effects of changes in Yuba-Bear and Drum-Spaulding projects' flow regimes on YRDP and Narrows Project resource areas, the actual distribution and timing of the additional block of water would be subject to FERC's determination and consultation with applicable regulatory agencies. Under this consultation between FERC and the resource agencies, it is likely the water volume would be released to maximize the beneficial use of the water on local environmental resources within the tributaries, similar to a spring freshet, rather than as the block of flow currently represented in the modeling. A change of this nature would not negatively affect YRDP or Narrows Project operations, nor the analysis conducted for this evaluation as long as the flow was distributed over a reasonable duration of approximately 30-45 days in the April through May timeframe.

Similarly, while the Yuba-Bear and Drum-Spaulding projects export substantial volumes of water from the Yuba River watershed utilizing many reservoirs spread over a large geographic area with a range of storage capacities, Yuba Water's analysis assumes the increased flows for Alternative 1 would be a result of decreased storage in Jackson Meadows, Bowman, and Spaulding reservoirs rather than any modification to out-of-basin diversions or from other Yuba-Bear and Drum-Spaulding project reservoirs. NID and PCWA have flexible options for addressing any real reductions in those exports, such as through conservation or increased use of other surface water or groundwater supplies. Under a more refined analysis, many variations of water management decisions could be made to balance reservoir storage for recreational or water temperature benefit with water supply deliveries under consultation with FERC and resource agencies.

To the extent possible, the additional release from the Middle Yuba River would be diverted into the Lohman Ridge Tunnel and into New Bullards Bar Reservoir for release later in the year. If the tunnel was already full, the water would be released down the Middle Yuba River and would displace similar releases from New Bullards Bar Reservoir, if operations were for flow requirements below Englebright Dam.

New Bullards Bar Dam and Reservoir

The increased volume of inflow from NID and PG&E's projects would either be diverted into New Bullards Bar Reservoir, or used to offset releases from New Bullards Bar Reservoir. In dry and critical years, New Bullards Bar Reservoir typically operates to meet flow requirements and agricultural water supplies in the lower Yuba River rather than for storage management; as long as the releases from upstream projects were within Yuba Water's ability to re-regulate them in New Bullards Bar and Englebright Reservoir, the increased inflow would result in slightly increased storage in New Bullards Bar Reservoir until they were released in the fall, after which time New Bullards Bar Reservoir storage would be essentially the same as under the Proposed Projects Future Condition.

While unusual in dry and critical years, if New Bullards Bar would otherwise have been operated to meet a 650,000 acre-foot end-of-September storage target, Yuba Water would operate for an end-of-September storage of 655,200 acre-feet, an increase of 5,200 acre-feet, or the equivalent of 175 cfs for the first 15 days of October, so that New Bullards Bar Reservoir storage would be essentially the same as under the Proposed Projects Future Condition on October 15, with the exception of any differences in reservoir evaporation.

Alternative 1 includes a measure to increase Englebright Reservoir water surface elevations in the fall of dry and critical years to provide for improved water temperatures in the lower Yuba River. New Bullards Bar Reservoir would increase releases starting on August 26 with the intent of raising Englebright Reservoir's water surface elevation by September 9. Englebright Reservoir water surface elevation would be maintained around 525 feet through October 15, at which time New Bullards Bar Reservoir releases would slowly be decreased, allowing Englebright Reservoir's water surface elevation to drop back to 519 feet by November 1. After reducing Englebright Reservoir water surface back to 519 feet, New Bullards Bar Reservoir storage would be essentially the same as under the Proposed Projects Future Condition, with the exception of any difference in reservoir evaporation.

Operations for flood management would continue to be governed by the USACE WCM.

5.5.1.5.2 Lower Yuba River

Englebright Dam and Reservoir

Under Alternative 1, Englebright Dam and Reservoir would be operated similarly as under the Existing Conditions, with similar overall priorities. Release decisions through the Narrows 1 and Narrows 2 powerhouses would be the same.

As described above, Yuba Water assumed a portion of the additional releases from the Yuba-Bear and Drum-Spaulding projects would be to the South Yuba River. Increased inflow to Englebright Reservoir from the South Yuba River would generally offset releases from the New Colgate

Powerhouse, total Englebright Reservoir inflow and outflow during this period would remain essentially the same as under the Proposed Project.

However, under Alternative 1, Yuba Water would increase the elevation of Englebright Reservoir from its normal operating elevation of approximately 519 feet to 525 feet between September 9 and October 15 in dry and critical years. New Bullards Bar Reservoir's operations for this measure are described above. Actions to increase Englebright Reservoir's water surface elevation would be driven by New Bullards Bar Reservoir operations; releases from the Narrows 1 and Narrows 2 powerhouses would not change in response to the variations in water surface elevation.

Lower Yuba River Flows

Under Alternative 1, the YRDP and Narrows Project would operate similarly as described for the Proposed Projects Future Condition scenario, with similar overall priorities. However, under Alternative 1, Yuba Water would include a 175 cfs increased flow requirement at Smartsville and Marysville between September 1 and October 15 to provide improved water temperature conditions compared to the Proposed Projects Future Conditions. The 175 cfs requirement would be additive to whatever other required flow there was at the Marysville gage. 175 cfs for 45 days represents 15,619 acre-feet of water, essentially the same volume FERC would require from the upstream projects earlier in the year.

Agricultural Water Supply Deliveries

Operations to provide agricultural water supply deliveries would be the same under Alternative 1 as under the Proposed Projects Future Conditions. Any differences in shortages would be a result of a change in New Bullards Bar Reservoir storage.

Yuba Accord Transfers

The portion of Alternative 1 flow considered potentially transferable is based on measured flows at the Marysville gage above the Transfer Baseline flow. Transfer Baseline operations for Alternative 1 would be based on the same inflows to the YRDP and Narrows Project as Alternative 1, including the 15,600-acre-foot release from upstream projects in dry and critical years. With verification of the released volume from the upstream projects, Alternative 1's 175 cfs of additional flow above the Smartsville and Marysville flow requirement between September 1 and October 15 is assumed to be applied to the Transfer Baseline conditions as well, so it would not result in any additional transferrable flow for Yuba Water.

Downstream from Yuba River

Under Alternative 1, flows in the Feather and Sacramento rivers and Delta would essentially be the same as those under the Future Baseline, and the effect of Alternative 1 on downstream resources would effectively be the same as under Existing Conditions.

5.5.1.6 Alternative 2

Yuba Water's basic operations under Alternative 2 would be similar to the Proposed Projects Future Conditions, but would be impaired by Yuba Water's required implementation of that alternative. Alternative 2 includes all of the Proposed Projects requirements and assumes NID and PG&E's projects would be operated to meet their proposed FERC 4(e) requirements, with several additional

elements described as Sacramento/Delta Tributary Inflow and Cold Water Habitat Objectives within the SWRCB Program of Implementation (POI) in Chapter 4 of the latest draft of the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Watershed (SWRCB 2024). The POI includes a regulatory pathway, described in Section 4.4.2.

There is substantial uncertainty around how the SWRCB regulatory pathway would be implemented. Modeling for Alternative 2 assumes that Yuba Water would operate generally consistently with current operational paradigms, but the substantial changes in underlying requirements would likely result in substantial changes to operational practices with even greater emphasis on protecting future stored water supplies than current practices.

The SWRCB regulatory pathway includes an assumption that 55% of the unimpaired flow would be provided at three locations in the Yuba River watershed: (1) on the Middle Yuba River at its confluence with the North Yuba River; (2) on the South Yuba River at Jones Bar; and (3) on the Yuba River near Marysville. The approach for representing flows at each location is described below.

5.5.1.6.1 Areas Upstream of Englebright Dam

Our House and Log Cabin Diversion Dams

Under this analysis, NID's releases from the Milton Diversion Dam would be to meet their proposed FERC 4(e) requirements, and the 55% unimpaired flow at the mouth of the Middle Yuba River would be met through a combination of accretions between the Milton Diversion Dam and Our House Dam, accretions between Our House and Log Cabin Dams and the confluence of the Middle Yuba and North Yuba rivers, and Lohman Ridge Tunnel closures. While this would likely result in substantial reductions in out-of-basin diversions from the Yuba-Bear and Drum-Spaulding projects, since the implementation of the SWRCB regulatory pathway would be a result of SWRCB's processes, potential water supply reductions resulting from reductions in out-of-basin diversions are not evaluated in this report.

New Bullards Bar Dam and Reservoir

The unimpaired flow requirement on the Yuba River near Marysville would primarily be met through increased releases from New Bullards Bar Dam. New Bullards Bar Dam releases for the unimpaired flow requirement would be limited to its release capacity from the New Colgate Powerhouse and any flood management spills.

In addition to a 55% unimpaired flow requirement at the three locations described above, Alternative 2 includes an end-of-September storage requirement of 600,000 acre-feet in wet, above normal, and below normal years, and 400,000 acre-feet in dry and critical years. Agricultural water supply deliveries would be reduced as needed to meet the 600,000- or 400,000-acre-foot storage requirements.

The unimpaired flow requirement on the South Yuba River would be met through increased releases from Bowman and Spaulding dams and accretions upstream from Jones Bar. The division between Bowman and Spaulding Dams is based on their respective portion of unimpaired flows upstream from the dams.

Operations for flood management would continue to be governed by the USACE WCM.

5.5.1.6.2 Lower Yuba River

Englebright Dam and Reservoir

Englebright Dam would spill as needed to ensure adequate flows near Marysville. This would likely require that Englebright Reservoir storage be maintained closer to the top of Englebright Dam in winter months so it could spill the required flows when needed. General operations of the Narrows 1 and Narrows 2 powerhouses would not be affected by Alternative 2.

Lower Yuba River Flows

Under Alternative 2, Yuba River flow below Englebright Dam would be substantially higher in the spring in response to the 55% unimpaired flow requirement near Marysville. The Proposed Projects flow requirements would be maintained under Alternative 2, but the increased spring flows would reduce the extent to which flows exceed required flows due to lower storage in New Bullards Bar Reservoir.

Agricultural Water Supply Deliveries

Since Englebright Dam releases would be limited to inflows from the New Colgate Powerhouse, the Middle Yuba River, and the South Yuba River, agricultural diversions would be reduced as needed to provide 55% of basin-wide unimpaired flow near Marysville. Similarly, agricultural water supply diversions would be reduced, as needed, so New Bullards Bar Reservoir can reach its end-of-September storage requirements. While shortages were limited to 50% of demand under operations for the Existing Condition, Future Baseline, Proposed Projects and Alternative 1, diversions as low as 2% of demand are used to meet the Alternative 2 storage requirements.

Yuba Accord Transfers

While Alternative 2 could result in increased flows relative to the Alternative 2 Transfer Baseline, primarily due to differences in July through September flow requirements that are the Yuba Accord required flows with the changes included in the FERC FEIS, Yuba Water would not participate in groundwater substitution transfers out of the necessity of protecting local groundwater supplies combined with SGMA. Furthermore, Yuba Water would make every effort to protect its local water supplies, so New Bullards Bar Reservoir storage operations, including under the Alternative 2 Transfer Baseline, would likely be different from current operations, but the lack of detail in how the SWRCB regulatory pathway would be implemented makes it speculative to say exactly what those operational changes would be. Additionally, there is substantial uncertainty about how the CVP and SWP operations would respond to the SWRCB regulatory pathway, and under what conditions transfers would be possible. As a result, it is reasonable to assume there would not be any Yuba Accord transfers under Alternative 2. Since Yuba Accord transfers provide a meaningful water supply benefit to SWP and CVP contractors, this would reduce water supply availability to those water users.

Downstream from Yuba River

Under Alternative 2, there would be substantially more flow from the Yuba River into the Feather River in the spring and substantially less in the summer. If the SWRCB regulatory pathway was in

place, it is likely other reservoirs in the Sacramento Valley, including Oroville Reservoir, would similarly be operating to meet an unimpaired flow-based alternative, in which case the Yuba River contribution to the Feather and Sacramento Rivers and Delta would remain relatively small. The reduction in non-transferable Yuba River flow in summer months would reduce water availability to other water users and would potentially require the SWP and CVP to increase releases from their respective reservoirs to ensure Delta water quality and flow requirements were met.

If the SWRCB pathway was applied to the Yuba River alone, then the Yuba River contribution would result in substantially higher Feather and Sacramento River flows into the Delta in the spring, and moderately less in the summer.

5.5.1.7 No Project Alternative

Under the No Project Alternative, Yuba Water would not operate to meet any FERC-related requirements, and operations would instead be based on meeting requirements described in water rights and agreements. Differences between the No Project Alternative and the Existing Condition isolate the effects of Yuba Water being able to generate electricity rather than just operate to achieve its flood-control and water-supply missions as identified in the Yuba County Water Agency Act. As discussed below, there are few, if any, environmental effects that are attributable specifically to Yuba Water's continued generation of hydroelectricity. For the most part, descriptions of the Existing Condition from Section 5.5.1.1 remain applicable under the No Project Alternative. Further details are provided below.

5.5.1.7.1 Areas Upstream of Englebright Dam

Our House and Log Cabin Diversion Dams

Operations at Our House and Log Cabin diversion dams would be to meet flow requirements included in Yuba Water's 1965 Agreement with CDFW which are included in Yuba Water's consumptive water rights. Requirements in the 1965 Agreement mirror those in the existing YRDP FERC license, resulting flows below Our House and Log Cabin diversion dams would be the same as under Existing Conditions. Diversions into the Lohman Ridge and Camptonville Tunnels, while not providing any hydropower generation value from the New Colgate Powerhouse, would be maintained the same as under Existing Conditions for storage in New Bullards Bar Reservoir for subsequent water supply and water temperature management.

New Bullards Bar Dam and Reservoir

New Bullards Bar Dam and Reservoir operations would be the same as under Existing Conditions, and operations for flood management would continue to be governed by the USACE WCM.

Due to Yuba Water's Yuba Accord water transfer program, New Bullards Bar Reservoir would be operated to meet the same storage targets as under the Existing Conditions. Yuba Water would deliver water from New Bullards Bar Reservoir for member unit water supplies without shortages unless end-of-September storage was forecasted to be less than 440,000 acre-feet in the first year of a drought or 400,000 acre-feet in subsequent drought years.

5.5.1.7.2 Lower Yuba River

Englebright Dam and Reservoir

Under the No Project Alternative, at Englebright Dam and Reservoir without the Narrows 1 and 2 powerhouses, Yuba Water would either make releases through the Narrows 2 Full Flow Bypass, from the Narrows 1 Powerhouse bypass, or through spills at Englebright Dam. Because New Colgate Powerhouse would not be operating for peaking and ancillary services, releases from New Bullards Bar Reservoir would likely be at more even rates, resulting in less storage and water level fluctuations throughout the day and week. Total flow below Englebright Dam would continue to be based on releases from New Bullards Bar Dam and inflow from the South Yuba and Middle Yuba Rivers for either New Bullards Bar Reservoir storage management or to meet lower Yuba River flow requirements and water supply deliveries.

Lower Yuba River Flows

With similar release capacity from Englebright Dam under the No Project Alternative, lower Yuba River flows would continue to be made for the Smartsville and Marysville flow requirements described in the Yuba Accord and agricultural water supply deliveries from diversion points near Daguerre Point Dam. Flow fluctuation and ramping constraints are similarly contained in the Yuba Accord.

Agricultural Water Supply Deliveries

Water supply deliveries would continue as under the Existing Conditions scenario. With release capacity from New Bullards Bar Dam maintained through a New Colgate energy dissipation device, shortages would be based on periods when New Bullards Bar Reservoir storage was projected to fall below 440,000 acre-feet in the first year of a drought or 400,000 acre-feet in subsequent years. Shortages under No Project Alternative would continue to be limited to a maximum of 50% of total annual demand. Groundwater would be pumped, up to the region's pumping capacity, to make up any shortages in surface water deliveries.

Yuba Accord Transfers

Assuming that the SWRCB approves Yuba Water's pending petition to extend the term of Yuba Accord transfers, those transfers would continue uninterrupted under the No Project Alternative. Since Yuba Water would be maintaining its release capacity from New Bullards Bar Dam, Yuba Accord transfers would be the same as under Existing Conditions.

Downstream from Yuba River

Under the No Project Alternative, flows in the Feather and Sacramento rivers and Delta would essentially be the same as those under Existing Conditions and the effect of the No Project Alternative on downstream resources would effectively be the same as under Existing Conditions.

5.5.2 Proposed Projects compared to the Existing Condition

Operations under Existing Conditions are summarized in Section 5.5.1.1, and operations under the Proposed Projects are summarized in Section 5.5.1.3.

As described in Section 5.4.1.1, there are not expected to be any construction-related effects by the Proposed Projects on water supplies.

YRDP Impact SW-PP-1: Rate or Amount of Surface Runoff from YRDP Operations

Under the Proposed Project, the YRDP would continue to operate according to the USACE's New Bullards Bar Dam WCM. While the effect of the Proposed Projects on individual flood events might be slightly different from under the Existing Condition, the Proposed Projects would not substantially increase the rate or amount of surface runoff from YRDP operations.

Accordingly, impacts for surface runoff would be **less than significant**. No CEQA mitigation is required.

YRDP Impact SW-PP-2: Impede or Redirect Flood Flows

Operations of the YRDP would, by design, impede or redirect flood flows. However, since the YRDP would continue to operate according to the USACE New Bullards Bar Dam WCM, there would not be an increased flood risk to people or property. With the addition of the ARC Spillway, as discussed in its EIR, the Proposed Projects would potentially reduce peak flows.

Accordingly, impacts for flood flows for the YRDP would be **less than significant**, and with the addition of the ARC Spillway, **potentially beneficial**. No CEQA mitigation is required.

YRDP Impact SW-PP-3: Water Supply Shortages from YRDP Operations

Under modeled conditions for both the Existing Condition and Proposed Projects, there would be agricultural water supply shortages to Yuba Water member units in four years out of the period of record. The Proposed Projects would result in reductions in agricultural water supply shortages in 1977 relative to the Existing Conditions, but would result in increased shortages in the other three years, 2014, 2015, and 2021, with a peak increase of 26,615 acre-feet in 2015. However, while the average annual shortage would increase by approximately 700 acre-feet per year, there would not be an increase in the frequency of shortages between the two scenarios. Table 5.5-1 shows annual shortages for the Proposed Projects and Existing Conditions for the four years with shortages within the simulation period of record.

Table 5.5-1. Comparison of Simulated Annual Surface Water Supply Shortages for the Proposed Projects Relative to the Existing Condition.

Calendar Year	Volume of Shortage (AF)		Change in Volume of Shortage from Basis of Comparison (AF)
	Existing Condition	Proposed Projects	
1977	139,644	133,555	-6,089
2014	123,813	130,300	6,487
2015	42,902	69,516	26,615
2021	30,009	37,781	7,772

Key: AF = Acre-feet

Modeled shortages in 1977 conditions would be decreased relative to the Existing Condition. In other modeled years, shortages under the Proposed Projects would be greater than under Existing Conditions, while occurring at a similar frequency, but as shown in Chapter 6, would not result in

groundwater levels falling below local management levels. Accordingly, Proposed Projects impacts for the YRDP would be **less than significant**, and no CEQA mitigation is required.

YRDP Impact SW-PP-4: Yuba Accord Transfers Resulting from YRDP Operations

The Proposed Projects would slightly reduce Yuba Accord stored water transfers compared to the Existing Condition on both a long-term average, and on a dry and critical year average. Table 5.5-2 shows a comparison of average annual Yuba Accord stored water transfers for the Proposed Projects and Existing Conditions for all years, and in dry and critical years.

Table 5.5-2. Comparison of Average Annual and Dry and Critical Year Yuba Accord Stored Water Transfers for the Proposed Projects Relative to the Existing Condition.

	Existing Condition (AF)	Proposed Project (AF)	Change from Basis of Comparison (AF)	Percent Change from Basis of Comparison (%)
Average All Years	44,638	43,444	-1,194	-3
Dry and Critical Years	48,655	46,191	-2,465	-5

Key: AF = Acre-feet

While there would be small reductions in Yuba Accord transfer volumes under the Proposed Project, the changes are less than 20%. Accordingly, Proposed Projects impacts for the YRDP would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact SW-PP-1: Rate or Amount of Surface Runoff from Narrows Operations

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River, the Narrows Project does not noticeably affect flows below Englebright Dam during high-flow events.

Impacts of the Narrows Project under the Proposed Projects would be **less than significant** on the rate or amount of runoff downstream from Englebright Dam. No CEQA mitigation is required.

Narrows Impact SW-PP-2: Impede or Redirect Flood Flows

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River, the Narrows Project does not noticeably affect flows below Englebright Dam during high-flow events.

Impacts of the Narrows Project under the Proposed Projects would be **less than significant** on flood flows downstream from Englebright Dam. No CEQA mitigation is required.

Narrows Impact SW-PP-3: Water Supply Shortages from Narrows Operations

Under the Proposed Narrows Project, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet the Proposed YRDP Project requirements, but the Proposed Narrows Project does not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to the Proposed Narrows Project.

Accordingly, Proposed Projects impacts for the Narrows Project would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact SW-PP-4: Yuba Accord Transfers Resulting from Narrows Operations

Under the Proposed Narrows Project, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet the Proposed YRDP Project requirements, but the Proposed Narrows Project does not include additional flow requirements. As a result, there would be negligible effects on water transfers attributable to the Proposed Narrows Project.

Accordingly, Proposed Projects impacts for the Narrows Project would be **less than significant**, and no CEQA mitigation is required.

5.5.3 Proposed Projects Compared to the Future Baseline

Operations under the Future Baseline are summarized in Section 5.5.1.2, and operations under the Proposed Projects Future Conditions are summarized in Section 5.5.1.4.

As described in Section 5.4.1.1, there are not expected to be any construction-related effects by the Proposed Projects on water supplies.

YRDP Impact SW-FPP-1: Rate or Amount of Surface Runoff from YRDP Operations

Under the Proposed Projects, the YRDP would continue to operate according to the USACE's New Bullards Bar Dam WCM. While the effect of the Proposed Projects on individual flood events might be slightly different from under the Future Baseline, the Proposed Projects would not increase the flood risk nor create flooding for downstream communities.

Accordingly, impacts for surface runoff would be **less than significant**. No CEQA mitigation is required.

YRDP Impact SW-FPP-2: Impede or Redirect Flood Flows

Operations of the YRDP would, by design impede or redirect flood flows. However, since the Proposed Projects would continue to operate according to the USACE New Bullards Bar Dam WCM, there would not be an increased flood risk to people or property.

Accordingly, impacts for flood flows for the YRDP would be **less than significant**, and with the addition of the ARC Spillway, **potentially beneficial** No CEQA mitigation is required.

YRDP Impact SW-FPP-3: Water Supply Shortages from YRDP Operations

The Proposed Projects would reduce agricultural water supply shortages under hydrologic conditions for the modeled year of 1977 relative to the Future Baseline, but would result in increases in shortages in the modeled years of 2014, 2015, and 2021, with a peak increase of 27,502 acre-feet. However, while there would be an increase in average annual shortages of approximately 700 acre-feet per year, there would not be an increase in the frequency of shortages under the Proposed Projects, relative to the Future Baseline. Table 5.5-3 shows annual shortages for the Proposed Projects and Future Baseline for the four years with shortages.

Table 5.5-3. Comparison of Simulated Annual Surface Water Supply Shortages for the Proposed Projects Relative to the Future Baseline.

Calendar Year	Volume of Shortage (AF)		Change in Volume of Shortage from Basis of Comparison (AF)
	Future Baseline	Proposed Project	
1977	139,644	133,530	-6,114
2014	59,548	65,419	5,871
2015	29,185	56,688	27,502
2021	4,673	12,918	8,245

Key: AF = Acre-feet

Modeled shortages in 1977 conditions would be decreased relative to the Future Baseline. In other modeled years with shortages, shortages under the Proposed Projects would be greater than under Future Baseline, and shortages would occur at a similar frequency, but as shown in Chapter 6, would not result in groundwater levels falling below local management levels. Accordingly, Proposed Projects impacts for the YRDP would be **less than significant**, and no CEQA mitigation is required.

YRDP Impact SW-FPP-4: Yuba Accord Transfers Resulting from YRDP Operations

The Proposed Projects would slightly reduce Yuba Accord stored water transfers compared to the Future Baseline on both a long-term average, and on a dry and critical year average. Table 5.5-4 shows a comparison of average annual Yuba Accord stored water transfers for the Proposed Projects and Future Baseline for all years, and in dry and critical years.

Table 5.5-4. Comparison of Average Annual and Dry and Critical Year Yuba Accord Stored Water Transfers for the Proposed Projects Relative to the Future Baseline.

	Future Baseline (AF)	Proposed Project (AF)	Change from Basis of Comparison (AF)	Percent Change from Basis of Comparison (%)
Average All Years	36,968	36,650	-318	-1
Dry and Critical Years	36,865	35,489	-1,376	-4

Key: AF = Acre-feet

While there would be small reductions in Yuba Accord transfer volumes under the Proposed Project, the changes are less than 20%. Accordingly, Proposed Projects impacts for the YRDP would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact SW-FPP-1: Rate or Amount of Surface Runoff from Narrows Operations

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River, the Narrows 1 does not noticeably affect lower Yuba River flows during high-flow events.

Impacts of the Narrows Project under the Proposed Projects would be **less than significant** on the rate or amount of runoff downstream from Englebright Dam. No CEQA mitigation is required.

Narrows Impact SW-FPP-2: Impede or Redirect Flood Flows

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River, the Narrows 1 does not noticeably affect lower Yuba River flows during high-flow events.

Impacts of the Narrows Project under the Proposed Projects would be **less than significant** on flood flows downstream from Englebright Dam. No CEQA mitigation is required.

Narrows Impact SW-FPP-3: Water Supply Shortages from Narrows Operations

Under the Proposed Narrows Project, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet the Proposed YRDP Project requirements, but the Proposed Narrows Project does not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to the Proposed Narrows Project.

Accordingly, Proposed Projects impacts for the Narrows Project would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact SW-FPP-4: Yuba Accord Transfers Resulting from Narrows Operations

Under the Proposed Narrows Project, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet the Proposed YRDP Project requirements, but the Proposed Narrows Project does not include additional flow requirements. As a result, there would be negligible effects on water transfers attributable to the Proposed Narrows Project.

Accordingly, Proposed Projects impacts for the Narrows Project would be **less than significant**, and no CEQA mitigation is required.

5.5.4 Alternative 1 compared to the Existing Condition

Operations under Existing Conditions are summarized in Section 5.5.1.1, and operations under Alternative 1 are summarized in Section 5.5.1.5.

As described in Section 4.4, this comparison is misleading for the water resources analysis; it is provided for informational purposes only.

As described in Section 5.4.1.1, there are not expected to be any construction-related effects by Alternative 1 on water supplies.

YRDP Impact SW-Alt1-1: Rate or Amount of Surface Runoff from YRDP Operations

Under Alternative 1, the YRDP would continue to operate according to the USACE's New Bullards Bar Dam WCM. While the effect of Alternative 1 on individual flood events might be slightly different from under the Existing Condition, Alternative 1 would not increase the flood risk nor create flooding for downstream communities.

YRDP Impact SW-ALT1-2: Impede or Redirect Flood Flows

Operations of the YRDP would, by design impede or redirect flood flows. However, since Alternative 1 would continue to operate according to the USACE New Bullards Bar Dam WCM, there would not be an increased flood risk to people or property. Inclusion of the ARC Spillway could reduce the magnitude of flood flows.

YRDP Impact SW-Alt1-3: Water Supply Shortages from YRDP Operations

Alternative 1 would reduce agricultural water supply shortages under hydrologic conditions for 1977, 2014, and 2021 relative to the Existing Conditions, but would result in increases in shortages in 2015, with a peak increase of 12,755 acre-feet. While average annual shortages would increase by approximately 1,100 acre-feet per year, there would be no change in the frequency of shortages between Alternative 1 and the Existing Condition. Table 5.5-5 shows annual shortages for Alternative 1 and Future Baseline for the four years with shortages.

Table 5.5-5. Comparison of Annual Surface Water Supply Shortages for the Proposed Projects Relative to the Future Baseline.

Calendar Year	Volume of Shortage (AF)		Change in Volume of Shortage from Basis of Comparison (AF)
	Existing Condition	Alternative 1	
1977	139,644	133,530	-6,114
2014	123,813	69,016	-54,797
2015	42,902	55,657	12,755
2021	30,009	20,529	-9,480

Key: AF = Acre-feet

Modeled shortages under 1977, 2014, and 2021 conditions would be decreased relative to Existing Conditions. Under 2015 conditions, shortages under Alternative 1 would occur at a similar frequency, and would be greater than under Existing Conditions, but as shown in Chapter 6, would not result in groundwater levels falling below local management levels.

YRDP Impact SW-Alt1-4: Yuba Accord Transfers Resulting from YRDP Operations

Alternative 1 would decrease Yuba Accord stored water transfers compared to the Existing Condition on both a long-term average, and on a dry and critical year average. Table 5.5-6 shows a comparison of average annual Yuba Accord stored water transfers under Alternative 1 and the Existing Condition for all years, and in dry and critical years.

Table 5.5-6. Comparison of Average Annual and Dry and Critical Year Yuba Accord Stored Water Transfers for Alternative 1 Relative to the Existing Condition.

	Existing Condition (AF)	Alternative 1 (AF)	Change from Basis of Comparison (AF)	Percent Change from Basis of Comparison (%)
Average All Years	44,638	36,417	-8,221	-18
Dry and Critical Years	48,655	34,736	-13,920	-29

There would be sizeable decreases in Yuba Accord transfer volumes under Alternative 1 of greater than 20%.

Narrows Impact SW-Alt1-1: Rate or Amount of Surface Runoff from Narrows Operations

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River; without the Narrows Project, there would be an increased spill over Englebright Dam equivalent to the Narrows 1 Powerhouse capacity and no net change in lower Yuba River flows during high-flow events.

Narrows Impact SW-Alt1-2: Impede or Redirect Flood Flows

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River, the Narrows Project would not noticeably affect flows below Englebright Dam during high-flow events.

Narrows Impact SW-Alt1-3: Water Supply Shortages from Narrows Operations

Under Alternative 1, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to Narrows Project operations.

Narrows Impact SW-Alt1-4: Yuba Accord Transfers Resulting from Narrows Operations

Under Alternative 1, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible effects on water transfers attributable to Narrows Project operations.

5.5.5 Alternative 1 Compared to the Future Baseline

Operations under the Future Baseline are summarized in Section 5.5.1.2, and operations under Alternative 1 are summarized in Section 5.5.1.5.

As described in Section 5.4.1.1, there are not expected to be any construction-related effects by Alternative 1 on water supplies.

YRDP Impact SW-FAlt1-1: Rate or Amount of Surface Runoff from YRDP Operations

Under Alternative 1, the YRDP would continue to operate according to the USACE's New Bullards Bar Dam WCM. While the effect of Alternative 1 on individual flood events might be slightly different from under the Future Baseline, Alternative 1 would not increase the flood risk nor create flooding for downstream communities.

Accordingly, impacts for surface runoff would be **less than significant**.

YRDP Impact SW-FAlt1-2: Impede or Redirect Flood Flows

Operations of the YRDP would, by design, impede or redirect flood flows. However, since Alternative 1 would continue to operate according to the USACE New Bullards Bar Dam WCM, there would not be an increased flood risk to people or property.

Accordingly, impacts for flood flows for the YRDP would be **less than significant**, and with the addition of the ARC Spillway, **potentially beneficial**.

YRDP Impact SW-FAlt1-3: Water Supply Shortages from YRDP Operations

Alternative 1 would reduce agricultural water supply shortages under hydrologic conditions for 1977 relative to the Future Baseline, but would result in increases in shortages in 2014, 2015, and 2021, with a peak increase of 26,471 acre-feet. While average annual shortages would increase by approximately 900 acre-feet per year, there would be no change in the frequency of shortages between Alternative 1 and the Future Baseline. Table 5.5-7 shows annual shortages for Alternative 1 and the Future Baseline for the four years with shortages.

Table 5.5-7. Comparison of Annual Surface Water Supply Shortages for Alternative 1 Relative to the Future Baseline.

Calendar Year	Volume of Shortage (AF)		Change in Volume of Shortage from Basis of Comparison (AF)
	Future Baseline	Alternative 1	
1977	139,644	133,530	-6,114
2014	59,548	69,016	9,468
2015	29,185	55,657	26,471
2021	4,673	20,529	15,856

Key: AF = Acre-feet

Modeled shortages in 1977 conditions would be decreased relative to the Future Baseline. In other modeled years, shortages under Alternative 1 would be greater than under Future Baseline while occurring at similar frequencies, but as shown in Chapter 6, would not result in groundwater levels falling below local management levels. Accordingly, Alternative 1 impacts for the YRDP would be **less than significant**.

YRDP Impact SW-FAlt1-4: Yuba Accord Transfers Resulting from YRDP Operations

Alternative 1 would slightly decrease Yuba Accord stored water transfers compared to the Future Baseline on both a long-term average, and on a dry and critical year average. Table 5.5-8 shows a comparison of average annual Yuba Accord stored water transfers for Alternative 1 and the Future Baseline for all years, and in dry and critical years.

Table 5.5-8. Comparison of Average Annual and Dry and Critical Year Yuba Accord Stored Water Transfers for the Alternative 1 Relative to the Future Baseline.

	Future Baseline (AF)	Alternative 1 (AF)	Change from Basis of Comparison (AF)	Percent Change from Basis of Comparison (%)
Average All Years	36,968	36,417	-551	-1
Dry and Critical Years	36,865	34,736	-2,130	-6

Key: AF = Acre-feet

While there would be small reductions in Yuba Accord transfer volumes under Alternative 1, the changes are less than 20%. Accordingly, Alternative 1 impacts for the YRDP would be **less than significant**.

Indirect Impact SW-FAlt1-1: Potential Water Supply Shortages for NID and PG&E customers from Alternative 1 YB/DS operations.

As described above, Alternative 1 assumes FERC would require 15,600 acre-feet of additional releases from NID and PG&E's projects above their respective proposed FERC 4(e) requirements in the spring of dry and critical years. Yuba Water has modeled these operations with 5,000 acre-feet on the Middle Yuba River and 10,600 acre-feet from the South Yuba River as a block of flow on top of minimum flows in April to provide a reasonable representation of inflows to the YRDP and Narrows Project for use in evaluating the effects of changes in Yuba-Bear and Drum-Spaulding projects' flow regimes on YRDP and Narrows Project resource areas. The actual distribution and timing of the additional block of water would be subject to FERC's determination and consultation with applicable regulatory agencies. Yuba Water's programmatic analysis conservatively assumes reductions in out-of-basin diversions could result in reductions in Yuba River water supply deliveries to NID and PCWA customers.

Yuba Water's modeling indicates there would be reductions in Spaulding Canals' diversions of at least 1% in 17 out of 52 years, and at least 5% in 4 years, with an average reduction of 2.6 TAF and a maximum of 10.5 TAF. These reductions in Spaulding Canals' diversions could potentially represent reductions in water supply deliveries to NID and PCWA customers. However, NID, PG&E and other water suppliers that use water exported from the Yuba River watershed via the Yuba-Bear and Drum-Spaulding projects would have various water management measures available to them, potentially in consultation with FERC and the resource agencies, to avoid significant water supply reductions.

Moreover, in response to reductions in supplies from the Yuba River watershed, it is reasonably foreseeable that NID water users could make up for reductions in Yuba River water supplies with a combination of additional groundwater pumping, conservation, and increased purchases from PG&E (NID 2021). PCWA could make up for shortages with a combination of additional groundwater pumping, conservation, and increased diversions from PCWA's Middle Fork Project (PCWA 2021).

Overall, it is likely that the reduced Spaulding Canal diversions under Alternative 1 would not result in significant reductions in water supplies to NID and PCWA water users, given available operational measures to avoid water supply reductions and available alternative water supplies. Accordingly, this impact would be **less than significant**.

Narrows Impact SW-FAlt1-1: Rate or Amount of Surface Runoff from Narrows Operations

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Impacts of the Narrows Project under Alternative 1 would be **less than significant** on the rate or amount of runoff downstream from Englebright Dam.

Narrows Impact SW-FAlt1-2: Impede or Redirect Flood Flows

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Impacts of the Narrows Project under Alternative 1 would be **less than significant** on flood flows downstream from Englebright Dam.

Narrows Impact SW-FAlt1-3: Water Supply Shortages from Narrows Operations

Under Alternative 1, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to Narrows Project operations.

Accordingly, Alternative 1 impacts for the Narrows Project would be **less than significant**.

Narrows Impact SW-FAlt1-4: Yuba Accord Transfers Resulting from Narrows Operations

Under Alternative 1, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible effects on water transfers attributable to Narrows Project operations.

Accordingly, Alternative 1 impacts for the Narrows Project would be **less than significant**.

5.5.6 Alternative 2 Compared to Existing Condition

Operations under Existing Conditions are summarized in Section 5.5.1.1, and operations under Alternative 2 are summarized in Section 5.5.1.6.

As described in Section 4.4, this comparison is misleading for the water resources analysis; it is provided for informational purposes only.

As described in Section 5.4.1.1, there are not expected to be any construction-related effects by the Alternative 2 on water supplies.

YRDP Impact SW-Alt2-1: Rate or Amount of Surface Runoff from YRDP Operations

Under Alternative 2, the YRDP would continue to operate according to the USACE's New Bullards Bar Dam WCM. While the effect of Alternative 2 on individual flood events might be slightly different from under the Existing Condition, Alternative 2 would not increase the flood risk nor create flooding for downstream communities.

YRDP Impact SW-ALT2-2: Impede or Redirect Flood Flows

Operations of the YRDP would, by design impede or redirect flood flows. However, since Alternative 2 would continue to operate according to the USACE New Bullards Bar Dam WCM, there would not be an increased flood risk to people or property.

YRDP Impact SW-Alt2-3: Water Supply Shortages from YRDP Operations

Alternative 2 would result in agricultural water supply shortages under hydrologic conditions for 49 out of the 52 years in the period of record, and the average annual shortage would increase by approximately 45,000 acre-feet per year. Shortages under Alternative 2 would increase in all of those 49 years, relative to the Existing Conditions, with a peak increase of 247,617 acre-feet in 1992. Table 5.5-9 shows a comparison of shortages under Alternative 2 and Existing Conditions. Years without shortages are not included in this table.

Under Alternative 2, there would a substantial increase in both the frequency and magnitude of shortages. As shown in Chapter 6, the reduction in surface water deliveries would result in increased groundwater pumping; the increased groundwater pumping to maintain a similar level of water supply for Yuba Water member units would result in groundwater levels dropping below local management levels for groundwater.

YRDP Impact SW-Alt2-4: Yuba Accord Transfers Resulting from YRDP Operations

While Alternative 2 might result in increased flows relative to the Alternative 2 Transfer Baseline, primarily due to differences in July through September flow requirements, Yuba Water would make every effort to protect its local water supplies, so New Bullards Bar Reservoir storage operations would likely be different from current operations, but it is speculative to say exactly what those operations would be. Additionally, there is substantial uncertainty about how the CVP and SWP operations would respond to the SWRCB POI, and under what conditions transfers would be possible. As a result, it is reasonable to assume there would not be any Yuba Accord transfers under Alternative 2.

Narrows Impact SW-Alt2-1: Rate or Amount of Surface Runoff from Narrows Operations

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Narrows Impact SW-Alt2-2: Impede or Redirect Flood Flows

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Table 5.5-9. Comparison of Simulated Annual Surface Water Supply Shortages for Alternative 2 Relative to the Existing Conditions.

Calendar Year	Volume of Shortage (AF)		Change in Volume of Shortage from Basis of Comparison (AF)

Key: AF = Acre-feet

Narrows Impact SW-Alt2-3: Water Supply Shortages from Narrows Operations

Under Alternative 2, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to Narrows Project operations.

Narrows Impact SW-Alt2-4: Yuba Accord Transfers Resulting from Narrows Operations

Under Alternative 2, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible effects on water transfers attributable to Narrows Project operations.

5.5.7 Alternative 2 Compared to Future Baseline

Operations under the Future Baseline are summarized in Section 5.5.1.2, and operations under Alternative 2 are summarized in Section 5.5.1.6.1.

As described in Section 5.4.1.1, there are not expected to be any construction-related effects by Alternative 2 on water supplies.

YRDP Impact SW-FAlt2-1: Rate or Amount of Surface Runoff from YRDP Operations

Under Alternative 2, the YRDP would continue to operate according to the USACE's New Bullards Bar Dam WCM. While the effect of Alternative 2 on individual flood events might be slightly different from under the Future Baseline, Alternative 2 would not increase the flood risk nor create flooding for downstream communities.

Accordingly, impacts for surface runoff would be **less than significant**.

YRDP Impact SW-FALT2-2: Impede or Redirect Flood Flows

Operations of the YRDP would, by design impede or redirect flood flows. However, since Alternative 2 would continue to operate according to the USACE New Bullards Bar Dam WCM, there would not be an increased flood risk to people or property.

Accordingly, impacts for flood flows for the YRDP would be **less than significant**, and with the addition of the ARC Spillway, **potentially beneficial**.

YRDP Impact SW-FAlt2-3: Water Supply Shortages from YRDP Operations

Alternative 2 would result in agricultural water supply shortages for 49 out of the 52 years in the period of record, with an average annual increase in water supply shortages of approximately 47,000 acre-feet per year. Shortages under Alternative 2 would be greater than the Future Baseline in all 49 years, with a peak increase of 247,617 acre-feet in 1992. Table 5.5-10 shows a comparison of shortages under Alternative 2 and Existing Conditions.

Table 5.5-10. Comparison of Annual Surface Water Supply Shortages for Alternative 2 Relative to the Future Baseline.

Calendar Year	Volume of Shortage (AF)		Change in Volume of Shortage from Basis of Comparison (AF)
	Future Baseline	Alternative 2	
1970	0	200,572	200,572
1971	0	1,150	1,150

2008	0	119,547	119,547
2009	0	202,457	202,457
2010	0	4,308	4,308
2011	0	238	238
2012	0	60,430	60,430
2013	0	1,997	1,997
2014	59,548	260,361	200,813
2015	29,185	243,751	214,566
2016	0	5,530	5,530

Calendar Year	Volume of Shortage (AF)		Change in Volume of Shortage from Basis of Comparison (AF)
	Future Baseline	Alternative 2	
2017	0	326	326
2018	0	141,831	141,831
2019	0	1,788	1,788
2020	0	405	405
2021	4,673	145,661	140,988

Key: AF = Acre-feet

As shown in Chapter 6, the increased frequency and magnitude of groundwater pumping to replace reductions in surface water supplies under Alternative 2 would result in groundwater levels falling below local management levels. While mitigation measures within the GSP could avoid groundwater-related impacts, they would not resolve water supply shortages. Accordingly, this impact would be **potentially significant and unavoidable**.

YRDP Impact SW-FAlt2-4: Yuba Accord Transfers Resulting from YRDP Operations

While Alternative 2 might result in increased flows relative to the Alternative 2 Transfer Baseline, primarily due to differences in July through September flow requirements, Yuba Water would make every effort to protect its local water supplies, so New Bullards Bar Reservoir storage operations would likely be different from current operations, but it is speculative to say exactly what those operations would be. Additionally, there is substantial uncertainty about how the CVP and SWP operations would respond to the SWRCB POI, and under what conditions transfers would be possible. As a result, it is reasonable to assume there would not be any Yuba Accord transfers under Alternative 2.

There would be no Yuba Accord transfers under Alternative 2, accordingly, Alternative 2 impacts for the YRDP would be **significant and unavoidable**.

Narrows Impact SW-FAlt2-1: Rate or Amount of Surface Runoff from Narrows Operations

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Impacts of the Narrows Project under Alternative 2 would be **less than significant** on the rate or amount of runoff downstream from Englebright Dam.

Narrows Impact SW-FAlt2-2: Impede or Redirect Flood Flows

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Impacts of the Narrows Project under Alternative 2 would be **less than significant** on flood flows downstream from Englebright Dam.

Narrows Impact SW-FAlt2-3: Water Supply Shortages from Narrows Operations

Under Alternative 2, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to Narrows Project operations.

Accordingly, Alternative 2 impacts for the Narrows Project would be **less than significant**.

Narrows Impact SW-FAlt2-4: Yuba Accord Transfers Resulting from Narrows Operations

Under Alternative 2, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Narrows Project would not include additional flow requirements. As a result, there would be negligible effects on water transfers attributable to Narrows Project operations.

Accordingly, Alternative 2 impacts for the Narrows Project would be **less than significant**.

5.5.8 No Project Alternative Compared to the Existing Condition

As described in Section 5.5.1.7, operations of the YRDP and Narrows Project under the No Project Alternative would be essentially the same as under Existing Condition.

Operations of the Narrows Project do not materially affect operations of the YRDP; under a No Project Alternative for the Narrows Project, there would similarly be no material effects on operations of the YRDP.

YRDP Impact SW-NP-1: Rate or Amount of Surface Runoff from YRDP Operations

Under the No Project Alternative, the YRDP would continue to operate according to the USACE's New Bullards Bar Dam WCM. While the effect of the No Project Alternative on individual flood events might be slightly different from under the Existing Conditions, the No Project Alternative would not increase the flood risk nor create flooding for downstream communities.

Accordingly, impacts for surface runoff would be **less than significant**.

YRDP Impact SW-NP-2: Impede or Redirect Flood Flows

Operations of the YRDP would, by design impede or redirect flood flows. However, since the No Project Alternative would continue to operate according to the USACE New Bullards Bar Dam WCM, there would not be an increased flood risk to people or property.

Accordingly, impacts for flood flows for the YRDP would be **less than significant**.

YRDP Impact SW-NP-3: Water Supply Shortages from YRDP Operations

Yuba Water would operate New Bullards Bar Reservoir essentially the same under the No Project Alternative as under Existing Conditions. As a result, there would not be any noticeable effect on water supply deliveries from near Daguerre Point Dam. Shortages under the No Project Alternative would be effectively identical to the Existing Condition, operations for the No Project Alternative would have **less than significant impact** for water supply.

YRDP Impact SW-NP-4: Yuba Accord Transfers Resulting from YRDP Operations

Yuba Water would effectively operate New Bullards Bar Reservoir to meet Yuba Accord water transfers the same under the No Project Alternative as under Existing Conditions. As a result, there would not be any appreciable effect on Yuba Accord water transfers, so the No Project Alternative would have **less than significant impact** on water transfers.

Narrows Impact SW-NP-1: Rate or Amount of Surface Runoff from Narrows Operations

Englebright Reservoir storage is primarily a factor of YRDP operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Impacts of the Narrows Project under the No Project Alternative would be **less than significant** on the rate or amount of runoff downstream from Englebright Dam.

Narrows Impact SW-NP-2: Impede or Redirect Flood Flows

Englebright Reservoir storage is primarily a factor of New Bullards Bar Dam operations. While the Narrows Project contributes to release capacity at Englebright Dam, it does not regulate higher flows from Englebright Dam to the lower Yuba River.

Impacts of the Narrows Project under the No Project Alternative would be **less than significant** on flood flows downstream from Englebright Dam.

Narrows Impact SW-NP-3: Water Supply Shortages from Narrows Operations

Without the presence of the Narrows 1 Powerhouse, Yuba Water would be able to provide adequate flows to meet both the required flows and the agricultural water supply demand through either spills at Englebright Dam or through the Narrows 2 Full Flow Bypass.

Accordingly, No Project Alternative impacts for the Narrows Project would be **less than significant**.

Narrows Impact SW-NP-4: Yuba Accord Transfers Resulting from Narrows Operations

Without the presence of the Narrows 1 Powerhouse, Yuba Water would be able to provide adequate flows to meet required Yuba Accord transfer flows through either spills at Englebright Dam or through the Narrows 2 Full Flow Bypass.

Accordingly, No Project Alternative impacts for the Narrows Project would be **less than significant**.

5.6 Cumulative Impact Assessment

Hydrologic modeling was used to evaluate the potential cumulative effects of the Proposed Projects and alternatives in combination with other likely changes in operations on hydrology and water supply. The projects that have been adequately defined (e.g., in recent project-level environmental documents) and that have the potential to contribute to cumulative impacts are included in the quantitative assessment of the Proposed Projects' and alternatives cumulative

impacts. For analytical purposes of this DEIR, the projects that are considered well defined and "reasonably foreseeable" are described in Chapter 4. To the extent feasible, potential cumulative impacts on resources dependent on hydrology or water supply (e.g., reservoir surface elevation) are analyzed quantitatively.

As described in Chapter 4, because several projects considered as part of the cumulative condition cannot be accurately characterized for hydrologic modeling purposes at this time, either due to the nature of the particular project or because specific operations details are only in the preliminary phases of development, these projects are evaluated qualitatively. Only those projects that could affect surface water resources are included in the qualitative evaluation that is presented in subsequent sections of this chapter.

Although most of the projects described in Chapter 4 could have project-specific impacts that will be addressed in future project-specific environmental documentation, future implementation of these projects is not expected to result in cumulative impacts to regional water supply operations, or water-related and water dependent resources that also could be affected by the Proposed Projects or alternatives (see Chapter 4). For this reason, only the limited numbers of projects with the potential to cumulatively impact surface water resources are specifically considered qualitatively in the cumulative impacts analysis for surface water resources:

FERC Hydropower Projects in the Yuba River Watershed

- South Feather Power Project (FERC Project 2088-068) Relicensing
- Yuba-Bear Hydroelectric Project (Yuba-Bear Project) (FERC Project No. 2266) Relicensing,
- Upper Drum-Spaulding Hydroelectric Projects (FERC No. 2310)
- Lower Drum Hydroelectric Project (FERC No. 14531) Relicensing

Water Supply and Water Management Projects

- Yuba Subbasins Water Management Plan: A Groundwater Sustainability Plan (GSP) Implementation
- WWD In-Lieu Recharge Project
- Yuba County Integrated Regional Water Management Plan (IRWMP) Implementation
- Various Water Supply Improvement Projects

Water Transfer and Acquisition Programs

- Lower Yuba River Accord Water Transfer Program Extension

Flood Control Projects

- New Bullards Bar Dam ARC Spillway Project
- USACE NBB Dam and Reservoir Water Control Manual (WCM) Update

- 500-year Flood Protection Project
- Marysville Ring Levee
- Yuba River North Training Wall (NTW) Project
- Goldfields Multi-Benefit Project

Ecosystem Restoration and Fisheries Improvement Projects

- Bay-Delta Water Quality Control Plan Update – HR & L

5.6.1 Cumulative Condition with Proposed Projects compared to the Existing Condition

5.6.1.1 Cumulative Impacts on Surface Water Resources Resulting from Construction Activities

Construction activities associated with the Proposed Projects under the YRDP Relicensing will occur in distinct locations from construction activities other projects considered for cumulative effects. Construction of the ARC Spillway or any levee modifications would be scheduled and include BMPs to minimize potential effects on YRDP or Narrows Project operations, particularly water supply and flood management operations, and to avoid any erosion or siltation effects. Hence, construction-related impacts of the YRDP and Narrows Projects are unlikely to cumulate with effects from other past, present, or reasonably foreseeable projects to adversely affect surface water resources.

5.6.1.2 Cumulative Impacts on Surface Water Resources from Operations

Under the Cumulative Condition, the YRDP Relicensing Project will change YRDP operations which influences reservoir storages, flows, and water supply deliveries in the YRDP Project Area. Narrows Project operations under the Cumulative Condition will effectively remain the same as under the Existing Condition. Implementation of NID and PG&E's proposed 4(e) license conditions have been considered through hydrologic modeling. All other projects considered in the surface water cumulative assessment are addressed qualitatively.

5.6.1.2.1 Areas Upstream from Englebright Dam

Relicensing of the Yuba-Bear and Drum-Spaulding projects has been explicitly incorporated in the modeling of the Proposed Projects Cumulative Condition; those projects would generally increase the volume of inflows to the YRDP and Narrows Project and would not reduce water supply deliveries to Yuba Water customers or Yuba Accord water transfers. The WCM Update could potentially result in increased flexibility of New Bullards Bar Reservoir operations, freeing up water for water supply deliveries. The WCM Update is designed to reduce flood risk.

5.6.1.2.2 Lower Yuba River and Downstream

The various water supply and water management projects listed in Section 5.6 are intended to individually improve the region's water supply management flexibility and to drive investments

towards improved water supply reliability. The projects should complement each other and provide a benefit for the region and downstream.

The Bay-Delta Water Quality Control Plan Update – HR&L (HR&L) program consists of flow and habitat actions. For the flow actions, Yuba Water has committed to releasing up to 50,000 acre-feet of water above the Yuba Accord flows in above normal, below normal, and dry years in the April through June period when New Bullards Bar Reservoir's forecasted end-of-September storage is over 600,000 acre-feet. The pattern of releases would be subject to the input from a science panel for fisheries-related benefits to the Yuba River and the Delta, but would generally be in the range of 300 cfs to 600 cfs across one to two months. In the year of a HR&L release, there would not be a noticeable effect on agricultural water supply deliveries since those would only be affected if end-of-September storage was forecasted to be below 440,000 acre-feet, and while there could potentially be a small reduction in Yuba Accord transfers, changes would not likely be substantive. Ending a year with reduced storage due to the HR&L program could have an effect on water supply deliveries in the following year if the following year was extremely dry, but since the North Yuba Index would reflect the lower end-of-September storage and water supply delivery shortages typically occur when the previous year's storage was lower than 600,000 acre-feet, the HR&L program would not contribute towards additional water supply shortages. Entering the winter with slightly lower storage could result in reduced New Bullards Bar Dam spills and improved flood management capabilities. While the statewide HR&L program might reduce water supply availability to water users in other parts of the state, Yuba Accord water transfers under the Proposed Projects and Yuba Water's HR&L program would contribute positively towards water supply reliably for water users outside of the Yuba River watershed.

The Yuba Accord Extension would allow the YRDP and Narrows Project to continue to operate according to the Proposed Projects requirements, so there would be no change in water supply or flood management operations. Operations under Yuba Water's HR&L program are designed to be complimentary to the Yuba Accord Extension and the Proposed Projects; the three programs would continue to provide water supplies to both Yuba Water member units and downstream water users.

Flood-management-focused projects like the 500-year Flood Protection Project and levee improvements would be cumulatively beneficial for flood-protection both within the Yuba River region and along the Feather River. The Proposed Projects would not reduce the flood related benefits of any of the flood protection programs. These projects would be cumulatively beneficial to flood protection and water supply.

5.6.1.3 Proposed Projects Cumulative Condition Impact Determinations

YRDP Cumulative Impact SW-PP-1: Impacts to surface water resources

Under the cumulative condition, including the Proposed Projects, the cumulative impact to surface water resources would be less than significant for the reasons above. The Proposed YRDP Project would result in a **less than significant cumulative impact** to surface water resources.

Narrows Cumulative Impact SW-PP-1: Impacts to surface water resources

Under the cumulative condition, including the Proposed Projects, the cumulative impact to surface water resources would be less than significant for the reasons above. The Proposed Narrows Project would result in a **less than significant cumulative impact** to surface water resources.

5.6.2 Cumulative Condition with Alternative 1 compared to the Existing Condition

5.6.2.1 Cumulative Impacts on Surface Water Resources Resulting from Construction Activities

Construction activities planned under Alternative 1 do not differ from those planned under the Proposed Projects. Therefore, the assessment of the Proposed Projects cumulative impacts above applies also to the cumulative impacts of construction under Alternative 1.

5.6.2.2 Cumulative Impacts on Surface Water Resources from Operations

Since Alternative 1 is very similar to the Proposed Projects, the effect of projects considered for the surface water resource cumulative impacts analysis, when combined with Alternative 1, would be similar as when combined with the Proposed Projects. Accordingly, the assessment of effects of other projects considered in the surface water resources cumulative analysis with Alternative 1 operations would be consistent with the discussion under the Proposed Projects cumulative analysis above.

5.6.2.3 Alternative 1 Cumulative Condition Impact Determinations

YRDP Cumulative Impact SW-Alt1-1: Impacts to surface water resources

Under the cumulative condition, including Alternative 1, the cumulative impact to surface water resources would be less than significant. The YRDP Alternative 1would result in a **less than significant cumulative impact** to surface water resources.

Narrows Cumulative Impact SW-Alt1-1: Impacts to surface water resources

Under the cumulative condition, including Alternative 1, the cumulative impact to surface water resources would be less than significant. The Narrows Project Alternative 1 would result in a **less than significant cumulative impact** to surface water resources.

5.6.3 Cumulative Condition with Alternative 2 compared to the Existing Condition

5.6.3.1 Cumulative Impacts on Surface Water Resources Resulting from Construction Activities

Construction activities planned under Alternative 2 do not differ from those planned for the YRDP Relicensing Project under the Proposed Projects scenario. Therefore, the assessment of the Proposed Projects cumulative impacts above applies also to the cumulative impacts of construction under Alternative 2.

5.6.3.2 Cumulative Impacts on Surface Water Resources from Operations

Changes in operations of the YRDP under the Cumulative Condition (Alternative 2) scenario relative to the Existing Condition scenario are essentially equivalent to those described for the Alternative 2 scenario vs Existing Condition scenario. Accordingly, implementation of changes in flow requirements in YRDP reaches and in reaches upstream of the YRDP are reflected in the previously discussed Alternative 2 vs Existing Condition comparison.

Since Alternative 2 represents an alternative to the HR&L program, they would not both be implemented. But other projects considered under Cumulative Conditions for surface water resources could still be implemented.

If Alternative 2 were implemented for the Yuba River, it is likely it would be similarly implemented on other tributaries throughout the state. The combination of Alternative 2 with similar operations on other tributaries would likely result in widespread reductions in water supply to water users throughout the state, increasing the potential impact on water supply.

Alternative 2 would result in potentially significant impacts on water supply deliveries to Yuba Water member units and on Yuba Accord water transfers. Those same impacts would be expected to remain under Cumulative Conditions (Alternative 2). Yuba Water would cease water transfer operations under Alternative 2, and it is likely other water transferors would similarly elect not to transfer water if conditions similar to Alternative 2 were implemented in their watersheds. Thus, the combination of Alternative 2 with similar operations on other tributaries would likely result in substantial reductions in water transfers throughout California, potentially increasing the potential impacts.

As described in Section 5.5.6 and 5.5.7, the Narrows Project has a relatively small role in managing flows, and its operations would not vary substantially from those under Existing Condition, or otherwise in lieu of Alternative 2.

5.6.3.3 Alternative 2 Cumulative Condition Impact Determinations

YRDP Cumulative Impact SW-Alt2-1: Impacts to surface water resources

Under the cumulative condition, including Alternative 2, the cumulative impact to surface water resources would be significant. The YRDP Alternative 2's incremental contribution to the cumulative impact to surface water resources would be cumulatively considerable. There is no potential mitigation for the potential cumulative impacts, the YRDP Alternative 2 would result in **a significant and unavoidable cumulative impact** to surface water resources.

Narrows Cumulative Impact SW-Alt2-1: Impacts to surface water resources

Under the cumulative condition, including Alternative 2, the Narrows Project Alternative 2's incremental contribution to the cumulative impact of Surface Water Resources would not be cumulatively considerable. The Narrows Project Alternative 2 would result a **less than significant cumulative impact** to surface water resources.

CHAPTER 6

GROUNDWATER RESOURCES

6.1 Introduction

This section describes the groundwater conditions in the North Yuba and South Yuba Subbasins of the Sacramento Valley Groundwater Basin (Yuba Subbasins), identifies the regulatory context and policies related to groundwater resources, and evaluates potential direct, indirect, and cumulative groundwater impacts of the Proposed Projects and alternatives.

6.2 Environmental Setting

The information provided below reflects the current environmental setting and affected environment in the Yuba Subbasins that may be influenced by implementation of the Proposed Projects. This discussion is limited to the Yuba Subbasins as this area is potentially impacted by changes in surface water availability for diversion for agricultural use due to Proposed Projects-related changes in Yuba River streamflow. Reduction in surface water diversions often results in increases in groundwater pumping, which can create impacts. Groundwater resources in other areas along the Yuba River are not impacted as there are no major surface water diversions that could be impacted by changes in Yuba River streamflow.

6.2.1 Yuba Subbasins

This section describes the boundaries of the Yuba Subbasins for groundwater resources and the environmental setting/affected environment. More detailed information on the environmental setting can be found in the Yuba Subbasins Groundwater Sustainability Plan (GSP) (YCWA 2024a) as well as Hydrogeologic Understanding of the Yuba Basin (Hydrogeologic Understanding Report [HUR]) (YCWA 2008) and Groundwater Management Plan (YCWA 2010).

The Yuba Subbasins are the groundwater subbasins underlying part of Yuba County. The main surface water features are the Yuba, Feather, and Bear Rivers. The Yuba River runs through the Yuba Subbasins, dividing the groundwater system underlying western Yuba County into the North Yuba and South Yuba Subbasins. The GSP defines these two subbasins as follows (YCWA 2024a):

> *North Yuba Subbasin (Basin Number 5-021.60) encompasses approximately 94 square miles (60,323 acres) in the eastern central portion of the Sacramento Valley Groundwater Basin. It is bounded on the west by the Yuba-Sutter County line, on the south by the Yuba River, on the east by the Sierra Nevada foothills, and on the north by the boundary between Butte-Yuba County line, except where Ramirez Water District's northern boundary is located north of the Butte-Yuba County line, in which case the northern boundary of Ramirez Water District is the subbasin's northern boundary.*
>
> *South Yuba Subbasin (Basin Number 5-021.61) encompasses approximately 170 square miles (108,886 acres) directly south of the North Yuba Subbasin. It is bounded on the west*

by the Yuba-Sutter County line, on the north by the Yuba River, on the east by the Sierra Nevada foothills, and on the south by the boundary between Yuba County and both Sutter County and Placer County, except where Dry Creek Mutual Water Company's southern boundary is located south of the Sutter-Yuba County line, in which case the southern boundary of Dry Creek Mutual Water Company is the subbasin's southern boundary.

The Yuba Subbasins form a portion of the larger Sacramento Valley Groundwater Basin (Sacramento Basin). However, the two subbasins are partially hydraulically separated from the rest of the Sacramento Basin by the Feather River, the Bear River, and Honcut Creek. The North Yuba and South Yuba Subbasins are believed to not be hydraulically isolated from each other by the Yuba River except near the surface. Since the underlying geology of the two subbasins is similar, the description of the geologic setting below treats the North Yuba Subbasin and South Yuba Subbasin as if they were one larger subbasin.

For many years, groundwater has been an important source of water supply to Yuba Water Member Units and other local water purveyors. The Member Units are Brophy Water District (BWD), Browns Valley Irrigation District (BVID), Cordua Irrigation District (CID), Dry Creek Mutual Water Company (DCMWC), Hallwood Irrigation Company (HIC), Ramirez Water District (RWD), South Yuba Water District (SYWD), and Wheatland Water District (WWD). The boundaries of the eight Member Units are depicted in Figure 6.2-1. There are five local water purveyors: California Water Service (serving the City of Marysville), Olivehurst Public Utility District (OPUD), Linda County Water District, City of Wheatland, and Beale Air Force Base (AFB) Figure 6.2-1.

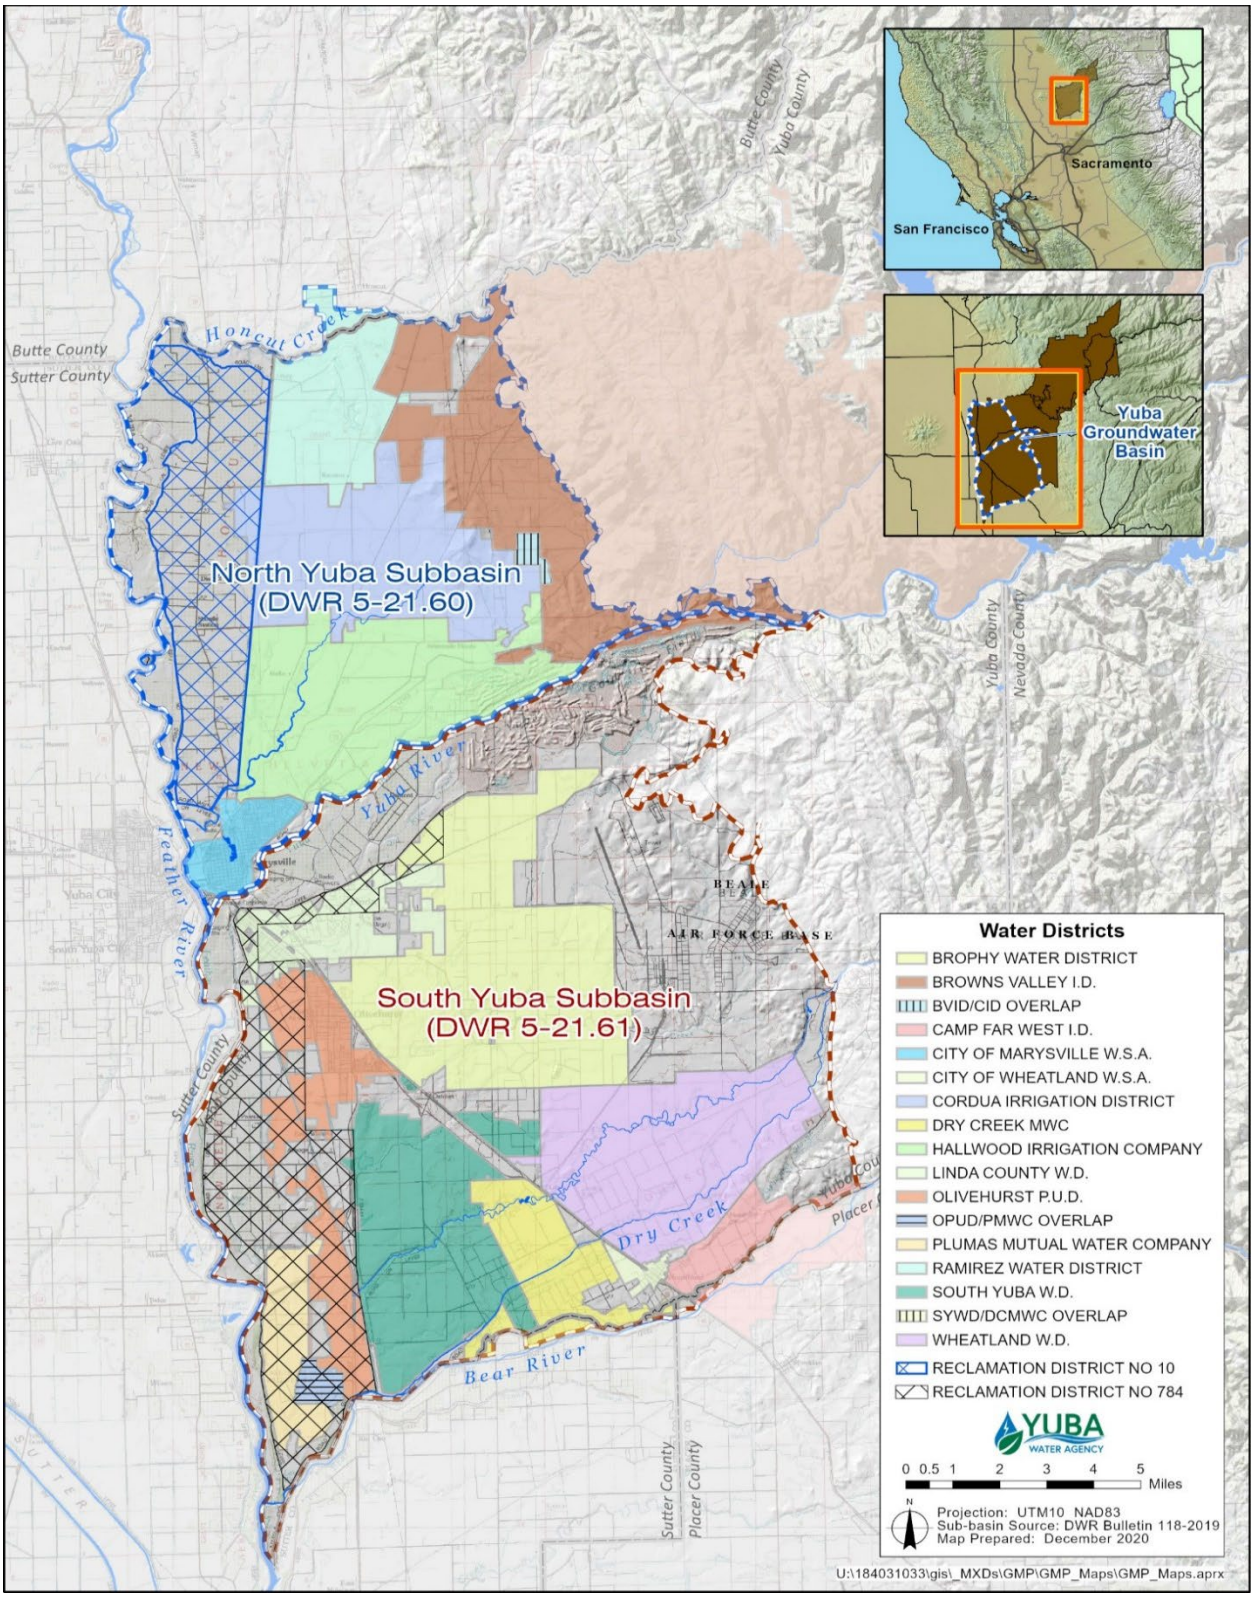

Figure 6.2-1. North Yuba and South Yuba Groundwater Subbasins and Local Water Purveyors.
Source: YCWA 2024a.

6.2.2 Hydrogeology of the Yuba Subbasins

This section presents a brief overview on geology and hydrology of the Yuba Subbasins, which lie at the base of the Sierra Nevada Foothills and form a portion of the Sacramento Valley Groundwater Basin. Sources used to describe the geology of the Yuba Subbasins are the Yuba Subbasins GSP (YCWA 2024a); Hydrogeologic Understanding of the Yuba Basin (YCWA 2008); DWR's Bulletin 118 (1978 and 2003 Update) (DWR 2003); the California Department of Conservation, Division of Mines and Geology, Chico Quadrangle Topology Map (Saucedo and Wagner 1992); and several US Geological Survey publications (Harwood and Helley 1987; Olmstead and Davis 1961; and Page 1974, 1980, and 1986). For more detailed information, please refer to these documents. The geologic and hydrogeologic setting in the Yuba Subbasins ranges from young alluvial deposits that store and transmit groundwater to underlying continental formations that do not store or yield a significant amount of groundwater.

6.2.2.1 Primary Groundwater-Bearing Formations

Primary water-bearing formations include surface basin deposits and the Older Alluvium (Modesto/Riverbank), Laguna, and Mehrten formations, which comprise the majority of the Yuba Subbasin alluvial aquifer system.

6.2.2.1.1 Surface Basin Deposits

Surface deposits occur at or near the ground surface and are composed of stream channel and floodplain deposits, and dredger tailings, along the present-day stream channels of the Yuba, Bear, and Feather Rivers and Honcut Creek, and within the incised channels of the smaller drainages. Surface geology for the Yuba Subbasins consists mainly of alluvial valley sediments that gradually increase in thickness toward the west. The recent alluvial deposits are mainly highly permeable, coarse-grained gravels containing boulders and rounded cobbles as well as sands, and can be up to 110 feet thick. The high permeability of these stream channel deposits allows them to act as a large recharge area. Reported well yields within these deposits are from 2,000 to 4,000 gallons per minute (gpm) (DWR 2003).

The dredger tailings extend downstream from the Sierra Nevada Foothills along the Yuba River for 15 miles and are large piles of very coarse gravels and cobbles. These piles have been dredged for gold and range in thickness between 60 feet to 80 feet in the eastern area, and 100 feet to 125 feet in the west (DWR 2003). These materials are highly permeable.

6.2.2.1.2 Modesto/Riverbank Formations

The older floodplain deposits of the Modesto Formation lie above the recent alluvium and create a 1- to 2-mile-wide band of terraces on both sides of the Feather River. The Modesto Formation and the older Riverbank Formation also form terraces along the banks of the smaller drainages, including Reeds Creek, Dry Creek, and Jack Slough, which are filled with recent alluvium (Saucedo and Wagner 1992).

6.2.2.1.3 Laguna Formation

Compared to the other formations located in the Yuba Subbasins, the Laguna Formation is the thickest and most extensive water-bearing formation (YCWA 2008). This formation is exposed

along the eastern boundary. It is also exposed in isolated hills between Beale AFB and WWD, where thin, surrounding younger sediments allow the Laguna Formation to be exposed in "windows." Farther west, the formation is found only in deep wells. This formation consists of a heterogeneous mix of generally poorly sorted clay, silt, sand, and gravel. Specifically, in the Sacramento Valley, the Laguna Formation contains abundant beds of somewhat clayey silt to silty fine sand, some well-sorted sand in relatively thin zones, and scarce, poorly sorted gravel beds (Page 1986).

6.2.2.1.4 Mehrten Formation

The Mehrten Formation is an important source of fresh groundwater in the Central Valley. This sequence of volcanic rocks was deposited in the late Miocene through Pliocene ages. In the Sacramento Valley, the formation consists of two general units: (1) an overlying unit composed of unconsolidated black sands interbedded with blue-to-brown clay and (2) an underlying unit of hard, very dense tuff-breccia. The black sands are well-sorted, commonly found in beds of about 6 feet to as much as 20 feet thick and yield good volumes of water. The tuff-breccias yield little water, although large yields have been obtained beneath the unit from partially confined systems (DWR 1978).

The Mehrten Formation ranges from 190 feet to 500 feet thick (Page 1986; Helley and Harwood 1985). Surficial exposures of this unit are limited to a few square miles in the northeast corner of the Yuba Subbasins, dipping to the west and extending to great depths (Saucedo and Wagner 1992). Generally, the Mehrten Formation yields large quantities of water to wells, although hydraulic conductivity in the Mehrten (the ease with which water moves through pore spaces) varies from place to place (Page 1986).

These groundwater-bearing formations are underlain by geologic deposits and formations that do not store or produce groundwater. Those include Eocene and Cretaceous Rocks and Sierra Nevada Basement Rocks.

6.2.2.2 Groundwater Flow Conditions, Recharge, and Discharge

Groundwater occurs within unconfined, semi-confined, or confined conditions throughout the Yuba Subbasins. Well drillers' reports for deeper wells show changes in groundwater levels with depth, suggesting that groundwater is possibly confined or semi-confined by overlying clay layers. The degree of confinement appears to increase with depth based on drillers' logs and water level data. Aquifer tests suggest semi-confined or confined conditions at depths exceeding approximately 100 feet (Woodard & Curran 2022). Figure 6.2-2 shows a recent interpretation of groundwater elevations in the Yuba Subbasins based on groundwater elevation data collected by Yuba Water and DWR in March 2023, representing spring or seasonal high conditions (YCWA 2024b). Based on the interpreted spring 2023 groundwater elevation conditions shown, the general flow of groundwater in the Yuba Subbasin is in a southwesterly direction from the Sierra Nevada foothills in the east, either flowing into the Sutter Subbasin to the west, discharging to the Feather River, or flowing toward small pumping depressions near Highway 70, with a groundwater surface that is a subdued representation of topography. Like the topography, the hydraulic gradient is relatively steeper in eastern portions of the Yuba Subbasins and gradually flattens toward the west.

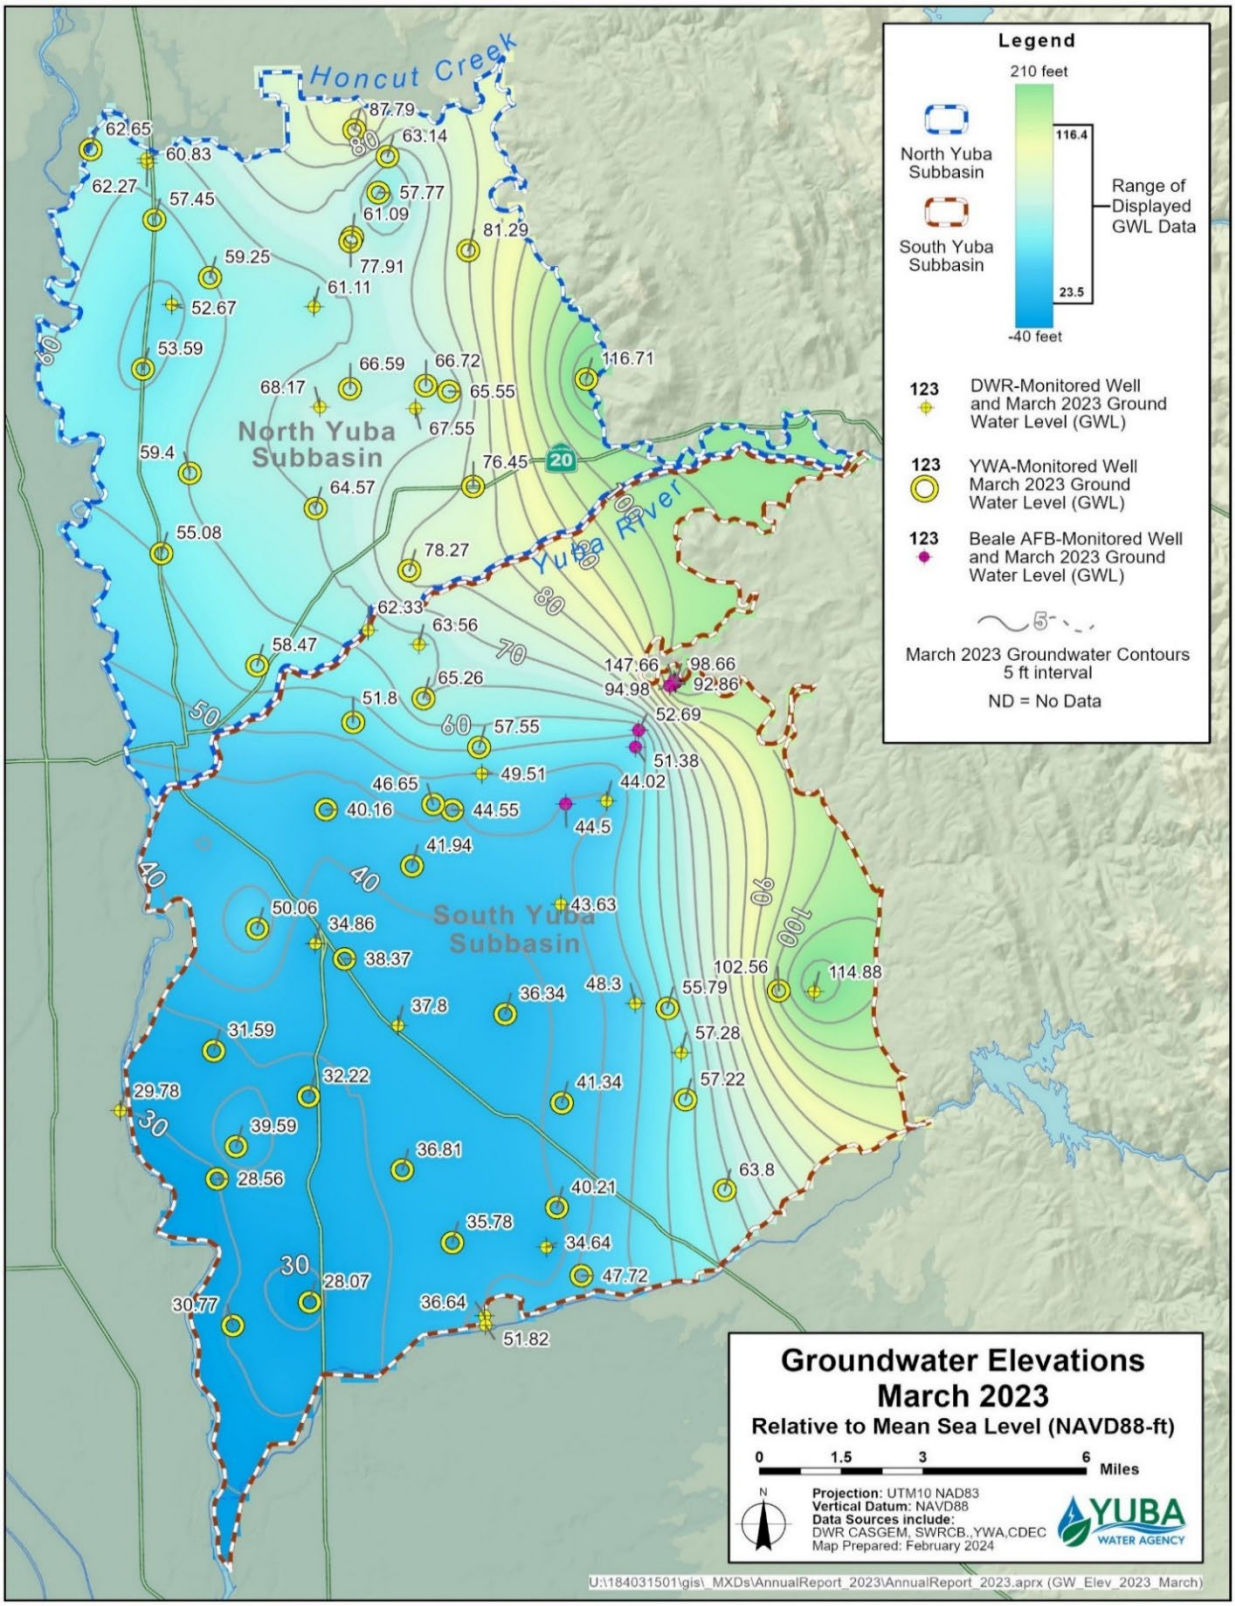

Figure 6.2-2. Spring 2023 Groundwater Elevations in the North and South Yuba Subbasins.
Source: YCWA 2024b.

As a result of hydraulic mining between 1852 and 1884, the Yuba River was filled with more debris than all the other tributaries of the Sacramento River combined. The 684 million cubic yards of gold-bearing material that washed into the Yuba River represent more than triple the volume of earth excavated during the construction of the Panama Canal (Bezerra and West 2005). Efforts to manage the debris included the 1899 Project, which included, among other components, the storage of mining debris in the Yuba River and the construction of training walls to confine the river channel within well-defined limits (USACE 1981).

The Yuba Goldfields, an area within the Yuba Subbasins known for historical gold dredging operations, is a location of substantial groundwater recharge in the Yuba Subbasins (Figure 6.2-3). This recharge is attributed to several mechanisms, including the following:

- large piles of coarse gravels and cobbles with high transmissivity and capacity for storage in the present Yuba River channel and Yuba Goldfields;
- the deep original river channel in the metavolcanic bedrock and groundwater flow occurrence between the bedrock and coarse gravel lenses; and
- the occurrence of high winter flow in the Yuba River, recharging groundwater in the Yuba Goldfields.

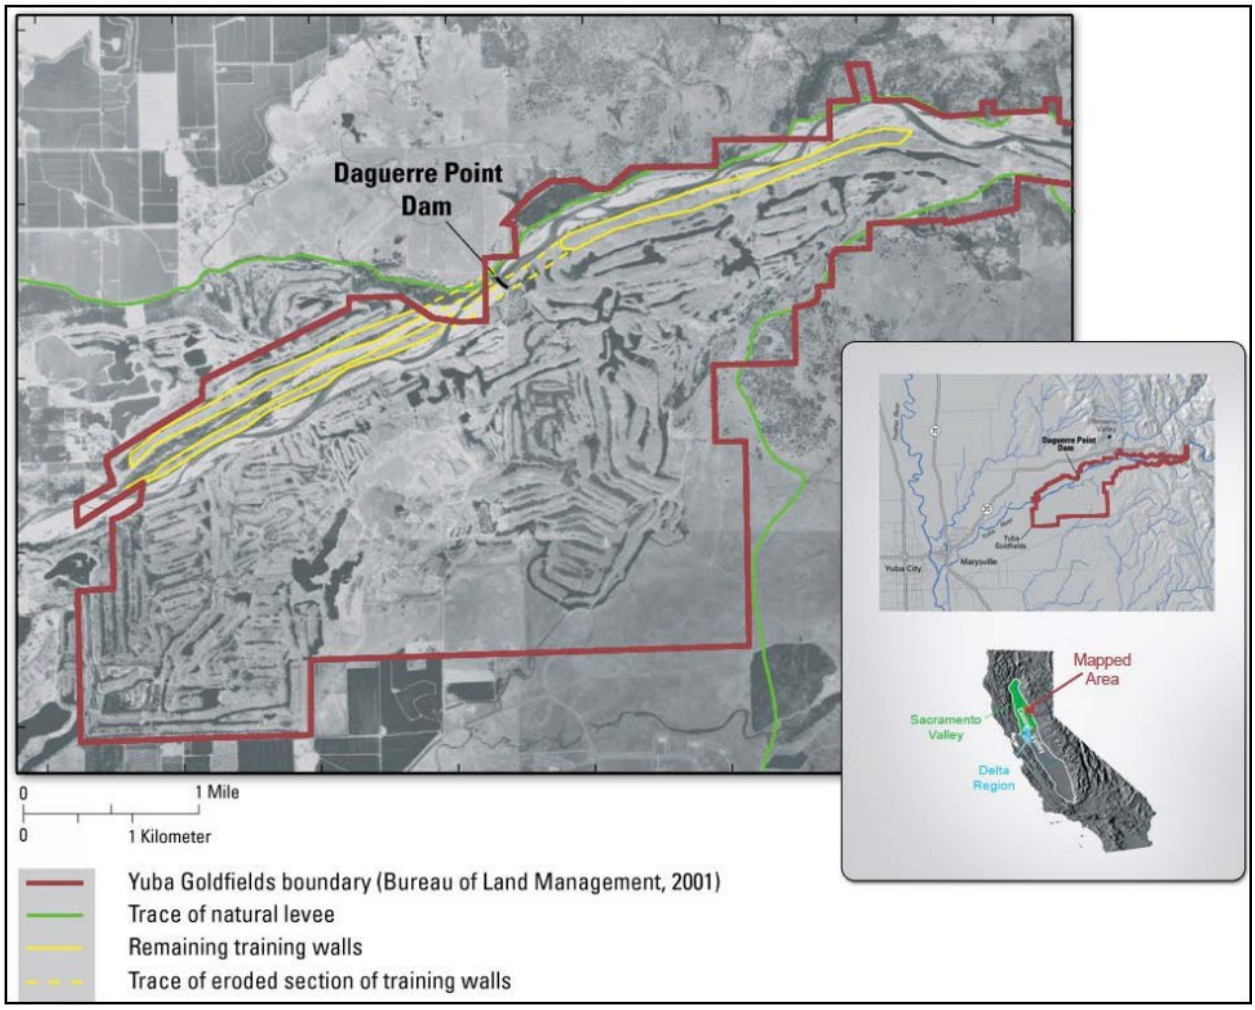

Figure 6.2-3. Location of Yuba Goldfields.
Source: YCWA 2024a

6.2.2.3 Groundwater Storage Conditions

The total volume of freshwater within the Yuba Subbasins is estimated to be 5 million acre-feet, extending to depths between 200 to 900 feet below ground surface (YCWA 2024a).

The estimated volume of freshwater in the Yuba Subbasins should be interpreted cautiously because the volume does not represent the usable amount of groundwater. The usable volume of groundwater in the Yuba Subbasins is generally assumed to extend to 200 feet below ground surface, even though some wells extend to much greater depth. Groundwater levels within the basin are managed within a safe range well within the upper extents of usable groundwater to avoid negative impacts such as dewatering existing production wells, significantly increasing operational cost of groundwater extraction, and significantly decreasing groundwater quality or quantity.

Groundwater level and storage conditions are managed through the Yuba Subbasins GSP's sustainable management criteria for groundwater levels. The sustainable management criteria include minimum thresholds for 31 representative monitoring wells in the Yuba Subbasins. Exceedance of the minimum threshold at more than 25 percent of the representative monitoring

wells for two consecutive years is considered an undesirable result. Yuba Water, as the implementing GSA, must avoid undesirable results. 26 of the 31 representative monitoring wells have minimum thresholds of 75 feet below ground surface. The remaining 5 representative monitoring wells have minimum thresholds of between 84 and 132 feet below ground surface. Since adoption of the Yuba Subbasins GSP in January 2020, no minimum thresholds have been exceeded at any of the representative monitoring wells.

Additionally, the GSP includes a threshold at the same or higher elevation than the minimum thresholds, termed local management levels. The local management level represents the lowest groundwater levels that are locally desired. Distinct from the minimum threshold, these non-regulatory levels may be higher than levels that would constitute "significant and unreasonable results" under SGMA (i.e., the regulatory "floor" established under SGMA). These local management levels guide adaptive management in the Yuba Subbasins and provide a level of protection to help avoid undesirable results.

Additional information on the GSP is provided in Section 6.3.1.1.

6.2.2.4 Local Groundwater Usage

Use of groundwater for irrigation in the Yuba Subbasins had been generally stable for decades, while the smaller municipal groundwater use has developed gradually as the need for water has increased with modest urban growth. Currently, Yuba Water has water service agreements to deliver surface water to its Member Units from the lower Yuba River as part of the YRDP. Yuba Water provides water to its Member Units representing 79,950 gross acres (YCWA 2021). Landowners within the Member Units have existing capacity to pump groundwater to meet a portion of their demands. More than 200 production wells are located within the Member Units' service areas. Five municipal purveyors located within the Yuba Subbasins (California Water Service [serving the City of Marysville], OPUD, Linda County Water District, City of Wheatland, and Beale AFB) rely on groundwater to meet all of their municipal and industrial water demands. Currently, approximately 33 production wells are operated by these municipal purveyors. Groundwater also supplies all private potable users within the Yuba Subbasins. Other water purveyors in Yuba County outside of the Yuba Subbasins use combinations of groundwater and surface water supplies to meet their demands.

Figure 6.2-4 and Figure 6.2-5 show groundwater production from Water Year (WY) 1991 to 2023 together with the annual and cumulative change in storage from WY 1961 to 2023 (YCWA 2024b). In WY 2023 (October 2022 to September 2023), the North Yuba Subbasin saw an increase of groundwater in storage of approximately 23,000 acre-feet (AF) and the South Yuba Subbasin saw an increase of groundwater in storage of approximately 57,000 AF. These increases are largely due to the wet conditions in WY 2023, which followed drier years; the reduced groundwater use and increased recharge during WY 2023, compared to earlier years, resulted in the increase in groundwater in storage. Cumulative change in storage since WY 1961 was approximately -1,000 AF and +182,000 AF by WY 2023 in the North Yuba and South Yuba Subbasins, respectively. Between WY 1991 and 2023, groundwater production in the North Yuba Subbasin ranged from 37,831 AF in WY 2012 to 90,458 AF in WY 2001. During the same time period, groundwater production in the South Yuba Subbasin ranged from 71,139 AF in WY 2023 to 159,044 AF in WY

1991. This represents long-term stable conditions in the North Yuba Subbasin and long-term improvement in conditions in the South Yuba Subbasin.

Historically, irrigation demands in most of the North Yuba Subbasin have been sufficiently supplied by diversions from the Yuba River. An exception is RWD, which relied substantially on groundwater until surface water deliveries began in 1978. In addition to the surface water received from Yuba Water under its water rights, HIC, CID, and BVID also divert water supplies under their own water rights on the lower Yuba River. Farmers in Reclamation District 10, in the western portion of the North Yuba Subbasin, use groundwater as their primary source of water for irrigation.

In the South Yuba Subbasin, surface water supplies were historically limited. Agricultural and urban water users in this area relied heavily on groundwater supply until 1983 when Yuba Water began to provide Yuba River water, through the Yuba Main Canal, to BWD and SYWD. In 1998, DCMWC started receiving surface water from Yuba Water. In 2010, following completion of the Yuba Wheatland Canal Project, Yuba Water began delivering surface water to WWD, which allowed WWD to reduce its groundwater pumping, thereby providing in lieu recharge of the Subbasin. Plumas MWC diverts water from the Feather River under a settlement agreement with DWR. BWD, SYWD, DCMWC, and WWD currently receive surface water from the Yuba River, while areas not served by agricultural water purveyors rely fully on groundwater.

Figure 6.2-6 and Figure 6.2-7 show historical groundwater elevation data (hydrographs) for the North Yuba and South Yuba Subbasins, respectively. Figure 6.2-6, for the North Yuba Subbasin, shows that, in general, groundwater levels in this subbasin were not drawn down extensively because of the historical surface water supply to the Member Units in this area. Figure 6.2-7 suggests that, prior to the delivery of surface water to the Member Units, groundwater pumping resulted in declining groundwater levels throughout the South Yuba Subbasin, and in some areas, groundwater depressions were evident. Since the delivery of surface water to the Member Units began in 1983, groundwater elevations have risen to historical high levels in some areas and have exceeded historical high levels in other areas. Surface water deliveries have a significant effect on groundwater levels. Since the early 1980s, groundwater levels have increased by approximately 100 feet in some areas.

Groundwater pumping capacity through private groundwater wells exists within the Member Units primarily as a result of historical needs for groundwater supplies prior to current levels of surface water deliveries and, to a lesser degree, to support groundwater substitution transfers. The groundwater pumping capacity within the Member Units was estimated as 120,000 AF in 2007 (YCWA 2007). Since that time, WWD began receiving surface water deliveries. The pumping capacity within WWD can be estimated by its highest annual pumping during subsequent groundwater substitution transfers: 11,500 AF in 2009. Thus, the combined pumping capacity within the current Member Units is an estimated 131,500 acre-feet per year (AFY).

6.2.3 Hydrogeology East of the Yuba Subbasins

Groundwater in the eastern portion of the county, east of the alluvial Yuba Subbasins, occurs in fractured bedrock. Unlike alluvial aquifers, in fractured bedrock, groundwater is stored or transmitted only through the fractures. The quantity of storage or flow depends on the size and location of fractures, interconnection of fractures, and amount of material that may be clogging the fractures. Fractures make up a small percentage of rock volume, so the total storage and flow is typically small in these systems (DWR 2004). Groundwater use in this portion of the county is typically low, primarily small domestic wells, in contrast to larger agricultural and public water supply wells within the Yuba Subbasins.

6.2.4 Local Groundwater and Surface Water Interactions

The main surface water features in the Yuba Subbasins are the Yuba, Feather, and Bear Rivers. The North Yuba Subbasin is bounded on the north by a smaller surface water feature, Honcut Creek. Other surface water bodies and wetland communities, such as surface-ponding vernal pools and groundwater dependent ecosystems (GDEs), are present in the Yuba Subbasins (CDFW 2024 and YCWA 2024a, respectively), as described below.

The Yuba River, running between the North Yuba and South Yuba Subbasins, plays an important role in resource management and planning, including flood management, power generation, water quality, fisheries, and recreation. The upper reach of the portion of the Yuba River within the Yuba Subbasins, generally upstream of Daguerre Point Dam, is an important recharge zone for the Yuba Subbasins. The Feather River is a principal tributary of the Sacramento River, flowing through Butte County and between Yuba and Sutter Counties. It drains part of the northern Sierra Nevada Mountains and a small portion of the middle part of the Sacramento Valley. Honcut Creek is a major tributary to the lower Feather River, flowing between Butte and Yuba Counties. Downstream from the confluence with Honcut Creek, the lower Feather River meets with the Yuba River at Marysville. Further downstream, the lower Feather River meets with the Bear River along the southern boundary of the South Yuba Subbasin.

Interconnected surface waters are surface water features that are hydraulically connected by a continuous saturated zone to the underlying aquifer. In other words, interconnected surface waters exist where groundwater table elevations and surface water features intersect at the same elevations and locations. Within the Yuba Subbasins, all surface water systems are thought to be interconnected with at least shallow groundwater (YCWA 2024a). Interconnected surface waters are classified as either gaining or losing, meaning the surface water feature is either gaining water from groundwater or losing water into groundwater, with that relationship potentially variable over time.

The interaction between groundwater and surface water within the Yuba Subbasins is analyzed through use of the Yuba Groundwater Model (YGM) (YCWA 2019) as documented in Appendix 6A. As in most of California, the direct measurement of the gain or loss to groundwater from surface water bodies is not feasible in the Yuba Subbasins. The YGM provides information to characterize the interconnected surface water system. Each stream node in the YGM is characterized by model output as either gaining, losing, or mixed, as shown in Figure 6.2-8 (YCWA 2024a).

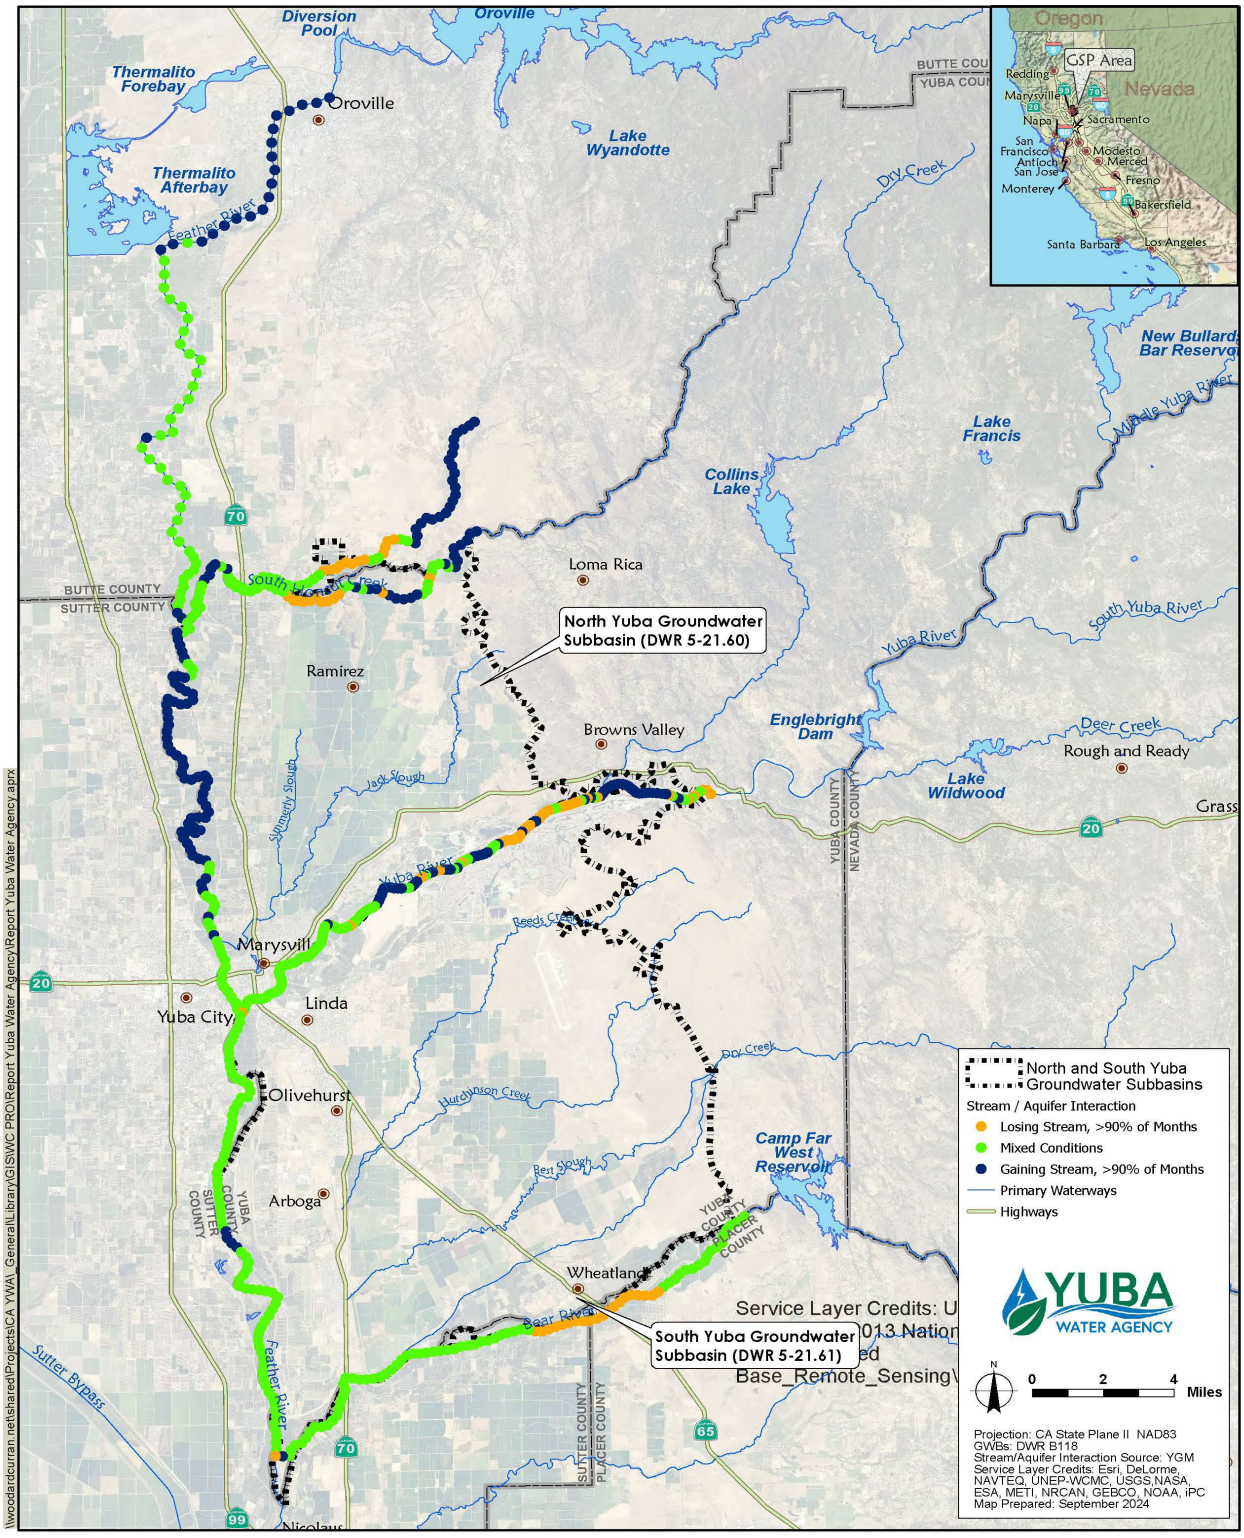

Figure 6.2-8. Gaining and Losing Portions of Major Rivers, Based on YGM Output.
Source: YCWA 2024a

The node is considered gaining if model output indicates that the reach experiences net gaining conditions during 90 percent of all modeled simulated months under historical conditions and considered losing if model output indicates net losing conditions during 90 percent of all months. All other nodes are classified as mixed. Details on inflows, losses, and gains from each major river in the Yuba Subbasins are provided below, with values presented as average annual volumes based on YGM output reported in the Yuba Subbasins GSP (YCWA 2024a).

6.2.4.1 Surface Water-Ponding Vernal Pools

In addition to the rivers, surface water-ponding vernal pools are located in the local study area. Locations of the vernal pools are available from CDFG based on California Natural Diversity Database (CNDDB). In general, the vernal pools found in the study area do not depend upon groundwater to maintain pool levels (Williamson et al. 2005) but instead are recharged by direct precipitation and surface water flows (e.g., agricultural). Groundwater pumping associated with implementation of the Proposed Projects would not affect these resources.

6.2.4.2 Groundwater Dependent Ecosystems

GDEs are defined in the GSP Emergency Regulations as "ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" (California Code of Regulations, Title 23, Section 351(m)). The identification of GDEs was performed as part of the Yuba Subbasins GSP (YCWA 2024a) using the Natural Communities Commonly Associated with Groundwater (NCCAG) database. The NCCAG database was developed by a working group composed of DWR, California Department of Fish and Wildlife, and The Nature Conservancy by reviewing publicly available state and federal agency datasets that mapped California vegetation, wetlands, springs, and seeps and by conducting a screening process to retain types and locations commonly associated with groundwater. The results were compiled into the NCCAG database with two habitat classes defined. The first class includes wetland features commonly associated with the surface expression of groundwater under natural, unmodified conditions. The second class includes vegetation types commonly associated with the surface presence of groundwater (i.e., phreatophytes). Steps taken to identify GDEs based on the NCCAG dataset are detailed in the Yuba Subbasins GSP (YCWA 2024a).

The Yuba Subbasins GSP includes an examination of GDEs and the potential impacts from groundwater pumping within the basin. The GSP concluded that groundwater pumping for all purposes would be unlikely to affect GDEs primarily because wells in the basin are generally pumping the deeper aquifer, GDEs are supported by shallow groundwater, and "deep pumping" has limited impacts on shallow groundwater conditions. The GSP determined that the shallow groundwater system is mostly driven by river stage and likely with some contributions from nearby irrigated agriculture (YCWA 2024a).

6.2.5 Local Groundwater Quality

Groundwater throughout the Yuba Subbasins has relatively consistent water quality characteristics and meets local needs for municipal, domestic, and agricultural uses (YCWA 2024a). While small drinking water systems or large public drinking water systems in Yuba County are able to meet regulatory requirements for water quality, system operators often have a plan or manage around a

few water quality issues. There is naturally occurring arsenic, iron, and manganese that may exceed the Maximum Contaminant Level or Secondary Maximum Contaminant Levels. Such concentrations may be addressed through filtration, reverse osmosis, or blending, or may not be used for potable uses. Exceedances may be caused by localized conditions and may not be reflective of regional water quality. As an alternative to treatment or blending, wells can be drilled to different depths or at different locations to avoid lower quality water. Further, like most of the Central Valley, the Yuba Subbasins are at risk of increasing salt and nutrient conditions largely due to agricultural and urban uses of water. Currently, salt and nutrient concentrations are good across the majority of the Yuba Subbasins, although shallow groundwater conditions are isolated areas may have higher concentrations.

Figure 6.2-9 presents the estimated base of freshwater in the Yuba Subbasins, below which groundwater above is generally fresh (low salinity) and groundwater below is generally saline (YCWA 2024a). The base of freshwater surface generally follows the underlying basement structure and dips (increase in depth) to the west into the Sacramento Valley. It appears to be above Eocene marine strata and is currently within Pliocene to Miocene continental deposits. This is most likely caused by high artesian pressures and upward vertical gradients in deep aquifers in the Yuba Subbasins. This suggests that migration of poor-quality water into continental sediments that previously contained freshwater has occurred over geologic time. Based on water chemistry data, the brackish water in the lower part of aquifers near the base of freshwater is classified as sodium-chloride type water. The presence of brackish water in the deeper aquifer combined with upward vertical gradients presents the potential for upward migration of brackish water into overlying freshwater aquifers, or upconing beneath areas of pumping. Prolonged groundwater extraction in these areas may result in regional groundwater quality degradation and may ultimately reduce the thickness of the freshwater aquifers in the Yuba Subbasins.

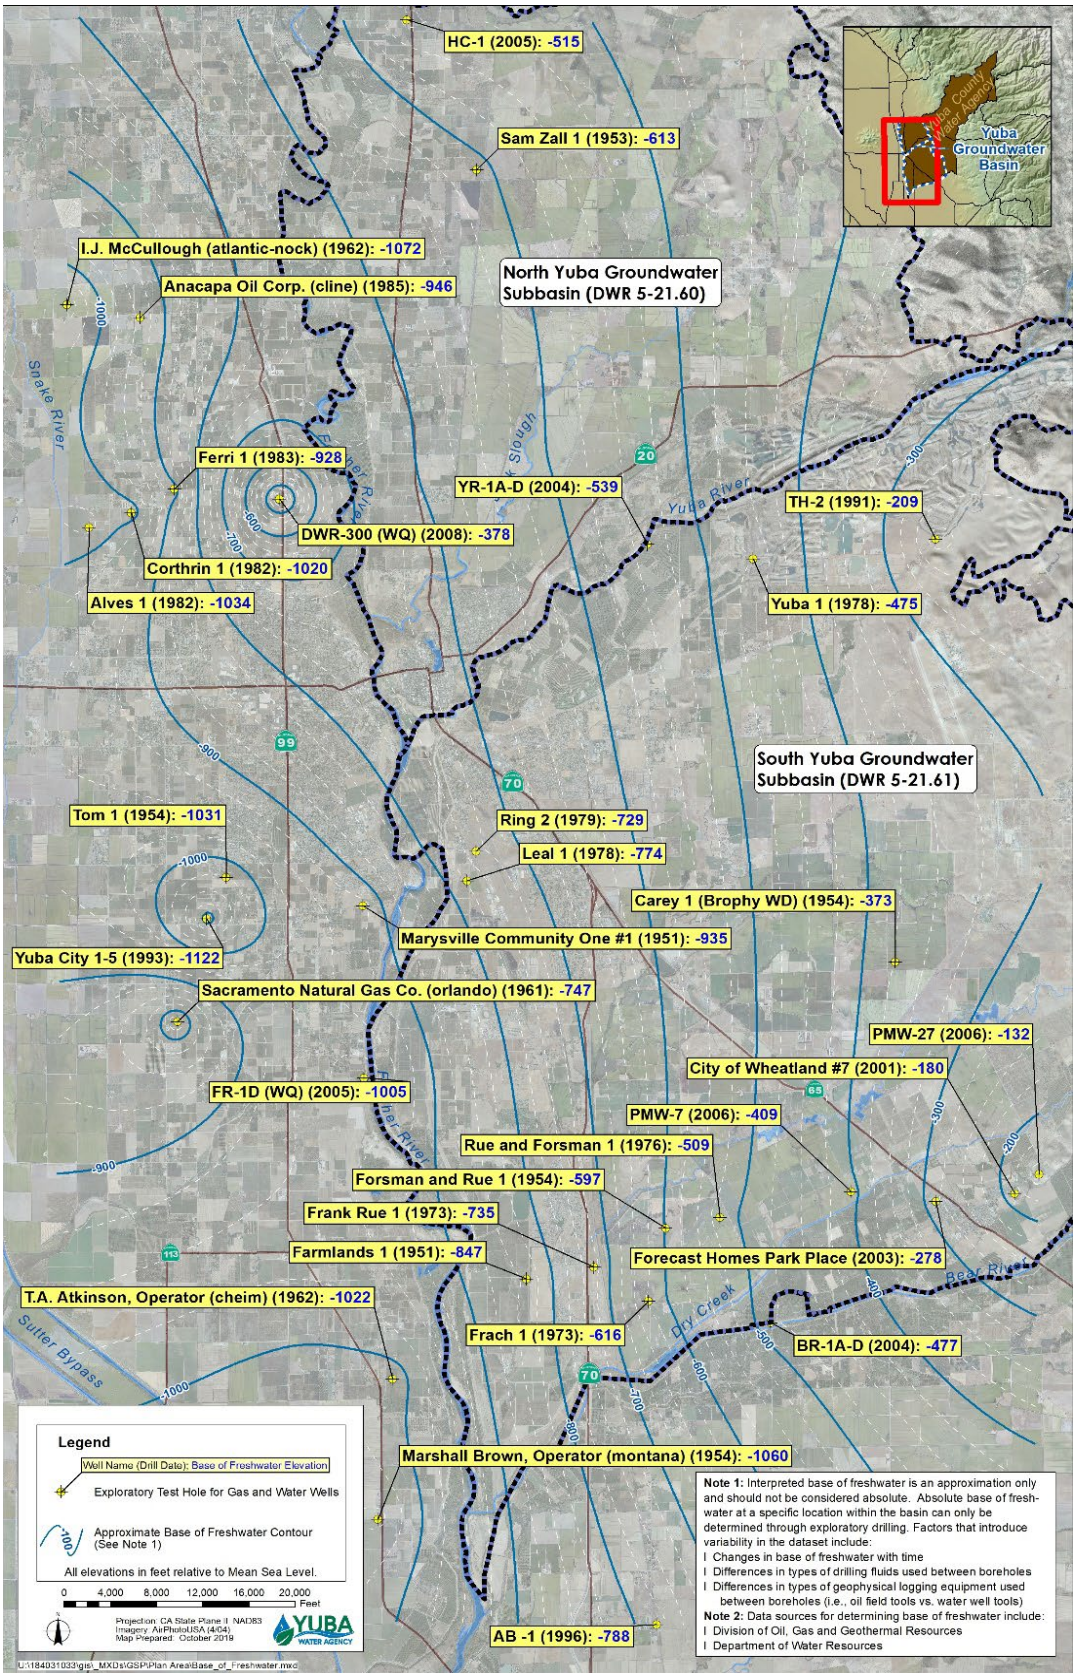

Figure 6.2-9. Base of Freshwater in Yuba Subbasins.
Source: YCWA 2024a

6.2.6 Local Land Subsidence

Land subsidence is known to occur due to groundwater extraction, causing the permanent compaction of compressible clays and decline of groundwater levels as well as differential settling of the land surface, resulting in potential infrastructure damage. To date, inelastic land subsidence has not been observed within the Yuba Subbasins and is not considered a major issue, based on historical responses to lowered groundwater levels in the South Yuba Subbasin in the 1980s (YCWA 2024a). If land subsidence were to occur in the future, levees, canals, and pipelines would become vulnerable by reducing the ability to deliver surface water by gravity and reduced ability to convey floodwater.

Yuba Water actively coordinates with DWR to monitor potential land subsidence within the Yuba Subbasins. The National Oceanic and Atmospheric Administration's National Geodetic Survey (NGS) established a subsidence monitoring network that includes 19 NGS monuments in or near Yuba County. This network was increased in size by Yuba Water to add three additional monuments in 2007. The network was intended to be monitored by DWR on a 5- year schedule (YCWA 2010) and was initially surveyed in 2007. DWR was unable to survey the monuments in 2013 due to budgetary limitations but surveyed the monuments in 2018. Results from the 2018 monitoring, shown in Figure 6.2-10, indicate little to no statistically significant land subsidence for the Yuba Subbasin, with all monitored locations in and near the subbasins having subsidence in the lowest category of less than 0.20 feet since 2008 (DWR 2018).

6.3 Regulatory Setting

6.3.1 State

6.3.1.1 Sustainable Groundwater Management Act of 2014

In 2014, in response to continued overdraft of many of California's groundwater basins, the State of California enacted the Sustainable Groundwater Management Act (SGMA), which took effect January 1, 2015. The purpose of SGMA is to help protect groundwater resources and provide local and regional agencies with the authority to manage groundwater in a sustainable manner. SGMA requires local agencies to form groundwater sustainability agencies (GSAs) for high and medium priority basins, as defined under the SGMA 2019 Basin Prioritization (DWR 2020). For such basins, SGMA requires preparation of a GSP by overlying GSAs to reach sustainability within 20 years of implementing their GSPs.

The California Department of Water Resources (DWR) has the authority to provide regulatory oversight through the evaluation and assessment of GSPs. DWR is also charged with providing on-going assistance to GSAs through development of best management practices and guidance, planning assistance, technical assistance, and financial assistance.

DWR has identified the North Yuba Subbasin as a medium-priority subbasin and the South Yuba Subbasin as a high-priority subbasin, with neither subbasin designated as critically over drafted (DWR 2020). These categorizations triggered SGMA requirements for both subbasins to develop their GSPs by January 31, 2022.

The goal of the GSPs is to establish a plan for sustainable management of the groundwater basins. SGMA defines sustainable groundwater management as the management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing one or more of the following undesirable results:

1. Chronic lowering of groundwater levels, indicating a significant and unreasonable depletion of supply
2. Significant and unreasonable reduction of groundwater storage
3. Significant and unreasonable seawater intrusion
4. Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies
5. Significant and unreasonable land subsidence that substantially interferes with surface land uses
6. Depletions of surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water.

If the local groundwater agency's management of the basin causes or fails to correct any of these undesirable results, the State could intervene in the management of groundwater in the Subbasin (YCWA 2024a).

6.3.2 Local

6.3.2.1 Lower Yuba River Accord – Conjunctive Use Agreements

The Lower Yuba River Accord (YCWA 2007), also referred to as the Yuba Accord, comprises three important agreements: Fisheries Agreement, Water Purchase Agreement, and Conjunctive Use Agreements with each Member Unit. The Fisheries Agreement establishes variable instream flow levels to benefit wild salmon and steelhead on the Lower Yuba River. The Water Purchase Agreement creates a long-term water transfer program under which Yuba River water is transferred to other users in California. The eight Conjunctive Use Agreements establish a comprehensive groundwater program in Yuba County to improve overall water supply reliability for local farmers. The following discussion focuses on the Conjunctive Use Agreements based on their relevancy to the Proposed Projects and alternatives.

Yuba Water holds Conjunctive Use Agreements with all eight Member Units to provide long-term water supply reliability, establish a comprehensive stewardship program of surface water and groundwater supplies including improved conservation, efficiency, and conjunctive use measures; and enable conversion of diesel motors to electric motors to improve efficiency and air quality. All Conjunctive Use Agreements were executed in March 2009, with the exception of Cordua Irrigation District, which was executed in January 2021. The Agreements require the implementation of an array of conjunctive use measures and help meet local water supply needs in dry years to facilitate Yuba Water's operation of its storage facilities to meet higher instream flow requirements in the Lower Yuba River, as called for in the Fisheries Agreement, and meet the commitments of transfer water in the Water Purchase Agreement.

Contents of the Conjunctive Use Agreements include:

- Groundwater pumping in Schedule 6 years (including volumes and percent allocation to each Member Unit as well as payment), which requires operation of a groundwater substitution program up to 30,000 acre-feet to supplement storage releases
- Groundwater pumping to implement the Phase 8 Settlement Agreement (including volumes and percent allocation to each Member Unit as well as payment), which refers to the "Short-Term Agreement to Guide Implementation of "Short-Term Water management Actions to Meet Local Water Supply Needs and to Make Water Available to the SWP [State Water Project] and CVP [Central Valley Project] to Assist in Meeting the Requirements of the 1995 Water Quality Control Plan and to resolve Phase 8 Issues" (NCWA 2003)
- Payments for groundwater pumping to mitigate for deficiencies in supplemental water supplies resulting from implementation of the Fisheries Agreement and Water Purchase Agreement
- Groundwater substitution transfer program (including how determining a transfer will occur, payment provisions, and reservation of water for terms of the Fisheries Agreement)

- Conference Years (including determining supplies available and operating plan); where Yuba Water will operate the Yuba River Development Project so that (a) flows in the Yuba River comply with the instream flow requirements for Yuba Water's FERC License, except that Yuba Water will not pursue any of the flow reductions authorized by article 33(c) of that license, plus any additional instream flows agreed to by the River Management Team's Planning Group; and (b) total diversions at Daguerre point Dam do not exceed 250,000 acre-feet per year
- Provisions of the Conjunctive Use Agreement
- Groundwater pumping requirements
- Groundwater Monitoring and Reporting Program/Third-Party Impacts Plan

6.3.2.2 Yuba Water Agency Groundwater Sustainability Plan

The *Yuba Subbasins Water Management Plan: A Groundwater Sustainability Plan* (Yuba Subbasins GSP) was originally adopted by Yuba Water on January 20, 2020, and subsequently approved by the California Department of Water Resources on November 18, 2021. SGMA requires the evaluation and assessment of an approved GSP at least every five years. Yuba Water completed its first evaluation of the GSP and an amended GSP (YCWA 2024a) was adopted by Yuba Water on January 7, 2025, which is presently under review by DWR. Yuba Water Agency GSA is one of three GSAs, along with City of Marysville GSA and Cordua Irrigation District GSA, responsible for development and implementation of the GSP. The purpose of the GSP is to verify and maintain sustainable groundwater management in the North Yuba and South Yuba Subbasins (Bulletin 118 Basin Numbers 5-021.60 and 5-021.61, respectively), collectively referred to as the Yuba Subbasins, by meeting the regulatory requirements set forth in SGMA (California Water Code Sections 10720 – 10737.8). Among other things, the Yuba Subbasins GSP includes identification of the Plan area, a hydrogeologic conceptual model, a description of existing groundwater conditions, water budgets, sustainable management criteria, and identification of monitoring networks, projects, and other management actions for implementation of the GSP.

Since adoption of the original Yuba Subbasins GSP in 2020, Yuba Water Agency GSA, City of Marysville GSA, and Cordua Irrigation District GSA have worked to collaboratively implement the GSP in order to achieve the sustainability goal for the Yuba Subbasins, which is "to maintain a locally managed, economically viable, sustainable groundwater resource for existing and future beneficial use in Yuba County by continuing existing management to maintain operation within the sustainable yield or by modification of existing management to address unforeseen future conditions" (YCWA 2024a). The Yuba Subbasins GSP was approved by DWR with recommended corrective actions that have been addressed in the amended GSP, which was submitted to DWR prior to the January 31, 2025, deadline. Yuba Water continues to implement the GSP through monitoring of conditions, comparing those monitoring results with the sustainable management criteria, reporting the conditions annually to DWR, evaluating the GSP, implementing adaptive management strategies, and funding these activities. Monitoring and management under the GSP are focused on five sustainability indicators: chronic lowering of groundwater levels, reduction of groundwater storage, degraded water quality, land subsidence, and depletions of interconnected surface water.

In addition to being a sustainability indicator, groundwater levels are used as a proxy for the reduction of groundwater storage and depletion of interconnected surface water sustainability indicators (YCWA 2024a). By avoiding undesirable results related to groundwater levels, the GSP indicates that undesirable results related to the sustainability indicators of chronic lowering of groundwater levels, reduction of groundwater storage, and depletions of interconnected surface water will all be avoided. The Yuba Subbasins GSP includes a detailed description of the development of the minimum threshold water levels and how monitoring is done to assess compliance.

6.3.2.2.1 Minimum Thresholds for Chronic Lowering of Groundwater Levels

Minimum thresholds for chronic lowering of groundwater levels were selected in the GSP to represent conditions that are just above conditions that could collectively (cumulatively) generate undesirable results in the Yuba Subbasins. These minimum thresholds were developed by selecting the deeper of (1) the bottom of the shallowest domestic well near a monitoring well, adjusted for March measurements, (2) the historical low March groundwater level from 1985 to present (incorporating recent monitoring and HUR [YCWA 2008] interpolated values) at the monitoring well, or (3) 75 feet.

The minimum thresholds are based on each representative monitoring well's proximity to shallow wells and on historical groundwater levels at the representative monitoring well. Domestic wells were used for this threshold, as they are generally shallower than agricultural and municipal wells and thus considered more conservative for setting thresholds. Additionally, the loss of a domestic well usually results in a loss of water for consumption, cooking, and sanitary purposes, which can often have substantial impacts on the users of the water and can be financially difficult for the well owner to replace.

Historically low groundwater levels at each representative monitoring well were also incorporated into the analysis. Groundwater levels have fluctuated over time in the Yuba Subbasins, notably in the South Yuba Subbasin (as discussed in detail in Section 2.2.2.1 of the GSP). The GSP determined that historical conditions were not significant and unreasonable, thus this analysis considers those historical levels as being appropriate for future operations. The use of historical low groundwater levels also addresses a shortcoming in the domestic well database. The DWR Well Completion Report Map Application database that was used in development of the minimum thresholds includes domestic wells that are potentially not in use, due to age or other factors. And, like most databases, the dataset may contain errors that can be difficult to identify and rectify. Domestic wells that are shallower than the historical low groundwater level at the well would likely have run dry and either been abandoned or deepened since that time or may be due to an error in the dataset. Future installed domestic wells would be informed by the GSP and, potentially, updated county construction standards.

The minimum thresholds were developed for March groundwater level data to limit impacts of active groundwater pumping resulting in localized drawdowns that are most likely to occur in late summer or fall, which can cause erratic measurements that may not be indicative of regional conditions. A March monitoring period is thus considered a more reliable and consistent indicator of regional groundwater level conditions. To use March data, the annual change in groundwater level between the annual low groundwater level data and the average March groundwater level was identified. The depth of the shallowest domestic well was then adjusted upward (to the higher

elevation) by the average of the three largest March-to-annual-low changes to reflect March elevations that would be reasonably expected to result in groundwater levels near the bottom of the well during late summer or early fall, when groundwater levels are typically at their lowest (YCWA 2024a: Figure 4-4). This process is explained in Appendix L of the Yuba Subbasins GSP.

A minimum depth of 75 feet bgs was incorporated to represent economically accessible water that is also similar to historical lows in the South Yuba Subbasin that were reached without significant and unreasonable results. The 75- foot depth is also consistent within domestic well construction requirements in many other Central Valley counties, which incorporate minimum sanitary seal depths of up to 50 to 100 feet bgs, making the total well depths deeper than that level.

Monitoring wells used to determine changes in groundwater levels are located throughout the Yuba Subbasins (YCWA 2024a: Table 4-1). The Yuba Subbasins GSP identifies the minimum threshold elevations for each representative monitoring well in the Yuba Subbasins (YCWA 2024a: Figure 4-6). The Yuba Subbasins GSP also includes hydrographs for each representative monitoring well, including the ground surface elevation, historical groundwater levels, minimum threshold, interim milestones, and measurable objectives developed in the GSP for each representative monitoring well in the Yuba Subbasins (YCWA 2024a). All GSP annual reports (Water Years 2020, 2021, 2022, and 2023) show all representative monitoring wells with groundwater levels above minimum thresholds. The time period covered by the annual reports included periods of drought, with shortages for agricultural surface water deliveries and groundwater substitution transfers.

The GSP defines undesirable results as exceedance of the minimum threshold at more than 25 percent of representative monitoring wells for two consecutive years at each location based on the March measurement, reflective of the long-term regional approach to sustainability in the GSP.

6.3.2.2.2 Additional Criteria for Chronic Lowering of Groundwater Levels

To capture the full range of desired groundwater conditions within the Yuba Subbasins specific to the groundwater levels sustainability indicator, two additional non-regulatory levels were developed:

- Historically full aquifer level: The historically full aquifer level is a non-regulatory value that indicates historically high groundwater levels, representing the typical upper bound of groundwater levels during conjunctive water management operations.
- Local management level: The local management level represents the lowest groundwater levels that are locally desired. Distinct from the minimum threshold, these non-regulatory levels may be higher than levels that would constitute "significant and unreasonable results" under SGMA (i.e., the regulatory "floor" established under SGMA). These local management levels guide adaptive management in the Yuba Subbasins and provide a level of protection to help avoid undesirable results.

The quantitative nature of these criteria allows the GSP to demonstrate sustainability.

Sustainable Yield Estimate for the Yuba Subbasins

Under the Yuba Subbasins GSP, sustainable yield was defined as the amount of groundwater that can be withdrawn on a long-term average basis without causing undesirable results (YCWA

2024a). Based on the methodology described in the Yuba Subbasins GSP, sustainable yield is estimated as 239,000 AFY, split as 93,000 AFY in the North Yuba Subbasin and 146,000 AFY in the South Yuba Subbasin (YCWA 2024a). Because the Yuba Subbasins are operated under conjunctive water management, it is important to understand that the sustainable yield is a long-term value. Thus, groundwater pumping may exceed these values during certain years, balanced by other years with reduced pumping, so that the long-term average level of pumping remains at or below the sustainable yield. The average groundwater pumping in the Yuba Subbasins from 2019-2023 was 166,313 AFY (YCWA 2024b), 72,687 AFY below the sustainable yield value. It should also be noted that these estimates are provided as a reference to assist in achieving sustainability when identifying future projects and management actions. SGMA does not incorporate these estimates directly into the sustainable management criteria. Rather, sustainability under SGMA is demonstrated by avoiding the undesirable results (as set forth in the sustainability indicators).[1]

6.4 Impact Assessment Methodology

6.4.1 Groundwater Analytical Approach

6.4.1.1 Background

As the Narrows Project would not involve any construction activities, construction impacts related to the Narrows Project are not analyzed. None of the construction-related activities associated with the YRDP would affect New Bullards Bar Reservoir's ability to make releases through the New Colgate Powerhouse, nor would any construction activities affect releases from Englebright Reservoir or agricultural diversion structures near Daguerre Point Dam. Accordingly, there would be no construction-related impacts from the Proposed Projects or their alternatives on agricultural water and thus no impacts on groundwater conditions. Because of this, construction impacts associated with groundwater are not analyzed further.

Potential groundwater impacts resulting from the Proposed Projects or alternatives are associated with surface water shortages from diversions from the lower Yuba River. As explained in Section 6.2.3, groundwater east of the alluvial Yuba Subbasins occurs in fractured bedrock and is not significantly affected by changes in Yuba River flow and stage. Accordingly, groundwater impacts in those areas are not analyzed further.

As previously described, SGMA requires that GSAs demonstrate sustainable groundwater use as shown by the avoidance of undesirable results evaluated through six sustainability indicators. Yuba Water Agency Board of Directors adopted the amended Yuba Subbasins GSP in January 2025[2] (YCWA 2024a), which supersedes the original GSP adopted in January 2020 that was approved

[1] For details on quantitative threshold values associated with each of the five sustainability indicators and the two additional non-regulatory levels, see Section 4.4 (Quantitative Sustainable Management Criteria) in the Yuba Subbasins GSP, including:

- Table 4-1: Minimum Thresholds, Measurable Objectives, and Historically-Full Aquifer Levels for Chronic Lowering of Groundwater Levels
- P. 4-23 – Minimum thresholds for reduction of groundwater storage
- P. 4-25 – Minimum thresholds for degraded water quality
- P. 4-26 – Minimum thresholds for land subsidence
- P. 4-26 – Minimum thresholds for depletions of interconnected surface water

[2] The Amended GSP is currently under review by DWR as of January 2025.

by DWR. Consistent with SGMA, the YGM was developed for the Yuba Subbasins, and the Yuba Subbasins GSP guides management of basin activities. This DEIR considers the sustainable management criteria for the five SGMA sustainability indicators that the GSP found to apply to the Yuba Subbasins as thresholds of significance for purposes of this analysis (seawater intrusion is not present in the Yuba Subbasins and not likely to occur).

The Proposed Projects generally have the potential to affect three of SGMA's sustainability indicators[3]: groundwater levels, groundwater storage, and depletions of interconnected surface water. The groundwater level analysis applies to these three SGMA sustainability indicators, as groundwater levels are used as proxy for the reduction of groundwater storage and depletions of interconnected surface water sustainability indicators. Therefore, this analysis focuses on the Proposed Projects' potential to cause chronic lowering of groundwater levels, which is the driving factor in maintaining sustainability in the Yuba Subbasins. Groundwater levels also reflect the ability of infrastructure to economically access groundwater and the sustainability of GDEs, to the extent they are connected to the aquifer that is being accessed for water supplies.

The environmental impact analysis for groundwater resources was developed through modeling of surface water deliveries under the Proposed Projects and the alternatives compared to surface water deliveries under the Existing Condition and the Future Baseline. Surface water modeling was performed using the YRDP Operations Model. Additional details on the modeling, including details on the scenarios used in the following subsections, are provided in Chapter 5, Surface Water Resources.

Reduction in surface water delivery is considered a potential impact to groundwater resources as deficiencies in surface water deliveries typically result in additional groundwater pumping to meet agricultural demands. In some cases, fallowing may occur rather than groundwater pumping, notably when the total reduction in surface water delivery exceeds the aggregate groundwater pumping capacity. For this analysis, groundwater pumping was assumed regardless of overall pumping capacity, as additional groundwater production wells could be installed to meet the demand rather than fallowing.

Groundwater analysis was performed with two different methods, based on the magnitude of increase in pumping. The Proposed Projects and Alternative 1 have small increases in pumping or small decreases in pumping and are analyzed through an analysis of the additional pumping in relation to the groundwater budget. Alternative 2 has a much higher increase in pumping and is analyzed through groundwater modeling to provide sufficient detail for this greater change in groundwater conditions.

The Proposed Projects and Alternative 1 use a groundwater-budget-based analytical approach. The groundwater budget was developed as part of the GSP (YCWA 2024a) through the use of the YGM and quantifies the inflows to and outflows from the groundwater system in the Yuba Subbasins. This allows for the change in groundwater pumping simulated by the YRDP Operations Model to be put into the context of the groundwater system. That is, the change in pumping on an average annual basis is compared to the overall groundwater budget to estimate the level of overdraft, if any, resulting from the change in pumping. That rate of decline, or overdraft, is then

[3] For details on the sustainability indicators, see Section 4.1 (Sustainability Indicators), page 4-2, in the Yuba Subbasins GSP.

applied over the entire Yuba Subbasins to estimate the impact to groundwater conditions. This approach of analyzing regional conditions is consistent with the long-term regional approach of the GSP, where minimum thresholds must be exceeded by 25 percent of wells for two consecutive years to be considered significant and unreasonable.

The average annual rate of decline is applied over a 5-year period, as impacts of increased groundwater pumping initially accrue to groundwater storage (and thus groundwater levels), with impacts shifting over time to the surface water system. The 5-year period was selected based on analysis performed in the GSP, which indicated that groundwater conditions generally stabilize within 5 years of pumping. Thus, after 5 years of pumping, the rate of declines in groundwater levels would be expected to be lower (YCWA 2024a), and this groundwater level impact would be indicative of the average impact over the life of the project.

Alternative 2 uses a groundwater-model-based analytical approach using the YGM due to the magnitude of potential impacts necessitating the use of the model to understand impacts to the hydrologic cycle. The YGM is an integrated water resources model designed to simulate the flow of surface water and groundwater in western Yuba County and southern Butte County. Developed using the Integrated Water Flow Model Version 2015 (IWFM-2015) software, the YGM incorporates detailed historical data from a recent 21-year period into baselines, including hydrogeologic conditions, land use, crop patterns, surface water diversions, and groundwater substitution transfer pumping. The YGM has been used for a wide range of hydrologic analyses, including the development of the GSP.

For use in this analysis, the Existing Condition and Future Baseline previously developed for the GSP were both modified to incorporate Alternative 2. The agricultural water supply shortages described in Section 5.5.7.2 were incorporated into the Alternative 2 YGM scenarios, one based on the Existing Condition and one based on the Future Baseline. The Alternative 2 YGM scenarios incorporate an increase in agricultural pumping and a decrease in surface water diversion equivalent to water supply shortages. This increased pumping and decreased diversion is first applied across Member Units without pre-1914 water rights (Brophy Water District, Dry Creek Mutual Water Company, Ramirez Water District, South Yuba Water District, and Wheatland Water District) with remaining volume, if any, distributed across the remaining Member Units (Browns Valley Irrigation District, Cordua Irrigation District, and Hallwood Irrigation Company), in proportion to the Member Unit's use in the associated baseline. The YGM Future Baseline simulates a 63-year-long hydrologic sequence, of which the hydrologic conditions are based on water years 1997 through 2017, repeated three times. This approach was also used in the development of water budgets and sustainable management criteria in the GSP. Thus, the Alternative 2 YGM scenario incorporates shortages described in Section 5.5.7.2 for this time period.

The Alternative 2 YGM scenarios provide simulated groundwater level data at the GSP's representative monitoring wells. Consistent with the GSP, the simulated March groundwater levels at each representative monitoring well are compared against the significance criteria.

6.4.1.2 Approach – Groundwater Levels, Storage, and Depletions of Interconnected Surface Water

An analysis was conducted of impacts on groundwater levels. As the GSP uses groundwater levels as a proxy for storage and for depletions of interconnected surface water, this analysis also covers the impacts associated with storage and with depletions of interconnected surface water.

For the Proposed Projects and Alternative 1, analyses of long-term regional impacts to the groundwater system were performed using available groundwater budget data combined with the change in overall groundwater pumping for each alternative. This approach, as opposed to a costly and time-consuming groundwater modeling exercise using the YGM, is appropriate, proportional to the potential impacts, and sufficient to inform decision makers and the public.

Groundwater budgets developed for the GSP (YCWA 2024a) show generally balanced inflows and outflows for historical, current, projected, and projected with climate change conditions. These balanced conditions are reflective of sustainable groundwater conditions. The inflows and outflows are also similar in magnitude across the different temporal periods. The North Yuba Subbasin has inflows and outflows of approximately 120,000 AFY (Table 6.41) and the South Yuba Subbasin has inflows and outflows of approximately 170,000 AFY (Table 6.42). Cumulatively, there are approximately 290,000 AFY of inflows and outflows for the North Yuba and South Yuba Subbasins. Focusing on the outflows, 60,000 AFY of North Yuba groundwater extraction and 100,000 AFY of South Yuba groundwater extraction collectively contribute 160,000 AFY, approximately 55 percent, of the total outflows from the two subbasins.

Table 6.4-1. Groundwater Budgets, Annual Average Conditions, North Yuba Subbasin.

Component	Historical Budget Volume (AFY)	Current Budget Volume (AFY)	Projected Water Volume (AFY)	Projected Water Volume with Climate Change (AFY)
INFLOWS				
Subsurface inflow	36,300	36,800	36,800	37,200
Wyandotte Creek	7,600	7,100	7,200	7,300
Sutter	21,600	22,200	22,300	22,600
South Yuba	7,100	7,500	7,300	7,300
Deep percolation of rainfall	16,900	16,100	16,000	16,300
Deep percolation of applied water	23,300	22,500	22,300	22,400
Recharge from rivers and streams	10,100	10,600	10,700	10,900
Recharge from conveyance systems	6,000	6,300	6,200	6,400
Recharge from Goldfields	16,200	16,400	16,600	16,500
Groundwater inflow from foothills	4,700	4,300	4,300	4,300
Other	7,000	6,300	6,200	6,300
Total Inflow	***120,500***	***119,300***	***119,100***	***120,300***
OUTFLOWS				
Groundwater extraction	58,800	59,400	59,100	59,900
Discharge to rivers and streams	22,200	21,900	21,700	21,600
Subsurface outflow	15,000	13,900	14,300	14,600
Wyandotte Creek	5,500	5,500	5,400	5,600

Note: Further refinements of the YGM in the future, including to boundary conditions, aquifer parameters, soil parameters, stream geometry parameters, water management assumptions, and others may result in changes to the water budget component estimates.

An increase in groundwater pumping would result in lower groundwater levels. While impacts from increased groundwater extraction would be focused near wells serving agricultural lands formerly receiving surface water, impacts can be approximated assuming a uniform distribution across the 80,000 acres of Member Unit area currently receiving surface water. These impacts are spread uniformly by dividing the total increase in pumping by the total surface area. The result is a volume per acre representing the annual change in groundwater storage compared to the Existing Condition, presented in units of acre-feet per acre. Since groundwater is stored within a matrix of gravel, sand, silt, and clay, the annual change in storage results in a much larger drop in groundwater levels than would be suggested by the total water volume. Using a typical specific yield for the Yuba Subbasins of 0.1, this equates to a reduction in groundwater levels, in feet, that is 10 times the storage value, again compared to the Existing Condition. This reduction in groundwater levels would continue on a long-term average basis, except to the extent water is provided from other portions of the hydrologic system. Note that the rate of decline may be faster if pumping occurs in semi-confined or confined portions of the aquifer, as this rate of reduction in groundwater levels is based on unconfined conditions.

Over time, other components of the system would adjust to this lower groundwater level, including increased recharge from streams, reduced discharge to streams, decreased outflow to neighboring subbasins, and/or increased inflow from neighboring subbasins. Each of these components has potential impacts associated with them. The total impact to groundwater in storage (declining groundwater levels) and other impacts to the hydrologic system (depletions of surface water system and neighboring subbasins) would, on a long-term basis, equal the total increase in

groundwater extraction associated with the alternative. Estimating the breakdown of those components requires the use of a groundwater model. However, for relatively small changes in the system such as under the Proposed Projects and Alternative 1, it can be assumed that the early impacts are to lowered groundwater levels, with a shift towards depletions of surface water systems over time (DWR 2024). The long-term decline is approximated using a 5-year period at the calculated annual rate of decline. The 5-year period is used as the GSP indicates that 90 percent of depletions of interconnected surface water occur within 5 years of pumping, suggesting that groundwater level declines are at a lower rate after that period.

Assuming the initial impacts are to groundwater storage and thus groundwater levels, 5 years of decline would result in five times the annual rate of decline in groundwater levels. The result, estimated 5-year decline in groundwater levels due to the Proposed Projects or Alternative 1, is then subtracted from the most recently published March groundwater levels at the representative monitoring wells and compared to the corresponding local management level, as defined in the GSP.

Impacts would be considered significant if 25 percent of the wells were found to exceed the local management level for two consecutive years. This significance criterion is based on the GSP definition of undesirable results, which is 25 percent of wells exceeding the minimum threshold for two consecutive years. Local management levels are used here instead of minimum thresholds as local management levels indicate "locally preferred" minimum groundwater levels. Groundwater levels below the local management level may not be significant and unreasonable—the requirement by SGMA for minimum thresholds—but would be significant as dewatering of domestic wells would be likely if local management levels were exceeded on a regional basis. While the GSP uses local management levels as an adaptive management criterion based on exceedances at any representative monitoring wells, the 25 percent over 2 years component of undesirable results is retained to indicate regional significance rather than localized impacts.

For Alternative 2, analyses of long-term regional impacts to the groundwater system were performed using the YGM. This more detailed approach is appropriate for Alternative 2 due to the larger magnitude of the increase in groundwater pumping. The YGM is able to simulate the changes in the broader groundwater/surface water system as a result of pumping triggered by surface water deficiencies. Initially, this has lowered groundwater levels and associated reduction in groundwater storage. Over time, the lowered groundwater levels propagate across the region, resulting in increases in recharge from surface water bodies, decreases in groundwater discharge to surface water bodies, and changes in subsurface flows at the boundaries of the Yuba Subbasins. While a water budget approach is appropriate for smaller volumes of pumping, larger volumes of pumping, such as under Alternative 2, have wide reaching impacts to both the groundwater and surface water model, necessitating the use of the YGM.

Consistent with the Proposed Project and Alternative 1, impacts would be considered significant if 25 percent of the wells were found to exceed the local management level for two consecutive years.

6.4.1.3 Approach – Groundwater Quality

The Yuba Subbasins are, in general, healthy with respect to groundwater quality. Groundwater quality samples collected as part of monitoring under the GSP indicate that regional ambient groundwater quality is suitable for the beneficial uses of groundwater in the Yuba Subbasins. The GSP includes electrical conductivity values, an indicator of salinity, over a period starting in the mid-1960s at key wells. The trends at each well do not suggest impacts from pumping or water levels, including dry years with increased pumping or the period from the 1970s and early 1980s when groundwater levels in the South Yuba Subbasin reached historical lows. Thus, while any increase in pumping increases the potential for water quality issues associated with upwelling of deeper saline water or migration of plumes, increases in groundwater pumping within historical ranges of groundwater levels are not expected to impact groundwater quality. The same analysis used for groundwater level is thus incorporated for groundwater quality.

6.4.1.4 Approach – Land Subsidence

It is thought that there are not significant quantities of compressible clays in the upper portions of the aquifer in the Yuba Subbasins, therefore limiting the risk of subsidence if those materials dewater. Additionally, local management levels and minimum thresholds for the chronic lowering of groundwater levels are established at levels above which land subsidence would not occur. Thus, while any increase in pumping increases the potential for subsidence, increases in groundwater pumping within historical ranges of groundwater levels are not expected to result in subsidence. The same analysis used for groundwater level is thus incorporated for land subsidence.

6.4.1.5 Approach – Indirect Impacts

For the programmatic analysis of YB/DS operations under Alternative 1, potential reductions in water supplies from NID and PG&E associated with the 15,600 AF of additional flow from the YB/DS projects in Dry and Critical WYs were used to identify whether any such reduction would result in groundwater pumping that could have potential groundwater impacts.

6.4.2 Impact Indicators and Significance Criteria

The thresholds of significance for impacts are based on the environmental checklist in Appendix G to the State CEQA Guidelines, as amended, and were refined to address potential impacts specific to groundwater resources in the Project Area. The environmental analysis conducted in this DEIR will apply the following significance thresholds to determine the potential impacts of the Proposed Projects and alternatives.

An impact on groundwater resources would be considered significant if implementation of the Proposed Projects or alternatives would conflict with or obstruct implementation of the GSP by resulting in any of the following:

- **Impact GW-1:** A reduction in groundwater levels, as a result of increases in groundwater pumping resulting from decreases in average annual surface water supply availability, to the extent that 25 percent of representative monitoring wells exceed local management levels for groundwater levels for two consecutive years, as defined in the GSP (YCWA

2024a), would be considered significant. This reduction in groundwater levels would also result in significant impacts, as described in Section 6.4.1, related to:
    - Groundwater storage
    - Groundwater quality
    - Land subsidence
    - Depletion of interconnected surface water

- **Indirect Impact GW-1**: Alternative 1 has the ability to affect diversions from NID and PG&E's Yuba-Bear and Drum-Spaulding projects to the Drum and South Yuba Canals (combined in modeling as Spaulding Canals). An impact to groundwater would occur if the reduction in NID and PG&E's water supply deliveries relative to the Future Baseline resulted in groundwater pumping that substantially decreased groundwater supplies or interfered substantially with groundwater recharge such that the project may impede sustainable groundwater management or conflict with or obstructed implementation of a water quality control plan or groundwater sustainability plan.

6.5 Environmental Impact Analysis

6.5.1 Proposed Projects Compared to the Existing Condition

YRDP Impact GW-PP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under the Proposed YRDP Project, on average 700 AFY more groundwater would be pumped than under the Existing Condition. This level of pumping change would not conflict with or obstruct implementation of the GSP. A change of 700 AFY is a negligible volume of additional groundwater pumping within the Yuba Subbasins.

The increased groundwater extraction would result in lower groundwater levels. While the impacts from increased groundwater extraction would be focused near wells serving agricultural lands formerly receiving surface water, impacts can be approximated assuming a uniform distribution across the 80,000 acres of Member Unit area currently receiving surface water. Impacts of 700 AFY over 80,000 acres results in 0.00875 AF/acre of less groundwater in storage each year on average (700 AFY ÷ 80,000 acres = 0.00875 AF/acre per year), compared to the Existing Condition. Because groundwater is stored within a matrix of gravel, sand, silt, and clay, the 0.00875 AF/acre of reduced water results in a much larger drop in groundwater levels than would be suggested by the total water volume. Using a typical specific yield for the Yuba Subbasins of 0.1, this equates to a reduction in groundwater levels of 0.0875 feet/year on average, compared to the Existing Condition. This 0.0875 feet/year reduction would continue on a long-term average basis, except to the extent water is provided from other portions of the hydrologic system. Note that the rate of decline may be faster if pumping occurs in semi-confined or confined portions of the aquifer, as this 0.0875 feet/year value is based on unconfined conditions.

Assuming the initial impacts are to groundwater storage and thus groundwater levels, five years of decline would result in approximately 0.438 feet (5.25 inches) of decline in groundwater levels. The 0.438 feet of decline in groundwater levels is applied to the most recent reported March groundwater levels for GSP compliance with local management levels (March 2023). March 2023 groundwater levels were between 28 and 148 feet above mean sea level (YCWA 2024b). A decline

of 0.438 feet would result in 0 out of 13 wells (0 percent) in the North Yuba Subbasin and 0 out of 18 wells (0 percent) in the South Yuba Subbasin violating the local management level.

As explained above, a reduction in groundwater levels resulting in 25 percent of monitoring wells violating local management levels for 2 consecutive years would also indicate adverse impacts related to groundwater storage, groundwater quality, land subsidence, and depletions of interconnected surface water. As less than 25 percent of the wells would violate the local management level as a result of the Proposed YRDP Project, these impacts would be **less than significant**. No CEQA mitigation is required.

Narrows Impact GW-PP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under the Proposed Narrows Project, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Proposed Narrows Project does not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to the Proposed Narrows Project and thus no associated significant changes in groundwater. Accordingly, the impacts of the Proposed Narrows Project on groundwater levels would be **less than significant**, and no CEQA mitigation is required.

6.5.2 Proposed Projects Compared to the Future Baseline

YRDP Impact GW-FPP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under the Proposed YRDP Project, on average 700 AFY more groundwater would be pumped than in the Future Baseline. As explained above for YRDP Impact GW-PP-1, a change of 700 AFY is a negligible volume of additional groundwater pumping within the Yuba Subbasins and would result in **less than significant** impacts to groundwater levels and associated stability indicators. No CEQA mitigation is required.

Narrows Impact GW-FPP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under the Proposed Narrows Project, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but the Proposed Narrows Project does not include additional flow requirements. As a result, there would be negligible agricultural water supply-related impacts attributable to the Proposed Narrows Project and thus no associated significant changes in groundwater. Accordingly, the impacts of the Proposed Narrows Project on groundwater levels would be **less than significant**, and no CEQA mitigation is required.

6.5.3 Alternative 1 Compared to the Existing Condition

As described in Section 4.4, this comparison is misleading for the water resources analysis; it is provided for informational purposes only.

YRDP Impact GW-Alt1-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under Alternative 1 YRDP operations, on average, 1,100 AFY less groundwater would be pumped than under the Existing Condition. A decrease in pumping would likely result in higher groundwater levels and therefore would not conflict with or obstruct implementation of the GSP.

Narrows Impact GW-Alt1-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under Alternative 1, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but there would be no additional Narrows Project flow requirements under Alternative 1. As a result, there would be negligible agricultural water supply-related impacts attributable to the Narrows Project operations under Alternative 1 and thus no associated significant changes in groundwater.

6.5.4 Alternative 1 Compared to the Future Baseline

YRDP Impact GW-FAlt1-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under Alternative 1 YRDP operations, on average, 900 AFY more groundwater would be pumped than in the Future Baseline. This level of pumping change would not conflict with or obstruct implementation of the GSP. A change of 900 AFY is a negligible volume of additional groundwater pumping within the Yuba Subbasins.

The increased groundwater extraction would result in lower groundwater levels. While the impacts from increased groundwater extraction would be focused near wells serving agricultural lands formerly receiving surface water, impacts can be approximated assuming a uniform distribution across the 80,000 acres of Member Unit area currently receiving surface water. Impacts of 900 AFY over 80,000 acres results in 0.01125 AF/acre of less groundwater in storage each year on average (900 AFY ÷ 80,000 acres = 0.01125 AF/acre per year), compared to the Future Baseline. Because groundwater is stored within a matrix of gravel, sand, silt, and clay, the 0.01125 AF/acre of reduced water results in a much larger drop in groundwater levels than would be suggested by the total water volume. Using a typical specific yield for the Yuba Subbasins of 0.1, this equates to a reduction in groundwater levels of 0.1125 feet/year on average, compared to the Future Baseline. This 0.1125 feet/year reduction would continue on a long-term average basis, except to the extent water is provided from other portions of the hydrologic system. Note that the rate of decline may be faster if pumping occurs in semi-confined or confined portions of the aquifer, as this 0.1125 feet/year value is based on unconfined conditions.

Assuming the initial impacts are to groundwater storage and thus to groundwater levels, 5 years of decline would result in approximately 0.563 feet (6.75 inches) of decline in groundwater levels. The 0.563 feet of decline in groundwater levels is applied to the most recent reported March groundwater levels for GSP compliance (March 2023). March 2023 groundwater levels were between 28 and 148 feet above mean sea level (YCWA 2024b). A decline of 0.563 feet would result in 0 out of 13 wells (0 percent) in the North Yuba Subbasin and 0 out of 18 wells (0 percent) in the South Yuba Subbasin violating the local management level.

As explained above, a reduction in groundwater levels resulting in 25 percent of monitoring wells violating local management levels for two consecutive years would also indicate adverse impacts related to groundwater storage, groundwater quality, land subsidence, and depletions of interconnected surface water. As less than 25 percent of the wells would exceed the local management level as a result of YRDP operations under Alternative 1, these impacts would be **less than significant**.

Narrows Impact GW-FAlt1-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under Alternative 1, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but there would be no additional Narrows Project flow requirements under Alternative 1. As a result, there would be negligible agricultural water supply-related impacts attributable to Narrows Project operations under Alternative 1 and thus no associated significant changes in groundwater. Accordingly, the impacts of Narrows Project operations on groundwater levels under Alternative 1 would be **less than significant**.

Indirect Impact GW-FAlt1-1: Indirect Impacts on Groundwater Resources from Alternative 1 YB/DS Operations Upstream of the YRDP

Alternative 1 includes a contribution of 15,600 AF of water from the Yuba-Bear/Drum-Spaulding projects that would be provided under new FERC licenses for those projects in dry and critically dry years. The following discussion provides a programmatic analysis of the potential indirect impacts to groundwater associated with this component of Alternative 1, relative to the Future Baseline.

As discussed in Chapter 5, Yuba Water's modeling indicates there would be reductions in Spaulding Canals' diversions of at least 1 percent in 17 out of 52 years, and at least 5 percent in 4 out of 52 years, with an average reduction of 2.6 TAF and a maximum of 10.5 TAF. In response to reductions in supplies from the Yuba River watershed, NID water users could make up for reductions in Yuba River water supplies with a combination of additional groundwater pumping, conservation, and increased purchases from PG&E (NID 2021). PCWA could make up for shortages with a combination of additional groundwater pumping, conservation, and increased diversions from PCWA's Middle Fork Project (PCWA 2021).

For purposes of this programmatic analysis, it is reasonably foreseeable that YB/DS operations under Alternative 1 would include available protective measures developed in collaboration with regulatory agencies to ensure that Alternative 1 would not result in conflicts with or obstruct implementation of a water quality control plan or GSP. Furthermore, the operation of Alternative 1 is unlikely to result in groundwater pumping that would substantially decrease groundwater supplies or interfere substantially with groundwater recharge such that the project may impede sustainable groundwater management. Therefore, indirect groundwater impacts would be **less than significant**. As explained in Chapter 3, the YB/DS relicensings are subject to their own CEQA process. To the extent that YB/DS operations under new FERC licenses would have impacts that are beyond the scope of those disclosed in this EIR or other CEQA documents, those impacts may need to be addressed through subsequent project-level CEQA review as more concrete information about those operations becomes available.

6.5.5 Alternative 2 Compared to the Existing Condition

For use in this analysis, the Existing Condition and the Future Baseline previously developed for the GSP were modified to incorporate Alternative 2. The agricultural water supply shortages described in Section 5.5.7.2 were incorporated into the Alternative 2 YGM scenarios. The Alternative 2 YGM scenarios incorporate an increase in agricultural pumping and decrease in surface water diversion equivalent to the water supply shortages. This increased pumping and decreased diversion is first applied evenly across Member Units without pre-1914 water rights (Brophy Water District, Dry Creek Mutual Water Company, Ramirez Water District, South Yuba Water District, and Wheatland Water District) with remaining volume, if any, distributed evenly across the remaining Member Units (Browns Valley Irrigation District, Cordua Irrigation District, and Hallwood Irrigation Company), as shown in Table 6.5-3. Alternative 2 would result in a total average annual shortage (or increased groundwater pumping) of 47,100 AFY on average with a maximum annual shortage of 247,400 AFY.

Table 6.5-3. Average Annual and Maximum Annual Shortage, and Equivalent Increases in Groundwater Pumping, by Member Unit, within the YGM Scenario 2 Simulation Period

Member Unit	Average Annual Shortage (AFY)	Maximum Annual Shortage (AFY)
Brophy Water District	14,000	47,600
Browns Valley Irrigation District	2,600	21,900
Cordua Irrigation District	7,500	63,200
Dry Creek Mutual Water Company	2,400	9,100
Hallwood Irrigation District	6,800	56,700
Ramirez Water District	3,500	12,300
South Yuba Water District	7,000	24,200
Wheatland Water District	3,300	12,400

The YGM Existing Condition and Future Baseline both simulate hydrologic conditions based on water years 1997 through 2017, repeated three times; thus, the Alternative 2 YGM scenarios incorporate shortages described in Section 5.5.7.2 for this time period.

Under both baselines, the shortages and equivalent increases in pumping are focused during the irrigation season, as shown in Figure 6.5-1, which shows the increases in pumping by Member Unit on a monthly basis.

Figure 6.5-1. Monthly Shortages, and Equivalent Increases in Groundwater Pumping, by Member Unit, within the YGM Scenario 2 Simulation Period.

The Alternative 2 YGM scenarios provide simulated groundwater level data at the GSP's representative monitoring wells. Consistent with the GSP, the simulated March groundwater levels at each representative monitoring well are compared against the local management levels. These results are aggregated and compared against the significance criteria. Conditions where either the North Yuba or South Yuba Subbasin meets the significance criteria would be considered potentially significant.

YRDP Impact GW-Alt2-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Alternative 2 causes local management level exceedances in the Yuba Subbasins, with groundwater levels in 14 representative monitoring wells (45 percent) deeper than the GSP-defined local management level for two consecutive March measurements (simulated March groundwater levels under 2016 and 2017 hydrologic conditions). Figure 6.5-2 shows the locations of these wells.

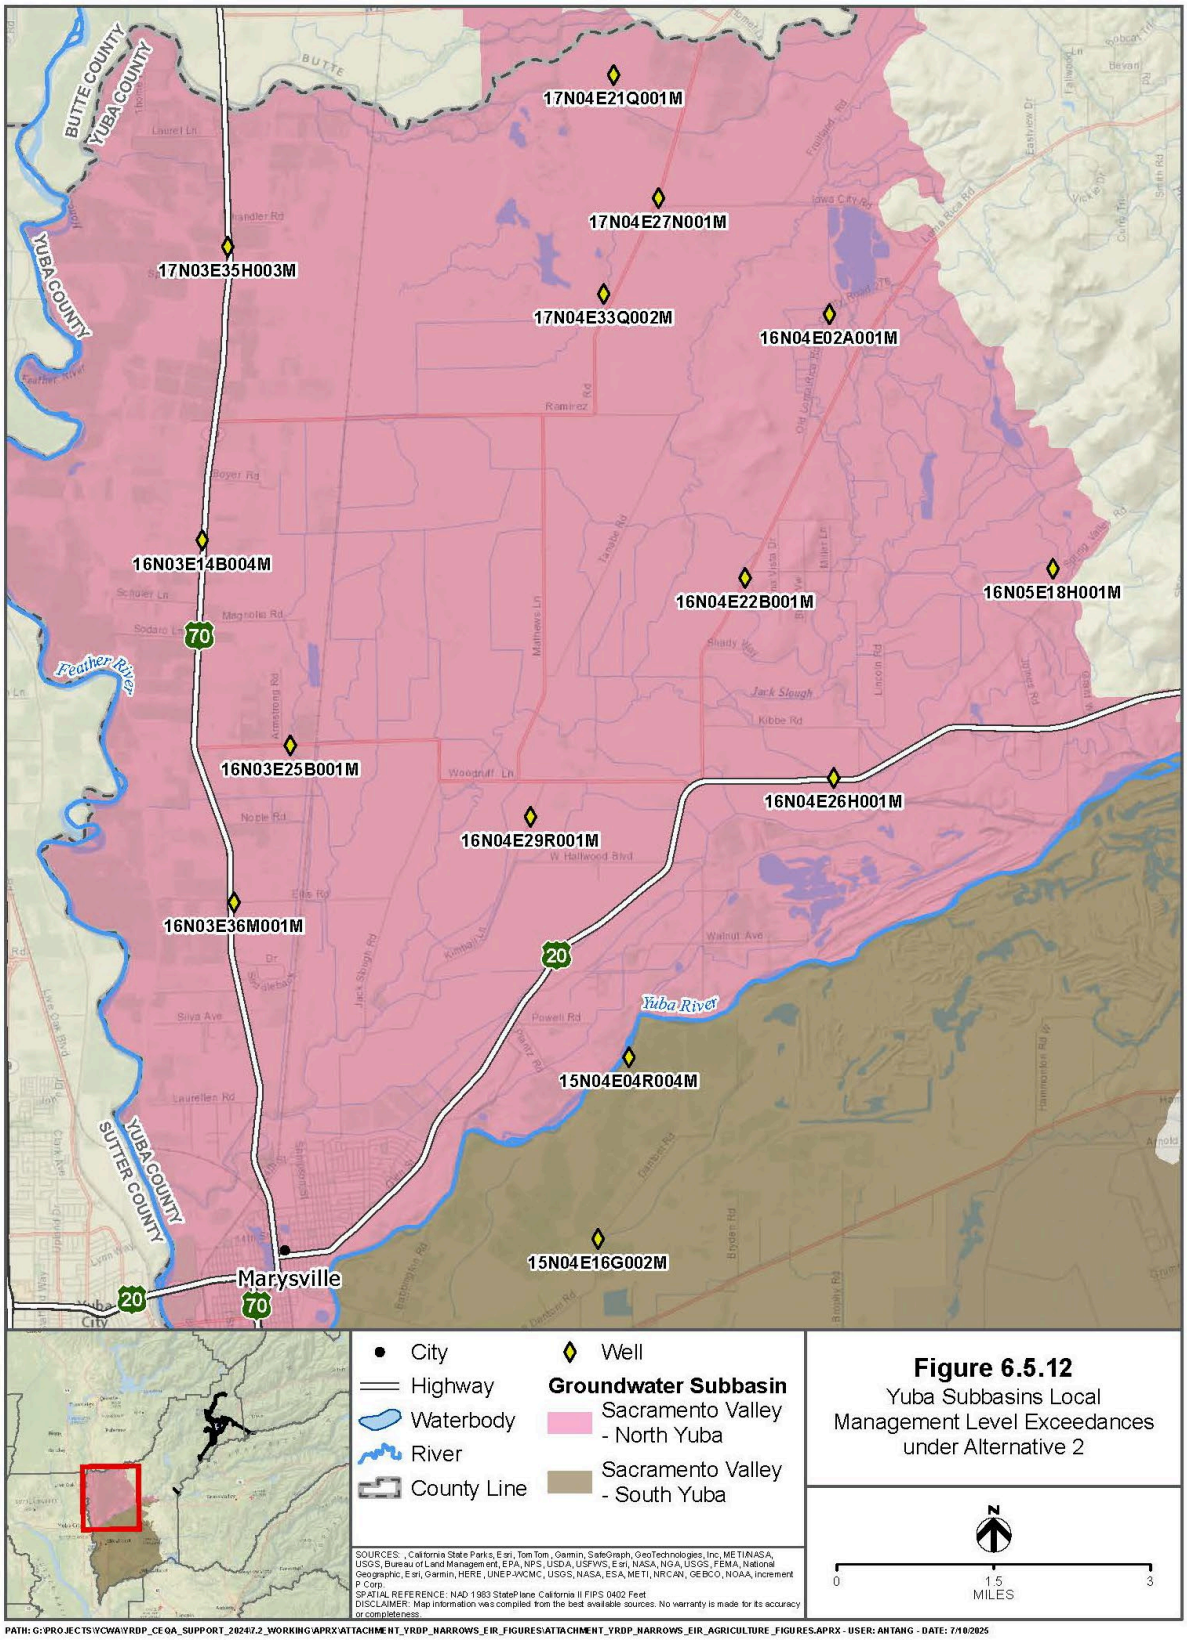

Figure 6.5-2. Yuba Subbasins Local Management Level Exceedances under Alternative 2.

Narrows Impacts GW-Alt2-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under Alternative 2, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but there would be no additional Narrows Project flow requirements under Alternative 2. As a result, there would be negligible agricultural water supply-related impacts attributable to Narrows Project operations under Alternative 2 and thus no associated significant changes in groundwater.

6.5.6 Alternative 2 Compared to the Future Baseline

The analysis used for Alternative 2 compared to the Future Baseline is described above in Section 6.5.5. From a groundwater perspective, the Existing Condition and Future Baseline are similar, with Future Baseline incorporating some level of urbanization in portions of the Yuba Subbasins. Alternative 2 incorporates a dramatic increase in surface water shortages and associated groundwater production. The differences between Alternative 2 and either the Existing Condition or Future Baseline are much greater than the small difference between the Existing Condition and Future Baseline themselves. As such, the impacts of Alternative 2 as expressed as local management level exceedances are the same when compared using either the Existing Condition or Future Baseline.

YRDP Impact GW-FAlt2-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Alternative 2 causes local management level exceedances in the Yuba Subbasins, with groundwater levels in 14 representative monitoring wells deeper than the GSP-defined local management level for two consecutive March measurements (simulated March groundwater levels under 2016 and 2017 hydrologic conditions) (see Figure 6.5-2).

These 14 wells represent 45 percent of the representative monitoring wells in the Yuba Subbasins. This meets the significance criteria for groundwater levels and indicates that substantial adverse impacts related to groundwater storage, groundwater quality, land subsidence, and depletions of interconnected surface water would occur. These impacts could not be avoided through securing alternate water supplies or increasing the efficiency of existing water uses, as there are no economically feasible alternate water supplies for the area, and local growers already use advanced techniques for efficient water use. Accordingly, Alternative 2 YRDP operations would result in **significant and unavoidable** impacts.

Narrows Impacts GW-FAlt2-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under Alternative 2, Yuba Water would continue to operate the Narrows 1 Powerhouse in coordination with the YRDP's Narrows 2 Powerhouse to meet YRDP requirements, but there would be no additional Narrows Project flow requirements under Alternative 2. As a result, there would be negligible agricultural water supply-related impacts attributable to Narrows Project operations under Alternative 2 and thus no associated significant changes in groundwater. Accordingly, the impacts of Narrows Project operations on groundwater levels under Alternative 2 would be **less than significant**.

6.5.7 No Project Alternative Compared to the Existing Condition

YRDP Impact GW-NP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under the No Project Alternative, Yuba Water would cease YRDP hydropower generation but would continue existing YRDP operations for flood control and water supply purposes. Because operations for water supply purposes would be essentially unchanged, no changes to groundwater pumping within the Yuba Subbasins would be expected. YRDP operations under the No Project Alternative would thus have **no impact** on groundwater resources.

Narrows Impacts GW-NP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

Under the No Project Alternative, Yuba Water would cease Narrows Project hydropower generation but would continue existing Narrows Project operations for flood management and water supply purposes. Because operations for water supply purposes would be essentially unchanged, no changes to groundwater pumping within the Yuba Subbasins would be expected. Narrows Project operations under the No Project Alternative would thus have **no impact** on groundwater resources.

6.6 Cumulative Impact Assessment

The purpose of the cumulative analysis is to determine whether the incremental effects of the Proposed Projects (i.e., the YRDP and Narrows Project FERC relicensings) would be expected to be "cumulatively considerable" when viewed in connection with the effects of past projects, other current projects, and probable future projects (Public Resources Code Section 21083, subdivision (b)(2)). The following sections describe this analysis for the projects discussed in Section 6.5 above.

Hydrologic modeling was used to evaluate the potential cumulative effects of the Proposed Projects and alternatives in combination with other likely changes in operations on hydrology and water supply. The projects that have been adequately defined (e.g., in recent project-level environmental documents) and that have the potential to contribute to cumulative impacts are included in the quantitative assessment of the Proposed Projects' and alternatives cumulative impacts. For analytical purposes of this DEIR, the projects that are considered well defined and "reasonably foreseeable" are described in Chapter 4. The assumptions used to categorize future hydrologic cumulative conditions that are quantitatively simulated are presented in Chapter 5. To the extent feasible, potential cumulative impacts on resources dependent on hydrology or water supply are analyzed quantitatively.

As described in Chapter 4, because several projects considered as part of the cumulative condition cannot be accurately characterized for hydrologic modeling purposes at this time, either due to the nature of the particular project or because specific operations details are only in the preliminary phases of development, these projects are evaluated qualitatively. Only those projects that could affect groundwater resources are included in the qualitative evaluation that is presented in subsequent sections of this chapter.

Although most of the projects described in Chapter 4 could have project-specific impacts that will be addressed in future project-specific environmental documentation, future implementation of these projects is not expected to result in cumulative impacts to regional water supply operations, or water-related and water dependent resources that also could be affected by the Proposed Projects or the alternatives (see Chapter 4). For this reason, only the limited numbers of projects with the potential to cumulatively impact groundwater resources are specifically considered qualitatively in the cumulative impacts analysis for groundwater resources:

- FERC Hydropower Projects in the Yuba River Watershed:
    - *South Feather Power Project (FERC Project 2088-068) Relicensing*
    - *Yuba-Bear Hydroelectric Project (Yuba-Bear Project) (FERC Project No. 2266) Relicensing,*
    - *Upper Drum-Spaulding Hydroelectric Projects (FERC No. 2310)*
    - *Lower Drum Hydroelectric Project (FERC No. 14531) Relicensing*
- Water Storage and Conveyance Projects:
    - *Yuba Subbasins Water Management Plan: A Groundwater Sustainability Plan (GSP) Implementation*
    - *WWD In-Lieu Recharge Project*
    - *Yuba County Integrated Regional Water Management Plan (IRWMP) Implementation*
    - *Various Water Supply Improvement Projects*
- Water Transfer and Acquisition Programs:
    - *Lower Yuba River Accord Water Transfer Program Extension*
- Flood Control Projects:
    - *New Bullards Bar Dam ARC Spillway Project*
    - *USACE NBB Dam and Reservoir Water Control Manual (WCM) Update*
    - *500-year Flood Protection Project*
    - *Marysville Ring Levee*
    - *Yuba River North Training Wall (NTW) Project*
    - *Goldfields Multi-Benefit Project*
- Ecosystem Restoration and Fisheries Improvement Projects:
    - *Bay-Delta Water Quality Control Plan Update – HR & L*
- Other Local Projects in the Yuba Region:
    - *Cordua Groundwater Monitoring Well*

These projects are described in Chapter 4, and their impacts related to groundwater resources are addressed below.

6.6.1 Cumulative Condition with Proposed Projects Compared to the Existing Condition

As described in Section 6.4.1, there are not expected to be any construction-related effects by the Proposed Projects on groundwater. Therefore, construction-related activities under the Proposed Projects would not contribute to cumulative effects with other past, present, or reasonably foreseeable projects to adversely affect groundwater resources in the Yuba River or downstream. Moreover, the Proposed Projects would not result in any groundwater impacts east of the alluvial Yuba Subbasins and therefore would not contribute to cumulative effects in those areas.

As described in Section 6.4.1, potential groundwater impacts are associated with surface water shortages from diversions from the lower Yuba River or from direct impacts to groundwater resources in the Yuba Subbasin. None of the cumulative projects listed above would increase groundwater pumping, decrease groundwater recharge, or otherwise change groundwater relative to the Existing Condition, and therefore these projects would not have a direct impact on groundwater resources that would combine with the impacts of the Proposed Projects to create a significant cumulative impact. One project, Cordua Groundwater Monitoring Well, would improve groundwater monitoring but would have no impact on groundwater conditions. Additionally, none of the cumulative projects would result in agricultural surface water shortages that would indirectly impact groundwater resources.

Overall, the Proposed Projects would not result in any significant impacts to groundwater, and as explained above, the less-than-significant groundwater impacts of the Proposed Projects would not combine with effects of other cumulative past, present, and future projects to create a significant cumulative impact. Thus, under the Cumulative Condition, including the Proposed Projects, the cumulative impact to groundwater resources would be less than significant.

YRDP Cumulative Impact GW-PP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

As explained above, under the Cumulative Condition, including the Proposed Projects, there would not be a significant cumulative impact to groundwater resources relative to the Existing Condition. Accordingly, the Proposed YRDP Project would result in a **less than significant cumulative impact** to groundwater.

Narrows Cumulative Impact GW-PP-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

As explained above, under the Cumulative Condition, including the Proposed Projects, there would not be a significant cumulative impact to groundwater resources relative to the Existing Condition. Accordingly, the Proposed Narrows Project would result in a **less than significant cumulative impact** to groundwater.

6.6.2 Cumulative Condition with Alternative 1 Compared to the Existing Condition

The Cumulative Condition, including Alternative 1, would include the same cumulative past, present, and future projects and the same non-flow YRDP and Narrows Project operations addressed above in Section 6.6.1. Overall, Alternative 1 would not result in any significant impacts to groundwater, and the less-than-significant groundwater impacts under Alternative 1 would not combine with effects of other cumulative past, present, and future projects to create a significant cumulative impact. Thus, under the Cumulative Condition, including Alternative 1, the cumulative impact to groundwater resources would be less than significant.

YRDP Cumulative Impact GW-Alt1-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

As explained above, under the Cumulative Condition, including Alternative 1, there would not be a significant cumulative impact to groundwater resources relative to the Existing Condition. Accordingly, YRDP operations under Alternative 1 would result in a **less than significant cumulative impact** to groundwater.

Narrows Cumulative Impact GW-Alt1-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

As explained above, under the Cumulative Condition, including Alternative 1, there would not be a significant cumulative impact to groundwater resources relative to the Existing Condition. Accordingly, Narrows Project operations under Alternative 1 would result in a **less than significant cumulative impact** to groundwater.

6.6.3 Cumulative Condition with Alternative 2 Compared to the Existing Condition

The Cumulative Condition, including Alternative 2, would include most of the same cumulative past, present, and future projects and the same non-flow YRDP and Narrows Project operations as for the cumulative conditions described under the Proposed Projects in Section 6.6.1. However, as explained above, YRDP operations under Alternative 2 would result in significant and unavoidable groundwater impacts. Accordingly, under the Cumulative Condition, including Alternative 2, there would be a significant cumulative groundwater impact.

YRDP Cumulative Impact GW-Alt2-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

As explained above, under the Cumulative Condition, including Alternative 2, there would be a significant cumulative impact to groundwater resources relative to the Existing Condition. This significant impact would be largely attributable to YRDP operations under Alternative 2, and therefore the incremental contribution of those operations to the cumulative impact would be cumulatively considerable. As explained above, this impact cannot be reduced through alternative water supplies or increased efficiency of water use. Accordingly, YRDP operations under Alternative 2 would result in a **significant and unavoidable cumulative impact** to groundwater.

Narrows Cumulative Impact GW-Alt2-1: Operational Impacts on Groundwater Levels and Associated Sustainability Indicators

As explained above, under the Cumulative Condition, including Alternative 2, there would be a significant cumulative impact to groundwater resources relative to the Existing Condition. However, this significant impact would be largely attributable to YRDP operations under Alternative 2. Narrows Project operations under Alternative 2 would continue to be coordinated with YRDP operations but would not include additional flow requirements that would significantly change groundwater. Thus, Narrows Project operations under Alternative 2 would not have a cumulatively considerable incremental contribution to the cumulative impact and would therefore result in a **less than significant cumulative impact** to groundwater.

CHAPTER 7

ENERGY

7.1 Introduction

This section describes the environmental setting and regulatory framework related to energy, and it identifies direct, indirect, and cumulative impacts of the Proposed Projects and the alternatives during construction, and O&M. The analysis focuses on the anticipated energy consumption of the Proposed Projects' construction and operations, and if such consumption would be wasteful and inefficient. It will also address electrical generation resulting from the Proposed Projects and the alternatives, and its potential impacts.

7.2 Environmental Setting

7.2.1 Electrical Generation

The purpose of the YRDP is to continue to provide a source of hydroelectric power and flood control and serve as a water supply for both domestic and irrigation purposes (FERC 2019). Yuba Water owns four powerhouses in the Yuba River watershed, all providing hydroelectric power. The powerhouses and their nameplate generation capacity are as follows:

- New Colgate – 315 MW,
- Narrows 1 – 12 MW,
- Narrows 2 – 55 MW, and
- NBB Minimum Flow – 150 kW.

The New Colgate Powerhouse is used for a combination of generation and ancillary services. Yuba Water generally dispatches its generation according to California Independent System Operator (CAISO) system-wide demands. Ancillary services are another CAISO market of energy products used to maintain grid stability and reliability. Depending on energy demand, the New Colgate Powerhouse generation can ramp up (or down) from a minimum of 1 MW to the nameplate capacity of 315 MW. When releases from New Bullards Bar Dam exceed approximately 20,000 cfs, the water surface elevation in the New Colgate Powerhouse tailrace is too high for operations, so the New Colgate Powerhouse ceases operations.

The New Bullards Bar Minimum Flow Powerhouse is operated as a baseload facility – a facility that assists in providing the minimum level of constant power supply that a utility or power grid must produce to meet the continuous and consistent demand for electricity (FERC 2019). The Narrows 2 Powerhouse, is also operated as a baseload facility, as is the Narrows 1 Powerhouse, acquired from PG&E in 2020 (YCWA 2023).

Yuba Water operates both Narrows 1 and Narrows 2 powerhouses to provide flow to the lower Yuba River. Due to its ability to being qualified as a renewable energy source, Yuba Water

preferentially operates the Narrows 1 Powerhouse, except during its annual maintenance outage period, generally scheduled for 14 days in early June. The Narrows 2 Powerhouse includes both a partial bypass and a full-flow bypass that are used when releases from the Narrows 2 Powerhouse are lower than the powerhouse's minimum generating flow (around 350 cfs). There is also a 14-day annual maintenance outage at the Narrows 2 Powerhouse, which has historically been in early September. Other than during these outage periods, Yuba Water generally operates the two powerhouses based on the total scheduled release from Englebright Dam. See Table 7.2-1 for a summary of how each powerhouse is operated at varied flow ranges. When flows below Englebright Dam exceed 4,130 cfs, both powerhouses operate at maximum levels, and Englebright Dam spills any remaining flow. Both powerhouses can continue to operate under extremely high flows over Englebright Dam.

Table 7.2-1. Typical distribution of flows under normal operations (i.e., excluding brief transition periods) among Narrows 2 Powerhouse (generation only), Partial Bypass, Full Bypass and Narrows 1 Powerhouse.

Range of Flow Releases to Yuba River (cfs)	Narrows 2 Powerhouse Release (generation)[1] (cfs)	Partial Bypass Release[1] (cfs)	Full Bypass Release[1] (cfs)	Narrows 1 Powerhouse Release[2] (cfs)
Up to 150	0	Up to 150	Typically not used	0
150 - 730	0	Typically not used	0	150 - 730
730 – 900	0	Up to 170	0	730
900 – 1,080	350	Typically not used	Used When Narrows 2 Powerhouse not available	550 - 730
1,080 - 4,130	350 - 3,400	Typically not used	Used When Narrows 2 Powerhouse not available	730
> 4,130	3,400	Typically not used	Used When Narrows 2 Powerhouse not available 0	730

1 The typical operating flow ranges of Narrows 2 facilities are limited by long-term reliability considerations, such as vibration and cavitation of the runner; and are as follows: the Narrows 2 Powerhouse between 350 and 3,400 cfs; the Partial Bypass between 0 and 230 cfs (with physical capacity to release as high as 650 cfs); and the Full Bypass between 150 and 3,000 cfs.

2 The use of the Narrows 1 Powerhouse is prioritized due to Narrows 1 Powerhouse being classified as a renewable energy source, and the economic value that accompanies the classification.

The YRDP generates an average of about 1,189 gigawatt-hours (GWh) of electricity annually, and it has an authorized installed capacity of 361.9 MW (FERC 2019). The Narrows 1 Powerhouse generated approximately 75.38 GWh of electricity in 2021 (YCWA 2023). Yuba Water schedules the energy output into the CAISO energy markets. Yuba Water uses Shell Energy North America (Shell) as its scheduling coordinator (Shell schedules the electricity of the YRDP into the CAISO's day ahead and real time markets). As previously stated, Yuba Water participates in the CAISO energy and ancillary services markets[1] for the New Colgate Powerhouse, and the energy market for Narrows 1 and Narrows 2 powerhouses. Yuba Water sells energy from the Narrows 1 Powerhouse to the Renewable Energy Credit market and sells the carbon free energy attribute from its Colgate units and Narrows 2.

[1] Ancillary services are energy products used to help maintain grid stability and reliability. Ancillary services certification is required for participating generators to bid ancillary services (CAISO 2025). Yuba Water regularly participates in the Spinning Reserve, Regulation Up, and Regulation Down ancillary services markets. Regulation energy is used to control system frequency, which must be maintained very narrowly around 60 hertz, and varies as generators change their energy output. Resources providing regulation are certified by the CAISO and must respond to automatic control signals to increase or decrease their operating levels depending upon the need. Spinning reserve is standby capacity from generation units already connected or synchronized to the grid and that can deliver their energy in 10 minutes when dispatched.

Yuba Water also sells the Resource Adequacy (RA) product into the CAISO market so entities (including municipalities, community choice aggregation organizations, direct access providers, and investment owned utilities) can meet their California Public Utility Commission (CPUC) reliability requirements[2]. All the electrical output from the YRDP is sold at the interconnect with the PG&E grid just outside of the New Colgate powerhouse. Yuba Water is not a retail electric utility; it sells its electricity wholesale on to the market, so its electricity is sent to other utilities like PG&E, which serve their own customers and manage their own transmission and distribution networks.

No transmission lines are associated with any of the developments. The New Bullards Bar minimum flow unit ties into the electric grid at the transformer next to the unit. The New Colgate Powerhouse ties into the grid at the New Colgate Switchyard adjacent to the powerhouse. Both Narrows powerhouses are connected to the power grid via the PG&E Narrows No. 1 and Narrows No. 2 Transmission Line Project, which is composed of a 1,100-foot-long, three-phase 11-kV transmission line from the Narrows 1 Powerhouse to a substation that interconnects with the electric grid.

The YRDP and Narrows Projects lie within CAISO's North of Path 15 (NP15) region. This region covers the northern part of California. Path 15 is a critical transmission corridor consisting of three 500 kilovolt (kV) lines and several 230 kV lines that facilitate the flow of electricity between Northern and Southern California. The NP15 area is used for energy trading within the CAISO market. Yuba Water's energy generation supports reliability and stability within NP15, helping to ensure NP15 can handle peak demands. The cost of energy is based on a regulated market, and is consistent across NP15, but losses and congestion across the transmission network result in varied locational marginal prices (LMP). The New Colgate Powerhouse's LMP nodes are COLGATE_1_7_B1 and COLGATE_2_7_B1. The Narrows 1 Powerhouse's LMP node is NARROWS_1_B1 and Narrows 2 Powerhouse's node is NARROWS_2_B1. These nodes are used to determine the price of electricity at these specific locations.

Upstream from the YRDP and Narrows Project, and also within NP15, NID's Yuba-Bear Project and PG&E's Upper Drum-Spaulding Project and Lower Drum Project projects also have multiple hydropower plants in the Yuba River watershed. NID's Yuba-Bear Project includes four powerhouses with a combined generation capacity of 79.32 MW. Bowman and Rollins powerhouses are operated as base-load plants, while Dutch Flat No. 2 and Chicago Park powerhouses are operated to meet intermediate loads with some peaking operations (NID 2011). PG&E's combined projects have 9 powerhouses with a combined generation capacity of 191.5 MW. Nine of the powerhouses (Spaulding No. 1, No. 2, and No. 3, Deer Creek, Alta, Halsey, Wise, Wise No. 2, and Newcastle are operated as base-loaded plants. Dutch Flat No. 1 Powerhouse is operated for intermediate amounts of peaking, and Drum No. 1 and No. 2 powerhouses are operated as peaking plants (PG&E 2011).

[2] The California Public Utilities Commission (CPUC) Resource Adequacy (RA) program requires that Load Serving Entities (LSE) procure of 90% of their System Resource Adequacy obligation by the end of October each year for the five summer of the of the coming year. The System RA is their California Energy Commission (CEC)-adjusted forecast plus a planning reserve margin of 17%. Each month, the LSE's must procure 100% of their monthly System RA obligation.

The increase in renewable energy, particularly solar generation, over recent years has had a dramatic effect on California's energy markets. Figure 7.2-1 shows monthly solar generation in California since 2018 (CAISO 2024a).

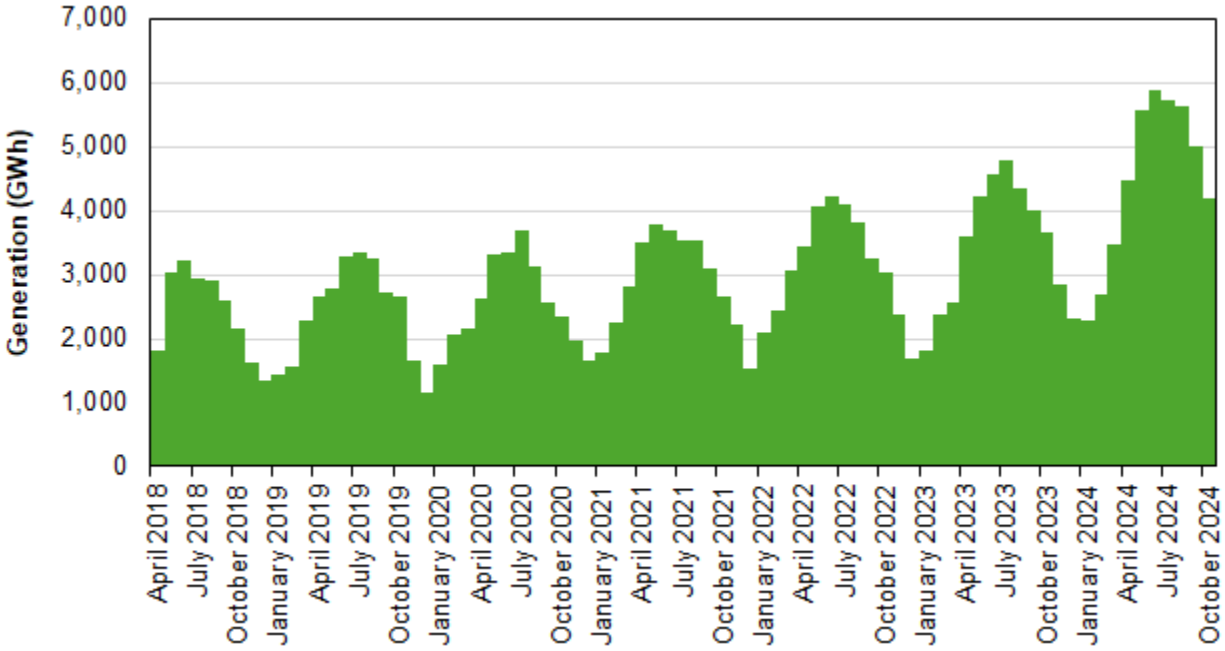

Figure 7.2-1. Comparison of Historical Monthly California Solar Generation.
Source: CAISO 2024

The increase in solar generation has led to an increase in over-generation within the CAISO areas. CAISO often relies on exports to neighboring balancing areas, such as those in the Pacific Northwest, Desert Southwest, and Baja California, to mitigate for over-generation periods; exports allow the system to maintain balance without resorting to curtailments. Over-generation typically occurs when there is an excess of renewable output, particularly midday solar, and low system demand (CAISO 2024c). This typically occurs during the spring, particularly during mild weather. The increase in solar generation coincides with an increase in exports. Figure 7.2-2 shows a comparison of historical monthly California energy exports.

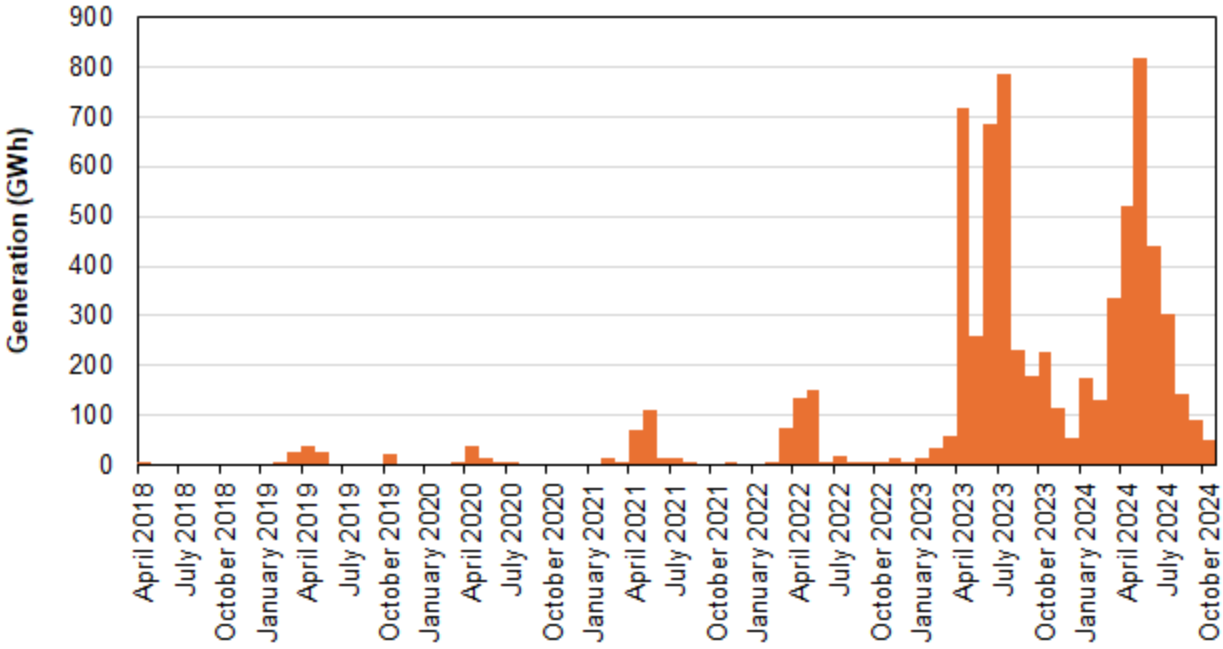

Figure 7.2-2. Comparison of Historical Monthly California Energy Exports.
Source: CAISO 2024

CAISO defines net demand as total electricity demand minus generation from wind and solar resources; California's increase in over-generation occurs in the middle of the day, when available solar generation exceeds the demand, resulting in a negative net generation. However, solar generation is reduced as the sun goes down in the evening, corresponding with the time of the day with the highest demand, resulting in a need for large quantities of replacement energy to come online quickly in the evening, this sudden increase in demand for generation is referred to as the "evening ramp". Figure 7.2-3 shows the comparison of historical hourly demand, net demand, and solar generation for May 11, 2024. Note that the evening ramp requires nearly 25 GW of additional generation resources to be dispatched between 16:00 and 20:00 in the evening.

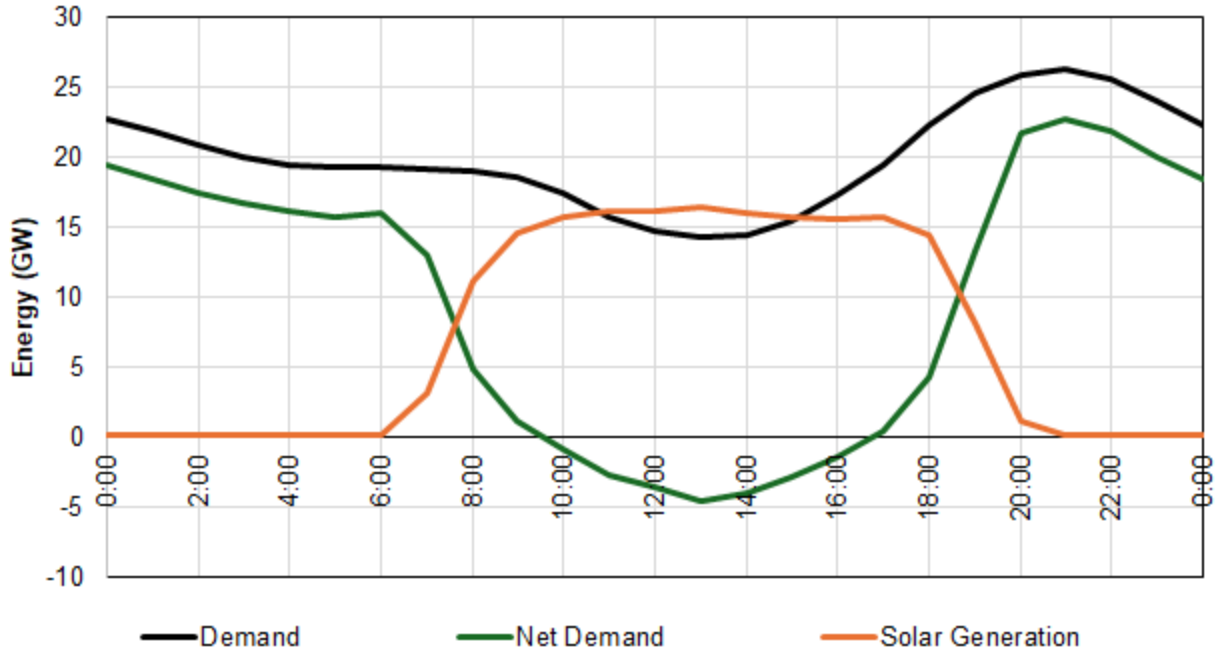

Figure 7.2-3. Comparison of Historical Hourly Demand, Net Demand, and Solar Generation for May 11, 2024.
Source: CAISO 2024b

The New Colgate Powerhouse provides a flexible generation resource that helps the CAISO respond to the evening ramp by providing a flexible generation resource. Additionally, there have been multiple periods recently when the CAISO called on generators to increase their output and warned California residents about the possibility of rolling blackouts. For example, in September 2022, amidst a severe heat wave in California, the CAISO issued a Flex Alert urging voluntary energy conservation, and, at the peak of the heatwave, the CAISO declared an Energy Emergency Alert, signaling all resources were committed or forecasted to be use, and that energy deficiencies were expected. On September 6, 2022, California reached its historical peak energy demand of 52,061 megawatts, but with CAISO's response measures, system operations remained reliable, and no outages were needed. CAISO was able to maintain reliability during the emergency through its Resource Adequacy program and with coordination and communication with California utilities, including Yuba Water; Yuba Water received authorization and a request from CAISO (CAISO 2022) on September 1 to provide additional generation between 16:00 and 21:00 for the week of September 2 through 7, 2022, to help maintain grid reliability through the heat wave. Yuba Water increased both New Colgate and the Narrows 2 Powerhouses' output during this emergency, compared to planned releases. Figure 7.2-4 shows generation from the New Colgate, Narrows 1, and Narrows 2 powerhouses immediately before, during, and after the emergency period.

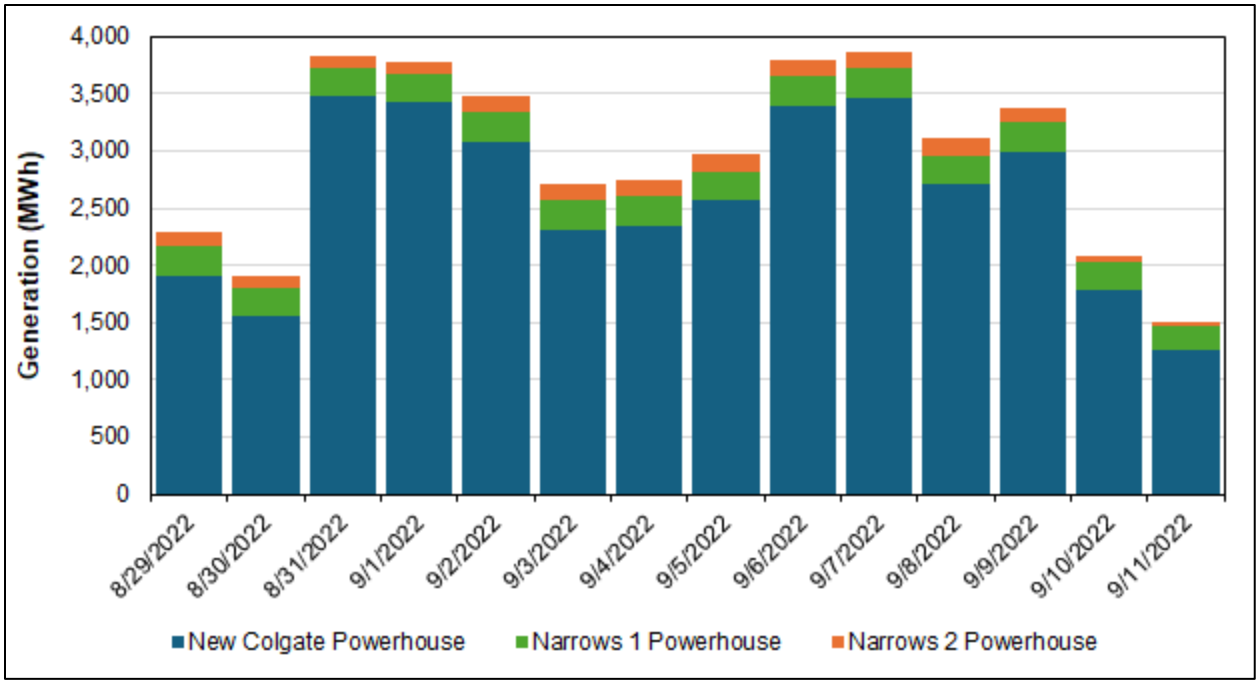

Figure 7.2-4. Historical Daily Yuba Water Generation During September 2 through 7, 2022 Heat Wave.

A trend that is becoming more pronounced is the need for generation in the morning ramp hours (hours 06:00 to 08:00 depending on the time of year). At times, the morning ramp hours do not have sufficient solar, wind or batteries to provide to the grid. In addition, when electricity demand increases in the morning ramp hours in the CAISO real time market and the response time to provide generation is not long enough for natural gas generation (i.e., natural gas generation can take hours to be ready to provide electricity on the grid) the hydroelectricity from Yuba Water provides necessary generation to the grid.

7.2.2 Energy Consumption

Hydropower is a major energy source in California. In WY 2024 (October 1, 2023, through September 30, 2024), the most recent year for which data are available, California consumed approximately 212,259 GWh of electricity. Figure 7.2-5 shows a comparison of various sources of generation for 2024 (CAISO 2024).

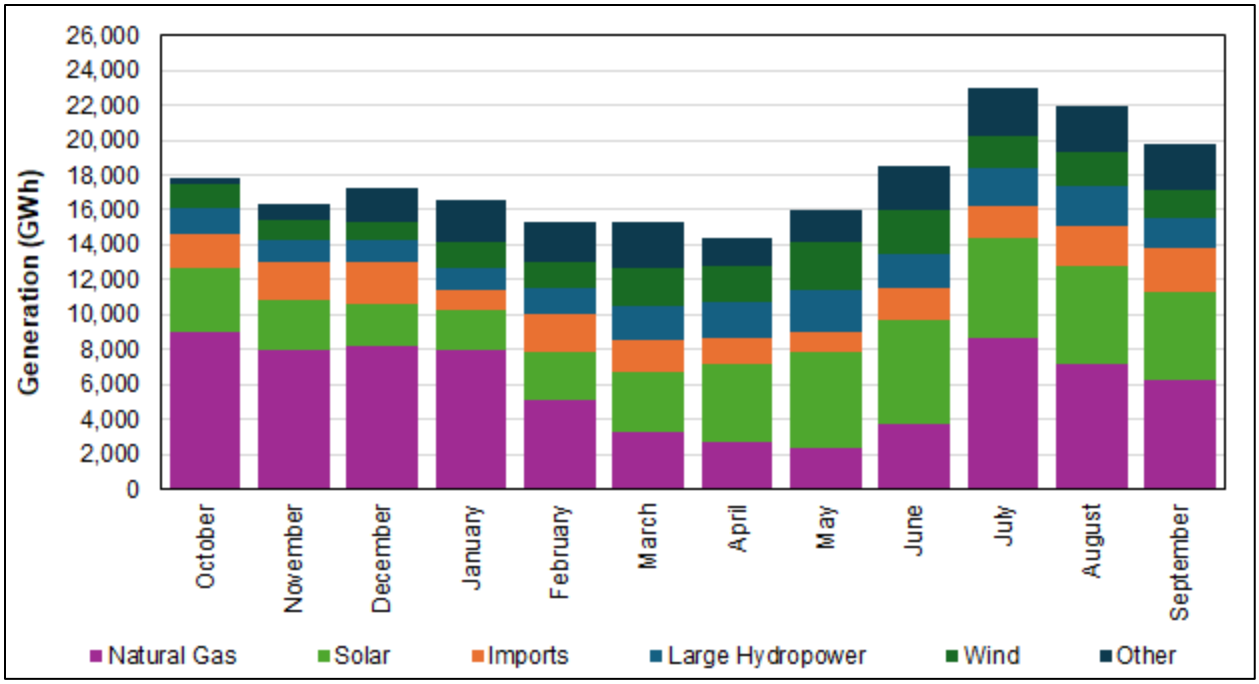

Figure 7.2-5. Comparison of California Generation Sources for WY 2024.
Source: CAISO 2024

In WY 2024, natural gas made up 34% of the total generation, solar generation accounted for 23%, imports from out of state accounted for 11%, wind and large hydropower (from hydropower plants larger than 30 MW) accounted for 10%, and other sources, including batteries, nuclear, and small hydropower (hydropower facilities with less than 30 MW capacity) accounted for 12%.

The three-county area within which the Proposed Projects are located receives electrical service from PG&E, an investor-owned utility serving most of northern and central California. In 2022, the most recent year for which data are available, the total electricity consumption for Yuba County was approximately 572 million kWh, of which approximately 258 million kWh were consumed by residential uses and the remainder by non-residential uses. For Nevada County, total electricity consumption in 2022 was approximately 697 million kWh, of which approximately 437 million kWh were consumed by residential uses. Sierra County consumed approximately 23 million kWh of electricity in 2022, of which approximately 14 million kWh were consumed by residential uses (CEC 2022a).

Natural gas is also a significant source of energy that is consumed by residences and businesses. Aside from electricity generation, natural gas is also used for heating and cooking. PG&E is the sole provider of natural gas services in Yuba and Nevada Counties. In 2022, Yuba County consumed approximately 11 million therms of natural gas, of which approximately 7.5 million therms were consumed by residential uses and the remainder by non-residential uses. For Nevada County, total natural gas consumption in 2022 was approximately 23 million therms, of which approximately 16 million therms were consumed by residential uses and the remainder by non-residential uses (CEC 2022b). No natural gas service is provided in Sierra County; instead, propane is commonly used, provided through private companies and stored in individual tanks.

7.3 Regulatory Setting

7.3.1 Federal

7.3.1.1 Federal Power Act

In 1920, Congress passed the Federal Water Power Act, which gave the Federal Power Commission (FPC), the Federal Energy Regulatory Commission's (FERC) predecessor, its original authority to license and regulate non-federal hydropower projects. As Congress expanded the regulatory authority of the FPC, the Federal Water Power Act ultimately became Part I of the Federal Power Act (FPA). Part I of the FPA has been amended by subsequent statutes including the Electric Consumers Protection Act of 1986, the Energy Policy Act of 1992, the Hydropower Regulatory Efficiency Act of 2013, and the America's Water Infrastructure Act of 2018.

FERC relies on these authorities to carry out its hydropower responsibilities, including: the issuance of preliminary permits; determinations regarding qualifying conduit facilities; the issuance of licenses for the construction and operation of new projects; the issuance of relicenses for existing projects; the investigation and assessment of headwater benefits; and the oversight of all ongoing project operations, including dam safety and security inspections, public safety, and environmental monitoring. While FERC's responsibility under the FPA is to strike an appropriate balance among the many competing developmental and non-developmental interests, including environmental, several other statutes affect hydropower regulation. These include, but are not limited to, NEPA, the Clean Water Act, the Coastal Zone Management Act, the Endangered Species Act, the Fish and Wildlife Coordination Act, and the National Historic Preservation Act.

7.3.1.2 North American Electric Reliability Corporation (NERC)

The North American Electric Reliability Corporation (NERC) has several requirements for hydropower generators to ensure the reliability and stability of the bulk power system. Key requirements include:

- Generator Operation for Maintaining Network Voltage Schedules (VAR-002-4.1): Hydropower generators must operate in automatic voltage control mode with their automatic voltage regulator (AVR) in service and controlling voltage, unless instructed otherwise by the Transmission Operator.

- Modeling and Data Requirements: Hydropower generators must develop, validate, and submit models of their generators, governors, exciters, and turbines. These models must be updated every five years or when equipment is modified.

- Reactive Power and Voltage Control: Generators must maintain the voltage or reactive power schedule provided by the Transmission Operator, within the capabilities of the generating facility.

- Disturbance Monitoring and Reporting: Generators must monitor and report disturbances to ensure accurate simulation of the dynamic response of the generator under various conditions.

These requirements help maintain grid stability and ensure that hydropower generators contribute effectively to the overall reliability of the power system.

7.3.1.3 Western Electricity Coordinating Council

The Western Electricity Coordinating Council (WECC) has specific requirements for hydropower generators to ensure reliability and stability of the power system in the Western Interconnection. Requirements include:

- Generating Facility Data Requirements: Hydropower generators must provide detailed data about their facilities, including generator models, governor models, exciter models, and turbine models. This data is crucial for transmission planning and system reliability.

- Model Validation and Testing: Generators must validate and test their models to ensure they accurately represent the dynamic behavior of the generating units. This includes baseline tests and periodic validation to maintain model accuracy.

- Over Excitation System Limiter (OEL) and Over Excitation Protection (OEP) Testing: Generators must perform tests to ensure their excitation systems are properly limited and protected.

- Coordination with NERC Requirements: WECC requirements often align with NERC standards, including the development, validation, and submission of generator models for facilities 20 MVA and larger.

As with the NERC requirements, the WECC requirements help maintain grid stability and ensure that hydropower generators contribute effectively to the overall reliability of the power system.

7.3.1.4 Institute of Electrical and Electronics Engineers

The Institute of Electrical and Electronics Engineers (IEEE) provides standards for the design, O&M of hydropower facilities. These include guidelines for electrical equipment, safety protocols, and performance testing. IEEE standards for hydropower cover a wide range of topics to ensure the safe, efficient, and reliable operation of hydroelectric power plants. Here are some key standards:

- IEEE 125-2007: Recommended Practice for Preparation of Equipment Specifications for Speed-Governing of Hydraulic Turbines Intended to Drive Electric Generators. This standard provides guidelines for specifying speed-governing systems.

- IEEE 492-1999 (R2011): Guide for Operation and Maintenance of Hydro-Generators. It offers best practices for the O&M of hydro-generators.

- IEEE 666-2007: Design Guide for Electric Power Service Systems for Generating Stations. This guide covers the design of electric power service systems in hydroelectric plants.

- IEEE 1010-2006: Guide for Control of Hydroelectric Power Plants. It documents industry practices for control system logic, configurations, and control modes in hydroelectric plants.

- IEEE 1248-2020: Guide for the Commissioning of Electrical Systems in Hydroelectric Power Plants. This guide provides procedures for the inspection and testing of electrical systems from installation to commercial operation.

- IEEE 1249-2013: Guide for Computer-Based Control for Hydroelectric Power Plant Automation. It addresses the application and design of computer-based control systems for automation.

These standards help ensure that hydroelectric power plants operate safely, efficiently, and reliably.

7.3.2 State

7.3.2.1 California Green Building Standards Code

The California Green Building Standards Code, or CALGreen, is published in its entirety every three years by order of the State Legislature. The latest version was published in 2022. The 2025 version is currently in the publication and market readiness activities stage, and this version is scheduled to take effect on January 1, 2026.

CALGreen features regulations for energy efficiency, water efficiency and conservation, material conservation and resource efficiency, environmental quality, and other matters. It also includes mandatory measures for residential and non-residential buildings, along with appendices containing voluntary measures for residential and non-residential uses. Yuba, Nevada, and Sierra Counties all have adopted the 2022 CALGreen.

7.3.2.2 California Energy Code

The California Energy Code (California Code of Regulations Title 24, Part 6), with its building energy efficiency standards, is designed to reduce wasteful, uneconomical, and unnecessary consumption of energy. The Energy Code is updated every three years, with the most recent update in 2022. Yuba, Nevada, and Sierra Counties all have adopted the 2022 California Energy Code.

The Energy Code contains energy and water efficiency requirements, along with indoor air quality requirements, for newly constructed buildings, additions to existing buildings, and alterations to existing buildings. The Energy Code is conceptually divided into three basic sets. First is a basic set of mandatory requirements that apply to all buildings. Second is a set of performance standards – the energy budgets – that vary by climate zone (of which there are 16 in California) and building type; thus, the Energy Code is tailored to local conditions and provide flexibility in how energy efficiency in buildings can be achieved. The third set constitutes an alternative to the performance standards, which is a set of prescriptive packages that provide a recipe or a checklist compliance approach.

7.3.2.3 Renewables Portfolio Standard

California's Renewables Portfolio Standard program, originally established in 2002 by SB 1078, encourages greater provision of electricity from renewable resources. “Renewable resources” include solar, wind, geothermal, biomass, and small hydroelectric, the latter generating up to 30 MW, or 40 MW if operated as part of a water supply or conveyance system. The New Bullards Bar Minimum Flow and Narrows 1 Powerhouses are considered small hydroelectric facilities as defined by the Renewables Portfolio Standard.

Initially, SB 1078 required that 20% of electricity retail sales in California must be generated by renewable resources by 2017. Subsequent renewables targets included 33% by 2020 and 50% by 2030. Most recently, SB 100, enacted in 2018, increased the renewables target in 2030 to 60% and requires all the state's electricity to come from carbon-free resources by 2045. In 2020, California received 34.5% of its retail electricity from renewable resources, thereby meeting the 2020 target. As of 2022, 39.4% of California’s retail electricity came from renewable resources (CEC 2024).

7.3.2.4 Resource Adequacy Program

The CPUC adopted a Resource Adequacy policy in 2004 to ensure the reliability of electric service in California. The CPUC established Resource Adequacy obligations applicable to all Load Serving Entities (LSEs) within the CPUC’s jurisdiction, including investor-owned utilities (IOUs), energy service providers (ESPs), and community choice aggregators (CCAs). The CPUC’s Resource Adequacy policy framework – implemented as the Resource Adequacy program - guides resource procurement and promotes infrastructure investment by requiring that LSEs procure capacity so that capacity is available to the CAISO when and where needed. On June 20, 2024, the CPUC released Decision (D.) 24-06-004 that resolves issues scoped in Track 1 of the Resource Adequacy (RA) Proceeding, Rulemaking (R.) 23-10-011. Specifically, the Decision affirms the Commission’s decision to implement the Slice of Day (SOD) Framework for the 2025 RA compliance year, as summarized below.[3] Additionally, it sets the near-term reliability requirements for CPUC’s jurisdictional Load Serving Entities’ (LSE) obligations to procure System, Local, and Flexible RA capacity. The Decision adopts Local Capacity Requirements (LCR) for 2025 through 2027, Flexible Capacity Requirements (FCR) for 2025, and sets a 17 percent Planning Reserve Margin (PRM) for LSEs under the SOD Framework. The Decision also makes rule clarifications and refinements to the RA program.

Under the SOD framework, each LSE will procure their load share of system capacity for each of the 24 hours of the day. As the system experiences more variable renewable energy and storage, and as the periods of system scarcity or stress conditions emerge outside of the system peak hours, it is increasingly important for all LSEs to procure reliability capacity to meet the periods of system stress and not just ‘peak’ load.

[3] The CPUC requires all LSEs to maintain adequate generating capacity to meet each LSE’s local, system, and flexible demands. To meet local requirements, LSEs must procure resources sited in locations where supply is needed due to insufficient transmission. For system requirements, LSEs must contract for or generate sufficient resources to meet their share of the system’s peak demand, plus a PRM. To meet flexible requirements, LSEs must procure resources that can ramp up or down on short notice to meet variations in demand and production.

Local RA requirements are set annually to ensure that transmission constrained local areas have sufficient resources to serve load based on a 1-in-10 weather year[4] and N-1-1[5] contingency criteria. Flexible requirements were developed in response to the increased penetration of variable resources on the system and the need to ensure there would be enough flexible capacity to meet energy demands when variable energy resources stop producing. Flexible RA requirements are set based on an annual CAISO study that looks at the largest three-hour ramp for each month needed to run the system reliably (CPUC 2024).

7.3.3 Regional/Local

7.3.3.1 Yuba Water's Water Rights for Power

Yuba Water holds pre-1914 appropriative rights dating from 1897 and post-1914 appropriative water rights reflected and confirmed by water-right licenses, for the purposes of operating the YRDP for hydroelectric power generation. Table 7.3-1 lists the post-1914 appropriative water-right licenses held by Yuba Water for power generation.

Table 7.3-1. Water-right licenses held by Yuba Water for operation of the Project for power generation.

Priority (date)	SWRCB Designation (application)	SWRCB Designation (license)	Source (waterbody)	Amount & Place of Diversion or Storage (amount & place)		Season (period)		Place of Beneficial Use (powerhouse)
2/11/1921	2197	435	North Yuba River	700 cfs at NBB Dam		1/1 - 12/31		New Colgate Powerhouse
				5,000 ac-ft/yr at NBB Dam		about 12/15 to about 7/15		
9/7/1922	3026	436	North Yuba River	10,000 ac-ft/yr at NBB Dam		about 12/15 to about 7/15		New Colgate Powerhouse
4/30/1926	5004	777	North Yuba River	15,000 ac-ft/yr at NBB Dam		about 12/15 to about 7/15		New Colgate Powerhouse
Priority (date)	SWRCB Designation (application)	SWRCB Designation (license)	Source (waterbody)	Amount & Place of Diversion or Storage (amount & place)		Season (period)		Place of Beneficial Use (powerhouse)
7/30/1927	5631	11565	Middle Yuba River	810 cfs at Our House Dam	490,000 ac-ft/yr storage in NBB Res	1/1-12/31 (dir. div.)	10/15 to 6/30 (stor.)	New Colgate Powerhouse and Narrows 2 Powerhouse
			Oregon Creek	240 cfs at Log Cabin Dam		1/1-12/31 (dir. div.)		
			North Yuba River	1,800 cfs at NBB Dam		11/1- 7/31 (dir. div.)		
			Yuba River	1,800 cfs at USACE's Englebright Dam		1/1- 12/31		
3/1/1939	9516	3050	North Yuba River	100 cfs at NBB Dam		1/1 - 12/31		New Colgate Powerhouse
9/12/1941	10282	5544	North Yuba River	5,335 ac-ft/yr at NBB Dam		about 10/1 to about 3/1		New Colgate Powerhouse
								Narrows 2 Powerhouse

[4] The CPUC 1-in-10 weather year refers to a weather scenario that is expected to occur with a 10% probability in a given year. In this context, it means higher-than-average temperatures that lead to increased electricity demand, especially during peak hours. This scenario ensures the electric grid can handle unusually high demand due to rare but foreseeable weather events.

[5] The N-1-1 contingency planning standard means the system can withstand two consecutive failures where after the first failure occurs, the system adjusts, and then a second, different failure occurs, and the system must remain stable and avoid cascading outages. The standard is important for ensuring high reliability in the electric grid during extreme weather events or high-demand periods.

Table 7.3-1. (Continued).

Priority (date)	SWRCB Designation (application)	SWRCB Designation(license)	Source (waterbody)	Amount & Place of Diversion or Storage (amount & place)		Season (period)	Place of Beneficial Use (powerhouse)
2/20/1953	15205	11566	Middle Yuba River	3,200 ac-ft/yr at Log Cabin Dam; storage in NBB Res.		5/1- 6/30	New Colgate Powerhouse and Narrows 2 Powerhouse
			North Yuba River	245 cfs and 700 ac-ft/yr at NBB Dam		3/15- 6/15 (dir. div.); 5/1- 6/30 (stor.)	
			Yuba River	800 cfs at USACE's Englebright Dam		11/1-7/15	
10/2/1953	15563	11567	Middle Yuba River	30,000 ac-ft/yr at Our House Dam	all storage in NBB Res.	10/15 - 6/30	New Colgate Powerhouse and Narrows 2 Powerhouse
			Oregon Creek	1,400 ac-ft/yr at Log Cabin Dam		10/15 - 6/30	
			North Yuba River	146,000 ac-ft/yr at NBB Dam		10/15 - 6/30	
			Yuba River	910 cfs at USACE's Englebright Dam		11/1 - 6/30	

7.4 Impact Assessment Methodology

The impact analysis for energy follows the approach in the general overview described in Chapter 4. Due to the interconnected nature of California's energy market, changes in generation from the YRDP and Narrows Projects have the potential to affect the NP15 region; the primary study area for Power Production and Energy Consumption is the NP15 region. There is no secondary study area for Power Production and Energy Consumption.

7.4.1 Power Production Effects

7.4.1.1 Construction

None of the construction-related projects associated with the Proposed Projects or the alternatives would affect New Bullards Bar Reservoir's ability to make releases through the New Colgate Powerhouse; if constructed, the Tailwater Depression System (TDS) would be constructed during a planned New Colgate Powerhouse outage, nor would any projects affect releases through the Narrows 1 or Narrows 2 powerhouses. Accordingly, there would be no construction-related impacts from the Proposed Projects or their alternatives energy generation. Because of this, construction impacts associated with energy generation are not further analyzed in this chapter.

7.4.1.2 Operations

The operations analysis evaluates impacts related to hydrologic changes from the Proposed Projects and alternatives including changes in generation from the New Colgate, Narrows 1, Narrows 2, and New Bullards Bar Minimum Flow powerhouses.

Potential generation impacts are assessed based on evaluation of model results from Yuba Water's Yuba River Development Project Model (YRDPM). The YRDPM includes representation of a long-term period of record of hydrology (WY 1970 through 2021), current and proposed facilities, and current and proposed operational requirements. Changes in simulated generation as a result of the Proposed Projects and alternatives, relative to the bases of comparison, are used to determine

potential impacts. More information about the YRDPM, including assumptions, inputs, and model limitations, is available in Appendix 5-1, Yuba Water Operations Model Technical Memorandum. Changes in simulated monthly generation as a result of each alternative's assumptions will be compared to the appropriate basis of comparison to determine changes in generation resulting from each alternative.

While the YRDPM provides the majority of the information used for the impact assessment, Yuba Water also relied on its New Colgate Generation Optimization Model (Colgate Optimization Model), documented in Appendix 7A. The Colgate Optimization Model computed hourly operations of the New Colgate Powerhouse using the daily YRDPM output and historical (water year 2024) energy and ancillary services prices. The Colgate Optimization Model optimized hourly operations to maximize energy-related revenue of the New Colgate Powerhouse. Outputs include hourly flow and generation, and generation capacity. The New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 1 and Narrows 2 powerhouses' capacities are based on releases. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from either the Narrows 1 or 2 powerhouses would reduce the amount of RA the YRDP can provide. As a result of Yuba Water's participation in the Resource Adequacy program, the generation capacity will be used to evaluate changes in potential for providing resource adequacy to the CAISO grid.

Alternative 1 also includes the requirement that NID and PG&E release an additional 15,600 acre-feet of water in April and May of dry and critical years to offset increased YRDP and Narrows Project releases for water temperature management in September and October. Because the actual relative contribution of flow from NID and PG&E has not been defined, nor which reservoirs or powerhouses would be used to make the releases, this impact analysis utilizes information from NID (NID 2023) regarding changes in average annual generation in dry and critically dry years between NID's Scenario 2, All FEIS and NID's Alternative 1, YCWA Proposal, to characterize potential changes to NID and PG&E generation that could occur under Alternative 1 at a programmatic level.

Table 7.4-1 shows the appropriate basis of comparison for each alternative. A comprehensive description of each alternative and the intent of each comparison is described in Chapter 3.

Table 7.4-1. Summary of Scenario Comparisons

Alternative Scenario Number	Alternative Scenario Name	Basis of Comparison Number	Basis of Comparison Name
3	No Project	1	Existing Condition
4	Proposed Projects	1	Existing Condition
5	Proposed Projects (Future)	2	Future Baseline
6	Alternative 1	1	Existing Condition
6	Alternative 1	2	Future Baseline
9	Alternative 2	1	Existing Condition
9	Alternative 2	2	Future Baseline
7	Proposed Projects Cumulative Condition	1	Existing Condition
8	Alternative 1 Cumulative Condition	1	Existing Condition
10	Alternative 2 Cumulative Condition	1	Existing Condition

While the No Project Alternative is functionally equivalent to the Existing Condition from a flow perspective, it assumes a complete loss of YRDP and Narrows Project generation.

7.4.2 Energy Effects

CEQA requires that an EIR include a discussion of the potential energy impacts of a project, with particular emphasis on avoiding or reducing inefficient, wasteful, and unnecessary consumption of energy (California Public Resources Code Section 21100(b)(3)). CEQA Guidelines Appendix F explains that potentially significant energy implications of a project shall be considered in an EIR to the extent relevant and applicable to the project. The EIR should discuss energy conservation issues and the energy requirements of the project, along with energy-consuming equipment and processes to be used during project construction and operations, including energy consumed by vehicle trips. As explained in Appendix F, the means of achieving the goal of conserving energy include: (i) decreasing overall per capita energy consumption; (ii) decreasing reliance on fossil fuels such as coal, natural gas and oil, and (iii) increasing reliance on renewable energy sources. Appendix F further notes that potentially significant energy implications of a project shall be considered in an EIR to the extent relevant and applicable to the project and includes the following list of energy impact possibilities:

1. The project's energy requirements and its energy use efficiencies by amount and fuel type for each stage of the project including construction, O&M and/or removal. If appropriate, the energy intensiveness of materials may be discussed.

2. The effects of the project on local and regional energy supplies and on requirements for additional capacity.

3. The effects of the project on peak and base period demands for electricity and other forms of energy.

4. The degree to which the project complies with existing energy standards.

5. The effects of the project on energy resources.

6. The project's projected transportation energy use requirements and its overall use of efficient transportation alternatives.

Appendix F explains that in many instances specific items may not apply or additional items may be needed, but where items listed are applicable or relevant to the project, they should be considered in the EIR. A desktop analysis was completed to collect and analyze data related to energy use by the Proposed Projects. For construction activities, the analysis will focus on the use of fossil fuels, electricity, and other sources by construction equipment and vehicles. For operations, the analysis will evaluate potential energy use by structures associated with the Proposed Projects and the effect of the Proposed Projects and Alternatives on energy supplies.

7.4.3 Impact Indicators and Significance Criteria

7.4.3.1 Power Production

Reoperation of the YRDP under the Proposed Projects or the alternatives may result in reduced generation in some years due to changes in flows through the powerhouses or head in the upstream reservoirs as a result of operations for each scenario. A reduction in combined generation from the

four power plants, relative to the appropriate basis of comparison, as a result of each alternatives' operations, at a frequency and magnitude that could disrupt CAISO grid stability, would be considered significant (CAISO 2021).

The flexible nature of operations of the New Colgate Powerhouse allows it to avoid generation during low-demand hours (e.g., when solar and batteries operate), and to provide generation during high-demand hours (e.g., hours when there is less generation available on the CAISO grid, which is usually met by dispatchable generation like natural gas or some hydroelectricity units like the ones operated by the Yuba Water Agency). While modeling for the YRDP and Narrows Project relicensing uses daily timestep, a reduction in YRDP and Narrows Project generation of approximately 10% to 15% would start to impinge on Yuba Water's ability to provide energy during high-demand hours. A 10% reduction in generation would represent a loss of generation to roughly 1,400 homes. Accordingly, a threshold of 10% reduction in daily average generation is used to represent a significant threshold. While the Minimum Flow Powerhouse provides additional generation, its maximum capacity is a small fraction of the New Colgate and Narrows 2 Powerhouse, and while its generation is included in the accumulated quantities of generation, its role is minimal and is generally not mentioned in discussions of impacts of the Proposed Projects and alternatives.

Since it can be operated flexibly through the day, the New Colgate Powerhouse's capacity to provide RA services is based on the powerhouse's capacity to generate, which is primarily a factor of the amount of water stored in New Bullards Bar Reservoir. The Narrows 1 and 2 powerhouses do not vary flows through the day, so their capacity to provide RA services is based on planned releases. A reduction in YRDP and Narrows Project ability to provide RA services would require LSEs to procure other local RA assets, but most regional generators already participate in the RA market, so replacing Yuba Water's RA would be challenging. CAISO requires a 17% PRM as a standard for ensuring grid reliability. This margin is intended to provide a buffer to account for unexpected events such as generator outages or extreme weather. A reduction in local generation that approaches or exceeds this margin could compromise reliability. Therefore, a reduction in YRDP and Narrows Project capacity of 15% could be potentially significant.

The Narrows Project is qualified as a renewable energy source under the Renewables Portfolio Standard. As a result, Yuba Water preferentially runs the Narrows 1 Powerhouse over the YRDP's Narrows 2 Powerhouse. However, if the Proposed Projects or an alternative resulted in a reduction in generation from the Narrows 1 Powerhouse, it would represent a reduction in renewable energy on the CAISO grid. While there is excess renewable generation available during the spring, reductions in renewable energy generation during the summer could interfere with the State's SB 100 renewable energy objectives. Accordingly, an average monthly reduction of greater than 1% between July and October could be potentially significant.

Generation revenue from the YRDP and Narrows Project is used to fund the O&M of Yuba Water's facilities generally, as well as many of Yuba Water's programs. These programs include supporting Yuba County's disadvantaged communities and fisheries and aquatic habitat enhancement projects on the lower Yuba River. Generation revenue varies greatly from year to year, so Yuba Water's ability to fund these programs, as well as its fundamental O&M costs, depends on long-term, predictable revenue. Yuba Water's Amended License Application (AFLA) for the YRDP estimated average annual gross power benefits of approximately $51,000,000, and

average annual costs of approximately $32,000,000, and a net annual benefit of around $19,000,000 using 2016 energy value for the Existing Condition scenario (Yuba Water 2017). Based on these benefits and costs, a 10% reduction in YRDP generation value, or approximately $5,000,000, would be more than a quarter of the net benefit of the Existing Condition. Accordingly, a reduction in average annual generation-related revenue greater than 10% would result in a significant reduction in Yuba Water's ability to fund its programs over the long term.

Operations for Alternative 1 could lead to changes in timing and magnitude of generation by NID and PG&E. Power generation in April and May could be increased if the Alternative 1 releases were made from the Bowman and Spaulding No. 2 powerhouses, or if releases came from NID's Milton Diversion Dam, there would be no additional generation. Depending on whether NID and PG&E elected to make the releases from reservoir storage or by reducing out-of-basin diversions through the Drum and South Yuba tunnels, there could be reductions in generation within their respective systems, likely at different times of the year. For base-loaded plants, any increase or decrease in generation would be spread throughout the day, but a decrease in generation from a peaking plant would likely reduce the runtime of the plant rather than the peak output. The maximum potential effect would result from forgoing generation from the full 15,600 acre-feet of release throughout a chain of cascading hydropower plants in April or May.

Accordingly, for energy supplies, the Proposed Projects or the alternatives would have a significant impact, relative to the appropriate basis of comparison, if they would:

- **Impact EN-1:** Result in an average monthly decrease in total combined generation from New Colgate, Minimum Fish Flow, and Narrows 2 powerhouses of greater than 10%.

- **Impact EN-2:** Result in an average monthly decrease in total combined generation capacity from New Colgate and Narrows 2 powerhouses of greater than 15%.

- **Impact EN-3** Result in an average monthly decrease in total generation from the Narrows 1 Powerhouse of greater than 1%.

- **Impact EN-4:** Result in an average monthly decrease in generation capacity from Narrows 1 Powerhouse of greater than 15%.

- **Impact EN-5:** Result in decrease in an average annual generation-related revenue from the YRDP greater than 10%

- **Impact EN-6**: Result in decrease in an average annual generation-related revenue from the Narrows Project greater than 10%

Alternative 1 has the ability to affect NID and PG&E's Yuba-Bear and Drum-Spaulding projects' hydropower generation. An impact to NID and PG&E's hydropower generation would occur if there was a substantial reduction in generation relative to the Future Baseline.

7.4.3.2 Energy Consumption

For energy consumption, impact indicators and significance criteria rely upon the CEQA Guidelines Appendix G: Environmental Checklist Form. Under CEQA Guidelines Appendix G, the Proposed Projects and alternatives may have a significant impact on energy if they would:

- **Impact EN-7:** Result in potentially significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources during YRDP construction.
- **Impact EN-8:** Result in potentially significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources during YRDP operations.
- **Impact EN-9:** Result in potentially significant environmental impact due to wasteful, inefficient, or unnecessary consumption of energy resources during Narrows Project operation.
- **Impact EN-10:** Conflict with or obstruct a state or local plan for renewable energy or energy efficiency as a result of YRDP construction activities.
- **Impact EN-11**: Conflict with or obstruct a state or local plan for renewable energy or energy efficiency as a result of YRDP operations.
- **Impact EN-12:** Conflict with or obstruct a state or local plan for renewable energy or energy efficiency as a result of Narrows Project operations,

Energy consumption impacts of the Proposed Projects and the alternatives are evaluated relative to the Existing Condition, rather than the Future Baseline. This is because these impacts involve construction or operational activities that are not affected by flows, or because it is not feasible or necessary to precisely distinguish between the magnitudes of these impacts based on quantitative differences in flows.

7.5 Environmental Impact Analysis

7.5.1 Proposed Projects compared to the Existing Condition

7.5.1.1 Energy Production

YRDP Impact EN-PP-1: Change in Monthly Generation from YRDP Operations

Operations for the YRDP include increased flow requirements in the Middle Yuba River below Our House Dam, increased flow requirements in Oregon Creek below Log Cabin Dam, increased flows in the North Yuba River below New Bullards Bar Dam, and periodic closures of the Lohman Ridge Tunnel. These elements of the Proposed Projects would each contribute to a reduction in flows from the New Colgate Powerhouse and a reduction in generation. Since flows in the lower Yuba River are not changing substantially, there would not be substantial changes in generation at the Narrows 2 Powerhouse. Table 7.5-1 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse, and Minimum Flow Powerhouse.

Table 7.5-1. Comparison of Average Monthly Generation for YRDP Facilities Relative to Existing Condition.

Month	YRDP Generation (GWh)		Change in YRDP Generation from Basis of Comparison	
	Existing Condition	Proposed Projects	(GWh)	(%)
October	51.8	51.4	-0.5	-1%
November	49.5	47.2	-2.3	-5%
December	64.0	60.2	-3.8	-6%
January	84.5	79.5	-5.0	-6%
February	96.6	92.1	-4.5	-5%
March	151.7	148.2	-3.5	-2%
April	132.6	130.8	-1.8	-1%
May	174.3	165.7	-8.6	-5%
June	176.9	166.8	-10.1	-6%
July	155.5	149.6	-5.9	-4%
August	134.9	127.9	-7.0	-5%
September	63.7	61.2	-2.5	-4%

Key: MW = Megawatt

While there is a reduction in average YRDP generation in most months under the Proposed Projects relative to the Existing Conditions, average generation reductions reach their maximum of 6% in December, January, and June. Other months have smaller reductions; as such, average monthly decreases would not be greater than 10%. Accordingly, YRDP operational impacts would be **less than significant**, and no CEQA mitigation is required.

YRDP Impact EN-PP-2: Change in Monthly Generation Capacity from YRDP Operations

The New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 2 Powerhouse's capacity is based on its planned flows. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from the Narrows 2 Powerhouse would reduce the amount of RA the YRDP can provide. Table 7.5-2 shows a comparison of generation capacity from the New Colgate and Narrows 2 powerhouses relative to the Existing Condition.

Table 7.5-2. Comparison of Average Monthly Generation Capacity for New Colgate and Narrows 2 Powerhouses Relative to Existing Condition.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	Proposed Projects	(MW)	(%)
October	299	300	0	0%
November	289	289	0	0%
December	282	282	0	0%
January	280	279	-1	0%
February	285	284	0	0%
March	315	315	0	0%
April	339	339	1	0%
May	358	358	0	0%
June	359	358	-1	0%
July	340	340	-1	0%
August	326	325	-1	0%
September	307	307	0	0%

Key: MW = Megawatt

There is a very small decrease in generation capacity in January, June, July, and August; otherwise, no capacity changes would occur, with even a slight increase in April. Under the Proposed Projects relative to the Existing Conditions, average generation capacity reductions do not even amount to 1% of the Existing Condition capacity. Accordingly, YRDP operational impacts would be **less than significant**, and no CEQA mitigation is required.

YRDP Impact EN-PP-3: Reduction in Generation-Related Revenue from YRDP Operations

While the New Colgate Powerhouse's flexible operations allow it to target hours of high energy demand and the associated higher economic value, the Narrows 2 Powerhouse runs consistently through every hour of a day. The New Colgate Powerhouse's operational flexibility allows it to adjust generation to minimize the economic effects of reductions in generation shown in Table 7.5-1. Table 7.5-3 shows a comparison of the average annual generation revenue for the YRDP relative to the Existing Condition.

Table 7.5-3. Comparison of Average Annual Generation Revenue for YRDP Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	Proposed Projects	(1M$)	(%)
New Colgate PH	59.0	59.0	-0.1	0%
Narrows 2 PH	5.7	5.7	0.0	-1%
Total YRDP	64.8	64.7	-0.1	0%

Key: $1M = Millions of Dollars

There are very small reductions in annual generation revenue from YRDP relative to the Existing Condition, but average generation revenue reductions would not exceed 10% of the Existing

Condition revenue. Accordingly, YRDP operational impacts would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact EN-PP-1: Change in Monthly Generation from Narrows 1 Operations

Due to its ability to provide renewable energy, the Narrows 1 Powerhouse is almost always run at its full capacity. There are some periods when releases would be slightly changed due to differences in Englebright Dam releases, particularly when desired Englebright Dam releases are in the 900 to 1,080 cfs and the Narrows 1 Powerhouse is providing flows above the Narrows 2 Powerhouse minimum capacity. As a result, there could be small change in generation, Table 7.5-4 shows a comparison of monthly generation for the Narrows Project relative to the Existing Condition.

Table 7.5-4. Comparison of Average Monthly Generation for Narrows 1 Powerhouse Relative to Existing Condition.

Month	Narrows Project Generation (GWh)		Change in Narrows Project Generation from Basis of Comparison	
	Existing Condition	Proposed Projects	(GWh)	(%)
July	8.2	8.3	0.0	0%
August	7.9	8.1	0.1	2%
September	7.2	7.7	0.5	7%
October	8.2	8.1	0.0	0%

Key: MW = Megawatt

Narrows 1 Powerhouse generation is generally increased during summer months and therefore would contribute to the state meeting its SB100 goals. Accordingly, Narrows 1 operational impacts would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact EN-PP-2: Change in Monthly Generation Capacity from Narrows 1 Operations

The Narrows 1 Powerhouse's ability to provide capacity is based on its planned flows. Since there are very few changes in planned flows for the Narrows 1 Powerhouse under the Proposed Project, relative to the Existing Condition, there are very small changes in generation capacity. Table 7.5-5 shows a comparison of average monthly generation capacity for the Narrows 1 Powerhouse relative to the Existing Condition.

Table 7.5-5. Comparison of Average Monthly Generation Capacity for Narrows 1 Powerhouse Relative to Existing Condition

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	Proposed Projects	(MW)	(%)
October	10.9	10.8	-0.1	-1%
November	10.9	10.9	-0.1	-1%
December	11.2	11.2	-0.1	-1%
January	11.3	11.3	0.0	0%
February	11.4	11.3	0.0	0%
March	11.5	11.4	0.0	0%
April	11.3	11.3	0.1	1%
May	11.5	11.5	0.0	0%
June	7.8	7.8	0.0	0%
July	10.1	10.1	0.0	0%
August	11.1	11.1	-0.1	-1%
September	10.5	10.6	0.2	2%

Key: MW = Megawatt

There are a very small changes in generation capacity in October, November, December, and August under the Proposed Projects relative to the Existing Conditions, but average generation capacity reductions do not exceed 5% of the Existing Condition capacity. Accordingly, Narrows 1 operational impacts would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact EN-PP-3: Reduction in Generation-Related Revenue from Narrows 1 Operations

Since there are very few changes in Narrows 1 Powerhouse generation; in fact, there is a small increase in overall generation. However, changes in generation shown in Table 7.5-5 do not result in a notable change in Narrows Project generation revenue. Table 7.5-6 shows a comparison of Narrows Project generation revenue for the Proposed Projects and Existing Condition scenarios.

Table 7.5-6. Comparison of Average Annual Generation Revenue for Narrows 1 Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	Proposed Projects	(1M$)	(%)
Narrows 1 PH	11.2	11.2	0.0	0%

Key: $1M = Millions of Dollars

There are very small reductions in annual generation revenue from Narrows 1 relative to the Existing Condition, but average generation revenue reductions would not exceed 10% of the Existing Condition revenue. Accordingly, Narrows 1 impacts would be **less than significant**, and no CEQA mitigation is required.

7.5.1.2 Energy Consumption

YRDP Impact EN-PP-4: Energy Consumption by YRDP Construction Activities

The proposed YRDP would involve the use of gasoline- and diesel-fueled vehicles and equipment during construction activities and the import/export of materials to and from the construction site. Construction activities would occur over an approximately 20-year period, with work to be done seasonally for no more than seven months in one year. The use of fuel and other energy resources during YRDP construction would be non-recoverable and potentially significant. See Appendix 2A-3 for information regarding construction equipment uses and workers during each stage of YRDP construction, which was used in the analysis in Chapter 15, Air Quality and Greenhouse Gas Emissions.

As required by MM AQ-2 - described in Chapter 15, Air Quality - all construction equipment shall be required to use EPA Tier 4 engines. In addition to reducing pollutant emissions, Tier 4 engines use 5-10% less fuel than the predecessor Tier 3 engines (ATL Diesel 2020). Therefore, YRDP construction activities would use more fuel-efficient construction equipment. Fuel consumption associated with vehicle trips would be typical of that associated with construction projects in rural areas. There are no unusual circumstances, such as lack of access, that would lead to greater fuel consumption. In addition, these vehicles would be subject to more stringent fuel economy standards (see Chapter 15), which would further reduce potential fuel consumption.

Based on the information provided above, energy consumption associated with YRDP construction would not be considered wasteful, inefficient, or unnecessary. Therefore, impacts would be **less than significant**. No additional CEQA mitigation would be required.

YRDP Impact EN-PP-5: Energy Consumption by YRDP Operations

Energy consumption would be associated primarily with the operation of non-recreational YRDP facilities. Exhibit D of the AFLA states that some of the generated power is used at the powerhouses for station use. Station energy use annually is about 1 MWh at New Colgate Powerhouse and less than 0.1 MWh each at the New Bullards Bar Minimum Flow and Narrows 2 Powerhouses (YCWA 2017). Compared with the 1,189 GWh of electricity generated annually by YRDP, station use of electricity is minimal. As indicated in Table 7.5-2, YRDP hydropower operations would not noticeably change, so station use is not expected to significantly change.

With respect to the YRDP recreation facilities, as noted in Chapter 2, Project Description, and in Appendix 2A-14, existing recreation facilities have limited electrical connections. The proposed Kelly Ridge Campground would have up to six RV sites with electric hookups. No other new electric hookups are proposed. Any electrical use at the recreation facilities would be limited to the time the facilities are open, so electrical use would be seasonal and is not anticipated to increase substantially compared to existing electrical use.

Electricity would be provided through the existing PG&E power poles and transmission lines, and emergency power may be obtained from facilities within the YRDP footprint. No additional trips would be generated for O&M, as activities would be coordinated and combined with existing maintenance trips. Therefore, impacts related to YRDP operations would be **less than significant**. No CEQA mitigation would be required.

YRDP Impact EN-PP-6: YRDP Construction Conflicts with Renewable Energy or Energy Efficiency Plans

As discussed under YRDP Impact EN-PP-4, YRDP construction activities would primarily involve fuel consumption, which would be non-recoverable but not wasteful, inefficient, or unnecessary. As such, YRDP construction would not conflict with renewable energy plans such as the Renewables Portfolio Standard or the Resource Adequacy Program. Construction activities would not conflict with local renewable energy or energy efficiency plans, as no local energy plans would apply. Therefore, impacts related to YRDP construction would be **less than significant**. No CEQA mitigation would be required.

YRDP Impact EN-PP-7: YRDP Operational Conflicts with Renewable Energy or Energy Efficiency Plans

Proposed YRDP operations would not conflict with local renewable energy or energy efficiency plans, as no local energy plans would apply. All facilities would be constructed in accordance with applicable provisions of the California Green Building Standards Code and the California Energy Code. Operations would not affect NID facilities, and solar-powered lighting would be used at two entrance station kiosks.

Because of this, YRDP operations would not conflict with or obstruct State or local energy efficiency codes. Moreover, as the Proposed YRDP Project would continue to generate hydroelectric power, it would not conflict with the attainment of renewable energy targets set forth in the Renewables Portfolio Standard. Therefore, impacts related to YRDP operations would be **less than significant**. No CEQA mitigation would be required.

Narrows Impact EN-PP-4: Energy Consumption by Narrows 1 Operations

Energy consumption would be limited to what is needed for the operation of the Narrows and associated facilities. The Narrows 1 Powerhouse is estimated to require less than 1 kW of electricity annually during operations (YCWA 2023). Compared with the approximately 75.38 GWh of electricity generated in one year, station use of electricity is minimal. As indicated in Tables 7.5-2 and 7.5-3, Narrows 1 hydropower operations would not noticeably change, so station use is not expected to significantly change.

Operational electricity would come from the existing PG&E power poles and transmission lines, and emergency power may be obtained from facilities within the Narrows footprint. No additional trips would be generated for O&M as activities would be coordinated and combined with existing maintenance trips. Therefore, impacts related to Narrows operations would be **less than significant**. No CEQA mitigation would be required.

Narrows Impact EN-PP-5: Narrows 1 Operational Conflicts with Renewable Energy or Energy Efficiency Plans

Proposed Narrows Project operations would not conflict with local renewable energy or energy efficiency plans, as no local energy plans would apply. The Narrows Project does not propose the construction of new or expanded facilities. Moreover, as the Proposed Narrows Project would continue to generate hydroelectric power, it would not conflict with the attainment of renewable

energy targets set forth in the Renewables Portfolio Standard. Therefore, impacts on renewable energy or energy efficiency plans related to Narrows Project operations would be **less than significant**. No CEQA mitigation would be required.

7.5.2 Proposed Projects compared to the Future Baseline

7.5.2.1 Energy Production

YRDP Impact EN-FPP-1: Change in Monthly Generation from YRDP Operations

Operations for the YRDP include increased flow requirements in the Middle Yuba River below Our House Dam, increased flow requirements in Oregon Creek below Log Cabin Dam, increased flows in the North Yuba River below New Bullards Bar Dam, and periodic closures of the Lohman Ridge Tunnel. These elements will each contribute to a reduction in flows from the New Colgate Powerhouse and a reduction in generation. Since flows in the lower Yuba River are not changing substantially, there would not be substantial changes in generation at the Narrows 2 Powerhouse. Table 7.5-7 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse.

Table 7.5-7. Comparison of Average Monthly Generation for YRDP Facilities Relative to Future Baseline.

Month	YRDP Generation (GWh)		Change in YRDP Generation from Basis of Comparison	
	Future Baseline	Future Proposed Projects	(GWh)	(%)
October	50.3	49.1	-1.2	-2%
November	48.3	45.7	-2.6	-5%
December	64.9	60.2	-4.7	-7%
January	85.7	80.3	-5.4	-6%
February	99.7	93.9	-5.8	-6%
March	157.2	152.6	-4.7	-3%
April	134.0	131.8	-2.2	-2%
May	175.1	167.3	-7.8	-4%
June	175.7	166.4	-9.3	-5%
July	158.2	152.9	-5.3	-3%
August	137.4	131.2	-6.2	-5%
September	62.2	58.9	-3.3	-5%

Key: MW = Megawatt

While there is a reduction in average YRDP generation in most months relative to the Future Baseline, average generation reductions reach their maximum of 7% in December. Other months have smaller reductions as such, average monthly decreases would not be greater than 10%. Accordingly, YRDP operational impacts would be **less than significant**, and no CEQA mitigation is required.

YRDP Impact EN-FPP-2: Change in Monthly Generation Capacity from YRDP Operations

The New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 2 Powerhouse's capacity is based on its planned flows. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from the Narrows 2 Powerhouse would reduce the amount of RA the YRDP can provide. Table 7.5-8 shows a comparison of generation capacity from the New Colgate and Narrows 2 powerhouses for the Proposed Projects and Future Baseline scenarios.

Table 7.5-8. Comparison of Average Monthly Generation Capacity for YRDP Facilities Relative to Future Baseline.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Future Baseline	Future Proposed Projects	(MW)	(%)
October	301	299	-2	-1%
November	290	285	-6	-2%
December	285	279	-6	-2%
January	280	274	-5	-2%
February	291	280	-11	-4%
March	323	314	-9	-3%
April	340	346	6	2%
May	359	357	-2	0%
June	359	359	-1	0%
July	342	342	-1	0%
August	328	327	-1	0%
September	308	307	-1	0%

Key: MW = Megawatt

There are very small changes in generation capacity in October, November, December, January, February, and March, under the Proposed Projects relative to the Future Baseline, average generation capacity reductions are less than 15% of the Future Baseline capacity. Accordingly, YRDP operational impacts would be **less than significant**, and no CEQA mitigation is required.

YRDP Impact EN-FPP-3: Reduction in Generation-Related Revenue from YRDP Operations

While the New Colgate Powerhouse's flexible operations allow it to target hours of high energy demand and the associated higher economic value, the Narrows 2 Powerhouse runs consistently through every hour of a day. The New Colgate Powerhouse's operational flexibility allows it to adjust generation to minimize the economic effects of reductions in generation shown in Table 7.5-7. Table 7.5-9 shows a comparison of the average annual generation revenue for the YRDP facilities relative to the Future Baseline.

Table 7.5-9. Comparison of Average Annual Generation Revenue for YRDP Facilities Relative to Future Baseline.

	Generation Revenue ($1M)		Change in Revenue	
	Future Baseline	Future Proposed Projects	(1M$)	(%)
New Colgate PH	59.4	57.0	-2.4	-4%
Narrows 2 PH	5.9	5.9	0.0	0%
Total YRDP	65.3	63.0	-2.4	-4%

Key: $1M = Millions of Dollars

There are very small changes in annual generation revenue relative to the Future Baseline, but average generation revenue reductions do not exceed 10% of the Future Baseline revenue. Accordingly, YRDP operational impacts would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact EN-FPP-1: Change in Monthly Generation from Narrows 1 Operations

Due to its ability to provide renewable energy, the Narrows 1 Powerhouse is almost always run at its full capacity. There are some periods when releases would be slightly changed due to differences in Englebright Dam releases, particularly when desired Englebright Dam releases are in the 900 to 1,080 cfs and the Narrows 1 Powerhouse is providing flows above the Narrows 2 Powerhouse minimum capacity. As a result, there could be small change in generation, Table 7.5-10 shows a comparison of monthly generation for the Narrows 1 Powerhouse relative to the Future Baseline scenario.

Table 7.5-10. Comparison of Average Monthly Generation for Narrows 1 Relative to Future Baseline.

Month	Narrows Project Generation (GWh)		Change in Narrows Project Generation from Basis of Comparison	
	Future Baseline	Future Proposed Projects	(GWh)	(%)
July	8.3	8.3	0.1	1%
August	7.9	8.1	0.1	2%
September	7.2	7.7	0.5	7%
October	8.2	8.1	-0.1	-1%

Key: MW = Megawatt

Narrows 1 Powerhouse generation is generally increased during summer months, but there would be an approximately 1% reduction in generation in October. Therefore, it would contribute to the state meeting its SB100 goals. Accordingly, Narrows 1 operational impacts would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact EN-FPP-2: Change in Monthly Generation Capacity from Narrows 1 Operations

The Narrows 1 Powerhouse's ability to provide capacity is based on its planned flows. Since there are very few changes in planned flows for the Narrows 1 Powerhouse under the Proposed Projects, relative to the Future Baseline, there are very small changes in generation capacity. Table 7.5-11 shows a comparison of average monthly generation capacity for the Narrows 1 Powerhouse relative to the Future Baseline.

Table 7.5-11. Comparison of Average Monthly Generation Capacity for Narrows 1 Relative to Future Baseline.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Future Baseline	Future Proposed Projects	(MW)	(%)
October	11.0	10.9	-0.1	0.0
November	11.0	10.9	-0.1	0.0
December	11.3	11.2	-0.1	0.0
January	11.3	11.3	0.0	0.0
February	11.4	11.3	0.0	0.0
March	11.5	11.4	0.0	0.0
April	11.3	11.3	0.1	0.0
May	11.5	11.5	0.0	0.0
June	7.9	7.8	-0.1	0.0
July	10.0	10.1	0.1	0.0
August	11.1	11.1	0.0	0.0
September	10.5	10.7	0.2	0.0

Key: MW = Megawatt

There are a very small changes in generation capacity in October, November, December, and August under Narrows 1 relative to the Future Baseline, but average generation capacity reductions do not exceed 5% of the Future Baseline capacity. Accordingly, Narrows 1 operational impacts would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact EN-FPP-3: Reduction in Generation-Related Revenue from Narrows 1 Operations

There are very few changes in Narrows 1 Powerhouse generation; in fact, there is a small increase in overall generation. However, changes in generation shown in Table 7.5-11 do not result in a notable change in Narrows Project generation revenue. Table 7.5-12 shows a comparison of Narrows Project generation revenue relative to the Future Baseline scenarios.

Table 7.5-12. Comparison of Average Annual Generation Revenue for Narrows 1 Relative to Future Baseline.

	Generation Revenue ($1M)		Change in Revenue	
	Future Baseline	Future Proposed Projects	(1M$)	(%)
Narrows 1 PH	11.2	11.2	0.0	0%

Key: $1M = Millions of Dollars

There are very small decreases in annual generation revenue relative to the Future Baseline, but average generation revenue reductions do not exceed 10% of the Future Baseline revenue. Accordingly, Narrows operational impacts would be **less than significant**, and no CEQA mitigation is required.

7.5.3 Alternative 1 compared to the Existing Condition

As described in Section 4.4, comparison of flow-related impacts to the Existing Condition is misleading; as such, flow-related impacts are analyzed relative to the Future Baseline. Comparisons of these impacts to the Existing Condition are presented for informational purposes only. However, construction impacts and impacts not related to flows are analyzed relative to the Existing Condition.

7.5.3.1 Energy Production

YRDP Impact EN-Alt1-1: Change in Monthly Generation by YRDP Operations

YRDP Operations under Alternative 1 include increased flow requirements in the Middle Yuba River below Our House Dam, increased flow requirements in Oregon Creek below Log Cabin Dam, increased flows in the North Yuba River below New Bullards Bar Dam, and periodic closures of the Lohman Ridge Tunnel. These elements of Alternative 1 will each contribute to a reduction in flows from the New Colgate Powerhouse and a reduction in generation. Since flows in the lower Yuba River are not changing substantially, there would not be substantial changes in generation at the Narrows 2 Powerhouse. Table 7.5-13 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse.

Table 7.5-13. Comparison of Average Monthly Generation for Alternative 1 Relative to Existing Condition.

Month	YRDP Generation (GWh)		Change in YRDP Generation from Basis of Comparison	
	Existing Condition	Alternative 1	(GWh)	(%)
October	8.2	8.2	0.0	0%
November	7.9	7.8	-0.1	-1%
December	8.3	8.1	-0.2	-3%
January	8.3	8.3	0.0	0%
February	7.5	7.5	-0.1	-1%
March	8.2	8.1	-0.1	-2%
April	7.7	7.8	0.2	2%
May	8.3	8.3	0.0	0%
June	4.3	4.3	0.0	1%
July	8.2	8.3	0.1	1%
August	7.9	8.1	0.1	2%
September	7.2	7.9	0.7	10%

Key: MW = Megawatt

YRDP Impact EN-Alt1-2: Change in Monthly Generation Capacity from YRDP Operations

The New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 2 Powerhouse's capacity is based on its planned flows. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from the Narrows 2 Powerhouse

would reduce the amount of RA the YRDP can provide. Table 7.5-14 shows a comparison of generation capacity from the New Colgate and Narrows 2 powerhouses for the Alternative 1 and Existing Condition.

Table 7.5-14. Comparison of Average Monthly Generation Capacity for Alternative 1 Relative to Existing Condition.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	Alternative 1	(MW)	(%)
October	299	299	0	0%
November	289	285	-4	-1%
December	282	280	-2	-1%
January	280	274	-7	-2%
February	285	280	-5	-2%
March	315	314	-1	0%
April	339	344	5	1%
May	358	358	0	0%
June	359	359	0	0%
July	340	342	2	0%
August	326	327	1	0%
September	307	308	1	0%

Key: MW = Megawatt

YRDP Impact EN-Alt1-3: Reduction in Generation-Related Revenue Operations

While the New Colgate Powerhouse's flexible operations allow it to target hours of high energy demand and the associated higher economic value, the Narrows 2 Powerhouse runs consistently through every hour of a day. The New Colgate Powerhouse's operational flexibility allows it to adjust generation to minimize the economic effects of reductions in generation shown in YRDP Operations under Alternative 1 include increased flow requirements in the Middle Yuba River below Our House Dam, increased flow requirements in Oregon Creek below Log Cabin Dam, increased flows in the North Yuba River below New Bullards Bar Dam, and periodic closures of the Lohman Ridge Tunnel. These elements of Alternative 1 will each contribute to a reduction in flows from the New Colgate Powerhouse and a reduction in generation. Since flows in the lower Yuba River are not changing substantially, there would not be substantial changes in generation at the Narrows 2 Powerhouse. Table 7.5-14 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse. Table 7.5-15 shows a comparison of the average annual generation revenue for Alternative 1 and the Existing Condition.

Table 7.5-15. Comparison of Average Annual Generation Revenue for Alternative 1 Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	Alternative 1	(1M$)	(%)
New Colgate PH	59.0	57.1	-1.9	-3%
Narrows 2 PH	5.7	6.0	0.2	4%
Total YRDP	64.8	63.1	-1.7	-3%

Key: $1M = Millions of Dollars

Narrows Impact EN-Alt1-1: Change in Monthly Generation from Narrows 1 Operations

Due to its ability to provide renewable energy, the Narrows 1 Powerhouse is almost always running at full capacity. There are some periods when releases would be slightly changed due to differences in Englebright Dam releases, particularly when desired Englebright Dam releases are in the 900 to 1,080 cfs and the Narrows 1 Powerhouse is providing flows above the Narrows 2 Powerhouse minimum capacity. As a result, there could be small change in generation, Table 7.5-16 shows a comparison of monthly generation for Alternative 1 and the Existing Condition.

Table 7.5-16. Comparison of Average Monthly Generation for Alternative 1 Relative to Existing Condition.

Month	Narrows Project Generation (GWh)		Change in Narrows Project Generation from Basis of Comparison	
	Existing Condition	Alternative 1	(GWh)	(%)
July	8.2	8.3	0.0	0%
August	7.9	8.1	0.1	2%
September	7.2	7.7	0.5	7%
October	8.2	8.1	0.0	0%

Key: MW = Megawatt

Narrows Impact EN-Alt1-2: Change in Monthly Generation Capacity from Narrows 1 Operations

The Narrows 1 Powerhouse's ability to provide capacity is based on its planned flows. Since there are very few changes in planned flows for the Narrows 1 Powerhouse under the Alternative 1, relative to the Existing Condition, there are very small changes in generation capacity. Table 7.5-17 shows a comparison of average monthly generation capacity for the Narrows 1 Powerhouse for the Alternative 1 and Existing Condition.

Table 7.5-17. Comparison of Average Monthly Generation Capacity for Alternative 1 Relative to Existing Condition.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	Alternative 1	(MW)	(%)
October	10.9	11.0	0.0	0%
November	10.9	10.9	-0.1	-1%
December	11.2	11.2	-0.1	-1%
January	11.3	11.3	0.0	0%
February	11.4	11.3	0.0	0%
March	11.5	11.4	0.0	0%
April	11.3	11.3	0.1	1%
May	11.5	11.5	0.0	0%
June	7.8	7.8	0.0	0%
July	10.1	10.1	0.1	1%
August	11.1	11.1	0.0	0%
September	10.5	10.7	0.3	2%

Key: MW = Megawatt

Narrows Impact EN-Alt1-3: Reduction in Generation-Related Revenue from Narrows 1 Operations

There are very few changes in Narrows 1 Powerhouse generation. In fact, there is a small increase in overall generation. However, changes in generation shown in Table 7.5-17 do not result in a notable change in Narrows Project generation revenue. Table 7.5-18 shows a comparison of Narrows Project generation revenue for Alternative 1 and the Existing Condition.

Table 7.5-18. Comparison of Average Annual Generation Revenue for Alternative 1 Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	Alternative 1	(1M$)	(%)
Narrows 1 PH	11.2	11.2	0.0	0%

Key: $1M = Millions of Dollars

7.5.3.2 Energy Consumption

YRDP Impact EN-Alt1-4: Energy Consumption by YRDP Construction

Alternative 1 would include the same YRDP construction activities as the Proposed Projects and therefore would have the same associated impacts. For the same reasons explained above for YRDP Impact EN-PP-4, this impact would be **less than significant**.

YRDP Impact EN-Alt1-5: Energy Consumption by YRDP Operations

Alternative 1 would include the same YRDP facilities and the same non-flow YRDP operations as the Proposed Projects and would therefore have the same associated impacts. Differences in flow-based operations would not result in substantially different energy consumption

requirements. Thus, for the same reasons explained for YRDP Impact EN-PP-5, this impact would be **less than significant**.

YRDP Impact EN-Alt1-6: YRDP Construction Conflicts with Renewable Energy or Energy Efficiency Plans

Alternative 1 would include the same YRDP construction activities as the Proposed Projects and therefore would have the same associated impacts. For the same reasons explained above for YRDP Impact EN-PP-6, this impact would be **less than significant**.

YRDP Impact EN-Alt1-7: YRDP Operational Conflicts with Renewable Energy or Energy Efficiency Plans

Alternative 1 would include the same YRDP facilities and the same non-flow YRDP operations as the Proposed Projects and would therefore have the same associated impacts described above for YRDP Impact EN-PP-7. Under Alternative 1, the YRDP would continue to generate hydroelectric power. For these reasons, YRDP operations under Alternative 1 would not conflict with renewable energy or energy efficiency plans, and this impact would be **less than significant**.

Narrows Impact EN-Alt1-4: Energy Consumption by Narrows 1 Operations

Alternative 1 would include the same Narrows Project facilities and non-flow Narrows Project operations as the Proposed Projects and would therefore have the same associated impacts. Differences in flows would not result in substantially different energy consumption requirements. Thus, for the same reasons explained for Narrows Impact EN-PP-4, this impact would be **less than significant**.

Narrows Impact EN-Alt1-5: Narrows 1 Operational Conflicts with Renewable Energy or Energy Efficiency Plans

Alternative 1 would include the same Narrows Project facilities and the same non-flow Narrows Project operations as the Proposed Projects and would therefore have the same associated impacts described above for Narrows Impact EN-PP-5. Under Alternative 1, the Narrows Project would continue to generate hydroelectric power. For these reasons, Narrows Project operations under Alternative 1 would not conflict with renewable energy or energy efficiency plans, and this impact would be **less than significant**.

7.5.4 Alternative 1 compared to the Future Baseline

7.5.4.1 As noted in Section 7.5.3, flow-related impacts are analyzed relative to the Future Baseline. Energy Production

YRDP Impact EN-FAlt1-1: Change in Monthly Generation from YRDP Operations

YRDP operations under Alternative 1 include increased flow requirements in the Middle Yuba River below Our House Dam, increased flow requirements in Oregon Creek below Log Cabin Dam, increased flows in the North Yuba River below New Bullards Bar Dam, and periodic closures of the Lohman Ridge Tunnel. These elements of Alternative 1 will each contribute to a

reduction in flows from the New Colgate Powerhouse and a reduction in generation. Since flows in the lower Yuba River are not changing substantially, there would not be substantial changes in generation at the Narrows 2 Powerhouse. Table 7.5-19 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse.

Table 7.5-19. Comparison of Average Monthly Generation for Alternative 1 Relative to Future Baseline.

Month	YRDP Generation (GWh)		Change in YRDP Generation from Basis of Comparison	
	Future Baseline	Alternative 1	(GWh)	(%)
October	51.8	49.8	-2.0	-4%
November	49.5	46.1	-3.4	-7%
December	64.0	60.7	-3.3	-5%
January	84.5	80.1	-4.4	-5%
February	96.6	93.8	-2.8	-3%
March	151.7	151.9	0.2	0%
April	132.6	129.4	-3.2	-2%
May	174.3	168.1	-6.1	-4%
June	176.9	166.5	-10.4	-6%
July	155.5	152.3	-3.1	-2%
August	134.9	131.3	-3.6	-3%
September	63.7	63.4	-0.3	0%

Key: MW = Megawatt

While there is a reduction in average YRDP generation in most months under Alternative 1 relative to the Future Baselines, average generation reductions reach their maximum of 7% in November. Other months have smaller reductions. Accordingly, YRDP operational impacts under Alternative 1 would be **less than significant**.

YRDP Impact EN-FAlt1-2: Change in Monthly Generation Capacity from YRDP Operations

The New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 2 Powerhouse's capacity is based on its planned flows. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from the Narrows 2 Powerhouse would reduce the amount of RA the YRDP can provide. Table 7.5-20 shows a comparison of generation capacity from the New Colgate and Narrows 2 powerhouses for Alternative 1 and Future Baseline.

Table 7.5-20. Comparison of Average Monthly Generation Capacity for Alternative 1 Relative to Future Baseline.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Future Baseline	Alternative 1	(MW)	(%)
October	301	299	-1	0%
November	290	285	-6	-2%
December	285	280	-6	-2%
January	280	274	-6	-2%
February	291	280	-11	-4%
March	323	314	-9	-3%
April	340	344	3	1%
May	359	358	-1	0%
June	359	359	0	0%
July	342	342	0	0%
August	328	327	-1	0%
September	308	308	0	0%

Key: MW = Megawatt

There are very small changes in generation capacity all months except for April, June, July, and September under Alternative 1 relative to the Future Baseline, average generation capacity reductions are less than 15% of the Future Baseline capacity. Accordingly, YRDP operational impacts under Alternative 1 would be **less than significant**.

YRDP Impact EN-FAlt1-3: Reduction in Generation-Related Revenue from YRDP Operations

While the New Colgate Powerhouse's flexible operations allow it to target hours of high energy demand and the associated higher economic value, the Narrows 2 Powerhouse runs consistently through every hour of a day. The New Colgate Powerhouse's operational flexibility allows it to adjust generation to minimize the economic effects of reductions in generation shown in YRDP operations under Alternative 1 include increased flow requirements in the Middle Yuba River below Our House Dam, increased flow requirements in Oregon Creek below Log Cabin Dam, increased flows in the North Yuba River below New Bullards Bar Dam, and periodic closures of the Lohman Ridge Tunnel. These elements of Alternative 1 will each contribute to a reduction in flows from the New Colgate Powerhouse and a reduction in generation. Since flows in the lower Yuba River are not changing substantially, there would not be substantial changes in generation at the Narrows 2 Powerhouse. Table 7.5-19 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse. Table 7.5-21 shows a comparison of the average annual generation revenue for Alternative 1 relative to the Future Baseline.

Table 7.5-21. Comparison of Average Annual Generation Revenue for Alternative 1 Relative to Future Baseline.

	Generation Revenue ($1M)		Change in Revenue	
	Future Baseline	Alternative 1	(1M$)	(%)
New Colgate PH	59.4	57.1	-2.3	-4%
Narrows 2 PH	5.9	6.0	0.0	1%
Total YRDP	65.3	63.1	-2.2	-3%

Key: $1M = Millions of Dollars

There are small decreases in annual generation revenue under Alternative 1 relative to the Future Baseline, but average generation revenue reductions do not exceed 10% of Future Baseline revenue. Accordingly, YRDP impacts under Alternative 1 would be **less than significant**.

Narrows Impact EN-FAlt1-1: Change in Monthly Generation from Narrows 1 Operations

Due to its ability to provide renewable energy, the Narrows 1 Powerhouse is almost always run at its full capacity. There are some periods when releases would be slightly changed due to differences in Englebright Dam releases, particularly when desired Englebright Dam releases are in the 900 to 1,080 cfs and the Narrows 1 Powerhouse is providing flows above the Narrows 2 Powerhouse minimum capacity. As a result, there could be small change in generation, Table 7.5-22 shows a comparison of monthly generation for the Alternative 1 and Future Baseline.

Table 7.5-22. Comparison of Average Monthly Generation for Alternative 1 Relative to Future Baseline.

Month	Narrows Project Generation (GWh)		Change in Narrows Project Generation from Basis of Comparison	
	Future Baseline	Alternative 1	(GWh)	(%)
July	8.3	8.3	0.1	1%
August	7.9	8.1	0.2	2%
September	7.2	7.9	0.7	9%
October	8.2	8.2	0.0	0%

Key: MW = Megawatt

Narrows 1 Powerhouse generation is generally increased during summer months, and therefore would contribute to the state meeting its SB100 goals. Accordingly, Narrows 1 operational impacts would be **less than significant**, and no CEQA mitigation is required.

Narrows Impact EN-FAlt1-2: Change in Monthly Generation Capacity from Narrows 1 Operations

The Narrows 1 Powerhouse's ability to provide capacity is based on its planned flows. Since there are very few changes in planned flows for the Narrows 1 Powerhouse under the Alternative 1, relative to the Future Baseline, there are very small changes in generation capacity. Table 7.5-23 shows a comparison of average monthly generation capacity for the Narrows 1 Powerhouse for Alternative 1 under the Future Baseline.

Table 7.5-23. Comparison of Average Monthly Generation Capacity for Alternative 1 Relative to Future Baseline.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Future Baseline	Alternative 1	(MW)	(%)
October	11.0	11.0	0.0	0%
November	11.0	10.9	-0.1	-1%
December	11.3	11.2	-0.1	-1%
January	11.3	11.3	0.0	0%
February	11.4	11.3	0.0	0%
March	11.5	11.4	0.0	0%
April	11.3	11.3	0.1	1%
May	11.5	11.5	0.0	0%
June	7.9	7.8	-0.1	-1%
July	10.0	10.1	0.1	1%
August	11.1	11.1	0.0	0%
September	10.5	10.7	0.2	2%

Key: MW = Megawatt

There are very small decreases in generation capacity in November, December, and June under Alternative 1 relative to the Future Baseline, but average generation capacity reductions do not exceed 5% of the Future Baseline capacity. Accordingly, Narrows operational impacts under Alternative 1 would be **less than significant**.

Narrows Impact EN-FAlt1-3: Reduction in Generation-Related Revenue from Narrows 1 Operations

There are very few changes in Narrows 1 Powerhouse generation; in fact, there is a small increase in overall generation. However, changes in generation shown in Table 7.5-23 do not result in a notable change in Narrows Project generation revenue. Table 7.5-24 shows a comparison of Narrows Project generation revenue for Alternative 1 under the Future Baseline.

Table 7.5-24. Comparison of Average Annual Generation Revenue for Alternative 1 Relative to Future Baseline.

	Generation Revenue ($1M)		Change in Revenue	
	Future Baseline	Alternative 1	(1M$)	(%)
Narrows 1 PH	11.2	11.2	0.0	0%

Key: $1M = Millions of Dollars

There are small changes in annual generation revenue under Alternative 1 relative to the Future Baseline, but average generation revenue reductions do not exceed 10% of the Future Baseline revenue. Accordingly, Narrows operational impacts under Alternative 1 would be **less than significant**.

Indirect Impact EN-FAlt1-1: Potential Reduction in Energy Generation from NID and PG&E Project Operations under Alternative 1

Alternative 1 includes 15,600 acre-feet of additional releases from NID and PG&E's projects above their respective proposed FERC 4(e) requirements in the spring of dry and critical years. For purposes of the programmatic analysis of indirect impacts associated with Alternative 1 YB/DS operations, Yuba Water has modeled these operations with 5,000 acre-feet on the Middle Yuba River and 10,600 acre-feet from the South Yuba River as a block of flow on top of minimum flows in April to provide a reasonable representation of inflows to the YRDP and Narrows Project for use in evaluating the effects of changes in Yuba-Bear and Drum-Spaulding projects' flow regimes on YRDP and Narrows Project resource areas. The actual distribution and timing of the additional block of water would be subject to FERC's determination and consultation with applicable regulatory agencies.

NID's modeling for Alternative 1 using a similar distribution of responsibility between NID and PG&E for the 15,600 acre-feet indicated an average annual reduction in generation of 2.3% for PG&E and a reduction in average annual generation of 2.2% for NID in dry and critical years. Based on the other information provided by NID, Alternative 1 would represent a total combined reduction in generation of 2.3% relative to NID's Yuba-Bear and PG&E's Drum-Spaulding projects' combined average annual generation in dry and critical years, under operations for their respective 4(e) conditions (NID 2023). No information is available for change in average annual generation.

In response to the reduction in generation from the NID and PG&E projects, CAISO would likely be able to procure additional generation from other resources. Reduction in generation from baseload plants during the day could largely be replaced through reductions in CAISO exports. Plants with peaking capabilities should be able to maintain their ability to generate during periods with high demand. Accordingly, impacts on NID and PG&E energy production due to Alternative 1 YB/DS operations would be **less than significant**. As explained in Chapter 3, the YB/DS relicensings are subject to their own CEQA process. To the extent that YB/DS operations under new FERC licenses would have impacts that are beyond the scope of those disclosed in this EIR or other CEQA documents, those impacts may need to be addressed through subsequent project-level CEQA review as more concrete information about those operations becomes available.

7.5.5 Alternative 2 compared to the Existing Condition

As described in Section 4.4, comparison of flow-related impacts to the Existing Condition is misleading; as such, flow-related impacts are analyzed relative to the Future Baseline. Comparisons of these impacts to the Existing Condition are presented for informational purposes only. However, construction impacts and impacts not related to flows are analyzed relative to the Existing Condition.

7.5.5.1 Energy Production

YRDP Impact EN-Alt2-1: Change in Monthly Generation from YRDP Operations]

YRDP Operations under Alternative 2 include all of the elements described for the Proposed Projects plus the unimpaired flow requirements. The increased Middle Yuba River flow requirements will preclude diversion through the Lohman Ridge and Camptonville tunnels into New Bullards Bar Reservoir. Elements of Alternative 2 will contribute to a general reduction in flows through the New Colgate Powerhouse and a reduction in generation, particularly in the summer, but the higher unimpaired flow requirements will result in higher spring releases when there is already ample generation from renewable resources available. There will be an accompanying shift to higher spring flows from the Narrows 2 Powerhouse and higher frequency of spills over Englebright Dam, resulting in higher spring generation at Narrows 2 Powerhouse, but less overall generation. Table 7.5-25 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse.

Table 7.5-25. Comparison of Average Monthly Generation for Alternative 2 Relative to Existing Condition.

Month	YRDP Generation (GWh)		Change in YRDP Generation from Basis of Comparison	
	Existing Condition	Alternative 2	(GWh)	(%)
October	51.8	45.2	-6.6	-13%
November	49.5	46.9	-2.6	-5%
December	64.0	69.7	5.7	9%
January	84.5	89.9	5.4	6%
February	96.6	100.6	3.9	4%
March	151.7	140.7	-11.0	-7%
April	132.6	146.9	14.3	11%
May	174.3	179.6	5.4	3%
June	176.9	165.1	-11.8	-7%
July	155.5	123.0	-32.5	-21%
August	134.9	98.5	-36.4	-27%
September	63.7	48.7	-15.0	-23%

Key: MW = Megawatt

YRDP Impact EN-Alt2-2: Change in Monthly Generation Capacity from YRDP Operations

As described above, the New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 2 Powerhouse's capacity is based on its releases. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from the Narrows 2 Powerhouse would reduce the amount of RA the YRDP can provide. Table 7.5-26 shows a comparison of generation capacity from the New Colgate and Narrows 2 powerhouses for Alternative 2 the Existing Condition.

Table 7.5-26. Comparison of Average Monthly Generation Capacity for Alternative 2 Relative to Existing Condition.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	Alternative 2	(MW)	(%)
October	299	294	-6	-2%
November	289	283	-6	-2%
December	282	281	-1	0%
January	280	285	5	2%
February	285	298	13	5%
March	315	321	6	2%
April	339	349	10	3%
May	358	358	0	0%
June	359	351	-7	-2%
July	340	329	-11	-3%
August	326	315	-11	-3%
September	307	300	-6	-2%

Key: MW = Megawatt

YRDP Impact EN-Alt2-3: Reduction in Generation-Related Revenue from YRDP Operations

While the New Colgate Powerhouse's flexible operations allow it to target hours of high energy demand and the associated higher economic value, the Narrows 2 Powerhouse runs consistently through every hour of a day. The New Colgate Powerhouse's operational flexibility allows it to adjust generation to minimize the economic effects of reductions in generation shown in YRDP Operations under Alternative 2 include all of the elements described for the Proposed Projects plus the unimpaired flow requirements. The increased Middle Yuba River flow requirements will preclude diversion through the Lohman Ridge and Camptonville tunnels into New Bullards Bar Reservoir. Elements of Alternative 2 will contribute to a general reduction in flows through the New Colgate Powerhouse and a reduction in generation, particularly in the summer, but the higher unimpaired flow requirements will result in higher spring releases when there is already ample generation from renewable resources available. There will be an accompanying shift to higher spring flows from the Narrows 2 Powerhouse and higher frequency of spills over Englebright Dam, resulting in higher spring generation at Narrows 2 Powerhouse, but less overall generation. Table 7.5-25 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse. Table 7.5-27 shows a comparison of the average annual generation revenue for Alternative 2 relative to the Existing Condition.

Table 7.5-27. Comparison of Average Annual Generation Revenue for Alternative 2 Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	Alternative 2	(1M$)	(%)
New Colgate PH	59.0	54.7	-4.4	-7%
Narrows 2 PH	5.7	6.3	0.6	10%
Total YRDP	64.8	61.0	-3.8	-6%

Key: $1M = Millions of Dollars

Narrows Impact EN-Alt2-1: Change in Monthly Generation from Narrows 1 Operations

Due to its ability to provide renewable energy, the Narrows 1 Powerhouse is almost always running at full capacity. There are some periods when releases would be slightly changed due to differences in Englebright Dam releases, particularly when desired Englebright Dam releases are in the 900 to 1,080 cfs and the Narrows 1 Powerhouse is providing flows above the Narrows 2 Powerhouse minimum capacity. Since Alternative 2 decreases summer flows, there are more periods when Englebright Dam releases are in this range, and as a result, there will be reductions in Narrows Project generation, Table 7.5-28 shows a comparison of monthly generation for Alternative 2 relative to the Existing Condition.

Table 7.5-28. Comparison of Average Monthly Generation for Alternative 2 Relative to Existing Condition.

Month	Narrows Project Generation (GWh)		Change in Narrows Project Generation from Basis of Comparison	
	Existing Condition	Alternative 2	(GWh)	(%)
July	8.2	7.2	-1.0	-12%
August	7.9	7.1	-0.9	-11%
September	7.2	7.3	0.1	2%
October	8.2	8.1	0.0	0%

Key: MW = Megawatt

Narrows Impact EN-Alt2-2: Change in Monthly Generation Capacity [Operations]

The Narrows 1 Powerhouse's ability to provide capacity is based on its planned flows. Under Alternative 2, there will be notable reductions in planned flows for the Narrows 1 Powerhouse under Alternative 2, relative to the Existing Condition, in the summer. There are associated reductions in generation capacity in the summer. Table 7.5-29 shows a comparison of average monthly generation capacity for the Narrows 1 Powerhouse for Alternative 2 relative to the Existing Condition.

Table 7.5-29. Comparison of Average Monthly Generation Capacity for Alternative 2 Relative to Existing Condition.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	Alternative 2	(MW)	(%)
October	10.9	10.8	-0.1	-1%
November	10.9	10.9	-0.1	-1%
December	11.2	11.1	-0.1	-1%
January	11.3	11.4	0.1	1%
February	11.4	11.4	0.0	0%
March	11.5	11.5	0.0	0%
April	11.3	11.5	0.2	2%
May	11.5	11.5	0.1	1%
June	7.8	7.9	0.1	1%
July	10.1	9.6	-0.4	-4%
August	11.1	10.5	-0.6	-5%
September	10.5	10.8	0.3	3%

Key: MW = Megawatt

Narrows Impact EN-Alt2-3: Reduction in Generation-Related Revenue from Narrows Operations

There are decreases in Narrows 1 Powerhouse generation; the associated changes in generation shown in Table 7.5-29 do not result in a notable change in Narrows Project generation revenue. Table 7.5-30 shows a comparison of Narrows Project generation revenue for Alternative 2 relative to the Existing Condition.

Table 7.5-30. Comparison of Average Annual Generation Revenue for Alternative 2 Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	Alternative 2	(1M$)	(%)
Narrows 1 PH	11.2	11.2	-0.1	-1%

Key: $1M = Millions of Dollars

7.5.5.2 Energy Consumption

YRDP Impact EN-Alt2-4: Energy Consumption by YRDP Construction

Alternative 2 would include the same YRDP construction activities as the Proposed Projects and therefore would have the same associated impacts. For the same reasons explained above for YRDP Impact EN-PP-4, this impact would be **less than significant**.

YRDP Impact EN-Alt2-5: Energy Consumption by YRDP Operations

Alternative 2 would include the same YRDP facilities and the same non-flow YRDP operations as the Proposed Projects and would therefore have the same associated impacts. Differences in flow-based operations would not result in substantially different energy consumption

requirements. Thus, for the same reasons explained for YRDP Impact EN-PP-5, this impact would be **less than significant**.

YRDP Impact EN-Alt2-6: YRDP Construction Conflicts with Renewable Energy or Energy Efficiency Plans

Alternative 2 would include the same YRDP construction activities as the Proposed Projects and therefore would have the same associated impacts. For the same reasons explained above for YRDP Impact EN-PP-6, this impact would be **less than significant**.

YRDP Impact EN-Alt2-7: YRDP Operational Conflicts with Renewable Energy or Energy Efficiency Plans

Alternative 2 would include the same YRDP facilities and the same non-flow YRDP operations as the Proposed Projects and would therefore have the same associated impacts described above for YRDP Impact EN-PP-7. Under Alternative 2, the YRDP would continue to generate hydroelectric power, though power generation under Alternative 2 would generally be reduced as a result of the unimpaired flow requirements. Overall, YRDP operations under Alternative 2 would not conflict with renewable energy or energy efficiency plans, and this impact would be **less than significant**.

Narrows Impact EN-Alt2-4: Energy Consumption by Narrows Operations

Alternative 2 would include the same Narrows Project facilities and non-flow Narrows Project operations as the Proposed Projects and would therefore have the same associated impacts. Differences in flows would not result in substantially different energy consumption requirements. Thus, for the same reasons explained for Narrows Impact EN-PP-4, this impact would be **less than significant**.

Narrows Impact EN-Alt2-5: Narrows 1 Operational Conflicts with Renewable Energy or Energy Efficiency Plans

Alternative 2 would include the same Narrows Project facilities and the same non-flow Narrows Project operations as the Proposed Projects and would therefore have the same associated impacts described above for Narrows Impact EN-PP-5. Under Alternative 2, the Narrows Project would continue to generate hydroelectric power, though power generation under Alternative 2 would generally be reduced as a result of the unimpaired flow requirements. Overall, Narrows Project operations under Alternative 2 would not conflict with renewable energy or energy efficiency plans, and this impact would be **less than significant**.

7.5.6 Alternative 2 compared to the Future Baseline

As noted in Section 7.5.5, flow-related impacts are analyzed relative to the Future Baseline.

7.5.6.1 Energy Production

YRDP Impact EN-FAlt2-1: Change in Monthly Generation from YRDP Operations

YRDP operations under Alternative 2 include all of the elements described for the Proposed Projects plus the unimpaired flow requirements. The increased Middle Yuba River flow requirements will preclude diversion through the Lohman Ridge and Camptonville tunnels into New Bullards Bar Reservoir. Elements of Alternative 2 will contribute to a general reduction in flows through the New Colgate Powerhouse and a reduction in generation, particularly in the summer, but the higher unimpaired flow requirements will result in higher spring releases when there is already ample generation from renewable resources available. There will be an accompanying shift to higher spring flows from the Narrows 2 Powerhouse and higher frequency of spills over Englebright Dam, resulting in higher spring generation at Narrows 2 Powerhouse, but less overall generation. Table 7.5-31 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse.

Table 7.5-31. Comparison of Average Monthly Generation for Alternative 2 Relative to Future Baseline.

Month	YRDP Generation (GWh)		Change in YRDP Generation from Basis of Comparison	
	Future Baseline	Alternative 2	(GWh)	(%)
October	50.3	45.2	-5.1	-10%
November	48.3	46.9	-1.4	-3%
December	64.9	69.7	4.8	7%
January	85.7	89.9	4.2	5%
February	99.7	100.6	0.9	1%
March	157.2	140.7	-16.5	-11%
April	134.0	146.9	12.9	10%
May	175.1	179.6	4.5	3%
June	175.7	165.1	-10.6	-6%
July	158.2	123.0	-35.2	-22%
August	137.4	98.5	-38.9	-28%
September	62.2	48.7	-13.4	-22%

Key: MW = Megawatt

Alternative 2 would result in large reductions in average monthly generation in several months, particularly in March, July, August, and September when reductions in generation would exceed 10%. This degree of reduced generation, particularly in the summer when reductions in generation exceed 20%, would represent a substantial risk to CAISO grid stability. Other generation resources are typically already utilized during high-demand periods, so it is not reasonable to assume other carbon-free resources could mitigate for reductions in YRDP generation. Accordingly, Alternative 2 impacts for the YRDP would be **potentially significant and unavoidable**.

YRDP Impact EN-FAlt2-2: Change in Monthly Generation Capacity from YRDP Operations

The New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 2 Powerhouse's capacity is based on its planned flows. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from the Narrows 2 Powerhouse would reduce the amount of RA the YRDP can provide. Table 7.5-32 shows a comparison of generation capacity from the New Colgate and Narrows 2 powerhouses for Alternative 2 relative to the Future Baseline.

Table 7.5-32. Comparison of Average Monthly Generation Capacity for Alternative 2 Relative to Future Baseline.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Future Baseline	Alternative 2	(MW)	(%)
October	301	294	-7	-2%
November	290	283	-7	-3%
December	285	281	-4	-1%
January	280	285	6	2%
February	291	298	7	3%
March	323	321	-2	-1%
April	340	349	8	2%
May	359	358	-1	0%
June	359	351	-8	-2%
July	342	329	-13	-4%
August	328	315	-13	-4%
September	308	300	-8	-2%

Key: MW = Megawatt

There are relatively small changes in generation capacity all months except for January, February, April, and May under Alternative 2 relative to the Future Baselines, and average generation capacity reductions are less than 5% of the Future Baseline capacity. Accordingly, YRDP operational impacts under Alternative 2 would be **less than significant**.

YRDP Impact EN-FAlt2-3: Reduction in Generation-Related Revenue from YRDP Operations

While the New Colgate Powerhouse's flexible operations allow it to target hours of high energy demand and the associated higher economic value, the Narrows 2 Powerhouse runs consistently through every hour of a day. The New Colgate Powerhouse's operational flexibility allows it to adjust generation to minimize the economic effects of reductions in generation shown in YRDP operations under Alternative 2 include all of the elements described for the Proposed Projects plus the unimpaired flow requirements. The increased Middle Yuba River flow requirements will preclude diversion through the Lohman Ridge and Camptonville tunnels into New Bullards Bar Reservoir. Elements of Alternative 2 will contribute to a general reduction in flows through the New Colgate Powerhouse and a reduction in generation, particularly in the summer, but the higher unimpaired flow requirements will result in higher spring releases when there is already ample generation from renewable resources available. There will be an accompanying shift to higher

spring flows from the Narrows 2 Powerhouse and higher frequency of spills over Englebright Dam, resulting in higher spring generation at Narrows 2 Powerhouse, but less overall generation. Table 7.5-31shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse. Table 7.5-33 shows a comparison of the average annual generation revenue for Alternative 2 relative to the Future Baseline.

Table 7.5-33. Comparison of Average Annual Generation Revenue for Alternative 2 Relative to Future Baseline.

	Generation Revenue ($1M)		Change in Revenue	
	Future Baseline	Alternative 2	(1M$)	(%)
New Colgate PH	59.4	54.7	-4.7	-8%
Narrows 2 PH	5.9	6.3	0.4	6%
Total YRDP	65.3	61.0	-4.4	-7%

Key: $1M = Millions of Dollars

Reduction in average annual generation-related revenue from the YRDP would be reduced by an average of 7%. A reduction of this magnitude would result in substantial year-to-year uncertainty in revenue stability and would challenge Yuba Water's ability to reliably fund its programs. Accordingly, YRDP operational impacts under Alternative 2 impacts would **be potentially significant and unavoidable**.

Narrows Impact EN-FAlt2-1: Change in Monthly Generation from Narrows 1 Operations

Due to its ability to provide renewable energy, the Narrows 1 Powerhouse is almost always running at full capacity. There are some periods when releases would be slightly changed due to differences in Englebright Dam releases, particularly when desired Englebright Dam releases are in the 900 to 1,080 cfs and the Narrows 1 Powerhouse is providing flows above the Narrows 2 Powerhouse minimum capacity. Since Alternative 2 decreases summer flows, there are more periods when Englebright Dam releases are in this range, and as a result, there will be reductions in Narrows Project generation, Table 7.5-34 shows a comparison of monthly generation for Alternative 2 relative to the Future Baseline.

Table 7.5-34. Comparison of Average Monthly Generation for Alternative 2 Relative to Future Baseline.

Month	Narrows Project Generation (GWh)		Change in Narrows Project Generation from Basis of Comparison	
	Future Baseline	Alternative 2	(GWh)	(%)
July	8.3	7.2	-1.1	-13%
August	7.9	7.1	-0.8	-11%
September	7.2	7.3	0.1	1%
October	8.2	8.1	-0.1	-1%

Key: MW = Megawatt

Alternative 2 would result in large reductions in average monthly generation in several months, particularly in July and August when reductions in generation would exceed 10%. This degree of reduced generation, particularly in the summer, would represent a substantial risk to California's renewable energy goals. Other generation resources are typically already utilized during high-

demand periods, so it is not reasonable to assume other renewable energy resources could mitigate for reductions in YRDP generation. Accordingly, Narrows 1 operational impacts under Alternative 2 would be **potentially significant and unavoidable**.

Narrows Impact EN-FAlt2-2: Change in Monthly Generation Capacity from Narrows 1 Operations

The Narrows 1 Powerhouse's ability to provide capacity is based on its planned flows. Under Alternative 2, there will be notable reductions in planned flows for the Narrows 1 Powerhouse under the Alternative 2, relative to the Future Baseline, in the summer. There are associated reductions in generation capacity in the summer. Table 7.5-35 shows a comparison of average monthly generation capacity for the Narrows 1 Powerhouse for Alternative 2 relative to the Future Baseline.

Table 7.5-35. Comparison of Average Monthly Generation Capacity for Alternative 2 Relative to Future Baseline.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Future Baseline	Alternative 2	(MW)	(%)
October	11.0	10.8	-0.1	-1%
November	11.0	10.9	-0.1	-1%
December	11.3	11.1	-0.1	-1%
January	11.3	11.4	0.1	1%
February	11.4	11.4	0.0	0%
March	11.5	11.5	0.0	0%
April	11.3	11.5	0.2	2%
May	11.5	11.5	0.1	1%
June	7.9	7.9	0.0	0%
July	10.0	9.6	-0.4	-4%
August	11.1	10.5	-0.6	-5%
September	10.5	10.8	0.3	3%

Key: MW = Megawatt

Alternative 2 would reduce the average monthly generation capacity at Narrows 1 Powerhouse by as much as 5% in August. There are average monthly reductions in capacity in October, November, December, July, and August, but average generation capacity reductions are less than 5% of the Future Baseline capacity. Accordingly, Narrows 1 operational impacts under Alternative 2 would be **less than significant**.

Narrows Impact EN-FAlt2-3: Reduction in Generation-Related Revenue from Narrows 1 Operations

There are decreases in Narrows 1 Powerhouse generation; the associated changes in generation shown in Table 7.5-34 do not result in a notable change in Narrows Project generation revenue. Table 7.5-36 shows a comparison of Narrows Project generation revenue for Alternative 2 relative to the Future Baseline.

Table 7.5-36. Comparison of Average Annual Generation Revenue for Alternative 2 Relative to Future Baseline.

	Generation Revenue ($1M)		Change in Revenue	
	Future Baseline	Alternative 2	(1M$)	(%)
Narrows 1 PH	11.2	11.2	-0.1	-1%

Key: $1M = Millions of Dollars

There are small changes in annual generation revenue under Alternative 2 relative to the Future Baselines, but average generation revenue reductions do not exceed 5% of the Future Baseline revenue. Accordingly, Narrows 1 operational impacts under Alternative 2 would be **less than significant**.

7.5.7 No Project Alternative compared to the Existing Condition

7.5.7.1 Energy Production

YRDP Impact EN-NP-1: Change in Monthly Generation from YRDP Operations

YRDP operations under the No Project Alternative would result in an elimination of generation from the YRDP. None of the facilities would provide any generation. Table 7.5-37 shows a comparison of combined generation from the New Colgate Powerhouse, Narrows 2 Powerhouse and Minimum Flow Powerhouse.

Table 7.5-37. Comparison of Average Monthly Generation for No Project Alternative Relative to Existing Condition.

Month	YRDP Generation (GWh)		Change in YRDP Generation from Basis of Comparison	
	Existing Condition	No Project Alternative	(GWh)	(%)
October	51.8	0.0	-51.8	-100%
November	49.5	0.0	-49.5	-100%
December	64.0	0.0	-64.0	-100%
January	84.5	0.0	-84.5	-100%
February	96.6	0.0	-96.6	-100%
March	151.7	0.0	-151.7	-100%
April	132.6	0.0	-132.6	-100%
May	174.3	0.0	-174.3	-100%
June	176.9	0.0	-176.9	-100%
July	155.5	0.0	-155.5	-100%
August	134.9	0.0	-134.9	-100%
September	63.7	0.0	-63.7	-100%

Key: MW = Megawatt

No Project Alternative would result in complete elimination of YRDP generation. This would represent a substantial risk to CAISO grid stability. Accordingly, YRDP operational impacts under the No Project Alternative would be **potentially significant and unavoidable**.

YRDP Impact EN-NP-2: Change in Monthly Generation Capacity from YRDP Operations

The New Colgate Powerhouse's generation capacity is based on storage in New Bullards Bar Reservoir and the Narrows 2 Powerhouse's capacity is based on its planned flows. A reduction in New Bullards Bar Reservoir storage and a reduction in releases from the Narrows 2 Powerhouse would reduce the amount of RA the YRDP can provide. Table 7.5-38 shows a comparison of generation capacity from the New Colgate and Narrows 2 powerhouses for the No Project Alternative relative to the Existing Condition.

Table 7.5-38. Comparison of Average Monthly Generation Capacity for No Project Alternative Relative to Existing Condition.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	No Project Alternative	(MW)	(%)
October	299	0	-299	-100%
November	289	0	-289	-100%
December	282	0	-282	-100%
January	280	0	-280	-100%
February	285	0	-285	-100%
March	315	0	-315	-100%
April	339	0	-339	-100%
May	358	0	-358	-100%
June	359	0	-359	-100%
July	340	0	-340	-100%
August	326	0	-326	-100%
September	307	0	-307	-100%

Key: MW = Megawatt

The No Project Alternative would result in a complete loss of generation capacity from the YRDP. This would represent a risk to grid stability due to the elimination of the YRDP's RA services. Accordingly, YRDP operational impacts under the No Project Alternative would be **potentially significant and unavoidable**.

YRDP Impact EN-NP-3: Reduction in Generation-Related Revenue from YRDP Operations

The No Project Alternative would result in a complete loss of generation-related revenue for Yuba Water. Table 7.5-39 shows a comparison of the average annual generation revenue for the No Project Alternative relative to the Existing Condition.

Table 7.5-39. Comparison of Average Annual Generation Revenue for No Project Alternative Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	No Project Alternative	(1M$)	(%)
New Colgate PH	59.0	0.0	-59.0	-100%
Narrows 2 PH	5.7	0.0	-5.7	-100%
Total YRDP	64.8	0.0	-64.8	-100%

Key: $1M = Millions of Dollars

Elimination of average annual generation-related revenue from the YRDP would result in a loss of Yuba Water's ability to fund its programs. Accordingly, YRDP operational impacts under the No Project Alternative would **be potentially significant and unavoidable**.

Narrows Impact EN-NP-1: Change in Monthly Generation from Narrows 1 Operations

The No Project Alternative would result in the loss of all generation from the Narrows 1 Powerhouse. Table 7.5-40 shows a comparison of monthly generation for the No Project Alternative and Existing Condition.

Table 7.5-40 Comparison of Average Monthly Generation for No Project Alternative Relative to Existing Condition.

Month	Narrows Project Generation (GWh)		Change in Narrows Project Generation from Basis of Comparison	
	Existing Condition	No Project Alternative	(GWh)	(%)
July	8.2	0.0	-8.2	-100%
August	7.9	0.0	-7.9	-100%
September	7.2	0.0	-7.2	-100%
October	8.2	0.0	-8.2	-100%

Key: MW = Megawatt

No Project Alternative would result in total elimination of generation from the Narrows Project. This degree of reduced generation would represent a substantial risk to CAISO grid stability and, as a renewable energy facility, loss of Narrows 1 Powerhouse generation would interfere with California's green energy goals. Accordingly, No Project Alternative impacts for the Narrows Project would be **potentially significant and unavoidable**.

Narrows Impact EN-NP-2: Change in Monthly Generation Capacity from Narrows 1 Operations

The Narrows 1 Powerhouse's ability to provide capacity is based on its planned flows. Under No Project Alternative, there will be releases through the Narrows 1 Powerhouse. There would be a resulting complete loss of generation capacity. Table 7.5-41 shows a comparison of average monthly generation capacity for the Narrows 1 Powerhouse for the No Project Alternative relative to the Existing Condition.

Table 7.5-41. Comparison of Average Monthly Generation Capacity for No Project Alternative Relative to Existing Condition.

Month	Generation Capacity (MW)		Change in Generation Capacity	
	Existing Condition	No Project Alternative	(MW)	(%)
October	10.9	0	-10.9	-100%
November	10.9	0	-10.9	-100%
December	11.2	0	-11.2	-100%
January	11.3	0	-11.3	-100%
February	11.4	0	-11.4	-100%
March	11.5	0	-11.5	-100%
April	11.3	0	-11.3	-100%
May	11.5	0	-11.5	-100%
June	7.8	0	-7.8	-100%
July	10.1	0	-10.1	-100%
August	11.1	0	-11.1	-100%
September	10.5	0	-10.5	-100%

Key: MW = Megawatt

The No Project Alternative would result in a complete loss of generation capacity from the Narrows Project. This would represent a risk to grid stability due to the elimination of the Narrows 1 Powerhouse's RA services. Accordingly, Narrows 1 operational impacts under the No Project Alternative would be **potentially significant and unavoidable**.

Narrows Impact EN-NP-3: Reduction in Generation-Related Revenue from Narrows 1 Operations

The No Project Alternative would eliminate generation-based revenue from the Narrows Project. Table 7.5-42 shows a comparison of Narrows Project generation revenue for the No Project Alternative and Existing Condition.

Table 7.5-42. Comparison of Average Monthly Generation Revenue for No Project Alternative Relative to Existing Condition.

	Generation Revenue ($1M)		Change in Revenue	
	Existing Condition	No Project Alternative	(1M$)	(%)
Narrows 1 PH	11.2	0.0	-11.2	-100%

Key: $1M = Millions of Dollars

Elimination of average annual generation-related revenue from the Narrows Project would result in a loss of Yuba Water's ability to fund its programs. Accordingly, Narrows 1 operational impacts under the No Project Alternative would **be potentially significant and unavoidable**.

7.5.7.2 Energy Consumption

YRDP Impacts EN-NP-4: YRDP Energy Consumption from YRDP Construction

No YRDP construction would occur under the No Project Alternative. Accordingly, there would be **no impacts** related to wasteful, inefficient, or unnecessary energy consumption (EN-NP-4) or conflicts with renewable energy or energy efficiency plans (EN-NP-6) from construction activities.

YRDP Impact EN-NP-5: YRDP Energy Consumption from YRDP Operations

Under the No Project Alternative, hydropower generation would cease but other existing YRDP operations for flood management and water supply purposes would continue. No new facilities requiring additional energy would be constructed. Accordingly, YRDP operations under the No Project Alternative would not result in significantly more demands for energy, let alone wasteful, inefficient, or unnecessary energy consumption. Therefore, **no impact** would occur.

YRDP Impacts EN-NP-6: YRDP Conflicts with Renewable Energy or Energy Efficiency Plans from YRDP Construction

No YRDP construction would occur under the No Project Alternative. Accordingly, there would be **no impacts** related to conflicts with renewable energy or energy efficiency plans from construction activities.

YRDP Impact EN-NP-7: YRDP Operational Conflicts with Renewable Energy or Energy Efficiency Plans

Under the No Project Alternative, hydropower generation would cease but other existing YRDP operations for flood management and water supply purposes would continue. The complete loss of YRDP hydropower generation under the No Project Alternative would mean the loss of electricity available to the grid.

It is possible that the loss could be compensated for with new electricity sources, increased production from existing sources, and/or electricity imported from outside California. Potential sources that could compensate for this loss include renewable resources, which would be consistent with the objectives of the Renewables Portfolio Standard and associated legislation. However, it cannot be determined if this loss could be made up entirely by renewable sources, and whether electricity from these sources can be provided in a timely manner. Other sources of electricity may use fossil fuels, which would conflict with the Renewables Portfolio Standard. Chapter 15, Air Quality, discusses the potential impacts of using fossil fuels for power in more detail. Given the uncertainty as to how this potential loss of electricity would be compensated for, impacts related to potential conflicts with renewable energy or energy efficiency plans are considered **potentially significant and unavoidable**.

Narrows Impact EN-NP-4: Narrows Project Energy Consumption

Under the No Project Alternative, hydropower generation would cease but other existing Narrows Project operations for flood management and water supply purposes would continue. No new facilities requiring additional energy would be constructed. Accordingly, Narrows Project

operations under the No Project Alternative would not result in significantly more demands for energy, let alone wasteful, inefficient, or unnecessary energy consumption. Therefore, **no impact** would occur.

Narrows Impact EN-NP-5: Narrows Project Conflicts with Renewable Energy or Energy Efficiency Plans

Under the No Project Alternative, hydropower generation would cease but other existing Narrows Project operations for flood management and water supply purposes would continue. The complete loss of Narrows Project hydropower generation under the No Project Alternative would mean the loss of electricity available to the grid. As discussed under YRDP Impact EN-NP-7, the loss could be compensated for with electricity from renewable sources. However, other sources may also be used, and it is not known if the loss can be entirely compensated for with renewable sources. Therefore, the compensation for this loss could conflict with applicable renewable energy or energy efficiency plans, especially the Renewables Portfolio Standard. Because of this, the impact is considered **potentially significant and unavoidable**.

7.6 Cumulative Impact Assessment

Hydrologic modeling was used to evaluate the potential cumulative effects of the Proposed Projects and alternatives in combination with other likely changes in operations on energy generation. The projects that have been adequately defined (e.g., in recent project-level environmental documents) and that have the potential to contribute to cumulative impacts are included in the quantitative assessment of the Proposed Projects' and alternatives cumulative impacts. For analytical purposes of this DEIR, the projects that are considered well defined and "reasonably foreseeable" are described in Chapter 4. To the extent feasible, potential cumulative impacts on resources dependent on hydrology or water supply (e.g., reservoir surface elevation) are analyzed quantitatively.

As described in Chapter 4, several projects considered as part of the cumulative condition cannot be accurately characterized for hydrologic modeling purposes at this time, either due to the nature of the particular project or because specific operations details are only in the preliminary phases of development. Therefore, these projects are evaluated qualitatively. Only those projects that could affect power generation are included in the qualitative evaluation that is presented in subsequent sections of this chapter.

Although most of the projects described in Chapter 4 could have project-specific impacts that will be addressed in future project-specific environmental documentation, future implementation of these projects is not expected to result in cumulative impacts to regional power production and energy consumption that also could be affected by the Proposed Projects or alternatives (see Chapter 4). For this reason, only the limited numbers of projects with the potential to cumulatively impact power production and energy consumption are specifically considered qualitatively in the cumulative impacts analysis for power production and energy consumption resources:

- FERC Hydropower Projects in the Yuba River Watershed
    - South Feather Power Project (FERC Project 2088-068) Relicensing
    - Yuba-Bear Hydroelectric Project (Yuba-Bear Project) (FERC Project No. 2266) Relicensing,
    - Upper Drum-Spaulding Hydroelectric Projects (FERC No. 2310)
    - Lower Drum Hydroelectric Project (FERC No. 14531) Relicensing
- Flood Control Projects
    - New Bullards Bar Dam ARC Spillway Project
    - USACE NBB Dam and Reservoir Water Control Manual (WCM) Update
- Ecosystem Restoration and Fisheries Improvement Projects
    - Bay-Delta Water Quality Control Plan Update – HR & L

7.6.1 Cumulative Condition with Proposed Projects compared to the Existing Condition

Under the Cumulative Condition, the YRDP Relicensing will change YRDP operations which influences reservoir storages and flows from the New Colgate and Narrows 2 powerhouses. Narrows Project operations under the Cumulative Condition will remain the same as under the Existing Condition. Implementation of upstream relicensing projects and ARC Spillway operations have been considered through hydrologic modeling. All other projects considered in the power production and energy consumption cumulative assessment are addressed qualitatively.

Relicensing of the Yuba-Bear and Drum-Spaulding projects could reduce generation of those projects. When combined with changes in YRDP and Narrows Project generation, there would be a general reduction in generation.

The Bay-Delta Water Quality Control Plan Update – HR&L project has the potential to require increased releases from New Bullards Bar Reservoir during the spring months of above normal, below normal, and dry years, but would only occur when New Bullards Bar Reservoir storage would be forecasted to have an end-of-September storage greater than 600,000 acre-feet. In the year of a HR&L release, there would be an increase in springtime generation from the New Colgate Powerhouse and a reduction in New Colgate Powerhouse capacity due to the reduced New Bullards Bar Reservoir storage, but overall changes would not likely be substantive. Ending a year with reduced storage due to the HR&L program could have an effect on YRDP generation and capacity in the following year if the following year was extremely dry, but entering the winter with slightly lower storage could result in fewer spills, which could allow the New Colgate Powerhouse to run more in the winter.

Flood-management-focused projects like the ARC Spillway Project and WCM Update would not have a cumulatively significant effect on energy production. The ARC Spillway would allow New Bullards Bar Dam to release more flow earlier in a storm, which could extend the period of New Colgate Powerhouse shutdown. Construction of the ARC Spillway or any levee modifications would be scheduled and include BMPs to minimize potential effects on YRDP or Narrows Project operations, particularly water supply and flood management operations.

As explained above, construction activities under the Proposed YRDP Project would not impact any of the power production indicators and therefore would not contribute to potential cumulative power production impacts. Additionally, as explained above, none of the construction or operational activities that would occur under the Proposed Projects would result in significant impacts related to wasteful, inefficient, or unnecessary energy consumption or conflicts with renewable energy or energy efficiency plans. These types of impacts are highly project-dependent and generally would not be expected to combine with similar impacts from other past, present, and future projects to create a significant cumulative impact.

For these reasons, under the Cumulative Condition, including the Proposed Projects, there would not be a significant impact to power production or energy consumption.

7.6.1.1 Proposed Projects Cumulative Condition Impact Determinations

YRDP Cumulative Impact EN-PP-1: YRDP impacts to power production and energy consumption

Under the cumulative condition, including the Proposed Projects, the cumulative impact to power production and energy consumption would be less than significant. Accordingly, the Proposed YRDP Project would result in a **less than significant cumulative impact** to power production and energy consumption.

Narrows Cumulative Impact EN-PP-1: Narrows Project impacts to power production and energy consumption

Under the cumulative condition, including the Proposed Projects, the cumulative impact to power production and energy consumption would be less than significant. Accordingly, the Proposed Narrows Project would result in a **less than significant cumulative impact** to power production and energy consumption.

7.6.2 Cumulative Condition with Alternative 1 compared to the Existing Condition

Construction and non-flow operational activities planned under Alternative 1 do not differ from those planned under the Proposed Projects, and would therefore have the same associated incremental contribution to the cumulative condition discussed in Section 7.6.1 above. The Alternative 1 Cumulative Condition includes the same cumulative past, present, and future projects identified in Section 7.6 above, which would have the same associated contributions to the cumulative condition discussed in Section 7.6.1 above.

Changes in operations of the YRDP under the Cumulative Condition with Alternative 1 scenario relative to the Existing Condition scenario are essentially equivalent or very similar to those described for the Alternative 1 scenario vs Existing Condition scenario. Implementation of changes in flows in the Yuba-Bear and Drum-Spaulding relicensing projects in YRDP reaches and in reaches upstream of the YRDP are reflected in the previously analyzed Alternative 1 and Existing Condition comparison. Overall, power production would not significantly change under the Cumulative Condition, including Alternative 1, relative to the Existing Condition. For these reasons, under the Cumulative Condition, including Alternative 1, there would **not be a significant impact** on power production or energy consumption.

7.6.2.1 Alternative 1 Cumulative Condition Impact Determinations

YRDP Cumulative Impact EN-Alt1-1: YRDP impacts to power production and energy consumption

Under the cumulative condition, including Alternative 1, the cumulative impact to power production and energy consumption would be less than significant. Accordingly, YRDP construction and operations under Alternative 1 would result in a **less than significant cumulative impact** to power production and energy consumption.

Narrows Cumulative Impact EN-Alt1-1: Narrows Project impacts to power production and energy consumption

Under the cumulative condition, including Alternative 1, the cumulative impact to power production and energy consumption would be less than significant. Accordingly, Narrows Project operations under Alternative 1 would result in a **less than significant cumulative impact** to power production and energy consumption.

7.6.3 Cumulative Condition with Alternative 2 compared to the Existing Condition

Construction and non-flow operational activities planned under Alternative 2 do not differ from those planned under the Proposed Projects scenario and would therefore have the same associated incremental contribution to the cumulative condition discussed in Section 7.6.1 above.

Changes in operations of the YRDP under the Alternative 2 Cumulative Condition scenario relative to the Existing Condition scenario are essentially equivalent or very similar to those described for the Alternative 2 scenario vs Existing Condition scenario. Implementation of changes in flow requirements in YRDP reaches and in reaches upstream of the YRDP are reflected in the previously analyzed Alternative 2 vs Existing Condition comparison. Overall, power production would significantly decrease under the Cumulative Condition, including Alternative 2, relative to the Existing Condition.

Since Alternative 2 represents an alternative to the HR&L program, they would not both be implemented. However, other projects considered under Cumulative Conditions for power production and energy consumption resources could still be implemented.

If Alternative 2 were implemented for the Yuba River, it is likely it would be similarly implemented on other tributaries throughout the state. The combination of Alternative 2 with similar operations on other tributaries would likely result in widespread reductions in power production throughout the state, increasing the potential impact on the CAISO grid.

Alternative 2 would result in potentially significant impacts on generation from the YRDP. Those same impacts would be expected to remain under Cumulative Conditions (Alternative 2), and inclusion of cumulative projects described above and the implementation of an Alternative 2-like requirements throughout the state would increase the potentially significant impacts. For these reasons, under the Cumulative Condition, including Alternative 2, the cumulative impact to power production and energy resources would be significant.

7.6.3.1 Alternative 2 Cumulative Condition Impact Determinations

YRDP Cumulative Impact EN-Alt2-1: YRDP impacts to power production and energy consumption

Under the cumulative condition, including Alternative 2, the cumulative impact to power production and energy consumption resources would be significant. For the same reasons that the individual impacts of YRDP operations under Alternative 2 would be potentially significant and unavoidable, the incremental contribution of those operations to the cumulative impact would be cumulatively considerable. As explained above, there is no potential mitigation for the potential cumulative impacts. Accordingly, YRDP activities under Alternative 2 would result in **a significant and unavoidable cumulative impact** to power production and energy consumption.

Narrows Cumulative Impact EN-Alt2-1: Narrows Project impacts to power production and energy consumption

Under the cumulative condition, including Alternative 2, the cumulative impact to power production and energy consumption resources would be significant. For the same reasons that the individual impacts of Narrows Project operations under Alternative 2 would be potentially significant and unavoidable, the incremental contribution of those operations to the cumulative impact would be cumulatively considerable. As explained above, there is no potential mitigation for the potential cumulative impacts. Therefore, the Narrows Project operations under Alternative 2 would result in a **significant and unavoidable cumulative impact** to power production and energy consumption.

7.6.4 No Project Alternative Cumulative Condition compared to the Existing Condition

Under the No Project Alternative Cumulative Condition there would be a complete loss of generation from the YRDP and Narrows Project. At the same time, the new FERC licenses for the Yuba-Bear and Drum-Spaulding projects would result in reduced power production relative to the Existing Condition. None of the other projects included in the cumulative condition analysis include generation, so they would not have a cumulative effect on generation when combined with the No Project Alternative. With the loss of generation of the YRDP and Narrows Project, there would be a loss of total energy generation or generation capacity, and consequently generation-

related revenues, that would exceed the significance thresholds for power generation established in Section 7.4.3.1 above.

Accordingly, under the Cumulative Condition, including the No Project Alternative, the cumulative impact to power production and energy consumption would be significant.

7.6.4.1 No Project Alternative Cumulative Condition Impact Determinations

YRDP Cumulative Impact EN-NP-1: YRDP impacts to power production and energy consumption

Under the cumulative condition, including the No Project Alternative, the cumulative impact to power production and energy consumption resources would cumulatively significant. For the same reasons that the individual impacts of YRDP operations under the No Project Alternative would be potentially significant and unavoidable, the incremental contribution of those operations to the cumulative impact would be cumulatively considerable. As explained above, there is no potential mitigation for the potential cumulative impacts; therefore, YRDP activities under the No Project Alternative would result in a **significant and unavoidable cumulative impact** to power production and energy consumption.

Narrows Cumulative Impact EN-NP-1: Narrows Project impacts to power production and energy consumption

Under the cumulative condition, including the No Project Alternative, the cumulative impact to power production and energy consumption would cumulatively significant. For the same reasons that the individual impacts of Narrows Project operations under the No Project Alternative would be potentially significant and unavoidable, the incremental contribution of those operations to the cumulative impact would be cumulatively considerable. As explained above, there is no potential mitigation for the potential cumulative impacts; therefore, the Narrows Project operations under the No Project Alternative would result in a **significant and unavoidable cumulative impact** to power production and energy consumption.

CHAPTER 8

SURFACE WATER QUALITY

8.1 Introduction

This chapter describes the existing surface water quality conditions in the geographic extent of the environmental setting (i.e., Project Area), identifies relevant regulations, plans and policies, and evaluates potential impacts on surface water quality in Project Area waterbodies that could result from construction and O&M of the Proposed Projects and alternatives.

8.2 Environmental Setting

This section describes existing surface water quality conditions within the Project Area to inform analyses of potential impacts of the Proposed Projects and alternatives.

8.2.1 Geographic Extent of the Environmental Setting

8.2.1.1 Yuba River Development Project

The geographic area that could be affected by the YRDP and that has been identified for this DEIR includes the following Yuba River watershed waterbodies (refer to Figure 4.3-1 in Chapter 4, "Framework for the Environmental Analysis").

- New Bullards Bar Reservoir.
- North Yuba River below New Bullards Bar Dam to its confluence with the Middle Yuba River.
- Log Cabin Diversion Dam Impoundment on Oregon Creek.
- Oregon Creek below Log Cabin Diversion Dam downstream to its confluence with the Middle Yuba River.
- Our House Diversion Dam Impoundment on the Middle Yuba River.
- Middle Yuba River below Our House Diversion Dam to its confluence with the North Yuba River.
- Upper Yuba River (confluence of North and Middle Yuba rivers downstream to Englebright Reservoir).
- Englebright Reservoir.
- Lower Yuba River below Englebright Dam to its confluence with the Feather River.

In addition, due to the potential for indirect impacts or indirect cumulative impacts that may occur as a result of potential YB/DS operational changes associated with the provision of 15.6 TAF under Alternative 1 (refer to Chapter 4), the following additional areas are included in the surface water quality Project Area.

- Jackson Meadows Reservoir.
- Middle Yuba River below Jackson Meadows Dam and Milton Diversion Dam to the Our House Diversion Dam Impoundment.
- Bowman Lake.

- Canyon Creek below Bowman Lake and Bowman-Spaulding Diversion Dam to its confluence with the South Yuba River.
- Fordyce Lake.
- Fordyce Creek from Fordyce Lake to Lake Spaulding.
- Lake Spaulding.
- South Yuba River below Lake Spaulding to Englebright Reservoir.

8.2.1.2 Narrows Project

The geographic area that could be affected by the Narrows Project that has been identified for this DEIR includes the lower Yuba River below Englebright Dam to its confluence with the lower Feather River.

8.2.1.3 Areas Downstream of the Lower Yuba River

Lower Yuba River outflows and water temperatures have the potential to influence flow and water temperature-related conditions in the Feather River downstream of the Yuba River, the Sacramento River downstream of the Feather River, and the Delta. Therefore, these areas are considered in the surface water quality Project Area.

8.2.2 Yuba River Watershed

Existing water quality conditions in Project Area waterbodies in the Yuba River watershed have been characterized extensively in other documents prepared in support of Yuba Water projects and FERC relicensing applications. FERC's (2019) FEIS for the YRDP hydropower relicensing effort describes existing water quality conditions in the lower Yuba River. The water quality characterization in the FEIS[1] is based largely on information provided in Yuba Water's YRDP relicensing study reports[2] and YRDP AFLA[3] (Yuba Water 2017). These documents relied on water quality data collected by Yuba Water in 2009 and 2012, which document water quality conditions from the upper Yuba River watershed to the lower Yuba River (Yuba Water 2010a[4], 2013[5]). Yuba Water's (2023) FLA[6] for the Narrows Project also provides information regarding lower Yuba River water quality relevant to the Narrows FERC relicensing process. These documents are incorporated herein by reference and available for review at Yuba Water's office located at 1220 F Street, Marysville, CA 95901. The major points regarding water quality conditions in the Project Area are briefly summarized below.

In general, water quality of Project Area waterbodies in the Yuba River watershed is high within and between seasons. Most analyte concentrations have been at non-detect levels or just above the analytical reporting limit. Waters are generally clear, with an average turbidity less than 36 Nephelometric Turbidity Units (NTU) and dissolved oxygen concentrations near or at saturation levels. Alkalinity is generally low (<100 milligrams per liter [mg/L] as $CaCO_3$) and pH is near

[4] https://www.yubawater.org/DocumentCenter/Index/31
[5] https://www.yubawater.org/DocumentCenter/View/1297/TM-2-3-PDF
[6] https://www.yubawater.org/357/Narrows-Relicensing

neutral. Fecal coliform bacteria are not found near potential sources. Nutrient levels are low with nitrogen compound concentrations less than 0.2 mg/L as nitrogen (N), ortho-phosphate concentrations less than 0.10 mg/L as phosphorus, and total phosphorous concentrations generally less than 1 mg/L.

Low nutrient concentrations and high water clarity, driven largely by lack of development in the watershed, indicate that New Bullards Bar Reservoir and Englebright Reservoir are mesotrophic to oligotrophic, consistent with other lower elevation Sierra Nevada reservoirs. Water quality conditions remain generally consistent from upstream to downstream of the reservoirs.

Additional details regarding water quality conditions in Project Area waterbodies are provided in the impact discussions in Section 8.5 to support waterbody-specific analyses.

Beneficial uses of the Yuba River, as designated in the CVRWQCB's "Water Quality Control Plan for the Sacramento and the San Joaquin River Basins (Basin Plan)," are presented in Table 8.2-1 (CVRWQCB 2019: p. 2-9). The beneficial uses of the other Project Area waterbodies in the Yuba River watershed are not specifically designated in the Basin Plan. The Basin Plan states, "The beneficial uses of any specifically identified water body generally apply to its tributary streams…" (CVRWQCB 2019: p. 2-3). Thus, the beneficial uses of the Project Area waterbodies in the upper Yuba River watershed are considered to be the same as those listed in Table 8.2-1 for "sources to Englebright Reservoir."

Table 8.2-1. Beneficial Uses of Project Area Waterbodies in the Yuba River Watershed.

[a] "Sources to Englebright" includes the North Yuba River, Middle Yuba River, and South Yuba River.

The SWRCB has determined that several Project Area waterbodies have constituent impairments and included those waterbodies on its CWA Section 303(d) list (SWRCB 2024). Table 8.2-2 provides a summary of the CWA Section 303(d) listings for Project Area waterbodies. Project Area waterbodies not included in Table 8.2-2 are not on the CWA Section 303(d) list of impaired

waterbodies.

Table 8.2-2. CWA Section 303(d)-Listed Project Area Waterbodies in the Yuba River Watershed, Constituent Impairment, and Basis for Listing.

Waterbody / Reach	Constituent Impairment	Basis for Listing	Potential Source
New Bullards Bar Reservoir	Mercury	Exceeds statewide prey fish objective and statewide sport fish objective	Unknown
Englebright Reservoir	Mercury	Exceeds statewide sport fish objective	Unknown
North Yuba River	Mercury	Exceeds statewide sport fish objective	Unknown
Yuba River (confluence of North and Middle Yuba Rivers to Englebright Reservoir)	Chromium	Exceeds objective based on drinking water primary MCL	Unknown
	Mercury	Exceeds statewide sport fish objective	Unknown
Oregon Creek (Yuba and Sierra Counties)	Copper	Exceeds CTR chronic criterion for protection of freshwater aquatic life	Unknown
	Iron	Exceeds National Recommended Water Quality Criterion for chronic protection of freshwater aquatic life	Unknown
Yuba River (Englebright Dam to lower Feather River)	Copper	Exceeds CTR chronic criterion for protection of freshwater aquatic life	Unknown
	Mercury	Exceeds CTR criterion for protection of human health and statewide sport fish objective	Unknown
Lake Spaulding	Mercury	Exceeds statewide sport fish objective	Unknown
South Yuba River (Lake Spaulding to Englebright Reservoir)	Chromium	Exceeds objective based on drinking water primary MCL	Unknown
	Copper	Exceeds CTR chronic criterion for protection of freshwater aquatic life	Unknown
	Iron	Exceeds National Recommended Water Quality Criterion for chronic protection of freshwater aquatic life	Unknown
	Mercury	Exceeds statewide sport fish objective	Unknown
	Temperature	Exceeds thresholds for steelhead, salmon, and trout	Unknown

Source: SWRCB 2024
CTR = California Toxics Rule; MCL = maximum contaminant level

8.2.3 Areas Downstream of the Lower Yuba River

The lower Yuba River is a tributary to the lower Feather River. The lower Feather River begins at Oroville Dam, which is owned and operated by DWR and is part of the SWP. Water quality of the lower Feather River is influenced by agricultural and municipal land and water use in the watershed, but is generally suitable for the designated beneficial uses, which are listed in Table 8.2-3. The SWRCB has identified the Feather River from Oroville Dam to the Sacramento River on its CWA Section 303(d) list as being impaired for mercury, polychlorinated biphenyls, and unknown toxicity (SWRCB 2024).

Table 8.2-3. Beneficial Uses of Waterbodies in the Lower Feather River, Sacramento River, and Sacramento-San Joaquin Delta.

Beneficial Use Designation	Lower Feather River (Fish Barrier Dam to Sacramento River)	Sacramento River (Colusa Basin Drain to I Street Bridge)	Sacramento-San Joaquin Delta
Municipal and Domestic Supply	X	X	X
Irrigation Watering	X	X	X

Wildlife Habitat	X	X	X
Navigation	--	X	X

Source: CVRWQCB 2019

The lower Feather River is tributary to the lower Sacramento River. The lower Sacramento River begins at Shasta Dam, which is owned and operated by Reclamation and is part of the CVP. The Sacramento River also is generally characterized as having good water quality that supports its beneficial uses, which are listed in Table 8.2-3. The SWRCB has listed the Sacramento River from Knights Landing to the Delta on its CWA Section 303(d) list as impaired for chlordane, DDT, dieldrin, mercury, polychlorinated biphenyls, temperature, and unknown toxicity (SWRCB 2024).

The lower Sacramento River is a tributary to the Delta. Delta water quality is generally suitable to support its beneficial uses, which are listed in Table 8.2-3. Existing water quality constituents of concern in the Delta can be categorized broadly as salinity, metals, pesticides, nutrient enrichment and associated eutrophication, turbidity, and organic carbon. The Sacramento River is the dominant source of freshwater inflow to the Delta, contributing about 74 percent of total inflow, followed by the San Joaquin River (14%), Yolo Bypass (8%), and the Cosumnes, Mokelumne, and Calaveras rivers, referred to as the "eastside tributaries" (4%) (Delta Stewardship Council 2018). Certain regions of the Delta are included on the SWRCB's CWA Section 303(d) list for various constituent impairments, including mercury, electrical conductivity, and certain pesticides (SWRCB 2024).

8.3 Regulatory Setting

This section includes applicable laws, regulations, plans, and other programs relevant to surface water quality in the Project Area.

8.3.1 Federal

8.3.1.1 Clean Water Act

The CWA establishes the basic structure for regulating discharges of pollutants into the waters of the United States (including wetlands) and regulating quality standards for surface waters and gave the EPA the authority to implement control programs. The CWA authorizes EPA to delegate many permitting, administrative, and enforcement aspects of the CWA to state governments, with EPA retaining oversight responsibilities. The EPA has delegated various authorities to establish water quality standards and regulating controllable factors affecting water quality to the State of California. Federal regulations and policies relevant to implementing the Proposed Projects include CWA Section 401 water quality certifications, Section 402 establishing the National Pollutant Discharge Elimination System (NPDES) permit program, Section 404 regulating the discharge of dredged or fill material into waters of the United States, and Section 303(d) addressing water quality-related impairments of surface waters.

8.3.1.1.1 Section 401 – Water Quality Certifications

Section 401 of the CWA requires any person applying for a federal permit or license to conduct any activity, including the construction or operation of facilities, which may result in any discharge into the navigable waters, to provide the licensing or permitting agency with a certification from the state in which the discharge originates or will originate that the discharge will comply with all applicable water quality standards, limitations, and restrictions. No license or permit may be issued by a federal agency until Section 401 certification has been granted by the applicable state agency, and no license or permit may be issued if certification has been denied. Examples of permits or licenses that are subject to Section 401 of the CWA include permits issued under Section 404 of the CWA and permits issued under Sections 9 and 10 of the Rivers and Harbors Act. The SWRCB administers the Section 401 Water Quality Certification (WQC) for the Project Area.

8.3.1.1.2 Section 402 – NPDES Permit Program

Section 402 of the CWA established the NPDES permit program that regulates point and non-point source discharges to waters of the United States. In California, the SWRCB and nine RWQCBs administer the NPDES permit program. The NPDES permit program requires permits for discharges from construction activities that disturb one or more acre.

8.3.1.1.3 Section 404 – Discharge of Dredged for Fill Material

Section 404 of the CWA established a program to regulate the discharge of dredged or fill material into waters of the United States. The USACE administers the program and reviews and issues permits. The basic premise of the program is that no discharge of dredged or fill material may be permitted if (1) a practicable alternative exists that is less damaging to the aquatic environment or (2) the nation's waters would be significantly degraded. In other words, when applying for a permit, the applicant must demonstrate that steps have been taken to avoid impacts on wetlands, streams, and other aquatic resources; that potential impacts have been minimized; and that compensation will be provided for all remaining unavoidable impacts.

8.3.1.1.4 Section 303(d) – Water Quality-Related Impairments of Surface Waterbodies

Section 303(d) of the CWA requires states to develop a list of waterbodies (or sections of waterbodies) that will not attain water quality standards after implementation of minimum required levels of treatment by point-source dischargers (i.e., municipalities and industries). The law requires that states establish priority rankings for waters on the lists and develop total maximum daily loads (TMDLs) for these waters. TMDL is the amount of loading that the waterbody can receive and still achieve water quality standards. The TMDL must include an allocation of allowable loadings to point and non-point sources, with consideration of background loadings and a margin of safety.

8.3.1.2 Federal Antidegradation Policy

The federal antidegradation policy is designed to protect existing uses and the level of water quality necessary to protect existing uses and provide protection for higher quality and national water resources. The federal policy directs states to adopt a statewide policy that includes the following primary provisions (C.F.R., Title 40, Part 131.12):

1. Existing instream water uses and the level of water quality necessary to protect the existing uses shall be maintained and protected.
2. Where the quality of waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the state finds, after full satisfaction of the intergovernmental coordination and public participation provisions of the state's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located.
3. Where high quality waters constitute an outstanding National resource, such as waters of national and state parks and wildlife refuges and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected.

8.3.2 State

8.3.2.1 Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act (Porter-Cologne Act) is California's statutory authority for the protection of water quality. Under the Porter-Cologne Act, California must adopt water quality policies, plans, and objectives that ensure that beneficial uses of the state are reasonably protected. The act requires California's nine RWQCBs to adopt water quality control plans and establish water quality objectives, and authorizes SWRCB and the RWQCBs to issue and enforce permits containing requirements for the discharge of waste to surface waters and land. The Project Area is located within the CVRWQCB jurisdiction.

8.3.2.2 Water Quality Control Plan

Under the Porter-Cologne Act, each RWQCB must formulate and adopt a water quality control plan (known as a Basin Plan) for its region. The CVRWQCB has adopted the "Water Quality Control Plan for the Sacramento and the San Joaquin River Basins (Basin Plan)" (CVRWQCB 2019). The Basin Plan consists of: (1) beneficial uses to be protected; (2) water quality objectives

for the reasonable protection of beneficial uses; (3) a program of implementation for achieving the water quality objectives; and (4) a surveillance and monitoring program.

8.3.2.3 Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California

The "Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California" applies to discharges of toxic pollutants into inland surface waters, enclosed bays, and estuaries (SWRCB 2005). The policy describes methods for determining the need for and setting of effluent limits in NPDES permits from the federal National Toxics Rule and California Toxics Rule (CTR) criteria and priority pollutant objectives established in state water quality control plans. The policy also establishes certain monitoring requirements and chronic toxicity control provisions and includes special provisions for certain types of discharges.

8.3.2.4 SWRCB Resolution No. 68-16 (Statement of Policy with Respect to Maintaining High Quality of Waters in California)

The goal of SWRCB Resolution No. 68-16 ("Statement of Policy with Respect to Maintaining High Quality of Waters in California") is to maintain high-quality waters where they exist in the state. SWRCB Resolution No. 68-16 states, in part, the following.

1. Whenever the existing quality of water is better than the quality established in policies as of the date on which such policies become effective, such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial use of such water and will not result in water quality less than that prescribed in the policies.

2. Any activity which produces or may produce a waste or increased volume or concentration of waste and which discharges or proposes to discharge to existing high-quality waters will be required to meet waste discharge requirements which will result in the best practicable treatment or control of the discharge necessary to assure that: (a) a pollution or nuisance will not occur and (b) the highest water quality consistent with maximum benefit to the people of the State will be maintained.

The SWRCB has interpreted Resolution No. 68-16 to incorporate the federal antidegradation policy, which is applicable if a discharge that began after November 28, 1975, would lower existing surface water quality.

8.3.2.5 SWRCB Construction Stormwater General Permit

The SWRCB adopted a general NPDES permit for stormwater discharges associated with construction activity (Construction Stormwater General Permit) in Order No. 2022-0057-DWQ/NPDES Permit CAS000002, which became effective on September 1, 2023. Construction activities that disturb one or more acre of land are required to obtain coverage under the Construction Stormwater General Permit, which involves filing of a Notice of Intent and preparation and implementation of a stormwater pollution prevention plan (SWPPP) that specifies BMPs to reduce or eliminate sediment and other pollutants in stormwater as well as non-stormwater discharges. The Construction Stormwater General Permit requires implementation of

BMPs that control pollutant discharges using the best available technology economically achievable for toxic and non-conventional contaminants, the best conventional technology for conventional contaminants, and any other necessary BMPs to meet water quality standards. The Construction Stormwater General Permit includes specific requirements based on the "risk level" of the site. The Construction Stormwater General Permit contains technology-based numeric action levels for pH and turbidity and requires visual monitoring for potential contaminant runoff at all sites, and effluent monitoring at all risk level 2 and 3 sites, with follow-up actions required for exceedances of numeric action levels.

8.3.3 Local

8.3.3.1 Yuba County 2030 General Plan

The following goals and policies from the Yuba County 2030 General Plan relate to water quality effects in the Project Area (Yuba County 2011).

GOAL HS 3: Water Quality. Preserve, protect, and improve the quality of regional water supplies.

- **Policy HS 3.1.** County and regional water supply providers should monitor and proactively address water quality problems, with a focus on achieving and maintaining adequate water quality for "beneficial uses" of area waterways identified in the Yuba County Integrated Regional Water Management Plan. "Beneficial uses" in Yuba County include municipal and domestic supply, agricultural supply, industrial service supply, and industrial process supply.

GOAL HS 8: Geology and Soils. Reduce risk to people and property from geologic hazards and soil limitations.

- **Policy HS 8.5.** An erosion and sediment control plan meeting County standards for preventing increased discharge of sediment is required for:
    - Projects that propose to grade more than 10,000 square feet of area having a slope greater than 10 percent.
    - Clearing and grubbing areas of one acre or more regardless of slope.
    - Projects where more than 2,500 square feet will be inadequately protected from erosion during any portion of the rainy season.
    - Projects that involve grading will occur within 50 feet of any watercourse; or
    - Where the County determines that the grading will or may pose a significant erosion, or sediment discharge hazard for any reason.

  Projects having more than 1 acre of soil disturbance covered under the SWRCB's Construction Stormwater General Permit, discussed above, may still be subject to a plan check to ensure the SWPPP meets County standards.

- **Policy HS 8.6.** Project applicants may be required to show evidence of coverage, or application for coverage, under an NPDES general construction permit and a SWPPP with a State-issued Waste Discharger Identification number, if applicable. Grading activities

shall be located and designed to avoid contributing to the violation of provisions of any applicable NPDES stormwater discharge permit.

- **Policy HS 8.8.** For engineered grading, the peak off-site storm water discharge from the project site shall not exceed pre-construction conditions unless the applicant demonstrates that downstream storm water conveyance systems have sufficient capacity to handle the increased flow rate without exceeding established design standards, subject to County approval.

8.3.3.2 Yuba County Code

Yuba County Code Chapter 11.23, "Grading, Drainage, and Erosion Control" details the requirements for county grading permits and related geotechnical investigations and inspections that would be required for buildings meant for public occupancy in areas with potential risk related to geologic conditions or soil limitations, as identified on county-maintained maps.

8.4 Impact Assessment Methodology

This section describes the assessment methods used to analyze the effects on water quality in the Project Area waterbodies that could result from construction and O&M of the Proposed Projects and Alternatives 1 and 2, and the thresholds of significance that determine the significance of effects.

8.4.1 Facility Construction-Related Impacts

Water quality effects related to modification of power generation- and water conveyance-related facilities for the YRDP Relicensing Project (i.e., New Colgate Powerhouse New Tailwater Depression System, Our House Diversion Dam and Log Cabin Diversion Dam Fish Release Outlets, Lohman Ridge Diversion Tunnel Intake) were assessed considering the many aspects of the work that would be involved and potential environmental exposure to contaminants. The types of materials and contaminants that may be handled, stored, used, or produced and released to the environment, and the related fate and transport and potential for discharge to adjacent waterbodies were considered. Also considered was the location of the construction activities within the watershed relative to other project activities, duration of work, whether work would be conducted within waterbody channels, and plans for implementing erosion control and pollution prevention BMPs during and following completion of construction activities.

A construction impact determination for water quality impacts related to modification of power generation- and water conveyance-related facilities for the YRDP Relicensing Project is made relative to the Existing Condition in the following impact discussion.

- YRDP Impact WQ-PP-1: Impacts on Surface Water Quality from Modification of Power Generation- and Water Conveyance-Related Facilities for the YRDP Relicensing Project.

Impact determinations associated with construction activities that would occur from the proposed YRDP implementation plans, including the *Recreation Facilities Plan*, which would involve construction activities over a 20-year timeframe, are addressed in the following section.

As discussed in Chapter 4, because facility construction-related activities are identical for both the

YRDP Relicensing Project and Alternatives 1 and 2, the above-listed impact analysis is presented once, and not repeated in the subsequent discussion of potential impacts related to Alternatives 1 and 2. Furthermore, because no new facilities are proposed for the Narrows Relicensing Project, there would be no related construction impacts on surface water quality related to this project.

8.4.2 Implementation Plan Impacts

Water quality effects from the YRDP implementation plans were assessed considering the location, frequency, and types of activities that would be conducted. The types of materials and contaminants that may be handled, stored, used, or produced and released to the environment, and the related fate and transport and potential for discharge to adjacent waterbodies was considered. Also considered was the location of the implementation plan activities within the watershed relative to other project activities, duration of work, whether work would be conducted within waterbody channels, and plans for implementing erosion control and pollution prevention BMPs during and following completion of implementation plan activities.

Implementation plan impact determinations are made relative to the Existing Condition in the following impact discussions.

- YRDP Impact WQ-PP-2: Impacts on Surface Water Quality from Implementation of the YRDP Recreation Facilities Plan.
- YRDP Impact WQ-PP-3: Impacts on Surface Water Quality from Implementation of the YRDP Log Cabin and Our House Diversion Dams Sediment Management Plan.
- YRDP Impact WQ-PP-4: Impacts on Surface Water Quality from Other YRDP Implementation Plans.

As discussed in Chapter 4, because implementation plan activities are identical for both the YRDP Relicensing Project and Alternatives 1 and 2, the above-listed impact analyses are presented once, and not repeated in the subsequent discussion of potential impacts related to Alternatives 1 and 2.

8.4.3 Water Operations-Related Impacts

Operations-related changes that could affect surface water quality in the Project Area waterbodies upstream of Englebright Dam, the lower Yuba River, and areas downstream of the lower Yuba River would be primarily due to changes in reservoir storage and elevation, and river and creek flow rates that would occur under the Proposed Projects and Alternatives 1 and 2. As described in Chapters 2, 3 and 5, no substantial changes in Narrows Project operations would occur under the Proposed Projects or Alternatives 1 and 2. Operations-related impacts to surface water quality under the Narrows Project would be only due to a limited number of amended and/or new proposed FERC license conditions. Consequently, operations-related surface water quality impacts evaluated for the YRDP Relicensing Project and Narrows Relicensing Project considered the following.

YRDP

- Areas Upstream of Englebright Dam
    - Quantitative changes in simulated flows and water temperatures

    - Qualitative changes to surface water quality associated with operations or additional operations-related activities
        - Reservoir operations
        - Spills at project dams
        - Powerhouse operations
        - Diversion dam operations
        - License implementation plans
- Lower Yuba River
    - Quantitative changes in simulated flows and water temperatures
    - Qualitative changes to surface water quality associated with operations or additional operations-related activities
        - Powerhouse operations
        - License implementation plans
- Areas Downstream of the Lower Yuba River
    - Quantitatively informed qualitative changes in flow and surface water quality conditions in areas downstream of the lower Yuba River

Under the Alternative 1 analyses for the YRDP, indirect operations-related impacts are qualitatively evaluated in reaches and reservoirs upstream of the YRDP in the Middle Yuba River and South Yuba River watersheds.

Narrows Project

- Qualitative changes to surface water quality associated with operations or additional operations-related activities
    - Amended and/or newly proposed FERC license conditions

Assessment of the potential effects of operations-related changes to river and creek flow rates on surface water quality considered the degree to which flow changes can result in changes in constituent concentrations (e.g., trace metals concentrations, mercury loading) and physical parameters (e.g., pH, turbidity). In addition, reservoir storage and elevation changes were evaluated to determine whether reservoir stratification would be affected, potentially resulting in effects on physical processes that would affect dissolved oxygen, nutrient cycling, or release of trace metals and mercury into the water column.

Water temperature is addressed within this section with respect to effects on dissolved oxygen. Detailed analysis regarding water temperature and effects on beneficial uses is provided in Chapter 9, "Fisheries Resources," as aquatic life beneficial uses of Project Area waterbodies would be most sensitive to changes in temperature due to Proposed Projects and Alternatives 1 and 2.

Reservoir storage and river flow rate model results from Yuba Water's YRDPM supported the assessment. The YRDPM includes representation of a long-term period of record of hydrology (water years 1970–2021), member unit water supply demands, current and proposed facilities, and

current and proposed operational requirements. Changes in simulated flows as a result of the Proposed Projects and Alternatives 1 and 2 relative to the bases of comparison were used to determine potential surface water quality impacts. More information about the YRDPM, including assumptions, inputs, and model limitations, is provided in Appendix 5A, "Yuba Water Operations Model Technical Memorandum."

A "dual baseline" approach was applied to the assessment of impacts from operations-related changes in reservoir storage and river and creek flow rates. This involved the use of a Future Baseline in addition to the use of the typical Existing Condition basis of comparison under CEQA. Table 8.4-1 shows the appropriate comparison for the Proposed Projects and Alternatives 1 and 2 for determination of water operations-related impacts. Evaluations involving the Future Baseline were conducted to make a meaningful comparison among the Proposed Projects and Alternatives 1 and 2. Refer to Chapter 4 for a comprehensive explanation as to why a Future Baseline has been considered and why it is appropriate to use a Future Baseline as part of the analyses conducted for the Proposed Projects.

Table 8.4-1. Summary of Scenario Comparisons for Project and Alternative Impact Determinations.

Scenario Name	Basis of Comparison	Impacts	Use in Analysis
Proposed Projects (existing YB/DS / no FERC 4(e) Conditions)	Existing Condition	YRDP Impacts WQ-PP-5 through WQ-PP-12	For CEQA impact determinations
Proposed Projects (with YB/DS with FERC 4(e) Conditions)	Future Baseline	YRDP Impacts WQ-FPP-5 through WQ-FPP-12	For CEQA impact determinations
Alternative 1 (includes YB/DS with FERC 4(e) Conditions)	Existing Condition	YRDP Impacts WQ-Alt1-5 through WQ-Alt1-12	For information purposes only
Alternative 1 (includes YB/DS with FERC 4(e) Conditions)	Future Baseline	YRDP Impacts WQ-FAlt1-5 through WQ-FAlt1-12	For CEQA impact determinations
Alternative 2 (includes YB/DS with FERC 4(e) Conditions)	Existing Condition	YRDP Impacts WQ-Alt2-5 through WQ-Alt2-12	For information purposes only
Alternative 2 (includes YB/DS with FERC 4(e) Conditions)	Future Baseline	YRDP Impacts WQ-FAlt2-5 through WQ-FAlt2-12	For CEQA impact determinations

FERC = Federal Energy Regulatory Commission
YB/DS = Yuba-Bear/Drum-Spaulding

As explained in Chapter 4, all significance conclusions for reservoir storage and river and creek flow-dependent impact analyses related to the Proposed Projects are based on a comparison to the Existing Condition and Future Baseline. Significance conclusions for impacts of the Proposed Projects that could affect water quality in ways other than changes in reservoir storage and river and creek flows (e.g., effects from construction and implementation plans) are based on comparison to the Existing Condition.

This chapter evaluates the potential water-related operational impacts of Alternatives 1 and 2 relative to the Existing Condition for informational purposes only. As explained in Chapter 4, because these comparisons would result in misleading impact determinations, this chapter does not use the Existing Condition to draw significance conclusions for impacts resulting from changes in reservoir storage and river and creek flows under Alternatives 1 and 2. Rather significance conclusions are based on comparisons between these alternatives and the Future Baseline. Significance conclusions for potential impacts not related to reservoir storage and river and creek

flow changes (e.g., effects from construction and implementation plans) are based on comparison to the Existing Condition.

8.4.4 Routine Operations- and Maintenance-Related Impacts

Routine operations- and maintenance-related water quality effects were assessed considering the location, frequency, and types of activities that would be conducted with the Proposed Projects and Alternatives 1 and 2 relative to the frequency and types of routine O&M activities that currently occur under the Existing Condition. The types of materials and contaminants that may be handled, stored, used, or produced and released to the environment, and the related fate and transport and potential for discharge to adjacent waterbodies was considered. Also considered was the location of the routine O&M activities within the watershed relative to other project activities, whether work would be conducted within waterbody channels, and plans for implementing erosion control and pollution prevention BMPs during and following completion of O&M activities.

Routine O&M impact determinations are made relative to the Existing Condition in the following impact discussions.

- YRDP Impact WQ-PP-13: Impacts on Surface Water Quality from Other Operations and Maintenance of the YRDP Relicensing Project.
- YRDP Impact WQ-Alt1-13: Impacts on Surface Water Quality from Other Operations and Maintenance of Alternative 1.
- YRDP Impact WQ-Alt2-13: Impacts on Surface Water Quality from Other Operations and Maintenance of Alternative 2.

Because no new facilities are proposed for the Narrows Project, and O&M activities at the facilities would be within the range of activities that occur under the Existing Condition, there would be no O&M impacts on surface water quality related to this project.

8.4.5 Impact Indicators and Significance Criteria

Significance criteria applied to make surface water quality impact determinations are based on questions presented in CEQA Guidelines Appendix G, "Environmental Checklist," Section X, "Hydrology and Water Quality." An impact on surface water quality would be significant if implementation of the Proposed Projects or Alternatives 1 or 2 would:

1. Violate any water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality; or
2. Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would:
    a. Result in substantial erosion or siltation on- or off-site; or
    b. Create or contribute runoff water that would provide substantial additional sources of polluted runoff; or
3. Risk release of pollutants due to project inundation in flood hazard zones.

4. Conflict with or obstruct implementation of a water quality control plan.

These significance criteria also were applied to the No Project Alternative. How the Proposed Projects, Alternatives 1 and 2, and the No Project Alternative were evaluated relative to the above significance criteria is explained below.

Significance Criterion #1

Significance Criterion #1 addresses three components of a potential surface water quality impact: (1) violate any water quality standard; (2) violate waste discharge requirements; or (3) otherwise substantially degrade surface water quality.

A "water quality standard" consists of the designated beneficial uses of a waterbody and the water quality criteria (referred to as "objectives" in California) that when met result in protection of the beneficial uses. Therefore, impact determinations made relative to violation of any water quality standard considered the designated beneficial uses of the waterbody and the applicable water quality criteria/objectives. Water quality criteria/objectives have exposure durations associated with them based on the associated beneficial use protection. For example, criteria/objectives for the protection of aquatic life typically apply either on a short-term, acute (i.e., 1-hour exposure) basis or a longer-term, chronic (i.e., 4-day average) basis. Furthermore, aquatic life criteria are typically not absolute values never to be exceeded, rather they are not to be exceeded more than once in a three-year period, which recognizes that an infrequent marginal exceedance of a water quality criteria/objective provides a high degree of protection (EPA 1994; p. 3-3). Criteria/objectives for human health protection are typically for protection over a lifetime (i.e., 70 years) of exposure. Therefore, significant or potentially significant impact determinations are made relative to Significance Criterion #1 when water quality with the Proposed Projects or alternative would cause water quality changes that would result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that could result in adverse effects on beneficial uses. A less-than-significant impact determination is made when the potential exceedance of water quality criteria/objectives would be of low magnitude and of limited geographic extent such that there would be no adverse effects on beneficial uses of the waterbody.

Waste discharge requirements issued by the CVRWQCB and SWRCB implement applicable water quality criteria/objectives based on designated beneficial uses of the waters receiving the discharge. Therefore, the above-described considerations for making impact determinations relative to violation of water quality standards were applied for making determinations relative to violation of waste discharge requirements as well.

Water quality degradation occurs when there is a lowering of water quality (i.e., an increase in pollutant levels or depletion of an important constituent such as dissolved oxygen) due to an action or discharge. Water quality degradation can have an adverse environmental effect if resulting water quality conditions increase the likelihood of water quality criteria/objectives exceedances and adverse effects on beneficial uses. As discussed above, frequency, magnitude, and geographic extent of water quality degradation is relevant to determining whether water quality degradation would cause this to occur. And the significance criterion, consistent with the Appendix G checklist question, refers to "substantial" water quality degradation. Therefore, significant or potentially significant impact determinations are made relative to Significance Criterion #1 when the Proposed Projects or alternative would cause water quality degradation on a long-term basis that

eliminates a substantial amount of a waterbody's available assimilative capacity which, in turn, increases the likelihood of water quality criteria/objectives exceedances and adverse effects on beneficial uses. Less-than-significant impact determinations are made if the water quality degradation would be of short duration, low frequency, unlikely to rise to the level of causing a water quality objective/criterion to be exceeded, and/or of limited geographic extent, thus posing negligible risk for adverse effects on beneficial uses of the waterbody.

For waterbodies on the SWRCB's CWA Section 303(d) list due to specific constituent impairments (e.g., mercury), long-term "measurable" degradation was the basis for making impact determinations in recognition that this determination should be more sensitive when water quality conditions in a waterbody are already impaired.

Significance Criterion #2

Significance Criterion #2 addresses potential impacts on surface water quality through alterations of a water course or on-land activities that could result in the discharge of pollutants. The significance criterion refers to "substantial" erosion or siltation and additional sources of polluted runoff as the basis for making a significant or potentially significant impact determination, consistent with the Appendix G checklist question. Therefore, as with Significance Criterion #1, significant or potentially significant impact determinations are made relative to Significance Criterion #2 when the potential for erosion or siltation or polluted runoff with the Proposed Projects or alternative would cause either exceedance of a water quality standard, as defined above, or water quality degradation on a long-term basis that eliminates a substantial amount of a waterbody's available assimilative capacity that increases the likelihood of water quality criteria/objectives exceedances and adverse effects on beneficial uses. Less-than-significant impact determinations are made if the potential for erosion or siltation or polluted runoff would be of short duration, low frequency, of limited geographic extent, and/or the resulting discharges would cause low magnitude siltation and low magnitude effects on pollutant levels that pose negligible risks for adverse effects on beneficial uses of the waterbody.

Significance Criterion #3

Significance Criterion #3 addresses whether components of the Proposed Projects or alternatives would conflict with a water quality control plan. The relevant water quality control plan for the Project Area is the "Water Quality Control Plan for the Sacramento and the San Joaquin River Basins" (Basin Plan) (CVRWQCB 2019). The Basin Plan defines beneficial uses, water quality objectives to protect beneficial uses, a program of implementation for achieving water quality objectives, and a surveillance and monitoring program.

8.5 Environmental Impact Analysis

This section presents the impacts of the Proposed Projects and alternatives on water quality of Project Area waterbodies.

8.5.1 Proposed Projects compared to the Existing Condition

Construction, operations, and maintenance activities for the Proposed Projects under the new FERC licenses have the potential to affect surface water quality of waterbodies in the Project Area. The discussions below address these potential impacts.

YRDP Impact WQ-PP-1: Impacts on Surface Water Quality from Modification of Power Generation- and Water Conveyance-Related Facilities for the YRDP.
A component of the YRDP Relicensing Project is modifications at the New Colgate Powerhouse, Our House and Log Cabin Diversion Dams, and Lohman Ridge Diversion Tunnel. Modification of these facilities would involve a variety of construction-related activities, such as vegetation removal, excavation, surface grading, trenching, road construction, soil stockpiling, and other general facility construction activities (i.e., concrete, steel, carpentry, and other building trades). These activities could result in stormwater-related soil erosion and runoff. Construction activities also would involve the transport, handling, and use of a variety of hazardous substances and nonhazardous materials. Typical construction-related contaminants include petroleum products for O&M of machinery (e.g., fuel, oils, solvents), concrete, paints and other coatings, cleaning agents, debris, and trash. Construction activities also would involve material storage and laydown areas. Table 8.5-1 presents the potential hazards to surface water quality that could occur from construction activities for each project component and the nearest waterbody. As shown in Table 8.5-1, construction activities at each YRDP facility would occur at separate locations adjacent to different Project Area waterbodies and would be of short duration (i.e., 6 months or less).

Note that the ARC Spillway component of the YRDP has undergone separate project-specific CEQA compliance (see Chapter 2, "Project Description") and Yuba Water issued a final EIR that fully analyzed construction-related impacts of the ARC Spillway Project (Yuba Water 2024). Yuba Water's analysis of potential construction impacts on surface water quality from the ARC Spillway were determined to be less than significant after mitigation (Yuba Water 2024). Therefore, construction impacts of the ARC Spillway component of the YRDP are not included in the discussion of YRDP construction-related impacts, but are addressed in the cumulative impacts assessment in Section 8.6.

Table 8.5-1. Potential Water Quality Effects from YRDP Facility Construction.

YRDP Facility	Nearest Waterbody	Work Areas and Duration	Potential Hazards to Water Quality
New Colgate Powerhouse New Tailwater Depression System	• New Bullards Bar Reservoir • Lower Yuba River	• Confined to powerhouse, yard, and immediate vicinity. • No in-water work. • No undisturbed areas are anticipated to be disturbed as a result of the work. • Duration: 5 months	• Spill of concrete, toxic chemicals and other hazardous materials on land could enter adjacent waterbodies.
Our House Diversion Dam and Log Cabin Diversion Dam Fish Release Outlets	• Middle Yuba River • Oregon Creek	• Confined to the dam outlet area and immediate vicinity. • In-water work from floating barge. • No undisturbed areas are anticipated to be disturbed as a result of the work. • Duration: 6 months	• Spill of concrete, toxic chemicals and other hazardous materials on land could enter adjacent waterbodies or directly spill into waterbodies.

YRDP Facility	Nearest Waterbody	Work Areas and Duration	Potential Hazards to Water Quality
Lohman Ridge Diversion Tunnel Intake	• Middle Yuba River	• All work would be confined to the tunnel intake and immediate vicinity. • No in-water work. • No undisturbed areas are anticipated to be disturbed as a result of the work. • Duration: 6 months	• Spill of concrete, toxic chemicals and other hazardous materials on land could enter adjacent waterbodies.

YRDP = Yuba River Development Project

Aquatic life beneficial uses are the beneficial uses of Project Area waterbodies most sensitive to the construction-related contaminants that could be discharged. For a comprehensive discussion of YRDP construction-related effects on aquatic life beneficial uses (e.g., warm and cold freshwater habitat, fish migration), refer to Chapter 9, "Fisheries Resources." Other beneficial uses, such as municipal and domestic supply, contact and non-contact recreation, and irrigation, would be less sensitive to water quality disturbances from construction activities compared to aquatic life beneficial uses. These beneficial uses typically require greater exposure duration and/or concentrations of typical construction-related contaminants compared to aquatic life beneficial uses before an adverse effect would occur.

Yuba Water would implement construction-related measures for water quality protection, as identified in Chapter 2, Section 2.7.1.5, "Summary of FERC-Approved YRDP Implementation Plans." Relevant implementation plans and short descriptions of how they would reduce impacts on water quality from construction activities are summarized in Table 8.5-2.

Table 8.5-2. YRDP Implementation Plans That Address Construction-Related Water Quality Effects.

YRDP Implementation Plan	Elements Relevant to Water Quality Protection	Resulting Effect on Water Quality
Hazardous Materials Management Plan (WR1)	• Construction contractors required to have a work-specific spill prevention and control plan in place. • Required training on spill response and stocking of cleanup materials onsite. • Hazardous materials stored away from storm drains and watercourses.	• Reduces likelihood of a spill of toxic chemicals and other hazardous materials occurring on-site and reduces likelihood of contaminants from a spill being discharged to adjacent waterbodies.
Erosion and Sediment Control Plan (GS1)	• BMPs for control of erosion and sedimentation during construction. • Development of a SWPPP. • Postconstruction erosion control measures.	• Reduces potential for discharge of suspended sediment to adjacent waterbodies, thus also reducing the potential for discharge of on-site contaminants and reducing potential for increased turbidity and TSS levels in adjacent waterbodies.
Integrated Vegetation Management Plan (TR1)	• Restoration of native vegetation in disturbed areas.	• Reduces potential for discharge of suspended sediment to adjacent waterbodies, thus also reducing the potential for discharge of on-site contaminants and reducing potential for increased turbidity and TSS levels in adjacent waterbodies.

BMP = best management practice; SWPPP = stormwater pollution prevention plan; TSS = total suspended solids.

In addition, as described in Chapter 17, "Hazards and Hazardous Materials," Yuba Water already has in place spill prevention, control, and countermeasure (SPCC) plans for New Colgate

Powerhouse, New Colgate Penstock Shutoff Valve, and New Bullards Bar Dam, which would be implemented during project construction activities at these facilities. The SPCC Plans have been developed in accordance with the regulatory requirements of Title 40 of the C.F.R., Part 112, which must include specific measures and practices to prevent oil and oil containing products (i.e., gasoline, diesel fuel, motor oil, hydraulic fluid, aviation fuel, oil-based paint, oil-based paint thinner, roofing tar, and petroleum-based solvents) from being discharged to navigable waters of the United States and adjoining shorelines.

Furthermore, SWPPPs would be developed in accordance with the SWRCB's Construction Stormwater General Permit (Order No. 2022-0057-DWQ/NPDES Permit CAS000002). The development of the SWPPPs and applicability of other provisions of the Construction Stormwater General Permit depends on the "risk" classification for the construction, which is determined based on the potential for erosion to occur as well as the susceptibility of the receiving water to potential adverse effects of construction. While the determination of project risk level and planning and development of the SWPPPs and associated BMPs to be implemented would be completed as a part of final design and contracting for the work, the responsibility for compliance with the provisions of the Construction Stormwater General Permit necessitates that BMPs are applied to all disturbance activities. In addition to BMPs, the SWPPPs would include BMP inspection and monitoring activities, and identify responsibilities of all parties, contingency measures, agency contacts, and training requirements and documentation for those personnel responsible for installation, inspection, maintenance, and repair of BMPs.

The Construction Stormwater General Permit contains numeric action levels for pH and turbidity, specifies storm event water quality monitoring to determine if construction is resulting in elevated discharges of these constituents, and prescribes monitoring for any non-visible contaminants determined to have been potentially released. If a numeric action level is determined to have been exceeded, the Construction Stormwater General Permit requires the discharger to conduct a construction site and runoff evaluation to determine whether contaminant sources associated with the site's construction activity may have caused or contributed to the exceedance and immediately implement corrective actions if they are needed. The Construction Stormwater General Permit also specifies runoff reduction requirements for all sites not covered by a municipal NPDES permit, to minimize postconstruction stormwater runoff impacts.

Finally, YRDP construction would be subject to requirements in the SWRCB-issued CWA Section 401 WQC issued for the project. Yuba Water proposes 38 conditions be included in the WQC for the YRDP Relicensing Project, including the following conditions pertaining to protecting water quality when construction or ground-disturbance activities are occurring.

- Yuba Water Proposed WQC Condition 16, Hazardous Materials, requires implementation of the Hazardous Materials Management Plan listed in Table 8.5-2.
- Yuba Water Proposed WQC Condition 18, Construction and Maintenance, requires compliance with the SWRCB's Construction Stormwater General Permit, implementation of the Erosion and Sediment Control Plan listed in Table 8.5-2, and preparation and implementation of Water Quality Monitoring and Protection Plans (WQMP Plans).

The WQMP Plans in Yuba Water Proposed WQC Condition 18 must demonstrate compliance with sediment and turbidity water quality objectives in the Basin Plan and be consistent with the

U.S. Forest Service's "National Best Management Practices for Water Quality Management on National Forest Service Lands." WQMP Plans would identify control measures for activities with the potential to cause erosion, stream sedimentation, fugitive dust, soil mass movement, release of hazardous materials, or other water quality impairment. Control measures may include diverting runoff from disturbed areas, measures to dissipate energy and prevent erosion, revegetation, and monitoring and maintenance. Additional details are provided in Appendix 2E.

In summary, construction activities for modification of power generation- and water conveyance-related facilities listed in Table 8.5-1 would be short in duration (i.e., 6 months or less) and at geographically separate locations. With implementation of the measures and BMPs included in the YRDP implementation plans, compliance with the SWRCB Construction Stormwater General Permit, and compliance with the conditions in the SWRCB-issued CWA Section 401 WQC for the project, pollutant discharges to surface waters would be minimized and controlled such that construction of YRDP water conveyance and power generation facilities would not cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies. Furthermore, because of the short duration and separate locations, impacts to surface water quality from construction activities at the YRDP facilities listed in Table 8.5-1 would not combine with impacts from construction activities associated with the YRDP implementation plans (addressed in YRDP Impacts WQ-PP-2, WQ-PP-3, and WQ-PP-4) or other O&M activities (addressed in YRDP Impact WQ-PP-13) to cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies.

CEQA Conclusion

Based on the above analysis, construction of power generation- and water conveyance-related facilities for the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Project Area waterbodies. Furthermore, construction of these facilities would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies. Therefore, impacts on surface water quality from construction of YRDP Relicensing Project power generation- and water conveyance-related facilities would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-2: Impacts on Surface Water Quality from Implementation of the YRDP Recreation Facilities Plan.

A component of the YRDP Relicensing Project is the *Recreation Facilities Plan* described in Chapter 2, Section 2.7.1.1.3, "YRDP Recreation Facilities." The *Recreation Facilities Plan* proposes rehabilitation of existing recreational facilities and construction of new facilities, which could affect water quality of Project Area waterbodies in the vicinity of the facilities. The scale of construction activities at each recreational facility would vary, with activities ranging from

carpentry and painting to grading for new campground and day use facilities to excavation to replace underground water distribution systems to in-water work to make boat ramp improvements. The risk to water quality would vary with each type of facility improvement and the distance of the activity to the nearest creek, river, or reservoir.

Construction activities would occur over a 20-year period, beginning the first full calendar year of the new FERC license (refer to Table 3.5-1 in Appendix 2B-14 for a schedule of major rehabilitation and improvements over the license term). Some construction activities would occur within the vicinity of Project Area waterbodies, such as the campgrounds, trails, day use areas, and boat ramps adjacent to New Bullards Bar Reservoir. Other construction activities would occur in upland areas. Construction activities at each site are largely planned to occur within a single year. For example, construction of improvements at the Cottage Creek Campground are planned to occur in License Year 2. Because construction activities would be distributed over a 20-year period, be spatially dispersed, and construction of most improvements would be completed within a single license year, the associated potential impacts to surface water quality of Project Area waterbodies from construction of individual facility improvements would not overlap or be additive.

As discussed in YRDP Impact WQ-PP-1, the YRDP Relicensing Project includes implementation plans for hazardous materials management, erosion and sediment control, and vegetation management that would reduce the potential discharge of pollutants from construction activities to surface waterbodies in the Project Area. Furthermore, the SWPPPs that would be required by the SWRCB's Construction Stormwater General Permit, where there would be a disturbance of one acre or more, would require application of construction BMPs to minimize and control discharges of pollutants to surface waters. Finally, construction activities would be subject to requirements in the CWA Section 401 WQC issued for the YRDP Relicensing Project. Consequently, for the same reasons described in YRDP Impact WQ-PP-1, construction activities for the *Recreation Facilities Plan* would not cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies.

Operation of the rehabilitated and new YRDP recreational facilities would not cause water quality in Project Area surface waterbodies to differ appreciably from that which occurs under the Existing Condition. Most of the *Recreation Facilities Plan* consists of rehabilitation of existing facilities where recreation activities occur under the Existing Condition. As discussed in Chapter 11, "Recreation," Section 11.5, "Environmental Analysis," the proposed recreational facility improvements would focus recreational use along river stretches through trail and access improvements to minimize overuse at existing facilities by providing additional locations for recreational use. Furthermore, the *Recreation Facilities Plan* requires that Yuba Water conduct routine maintenance activities, includes a monitoring program that would identify increases in use and facility occupancy, and includes a monitoring program with guidance on mitigating increased use either through management actions or the development of additional capacity to meet increased use and recreational demand to minimize the potential adverse effect on the physical environment from increased use. Hence, the routine maintenance and monitoring activities would ensure that recreational use-related factors that could lead to adverse effects on water quality (e.g., erosion and associated high-turbidity runoff, pollutant runoff, trash) in nearby waterbodies are not allowed

to substantially increase following plan implementation. Consequently, recreation-related effects on surface water quality that would occur from operation of the rehabilitated recreational facilities would not be substantially greater than that which occurs for the Existing Condition. Likewise, water quality effects on adjacent waterbodies that would occur from operation of new recreational facilities, while implementing routine maintenance and monitoring activities, would not be substantial compared to the Existing Condition.

Therefore, implementation of the *Recreation Facilities Plan* would not result in an increase in recreational activity that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies.

CEQA Conclusion

Based on the above analysis, implementation of the YRDP *Recreation Facilities Plan* would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Project Area waterbodies. Furthermore, the YRDP *Recreation Facilities Plan* would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies. Therefore, impacts from implementation of the YRDP *Recreation Facilities Plan* on surface water quality would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-3: Impacts on Surface Water Quality from Implementation of the YRDP Log Cabin and Our House Diversion Dams Sediment Management Plan.
The primary activities of the YRDP's *Log Cabin and Our House Diversion Dams Sediment Management Plan* are: (1) passage of sediment through the dams; (2) mechanical removal of sediment behind the dams, and (3) stockpiling of mechanically removed sediment. Effects of these activities on surface water quality of Project Area waterbodies are addressed separately below.

Passage of Sediment

Sediment releases between October 1 and March 21 for at least nine consecutive days. Sediment releases could occur more than once during this period. Downstream sediment passage would result in short term increased downstream turbidity and total suspended solids (TSS) levels during a time of already high levels. Following its release, the sediment would settle and natural geomorphic processes would take over. Sediment passage would be subject to water quality-related conditions in permits, including the SWRCB's CWA Section 401 WQC, which would require compliance with water quality objectives for turbidity.

There have been three sediment passage events at Our House Diversion Dam—two in 2017 and one in 2019 (Yuba Water 2018). Thus, this activity occurs under the Existing Condition at that facility. No sediment passage events have been conducted at Log Cabin Diversion Dam (Yuba Water 2018); sediment removal has occurred, as discussed further below. Data from the 2017 sediment passage event at Our House Diversion Dam show that turbidity levels below the

diversion dam were close to that of the inflow, largely due to the overall high flows in the Middle Yuba River during the event. Turbidity levels ranged between 5 NTU and 267 NTU upstream of Our House Diversion Dam and between 5 NTU and 279 NTU downstream of Our House Diversion Dam (Yuba Water 2020). Similar turbidity conditions would likely occur during future sediment passage events at both diversion dams given that the events would occur when flows are relatively high (i.e., at least 540 cfs into the Log Cabin Diversion Dam impoundment and at least 1,500 cfs into the Our House Diversion Dam impoundment).

In summary, the passage of sediment would be timed to occur when flow rates, turbidity, and TSS are naturally high and adherence to permit conditions to protect water quality would be required. As such, passage of sediment would not cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Oregon Creek or the Middle Yuba River.

The sediment passage events would result in temporary suspension of sediments that would settle out of the water column downstream and be redistributed by high winter flows. Passage of sediment would likely not exacerbate the CWA Section 303(d) impairments for copper and iron in Oregon Creek or mercury and chromium impairments in the upper Yuba River, downstream of the Middle River confluence, as explained further below.

Copper. Copper is a naturally occurring element. The CWA Section 303(d)-listing of Oregon Creek for copper impairment is based on data reported to the SWRCB by the South Yuba River Citizens League (SYRCL) exceeding the CTR criterion for the chronic protection of freshwater aquatic life of 9 µg/L, expressed as the dissolved fraction (SWRCB 2024). The SWRCB determined that 5 out of 14 creek samples collected between July 2002 and October 2004 exceeded the criterion. The SYRCL dataset includes copper values that range from 1.1–34 µg/L, with the five highest concentrations being 9.6 µg/L, 15 µg/L, 16 µg/L, 19 µg/L and 34 µg/L. Natural receiving waters typically do not contain copper concentrations in the range of this dataset, especially in the range of the highest report concentrations. Yuba Water, as part of its FERC monitoring requirements, collected and analyzed water samples from Oregon Creek above and below Log Cabin Dam in fall of 2009 and spring and summer of 2012. Total recoverable copper concentrations reported by Yuba Water in Oregon Creek for these six monitoring events were all <0.35 µg/L (Yuba Water 2010a, 2013). For the same six monitoring events, total recoverable copper concentrations reported for other sites located in the North Yuba River and Middle Yuba River were all <0.53 µg/L. Hence, based on conflicting datasets, it is unclear whether Oregon Creek actually experiences copper concentrations above applicable CTR criteria.

Another important consideration in determining the degree of copper impairment in Oregon Creek is how the CTR criteria for copper are determined. The CTR copper criteria are equations that are a function of water hardness to reflect empirical data showing that toxicity of copper decreases as hardness increases. Other constituents, such as dissolved organic carbon, sulfate, sodium, alkalinity, and pH, are also known to affect copper bioavailability, thus toxicity. To account for the effects of these other constituents on copper bioavailability and promulgate copper criteria appropriate for the conditions under which they are applied, the CTR copper criteria equation includes a multiplier called a "water-effect ratio" (WER). Many waters having pH above 6.5 and dissolved organic carbon concentration above 1 mg/L have a WER greater than 1. A site-specific

WER equal to 2 would change the default criterion of 9 µg/L applied by the SWRCB to 18 µg/L. Absent site-specific information, the CTR set the default value for the WER equal to 1, which is what was applied for the SWRCB CWA Section 303(d) listing. Only when the site-specific WER is determined and applied to the CTR copper equation do we know the criterion for the site that provides the level of protection to aquatic life intended by EPA. EPA has since published updated water quality criteria for copper for the protection of freshwater aquatic life to be a "biotic ligand model" to directly account for the effect of various site-specific water quality conditions on copper bioavailability (EPA 2007). This further contributes to the uncertainty regarding Oregon Creek being impaired for copper.

The most toxic form of copper to aquatic life is the free copper ion (Cu^{2+}). However, the free copper ion has a strong tendency to bind to various dissolved organic ligands and solid phases in the water column, thereby making it biologically unavailable for uptake into aquatic life where it can cause toxicity. This process in freshwaters results in copper rather quickly precipitating into the sediments. Copper in sediment binds to various inorganic and organic constituents, such as hydrous manganese oxides and iron oxides, clay, organic matter, and sulfides.

Remobilization of copper into the water column can occur under suitable pH and oxidation-reduction conditions. However, when sediments are released from a reservoir into a stream, copper tends to remain adsorbed to the sediment particles. Skeaff et al. (2002) found that copper partitioned from water to sediment 200–300 times faster than the reverse, meaning that the remobilization of rate of copper from the sediment to the water column is typically small. Hence, copper free ions remobilized into the water column following a sediment flushing event would re-adsorb to particulates and organic carbon in the water column quickly, thereby becoming unavailable for uptake and toxicity in aquatic life. As adsorption and complexation continues, copper would precipitate out of the water column and back into the sediments of the river within days of the flushing event (Skeaff et al. 2002).

When sediment is flushed through Log Cabin Diversion Dam, the temporarily increased sediment load would likely increase total and dissolved organic carbon levels temporarily and certainly would increase total suspended solid levels in Oregon Creek. At pH levels between 6.5 and 9 and dissolved organic carbon concentrations between 1 and 6 mg/L, the typical range for these parameters in the creek, a very high percentage of copper (including up to 100% at pH of 8 or higher and a dissolved organic carbon of 6 mg/L or higher) would be bound to organic matter, thus not bioavailable to cause toxicity to aquatic life (Smith et al. 2015). Likewise, copper would also tend to bind to sediment particles, as discussed above. The higher the percentage of measured total recoverable copper in the water column that is either complexed with dissolved organic ligands or adsorbed to sediment particles, the lower the bioavailable fraction and thus the lower the potential for toxicity to aquatic life.

Based on the above findings, periodic releases of sediment from Log Cabin Diversion Dam into Oregon Creek would not result in a substantial, if any, increase in bioavailable copper in the creek or downstream waterbodies and thus would not cause toxicity to aquatic life or make the existing CWA Section 303(d) impairment for copper in Oregon Creek measurably worse.

Iron. Iron is one of the most abundant elements in the earth's crust, and it is an essential micronutrient for microflora, plants and animals. Iron is a common element in many rocks and is

an important component of many soils, especially clay soils where it is usually a major constituent. The ferrous, or bivalent (Fe^{2+}), and the ferric, or trivalent (Fe^{3+}), ions are the primary forms of concern in the aquatic environment (Great Lakes Environmental Center 2004). Solubility of ferrous and ferric forms is complex in freshwaters and is dependent on variables such as oxidation-reduction potential, pH, temperature, and dissolved organic carbon. The ferrous form can persist in waters devoid of dissolved oxygen and has higher water solubility (Great Lakes Environmental Center 2004). In oxygenated waters with a pH of 6–8, ferric iron is the dominant form, which has low solubility and forms insoluble oxides/hydroxides that precipitate out of the water column (Cardwell et al. 2023). For practical purposes, the ferric form is insoluble. While generally not considered toxic to aquatic life in moderate amounts, precipitation of large amounts of iron oxide floc can have negative impacts on aquatic organisms primarily through physical means such as clogging gills and smothering benthic invertebrates or fish eggs in the sediments (Cardwell et al. 2023). Also, particulate iron can settle and have adverse effects on bottom-dwelling invertebrates, plants, or incubating fish eggs (Cardwell et al. 2023). For iron, the primary concerns about toxicity to aquatic life result from release of iron under acidic conditions like acid mine drainage or acid rain (Cardwell et al. 2023).

The CWA Section 303(d)-listing of Oregon Creek as impaired for iron is based on data collected in 2001–2006 by SYRCL and submitted to the SWRCB. Two of 12 samples were greater than the EPA's chronic criterion for the protection of freshwater aquatic life of 1,000 µg/L (expressed as total recoverable), one at 1,090 µg/L and the other at 2,280 µg/L (SWRCB 2024). The remaining 10 sample concentrations ranged from 55–584 µg/L. Yuba Water also measured iron concentrations in Oregon Creek upstream and downstream of Log Cabin Diversion Dam in fall 2009 and spring and summer 2012. Iron concentrations were 1,770 µg/L (upstream) and 56.4 µg/L (downstream) in fall 2009, 27 µg/L (upstream) and 50 µg/L (downstream) in spring 2012, and 21 µg/L (upstream) and 1,760 µg/L (downstream) in summer 2012 (Yuba Water 2010a, 2013). Therefore, the SYRCL and Yuba Water data for Oregon Creek iron are somewhat consistent.

When sediment is released from a dam into a stream, the iron within those sediments is likely to oxidize to ferric iron (Fe^{3+}), which is less soluble, thus tends to form a floc that precipitates out as iron oxide (rust). This occurs due to the sudden exposure to oxygenated water, particularly if the reservoir behind the dam had low oxygen levels and contained iron in a reduced form (i.e., ferrous iron [Fe^{2+}]). The iron oxide floc is only a temporary effect of the oxidation process in oxygenated waters, is typically not toxic to aquatic life due to lack of bioavailability, and will eventually be washed away by natural processes.

In their study of iron toxicity to green algae, the cladoceran *Ceriodaphnia dubia*, and fathead minnow, Cardwell et al. (2023) found that exposures to high levels of total iron, greater than solubility limits, were necessary to illicit a toxic response in these organisms. Toxicity responses in test organisms were affected by water hardness, dissolved organic carbon, and pH. At water hardness of 86 mg/L (as $CaCO_3$), dissolved organic carbon of 2.1 mg/L, and a pH of 7.6, the 95 percent confidence interval about the 72-hour ten percent effect level (EC10) endpoint for growth of the green algae (i.e., a 10% reduction in growth relative to a control) was 5,330–6,811 µg/L total iron. For similar hardness, dissolved organic carbon, and pH levels, the EC10 for growth in fathead minnow and reproduction in *C. dubia* ranged from 2,915–31,314 µg/L total iron. These toxicity testing data show the very low toxicity of iron in most natural waters.

Oregon Creek pH is typically above 6.5, hardness generally varies from about 34–81 mg/L (as $CaCO_3$), and dissolved organic carbon tends to be rather high, ranging from about 5–9 mg/L (Yuba Water 2013). Therefore, iron low-level toxicity (i.e., 10% reduction in organism growth/reproduction) to the test organisms identified above would begin to occur in Oregon Creek at total iron concentrations within the range of 2,915–31,314 ug/L or higher because of the relatively high dissolved organic carbon levels. Because of the mediating effects of Oregon Creek's hardness, dissolved organic carbon, and pH on iron toxicity, toxic effects to aquatic life would likely not occur in the creek when total iron concentrations are 2,280 µg/L, which was the basis for the CWA Section 303(d) listing.

The EPA's iron criterion of 1,000 µg/L for aquatic life protection was first published in 1976 in the "Red Book" (EPA 1976). This criterion was derived primarily from a single field study where trout and other fish species in a polluted Colorado stream affected by acid mine drainage were found to be absent at concentrations exceeding 1,000 µg/L total iron (EPA 1976). Further justification of this criterion relied on acute laboratory toxicity tests for only a few freshwater fish species and a sensitive aquatic invertebrate. In the early 2000s, efforts were undertaken by Great Lakes Environmental Center (2004) to begin updating the criterion based on more relevant data and natural environmental factors affecting iron bioavailability. The study found that a concentration of 1,740 µg/L total iron will ensure propagation of aquatic life, which is the objective of national aquatic life criteria (Great Lakes Environmental Center 2004).

Based on the discussion above, the EPA's aquatic life criterion for iron of 1,000 µg/L may be overly restrictive because it does not reflect current science demonstrating that site-specific factors affect iron toxicity, particularly the lower toxicity of iron in natural waters. Considering data in the current scientific literature, Oregon Creek likely does not experience iron toxicity to aquatic life under the Existing Condition and likely would not experience iron toxicity upon implementation of the periodic sediment releases from Log Cabin Diversion Dam. Because the sediment releases would occur under high flow conditions and the sediments would be distributed downstream according to natural hydrogeomorphic processes, any iron oxide floc that may develop also would be distributed and not occur at levels that would cause clogging of fish gills or smothering of benthic invertebrates or fish eggs in the sediments. Based on these findings, implementation of the Sediment Management Plan would not make the CWA Section 303(d) listing for iron in Oregon Creek measurably worse.

Chromium. In environmental situations chromium (III) and chromium (VI) can inter-convert, with reduction of chromium (VI) to chromium (III) generally being favored in most environmental situations.

Chromium is CWA Section 303(d)-listed for the upper Yuba River reach from the confluence of the North Yuba River and Middle Yuba River to Englebright Reservoir. This listing is based on data reported to the SWRCB by SYRCL exceeding the state's drinking water maximum contaminant level (MCL) of 50 µg/L, which is applied in the Basin Plan as a water quality objective. Three samples collected over a one-month period in 2003 measured 31 µg/L, 54 µg/L, and 53 µg/L (SWRCB 2024). From a scientific and statistical perspective, this is not enough data to definitively indicate that the municipal and domestic water supply beneficial use designated for this river reach is impaired due to chromium concentrations. Furthermore, the drinking water MCL is applied as a running annual average, whereas the SRCYL data were not averaged to make the

impairment determination. Finally, these data are highly inconsistent with data collected by Yuba Water in 2009 and 2012 that showed total chromium concentrations in waterbodies from the upper Yuba River system to Marysville on the lower Yuba River to all be 0.5 µg/L or less (Yuba Water 2010a, 2013).

Periodic flushing of sediment from behind Our House Diversion Dam into the Middle Yuba River is not expected to change chromium levels in the upper Yuba River by magnitude and duration that would make the current CWA Section 303(d) listing for chromium measurably worse. This is because the occasional sediment flushes during high flow events will be re-distributed downstream along with the high sediment loads that flush through the system during the winter months annually and will not substantially change chromium concentrations in the downstream river channels on a long-term basis, which are on average less than the drinking water MCL.

Mercury. The bioavailable form of mercury is methylmercury. Mercury methylation is a process where mercury is converted into an organometallic methylmercury cation (CH_3Hg^+). Methylation of mercury occurs primarily in anoxic environments. Anaerobic sulfate-reducing bacteria at the sediment-water interface are primarily responsible for mercury methylation in aquatic systems. Iron-reducing bacteria also do this to a lesser degree. Mercury methylation occurs under anoxic conditions in sediments, flooded shoreline soils, and to a lesser degree in the water column (SWRCB 2017a, Alpers et al. 2008). Mercury is tightly bound to insoluble metal oxides under oxic conditions, but under anoxic conditions it is released and forms iron and manganese hydrous oxides. Increased methylmercury is also associated with wetting and drying cycles. This is likely due to oxidation of organic matter and sulfate under dry conditions. The oxidized materials fuel bacterial sulfate reduction once the soils are wetted and anoxia sets in after a few days (SWRCB 2017a).

The methylation process is affected by many factors, including the following.

- Physical/chemical factors: temperature, pH, redox potential, organic carbon (amount of and type), dissolved oxygen/redox, salinity, nutrients, sulfate/sulfides, suspended sediment, sediment grain size distribution, presence of other ions, mercury speciation, inorganic mercury sources, and demethylation rates.
- Biological factors: microbial communities, electron donor and acceptor abundance for microbial communities.
- Hydrodynamic factors: wetting/drying cycles or reservoir water fluctuations, stratification, turbulence affecting sediment resuspension, residence time, water depth.

Releases of mercury into Oregon Creek and the Middle Yuba River with sediment passage downstream of the Log Cabin Diversion Dam and Our House Diversion Dam, respectively, would be subject to oxygenated conditions. In such waters, the highly bioavailable methylmercury that accumulates in aquatic organisms is transformed into less bioavailable elemental mercury through microbial demethylation and photodemethylation. Mercury can also undergo biotransformation into methylmercury in the water column, but this methylation process predominantly occurs by anaerobic sulfate-reducing bacteria at the sediment-water interface. Thus, the less bioavailable elemental mercury form dominates in oxygenated surface waters.

The bioaccumulative fraction is of greatest concern because beneficial uses are not impaired by direct toxicity of mercury to aquatic life. The EPA's chronic water quality criterion for the protection of freshwater species is 770 nanograms per liter (ng/L) total mercury. In comparison, concentrations of total mercury in the Middle Yuba River in 2009 and 2012 ranged 0.65–2.03 ng/L and concentrations in Oregon Creek ranged 0.6–1.1 ng/L (Yuba Water 2010a, 2013). Likewise, reported surface water concentrations are well below the 50 ng/L CTR criterion for the protection of human health. Rather, mercury impairments are related to elevated concentrations in fish tissues that pose a risk to humans and aquatic-dependent wildlife that consume fish and are the most susceptible to neurotoxicity from mercury. The Statewide Sport Fish Water Quality Objective for the protection of human health and wildlife is 0.2 milligrams per kilogram (mg/kg) wet weight skinless fillet samples of trophic level 3, or trophic level 4 fish, whichever is highest in the waterbody (SWRCB 2017b). Fish tissue mercury in the Middle Yuba River collected 1980–1994 exceeded 0.2 mg/kg in Sacramento pikeminnow fillets but not in rainbow trout samples (SWRCB 2024).

The bioaccumulation of methylmercury up the food web (i.e., concentrations increase with higher trophic levels) is a process that takes weeks to months in fishes. Thus, fish tissues reflect long-term average methylmercury concentrations to which they are exposed and are not sensitive to short-term episodic changes in surface water concentrations, such as those that would occur with the sediment flushing. Sediment passage downstream would not occur over a sufficiently long duration for bioaccumulation up the food web to be reflected in fish tissues. In addition, such events would occur during high flows in the winter months when sediment transport would be similar to the Existing Condition.

Furthermore, total mercury concentrations in sediment impounded by the Our House Diversion Dam and the Log Cabin Diversion Dam are low. Total mercury concentrations in sediment sampled during a 1997 sediment removal event at Our House Diversion Dam were at natural background levels (Yuba Water 2018). Samples in 2018 were below reporting limits in six of ten samples and ranged 0.03–0.092 mg/kg dry weight in the three samples with detected concentrations (Yuba Water 2020). These concentrations are below the consensus-based threshold effect concentration of 0.18 mg/kg mercury, below which adverse effects are unlikely to occur (MacDonald et al. 2000).

Finally, any potential changes in surface water mercury concentrations associated with sediment passage downstream of the Log Cabin and Our House Diversion Dams would be subject to subject to water quality-related conditions in permits, such as the SWRCB's CWA Section 401 WQC for the YRDP, that would require compliance with water quality objectives for mercury.

Based on the above findings, periodic releases of sediment from Log Cabin and Our House Diversion Dams would not result in a substantial increase, if any increase, in surface water or fish tissue mercury concentrations in Oregon Creek, Middle Yuba River, or downstream waterbodies and, thus, would not cause toxicity to aquatic life, aquatic dependent wildlife, and human health or make the existing CWA Section 303(d) impairment for mercury in the upper Yuba River or downstream waterbodies measurably worse.

Mechanical Removal of Sediment

Mechanical removal of sediment would occur during the drier months when inflows are low. The pool of water behind the dams would be drawn down and inflows would be diverted around the area to be excavated so that sediment removal would occur in the dry, meaning flowing water would not be present.

Sediment removal events occurred at Log Cabin Diversion Dam in 1972, 1997, 2014, and 2017. Sediment removal events at Our House Diversion Dam occurred in 1986, 1992, 1997, 2006, and 2017, thus this activity occurs under the Existing Condition. Sediment was tested for mercury during the 1997 removal event and levels were found to be at natural background levels (Yuba Water 2018).

Sediment would be tested for metals and characterized prior to removal to determine if the sediment can be stockpiled or must be handled as hazardous material in accordance with applicable local, state, and federal regulations. BMPs would be implemented to minimize effects to water quality, including stabilization of disturbed soils, use of erosion control measures, spill prevention and containment measures, no operation of heavy equipment or excavation in flowing water, cessation of work if downstream turbidity or dissolved oxygen levels are outside of water quality objectives, and reseeding of areas left barren from equipment use to achieve 70 percent uniform ground cover (Yuba Water 2018). Sediment removal also would be subject to water quality-related conditions in permits, such as the SWRCB's CWA Section 401 WQC for the YRDP and Construction Stormwater General Permit if one or more acre would be disturbed.

With implementation of the BMPs and compliance with permits required to remove the sediment, pollutant discharges to surface waters would be minimized and controlled such that sediment removal would not cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies.

Removal of sediment from Oregon Creek and Middle Yuba River would result in trace metals and mercury trapped in the sediments also being removed from the channels. Therefore, the mechanical removal of sediment would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in Oregon Creek (copper and iron) or upper Yuba River (mercury and chromium), or any other water quality constituents.

Sediment Stockpiling

Placement of sediment at stockpile sites has the potential to disturb soils and result in runoff of sediment at the sites. However, such activities would be temporary and short-term and would not be likely to result in substantial soil erosion or loss of topsoil. Silt fencing would be installed at the perimeter of the stockpile area to minimize runoff of sediment. The surface of the stockpile would be compacted and hydroseeded for long-term erosion control. With implementation of these control measures, sediment stockpiling would not cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies.

CEQA Conclusion

Based on the above analysis, implementation of the *Log Cabin and Our House Diversion Dams Sediment Management Plan* would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Project Area waterbodies. Furthermore, implementation of the Sediment Management Plan would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies. Therefore, the impacts on surface water quality from implementing the *Log Cabin and Our House Diversion Dams Sediment Management Plan* would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-4: Impacts on Surface Water Quality from Other YRDP Implementation Plans.

A component of the YRDP is several implementation plans, identified in Chapter 2, Section 2.7.1.5, "Summary of FERC-Approved YRDP Implementation Plans," that are intended to improve the Existing Condition and provide benefits overall to environmental resources. Some implementation plans involve activities that could affect surface water quality, either adversely through potential discharge of pollutants or beneficially through control of discharges and pollutants, and other implementation plans would have little to no effect on surface water quality because the plans would involve little to no interaction with Project Area waterbodies. Impacts on surface water quality from the *Recreation Facilities Plan*, which is one of the YRDP implementation plans, are addressed separately in YRDP Impact WQ-PP-2. Impacts on surface water quality from the *Log Cabin and Our House Diversion Dams Sediment Management Plan*, another YRDP implementation plan, are addressed separately in YRDP Impact WQ-PP-3.

Table 8.5-3 lists the implementation plans that would have minimal to no impact on surface water quality because the plan activities would not involve the handling of pollutants that could be discharged to surface waters, would not disturb land such that there would an increased potential for erosion and introduction of suspended solids into surface waters, or would not affect stream flows such that there would be flow-related changes to water quality relative to activities that occur under the Existing Condition.

Table 8.5-3. YRDP Implementation Plans That Would Have Minimal or No Impact on Surface Water Quality.

YRDP Implementation Plan (Yuba Water Designation)	Rationale for Concluding Plan Would Have Minimal to No Impact on Surface Water Quality
Bald Eagle and American Peregrine Falcon Management Plan (TR2)	• Plan implementation would not introduce pollutants that would degrade water quality; plan focus is on monitoring and protecting birds and nests.
Bat Management Plan (TR4)	• Plan implementation would not introduce pollutants that would degrade water quality; plan focus is on monitoring and excluding bats from facilities.
Drought Management Plan (WR9)	• Plan implementation would not introduce pollutants that would degrade water quality; plan focus is on flow management decisions during droughts.
Fire Prevention and Response Plan (LU2)	• Plan implementation would not introduce pollutants that would degrade water quality; plan focus is on procedures for reporting and preventing fires.
Historic Properties Management Plan (CR1)	• Plan implementation would not introduce pollutants that would degrade water quality; plan focus is on treatment and management of cultural resources.

YRDP Implementation Plan (Yuba Water Designation)	Rationale for Concluding Plan Would Have Minimal to No Impact on Surface Water Quality
Lower Yuba River Aquatic Monitoring Plan (AR8)	• Sediment disturbance would be associated with monitoring of fish, riparian vegetation cover, channel substrate, and benthic macroinvertebrates, and would be temporary and limited spatially to areas in which samples are collected, which would result in negligible, temporary disturbance of sediment from personnel wading into surface waters.
Lower Yuba River Restoration Plan	• Planting 100 acres of riparian vegetation would result in minimal disturbance of soils and result in improved shoreline stability.
New Bullards Bar Reservoir Fish Stocking Plan (AR6)	• This action would not introduce pollutants that would degrade water quality; plan is focused on fish stocking, which occurs under the Existing Condition.
Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan (GS3)	• This action would not introduce pollutants that would degrade water quality; plan is focused on allowing woody material to pass downstream of dams.
Ringtail Management Plan (TR3)	• This action would not introduce pollutants that would degrade water quality; plan focus is on installing devices to exclude ringtail from YRDP facilities.
Upper Yuba River Aquatic Monitoring Plan (AR7)	• Sediment disturbance would be associated with monitoring of fish, benthic macroinvertebrates, and other aquatic life, and would be temporary and limited spatially to areas in which samples are collected, which would result in negligible, temporary disturbance of sediment from personnel wading into surface waters.
Visual Resources Management Plan (VR1)	• This action would not introduce pollutants that would degrade water quality; plan is focused on painting facilities to improve aesthetics and blend with surrounding areas. BMPs and permits to ensure that paints are not introduced into waterbodies are addressed under YRDP Impact WQ-PP-1.
Water Temperature Monitoring Plan (WR7)	• This action would not introduce pollutants that would degrade water quality; plan is focused on personnel installing temperature loggers and periodically downloading data, which would result in negligible, temporary disturbance of sediment from personnel wading into surface waters.
Water Quality Monitoring Plan (WR8)	• This action would not introduce pollutants that would degrade water quality; plan is focused on personnel collecting water quality data using in-situ measuring devices and sample collection containers, which would result in negligible, temporary disturbance of sediment from personnel wading into surface waters.

Table 8.5-4 presents the implementation plans with components that have the potential to temporarily degrade water quality of Project Area waterbodies.

Table 8.5-4. YRDP Implementation Plans With Potential to Temporarily Degrade Surface Water Quality.

YRDP Implementation Plan	Elements Relevant to Water Quality	Affected Waterbody	Resulting Effect on Water Quality
Aquatic Invasive Species Management Plan (AR5)	• Control/eradication measures may involve chemical applications and manual removal from sediments.	• New Bullards Bar Reservoir • Log Cabin Diversion Dam Impoundment • Our House Diversion Dam Impoundment • North Yuba River • Willow Creek (upstream to the outlet of the Camptonville tunnel outlet) • Little Oregon Creek • Indian Creek • Mill Creek • Lost Creek • Slate Creek.	• Introduction of chemicals or herbicides into water column. • Temporary elevated turbidity and TSS levels.

YRDP Implementation Plan	Elements Relevant to Water Quality	Affected Waterbody	Resulting Effect on Water Quality
Large Woody Material Management Plan	• Placement of large woody debris in the lower Yuba River.	• Lower Yuba River	• Temporary elevated turbidity and TSS levels.
Narrows Reach Fish Stranding Prevention Plan	• Potential structural measures to reduce fish stranding events.	• Lower Yuba River	• Spill of concrete, toxic chemicals and other hazardous materials on land that could potentially enter adjacent waterbodies during construction.
Streamflow and Reservoir Level Compliance Monitoring Plan	• Maintenance of existing USGS gages. • Modification of three USGS gages.	• New Bullards Bar Reservoir • Middle Yuba River • Oregon Creek	• Temporary elevated turbidity and TSS levels.
Transportation System Management Plan (LU1)	• Road, ditch, and culvert improvements.	• New Bullards Bar Reservoir • Middle Yuba River • Oregon Creek • Miscellaneous local drainages	• Temporary, elevated turbidity and TSS levels.

TSS = total suspended solids; USGS = U.S. Geological Survey

Implementation of the *Aquatic Invasive Species Management Plan* may result in the use of aquatic herbicides or other chemical treatment to reduce or eliminate invasive species. Chemical treatment application would have to be in compliance with local, state, and federal regulations, and consistent with the registered use of the treatment regarding application rates and monitoring. These factors would minimize the potential for chemical concentrations to reach levels that would have unintended adverse effects on Project Area waterbody beneficial uses. Manual removal of invasive species could result in temporary suspension of sediments, resulting in localized increases in turbidity and TSS levels. However, once work in an area is complete, the turbidity and TSS levels would return to normal ambient levels.

Implementation of the *Large Woody Material Management Plan* may result in temporary, localized elevated turbidity and TSS levels in areas where large woody material is collected, as well as when it is placed. This plan would not result in the introduction of pollutants to waterways. If heavy equipment would be involved in the collection and placement of large woody material, the risks to water quality would be from accidental discharge or spills of fuel.

Similarly, implementation of the *Streamflow and Reservoir Level Compliance Monitoring Plan* may result in temporary, localized elevated turbidity and TSS levels during maintenance of existing monitoring gages. Temporary, localized elevated turbidity and TSS levels may also occur during installation of new gages. Spills from equipment that may be required for gage installation would pose a risk to water quality.

The installation of structures that may be needed to implement the *Narrows Reach Fish Stranding Prevention Plan* could result in temporary, localized elevated turbidity and TSS levels and risk of spills into receiving waters.

Finally, the road rehabilitation and maintenance activities to be implemented for the *Transportation System Management Plan* could similarly result in temporary, localized elevated

turbidity and TSS levels and risk of spills into receiving waters where work is conducted at or in the vicinity of stream crossings.

The potential for degradation of surface water quality with implementation of the *Large Woody Material Management Plan, Streamflow and Reservoir Level Compliance Monitoring Plan,* and *Transportation System Management Plan* would be reduced with implementation of the *Erosion and Sediment Control Plan, Hazardous Materials Management Plan, and Integrated Vegetation Management Plan*. The elements of these plans related to water quality protection and resulting effects on water quality are listed in Table 8.5-5.

Table 8.5-5. YRDP Implementation Plans With Potential to Reduce Impacts on Surface Water Quality.

YRDP Implementation Plan	Elements Relevant to Water Quality	Resulting Effect on Water Quality
Erosion and Sediment Control Plan (GS1)	• BMPs for control of erosion and sedimentation during routine maintenance and emergency erosion threats. • Forest Service BMPs for maintenance on National Forest land.	• Reduces potential for discharge of suspended sediment to adjacent waterbodies, thus also reducing the potential for discharge of on-site contaminants and reducing potential for increased turbidity and TSS levels in adjacent waterbodies
Hazardous Materials Management Plan (WR1)	• Database of hazardous materials stored, used or transported for routine O&M. • Training in the safe handling of hazardous materials and cleanup of spills. • Vehicles and equipment not maintained or refueled where hazardous materials may enter a watercourse. • Storage of hazardous materials in place where they cannot enter a watercourse. • Cleanup and spill materials within 3 hours of each facility.	• Reduces likelihood of a spill of toxic chemicals and other hazardous materials occurring on-site and reduces likelihood of contaminants from a spill being discharged to adjacent waterbodies.
Integrated Vegetation Management Plan (TR1)	• Restoration of native vegetation in disturbed areas subject to continual disturbance	• Reduces potential for discharge of suspended sediment to adjacent waterbodies, thus also reducing the potential for discharge of on-site contaminants and reducing potential for increased turbidity and TSS levels in adjacent waterbodies

BMPs = best management practices; TSS = total suspended solids

None of the YRDP implementation plans discussed above would involve actions that would substantially alter the existing drainage pattern of the site. Implementation of the *Erosion and Sediment Control Plan* and *Integrated Vegetation Management Plan* along with use of applicable BMPs and consistent achievement of regulatory compliance would ensure that turbidity and TSS levels would not reach sufficiently high levels for a sufficiently long period of time to cause related adverse effects on waterbody beneficial uses. Likewise, implementation of the *Hazardous Materials Management Plan* and applicable BMPs would ensure that accidental discharge or spills of fuel from use of heavy equipment in or immediately adjacent to waterbodies would not occur with frequency or magnitude to cause adverse contaminant-related impacts to waterbody beneficial uses.

Activities conducted for these implementation plans have the potential to overlap in time with each other, the construction activities addressed in YRDP Impact WQ-PP-1, the *Recreation Facilities Plan* activities addressed in YRDP Impact WQ-PP-2, as well as routine O&M addressed in YRDP Impact WQ-PP-13. However, the potential effects to water quality described above would not combine with these other project components to result in conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies due to the relatively short duration and geographic separation of the activities in the watershed.

CEQA Conclusion

Based on the above analysis, implementation of the other YRDP implementation plans[7] would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality of Project Area waterbodies. Furthermore, implementation of the other YRDP implementation plans would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies. Therefore, the impacts on surface water quality from implementation of other YRDP implementation plans would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-5: Impacts on New Bullards Bar Reservoir Water Quality from Operation of the YRDP.

The analysis below addresses impacts on New Bullards Bar Reservoir water quality from operating the YRDP Relicensing Project. Operation of the YRDP does not involve alteration of existing drainage patterns around New Bullards Bar Reservoir. Alteration of existing drainage patterns could occur through YRDP facility modification or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

Reservoir water quality is affected, in part, by the quality and quantity of reservoir inflows and nonpoint watershed runoff, which in turn are affected, in part, by precipitation and upstream watershed land use activities. The YRDP Relicensing Project would not affect precipitation and upstream watershed land uses. North Yuba River inflow, which averages 560,000 ac-ft (Yuba Water 2010b, Table 2.1-1), also would be unaffected. Therefore, external contributions of constituents to New Bullards Bar Reservoir from these sources with the YRDP Relicensing Project would not differ from the Existing Condition due to project operations. YRDPM output shows that inflow via Camptonville Tunnel, which averages 185,000 ac-ft under the Existing Condition, would be reduced by an average 28 percent, due to more water remaining in the Middle Yuba River. As such, there would be reduced loading of constituents from this inflow source.

Reservoir water quality also can be affected by reservoir storage and water surface elevation, which may be affected by operation of the YRDP Relicensing Project. Reservoir storage can affect the dilution of watershed runoff and tributary inflows, which in turn can affect reservoir constituent

[7] YRDP implementation plans listed in Section 2.7.1.5, "Summary of FERC-Approved YRDP Implementation Plans" other than the *Recreation Facilities Plan* and *Log Cabin and Our House Diversion Dams Sediment Management Plan*.

concentrations. Reservoir water surface elevation can affect internal physical processes, such as temperature gradients from the water surface to the sediment, which in turn can affect other water quality parameters, such as dissolved oxygen and nutrient cycling conditions.

Temperature, dissolved oxygen, nutrients, and mercury would be the water quality constituents most affected by changes in reservoir end-of-month storage and water surface elevation. As such, these constituents are discussed further below. Other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) would be negligibly affected by the modeled differences in reservoir end-of-month storage and water surface elevation and instead would be most affected by external source contributions, which would not be changed by the YRDP Relicensing Project.

Changes in Reservoir Storage and Water Surface Elevation

Modeling results show small differences in New Bullards Bar Reservoir average end-of-month storage with the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-Reservoir-1). Average end-of-month storage with the YRDP Relicensing Project for the full simulation period is 1 percent lower in December, January, and May, and 0 percent different compared to the Existing Condition for the other nine months. Average end-of-month storage with the YRDP Relicensing Project also differed little by water year type, with the difference being 0 percent in critical years, 1 percent in dry years, 1–2 percent in below normal years, 0–1 percent in above normal years, and 0–2 percent in wet years compared to the Existing Condition.

Modeling results also show small differences in end-of-month water surface elevation with the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-Reservoir-2). Average end-of-month water surface elevation with the YRDP Relicensing Project for the full simulation period is 1 foot lower in December, January, and April through July, and no different for the other months compared to the Existing Condition. Average end-of-month water surface elevation with the YRDP Relicensing Project also differed little by water year type, with the difference being 1 foot lower to 1 foot higher in critical years, 1–2 feet lower in dry years, 1 foot lower to 3 feet higher in below normal years, 1 foot lower to 1 foot higher in above normal years, and 0–3 feet lower in wet years compared to the Existing Condition.

Temperature and Dissolved Oxygen

Dissolved oxygen concentrations in reservoirs are primarily affected by water temperature and amounts of oxygen-demanding substances present (e.g., organic matter in the water column and sediment). Water temperature affects oxygen solubility, with colder waters able to contain higher oxygen concentrations than warmer waters. Water temperature also affects the depth at which oxygenated inflows enter the reservoir. Colder inflows tend to move deep into the reservoir due to it having higher density, whereas warm water inflows tend to mix with the surface waters, particularly when the reservoir is thermally stratified during the late spring, summer and early fall months. High nutrient content can support aquatic plant and algae growth, which in turn generate oxygen during the day through photosynthesis and consume oxygen at night through respiration. During summer months, thermal stratification can cause dissolved oxygen to become depleted at the sediment water interface because there is little to no transfer of oxygen in the upper layer to the bottom of the reservoir.

With operation of the YRDP Relicensing Project, New Bullards Bar Reservoir would continue to thermally stratify seasonally as it does under the Existing Condition, with minimal effects on the elevation of the thermocline (i.e., the transition zone between the upper warm layer and lower, cool layer) given that the modeled differences in water surface elevation are 0–3 feet. With minimal effect on the reservoir temperature profile, dissolved oxygen concentrations in the reservoir's upper layer (called the epilimnion) and lower layer (called the hypolimnion) would be very similar to the Existing Condition. Finally, given the surface area of the reservoir would be very similar to the Existing Condition, wind fetch would continue to be substantial source of reaeration to maintain oxygen levels in the upper layer of the reservoir.

Thus, the differences in end-of-month storage and water surface elevation that could occur in some months with operation of the YRDP Relicensing Project would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles or otherwise cause more frequent dissolved oxygen depletions in the lower layer of the reservoir compared to the Existing Condition.

Nutrients

The reservoir nutrients addressed in this discussion are phosphorus and nitrogen because they tend to be the dominant rate-limiting nutrients in reservoirs. As described above, external source contributions of constituents to New Bullards Bar Reservoir with the YRDP Relicensing Project would not differ from the Existing Condition. Likewise, operation of the YRDP Relicensing Project would have negligible, if any, effect on aquatic life populations within the reservoir, which release nutrients to the water column and sediments when such life dies and decomposes. Hence, this internal source of nutrients to the water column and sediments would differ negligibly, if at all, from the Existing Condition with operation of the YRDP Relicensing Project.

Internal phosphorus loading in reservoirs is driven largely by thermal stratification. Lack of oxygen within the hypolimnion allows sediment-bound phosphorus to be released into the water column. As discussed above, the YRDP Relicensing Project would have minimal effects on the New Bullards Bar Reservoir thermocline and dissolved oxygen conditions relative to the Existing Condition. As such, internal phosphorus cycling processes in the reservoir would not differ substantially, if at all, from the Existing Condition.

Nitrogen in freshwater ecosystems readily undergoes many transformations from one form to another, between dissolved inorganic nitrogen (i.e., ammonium, nitrate, and nitrite), dissolved organic compounds, and particulate forms (Horne and Goldman 1994:135–145). These transformations occur through oxidation and reduction processes that are mainly mediated by microorganisms (Horne and Goldman 1994:135–145). As described above, reservoir dissolved oxygen conditions would not differ substantially, if at all, from the Existing Condition. As such, internal nitrogen cycling processes in the reservoir also would not differ substantially, if at all, from the Existing Condition.

Mercury

New Bullards Bar Reservoir is on the SWRCB's CWA Section 303(d) list of impaired waterbodies due to impairments from mercury (refer to Table 8.2-2 in Section 8.2.2). As described in further detail in YRDP Impact WQ-PP-3, the primary concern with mercury is bioaccumulation in the

aquatic food web, which poses the greatest risk to humans and aquatic-dependent wildlife that consume fish.

Of the factors that affect methylation processes (refer to discussion in YRDP Impact WQ-PP-3), operation of the YRDP Relicensing Project would affect reservoir storage or water surface elevation. As discussed previously, operation of the YRDP Relicensing Project would not result in substantial, if any, changes in reservoir temperature, dissolved oxygen or nutrients. Similarly, operation of the YRDP Relicensing Project would have little to no effect on salinity-related parameters, suspended sediment, organic carbon, and pH, as it would not affect internal or external sources of these constituents. Furthermore, based on the modeled differences in storage and water surface elevation, operation of the YRDP Relicensing Project would have little to no effect on the reservoir stratification, residence time, and water depth. This is because the basic approach to YRDP operations that occurs under the Existing Condition would occur with the YRDP Relicensing Project. The YRDP would continue to be operated largely as it is now and water surface elevation fluctuations would occur within the same range and at a similar frequency such that YRDP wetting and drying of soils in the reservoir would differ little, if at all, from the Existing Condition. Based on the parameter-specific findings described above, reservoir water column and sediment microbial communities would not differ substantially, if at all, for the YRDP Relicensing Project relative to the Existing Condition. Therefore, operation of the YRDP Relicensing Project would not produce long-term measurable increases in methylmercury within New Bullards Bar Reservoir.

Nevertheless, one of the proposed conditions for the CWA Section 401 WQC is Condition 19, "Mercury Management" (refer to Appendix 2E). This WQC condition would involve evaluating water quality and fish tissue data to determine if operations increase mobilization and methylation of mercury. If project operations are determined to increase mobilization and methylation of mercury, then a Mercury Management Plan would be developed in consultation with SWRCB and CVRWQCB staff and comply with the "Tribal Subsistence Beneficial Uses and Mercury Provisions of the Inland Surface Waters, Enclosed Bays, and Estuaries Plan" (SWRCB 2017b). The Mercury Management Plan would include a review of potential measures to reduce the amount of methylmercury or rate of mercury methylation in the watershed as effected by the Project (such as changes to Project operations related to power generation, reservoir management, sediment dredging, and/or sediment capping), and an examination of implementation measures feasibility. The Mercury Management Plan would also describe any necessary measures to protect human health from exposure through fish consumption (such as posting health warnings at reservoirs, operating recreational fishing as catch-and-release only, or ceasing to stock reservoirs) (Appendix 2E). With implementation of this WQC condition, beneficial uses would be further protected from any potential increases in methylmercury from project operations.

In summary, operation of the YRDP Relicensing Project would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) in New Bullards Bar Reservoir compared to the Existing Condition. As such, operation of the YRDP Relicensing Project would not cause exceedance of a reservoir water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial

uses of the reservoir. Furthermore, operation of the YRDP Relicensing Project would not cause measurable degradation for the CWA Section 303(d)-listed constituents in the reservoir.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in New Bullards Bar Reservoir. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to New Bullards Bar Reservoir. Therefore, impacts on New Bullards Bar Reservoir water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-6: Impacts on Englebright Reservoir Water Quality from Operation of the YRDP.

The analysis below addresses impacts on Englebright Reservoir water quality from operating the YRDP Relicensing Project. Operation of the YRDP Relicensing Project does not involve alteration of existing drainage patterns around Englebright Reservoir. Alteration of existing drainage patterns could occur through YRDP facility modification or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

As discussed in YRDP Impact WQ-PP-5 for New Bullards Bar Reservoir, Englebright Reservoir water quality is affected, in part, by the quality and quantity of reservoir inflows and nonpoint watershed runoff, which in turn are affected, in part, by precipitation and upstream watershed land use activities. The YRDP Relicensing Project would not affect precipitation and upstream watershed land uses. Upper Yuba River inflow also would be very similar to the Existing Condition (refer to Appendix 4C, Table C1-Flow-13). Therefore, external contributions of constituents (e.g., organic compounds, pesticides, trace metals, and other pollutants) to Englebright Reservoir from these sources with the YRDP Relicensing Project would not differ from the Existing Condition due to operations.

Also as discussed for New Bullards Bar Reservoir in YRDP Impact WQ-PP-5, Englebright Reservoir water quality can be affected by reservoir storage and water surface elevation, with temperature, dissolved oxygen, nutrients, and mercury being the water quality constituents most affected by changes in reservoir end-of-month storage and water surface elevation.

Modeling results show little to no difference in Englebright Reservoir average end-of-month storage with the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-Reservoir-3). The difference between average end-of-month storage with the YRDP Relicensing Project for the full simulation period and the Existing Condition is 0 percent. Average end-of-month storage is about 44,000–46,000 ac-ft, depending on month, and differences in end-of-month storage average less than 100 ac-ft.

Modeling results also show little to no difference in end-of-month water surface elevation with the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-

Reservoir-4). The difference in average end-of-month water surface elevation with the YRDP Relicensing Project for the full simulation period compared to the Existing Condition is less than 1 foot. Average end-of-month water surface elevation with the YRDP Relicensing Project also differed little by water year type, with the difference being 1 foot or less depending on month and water year type.

Because there would be little to no change in Englebright Reservoir end-of-month storage and water surface elevation, operation of the YRDP Relicensing Project would not result in substantial, if any, changes in reservoir temperature, dissolved oxygen or nutrients. Similarly, operation of the YRDP Relicensing Project would have little to no effect on salinity-related parameters, suspended sediment, organic carbon, and pH, as it would not affect internal or external sources of these constituents. Furthermore, based on the small differences in modeled storage and water surface elevation, operation of the YRDP Relicensing Project would have little to no effect on the reservoir stratification, residence time, and water depth. This is because the basic approach to YRDP operations that occurs under the Existing Condition would occur with the YRDP Relicensing Project. The YRDP would continue to be operated largely as it is now and water surface elevation fluctuations would occur within the same range and at a similar frequency such that YRDP wetting and drying of soils in the reservoir would differ little, if at all, from the Existing Condition. Finally, as described further in Impact WQ-PP-5, one of the proposed conditions of the CWA Section 401 WQC is Condition 19, Mercury Management (Appendix 2E) to ensure beneficial uses would be protected from increases in methylmercury from project operations. Therefore, operation of the YRDP Relicensing Project would not result in a long-term measurable increase in mercury in the North Yuba River below New Bullards Bar Dam. Therefore, operation of the YRDP Relicensing Project would not produce long-term measurable increases in methylmercury within Englebright Reservoir.

As such, operation of the YRDP Relicensing Project would not cause exceedance of a Englebright Reservoir water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the reservoir. Furthermore, operation of the YRDP Relicensing Project would not cause long-term measurable degradation for the CWA Section 303(d)-listed constituents in the reservoir.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Englebright Reservoir. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Englebright Reservoir. Therefore, impacts on Englebright Reservoir water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-7: Impacts on North Yuba River Water Quality below New Bullards Bar Dam from Operation of the YRDP.

The analysis below addresses impacts of operation of the YRDP Relicensing Project on the water quality of the North Yuba River from New Bullards Bar Dam to the confluence with the Middle Yuba River, which is approximately 2 miles downstream of the dam. Operation of the YRDP Relicensing Project does not involve alteration of existing drainage patterns in this reach of the North Yuba River. Alteration of existing drainage patterns could occur through YRDP facility modification or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

Water quality in the North Yuba River downstream of New Bullards Bar Dam is primarily affected by the quality of the water released from the reservoir. Water quality in this reach also is affected by river flow rates, which are affected by dam release rates. River flow rate affects water temperature, reaeration processes that affect dissolved oxygen levels, and sediment suspension and transport.

As discussed in YRDP Impact WQ-PP-5, operation of the YRDP Relicensing Project would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) in New Bullards Bar Reservoir compared to the Existing Condition. Furthermore, operations would not affect the level that water is released from the reservoir. Therefore, the quality of water released into the North Yuba River would be similar to, and likely nearly the same as, the water quality under the Existing Condition.

Modeled monthly average North Yuba River flow rates are higher with operation of the YRDP Relicensing Project during July through November over the entire simulation period and across all water year types compared to the Existing Condition (refer to Appendix 4C, Table C1-Flow-5). In July through November, modeled monthly average flow rates below the dam range from 8–9 cubic feet per second (cfs) for the Existing Condition and 14–43 cfs for the YRDP Relicensing Project for the full simulation period. The average flow increase in these months ranges from 6–34 cfs. In December through June, modeled monthly average flow rates are lower with operation of the YRDP Relicensing Project. In these months, the modeled monthly average flow rate ranges from 168–657 cfs for the Existing Condition and 120–642 cfs for the YRDP Relicensing Project.

The changes in the North Yuba River flow rate downstream of New Bullards Bar Dam would alter the temperature regime in this reach. Modeled monthly average temperatures below the dam range from about 45–53°F for the Existing Condition and about 45–51°F for the YRDP Relicensing Project for the full simulation period (refer to Appendix C, Table C1-Temp-6). Modeled monthly average temperatures are about 4–6°F lower in June through September compared to the Existing Condition. In December, January, April, and May, modeled monthly average temperatures differ from the Existing Condition by 0.0–0.1°F.

Temperature reductions in the North Yuba River at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 9–14°F lower with operation of the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-Temp-7). Modeled monthly average

temperatures at the confluence range from about 45–68°F for the Existing Condition and 45–61°F for the YRDP Relicensing Project for the full simulation period.

As water temperatures decrease, dissolved oxygen saturation levels increase. When holding constant for barometric pressure (i.e., 760 millimeters mercury), the saturation level ranges from 12 mg/L at 45°F to 9 mg/L at 68°F (Tchobanoglous and Schroeder 1987:p. 735). Turbulence and interaction of river water with the atmosphere that reaerates the river and maintains dissolved oxygen saturation levels would continue to occur with operation of the YRDP Relicensing Project. Therefore, the dissolved oxygen conditions in the North Yuba River below New Bullards Bar Dam with operation of the YRDP Relicensing Project would not differ substantially, if at all, from the Existing Condition.

The higher river flow rates compared to the Existing Condition would primarily occur in the summer months, when flow rates are relatively low (i.e., less than 100 cfs). Higher summer flow rates could result in higher turbidity or TSS, depending on the presence of fine sediment in the channel. However, summer flow rates are comparatively lower than winter flow rates that can reach greater than 30,000 cfs, when most of the sediment transport takes place. Therefore, increases in summer flow rates with operation of the YRDP Relicensing Project are not anticipated to result in substantial, if any, increases in river turbidity or TSS compared to the Existing Condition.

The North Yuba River is on the SWRCB's CWA Section 303(d) list of impaired waterbodies for impairments associated with mercury (refer to Table 8.2-2 in Section 8.2). The factors that affect mercury methylation are described in YRDP Impact WQ-PP-3. As just described, operation of the YRDP Relicensing Project is not expected to result in substantial, if any, differences in dissolved oxygen or TSS levels, thus measurable differences in other water quality constituents (e.g., salinity-related parameters, nutrients, trace metals, organic carbon) are not expected. Furthermore, the high flows that result in sediment transport in the winter months would continue similar to the Existing Condition. Therefore, the factors that affect mercury methylation would not change substantially, if at all, relative to the Existing Condition. Finally, as described further in Impact WQ-PP-5, one of the proposed conditions of the CWA Section 401 WQC is Condition 19, Mercury Management (Appendix 2E) to ensure beneficial uses would be protected from increases in methylmercury from project operations. Therefore, operation of the YRDP Relicensing Project would not result in a long-term measurable increase in mercury in the North Yuba River below New Bullards Bar Dam.

As such, operation of the YRDP Relicensing Project would not cause exceedance of a North Yuba River water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of the YRDP Relicensing Project would not cause long-term measurable degradation for the CWA Section 303(d)-listed constituents in the river.

As explained in Chapter 2, Yuba Water separately proposed construction of the ARC Spillway, which would ultimately be included in the new YRDP FERC license. Yuba Water previously analyzed the water quality impacts of operating the ARC Spillway in the ARC Spillway EIR and determined there could be potentially significant impacts to North Yuba River water quality from

drainage water discharges and erosion from use of the spillway, but that those impacts could be mitigated to a less-than-significant level (Yuba Water 2024). The analysis of those impacts in the ARC Spillway EIR is incorporated by reference.[8] Based on the small modeled flow differences described above and presented in Appendix 4C, Table C1-Flow-5 and Figures C1-Flow-13 through C1-Flow-24, ARC Spillway operations under the YRDP Relicensing Project would not result in any new or more severe potentially significant impacts compared to the impacts under the existing YRDP FERC license identified in the ARC Spillway EIR. Yuba Water previously identified and adopted mitigation measures (including one mitigation measure requested by the SWRCB) to reduce the water quality impacts associated with ARC Spillway operations to a less-than-significant level. As explained in Chapter 2, these previously adopted mitigation measures for ARC Spillway operations have been incorporated into the YRDP Relicensing Project and will continue to apply to ARC Spillway operations under the YRDP Relicensing Project. These mitigation measures are included below.

ARC Spillway Mitigation Measure HWQ-2: Obtain Coverage and Comply with Requirements of the General Order for Limited Threat Discharges to Surface Water (NPDES No. CAG995002/ Order R5-2016-0076-01)

Construction and operations involving dewatering will be subject to Central Valley RWQCB's Waste Discharge Requirement (WDR) R5-2016-0076-01 requirements for managing wastewater produced during dewatering activities or drainage collected during operation of the ARC Spillway. To obtain coverage under this General Order, which also serves as the NPDES Permit, the Discharger must submit a complete Notice of Intent and provide samples for analysis to determine the quality of the discharge (using tiers) and assign appropriate controls that will apply to the permit.

Yuba Water or its contractor(s) will obtain coverage under one or more of the following permit tiers, as applicable:

- Tier 1: Clean or relatively pollutant-free wastewaters that pose little or no threat to water quality.
  - Tier 1A: Discharges of less than 0.25 million gallons per day (MGD) or less than 4 months in duration, and
  - Tier 1B: Discharges greater than or equal to 0.25 MGD and greater than or equal to 4 months in duration.
- Tier 2: Discharges that may contain toxic organic constituents, volatile organic compounds, petroleum fuel pollution constituents, pesticides, inorganic constituents, chlorine, and/or other chemical constituents that require treatment prior to discharge.

Yuba Water or its contractor(s) will submit a separate Notice of Intent under the General Order for applicable construction and/or operation activities.

Timing: Before construction activities.

[8] https://www.yubawater.org/252/ARC-Spillway-at-New-Bullards-Bar-Dam

Responsibility: Yuba Water and its construction contractor(s).

ARC Spillway Mitigation Measure HWQ-4: Regularly Inspect the ARC Spillway Discharge Channel for Erosion

Following construction, the ARC Spillway discharge channel will be inspected for erosion on a regular basis. Multiple inspections will occur each year during the first 5 years of service. Inspections will be conducted immediately or as soon as possible after the first few spill events. These initial inspections of the discharge channel will include the following items:

- Verify and document that the discharge channel is clear and unobstructed by vegetation, soil/rock deposits, or debris to ensure full passage of flood flows.
- Examine the foundation at the toe of the spillway concrete structure (the toe of the flip bucket) for evidence of undercutting.
- Locate and map significant erosional features (deeper than 10 feet measured perpendicular to the slope of the hillside) observed on the channel bottom. Measure the depth (perpendicular to the slope) and width (across the eroded seam) at various points along the feature. Record for replication of measurements during subsequent inspections and trending analysis of the measurements.

After the first 5 years of operation, an annual inspection will be conducted as long as there are no issues in the first 5 years, including the following:

- The discharge channel remains clear and unobstructed by vegetation, soil/rock deposits, or debris to ensure full passage of flood flows.
- The discharge channel invert at the toe of the flip bucket does not show undercutting features deeper than 5 feet.
- Significant erosional features (deeper than 10 feet measured perpendicular to the slope of the hillside) observed on the channel bottom are not increasing in depth or width at a rate greater than 2 feet per year.

An aerial Light Detection and Ranging (LiDAR) survey of the ARC Spillway will be conducted after construction (and prior to operation) to document as-built conditions of the discharge channel and establish a baseline topographic surface that can be used to compare with subsequent surveys. These surveys will be repeated on a 10-year basis and supplemented with drone surveys to obtain high resolution aerial imagery. Analysis of the LiDAR data and aerial imagery will be performed by a qualified engineering geologist or engineer to monitor erosion trends.

An analysis of erosion features at the existing Primary Spillway indicated two major areas of erosion with maximum depth of erosion measured normal to the slope of about 40 feet at one area and approaching 60 feet at another area. If areas of new, concentrated erosion are identified on the ARC Spillway discharge channel during inspections that exceed the magnitude of erosion features observed in the Primary Spillway, Yuba Water will investigate the nature and causes of the erosion. If the results of that investigation indicate that significant additional erosion seems likely, Yuba Water will implement appropriate

remedial actions to the extent needed to prevent substantial prolonged erosion and ensure Dam and spillway safety.

Defects that may be evaluated for treatment typically will consist of shear zones or bands of intensely weathered rock that are more susceptible to erosion by high flows. Remedial actions may include excavation or other methods to remove weaker rock zones that may erode, backfilling erosional crevices with additional dental concrete treatments to eliminate or reduce the scour channels, or other methods as determined suitable by a qualified engineering geologist or engineer. If remedial treatment with dental concrete is determined to be required, a monitoring plan and appropriate measures will be developed and implemented to protect water quality consistent with the requirements of the Water Quality Control Plan for the California Regional Water Quality Control Board, Central Valley Region, Sacramento River Basin, and the San Joaquin River Basin.

Timing: After construction.

Responsibility: Yuba Water.

ARC Spillway Mitigation Measure HWQ-5: Conduct Turbidity Monitoring in the North Yuba River after Using the ARC Spillway

Monitor turbidity in the North Yuba River prior to, during, and after the first three uses of the ARC Spillway.

Timing: After construction.

Responsibility: Yuba Water.

As explained in the ARC Spillway EIR, ARC Spillway Mitigation Measures HWQ-2, HWQ-4, HWQ-5 would mitigate the potentially significant water quality impacts from ARC Spillway operations to a less-than-significant level. Because these impacts would not meaningfully change under the YRDP Relicensing Project from what was disclosed in the ARC Spillway EIR, the above mitigation measures will ensure that the water quality impacts from ARC Spillway operations will be mitigated to a less-than-significant level under the YRDP Relicensing Project. As explained in Chapter 2, these previously adopted mitigation measures for ARC Spillway operations have been incorporated into the YRDP Relicensing Project and will continue to apply to ARC Spillway operations under the YRDP Relicensing Project.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the North Yuba River below New Bullards Bar Dam. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the North Yuba River. Therefore, impacts on the North Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-8: Impacts on Oregon Creek Water Quality from Operation of the YRDP. The analysis below addresses impacts to Oregon Creek downstream of the Log Cabin Diversion Dam to the Middle Yuba River from operating the YRDP Relicensing Project. Operation of the YRDP Relicensing Project does not involve alteration of existing drainage patterns in this reach of Oregon Creek. Alteration of existing drainage patterns could occur through YRDP facility modification or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

Water quality in Oregon Creek downstream of the Log Cabin Diversion Dam is primarily dictated by the quality of creek water flowing into the impoundment formed by the dam. The slowing of the creek water caused by the dam results in settling of solids, but that would be unchanged by operation of the YRDP Relicensing Project. Therefore, for most water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon), the creek water released through the dam would be unchanged relative to the Existing Condition. Water quality also is affected by creek flow rates, which are affected by dam release rates. Creek flow rate affects water temperature, reaeration processes that affect dissolved oxygen levels, and sediment suspension and transport. Oregon Creek is on the SWRCB's CWA Section 303(d) list as impaired for copper and iron based on concentrations exceeding criteria for the protection of freshwater aquatic life (refer to Table 8.2-2 in Section 8.2), therefore, impacts from operation of the YRDP Relicensing Project on copper and iron are specifically addressed below.

Changes in River Flow Rates

Modeled monthly average Oregon Creek flow rates below the dam are higher in January through July over the entire simulation period with operation of the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-Flow-6). The modeled increases are greatest in April, May, and June. In these months, modeled flow rates average 9–24 cfs for the Existing Condition and 21–58 cfs for the YRDP Relicensing Project. Modeled monthly average flow rates are similar to the Existing Condition for July–March and range from 3–68 cfs for the Existing Condition and 3–71 cfs for the YRDP Relicensing Project.

Temperature and Dissolved Oxygen

The changes in the Oregon Creek flow downstream of Log Cabin Diversion Dam would alter the temperature regime in this reach. Modeled monthly average temperatures below the dam range from about 40–69°F for the Existing Condition and about 40–67°F for the YRDP Relicensing Project for the full simulation period (refer to Appendix 4C, Table C1-Temp-8). Modeled monthly average temperatures for the YRDP Relicensing Project are about 1–2°F lower in June through September compared to the Existing Condition.

Temperature reductions in Oregon Creek at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 1°F lower with operation of the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-Temp-9). Modeled monthly average temperatures at the confluence range from about 40–70°F for the Existing Condition and 40–69°F for the full simulation period.

The turbulence and interaction of creek water with the atmosphere that reaerates the creek and maintains dissolved oxygen saturation levels would continue to occur with operation of the YRDP Relicensing Project. Given this and the small temperature differences, the dissolved oxygen conditions in Oregon Creek with operation of the YRDP Relicensing Project would not differ substantially, if at all, from the Existing Condition.

Turbidity and TSS

The higher creek flow rates compared to the Existing Condition would primarily occur in the summer months, when flow rates are relatively low (i.e., less than 10 cfs). Higher summer flow rates could result in higher turbidity or TSS, depending on the presence of fine sediment in the channel. However, summer flow rates are comparatively lower than winter flow rates that can reach greater than 1,000 cfs, when most of the sediment transport takes place. Therefore, increases in summer flow rates with operation of the YRDP Relicensing Project are not anticipated to result in substantial, if any, increases in creek turbidity or TSS compared to the Existing Condition.

Copper

As detailed in YRDP Impact WQ-PP-3, the CWA Section 303(d)-listing of Oregon Creek for copper impairment is based on data from 2002–2004 showing concentrations greater than the default CTR criterion for the chronic protection of aquatic life. Also, as described in YRDP Impact WQ-PP-3, there are data from 2009 and 2012 showing copper concentrations well below the CTR criterion. Furthermore, there are many factors that bioavailability, hence toxicity, of copper. Therefore, the degree to which Oregon Creek actually has a copper-related impairment is unclear.

The creek water flowing into the Log Cabin Diversion Dam impoundment is the same water that would be released downstream of the dam, though some suspended solids present in the upstream water may settle out in the impoundment. Operation of the YRDP Relicensing Project would only change the release rates during certain months and water year types. The change in release rates would have little to no effect on downstream creek turbidity and TSS. Therefore, operation of the YRDP Relicensing Project would have little to no effect on copper concentrations or the concentrations of other water quality parameters (e.g., dissolved organic carbon, hardness, and alkalinity) that mitigate the toxicity of copper to aquatic life. As such, operation of the YRDP Relicensing Project would have little to no effect on any copper-related impairments that may be occurring in the creek.

Iron

As detailed in YRDP Impact WQ-PP-3, the CWA Section 303(d)-listing of Oregon Creek for iron impairment is based on data from 2002–2004 showing concentrations greater than the EPA's criterion for the chronic protection of aquatic life. Also, as described in YRDP Impact WQ-PP-3, the EPA's iron criterion does not reflect current science and there are many factors that bioavailability, hence toxicity, of iron. Therefore, the degree to which Oregon Creek actually has an iron-related impairment is unclear.

As stated above, the creek water flowing into the Log Cabin Diversion Dam impoundment is the same water that would be released downstream of the dam, and operation of the YRDP Relicensing Project would have little to no effect on creek turbidity and TSS. Therefore, operation of the YRDP Relicensing Project would have little to no effect on total iron concentrations or the concentrations

or other water quality parameters that iron forms bonds with. As such, operation of the YRDP Relicensing Project would have little to no effect on any iron-related impairments that may be occurring in the creek.

Therefore, operation of the YRDP Relicensing Project would not cause exceedance of an Oregon Creek water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the creek. Furthermore, operation of the YRDP Relicensing Project would not cause measurable degradation for the CWA Section 303(d)-listed constituents in the creek.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Oregon Creek. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Oregon Creek. Therefore, impacts on Oregon Creek water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-9: Impacts on the Middle Yuba River Water Quality from Operation of the YRDP.

The analysis below addresses impacts on Middle Yuba River water quality downstream of Our House Diversion Dam to the confluence with the North Yuba River. Operation of the YRDP Relicensing Project does not involve alteration of existing drainage patterns in this reach of the Middle Yuba River. Alteration of existing drainage patterns could occur through YRDP facility modification or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

Water quality in the Middle Yuba River downstream of the Our House Diversion Dam is primarily dictated by the quality of river water flowing into the impoundment formed by the dam. The slowing of the river water caused by the dam results in settling of solids, but that would be unchanged by operation of the YRDP Relicensing Project. Therefore, for most water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon), the river water released through the dam would be unchanged relative to the Existing Condition. Water quality also is affected by river flow rates, which are affected by dam release rates. River flow rate affects water temperature, reaeration processes that affect dissolved oxygen levels, and sediment suspension and transport. The Middle Yuba River is not on the SWRCB's CWA Section 303(d) list as an impaired waterbody (refer to Table 8.2-2 in Section 8.2) and water quality conditions are generally good and meet water quality objectives (Yuba Water 2013).

Changes in River Flow Rates

Modeled monthly average Middle Yuba River flow rates are higher year-round over the entire simulation period with operation of the YRDP Relicensing Project compared to the Existing

Condition (refer to Appendix 4C, Table C1-Flow-8). The increases are greatest in April, May, and June. In these months, modeled flow rates average 67–115 cfs for the Existing Condition and 195–278 cfs for the YRDP Relicensing Project. Modeled flow rates in July through March average 29–202 cfs for the Existing Condition and 35–267 cfs for the YRDP Relicensing Project, depending on month.

Temperature and Dissolved Oxygen

The changes in the Middle Yuba River downstream of Our House Diversion Dam would alter the temperature regime in this reach. Modeled monthly average temperatures below the dam with the YRDP Relicensing Project are nearly the same as those for the Existing Condition. Modeled monthly average temperatures below the dam range from about 40–71°F for both scenarios for the full simulation period (refer to Appendix 4C, Table C1-Temp-10). Because of the higher flow rates, temperatures would be lower further downstream of the dam. Downstream of the confluence with Oregon Creek, modeled monthly average temperatures are up to 1°F lower compared to the Existing Condition (Appendix 4C, Table C1-Temp-11). Upstream of the confluence with the North Yuba River modeled monthly average temperatures are up to 1.5°F lower compared to the Existing Condition (Appendix 4C, Table C1-Temp-12).

The turbulence and interaction of river water with the atmosphere that reaerates the river and maintains dissolved oxygen saturation levels would continue to occur with operation of the YRDP Relicensing Project. Given this and that the small temperature differences, the dissolved oxygen conditions and saturation levels in Middle Yuba River with operation of the YRDP Relicensing Project would not differ substantially, if at all, from the Existing Condition.

Turbidity and TSS

The higher river flow rates compared to the Existing Condition would primarily occur in the spring months when flow rates can already be high (i.e. >5,000 cfs). Higher flows would also occur in the summer months, when flow rates are much lower (i.e., <200 cfs). Higher flow rates could result in higher turbidity or TSS, depending on the presence of fine sediment in the channel. However, flow rates with the YRDP Relicensing Project would be within the range that occurs under the Existing Condition. Therefore, increases in summer flow rates with operation of the YRDP Relicensing Project are not anticipated to result in substantial, if any, increases in river turbidity or TSS compared to the Existing Condition.

As such, operation of the YRDP Relicensing Project would not cause exceedance of a Middle Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the Middle Yuba River. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site

or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Middle Yuba River. Therefore, impacts on the Middle Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-10: Impacts on Upper Yuba River Water Quality from Operation of the YRDP.

The analysis below addresses impacts of operating the YRDP Relicensing Project on water quality of the upper Yuba River, which is the reach of the Yuba River from the confluence of the North Yuba River and Middle Yuba River to Englebright Reservoir. Operation of the YRDP Relicensing Project does not involve alteration of existing drainage patterns in this reach of the Yuba River. Alteration of existing drainage patterns could occur through YRDP facility modification or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

Water quality in the upper Yuba River is primarily dictated by the quality of water flowing in from the North Yuba River and Middle Yuba River. As described in YRDP Impacts WQ-PP-8 and WQ-PP-9, water quality of the North Yuba River and Middle Yuba River would not differ substantially, if at all, from the Existing Condition. Therefore, upper Yuba River water quality at the confluence also would not differ substantially, if at, from the Existing Condition.

Water quality also is affected by tributary river flow rates. River flow rate affects water temperature, reaeration processes that affect dissolved oxygen levels, and sediment suspension and transport. The upper Yuba River is on the SWRCB's CWA Section 303(d) list as an impaired for mercury and chromium (refer to Table 8.2-2 in Section 8.2), therefore, impacts from operation of the YRDP Relicensing Project on mercury and chromium are specifically addressed below.

Changes in River Flow Rates

Modeled monthly average upper Yuba River flow rates are higher year-round over the entire simulation period with operation of the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C1-Flow-11). Modeled flow rates below the Middle Yuba River confluence average 44–1,077 cfs for the Existing Condition and 71–1,115 cfs for the YRDP Relicensing Project, depending on month.

Temperature and Dissolved Oxygen

The changes in the upper Yuba River flow rates would alter its temperature regime. Modeled monthly average temperatures below the confluence range from about 40–73°F for the Existing Condition and 40–66°F for the YRDP Relicensing Project for the full simulation period (refer to Appendix 4C, Table C1-Temp-13). Modeled monthly average temperatures for the YRDP Relicensing Project are about 6–9°F lower in the summer compared to the Existing Condition.

Temperature differences in the upper Yuba River at Colgate Powerhouse are smaller. Modeled monthly average temperatures at this location range from about 39–73°F for the Existing Condition and 39–71°F for the YRDP Relicensing Project for the full simulation period (refer to Appendix 4C, Table C1-Temp-14). Modeled monthly average temperatures for the YRDP Relicensing Project are about 1–3°F lower in the summer compared to the Existing Condition.

The turbulence and interaction of river water with the atmosphere that reaerates the river and maintains dissolved oxygen saturation levels would continue to occur with operation of the YRDP Relicensing Project. Given this, and that project operations would result in cooler water temperatures, the dissolved oxygen conditions and saturation levels in upper Yuba River with operation of the YRDP Relicensing Project would not differ substantially from, and may be higher than, the Existing Condition.

Turbidity and TSS

The higher river flow rates compared to the Existing Condition would primarily occur in the spring months when flow rates can already be high (i.e. >5,000 cfs). Higher flows would also occur in the summer months, when flow rates above Colgate Powerhouse are much lower (i.e., <200 cfs). Higher flow rates could result in higher turbidity or TSS, depending on the presence of fine sediment in the channel. However, flow rates with the YRDP Relicensing Project would be within the range that occurs under the Existing Condition. Therefore, increases in summer flow rates with operation of the YRDP Relicensing Project are not anticipated to result in substantial, if any, increases in river turbidity or TSS compared to the Existing Condition.

Mercury

The factors that affect mercury methylation are described in YRDP Impact WQ-PP-3. As just described, operation of the YRDP Relicensing Project is not expected to result in substantial, if any, differences in dissolved oxygen or TSS levels, or other water quality constituents (e.g., salinity-related parameters, nutrients, trace metals, organic carbon). Furthermore, the high flows that result in sediment transport in the winter months would continue similar to the Existing Condition. Therefore, the factors that affect mercury methylation would not change substantially, if at all, relative to the Existing Condition. Finally, as described further in YRDP Impact WQ-PP-5, one of the proposed conditions of the CWA Section 401 WQC is Condition 19, Mercury Management (Appendix 2E) to ensure beneficial uses would be protected from increases in methylmercury from project operations. Therefore, operation of the YRDP Relicensing Project would have little to no effect on mercury-related impairments in the upper Yuba River.

Chromium

As detailed in YRDP Impact WQ-PP-3, the CWA Section 303(d)-listing of the upper Yuba River for chromium impairment is based on data from 2002–2004 showing concentrations greater than the drinking water MCL. The average of these data, collected in a one-month period, is less than the drinking water MCL. Furthermore, there are data from 2009 and 2012 showing chromium concentrations well below the drinking water MCL. Therefore, the degree to which the upper Yuba River has a chromium-related impairment is unclear. Regardless, chromium concentrations in the water flowing into the upper Yuba River from the North Yuba River and Middle Yuba River would differ little, if at all, from the Existing Condition. Similarly, river turbidity and TSS is expected to be similar to the Existing Condition. As such, operation of the YRDP Relicensing Project would have little to no effect on any chromium-related impairments that may be occurring in the river.

Therefore, operation of the YRDP Relicensing Project would not cause exceedance of an upper Yuba River water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river.

Furthermore, operation of the YRDP Relicensing Project would not cause measurable degradation for the CWA Section 303(d)-listed constituents in the river.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the upper Yuba River. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the upper Yuba River. Therefore, impacts on the upper Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-11: Impacts on Lower Yuba River Water Quality from Operation of the YRDP.

The analysis below addresses impacts of operating the YRDP Relicensing Project on water quality of the lower Yuba River, which is the reach of the Yuba River downstream of Englebright Dam to the Feather River. Operation of the YRDP Relicensing Project does not involve alteration of existing drainage patterns in this reach of the Yuba River. Alteration of existing drainage patterns could occur through YRDP facility modification or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

Water quality in the lower Yuba River is primarily dictated by the quality of water released from Englebright Reservoir. Water quality also is affected by river flow rates, which are affected by dam release rates. River flow rate affects water temperature, reaeration processes that affect dissolved oxygen levels, and sediment suspension and transport.

As discussed in YRDP Impact WQ-PP-6, operation of the YRDP Relicensing Project would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) in Englebright Reservoir compared to the Existing Condition. Furthermore, operations would not affect the level that water is released from the reservoir. Therefore, the quality of water released into the lower Yuba River would be similar to, and likely nearly the same as, the water quality under the Existing Condition.

Modeled monthly average lower Yuba River flow rates with operation of the YRDP Relicensing Project are similar over the entire simulation period and across all water year types compared to the Existing Condition with differences being less than 5 percent (refer to Appendix 4C, Tables C1-Flow-1 through C1-Flow-4). Given that there would be little change in river flow rate, operation of the YRDP Relicensing Project would not contribute to higher turbidity or TSS levels, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon).

River temperatures with operation of the YRDP Relicensing Project are also similar over the entire simulation period and across all water year types compared to the Existing Condition, with differences in modeled monthly average temperatures being less than 0.5°F (refer to Appendix 4C, Tables C1-Temp-1 through C1-Temp-5).

The turbulence and interaction of river water with the atmosphere that reaerates the river and maintains dissolved oxygen saturation levels would continue to occur with operation of the YRDP Relicensing Project. Given this and that project operations would result in little to no change water temperatures, the dissolved oxygen conditions and saturation levels in lower Yuba River with operation of the YRDP Relicensing Project would not differ substantially from the Existing Condition.

The lower Yuba River is on the SWRCB's CWA Section 303(d) list of impaired waterbodies for impairments associated with mercury and copper (refer to Table 8.2-2 in Section 8.2.2). As just described, operation of the YRDP Relicensing Project is not expected to result in substantial, if any, changes in the river water quality at Englebright Dam or change in flows that would result in changes in water quality constituents, including TSS, mercury, or copper. Therefore, operation of the YRDP Relicensing Project would not result in a long-term measurable increase in mercury or copper in the lower Yuba River.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the lower Yuba River. Therefore, impacts on the lower Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-12: Impacts on the Lower Feather River, Sacramento River, and Delta from Operation of the YRDP.

The analysis below addresses impacts of operating the YRDP Relicensing Project on water quality of the lower Feather River, Sacramento River, and Delta. Operation of the YRDP Relicensing Project does not involve alteration of existing drainage patterns of or around these waterbodies.

As discussed in Chapter 4, Section 4.3.1.3, "Downstream Extent of the Project Area," operation of the YRDP Relicensing Project would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River. A sensitivity analysis conducted to compare Feather River flow rates downstream of the lower Yuba River under the Existing Condition and the YRDP Relicensing Project found that the average difference in monthly average flow rate would be 0.11 percent. Consequently, operation of the YRDP Relicensing Project would not result in detectable changes in Feather River flow rates immediately downstream of the Yuba River compared to the Existing Condition, and changes in water quality conditions downstream of the mouth of the Yuba River would not be measurable.

Therefore, operation of the YRDP Relicensing Project would cause little, if any, differences in lower Feather River water quality constituents (e.g., dissolved oxygen, salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Existing Condition. As such, Sacramento River and Delta water quality also would not be measurably affected by operation of the YRDP Relicensing Project. Therefore, operation of the YRDP Relicensing Project would not cause Feather River, Sacramento River, and Delta water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river. Furthermore, operation of the YRDP Relicensing Project would not result in long-term measurable increases in constituent impairments in these waterbodies.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Feather River, Sacramento River, or Delta. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Therefore, impacts on Feather River, Sacramento River, and Delta water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-13: Impacts on Surface Water Quality from Other Operation and Maintenance of the YRDP.

The YRDP Relicensing Project may result in minor changes in the timing, frequency, or location of routine O&M practices. However, any changes to routine O&M activities would remain within the range of current annual practices. Routine O&M of the YRDP does not involve alteration of existing drainage patterns. Alteration of existing drainage patterns could occur through YRDP facility modification, improvement, or restoration activities, which are addressed in YRDP Impacts WQ-PP-1, WQ-PP-2, WQ-PP-3, and WQ-PP-4.

Yuba Water would continue to implement SPCC plans for New Colgate Powerhouse, New Colgate Penstock Shutoff Valve, and New Bullards Bar Dam. Furthermore, the YRDP Relicensing Project includes the following conditions pertaining to protection of water quality when ground-disturbance activities are occurring.

- Yuba Water Proposed WQC Condition 16, Hazardous Materials, requires implementation of the Hazardous Materials Management Plan listed in Table 8.5-2.
- Yuba Water Proposed WQC Condition 18, Construction and Maintenance, requires implementation of the Erosion and Sediment Control Plan listed in Table 8.5-2, and preparation and implementation of WQMP Plans, as discussed in YRDP Impact WQ-PP-1.

With implementation of the measures and BMPs included in the YRDP implementation plans, and compliance with the conditions in the SWRCB-issued CWA Section 401 WQC for the project, pollutant discharges to surface waters would be minimized and controlled such that YRDP

Relicensing Project O&M activities would not cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies.

Routine O&M activities would potentially overlap in time with each other, with YRDP facility construction activities addressed in YRDP Impact WQ-P-1, the *Recreation Facilities Plan* activities addressed in YRDP Impact WQ-PP-2, and other implementation plan activities addressed in YRDP Impact WQ-PP-4. Furthermore, the routine O&M activities, YRDP facility construction activities, and implementation plan activities would overlap in time with YRDP Relicensing Project operations and associated effects on water quality described in YRDP Impacts WQ-PP-5 through WQ-PP-12. As described in these impact discussions, YRDP operations would cause little, if any, differences in water quality of Project Area waterbodies. Therefore, while these activities would overlap in time, the potential effects to water quality described above would not combine with these other project components to result in conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies due to the relatively short duration and geographic separation of these activities in the watershed and the BMPs that would be in place, as relevant to the activity, to minimize discharges to Project Area waterbodies.

CEQA Conclusion

Based on the above analysis, routine O&M associated with the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality of Project Area waterbodies. Furthermore, YRDP Relicensing Project routine O&M would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies. Therefore, the YRDP Relicensing Project operations- and maintenance-related impacts on surface water quality of Project Area waterbodies would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-PP-14: Risk of Release of Pollutants due to Project Inundation in Flood Hazard Zones from YRDP Operations.

The YRDP Relicensing Project consists of water storage and diversion facilities located within and adjacent to Project Area reservoirs and rivers where water levels fluctuate. In addition, some recreational facilities are located adjacent to Project Area reservoirs and rivers.

Modeling results show small (2 percent or less) differences in average New Bullards Bar Reservoir and Englebright Reservoir end-of-month storage and water surface elevations compared to the Existing Condition (refer to Appendix 4C, Tables C1-Reservoir-1 through C1-Reservoir-4). Modeling results also show that peak flow rates of Project Area rivers and creeks with the YRDP Relicensing Project would be the same or very similar to those that occur under the Existing Condition (refer to Appendix 4C, Figures C1-Flow-1 through C1-Flow-48). Therefore, project facilities within the YRDP Relicensing Project would not be at increased risk of inundation that

would result in an increased risk of release of pollutants to Project Area waterbodies compared to the Existing Condition.

Furthermore, YRDP Relicensing Project operations would not result in an increased risk of release of pollutants downstream of project facilities. Modeling results show that peak lower Yuba River flow rates with operation of the YRDP Relicensing Project are similar to the Existing Condition over the entire simulation period (refer to Appendix 4C, Figures C1-Flow-1 through C1-Flow-12).

Finally, as discussed in Chapter 4, Section 4.3.1.3, "Downstream Extent of the Project Area," operation of the YRDP Relicensing Project would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River. Consequently, the YRDP Relicensing Project would not result in an increased risk of release of pollutants downstream of the lower Yuba River.

CEQA Conclusion

Based on the above discussion, the YRDP Relicensing Project would have a **less-than-significant impact** on the risk of release of pollutants due to project inundation in flood hazard zones.

YRDP Impact WQ-PP-15: Consistency with Water Quality Control Plans.
The relevant water quality control plan for the Project Area is the "Water Quality Control Plan for the Sacramento and the San Joaquin River Basins" (Basin Plan) (CVRWQCB 2019). The Basin Plan defines beneficial uses, water quality objectives to protect beneficial uses, a program of implementation for achieving water quality objectives, and a surveillance and monitoring program.

Project construction and operation would be subject to meeting applicable water quality objectives in the CVRWQCB's Basin Plan, *as* implemented through various permits, where applicable, including the SWRCB's "NPDES General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities" (Construction Stormwater General Permit; Order No. 2022-0057-DWQ/NPDES Permit No. CAS000002) for construction activities that disturb one or more acre and the CWA Section 401 WQC issued for the Proposed Projects. Therefore, *construction, operation, and maintenance of* the *YRDP Relicensing Project* would not conflict with or obstruct the implementation of a water quality control plan,

CEQA Conclusion

Based on the above discussion, the construction and O&M of the YRDP Relicensing Project would have **no impact** on the implementation of a water quality control plan (i.e., Basin Plan), nor would the project conflict with a water quality control plan (i.e., Basin Plan).

Narrows Impact WQ-PP-1: Impacts on Surface Water Quality from Operation of the Narrows Project.
The analysis of potential operations-related impacts to surface water quality for the Narrows Relicensing Project is focused on Project Area waterbodies downstream of Englebright Dam, including the lower Yuba River, Feather River, Sacramento River, and Delta, because the Narrows Project does not involve any operations affecting areas upstream of Englebright Dam.

Yuba Water proposes to continue to operate the Narrows Relicensing Project in substantial conformance with existing operations, with minor modifications. The minor operations-related

modifications that could affect water quality include operating the project to assist the YRDP with meeting instream flow requirements in the lower Yuba River at Smartsville and maintaining a minimum water surface elevation in Englebright Reservoir. However, the effects of these operations on Englebright Reservoir and lower Yuba River compared to the Existing Condition would not be beyond those described for YRDP Impact WQ-PP-6 and YRDP Impact WQ-PP-11, respectively.

Any minimal effects of the Narrows Relicensing Project operations on lower Yuba River water quality would have little to no effect on the water quality of the Feather River, Sacramento River, and Delta, given modeling results that show hydrologic operations on the Yuba River have little effect on downstream hydrology, as discussed in YRDP Impact WQ-PP-12. Given that the comparative effect of the Narrows Relicensing Project on lower Yuba River flows would be much smaller, the Narrows Relicensing Project would not result in detectable changes in Feather River water quality or the water quality of the Sacramento River or Delta.

CEQA Conclusion

Based on the above analysis, operation of the Narrows Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River, lower Feather River, Sacramento River, or Delta. Furthermore, operation of the Narrows Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Finally, the project would not result in an increased risk of release of pollutants to Project Area waterbodies or conflict with or obstruct implementation of a water quality control plan. Therefore, impacts on Yuba River, Feather River, Sacramento River, and Delta water quality from operation of the Narrows Relicensing Project would be **less than significant**. No CEQA mitigation is required.

8.5.2 Proposed Projects Compared to the Future Baseline

The impact analyses below depend, in part, on differences in reservoir storage and river/creek flow rates with the Proposed Projects (future) compared to the Future Baseline. Impacts not dependent on changes in reservoir storage and river/creek flow rates are addressed in Section 8.5.1 relative to the Existing Condition and are not repeated here.

YRDP Impact WQ-FPP-5: Impacts on New Bullards Bar Reservoir Water Quality from Operation of the YRDP.

Modeled differences in New Bullards Bar Reservoir average end-of-month storage with operation of the YRDP Relicensing Project (future) compared to the Future Baseline are similar to those described in YRDP Impact WQ-PP-5 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C2-Reservoir-1). Modeled average end-of-month storage with the YRDP Relicensing Project (future) for the full simulation period is 1 percent lower in all months except March and April when there is 0 percent difference. Modeled average end-of-month storage with the YRDP Relicensing Project (future) also differed little by water year type, with the difference being 0 percent in critical years, 0–1 percent in dry years, 0–1 percent in below normal

years, 0–1 percent in above normal years, and 0–2 percent in wet years compared to the Future Baseline.

Modeled differences in average water surface elevation with the YRDP Relicensing Project (future) compared to the Future Baseline are also similar to those described for the YRDP Relicensing Project compared to the Existing Condition (Appendix 4C, Table C2-Reservoir-2). Modeled average end-of-month water surface elevation with the YRDP Relicensing Project (future) for the full simulation period is 0–2 feet lower, depending on month, compared to the Future Baseline, with the average difference ranging from 0–3 feet, depending on month and water year type.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-5, operation of the YRDP Relicensing Project (future) would not cause substantial, if any, differences in New Bullards Bar Reservoir temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause exceedance of a reservoir water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the reservoir. Furthermore, operation of the YRDP Relicensing Project (future) would not cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the reservoir.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in New Bullards Bar Reservoir. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to New Bullards Bar Reservoir. Therefore, impacts on New Bullards Bar Reservoir water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-6: Impacts on Englebright Reservoir Water Quality from Operation of the YRDP.

Modeled differences in Englebright Reservoir average end-of-month storage with operation of the YRDP Relicensing Project (future) compared to the Future Baseline are similar to those described in YRDP Impact WQ-PP-6 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C2-Reservoir-3). The difference between average end-of-month storage with the YRDP Relicensing Project (future) for the full simulation period and the Future Baseline is 0 percent. Average end-of-month storage is about 44,000–46,000 ac-ft, depending on month, and differences in end-of-month storage average less than 100 ac-ft.

Modeled differences in average water surface elevation with the YRDP Relicensing Project (future) compared to the Future Baseline are also similar to those described for the YRDP

Relicensing Project compared to the Existing Condition (Appendix 4C, Table C2-Reservoir-4). The difference in average end-of-month water surface elevation with the YRDP Relicensing Project (future) for the full simulation period compared to the Future Baseline is less than 1 foot. Average end-of-month water surface elevation with the YRDP Relicensing Project (future) also differed little by water year type, with the difference being 1 foot or less depending on month and water year type.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-6, operation of the YRDP Relicensing Project (future) would not cause substantial, if any, differences in Englebright Reservoir temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause exceedance of a reservoir water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the reservoir. Furthermore, operation of the YRDP Relicensing Project (future) would not cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the reservoir.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Englebright Reservoir. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Englebright Reservoir. Therefore, impacts on Englebright Reservoir water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-7: Impacts on North Yuba River Water Quality below New Bullards Bar Dam from Operation of the YRDP.

Modeled North Yuba River flow rates with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline are similar to those described in YRDP Impact WQ-PP-7 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C2-Flow-5). Modeled monthly average North Yuba River flow rates are higher with operation of the YRDP Relicensing Project (future) during July through November over the entire simulation period and across all water year types compared to the Future Baseline. In July through November, modeled monthly average flow rates below New Bullards Bar Dam range from 8–9 cfs for the Future Baseline and 14–43 cfs for the YRDP Relicensing Project (future) for the full simulation period. The average flow increase in these months ranges from 6–34 cfs. In December through June, modeled monthly average flow rates are lower with operation of the YRDP Relicensing Project (future). In these months, the average flow rate ranges from 169–663 cfs for the Future Baseline and 121–650 cfs for the YRDP Relicensing Project (future).

The modeled river temperatures with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the dam range from about 45–53°F for the Future Baseline and about 45–51°F for the YRDP Relicensing Project (future) for the full simulation period (refer to Appendix C, Table C2-Temp-6). Modeled monthly average temperatures are about 4–6°F lower in June through September compared to the Future Baseline. In December, January, April, and May, modeled monthly average temperatures differ from the Future Baseline by 0.0–0.1°F.

Temperature reductions in the North Yuba River at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 9–14°F lower with operation of the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix 4C, Table C2-Temp-7). Modeled monthly average temperatures at the confluence range from about 45–68°F for the Future Baseline and 45–61°F for the YRDP Relicensing Project (future) for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-7, operation of the YRDP Relicensing Project (future) would not cause substantial, if any, differences in the North Yuba River dissolved oxygen, turbidity, TSS, methylmercury, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause exceedance of a North Yuba River water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of the YRDP Relicensing Project (future) would result in a long-term measurable increase in mercury that would cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the river.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the North Yuba River below New Bullards Bar Dam. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the North Yuba River. Therefore, impacts on the North Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-8: Impacts on Oregon Creek Water Quality from Operation of the YRDP. Modeled Oregon Creek flow rates with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline are the same or nearly the same as those described in YRDP Impact WQ-PP-8 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C2-Flow-6). The modeled increases are greatest in April, May, and June. In these months, modeled flow rates average 9–24 cfs for the Future Baseline and 21–58 cfs for the YRDP Relicensing Project (future). Modeled monthly average flow rates are similar to the Future

Baseline for July–March and range from 3–68 cfs for the Future Baseline and 3–71 cfs for the YRDP Relicensing Project (future).

The modeled creek temperatures with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline also are the same or nearly the same as those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the Log Cabin Diversion Dam range from about 40–69°F for the Future Baseline and about 40–67°F for the YRDP Relicensing Project (future) for the full simulation period (refer to Appendix 4C, Table C2-Temp-8). Modeled monthly average temperatures for the YRDP Relicensing Project are about 1–2°F lower in June through September compared to the Future Baseline. Temperature reductions at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 1°F lower with operation of the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix 4C, Table C2-Temp-9). Modeled monthly average temperatures at the confluence range from about 40–70°F for the Future Baseline and 40–69°F for the YRDP Relicensing Project (future) for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-8, operation of the YRDP Relicensing Project (future) would not cause substantial, if any, differences in Oregon Creek dissolved oxygen, turbidity, TSS, copper, iron, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause exceedance of an Oregon Creek water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the creek. Furthermore, operation of the YRDP Relicensing Project (future) would not cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the creek.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Oregon Creek. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Oregon Creek. Therefore, impacts on Oregon Creek water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-9: Impacts on the Middle Yuba River Water Quality from Operation of the YRDP.

Modeled Middle Yuba River flow rates with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline are similar to those described in YRDP Impact WQ-PP-9 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C2-Flow-8). Modeled monthly average Middle Yuba River flow rates are higher year-round over the entire simulation period with operation of the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix 4C, Table C2-Flow-8). The increases are

greatest in April, May, and June. In these months, modeled flow rates average 64–114 cfs for the Future Baseline and 197–280 cfs for the YRDP Relicensing Project (future). Modeled flow rates in July through March average 31–201 cfs for the Future Baseline and 44–273 cfs for the YRDP Relicensing Project (future), depending on month.

The modeled river temperatures with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below Our House Diversion Dam with the YRDP Relicensing Project (future) are nearly the same as those for the Future Baseline. Modeled monthly average temperatures below the dam range from about 40–71°F for both scenarios for the full simulation period (refer to Appendix 4C, Table C2-Temp-10). Because of the higher flow rates, temperatures would be lower further downstream of the dam. Downstream of the confluence with Oregon Creek, modeled monthly average temperatures are up to 1°F lower compared to the Future Baseline (Appendix 4C, Table C2-Temp-11). Upstream of the confluence with the North Yuba River average temperatures are up to 1.6°F lower compared to the Future Baseline (Appendix 4C, Table C2-Temp-12).

Therefore, for the same reasons provided in YRDP Impact WQ-PP-9, operation of the YRDP Relicensing Project (future) would not cause substantial, if any, differences in Middle Yuba River dissolved oxygen, turbidity, TSS, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause exceedance of a Middle Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the Middle Yuba River. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Middle Yuba River. Therefore, impacts on the Middle Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-10: Impacts on Upper Yuba River Water Quality from Operation of the YRDP.

Modeled upper Yuba River flow rates with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline are similar to those described in YRDP Impact WQ-PP-10 for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average upper Yuba River flow rates are higher year-round over the entire simulation period with operation of the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix 4C, Table C2-Flow-11). Modeled flow rates below the Middle Yuba River confluence

average 46–1,084 cfs for the Future Baseline and 78–1,125 cfs for the YRDP Relicensing Project (future), depending on month.

The modeled river temperatures with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the confluence range from about 40–73°F for the Future Baseline and 40–66°F for the YRDP Relicensing Project (future) for the full simulation period (refer to Appendix 4C, Table C2-Temp-13). Modeled monthly average temperatures for the YRDP Relicensing Project (future) are about 5–8°F lower in the summer compared to the Future Baseline. Temperature differences in the upper Yuba River at Colgate Powerhouse are smaller. Modeled monthly average temperatures at this location range from about 39–73°F for the Future Baseline and 39–71°F for the YRDP Relicensing Project (future) for the full simulation period (refer to Appendix 4C, Table C2-Temp-14). Modeled monthly average temperatures for the YRDP Relicensing Project (future) are about 1–3°F lower in the summer compared to the Future Baseline.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-10, operation of the YRDP Relicensing Project (future) would not cause substantial, if any, differences in upper Yuba River dissolved oxygen, turbidity, TSS, mercury, chromium, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause exceedance of an upper Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of the YRDP Relicensing Project (future) would not cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the river.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the upper Yuba River. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the upper Yuba River. Therefore, impacts on the upper Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-11: Impacts on Lower Yuba River Water Quality from Operation of the YRDP.

Modeled lower Yuba River flow rates with operation of the YRDP Relicensing Project (future) and differences from the Future Baseline are similar to those described in YRDP Impact WQ-PP-11 for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average lower Yuba River flow rates with operation of the YRDP Relicensing Project (future) are similar over the entire simulation period and across all water year types compared to the Future

Baseline with differences being less than 5 percent (refer to Appendix 4C, Tables C2-Flow-1 through C2-Flow-4).

River temperatures with operation of the YRDP Relicensing Project (future) are also similar over the entire simulation period and across all water year types compared to the Future Baseline, with differences in modeled monthly average temperatures being less than 0.5°F (refer to Appendix 4C, Tables C2-Temp-1 through C2-Temp-5).

Therefore, for the same reasons provided in YRDP Impact WQ-PP-11, operation of the YRDP Relicensing Project (future) would not cause substantial, if any, differences in lower Yuba River dissolved oxygen, turbidity, TSS, mercury, copper, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause lower Yuba River water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river. Furthermore, operation of the YRDP Relicensing Project (future) would not result in a long-term measurable increase in mercury or copper in the lower Yuba River.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the lower Yuba River. Therefore, impacts on the lower Yuba River water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-12: Impacts on the Lower Feather River, Sacramento River, and Delta from Operation of the YRDP.

As discussed in YRDP Impact WQ-PP-12, the operation of the YRDP Relicensing Project would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River based on a sensitivity analysis comparing Feather River flow rates downstream of the lower Yuba River under the Existing Condition and with the YRDP Relicensing Project. For the same reasons, operation of the YRDP Relicensing Project would not result in detectable changes in Feather River flows immediately downstream of the Yuba River compared to the Future Baseline, and changes in water quality conditions downstream of the mouth of the Yuba River would not be measurable.

Therefore, operation of the YRDP Relicensing Project (future) would cause little, if any, differences in lower Feather River water quality constituents (e.g., dissolved oxygen, salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Existing Condition. As such, Sacramento River and Delta water quality also would not be measurably affected by operation of the YRDP Relicensing Project (future). Therefore, operation

of the YRDP Relicensing Project (future) would not cause Feather River, Sacramento River, and Delta water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river. Furthermore, operation of the YRDP Relicensing Project (future) would not result in long-term measurable increases in constituent impairments in these waterbodies.

CEQA Conclusion

Based on the above analysis, operation of the YRDP Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Feather River, Sacramento River, or Delta. Furthermore, operation of the YRDP Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Therefore, impacts on Feather River, Sacramento River, and Delta water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FPP-14: Risk of Release of Pollutants due to Project Inundation in Flood Hazard Zones from YRDP Operations.

The YRDP Relicensing Project consists of water storage and diversion facilities located within and adjacent to Project Area reservoirs and rivers where water levels fluctuate. In addition, some recreational facilities are located adjacent to Project Area reservoirs and rivers.

Modeling results show small (2 percent or less) differences in average New Bullards Bar Reservoir and Englebright Reservoir end-of-month storage and water surface elevations compared to the Future Baseline (refer to Appendix 4C, Tables C2-Reservoir-1 through C2-Reservoir-4). Modeling results also show that peak flow rates of Project Area rivers and creeks with the YRDP Relicensing Project would be the same or very similar to those that occur under the Future Baseline (refer to Appendix 4C, Figures C2-Flow-1 through C2-Flow-48). Therefore, project facilities with the YRDP Relicensing Project would not be at increased risk of inundation that would result in an increased risk of release of pollutants to Project Area waterbodies compared to the Future Baseline.

Furthermore, YRDP Relicensing Project operations would not result in an increased risk of release of pollutants downstream of project facilities. Modeling results show that peak lower Yuba River flow rates with operation of the YRDP Relicensing Project are similar to the Future Baseline over the entire simulation period (refer to Appendix 4C, Figures C2-Flow-1 through C2-Flow-12).

Finally, as discussed in Chapter 4, Section 4.3.1.3, "Downstream Extent of the Project Area," operation of the YRDP Relicensing Project would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River. Consequently, the YRDP Relicensing Project would not result in an increased risk of release of pollutants downstream of the lower Yuba River.

CEQA Conclusion

Based on the above discussion, the YRDP Relicensing Project would have a **less-than-significant impact** on the risk of release of pollutants due to project inundation in flood hazard zones.

Narrows Impact WQ-FPP-1: Impacts on Surface Water Quality from Operation of the Narrows Project.

Yuba Water proposes to continue to operate the Narrows Relicensing Project in substantial conformance with existing operations, with minor modifications. The minor operations-related modifications that could affect water quality include operating the project to assist the YRDP with meeting instream flow requirements in the lower Yuba River at Smartsville and maintaining a minimum water surface elevation in Englebright Reservoir. However, the effects of these operations on Englebright Reservoir and lower Yuba River compared to the Future Baseline would not be beyond those described for YRDP Impact WQ-FPP-6 and YRDP Impact WQ-FPP-11, respectively. Any minimal effects of the Narrows Relicensing Project operations on lower Yuba River water quality would have little to no effect on the water quality of the Feather River, Sacramento River, and Delta, given modeling results that show hydrologic operations on the Yuba River have little effect on downstream hydrology, as discussed in YRDP Impact WQ-FPP-12.

CEQA Conclusion

Based on the above analysis, operation of the Narrows Relicensing Project would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River, lower Feather River, Sacramento River, or Delta. Furthermore, operation of the Narrows Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Finally, the project would not result in an increased risk of release of pollutants to Project Area waterbodies or conflict with or obstruct implementation of a water quality control plan. Therefore, impacts on Yuba River, Feather River, Sacramento River, and Delta water quality from operation of the Narrows Relicensing Project would be **less than significant**. No CEQA mitigation is required.

8.5.3 Alternative 1 compared to the Existing Condition

Construction, operations, and maintenance activities for the Proposed Projects under the new FERC licenses have the potential to affect surface water quality of waterbodies in the Project Area. The discussions below address these potential impacts.

Note that operations-related impacts on surface water quality that are dependent on reservoir storage and river/creek flow rate changes do not have CEQA impact conclusions in this section. Discussion for surface water quality impacts that are dependent on reservoir storage and river/creek flow rate changes compared to the Existing Condition is provided for informational purposes only. CEQA impact conclusions for these impacts are based on the comparisons between Alternative 1 and the Future Baseline, presented in Section 8.5.4; refer to Section 8.4.3, "Water Operations-Related Impacts," for additional information regarding the use of the dual baseline for

impact determinations and rationale for CEQA conclusions being based on comparison to the Future Baseline.

The impact analyses below depend, in part, on differences in reservoir storage and river/creek flow rates and temperatures with Alternative 1 compared to the Future Baseline. To avoid repeating information presented for the same impact analyses in Section 8.5.1 for the YRDP Relicensing Project compared to the Existing Condition, the discussion below is focused on how the reservoir storage and river/creek flow rate and temperature differences for Alternative 1 compare to the Existing Condition, and how those differences would affect water quality, based on information presented for the same impacts in Section 8.5.1.

YRDP Impact WQ-Alt1-1: Impacts on Surface Water Quality from Modification of Power Generation- and Water Conveyance-Related Facilities for the YRDP.
Alternative 1 includes the same modifications to power generation- and water conveyance-related facilities as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-1, this impact would be **less than significant**.

YRDP Impact WQ-Alt1-2: Impacts on Surface Water Quality from Implementation of the YRDP Recreation Facilities Plan
Alternative 1 includes the same *Recreation Facilities Plan* as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-2, this impact would be **less than significant**.

YRDP Impact WQ-Alt1-3: Impacts on Surface Water Quality from Implementation of the YRDP Log Cabin and Our House Diversion Dams Sediment Management Plan
Alternative 1 includes the same *Log Cabin and Our House Diversion Dams Sediment Management Plan* as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-3, this impact would be **less than significant**.

YRDP Impact WQ-Alt1-4: Impacts on Surface Water Quality from Other YRDP Implementation Plans
Alternative 1 includes the same YRDP Implementation Plans as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-4, this impact would be **less than significant**.

YRDP Impact WQ-Alt1-5: Impacts on New Bullards Bar Reservoir Water Quality from Operation of Alternative 1.
Modeling results show small increases in New Bullards Bar Reservoir average end-of-month storage with Alternative 1 compared to the Existing Condition (refer to Appendix 4C, Table C3-Reservoir-1). Average end-of-month storage with Alternative 1 for the full simulation period is 1 percent higher in June through March, and 0 percent different in April and May compared to the Existing Condition. The higher average storage is primarily driven by higher storage in dry water years when modeled monthly average storage is up to 2 percent higher and critical water years when modeled monthly average storage is up to 6 percent higher compared to the Existing Condition.

Modeling results also show increases in end-of-month water surface elevation with Alternative 1 compared to the Existing Condition (refer to Appendix 4C, Table C3-Reservoir-2). Average end-

of-month water surface elevation with Alternative 1 for the full simulation period is 1–2 feet higher compared to the Existing Condition. The greatest increases are in dry and critical years. In dry years, average end-of-month water surface elevation with Alternative 1 is from 3–5 feet higher in May through September, and 0–1 foot higher in other months compared to the Existing Condition. In critical years, average end-of-month water surface elevation with Alternative 1 is from 9–11 feet higher in May through September and 3–7 feet higher in other months compared to the Existing Condition.

Temperature, dissolved oxygen, nutrients, and mercury would be the water quality constituents most affected by changes in reservoir end-of-month storage and water surface elevation. The quality of inflows would be unaffected by the alternative, and therefore would be the same or similar, hence other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) would be negligibly affected by differences in reservoir end-of-month storage and water surface elevation.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-6: Impacts on Englebright Reservoir Water Quality from Operation of Alternative 1.

Modeling results show little to no difference in Englebright Reservoir average end-of-month storage with Alternative 1 compared to the Existing Condition (refer to Appendix 4C, Table C3-Reservoir-3). Average end-of-month storage with Alternative 1 for the full simulation period is 3 percent higher in September, 2 percent higher in October, and 0 percent different in the other months compared to the Existing Condition.

Modeling results also show little to no difference in end-of-month water surface elevation with Alternative 1 compared to the Existing Condition (refer to Appendix 4C, Table C3-Reservoir-4). Average end-of-month water surface elevation with Alternative 1 for the full simulation period is 2 feet higher in September, 1 foot higher in October, and no different for the other months compared to the Existing Condition.

Because there would be little to no change in Englebright Reservoir end-of-month storage and water surface elevation, there would be little to no change in reservoir temperature, dissolved oxygen or nutrients. Furthermore, based on the small differences in modeled storage and water surface elevation, operation of Alternative 1 would have little to no effect on the reservoir stratification, residence time, and water depth that could affect water column mercury concentrations.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-7: Impacts on North Yuba River Water Quality below New Bullards Bar Dam from Operation of Alternative 1

Modeled North Yuba River flow rates with operation of Alternative 1 and differences from the Existing Condition are similar to those described in YRDP Impact WQ-PP-7 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C3-Flow-5). Modeled monthly average North Yuba River flow rates are higher with operation of Alternative 1 during July through November over the entire simulation period and across all water year types compared to the Existing Condition. In July through November, modeled monthly average flow rates below New Bullards Bar Dam range from 8–9 cfs for the Existing Condition and 14–43 cfs for Alternative 1 for the full simulation period. The average flow increase in these months ranges from 6–34 cfs. In December through June, modeled monthly average flow rates are lower with operation of Alternative 1. In these months, the modeled monthly average flow rate ranges from 168–657 cfs for the Existing Condition and 121–648 cfs for Alternative 1.

The modeled river temperatures with operation of Alternative 1 and differences from the Existing Condition also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the dam range from about 45–53°F for the Existing Condition and about 45–51°F for Alternative 1 for the full simulation period (refer to Appendix C, Table C3-Temp-6). Modeled monthly average temperatures are about 4–6°F lower in June through September compared to the Existing Condition. In December, January, April, and May, modeled monthly average temperatures differ from the Existing Condition by 0.0–0.1°F.

Temperature reductions in the North Yuba River at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 9–14°F lower with operation of Alternative 1 compared to the Existing Condition (refer to Appendix 4C, Table C3-Temp-7). Modeled monthly average temperatures at the confluence range from about 45–68°F for the Existing Condition and 45–61°F for Alternative 1 for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-7, operation of Alternative 1 would not cause substantial, if any, differences in the North Yuba River dissolved oxygen, turbidity, TSS, methylmercury, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 1 would not cause exceedance of a North Yuba River water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 1 would result in a long-term increase in mercury that would cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the river.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-8: Impacts on Oregon Creek Water Quality from Operation of Alternative 1

Modeled Oregon Creek flow rates with operation of Alternative 1 differences from the Existing Condition are the same or nearly the same as those described in YRDP Impact WQ-PP-8 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C3-Flow-6). The modeled increases are greatest in April, May, and June. In these months, modeled flow rates average 9–24 cfs for the Existing Condition and 21–58 cfs for Alternative 1. Modeled monthly average flow rates are similar to the Existing Condition for July–March and range from 3–68 cfs for the Existing Condition and 3–71 cfs for Alternative 1.

The modeled creek temperatures with operation of Alternative 1 and differences from the Existing Condition also are the same or nearly the same as those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the Log Cabin Diversion Dam range from about 40–69°F for the Existing Condition and about 40–67°F for Alternative 1 for the full simulation period (refer to Appendix 4C, Table C3-Temp-8). Modeled monthly average temperatures for Alternative 1 are about 1–2°F lower in June through September compared to the Existing Condition. Temperature reductions at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 1°F lower with operation of Alternative 1 compared to the Existing Condition (refer to Appendix 4C, Table C3-Temp-9). Modeled monthly average temperatures at the confluence range from about 40–70°F for the Existing Condition and 40–69°F for Alternative 1 for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-8, operation of Alternative 1 would not cause substantial, if any, differences in Oregon Creek dissolved oxygen, turbidity, TSS, copper, iron, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 1 would not cause exceedance of an Oregon Creek water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the creek. Furthermore, operation of Alternative 1 would not cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the creek.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-9: Impacts on the Middle Yuba River Water Quality from Operation of Alternative 1

Modeled Middle Yuba River flow rates with operation of Alternative 1 and differences from the Existing Condition are similar to those described in YRDP Impact WQ-PP-9 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C3-Flow-8). Modeled monthly average Middle Yuba River flow rates are higher year-round over the entire simulation period with operation of Alternative 1 compared to the Existing Condition. The increases are greatest in April, May, and June. In these months, modeled flow rates average 67–115 cfs for the Existing Condition and 197–244 cfs for Alternative 1. Modeled flow rates in July

through March average 29–202 cfs for the Existing Condition and 44–272 cfs for Alternative 1, depending on month.

The modeled river temperatures with operation of Alternative 1 and differences from the Existing Condition also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below Our House Diversion Dam with Alternative 1 are nearly the same as those for the Existing Condition. Modeled monthly average temperatures below the dam range from about 40–71°F for both scenarios for the full simulation period (refer to Appendix 4C, Table C3-Temp-10). Because of the higher flow rates, temperatures would be lower further downstream of the dam. Downstream of the confluence with Oregon Creek, modeled monthly average temperatures are up to about 2°F lower compared to the Existing Condition (Appendix 4C, Table C3-Temp-11). Upstream of the confluence with the North Yuba River modeled monthly average temperatures are also up to about 2°F lower compared to the Existing Condition (Appendix 4C, Table C3-Temp-12).

Therefore, for the same reasons provided in YRDP Impact WQ-PP-9, operation of Alternative 1 would not cause substantial, if any, differences in Middle Yuba River dissolved oxygen, turbidity, TSS, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 1 would not cause exceedance of a Middle Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-10: Impacts on Upper Yuba River Water Quality from Operation of Alternative 1

Modeled upper Yuba River flow rates with operation of Alternative 1 and differences from the Existing Condition are similar to those described in YRDP Impact WQ-PP-10 for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average upper Yuba River flow rates are higher year-round over the entire simulation period with operation of Alternative 1 compared to the Existing Condition (refer to Appendix 4C, Table C3-Flow-11). Modeled flow rates below the Middle Yuba River confluence average 44–1,077 cfs for the Existing Condition and 78–1,123 cfs for Alternative 1, depending on month.

The modeled river temperatures with operation of Alternative 1 and differences from the Existing Condition also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the Middle Yuba River confluence range from about 40–73°F for the Existing Condition and 40–66°F for Alternative 1 for the full simulation period (refer to Appendix 4C, Table C3-Temp-13). Modeled monthly average temperatures for Alternative 1 are about 5–8°F lower in the summer compared to the Existing Condition. Temperature differences in the upper Yuba River at Colgate Powerhouse are smaller. Modeled monthly average temperatures at this location range from about 39–73°F for the Existing Condition and 39–71°F for Alternative 1 for the full simulation period (refer to Appendix

4C, Table C3-Temp-14). Modeled monthly average temperatures for Alternative 1 are about 1–3°F lower in the summer compared to the Existing Condition.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-10, operation of Alternative 1 would not cause substantial, if any, differences in upper Yuba River dissolved oxygen, turbidity, TSS, mercury, chromium, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 1 would not cause exceedance of an upper Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 1 would not cause measurable water quality degradation for the CWA Section 303(d)-listed constituents in the river.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-11: Impacts on Lower Yuba River Water Quality from Operation of Alternative 1

Modeled lower Yuba River flow rates with operation of Alternative 1 and differences from the Existing Condition are similar to those described in YRDP Impact WQ-PP-11 for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average lower Yuba River flow rates with operation of Alternative 1 are similar over the entire simulation period and across all water year types compared to the Existing Condition with differences being less than 5 percent (refer to Appendix 4C, Tables C3-Flow-1 through C3-Flow-4).

River temperatures with operation of Alternative 1 are also similar over the entire simulation period and across all water year types compared to the Existing Condition, with differences in modeled monthly average temperatures being less than 0.5°F (refer to Appendix 4C, Tables C3-Temp-1 through C3-Temp-5).

Therefore, for the same reasons provided in YRDP Impact WQ-PP-11, operation of Alternative 1 would not cause substantial, if any, differences in lower Yuba River dissolved oxygen, turbidity, TSS, mercury, copper, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 1 would not cause lower Yuba River water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river. Furthermore, operation of Alternative 1 would not result in a long-term measurable increase in mercury or copper in the lower Yuba River.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-12: Impacts on the Lower Feather River, Sacramento River, and Delta from Operation of Alternative 1.
As discussed in Chapter 4, Section 4.3.1.3, "Downstream Extent of the Project Area," operation of Alternative 1 would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River. A sensitivity analysis conducted to compare Feather River flow rates downstream of the lower Yuba River under the Existing Condition and Alternative 1 found that the average difference in monthly average flow rate would be 0.36%. Consequently, operation of Alternative 1 would not result in detectable changes in Feather River flows immediately downstream of the Yuba River, compared to the Existing Condition, and changes in water quality conditions downstream of the mouth of the Yuba River would not be measurable.

Therefore, operation of Alternative 1 would cause little, if any, differences in lower Feather River water quality constituents (e.g., dissolved oxygen, salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Existing Condition. As such, Sacramento River and Delta water quality also would not be measurably affected by operation of Alternative 1. Therefore, operation of Alternative 1 would not cause Feather River, Sacramento River, and Delta water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river. Furthermore, operation of Alternative 1 would not result in long-term measurable increases in constituent impairments in these waterbodies.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-13: Impacts on Surface Water Quality from Other Operation and Maintenance of Alternative 1.
Alternative 1 includes the same O&M activities as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-13, this impact would be **less than significant**.

YRDP Impact WQ-Alt1-14: Risk of Release of Pollutants due to Project Inundation in Flood Hazard Zones from YRDP Operations.
Alternative 1 consists of water storage and diversion facilities located within and adjacent to Project Area reservoirs and rivers where water levels fluctuate. In addition, some recreational facilities are located adjacent to Project Area reservoirs and rivers.

Modeling results show small (2 percent or less) differences in average New Bullards Bar Reservoir and Englebright Reservoir end-of-month storage and water surface elevations compared to the Existing Condition (refer to Appendix 4C, Tables C3-Reservoir-1 through C3-Reservoir-4). Modeling results also show that peak flow rates of Project Area rivers and creeks with Alternative 1 would be the same or very similar to those that occur under the Existing Condition (refer to Appendix 4C, Figures C3-Flow-1 through C3-Flow-48). Therefore, project facilities with Alternative 1 would not be at increased risk of inundation that would result in an increased risk of release of pollutants to Project Area waterbodies compared to the Existing Condition.

Furthermore, Alternative 1 operations would not result in an increased risk of release of pollutants downstream of project facilities. Modeling results show that peak lower Yuba River flow rates with operation of Alternative 1 are similar to the Existing Condition over the entire simulation period (refer to Appendix 4C, Figures C3-Flow-1 through C3-Flow-12).

Finally, as discussed in Chapter 4, Section 4.3.1.3, "Downstream Extent of the Project Area," operation of Alternative 1 would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River. Consequently, Alternative 1 would not result in an increased risk of release of pollutants downstream of the lower Yuba River.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt1-15: Consistency with Water Quality Control Plans.
Alternative 1 includes the same construction, operations, and maintenance activities as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-15, the YRDP Relicensing Project would have **no impact** on the implementation of a water quality control plan (i.e., Basin Plan), nor would the project conflict with a water quality control plan (i.e., Basin Plan).

Indirect Impact WQ-Alt1-1: Indirect Impacts on Water Quality of Reservoirs and Rivers Upstream of the YRDP from Alternative 1 YB/DS Operations.
Alternative 1 includes a contribution of 15,600 ac-ft of water from the Yuba-Bear/Drum-Spaulding projects that would be provided under new FERC licenses for those projects. The following discussion provides a programmatic analysis of the potential indirect impacts to water quality in waterbodies upstream of the YRDP associated with this component of Alternative 1, relative to the Existing Condition. As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YB/DS operations under Alternative 1 could result in lower storage in Jackson Meadows Reservoir, Bowman Lake, Fordyce Lake, and Lake Spaulding in all months and most water year types, particularly dry and critical years, compared to the Existing Condition. Lower storage volumes compared to the Existing Condition could result in higher water temperatures in these reservoirs under Alternative 1. Differences in other water quality constituent levels are not anticipated, given that the watershed inputs to the reservoirs and inflow quality would be the same as under the Existing Condition.

YB/DS operations under Alternative 1 also could result in modified flow rates in the following waterbodies.

- Middle Yuba River from Jackson Meadows Reservoir to Our House Diversion Dam
- Canyon Creek below Bowman Lake and Bowman-Spaulding Conduit Diversion Dam
- Fordyce Creek below Fordyce Lake
- South Yuba River below Lake Spaulding to Jones Bar

The primary effects on water quality from changes in flow rates are water temperature and turbidity and TSS levels. In months with lower flows, the waterbodies could have higher water temperatures, and lower turbidity and TSS levels. Conversely, in months with higher flows, the waterbodies could have lower water temperatures, but higher turbidity and TSS levels. See Chapter 9, Section 9.5.2.2.3, "Additional Operations-Related Impacts," and supporting Appendix 9C for discussion of anticipated temperature changes and effects on aquatic life beneficial uses, which is the beneficial use of these waterbodies most sensitive to temperature changes. Turbidity and TSS levels are expected to be within the range that occurs under the Existing Condition given that higher flows would be due to project operations, not associated with storm events. Dissolved oxygen levels are expected to be maintained near saturation due to the turbulent nature of the rivers and creeks. Differences in other water quality constituent levels are not anticipated given that the upstream watershed inputs to the rivers and creeks would be unaffected by the YB/DS operations.

Therefore, YB/DS operations under Alternative 1 would not cause water quality in the affected waterbodies to change by a frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses. As further discussed in Appendix 9C, water temperature conditions for the fish species evaluated in the YB/DS reaches under Alternative 1 relative to the Existing Condition could, but would not necessarily be substantially affected because of the operational flexibility of the upstream reservoirs and diversions in the manner in which the 15.6 TAF could be provided.

Narrows Impact WQ-Alt1-1: Impacts on Surface Water Quality from Operation of the Narrows Project.
Yuba Water proposes to continue to operate the Narrows Project under Alternative 1 in substantial conformance with existing operations, with minor modifications. The minor operations-related modifications that could affect water quality include operating the project to assist the YRDP with meeting instream flow requirements in the lower Yuba River at Smartsville and maintaining a minimum water surface elevation in Englebright Reservoir. However, the effects of these operations on Englebright Reservoir and lower Yuba River compared to the Existing Condition would not be beyond those described for YRDP Impact WQ-Alt1-6 and YRDP Impact WQ-Alt1-11, respectively. Any minimal effects of the Narrows Project operations under Alternative 1 on lower Yuba River water quality would have little to no effect on the water quality of the Feather River, Sacramento River, and Delta, given modeling results that show hydrologic operations on the Yuba River have little effect on downstream hydrology, as discussed in YRDP Impact WQ-Alt1-12.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

8.5.4 Alternative 1 compared to the Future Baseline

The impact analyses below depend, in part, on differences in reservoir storage and river/creek flow rates with Alternative 1 compared to the Future Baseline. Impacts of Alternative 1 not dependent on changes in reservoir storage and river/creek flow rates related to construction, operations,

and/or maintenance activities, and implementation plans are compared to the Existing Condition. Refer to Section 8.5.3 for those impacts.

YRDP Impact WQ-FAlt1-5: Impacts on New Bullards Bar Reservoir Water Quality from Operation of Alternative 1.

Modeled differences in New Bullards Bar Reservoir average end-of-month storage with operation of Alternative 1 compared to the Future Baseline are similar to those described in YRDP Impact WQ-FPP-5 for the YRDP Relicensing Project compared to the Future Baseline (refer to Appendix 4C, Table C4-Reservoir-1). Modeled average end-of-month storage with Alternative 1 for the full simulation period is 1–2 percent lower in September through February, and 0 percent different in March through August compared to the Future Baseline. Average end-of-month storage with Alternative 1 also differed little by water year type, with the difference being 0–2 percent in critical years, 0–2 percent in dry years, 0–1 percent in below normal years, 0–2 percent in above normal years, and 0–2 percent in wet years compared to the Future Baseline.

Modeled differences in average water surface elevation with Alternative 1 compared to the Future Baseline are also similar to those described for the YRDP Relicensing Project compared to the Future Baseline (Appendix 4C, Table C4-Reservoir-2). Modeled average end-of-month water surface elevation for Alternative 1 for the full simulation period is 0–3 feet lower, depending on month.

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-5, operation of Alternative 1 would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Future Baseline. As such, operation of Alternative 1 would not cause exceedance of a New Bullards Bar Reservoir water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the reservoir. Furthermore, operation of Alternative 1 would not result in a long-term measurable increase in mercury in the reservoir, thus would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the reservoir.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in New Bullards Bar Reservoir. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to New Bullards Bar Reservoir. Therefore, impacts on New Bullards Bar Reservoir water quality from operation of Alternative 1 would be **less than significant**.

YRDP Impact WQ-FAlt1-6: Impacts on Englebright Reservoir Water Quality from Operation of Alternative 1.

Modeled differences in Englebright Reservoir average end-of-month storage with operation of Alternative 1 compared to the Future Baseline are similar to those described in YRDP Impact WQ-FPP-6 for the YRDP Relicensing Project compared to the Future Baseline (refer to Appendix 4C, Table C4-Reservoir-3). Modeled average end-of-month storage with Alternative 1 for the full simulation period is 3 percent higher in September, 2 percent higher in October, and 0 percent different in the other months compared to the Future Baseline.

Modeled differences in average water surface elevation with Alternative 1 compared to the Future Baseline are also similar to those described for the YRDP Relicensing Project compared to the Future Baseline (refer to Appendix 4C, Table C4-Reservoir-4). Average end-of-month water surface elevation with Alternative 1 for the full simulation period is 2 feet higher in September, 1 foot higher in October, and no different for the other months compared to the Future Baseline.

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-6, operation of Alternative 1 would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Future Baseline. As such, operation of Alternative 1 would not cause Englebright Reservoir water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the reservoir. Furthermore, operation of Alternative 1 would not result in a long-term measurable increase in mercury in the reservoir.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Englebright Reservoir. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Englebright Reservoir. Therefore, impacts on Englebright Reservoir water quality from operation of Alternative 1 would be **less than significant**.

YRDP Impact WQ-FAlt1-7: Impacts on North Yuba River Water Quality below New Bullards Bar Dam from Operation of Alternative 1

Modeled North Yuba River flow rates with operation of Alternative 1 and differences from the Future Baseline are similar to those described in YRDP Impact WQ-FPP-7 for the YRDP Relicensing Project compared to the Future Baseline (refer to Appendix 4C, Table C4-Flow-5). Modeled monthly average North Yuba River flow rates are higher with operation of Alternative 1 during July through November over the entire simulation period and across all water year types compared to the Future Baseline. In July through November, modeled monthly average flow rates below New Bullards Bar Dam range from 8–9 cfs for the Future Baseline and 14–43 cfs for Alternative 1 for the full simulation period. The average flow increase in these months ranges from

6–34 cfs. In December through June, modeled monthly average flow rates are lower with operation of Alternative 1. In these months, the modeled monthly average flow rate ranges from 169–663 cfs for the Future Baseline and 121–648 cfs for Alternative 1.

The modeled river temperatures with operation of Alternative 1 and differences from the Future Baseline also are similar to those described for the YRDP Relicensing Project compared to the Future Baseline. Modeled monthly average temperatures below the dam range from about 45–53°F for the Future Baseline and about 45–51°F for Alternative 1 for the full simulation period (refer to Appendix C, Table C4-Temp-6). Modeled monthly average temperatures are about 4–6°F lower in June through September compared to the Future Baseline. In December, January, April, and May, modeled monthly average temperatures differ from the Future Baseline by 0.0–0.1°F.

Temperature reductions in the North Yuba River at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 9–14°F lower with operation of Alternative 1 compared to the Future Baseline (refer to Appendix 4C, Table C4-Temp-7). Modeled monthly average temperatures at the confluence range from about 45–68°F for the Future Baseline and 45–61°F for Alternative 1 for the full simulation period.

Because the above-described differences in river flow rate and temperature are either the same as or nearly the same as those for the YRDP Relicensing Project (future) compared to the Future Baseline, for the same reasons provided in YRDP Impact WQ-FPP-7, operation of Alternative 1 would not cause substantial, if any, differences in the North Yuba River dissolved oxygen, turbidity, TSS, methylmercury, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 1 would not cause exceedance of a North Yuba River water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 1 would result in a long-term measurable increase in mercury that would cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the river.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the North Yuba River below New Bullards Bar Dam. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the North Yuba River. Therefore, impacts on the North Yuba River water quality from operation of Alternative 1 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt1-8: Impacts on Oregon Creek Water Quality from Operation of Alternative 1

Modeled Oregon Creek flow rates with operation of the Alternative 1 and differences from the Future Baseline are the same or nearly the same as those described in YRDP Impact WQ-FPP-8

for the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix 4C, Table C4-Flow-6). The modeled increases are greatest in April, May, and June. In these months, modeled flow rates average 9–24 cfs for the Future Baseline and 21–58 cfs for Alternative 1. Modeled monthly average flow rates are similar to the Future Baseline for July–March and range from 3–68 cfs for the Future Baseline and 3–71 cfs for Alternative 1.

The modeled creek temperatures with operation of Alternative 1 and differences from the Future Baseline also are the same as those described for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average temperatures below the Log Cabin Diversion Dam range from about 40–69°F for the Future Baseline and about 40–67°F for Alternative 1 for the full simulation period (refer to Appendix 4C, Table C4-Temp-8). Modeled monthly average temperatures for Alternative 1 are about 1–2°F lower in June through September compared to the Future Baseline. Temperature reductions at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 1°F lower with operation of Alternative 1 compared to the Future Baseline (refer to Appendix 4C, Table C4-Temp-9). Modeled monthly average temperatures at the confluence range from about 40–70°F for the Future Baseline and 40–69°F for the YRDP Relicensing Project (future) for the full simulation period.

Because the above-described differences in river flow rate and temperature are either the same as or nearly the same as those for the YRDP Relicensing Project (future) compared to the Future Baseline, for the same reasons provided in YRDP Impact WQ-FPP-8, operation of Alternative 1 would not cause substantial, if any, differences in Oregon Creek dissolved oxygen, turbidity, TSS, copper, iron, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 1 would not cause exceedance of an Oregon Creek water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the creek. Furthermore, operation of Alternative 1 would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the creek.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Oregon Creek. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Oregon Creek. Therefore, impacts on Oregon Creek water quality from operation of Alternative 1 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt1-9: Impacts on the Middle Yuba River Water Quality from Operation of Alternative 1

Modeled Middle Yuba River flow rates with operation of Alternative 1 and differences from the Future Baseline are the same as or nearly the same as those described in YRDP Impact WQ-FPP-9 for the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix

4C, Table C4-Flow-8). Modeled monthly average Middle Yuba River flow rates are higher year-round over the entire simulation period with operation of Alternative 1 compared to the Future Baseline (refer to Appendix 4C, Table C4-Flow-8). The increases are greatest in April, May, and June. In these months, modeled flow rates average 64–114 cfs for the Future Baseline and 197–280 cfs for Alternative 1. Modeled flow rates in July through March average 31–201 cfs for the Future Baseline and 44–272 cfs for Alternative 1, depending on month.

The modeled river temperatures with operation of Alternative 1 and differences from the Future Baseline also are similar to those described for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average temperatures below Our House Diversion Dam with Alternative 1 are nearly the same as those for the Future Baseline. Modeled monthly average temperatures below the dam range from about 40–71°F for both scenarios for the full simulation period (refer to Appendix 4C, Table C4-Temp-10). Because of the higher flow rates, temperatures would be lower further downstream of the dam. Downstream of the confluence with Oregon Creek, modeled monthly average temperatures are up to about 1°F lower compared to the Future Baseline (Appendix 4C, Table C4-Temp-11). Upstream of the confluence with the North Yuba River average temperatures are up to 1.6°F lower compared to the Future Baseline (Appendix 4C, Table C4-Temp-12).

Because the above-described differences in river flow rate and temperature are either the same as or nearly the same as those for the YRDP Relicensing Project (future) compared to the Future Baseline, for the same reasons provided in YRDP Impact WQ-FPP-9, operation of Alternative 1 would not cause substantial, if any, differences in Middle Yuba River dissolved oxygen, turbidity, TSS, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 1 would not cause exceedance of a Middle Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the Middle Yuba River. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Middle Yuba River. Therefore, impacts on the Middle Yuba River water quality from operation of Alternative 1 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt1-10: Impacts on Upper Yuba River Water Quality from Operation of Alternative 1

Modeled upper Yuba River flow rates with operation of Alternative 1 and differences from the Future Baseline are the same as or nearly the same as those described in YRDP Impact WQ-FPP-10 for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average upper Yuba River flow rates are higher year-round over the entire simulation period with

operation of Alternative 1 compared to the Future Baseline (refer to Appendix 4C, Table C4-Flow-11). Modeled flow rates below the Middle Yuba River confluence average 46–1,084 cfs for the Future Baseline and 78–1,123 cfs for the YRDP Relicensing Project (future), depending on month.

The modeled river temperatures with operation of Alternative 1 and differences from the Future Baseline also are the same as or nearly the same as those described for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average temperatures below the confluence range from about 40–73°F for the Future Baseline and 40–66°F for Alternative 1 for the full simulation period (refer to Appendix 4C, Table C4-Temp-13). Modeled monthly average temperatures for Alternative 1 are about 5–8°F lower in the summer compared to the Future Baseline. Temperature differences in the upper Yuba River at Colgate Powerhouse are smaller. Modeled monthly average temperatures at this location range from about 39–73°F for the Future Baseline and 39–71°F for Alternative 1 for the full simulation period (refer to Appendix 4C, Table C4-Temp-14). Modeled monthly average temperatures for the YRDP Relicensing Project (future) are about 1–3°F lower in the summer compared to the Future Baseline.

Because the above-described differences in river flow rate and temperature are either the same as or nearly the same as those for the YRDP Relicensing Project (future) compared to the Future Baseline, for the same reasons provided in YRDP Impact WQ-FPP-10, operation of Alternative 1 would not cause substantial, if any, differences in upper Yuba River dissolved oxygen, turbidity, TSS, mercury, chromium, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 1 would not cause exceedance of an upper Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 1 would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the river.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the upper Yuba River. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the upper Yuba River. Therefore, impacts on the upper Yuba River water quality from operation of Alternative 1 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt1-11: Impacts on Lower Yuba River Water Quality from Operation of Alternative 1

Modeled lower Yuba River flow rates with operation of Alternative 1 and differences from the Future Baseline are similar to those described in YRDP Impact WQ-FPP-11 for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average lower Yuba River flow rates with operation of Alternative 1 are similar over the entire simulation period

and across all water year types compared to the Future Baseline with differences being less than 5 percent (refer to Appendix 4C, Tables C4-Flow-1 through C4-Flow-4).

River temperatures with operation of Alternative 1 are also similar over the entire simulation period and across all water year types compared to the Future Baseline, with differences in modeled monthly average temperatures being less than 0.5°F (refer to Appendix 4C, Tables C4-Temp-1 through C4-Temp-5).

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-11, operation of Alternative 1 would not cause substantial, if any, differences in lower Yuba River dissolved oxygen, turbidity, TSS, mercury, copper, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of the YRDP Relicensing Project (future) would not cause lower Yuba River water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river. Furthermore, operation of Alternative 1 would not result in a long-term measurable increase in mercury or copper in the lower Yuba River.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the lower Yuba River. Therefore, impacts on the lower Yuba River water quality from operation of Alternative 1 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt1-12: Impacts on the Lower Feather River, Sacramento River, and Delta from Operation of Alternative 1.

As discussed in YRDP Impact WQ-Alt1-12, the operation of Alternative 1 would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River based on a sensitivity analysis comparing Feather River flow rates downstream of the lower Yuba River under the Existing Condition and with the YRDP Relicensing Project. For the same reasons, operation of Alternative 1 would not result in detectable changes in Feather River flows immediately downstream of the Yuba River compared to the Future Baseline, and changes in water quality conditions downstream of the mouth of the Yuba River would not be measurable.

Therefore, operation of Alternative 1 would cause little, if any, differences in lower Feather River water quality constituents (e.g., dissolved oxygen, salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Future Baseline. As such, Sacramento River and Delta water quality also would not be measurably affected by operation of Alternative 1. Therefore, operation of Alternative 1 would not cause Feather River, Sacramento River, and Delta water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect

to the constituents of concern, and thus would not adversely affect any beneficial uses in the river. Furthermore, operation of Alternative 1 would not result in long-term measurable increases in constituent impairments in these waterbodies.

CEQA Conclusion

Based on the above analysis, operation of Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Feather River, Sacramento River, or Delta. Furthermore, operation of Alternative 1 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Therefore, impacts on Feather River, Sacramento River, and Delta water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt1-14: Risk of Release of Pollutants due to Project Inundation in Flood Hazard Zones from YRDP Operations.

Alternative 1 consists of water storage and diversion facilities located within and adjacent to Project Area reservoirs and rivers where water levels fluctuate. In addition, some recreational facilities are located adjacent to Project Area reservoirs and rivers.

Modeling results show small (2 percent or less) differences in average New Bullards Bar Reservoir and Englebright Reservoir end-of-month storage and water surface elevations compared to the Future Baseline (refer to Appendix 4C, Tables C4-Reservoir-1 through C4-Reservoir-4). Modeling results also show that peak flow rates of Project Area rivers and creeks with the YRDP Relicensing Project would be the same or very similar to those that occur under the Future Baseline (refer to Appendix 4C, Figures C4-Flow-1 through C4-Flow-48). Therefore, project facilities with Alternative 1 would not be at increased risk of inundation that would result in an increased risk of release of pollutants to Project Area waterbodies compared to the Future Baseline.

Furthermore, Alternative 1 operations would not result in an increased risk of release of pollutants downstream of project facilities. Modeling results show that peak lower Yuba River flow rates with operation of Alternative 1 are similar to the Future Baseline over the entire simulation period (refer to Appendix 4C, Figures C4-Flow-1 through C4-Flow-12).

Finally, as discussed in Chapter 4, Section 4.3.1.3, "Downstream Extent of the Project Area," operation of the YRDP Relicensing Project would not result in a measurable change in lower Feather River flows downstream of the confluence with the lower Yuba River. Consequently, the YRDP Relicensing Project would not result in an increased risk of release of pollutants downstream of the lower Yuba River.

CEQA Conclusion

Based on the above discussion, Alternative 1 would have a **less-than-significant impact** on the risk of release of pollutants due to project inundation in flood hazard zones.

Indirect Impact WQ-FAlt1-1: Indirect Impacts on Water Quality of Reservoirs and Rivers Upstream of the YRDP from Alternative 1 YB/DS Operations.
Alternative 1 includes a contribution of 15,600 ac-ft of water from the Yuba-Bear/Drum-Spaulding projects that would be provided under new FERC licenses for those projects. The following discussion provides a programmatic analysis of the potential indirect impacts to water quality in waterbodies upstream of the YRDP associated with this component of Alternative 1 compared to the Future Baseline.

YB/DS operations under Alternative 1 could result in lower storage in Jackson Meadows Reservoir, Bowman Lake, Fordyce Lake, and Lake Spaulding in all months and most water year types, particularly dry and critical years, compared to the Future Baseline. Lower storage volumes compared to the Future Baseline could result in higher water temperatures in these reservoirs under Alternative 1. Differences in other water quality constituent levels are not anticipated, given that the watershed inputs to the reservoirs and inflow quality would be the same as under the Future Baseline.

YB/DS operations under Alternative 1 also could result in modified flow rates in the following waterbodies.

- Middle Yuba River from Jackson Meadows Reservoir to Our House Diversion Dam
- Canyon Creek below Bowman Lake and Bowman-Spaulding Conduit Diversion Dam
- Fordyce Creek below Fordyce Lake
- South Yuba River below Lake Spaulding to Jones Bar

The primary effects on water quality from changes in flow rates are water temperature and turbidity and TSS levels. In months with lower flows, the waterbodies could have higher water temperatures, and lower turbidity and TSS levels. Conversely, in months with higher flows, the waterbodies could have lower water temperatures, but higher turbidity and TSS levels. See Chapter 9, Section 9.5.2.2.3, "Additional Operations-Related Impacts," and supporting Appendix 9C for discussion of anticipated temperature changes and effects on aquatic life beneficial uses, which is the beneficial use of these waterbodies most sensitive to temperature changes. Turbidity and TSS levels are expected to be within the range that occurs under the Future Baseline given that higher flows would be due to project operations, not associated with storm events. Dissolved oxygen levels are expected to be maintained near saturation due to the turbulent nature of the rivers and creeks. Differences in other water quality constituent levels are not anticipated, given that the upstream watershed inputs to the rivers and creeks would be unaffected by the YB/DS operations. In addition, YB/DS operations would be subject to separate CWA Section 401 water quality certifications, which include provisions for the protection of water quality and maintenance of water quality standards.

Therefore, YB/DS operations under Alternative 1 would not cause water quality in the affected waterbodies to change by a frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses. As further discussed in Appendix 9C, water temperature conditions for the fish species evaluated in the YB/DS reaches under Alternative 1 relative to the Future Baseline could, but would not necessarily

be substantially affected because of: (1) operational flexibility (e.g., geographic source) of the YB/DS reservoirs in providing the 15.6 TAF; (2) permutations in the allocation (e.g., variable amounts) among YB/DS reservoirs; (3) the potential for provision of the 15.6 TAF through reductions in diversions (and exports out of the upper Yuba River Watershed), releases from storage, or a combination thereof; (4) implementation of ramping rates (both increases and decreases); and (5) resource agency technical assistance in fashioning the releases.

CEQA Conclusion

For purposes of this programmatic analysis, it is reasonably foreseeable that YB/DS operations under Alternative 1 would include available protective measures developed in collaboration with regulatory agencies to ensure that Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in waterbodies upstream of the YRDP. Furthermore, operation of Alternative 1 are unlikely to substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff in waterbodies upstream of the YRDP. Therefore, indirect surface water quality impacts on waterbodies upstream of the YRDP would be **less than significant**. As explained in Chapter 3, the YB/DS relicensings are subject to their own CEQA process. To the extent that YB/DS operations under new FERC licenses would have impacts that are beyond the scope of those disclosed in this EIR or other CEQA documents, those impacts may need to be addressed through subsequent project-level CEQA review as more concrete information about those operations becomes available. the upstream reservoirs and diversions in the manner in which the 15.6 TAF could be provided.

Narrows Impact WQ-FAlt1-1: Impacts on Surface Water Quality from Operation of the Narrows Project.

Yuba Water proposes to continue to operate the Narrows Project under Alternative 1 in substantial conformance with existing operations, with minor modifications. The minor operations-related modifications that could affect water quality include operating the project to assist the YRDP with meeting instream flow requirements in the lower Yuba River at Smartsville and maintaining a minimum water surface elevation in Englebright Reservoir. However, the effects of these operations on Englebright Reservoir and lower Yuba River compared to the Future Baseline would not be beyond those described for YRDP Impact WQ-FAlt1-6 and YRDP Impact WQ-FAlt1-11, respectively. Any minimal effects of the Narrows Project operations under Alternative 1 on lower Yuba River water quality would have little to no effect on the water quality of the Feather River, Sacramento River, and Delta, given modeling results that show hydrologic operations on the Yuba River have little effect on downstream hydrology, as discussed in YRDP Impact WQ-FAlt1-12.

CEQA Conclusion

Based on the above analysis, operation of the Narrows Project under Alternative 1 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River, lower Feather River, Sacramento River, or Delta. Furthermore, operation of the Narrows Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in

substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Finally, operation of the Narrows Project under Alternative 1 would not result in an increased risk of release of pollutants to Project Area waterbodies or conflict with or obstruct implementation of a water quality control plan. Therefore, impacts on Yuba River, Feather River, Sacramento River, and Delta water quality from operation of the Narrows Project under Alternative 1 would be **less than significant**. No CEQA mitigation is required.

8.5.5 Alternative 2 compared to the Existing Condition

Construction, operations, and maintenance activities for the Proposed Projects under the new FERC licenses have the potential to affect surface water quality of waterbodies in the Project Area. The discussions below address these potential impacts.

Note that operations-related impacts on surface water quality that are dependent on reservoir storage and river/creek flow rate changes do not have CEQA impact conclusions in this section. Discussion for surface water quality impacts that are dependent on reservoir storage and river/creek flow rate changes compared to the Existing Condition is provided for informational purposes only. CEQA impact conclusions for these impacts are based on the comparisons between the alternative and the Future Baseline, presented in Section 8.5.6; refer to Section 8.4.3, "Water Operations-Related Impacts," for additional information regarding the use of the dual baseline for impact determinations.

YRDP Impact WQ-Alt2-1: Impacts on Surface Water Quality from Modification of Power Generation- and Water Conveyance-Related Facilities for the YRDP.
Alternative 2 includes the same modifications to power generation- and water conveyance-related facilities as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-1, this impact would be **less than significant**.

YRDP Impact WQ-Alt2-2: Impacts on Surface Water Quality from Implementation of the YRDP Recreation Facilities Plan
Alternative 2 includes the same *Recreation Facilities Plan* as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-2, this impact would be **less than significant**.

YRDP Impact WQ-Alt2-3: Impacts on Surface Water Quality from Implementation of the YRDP Log Cabin and Our House Diversion Dams Sediment Management Plan
Alternative 2 includes the same *Log Cabin and Our House Diversion Dams Sediment Management Plan* as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-3, this impact would be **less than significant**.

YRDP Impact WQ-Alt2-4: Impacts on Surface Water Quality from Other YRDP Implementation Plans
Alternative 2 includes the same implementation plans as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-4, this impact would be **less than significant**.

YRDP Impact WQ-Alt2-5: Impacts on New Bullards Bar Reservoir Water Quality from Operation of Alternative 2.

Modeling results show substantial decreases in New Bullards Bar Reservoir average end-of-month storage with Alternative 2 compared to the Existing Condition (refer to Appendix 4C, Table C5-Reservoir-1). Average end-of-month storage with Alternative 2 for the full simulation period is 5–11 percent lower depending on month for the full simulation period compared to the Existing Condition. Lower storage would occur across all water year types.

Modeling results also show substantial decreases in end-of-month water surface elevation with Alternative 2 compared to the Existing Condition (refer to Appendix 4C, Table C5-Reservoir-2). Average end-of-month water surface elevation with Alternative 2 for the full simulation period is 10–22 feet lower, depending on month, compared to the Existing Condition. The greatest decreases in water surface elevation are in dry years, when modeled reductions average up to 41 feet in June.

Temperature would be the water quality condition most affected by changes in reservoir end-of-month storage and water surface elevation, with the primary effect being a smaller coldwater pool. The reservoir would continue to stratify seasonally as it does under the Existing Condition. The differences in reservoir residence time and potential more frequent fluctuations in water surface elevation could affect sediment wetting and drying cycles, which may affect methylmercury formation and water column concentrations. There could also be seasonal differences in nutrient cycling, which could affect primary productivity and algal blooms, which in turn could result in oxygen depletion in the reservoir hypolimnion when the algae die and decay. Substantial difference in other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) are not expected compared to the Existing Condition because levels of these constituents are primarily affected by inflow quality, which is not expected to be substantially different from the Existing Condition.

This alternative includes all the proposed measures and conditions of the Proposed Projects. This includes all proposed CWA Section 401 WQC conditions, including Condition 19, "Mercury Management" (refer to Appendix 2E). This also includes proposed Water Quality Monitoring Plan (WR8), which would involve monitoring water quality conditions in YRDP reservoirs and impoundments and YRDP-affected reaches of the North, Middle, and mainstream Yuba rivers, and in Oregon Creek. Even with the proposed water quality-related conditions and measures, the degree to which anticipated changes in water temperatures, nutrient cycling, and methylmercury formation would have an adverse effect on reservoir beneficial uses is uncertain, but it could be adverse for aquatic life and recreation-related beneficial uses.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

YRDP Impact WQ-Alt2-6: Impacts on Englebright Reservoir Water Quality from Operation of Alternative 2.

Modeling results show little to no difference in Englebright Reservoir average end-of-month storage with Alternative 2 compared to the Existing Condition (refer to Appendix 4C, Table C5-Reservoir-3). Average end-of-month storage with Alternative 2 for the full simulation period is 2

percent higher in April and May, 1 percent higher in June, and 0 percent different in the other months compared to the Existing Condition.

Modeling results also show little to no difference in end-of-month water surface elevation with Alternative 2 compared to the Existing Condition (refer to Appendix 4C, Table C5-Reservoir-4). Average end-of-month water surface elevation with Alternative 2 for the full simulation period is 1 foot higher in April, May, and June, and no different for the other months compared to the Existing Condition.

Because there would be little to no change in Englebright Reservoir end-of-month storage and water surface elevation, there would be little to no change in reservoir temperature, dissolved oxygen or nutrients. Furthermore, based on the small differences in modeled storage and water surface elevation, operation of Alternative 2 would have little to no effect on the reservoir stratification, residence time, and water depth that could affect water column mercury concentrations, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon).

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

YRDP Impact WQ-Alt2-7: Impacts on North Yuba River Water Quality below New Bullards Bar Dam from Operation of Alternative 2

Modeled North Yuba River flow rates with operation of Alternative 2 and differences from the Existing Condition are somewhat similar to those described in YRDP Impact WQ-PP-7 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C5-Flow-5). Modeled monthly average North Yuba River flow rates are higher with operation of Alternative 2 during July through November over the entire simulation period and across all water year types compared to the Existing Condition. In July through November, modeled monthly average flow rates below New Bullards Bar Dam range from 8–9 cfs for the Existing Condition and 14–58 cfs for Alternative 2 for the full simulation period. The average flow increase in these months ranges from 6–49 cfs. In December through June, modeled monthly average flow rates are lower with operation of Alternative 2. In these months, the modeled monthly average flow rate ranges from 168–657 cfs for the Existing Condition and 102–543 cfs for Alternative 2.

The modeled river temperatures with operation of Alternative 2 and differences from the Existing Condition also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the dam range from about 45–53°F for the Existing Condition and about 45–51°F for Alternative 2 for the full simulation period (refer to Appendix C, Table C5-Temp-6). Modeled monthly average temperatures are about 4–6°F lower in June through September compared to the Existing Condition. In December, January, April, and May, modeled monthly average temperatures differ from the Existing Condition by 0.0–0.1°F.

Temperature reductions in the North Yuba River at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 9–14°F lower with operation of Alternative 2 compared to the Existing

Condition (refer to Appendix 4C, Table C5-Temp-7). Modeled monthly average temperatures at the confluence range from about 45–68°F for the Existing Condition and 45–61°F for Alternative 2 for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-7, operation of Alternative 2 would not cause substantial, if any, differences in the North Yuba River dissolved oxygen, turbidity, TSS, methylmercury, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 2 would not cause exceedance of a North Yuba River water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 2 would result in a long-term measurable increase in mercury that would cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the river.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

YRDP Impact WQ-Alt2-8: Impacts on Oregon Creek Water Quality from Operation of Alternative 2

Modeled Oregon Creek flow rates with operation of Alternative 2 differences from the Existing Condition are somewhat similar to those described in YRDP Impact WQ-PP-8 for the YRDP Relicensing Project compared to the Existing Condition (refer to Appendix 4C, Table C5-Flow-6). The modeled increases are greatest in April, May, and June. In these months, modeled flow rates average 9–24 cfs for the Existing Condition and 21–54 cfs for Alternative 2. Modeled monthly average flow rates are similar to the Existing Condition for July–March and range from 3–68 cfs for both the Existing Condition and Alternative 2.

The modeled creek temperatures with operation of Alternative 2 and differences from the Existing Condition also are similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the Log Cabin Diversion Dam range from about 40–69°F for the Existing Condition and about 40–67°F for Alternative 2 for the full simulation period (refer to Appendix 4C, Table C5-Temp-8). Modeled monthly average temperatures for Alternative 2 are about 1–2°F lower in June through September compared to the Existing Condition. Temperature reductions at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 1°F lower with operation of Alternative 2 compared to the Existing Condition (refer to Appendix 4C, Table C5-Temp-9). Modeled monthly average temperatures at the confluence range from about 40–70°F for the Existing Condition and 40–69°F for Alternative 2 for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-8, operation of Alternative 2 would not cause substantial, if any, differences in Oregon Creek dissolved oxygen, turbidity, TSS, copper, iron, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 2 would not cause exceedance of an Oregon Creek water quality objective/criterion by frequency,

magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the creek. Furthermore, operation of Alternative 2 would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the creek.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

YRDP Impact WQ-Alt2-9: Impacts on the Middle Yuba River Water Quality from Operation of Alternative 2

Modeled Middle Yuba River flow rates with operation of Alternative 2 and differences from the Existing Condition would be higher than those described in YRDP Impact WQ-PP-9 for the YRDP Relicensing Project compared to the Existing Condition in all months (refer to Appendix 4C, Table C5-Flow-8). Modeled monthly average Middle Yuba River flow rates are higher year-round over the entire simulation period with operation of Alternative 2 compared to the Existing Condition. The increases are greatest, on a percent basis, in April, May, and June. In these months, modeled flow rates average 67–115 cfs for the Existing Condition and 276–483 cfs for Alternative 2. Modeled flow rates in July through March average 29–202 cfs for the Existing Condition and 44–441 cfs for Alternative 2, depending on month.

The modeled river temperatures with operation of Alternative 2 and differences from the Existing Condition are lower than those described for the YRDP Relicensing Project compared to the Existing Condition due to higher river flow rates. Modeled monthly average temperatures below Our House Diversion Dam with Alternative 2 are nearly the same as those for the Existing Condition in October through April and about 0.5–1°F lower in May through September. Modeled monthly average temperatures below the dam range from about 40–71°F for both scenarios for the full simulation period (refer to Appendix 4C, Table C5-Temp-10). Because of the higher flow rates, temperatures would be lower further downstream of the dam. Downstream of the confluence with Oregon Creek, modeled monthly average temperatures are up to about 2°F lower compared to the Existing Condition (Appendix 4C, Table C5-Temp-11). Upstream of the confluence with the North Yuba River modeled monthly average temperatures are also up to about 2°F lower compared to the Existing Condition (Appendix 4C, Table C5-Temp-12).

Therefore, for the same reasons provided in YRDP Impact WQ-PP-9, operation of Alternative 2 would not cause substantial, if any, differences in Middle Yuba River dissolved oxygen, turbidity, TSS, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 2 would not cause exceedance of a Middle Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

YRDP Impact WQ-Alt2-10: Impacts on Upper Yuba River Water Quality from Operation of Alternative 2

Modeled upper Yuba River flow rates with operation of Alternative 2 and differences from the Existing Condition would be higher than those described in YRDP Impact WQ-PP-10 for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average upper Yuba River flow rates are higher year-round over the entire simulation period with operation of Alternative 2 compared to the Existing Condition (refer to Appendix 4C, Table C5-Flow-11). Modeled flow rates below the Middle Yuba River confluence average 44–1,077 cfs for the Existing Condition and 76–1,167 cfs for Alternative 2, depending on month.

The modeled river temperatures with operation of Alternative 2 and differences from the Existing Condition would be similar to those described for the YRDP Relicensing Project compared to the Existing Condition. Modeled monthly average temperatures below the Middle Yuba River confluence range from about 40–73°F for the Existing Condition and 40–66°F for Alternative 2 for the full simulation period (refer to Appendix 4C, Table C5-Temp-13). Modeled monthly average temperatures for Alternative 2 are about 5–8°F lower in the summer compared to the Existing Condition. Temperature differences in the upper Yuba River at Colgate Powerhouse are smaller. Modeled monthly average temperatures at this location range from about 39–73°F for the Existing Condition and 39–71°F for Alternative 2 for the full simulation period (refer to Appendix 4C, Table C5-Temp-14). Modeled monthly average temperatures for Alternative 2 are about 1–4°F lower in the summer compared to the Existing Condition.

Therefore, for the same reasons provided in YRDP Impact WQ-PP-10, operation of Alternative 2 would not cause substantial, if any, differences in upper Yuba River dissolved oxygen, turbidity, TSS, mercury, chromium, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. As such, operation of Alternative 2 would not cause exceedance of an upper Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 2 would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the river.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

YRDP Impact WQ-Alt2-11: Impacts on Lower Yuba River Water Quality from Operation of Alternative 2

Modeled lower Yuba River flow rates with operation of Alternative 2 and differences from the Existing Condition are substantially higher in some months than those described in YRDP Impact WQ-PP-11 for the YRDP Relicensing Project. Modeled monthly average lower Yuba River flow rates with operation of Alternative 2 are higher particularly in November through May, and lower in July through September over the entire simulation period and across all water year types compared to the Existing Condition with differences sometimes being greater than 10 percent (refer to Appendix 4C, Tables C5-Flow-1 through C5-Flow-4).

River temperatures with operation of Alternative 2 are similar or slightly cooler during November through April, and warmer in May through October over the entire simulation period and across all water year types compared to the Existing Condition. Modeled monthly average temperatures are about 0–1°F lower in November through April and about 3–5°F warmer in June through August compared to the Existing Condition (refer to Appendix 4C, Tables C5-Temp-1 through C5-Temp-5).

As discussed in YRDP Impact WQ-Alt2-6, operation of the YRDP Relicensing Project would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) in Englebright Reservoir compared to the Existing Condition. Furthermore, operations would not affect the level that water is released from the reservoir. Therefore, the quality of water released into the lower Yuba River would be similar to the water quality under the Existing Condition.

While river flow rates would differ from the Existing Condition, sometimes by more than 10 percent, operation of Alternative 2 would not cause substantial, if any, differences in lower Yuba River dissolved oxygen, turbidity, TSS, mercury, copper, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Existing Condition. River flows could maintain dissolved oxygen levels near saturation. The higher flow rates would primarily occur in months with already comparatively higher flow rates, therefore, little to no difference in TSS, mercury, copper, or other water quality constituents (e.g., salinity-related parameters, nutrients, trace metals, organic carbon) is expected. As such, operation of Alternative 2 would not cause lower Yuba River water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

YRDP Impact WQ-Alt2-12: Impacts on the Lower Feather River, Sacramento River, and Delta from Operation of Alternative 2.

Operation of Alternative 2 would result in modified flows in the lower Yuba River. Operation of Alternative 2 does not involve alteration of existing drainage patterns in the lower Feather River, Sacramento River, or Delta. The analysis below focuses on effects to water quality of these waterbodies from modified lower Yuba River flows.

Alternative 2 operations have the potential to affect the water quality of the lower Feather River through changes to Yuba River tributary inflows. The primary way in which Alternative 2 operations could affect lower Feather River water quality is through changes in the quantity and timing of lower Yuba River inflows.

Modeling results show higher Yuba River flow rates at Marysville in October through June, particularly during November, December, April, and May, and lower flow rates in July through September (Appendix 4C, Table C5-Flow-4). For the Existing Condition, modeled monthly

average flow rates range from 541 cfs in October to 4,575 cfs in March. For Alternative 2, modeled monthly average flow rates range from 559 cfs in October to 4,685 cfs in March.

Greater Yuba River inflows to the Feather River would mean that lower Feather River water quality conditions would be more influenced by Yuba River water quality, assuming Feather River flow rates stay as they are under the Existing Condition and release rates from Oroville Reservoir are unchanged in response to the higher Yuba River flow contribution. Table 8.5-6 presents the monthly average lower Yuba River flow rates with historical monthly average flow rates for the Feather River and the Sacramento River. While comparing modeled flow rates to historical flow rates may be viewed as an "apples to oranges" comparison because of different hydrologic periods and methods for deriving the data, it does provide an indication of the relative influence that higher Yuba River outflows could have on Feather River water quality conditions.

Table 8.5-6. Comparison of Modeled Differences in Lower Yuba River Flow Rate to Historical Flow Rates for the Feather River and Sacramento River.

Month	Feather River Flow Rate Upstream of Yuba River: Historical [1] (cfs)	Sacramento River Flow Rate at Verona (downstream of Feather River): Historical [2] (cfs)	Yuba River Flow Rate near Marysville for Alternative 2: Modeled [3] (cfs)	Yuba River Flow Rate Difference from the Existing Condition: Modeled [3] (cfs)	Yuba River Flow Rate Difference as a Percent of Feather River Flow Rate	Yuba River Flow Rate Difference as a Percent of Sacramento River Flow Rate
January	6,751	27,204	3,640	179	3%	1%
February	12,676	30,194	4,276	225	2%	1%
March	12,342	30,501	4,685	110	1%	0%
April	11,532	23,020	4,087	865	8%	4%
May	8,679	17,984	3,892	647	7%	4%
June	6,363	15,252	2,794	180	3%	1%
July	6,035	14,372	1,159	-2	0%	0%
August	6,066	14,355	852	-210	-3%	-1%
September	5,794	13,853	627	-88	-2%	-1%
October	3,958	9,782	559	17	0%	0%
November	3,059	10,051	921	149	5%	1%
December	4,628	19,346	2,136	228	5%	1%

[2] Data for the Sacramento River at Verona for January 1991 through February 2025. Source: California Data Exchange Center 2025b.

[3] From Appendix 4C, Table C5-Flow-4, Average monthly flow in the lower Yuba River near Marysville under the Alternative 2 and Existing Condition scenarios over the entire simulation period and by water year type.

As shown in Table 8.5-6, the average increase in Yuba River inflow into the Feather River would be 8 percent in April, 7 percent in May, and 0–5 percent in the remaining months of the year, with the exceptions of August and September. In August and September, modeled monthly average Yuba River inflow under Alternative 2 is about 88–210 cfs lower than for the Existing Condition. For water quality constituents with concentrations that are higher in the Feather River than in the Yuba River, the increased Yuba River inflow, particularly in April and May, could improve water quality conditions in the Feather River. Examples may include further dilution of pesticides or

TSS. Conversely, for water quality constituent concentrations that are higher in the Yuba River than in the Feather River, the higher Yuba River inflow would worsen water quality downstream of the confluence for these constituents. For all other months when the change in Yuba River inflow would be 5 percent or less of background Feather River flow, water quality changes would be small and likely not measurable for most constituents.

Similarly, the average changes of higher Yuba River inflows to the Feather River would mean that water quality conditions in the Sacramento River downstream of the Feather River would be more influenced by Yuba River water quality, assuming Sacramento River flow rates stay as they are under the Existing Condition and release rates from Shasta Reservoir are unchanged in response to the higher Yuba River flow contribution to the Sacramento River. As shown in Table 8.5-6, the average changes in Yuba River flow would be 4 percent, or less, of background Sacramento River flow with most monthly average changes being 1 percent or less. Such small additional Yuba River flow contributions to the Sacramento River would not change Sacramento River water quality substantially, if even measurably, for any water quality constituent/parameter.

The modeled changes in Yuba River flows would have little to no effect on Delta water quality. Total Delta inflows from the Sacramento River, Yolo Bypass, San Joaquin River, and east side tributaries (i.e., Mokelumne, Calaveras, and Cosumnes rivers) average 21.8 million ac-ft per year. In contrast, the average additional inflow to the Delta from the Yuba River, based on the average changes in Table 8.5-6 is about 0.1 million ac-ft, which is about 0.5 percent of the annual average Delta inflow. Nevertheless, the small additional Delta inflow that could occur in April and May could result in small salinity improvements in some areas of the Delta. However, if the coordinated operations of the CVP and SWP reacts to the larger flow contribution from the Yuba River, thereby commensurately reducing concurrent releases from Shasta, Oroville, or Folsom reservoirs, then no improved salinity conditions would occur in the Delta.

Overall, these waterbodies would still be high quality waters, and these flow differences would not exacerbate CWA Section 303(d) impairments.

This discussion and the percentage of Yuba River flow rates relative to the Feather River, Sacramento River, and Delta inflow ignore the fact that implementation of Alternative 2 by Yuba Water would mean that the CVP also would be operated to release more water into the Sacramento River and the SWP would be operated to release more water into the Feather River, adding to Delta inflow. Therefore, the effects of the higher Yuba River inflow rates on water quality in these waterbodies would likely not be detectable.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the Feather River, Sacramento River, or Delta. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Therefore, impacts from operation of Alternative 2 on Feather River, Sacramento River, and Delta water quality would be **less than significant**.

YRDP Impact WQ-Alt2-13: Impacts on Surface Water Quality from Other Operation and Maintenance of Alternative 2.
Alternative 2 includes the same O&M activities as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-13, this impact would be **less than significant**.

YRDP Impact WQ-Alt2-14: Risk of Release of Pollutants due to Project Inundation in Flood Hazard Zones from YRDP Operations.
Alternative 2 consists of water storage and diversion facilities located within and adjacent to Project Area reservoirs and rivers where water levels fluctuate. In addition, some recreational facilities are located adjacent to Project Area reservoirs and rivers.

Modeling results show substantial decreases in average New Bullards Bar Reservoir and Englebright Reservoir end-of-month storage and water surface elevations compared to the Existing Condition (refer to Appendix 4C, Tables C5-Reservoir-1 through C5-Reservoir-4). Modeling results also show that peak flow rates of Project Area rivers and creeks with Alternative 2 would be the same or very similar to those that occur under the Existing Condition (refer to Appendix 4C, Figures C5-Flow-1 through C5-Flow-48). Therefore, project facilities with Alternative 2 would not be at increased risk of inundation that would result in an increased risk of release of pollutants to Project Area waterbodies compared to the Existing Condition.

Furthermore, Alternative 2 operations would not result in an increased risk of release of pollutants downstream of project facilities. Modeling results show that peak lower Yuba River flow rates with operation of Alternative 2 are similar to the Existing Condition over the entire simulation period (refer to Appendix 4C, Figures C5-Flow-1 through C5-Flow-12).

Finally, as discussed in YRDP Impact WQ-Alt2-12, operation of Alternative 2 would result in small (5% or less) changes in lower Feather River flows downstream of the confluence with the lower Yuba River when river flow rates are highest, and smaller (1% or less) changes in Sacramento River flow rates. Consequently, Alternative 2 would not result in an increased risk of release of pollutants downstream of the lower Yuba River.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.4.

YRDP Impact WQ-Alt2-15: Consistency with Water Quality Control Plans.
Alternative 2 includes the same construction, operations, and maintenance activities as the Proposed Projects. Thus, for the same reasons explained for YRDP Impact WQ-PP-15, the YRDP Relicensing Project would have **no impact** on the implementation of a water quality control plan (i.e., Basin Plan), nor would the project conflict with a water quality control plan (i.e., Basin Plan).

Narrows Impact WQ-Alt2-1: Impacts on Surface Water Quality from Operation of the Narrows Project.
Yuba Water proposes to continue to operate the Narrows Project under Alternative 2 in substantial conformance with existing operations, with minor modifications. The minor operations-related modifications that could affect water quality include operating the project to assist the YRDP with meeting instream flow requirements in the lower Yuba River at Smartsville and maintaining a

minimum water surface elevation in Englebright Reservoir. However, the effects of these operations on Englebright Reservoir and lower Yuba River compared to the Existing Condition would not be beyond those described for YRDP Impact WQ-Alt2-6 and YRDP Impact WQ-Alt2-11, respectively. Any minimal effects of the Narrows Project operations under Alternative 2 on lower Yuba River water quality would have little to no effect on the water quality of the Feather River, Sacramento River, and Delta, given modeling results that show hydrologic operations on the Yuba River have little effect on downstream hydrology, as discussed in YRDP Impact WQ-Alt2-12.

As described in Section 8.4.3, this discussion is provided for informational purposes and the appropriate comparison for impact determinations is to the Future Baseline, which is presented in Section 8.5.6.

8.5.6 Alternative 2 compared to the Future Baseline

The impact analyses below depend, in part, on differences in reservoir storage and river/creek flow rates with Alternative 2 compared to the Future Baseline. Impacts of Alternative 2 not dependent on changes in reservoir storage and river/creek flow rates related to construction, operations, and/or maintenance activities, and implementation plans are compared to the Existing Condition. Refer to Section 8.5.5 for those impacts.

YRDP Impact WQ-FAlt2-5: Impacts on New Bullards Bar Reservoir Water Quality from Operation of Alternative 2.
Modeling results show substantial decreases in New Bullards Bar Reservoir average end-of-month storage with Alternative 2 relative to the Future Baseline (refer to Appendix 4C, Table C6-Reservoir-1). Average end-of-month storage with Alternative 2 for the full simulation period is 7–11 percent lower depending on month for the full simulation period compared to the Future Baseline. Lower storage would occur across all water year types.

Modeling results also show substantial decreases in end-of-month water surface elevation with Alternative 2 compared to the Future Baseline (refer to Appendix 4C, Table C6-Reservoir-2). Average end-of-month water surface elevation with Alternative 2 for the full simulation period is 14–24 feet lower, depending on month, compared to the Future Baseline. The greatest decreases in water surface elevation are in dry years, when modeled reductions average up to 46 feet in June.

Temperature would be the water quality condition most affected by changes in reservoir end-of-month storage and water surface elevation, with the primary effect being a smaller coldwater pool. The reservoir would continue to stratify seasonally as would under the Future Baseline. The differences in reservoir residence time and potential more frequent fluctuations in water surface elevation could affect sediment wetting and drying cycles, which may affect methylmercury formation and water column concentrations. There could also be seasonal differences in nutrient cycling, which could affect primary productivity and algal blooms, which in turn could result in oxygen depletion in the reservoir hypolimnion when the algae die and decay. Substantial difference in other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Future Baseline would be unlikely because levels of these constituents are primarily affected by inflow quality, which is not expected to be substantially different from the Future Baseline.

This alternative includes all the proposed measures and conditions of the Proposed Projects. This includes all proposed CWA Section 401 WQC conditions, including Condition 19, "Mercury Management" (refer to Appendix 2E). This also includes proposed Water Quality Monitoring Plan (WR8), which would involve monitoring water quality conditions in YRDP reservoirs and impoundments and YRDP-affected reaches of the North, Middle, and mainstream Yuba rivers, and in Oregon Creek. Even with the proposed water quality-related conditions and measures, the degree to which anticipated changes in water temperatures, nutrient cycling, and methylmercury formation would have an adverse effect on reservoir beneficial uses is uncertain, but it could be adverse for aquatic life and recreation-related beneficial uses.

The SWRCB's environmental analysis in the Draft Staff Report for the updates to the Bay-Delta Plan considers potential effects to upstream reservoir water quality a potentially significant impact (SWRCB 2023, p.1-34). The SWRCB's (2023) Draft Staff Report includes "Mitigation Measure MM-SW-a,f:" to address potentially significant water quality impacts. This mitigation measure addresses mercury impacts, temperature control and reservoir management, harmful algae blooms and invasive aquatic weeds, and municipal water quality protection. However, even with implementation of this mitigation measure, the SWRCB concluded that water quality impacts would remain potentially significant (SWRCB 2023, pp.1-19, 1-34).

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to New Bullards Bar Reservoir. However, operation of Alternative 2 could result in violation of water quality standards or otherwise substantially degrade surface water quality in New Bullards Bar Reservoir. With implementation of the SWRCB's proposed mitigation, this impact would remain potentially significant. Therefore, surface water quality impacts from operation of Alternative 2 on New Bullards Bar Reservoir would be **potentially significant and unavoidable**.

YRDP Impact WQ-FAlt2-6: Impacts on Englebright Reservoir Water Quality from Operation of Alternative 2.

Modeling results show little to no difference in Englebright Reservoir average end-of-month storage with Alternative 2 compared to the Future Baseline (refer to Appendix 4C, Table C6-Reservoir-3). Average end-of-month storage with Alternative 2 for the full simulation period is 2 percent higher in April and May, 1 percent higher in June, and 0 percent different in the other months compared to the Future Baseline.

Modeling results also show little to no difference in end-of-month water surface elevation with Alternative 2 compared to the Future Baseline (refer to Appendix 4C, Table C6-Reservoir-4). Average end-of-month water surface elevation with Alternative 2 for the full simulation period is 1 foot higher in April, May, and June, and no different for the other months compared to the Future Baseline.

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-6, operation of Alternative 2 would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles,

phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) compared to the Future Baseline. As such, operation of Alternative 2 would not cause Englebright Reservoir water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the reservoir. Furthermore, operation of Alternative 2 would not result in a long-term measurable increase in mercury in the reservoir.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Englebright Reservoir. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Englebright Reservoir. Therefore, impacts on Englebright Reservoir water quality from operation of Alternative 2 would be **less than significant**.

YRDP Impact WQ-FAlt2-7: Impacts on North Yuba River Water Quality below New Bullards Bar Dam from Operation of the Alternative 2

Modeled North Yuba River flow rates with operation of Alternative 2 and differences from the Future Baseline are somewhat similar to those described in YRDP Impact WQ-FPP-7 for the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix 4C, Table C6-Flow-5). Modeled monthly average North Yuba River flow rates are higher with operation of Alternative 2 during July through November over the entire simulation period and across all water year types compared to the Future Baseline. In July through November, modeled monthly average flow rates below New Bullards Bar Dam range from 8–9 cfs for the Future Baseline and 14–58 cfs for Alternative 2 for the full simulation period. The average flow increase in these months ranges from 6–49 cfs. In December through June, modeled monthly average flow rates are lower with operation of Alternative 2. In these months, the modeled monthly average flow rate ranges from 169–663 cfs for the Future Baseline and 102–543 cfs for Alternative 2.

The modeled river temperatures with operation of Alternative 2 and differences from the Future Baseline also are similar to those described for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average temperatures below the dam range from about 45–53°F for the Future Baseline and about 45–51°F for Alternative 2 for the full simulation period (refer to Appendix C, Table C6-Temp-6). Modeled monthly average temperatures are about 4–6°F lower in June through September compared to the Future Baseline. In December, January, April, and May, modeled monthly average temperatures differ from the Future Baseline by 0.0–0.1°F.

Temperature reductions in the North Yuba River at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 9–14°F lower with operation of Alternative 2 compared to the Future Baseline (refer to Appendix 4C, Table C6-Temp-7). Modeled monthly average temperatures at the

confluence range from about 45–68°F for the Future Baseline and 45–61°F for Alternative 2 for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-7, operation of Alternative 2 would not cause substantial, if any, differences in the North Yuba River dissolved oxygen, turbidity, TSS, methylmercury, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 2 would not cause exceedance of a North Yuba River water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 2 would result in a long-term measurable increase in mercury that would cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the river.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the North Yuba River below New Bullards Bar Dam. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the North Yuba River. Therefore, impacts on the North Yuba River water quality from operation of Alternative 2 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt2-8: Impacts on Oregon Creek Water Quality from Operation of Alternative 2

Modeled Oregon Creek flow rates with operation of Alternative 2 differences from the Future Baseline are somewhat similar to those described in YRDP Impact WQ-FPP-8 for the YRDP Relicensing Project (future) compared to the Future Baseline (refer to Appendix 4C, Table C6-Flow-6). The modeled increases are greatest in April, May, and June. In these months, modeled flow rates average 9–24 cfs for the Future Baseline and 21–54 cfs for Alternative 2. Modeled monthly average flow rates are similar to the Future Baseline for July–March and range from 3–68 cfs for both the Future Baseline and Alternative 2.

The modeled creek temperatures with operation of Alternative 2 and differences from the Future Baseline also are similar to those described for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average temperatures below the Log Cabin Diversion Dam range from about 40–69°F for the Future Baseline and about 40–67°F for Alternative 2 for the full simulation period (refer to Appendix 4C, Table C6-Temp-8). Modeled monthly average temperatures for Alternative 2 are about 1–2°F lower in June through September compared to the Future Baseline. Temperature reductions at the confluence with the Middle Yuba River exhibit a similar seasonal pattern, with modeled monthly average temperatures in June through September being about 1°F lower with operation of Alternative 2 compared to the Future Baseline (refer to Appendix 4C, Table C6-Temp-9). Modeled monthly average temperatures at the confluence range from about 40–70°F for the Future Baseline and 40–69°F for Alternative 2 for the full simulation period.

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-8, operation of Alternative 2 would not cause substantial, if any, differences in Oregon Creek dissolved oxygen, turbidity, TSS, copper, iron, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 2 would not cause exceedance of an Oregon Creek water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the creek. Furthermore, operation of Alternative 2 would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the creek.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Oregon Creek. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Oregon Creek. Therefore, impacts on Oregon Creek water quality from operation of Alternative 2 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt2-9: Impacts on the Middle Yuba River Water Quality from Operation of Alternative 2

Modeled Middle Yuba River flow rates with operation of Alternative 2 and differences from the Future Baseline would be higher than those described in YRDP Impact WQ-FPP-9 for the YRDP Relicensing Project (future) compared to the Future Baseline in all months (refer to Appendix 4C, Table C6-Flow-8). Modeled monthly average Middle Yuba River flow rates are higher year-round over the entire simulation period with operation of Alternative 2 compared to the Future Baseline. The increases are greatest, on a percent basis, in April, May, and June. In these months, modeled flow rates average 64–114 cfs for the Future Baseline and 276–483 cfs for Alternative 2. Modeled flow rates in July through March average 31–201 cfs for the Future Baseline and 44–441 cfs for Alternative 2, depending on month.

The modeled river temperatures with operation of Alternative 2 and differences from the Future Baseline are lower than those described for the YRDP Relicensing Project (future) compared to the Future Baseline due to higher river flow rates. Modeled monthly average temperatures below Our House Diversion Dam with Alternative 2 are nearly the same as those for the Future Baseline with differences ranging from 0.0–0.1°F (refer to Appendix 4C, Table C6-Temp-10). Modeled monthly average temperatures below the dam range from about 40–71°F for both scenarios for the full simulation period (refer to Appendix 4C, Table C6-Temp-10). Because of the higher flow rates, temperatures would be lower further downstream of the dam. Downstream of the confluence with Oregon Creek, modeled monthly average temperatures are up to about 2°F lower compared to the Future Baseline (Appendix 4C, Table C6-Temp-11). Upstream of the confluence with the North Yuba River modeled monthly average temperatures are also up to about 2°F lower compared to the Future Baseline (Appendix 4C, Table C6-Temp-12).

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-9, operation of Alternative 2 would not cause substantial, if any, differences in Middle Yuba River dissolved oxygen, turbidity, TSS, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 2 would not cause exceedance of a Middle Yuba River water quality objective/criterion by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the Middle Yuba River. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Middle Yuba River. Therefore, impacts on the Middle Yuba River water quality from operation of Alternative 2 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt2-10: Impacts on Upper Yuba River Water Quality from Operation of Alternative 2

Modeled upper Yuba River flow rates with operation of Alternative 2 and differences from the Future Baseline would be higher than those described in YRDP Impact WQ-FPP-10 for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average upper Yuba River flow rates are higher year-round over the entire simulation period with operation of Alternative 2 compared to the Future Baseline (refer to Appendix 4C, Table C6-Flow-11). Modeled flow rates below the Middle Yuba River confluence average 46–1,084 cfs for the Future Baseline and 76–1,167 cfs for Alternative 2, depending on month.

The modeled river temperatures with operation of Alternative 2 and differences from the Future Baseline would be similar to those described for the YRDP Relicensing Project (future) compared to the Future Baseline. Modeled monthly average temperatures below the Middle Yuba River confluence range from about 40–73°F for the Future Baseline and 40–66°F for Alternative 2 for the full simulation period (refer to Appendix 4C, Table C6-Temp-13). Modeled monthly average temperatures for Alternative 2 are about 5–8°F lower in the summer compared to the Future Baseline. Temperature differences in the upper Yuba River at Colgate Powerhouse are smaller. Modeled monthly average temperatures at this location range from about 39–73°F for the Future Baseline and 39–71°F for Alternative 2 for the full simulation period (refer to Appendix 4C, Table C6-Temp-14). Modeled monthly average temperatures for Alternative 2 are about 1–4°F lower in the summer compared to the Future Baseline.

Therefore, for the same reasons provided in YRDP Impact WQ-FPP-10, operation of Alternative 2 would not cause substantial, if any, differences in upper Yuba River dissolved oxygen, turbidity, TSS, mercury, chromium, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. As such, operation of Alternative 2 would not cause exceedance of an upper Yuba River water quality objective/criterion

by frequency, magnitude or geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the river. Furthermore, operation of Alternative 2 would not cause additional water quality degradation for the CWA Section 303(d)-listed constituents in the river.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the upper Yuba River. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the upper Yuba River. Therefore, impacts on the upper Yuba River water quality from operation of Alternative 2 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt2-11: Impacts on Lower Yuba River Water Quality from Operation of Alternative 2

Modeled lower Yuba River flow rates with operation of Alternative 2 and differences from the Future Baseline are substantially higher in some months than those described in YRDP Impact WQ-FPP-11 for the YRDP Relicensing Project (future). Modeled monthly average lower Yuba River flow rates with operation of Alternative 2 are higher particularly in November through May, and lower in July through September over the entire simulation period and across all water year types compared to the Future Baseline with differences sometimes being greater than 10 percent (refer to Appendix 4C, Tables C6-Flow-1 through C6-Flow-4).

River temperatures with operation of Alternative 2 are similar or slightly cooler during November through April, and warmer in May through October over the entire simulation period and across all water year types compared to the Future Baseline. Modeled monthly average temperatures are about 0–1°F lower in November through April and about 3–5°F warmer in June through August compared to the Future Baseline (refer to Appendix 4C, Tables C6-Temp-1 through C6-Temp-5).

As discussed in YRDP Impact WQ-FAlt2-6, operation of the YRDP Relicensing Project would not cause substantial, if any, differences in the temperature and dissolved oxygen profiles, phosphorus and nitrogen cycling, methylmercury formation, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, TSS and turbidity, organic carbon) in Englebright Reservoir compared to the Future Baseline. Furthermore, operations would not affect the level that water is released from the reservoir. Therefore, the quality of water released into the lower Yuba River would be similar to the water quality under the Future Baseline.

While river flow rates would differ from the Future Baseline, sometimes by more than 10 percent, operation of Alternative 2 would not cause substantial, if any, differences in lower Yuba River dissolved oxygen, turbidity, TSS, mercury, copper, or other water quality constituents (e.g., salinity-related parameters, pesticides, trace metals, organic carbon) compared to the Future Baseline. River flows could maintain dissolved oxygen levels near saturation. The higher flow rates would primarily occur in months with already comparatively higher flow rates, therefore,

little to no difference in TSS, mercury, copper, or other water quality constituents (e.g., salinity-related parameters, nutrients, trace metals, organic carbon) is expected. As such, operation of Alternative 2 would not cause lower Yuba River water quality to differ by frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the river.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the lower Yuba River. Therefore, impacts on the lower Yuba River water quality from operation of Alternative 2 would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt2-12: Impacts on the Lower Feather River, Sacramento River, and Delta from Operation of Alternative 2

As discussed in YRDP Impact WQ-Alt2-12, Alternative 2 operations have the potential to affect the water quality of the lower Feather River through changes to Yuba River tributary inflows. Modeling results show higher Yuba River flow rates at Marysville in October through June, particularly during November, December, April, and May, and lower flow rates in July through September (Appendix 4C, Table C6-Flow-4). For the Future Baseline, modeled monthly average flow rates range from 544 cfs in October to 4,707 cfs in March. For Alternative 2, modeled monthly average flow rates range from 559 cfs in October to 4,685 cfs in March.

The lower Yuba River flow rates and the modeled differences are comparable to those described in YRDP Impact WQ-Alt2-12 for Alternative 2 compared to the Existing Condition. Therefore, for the same reasons provided in YRDP Impact WQ-Alt2-12, the changes in lower Yuba River flows with Alternative 2 would likely result in undetectable changes in the water quality of the lower Feather River, Sacramento River, and Delta water quality.

CEQA Conclusion

Based on the above analysis, operation of Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Feather River, Sacramento River, or Delta. Furthermore, operation of Alternative 2 would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Therefore, impacts on Feather River, Sacramento River, and Delta water quality from operation of the YRDP Relicensing Project would be **less than significant**. No CEQA mitigation is required.

YRDP Impact WQ-FAlt2-14: Risk of Release of Pollutants due to Project Inundation in Flood Hazard Zones from YRDP Operations

Alternative 2 consists of water storage and diversion facilities located within and adjacent to Project Area reservoirs and rivers where water levels fluctuate. In addition, some recreational facilities are located adjacent to Project Area reservoirs and rivers.

Modeling results show substantial decreases in average New Bullards Bar Reservoir and Englebright Reservoir end-of-month storage and water surface elevations compared to the Future Baseline (refer to Appendix 4C, Tables C6-Reservoir-1 through C6-Reservoir-4). Modeling results also show that peak flow rates of Project Area rivers and creeks with Alternative 2 would be the same or very similar to those that occur under the Future Baseline (refer to Appendix 4C, Figures C6-Flow-1 through 65-Flow-48). Therefore, project facilities with Alternative 2 would not be at increased risk of inundation that would result in an increased risk of release of pollutants to Project Area waterbodies compared to the Future Baseline.

Furthermore, Alternative 2 operations would not result in an increased risk of release of pollutants downstream of project facilities. Modeling results show that peak lower Yuba River flow rates with operation of Alternative 2 are similar to the Future Baseline over the entire simulation period (refer to Appendix 4C, Figures C6-Flow-1 through C6-Flow-12).

Finally, as discussed in YRDP Impact WQ-FAlt2-12, operation of Alternative 2 would result in small (5% or less) changes in lower Feather River flows downstream of the confluence with the lower Yuba River when river flow rates are highest, and smaller (1% or less) changes in Sacramento River flow rates. Consequently, Alternative 2 would not result in an increased risk of release of pollutants downstream of the lower Yuba River.

CEQA Conclusion

Based on the above discussion, Alternative 2 would have a **less-than-significant impact** on the risk of release of pollutants due to project inundation in flood hazard zones.

Narrows Impact WQ-FAlt2-1: Impacts on Surface Water Quality from Operation of the Narrows Project.

Yuba Water proposes to continue to operate the Narrows Project under Alternative 2 in substantial conformance with existing operations, with minor modifications. The minor operations-related modifications that could affect water quality include operating the project to assist the YRDP with meeting instream flow requirements in the lower Yuba River at Smartsville and maintaining a minimum water surface elevation in Englebright Reservoir. However, the effects of these operations on Englebright Reservoir and lower Yuba River compared to the Future Baseline would not be beyond those described for YRDP Impact WQ-FAlt2-6 and YRDP Impact WQ-FAlt2-11, respectively. Any minimal effects of the Narrows Project operations under Alternative 2 on lower Yuba River water quality would have little to no effect on the water quality of the Feather River, Sacramento River, and Delta, given modeling results that show hydrologic operations on the Yuba River have little effect on downstream hydrology, as discussed in YRDP Impact WQ-FAlt2-12.

CEQA Conclusion

Based on the above analysis, operation of the Narrows Project under Alternative 2 would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in the lower Yuba River, lower Feather River, Sacramento River, or Delta. Furthermore, operation of the Narrows Relicensing Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to these waterbodies. Finally, operation of the Narrows Project under Alternative 2 would not result in an increased risk of release of pollutants to Project Area waterbodies or conflict with or obstruct implementation of a water quality control plan. Therefore, impacts on Yuba River, Feather River, Sacramento River, and Delta water quality from operation of the Narrows Project under Alternative 2 would be **less than significant**. No CEQA mitigation is required.

8.5.7 No Project Alternative compared to the Existing Condition

Under the scenario where no FERC license is accepted for either the YRDP or the Narrows Project, no construction or modification to YRDP facilities or operations would occur under the No Project Alternative. Therefore, there would be no direct alteration of an existing drainage pattern and no construction-related effects on surface water quality in the Project Area.

As described in Chapter 3, Section 3.5, "No Project Alternative," generally river flow and reservoir storage conditions would be similar to those under the Existing Condition, with a few exceptions. The No Project Alternative would result in less fluctuations of river inflows into Englebright Reservoir, therefore less fluctuations in reservoir water surface elevations relative to the Existing Condition. Inflow differences would be modulated in Englebright Reservoir such that there would be no changes in lower Yuba River flows. As described in Section 8.5.1 for the Proposed Projects, small differences in river flow rates and reservoir storage fluctuations would not result in substantial, if any, differences in the surface water quality of Project Area waterbodies compared to the Existing Condition. As such, the No Project Alternative also would not change levels of CWA Section 303(d)-listed constituents by magnitude and duration that would make conditions in an impaired waterbody worse.

As described in Chapter 3, the lost revenue from hydropower sales could adversely affect Yuba Water's ability to maintain recreational facilities, restoration projects, and routine maintenance that currently occurs under the Existing Condition. The degree to which this could occur is somewhat speculative, but could mean that recreational facilities and access roads would fall into disrepair. The extent to which this could have adverse effects on surface water quality would depend on proximity of the facilities to Project Area waterbodies. Roads and trails not properly maintained could experience washouts during heavy rainfall events, which could contribute additional temporary elevated suspended sediment to adjacent waterbodies compared to the Existing Condition. Similarly, recreation sites, such as campgrounds and day use areas, that are not properly maintained could contribute to elevated suspended sediment levels in stormwater runoff, which could result in additional temporary elevated suspended sediment levels in adjacent waterbodies compared to levels under the Existing Condition. Therefore, there could be substantial

alteration of the existing drainage patterns at some YRDP sites that could result in substantial erosion or siltation. Elevated suspended sediment in adjacent Project Area waterbodies would be localized, with sediment settling out in the vicinity of the discharge and no widespread elevated suspended sediment conditions in areas downstream. Therefore, the potential additional erosion is not expected to provide substantial additional sources of polluted runoff to Project Area waterbodies such that beneficial uses would be adversely affected.

O&M activities to operate the YRDP and Narrows Project for flood control and water supply purposes would continue to occur as they do now under the Existing Condition. This includes the periodic removal and/or flushing of sediment from the impoundments behind the Our House Diversion Dam on the Middle Yuba River and Log Cabin Diversion Dam on Oregon Creek. There have been three sediment passage events at Our House Diversion Dam, two in 2017 and one in 2019 and none at Log Cabin Diversion Dam (Yuba Water 2018). Sediment removal events occurred at Log Cabin Diversion Dam in 1972, 1997, 2014, and 2017. Sediment removal events at Our House Diversion Dam occurred in 1986, 1992, 1997, 2006, and 2017. The frequency of sediment flushing and removal events would likely occur at a similar frequency under the No Project Alternative. Therefore, substantial differences in water quality in Project Area waterbodies would not occur from this O&M activity.

Other O&M activities that involve work at YRDP water conveyance facilities would likely result in little to no change in the water quality of Project waterbodies, because those activities would be similar in nature, timing, and frequency to that occurring under the Existing Condition. Maintenance of the YRDP does not involve alteration of existing drainage patterns.

Construction, operations, and maintenance activities under the scenario in which a FERC license is accepted for the YRDP but not the Narrow Project would be similar that which would occur with the Proposed Projects (refer to Chapter 3, Section 3.5, No Project Alternative). Because construction, operations, and maintenance activities for this scenario would be similar to the Proposed Projects, the effects to water quality of Project Area waterbodies from these activities would be similar to that described in Section 8.5.1 for the Proposed Projects.

Therefore, based on the above analysis, the No Project Alternative would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality of Project Area waterbodies. The No Project Alternative could result in alteration of the existing drainage pattern of a site or area that would result in substantial erosion or siltation on- or off-site, but is not expected to create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies. Finally, the No Project Alternative would not result in an increased risk of release of pollutants to Project Area waterbodies or conflict with or obstruct implementation of a water quality control plan. Therefore, the following impacts on surface water quality from the No Project Alternative would be **less than significant**.

- YRDP Impact WQ-NP-1: Impacts on Surface Water Quality from Modification of Power Generation- and Water Conveyance-Related Facilities for the YRDP Relicensing Project.
- YRDP Impact WQ-NP-2: Impacts on Surface Water Quality from Implementation of the YRDP Recreation Facilities Plan.

- YRDP Impact WQ-NP-3: Impacts on Surface Water Quality from Implementation of the YRDP Log Cabin and Our House Diversion Dams Sediment Management Plan.
- YRDP Impact WQ-NP-4: Impacts on Surface Water Quality from Other YRDP Implementation Plans.
- YRDP Impact WQ-NP-5: Impacts on New Bullards Bar Reservoir Water Quality from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-6: Impacts on Englebright Reservoir Water Quality from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-7: Impacts on North Yuba River Water Quality below New Bullards Bar Dam from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-8: Impacts on Oregon Creek Water Quality from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-9: Impacts on the Middle Yuba River Water Quality from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-10: Impacts on Upper Yuba River Water Quality from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-11: Impacts on Lower Yuba River Water Quality from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-12: Impacts on the Lower Feather River, Sacramento River, and Delta from Operation of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-13: Impacts on Surface Water Quality from Other Operations and Maintenance of the YRDP Relicensing Project.
- YRDP Impact WQ-NP-14: Risk of Release of Pollutants due to Project Inundation in Flood Hazard Zones from YRDP Relicensing Project Operations.
- YRDP Impact WQ-NP-15: Consistency with Water Quality Control Plans.
- Narrows Impact WQ-NP-1: Impacts on Surface Water Quality from Operation of the Narrows Relicensing Project.

8.6 Cumulative Impact Assessment

The cumulative impact assessment for surface water quality considers past, present, and reasonably foreseeable future projects in the Project Area in combination with the effects of the Project Projects, Alternative 1, or Alternative 2. Present and reasonably foreseeable future projects are listed in Chapter 4, Table 4.9-1, "Cumulative Project List." The geographic scope for the cumulative impact assessment is the same as that for the project-level assessment in Section 8.5, which includes waterbodies in the Yuba River watershed downstream to the Delta.

If a cumulative water quality condition is determined to be significant relative to the Existing Condition, then further assessment is conducted to determine whether the individual contribution of the Proposed Projects or alternatives to the significant cumulative condition would be

"cumulatively considerable," thus significant. Table 8.6-1 presents the comparisons evaluated to identify cumulatively significant impacts.

Table 8.6-1. Summary of Cumulative Scenario Comparisons for Project and Alternative Impact Determinations.

Scenario Name	Basis of Comparison
Cumulative Condition (Proposed Projects)	Existing Condition
Cumulative Condition (Alternative 1)*	Existing Condition
Cumulative Condition (Alternative 2)*	Existing Condition

*Includes YB/DS with FERC 4(e) conditions.

The discussion of cumulative impacts is organized into three separate sections: (1) upper Yuba River watershed (i.e., waterbodies upstream of Englebright Dam); (2) lower Yuba River (i.e., downstream of Englebright Dam); and (3) areas downstream of the lower Yuba River. This organization corresponds to the grouping of cumulative projects in Table 4.9-1.

8.6.1 Cumulative Condition with Proposed Projects compared to the Existing Condition

8.6.1.1 Upper Yuba River Watershed

Water in the Project Area reservoirs, rivers, and creeks in the upper Yuba River watershed is of generally good quality and meets Basin Plan objectives for the majority of constituents in the majority of locations (refer to Section 8.2.2). However, several waterbodies are CWA Section 303(d)-listed as impaired due to high levels of specific constituents (refer to Section 8.2.2). The North Yuba River, upper Yuba River (confluence of North and Middle Yuba Rivers to Englebright Reservoir), New Bullards Bar Reservoir, and Englebright Reservoir are listed as impaired for mercury. The upper Yuba River is also listed for chromium impairments. Oregon Creek is listed for copper and iron impairments.

Regulatory efforts are underway to address mercury impairments in Project Area waterbodies, such as restrictions on suction dredging and continued cleanup actions on mine drainage in the upper watershed. The SWRCB is developing a statewide mercury control program for reservoirs and a Central Valley mercury control program for rivers. Although positive mercury reduction efforts are likely to continue into the foreseeable future, a key challenge surrounds the pool of mercury deposited in the watershed that cannot be readily or rapidly reduced and serves as a source for continued methylation and bioaccumulation by biota. Also, atmospheric deposition of mercury is expected to continue in the future. Thus, mercury-related impairments are expected to part of the cumulative water quality condition in Project Area waterbodies, but not exacerbated by the cumulative projects, including the Proposed Projects, as explained further below. As discussed in the impact analyses in Section 8.5.1, the degree to which Project Area waterbodies are actually impaired for copper, iron, and chromium is uncertain based on the data used for the CWA Section 303(d) listings and current science on effects thresholds.

The future cumulative water quality condition of waterbodies within the upper Yuba River watershed with the cumulative projects listed in Table 4.9-1 is expected to be similar to the Existing Condition and waterbody impairments are not expected to be measurably worse, as

explained below. Much of the upper Yuba River watershed is rural and forested and these land uses are expected to continue into the foreseeable future. Thus, no new, sustained point source contributions of contaminants are anticipated that would result in a worsening of water quality in upper Yuba River watershed waterbodies compared to the Existing Condition.

The cumulative projects listed in Table 4.9-1 occurring in the upper Yuba River watershed consist of forest restoration and fuels reduction, as well as the YB/DS FERC relicensing projects, which involve facility construction, modifications to operations related to minimum flows and ramping rates, maintenance activities, recreation facility improvements, and other implementation plans. The forest restoration and fuels reductions projects may result in ground disturbances, resulting in some risk of water quality degradation or exceedance of water quality standards, however, those effects would be temporary and limited to the immediate vicinity of the work area. The YB/DS FERC relicensing projects also could have some limited, temporary effects on water quality from construction activities. However, construction-related BMPs would be expected to be implemented to minimize effects, and the projects are subject to a CWA Section 401 WQC. YB/DS operations-related changes in waterbody flow rates would not be expected to result in substantial, if any, changes in water quality given that the source waters would be the same, only the quantity of water in the project reservoirs and downstream rivers and creeks would differ somewhat on a seasonal basis.

Yuba Water's ARC Spillway also is a cumulative project listed in Table 4.9-1, which would be implemented at New Bullards Bar Dam. Yuba Water previously identified and adopted mitigation measures to reduce the water quality impacts associated with ARC Spillway operations to a less-than-significant level. As explained in Chapter 2, these previously adopted mitigation measures for ARC Spillway operations have been incorporated into the YRDP Relicensing Project and will continue to apply to ARC Spillway operations under the YRDP Relicensing Project. Furthermore, the ARC Spillway project includes mitigation measures to address potential construction-related impacts to water quality. The adopted mitigation measures will ensure that the water quality impacts from ARC Spillway project will be mitigated to a less-than-significant level.

As described for the Proposed Projects in Section 8.5.1, YRDP Impact WQ-PP-1, construction associated with YRDP water conveyance facilities would occur at separate locations adjacent to different Project Area waterbodies and would be of short duration (i.e., 6 months or less). Construction activities associated with the implementation plans, including the *Recreation Facilities Plan*, similarly would be of relatively short duration (i.e., about 1 year or less) and at separate locations, as described in YRDP Impacts WQ-PP-2 and WQ-PP-4. Furthermore, the YRDP includes implementation plans for hazardous materials management, erosion and sediment control, and vegetation management that would reduce the potential discharge of pollutants from construction activities to surface waterbodies in the Project Area. The SWPPPs that would be required by the SWRCB's Construction Stormwater General Permit, where there would be a disturbance of one acre or more, would require application of construction BMPs to minimize and control discharges of pollutants to surface waters. Finally, the YRDP would be subject to requirements in the SWRCB-issued CWA Section 401 WQC. With implementation of the YRDP Relicensing Project control measures and BMPs, any construction-related effect of the YRDP Relicensing Project on surface water quality would be of small magnitude, geographically limited, and temporary in nature. YRDP construction activities would not combine with the cumulative projects in Table 4.9-1 to cause exceedance of a water quality objective/criterion by frequency,

magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of upper Yuba River watershed waterbodies. Because no new facilities are proposed for the Narrows Relicensing Project, there is no potential for cumulative impacts on water quality from construction activities related to this project.

Operation of the Project Projects also would negligibly affect cumulative water quality conditions of Project Area waterbodies in the upper Yuba River watershed. Differences in modeled reservoir storage and river/creek flow rates and temperatures for the cumulative condition with the Proposed Projects are very similar to or identical to those described for the Proposed Projects relative to the Existing Condition in Section 8.5.1 (refer to Appendix 4B, "Summary of Changes in Modeled Riverine Flows and Water Temperatures" and Appendix 4C, "Hydrologic and Water Temperature Data Products"). Therefore, for the same reasons provided in Section 8.5.1, YRDP Impact WQ-PP-5 through YRDP WQ-PP-10 and Narrows Impact WQ-PP-1, water quality of upper Yuba River watershed Project Area waterbodies would be negligibly affected by operation of the Proposed Projects. Operations for some projects listed in Table 4.9-1 could result in modifications to river flow regimes and reservoir storage compared to the Existing Condition, such as the YB/DS FERC relicensing projects in the upper Yuba River watershed. The waterbodies that would be affected by operation of Proposed Projects do not overlap with the YB/DS FERC relicensing waterbodies and these projects would not change sources of contaminants within the watershed, which are not significant given that the watershed is largely undeveloped. Therefore, the cumulative effect of operation of the Proposed Projects combined with the projects listed in Table 4.9-1 in the upper Yuba River watershed would not result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies in the upper Yuba River watershed.

Implementation of the YRDP *Recreation Facilities Plan*, *Sediment Management Plan*, and other implementation plans, along with routine O&M also would have minimal effect on water quality constituents in Project Area waterbodies in the upper Yuba River watershed, as described in YRDP Impacts WQ-PP-2 through WQ-PP-4, and WQ-PP-13. While the implementation plan activities and routine O&M would overlap in time with project operations and the cumulative projects listed in Table 4.9-1, the potential effects to water quality would not combine with these other project components to result in cumulative conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies in the upper Yuba River watershed due to the geographic separation of these activities in the watershed and the BMPs that would be in place, as relevant to the activity, to minimize discharges to Project Area waterbodies.

Based on the above analysis, the cumulative condition, including the Proposed Projects, would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Project Area waterbodies in the upper Yuba River watershed. Furthermore, the cumulative condition, including the Proposed Projects, would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that

would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies in the upper Yuba River watershed. Where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. Therefore, under the Cumulative Condition, including the Proposed Projects, the cumulative impact on water quality of Project Area waterbodies in the upper Yuba River watershed would be less than significant.

8.6.1.2 Lower Yuba River

Lower Yuba River water quality is of generally good quality and meets Basin Plan objectives for the majority of constituents (refer to Section 8.2.2). However, the lower Yuba River is CWA Section 303(d)-listed as impaired related to elevated concentrations of mercury and copper. As described above for the upper Yuba River watershed, regulatory efforts are underway to address mercury impairments, while there is some uncertainty regarding the degree to which the river has actual copper-related impairments when all relevant data and current science on effects thresholds are considered.

The future cumulative water quality condition of the lower Yuba River with the cumulative projects listed in Table 4.9-1 is expected to be generally similar to the Existing Condition. As described in Section 8.6.1.1, water quality of upper Yuba River watershed waterbodies is expected to be similar to the Existing Condition with the cumulative projects, including the Proposed Projects. Therefore, the water released into the lower Yuba River from Englebright Reservoir is expected to be similar to the Existing Condition.

Cumulative projects listed in Table 4.9-1 that could affect the lower Yuba River involve water supply management and transfer, minimum instream flows for fish habitat improvements, habitat restoration, and levee and flood protection improvements, among others. To the extent that projects in the vicinity of the lower Yuba River involve construction, those activities would be expected to have a limited effect on water quality due to implementation of construction BMPs, and effects would be temporary. Water supply and transfer projects could result in seasonal and water year-type differences in river flow rates, but water quality of the waterbodies downstream of the lower Yuba River would be expected to be similar to the Existing Condition given that the source waters would be the same, only the quantity of water would differ seasonally.

YRDP Relicensing Project construction activities would be limited to areas upstream of Englebright Reservoir. Given the construction-related BMPs that would be implemented and the volume of potential discharges relative to upstream river flow rates and reservoir volumes, project construction in the upper Yuba River watershed would not affect cumulative lower Yuba River water quality conditions. Because no new facilities are proposed for the Narrows Relicensing Project, there is no potential for cumulative impacts on water quality from construction activities related to this project.

Operation of the Project Projects also would negligibly affect cumulative water quality conditions in the lower Yuba River. Differences in modeled river flow rates and temperatures for the cumulative condition with the Proposed Projects are very similar to or identical to those described for the Proposed Projects relative to the Existing Condition in Section 8.5.1 (refer to Appendix 4B and Appendix 4C for modeling results). Therefore, for the same reasons provided in Section 8.5.1,

YRDP Impact WQ-PP-11 and Narrows Impact WQ-PP-1 regarding water operations-related impacts, lower Yuba River water quality would be negligibly affected by operation of the Proposed Projects. Similarly, as discussed above, lower Yuba River water quality with the cumulative projects listed in Table 4.9-1 is expected to be similar to the Existing Condition. Therefore, the cumulative effect of operation of the Proposed Projects combined with the projects listed in Table 4.9-1 would not result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the lower Yuba River.

Proposed Project implementation plan activities and routine O&M would overlap in time with project operations and the cumulative projects listed in Table 4.9-1, however, the potential for these activities to affect lower Yuba River water quality would be limited, as these activities would occur primarily upstream of Englebright Dam. Therefore, the potential effects to water quality would not combine with these other project components to result in cumulative conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the lower Yuba river due to the geographic separation of these activities in the watershed and the BMPs that would be in place, as relevant to the activity, to minimize discharges to Project Area waterbodies.

Based on the above analysis, the cumulative condition, including the Proposed Projects, would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade lower Yuba River water quality. Furthermore, the cumulative condition, including the Proposed Projects, would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the lower Yuba River. Where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. Therefore, under the Cumulative Condition, including the Proposed Projects, the cumulative impact on water quality of the lower Yuba River would be less than significant.

8.6.1.3 Areas Downstream of the Lower Yuba River

Feather River, Sacramento River, and Delta waters are generally of good quality and suitable to support designated beneficial uses (refer to Section 8.2.3). However, these waterbodies are CWA Section 303(d)-listed for certain constituent impairments (refer to Section 8.2.3).

Cumulative projects listed in Table 4.9-1 affecting areas downstream of the lower Yuba River consist primarily of FERC relicensing, water storage and conveyance projects, and the ongoing update to the Bay-Delta Plan. Some of these projects could result in seasonal and water year-type differences in tributary river flow rates, which could affect water quality of these downstream waterbodies, depending on the seasonal timing and flow rate changes.

On the Feather River and Sacramento River, the FERC relicensing projects and coordinated operations of the SWP and CVP could affect river flow rates, but river water quality would be expected to be similar to the Existing Condition given that the source waters would be the same, only the quantity of water may differ seasonally.

FERC relicensing projects, coordinated long-term operation of the CVP and SWP, water transfers, the Sites Reservoir Project, the Bay-Delta Update (and associated proposed Healthy Rivers and Landscapes Program), and the Delta Conveyance Project could alter Delta inflows relative to the Existing Condition, which could alter water quality conditions, particularly for salinity-related constituents (e.g., electrical conductivity, chloride, bromide). Generally, these projects would be required to be operated or implemented to ensure compliance with Bay-Delta Plan water quality objectives for protection of beneficial uses, including agricultural, municipal and industrial, and fish and wildlife beneficial uses. Furthermore, projects involving construction would include BMPs and other measures to minimize or mitigate impacts on water quality.

Cumulative Delta water quality conditions will also be affected by urban development and agricultural land uses in the watershed and associated nonpoint source discharges, climate change effects on sea level rise and associated salinity intrusion, and changes in water quality regulations (e.g., completion of TMDLs, adoption of new or more restrictive criteria/objectives). The associated effects on Delta water quality will vary. Urban development may produce increased constituent loadings to Delta waters through increased urban stormwater runoff and increased municipal wastewater discharges. Sea level rise is anticipated to cause salinity increases in the western and southern Delta. Conversely, water quality regulations, such as NPDES permit requirements imposed on urban stormwater runoff and municipal wastewater dischargers, completion of TMDLs to lessen or eliminate existing beneficial use impairments through improved water quality, and new or more restrictive water quality objectives adopted to reflect updated science regarding effects on beneficial uses generally would result in improvements in Delta water quality.

The cumulative effects of the cumulative projects listed Table 4.9-1, the Proposed Projects, future development, and regulatory actions on Delta water quality are uncertain given the scope and complexity of how these factors interact to affect Delta water quality. Given the uncertainty, this analysis concludes that cumulative effect of these projects and factors could result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the Delta.

The cumulative condition, including the Proposed Projects, is not expected to substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Delta. Furthermore, where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. However, based on the above analysis, the cumulative condition, including the Proposed Projects, could substantially degrade surface water quality in the Delta. Therefore,

under the cumulative condition, including the Proposed Projects, the cumulative impact on Delta water quality is considered significant.

YRDP Relicensing Project construction activities would be limited to areas upstream of Englebright Dam. Because no new facilities are proposed for the Narrows Relicensing Project there would be no cumulative impacts on Delta water quality resulting from construction activities related to this project. Furthermore, based on analysis presented in Section 8.5.1, YRDP Impact WQ-PP-12, operation of the Proposed Projects would not result in detectable changes in Feather River flows downstream of the Yuba River, the Sacramento River downstream of the Feather River, or the Delta compared to the Existing Condition. Therefore, the Proposed Projects' incremental contribution to the cumulative impact on Feather River, Sacramento River, and Delta water quality would not be cumulatively considerable.

8.6.1.4 Cumulative Impact Determination

YRDP Cumulative Impact WQ-PP-1. Cumulative Impacts on Surface Water Quality from Construction, Operation, and Maintenance of the YRDP
Based on the above discussion, the cumulative water quality condition, including the YRDP Relicensing Project, in Project Area waterbodies within the upper Yuba River watershed, lower Yuba River, the Feather River, and Sacramento River would be less than significant. However, the cumulative water quality condition in the Delta, including the YRDP Relicensing Project, could be significant. The YRDP Relicensing Project contribution to the significant cumulative water quality condition in the Delta would not be cumulatively considerable. As such the YRDP Relicensing Project would result in a **less than significant cumulative impact** on water quality.

Narrows Cumulative Impact WQ-PP-1. Cumulative Impacts on Surface Water Quality from Operation and Maintenance of the Narrows Project
Based on the above discussion, the cumulative water quality condition, including the Narrows Relicensing Project, in Project Area waterbodies downstream of the project (i.e., the lower Yuba River, the Feather River, and Sacramento River) would be less than significant. However, the cumulative water quality condition in the Delta, including the Narrows Relicensing Project, could be significant. The Narrows Relicensing Project contribution to the significant cumulative water quality condition in the Delta would not be cumulatively considerable. As such the Narrows Relicensing Project would result in a **less than significant cumulative impact** on water quality.

8.6.2 Cumulative Condition with Alternative 1 compared to the Existing Condition

8.6.2.1 Upper Yuba River Watershed

The future cumulative water quality conditions in Project Area reservoirs, rivers, and creeks in the upper Yuba River watershed considering past, present, and reasonably foreseeable projects listed in Table 4.9-1, with Alternative 1, would be similar to the cumulative water quality conditions that would occur with the Proposed Projects, as described in Section 8.6.1.1. The primary reason for cumulative water quality conditions with Alternative 1 being similar to cumulative conditions with the Proposed Projects is that the mechanisms by which the projects could affect water quality in

upper Yuba River watershed waterbodies would be the same. There could be some differences in the YB/DS reservoirs and waterbodies downstream of these reservoirs, as explained below.

Alternative 1 includes a contribution of 15,600 ac-ft of water from the YB/DS projects that would be provided under new FERC licenses for those projects. As described in YRDP Indirect Impact WQ-Alt1-1, operations under Alternative 1 could result in lower YB/DS reservoir storage in affected reservoirs and modified flow rates in the rivers and creeks downstream of the YB/DS reservoirs. Differences in water quality constituent levels are not anticipated given that the watershed inputs to the reservoirs and inflow quality would be the same as under the Existing Condition. There could be some minor differences in downstream river and creek TSS and turbidity, but differences in other water quality constituent levels are not anticipated, given that the watershed inputs to the rivers and creeks would be the same as under the Existing Condition.

For the same reasons provided for the Proposed Projects, Alternative 1 construction activities for the YRDP would not combine with the cumulative projects in Table 4.9-1 to cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of upper Yuba River watershed waterbodies. Because no new facilities are proposed for the Narrows Project under Alternative 1, there is no potential for cumulative impacts on water quality from construction activities related to this project.

Operation of Alternative 1 also would negligibly affect cumulative water quality conditions of Project Area waterbodies in the upper Yuba River watershed. Differences in modeled reservoir storage and river/creek flow rates and temperatures for the cumulative condition with Alternative 1 are very similar to or identical to those described for Alternative 1 relative to the Existing Condition in Section 8.5.3 (refer to Appendix 4B and Appendix 4C for modeling results). Therefore, for the same reasons provided in Section 8.5.3, YRDP Impact WQ-Alt1-5 through YRDP WQ-Alt1-10 and Narrows Impact WQ-Alt1-1,water quality of upper Yuba River watershed Project Area waterbodies would be negligibly affected by operations-related effects on reservoir storage and river/creek flow rates under Alternative 1.

Alternative 1 would include the same non-flow components as the Proposed Projects, including implementation plans, and routine O&M activities. Therefore, for the same reasons provided in Section 8.6.1.1 for the Proposed Projects, the cumulative projects listed in Table 4.9-1 would not combine with these other project components to result in cumulative conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of Project Area waterbodies in the upper Yuba River watershed due to the geographic separation of these activities in the watershed and the BMPs that would be in place, as relevant to the activity, to minimize discharges to Project Area waterbodies.

Therefore, the cumulative condition, including Alternative 1, would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade surface water quality in Project Area waterbodies in the upper Yuba River watershed. Furthermore, the cumulative condition, including Alternative 1, would not substantially alter the existing drainage

pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to Project Area waterbodies in the upper Yuba River watershed. Where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. Therefore, under the cumulative condition, including Alternative 1, the cumulative impact on water quality of Project Area waterbodies in the upper Yuba River watershed would be less than significant.

8.6.2.2 Lower Yuba River

The future cumulative water quality conditions in the lower Yuba River considering past, present, and reasonably foreseeable projects listed in Table 4.9-1, with Alternative 1, would be similar to the cumulative water quality conditions that would occur with the Proposed Projects, described in Section 8.6.1.1. The primary reason for cumulative water quality conditions with Alternative 1 being similar to cumulative conditions with the Proposed Projects is that the mechanisms by which the projects could affect water quality in the lower Yuba River would be the same.

YRDP Relicensing Project construction activities would be limited to areas upstream of Englebright Reservoir. Given the construction-related BMPs that would be implemented and the volume of potential discharges relative to upstream river flow rates and reservoir volumes, project construction in the upper Yuba River watershed would not affect cumulative lower Yuba River water quality conditions. Because no new facilities are proposed for the Narrows Relicensing Project, there is no potential for cumulative impacts on water quality from construction activities related to this project.

Operation of Alternative 1 also would negligibly affect cumulative water quality conditions in the lower Yuba River. Differences in modeled river flow rates and temperatures for the cumulative condition with Alternative 1 are very similar to or identical to those described for Alternative 1 relative to the Existing Condition in Section 8.5.3 (refer to Appendix 4B and Appendix 4C for modeling results). Therefore, for the same reasons as provided in Section 8.5.3, YRDP Impact WQ-Alt1-11 and Narrows Impact WQ-Alt1-1 regarding water operations-related impacts, lower Yuba River water quality would be negligibly affected by operation of Alternative 1. Similarly, as discussed above, lower Yuba River water quality with the cumulative projects listed in Table 4.9-1 is expected to be similar to the Existing Condition. Therefore, the cumulative effect of operation of Alternative 1 combined with the projects listed in Table 4.9-1 would not result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the lower Yuba River.

As discussed in Section 8.6.1.2 for the Proposed Projects, implementation plan activities and routine O&M with Alternative 1 would overlap in time with project operations and the cumulative projects listed in Table 4.9-1, however, the potential for these activities to affect lower Yuba River water quality would be limited, as these activities would occur primarily upstream of Englebright Dam. Therefore, the potential effects to water quality would not combine with these other project components to result in cumulative conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse

effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the lower Yuba river due to the geographic separation of these activities in the watershed and the BMPs that would be in place, as relevant to the activity, to minimize discharges to Project Area waterbodies.

Therefore, the cumulative condition, including Alternative 1, would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade lower Yuba River water quality. Furthermore, the cumulative condition, including Alternative 1, would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the lower Yuba River. Where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. Therefore, under the cumulative condition, including Alternative 1, the cumulative impact on water quality of the lower Yuba River would be less than significant.

8.6.2.3 Areas Downstream of the Lower Yuba River

For same reasons described for the Proposed Projects in Section 8.6.1.3, Feather River and Sacramento River water quality under the cumulative condition is expected to be similar to the Existing Condition given that the source waters would be the same, only the quantity of water may differ seasonally. Cumulative Delta water quality conditions are uncertain given the scope and complexity of the factors that interact to affect Delta water quality. Given the uncertainty, the cumulative condition could result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the Delta.

As such, the cumulative condition, including Alternative 1, is not expected to substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Delta. Furthermore, where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. However, based on the above analysis, the cumulative condition, including Alternative 1, could substantially degrade surface water quality in the Delta. Therefore, under the cumulative condition, including Alternative 1, the cumulative impact on Delta water quality is considered significant.

YRDP construction activities under Alternative 1 would be limited to areas upstream of Englebright Dam. Because no new facilities are proposed for the Narrows Project under Alternative 1 there would be no cumulative impacts on Delta water quality resulting from construction activities related to this alternative. Furthermore, based on analysis presented in Section 8.5.3, YRDP Impact WQ-Alt1-12, operation of Alternative 1 would not result in detectable changes in Feather River flows downstream of the Yuba River, the Sacramento River downstream

of the Feather River, or the Delta compared to the Existing Condition. Therefore, the incremental contribution of Alternative 1 to the cumulative impact on Feather River, Sacramento River, and Delta water quality would not be cumulatively considerable.

8.6.2.4 Cumulative Impact Determination

YRDP Cumulative Impact WQ-Alt1-1. Cumulative Impacts on Surface Water Quality from Construction, Operation, and Maintenance of the YRDP
Based on the above discussion, the cumulative water quality condition, including Alternative 1, in Project Area waterbodies within the upper Yuba River watershed, lower Yuba River, the Feather River, and Sacramento River would be less than significant. However, the cumulative water quality condition in the Delta, including Alternative 1, could be significant. The contribution of Alternative 1 to the significant cumulative water quality condition in the Delta would not be cumulatively considerable. As such Alternative 1 would result in a **less than significant** cumulative impact on water quality.

Narrows Cumulative Impact WQ-Alt1-1. Cumulative Impacts on Surface Water Quality from Operation and Maintenance of the Narrows Project
Based on the above discussion, the cumulative water quality condition, including Alternative 1, in Project Area waterbodies downstream of the Narrows Project (i.e., the lower Yuba River, the Feather River, and Sacramento River) would be less than significant. However, the cumulative water quality condition in the Delta, including Alternative 1, could be significant. The contribution of Alternative 1 to the significant cumulative water quality condition in the Delta would not be cumulatively considerable. As such Alternative 1 would result in a **less than significant** cumulative impact on water quality.

8.6.3 Cumulative Condition with Alternative 2 compared to the Existing Condition

8.6.3.1 Upper Yuba River Watershed

For the same reasons provided for the Proposed Projects, Alternative 2 construction activities for the YRDP would not combine with the cumulative projects in Table 4.9-1 to cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of upper Yuba River watershed waterbodies. Because no new facilities are proposed for the Narrows Project under Alternative 2, there is no potential for cumulative impacts on water quality from construction activities related to this project.

Also, Alternative 2 would include the same non-flow components as the Proposed Projects, including implementation plans, and routine O&M activities. Therefore, for the same reasons provided in Section 8.6.1.1 for the Proposed Projects, the cumulative projects listed in Table 4.9-1 would not combine with these other project components to result in cumulative conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial

uses of Project Area waterbodies in the upper Yuba River watershed due to the geographic separation of these activities in the watershed and the BMPs that would be in place, as relevant to the activity, to minimize discharges to Project Area waterbodies.

Operation of Alternative 2 involves implementation of the SWRCB's proposed update to the Bay-Delta Plan regarding providing specified unimpaired flows in the Yuba River watershed rivers and minimum end-of-September reservoir storage (refer to Chapter 3, Section 3.4 for additional information). The relevant future cumulative condition for this alternative is implementation of the Bay-Delta Plan update across the entire Sacramento River watershed, as analyzed by the SWRCB in its Draft Staff Report for the update (SWRCB 2023).

Operation of Alternative 2 has the potential to result in adverse cumulative water quality condition in New Bullards Bar Reservoir. Differences in modeled New Bullards Bar Reservoir storage for the cumulative condition with Alternative 2 are very similar to or identical to those described for Alternative 2 relative to the Existing Condition in Section 8.5.5, YRDP Impact WQ-Alt2-5 (refer to Appendix 4B and Appendix 4C for modeling results). Therefore, for the same reasons provided in Section 8.5.5, YRDP Impact WQ-Alt2-5, Alternative 2 would have a potentially significant impact to New Bullards Bar Reservoir water quality due to potential effects on reservoir temperature, nutrients, dissolved oxygen, and methylmercury, which could have adverse effects on beneficial uses.

Operation of Alternative 2 would negligibly affect cumulative water quality conditions of other Project Area waterbodies in the upper Yuba River watershed. Differences in modeled Englebright Reservoir storage and river/creek flow rates and temperatures for the cumulative condition with Alternative 2 are very similar to or identical to those described for Alternative 2 relative to the Existing Condition in Section 8.5.5 (refer to Appendix 4B and Appendix 4C for modeling results). Therefore, for the same reasons provided in Section 8.5.5, YRDP Impact WQ-Alt2-6 through YRDP WQ-Alt2-10 and Narrows Impact WQ-Alt1-1,water quality of other upper Yuba River watershed Project Area waterbodies would be negligibly affected by operations-related effects on reservoir storage and river/creek flow rates under Alternative 2.

As such, the cumulative condition, including Alternative 2, is not expected to substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Delta. Furthermore, where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. However, based on the above analysis, the cumulative condition, including Alternative 2, could substantially degrade New Bullards Bar Reservoir water quality. Therefore, under the cumulative condition, including Alternative 2, the cumulative impact on New Bullards Bar Reservoir water quality is considered significant. YRDP operations under Alternative 2 would be responsible for these adverse water quality effects. Therefore, Alternative 2 would have a cumulatively considerable contribution to the potentially significant cumulative impact on New Bullards Bar Reservoir water quality.

The SWRCB similarly concluded that the proposed Bay-Delta Plan amendments, when combined with relevant projects and programs, would result in a potentially significant cumulative impact to water quality (SWRCB 2023, p. 7.23-49). Potential water quality impacts included increases in contaminant concentrations in waterbodies downstream of reservoirs, increased methylmercury production and increased harmful algal blooms in reservoirs (SWRCB 2023, pp. 7.23-49–7.23-50).

8.6.3.2 Lower Yuba River

The future cumulative water quality conditions in the lower Yuba River considering past, present, and reasonably foreseeable projects listed in Table 4.9-1 with Alternative 2 would be similar to the cumulative water quality conditions that would occur with the Proposed Projects, described in Section 8.6.1.1. The primary reason for cumulative water quality conditions with Alternative 2 being similar to cumulative conditions with the Proposed Projects is that the mechanisms by which the projects could affect water quality in the lower Yuba River would be the same.

YRDP Relicensing Project construction activities would be limited to areas upstream of Englebright Reservoir. Given the construction-related BMPs that would be implemented and the volume of potential discharges relative to upstream river flow rates and reservoir volumes, project construction in the upper Yuba River watershed would not affect cumulative lower Yuba River water quality conditions. Because no new facilities are proposed for the Narrows Relicensing Project, there is no potential for cumulative impacts on water quality from construction activities related to this project.

Operation of Alternative 2 also would negligibly affect cumulative water quality conditions in the lower Yuba River. Differences in modeled river flow rates and temperatures for the cumulative condition with Alternative 2 are very similar to or identical to those described for Alternative 2 relative to the Existing Condition in Section 8.5.5 (refer to Appendix 4B and Appendix 4C for modeling results). Therefore, for the same reasons as provided in Section 8.5.5, YRDP Impact WQ-Alt1-11 and Narrows Impact WQ-Alt1-1 regarding water operations-related impacts, lower Yuba River water quality would be negligibly affected by operation of Alternative 2. Similarly, as discussed above, lower Yuba River water quality with the cumulative projects listed in Table 4.9-1 is expected to be similar to the Existing Condition. Therefore, the cumulative effect of operation of Alternative 2 combined with the projects listed in Table 4.9-1 would not result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the lower Yuba River.

As discussed in Section 8.6.1.2 for the Proposed Projects, implementation plan activities and routine O&M with Alternative 2 would overlap in time with project operations and the cumulative projects listed in Table 4.9-1, however, the potential for these activities to affect lower Yuba River water quality would be limited, as these activities would occur primarily upstream of Englebright Dam. Therefore, the potential effects to water quality would not combine with these other project components to result in cumulative conditions that would cause exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the lower Yuba river due to the geographic separation of these activities in the watershed and the BMPs that would be in place, as relevant to the activity, to minimize discharges to Project Area waterbodies.

Therefore, the cumulative condition, including Alternative 2, would not result in violation of water quality standards or waste discharge requirements or otherwise substantially degrade lower Yuba River water quality. Furthermore, the cumulative condition, including Alternative 2, would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the lower Yuba River. Where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. Therefore, under the cumulative condition, including Alternative 2, the cumulative impact on water quality of the lower Yuba River would be less than significant.

8.6.3.3 Areas Downstream of the Lower Yuba River

For same reasons described for the Proposed Projects in Section 8.6.1.3, Feather River and Sacramento River water quality under the cumulative condition is expected to be similar to the Existing Condition given that the source waters would be the same, only the quantity of water may differ seasonally. Cumulative Delta water quality conditions are uncertain given the scope and complexity of the factors that interact to affect Delta water quality. Given the uncertainty, the cumulative condition could result in exceedance of a water quality objective/criterion by frequency, magnitude, and geographic extent that would result in adverse effects on beneficial uses, or substantial long-term degradation of water quality that would increase the likelihood of adverse effects on beneficial uses of the Delta.

As such, the cumulative condition, including Alternative 2, is not expected to substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or through the addition of impervious surfaces, in a manner that would result in substantial erosion or siltation on- or off-site or create or contribute runoff water that would provide substantial additional sources of polluted runoff to the Delta. Furthermore, where relevant, cumulative projects would be subject to environmental regulatory permits, such as a CWA Section 401 WQC or waste discharge requirements, which would result in implementation of the applicable Basin Plan. However, based on the above analysis, the cumulative condition, including Alternative 2, could substantially degrade surface water quality in the Delta. Therefore, under the cumulative condition, including Alternative 2, the cumulative impact on Delta water quality is considered significant.

YRDP construction activities under Alternative 2 would be limited to areas upstream of Englebright Dam. Because no new facilities are proposed for the Narrows Project under Alternative 2 there would be no cumulative impacts on Delta water quality resulting from construction activities related to this alternative. Furthermore, based on analysis presented in Section 8.5.5, YRDP Impact WQ-Alt2-12, operation of Alternative 2 would not result in detectable changes in Feather River flows downstream of the Yuba River, the Sacramento River downstream of the Feather River, or the Delta compared to the Existing Condition. Therefore, the incremental contribution of Alternative 2 to the cumulative impact on Feather River, Sacramento River, and Delta water quality would not be cumulatively considerable.

8.6.3.4 Cumulative Impact Determination

YRDP Cumulative Impact WQ-Alt2-1. Cumulative Impacts on Surface Water Quality from Construction, Operation, and Maintenance of the YRDP
Based on the above discussion, the cumulative water quality condition, including Alternative 2, in Project Area waterbodies within New Bullards Bar Reservoir could be significant. The cumulative water quality condition in the Delta, including Alternative 2, also could be significant. The cumulative water quality condition of the other Project Area waterbodies would be less than significant. The contribution of Alternative 2 to the significant cumulative water quality condition in the Delta would not be cumulatively considerable. However, the contribution of Alternative 2 to the significant cumulative water quality condition in New Bullards Bar Reservoir would be cumulatively considerable. As such Alternative 2 would result in a **significant** cumulative impact on water quality.

The SWRCB's (2023) Draft Staff Report includes "Mitigation Measure MM-SW-a,f:" to address potentially significant water quality impacts. This mitigation measure addresses mercury impacts, temperature control and reservoir management, harmful algae blooms and invasive aquatic weeds, and municipal water quality protection. However, even with implementation of this mitigation measure, the SWRCB concluded that water quality impacts would remain potentially significant (SWRCB 2023, pp.1-19, 1-34). As such Alternative 2 would result in a **significant and unavoidable** impact on water quality.

Narrows Cumulative Impact WQ-Alt2-1. Cumulative Impacts on Surface Water Quality from Operation and Maintenance of the Narrows Project
Based on the above discussion, the cumulative water quality condition, including Alternative 2, in Project Area waterbodies downstream of the Narrows Project (i.e., the lower Yuba River, the Feather River, and Sacramento River) would be less than significant. However, the cumulative water quality condition in the Delta, including Alternative 2, could be significant. The contribution of Alternative 2 to the significant cumulative water quality condition in the Delta would not be cumulatively considerable. As such Alternative 2 would result in a **less than significant** cumulative impact on water quality.

CHAPTER 9

FISHERIES RESOURCES

9.1 Introduction

This chapter describes the environmental setting, regulatory setting, impact assessment methodology and impact analyses for fisheries resources for the Proposed Projects and Alternatives. This section also summarizes information regarding specific topics and analyses that are addressed in more detail in the following appendices referenced in this chapter.

- Appendix 9A - Lower Yuba River Anadromous Fisheries Resources
- Appendix 9B - Lower Yuba River Flow-Dependent Habitat Availability Methodology
- Appendix 9C - Fisheries Simulated Operations Analyses
- Appendix 9D - Upper Yuba River Watershed Fisheries Data Products
- Appendix 9E - Lower Yuba River Fisheries Data Products

9.2 Environmental Setting

This section summarizes available information regarding fisheries resources in the Project Area under existing conditions to inform analyses of potential impacts of the Proposed Projects and Alternatives.

9.2.1 Geographic Extent of the Environmental Setting

9.2.1.1 Yuba River Development Project

The geographic area that could be affected by the YRDP and that has been identified for this DEIR includes the following Yuba River Watershed streams and waterbodies (Figure 9.2-1).

- North Yuba River below its confluence with Slate Creek downstream to New Bullards Bar Reservoir.
- New Bullards Bar Reservoir (NBBR).
- North Yuba River below New Bullards Bar Dam (NBBD) to its confluence with the Middle Yuba River.
- Log Cabin Diversion Dam (LCDD) Impoundment on Oregon Creek.
- Oregon Creek below LCDD downstream to its confluence with the Middle Yuba River.
- Our House Diversion Dam (OHDD) Impoundment on the Middle Yuba River.
- Middle Yuba River below OHDD to its confluence with the North Yuba River.

- Upper Yuba River (confluence of North and Middle Yuba rivers downstream to Englebright Reservoir).
- Englebright Reservoir.
- Lower Yuba River below Englebright Dam to its confluence with the Feather River.

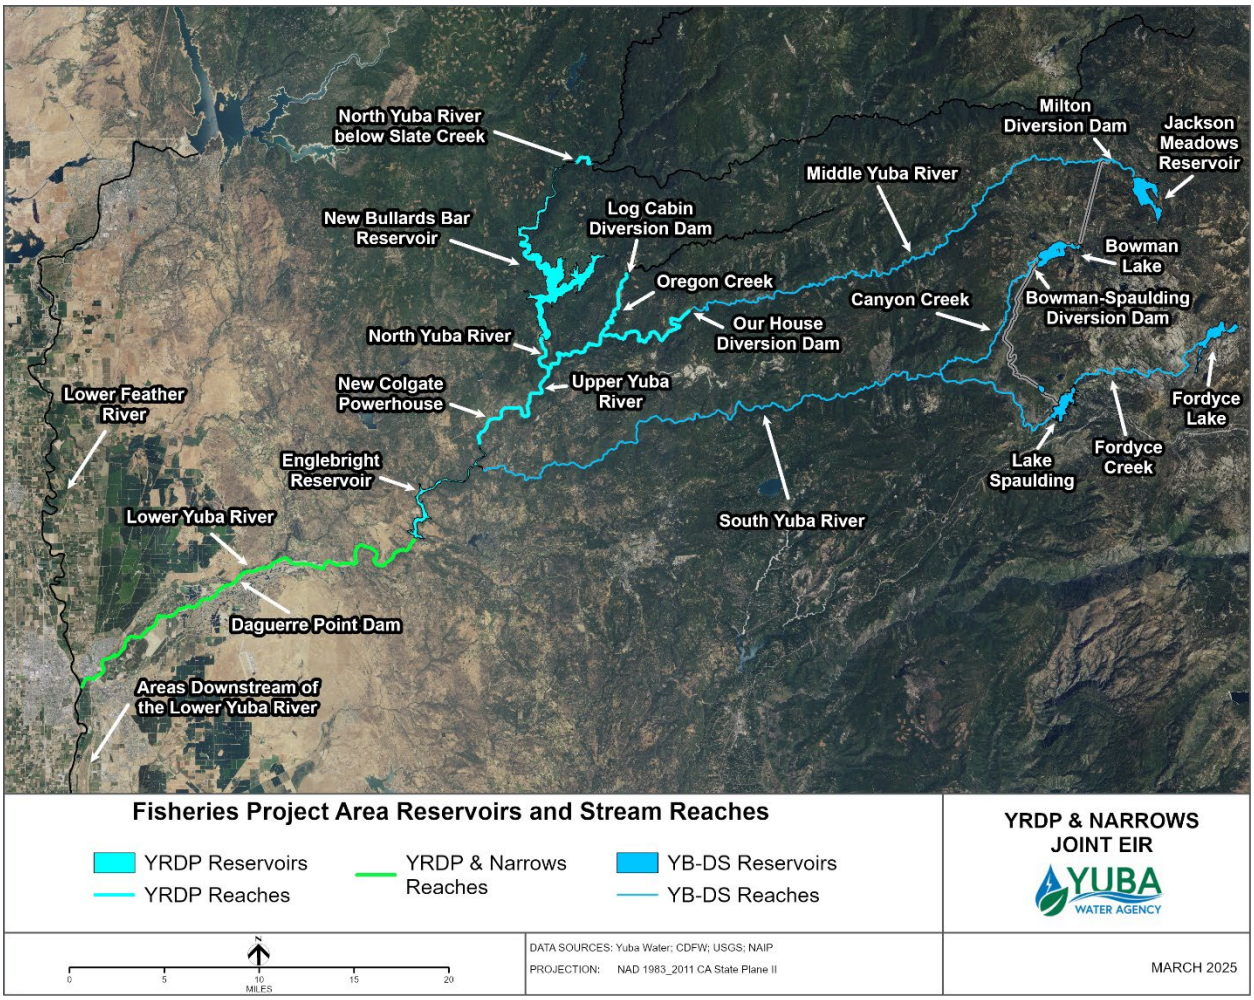

Figure 9.2-1. Fisheries Project Area reservoirs and stream reaches.

In addition, due to the potential for indirect impacts or indirect cumulative impacts that may occur because of potential YB/DS operational changes associated with the provision of 15.6 TAF under Alternative 1 (see Chapter 4 of this DEIR), the following additional areas are included in the Project Area.

- Jackson Meadows Reservoir.
- Middle Yuba River below Jackson Meadows Dam and Milton Diversion Dam to the OHDD Impoundment.
- Bowman Lake.

- Canyon Creek below Bowman Lake and Bowman-Spaulding Canal Diversion Dam to its confluence with the South Yuba River.
- Fordyce Lake.
- Fordyce Creek from Fordyce Lake to Lake Spaulding.
- Lake Spaulding.
- South Yuba River below Lake Spaulding to Englebright Reservoir.

9.2.1.2 Narrows Project

The geographic area that could be affected by the Narrows Project that has been identified for this DEIR includes the lower Yuba River below Englebright Dam to its confluence with the lower Feather River.

9.2.1.3 Areas Downstream of the Lower Yuba River

Lower Yuba River outflows and water temperatures have the potential to influence flow and water temperature-related conditions in the lower Feather River downstream of the lower Yuba River, the Sacramento River downstream of the Feather River, and the Delta. Therefore, these areas are considered in the fisheries Project Area.

9.2.2 YRDP Reaches and Reservoirs Upstream of Englebright Dam

The FERC and USACE (2019) Final Environmental Impact Statement for Hydropower License, Yuba River Development Project (FEIS) described existing physical habitat and fisheries resources in the upper Yuba River Watershed affected by the YRDP based largely on information provided in YRDP relicensing study reports[1] and YRDP Amended Final License Application (AFLA; Yuba Water 2017), which described conditions that existed as of the early 2010s.

9.2.2.1 North Yuba River Watershed

9.2.2.1.1 North Yuba River Downstream from Confluence with Slate Creek

The geographic scope for the YRDP (FERC and USACE 2019) includes the North Yuba River from the confluence with Slate Creek downstream approximately 0.1 miles to the ordinary high-water mark of NBBR. This confluence has a small fine sediment deposit of 0.6 acres, which is primarily influenced by high flow events in the North Yuba River and Slate Creek combined with

[1] Yuba Water's YRDP Relicensing TMs that provide relevant information regarding fisheries resources and physical habitat conditions in the YRDP project area in the upper Yuba River Watershed include: TM 1-1 – Channel Morphology Upstream of Englebright Reservoir (Yuba Water 2013a), TM 2.4 – Bioaccumulation (Yuba Water 2012a), TM 2-5 – Water Temperature Monitoring (Yuba Water 2013b), TM 2-6 – Water Temperature Models (Yuba Water 2013c), TM 3-1 – Aquatic Macroinvertebrates Upstream of Englebright Reservoir (Yuba Water 2013d), TM 3-7 – Reservoir Fish Populations (Yuba Water 2012b), TM 3-8 – Stream Fish Populations Upstream of Englebright Reservoir (Yuba Water 2013e), TM 3-10 – Instream Flow Upstream of Englebright Reservoir (Yuba Water 2013f), TM 3-11 – Entrainment (Yuba Water 2013g), TM 3-12 – New Colgate Powerhouse Ramping (Yuba Water 2012c), and TM 6-1 – Riparian Habitat Upstream of Englebright Reservoir (Yuba Water 2013h).

high elevations of the reservoir that create a backwater effect at this confluence (Yuba Water 2013a).

During surveys in 2008 and 2009, rainbow trout represented the most abundant species (1,602-4,566 fish/mile) followed by Sacramento sucker, Sacramento pikeminnow, and brown trout (Yuba Water 2017). Multiple age classes of both rainbow trout and brown trout were captured during this effort with young-of-year trout being the most abundant (Yuba Water 2017). This section of the North Yuba River is not addressed further in this DEIR because there are no changes in modeled flows and water temperatures under the Proposed Projects or alternative scenarios relative to the bases of comparison.

9.2.2.1.2 New Bullards Bar Reservoir

New Bullards Bar Reservoir (NBBR), which is formed by the impoundment of the North Yuba River by NBBD, supports both coldwater and warmwater fisheries and has a long history of fish stocking activities by CDFW dating back to 1959 (see Yuba Water 2017). Salmonid species have been the primary fish species planted in the reservoir. These have included rainbow trout (*Oncorhynchus mykiss*), kokanee (*O. nerka*), brook trout (*Salvelinus fontinalis*), and cutthroat trout (*O. clarkii*) (Yuba Water 2017). Although warmwater fish species, both centrarchids and ictalurids (crappie, black bass, and sunfish), have historically been reported to occur in NBBR, limited recreational fisheries historically existed for these warmwater fish species (Yuba Water et al. 2007). NBBR supports a very significant salmonid fishery emphasizing kokanee salmon and is known for having some of the best kokanee salmon fishing in California (Yuba Water et al. 2007). Yuba Water (2017) documented 11 fish species during reservoir fisheries sampling in NBBR during sampling events in January and June of 2012 with gill netting and boat electrofishing. Spotted bass (*Micropterus punctulatus*) was the most common species collected, accounting for about 66% of the total catch. Other common species included bluegill (*Lepomis macrochirus*), green sunfish (*L. cyanellus*), rainbow trout, kokanee, and common carp (*Cyprinus carpio*). Less common species recorded included Sacramento sucker (*Catostomus occidentalis*), Sacramento pikeminnow (*Ptychocheilus grandis*), white catfish (*Ameiurus catus*), brown bullhead (*A. nebulosus*), and white crappie (*Pomoxis annularis*). Largemouth bass (*M. salmoides*) and smallmouth bass (*M. dolomieu*), which were historically documented in the reservoir, were not found during Yuba Water's study (Yuba Water 2017).

During 2012, tributaries to NBBR were assessed for fish passage impediments. The water surface elevation of NBBR can affect the extent of riverine habitat in tributaries to the reservoir. Surveys in 2012 were conducted within the ordinary high water surface elevation of the reservoir despite the surface elevation of the reservoir being lower than normal during the actual survey. Surveys on nine accessible tributaries found no permanent barriers (Yuba Water 2017). Operational changes in NBBR do not appear to create fish passage impediments for upstream migration (Yuba Water 2017). Fisheries surveys conducted in the nine tributaries only observed rainbow trout, Sacramento sucker, and brown trout (Yuba Water 2017). Additionally, four other tributaries were surveyed, with multiple passage impediments identified at low reservoir levels. However, it is expected that these passage impediments would be inundated at normal reservoir levels and, therefore, would not restrict access into these tributaries by adfluvial fish species during typical reservoir operations.

9.2.2.1.3 North Yuba River Below New Bullards Bar Dam

The North Yuba River below NBBD extends for about 2.3 miles downstream to its confluence with the Middle Yuba River. The following description is generally taken from Yuba Water's habitat mapping of the North Yuba River below NBBD (Yuba Water 2013a). The channel of the North Yuba River (NBBD Reach) is dominated by gradients below 3 percent with an average gradient of 2%. Most of the reach is composed of bedrock and car- and house-sized boulders that separate large mid-channel pools. There are very short and infrequent areas of cobble-sized deposits, but most of the substrate is large and immobile. There is no apparent floodplain or terrace development. Aquatic habitat is dominated by pocketwater and mid-channel pools. Instream object cover is reported to be restricted to boulders, but the depth of pools can also provide cover to resident rainbow trout. Habitat mapping found that trout spawning-sized gravel accumulations and large woody material were rare, and potential natural barriers to resident trout upstream movement likely are very common in the confined, steep channel. Bank erosion also was rare, given the bedrock/boulder channel margins (Yuba Water 2013a).

Yuba Water's 2012 fish population surveys found that Sacramento sucker represented 84.6 percent of collected fish (3,203 fish/mile), followed by 15.0 percent for rainbow trout (567 fish/mi), and a single Sacramento pikeminnow (Yuba Water 2017). During 2013 sampling, rainbow trout represented 74.6 percent of the fish observed (534 fish/mi), whereas Sacramento sucker decreased to 25.4 percent of the represented catch (181 fish/mi). Sacramento pikeminnow was not observed during 2013. All of the Sacramento suckers observed during 2012 were young-of-year (YOY) fish. Rainbow trout were predominantly YOY fish, with relatively low numbers of older age-classes (Yuba Water 2017).

9.2.2.2 Middle Yuba River Watershed

9.2.2.2.1 Our House Diversion Dam Impoundment

Built in 1978, OHDD is a 70-foot-tall impoundment on the Middle Yuba River approximately 12.6 miles upstream of the confluence with the North Yuba River (i.e., Our House Diversion Dam Reach). At ordinary high water surface elevation, OHDD impounds 280 acre-feet and is used to divert up to 860 cfs of water through the Lohman Ridge Diversion Tunnel to the LCDD impoundment on Oregon Creek. Water is released from OHDD by way of two release outlets: (1) a fish release outlet used to discharge water into the downstream Middle Yuba River to maintain minimum instream flows; and (2) a rarely used low-level outlet (FERC and USACE 2019). Only one site description was conducted during electrofishing upstream of OHDD. The habitat was described as low-gradient riffle and glide habitat with no suitable spawning substrate or presence of large woody material (Yuba Water 2017). There were no identified fish passage issues.

During fisheries surveys in 2012 and 2013, four fish species were captured including Sacramento sucker, rainbow trout, Sacramento pikeminnow, and brown trout (Yuba Water 2017; Yuba Water 2013b; FERC and USACE 2019). Multiple age classes (0 and 2+) of rainbow trout were present in captures upstream of OHDD during electrofishing surveys in 2012; however, this species was not captured during 2013 (Yuba Water 2017). Species estimates for sampling include 409 fish per mile for rainbow trout in 2012, 131 fish per mile in 2012 and 16 fish per mile in 2013 for Sacramento pikeminnow, and 917 fish per mile in 2012 and 160 fish per mile in 2013 for

Sacramento sucker (Yuba Water 2017). The reach of the Middle Yuba River upstream of the OHDD is characterized as a transitional area between a coldwater and warmwater fishery (Yuba Water 2017). Snorkel surveys from 2008 and 2009 estimated approximately 273-375 rainbow trout per mile, 318-1,885 Sacramento sucker per mile, and 0-68 Sacramento pikeminnow per mile (Yuba Water 2017).

9.2.2.2.2 Middle Yuba River downstream of Our House Diversion Dam

The Middle Yuba River is one of the primary tributaries to the upper Yuba River, which is formed at the confluence of the North Yuba and Middle Yuba rivers. Geology within the Middle Yuba River generally consists of bedrock and boulder substrates, which stabilize the streambed and prevent lateral movement of the channel (FERC and USACE 2019). Large woody debris and spawning gravels are rare within the Middle Yuba River (FERC and USACE 2019). The Middle Yuba River downstream of the OHDD is characterized by an average gradient of 2.5% (Yuba Water 2013a). The channel of the Middle Yuba River is moderately armored, with armoring ratios between 1.4 and 2.7. However, just downstream of Oregon Creek, this ratio is 5.4, indicating strong armoring. Riparian vegetation has increased when comparing photographic analysis from 1969 to 2009 (Yuba Water 2013a). Habitats downstream of the dam include runs, pocket-water, and pools and no large woody material (Yuba Water 2017). Spawning gravel for trout is present downstream of OHDD (Yuba Water 2017).

Surveys downstream of OHDD detected rainbow trout, Sacramento sucker, smallmouth bass, and Sacramento pikeminnow during snorkel surveys in 2012 and 2013 (Yuba Water 2017). Although hardhead was present in past captures during previous surveys (Gast et al. 2005), no hardhead were observed during surveys in 2012 and 2013 (Yuba Water 2017). Sampling in 2012 and 2013 indicated that rainbow trout and smallmouth bass were the most abundant species near RM 12.5. Estimates for rainbow trout were 453 fish/mile in 2012 and 450 fish/mile in 2013, while smallmouth bass were 88 fish/mile in 2012 and 708 fish/mile in 2013 (Yuba Water 2017). Sacramento pikeminnow and Sacramento sucker were not captured during 2012, but 11 fish/mile were estimated for both species from captures during 2013 (Yuba Water 2017). Upstream up the confluence with Oregon Creek near RM 5.0, smallmouth bass were the most abundant species comprising >80 percent of fishes during both 2012 and 2013, with an estimated 1,915 fish/mile in 2012 and 1,282 fish/mile in 2013 (Yuba Water 2017). Rainbow trout estimated densities were 155 fish/mile and 90 fish/mile in 2012 and 2013, respectively (Yuba Water 2017).

9.2.2.2.3 Middle Yuba River Downstream of Oregon Creek

The Middle Yuba River downstream of the confluence with Oregon Creek and upstream of the confluence with the North Yuba River is designated as the Oregon Creek Reach (Yuba Water 2017). This reach of the Middle Yuba River contains low flow barriers at RM 0.2 and 3.2 and a 13-foot-tall cascade at RM 0.4 (Gast et al. 2005). Upstream of the cascade, habitats in this reach include deep pools and deep runs (Yuba Water 2017). Spawning gravel was observed during 2012 but not during 2013 (Yuba Water 2017).

Fish sampling at RM 3.3 in 2012 and 2013 documented rainbow trout, smallmouth bass, and Sacramento sucker with rainbow trout as the most abundant species (Yuba Water 2017). Rainbow trout estimates were 613 fish/mile and 212 fish/mile during 2012 and 2013, respectively.

Smallmouth bass estimates were 126 fish/mile and 212 fish/mile, and Sacramento sucker were 91 fish/mile and 65 fish/mile in 2012 and 2013, respectively. Farther downstream at RM 1.0, smallmouth bass were the most abundant species with 520 fish/mile and 1,345 fish/mile in 2012 and 2013, respectively. Rainbow trout were the second most dominant species with 470 fish/mile and 38 fish/mile in 2012 and 2013, respectively. Sacramento pikeminnow were only observed during 2012 with an estimate of 40 fish/mile.

9.2.2.3 Oregon Creek Watershed

9.2.2.3.1 Log Cabin Diversion Dam Impoundment

Oregon Creek is a tributary to the Middle Yuba River and extends downstream for approximately 17 miles before being impounded by the LCDD. Built in 1968, LCDD is a 43-foot-tall impoundment on Oregon Creek approximately 4.3 miles upstream of the confluence of Oregon Creek and the Middle Yuba River, and this dam does not provide upstream fish passage. The LCDD is used to divert up to 1,100 cfs during winter and spring flows (including flows diverted from the Middle Yuba River at OHDD through the Lohman Ridge Diversion Tunnel) to NBBR through the Camptonville Diversion Tunnel. At ordinary high water surface elevation, the dam impounds 90 acre-feet (FERC and USACE 2019). A fish release outlet discharges water downstream into Oregon Creek to maintain minimum instream flows, and the dam also has a rarely used low-level outlet (FERC and USACE 2019). Only one site description was conducted during electrofishing upstream of LCDD. The habitat was described as low-gradient riffle, run, and pool habitat with 3.0-9.0 square meters of suitable spawning gravel and a small amount (< 10) identified large woody material (Yuba Water 2017). There were no identified fish passage issues. Surveys were conducted by Yuba Water in Oregon Creek during 2012 and 2013 immediately upstream of LCDD (Yuba Water 2017).

During fisheries surveys in 2012 and 2013, Yuba Water documented three species upstream of LCDD during electrofishing. Species captured included Sacramento sucker, rainbow trout, and Sacramento pikeminnow (FERC and USACE 2019; Yuba Water 2013b). Sacramento sucker were the most abundant species (Yuba Water 2017). All life stages of rainbow trout were present in captures (FERC and USACE 2019). Rainbow trout estimates ranged from 72-263 fish per mile in 2012 and 2013, respectively (Yuba Water 2017). Sacramento pikeminnow were less frequent and ranged from 18 to 38 fish per mile in 2012 and 2013, respectively (Yuba Water 2017). Hardhead are reported to have historically occupied Oregon Creek upstream of the dam (Yuba Water 2017).

9.2.2.3.2 Oregon Creek downstream of Log Cabin Diversion Dam

Surveys were conducted by Yuba Water in Oregon Creek during 2012 and 2013 downstream of LCDD to the confluence with the Middle Yuba River (Yuba Water 2017). Habitat in Oregon Creek downstream of LCDD ranges from low gradient riffles and pools in the upper and middle sections of Oregon Creek to bedrock falls and steep gradients in the lower section of Oregon Creek (FERC and USACE 2019). Spawning gravel was present downstream of the dam in 2012 but not in 2013 and further investigation determined that spawning gravel was typically located outside of the active channel (Yuba Water 2017). Oregon Creek has an armoring ratio of 1.7, which indicates moderate armoring of the channel. The majority (68%) is low gradient of 1-3% while the remainder

(32%) is 3-8% (Yuba Water 2013a). Floodplain vegetation has increased when comparing photographic analysis from 1969 to 1993 (Yuba Water 2013a).

Rainbow trout were the most dominant species downstream of the dam representing ≥ 80 percent of species composition with Sacramento sucker and smallmouth bass comprising ≤ 20 percent cumulatively. Estimates for rainbow trout downstream of the dam were 2,266 fish/mile in 2012 and 1,430 fish/mile in 2013 (FERC and USACE 2019), and multiple age classes of rainbow trout were captured (Yuba Water 2017).

9.2.2.4 Upper Yuba River Watershed

The upper Yuba River (i.e., the Yuba River from the confluence of the North Yuba and Middle Yuba rivers downstream to the ordinary high-water mark of Englebright Reservoir) is comprised of the Middle/North Yuba River (upstream of New Colgate Powerhouse) and New Colgate Powerhouse (downstream of New Colgate Powerhouse) reaches, and is predominantly bedrock-controlled with only very short boulder/cobble sections. Consequently, the channel is laterally and vertically stable. Sinuosity is very low as there are no plan and profile sections strongly influenced by alluvial deposition. Pools are large and deep, and separated by long sections of pocketwater that runs through and under very large boulders. Finer sediment (cobble and finer) accumulations are uncommon. Though not very steep, according to the mapped gradient of 1.8 percent, high gradient riffles dominate the gradient "steps." The river flows through bedrock canyons, and the vertical walls inhibit ground access. The only location that was ground-mapped was the area just above and below New Colgate Powerhouse (25% of the reach). Habitat is dominated by mid-channel pools and pocketwater formed between large boulders. Boulders were the only instream cover type identified, although deep pools likely also provide some cover. Large woody debris was not found, and trout spawning-sized gravel accumulations were uncommon (Yuba Water 2013a). A comparative photographic analysis from 1998 to 2009 indicates that riparian vegetation has increased over that time (Yuba Water 2013a).

9.2.2.4.1 Middle/North Yuba River Reach

The Middle/North Yuba River Reach is the portion of the upper Yuba River downstream of the confluence of the North Yuba and Middle Yuba rivers. Habitat in this reach of the Yuba River is dominated by deep water with some small glides in the upper section near RM 39.6 (Yuba Water 2017). Surveys did not detect spawning gravel, large woody material, or impediments to fish passage (Yuba Water 2017). Farther downstream near RM 35.0, habitats included pock-water and pools with less depth than upstream. Additionally, a small amount of spawning gravel (i.e., 3.0 m^2) was observed during both 2012 and 2013.

Fish sampling occurred upstream of the New Colgate Powerhouse during 2012 and 2013. Rainbow trout and smallmouth bass were the most abundant species with rainbow trout comprising >61 percent of fishes in 2012 and smallmouth bass comprising >78% of fishes in 2013 near RM 39.6 (Yuba Water 2017). Density estimates were 543 rainbow trout/mile during 2012 and 243 rainbow trout/mile during 2013, while density estimates of smallmouth bass were 337 fish/mile during 2012 and 889 fish/mile during 2013 (Yuba Water 2017). Sacramento pikeminnow and Sacramento sucker were also observed but in low abundance. Farther downstream at RM 35.0, smallmouth bass were the dominant species during both 2012 and 2013 with estimates of 1,409 fish/mile and

1,257 fish/mile during 2012 and 2013, respectively (Yuba Water 2017). Rainbow trout were also observed but represented less than 7% of the total number of fishes during 2012 and less than 2 percent during 2013 (Yuba Water 2017).

9.2.2.4.2 New Colgate Powerhouse Reach

The New Colgate Powerhouse Reach is the portion of the upper Yuba River that extends downstream from the New Colgate Powerhouse to the ordinary high-water mark of Englebright Reservoir. Habitat in this area is characterized by low gradient riffles, high gradient riffles, runs, steps, and pools (Yuba Water 2017). Some spawning gravel was noted in the area downstream of New Colgate Powerhouse near RM 33.7 (Yuba Water 2017).

Rainbow trout were generally the only species observed during fish surveys downstream of New Colgate Powerhouse with the exception of one individual adult brown trout during 2012. Rainbow trout density estimates were 323 fish/mile and 560 fish/mile during 2012 and 2013, respectively (Yuba Water 2017). Multiple age classes from 0-2+ were observed in this reach. Additionally, this reach is used for spawning by kokanee based on observations of kokanee carcasses downstream of the powerhouse (Yuba Water 2017).

9.2.2.4.3 Englebright Reservoir

Englebright Reservoir is located downstream of the upper Yuba and South Yuba rivers. With a storage capacity of approximately 70 TAF, Englebright Reservoir essentially serves as a re-regulating afterbay for releases from NBBD and generally acts as a flow-through facility. Yuba Water does not own the Englebright Dam or Englebright Reservoir, and these are not licensed as part of the Yuba River Development Project (Yuba Water 2017; FERC and USACE 2019). However, data from sampling and surveys of Englebright Reservoir are important for informing management decisions for the upper Yuba River Watershed and natural resources. Englebright Reservoir supports warmwater and coldwater fish species, including rainbow trout, brown trout, catfish, crappie, smallmouth bass, green sunfish and bluegill (USACE 2020). Yuba Water's fish population sampling at Englebright Reservoir during 2012 documented 11 fish species with gill netting and boat electrofishing. Sacramento sucker (n=114, 31.5%) and spotted bass (n=96, 26.5%) were the more common species collected, followed by hardhead, rainbow trout, bluegill, and Sacramento pikeminnow. Englebright Reservoir has been stocked with fish since 1950 (Yuba Water 2017) and stocking continues annually to support the recreational fishery. Historical stocking included brown trout and rainbow trout (Yuba Water 2017). Rainbow trout were the only salmonid recently stocked in Englebright Reservoir according to the CDFW online fish stocking query tool, and continue to be stocked (CDFW 2025).

Survey results from 2012 (Yuba Water 2017) observed kokanee carcasses near New Colgate Powerhouse, which likely migrated upstream from Englebright Reservoir to spawn in upstream reaches of the upper Yuba River, indicating there are no substantive fish passage impediments that prevent fishes from migrating upstream of the reservoir in the upper Yuba River.

9.2.3 Reaches and Reservoirs Upstream of the YRDP

9.2.3.1 Middle Yuba River Watershed

9.2.3.1.1 Jackson Meadows Reservoir

Jackson Meadows Reservoir is a reservoir on the Middle Yuba River, which is impounded by the Jackson Meadows Dam. This reservoir is part of the NID's Yuba-Bear project and has a capacity of 64,641 acre-feet of storage. Jackson Meadows Dam has two low-level outlets and a three-bay spillway. Water is released from Jackson Meadows Dam into the Middle Yuba River, which travels downstream to Milton Diversion Dam impoundment and then is subsequently released back into the Middle Yuba River from Milton Diversion Dam or diverted to Bowman Lake via the Milton-Bowman Diversion Conduit. A majority of the water released from Jackson Meadows Dam is diverted into the Milton-Bowman Diversion Conduit.

Sampling in Jackson Meadows Reservoir captured rainbow trout, brown trout, brook trout, Lahontan cutthroat trout, tui chub, Lahontan redside, and speckled dace, brown bullhead (FERC 2014). Historical records indicate that brown bullhead and Artic grayling occurred in Jackson Meadows Reservoir, but Artic grayling are believed to be extirpated (FERC 2014). Previous fish stocking occurred for rainbow trout, brown trout, brook trout, and Eagle Lake rainbow trout (FERC 2014). Fish are stocked annually in Jackson Meadows Reservoir according to the CDFW online fish stocking query tool.

9.2.3.1.2 Middle Yuba River below Jackson Meadows Dam to Our House Diversion Dam

The Middle Yuba River upstream of OHDD has two impoundments including Jackson Meadows Reservoir (the most upstream impoundment) followed by the Milton Diversion Dam impoundment. This area of the Middle Yuba River is divided into two reaches based on their location downstream of these dams. These reaches are referred to as the Jackson Meadows Dam Reach (downstream of Jackson Meadows Dam to Milton Diversion Dam impoundment) and Milton Diversion Dam Reach (downstream of Milton Diversion Dam impoundment to OHDD). The Jackson Meadows Dam Reach is approximately 1.6 miles long with a 3.9 percent gradient. This reach of the Middle Yuba River is used for water conveyance between Jackson Meadows Reservoir to Milton Diversion Dam. Habitat in the Jackson Meadows Dam Reach is characterized by riparian forests with large portions of unvegetated rocky slopes. The Milton Diversion Dam Reach is approximately 32 miles long with a 2.8 percent gradient. There is a large wetland at the inflow to the Milton Diversion Dam impoundment. Under the existing license, the minimum instream flow requirement downstream of Milton Diversion Dam is 3 cfs. There are several tributaries between Milton Diversion Dam and OHDD (e.g., Wolf and Kanaka creeks) that contribute flow and affect water temperature in this reach (FERC 2014).

Fish species historically present in the Middle Yuba River included rainbow trout, brown trout, brook trout, cutthroat trout, Lahontan cutthroat trout, Sacramento sucker, Sacramento pikeminnow, hardhead, and smallmouth bass (FERC 2014). Sampling in 2008 and 2009 captured only rainbow trout, brown trout, Sacramento sucker, Sacramento pikeminnow, and Lahontan redside, with both trout species comprising the majority of the catch (FERC 2014).

Fish species in the Jackson Meadows Dam Reach that were captured during relicensing studies in 2008 and 2009 include rainbow trout, brown trout, and Lahontan redside (FERC 2014). Fish species historically present but believed to be extirpated include brook trout and cutthroat trout. Fish species in the Milton Diversion Dam Reach that were captured during relicensing studies in 2008 and 2009 include rainbow trout, brown trout, Sacramento sucker, and Sacramento pikeminnow. Fish species historically present include brook trout, cutthroat trout, hardhead, largemouth bass, and smallmouth bass.

9.2.3.2 South Yuba River Watershed

9.2.3.2.1 Bowman Lake

Bowman Lake provides habitat for fish species including rainbow trout, brown trout, kokanee, Lahontan redside, and speckled dace. Historical records indicate golden shiner and green sunfish also occurred in Bowman Lake (FERC 2014). Eagle Lake rainbow trout and kokanee were historically stocked in Bowman Lake from 2002-2009 (FERC 2014). No fish stocking was done in 2024 per the CDFW fish stocking online query tool.

9.2.3.2.2 Canyon Creek

Water is released from Bowman Lake into the Bowman-Spaulding Canal Diversion Dam (BSCDD) impoundment, and then from BSCDD into Canyon Creek. Canyon Creek downstream of BSCDD is about 10 miles from the dam to the confluence with the South Yuba River. This reach is characterized by granite bedrock in the upstream portion of this reach and dense forest and steep slopes in the downstream portion (FERC 2014).

Fish capture data is limited for Canyon Creek, however, sampling in 2008 and 2009 captured rainbow trout, brown trout, and brook trout in the Canyon Creek and Texas Creek sub-basins (FERC 2014).

9.2.3.2.3 Fordyce Lake and Creek

Water released from Fordyce Lake Dam flows into Fordyce Creek which flows into Lake Spaulding. During sampling in 2009, Lahontan cutthroat trout, rainbow trout, brown trout, brook trout, and tui chub were captured in Fordyce Lake (FERC 2014). Rainbow trout were historically stocked in Fordyce Lake during 2002-2009 (FERC 2014). No fish stocking was done in 2024 as per the CDFW fish stocking online query tool. Fisheries surveys in Fordyce Creek downstream of Fordyce Lake Dam identified rainbow trout, brown trout and roach (NID and PG&E 2009).

9.2.3.2.4 Lake Spaulding

Lake Spaulding has a storage capacity of 75,912 ac-ft and is impounded by Lake Spaulding Dam No. 1 and Lake Spaulding Dam No. 2. Water flows into Lake Spaulding from Fordyce Lake via the Fordyce Lake dam spillway and outlet to Fordyce Creek. Water released from Lake Spaulding flows into the South Yuba River, Jordan Creek, South Yuba canal, and Drum canal depending on whether water is released from Lake Spaulding Dam No.1 or Lake Spaulding Dam No. 2.

During sampling in 2009, rainbow trout, Chinook salmon, brown trout, brook trout, pond smelt, Sacramento pikeminnow, Lahontan redside, Sacramento sucker, and smallmouth bass were identified in Lake Spaulding (FERC 2014). Chinook salmon were historically stocked in Fordyce Lake between 2002-2009 (FERC 2014). No fish stocking was done in 2024 as per the CDFW fish stocking online query tool.

9.2.3.2.5 South Yuba River below Spaulding Dam to Englebright Reservoir

The South Yuba River flows out from both the Lake Spaulding Dam No. 1 through the low-level outlet and through Lake Spaulding Dam No. 2 through the powerhouse via the South Yuba canal. The South Yuba River from Lake Spaulding to the ordinary high-water mark of Englebright Reservoir is approximately 41.1 miles with a mean gradient of 2 percent.

During sampling in 2008 and 2009, rainbow trout and brown trout were captured in the South Yuba River below the Lake Spaulding No. 2 Powerhouse. Brook trout and Sacramento pikeminnow were historically present; however, they are now believed to be extirpated in this reach. During sampling in 2008 and 2009, rainbow trout, brown trout, Sacramento sucker, Sacramento pikeminnow, smallmouth bass, and green sunfish were captured in downstream reaches.

9.2.4 Lower Yuba River

As described above, FERC and USACE (2019) described existing physical habitat and fisheries resources in the lower Yuba River based largely on information provided in Yuba Water's Yuba YRDP relicensing study reports[2] and Yuba Water 2017, which described conditions that existed as of the early 2010s. Further, Yuba Water's (2023a) Final License Application (FLA) for the Narrows Hydropower Project (Narrows) provided available updated information regarding lower Yuba River fisheries resources relevant to the Narrows FERC relicensing process.

The lower Yuba River extends for about 24 miles downstream of Englebright Dam. Geomorphic reaches were delineated by Wyrick and Pasternack (2012) into eight segments based on the longitudinal profile and associated geomorphic variables. Tributary junctions form the upstream boundary of two reaches, and dams form the boundary for two more reaches. The other reach boundaries are formed by hydro-geomorphic variables such as the onset of emergent floodplain gravel, transition from confined bedrock valley to wider, meandering system, and decreases in bed

[2] Yuba Water's YRDP Relicensing TMs that provide relevant information regarding fisheries resources and physical habitat conditions in the lower Yuba River include: TM 1-2 – Channel Morphology Downstream of Englebright Dam (Yuba Water 2013i), TM 2.4 – Bioaccumulation (Yuba Water 2012a), TM 2-5 – Water Temperature Monitoring (Yuba Water 2013b), TM 2-6 – Water Temperature Models (Yuba Water 2013c), TM 3.2 – Aquatic Macroinvertebrates Downstream of Englebright Dam (Yuba Water 2013j), TM 3-9 – Non-ESA-Listed Fish Populations Downstream of Englebright Dam (Yuba Water 2012d), TM 6-2 – Riparian Habitat Downstream of Englebright Dam (Yuba Water 2013k), TM 7-8 ESA/CESA-Listed Salmonids Downstream of Englebright Dam (Yuba Water 2013l), TM 7-9 Green Sturgeon Downstream of Englebright Dam (Yuba Water 2013m), TM 7-10 – Instream Flow Downstream of Englebright Dam (Yuba Water 2013n), TM 7-11 – Fish Behavior and Hydraulics Near Narrows 2 Powerhouse and TM 7-11a – Radio Telemetry Study of Spring- and Fall-run Chinook Salmon Downstream of Narrows 2 Powerhouse (Yuba Water 2016), TM 7-12 – Evaluation of Project Effects on Daguerre Point Dam and Hallwood-Cordua Fish Facilities (Yuba Water 2013o), and TM 7-13 – Fish Stranding Associated with Shutdown of Narrows 2 Powerhouse Partial Bypass (Yuba Water 2014).

channel slope. Table 9.2-1 provides length and gradient of each of the reaches. Figure 9.2-2 provides a map of the geomorphic reaches in relation to local landmarks.

Table 9.2-1. Geomorphic reaches in the Yuba River downstream from Englebright Dam.

Reach Name	Description	Gradient (%)	Start (RM)	End (RM)	Length (mi)
Englebright Dam	Confluence with Deer Creek to Englebright Dam	0.31	23.4	24.3	0.9
Narrows	Deer Creek to emergent gravel at canyon mouth	Not Measurable	22.3	23.4	1.1
Timbuctoo Bend	Upstream of Hwy 20 Bridge to end of emergent gravel bar by Blue Point Mine	0.20	18.6	22.3	3.8
Parks Bar	Dry Creek to 0.35 mi upstream of Hwy 20 Bridge	0.19	13.9	18.6	4.7
Dry Creek	Daguerre Point Dam to Dry Creek	0.14	11.6	13.9	2.3
Daguerre Point Dam	RM 8.3 to Daguerre Point Dam	0.18	8.3	11.6	3.3
Hallwood	RM 3.3 to slope break near Eddie Drive at RM 8.3	0.13	3.3	8.3	5.0
Marysville	Junction with Feather River to RM 3.3	0.05	0.0	3.3	3.3
Total		0.16	0.0	24.3	24.3

9.2.5 Fish Species of Management Concern

In addition to fish species listed as threatened or endangered under the Federal ESA or California ESA (CESA), Yuba Water searched several additional sources including the CNDDB, the July 2024 Special Animals List maintained by CDFW (CNDDB 2024), NMFS and USFWS online databases, and environmental documents to identify other fish species of management concern that may occur within the Project Area. These other fish species include: (1) species that are formally proposed for federal listing or are candidates for federal listing as threatened or endangered; (2) federal species of concern; (3) species managed by the Pacific Fisheries Management Council (PFMC); (4) species that are candidates for State listing as threatened or endangered; (5) species identified by CDFW as California Species of Special Concern; and (6) species designated by California statute as fully protected (i.e., California Fish and Game Code, Section 5515 [fish]). Additional fish species evaluated include focal species addressed in FERC Relicensing processes and those that have tribal, recreational, or commercial importance.

9.2.5.1 Areas Upstream of Englebright Dam

No ESA or CESA-listed fish species are present within the Project Area upstream of Englebright Dam. California State species of special concern with the potential to occur in the upper Yuba River Watershed include hardhead and the Central California roach subspecies. Additional fish species of management concern considered in this DEIR include native species that have been the focus of FERC Relicensing processes in the Project Area (described below) and species that are of commercial or recreational importance. Target species and life stages for habitat modeling during the YRDP Relicensing studies were selected by YRDP Relicensing Participants (including NMFS, USFWS, CDFW, and USFS) based on species importance and YRDP O&M activities (Yuba Water 2013f). Species included for the YRDP reaches of upper Yuba River Watershed were rainbow trout, hardhead, Sacramento pikeminnow, and Sacramento sucker. YB/DS Relicensing Participants also evaluated habitat availability for rainbow trout, Sacramento sucker, and hardhead/pikeminnow[3], depending on the reach, in the Middle Yuba River upstream of OHDD, Canyon Creek downstream of the BSCDD, Fordyce Creek below Fordyce Lake Dam, and in reaches of the South Yuba River downstream of Lake Spaulding (NID and PG&E 2010). Rainbow trout was the focal fish species targeted for habitat enhancement by both the YRDP Relicensing Participants (FERC and USACE 2019) and the YB/DS Relicensing Participants (FERC 2014). Additional fish species that are of recreational importance in the upper Yuba River Watershed include kokanee and black bass. Brief descriptions of fish species of management concern in areas upstream of Englebright Dam are provided below.

9.2.5.1.1 Rainbow trout

Rainbow trout occur throughout the upper Yuba River Watershed, including the North Yuba River below NBBD, the upper Yuba River, the Middle Yuba River, Canyon Creek, Fordyce Creek, the South Yuba River, and in all reservoirs and diversion dam impoundments (Yuba Water 2017; NID and PG&E 2009). Stocking of trout occurs annually in the Yuba River Watershed.

Optimal rainbow trout habitat is characterized by conditions similar to those described for brown trout, including: (1) silt-free rocky substrate in riffle-run areas; (2) an approximately 1:1 pool-to-riffle ratio, with areas of slow, deep water; (3) well-vegetated and stable stream banks; and (4) abundant instream cover (Raleigh et al. 1984). Rainbow trout spawn during April through June in the YRDP reaches of the upper Yuba River Watershed (Yuba Water 2017), as well as in the Middle Yuba River upstream of OHDD and in the South Yuba River downstream of Spaulding Dam (NID and PG&E 2010). In Fordyce Creek below Fordyce Lake Dam and in Canyon Creek below the BSCDD, rainbow trout spawn during May through July (NID and PG&E 2010). Fry rearing may occur during May through October, with juveniles and adults rearing year-round (NID and PG&E 2010). Rainbow trout fry prefer relatively shallow water and slow water velocities, particularly in pool habitats within 1 meter of cover (Raleigh et al. 1984). Both juvenile and adult rainbow trout are opportunistic feeders and consume a wide variety of foods, particularly aquatic insects (Raleigh et al. 1984).

[3] Due to similar habitat preferences by hardhead and Sacramento pikeminnow, a single set of habitat-flow relationships were developed by lifestage for hardhead and Sacramento pikeminnow.

9.2.5.1.2 Hardhead

Hardhead is typically found within larger mid- and low-elevation streams where summer mean daily water temperatures exceed about 20°C (68°F) (Moyle 2002). Historically, hardhead was considered a widespread and locally abundant species within its range. However, substantial alteration of its relatively specialized habitat requirements as well as predation and competition from introduced black bass and other centrarchids have resulted in population declines and isolated populations (Moyle 2002). Smallmouth bass have been reported to result in diminished hardhead abundance in the Central Valley, including in the upper Kings River and in the South Yuba River (Moyle et al. 1995). In the Sacramento River drainage, hardhead is present in most of the larger tributary streams.

Adult hardhead generally rear in clear, deep (>3 ft) pools with sand-gravel-boulder substrates and slow water velocities (Moyle 2002). Juvenile hardhead concentrate in shallow water close to the stream margin (Moyle and Baltz 1985). Hardhead spawning occurs during the spring, when hardhead migrate upstream to gravel riffles, often within tributary streams (Moyle 2002). Hardhead have been reported to spawn primarily during April and May (Grant and Maslin 1999); juvenile recruitment data suggest that hardhead spawn by May and June in most Central Valley streams (Wang 1986). However, spawning may extend into August in some foothill streams (Moyle 2002). In Pine Creek in Tehama County, spawning adults aggregated upstream or downstream of their home pools during spring to spawn, and returned to their home pools after spawning (Grant and Maslin 1999). Although considered a riverine species, hardhead has become well established in mid-elevation reservoirs. The initial establishment of hardhead in recently impounded reservoirs has been reported to be the result of residual populations of juvenile fish growing to large sizes before populations of predatory centrarchids, primarily black bass, were established (Moyle et al. 1995). Power supply reservoirs, which do not draw down over the summer, and which exhibit relatively constant water surface elevations with short-term fluctuations, can inhibit the success of centrarchids and instead favor native stream fishes such as hardhead (and Sacramento pikeminnow and Sacramento sucker) (Moyle 2002). Spawning adults from larger rivers and reservoirs migrate upstream into tributary streams to spawn during the spring (Moyle et al. 1995).

Hardhead has been reported to occur in the upper Yuba River Watershed, including New Bullards Bar and Englebright reservoirs (Yuba Water 2017). Within YRDP reaches upstream of Englebright Dam, fish population studies for the YRDP relicensing found hardhead only in Englebright Reservoir where juveniles and adults were documented (Yuba Water 2017). Hardhead was the third-most common species collected during YRDP Relicensing surveys in Englebright Reservoir, and ranked fourth in biomass (Yuba Water 2017). The length-frequency distribution of hardhead displayed a wide range of ages present in the reservoir, including age-0 and adult fish, indicating the occurrence of natural reproduction (Yuba Water 2017). Englebright Reservoir exhibits relatively stable water surface elevations, but does exhibit short-term fluctuations of approximately 10 ft during the spring, which may help favor native species such as hardhead relative to centrarchids. Although hardhead were not observed or collected in the North Yuba River downstream of NBBD or in the upper Yuba River upstream of Englebright Reservoir during any of the YRDP relicensing studies (Yuba Water 2017), based on the presence of juvenile and adult lifestages in Englebright Reservoir and their upstream migration behavior to spawn in gravel riffles, it is reasonable to assume that hardhead successfully spawn in the upper Yuba River and/or

the South Yuba River. Because water temperatures under existing conditions (see Appendix 4C) are outside of the suitable hardhead spawning water temperature range (59-64.4°F; Wang 1986) during April-June all of the time immediately below NBBD and most (70%) of the time in the lowermost portion of the NBBD Reach (i.e., immediately upstream of the confluence with the Middle Yuba River), spawning and subsequent rearing could be generally expected to be limited to areas downstream of the North Yuba River. As shown in the lower Yuba River (see Section 9.2.5.2.7 below), juvenile hardhead appear to migrate downstream soon after emergence so they would be unlikely to rear in the North Yuba River downstream of NBBD.

Hardhead historically may have occupied the Middle Yuba River and Oregon Creek (Yuba Water 2017), but no hardhead were found in YRDP reaches during YRDP relicensing studies (Yuba Water 2017). Similarly, no hardhead were found in reaches of the Middle Yuba River upstream of the OHDD impoundment during YB/DS relicensing studies (FERC 2014). Although hardhead were not identified during YB/DS relicensing fish studies during 2008 and 2009 in the South Yuba River below Spaulding Dam, Placer County Water Agency reported that surveys during 2012 collected hardhead in the lower to mid portions of the river between RM 8 (near Jones Bar) and RM 20.2 (near Humbug Creek) (FERC 2014). Hardhead were reportedly not observed in YB/DS reservoirs during YB/DS relicensing studies (FERC 2014).

9.2.5.1.3 Central California Roach

The Central California roach is part of the California roach complex, which is composed of various subspecies. The Central California roach is found in the Sacramento and San Joaquin River drainages, except the Pit River, and in other tributaries to San Francisco Bay. The Central California roach is generally found in small, warm intermittent streams, and is most abundant in mid-elevation streams in the Sierra foothills and in the lower reaches of some coastal streams (Moyle 2002). Although roach are abundant in many streams, roach populations have been extirpated from many streams and stream reaches due to human disturbances including diversions and introduced predatory fishes (particularly green sunfish) (Moyle 2002). Brown and Moyle (1993) found that roach were most abundant when they were the only fish species observed. Roach are tolerant of very high water temperatures (86°F to 95°F) and low oxygen levels (1 to 2 mg/L) (Taylor et al. 1982), but they also can be found in cold, well-aerated clear "trout" streams (Taylor et al. 1982), human-modified habitats, and main channels of rivers (Moyle 2002).

Reproduction occurs from March through early July, with spawning typically initiating after water temperatures reach approximately 61°F (Moyle 2002). During the spawning season, schools of fish move into shallow areas with moderate flow and gravel/rubble substrate (Moyle 2002). Females deposit adhesive eggs in the substrate interstices or within emergent vegetation and the eggs are fertilized by attendant males. The eggs hatch within two to three days, and fry remain in the substrate interstices or among emergent vegetation until they are free-swimming (Moyle 2002).

Within the areas upstream of Englebright Dam, Central California roach have been reported to historically occur downstream of NBBD, however, roach were not identified during any of the YRDP relicensing fish population surveys (Yuba Water 2017). The prevalence of smallmouth bass in the upper Yuba River upstream of Englebright Reservoir could be a factor in the lack of recent roach observations. During YB/DS relicensing fish population surveys, roach were identified in Fordyce Creek below Fordyce Lake Dam (NID and PG&E 2009).

9.2.5.1.4 Sacramento pikeminnow

Sacramento pikeminnow are widespread in central California streams and are often in low- to mid-elevation streams with deep pools, slow runs, undercut banks and overhanging vegetation (Moyle 2002). They are most abundant in lightly disturbed reaches with riparian vegetation that also contain other native fish species, particularly hardhead and Sacramento sucker (Moyle 2002). Sacramento pikeminnow typically moves upstream to spawn during April through May in gravel substrates (Moyle 2002). Young feed on macroinvertebrates and switch to larger prey items such as other fish as they grow. Larval rearing occurs in shallows habitats and fish transition to deep water as they develop into juveniles and adults. Sexual maturation occurs at approximately 3 or 4 years old.

Sacramento pikeminnow were found in relatively low abundances but were found throughout the YRDP reaches (Yuba Water 2013e). Sacramento pikeminnow (and Sacramento sucker) was the most abundant sampled non-salmonid species in the YB/DS reaches (NID and PG&E 2009). The highest estimated abundance for Sacramento pikeminnow in the YB/DS reaches was on the South Yuba River (NID and PG&E 2009). Sacramento pikeminnow was the most common fish species collected during surveys in Lake Spaulding (FERC 2014).

9.2.5.1.5 Sacramento sucker

Sacramento suckers are found in a wide variety of waters ranging from cold, fast-flowing streams to warm sloughs (Moyle 2002). They are often associated with other native minnows, particularly Sacramento pikeminnow, hardhead and roach, but also are found in waters dominated by non-native fish species (Moyle 2002). Sacramento suckers typically migrate upstream into a tributary to a large river or reservoir to spawn between late February and June (Moyle 2002). Eggs are adhesive and are deposited over gravel substrate. Sacramento sucker feed on a variety of prey items include macroinvertebrates, detritus, and plant matter.

Sacramento sucker was commonly found throughout the YRDP reaches during YRDP relicensing studies and in the YB/DS reaches during YB/DS relicensing studies (Yuba Water 2017; FERC 2014).

9.2.5.1.6 Black Bass

Black bass in the Centrarchidae family are non-native to California, and this family includes species such as the largemouth bass (*Micropterus salmoides*), smallmouth bass (*Micropterus dolomieu*), and spotted bass. Black bass are commonly stocked for recreation. Black bass typically spawn from March through June (Moyle 2002). Young bass use shoreline habitats and then transition to deeper water as they grow older. Smallmouth bass are found throughout the YRDP reaches but were absent at the furthest upstream sites on the North Yuba River, Oregon Creek and Middle Yuba River (Yuba Water 2013e).

9.2.5.1.7 Kokanee

Kokanee are a resident form of sockeye salmon. This adfluvial species spawns in streams during the fall, creating redds similar to other salmonids. Typically, fry emerge from redds in the spring and summer and out-migrate to lakes (Moyle 2002). Kokanee are largely planktivorous, feeding

on zooplankton but they also feed on aquatic macroinvertebrates and forage fishes (Moyle 2002). Kokanee were stocked in reservoirs throughout California, including Englebright and New Bullards Bar reservoirs, and have been observed in the upper Yuba River upstream of Englebright Reservoir and in the North Yuba River upstream of NBBR (Yuba Water 2013e).

9.2.5.2 Lower Yuba River

Fish species of management concern in the lower Yuba River and their status are identified in Table 9.2-2.

Species and lifestage-specific periodicities for the lower Yuba River are shown in Table 9.2-3, and are modified from RMT (2013) and Yuba Water (2017) based on more recent monitoring data and information (described in the table footnotes). Detailed descriptions of the life histories, habitat preferences, status, and factors affecting the anadromous fish species of spring-run Chinook salmon, fall-run Chinook salmon, steelhead, and green sturgeon in the lower Yuba River under existing conditions are provided in Appendix 9A – *Anadromous Fisheries Resources of the Lower Yuba River*. Brief summaries of the information provided in Appendix 9A for spring-run and fall-run Chinook salmon, steelhead, and green sturgeon, as well as brief descriptions of available formation for the other fish species of management concern, are provided below.

Table 9.2-2. Fish species of management concern with the potential to occur in the lower Yuba River.

Common Name/ (Scientific Name)	*Status*[1]

Striped bass							*X*
American shad							*X*

[1] *NMFS-SC = Classified as a Species of Concern by NMFS.*
USFWS-SC = Designated as a Species of Concern by USFWS.
CDFW-SSC = Designated as a Species of Special Concern by CDFW.
PFMC = Managed by the PFMC.

[2] Although there were some reported observations of Sacramento hitch (*Lavinia exilicauda*) during RST surveys conducted over 20 years ago, they have not been reported in the lower Yuba River during any other surveys, including CDFG (1991) snorkeling and electrofishing surveys, RST surveys after about 2001, Kozlowski (2004) snorkeling and electrofishing surveys, VAKI Riverwatcher™ data from 2004 through 2017, and RMT snorkeling surveys during 2012, 2014 and 2015. Hitch prefer warm, slow-moving waters and have shown a preference for water temperatures of 81-84°F (Knight 1985 as cited in Moyle 2002). Additionally, the lower Yuba River is located outside of the identified range of Sacramento hitch in the CNDDB. For these reasons, Yuba Water has eliminated Sacramento hitch from further consideration in this EIR.

[3] Although chum salmon (*O. keta*) reportedly have been observed in the lower Yuba River in the past, more recent VAKI Riverwatcher™ data indicate that chum salmon observations are rare (2 records during 2013, 1 record during 2017, 2 records during 2018, and 1 record during 2020). Yuba Water (2017) also reports that "Pink and chum salmon are unique visitors to Central Valley streams and have not sustained a viable population in California for over 70 years." For these reasons, Yuba Water has eliminated chum salmon from further consideration in this EIR.

[4] Although two rare observations (9 records during 2011, 2 records during 2013) of pink salmon (*O. gorbuscha*) in the lower Yuba River have been reported, there have been no observations of pink salmon in the VAKI Riverwatcher™ data from 2014 through February 2022. Hence, Yuba Water has eliminated pink salmon from further consideration in this EIR.

[5] CDFW (2015) reports that Sacramento splittail (*Pogonichthys macrolepidotus*) only rarely enter the lower reaches of the Feather River. Although UC Davis (2012) lists the Yuba River downstream of Englebright Dam among the watersheds where splittail occurs, no reference is provided for this determination, and Yuba Water could not find any verified observations of splittail nor was it found during Yuba Water's relicensing studies for the YRDP (Yuba Water 2017). Recent review of VAKI Riverwatcher™ data indicates that no Sacramento splittail have been observed in the lower Yuba River from January 2004 through February 2022. Consequently, Yuba Water has eliminated Sacramento splittail from further consideration in this EIR.

[1] The Yuba River spring-run Chinook salmon YOY (fry and juvenile) rearing period extends from mid-November through June, while the over-summer rearing period exhibited by spring-run Chinook salmon juveniles exhibiting the yearling+ rearing strategy extends from July through mid-November.

[2] Examination of Yuba River RST data (1999-2009) demonstrates that YOY spring-run downstream migration extends from late November through June. Yearling+ individuals emigrate during fall and winter freshets. The application of the Seasonal Flow Detection Algorithm tool (Patterson et al. 2020) to lower Yuba River modeled flows (WY 1970-2017) indicated that the initial freshet date ranged from mid- to late October through mid-December, with a median date of November 29. To cover the vast majority of freshet timing and associated yearling+ emigration, the yearling+ downstream migration period includes all of November, and the overall YOY & yearling+ emigration period extends from November through June.

[3] Fall-run Chinook salmon adult immigration timing based on acoustic telemetry (2009-2011) and VAKI Riverwatcher™ data (2004-2020) used for run differentiation (Poxon and Bratovich 2020).

[4] Although the adult immigration and holding lifestage for steelhead was presented in RMT (2013) and Yuba Water (2017) as extending from August through March, updated analysis of VAKI Riverwatcher™ data indicate that the time period for this lifestage should be revised to extend from September through March.

[5] Examination of year-round (2007 and 2008) Yuba River RST data not affected by rapid initiation of water transfer (2001) demonstrates that the majority of YOY steelhead downstream migration extends from May through July. Year-round RST data (2001, 2007 and 2008) show that yearling+ individuals primarily emigrate during December through April. Because RST data show that juvenile steelhead emigrants are captured to a certain extent during all months of the year, the steelhead juvenile downstream migration period in the lower Yuba River is defined as

occurring year-round, although the majority of steelhead (YOY and yearling+) juvenile outmigrants are captured during February through July.

[6] Based on upstream migration timing of acoustically-tagged adult green sturgeon in the Sacramento River, Colborne et al. (2022) identified that adults primarily migrate upstream during mid-February through mid-May. However, adult green sturgeon are reported to enter the Feather and Yuba rivers between early April and mid-May (CDFW and DWR unpublished data, as cited in Beccio 2022), and observations of green sturgeon eggs and/or larvae in the lower Yuba River indicate that green sturgeon spawning in the lower Yuba River extends from June through July. Consequently, the green sturgeon adult upstream migration and holding period in the lower Yuba River is defined as extending from April through June.

[7] Green sturgeon eggs were documented by CDFW in the lower Yuba River in the DPD plunge pool on June 15, 2018 (Beccio 2018). Additionally, one late-stage green sturgeon larva was collected in the lower Yuba River downstream of DPD on August 22, 2019 (Beccio 2019), and five larval green sturgeon were collected by DWR in RSTs in the lower Yuba River on July 6-7, 2023 (C. Campos pers. comm., July 25, 2023). Based on early lifestage developmental timing described in NMFS (2018), the date of spawning for these green sturgeon larvae documented in the lower Yuba River is estimated to be between June 15 and July 22. The green sturgeon embryo incubation period is reported to extend for 6-8 days (Deng et al. 2002; NMFS 2018). Consequently, the green sturgeon spawning and embryo incubation period in the lower Yuba River is defined as extending from June through July.

[8] Based on downstream migration timing of acoustically-tagged adult green sturgeon in the Sacramento River (Colborne et al. 2022), adults primarily migrate upstream during mid-February through mid-May, and the downstream migration of adults extended primarily from mid-April through July ("early downstream migration") and October through mid-February ("late downstream migration"). However, given the estimated spawn timing for green sturgeon in the lower Yuba River of June through July, the early period of adult post-spawn downstream migration is defined as extending from June through July, while the late period of adult post-spawn downstream migration is defined as extending from October through mid-February. The adult post-spawn holding period consequently is defined as extending from June through mid-February, although adult post-spawn holding has been reported to occur year-round in Sacramento and Feather rivers (Beccio 2022; Miller et al. 2020 as cited in Colborne et al. 2022), and in the lower Yuba River on one occasion (Beccio 2022) during an extremely dry year.

[9] Kynard et al. (2005) laboratory studies indicated that juvenile green sturgeon continued to migrate downstream at night for the first six months of life. NMFS (2018) states "it is unknown how long juveniles remain in upriver rearing habitats after metamorphosis, but they likely spend the first several months in freshwater environments." However, as requested by CDFW staff during discussions regarding the design of the Nature-like Fishway at Daguerre Point, the green sturgeon juvenile rearing and downstream migration period in the lower Yuba River is defined as extending from July through January (C. Purdy pers. comm., May 15, 2023).

[10] The lifestage periodicities identified for lamprey apply to both Pacific lamprey and river lamprey, although river lamprey are much less common than Pacific lamprey in the lower Yuba River.

[11] Based on RST survey data from WY 2004 through WY 2012 at the Red Bluff Diversion Dam on the Sacramento River, the primary emigration period of Pacific lamprey macrophthalmia ranged from November to May (Goodman et al. 2015).

9.2.5.2.1 Spring-run Chinook Salmon

Phenotypic adult spring-run Chinook salmon in the lower Yuba River migrate upstream of DPD from May through September and utilize a broad expanse of the lower Yuba River during the summer holding period, particularly immediately downstream of DPD (RMT 2013). In general, acoustically-tagged spring-run Chinook salmon exhibited an extended holding period, followed by a rapid movement into upstream areas (upper Timbuctoo Reach, Narrows Reach, and Englebright Dam Reach) during September. Based on acoustic tagging, redd survey and carcass survey data, the spring-run Chinook salmon spawning period in the lower Yuba River extends from September 1 through mid-October (RMT 2013). The vast majority of spring-run Chinook salmon spawning occurs upstream of DPD, particularly in the Parks Bar and Timbuctoo reaches (RMT 2013). During the 2009 and 2010 near-census redd surveys only 3-4% of redds constructed during September were located below DPD. Based on 2012, 2014 and 2015 RMT snorkel surveys,

Chinook salmon fry and juveniles were observed in greatest numbers in the Timbuctoo Bend, Parks Bar and Dry Creek reaches upstream of DPD (RMT, unpublished data). Although juvenile spring-run Chinook salmon can rear year-round, rotary screw trap (RST) monitoring data indicate that the vast majority of spring-run Chinook salmon emigrate as post-emergent fry during late November and December.

Summary of Spring-run Chinook Salmon Status in the Lower Yuba River

Based on information and analyses presented in Appendix 9A, annual escapement of phenotypic spring-run Chinook salmon upstream of DPD ranged from 235 in 2015 to 5,275 in 2005, and averaged approximately 1,841 fish annually for the years when data were available from 2004-2023. The phenotypic spring-run Chinook salmon annual population abundance in the lower Yuba River from 2004-2023 is exhibiting a declining trend, although not statistically significant. The influence of hatchery strays is highly variable, but the minimum percentage of hatchery (ad-clipped) contribution to the annual population is increasing over time.

Summary of Factors Affecting Spring-run Chinook Salmon in the Lower Yuba River

Table 9.2-4 includes a comprehensive list of factors/stressors affecting the status of spring-run Chinook salmon in the lower Yuba River under existing conditions (based on information and analyses presented in Appendix 9A), including factors/stressors which have no clear nexus to the Proposed Projects and occur outside of the Project Area, but are included simply in an effort to establish an understanding of the population's ability to withstand additional adverse effects potentially associated with the Proposed Projects or alternatives.

Table 9.2-4. Relative magnitudes of factors/stressors affecting lower Yuba River spring-run Chinook salmon under existing conditions.

Spring-run Chinook Salmon Factor/Stressor	Factor/Stressor Magnitude
Passage Impediments/Barriers	
• Englebright Dam	High
• Daguerre Point Dam	High
Entrainment	
• South Yuba/Brophy	Low
• Hallwood-Cordua	Medium
• BVID	Low
Predation	Low to Medium
Poaching	Medium to High
Hatchery Effects	High
Spawning Habitat Availability	Low
Narrows 1 and 2 Operations	Low
Redd Dewatering	Low
Stranding and Isolation	
• Adults (including Deer Creek)	Medium
• Juveniles	Low to Medium

Spring-run Chinook Salmon Factor/Stressor	Factor/Stressor Magnitude
Harvest/Angling	Low
Natural River Morphology and Function	High
Riparian Habitat and Large Woody Material (LWM)	Medium to High
Floodplain Habitat Connectivity & Availability	Low to Medium
Water Quality	Low
Water Temperature Suitability	Low to Medium
Aquatic Invasive Species	Low

9.2.5.2.2 Fall- and Late Fall-run Chinook Salmon

Adult fall-run Chinook salmon immigration and staging generally occurs in the lower Yuba River from mid-July through December (Poxon and Bratovich 2020). The lower Yuba River fall-run Chinook salmon spawning period has been reported to extend from October through December (RMT 2013). Escapement surveys suggest that approximately three-fourths of fall-run Chinook salmon spawning in the lower Yuba River occurs above DPD (see Appendix 9A). Most fall-run Chinook salmon exhibit downstream movement as fry shortly after emergence from gravels, although some individuals rear in the river for up to several months. Thus, the fry rearing lifestage is considered to extend from mid-December through April, the juvenile rearing lifestage extends from mid-January through June, and the fry and juvenile downstream movement lifestage generally extends from mid-December through June (RMT 2013). Although late fall-run Chinook salmon populations occur primarily in the Sacramento River, incidental observations of late fall-run Chinook salmon have been reported to occur in the lower Yuba River (RMT 2013).

Summary of Fall-run Chinook Salmon Status in the Lower Yuba River

Based on information and analyses presented in Appendix 9A, total annual escapement of fall-run Chinook salmon in the lower Yuba River ranged from 1,007 fish in 2007 to 11,181 fish in 2013 and averaged approximately 4,971 fish annually for the years when data were available from 2004-2023. Trend analyses in fall-run Chinook salmon abundance in the lower Yuba River utilizing updated data and information from 2004-2015, 2018, and 2020-2023 demonstrate that the abundance of fall-run Chinook salmon in the lower Yuba River has exhibited a slight although not statistically significant increase over the years examined. Similar to the results for spring-run Chinook salmon, the trend in the proportional contribution of adipose fin-clipped fish to the total annual run of fall-run Chinook salmon upstream of DPD has increased over time.

Summary of Factors Affecting Fall-run Chinook Salmon in the Lower Yuba River

The magnitude of many of the stressors/factors affecting fall-run Chinook salmon in the lower Yuba River under existing conditions are similar to those as characterized for spring-run Chinook salmon. Key stressors (i.e., identified as “medium to high” and “high” magnitudes) affecting fall-run Chinook in the lower Yuba River under existing conditions include the following.

- Englebright Dam – High
- Hatchery Effects – High

- The habitat area of particular concern (HAPC) of "Complex Channels and Floodplain Habitats" (represented by the combination of *Floodplain Habitat Connectivity & Availability* and *Natural River Morphology*) – Medium to High
- Riparian Habitat and Large Woody Material (LWM) – Medium to High

9.2.5.2.3 Steelhead

Based on VAKI Riverwatcher™ data at DPD extending from January 2004 through February 2022, the majority of upstream migration of adult steelhead extends from September through March. Most (>90%) of steelhead spawning occurs upstream of DPD, particularly in the Timbuctoo Bend and Parks Bar reaches (RMT 2013). In the lower Yuba River, juvenile steelhead exhibit variable durations of rearing, ranging from a few months to 3 years (RMT 2013). However, based on RST surveys and snorkel surveys, the majority of steelhead juveniles appear to leave the lower Yuba River as YOY during the spring to continue rearing in downstream areas. During RMT snorkel surveys in 2014, the vast majority of steelhead fry observed were located in the Timbuctoo Bend Reach, followed by the Englebright Dam Reach (RMT, unpublished data). Steelhead juvenile observations also were primarily in the Timbuctoo Bend and Englebright Dam reaches, with fewer observations in the remaining reaches.

Summary of Steelhead Status in the Lower Yuba River

Based on updated data and information presented in Appendix 9A, uncorrected VAKI Riverwatcher counts for the 11 biological years (2010/2011 through 2015/2016, 2017/2018, and 2018/2019 through 2022/2023) when annual time series of reliable counts are available indicate that counts of adult steelhead passing upstream of DPD ranged from 27 in 2015/2016 to 527 in 2010/2011, with an annual average of 200 individuals. Adult steelhead passage counts at DPD from 2018 through 2023 demonstrate an increase in the number of steelhead from prior years, with a marked increase in abundance during the 2020/2021 and 2021/2022 biological years. Overall, from 2010/11 – 2021/2022, annual counts of adult steelhead passage upstream of DPD are generally stable and exhibit a slight although not statistically significant increasing trend. Hatchery contribution to annual adult steelhead escapement upstream of DPD is a regular occurrence based on the observation of adipose fin-clipped adult steelhead passing through the VAKI Riverwatcher™ photogrammetric system at DPD.

Summary of Factors Affecting Steelhead in the Lower Yuba River

The relative magnitudes of factors/stressors affecting steelhead in the lower Yuba River under existing conditions are shown in Table **9.2-5**, based on information presented in Appendix 9A. Table 9.2-5 includes a comprehensive list of factors affecting the status of steelhead in the lower Yuba River under existing conditions, including factors which have no clear nexus to the Proposed Projects and occur outside of the Project Area, but are included simply in an effort to establish an understanding of the population's ability to withstand additional adverse effects potentially associated with the Proposed Projects or alternatives.

Table 9.2-5. Relative magnitudes of factors/stressors affecting lower Yuba River steelhead under existing conditions.

Steelhead Factor/Stressor	Present Factor/Stressor Magnitude
Passage Impediments/Barriers	
• Englebright Dam	High
• Daguerre Point Dam	High
Entrainment	
• South Yuba/Brophy	Low
• Hallwood-Cordua	Medium to High
• BVID	Low
Predation	Low to Medium
Poaching	Medium
Hatchery Effects	High
Spawning Habitat	Low
Narrows 1 and 2 Operations	Low
Redd Dewatering	Medium to High
Stranding and Isolation	
• Adults	Low
• Juveniles	Low to Medium
Harvest/Angling	Low
Natural River Morphology and Function	High
Riparian Habitat and LWM	Medium to High
Floodplain Habitat Connectivity & Availability	Low to Medium
Water Quality	Low
Water Temperature Suitability	Low
Aquatic Invasive Species	Low

9.2.5.2.4 Green Sturgeon

As described in Appendix 9A, limited information regarding green sturgeon distribution, movement, and behavioral patterns, as well as lifestage-specific habitat utilization preferences is available for the lower Yuba River. Over the course of annual sturgeon egg matt surveys in the DPD plunge pool starting in 2017, CDFW observed adult green sturgeon during June into early August and eggs were observed on June 15, 2018 (Beccio 2018). One early-stage juvenile green sturgeon (40 mm FL) was captured in an edgewater habitat about 200 m downstream of DPD on August 19, 2019 (Beccio 2019). During July of 2023, five early lifestage (24-28 mm) juvenile green sturgeon were caught during RST monitoring in the lower Yuba River downstream of DPD (C. Campos, pers. comm., July 25, 2023).

Based on the adult and egg observations during the egg matt surveys and juvenile observations, green sturgeon spawning and incubation may occur in the lower Yuba River below DPD during June through July. After hatching, larval green sturgeon may remain in the gravels for about

10-14 days before starting exogenous feeding and dispersal (NMFS 2016). The duration of green sturgeon juvenile rearing in the lower Yuba River before moving downstream is not known. Adult green sturgeon holding after spawning may continue into the following winter.

Current scientific information indicates that the Southern DPS of green sturgeon population has been relegated to a single, independent population, which principally spawns in the mainstem Sacramento River (NMFS 2021), but also may breed opportunistically in the lower Feather and Yuba rivers (NMFS 2016). Therefore, by contrast to spring-run Chinook salmon and steelhead, stressors identified for green sturgeon occurring in the lower Yuba River do not represent population-level stressors. There also is greater uncertainty in the identification of the relative magnitude of stressors affecting green sturgeon in the lower Yuba River relative to spring-run Chinook salmon and steelhead. Nonetheless, based on information presented in Appendix 9A, the following stressors (and associated relative magnitudes) have been identified for green sturgeon in the lower Yuba River under existing conditions for the purpose of evaluating whether and to what extent the Proposed Projects may influence these stressors.

- Passage Impediments/Barriers - Low
- Poaching - Medium
- Predation (eggs) – Low to Medium
- Water Temperature - Low

9.2.5.2.5 Pacific Lamprey and River Lamprey

Snorkel and electrofishing surveys have shown that Pacific lamprey is abundant and well distributed within the lower Yuba River (Yuba Water 2017; Yuba Water 2023a). River lampreys were consistently observed emigrating past the RST survey sites in the lower Yuba River between 1999 and 2010 (Yuba Water 2017). The adult migration into freshwater towards upstream spawning areas primarily begins between early March and late June (Moyle 2002). Pacific lampreys have been reported to spawn between March and July, depending on the location (USFWS 2010), which indicates that eggs could be incubating as late as August. Following ammocoete metamorphosis, downstream migration coincides with high flow events in late winter and early spring (Moyle 2002). Juvenile Pacific lamprey downstream migration has occurred throughout the year in the lower Yuba River with the peak of migration occurring between December and February (Yuba Water 2017).

9.2.5.2.6 Central California Roach

Central California roach life history information is summarized above under Section 9.2.5.1. Central California roach have been documented during RST monitoring on the lower Yuba River (RMT 2013). More recently, there have been no observations of roach in the VAKI Riverwatcher™ fish monitoring system at Daguerre Point Dam from 2015 through February 2022. During the RMT 2012, 2014 and 2015 snorkel surveys, 20 juvenile roach were identified (RMT, unpublished data). Spawning reportedly occurs from March through early July, typically initiating after water temperatures reach approximately 61°F (Moyle 2002).

9.2.5.2.7 Hardhead

Hardhead life history information is summarized above under Section 9.2.5.1. Adult and juvenile hardhead have been documented in the lower Yuba River downstream of Englebright Dam during various surveys conducted since the late 1980s (reviewed by Yuba Water 2017). Juvenile hardhead were routinely collected during juvenile salmon emigration studies on the Yuba River between 1999 and 2009 (Yuba Water 2017; RMT 2013). However, only a few hardhead were observed during the RMT's 2012, 2014 and 2015 snorkel surveys (RMT, unpublished data). More recently, hardhead have been recorded annually in the VAKI Riverwatcher™ fish monitoring system at DPD from 2015 through February 2022. Hardhead spawning occurs during the spring when hardhead migrate upstream to gravel riffles, often within tributary streams (Moyle 2002). This upstream migration behavior by spawning adult hardhead is supported by the VAKI Riverwatcher™ data at DPD, which show adult hardhead moving upstream during primarily April through June, and juvenile hardhead moving downstream between April and August (particularly during June) (Yuba Water 2021).

9.2.5.2.8 White Sturgeon

Insufficient information is available to characterize white sturgeon life history in the lower Yuba River. However, adult white sturgeon have reportedly been observed in the lower Yuba River downstream of DPD (Beccio 2019). White sturgeon primarily spawn in a short reach of the middle Sacramento River between Knights Landing and Colusa (Schaffter 1997), although some spawning also occurs in tributaries including the Feather River (DWR 2022). Spawning adults likely migrate upstream to the lower reaches of the Sacramento River during winter in response to higher flows (Schaffter 1997), but may be migrating between fall and spring (DWR 2022). Adults spawn from February to June and return to the Delta after spawning (Schaffter 1997). The early life history of white sturgeon is not well understood, but current evidence indicates that dispersed, fertilized eggs settle to the bottom of the river and stick to hard surfaces. Eggs hatch into the larval stage after about 12 days. The newly hatched larvae swim actively for several days before settling to the bottom of the channel. Juveniles move rapidly down-river during their first year, taking up residence in the freshwater region of the estuary (CDFW 2022).

Although white sturgeon adults have been reportedly observed in the lower Yuba River, white sturgeon was not a focal species of evaluation by the YRDP Relicensing Participants (including NMFS, CDFW, USFWS and USFS) in the lower Yuba River, and are not known to spawn in the lower Yuba River. Nonetheless, because adult white sturgeon have been observed in the lower Feather River during spring and summer months (Seesholtz et al. 2016), this DEIR assumes that adult white sturgeon may have the potential to occur in the lower Yuba River downstream of DPD during various times of the year.

9.2.5.2.9 Striped Bass and American Shad

Although not species of focal evaluation, non-native striped bass and American shad are considered in this analysis as appropriate given their status as commercially and recreationally important fish species.

CDFG (1991) reported that striped bass are unable to access the lower Yuba River upstream of DPD, but they have occasionally accessed the fish ladders at DPD and have been identified in the lower Yuba River downstream of DPD during snorkel surveys and other fisheries studies (RMT 2013). However, striped bass were not observed in the lower Yuba River during the most recent snorkel surveys conducted during 2012, 2014 and 2015 (RMT, unpublished data). Spawning and initial rearing could occur in the lower Yuba River during April through June. Striped bass spawn in water temperatures ranging from about 59 to 68°F, and can tolerate temperatures up to 77°F or higher (Moyle 2002).

In 2018, American shad eggs were collected from several of the egg mats placed below DPD as part of CDFW's sturgeon spawning study (Beccio 2018). American shad have primarily been observed downstream of DPD during snorkel and RST surveys, but also have been observed accessing the fish ladders at DPD (RMT 2013). American shad were not observed in the lower Yuba River during the most recent snorkel surveys conducted during 2012, 2014 and 2015 (RMT, unpublished data). Spawning and initial rearing could occur in the lower Yuba River during April through June. American shad are reported to spawn at water temperatures ranging from about 46 to 79°F (USFWS 1967).

9.2.5.3 Areas Downstream of the Lower Yuba River

Areas downstream of the lower Yuba River include the Feather River downstream of the lower Yuba River, the Sacramento River downstream of the confluence with the lower Feather River and the Delta. Fish species of management concern in areas downstream of the lower Yuba River include the same fish species addressed in the lower Yuba River, in addition to Sacramento River winter-run Chinook salmon, Sacramento splittail, and Delta fish species (delta smelt, longfin smelt, starry flounder). Most anadromous salmonid, and green and white sturgeon, spawning occurs upstream of the lower Yuba River confluence within the Feather River and upstream of the lower Feather River confluence within the Sacramento River. Because the Feather River downstream of the Yuba River and the Sacramento River downstream of the Feather River primarily serve as migratory corridors, the primary lifestages in these reaches considered in this DEIR include the adult and juvenile migratory (and transient rearing) lifestages for all runs of Chinook salmon, steelhead, and Pacific lamprey, and the migration and rearing lifestages of green sturgeon and white sturgeon, Sacramento splittail, American shad and striped bass. All relevant lifestages of Delta fish species (delta smelt, longfin smelt, starry flounder) are evaluated for the Proposed Projects and alternatives.

9.3 Regulatory Setting

The Federal, State, and local plans, policies, regulations, and laws discussed in this DEIR are relevant to the Proposed Projects and alternatives. Other environmental laws not relevant to the Proposed Projects and alternatives are not discussed.

9.3.1 Federal Plans, Policies, Regulations, and Laws

9.3.1.1 Endangered Species Act

Under the Endangered Species Act (ESA), the Secretary of the Interior and the Secretary of Commerce jointly have the authority to list a species as threatened or endangered (16 U.S.C. Section 1533(c)). Pursuant to ESA requirements, a Federal agency proposing to implement or approve a project within its jurisdiction must determine whether any Federally listed threatened or endangered species may be present in the project area and determine whether the project would result in "take" of any such species. In addition, the agency is required to determine whether the project is likely to jeopardize the continued existence of any species proposed to be listed under the ESA or result in the destruction or adverse modification of critical habitat proposed to be designated for such species (16 U.S.C. Sections 1536(3), (4)). Section 7 of the ESA provides a means for authorizing incidental take of Federally endangered or threatened species that result from Federally conducted, permitted, or funded projects. Similarly, Section 10 authorizes incidental take of Federally endangered or threatened species that result from non-Federal projects.

9.3.1.1.1 Critical Habitat Designations

The ESA also requires the designation of "critical habitat" for listed species. "Critical habitat" is defined as: (1) specific areas within the geographical area occupied by the species at the time it is listed, on which are found those physical or biological features essential to the conservation of the species, and which may require special management considerations or protection; and (2) specific areas outside the geographic area occupied by the species at the time it is listed if the agency determines that the area itself is essential for conservation of the species (16 USC §1532(5)(a) and is capable of being occupied by the species (*Weyerhaeuser Co. v. United States Fish & Wildlife Serv.*, 139 S. Ct. 361, 368 (2018) (only "habitat" of an endangered species is eligible for designation as "critical habitat.")). As discussed above, critical habitat has been designated for spring-run Chinook salmon, steelhead, and green sturgeon in the lower Yuba River.

9.3.1.1.2 National Marine Fisheries Service Recovery Planning for Salmon, Steelhead, and Green Sturgeon in California

In the Central Valley, NMFS is responsible for facilitating the development of recovery plans for the following species addressed in this analysis:

- Central Valley Spring-run Chinook Salmon ESU
- Central Valley Steelhead DPS
- Southern DPS of North American Green Sturgeon

The NMFS (2014) recovery plan describes the steps, strategy, and actions recommended to return spring-run Chinook salmon and steelhead to viable status in the Central Valley, with the goal of ensuring their long-term persistence and evolutionary potential. For the Central Valley Chinook salmon ESUs and the steelhead DPS to achieve recovery, the recovery strategy is focused on two principles: (1) functioning, diverse, and interconnected habitats are necessary for a species to be viable; and (2) species viability is determined by spatial structure, diversity, productivity, and

abundance. In 2018, NMFS completed a recovery plan for the Southern DPS of North American green sturgeon. To achieve delisting, the objective of the recovery plan is to increase green sturgeon abundance, distribution, productivity, and diversity by alleviating significant threats to the species, including blockage of access to spawning habitat in the Sacramento River, critical flow and water temperature patterns, harvest and poaching rates, entrainment, invasive species, exposure to contaminants, and loss of habitat and related estuarine/Delta function (NMFS 2018).

9.3.1.1.3 Pacific Lamprey Conservation Initiative

USFWS' strategy to improve the status of lampreys is carried out through the Pacific Lamprey Conservation Initiative (PLCI), which promotes implementation of conservation measures for Pacific Lamprey across their range. The PLCI includes an assessment of Pacific lamprey, a Conservation Agreement (USFWS 2022); and Regional Implementation Plans (RIPs). As described in USFWS (2022), for the purpose of implementing conservation actions, Pacific Lamprey distribution has been divided into 18 Regional Management Units (RMUs). Each of these RMUs includes several 4th level Hydrologic Unit Codes, which are the finer scale geographic units used to evaluate lamprey status, threats, and conservation needs. The Fisheries Project Area for this DEIR includes areas of the Sacramento RMU, including the lower Yuba River, lower Feather River downstream of the lower Yuba River, Sacramento River downstream of the lower Feather River, and the Delta.

The RIP for the Sacramento RMU (Boyce et al. 2022) includes status and distribution of Pacific lamprey in the Sacramento River Watershed, identifies threats and limiting factors to Pacific lamprey in the Sacramento RMU, and includes an implementation plan that identifies conservation efforts, knowledge gaps and implementation projects that will reduce risks to Pacific lamprey within the Sacramento RMU and its component watersheds. The principal implementation projects for the lower Yuba River include ensuring passage at DPD and evaluation of rearing habitat availability caused by sediment removal at the upstream dams and legacy mining impacts resulting in lack of fine sediment (Boyce et al. 2022). The primary concern in the lower Yuba River is limited fine sediments suitable for ammocoete rearing, particularly at the upstream reaches of the lower Yuba River (Boyce et al. 2022).

9.3.1.2 Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation Management Act, as amended by the Sustainable Fisheries Act (Public Law 104-297), was enacted primarily to establish a management system for conserving and managing commercial fisheries within the 200-mile Federal waters boundary of the U.S. The act also requires that all Federal agencies consult with NMFS on activities or proposed activities authorized, funded, or undertaken by that agency that may adversely affect EFH of commercially managed marine and anadromous fish species. EFH includes specifically identified waters and substrate necessary for fish spawning, breeding, feeding, or growing to maturity. EFH also includes all habitats necessary to allow the production of commercially valuable aquatic species, to support a long-term sustainable fishery, and to contribute to a healthy ecosystem (16 U.S.C. Section 1802(10)). Because EFH only applies to commercial fisheries, all Chinook salmon habitats are included, but not steelhead habitat.

Freshwater EFH for Pacific salmon (e.g., spring-run Chinook salmon and fall-/late fall-run Chinook salmon) includes waters currently or historically accessible to salmon within the Central Valley ecosystems, as described by Myers et al. (1998). In the Yuba River Watershed, potential project-related effects having the potential to affect EFH are limited to three geographic areas: (1) North Yuba River; (2) Yuba River upstream of Englebright Reservoir; and (3) lower Yuba River, as described below.

- **North Yuba River**. PFMC (2014) has designated Chinook salmon EFH "*To Salmon Creek, near Sierra City*."
    - *Reservoir* – Approximately 15.5 miles of the North Yuba River canyon from the NMWSE of the Reservoir at RM 17.8 to the Dam at RM 2.3.
    - *Dam Reach* – Approximately 2.3 miles of the North Yuba River from the New Bullards Bar Minimum Flow Release Powerhouse at RM 2.3 to the confluence of the North Yuba River with the Middle Yuba River at RM 0.0.
- **Upper Yuba River**. Although no Chinook salmon are present upstream of Englebright Dam, nor have they been present upstream of Englebright Dam since its construction in 1941, the following reaches are contained within designated EFH.
    - *Middle/North Yuba River Reach* – Approximately 5.8 miles of the Yuba River from the confluence of the North Yuba River and the Middle Yuba River at RM 40.0 to the New Colgate Powerhouse at RM 34.2.
    - *New Colgate Powerhouse Reach* – Approximately 2 miles of the Yuba River from New Colgate Powerhouse at RM 34.2 to the normal maximum water surface elevation of the USACE's Englebright Reservoir.
    - *Englebright Reservoir* – Approximately 7.9 miles of the Yuba River from the normal maximum water surface elevation of Englebright Reservoir at RM 32.2 to Englebright Dam at RM 24.3.
- **Lower Yuba River**. EFH is designated for the entire lower Yuba River starting at Englebright Dam extending downstream to the confluence with the Feather River.

9.3.1.3 Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act (16 U.S.C. Sections 661, et seq.) provides that fish and wildlife resources receive equal consideration with other features throughout the planning process of water resources development projects. The act requires consultation with USFWS, NMFS, and State fish and wildlife agencies where the waters of any stream or other body of water are proposed, authorized, permitted, or licensed to be impounded, diverted, or otherwise controlled or modified under a Federal permit or license. Consultation is undertaken for the purpose of preventing loss of and damage to wildlife resources. The project proponents are required to consider the recommendations of the consultation, but implementation of them is not mandated.

9.3.2 State Plans, Policies, Regulations, and Laws

9.3.2.1 California Endangered Species Act

Under the California Environmental Species Act (CESA, CFGC Sections 2050, et seq.), CDFW has the responsibility for maintaining a list of threatened and endangered species designated under State law (see FGC Section 2070). Pursuant to CESA requirements, an agency reviewing a proposed project within its jurisdiction must determine whether any State-listed endangered or threatened species may be present in the project area and determine whether the proposed project would result in take of any such species. Under CESA, "take" is defined as the action of or attempt to "pursue, hunt, shoot, capture, collect, or kill." CDFW may authorize the incidental take of a State-listed species under Section 2081 of the CFGC. For species that are listed as threatened or endangered under both ESA and CESA, and for which an incidental take permit has been issued in accordance with Section 7 or Section 10 of the ESA, CDFW may authorize take after certifying that the Federal incidental take permit is consistent with CESA, pursuant to Section 2080.1 of the CFGC.

9.3.2.2 California Fish and Game Code

9.3.2.2.1 Rivers, Lakes, and Streams

Under CFGC Section 1602, it is unlawful for any entity to substantially divert or obstruct the natural flow of or substantially change or use any material from the bed, channel, or bank of, any river, stream, or lake, or to deposit or dispose of debris, waste, or other material where it may pass into any river, stream, or lake, without first notifying CDFW of such activity and obtaining an agreement authorizing the activity.

9.3.2.2.2 Dams and Obstructions

Section 5937 of the CFGC requires the owner of any dam to allow sufficient water at all times to pass through a fishway, or in the absence of a fishway, allow sufficient water to pass over, around or through the dam, to keep in good condition any fish that may be planted or exist below the dam. During the minimum flow of water in any river or stream, permission may be granted by CDFW to the owner of any dam to allow sufficient water to pass through a culvert, waste gate, or over or around the dam, to keep in good condition any fish that may be planted or exist below the dam, when, in the judgment of CDFW, it is impracticable or detrimental to the owner to pass the water through the fishway.

9.3.2.3 California Environmental Quality Act Guidelines

Pursuant to State of California Environmental Quality Act (CEQA) Guidelines Section 15380, CEQA requires consideration of potential impacts not only to species that are listed Federally or by the State but also to species that are not listed but may be considered rare, threatened, or endangered. Accordingly, "A species not included in any listing identified in subdivision (c) [ESA and CESA listed species] shall nevertheless be considered to be endangered, rare or threatened, if the species can be shown to meet the criteria in subdivision (b)" (State CEQA Guidelines Section 15380(d)).

The CEQA provision requires the lead agency to consider potential impacts to a species even when the respective government agencies have not had an opportunity to determine whether the species' status warrants listing. To assess "impact significance" to populations of non-listed species as well as listed species, CDFW recommends that the lead agency consider population-level effects, proportion of the taxon's range affected by a project, regional effects, and impacts to habitat features.

9.3.2.4 Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act (California Water Code Sections 13000, et seq.) requires that each of the State's nine RWQCBs prepare and periodically update basin plans for water quality control. Each basin plan sets forth water quality standards for surface water and groundwater and actions to control nonpoint and point sources of pollution to achieve and maintain these standards. Basin plans offer an opportunity to protect wetlands by establishing water quality objectives. RWQCB jurisdiction includes both Federally protected waters and areas that meet the definition of "waters of the State." Waters of the State include all surface water and groundwater, including saline waters, within the State's boundaries. The RWQCBs have discretion to take jurisdiction over areas not Federally regulated under Section 401, provided they meet the definition of waters of the State. Mitigation requiring no net loss of wetlands functions and values of waters of the State is typically required by RWQCB.

9.3.3 Regional/Local Plans, Policies, Regulations, and Ordinances

9.3.3.1 Yuba County 2030 General Plan

Most of the policies included in the Natural Resources Element of the Yuba County 2030 General Plan (Yuba County 2011) apply exclusively to development projects. However, the following policy addressed public investments and therefore applies to the proposed project:

- **Policy NR 5.7**. New developments and public investments near Yuba County's streams and rivers shall be designed to avoid tree removal, erosion, or other modifications that would adversely affect salmonid habitat.

9.3.3.2 Yuba County Municipal Code

Chapter 11.44 of the Yuba County Municipal Code includes a section addressing protection of natural resources. However, this chapter focuses on design of subdivisions, connections between subdivisions, and adjacent uses and developments. Therefore, it does not apply to this project.

9.3.4 Habitat Conservation Plans

There are no adopted habitat conservation plans (HCPs) or California Natural Community Conservation plans (NCCPs) within the Fisheries Project Area, except for the Yolo County HCP/NCCP which encompasses a portion of the lower Sacramento River and Delta. Although the Yolo County HCP/NCCP does not directly address fish species, it does include goals and policies related to protecting and improving habitat conditions in the Yolo Bypass, which could indirectly benefit fish resources (Yolo Habitat Conservancy 2017).

9.4 Impact Assessment Methodology

This section describes the impact assessment methodology, impact indicators, and significance criteria used by Yuba Water to evaluate the effects of the Proposed Projects and alternatives on fisheries and aquatic habitat compared to the bases of comparison.

9.4.1 Construction-Related Impacts

9.4.1.1 Areas Upstream of Englebright Dam

As described in Chapter 2, Yuba Water's Proposed Projects include seven general changes to existing YRDP facilities, including: (1) modification to the OHDD fish release outlet; (2) modification to the LCDD fish release outlet; (3) modification to the Lohman Ridge Diversion Tunnel Intake; (4) modifications to recreation facilities at NBBR; (5) addition of a tailwater depression system at New Colgate Powerhouse; (6) addition of a new auxiliary flood control outlet (aka ARC Spillway) at NBBR; and (7) modifications to YRDP roads. No construction activities would occur under the Narrows Project.

Chapter 2 summarizes the YRDP proposed construction activities and provides general information about the proposed schedule for construction of key facilities to provide an understanding of the estimated overall 1- to 20-year facility construction period. Exhibit C of Yuba Water's 2017 AFLA (see Appendix 2A of this DEIR) describes Yuba Water's construction methods and schedule for the above changes, with the exception of recreation facilities and roads. The construction schedules (including sequencing and duration) for recreation facilities and for roads are described in Yuba Water's proposed Condition RR1 (Implement Recreation Facilities Plan) and proposed Condition LU1 (Implement Transportation System Management Plan), which are included in Appendix 2B of this DEIR. Where available and appropriate, resource impact analyses use the detailed construction schedule and sequencing information available to estimate potential impacts (e.g., air quality).

Recreation-related construction activities are scheduled to extend over the duration of the new FERC license, and the implementation schedule for the major rehabilitation and improvements at each existing recreation facility (covering new License Years 1 through 20) is described in proposed Condition RR1 (Implement Recreation Facilities Plan) (see Appendix 2B). The implementation schedule for new recreation facilities (i.e., improvements) also is described in the Recreation Plan. As shown in the implementation schedule, construction work at individual recreation facilities is generally planned to be conducted in phases (e.g., License Year 1, License Years 6-10, License Years 10-15, etc.). The majority of work on National Forest System (NFS) lands will occur within the first eleven years of the new license, with some work on Yuba Water facilities occurring during License Years 14 through 20. After Year 20, the need for replacement and/or redevelopment of facilities will be discussed and determined at annual coordination meetings with the USFS, as described in the Recreation Plan (Yuba Water 2022a).

Potential impacts to fisheries resources associated with construction activities were evaluated based on the following considerations. Potential construction-related impacts evaluated include: (1) physical disturbance; (2) release and exposure of sediments and turbidity; (3) noise, motion and vibration disturbance; (4) disturbance of aquatic habitat including riparian vegetation; (5)

release and exposure of construction-related contaminants; and (6) isolation/dewatering and fish relocation activities. The potential for pre-construction and construction-related impacts to affect fisheries and aquatic resources is dependent on the location and type of activity or construction and the potential for these activities to directly harm individuals and/or remove, damage, or alter onsite habitat conditions within and adjacent to the construction footprints for a given alternative.

The impact assessment took into consideration the potential for construction activities to affect a particular fish species or lifestage that may be present in or adjacent to the project activity. Depending on the specific activity evaluated, the impact assessment considered either all, or a combination of, the elements listed below, as feasible and appropriate:

- Review of available maps and aerial imagery to determine the proximity of permanent and temporary construction features to the lower Yuba River.
- Evaluation of the timing, extent (e.g., long-term or short-term duration), and severity of disturbance activities resulting from construction-related activities and the use of construction equipment.
- Determination if there is a potential for construction activities to adversely modify habitat or appreciably diminish the value of critical habitat.
- Identification of protection measures to minimize or mitigate for potential construction-related impacts on sensitive life stages of fish species that may be present during construction activities.

9.4.1.2 Lower Yuba River

As described in Chapter 2, Yuba Water's Proposed Projects includes changes to existing YRDP facilities located upstream of Englebright Reservoir. No construction activities would occur adjacent to or within the lower Yuba River. Although adverse effects to fish species in the lower Yuba River are not expected due to construction activities in the upper Yuba River Watershed, the same considerations identified above were applied to the lower Yuba River. No construction activities would occur under the Narrows Project.

9.4.2 Operations-Related Impacts

Changes to operations that could affect fisheries resources in the YRDP reaches and reservoirs upstream of Englebright Dam, reaches of the lower Yuba River, and areas downstream of the lower Yuba River are due to changes in YRDP operations that would occur under the Proposed Projects

and alternatives[4]. As described in Chapter 2, no substantial changes in Narrows Project operations would occur under the Proposed Projects or alternatives. Operations-related impacts to fisheries resources under the Narrows Project are only due to license conditions/implementation plans. Consequently, operations-related fisheries impacts evaluated for the YRDP and Narrows Project include the following.

YRDP

- Areas Upstream of Englebright Dam
    - Quantitative changes in simulated habitat conditions (flow-dependent habitat availability, water temperature suitability)
    - Quantitative and/or qualitative changes to fisheries resources associated with operations or additional operations-related activities
        - Reservoir operations
            - Warmwater and coldwater fisheries in New Bullards Bar and Englebright reservoirs
            - Fish access to NBBR tributaries
            - Entrainment into project intakes
        - Spills at project dams
        - Powerhouse operations
        - Diversion dam operations
        - License implementation plans
- Lower Yuba River
    - Quantitative changes in simulated habitat conditions (flow-dependent habitat availability, water temperature suitability)
    - Quantitative and/or qualitative changes to fisheries resources associated with operations or additional operations-related activities

[4] As described in Chapter 4, Yuba Water's proposed ARC Spillway was fully analyzed in a separate environmental review process, which included preparation of a Draft EIR and Final EIR, which has been certified by Yuba Water with issuance of a Notice of Determination. For completeness, this DEIR evaluates operations of the ARC Spillway as part of the YRDP Proposed Projects (and Alternatives) because: (1) it was included as part of Yuba Water's proposed (2017) AFLA; (2) it was included as part of the FERC Staff Alternative that was evaluated in FERC's (2019) FEIS; and (3) the ARC Spillway facilities and operations will be included as part of the new license for the YRDP that is issued by FERC. Yuba Water previously analyzed the potential fisheries impacts of operating the ARC Spillway in the ARC Spillway EIR and determined that there would be less-than-significant impacts to fisheries resources from use of the spillway (Yuba Water 2024). The analysis of those potential impacts in the ARC Spillway EIR is incorporated by reference. Based on the minor flow and water temperature differences between operation of the YRDP under the Existing Condition with and without ARC Spillway (Yuba Water 2024), and the impact analyses described in the following sections, ARC Spillway operations under the YRDP Relicensing Project (and Alternatives) would not result in any new or more severe potentially significant impacts compared to the impacts under the existing YRDP FERC license identified in the ARC Spillway EIR.

        - Powerhouse operations
        - License implementation plans
- Areas Downstream of the Lower Yuba River
    - Quantitatively-informed qualitative changes in simulated habitat conditions in areas downstream of the lower Yuba River

The programmatic analysis of indirect operations-related impacts evaluated in reaches and reservoirs upstream of the YRDP in the Middle Yuba River and South Yuba River watersheds, which could occur as a result of YB/DS operations under Alternative 1, includes review and application of hydrological simulations to address fisheries habitat conditions.

Narrows Project

- Quantitative and/or qualitative changes to fisheries resources associated with operations or additional operations-related activities
    - License implementation plans

9.4.2.1 Hydrology, Water Temperature and Habitat Modeling

Fisheries resources impact assessment methodologies include evaluation of simulated changes in hydrology, water temperature, and fisheries habitat under the Proposed Projects and alternative scenarios relative to the bases of comparison. Modeled flows are used to quantify flow-dependent habitat availability for multiple species and lifestages. Modeled flow-related outputs corresponding to species-specific lifestages for the above variables are presented as averages over the entire simulation period, as averages by water year type (WYT), and as cumulative probability exceedance (habitat duration) distributions. Modeled water temperatures are used in conjunction with species and lifestage-specific water temperature index values to assess site-specific water temperature suitability.

Models developed for planning and impact-assessment purposes represent the best available information with which to conduct evaluations of the Proposed Projects and alternatives on fisheries and aquatic resources in the project area. Moreover, modeling assumptions and results are used for comparative purposes rather than for absolute predictions. The focus of the analyses based on hydrologic and water temperature model output is on the differences in the results among comparative scenarios.

9.4.2.1.1 Operations (Hydrology) and Water Temperature Modeling

As described in Chapter 4, model scenarios were simulated using hydrologic, hydraulic and water temperature modeling over a 52-year period of record (WY 1970-2021) to evaluate potential flow- and water temperature-related changes under the Proposed Projects and each alternative scenario relative to a basis of comparison.

Operations modeling was conducted using an updated version of Yuba Water's Yuba River Development Project Model (YRDPM) to simulate hydrology in the lower Yuba River, upstream YRDP reservoirs, and upstream YRDP-influenced streams associated with operations of the

YRDP. The YRDPM simulates operations on a daily time-step. Potential impacts are assessed based on model results from Yuba Water's YRDPM. More information about the YRDPM, including assumptions, inputs, and model limitations, are provided in Appendix 5A, Yuba River Development Project Water Operations Model Technical Memorandum.

Yuba Water's analysis also utilized the "Mini-Model" described in Appendix 5E, Upstream Projects Mini-Model Technical Memorandum, to simulate operations of NID's and PG&E's YB/DS projects under various regulatory regimes including their existing and proposed FERC license requirements and the alternatives evaluated in this DEIR. Yuba Water developed the Mini-Model to provide a reasonable representation of inflows to the YRDP and Narrows Project for use in the YRDPM to characterize flow and water temperature regimes for impact assessment purposes in the YRDP Project Area.

Simulated daily flows and storages output from the YRDPM were used as inputs to the water temperature model. The water temperature model applied in this evaluation is an updated version of the Yuba River Watershed water temperature model developed by Yuba Water (2017), which simulates daily water temperatures for a period of record matching that of the updated YRDPM (WY 1970 through 2021). Detailed information about the water temperature model is provided in Appendix 5B, Yuba River Development Project Water Temperature Model Technical Memorandum.

9.4.2.1.2 Hydraulic and Habitat Modeling

YRDP Reaches Upstream of Englebright Dam

Yuba Water (2013f) describes the habitat modeling methodologies applied to the upper Yuba River Watershed reaches. During 2011-2013, Yuba Water conducted instream flow studies in one study reach of the North Yuba River, two sub-reaches of Oregon Creek, two reaches of the Middle Yuba River, and two reaches of the upper Yuba River. Eleven study sites were identified across the reaches, and between seven and 21 transects were placed in each site for a total of 132 transects. Studies were designed to ensure each mesohabitat was represented at least twice and were representative of their proportion within reaches or sub-reaches, with the exception of rarely occurring mesohabitat types. Yuba Water used the one-dimensional PHABSIM (Physical Habitat Simulation) method to model indices of fish habitat in each reach at specific flow rates. As described in Yuba Water (2013f), indices of fish habitat (weighted usable area, or WUA), were defined as the sum of stream surface area within a reach or sub-reach, weighted by multiplying this area by a composite habitat suitability index based on application of habitat suitability criteria (HSC) for several variables (water depth, water velocity, and substrate or cover), which range in value from 0.0 to 1.0. Resultant WUA values for specific flow rates were normalized to square units (i.e., either in feet or meters) per 1,000 linear stream units. As agreed upon by Yuba Water and YRDP Relicensing Participants, HSC developed for rivers in Nevada Irrigation District's Yuba-Bear Hydroelectric Project (FERC Project No. 2266) and PG&E's Drum-Spaulding Project (FERC Project No. 2310) relicensings were used for the target species (Yuba Water 2013f).

This DEIR utilizes habitat modeling that was carried out for the YRDP FERC relicensing in the following reaches and sub-reaches.

- Middle Yuba River
    - Our House Diversion Dam Reach
    - Oregon Creek Reach
- Oregon Creek
    - Log Cabin Sub-Reach
    - Celestial Valley Sub-Reach
- North Yuba River
    - New Bullards Bar Dam Reach
- Upper Yuba River
    - Middle/North Yuba River Reach
    - New Colgate Powerhouse Reach

Using PHABSIM, WUA-flow relationships were developed for four target fish species and seven lifestages, including spawning, juvenile and adult life stages of rainbow trout, juvenile and adult lifestages of Sacramento sucker, and juvenile and adult lifestages for the hardhead/Sacramento pikeminnow guild (Yuba Water 2013f).

YB/DS Reaches Upstream of the YRDP

For the programmatic analysis of upstream indirect impacts resulting from YB/DS operations under Alternative 1, this DEIR also utilizes habitat-flow relationships developed by NID and PG&E (2010) for the following YB/DS reaches upstream of the YRDP (see Figure 9.2-1).

- Middle Yuba River
    - Jackson Meadows Dam Reach (Jackson Meadows Dam downstream to Milton Diversion Dam)
    - Milton Diversion Dam Reach (Milton Diversion Dam downstream to OHDD)
        - Upper Milton Sub-Reach
        - Wolf Sub-Reach
        - Kanaka Sub-Reach
- Canyon Creek
    - Bowman-Spaulding Diversion Dam Reach (Bowman-Spaulding Diversion Dam downstream to the South Yuba River)
- Fordyce Creek
    - Fordyce Lake Dam Reach (Fordyce Dam downstream to Lake Spaulding)
- South Yuba River
    - Lake Spaulding Reach (Lake Spaulding Dam downstream to Englebright Reservoir)
        - Jordan Creek Sub-Reach
        - Canyon Creek Sub-Reach
        - Poorman Creek Sub-Reach
        - Humbug Creek Sub-Reach

Using PHABSIM, WUA-flow relationships were developed for several lifestages of four target fish species, including spawning, fry, juvenile and adult life stages of rainbow trout, juvenile and adult life stages of Sacramento sucker, and juvenile and adult lifestages for the hardhead/Sacramento pikeminnow guild (NID and PG&E 2010). Although WUA-flow relationships for the rainbow trout fry lifestage were developed, the adult and spawning lifestages were targeted for improvement by YB/DS Relicensing Participants (FERC 2014). Additionally, YRDP Relicensing Participants considered the YB/DS rainbow trout fry modeling results atypical and therefore did not apply the YB/DS rainbow trout fry habitat modeling to the YRDP reaches (Yuba Water 2013f). Consequently, the programmatic evaluation of indirect impacts to rainbow trout in reaches upstream of the YRDP focuses on the spawning, adult, and juvenile lifestages.

Lower Yuba River

Water velocities and water depths in the lower Yuba River were simulated by using a TUFLOW 2D hydrodynamic model of the lower Yuba River using a 2017 digital elevation model (DEM). The 2017 DEM was developed subsequent to high flows that occurred during winter of 2017 using Airborne Light Detection and Ranging (LiDAR), boat-based multibeam and single beam echosounding, and ground-based topographic surveying with Real-time kinematic (RTK) Global Positioning System (GPS) and robotic total stationing (Silva and Pasternack 2018). The 2D model was run with a 3'x3' computation mesh for flows ≤ 30,000 cfs and a 10'x10' mesh for flows >30,000 cfs. Water velocity, water depth, water surface elevation, shear stress and other variables were produced for discharges from 300 cfs to 110,400 cfs for the lower Yuba River downstream of Daguerre Point Dam, and for discharges from 300 cfs to 198,885 cfs upstream of Daguerre Point Dam.

Species and lifestage-specific habitat-flow relationships for the lower Yuba River were developed by applying HSC to modeled water depths and velocities and substrate (for spawning lifestages) and cover (for juvenile lifestages) data. Habitat-flow relationships for each species/lifestage were developed to encompass the entire range of flows across all model scenarios over the entire simulation period. Appendix 9B provides a detailed description of the development of the habitat-flow relationships for the lower Yuba River applied in this evaluation.

9.4.2.2 Model Output Application and Fisheries Analytical Approach

Yuba Water utilized post-processed model output results to determine whether, and to what degree, each alternative scenario would provide a substantive benefit to fish species of management concern, and whether the alternative scenario would result in re-directed adverse impacts to fish species relative to the basis of comparison. Yuba Water's analysis included evaluation of both physical habitat availabilities and water temperature suitabilities for multiple lifestages of species of management concern in areas upstream of Englebright Dam and in the lower Yuba River within the Project Area, as detailed below.

9.4.2.2.1 Flow-Dependent Habitat Availability

Flow-dependent habitat availability refers to the quantity (area) of habitat available to individual species and lifestages at a particular flow rate. Flow-dependent habitat availability is quantified by applying modeled daily flows to habitat-discharge relationships to produce daily amounts of

habitat for a particular species/lifestage. Flow-dependent habitat availability was quantified and evaluated for species and lifestages for which site-specific HSC were developed, or using HSC derived from the literature, and were applied to the areas upstream of Englebright Dam and the lower Yuba River during the YRDP FERC relicensing (Yuba Water 2017).

This impact assessment compares the long-term average habitat availability over the entire simulation period and average habitat availability by WYT[5] under comparative model scenarios. Due to the potential masking effect of comparing average values, this impact assessment also includes habitat duration analyses (or probability of exceedance distributions). A habitat duration curve is constructed in the same way as a flow duration curve but uses habitat values instead of discharge as the ordered data. The habitat duration curve shows the percentage of time a particular habitat value is exceeded over a specific period of evaluation (i.e., a lifestage-specific time period or a season within a year-round lifestage period).

YRDP Reaches Upstream of Englebright Dam

Flow-dependent habitat availability evaluations were conducted for rainbow trout and Sacramento sucker lifestages in all YRDP reaches (identified below). Consistent with Yuba Water (2013f), hardhead/pikeminnow habitat evaluations were conducted for the North Yuba River and upper Yuba River reaches. Habitat for juvenile and adult lifestages of rainbow trout, Sacramento sucker and hardhead/pikeminnow were evaluated year-round, and rainbow trout spawning habitat is evaluated during April through June. Rainbow trout fry were excluded from YRDP habitat modeling due to atypical modeling results (Yuba Water 2013f). Habitat (WUA) duration analyses were conducted for this DEIR by applying modeled daily flows to the previously-developed WUA-flow relationships using the following hydrologic model nodes for each habitat reach (Figure 9.4-1). Modeled daily flows across all scenarios were encompassed by the range of flows in the Yuba Water (2013f) WUA-flow relationships, except for the Oregon Creek above Middle Yuba River node, which exceeded the WUA-flow relationship flow range during 1 day under some scenarios.

- North Yuba River
    - New Bullards Bar Dam Reach
        - North Yuba River below NBBD (RM 2.3)
- Oregon Creek
    - Log Cabin Diversion Dam Sub-Reach
        - Oregon Creek below LCDD (RM 4.3)
        - Oregon Creek midway between Celestial Valley and Middle Yuba River (RM 1.0) [Oregon Creek above Middle Yuba River]
    - Celestial Valley Sub-Reach
        - Oregon Creek at Celestial Valley (RM 2.5)
- Middle Yuba River (reaches downstream of OHDD)
    - Our House Diversion Dam Reach
        - Middle Yuba River below OHDD (RM 12.6)

[5] WYTs are defined by the Smartsville Index.

        - Middle Yuba River midway between OHDD and Oregon Creek (RM 8.8)
    - Oregon Creek Reach
        - Middle Yuba River midway between Oregon Creek and North Yuba River (RM 2.3)

- Upper Yuba River
    - Middle/North Yuba River Reach
        - Upper Yuba River midway between Middle Yuba River and New Colgate Powerhouse (RM 37.1)
    - New Colgate Powerhouse Reach
        - Upper Yuba River below New Colgate Powerhouse (RM 34.2)

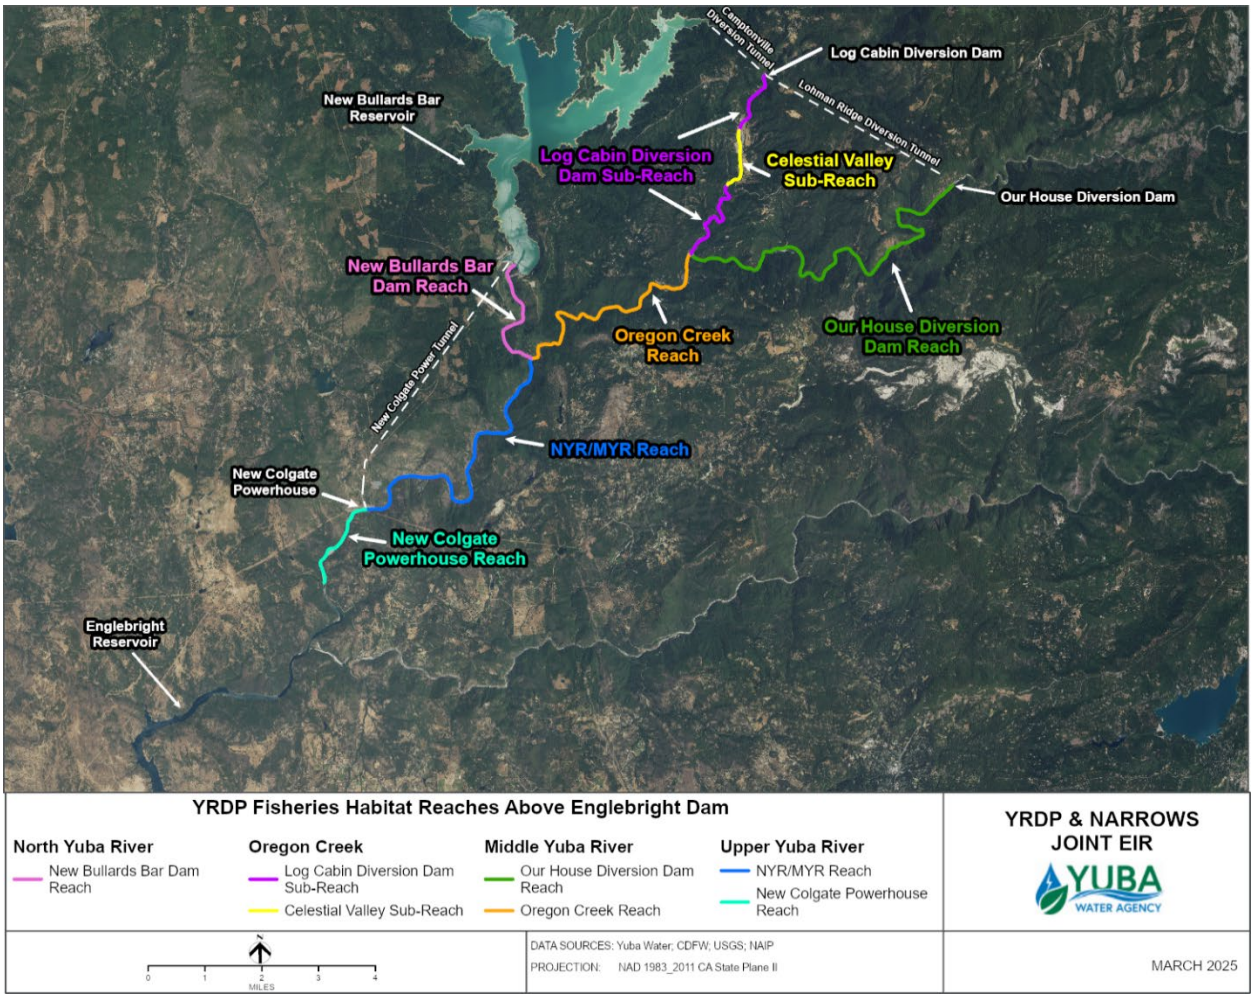

Figure 9.4-1. YRDP fisheries habitat reaches above Englebright Dam.

YB/DS Reaches Upstream of the YRDP

Trends in flow-dependent habitat availability changes associated with the provision of 15.6 TAF from upstream projects (YB/DS) were evaluated at a programmatic level for Alternative 1 for

rainbow trout, Sacramento sucker, and hardhead/pikeminnow in applicable reaches based on habitat-flow relationships and analyses presented in NID and PG&E (2010). Because the actual relative contribution of flow from the Middle Yuba River and South Yuba River watersheds and associated reservoir operations could vary, this impact analysis utilizes generalized trends in the hydrologic regimes in the Middle Yuba River and the general changes in flows modeled by NID (2023) in the South Yuba River and Canyon Creek as examples to characterize potential changes that could occur in fisheries habitat conditions under Alternative 1. Changes in flow-dependent habitat availability were evaluated based on directional changes in habitat associated with directional changes in flows (i.e., increases or decreases in habitat based on increases or decreases in flow) relative to the Existing Condition or Future Baseline under the following scenarios and assumptions.

- Existing Condition – The Base Case scenario in the FERC (2014) YB/DS FEIS (i.e., existing FERC license conditions for the YB/DS projects).
- Future Baseline – The new FERC licenses for the YB/DS projects including 4(e) flows and other flow-related license conditions (e.g., ramping rates, seasonal supplemental flows, etc.), as represented by the FERC staff alternative in the FERC (2014) FEIS.
- Alternative 1 – The same assumptions as Future Baseline above, with the addition of 15.6 TAF released by the YB/DS projects during April and May of Dry and Critical WYs.
    - For the Middle Yuba River, assumed that the 15.6 TAF would be evenly distributed across a 30 to 45-day period, such that Alternative 1 could result in a maximum increase in flow of approximately 175-260 cfs during the 30 to 45-day period (assuming all 15.6 TAF is provided in the Middle Yuba River).
    - For the South Yuba River and Canyon Creek, utilized the NID (2023) model scenarios as examples to characterize potential flow-related changes that could occur with implementation of the 15.6 TAF in these streams.

Because the intent of Alternative 1 is only to provide 15.6 TAF of water during April-May of Dry and Critical WYs, the evaluation of potential impacts to fisheries resources in YB/DS areas upstream of the YRDP under Alternative 1 focuses on changes that could occur during April and May of Dry and Critical WYs.

Lower Yuba River

Flow-dependent habitat availability analyses are conducted for the following species and lifestage-specific time periods. Time periods of evaluation are based on Yuba Water (2017) and more recent life history information described in Appendix 9A.

- Spring-run Chinook Salmon
    - Spawning (September through mid-October)
    - Fry Rearing (mid-November through mid-February)
    - Juvenile Rearing (year-round)

- Fall-run Chinook Salmon
    - Spawning (October through December)
    - Fry Rearing (mid-December through April)
    - Juvenile Rearing (mid-January through June)
- Steelhead
    - Spawning (January through April)
    - Fry Rearing (April through July)
    - Juvenile Rearing (year-round)
- Green Sturgeon
    - Adult Holding (April through mid-February)
    - Spawning (June and July)
- Lamprey
    - Spawning (March through July)
    - Ammocoete Rearing (year-round)

Habitat duration analyses were conducted for this DEIR by applying modeled daily flows to the habitat-flow relationships by hydrologic zone. Hydrologic zone (HZ) boundaries were based on points of primary inflows (accretion) and outflows (diversions) in the study area (Yuba Water 2013n; Figure 9.4-2).

For anadromous salmonid spawning and rearing lifestages, habitat availability is expressed as preferred habitat based on bioverification studies (see Appendix 9B) and is presented as area (acres or square feet). Habitat also is expressed as area (acres) for green sturgeon adult holding. Habitat is expressed as weighted usable area (WUA) for several lifestages (green sturgeon spawning, lamprey spawning and ammocoete rearing) based on the methodology applied by Yuba Water (2013f). For salmonid spawning lifestages, habitat availability also is expressed as percent of maximum habitat. The expression of percent of maximum habitat allows for evaluation of differences in the frequency of achieving 80% of maximum spawning habitat, which was identified by NMFS and USFWS (2013) as an indicator of population-level productivity[6].

[6] Expressing WUA as percent of maximum was conducted to provide biologic context for the results. In the NMFS and USFWS Klamath Project Operations Biological Opinion (2013), NMFS reports that available instream habitat of 80 percent of maximum (WUA) has been used as a guideline to develop minimum flow needs for the conservation of anadromous salmonids, and that: (1) NMFS assumes that at least 80 percent of maximum available habitat provides a wide range of conditions and habitat abundance in which populations can grow and recover; (2) where habitat availability is 80 percent of maximum or greater, habitat is not expected to limit individual fitness or population productivity or distribution, nor adversely affect the function of essential features of (coho) salmon critical habitat.

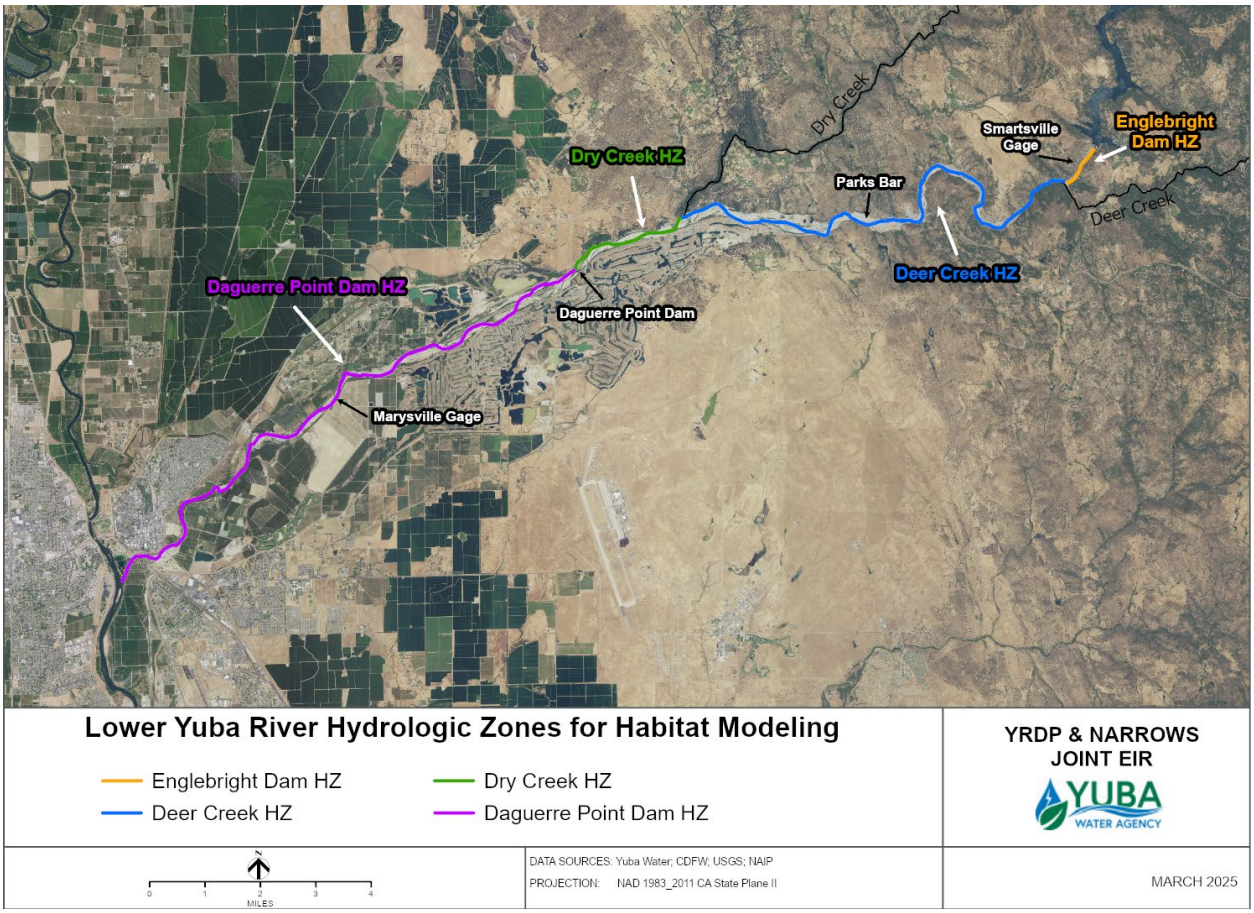

Figure 9.4-2. Hydrologic zone boundaries for habitat modeling in the lower Yuba River.

Based on species and lifestage-specific spatial distributions and habitat requirements (described in Appendix 9A), habitat availability for spring-run Chinook salmon and steelhead spawning is only evaluated upstream of DPD, whereas habitat availability for green sturgeon adult holding and spawning is only evaluated downstream of DPD. All other lifestages are evaluated throughout the lower Yuba River. Because anadromous fish spawning is not expected to occur or be successful outside of the bankfull channel (generally represented by habitat encompassed at 5,000 cfs) (Yuba Water 2017), the area of spawning habitat (and green sturgeon adult holding habitat) provided at flows greater than 5,000 cfs is restricted to the areal extent of the bankfull channel.

9.4.2.2.2 Water Temperature Suitabilities

For the fisheries impact assessment, water temperature index (WTI) values are used to evaluate whether the alternative scenarios would affect species and lifestage-specific thermal habitat suitability relative to the basis of comparison.

Areas Upstream of Englebright Dam

The USFWS and other resource agencies (CDFW, USFS) applied a 68°F (20°C) objective for the protection of coldwater fish species (particularly rainbow trout) in the Yuba River above Englebright Reservoir (USDOI 2017). Therefore, a water temperature of 68°F was identified as an upper indicator of thermal preference for rainbow trout adult and juvenile lifestages (Yuba Water

2017; FERC and USACE 2019). As described below, this is consistent with the identification of 68°F by Bratovich et al. (2012) as an upper tolerable (UT) water temperature index (WTI) value for adult steelhead (O. mykiss) immigration and juvenile steelhead rearing in the Yuba River Watershed. Consequently, 68°F is included as a WTI value for adult and juvenile rainbow trout in this DEIR.

FERC and USACE (2019) and Yuba Water (2017) also used 68°F as the indicator of water temperature suitability in the upper Yuba River Watershed for several other fish species and lifestages, including hardhead, Sacramento pikeminnow, and Sacramento sucker. Water temperature preference and tolerance information for these species is summarized below.

Cech et al. (1990) found that hardhead, Sacramento pikeminnow and Sacramento sucker exhibit similar metabolic rates and show similar responses to increased water temperature and decreased dissolved oxygen at water temperatures between 10 and 25°C (50 and 77°F). Myrick and Cech (2000) found that adult hardhead, Sacramento pikeminnow and Sacramento sucker exhibited similar swimming performance across water temperature treatments of 10, 15 and 20°C (50, 59 and 68°F). Thompson et al. (2012) found that adult and juvenile hardhead preferred water temperatures of about 69°F and 67°F, respectively. However, Thompson et al. (2012) also found that hardhead perform well (behaviorally and physiologically) at water temperatures between about 60.8 and 77.0°F, and that they reportedly avoid water temperatures between about 54 and 57°F. Juvenile hardhead appeared to have poor swimming performance at 11-16°C (51.8-60.8°F) (Thompson et al. 2012). In the South Fork American River, Cocherell et al. (2014) readily captured hardhead at water temperatures much cooler (about 46°F) than their reported preferred range. Sacramento sucker reportedly prefer water temperatures between about 68 and 77°F, although they are found in streams with water temperatures that rarely exceed 59-61°F (Moyle 2002). Sacramento pikeminnow exhibit preference for a wide range of water temperatures (56-82°F) depending on acclimation temperature (Knight 1985 as cited in Moyle 2002), but generally live in streams with summer water temperatures of 18-28°C (64.4-82.4°F) (Moyle 2002).

Based on the species-specific water temperature preferences and tolerances above, an index of thermal suitability for hardhead, Sacramento sucker, and Sacramento pikeminnow adults and juveniles for this DEIR includes the range of preferred water temperatures between about 61°F and 77°F. Evaluations of preferred suitability include identification of changes in the frequency of occurrence of water temperatures within this range.

Because suitable water temperatures for rainbow trout spawning and embryo incubation are lower than 68°F, the UT WTI value identified by Bratovich et al. (2012) for steelhead spawning (57°F) is used to evaluate thermal suitability for rainbow trout spawning and incubation during April through June. Because the suitable water temperature range for hardhead spawning is reportedly about 59-64.4°F (Wang 1986), 64°F is included as a WTI value for hardhead spawning during April through June. In addition, differences in the frequency of occurrence of water temperatures between about 59 and 64°F are considered in evaluating hardhead spawning thermal suitability.

Water temperature exceedance distributions are presented for each modeled scenario comparison with the WTI values by season for the year-round lifestages (excluding December through February when water temperatures are similar among scenarios and generally remain below WTI

values at evaluated locations) and separately for April through June with the spawning WTI values for rainbow trout and hardhead.

Due to the various potential permutations in potential reservoir operations under Alternative 1, water temperatures are addressed qualitatively below based on existing information and modeling conducted for the YB/DS projects.

Lower Yuba River

Water Temperature Index Value Analyses

Water temperature evaluation guidelines have been developed more extensively for Chinook salmon and steelhead than for other species. Chinook salmon and steelhead lifestage-specific WTI values developed by Bratovich et al. (2012) based on an extensive review of the fisheries literature with an emphasis on Central Valley streams were used to assess the effects of the alternatives relative to the basis of comparison. Both upper optimal WTI values and upper tolerable WTI values were defined and applied by for each lifestage of spring-run and fall-run Chinook salmon and steelhead in the lower Yuba River according to the following definitions (Table 9.4-1).

- **Upper Optimal Temperature (UO).** The upper optimum temperature represents the upper boundary of the optimum range and a water temperature value below which growth, reproduction, and/or behavior are not adversely affected by temperature.
- **Upper Tolerable Temperature (UT).** The upper tolerable temperature represents the upper boundary of a water temperature range within which fish can survive indefinitely, without experiencing substantial detrimental effects to physiological and biological functions such that survival occurs, but growth and reproduction success are at levels below optimal.

Chinook salmon adult holding WTI values are applied only to spring-run Chinook salmon because fall-run Chinook salmon generally enter freshwater in a sexually mature state and spawn soon after reaching freshwater spawning grounds. The Chinook salmon smoltification WTI values also are applied only to spring-run Chinook salmon, because fall-run Chinook salmon generally emigrate from Central Valley rivers as young-of-the-year shortly after emergence from the gravel (RMT 2013).

Table 9.4-1. Lifestage-specific Upper Optimal and Upper Tolerable WTI Values for Chinook Salmon and Steelhead.

Chinook Salmon			Steelhead		
Lifestage	**Upper Optimal WTI**	**Upper Tolerable WTI**	**Lifestage**	**Upper Optimal WTI**	**Upper Tolerable WTI**
Adult immigration	64°F	68°F	Adult immigration	64°F	68°F
Adult holding	61°F	65°F	Adult holding	61°F	65°F
Spawning	56°F	58°F	Spawning	54°F	57°F
Embryo incubation	56°F	58°F	Embryo incubation	54°F	57°F

Chinook Salmon			Steelhead		
Lifestage	**Upper Optimal WTI**	**Upper Tolerable WTI**	**Lifestage**	**Upper Optimal WTI**	**Upper Tolerable WTI**
Juv. rearing & downstream movement	61°F	65°F	Juv. rearing & downstream movement	65°F	68°F
Smoltification[7]	63°F	68°F	Smoltification	52°F	55°F

For other fish species of management concern in the lower Yuba River (green sturgeon, white sturgeon, lamprey), WTI values evaluated in this DEIR are presented in Table 9.4-2. The WTI values applied to green sturgeon lifestages are described in Yuba Water (2017). The adult immigration and holding WTI value for white sturgeon (77°F) is based on the upper limit of suitable water temperatures for adult white sturgeon identified in Israel et al. (2011). The WTI values applied to lamprey are based on studies and literature described in Close et al. (2001), Meeuwig et al. (2002), Meeuwig et al. (2005), and Clemens et al. 2016. Although limited water temperature preference data are available for adult lamprey, these sources suggest that 50–64°F is optimal for early lifestage development and water temperatures below 72°F are preferred by ammocoetes.

All of the WTI values evaluated in this document represent boundaries above which water temperatures could be considered to affect evaluated fish species. However, the WTI values are not meant to be significance thresholds but instead provide a mechanism by which to compare the resulting water temperatures associated with the alternative scenarios relative to the basis of comparison. Because water temperature suitability is a function of both the frequency and magnitude of exceedance relative to lifestage-specific WTI values, water temperature suitabilities are evaluated using seasonal water temperature exceedance probability distributions under alternative scenarios relative to the basis of comparison[8]. Lifestage-specific water temperature exceedance probability distributions are presented for individual lifestages (or portions of lifestages) occurring during the spring, summer and fall seasons. The winter season (December through February) and the month of March were not included in the water temperature exceedance probability figures and analyses because water temperature distributions are similar among scenarios and typically remain below lifestage-specific WTI values at evaluated locations.

Table 9.4-2. Lifestage-specific WTI Values and Ranges for Other Fish Species of Management Concern.

Species	Lifestage	Water Temperature Index Values and Ranges (°F)
Green sturgeon	Adult immigration and holding	61
	Spawning and embryo incubation	68
	Juvenile rearing and downstream movement	66
White sturgeon	Adult immigration and holding	77
Lamprey	Adult immigration	42–60

[7] Although Bratovich et al. (2012) identified a smolt emigration lifestage, the literature supporting the WTI value development for this lifestage was primarily related to the process of smoltification.

[8] Water temperature exceedance distributions during the warmest months of the year (i.e., June through September) (see Appendix 4C) were examined to evaluate the probability of exceeding the 77°F WTI value for this lifestage.

Species	Lifestage	Water Temperature Index Values and Ranges (°F)
	Spawning and embryo incubation	50–64
	Ammocoete rearing and downstream movement	72

Other fish species of management concern (hardhead, Central California roach, striped bass, American shad) reportedly prefer a relatively broad range of water temperatures (see Sections 9.2.5.1 and 9.2.5.2). Because the thermal tolerances of hardhead, Central California roach, striped bass, and American shad are typically broader than those identified for anadromous salmonids, the thermal suitabilities for these species were qualitatively assessed based on the evaluation of changes in water temperatures and suitabilities for species of primary management concern (i.e., spring-run and fall-run Chinook salmon, steelhead, green and white sturgeon, and lamprey).

Longitudinal Extent of Thermally Suitable Spring-run Chinook Salmon Spawning and Embryo Incubation Habitat

As described in Chapter 3 (Alternatives Description), Yuba Water (2022b) developed and evaluated a scenario that included both flow and non-flow actions to address FERC's Additional Information Request (AIR) to reduce water temperatures in the lower Yuba River from July through November of Dry and Critical water years (WYs). Based on an evaluation of existing thermal suitability for listed fish species during July through November, the September and October spring-run Chinook salmon spawning and initial embryo incubation period was targeted for improving water temperature conditions in the lower Yuba River during Dry and Critical WYs (Yuba Water 2022b). Consistent with Yuba Water (2022b), this DEIR includes an assessment of changes in the longitudinal extent of thermally suitable spring-run Chinook salmon spawning and embryo incubation habitat during September and October under the modeled alternative comparisons, with a focus on Dry and Critical WYs.

Estimation of the length of thermally suitable spawning habitat is restricted to downstream of the Narrows 1 Powerhouse (RM 23.9) due to a lack of suitable spawning gravel upstream of that location. For each scenario, the length of habitat (to the nearest 0.1 mile) extending downstream from Narrows 1 Powerhouse where water temperatures are at or below the Chinook salmon spawning UO and UT WTI values was estimated for each day during September and October of each model year. For each scenario, results are presented for complete spawning years (i.e., years where both September and October were modeled). Results are presented for each comparison as exceedance distributions of all daily lengths of thermally suitable habitat over the evaluation period and as average daily time-series of thermally suitable lengths of habitat over the September through October period. These analyses are conducted for the entire simulation period (spawning years 1970-2020) and separately for Dry and Critical WYs (as defined by the Smartsville Index).

9.4.2.3 Additional Operations-Related Impacts

In addition to simulated changes in species and lifestage-specific flow-dependent habitat availability and thermal suitability, the following sections describe the methodologies for evaluation of additional operations-related effects of the Proposed Projects and alternatives in the upper Yuba River Watershed and lower Yuba River.

9.4.2.3.1 YRDP Reaches and Reservoirs Upstream of Englebright Dam

Reservoir Fish Habitat Conditions

Warmwater Fish in New Bullards Bar Reservoir

As described in Yuba Water (2017), warmwater game fish species in NBBR include spotted bass, green sunfish, bluegill, crappies, and catfishes. In general, these fish use the warm upper layer of the reservoir and nearshore littoral habitats throughout most of the year. Seasonal changes in reservoir storage, as it affects reservoir water surface elevation, and the rates at which water surface elevation change during specific periods of the year, can directly affect the reservoir's warmwater fish. Decreases in reservoir water surface elevation during the warmwater fish spawning period can dewater nests, which can result in egg mortality and ultimately reduce initial year-class strength. Black bass spawning may begin as early as February, or as late as May, in southern and northern California reservoirs, respectively, and may possibly extend to July in some waters. However, the majority of black bass and other centrarchid spawning in California occurs from March through May (Lee 1999; Moyle 2002). Consequently, to evaluate the potential for operations-related effects to warmwater fish species in NBBR, the magnitude of change (feet mean sea level) in reservoir water surface elevation occurring under the Proposed Projects and Alternatives during each month of the primary spawning period for nest-building fish (March through June) was determined and compared to that modeled for the relevant baseline condition. Specifically, based on average monthly simulated WSEs during February through June, the frequency of monthly reductions in WSE of 6 feet or greater were calculated for March through June for each year over the 52-year simulation period for each comparison.

Review of available literature suggests that, on average, self-sustaining black bass populations in North America experience a nest success (i.e., the nest produces swim-up fry) rate of 60 percent (Friesen 1998; Goff 1986; Hunt and Annett 2002; Knotek and Orth 1998; Kramer and Smith 1962; Lukas and Orth 1995; Neves 1975; Philipp et al. 1997; Raffetto et al. 1990; Ridgway and Shuter 1994; Turner and MacCrimmon 1970). CDFG examined the relationship between California reservoir water surface elevation fluctuation rates and nesting success for black bass, and suggested that a reduction rate of approximately six feet per month would result in the potential for a 60 percent nest success rate for black bass (Lee 1999). Therefore, a decrease in reservoir water surface elevation of six feet or more per month is selected as the threshold beyond which spawning success of nest-building, warmwater fish could potentially result in long-term population declines.

Coldwater Fish in New Bullards Bar Reservoir

When NBBR is thermally stratified (generally April through November), coldwater fish within the reservoir reside primarily within the reservoir's metalimnion and hypolimnion where water temperatures remain suitable. Reduced reservoir storage during this period could reduce the reservoir's coldwater pool volume, thereby reducing the quantity of habitat available to coldwater fish species during these months. Reservoir coldwater pool size generally decreases as reservoir storage decreases, although not always in direct proportion because of the influence of reservoir basin morphometry. Therefore, to assess potential storage-related impacts on coldwater fish habitat availability in NBBR, end-of-month storage modeled for each year of the simulation period under

the Proposed Projects and Alternatives are compared to end-of-month storage under the relevant baseline conditions for each month of the April through November period.

Fish Access to New Bullards Bar Reservoir Tributaries

As described in Yuba Water (2017), fish passage studies of tributaries to NBBR indicated that all but one potential barrier to fish passage on tributaries accessible to reservoir fish would be inundated during spring and early summer (the period when fish would be expected to move into tributaries) under existing operations. Based on those results, potential effects to NBBR tributary fish access were evaluated through assessments of the extent to which a given scenario would result in substantial reductions in NBBR water surface elevations during the March through June timeframe.

Entrainment

New Colgate Power Tunnel

Water is supplied to the New Colgate Power Tunnel through two intakes at NBBD. The lower intake is at an elevation of 1,627.5 ft and the upper intake is at an elevation of 1,808 ft. Under existing YRDP operations, only the lower intake is used per direction from CDFW. As part of its YRDP relicensing, Yuba Water deployed gill nets in NBBR near NBBD (Yuba Water 2017). The analysis of potential effects to fish from entrainment into the New Colgate Power Tunnel in this DEIR is based on the results of Yuba Water's relicensing gill net sampling in NBBR, as well as evaluations of the extent to which YRDP operations would affect NBBR water surface elevations as well as the manner in which water is supplied to the New Colgate Power Tunnel.

Narrows 2 Power Tunnel Intake and Narrows Tunnel via USACE's Englebright Intake

As described in Yuba Water (2017) and Yuba Water (2023b), water is supplied to YRDP's Narrows 2 Power Tunnel via the Narrows 2 Power Tunnel Intake, and to the Narrows Project's Narrows Tunnel via USACE's Englebright Intake. The invert elevations of Yuba Water's YRDP Narrows 2 Power Tunnel Intake and the USACE's Englebright Intake (which supplies water to the Narrows Tunnel) are 439 and 460 ft, respectively. As part of its YRDP relicensing, Yuba Water deployed gill nets in Englebright Reservoir, with some nets near the intakes and at similar depths (Yuba Water 2017). The analysis of potential effects to fish from entrainment into the Narrows 2 Power Tunnel and Narrows Tunnel in this DEIR is based on the results of Yuba Water's relicensing gill net sampling in Englebright Reservoir, as well as evaluations of the extent to which YRDP operations would affect Englebright Reservoir water surface elevations.

Warmwater and Coldwater Fish in Englebright Reservoir

As described in Yuba Water (2017), warmwater game fish species in Englebright Reservoir include spotted bass, green sunfish, bluegill, redear sunfish, and smallmouth bass. Additionally, Yuba Water (2017) documented native fish species including hardhead and Sacramento sucker in Englebright Reservoir. Coldwater fish species in Englebright Reservoir include rainbow trout and brown trout (Yuba Water 2017). Water surface elevations in Englebright Reservoir remain relatively stable under existing operations because there is a specified water surface elevation operational range to protect beneficial uses associated with Skippers Cove Marina (Yuba Water

2017). Under the Proposed Projects and alternatives, YRDP and Narrows Project operations would not result in substantial changes to conditions for warmwater, native, or coldwater fish or aquatic habitat in Englebright Reservoir due to water surface elevation (and consequently storage) restrictions. Additionally, Yuba Water's Narrows Project Proposed Condition 3 (Fish Stocking) would continue stocking of rainbow trout at the same levels that occur under existing conditions. Consequently, the Proposed Projects and alternatives would be expected to result in similarly suitable conditions for warmwater, native, and coldwater fish and aquatic habitat in Englebright Reservoir relative to the bases of comparison, and these resources are not carried forward for further detailed analysis in this chapter.

Effects Related to Spills at New Bullards Bar Dam

Rapid changes in flow resulting from spills at NBBD have the potential to adversely affect fisheries resources in the North Yuba River downstream of NBBD through the mechanisms of fish stranding, temporary loss of habitat or restricted access to habitat, and reduced spawning success. However, Yuba Water did not document any fish stranding during its YRDP relicensing studies, and there is no available information as to the extent that fish stranding and other potential adverse effects to fisheries resources in the North Yuba River downstream of NBBD occur as a result of spills at NBBD. Under the Proposed Projects and alternatives, YRDP Condition AR4 (Control Project Spills at NBBD) would require Yuba Water to implement spill cessation operations at NBBD from May 1 through July 31, with spill reductions dependent on spill rates as described in Chapter 2. Although this condition would result in more gradual flow reductions between May and July subsequent to some spill events at NBBD during some Wet and Above Normal WYs, these spill events occur with relatively low frequency. Implementation of YRDP Condition AR4 under the Proposed Projects and alternatives would be expected to result in similar or reduced levels of spill-related impacts to fisheries resources in the North Yuba River downstream of NBBD relative to the bases of comparison. Consequently, this impact is not carried forward for further detailed analysis in this chapter.

Effects Related to Diversion Dams

YRDP operations at the OHDD and associated Lohman Ridge Tunnel on the Middle Yuba River, and the LCDD and associated Camptonville Tunnel on Oregon Creek, have the potential to affect fish and aquatic habitat through the mechanisms of restricted fish passage, entrainment, fish stranding, and effects to physical habitat conditions related to sediment and woody material management. The potential for effects to occur to fish due to these mechanisms under each alternative are assessed based on the results of potential impacts identified during YRDP relicensing studies, the extent to which conditions under each alternative would change YRDP operations at the diversion dams, and the inclusion of additional protective measures in the Proposed Projects and alternatives.

Fish Stranding Downstream of New Colgate Powerhouse

YRDP operations at New Colgate Powerhouse can result in flow fluctuations in the upper Yuba River downstream of New Colgate Powerhouse. These flow fluctuations have the potential to result in adverse effects to fisheries resources in the affected area through the mechanism of fish stranding. Stranding and potential for stranding were assessed by Yuba Water during visual

observation surveys conducted in 2012, which included surveys conducted prior to, during, and after ramping events (Yuba Water 2017). The study showed that few fish, only one of which was a rainbow trout and all of which were small sized, were stranded and all fish subsequently were able to return to the main channel (Yuba Water 2017). Based on these results, and because the Proposed Projects and alternatives would not substantially change the manner in which Yuba Water operates the New Colgate Powerhouse (i.e., as a hydro-peaking facility), these scenarios would not be expected to result in an increased potential for adverse effects to fisheries resources in the upper Yuba River downstream of the New Colgate Powerhouse relative to the bases of comparison. Consequently, this impact is not carried forward for further detailed analysis in this chapter.

Effects Related to License Implementation Plans

YRDP

As described in Chapter 2, Yuba Water would be required to develop and/or implement a number of license conditions and implementation plans once a new FERC license is issued for the YRDP. Several of the conditions (AR1, AR2, AR3, AR4, AR9, AR10, AR11, AR12, WR2, WR3, WR5, and WR6) would affect the manner in which Yuba Water operates the YRDP, and the effects of those conditions on operations have been incorporated into the YRDPM. Potential impacts to fisheries and aquatic resources that could result from these conditions are analyzed through assessments of simulated flows and water temperatures for each of the modeled alternative scenarios.

Other conditions associated with license implementation plans that may not result in changes in operations (and thereby cannot be easily analyzed through assessments of simulated flows and water temperatures), but which have the potential to result in effects to fisheries and aquatic resources in areas upstream of Englebright Dam through activities associated with plan implementation (based on descriptions provided in Chapter 2 and Yuba Water (2017)), include:

- AR5 – Implement Aquatic Invasive Species Management Plan
- AR6 – Implement New Bullards Bar Reservoir Fish Stocking Plan
- AR7 – Implement Upper Yuba River Aquatic Monitoring Plan
- GS1 – Implement the Erosion and Sediment Control Plan
- GS2 – Implement Log Cabin and Our House Diversion Dams Sediment Management Plan
- GS3 – Implement Our House and Log Cabin Diversion Dams and New Bullards Bar Reservoir Woody Material Management Plan
- RR3 – Provide Whitewater Boating Below Our House Dam
- WR4 – Implement Streamflow and Reservoir Level Compliance Monitoring
- WR7 – Implement Water Temperature Monitoring Plan

- WR8 – Implement Water Quality Monitoring Plan
- WR9 – Implement Drought Management Plan

The potential effects of Yuba Water's implementation of these YRDP license implementation plans under the Proposed Projects are evaluated through assessments of the extent to which activities associated with plan implementation could result in direct or indirect impacts to fisheries or aquatic habitat, changed conditions relative to the bases of comparison, as well as any identified BMPs or impact avoidance and minimization measures.

Narrows Project

As described in Chapter 2, Yuba Water has proposed to include in a new Narrows Project FERC license certain existing license conditions with modifications, as well as several new conditions. Of the seven modified or new conditions proposed by Yuba Water for inclusion in a new FERC license for the Narrows Project, only two have the potential to affect fisheries and aquatic resources in areas upstream of Englebright Dam:

- Yuba Water's Narrows Project Proposed Condition 3, Fish Stocking (in Englebright Reservoir)
- Yuba Water's Narrows Project Proposed Condition 5, Water Surface Elevation in Englebright Reservoir

Proposed Condition 5 addressing water surface elevations in Englebright Reservoir is a continuation of the minimum elevation requirements in the existing Narrows Project license, and therefore would not result in changed conditions for fish or fish habitat in Englebright Reservoir. Consequently, potential impacts of Proposed Condition 5 on fisheries resources upstream of Englebright Dam are not carried forward for further detailed analysis in this chapter.

As described in Chapter 2 and Yuba Water (2023a), Yuba Water's Narrows Project Proposed Condition 3 would require Yuba Water to stock Englebright Reservoir with 5,000 rainbow trout on an annual basis, with the timing and location of fish stocking to be coordinated with CDFW. Yuba Water's Narrows Project Proposed Condition 3 is a continuation of Article 403 of the existing FERC license for the Narrows Project, which requires the Licensee, in consultation with CDFW, to stock 5,000 rainbow trout in Englebright Reservoir. Consequently, implementation of Yuba Water's Narrows Project Proposed Condition 3 is not anticipated to result in changed conditions relative to the Existing Condition, and therefore is not carried forward for further detailed analysis in this chapter.

9.4.2.3.2 YB/DS Reaches Upstream of the YRDP

Under Alternative 1 programmatic analyses, additional potential operations-related YB/DS effects to areas upstream of the YRDP include potential rainbow trout redd scour, redd dewatering and juvenile stranding/isolation for hardhead, Sacramento pikeminnow, and Sacramento sucker in YB/DS reaches including the Middle Yuba River below Jackson Meadows Dam, Canyon Creek below Bowman Lake and the BSCDD, Fordyce Creek below Fordyce Lake Dam, and the South Yuba River below Spaulding Dam to Englebright Reservoir. These potential impacts are addressed

at a programmatic level through review of potential changes in hydrology based on the provision of the 15.6 TAF, including hydrology modeled by NID (2023) as examples to characterize potential changes that could occur during Dry and Critical WYs during applicable lifestage-specific time periods.

9.4.2.3.3 Lower Yuba River

In addition to potential changes in flow-dependent habitat availability and water temperature, other operations-related effects on fisheries resources evaluated in the lower Yuba River include the potential for salmonid redd dewatering, redd scour, and fry and juvenile stranding and isolation.

Chinook Salmon and Steelhead Redd Dewatering

Yuba Water (2017) developed the following flow reduction limitations measure (YRDP Proposed Condition AR9: Control Project Ramping and Flow Fluctuation Downstream of Englebright Dam, summarized in Chapter 2 – Project Description) to minimize the potential for spring-run Chinook salmon and steelhead redd dewatering in the lower Yuba River during controlled operational conditions.

- To minimize the potential for spring-run Chinook salmon redd dewatering, during the period from September 2 through December 31 (corresponding to the spring-run Chinook salmon spawning and incubation period), Licensee shall not reduce the flow downstream of Englebright Dam to less than the larger of: 1) the applicable minimum streamflow requirement specified in Yuba Water's YRDP Proposed Condition AR3; or 2) the flow that would result from applying the maximum flow reduction amount specified in Table 1 of this condition corresponding to the base flow range determined using the maximum 5-day average flow that occurred on days when this condition was in effect during that September 2 through December 31 period. During the period of September 2 through 5, the base flow range shall be determined by the average daily flow on September 1.
- To minimize the potential for steelhead redd dewatering, during the period from January 1 through May 31 (corresponding to the steelhead spawning and incubation period), Licensee shall not reduce the flow downstream of Englebright Dam to less than the larger of: 1) the applicable minimum streamflow requirement specified in Yuba Water's YRDP Proposed Condition AR3; or 2) the flow that would result from applying the maximum flow reduction amount specified in Table 2 of this condition corresponding to the base flow range determined using the maximum 5-day average flow that occurred on days when this condition was in effect during that January 1 through May 31 period. During the period of January 1 through 5, the base flow range shall be determined by the average daily flow on December 31. If this condition was not in effect on December 31, then the base flow range shall be the minimum flow authorized under the preceding paragraph on the latest date on which this condition was in effect. During the period from April 1 through May 31 when Flow Schedules 3 through 6 or Conference Years are in effect specified in Yuba Water's YRDP Proposed Condition WR3, Licensee may reduce the flow downstream of Englebright Dam to the applicable minimum streamflow requirement specified in Yuba Water's YRDP Proposed Condition AR3.

The maximum flow reductions possible for each flow range specified in Table 1 and Table 2 (see Tables 2.4-8 and 2.4-9 in Chapter 2) were developed by identifying the resultant decreased flow levels that would result in no more than about 1 percent of expected spring-run Chinook salmon and steelhead redds being dewatered using known spatial and depth distributions of spring-run Chinook salmon and steelhead redds and morphological unit-specific stage-discharge relationships. Because fall-run Chinook salmon spawning and embryo incubation extends from October 1 through March 31, YRDP Conditions 1 and 2, which would restrict flow reductions during the spring-run Chinook salmon and steelhead spawning and embryo incubation periods, also would restrict flow reductions during the fall-run Chinook salmon spawning and embryo incubation period in the Yuba River downstream of Englebright Dam. Therefore, no additional conditions were proposed for fall-run Chinook salmon. This condition would not apply to: (a) YRDP operations during emergencies; (b) to releases required by USACE's flood control criteria; (c) releases required to maintain a flood control buffer or for other flood control purposes; (d) bypasses of uncontrolled flows into Englebright Reservoir; (e) during times when Englebright Dam is spilling; or (f) when releases are governed by the limits of Table 3 of this condition (maximum flow reductions to enhance riparian seedling recruitment; see Table 2.4-10 in Chapter 2).

As described in Yuba Water (2017), this condition would minimize the potential for anadromous salmonid redd dewatering in the lower Yuba River during controlled YRDP operational conditions. Implementation of this condition would be beneficial because it would result in either similar or reduced potential for salmonid redd dewatering under the Proposed Projects and alternatives relative to the Existing Condition. Therefore, salmonid redd dewatering is not carried forward for further detailed analysis in this chapter.

Redd Scour

Because the Proposed Projects and Alternative scenarios could result in changes in flows in the lower Yuba River when flows are relatively high under the bases of comparison, the potential for scour and erosion in the lower Yuba River is considered in this evaluation. Gervasi et al. (2021) evaluated relationships between topographic change (scour and deposition) in the lower Yuba River and multiple hydrologic metrics. Topographic change was evaluated for three epochs (1999-2008, 2008-2014, 2014-2017) using digital elevation model (DEM) differencing. Hydrologic metrics evaluated for each epoch included instantaneous peak flow, volume of water released above six different discharge zones (bankfull – 5,000 cfs[9], 2x bankfull – 10,000 cfs, floodway – 21,100 cfs, 6x bankfull – 30,000 cfs, and flood-prone – 42,200 cfs), and duration of flow occurring above each of the six discharge zones. Gervasi et al. (2021) found that peak discharge was not correlated with total scour nor net export of sediment across the epochs. Instead, total scour correlated best with the hydrologic duration and volume metrics, particularly above the floodway stage. Therefore, potential effects on channel morphology and scour in the lower Yuba River were evaluated by comparing the duration (daily frequency) of modeled flows exceeding the bankfull and floodway stages under the Proposed Projects and Alternative scenarios at two representative locations – below Deer Creek and at Marysville. Although this analysis does not correlate specific

[9] Although the bankfull flow varies along the lower Yuba River, 5,000 cfs has been identified as a generalized indicator of bankfull flow in the lower Yuba River (Wyrick and Pasternack 2012).

flow rates to specific rates or amounts of scour, it is used as an indicator of potential impact to anadromous salmonid redds associated with scour.

Fry and Juvenile Stranding and Isolation

Juvenile salmonids and other aquatic organisms can become stranded on gravel bars or isolated in off-channel habitats (e.g., side channels, backwaters) as a result of flow fluctuations in rivers. Bar stranding or 'beaching' is the type of stranding that occurs on low-gradient bars in which fish are exposed to the air or isolated in tiny pockets of standing water that may be present between larger particles or below the substrate on the bar surface. Off-channel stranding or 'isolation' is the type of stranding that occurs in backwaters, secondary channels, and other floodplain habitats that become disconnected from the main river by receding flows.

As described by Yuba Water (2017), no relationship was observed between ramping rates in the lower Yuba River and the incidence of fry stranding on low gradient bars within the observed range of ramping rates (flow reductions of 100 to 200 cfs per hour at Narrows 2 Powerhouse). These ramping rates corresponded to changes in stage of 0.4 to 1 inch per hour at the study sites, well within the rates of stage change considered to be protective. A rate of 1 inch per hour is generally within the range of natural rates of stage reductions in unregulated rivers (Olson and Metzgar 1987, as cited in Yuba Water (2003), while recommended stage reduction levels for gravel bars of regulated rivers are typically 2.5–5 cm (1-2 inch) per hour to be protective of anadromous salmonids (WDF 1992). Nevertheless, some stranding of post-emergent Chinook salmon fry has been observed even at half this rate, suggesting that young fry have limited ability to detect or respond to receding water levels, regardless of the ramping rate. Similarly, surveys conducted by Yuba Water indicate that the small size and strong association of young fry with substrates limit their ability to detect or respond to receding water levels, regardless of ramping rate. Based on the densities and sizes of juvenile salmon observed in the lower Yuba River study sites, most if not all of the fish visible to divers in shallow, nearshore areas were able to avoid stranding during day and nighttime flow reductions under normal operations (i.e., planned operational changes). These fish were generally greater than 40 mm in length and were observed maintaining position and actively feeding above the substrate (Yuba Water 2017).

Sommer et al. (2005) found that juvenile-sized Chinook salmon did not appear to be particularly prone to stranding mortality as floodwaters receded in the Yolo Bypass. RST catch data in Yolo Bypass also did not indicate that stranding had a major influence on patterns of juvenile emigration (Sommer et al. 2005). As reported by Sommer et al. (2005), previous studies, including Higgins and Bradford (1996), reported that juvenile salmonids are relatively mobile and that most juveniles avoided being stranded during moderate rates of stage change.

As with bar stranding, the potential for off-channel stranding (isolation) is highest for Chinook salmon fry following uncontrolled peak runoff or spills in winter and early spring (December-March). Field surveys conducted by Yuba Water of potential off-channel stranding sites in the lower Yuba River before and after lower Yuba River flow reductions indicate that off-channel stranding is a site-specific phenomenon that depends on the complex interaction of hydrology, site conditions (stage-discharge relationships and channel and bar morphology), and species life history, habitat use, and behavior (Yuba Water 2017). Consequently, the potential for off-channel stranding for a given flow reduction varies by site, reach, and season.

While floodplain and off-channel habitats are sources of stranding mortality, studies have documented that there also are significant growth and potential survival benefits associated with floodplain and off-channel habitats that are used by Chinook salmon in the Central Valley (Limm and Marchetti 2009; Jeffres et al. 2008; Sommer et al. 2001, 2005). Field observations in the lower Yuba River indicate that the occurrence of off-channel isolation is relatively insensitive to flow ramping rates and is largely a function of the magnitudes of winter and spring flows (which determine the accessibility of fry to off-channel areas), site conditions (particularly channel and floodplain morphology), and seasonal abundance, habitat use, and emigration timing of juvenile salmon and steelhead (Yuba Water 2017). The fate of juvenile salmonids in isolated off-channel sites can also vary depending on the suitability of habitat conditions in these sites through the summer and fall. Although isolated juveniles may die from predation, water temperature shock, and oxygen depletion, and juveniles that survive isolation in off-channel habitats may be in relatively poorer condition, monitoring of off-channel sites in the lower Yuba River confirmed that some of these sites can support juvenile salmonids for long periods of time and provide favorable rearing conditions based on observed growth and survival (Yuba Water 2017).

As described in Chapter 2, the new FERC licenses for the YRDP and Narrows Project under the Proposed Projects would include three conditions (two under the YRDP and one under the Narrows Project) that Yuba Water would implement specifically to minimize the potential for fry and juvenile stranding and/or isolation in the lower Yuba River due to YRDP operations. The two YRDP conditions include YRDP Condition AR9 (Control Project Ramping and Flow Fluctuations Downstream of Englebright Dam) and FERC's draft YRDP license Article 409 (Develop and Implement a New Narrows Reach Fish Stranding Prevention Plan), while the Narrows Project condition is Yuba Water's Narrows Project Proposed Condition 2 (Ramping Rates). YRDP Condition AR9 would require Yuba Water to limit flow reduction rates and flow fluctuations to levels that FERC and USACE (2019, p. 2-195) found would be more protective of anadromous salmonids than existing YRDP operations. FERC's draft YRDP license Article 409 would require Yuba Water to develop, through consultation with USACE, CDFW, NMFS, USFWS, and SWRCB, a plan for preventing fish stranding downstream of Englebright Dam due to YRDP operations and for reporting potential fish stranding events to USFWS, NMFS, and CDFW. Yuba Water's Narrows Project Proposed Condition 2 would require Yuba Water to operate the Narrows Project to the same flow fluctuation limits as would be required for the Narrows 2 under the new YRDP license. Because these conditions would be implemented under the Proposed Projects and alternatives, salmonid fry and juvenile stranding due to normal project operations (i.e., planned operational changes) would be expected to occur less frequently under these scenarios relative to the bases of comparison. Consequently, salmonid fry and juvenile stranding due to normal operations is not carried forward for further detailed analysis in this DEIR.

Other Operations-related Effects at Narrows 1 and Narrows 2 Powerhouses

Fish Stranding, Isolation, and Redd Dewatering Due to Unanticipated Forced Outages

In addition to the potential for stranding and isolation of salmonids associated with planned operational changes at the Narrows 2 facility, unanticipated forced outages of the Narrows 2 and Narrows 1 powerhouses can occur, primarily due to equipment failure. Unanticipated outages of the powerhouses can result in a temporary reduction in flow in the lower Yuba River, potentially affecting various salmonid lifestages. Forced outages and their potential effects on salmonids in

the lower Yuba River during recent years are described in Section 3.2.3.5 of Appendix 9A, and are briefly summarized below.

- February 8, 2015 Minimum Flow Deviation - An equipment failure at the Narrows 2 Powerhouse resulted in flow at the Smartsville Gage dropping below the FERC-approved minimum flow requirement of 550 cfs for 45 minutes, with a minimum flow of 150 cfs. During surveys conducted the day after the deviation, biologists observed about 100 to 200 post-emergent Chinook salmon fry mortalities, unspecified as either spring-run or fall-run Chinook salmon, in the area extending from just downstream of Narrows 1 Powerhouse to the confluence with Deer Creek. Living juvenile Chinook salmon also were observed but were not quantified. Due to the adverse effects to fishery resources, FERC required that Yuba Water and PG&E develop a mitigation plan to remedy the adverse effects to the Yuba River fishery resulting from the minimum flow violation. Under the mitigation plan, Yuba Water installed 30 pieces of LWM at three locations to promote juvenile salmonid rearing in the lower Yuba River during 2019.
- August 17, 2020 Minimum Flow Deviation – A transmission line disturbance (likely a lightning strike) caused the Narrows 2 Powerhouse to trip offline, which ultimately resulted in flow at the Smartsville Gage dropping below the maximum 15% reduction allowed (relative to the daily average flow) for a total of 5 minutes. Yuba Water evaluated potential impacts to spring-run Chinook salmon adult holding and spawning, fall-run Chinook salmon pre-spawn staging, and over-summer juvenile rearing for both spring-run Chinook salmon and steelhead, and concluded that the unanticipated forced outage would not have resulted in impacts to spring-run or fall-run Chinook salmon spawning, and that it was unlikely that the event resulted in significant adverse impacts to spring-run Chinook salmon adult holding, fall-run Chinook salmon adult pre-spawn staging, and over-summer juvenile rearing for both spring-run Chinook salmon and steelhead.
- October 5, 2020 Minimum Flow Deviation – An equipment malfunction of the Narrows 1 hydro-controller caused an unanticipated reduction in releases from the Narrows 1 Powerhouse from 920 cfs to 673 cfs for a total of about 7 minutes. Yuba Water evaluated potential impacts to spring-run and fall-run Chinook salmon spawning and embryo incubation, fall-run Chinook salmon adult pre-spawn staging, and over-summer juvenile rearing for both spring-run Chinook salmon and steelhead, and concluded that the unanticipated flow reduction event would likely not have resulted in significant adverse impacts to spring-run or fall-run Chinook salmon spawning, fall-run Chinook salmon adult pre-spawn staging, or over-summer juvenile rearing for either spring-run Chinook salmon or steelhead. Modifications were made by Yuba Water staff to the equipment that malfunctioned to avoid or minimize the potential for future similar equipment malfunctions.
- March 14, 2022 Flow Fluctuation Deviation – An equipment malfunction of the Narrows 2 Full Bypass fixed-cone valve (FCV) ultimately resulted in an unanticipated increase in flow at the Smartsville Gage from 730 cfs to 920 cfs, and the maximum 15% flow fluctuation limit (relative to the daily average flow) was exceeded for approximately 30 minutes. Yuba Water evaluated the event for potential adverse environmental impacts and concluded that the event would likely not have resulted in

significant adverse impacts due to the relatively short duration of the event and the limited effect of the flow increase on stage.

- January 4, 2023 Minimum Flow Deviation – An equipment malfunction at the Narrows 2 Powerhouse following a transmission line disturbance (likely high winds) that caused the generator to trip offline ultimately resulted in flow at the Smartsville Gage dropping below the maximum 15% reduction allowed (relative to the daily average flow) for a total of about 35 minutes. Yuba Water evaluated the event for potential adverse impacts to Chinook salmon spawning/embryo incubation and fry rearing and concluded that the unanticipated flow reduction event would likely not have resulted in significant adverse impacts to the spring-run or fall-run Chinook salmon spawning or fry rearing lifestages.

As described above, occasional equipment failures at the Narrows 2 or Narrows 1 powerhouses have resulted in flow reductions or fluctuations below the Narrows 2 or Narrows 1 facilities, but flow reductions associated with these events have generally been extremely brief in duration. Recent events have been determined by Yuba Water to have not significantly adversely affected anadromous salmonid populations through the mechanisms of fry and/or juvenile stranding/isolation or redd dewatering. In the one instance when Yuba Water and FERC determined that an unanticipated forced outage at one of Yuba Water's facilities resulted in adverse impacts to fisheries resources in the lower Yuba River, FERC required Yuba Water to develop and implement habitat enhancement in the lower Yuba River to fully mitigate for the adverse impacts. Additionally, FERC's draft YRDP license Article 409 would require Yuba Water to develop, through consultation with USACE, CDFW, NMFS, USFWS, and SWRCB, a plan for preventing fish stranding downstream of Englebright Dam due to YRDP operations (including unanticipated forced outages) and for reporting potential fish stranding events to USFWS, NMFS, and CDFW. Because these conditions would be implemented under the Proposed Projects and alternatives, and because the frequency of unanticipated forced outages and associated flow fluctuations is not expected to increase under the Proposed Projects or alternatives, the potential for adverse impacts to fisheries resources in the lower Yuba River is not expected to increase under these scenarios relative to the bases of comparison. Consequently, potential impacts to fisheries resources in the lower Yuba River through the mechanisms of fry and juvenile stranding/isolation and redd dewatering due to unanticipated forced outages are not carried forward for detailed analysis in this chapter.

Effects Related to License Conditions/Implementation Plans

YRDP

As described in Chapter 2, Yuba Water would be required to develop and/or implement a number of license conditions and implementation plans once a new FERC license is issued for the YRDP. Several of the conditions (AR1, AR2, AR3, AR4, AR9, AR10, AR11, AR12, WR2, WR3, WR5, and WR6) would affect the manner in which Yuba Water operates the YRDP, and the effects of those conditions on operations have been incorporated into the YRDP Operations Model. Potential impacts to fisheries and aquatic resources that could result from these conditions are analyzed through assessments of simulated flows and water temperatures. Other conditions associated with license implementation plans that may not result in changes in operations (and thereby cannot easily be analyzed through assessments of simulated flows and water temperatures), but which

have the potential to result in effects to fisheries and aquatic resources in the lower Yuba River through activities associated with plan implementation (based on descriptions provided in Chapter 2 and Yuba Water (2017)), include:

- AR8 – Implement Lower Yuba River Aquatic Monitoring Plan
- Develop and Implement a New Lower Yuba River Riparian Restoration Plan (FERC Article 412)
- Develop and Implement a New Comprehensive Large Woody Material Enhancement Plan for the lower Yuba River (FERC Article 410)
- WR7 – Implement Water Temperature Monitoring Plan
- WR8 – Implement Water Quality Monitoring Plan
- WR9 – Implement Drought Management Plan

The potential effects of Yuba Water's implementation of these plans under the Proposed Projects are analyzed through assessments of the extent to which activities associated with plan implementation could result in direct or indirect impacts to fisheries or aquatic habitat, changed conditions relative to the bases of comparison, as well as any identified BMPs or impact avoidance and minimization measures.

Narrows Project

As described in Chapter 2, Yuba Water has proposed to include in a new Narrows Project FERC license certain existing license conditions with modifications, as well as several new conditions. The proposed conditions that have the potential to affect aquatic habitat conditions in the lower Yuba River (Condition 1 – Supplemental Flows, Condition 2 – Ramping Rates) are continuations of requirements in the existing FERC license for the Narrows Project, and therefore would not result in changed conditions in the lower Yuba River under the Proposed Projects relative to the Existing Condition. Consequently, these conditions are not carried forward for detailed analysis in this chapter.

9.4.2.3.4 Areas Downstream of the Lower Yuba River

To evaluate the potential for the Proposed Projects and alternatives to influence fisheries habitat conditions in areas downstream of the lower Yuba River, changes in simulated mean monthly Yuba River outflows and water temperatures under the Proposed Projects and alternatives were used to estimate the extent to which flows and water temperatures in the Feather River downstream of the lower Yuba River could be influenced. As described in Chapter 4, modeled changes in mean monthly flows from the lower Yuba River under the Proposed Projects and Alternative 1 scenarios represent minimal proportions of Feather River flows downstream of the lower Yuba River confluence. Similarly, based on an analysis of modeled monthly average water temperatures in the lower Yuba River at Marysville and average flow and water temperature data on the Feather River upstream of the lower Yuba River during the period of May through November, the Proposed Projects and Alternative 1 scenarios also would not result in notable changes in Feather River water temperatures immediately below the lower Yuba River (see Chapter 4). Therefore, there would also not be notable flow or water temperature-related changes in the Sacramento River

downstream of the Feather River confluence or in the Delta under the Proposed Projects or Alternative 1 relative to the bases of comparison.

Alternative 2 would result in greater changes in Yuba River outflow relative to the bases of comparison compared to the Proposed Projects and Alternative 1. Changes in Feather River and Sacramento River flows due to changes in modeled Yuba River outflow resulting from implementation of Alternative 2 and resultant changes in fisheries habitat availability or thermal suitability were evaluated by examining the proportionate increase in Feather River and Sacramento River flows.

9.4.3 Impact Indicators and Significance Criteria

The previously-described impact assessment methods and evaluation guidelines have been developed as a means to assess potential impacts of the Proposed Projects and the alternatives on fisheries resources associated with construction activities and operations of the YRDP and Narrows Project. Operations-related evaluations include multiple impact indicators by species and geographic location. Discussions of YRDP operations-related impacts are separated by: (1) simulated operations-related impacts (i.e., flow, water temperature and reservoir storage-related changes); and (2) other operations-related impacts (i.e., impacts associated with reservoir operations, powerhouse operations, diversion dam operations, and implementation of license conditions/implementation plans) that are not addressed through changes in simulated habitat conditions. As previously described, operations-related impacts of the Narrows Project are limited to license implementation plans.

The impact indicators summarized below are used to evaluate whether the Proposed Projects and alternatives would result in impacts to fisheries resources, species guilds[10], or particular species and lifestages by geographic location associated with: (1) simulated operations; and (2) other operations-related activities.

9.4.3.1 Simulated Operations Impacts

9.4.3.1.1 YRDP Reaches Upstream of Englebright Dam

Simulated operations impact indicators for fisheries resources in YRDP reaches upstream of Englebright Dam included changes in: (1) location-specific and season-specific habitat availability averages by WYT and habitat exceedance distributions; and (2) location-specific and season-specific water temperature exceedance distributions relative to WTI values. Changes in the following habitat availability impact indicators of about 10% were considered to be indicators of potentially substantial effects, and changes in frequency of exceedance of the following WTI values (or in frequency of occurrence within a WTI range) of about 10% or greater were considered

[10] Group of species that exploit similar resources or exhibit similar characteristics (e.g., hardhead/pikeminnow, warmwater reservoir fisheries, coldwater reservoir fisheries).

to be potentially substantial[11]. However, all season-specific changes in habitat availability and thermal suitability at all locations evaluated were considered together to identify impact determinations for each species in each river.

- Rainbow trout in the North Yuba River
    - Habitat availability for adult, spawning and juvenile lifestages below NBBD
    - Thermal suitability for adult and juvenile lifestages (68°F WTI value) below NBBD, and above the upper Yuba River
    - Thermal suitability for spawning (57°F WTI value) below NBBD, and above the upper Yuba River
- Sacramento sucker in the North Yuba River
    - Habitat availability for adult and juvenile lifestages below NBBD
    - Thermal suitability for adult and juvenile lifestages (61-77°F preferred range) below NBBD, and immediately upstream of the confluence with the Middle Yuba River
- Hardhead/Sacramento pikeminnow in the North Yuba River
    - Habitat availability for adult and juvenile lifestages below NBBD
    - Thermal suitability for adult and juvenile lifestages (61-77°F preferred range) below NBBD, and immediately upstream of the confluence with the Middle Yuba River
    - Thermal suitability for spawning hardhead (59-64°F preferred range) below NBBD, and immediately upstream of the confluence with the Middle Yuba River
- Rainbow trout in Oregon Creek
    - Habitat availability for adult, spawning and juvenile lifestages below LCDD, in Celestial Valley, and immediately upstream of the confluence with the Middle Yuba River
    - Thermal suitability for adult and juvenile lifestages (68°F WTI value) below LCDD, and immediately upstream of the confluence with the Middle Yuba River

[11] Potentially substantial changes in water temperature suitabilities are identified based upon changes in the frequency of exceeding species and lifestage-specific WTI values of 10% or more under the Proposed Projects or the alternative, relative to a basis of comparison (SWRCB 2016; Yuba Water 2017; DWR and Reclamation 2017). A change in the frequency of exceedance of 10% is assumed to be high enough to reveal the potential for a substantial change, yet minimize the potential for identifying a change due to error or uncertainty in the analytical methodologies and modeling (SWRCB 2016). Additionally, consistent with previous environmental documentation (e.g., SWRCB 2016; DWR and Reclamation 2017), changes in a habitat availability index of 10% or more are identified under the Proposed Projects and the alternatives, relative to the bases of comparison. However, a 10% difference in the probability of exceeding a WTI value or habitat availability index does not necessarily constitute an impact. Impact determinations are based upon consideration of all evaluated impact indicators for all lifestages of a particular species. An impact is considered potentially significant if implementation of the Proposed Projects or an alternative would adversely affect a species, relative to the basis of comparison, in consideration of all evaluated impact indicators for all lifestages.

    - Thermal suitability for spawning (57°F WTI value) below LCDD, and immediately upstream of the confluence with the Middle Yuba River
- Sacramento sucker in Oregon Creek
    - Habitat availability for adult and juvenile lifestages below LCDD
    - Thermal suitability for adult and juvenile lifestages (61-77°F preferred range) below LCDD, and immediately upstream of the confluence with the Middle Yuba River
- Rainbow trout in the Middle Yuba River
    - Habitat availability for adult, spawning and juvenile lifestages below OHDD, upstream of Oregon Creek, and between Oregon Creek and the upper Yuba River
    - Thermal suitability for adult and juvenile lifestages (68°F WTI value range) below OHDD, and above the upper Yuba River
    - Thermal suitability for spawning (57°F WTI value) below OHDD, and above the upper Yuba River
- Sacramento sucker in the Middle Yuba River
    - Habitat availability for adult and juvenile lifestages below OHDD, upstream of Oregon Creek, and between Oregon Creek and the upper Yuba River
    - Thermal suitability for adult and juvenile lifestages (61-77°F preferred range) below OHDD, and above the upper Yuba River
- Rainbow trout in the upper Yuba River
    - Habitat availability for adult, spawning and juvenile lifestages between the North Yuba River/Middle Yuba River confluence and New Colgate Powerhouse, and below New Colgate Powerhouse
    - Thermal suitability for adult and juvenile lifestages (68°F WTI value) below the North Yuba River/Middle Yuba River confluence, and below New Colgate Powerhouse
    - Thermal suitability for spawning (57°F WTI value) below the North Yuba River/Middle Yuba River confluence, and below New Colgate Powerhouse
- Sacramento sucker in the upper Yuba River
    - Habitat availability for adult and juvenile lifestages between the North Yuba River/Middle Yuba River confluence and New Colgate Powerhouse, and below New Colgate Powerhouse
    - Thermal suitability for adult and juvenile lifestages (61-77°F preferred range) below the North Yuba River/Middle Yuba River confluence, and below New Colgate Powerhouse

- Hardhead/Sacramento pikeminnow in the upper Yuba River
    - Habitat availability for adult and juvenile lifestages between the North Yuba River/Middle Yuba River confluence and New Colgate Powerhouse, and below New Colgate Powerhouse
    - Thermal suitability for adult and juvenile lifestages (61-77°F preferred range) below the North Yuba River/Middle Yuba River confluence, and below New Colgate Powerhouse
    - Thermal suitability for spawning hardhead (59-64°F preferred range) below the North Yuba River/Middle Yuba River confluence, and below New Colgate Powerhouse

9.4.3.1.2 New Bullards Bar Reservoir

Simulated operations impact indicators for fisheries resources in NBBR for the Proposed Projects and alternatives relative to the bases of comparison included: (1) simulated mean monthly reservoir WSE reductions of sufficient magnitude and frequency to substantially affect warmwater fish spawning, in consideration of whether the frequency of 6 ft or greater monthly reductions during March through June occurred with substantial frequency (differences of about 10% or more[12] over one or more months); (2) simulated mean monthly reservoir storage reductions of sufficient magnitude and frequency[13] to substantially affect resident coldwater reservoir fisheries, in consideration of whether differences in storage during April through November were sufficient to substantially affect coldwater pool volume and associated coldwater fisheries habitat availability; and (3) simulated mean monthly reservoir WSE reductions during March through June of sufficient magnitude and frequency[14] to substantially affect migratory fish species' access to NBBR tributaries.

- Warmwater fisheries in New Bullards Bar Reservoir
    - Changes in habitat conditions for warmwater fish spawning in NBBR based on changes in mean monthly simulated reservoir WSEs during March through June sufficient to substantially affect warmwater fisheries habitat in NBBR
- Coldwater fisheries in New Bullards Bar Reservoir
    - Changes in habitat conditions for coldwater fish residence in NBBR based on changes in mean monthly simulated reservoir storages during April through November sufficient to substantially affect coldwater fisheries habitat in NBBR
- Fish Access to New Bullards Bar Reservoir tributaries

[12] Although SWRCB (2016) used a fluctuation in WSEs of 15 ft or more, they also used a 10% increase in the frequency of WSE reduction as an indicator of significant change.

[13] A change in reservoir storage of about 10% or more over one or more months during the period of evaluation was used as an indicator of potential impact to reservoir coldwater fish habitat availability. SWRCB (2016) used a 10% or more reduction in end-of-September storage as an indicator of potentially significant impact to coldwater habitat availability.

[14] A change in reservoir storage of about 10% or more over one or more months during the period of evaluation was used as an indicator of potential impact to reservoir coldwater fish habitat availability (SWRCB 2016). Consequently, it was assumed that a change in reservoir WSEs of about 10% or more over one or more months during the period of evaluation serves as an applied indicator of potential impact to reservoir tributary fish habitat accessibility in this DEIR.

- Changes in monthly reservoir WSEs during March through June sufficient to substantially affect reservoir tributary access for migratory fish species

9.4.3.1.3 YB/DS Reaches Upstream of the YRDP

For Alternative 1 programmatic analyses, impact indicators for fisheries resources in YB/DS reaches upstream of the YRDP (i.e., YB/DS reaches in the Middle Yuba River upstream of OHDD, South Yuba River upstream of Englebright Reservoir, Canyon Creek and Fordyce Creek) included changes in the following location-specific and species/lifestage-specific habitat availability during April and May of Dry and Critical WYs. Due to the flexibility in how Alternative 1 could be implemented by the YB/DS projects in the reaches upstream of the YRDP, changes in flow-dependent habitat availability were based on directional changes in habitat associated with directional changes in flows (i.e., increases or decreases in habitat based on increases or decreases in flow) relative to the Future Baseline[15]. The programmatic assessment of whether impacts would be expected to be substantial considered the potential directional changes in habitat availability, the frequency of potential changes in habitat based on the occurrence of specific WYTs, the duration of potential changes in habitat relative to lifestage-specific periods, the potential flexibility in operations under Alternative 1, the focal species/lifestages and reaches targeted for enhancement and evaluated in the YB/DS FERC relicensing (FERC 2014), and whether special-status fish species have the potential to occur in these reaches.

- Rainbow trout in the Middle Yuba River
  - Habitat availability for adult, spawning and juvenile lifestages in the Jackson Meadows Dam Reach, Milton Diversion Dam Sub-reach, Wolf Creek Sub-reach and Kanaka Creek Sub-reach
- Sacramento sucker in the Middle Yuba River
  - Habitat availability for adult and juvenile lifestages in the Milton Diversion Dam Sub-reach, Wolf Creek Sub-reach and Kanaka Creek Sub-reach
- Hardhead/pikeminnow in the Middle Yuba River
