Path: I:\FR18s\FR18161220 Tulare Lake GSP\Figures\5-MonitoringNetwork\Figures\November2019_fig5-7_DMSTemplate.pdf

Table 1-1. GSP Requirements

Requirements
Groundwater conditions must be adequately defined and monitored to demonstrate the GSPs are achieving the sustainability goals for the basin
GSAs must be sufficiently defined and compatible to evaluate the effect of GSPs on adjacent basins
GSPs must meet substantial compliance standards
A GSA shall provide a description of basin setting and establish criteria that will maintain or achieve sustainable groundwater management
DWR will consider state policy regarding to the human right to water when implementing these regulations
The GSP sustainable groundwater management criteria, projects, and management actions should be based on the level of understanding of the basin setting including an understanding of uncertainty and data gaps
A GSP must achieve the sustainability goals for the basin in 20 years

Table 2-4. Beneficial Uses and Users by GSA

Stakeholder Group	Description
Mid-Kings River GSA	
Agricultural Users	Service area is composed of mostly agricultural lands and agricultural users.
Domestic Well Owners	There are domestic wells within the Mid-Kings River GSA, and it is understood that many rural domestic users will fall into the "de minimis extractor" category, so further work is being conducted to understand to what extent domestic users will be affected by GSP requirements.
Public Water Systems	Armona CSD, Home Garden CSD and Hardwick Water Company, as well as several transient public water systems for school districts are included in this category (Kings River-Hardwick, Pioneer, Hanford Christian).
Municipal Water Systems	City of Hanford
Local Land Use Planning Agencies	City of Hanford and Kings County
California Native American Tribes	See Appendix B, Section C.2
Disadvantaged Communities	Armona, Home Garde, Hardwick
Entities monitoring and reporting Subbasin groundwater elevations	Kings CWD monitors groundwater levels within its service area and is providing a subset of that information to the KRCD for submission to the CASGEM system.
South Fork Kings GSA	
Agricultural Users	Service area is composed of mostly agricultural lands and agricultural users.
Domestic Well Owners	There are domestic wells within the South Fork Kings GSA, and it is understood that many domestic users will fall into the "de minimis extractor" category, so further work is being conducted to understand to what extent domestic users will be affected by GSP requirements.
Municipal Well Operators	City of Lemoore, Stratford PUD
Local Land Use Planning Agencies	City of Lemoore, Kings County
California Native American Tribes	See Appendix B, Section C.2
Disadvantaged Communities	Community of Stratford
Entities monitoring and reporting Subbasin groundwater elevations	KRCD is the designated monitoring entity for the Kings and Tulare Lake Subbasins under CASGEM program. South Fork Kings GSA will coordinate its SGMA monitoring efforts with the CASGEM monitoring effort led by KRCD.
Southwest Kings GSA	
Agricultural Users	Approximately 99% of the GSA is composed of agricultural lands. Representatives of the agricultural community are currently involved on the GSA Board of Directors.
Domestic Well Owners	Only one or two landowners utilize a domestic well and are represented on the Board of Directors through member agencies.

See Acronyms and Abbreviations list for definitions.

Table 2-4. Beneficial Uses and Users by GSA (Continued)

Stakeholder Group	Description
Municipal Well Operators	Kettleman City CSD relies solely on surface water supply (effective October 2019). Their municipal wells are a back-up source to provide well water to residential and commercial customers within the GSA boundary in emergency situations when surface water is not accessible.
Local Land Use Planning Agencies	Kings County
California Native American Tribes	See Appendix D, Section C.2
Disadvantaged Communities	Kettleman City
Entities monitoring and reporting Subbasin groundwater elevations	KRCD is the designated monitoring entity for the Kings and Tulare Lake Subbasins under CASGEM program. Southwest Kings GSA will coordinate its SGMA monitoring efforts with the CASGEM monitoring effort led by KRCD.
El Rico GSA	
Agricultural Users	Represented through many of the GSA member agencies and/or by Kings County.
Domestic Well Owners	Represented through member agencies including Kings County or via exemption for small amounts of groundwater extraction.
Municipal Well Operators	City of Corcoran
Public Water Systems	City of Corcoran
Local Land Use Planning Agencies	City of Corcoran, Kings County
Surface Water Users	Represented through GSA member agencies
Disadvantaged Communities	City of Corcoran
Entities monitoring and reporting Subbasin groundwater elevations	Represented by GSA member agencies including TLBWSD that collects and reports data for multiple members of the agency via the Tulare Lake Coordinated Groundwater Management Plan.
Tri-County Water Authority GSA	
Agricultural Users	Composed almost entirely of agricultural users, including nut grower commodity groups and other agricultural use growers.
Domestic Well Owners	There are domestic wells within the GSA area, but because SGMA excludes “de minimis extractors,” it is anticipated that the GSP will exclude domestic wells from such requirements.
Local Land Use Planning Agencies	Kings County
Federal Government	Bureau of Land Management
Entities monitoring and reporting Subbasin groundwater elevations	Angiola WD, TLBWSD

Table 3-3. Generalized Stratigraphic Column for Tulare Lake Subbasin

System	Series	Geologic Unit		Lithologic Character	Maximum Thickness (feet)	Water-Bearing Character	Areas Where Important
QUATERNARY	Holocene	Tulare Formation	Flood Basin Deposits	Interbedded silt, clay, and fine sand. Interfingers with and age equivalent to Younger Alluvium.	<50	Poorly permeable, poor quality water, unconfined.	Not important source of water.
			Younger Alluvium	Interstratified and discontinuous beds of clay, silt, sand, and gravel, primarily located on recent alluvial fans and along stream channels. Interfingers with flood-basin and lake bed deposits.	0 - 100	Highly permeable, but largely unsaturated or seasonally saturated. Serves as conduit for recharge to underlying units.	May provide sufficient supplies for domestic and stock use where saturated.
	Pleistocene		Older Alluvium	Poorly to well sorted fine to coarse sand, gravel, silt and clay. Represents older alluvial fan material and contains well-developed soil profiles and hardpan horizons. Interfingers with lacustrine clays.	300 - 500	Moderately to highly permeable, unconfined and semiconfined. Yields large quantities of water to wells, major aquifer.	Important source of groundwater on eastern and northern portions of TLSB.
			Lacustrine Deposits	Corcoran Clay is extensive reduced clay formed in large fresh-water lake in late Pleistocene that extended throughout most of the San Joaquin Valley. Has been deformed across valley axis and has been dated at about 600,000 Ma.	50 - 200	Poorly permeable, forms major aquitard within San Joaquin Valley.	Occurs beneath nearly the entire TLSB, including Tulare Lake. Important aquitard on eastern and northern portions of TLSB.
				Tulare Lake bed clays are thick deposits that extend vertically from the surface beneath the former lake. These beds interfinger with alluvial and continental deposits to the east and west. Croft (1972) identified several of these interfingering lacustrine clay beds as the A-D and F clays. His E-clay is equivalent to the Corcoran Clay (above).	0 - 3,000	Poorly permeable, forms significant barrier to lateral groundwater flow in the TLSB and lateral tongues can form local confining conditions in alluvial and continental deposits.	Tulare Lake bed forms clay plug on western portion of TLSB. A and C clays are thin (10 - 60 feet) beds that may be important aquitards on the northern and eastern portions of TLSB.
TERTIARY	Pliocene		Continental Deposits, undifferentiated	Poorly to moderately sorted fine to medium sand, silt, gravel, and clay. Deposits may be reduced or oxidized. Provenance may be from Sierra Nevada or Coast Ranges. Sierran deposits typically arkosic and coarser grained than Coast Ranges deposits. Deposits from each provenance interfingering in an east-west line, depending upon major transgressive deposition from each mountain range.	2,000+	Poorly to moderately permeable, semi-confined to confined conditions. Yields significant quantities of groundwater, especially below Corcoran Clay.	Important source of groundwater on eastern and northern portions of TLSB and northwest and southeast of TLSB.
		San Joaquin Formation	Marine Deposits	Poorly sorted fine-grained sandstone, siltstone, and mudstone.	1,500+	Exposed in Kettleman Hills, dips steeply to east beneath Tulare formation. Semi-consolidated to consolidated, containing connate water of poor quality. Formation is poorly permeable and forms substantial aquitard at base of Tulare Formation.	No known beneficial uses of water, typical TDS of 3,000 to 20,000 mg/L.
		Etchegoin Formation	Marine Deposits	Silty and clayey sands, sandy silt, silty clay, blue sandstone, and conglomeratic sandstone.	3,000+	Exposed in Kettleman Hills, dips steeply to east beneath San Joaquin formation. Fine grained, interbedded nature, contains saline water.	No known wells into formation, not expected to be an aquifer.
	Miocene	Santa Margarita Formation	Marine Deposits	Fairly well-sorted to well-sorted gray sandstone.	0 - 600	Contains good quality water and yields significant water to wells for irrigation in places. However, sodium chloride front exists about 7 to 10 miles east of Highway 99.	Extensively used as aquifer in area from Terra Bella to Richgrove, east of Highway 99. Not an important aquifer in the TLSB.
	Eocene/Oligocene	Other Tertiary Sediments (undifferen-tiated)	Marine and Non-Marine Deposits		----	Few formations that contain usable water quality.	Too deep to be of concern in or near TLSB.
PRE-TERTIARY	Paleozoic/ Mesozoic	Metamorphic and Igneous Rocks	Basement Complex	Crystalline rocks of metamorphosed sedimentary and igneous rocks invaded by largely granitic plutonic rocks.	----	Largely impermeable, contain fractures, faults, and joints that may yield small quantities of water to domestic and stock wells.	Used as water source only in foothills and mountain areas of Sierra Nevada.

Notes: Generalized stratigraphic column after Hilton et al., 1963; Croft and Gordon, 1968; Davis et al., 1959; Loomis, 1990; and Wood, 2018.

Notes provided on next page.

See Acronyms and Abbreviations list for definitions.

1.) Values highlighted have been modified.
2.) Values with "0" indicate no surface water delivery to the best of our knowledge.
3.) Values with "-" have no verified data.
4.) Total flow from Peoples Canal is split 60% to Mid Kings, 40% to Melga.
5.) Last Chance Diversion is split 50% between Mid Kings and El Rico.
6.) Blakeley has added State Water from Lateral A for Southwest.
7.) Total flow from Deer Creek split 30% to El Rico, 70% to Tri-County.
8.) Tule River for El Rico includes the total of Elk Bayou and TID Spill.
8.) SWP from TLBWSD Split Throughout Tri-County & Southwest Kings.
9.) Kings River water in Tri-County was subtracted from the total in Empire Weir No. 2. 1976 and 2010 are 0 for Empire Weir No. 2 because of negative values.
10.) Lakeside is a portion of Kaweah River, Reduced Total Kaweah River between Mid Kings and El Rico
11.) Additional Tule River flow data added for Tri-County
12.) Empire West Side ID total from SWP reduce annual totals by 10%
13.) Dudley Ridge Water District reduce annual totals by 10%
14.) Lateral A (T200) & Lateral B (T206) reduce annual totals by 18% for El Rico & Tri-County
15.) Modifications to Peoples Canal and Last Chance as a result of discussions with Mid Kings River GSA 02/14/2019

Key	Average Annual
Wet Year	816,660
Dry Year	423,464
Average Precipitation	686,577
GSA Annual Totals	
Kings River Watershed Total	

Reduction in Entitlement	
Empire West Side ID Total from SWP	10%
Dudley Ridge State Turnouts	10%
Lateral A & B for El Rico & Tri-County	18%

Table 5-1. Summary of Existing & Proposed Monitoring Network Sites

Existing RMS Network	Water Level	Water Quality	Land Subsidence
Mid-King River GSA	25	18	11
South Fork King GSA	21	21	6
Southwest Kings GSA	2	2	4
El Rico GSA	10	3	5
Tri-County GSA	3	0	2
Total	61	44	28
Proposed Additions to RMS Network	**Water Level**	**Water Quality**	**Land Subsidence**
Mid-King River GSA	9	TBD	0
South Fork King GSA	4	TBD	1
Southwest Kings GSA	5	TBD	0
El-Rico GSA	13	TBD	1
Tri-County GSA	3	TBD	0
Total	34	0	2

Notes:

1) Summary of network includes nested (multiple casings installed in a single borehole) or clustered monitoring wells (multiple wells located close together) for water levels and water quality.

Table 5-7. Annual Reporting Requirements

SGMA Section	Annual Reporting Requirement	Input to DMS (or link)
356.2(b)(1)(B)	Hydrographs including water year type from Jan 2015(?) to current	Generated in DMS from water level data input by GSAs
356.2(b)(1)(A)	GW Elevation Contours (spring & fall)	Generated outside DMS using data from DMS then contour maps created and a linked PDF maps from the DMS
356.2(b)(2)	GW extraction by water use sector including method of determination and map	Determined outside DMS. Total use by sector input by each GSA then summarized for subbasin in DMS as a summary table
356.2(b)(3)	Surface Water use by source	Total by GSA for input to DMS and summarized for subbasin in DMS as a summary table
356.2(b)(4)	Total Water use by sector	DMS summary table of water supplies by sector per GSA
356.2(b)(5)(A)	Change in GW Storage maps	Calculated outside DMS from contour data using basin-wide method then total per GSA input into DMS as a summary table
356.2(b)(5)(B)	Graph with Water Year type, est. GW use, annual & cumulative GW Storage change	DMS generated basin total graph using data in DMS.

Table 5-8. Reporting Standards

Category of Information	Reporting Units
Water Volumes	AF
Surface Water Flows Groundwater Flows	AF/Y or CFS AF/Y
Field Measurements of Elevations Groundwater Surface Water Land Surface	to nearest 0.1 ft relative to NAVD 88
Reference Point Elevations	To within 0.5 feet, or best available information relative to NAVD 88
Geographic Locations	GPS coordinates by latitude and longitude in decimal degrees to five decimal places, to a minimum accurate of 30 feet, relative to NAD 83

See Acronyms and Abbreviations list for definitions.

Table 6-1. Summary of Projects and Management Actions Chosen for Mid-Kings River GSA

Project	Implementing Agency	Cost	Annual Yield (AF/Y)
Rehabilitation of Existing Recharge Basins	Kings County Water District	$ 800,000	1,500
Conveyance Improvements and Construction on Riverside Canal	Kings County Water District	$ 320,000	1,500
Fallowing Program	Mid-Kings River GSA	$ 1,380,000	6,250
Cartright Basin Improvements	Kings County Water District, Lakeside Irrigation Water District	$ 884,000	650
Last Chance Side Ditch Improvements	Kings County Water District, Landowners	$ 6,798,000	1,000
Recharge Basin Construction	Kings County Water District, Mid-Kings River GSA	$ 90,000,000	44,444

Table 6-2. Summary of Projects and Management Actions Chosen for South Fork Kings GSA

Project	Implemented by	Annualized Benefit (AF/Y)	Priority	Estimated CAPEX ($)
Groundwater Measurement and Reporting	South Fork Kings GSA/Landowners	1,500	High	$ 500,000
Surface Water Delivery Improvement	South Fork Kings GSA/Landowners	5,000	High	$ 5,000,000
On-Farm Improvements	South Fork Kings GSA/Landowners	2,500	Med	$ 1,000,000
Conservation Reuse	South Fork Kings GSA/Lemoore	1,000	Med	$ 1,000,000
Cropping/Fallowing Program	South Fork Kings GSA	13,000	High	$ 5,000,000
Demand Reduction Sub-Total		**23,000**		**$ 12,500,000**
Aquifer Storage and Recovery	South Fork Kings GSA/Landowners	13,000	High	$ 15,000,000
Surface Storage	South Fork Kings GSA/Landowners	2,000	Low	$ 6,000,000
Mid-Kings Recharge Basin	South Fork Kings GSA	7,000	Med	$ 28,000,000
Supply Enhancement Sub-Total		**22,000**		**$ 49,000,000**
TOTAL		**45,000**		**$ 61,500,000**

See Acronyms and Abbreviations list for definitions.

Table 6-3. Summary of Projects and Management Actions Chosen for El Rico GSA

Project	Annual Project Use (Days)	Acres	Cost/Acre	Average Annual Yield (AF/Y)	Total Cost	Project Life (Years)
Storage Ponds	60	5,000	$20,000	26,000	$100,000,000	60
Canal Lining/Piping	150		3M/mile	25,000	$100,000,000	60
Demand Reduction	360	5,000		15,000		
Total				**76,000**		

Table 6-4. Summary of Projects and Management Actions Chosen for Tri-County Water Authority GSA

Project	Annual Project Use (Days)	Acres	Cost/Acre	Average Annual Yield (AF/Y)	Total Cost	Project Life (Years)
Storage Ponds	60	1,500	30,000	15,000	$45,000,000	
Demand Reduction						
Total				**15,000**		

See Acronyms and Abbreviations list for definitions.

Table 6-5. Project and Management Actions

§354.44 Projects and Management Actions
(a) Each Plan shall include a description of the projects and management actions the Agency has determined may achieve the sustainability goal for the Subbasin, including projects and management actions to respond to changing conditions in the Subbasin.
(b) Each Plan shall include a description of the projects and management actions that include the following 1-9:
(c) Projects and management actions shall be supported by best available information and best available science.
(d) An Agency shall take into account the level of uncertainty associated with the Subbasin setting when developing projects or management actions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
Projects												
1	Infiltration Basin Project	The Subbasin may adopt a policy to incentivize groundwater extractors through subsidies to utilize designated lands for banking only and or designated lands for scheduled banking under contract during certain periods of the season.	The goal is to encourage landowners to fallow land and replenish the groundwater, as well as encourage water trading between GSAs in the Tulare Lake Subbasin.	The policy will begin shortly after GSP approval and will solicit volunteers first. Project lands area needed will designed by GSA.	Demand reduction will be based on acreage removed from farming practices.	No permits or regulatory processes are required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in the SGMA and related provisions to adopt ordinances.	Policy to be written by 2023 and implemented by 2025 and to remain indefinitely, but can be revised as needed.	A direct benefit to the groundwater levels will be accomplished through this policy. Groundwater elevation data will be utilized, and the amount (volume) of water recharged will be used as the evaluation method.	The management action may be accomplished through policy adoption by the Subbasin. Current water sources will be used in most cases and some external water sources may be needed.	Estimated cost to draft and adopt policy is $50,000. Costs associated with tracking resources have not been evaluated.	Chronic lowering of groundwater levels or depletion of supply during periods of drought may be partially offset by storing water in wetter years.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
2	Storage Project	The Subbasin may adopt a policy to incentivize groundwater extractors through subsidies to utilize designated lands for storage only and or designated lands for scheduled storage under contract during certain periods of the season.	The goal is to encourage landowners to fallow land and replenish the groundwater, as well as encourage GSA water trading between GSAs in the Tulare subbasin.	The policy will begin shortly after GSP approval and will solicit volunteers first. Project lands area needed will designed by GSA.	Demand reduction will be based on acreage removed from farming practices.	No permits or regulatory processes are required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in the SGMA and related provisions to adopt ordinances.	Policy to be written by 2023 and implemented by 2025 and to remain indefinitely, but can be revised as needed.	A direct benefit to the groundwater levels will be accomplished through this policy, for in-lieu groundwater supplies. Groundwater elevations will be utilized as the evaluation method.	The management action may be accomplished through policy adoption by the Subbasin. Existing surface water sources will be used.	Estimated cost to draft and adopt policy is $50,000. Costs associated with tracking resources have not been evaluated.	Chronic lowering of groundwater levels or depletion of supply during periods of drought may be partially offset by storing water in wetter years.	Level of uncertainty of the project is 4; in wet years there is water available for this area as well as the infrastructure to deliver it.

See Acronyms and Abbreviations list for definitions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
3	Existing Infrastructure and/or Rehabilitation of New Construction	The Subbasin may adopt efforts to fund projects to rehabilitate existing facilities and construct new facilities to divert, or bank water in areas conducive of these activities. Including diversion systems, check structures, banking facilities, and storage facilities. Also, would allow groundwater trading within the Subbasin. Not intended to restrict water right holders.	The goal is to modify or develop new facilities that can deliver a larger amount of water when needed, as well as service an area that does not have a delivery system.	Development of the projects will begin shortly after GSP approval.	These projects will work in conjunction with a banking project or other projects as needed.	No permits or regulatory processes are required for the Subbasin to adopt the project. The Subbasin has the power as outlined in the SGMA and related provisions to adopt ordinances or approve projects related to SGMA.	Projects to be included in the GSP. Soon after adoption of GSP projects to begin development.	A direct benefit to the groundwater levels will be accomplished through these projects, for in-lieu groundwater supplies. Groundwater elevations will be utilized as the evaluation method.	The management action may be accomplished through policy adoption by the Subbasin. Existing water sources will be used in most cases and some external water sources may be needed.	Estimated cost to draft and adopt policy is $50,000. Project costs will vary.	Chronic lowering of groundwater levels or depletion of supply during periods of drought may be partially offset by storing water in wetter years, trading of groundwater to minimize the concentration of pumping in one area.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
4	Lining and/or piping of canals	Larger canals may be piped or lined to increase capacity and/or efficiency of water deliveries.	Increased water supply or efficiency to reduce fallowed land.	The project will begin after assessment is made and funding is secured.	Demand reduction will be minimized to capturing more water via efficient delivery.	No permits or regulatory process is required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in the SGMA, and related provisions to adopt ordinances.	Project included in GSP, but funding not yet secured. Benefits would start upon completion of piping/lining. Benefits would accrue for duration of project.	A direct benefit to groundwater levels will be accomplished due to decreased pumping via increased deliveries.	Reliability is high, as many canals are used each year.	Estimated cost to line and pipe major canals is $100,000,000. Willing partners and participants are being approached.	Less extraction would occur. No extra monitoring required.	Level of uncertainty of the project is 3, because the project would save water year in and year out. However, the funding for the project is not yet certain.

See Acronyms and Abbreviations list for definitions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
5	Agricultural land fallowing subsidies	The Subbasin may adopt a policy to incentivize farmers to annually fallow land through leases.	The goal is to reduce irrigated acreage. The MO is the acreage of fallowed land and offset groundwater pumping.	The policy development will begin shortly after GSP approval.	Demand reduction will be based on acreage removed from farming practices and offset groundwater pumping.	No permits or regulatory processes are required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in the SGMA and related provisions to adopt ordinances.	Policy to be written by 2023 and implemented by 2025 and to remain indefinitely, but can be revised as needed.	A direct benefit to the groundwater levels will be accomplished through this policy, based on demand reduction. Groundwater elevations will be utilized as the evaluation method.	The management action may be accomplished through policy adoption by the Subbasin. No external water source is used.	Estimated cost to draft and adopt policy is $50,000.	Chronic lowering of groundwater levels or depletion of supply during periods of drought may be partially offset by permanent fallowing.	Level of uncertainty of the project is 2; in wet years there is water available for this area as well as the infrastructure to deliver it.
6	Aquifer Storage and Recovery (ASR)	ARS is a way to recharge an aquifer directly, using an existing well. ASR utilizes the aquifer as a means of local storage for use a later period..	Increased water levels and supply and reduce groundwater demand	Implementation will occur after GSP approval and landowner agreements are in place. The projects are likely to be implemented by individual landowners .	Demand reduction will occur, as the stormwater water will be used for recharge and will offset groundwater pumping.	It is expected that permits from the State Water Resources Control Board will be needed as well as Local compliance	Project can begin after adoption and approval of GSP upon GSA's development of the program.	A direct benefit to the groundwater levels will be accomplished through this policy. Groundwater elevation data will be utilized, and the amount (volume) of water injected will be used as the evaluation method.	Reliability is high, as there are many wells. Water source will be dependent on individual participants access to water.	Estimated total program cost is $15,000,000. Individual participants will fund projects.	Chronic lowering of groundwater levels or depletion of supply during periods of drought may be partially offset by storing water in wetter years.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
Outreach												
1	Education of groundwater use per acre	The Subbasin may adopt a policy which provides groundwater extractors their approximate groundwater extraction on a per acre basis, and how SGMA will be enforced, as well as other policies developed by the Subbasin.	The goal is to provide education and promote awareness of the Subbasin overdraft condition particularly for those groundwater extractors who do not have meters. The MO is annual statements of groundwater extraction in acre-feet.	Implementation to occur at year one and thereafter, if extractor exceeds their extraction amount.	If individual extractors are over drafting, demand reduction will occur with compliance of this policy.	No permits or regulatory process is required for the Subbasin to adopt the policy.	The policy has not been drafted. It is expected to commence shortly after the adoption of the GSP and be completed within the first three years.	The expected benefit is to educate extractors of overdraft; this is the first step in policing SGMA. Extractors will be monitored.	The management action may be accomplished by Subbasin policy adoption. No external water source is used.	Estimated $50,000 cost to draft and adopt policy.	Within the education course, a description of how recharge and groundwater extraction will be credited to each extractor during drought and other periods.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.

See Acronyms and Abbreviations list for definitions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
Assessment												
1	Pumping fees for groundwater allocation exceedances	Policy for exceedance of pumping beyond the current groundwater allocation. Can increase with each occurrence.	The goal is to incentivize groundwater extractors to pump only their groundwater allocation per year. The MO is the volume of groundwater extraction in acre-feet.	First phase of the policy will be written by 2023 and implemented by Jan 2025. Fees will increase every year after 2025 and with each occurrence.	This policy reduces demand and/or charges each extractor based on the budgeted amount of groundwater.	No permits or regulatory processes are required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in SGMA and related provisions to adopt ordinances, levy financial penalties, and enforce policies.	Policy is expected to be drafted and commence after the adoption of the GSP. Benefits will be added revenue to mitigate other projects in the area.	The expected benefit is to deter groundwater extractors from exceeding their allocation. Other benefits will be revenue for projects to mitigate local overdraft. The method of evaluation will be a summary of over-extractors and the reduction of those over-extractors over time.	The management action may be accomplished by Subbasin policy adoption and enforcement. No external water source is used.	Estimated $50,000 cost to draft and adopt policy. Initial GSA assessments will be needed to fund the development of this policy.	Chronic lowering of groundwater levels or depletion of supply during periods of drought may be offset by temporary increases in fee structure or groundwater pumping restrictions.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
2	Pumping fees for groundwater extractions	The Subbasin may adopt a policy to impose fees on groundwater extractors on a per acre-foot basis. Fees are intended to support GSA activities and are not intended to be overbearing.	The goal is to incentivize groundwater extractors to reduce pumping and look for other sources of water. The MO is the revenue generated to support GSA operations.	Policy to be written and implemented by 2025 and to remain indefinitely.	No direct reduction in demand.	No permits or regulatory processes are required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in the SGMA and related provisions to adopt ordinances, levy financial penalties, and enforce policies.	Policy is expected to be drafted and commence after the adoption of the GSP. Benefits will be added revenue to support GSA operations.	The expected benefits will provide funding for GSAs to operate under the SGMA.	The management action may be accomplished through policy adoption by the Subbasin and enforcement. No external water source is used.	Estimated $50,000 cost to draft and adopt policy. Initial GSA assessments will be needed to fund the development of this policy.	This policy in intended to be a part of the entire GSA operational Bylaws; there is no direct offset of chronic lowering of groundwater.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
Groundwater Allocation												
1	Flood Flows (spills into the Subbasin) include Tule River, Deer Creek, Cross-Creeks and Kings River	The Subbasin may adopt a policy for actions to divert flows during flood releases to needed areas and a credit system for those who divert.	Validate Water Rights and existing agreements. MO is to allocate water to the rightful owner.	Policy to be drafted by 2023 and implemented by 2025.	This management action alone may not generate a quantifiable demand reduction. However, it allocates water to be used in the proper service area.	No permits or regulatory processes are required for the Subbasin to adopt the policy. SWRCB is paying close attention to policies within a GSA that pertain to water rights and flood water diversion.	Policy to be written by 2023 and implemented by 2025 and to remain indefinitely, but can be revised as needed.	The expected benefit is to encourage diversion of flood flows to areas to make the most groundwater level impact.	Contract holder; reliability varies based on allocation.	Estimated $25,000 cost to draft and adopt policy.	Banked water will offset a depletion of supply during periods of drought.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.

See Acronyms and Abbreviations list for definitions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
2	Development of groundwater allocation	The Subbasin may adopt a policy which provides a finite groundwater allocation, either based on the modeling efforts or the sustainable yield. Ultimate groundwater allocation may take into consideration the existing water rights holders, disadvantaged communities (DACs) and CA Native American tribes. The Subbasin may allocate to agencies or individual landowners.	The goal is to ensure a fair groundwater allocation which clearly defines the acceptable groundwater extraction volume per year at a certain rate, based on crop growing season(s). The MO is the volume of groundwater extraction in acre-feet.	Policy to be written by 2023 and implemented by 2025.	This policy will be a direct reduction in demand as extractors will need to operate within the means of the allocation. Groundwater levels and pumped volumes will be used to evaluate demand reduction.	No permits or regulatory processes are required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in SGMA and related provisions to adopt ordinances.	Policy to be written by 2023 and implemented by 2025 and can be revised as needed.	The expected benefits may mitigate overdraft by ensuring groundwater supplies are withdrawn in a sustainable manner. Extractions will be monitored.	The management action may be accomplished by Subbasin policy adoption. No external water source is used.	Estimated $100,000 cost to draft and adopt policy.	Chronic lowering of groundwater levels or depletion of supply during periods of drought may be eliminated by implementation of sustainable change in groundwater allocation.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
3	Groundwater Marketing	This policy will include groundwater marketing. Marketing will include groundwater from within the Subbasin with options to market within the GSAs, between GSAs.	The goal is to set policy that encourages water marketing within the Subbasin while not causing undesirable results.	Policy to be written by 2023 and implemented by 2025.	This policy will be a direct reduction in demand as small volume extractors will be encouraged to fallow land and market groundwater within their allocated amount. Groundwater levels and market volumes will be used as the quantification of demand reduction.	No permits or regulatory processes are required for the Subbasin to conduct the study. Through the study, multiple jurisdictions and agencies may be contacted for the potential permits and regulatory requirements for new surface water supplies.	The water marketing strategy grant has been approved by the USBR; Funding opportunity to close in May of 2019. Other grant solicitations are expected.	The expected benefits include utilizing groundwater supplies within the Subbasin. Encourage demand reduction through fallowing. Groundwater levels and marketed volumes will be evaluated.	The management action may be accomplished by Subbasin policy adoption. No external water source is used.	Estimated cost is $100,000 to draft and adopt policy.	This policy will include the requirement that landowners who are a purchaser or seller of groundwater shall install a water meter on their wells and report all activities to their GSAs.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.

See Acronyms and Abbreviations list for definitions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
Development												
1	Require new developments (non-de minimis extractors) to prove sustainable water supplies	This policy requires all permitted developments (non-de minimis extractors) to prove sustainable water supplies based upon the current Subbasin groundwater allocation and constant with current State Law. The Subbasin may review and comment on all new development environmental documents to ensure water balance and corresponding mitigation measures are implemented. Requires County support.	The goal is to ensure all new developments (non-de minimis extractors) do not exceed the current Subbasin groundwater allocation and groundwater supplies are consumed or retained within the Subbasin boundary. The MO is to monitor and hold developers accountable as well as promote connection to city services where applicable.	To be implemented as a revision to the local ordinances.	Policy is to minimize undesirable effects by requiring construction of wells to be designed for MTs. To be implemented after approval of GSP.	The regulatory process may require cooperation from the county/city to ensure the Subbasin has had the opportunity to review and comment on the environmental documents prior to county/city approval. The Subbasin GSAs have the power as outlined in the SGMA and related provisions to adopt ordinances. Potential incorporation into a peer review process.	Policy to be written and implemented by 2023.	The expected benefits may mitigate overdraft by ensuring new developments utilize groundwater supplies in accordance with current Subbasin groundwater allocations, and groundwater supplies are consumed or retained within the Subbasin boundary. The method of evaluation may be quantifying the number of new developments that are approved with and without Subbasin comment/approval.	The management action may be accomplished through Subbasin policy adoption and coordination with the county/city. The Subbasin may request county/city development procedures to include the circulation of environmental documents and approval from Subbasin GSAs prior to county/city approval. No external water source is used.	Estimated cost to draft and adopt policy is $25,000.	Policy will help in data collection and extraction reporting as part of the permitting process.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
Monitoring Reporting												
1	Flood Flows (spills into the Subbasin) include Tule River, Deer Creek, Cross-Creeks and Kings River	The Subbasin may adopt a policy for actions to divert flows during flood releases to needed areas and a credit system for those who divert.	Validate the water right; MO is to allocate water to the rightful owner.	Policy will begin soon after GSP is approved and will help fill data gaps.	This management action alone may not generate a quantifiable demand reduction. However, it allocates water to be used in the proper service area.	No permits or regulatory processes are required for the Subbasin to adopt the policy. SWRCB is paying close attention to policies within a GSA that pertain to water rights and flood water diversion.	Policy to be written and implemented in 2023.	The expected benefit is the guarantee that purchased water is credited to correct area. Data gathered will fill data gaps. Groundwater elevations will be the method of evaluation.	Contract holder; reliability varies based on allocation.	Estimated cost to draft and adopt policy is $25,000.	Utilized contract volumes to be included in the calculation of the groundwater extraction proportionate share.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.

See Acronyms and Abbreviations list for definitions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
2	Registration of extraction facilities	The Subbasin may adopt a policy to require registration of a groundwater extraction facility within the Subbasin. Requires county support. Includes existing and future facilities.	The goal is to improve the Subbasin's database of groundwater extraction locations. The MO is the number of new registered facilities and fill data gaps.	The policy may be implemented shortly after the adoption of the GSP and remain until the Subbasin's overdraft has ended or indefinitely. The county must also support the policy.	This policy will help fill data gaps and give a better understanding of the groundwater within the Subbasin.	The regulatory process may require cooperation from the county to ensure new well permits issued within the Subbasin adhere to the Subbasin's policy. The Subbasin has the power as outlined in SGMA and related provisions to adopt ordinances.	Policy to be written and implemented in 2023.	The expected benefits may mitigate overdraft by improving the Subbasin's knowledge of groundwater extraction locations. The method of evaluation may be comparing the number of registered wells vs. the county/state databases known wells.	The management action may be accomplished by policy adoption by the Subbasin and coordination with the county. The Subbasin may request county well permit procedures to include the Subbasin's requirements prior to issuance. No external water source is used.	Estimated cost to draft and adopt policy is $25,000. There will be a cost to administer the policy, which is not known at this time.	Fill data gaps and include this information in the calculation of the groundwater extraction proportionate share.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
3	Require self-reporting of groundwater extraction, water level, and water quality data	The Subbasin may adopt a policy to require groundwater users (excluding de minimis extractors) to self-report groundwater extractions, static water levels, and water quality data twice per year.	The goal is to improve the Subbasin's database of groundwater extractions, water level and quality monitoring network, and serve other management actions.	This policy will fill data gaps. To be incorporated into a well testing policy for wells with meters. The policy may be implemented shortly after the adoption of the GSP and remain indefinitely or until Subbasin's overdraft has ended.	This policy will help fill data gaps and give a better understanding of the groundwater within the Subbasin.	No permits or regulatory processes are required for the Subbasin to adopt the policy. The Subbasin has the power as outlined in SGMA and related provisions to adopt ordinances, levy financial penalties, and charge administrative fees.	Policy to be written and implemented in 2023.	The expected benefits may mitigate overdraft by improving the Subbasin's knowledge of groundwater extractions, water levels, water quality and provide extractors with useful information. The method of evaluation may be reviewing the number of responses from groundwater users (excluding de minimis extractors), analyzing data validity/accuracy, and filling data gaps.	The management action may be accomplished by policy adoption by the Subbasin. The Subbasin may develop an online reporting tool. No external water source is used.	Estimated cost to draft and adopt policy is $25,000. There will be a cost to administer the policy, which is not known at this time, but is expected to be high.	Fill data gaps and include this information in the calculation of the groundwater extraction proportionate share.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.

See Acronyms and Abbreviations list for definitions.

#	Management Action (b)(1) *	Description (b)(1)	Measurable Objective (b)(1)	Circumstances of Implementation (b)(1)(A)	Quantification of Demand Reduction (b)(2)	Permitting & Regulatory Process (b)(3)	Status, Start, End, and Accrual of Benefits (b)(4)	Explanation of Benefits and Method of Evaluation (b)(5)	Explanation of Water Source and Reliability (b)(6)	Cost and Funding Options (b)(8)	Management of Groundwater Extraction and Recharge (b)(9)	Level of Uncertainty Associated with the Basin Setting, 1=uncertain 5=certain (d)
4	Require well meters, sounding tubes, and water quality sample ports	The Subbasin may adopt a policy to require meters, sounding tubes, and sample ports be installed on wells, pump and motor replacements, and well repairs (excluding de minimis extractors). Requires county support. Calibration of meters shall conform to Senate Bill 88.	The goal is to improve the Subbasin's data collection of groundwater extractions, water level and quality monitoring network. The MO is the number of well permits and filling the data gaps.	The policy may be implemented shortly after the adoption of the GSP and remain until Subbasin's overdraft has ended or indefinitely. The county must also support the policy.	This policy will help fill data gaps and give a better understanding of the groundwater within the Subbasin.	The regulatory process may require cooperation from the county to ensure new well permits issued within the Subbasin adhere to the Subbasin's policy. The Subbasin has the power as outlined in SGMA and related provisions to adopt ordinances.	Policy to be written and implemented in 2023.	The expected benefits may mitigate overdraft by improving the Subbasin's knowledge of groundwater extractions, water levels, water quality, and fill data gaps. The method of evaluation may be reviewing the number of well permits and confirming whether meters, sounding tubes, and sample ports were installed.	The management action may be accomplished by policy adoption by the Subbasin and coordination with the county. The Subbasin may request county well permit procedures to include the Subbasin's requirements prior to issuance. No external water source is used.	Estimated cost to draft and adopt policy is $25,000. There will be a cost to implement the policy, it is not known at this time, but is expected to be high.	Fill data gaps and include this information in the calculation of the groundwater extraction proportionate share.	Level of uncertainty of the project is 3; in wet years there is water available for this area as well as the infrastructure to deliver it.
Existing Contracts												
1	Flood Flows (spills into the Subbasin) include Tule River, Deer Creek, Cross-Creeks and Kings River	The Subbasin may adopt a policy for actions to divert flows during flood releases to needed areas and a credit system for those who divert.	Validate water rights and existing agreements. MO is to allocate water to the rightful owner.	Policy to be drafted by 2023 and implemented by 2025.	This management action alone may not generate a quantifiable demand reduction. However, it allocates water to be used in the proper service area.	No permits or regulatory processes are required for the Subbasin to adopt the policy. SWRCB is paying close attention to policies within a GSA that pertain to water rights and flood water diversion.	Policy to be written by 2023 and implemented by 2025 and to remain indefinitely, but can be revised as needed.	The expected benefit is to encourage diversion of flood flows to areas to make the most groundwater level impact.	Contract Holder; reliability varies based on allocation.	Estimated $25,000 cost to draft and adopt policy.	Diverted water will offset a depletion of supply during periods of drought.	Level of uncertainty of the project is 2; in wet years there is water available for this area as well as the infrastructure to deliver it.

* (b)1() refers to the subsection of §354.44 that the column addresses.

Note: The following sections were noted below because they apply to all management actions with very little variance.

Public Notice (b)(1)(B): The Subbasin may provide public notice in multiple formats and platforms, adopted policies may reside in Subbasin Board Meeting minutes and Subbasin Policy Manual available on the Subbasin website. Electronic notice may be provided to any person who requests email notifications. The Subbasin Board may hold regular monthly meetings and annual education workshops.

Legal Authority (b)(7): The Subbasin has the power as outlined in the SGMA, and related provisions to adopt ordinances, levy financial penalties, and enforce programs.

Cost & Funding Options (b)(8): Subbasin administrative and operating costs may be funded through various financial avenues discussed further in GSP Chapter 7.2.

See Acronyms and Abbreviations list for definitions.

APPENDIX B

STAKEHOLDER COMMUNICATION AND ENGAGEMENT PLAN

Appendix B: Stakeholder Communication & Engagement

A. Communication & Engagement Overview

As required by SGMA, GSAs must consider the interests of all beneficial uses and users of groundwater and include them in the GSP development process. The five GSAs within the Tulare Lake Subbasin developed a joint Communication & Engagement (**C&E**) Plan that addressed how stakeholders within the individual GSA boundaries (and when collaboration was plausible, at the subbasin-level) would be engaged through stakeholder education and opportunities for input and public review during the development and implementation of the GSP. This plan provides an overview of the Tulare Lake Subbasin GSAs, their stakeholders, and decision-making process; identifies opportunities for public engagement and discussion of how public input and responses would be used; describes how the Tulare Lake Subbasin GSAs encouraged the active involvement of diverse, social, cultural, and economic elements of the population within their individual boundaries and subbasin boundary; and the methods to be used to inform the public stakeholders about the progress of GSP development, public review and implementation. The Tulare Lake Subbasin GSAs' complete C&E Plan can be downloaded from the GSAs' individual websites.

As outlined by the DWR in the GSP Stakeholder Communication and Engagement Guidance Document, the Communication & Engagement Plan defines the Tulare Lake Subbasin GSAs' process for accomplishing the seven general steps in stakeholder communication and engagement:

- **Set Goals and Desired Outcomes –** Description of the situation at a high level with clear goals and objectives, identifying overriding concerns
- **Identify Stakeholders –** Development of a broad list of individuals, groups and organizations who need to be engaged in the process
- **Stakeholder Survey and Mapping –** Conducting a stakeholder survey to develop a "Lay of the Land" overview
- **Messages and Talking Points –** Definition of the key messages needed to effectively convey to the various subbasin stakeholders
- **Venues for Engaging –** Identification of opportunities (venues and methods) to engage stakeholders
- **Implementation Timeline –** Creation of a timeline to inform the process and highlight when to engage with stakeholders
- **Evaluation and Assessment –** Definition of a process to evaluate if communication and engagement goals are being met at the individual GSA level and through collaborative subbasin efforts

A.1 Communication Objectives to Support the GSP

The ultimate goal of communication objectives during the formation/coordination, GSP development, public review and implementation phases of the SGMA compliance, is to encourage active involvement of diverse,

social, cultural, and economic elements of the population within the GSA boundary. The Tulare Lake Subbasin GSAs have given beneficial users and users of groundwater opportunities to engage in the GSP process, and provided educational outreach opportunities for stakeholders while reaching out through specific communication avenues. As active stakeholders, members of the Boards of Directors and Stakeholder/Advisory Committees are direct representatives of their districts, communities and industries, and they continually gather feedback/input, and the concerns/needs of their constituents and report back to their respective meetings. Any stakeholder input received was reviewed by the GSA and Subbasin technical teams and taken into consideration during GSP development.

A.1.1 Phase 1: GSA Formation and Coordination

Phase 1: GSA Formation and Coordination was the first phase completed. This phase stretched from 2015 through 2018, and consisted of forming the individual GSAs, development of a subbasin coordination agreement, establishing the List of Interested Parties, and creating the Communication & Engagement Plan to outline communication efforts for the GSP development, public review and implementation phases. Stakeholder input was utilized during the GSA formation phase, as beneficial users and stakeholders with interests in groundwater usage within the GSAs' boundaries were notified via public meeting notices as soon as the process began.

A.1.2 Phase 2: GSP Preparation and Submission

Phase 2: GSP Preparation and Submission spanned from 2018 through January 31, 2020. With the goal of having the draft GSP before the end of the third quarter in 2019, 2018 was primarily the technical development of the plan, while working with GSA Boards of Directors, technical teams/committees, and GSA management at the subbasin level, as well as stakeholders for feedback and input. During the last quarter of 2018, the first round of public outreach meetings and interaction with stakeholder groups and other community organizations and entities was held with the purpose of educating and informing stakeholders about SGMA and the GSP process, while also soliciting feedback and input from these groups to consider and possibly include feedback and input into the GSP. Public outreach for this phase was completed by the individual GSAs.

A.1.3 Phase 3: GSP Review and Evaluation

During 2019, Phase 3: GSP Review and Evaluation, the communication and engagement efforts continued. Once the draft of the GSP was completed in September 2019, the public review process began. A 90-day comment period was held, with the GSP draft posted on the Tulare Lake Subbasin GSAs' websites for all stakeholders to conveniently download and review and provide comments. Outreach meetings were held during this phase both on subbasin-wide level, as well as by individual GSAs. These meetings focused on an overview of the GSP content, while giving stakeholders a public forum to provide their feedback and comments. The public review period concluded with a public hearing regarding the GSP Draft on December 2, 2019.

Once the public review period was completed, public comments were taken into consideration and incorporated into the final version of the Tulare Lake Subbasin GSP before submitting to the DWR by January 31, 2020. Following submittal, stakeholders will be given a second 60-day comment period through the DWR's SGMA portal at http://sgma.water.ca.gov/portal/. Comments will be posted to the DWR's website prior to the state agency's evaluation, assessment and approval.

A.1.4 Phase 4: Implementation and Reporting

Phase 4: Implementation and Reporting will begin once the plan is submitted by January 31, 2020. Even while the DWR is reviewing the GSP, SGMA-implementation at the GSA-level must begin. During the implementation phase, communication and engagement efforts will be shifted to educational and

informational awareness of the requirements and processes for reaching groundwater sustainability as set forth in the submitted GSP. Active involvement of all stakeholders will be encouraged during this phase, and public notices are required for any public meetings and prior to imposing, and later increasing, any fees. Public outreach for this phase will also be completed by the individual GSAs with collaborative subbasin-wide efforts when target audiences span more than one GSA boundary.

B. Tulare Lake Subbasin GSAs' Decision-Making Process

The Tulare Lake Subbasin GSAs' decision-making process is broken down by the roles of the subbasin management team, Board of Directors and Stakeholder/Advisory Committees. The roles of these subbasin and GSA entities and their responsibilities are outlined below.

- **Subbasin Management Team –** Comprised of a representative from each of the five GSAs working collaboratively to jointly manage groundwater within the Tulare Lake Subbasin and to develop a GSP. These individuals met on a monthly and then bi-weekly basis throughout the GSP development and public review phases.
- **Boards of Directors –** Adopts general policies regarding development and implementation of the individual GSAs and the GSP.
- **Stakeholder/Advisory Committees –** Representing all beneficial uses and users of groundwater within the individual GSA boundaries, makes recommendations to the Boards of Directors and technical consultants regarding feedback from stakeholders and adoption of a GSP that accounts for local interests. Not all GSAs have stakeholder/advisory committees, and while allowed within SGMA, these committees are not required.

B.1 Role of Boards of Directors

The Tulare Lake Subbasin GSAs' Boards of Directors all consistently function as the governing body of the specific GSA, formed to adopt general policies regarding development and implementation of the GSP. Governance of each GSA is described below, and meeting dates, times and locations for each board are noted. All meetings were open to the public during the formation, development and public review phases, and will continue to be open to the public during the implementation phase.

B.1.1 El Rico GSA

El Rico GSA's Board of Directors consists of seven directors: one representative appointed by the Tulare Lake Basin Water Storage District board, one representative appointed by the governing board of Salyer Water District, two representatives appointed by the Corcoran Irrigation District, two representatives appointed by Melga Water District, and one representative appointed by the Lovelace Reclamation District No. 739.

El Rico GSA's board meetings are held on the first Wednesday of each month at 1 p.m. at the Tulare Lake Basin Water Storage District's office, located at 1001 Chase Avenue in Corcoran, unless otherwise posted on the Kings River Region Groundwater Portal's calendar.

B.1.2 Mid-Kings River GSA

The Board of Directors of the Mid-Kings River GSA are appointed, three elected members of the KCWD, and one elected member of the City of Hanford. The Mid-Kings River GSA Board of Directors meet on the second Tuesday of every month at 1 p.m. at the Kings County Water District, located at 200 Campus Drive in Hanford.

B.1.3 South Fork Kings GSA

The governing board of the South Fork Kings GSA is composed of one appointee of each member agency as a "principal director." The principal director is an individual currently serving on the board or council of each of the members. Board of Directors meetings for the South Fork Kings GSA are held bi-monthly on the third Thursday of every February, April, June, August, October and December at 5:30 p.m. in the Lemoore City Council Chambers, located at 429 C Street in Lemoore.

B.1.4 Southwest Kings GSA

Southwest Kings GSA is governed by a five-person board of directors comprised of two members of the Dudley Ridge Water District, two members of the Tulare Reclamation District No. 761, and one director selected by a majority vote of the other four appointed members. The non-district member is a landowner, or his/her representative, who owns land in the white areas of the GSA boundary.

The Southwest Kings GSA's board meetings are held on the second Wednesday of every month at 3 p.m. at 286 W. Cromwell Avenue in Fresno. A monthly GSA status report is posted on the GSA's website.

B.1.5 Tri-County Water Authority GSA

The Tri-County Water Authority GSA JPA board of directors is comprised of four signatories and five board seats: Angiola Water District (general manager and a representative), Deer Creek Storm Water District (general manager and representative), Wilbur Reclamation District #825 (one representative), and County of Kings (non-voting representative). The Board of Directors meetings are held on the second Thursday of every other month at 1 p.m. at the Tri-County Water Authority Boardroom, located at 944 Whitley Avenue in Corcoran.

B.2 Role of Stakeholder/Advisory Committees

In Section 10727.8 "Public Notification and Participation; Advisory Committee" of the Sustainable Groundwater Management Act, GSAs may appoint and consult with an advisory committee for the purpose of developing and implementing a GSP. Through a stakeholder/advisory committee, a GSA is able to encourage the active involvement of diverse social, cultural, and economic elements of the population within the groundwater basin prior to and during the development and implementation of the GSP.

B.2.1 Tri-County Water Authority GSA

The Tri-County Water Authority GSA's Technical Advisory Committee and Stakeholder Advisory Committee meet jointly on the fourth Wednesday of every month at 10 a.m. at the Tri-County Water Authority, located at the 944 Whitley Avenue in Corcoran.

C. Beneficial Uses and Users of Groundwater

Based on the applicable interests identified in SGMA, Section 10723.2 "Consideration of All Interests of All Beneficial Uses and Users of Groundwater", the five Tulare Lake Subbasin GSAs (El Rico, Mid-Kings River, South Fork Kings, Southwest Kings and Tri-County Water Authority) identified the stakeholder groups with interests within their GSA boundaries. These specific stakeholder groups have financial, political, business or personal stakes in the management of groundwater within the jurisdiction of the Tulare Lake Subbasin and were the focus of communication and engagement efforts during the GSP development and public review phases, and will continue to be engaged during the implementation phase. These stakeholders are listed by GSA in **Table 1**, **Table 2**, **Table 3**, **Table 4** and **Table 5**.

C.1 Environmental Users of Groundwater

It should be noted that environmental users of groundwater within the Tulare Lake Subbasin were investigated by the El Rico GSA, MKRGSA, SFKGSA, SWKGSA and TCWA, but there were not any identified that have specific groundwater interests within the subbasin.

C.2 Native American Tribes

The only Native American Tribe within the Tulare Lake Subbasin boundary is the Santa Rosa Rancheria Tachi-Yokut Tribe. The Tachi-Yokut Tribe was invited to participate in GSP development via a letter sent on June 28, 2016 by the then Upper Tulare Lake GSA MOU Group (now known as the South Fork Kings GSA). A copy of the letter is included in the Appendix A of the Tulare Lake Subbasin GSAs' Communication & Engagement Plan. The Tribe's EPA director attended one of the South Fork Kings GSA's board meetings, and has been on their Interested Parties List since April 2017, receiving regular updates about GSP development within the SFKGSA and the Tulare Lake Subbasin. In addition, a Sacred Lands File & Native American Contacts List Request was also sent to the Native American Heritage Commission.

C.3 Subbasin Industries and DACs

C.3.1 Industries

Collaboration meetings were held with the companies and organizations within the following industries to make sure their organizational visions and groundwater needs for facility operations were taken into consideration during GSP development and implementation phases. While an overview of the main industries within the Tulare Lake Subbasin are described below, the industries specific to each GSA are described in **Section C.4**.

Agriculture

Agriculture is one of the top three industries in Kings County. According to the 2017 Kings County Agricultural Crop Report published by the Kings County Ag Commissioner's office, the county is the tenth largest agriculture production county in California and grossed over $2 billion in 2017. With over 818,000 acres of farmland, the top commodities produced in Kings County are milk, cotton, cattle, nuts (almonds, pistachios and walnuts), tomatoes, silage corn, grapes, and stone fruit. As one of the primary industries, agriculture is the largest private employer in the county.

Because of the significant presence of agriculture production within the Tulare Lake Subbasin, agriculture industry stakeholders needed to be involved and informed during the development and public review phases of the GSP. Implementation will have a significant direct impact on the industry, and ultimately the local, state and national economies. The Tulare Lake Subbasin GSAs engaged with agriculture stakeholders routinely on an individual GSA-basis, and collaboratively at a subbasin level.

Food Processing

Kings County is a home to multiple food processors. Four of the top employers within the county are food processing facilities, accounting for over 4,000 jobs for the local workforce. Within the South Fork Kings GSA, Leprino Foods, alone, is responsible for 40 percent of water usage and provides just over 1,000 jobs. Because of their direct tie to the agricultural industry and reliance on groundwater supplies, to operate their facilities, food processors are included in the groundwater sustainability management within the subbasin boundary. The Tulare Lake Subbasin GSAs met with the food processing companies within their GSA

boundaries on an individual basis for direct input and feedback during the GSP development and public review phases, and will continue to do so during the implementation phase.

Oil Production

Oil production is a main industry in certain areas of Kings County and the Tulare Lake Subbasin, primarily within in the Kettleman City area. Oil was discovered in the Kettleman Hills in 1928 at the Kettleman North Dome Oil Field. This oil field became one of the most productive oil fields in the United States in the early 1930s. Within this region, oil and agricultural production share the land surface, and will continue with joint usage of well drilling rigs and agricultural production activities such as grazing. The oil industry is considered a beneficial user of groundwater, and Tulare Lake Subbasin GSAs engaged with the oil companies within their GSA boundaries on an individual basis for direct input and feedback during the GSP development and public review phases, and will continue to do so during implementation phases.

C.3.2 DACs

Communication and educational outreach efforts with disadvantaged communities (**DAC**) and severely disadvantaged communities (**SDAC**) was needed for the development and implementation of the Tulare Lake Subbasin's GSP according to the Department of Water Resources' Best Management Practices. Information used to communicate to and engage the DACs in the GSP process, included an explanation of SGMA and soliciting feedback. GSA representatives regularly communicated with DACs and gave presentations on SGMA to community representatives, while gathering their feedback and input.

By including DACs and SDACs in communication efforts during the development, public review and implementation phases of the GSP, residents were more likely to participate and provide feedback that could be crucial to long-term solutions for groundwater sustainability within their communities. Any feedback received from DAC/SDAC residents was reviewed and evaluated by the Tulare Lake Subbasin GSAs during the GSP development and public review phases.

C.4 GSA-Specific Stakeholders

The GSAs worked cooperatively with their respective stakeholders throughout the development and public review of the GSP, and will continue to do so through the implementation phase.

C.4.1 El Rico GSA Stakeholders

The interests of the parties identified in **Table 1** were considered in the operation of the El Rico GSA and the development and implementation of the GSP. The primary industry within the El Rico GSA is agriculture. Other industries within the boundary include food processing, as well as warehousing and distribution, and standard commerce industry that is standard in a community of 10,000 people (automotive shops, supermarkets, etc.).

Table 1. Stakeholder Groups with Interests in the El Rico GSA

Stakeholder Group	Description
Agricultural Users	Represented through many of the GSA member agencies and/or by the County of Kings.
Domestic Well Owners	Represented through member agencies including the County of Kings or via exemption for small amounts of groundwater extraction.
Municipal Well Operators	City of Corcoran
Public Water Systems	City of Corcoran
Local Land Use Planning Agencies	City of Corcoran, County of Kings
Surface Water Users	Represented through GSA member agencies
Disadvantaged Communities	City of Corcoran
Entities monitoring and reporting groundwater elevations in all or part of a groundwater basin	Represented by GSA member agencies including Tulare Lake Basin Water Storage District that collects and reports data for multiple members of the agency via the Tulare Lake Coordinated Groundwater Management Plan.

C.4.2 Mid-Kings River GSA Stakeholders

The interests of all beneficial uses and users of groundwater within the MKRGSA are identified in **Table 2**. The primary industries within the Mid-Kings River GSA is agriculture and food processing.

Table 2. Stakeholder Groups with Interests in the Mid-Kings River GSA

Stakeholder Group	Description
Agricultural Users	Service area is composed of mostly agricultural lands and agricultural users
Domestic Well Owners	There are domestic wells within the MKRGSA area, and it is understood that many rural domestic users will fall into the “de minimis extractor” category, so further work is being conducted to understand to what extent domestic users will be affected by GSP requirements.
Public Water Systems	Armona CSD, Home Garden CSD and Hardwick Water Company, as well as several transient public water systems for school districts are included in this category (Kings River-Hardwick, Pioneer, Hanford Christian).
Municipal Water Systems	City of Hanford
Local Land Use Planning Agencies	City of Hanford and County of Kings
California Native American Tribes	See Section C.2.
Disadvantaged Communities	Armona, Home Garden, Hardwick
Entities monitoring and reporting groundwater elevations in all or part of a groundwater basin	Kings County Water District monitors groundwater levels within its service area and is providing a subset of that information to the Kings River Conservation District for submission to the CASGEM system.

C.4.3 South Fork Kings GSA Stakeholders

An initial list of stakeholders within the South Fork Kings GSA is described in **Table 3**. The primary industries within the South Fork Kings GSA is agriculture and food processing.

Table 3. Stakeholder Groups with Interests in the South Fork Kings GSA

Stakeholder Group	Description
Agricultural Users	Service area is composed of mostly agricultural lands and agricultural users
Domestic Well Owners	There are domestic wells within the SFKGSA, and it is understood that many domestic users will fall into the "de minimis extractor" category. Further work is being conducted to understand to what extent domestic users will be affected by GSP requirements.
Municipal Well Operators	City of Lemoore, Stratford Public Utility District
Local Land Use Planning Agencies	City of Lemoore, County of Kings
California Native American Tribes	See Section C.2.
Disadvantaged Communities	Community of Stratford
Entities monitoring and reporting groundwater elevations in all or part of a groundwater basin	KRCD is the designated monitoring entity for the Kings and Tulare Lake Subbasins under CASGEM program. SFKGSA will coordinate its SGMA monitoring efforts with the CASGEM monitoring effort led by KRCD.

C.4.4 Southwest Kings GSA Stakeholders

The interests of all beneficial uses and users of groundwater within the Southwest Kings GSA are described in **Table 4**. The primary industries within the Southwest Kings GSA are agriculture, oil production and commercial usage specific to Kettleman City.

Table 4. Stakeholder Groups with Interests in the Southwest Kings GSA

Stakeholder Group	Description
Agricultural Users	Approximately 99 percent of the GSA's area is composed of agricultural lands. Representatives of the agricultural community are currently involved on the GSA Board of Directors.
Domestic Well Owners	Only one or two landowners utilize a domestic well, and are represented on the Board of Directors through member agencies.
Municipal Well Operators	Kettleman City CSD relies solely on surface water supply (effective October 2019). Their municipal wells are a back-up source to provide well water to residential and commercial customers within the GSA boundary in emergency situations when surface water is not accessible.
Local Land Use Planning Agencies	County of Kings
California Native American Tribes	See Section C.2.
Disadvantaged Communities	Kettleman City
Entities monitoring and reporting groundwater elevations in all or part of a groundwater basin	KRCD is the designated monitoring entity for the Kings and Tulare Lake Subbasins under CASGEM program. SWKGSA will coordinate its SGMA monitoring efforts with the CASGEM monitoring effort led by KRCD.

C.4.5 Tri-County Water Authority GSA Stakeholders

The Tri-County Water Authority provided stakeholder groups identified in **Table 5** with opportunities to provide input throughout the process of developing, operating and implementing the GSA and GSP. The primary industry within the Tri-County Water Authority GSA is almost entirely agriculture.

Table 5. Stakeholder Groups with Interests in the Tri-County Water Authority GSA

Stakeholder Group	Description
Agricultural Users	Composed almost entirely of agricultural users, including nut grower commodity groups and other agricultural use growers
Domestic Well Owners	There are domestic wells within the GSA area, but because SGMA excludes "de minimis extractors," it is anticipated that the GSP will exclude domestic wells from such requirements.
Local Land Use Planning Agencies	County of Kings
Federal Government	Bureau of Land Management
Entities monitoring and reporting groundwater elevations in all or part of a groundwater basin	Angiola Water District, Tulare Lake Basin Water Storage District

D. Public Outreach Meetings/Stakeholder Involvement Opportunities

D.1 Communication & Outreach Methods

There were a variety of opportunities, venues and methods for the Tulare Lake Subbasin GSAs to connect with and engage stakeholders throughout GSA formation, GSP development, GSP review, and will continue to be utilized through the GSP implementation phases. Stakeholder groups identified in **Section C** were engaged through communication methods outlined in this section.

D.1.1 Printed Communication

Printed materials incorporated the visual imagery established through individual GSA branding efforts and was tailored for specific means of communication throughout the phases of GSP development, public review and implementation. Printed materials were also translated into Spanish, when necessary for thorough, diverse stakeholder education.

- **Fliers –** Fliers designed and tailored for stakeholder audiences, encompassed infographics and text with key messages that were pertinent for that phase of GSP development. Distribution was via GSA-website posting, direct mail, email, and direct distribution as handouts throughout communities, GSA and subbasin outreach meetings. For outreach to DACs/SDACs, fliers were available in both English and Spanish languages.
- **Letter Correspondence –** When letter correspondence was necessary, particularly during the public review and implementation phases, letters were distributed via email and/or direct mail. Letters included pertinent facts and explanations that needed to be communicated to specific stakeholder groups.
- **Presentation Materials –** Power Point presentations were utilized at educational/outreach public meetings. For a consistent message subbasin-wide, a draft presentation was developed for the GSP development and public review phases, with placeholder slides for GSAs to update with GSA-

specific information. Handouts of presentations and smaller versions of display boards were distributed to stakeholders in attendance, emailed to the Interested Parties list, and posted on individual GSAs' websites for stakeholders to access, particularly if they were unable to attend.

D.1.2 Digital Communication

Digital communication outlets were also designed to incorporate Tulare Lake Subbasin GSAs' branding and was a significant mode of communication through the GSP development and public review phases, and will continue to be crucial during the implementation phase.

- **Websites –** Public meeting notices, agendas and minutes of the Board of Directors and Stakeholder/Advisory Committee meetings were posted on the individual GSAs' websites. These websites serve as integral resources for stakeholders within the Tulare Lake Subbasin boundary. Electronic files of printed materials, presentations and other educational resources, and direct links to stakeholder surveys (English and Spanish versions) were also accessible via the websites.

  As printed materials were created, PDFs of the same information were added to the GSAs' websites. This served as a way for stakeholders to easily educate themselves on the GSP process and phases.

  Table 6. Tulare Lake Subbasin GSAs' Websites

GSA	Website
El Rico GSA	None – Meetings posted at kingsgroundwater.info
Mid-Kings River GSA	www.midkingsrivergsa.org
South Fork Kings GSA	southforkkings.org
Southwest Kings GSA	www.swkgsa.org
Tri-County Water Authority GSA	tcwater.org
Kings River Regional Groundwater Info Portal *(an additional online informational resource)*	kingsgroundwater.info

- **Interested Parties List –** As required by SGMA 10723.4 "Maintenance of Interested Persons List," the Tulare Lake Subbasin GSAs maintain contact lists and regularly distribute emails to those who have expressed interest in the GSAs' progress. These emails consist of meeting notices and other documents that are pertinent to the Tulare Lake Subbasin GSAs and their communication efforts. This process will continue through the GSP implementation phase.
- **Email Blasts –** Email blasts for meeting notices, stakeholder surveys, public review notices, and other crucial information were coordinated with community organizations and stakeholder groups by utilizing their distribution lists. Examples of these organizations are Kings County Farm Bureau, and water/irrigation districts within the individual GSAs' boundaries.

D.1.3 Media Coverage

Press releases were written and distributed to the media list of local newspaper publications. These press releases focused on notification of public engagement opportunities such as targeted stakeholder meetings, public review/comment processes and opportunities, and will be distributed for meetings and notifications during the GSP implementation.

D.1.4 Stakeholder Surveys

Stakeholder surveys were used for the deliberate polling of stakeholders to give them a direct voice in the GSP development phase. The South Fork Kings GSA and Southwest Kings GSA circulated physical surveys, while the remaining three GSAs conducted verbal surveys through one-on-one discussions with stakeholders

within their GSA boundaries. For the GSAs who administered physical stakeholder surveys, they developed both online and printed versions of their surveys. Survey links were posted as Google Forms on the individual GSAs' websites and were utilized in email blasts to the Interested Parties Lists. Hard copies were also available for distribution throughout the respective GSA. An outline of the survey questions is provided in **Table 7**.

Table 7. GSAs Circulating Stakeholder Surveys

GSA	Survey Questions
El Rico GSA	Conducted verbal stakeholder survey discussions.
Mid-Kings River GSA	Conducted verbal stakeholder survey discussions.
South Fork Kings GSA	1. How important are the following uses of water to you personally? *Please rank the categories with 1 being the most important use of water and 6 being the least important. (Municipal, Agricultural, Recreational, Mining/Petroleum, Manufacturing, Wildlife/Fisheries)* 2. How important are the following uses of water to the region? *Please rank the categories with 1 being the most important use of water and 6 being the least important. (Municipal, Agricultural, Recreational, Mining/Petroleum, Manufacturing, Wildlife/Fisheries)* 3. Please rank the categories with 1 being the most important for reason for managing groundwater and 5 being the least important. *(Ensure drinking water supply for domestic uses; My ability to earn a living is directly linked; Future economic growth for region; Ensure water supply for future generations; Provide reliable water for industry/business; Other)* 4. How knowledgeable do you consider yourself of local water issues? *(Circle one – Extremely Knowledgeable to Not Very Knowledge)* 5. How knowledgeable do you consider yourself of the new groundwater regulation, the Sustainable Groundwater Management Act? *(Circle one – Extremely Knowledgeable to Not Very Knowledge)* 6. Are you currently engaged in activity or discussions regarding groundwater management in your area? 7. How important to you is information on anticipated impacts of new state regulations. *(Circle one – Extremely Important to Not Very Important)* 8. Which format or formats would you prefer for receiving information about groundwater management planning process? *(Check all that apply – Newsletters, phone number to call for information, regular public meetings, electronic media, news stories, information through interest groups, don't know)* 9. Which applies to you? I am a stakeholder representing pumping for… (*Check all that apply – business use, small community use, domestic use, school use, agricultural use, federal use, industrial use, municipal use, tribal use, environmental use, does not apply)* 10. Which best describes the community in which you or your industry/business resides? *(Circle all that apply – Rural Kings County, within the City of Lemoore, within the Community of Stratford, outside of the South Fork Kings GSA service area, don't know)* 11. Please indicate your age range? *(Circle one – 25 and under, 26-35 years, 36-45 years, 46-55 years, 56-65 years, over 65 years, no answer)*
Southwest Kings GSA	1. Are you familiar with Sustainable Groundwater Management Act (SGMA) regulations? 2. Are you currently engaged in activity of discussions regarding groundwater management in this region? 3. Do you own or manage/operate land in this region? 4. Do you manage water resources? If yes, what is your role? 5. What is your primary interest in land or water resources management? 6. Do you have concerns about groundwater management? If so, what are they? 7. Do you have recommendations regarding groundwater management? If so, what are they?
Tri-County Water Authority GSA	Conducted verbal stakeholder survey discussions.

D.2 Tulare Lake Subbasin-Wide Outreach Efforts

The Tulare Lake Subbasin GSAs maintained a timeline of communication and outreach efforts completed throughout the GSA development and GSP development and public review phases, both on a subbasin-wide level and on the individual GSA level. Subbasin-wide public outreach meetings and presentations are shown in **Table 8**. **Figure 1**, **Figure 2** and **Figure 3** demonstrate a visual guide for consolidated subbasin and individual GSA stakeholder involvement completed since the GSAs were formed.

Table 8. Tulare Lake Subbasin-Wide Public Meetings, Notifications, Presentations & One-on-One Meetings

Event	Date
Kings County Water Commission Meeting – SGMA Update Presentation	May 21, 2018
Kings County Farm Bureau Board Meeting – SGMA Update Presentation	June 19, 2018
Kings County Ag/Water Commissions Joint Meeting – SGMA Update Presentation	March 25, 2019
Kings County Farm Bureau Meeting – GSP Public Review Presentation	August 20, 2019
Subbasin-Wide Public Review Outreach Meeting – Lakeside Community Church, Hanford	5:30 p.m., October 9, 2019
Subbasin-Wide Public Review Outreach Meeting – Lemoore Civic Auditorium, Lemoore	5:30 p.m., October 15, 2019
Subbasin-Wide Meeting regarding GSP with five GSA managers and County of Kings representatives (County Counsel SGMA liaison, CAO, Board of Supervisor Verboon)	November 6, 2019 at the TLBWSD office in Corcoran
Tulare Lake Subbasin GSP Public Hearing – Kings County Board of Supervisors Chambers	10 a.m., December 2, 2019

D.2.1 Public Noticing

I.D.2.1.1 Phase 1: GSA Formation and Coordination

During Phase 1: GSA Formation and Coordination, the five individual GSAs published public notices to notify stakeholders within their boundaries of the public hearings held prior to the official formation of the agencies. These notices are documented in **Table 9**.

Table 9. Public Notices for GSA Formation Public Hearings

GSA	Publication	Date Published	Date Public Hearing Held
El Rico GSA	The Corcoran Journal Visalia Times Delta The Bakersfield Californian	January 19, 2017; January 26, 2017 January 19, 2017; January 26, 2017 January 20, 2017; January 26, 2017	February 7, 2017
Mid-Kings River GSA	Hanford Sentinel	December 20, 2016; December 27, 2016	January 5, 2017

I.D.2.1.2 Phase 3: GSP Review and Evaluation

A 90-day comment period was held the last quarter of 2019, with the GSP draft posted on the Tulare Lake Subbasin GSAs' websites for all stakeholders to conveniently download and review and provide comments. Public notices were published in local newspapers to notify stakeholders of the start of the public review period 90 days prior to the public hearing, and published again within 45 days of the public hearing (**Table 10**).

Table 10. Public Notices for GSP Public Review & Public Hearing

Publication	Date Published	Purpose of Notice
The Bakersfield Californian	September 3, 2019; September 10, 2019	Notice of Public Review of Tulare Lake Subbasin Draft GSP
The Corcoran Journal	September 5, 2019; September 12, 2019	
Hanford Sentinel	September 3, 2019; September 10, 2019	
Visalia Times Delta	September 3, 2019; September 10, 2019	
The Bakersfield Californian	October 19, 2019; October 25, 2019	Notice of Public Hearing on Tulare Lake Subbasin Draft GSP, scheduled for December 2, 2019
The Corcoran Journal	October 24, 2019; October 31, 2019	
Hanford Sentinel	October 18, 2019; October 25, 2019	
Visalia Times Delta	October 31, 2019; November 7, 2019	

D.2.2 Interbasin Coordination Efforts

Tulare Lake Subbasin GSAs and technical consultants met with surrounding subbasins throughout the development of the GSP to discuss how to achieve sustainability on a regional level, develop interbasin agreements, address boundary issues, discuss groundwater monitoring and groundwater modeling, and share data when possible. Between the five GSAs, meetings were held periodically with other GSAs within the Kern, Tule, Kaweah, Kings and Westside subbasins. GSA managers were also involved with other GSA boards and technical committees in other subbasins due to some member agencies' boundaries crossing into other subbasins. This allowed the managers to communicate a regional perspective in sustainability discussions, as their stakeholders hold interests in more than one subbasin.

While inter-basin issues were communicated and discussed during these numerous meetings, due to time constraints and each subbasin progressing at a different pace in the development of their GSPs, resolutions to conflicts are acknowledged but impractical to fully analyze prior to the GSP submittal deadline of January 31, 2020. These discussions will continue, and resolutions will be addressed in annual reports and/or the 2025 Tulare Lake Subbasin GSP Update.

APPENDIX C

STAKEHOLDER COMMENTS AND RESPONSES

APPENDIX C – PUBLIC COMMENTS ON THE DRAFT GSP

The Groundwater Sustainability Agencies (GSAs) solicited public and stakeholder comments on the draft Tulare Lake Subbasin (Subbasin) Groundwater Sustainability Plan (GSP) from September 6, 2019, to December 2, 2019. During this period, the GSAs received comments transmitted to them in six letters and in one email. During the Public Hearing on December 2, 2019, one verbal comment was received. This section provides summaries of the comments contained in the letters and email and as presented verbally on the draft GSP and the responses to each comment.

Each letter, email, and verbal comment received is listed in Table C-1 and identified by comment author and date received by the GSAs.

Table C-1. List of Commenters

Comment ID	Comment Author	Comment Date
Organizations		
0-1	The Nature Conservancy	November 26, 2019
0-2	California Poultry Federation	November 27, 2019
0-3	Clean Water Action/Clean Water Fund; Local Government Commission; Audubon/California; The Nature Conservancy	December 2, 2019
0-4	Westlands Water District	December 2, 2019
0-5	Westlands Water District	December 2, 2019
Individuals		
I-1	Colleen Courtney	October 11,2019
I-2	Bill Miguel	October 15,2019
I-3	Bill Toss	December 2, 2019
I-4	Doug Verboon	December 2, 2019

Each of the comments is summarized below followed by responses from the GSAs. Hard copies of the comment correspondence received by the GSAs and a written summary of the verbal comment are compiled and presented following the comments and responses section.

Comment O-1

In The Nature Conservancy's letter to the South Fork Kings (SFK) GSA, they address the GSP's consideration of the beneficial uses and users of groundwater including environmental uses and users. The comment letter states:

> *Although there is a robust description of the confined (lower) and unconfined/semiconfined (upper) aquifers there is no explicit description with supporting data and information of how groundwater above the A- and C- clays in the upper aquifer interacts with the unconfined aquifer or is influenced by pumping in the unconfined portion of the aquifer. DWR's definition of a principal aquifer, is defined as an "aquifer of aquifer system that stores, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems."*
>
> *These shallow and perched areas within the upper aquifer range from near surface to 30 feet below ground surface and likely provide water supply to GDEs and ISWs. As such, they yield significant quantities of groundwater to surface water systems and beneficial users, and should not be dismissed because they do not yield groundwater for human use.*

These statements are the basis for the other resulting comments in their letter that request additional data and information, suggest that the GSA's and GSP recognize groundwater dependent ecosystems (GDEs) and interconnected surface water (ISW), and suggest a need for monitoring of these potential areas.

Response: Thank you for your letter and comments. Related to the Hydrologic Conceptual Model as presented in Section 3.1.8 of the draft GSP, there are geologic deposits in the Subbasin that are lacustrine clays named the A- through F-Clays. The A- through D-Clays may be more important locally in restricting the downward movement of groundwater. Figure 3-17 shows the areal extent of the A-Clay and the depth to groundwater above the A-Clay. Comparing this figure with your web-based GDE Pulse indicates an area along the South Fork Kings River where there would be the most interest in evaluating whether GDEs and ISWs occur.

From Section 4.0 of the draft GSP "Indicators for the sustainable management of groundwater were established under Sustainable Groundwater Management Act of 2014 (SGMA) based on factors that have the potential to impact the health and general well-being of the public. The following indicators were evaluated within the Subbasin: groundwater levels, groundwater storage volume, land subsidence, water quality, interconnected surface water, and seawater intrusion." ISW and seawater intrusion are not present within the Subbasin and were omitted from further consideration in the draft GSP. GDEs are not one of the sustainability indicators but rather dependent on ISW systems. Section 3.2.8 describes more fully the conditions found within the plan area.

It is also recognized that the GSP is adaptive in nature and will be updated as more information becomes available. It is noted in Section 5.4.1.2 that the ability to add and/or alter the existing monitor programs is envisioned. The individual GSAs will determine if or when additional

attempts will be made to collect that data. Temporal adjustments may be made for the different aquifer zones or in certain areas. For example, semi-annual water level readings in above the A-Clay wells is probably sufficient to capture seasonal and long-term trends in most of that aquifer zone because water levels in the aquifer are relatively stable in most of the area. Near the Kings River it may be desirable to collect more frequent data from above the A-Clay to better understand the relationship between the river and shallow groundwater.

Comment O-2

The California Poultry Federation (CPF) is the trade association for California's poultry industry. In their letter to the Southwest Kings (SWK) GSA, they expressed their support for effective measures to assure reliable water supplies. CPF's comments largely focused on 2 main issues:

1. Supply augmentation should be a top priority of the GSP.
2. Regarding demand management, the GSP does not explain precisely how it will be done and the public will need to have opportunities to participate in the development of demand management measures. Also, the GSAs should do their best to ameliorate economic impacts by adopting demand management measures that are cost-effective.

Response: Thank you for your letter and comments. The GSAs agree that supply augmentation should be a top priority for this Subbasin. Several supply augmentation projects and their implementation are described in Chapters 6 and 7.

The draft GSP has been revised to remove demand management or demand reduction as a definitive programmatic action. The potential for demand management is described in Section 6.4 only as an option for the GSAs should it be needed to meet the Sustainability Goal. If implementation is necessary, the GSAs are committed to executing such programs in a cost effective manner and with the input of the local communities.

Comment O-3

This letter was submitted to the Tri-County Water Authority GSA on behalf of the Clean Water Action/Clean Water Fund, Local Government Commission, Audubon/California, and The Nature Conservancy in the interests of disadvantaged communities (DACs), drinking water, and the environment. The letter presented a checklist of GSP review criteria and summary comments addressing 9 elements as indicated in the response.

Response: Thank you for your letter and comments. Responses to the summary comments in the letter are provided below.

1. **How the DACs were determined and engaged in the GSP development process.**
   DACs were identified using the California Department of Water Resources (DWR) DAC online mapping tool and associated Geographic Information System data (2018) and the Tulare Lake Basin DAC Water Study (published 2013). The GSAs conducted a substantial amount of stakeholder engagement, including outreach to DACs, during the development of the GSP. These efforts are described in detail in Appendix B.

2. **Financial assistance for DACs.**
   SGMA did not intend for the GSAs to provide financial assistance to entities in the Subbasin. Representatives of the GSAs will reasonably assist entities in identifying potential sources of financial assistance, if requested and necessary, and will provide other non-financial assistance to the extent that it is required in the SGMA regulations and the GSAs have the resources to do so.

3. **The development of Measurable Objectives and Minimum Thresholds Sustainable Management Criteria needs to be explained.**
   The development of Measurable Objectives and Minimum Thresholds are described in Chapter 4 of the draft GSP. The methods used and the rational for selecting these criteria are described in this chapter.

4. **There should be stakeholder engagement during GSP implementation.**
   The GSAs conducted a substantial amount of stakeholder engagement during the development of the GSP. These efforts are described in detail in Appendix B. The GSAs intend to continue stakeholder engagement efforts through GSP implementation.

5. **The potential for impacts to domestic water supply wells from GSP implementation.**
   Domestic water supply wells in the Subbasin typically are the shallowest wells in the Subbasin and have historically been subject to a dynamic groundwater system whereby water levels change frequently due to seasonal fluctuations and climatic changes (such as drought). Prior to SGMA, these wells also experienced gradual long-term decline of water levels due to the curtailment of federal and state surface water deliveries to the Subbasin. In this environment, owners of these wells have successfully adjusted by modifying the wells or drilling new wells. Under SGMA, water levels will continue to change frequently due to seasonal fluctuations and climatic changes and until the GSP is fully implemented, the wells may also experience gradual decline of water levels. However, as the GSP is

implemented, shallow water levels are expected to stabilize, thereby providing a positive benefit to domestic well owners.

6. **Groundwater Dependent Ecosystems should be addressed.**
   From Section 4.0 of the draft GSP "Indicators for the sustainable management of groundwater were established under SGMA based on factors that have the potential to impact the health and general well-being of the public. The following indicators were evaluated within the Subbasin: groundwater levels, groundwater storage volume, land subsidence, water quality, interconnected surface water, and seawater intrusion." Interconnected surface water and seawater intrusion are not present within the Subbasin and were omitted from further consideration in the draft GSP. GDEs are not one of the sustainability indicators but rather dependent on interconnected surface water systems. Section 3.2.8 describes more fully the conditions found within the plan area.

   It is also recognized that the GSP is adaptive in nature and will be updated as more information becomes available. It is noted in Section 5.4.1.2 that the ability to add and/or alter the existing monitor programs is envisioned. The following is offered; "The individual GSAs will determine if or when additional attempts will be made to collect that data. Temporal adjustments may be made for the different aquifer zones or in certain areas. For example, semi-annual water level readings in above the A-Clay wells is probably sufficient to capture seasonal and long-term trends in most of that aquifer zone because water levels in the aquifer are relatively stable in most of the area. Near the Kings River it may be desirable to collect more frequent data from above the A-Clay to better understand the relationship between the river and shallow groundwater."

7. **Climate change must be considered in development of the GSP.**
   As required by DWR, climate change is accounted for in the groundwater model (Appendix D) using assumptions and parameters provided by DWR.

8. **Drinking water should be considered in the water budget.**
   Municipal water use throughout the Subbasin is accounted for in the water budget. Water use from private domestic wells is not known nor is well construction known. The amount of water from domestic wells is estimated to be a *de minimis* amount in the overall water budget.

9. **Continued groundwater level decline during GSP implementation.**
   Per SGMA requirements, the GSAs have developed a GSP the implementation of which will result in groundwater sustainability for the Subbasin by 2040. At that point, average groundwater levels will become stable.

Comments O-4 and 0-5

Westlands Water District (Westlands) occupies the Westside Subbasin located to the southwest and adjacent to the Subbasin and is the GSA for this subbasin. In Westland's letters to the SWK GSA and SFK GSA (which are identical), they commented on 7 findings presented in the GSP, identified 3 discrepancies within the text, and offered 1 general comment.

Thank you for your letter and comments. Responses are provided below.

Finding 1 Comment
Finding 1 is in regard to groundwater flows into and out of the Subbasin and adjoining subbasins as described in Section 3.2.2 of the draft GSP. The letter states "*there is no substantial evidence to support the statements regarding groundwater flow directions out of the Subbasin to the Westside Subbasin.*"

Response: Potentiometric surface maps prepared by DWR from 1990 through 2016 clearly show that heads in the unconfined aquifer in the SFK GSA area are decreasing towards the southwest from the Subbasin into the Westside Subbasin. The winter 2014/2015 potentiometric surface map for the lower (confined) aquifer provided by Westlands in the comment letter also shows that groundwater from the SWK GSA is flowing towards the northwest towards a pumping depression southeast of Huron and to the southeast towards what appears to be a pumping center at the border between SFK GSA and SWK GSA with a contour of -160 feet. A review of the available water level elevation data for lower aquifer monitoring wells (some of it provided by Westlands) in this area of the Subbasin show between 1990 and 2016 the heads typically ranged from -100 feet to +100 feet. During this same period, wells in the Westside Subbasin typically ranged from -130 to +100 feet, generally lower than the wells in the Subbasin. A few new deep El Rico GSA wells started pumping in the 2014/2015 time range and had water level elevation in the -230 feet range, and may possibly be the source for the -160 foot contour shown on the map. However, these wells only operated in the last couple of years and are not representative of the long-term groundwater levels along the boundary between Subbasin and Westside Subbasin. In summary, there is evidence that between 1990 and 2016, the general direction of groundwater flow was from the Subbasin towards the Westside Subbasin both in the unconfined and confined aquifers.

Finding 2 Comment

The letter states *Figures 3-28b to 3-28d shows long term hydrographs for wells within the Tulare Lake Subbasin. Unfortunately, the data displayed by the hydrographs is pixelated, therefore unreviewable. Westlands GSA recommends revising the mentioned figures to display hydrographs using a higher resolution to allow the public to review.*

Response: These figures have been revised to show the hydrographs at a higher resolution.

Finding 3 Comment

Finding 3 is in regard to groundwater quality, as described in Section 3.2.5 in the draft GSP and shown on Figures 3-30 through 32. The letter states *We recommend that the draft GSP be revised to accurately convey groundwater quality data by aquifer and by the timeframe the data represents. In addition, we recommend that the groundwater quality data be reviewed for accuracy.*

Response: The groundwater quality data have been reviewed for accuracy and have been corrected where needed. Figures 3-30, 3-31, 3-32, and 3-33 have been revised to show the highest concentration of the constituents reported and the most recent concentrations. The source for the groundwater quality data used in these figures does not indicate the aquifer from which the data were collected.

Finding 4 Comment

The letter states *Figures 3-34 contains a legend that is incomplete and is unable to be reviewed. Westlands GSA recommends applying the corresponding color scheme to the vertical displacement legend to allow readers to be able to review the presented information.*

Response: The figure has been revised as recommended.

Finding 5 Comment

Finding 5 is in regard to the Sustainable Management Criteria presented in the draft GSP, specifically with respect to future water level decline. The letter states *The potential for curtailing historic underflow into the Westside Subbasin may be a substantial factor in contributing to significant and unreasonable subsidence and frustrate the Westlands' GSA ability to achieve the sustainability goal.*

Response: Thank you for your comment.

To evaluate your concern, the data developed within the draft GSP's was placed on a map showing the location of representative wells, aquifer representation, measurable objective, and

minimum thresholds. It should be noted that within the Tulare Lake GSP, there is a shallow zone above the A-Clay that is an additional aquifer that was not identified in the Westside Subbasin GSP. Thus the above E-Clay and Below E-Clay values were identified. Upon comparison for the above E-Clay designation, there are few wells in this zone in the westside basin. From the information, the data suggest that flow is from the Subbasin to the Westside Subbasin. For the below E-Clay aquifer, the data also suggest that the flow is from the Subbasin to the Westside Subbasin. So your initial suggestion that continued lowering of groundwater levels in the Tulare Lake GSP allows groundwater levels to become lower than levels established at 2015 is not supported. With the gradients that would result from these levels, it is recognized that groundwater outflow would continue to the Westside Subbasin. Per your point in your comment letter "The department shall evaluate whether a groundwater sustainability plan adversely affects the ability of an adjacent basin to implement their groundwater sustainability plan or impedes achievement of sustainability goals in an adjacent basin".

As to historical underflow that you mention in your comments, we would refer you to Figures 3-23 and 3-24. Historical groundwater flows have historically flown from the Westside Subbasin into the Subbasin. It is believed that groundwater pumping from within the Westside Subbasin has altered these flow paths and it appears that the Westlands GSP is proposing to continue this practice. As you stated, overlying and appropriative uses of groundwater within the Subbasin are entitled to legal and equitable protection against infringement by an action that deprives them of their historical inflows. More coordination is warranted between our subbasins to reach a resolution. We look forward to discussing with you more thoroughly these boundary conditions and how we might develop a solution.

Finding 6 Comment

Finding 6 is in regard to the Sustainable Management Criteria presented in the draft GSP, specifically with respect to future subsidence. The letter states *Westlands GSA is concerned that allowing subsidence rates as proposed may impact critical infrastructure such as roads, railroads, and may increase flood risks to existing land uses, especially near Corcoran where subsidence rates are critical, in the Westside Subbasin and other neighboring subbasins.*

Response: Thank you for your comment. The GSA's within the Subbasin are concerned about lowering of groundwater levels as well as land subsidence. To this end, it is recognized that land subsidence is a regional concern and based upon historical information, is thought to be a result of groundwater pumping beneath the Corcoran Clay. The historical data and model developed for the basin suggests that regionally the largest change in land subsidence is located Southeast of the Subbasin and within the Tule Subbasin. The rate of subsidence continues into the Subbasin with rates experienced in Lemoore being approximately half of the rate at the Corcoran site.

Section 4.4.1.3 has been revised to reflect this historic information and set a minimum threshold of 8 feet of subsidence at the Lemoore site. To quote from the revised GSP, "These values have been selected using historical subsidence data. There has been no information suggesting that there has been local significant damage to infrastructure in both these areas. At each five-year milestone, information from the groundwater model suggests subsidence will continue for the first five years until project and management actions are fully implemented."

Finding 7 Comment

Finding 7 is in regard to analysis in the groundwater model report presented in Appendix D of the draft GSP indicate the General Head Boundary (GHB) is driving groundwater flow out of the Westside Subbasin and into the Subbasin. The letter states *Westlands recommends reanalyzing the water level contour data from the numerical model and GSP.*

Response: The GHBs in the Westside Subbasin basically follows the boundary between Fresno and Kings Counties. The GHB heads were interpolated from water level elevation data provided by DWR and Westlands for wells near the edge of the model on both side of the county line. The resulting GHB heads have historically tended to decrease from north and southwest to a low area near the bend in the county line. The winter 2014/2015 potentiometric surface map for the lower (confined) aquifer provided by Westlands in the comment letter also shows that the water level elevation contours along the county (GHB) line are also converging towards a low area near the bend in the county line. We believe the GHBs heads utilized in the Westside Subbasin are a reasonable interpretation of historical water level elevation in the area.

Reporting Discrepancy #1

The letter states *Total lateral subsurface inflow into the Westside Subbasin shown in Figure D5-5 averages 72,296 AFY (67,347 from the Tulare Lake Subbasin and 4,948 AFY from the Kings Subbasin). Table 3-6 of the GSP shows average annual subsurface flow from the Tulare Lake Subbasin to the Westside Subbasin of 41,390. What is the source of this discrepancy?*

Response: The figure was referencing an incorrect cell and has been corrected.

Reporting Discrepancy #2

The letter states *In the graphic depicting aquifer specific fluxes in Figure D5-5, the sum of the "Net GW Flux" (which presumably is lateral subsurface flow between adjacent subbasins) totals 4,936 AFY while the total in the table shown in Figure D5-5 is 72,296 AFY. What is the source of this discrepancy?*

Response: The figure was referencing an incorrect cell and has been corrected.

Reporting Discrepancy #3

The letter states *Figure numbers in the Appendix D text do not correspond to the correct figures. Figure DS-10 is titled "Simulated Subsidence 1990-2016". Figure D5-8 shows "Groundwater Mass Balance Tule Subbasin".*

Response: The figure numbers have been corrected.

General Comment

Westlands recommended that GSA representatives from the two subbasins meet and confer at the earliest opportunity to determine whether an interbasin agreement can be reached. The agreement would be used to reach a cooperative resolution of important issues that will enable coordinated sustainable management in our GSAs.

Response: The GSAs in the Subbasin agree that efforts should be made to develop and interbasin agreement and look forward to the opportunity following submittal of the respective GSPs.

Comment I-1

In her email of October 11, 2019, Ms. Courtney made clear her opposition to the GSP and using groundwater for agriculture.

Response: Thank you for your email and comments. The comments do not pertain to the GSP's analysis. Opposition to the GSP has been noted and the email is included in full herein and will be forwarded to the DWR for consideration.

Comment I-2

The comment letter from Mr. Miguel has a number of points related to surface water supplies and the Kings River Water Association. While the letter recognizes that the GSP and GSA's have no authority, he goes on to assert that the GSP could be used to be a proponent of change and public awareness. The letter suggests that there has been an opportunity missed in the capture and use of surface water flows from the Kings River and that storage contemplated and permitted has not been fully utilized.

Response: Thank you for your letter and comments. As is recognized in the letter, the GSA's and GSP have no authority of surface water rights, diversion and beneficial uses of these rights. These surface water rights have historic origins, were initially exercised in the 1800s, predate statehood and more recently have been permitted by the State Water Resources Control Board. A watermaster has been charged with oversight of the river and assuring that the surface water diversions are in accordance with the licenses for diversion. As to your suggestion that additional

surface supplies could be utilized to offset overdraft, that is the plan. Please review Section 6.0 that identifies the projects envisioned to increased surface diversion and use. You will note that all the GSA's are planning on projects to divert and either recharge (where possible and the geologic conditions allow) or storage and reregulation of supply. These are most notable in the SFK, and El Rico, and Tri-County Water Agency GSA's. We look forward to the planning and implementation of these projects to allow for the continued farming and prosperity for the area.

Comment I-3

Mr. Toss provided a verbal comment at the Public Hearing on December 2, 2019, in which he stated that the demand reduction presented in Chapter 6 of the GSP as a management action to help achieve groundwater sustainability in the subbasin would be very damaging to Kings County and its growers. He requested that this management action be changed.

Response: Thank you for your comment. The draft GSP has been revised to remove demand management or demand reduction has a definitive programmatic action. The potential for demand management is described in Section 6.4 only as an option for the GSAs should it be needed to meet the Sustainability Goal. If implementation is necessary, the GSAs are committed to executing such programs in a cost effective manner and with the input of the local communities.

Comment I-4

Mr. Verboon is a Kings County Supervisor, but clarified that his comments were from him individually and "not on behalf of the Board of Supervisors". In his letter to the five GSAs, Mr. Verboon, on behalf of other signatories to the letter, made 3 main comments:

Comment 1: There were procedural defects that limited Kings County and its water uses in their opportunity to review and comment on the draft GSP.

Response: Thank you for your letter and comments. The GSAs understand that they have met their notice and other obligations to Kings County under Section 10728.4. The GSAs view that there were no procedural defects in the notice provided to the County. Consultation with Kings County took place at a meeting on November 6, 2019, roughly a month prior to the comment period close. Kings County chose to not submit any written or verbal comments on the draft GSP.

Comment 2: The projects presented in the draft GSP are too vague and non-committal.

Response: The draft GSP indicates that there exist a number of legal and practical uncertainties regarding project identification and adoption. Projects referenced in the draft GSP, and possibly others, will be identified and adopted by the GSAs, but only after sufficient data are collected, adequate analysis conducted, and funds are appropriated for the projects. Refer to Chapter 7 for further details on project implementation.

Comment 3: Land fallowing should be used as a demand reduction management action only as a last resort and after other demand reduction strategies and water recharge projects have been implemented.

Response: It appears that Mr. Verboon has interpreted the details of some groundwater model evaluations as planned GSA management strategies, and that is incorrect. Also, upon review, there were descriptions of land fallowing that were misleading and likely added to the confusion. These portion of the GSP have been revised. Also, the GSAs agree that supply augmentation should be a top priority for this Subbasin. Several supply augmentation projects and their implementation are described in Chapters 6 and 7.

Public Comment Letters

Subject: GSAS-Kings County Resident STATES NO ON GROUND WATER FOR AGRICULTURAL PURPOSES!

Colleen Courtney
14234 16th Avenue
Lemoore, CA 93245-9517
Email: colleencourtney66@gmail.com

October 11,2019

To: GSAS Commissioners Board;

HELL NO! These sod Busters DO NOT DRAIN the Valleys Ground Water for their crops that ships out of State or over seas for your personal Padding Their wallets!

NOT AT this Valleys populations expense for their personal gains!

We need that water for drinking for people, animales we eat and other business endeavors other than these Sod Busters causing our lungs to fill with their crop dirt, pesticides from those dam planes or choppers that keep sprayers on to do a turns. Bull shit!

You sod Busters use your homes water well resource to water your acreages! Or drill more water wells on your own property or truck in tankers of water from the Rockies or Serras!

Or tap into your local City water line. Their water line is petty much secured source for your crop of your own choice of Occupational decision of becoming a FATCAT Farmer! At the other people's thirst expense!

We are already breathing your property's dirt and pesticides! Your surface soil covers our house and vechicals in one month! And pushing your sludge mixed with our water down that dam drive away!

I am about to phone the Sheriffs Department on that sod buster's property that constantly trespasses and squats on our property and buries everything!
We accumulated more of his farm land than he actually possesses!

These sodbusters are like city slumlords just purchased cheap property sell high, cut costs, don't maintain, rape the earth, suck it out of every earthly nutrients, minerals possible drain others water for your sole purposes to pad your wallets. And in the end abandon the worthless property your raped the hell out of. To go to another place to fu ck up for the next generation to overhaul that damage you caused in the first place!

NO GROUND WATER To SOD BUSTERS!
And SOD BUSTERS are NOT in the
AGRICULTURAL COMMUNITIES!

The Real Farmers know how to take care of the earth and would not ever think of asking people to give up their drinking water for themselves and their animals. For his crops. This Farmer would sacrifice his crops for those people when it came to water rights. And not directed by padding his wallet!

VOTE NO ON GROUND WATER! Let these sod busters truck in their water from Rockies or Serras! Just a cheap expense compared to Shipping crops to New York or Over Seas!

Cheap son of a bitches! Go dry up!

Colleen Courtney

South Fork Kings Groundwater Sustainability Agency
4886 E Jensen Avenue
Fresno, CA 93725

TO: SFKGSA Board Members and members of the Public.

RE: Response to SFKGSA Sustainability Plan.

I use this opportunity to respond to the South Fork Kings Groundwater Sustainability Plan. I understand that the SFKGSA is limited in its scope of responsibility and governance, however I feel the SFKGSA can become a useful proponent and informational resource for public awareness.

The primary source of groundwater recharge is the sandy bottom of the Kings River. Domestic wells, agriculture wells, groundwater dependent ecosystems, and other beneficial users are dependent upon the river's natural surface water flows to recharge underground aquifers. These surface water flows are managed by the Kings River Water Association (KRWA) whose 28 member districts receive water from a designated "point of diversion" on the Kings River. It has become common practice to divert surface water from lower stream points of diversion to upper stream diversion points to reduce what is commonly termed "channel loss". However, channel loss is also groundwater recharge. These diversions have a direct and negative impact on holders of overlying groundwater rights by diminishing groundwater recharge and adding to groundwater overdraft.

PART 1.

GROUNDWATER RIGHT HOLDERS:

SUSTAINABLE GROUNDWATER MANAGEMENT ACT: 10723.2.

"The groundwater sustainability agency shall consider the interests of all beneficial uses and users of groundwater, as well as those responsible for implementing groundwater sustainability plans. These interests include, but are not limited to, all of the following:"

(a) Holders of overlying groundwater rights, including:

(1) Agricultural users.

(2) Domestic well owners.

(b) Municipal well operators.

(c) Public water systems.

(d) Local land use planning agencies.

(e) Environmental users of groundwater.

Excerpts from CALIFORNIA WATER CODE:

§ 1706. The person entitled to the use of water by virtue of an appropriation other than under the Water Commission Act or this code may change the point of diversion, place of use, or purpose of use if others are not injured by such change...

§ 1707. (a) (1) Any person entitled to the use of water, whether based upon an appropriative, riparian, or other right, may petition the board pursuant to this chapter, Chapter 6.6 (commencing with Section 1435) or Chapter 10.5 (commencing with Section 1725) for a change for purposes of preserving or enhancing wetlands habitat, fish and wildlife resources, or recreation in, or on, the water.

Being a public entity, it is incumbent on the SFKGSA monitor and quantify the amount of groundwater recharge lost due to points of diversion changes. Further, it is an inherent responsibility of the SFKGSA to challenge any such diversions per California Water Code Sections 1706 and 1707, and by other codes sections not mentioned, and to advocate on behalf of those harmed by such diversions.

PART 2.

DECISION 1290

In 1967 the State of California State Water Rights Board issued its Decision 1290, a pivotal benchmark for Kings River water management. The following are excerpts from the Decision:

Page 16: "The primary source of all ground water in the Kings River service area is the river and its distributaries...".

Page 21: "The contracts with members of the KRWA result in the controlled release of water from these reservoirs* (Courtright, Wishon, Pine Flat) *to satisfy downstream requirements for irrigation and ground-water recharge."

Page 35-36: "...the association* (KRWA) *members have planned their overall project to take maximum advantage of all storage facilities available to them. This includes recharge of ground water and underground storage as well as the storage of flood waters in Tulare Lake Basin and maximum retention in Pine Flat Reservoir. Consulting Engineer Henry Karrer testified to the effect that under certain ideal conditions, about 2,000,000 acre-feet could be stored and regulated in Pine Flat Reservoir in any one year (RT192). He also said that up to 1,000,000 acre-feet of water could be stored in the cellular dyke system in Tulare Lake Basin (RT 192)."

This position was reaffirmed in a July 30, 2019 letter to Mitchell Moody of the State Water Resource Control Board when stating; "Decision 1290 expressly recognized the KRWA member units planned their overall project to take maximum advantage of all available storage facilities...".

Present estimate of King River Basin groundwater overdraft is 120,000 acre-feet per year, while average annual floodwater diverted to the San Joaquin River is 100,000 acre-feet. Opportunities of using Tulare Lake as a storage facility have been repeatedly missed as it has become common practice to redirect flood release water away from the ***cellular dyke system in Tulare Lake Basin*** to the San Joaquin. The beneficial use of this un-stored water is then lost to all.

It is understandable that stakeholders who would be harmed by the flooding of the Tulare Lake Basin would wish that flood release waters be diverted. The flooding of the Tulare Lake Basin would cause economic hardship to business interests. However, as noted in Decision 1290 and empirically known, the Kings River waters do naturally flow to the Tulare Lake Basin, into what is known as Tulare Lake.

It is likewise understandable that this diversion of flood release water comes at an equal price to stakeholders outside the Tulare Lake Basin. Water diverted away from the dyke system storage facility is water waisted and unused for negating groundwater overdraft and recharge. If full usage of the cellular dyke system were utilized as stated in Decision 1290, groundwater overdraft could be diminished by as much as 100,000 per year.

With SGMA deadlines approaching, stakeholders up-stream of the Tulare Lake Basin find themselves mired in a groundwater overdraft problem. They face the economic consequence of fallowed land and tax surcharges for groundwater pumping, while 100,000 acre-feet of Kings River surface water is re-routed to the San Joaquin River. Simply put; until the cellular dyke system in Tulare Lake Basin is fully utilized as intended, upstream right-holders and stakeholders a will pay the price for the problem Tulare Lake Basin interests pass on.

As stated, SFKGSA is a public entity and has an inherent responsibility to monitor, quantify and make publicly known the amount of groundwater recharge lost and the groundwater overdraft resulting from the non-use of the cellular dyke storage system as stated in Decision 1290. Additionally, it is requested that the SFKGSA study and make known the impact changes in points of diversion (Part 1) and non-use of the cellular dyke storage system in Tulare Lake Basin (Part 2) have upon groundwater recharge and overdraft prior to implementation of overdraft enforcement procedures.

Thank you for your consideration.

Re: Tulare Lake Subbasin Groundwater Sustainability Plan, Preliminary Draft

Dear Agency Staff,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Groundwater Sustainability Plan (GSP) for the Tulare Lake Subbasin that is being prepared under the Sustainable Groundwater Management Act (SGMA).

TNC as a Stakeholder Representative for the Environment

TNC is a global, nonprofit organization dedicated to conserving the lands and waters on which all life depends. We seek to achieve our mission through science-based planning and implementation of conservation strategies. For decades, we have dedicated resources to establishing diverse partnerships and developing foundational science products for achieving positive outcomes for people and nature in California. TNC was part of a stakeholder group formed by the Water Foundation in early 2014 to develop recommendations for groundwater reform and actively worked to shape and pass SGMA.

Our reason for engaging is simple: California's freshwater biodiversity is highly imperiled. We have lost more than 90 percent of our native wetland and river habitats, leading to precipitous declines in native plants and the populations of animals that call these places home. These natural resources are intricately connected to California's economy providing direct benefits through industries such as fisheries, timber and hunting, as well as indirect benefits such as clean water supplies. SGMA must be successful for us to achieve a sustainable future, in which people and nature can thrive within the Tulare Lake Groundwater Subbasin and California.

We believe that the success of SGMA depends on bringing the best available science to the table, engaging all stakeholders in robust dialog, providing strong incentives for beneficial outcomes and rigorous enforcement by the State of California.

Given our mission, we are particularly concerned about the inclusion of nature, as required, in GSPs. TNC has developed a suite of tools based on best available science to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders efficiently incorporate nature into GSPs. These tools and resources are available online at

GroundwaterResourceHub.org. TNC's tools and resources are intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater, be considered in the development and implementation of GSPs (Water Code § 10723.2).

The GSP Regulations include specific requirements to identify and consider groundwater-dependent ecosystems (GDEs) [23 CCR §354.16(g)] when determining whether groundwater conditions are having potential effects on beneficial uses and users. GSAs must also assess whether sustainable management criteria may cause adverse impacts to beneficial uses and users, which include environmental uses, such as plants and animals. TNC has identified each part of GSPs where consideration of beneficial uses and users are required. That list is available here: https://groundwaterresourcehub.org/importance-of-gdes/provisions-related-to-groundwater-dependent-ecosystems-in-the-groundwater-s. Please ensure that environmental beneficial users are addressed accordingly throughout the GSP. Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decision, and using data collected through monitoring to revise decisions in the future. Over time, GSPs should improve as data gaps are reduced and uncertainties addressed.

To help ensure that GSPs adequately address nature as required under SGMA, TNC has prepared a checklist (**Attachment A**) for GSAs and their consultants to use. TNC believes the following elements are foundational for 2020 GSP submittals. For detailed guidance on how to address the checklist items, please also see our publication, *GDEs under SGMA: Guidance for Preparing GSPs*[1].

1. Environmental Representation

SGMA requires that GSAs consider the interests of all beneficial uses and users of groundwater. To meet this requirement, we recommend actively engaging environmental stakeholders by including environmental representation on the GSA board, technical advisory group, and/or working groups. This could include local staff from state and federal resource agencies, nonprofit organizations and other environmental interests. By engaging these stakeholders, GSAs will benefit from access to additional data and resources, as well as a more robust and inclusive GSP.

2. Basin GDE and ISW Maps

SGMA requires that GDEs and interconnected surface waters (ISWs) be identified in the GSP. We recommend using the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) provided online[2] by the Department of Water Resources (DWR) as a starting point for the GDE map. The NC Dataset was developed through a collaboration between DWR, the California Department of Fish and Wildlife (CDFW) and TNC. We also recommend using GDE Pulse, which is also available on the internet at https://gde.codefornature.org/#/home. We also recommend using the California Natural

[1]GDEs under SGMA: Guidance for Preparing GSPs is available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

[2] The Department of Water Resources' Natural Communities Commonly Associated with Groundwater dataset is available at: https://gis.water.ca.gov/app/NCDatasetViewer/

Diversity Database (CNDDB) provided by CDFW to look up species occurrences within your area.

3. Potential Effects on Environmental Beneficial Users

SGMA requires that potential effects on GDEs and environmental surface water users be described when defining undesirable results. In addition to identifying GDEs in the basin, TNC recommends identifying beneficial users of surface water, which include environmental users. This is a critical step, as it is impossible to define "significant and unreasonable adverse impacts" without knowing *what* is being impacted. For your convenience, we've provided a list of freshwater species within the boundary of the Tulare Lake Groundwater Subbasin (Subbasin) in **Attachment C**. Our hope is that this information will help your GSA better evaluate the impacts of groundwater management on environmental beneficial users of surface water. We recommend that after identifying which freshwater species exist in your basin, especially federal- and state-listed species, that you contact staff at CDFW, United States Fish and Wildlife Service (USFWS) and/or National Marine Fisheries Services (NMFS) to obtain their input on the groundwater and surface water needs of the organisms on the GSA's freshwater species list. We also refer you to the Critical Species Lookbook[3] prepared by TNC and partner organizations for additional background information on the water needs and groundwater reliance of critical species. Since effects to plants and animals are difficult and sometimes impossible to reverse, we recommend erring on the side of caution to preserve sufficient groundwater conditions to sustain GDEs and ISWs.

4. Biological and Hydrological Monitoring

If sufficient hydrological and biological data in and around GDEs is not available in time for the 2020/2022 plan, data gaps should be identified along with actions to reconcile the gaps in the monitoring network.

TNC has reviewed the Tulare Lake Preliminary Draft GSP and appreciates the use of some our relevant resources in addressing GDE-related topics. However, we consider it to be **inadequate** under SGMA since key environmental beneficial uses and users are not adequately identified and considered. In particular, 1) ISWs and GDEs are not adequately identified and evaluated for ecological importance or adequately considered in the basin's sustainable management criteria, and 2) connectivity and extent of the of ISWs and GDEs with the shallow / perched zones of the unconfined / semiconfined aquifer were not characterized. **Please present a more thorough analysis of the 1) connectivity of the shallow and perched portions of the unconfined aquifer, 2) extent of the perched and shallow areas within the aquifer, and 3) identification and evaluation of ISWs and GDEs in subsequent drafts of the GSP. Once potential GDEs and ISWs are identified, they must be considered when defining undesirable results and evaluated for further monitoring needs until data gaps are filled in the future. If they are not adequately defined, then they need to be identified as a data gap in the interim.**

Our specific comments related to the Tulare Lake GSP are provided in detail in **Attachment B** and are in reference to the numbered items in **Attachment A. Attachment C** provides a list of the freshwater species located in the Subbasin. **Attachment D** describes six best practices that GSAs and their consultants can apply when using local groundwater data to confirm a connection to groundwater for DWR's NC Dataset. **Attachment E** provides an overview of a new, free online tool (i.e., GDE Pulse) that allows GSAs to assess changes in GDE health using satellite, rainfall, and groundwater data.

[3] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

Thank you for fully considering our comments as you develop your GSP.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders / representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

* In reference to DWR's GSP annotated outline guidance document, available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/GD_GSP_Outline_Final_2016-12-23.pdf

Attachment B

TNC Evaluation of the
Tulare Lake Subbasin Groundwater Sustainability Plan, Preliminary Draft

A complete draft of the Tulare Lake Subbasin GSP is available at https://southforkkings.org/wp-content/uploads/2019/09/2019-0906-tulare-lake-subbasin-gsp-prelim-draft_for-upload.pdf for public review and comment and is dated August 2019. This attachment summarizes our comments on the complete public draft GSP. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 2.5.3 Beneficial Uses and Users (p. 2-28)]

- The flow chart on p. 2-28 shows the engagement process with groundwater users during the development and implementation of the GSP. Table 2-4 (pp. 2-47 to 2-49) identifies all the beneficial uses and users of groundwater within the Subbasin by GSA in greater detail, but does not include environmental uses and users. Users identified include agricultural, public water systems, domestic well owners, municipal water systems, planning agencies, Native American Tribes, Disadvantaged Communities, monitoring entities, and surface water users (as represented by GSA members). California Water Code §1305(f) defines that beneficial uses of waters of the State include "preservation and enhancement of fish, wildlife, and other aquatic resources and preserves". **Please expand Table 2-4 to include environmental uses and users that are present in the Subbasin, such as:**
    - **ecological areas; preserves; potential ISWs and GDEs; managed wetlands;**
    - **Protected Lands, including conservation areas; and**
    - **Public Trust Uses including wildlife, aquatic habitat, fisheries, and recreation.**

Checklist Items 2 to 4 - Description of the Plan Area (23 CCR §354.8)

[Section 2.0 Plan Area (pp. 2-1 to 2-2)]

- The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses and users of surface waters that may be affected by groundwater extraction in the Subbasin should be specified in the section and in Table 2-4. **Please elaborate on the "surface water uses and users" by identifying the environmental uses and users of surface water for all GSAs in Table 2-4. Please explicitly identify the environmental users and take particular note of the species with protected status and any critical habitat that exists within the Subbasin.** The following are resources that can be used:
    - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/

    - The list of freshwater species located in the Tulare Lake Subbasin in Attachment C of this letter.
    - The California Department of Fish and Wildlife's California Natural Diversity Database (CNDDB) for species occurrences.
    - The USFWS's Environmental Conservation Online System (ECOS) for mapping critical habitat, wildlife and contaminants - https://ecos.fws.gov/ecp/
- The GSP addresses state and federal land ownership to some degree, but there is no mention of uses related to open space areas, managed wetlands, natural preserve areas, or other protected lands that contain natural resources. Per the USFWS ECOS website the Kern National Wildlife Refuge Complex, Tulare Basin Wildlife Management Area (on southern boundary), and Pixley National Wildlife Refuge (to the east of Highway 43) abut the GSP area. Within these areas there is critical habitat mapped for the Buena Vista Lake ornate shrew (*Sorex ornatus relictus*) near the Lemoore Naval Air Station and in the Kern National Wildlife Refuge, and the vernal pool fairy shrimp (*Branchinecta lynchyi*) in the Pixley National Wildlife Refuge. These habitat areas or species are not addressed in the description of the plan area, nor are sensitive habitats within the plan area acknowledged.
    - **Please identify the natural resources within the plan area and elaborate on any and all state, federal or other land ownership that exists within the plan area that provide protection of natural resources.**
    - **Please address how the GSP will address natural resource management on a regional scale since management within the GSP could affect neighboring sensitive resources.**
- The GSP goes on to state on p. 2-2 that the primary land use designations are for agricultural, urban, residential, commercial and industrial lands; however, the figure on that page shows riparian vegetation and water surface land use classifications that amount to more than residential and semi-agricultural. **Please revise the statement concerning primary land use designations to accurately reflect the percentages on the chart (i.e., agricultural, urban, riparian vegetation, water surface, etc.). Please identify the natural resources within the plan area and elaborate on any and all state, federal or other land ownership that exists within the plan area that provide protection of natural resources.**
- On page 2-2, it is stated that it was not possible to differentiate types of well uses between irrigation and domestic extractors because DWR does not have that data. However, these data are available on well completion reports which may be accessed on line through the GeoTracker GAMA website (https://gamagroundwater.waterboards.ca.gov/gama/gamamap/public/Default.asp). This is the approach taken in almost every other GSP we have reviewed and is an important distinction of use as it relates to prioritization of project needs and management decisions. **Please either address this issue or identify this as a data gap to reconcile in the 5-year GSP update.**

[Section 2.1 Summary of Jurisdictional Areas and Other Features (pp. 2-3 to 2-10)]

- The Plan summarizes the GSP Area and describes the jurisdictional areas and entities of the GSAs, but does not say anything about the jurisdictional areas of the resource agencies. **Please elaborate on the jurisdictional areas of the resource agencies and what resources they are in place to protect.**
- With exception of a short description of the Kings River Fisheries Management Program in Section 2.2.2.4, the GSP does not provide a description of other instream flow requirements, if any, or how the water infrastructure is in compliance with regulatory requirements set to protect species of concern. **Please provide a description of any current and planned instream flow requirements for Tulare Subbasin streams / rivers including Kings, Tule, White, Kaweah, and St. John's Rivers; and undammed streams including Deer, Dry, Mill, Cottonwood, and Poso Creeks. If there are no other instream flow requirements in place or planned, then please state that in the document.**

[Section 2.2.1 Monitoring and Management Programs (pp. 2-11 to 2-12)]

- This section addresses the water resources management actions that are being undertaken to monitor groundwater level, extraction and quality; subsidence; irrigated lands; and surface water. Management of natural resources is not considered in this section but should be described in order to provide a context for how groundwater management actions will be coordinated with environmental requirements to prevent undesirable results. **Please include a description of the natural resource management and monitoring programs occurring within the GSP area that affects instream, wetland and riparian ecosystems that have the potential to be groundwater dependent (i.e., interconnected surface water [ISWs] and groundwater dependent ecosystems [GDEs]).**

[Section 2.3 Relation to General Plans (pp. 2-14 to 2-17)]

- The GSP includes a very short description of the general plans within the GSP area but fails to specifically elaborate on the goals and policies outlined in the plans, and how the GSP will fit in with or affect the general plans' goals and policies related to the protection and management of GDEs, ISWs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources, other GDEs and ISWs, and related threatened or endangered species.**
- This section should identify other land use plans, including Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with areas with instream flow requirements; or critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin, and any reaches with instream flow and critical habitat requirements. Please elaborate on the natural resources within the Subbasin and address how GSP implementation will coordinate with the**

goals of these plans and requirements. If there are no HCPs, NCCPs, or preservation areas that could be affected, then that should be stated. The Critical Species Lookbook[4] includes the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical species and their habitats for these aquatic ecosystems and its relationship to the GSP.**

- **Please describe how the GSP will coordinate with the General Plan elements within the GSP area. Specifically, please elaborate on conservation, recreation and open space elements.**
- This section states (p. 2-15) that "It is considered unlikely that any Kern County General Plan Policies have any practical relevance to the plan area". The Kern National Wildlife Refuge Complex abuts the GSP area and it is difficult to understand that the General Plan for Kern County does not address habitat concerns and conservation that could be directly or indirectly affected by potential groundwater management actions within and adjacent to the Kern Subbasin. **Please 1) elaborate on the Kern County General Plan's conservation elements, 2) how the Tulare Lake Subbasin's GSP will comply with or not impact conservation elements being employed within protected habitat areas adjacent to the Tulare Subbasin, and 3) expand this conversation to include other neighboring habitat areas, such as Pixley National Wildlife Refuge.**

[Section 2.3.4 Permitting Process for New or Replacement Wells (pp. 2-17 to 2-19)]

- This section summarizes well permitting requirements and county ordinances for the counties of Kings, Kern and Tulare. **Please include a discussion of the following in this section:**
    - Future well permitting must be coordinated with the GSP to assure achievement of the Plan's sustainability goals.
    - How the well permitting process incorporates protection of GDEs within the Subbasin.
    - The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). **The need for well permitting programs to comply with this requirement should be stated in the text.**

<u>Checklist Items 5 to 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)</u>

[Section 3.1.7 Definable Bottom of the Basin (pp. 3-16 to 3-19)]

- The GSP uses two methods (Water Quality and Geologic) to define the bottom of the basin but which method, or combination of the methods, that is being relied on for this GSP is not clearly stated. **Please explicitly state the final decision on how the bottom of the basin was determined, and what it was determined to be.**

[4] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

- Defining the bottom of the Subbasin based on geochemical properties is a suitable approach for defining the base of freshwater, however, as noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** This will prevent the possibility of extractors with wells deeper than the basin boundary (defined by the base of freshwater) from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary. **Please characterize groundwater well extractions from the deepest wells in relation to defining the basin bottom**.

[Section 3.1.8 Hydrogeologic Setting: Principal Groundwater Aquifers and Aquitards (pp. 3-19 to 3-23)]

- Although there is robust description of the confined (lower) and unconfined / semi-confined (upper) aquifers there is no explicit description with supporting data and information of how groundwater above the A- and C-clays in the upper aquifer interacts with the unconfined aquifer, or is influenced by pumping in the unconfined portion of the upper aquifer. DWR's definition of a principal aquifer, is defined as an "aquifer or aquifer system that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems" [*23 CCR §351(aa)*]. These shallow and perched areas within the upper aquifer range from near surface to 30 feet below ground surface (bgs) (Figure 3-17, p. 3-74) and likely provide water supply to GDEs and ISWs. As such, they yield significant quantities of groundwater to surface water systems and beneficial users, and should not be dismissed because they do not yield groundwater for human use. **Please expand the description of the upper aquifer to include the interaction of the unconfined and shallow areas of the upper aquifer. Include cross-sections to show their connectivity and relationship to potential ISWs and GDEs.**
- Regional geologic cross sections are provided in Figures 3-14a, 3-14b and 3-14c (pp. 3-69 to 3-71). These cross-sections do not include a graphical representation of the shallow groundwater-bearing zones that may be connected to GDEs and ISWs in the GSP area, and how they are connected to the upper aquifer system. **Please include example near-surface cross section details that depict the conceptual understanding of shallow groundwater and stream interactions at different locations, including the shallow zones, any perched aquifers, and the unconfined / semi-confined upper aquifer**.
- Based on the information provided in the GSP, it appears that the confined lower aquifer is being considered a principal aquifer because of the large amount of consumption for agriculture and municipal water supply, but this is not explicitly stated. The unconfined / semi-confined aquifer is stated to have limited use because of water quality. On pages 3-18 and 3-19, there is a discussion of water quality and although water with TDS higher than 3,000 is not considered suitable for water supply or most agriculture, it is potentially suitable for livestock and production of crops with higher tolerance to salinity. Conversely, in Section 3.1.11 (pages 3-25

and 3-26), the GSP states that the upper aquifer is primarily used for domestic and municipal supplies, and agricultural pumping does occur in the deeper portion of the upper aquifer. Also, if water in the unconfined aquifer is significantly supporting GDEs and ISWs, production of salt tolerant crops, or livestock operations, then it should also be identified as a principal aquifer. Even if ultimately the GSA doesn't define shallow groundwater as a principal aquifer, the text indicates current or future use that could impact ISWs and GDEs. **Thus, disregarding this shallow groundwater as a principal aquifer due to its water quality is not supported by the data and is inadequate.** SGMA requires GSAs to sustainably manage groundwater resources in all aquifers, especially if groundwater use and management can result in impacts to beneficial uses and users. Please refer to Best Practice #1 in Attachment D for further explanation and accompanying graphics. **Please explicitly enumerate the principal aquifer(s) and intervening aquitards, their relationship to each other, and their role in supplying groundwater to all beneficial uses and users of groundwater (including environmental).**

[Section 3.2 Groundwater Conditions (pp. 3-26 to 3-28)]

- Groundwater elevation contours are shown for 1905-1907, 1952, 1990, 1995, 2000, 2005, 2010 and 2016 on Figures 3-24 through 3-27 with respect to mean sea level. However, the wells used to contour groundwater levels in the upper aquifer do not necessarily monitor shallow or perched groundwater that may be in communication with GDEs and ISWs. In addition, depth to groundwater cannot be readily assessed from the maps because they are presented with respect to sea level. **Please provide the following:**
    1) **Groundwater level contour maps representative of the uppermost aquifer where GDEs and ISWs may be reliant. If this data does not exist, then identify it as a data gap that will be addressed in the GSP when the GSP is updated.**
    2) **Depth to water contour maps that allow interpretation of beneficial groundwater uses by environmental users.**
    3) **If these data are not available, please identify this as a data gap and outline measures to address the data gap in subsequent sections of the GSP.**

[Section 3.2.5 Groundwater Quality (pp. 3-30 to 3-31)]

- There is water quality information for the upper aquifer and a statement that increases in TDS concentrations, arsenic, nitrate and volatile organic chemicals (VOCs) are largely due to agricultural practices and pumping, but there is no information regarding water quality of the perched water or other areas of the upper aquifer to understand how water quality may affect GDEs, ISWs and associated aquatic species. **Please modify this section of the GSP to include data about water quality in the zones where GDEs are present. If there are no data available, then please recognize this as a data gap and specify that additional data will be collected and analyzed for the GSP update.**

Checklist Items 8 to 10 – Interconnected Surface Waters (ISWs) (23 CCR §354.16)

[Figure 3.1.10 Groundwater Recharge and Discharge Areas (p. 3-25)]

- The text states that "Some discharge is impacted by direct soil evaporation and evapotranspiration, particularly in areas where groundwater is less than 10 feet bgs." Elsewhere the text states that agricultural drainage must be provided in some areas, indicating very shallow groundwater, or makes reference to deeper groundwater levels of about 30 feet for groundwater above the A-Clay. Earlier in this comment letter we pointed out the discrepancy between the various shallow groundwater levels that are presented (see Section 3.2 Groundwater Conditions [pp. 3-26 to 3-28]). This GSP also states that riparian and emergent marsh ecosystems are prevalent in certain areas where they have not already been degraded by land development. **Please 1) rectify the discrepancies in groundwater levels, particularly as they pertain to ISWs and GDEs; and 2) include the locations of phreatophytes and other GDEs to provide a complete representation of evapotranspiration within all groundwater discharge areas. If the regional groundwater connection of phreatophytes and other GDEs is not known, 1) please identify this data gap, 2) provide an approach to address it, and 3) include the ISWs and GDEs as potential features on a figure until they can be more conclusively evaluated.**

[Section 3.2.8 Interconnected Surface Water and Groundwater Systems (pp. 3-33 to 3-34)]

- The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. ISWs can be either gaining or losing. The GSP disregards IWSs by stating that hydrologic conditions have been so altered that the ISWs that were historically connected are not any longer. There are inconsistencies throughout this GSP in regard to ISWs. The GSP states:
    - Section 3.1.10 (p. 3-25, also see the comment directly above): "Groundwater recharge in the Subbasin occurs primarily by two methods: 1) infiltration of surface water from the Kings River and unlined conveyances; and 2) infiltration of applied water for irrigation of crops." **ISWs can be either gaining or losing (see the definition above). If recharge primarily occurs through infiltration from rivers and streams, then these features must be included as an ISW with gaining and losing reaches defined on a map.**
    - Section 3.2.8 (p. 34): "A persistent, shallow perched water table at a depth of about 30 feet bgs is often present above the A-clay in the vicinity of surface water conveyances and below recharge facilities; however, this shallow perched zone is disconnected from the regional unconfined aquifer. Other localized shallow perched zones may exist elsewhere in the Subbasin, but these are not considered a significant source of groundwater." Section 3.1.8

states (p. 3-21) that the perched water is as shallow as 15 feet in some areas, and the groundwater elevation contour maps show it ranging from 0-20 feet AMSL. Data to support the claims about the nature of the perched aquifers is conflicting and the claims that perched units are disconnected or insignificant are not supported by data. **Please clarify the discrepancy between groundwater depths reported for the shallow perched water table that are provided in the text and on figures. If the location and size of other shallow perched zones is unknown, this information needs to be identified as a data gap, rather than a reason to completely disregard the features.** It is inadequate to assume that shallow perched zones are not a significant source of groundwater if they have not been fully characterized, and could be a significant source for GDEs and ISWs. **Please reconcile data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP to improve identification of ISWs prior to disregarding them in the GSP.**

Checklist Items 11 to 15 – Identifying and Mapping GDEs (23 CCR §354.16)

[Section 3.2.8.1 Groundwater Dependent Ecosystems (GDEs) (p. 3-34 to 3-35)]

- The text states (p. 3-35): "Groundwater pumping from the principal aquifer system is not likely to impact the occurrence of perched groundwater because the two systems are separated by the A-Clay aquitard. Perched groundwater above the A-Clay is not directly interconnected with the underlying unconfined / semiconfined aquifer in that pumping from the unconfined / semiconfined aquifer does not induce increased leakage through the A-Clay aquitard." This statement is not supported by the data provided in the GSP (see comments above) and is not a valid reason to disregard potential GSPs without further evidence. The A-Clay is reported to vary significantly in thickness and to contain permeable sands in some locations. **Please:**
    1) **Explicitly identify the principal aquifers;**
    2) **Provide data regarding the competence of the A-Clay as an aquitard**
    3) **Evaluate the potential degree of connection between the perched and unconfined aquifer based on objective data;**
    4) **Acknowledge the extent of the perched aquifers throughout the Subbasin as a data gap;**
    5) **Address data gaps associated with the interconnectivity with the unconfined / semiconfined aquifer to be reconciled in the GSP update; and**
    6) **Acknowledge the potential for GDEs and ISWs to be dependent on these groundwater resources.**
- Although this GSP did use the NCCAG database to preliminarily identify GDEs (p. 3-34), all were disregarded without acknowledgment of data gaps and further characterization of the natural communities in association with potential perched aquifers, and disparities in groundwater levels that have not yet been characterized. This evaluation potentially misses GDEs due to the potential for GDEs to utilize the

shallow and perched areas of the unconfined / semi-confined aquifer. The following comments apply:

- While depth to groundwater levels within 30 feet are generally accepted as being a proxy for deciding if polygons in the NC dataset are connected to groundwater, it is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time or during a discrete season can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Based on a study we recently submitted to *Frontiers in Environmental Science*, we've observed riparian forests along the Cosumnes River to experience a range in groundwater levels between 1.5 and 75 feet over seasonal and interannual timescales. Seasonal fluctuations in the regional water table can support perched groundwater near an intermittent river that seasonally runs dry due to such fluctuations. While perched groundwater itself cannot directly be managed due to its position in the vadose zone, the water table position within the regional aquifer (via pumping rate restrictions, restricted pumping at certain depths, restricted pumping around GDEs, well density rules, etc.) and its interactions with surface water (e.g., timing and duration) can be managed to prevent adverse impacts to ecosystems due to changes in groundwater quality and quantity under SGMA. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset seasonally and interannually, or to determine conclusively whether shallow groundwater is hydraulically connected (directly or indirectly) to underlying aquifers, include those polygons in the GSP until data gaps are reconciled in the monitoring network, and include specific measures and time tables to address the data gaps.**
- If there are insufficient groundwater level data in the shallow and perched zones, then the NCCAGs in these areas should be included as GDEs in the GSP until data gaps are reconciled in the monitoring network. **Confirmation of GDEs should be based on depth to groundwater in the shallow and perched areas. Please revise the GDE analysis in the GSP to include a complete analysis and identification of data gaps.**
- **Please provide depth to groundwater contour maps and note the following best practices for doing so:**
  - Are the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons to reflect local conditions relevant to ecosystems?

- Are the wells used for interpolating depth to groundwater screened within the surficial unconfined aquifer and capable of measuring the true water table?
- Is depth to groundwater contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to contour depth to groundwater.

o Groundwater requirements of GDEs vary with vegetation types and rooting depths. In identifying GDEs, care should be taken to consider rooting depths of vegetation. **Please indicate what vegetation is present in the potential GDEs, and whether the GDE was eliminated or retained based solely on a specified depth limit.** While Valley Oak (*Quercus lobata*) have been observed to have a maximum rooting depth of ~24 feet (https://groundwaterresourcehub.org/gde-tools/gde-rooting-depths-database-for-gdes/), rooting depths vary spatially and temporally based on local hydrologic conditions. Also, maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence effectively redistribute their root systems to straddle the water table as it fluctuates. Hence, many riparian, floodplain and desert ecosystem species are highly capable of accessing groundwater at much deeper depths when needed.

o Rohde, Froend and Howard (2017) acknowledged GDEs as ecosystems that can rely on groundwater for some or all their requirements. This publication can be found at: https://ngwa.onlinelibrary.wiley.com/doi/pdf/10.1111/gwat.12511. GDEs can rely on multiple water sources simultaneously and at different temporal and / or spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow). SGMA (Section 351.0) defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface". **Hence, we recommend using depth to groundwater contour maps derived from subtracting groundwater levels from a DEM, as described above, to identify whether a connection to groundwater exists for the wetlands mapped in Figure 3-38 in the Subbasin.**

Please refer to Attachments D and E of this letter for best practices for using local groundwater data to 1) verify whether polygons in the NC Dataset are supported by groundwater in an aquifer, and 2) verify ecosystem decline or recovery is correlated with groundwater levels.

- The GSP states (p. 3-35), "Most of these vegetation types/plant species [identified in the NCCGA] are associated with riparian habitat that rely on surface water", and goes on to disregard them because they are primarily located on the perched areas above the A-Clay layer and the " A-Clay is not directly interconnected with the underlying unconfined / semi-confined aquifer". Section 354.16 of the California Code of Regulations states that "each Plan shall provide a description of current and historical groundwater conditions in the basin, including data from January 1, 2015, to current conditions, based on the best available information that includes…GDEs". Just because GDEs are thought to rely on surface water and the perched areas are thought to not be directly connected to the unconfined aquifer, does not make them insignificant to the environment. Many data gaps exist that could clarify these statements, for example: 1) indirect and direct connection of perched aquifers have not been fully characterized, 2) the location and extent of perched areas have not been fully characterized, and 3) species composition and potential max rooting depths have not be tabulated. Many rare and protected species reside in GDEs since they are very unique ecosystems. **Please provide further information on the analysis of GDEs and potential ISWs, including citing field studies or modeling studies that show the hydrologic nature of these systems. Specifically indicate 1) which streams and GDE polygons were excluded, 2) identify any data gaps, and 3) ensure that GDE polygons are retained until data gaps are reconciled.**

Checklist Items 16 to 20 - Describing GDEs (23 CCR §354.16)

[Section 3.2.8.1 Groundwater Dependent Ecosystems (GDEs) (p. 3-34 to 3-35)]

- **Please provide information on the historical or current groundwater conditions specifically near the GDEs or the ecological conditions present**. **If data gaps exist, please acknowledge them and state how they may be reconciled in the future.** Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data (e.g., leaf area index, evapotranspiration or other data) to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the Tulare Lake GSP Area.

- **Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes vegetation or habitat types and rank the GDEs as having a high, moderate or low value. Explain how each rank was characterized.**
- **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs since some organisms rely on uplands and wetlands during different stages of their lifecycle**. Resources for this include the list of freshwater species located in the Subbasin that can be found in Attachment C of this letter, the Critical Species Lookbook, and the USFWS's ECOS and CDFW's CNDDB databases / mapping tools.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 3.3.1.2 Outflows (pp. 3-39 to 3-40)]

- Evapotranspiration (ET) is included as an outflow category in the water budget; however, it is only included as it pertains to crop water requirements. Groundwater outflow to the ET of natural ecosystems (i.e., GDEs, riparian areas, etc.) should be identified as a groundwater budget component. If the outflow is not known, it should be identified as a data gap and provisional information should be provided until an analysis can be performed to address the data gap. **Since natural ecosystems may be beneficial users of groundwater: 1) please provide a breakdown of ET for all land-cover types, including native and riparian vegetation (such as wetlands, riparian vegetation, phreatophytes and other communities); 2) identify any data gaps; 3) outline the actions needed to address them; 4) and the schedule for their implementation.**

Checklist Item 23-26 Sustainability Goal (23 CCR §354.24)

[Section 4.0 Sustainable Management Criteria (p. 4-1)]

- The GSP states that there is no ISW connectivity within the entire Subbasin, but data to support this broad assertion are insufficient to dismiss this sustainability indicator. It is acknowledged earlier in the GSP that recharge primarily occurs through surface streams / rivers and unlined canals; however, there isn't any quantitative analysis, monitoring data, or other information provided to support that ISWs are not present, and statements within the GSP are contradictory. **Please address ISWs in the Sustainable Management Criteria and the Sustainability Goal until sufficient data is available to conclude the status of ISWs.**
- The GSP states "Indicators for the sustainable management of groundwater were determined by SGMA based on factors that have the potential to impact the health and general well-being of the public." This chapter starts off by disregarding the environmental use and users of groundwater. Sweeping statements like this should be modified throughout the chapter to acknowledge all beneficial users. **Since GDEs and ISWs may be present in and near the GSP area due to the prevalence of shallow groundwater (please see comments under Checklist Items 16-20) they should be explicitly recognized in the establishment of sustainable management criteria for the groundwater level decline and ISW sustainability indicators. Please also update this section to recognize environmental beneficial groundwater uses as a component of the sustainable management goals.**

[Section 4.1 Sustainability Goal (pp. 4-1 to 4-3)]

- The Sustainability Goal states that "…the sustainability goal works as a tool for managing groundwater, basin-wide, on a long-term basis to protect quality of life through the continuation of existing economic industries in the area, including but not limited to agriculture". The overall theme is to protect groundwater resources for developed water users, particularly agriculture. **The narrative discussion of the sustainability goal should be expanded to include other beneficial uses and users of groundwater including environmental uses and users of groundwater.**
- The Discussion of Measures states that "management actions will be implemented to help mitigate overdraft based on the demand from beneficial uses and users", but developed users are the only parties identified in this chapter. Criteria used to evaluate the priority given to beneficial users during overdraft periods is not described. **Please update this section to provide a discussion of how human and environmental beneficial uses will be balanced in the implementation of management actions during periods of drought and overdraft.**
- **Since GDEs and ISWs may be present in the Subbasin (please see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal and Discussion of Measures. In addition, a statement about any intention to address pre-SGMA impacts should be included.**

- GDEs are dependent, in part, on suitable water quality; however, the GSP focuses on subsidence, groundwater levels and changes in groundwater storage; and only considers water quality for irrigation and domestic use. **Given that there are potential GDEs and ISWs in the Subbasin, and they may be affected by water quality they should be included in the Sustainability Goal and addressed in the Sustainable Management Criteria established for the Water Quality Sustainability Indicator.**

[Section 4.2.4 Groundwater Quality Indicator (pp. 4-5 to 4-6)]

- The GSP states that the GSAs will rely on the existing programs in place for monitoring groundwater quality, and the "local GSAs will focus on water quality issues that are related to groundwater pumping rather than on issues related to contamination". However, since much of the groundwater is being used for irrigation, which then leaches back into the soil or drains elsewhere and carries nutrients and other solutes with it, the GSA should monitor constituents related to agriculture in addition to those related to pumping, such as arsenic. This includes nitrates, phosphates, salts, sodium, boron, chloride and acidification from carbonic acid which affects soil biota, structure, geochemistry, GDEs and ISWs. **Please consider revising this section to include monitoring for agricultural constituents.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Section 4.5 Measurable Objectives (pp. 4-18 to 4-20)]

- This Measurable Objectives do not consider the water quality needs of GDEs and ISWs. **Please modify this section to include impacts from degraded water quality on the plant and wildlife communities, and species they support within these habitats**.
- This GSP states that "ISWs do not exist within the Subbasin". However, this conclusion was based on well groundwater levels that are not reasonably close to the drainages, shallow or nested monitoring wells to assess potential interaction with surface water and GDEs and connectivity to underlying aquifers, or hydrogeologic data that does not fully characterize the location and extent of perched and shallow zones within the upper aquifer. In addition, there are no supporting data and information that demonstrates shallow groundwater near the streams and rivers is not supporting ISWs or GDEs. As such, the data are insufficient to dismiss this sustainability indicator under the GSP regulations. **Please modify this section of the GSP to retain ISWs as a sustainability indicator, pending the characterization of the shallow / perched zones and analysis of monitoring data or monitoring from additional wells to be installed in the future.**
- Since there are wildlife refuges and protected wildlife area that contain critical habitat directly adjacent to the GSP area, the GSP needs to address these areas, whether there are potential GDEs or ISWs, and how management actions within the Subbasin would affect these sensitive habitats. **Please explain how the measurable objectives will benefit adjacent subbasins and not hinder the**

ability of adjacent subbasins to be sustainable; and how the measurable objectives would benefit adjacent critical habitat areas. What are the mechanisms for this benefit?

- Sweeping statements, such as (p. 4-20) "interconnected surface waters do not exist within the Subbasin, so this indicator will not be further discussed in terms of Measurable Objectives" are completely dismissive with disregard for data gaps. There is not enough evidence to make statements like these. Many of the wells are screened too deep, not in the proper location to make comparisons, and / or nested wells have not been installed to inform how shallow groundwater interacts with potential ISWs, GDEs or the unconfined aquifer. **Please include all potential ISWs in the analysis and develop measurable objectives and minimum thresholds for these, to be managed until data gaps prove they are not interconnected.**

Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28)

[Section 4.4.1.2 Description of Minimum Thresholds and Processes to Establish [for Groundwater Level Indicator (p. 4-13), Section 4.4.1.4 Description of Minimum Thresholds and Processes to Establish [for Groundwater Quality Indicator (p. 4-14), and Section 4.4.1.5 Description of Minimum Thresholds and Processes to Establish [for Interconnected Surface Water Intrusion (p. 4-14)]

- These Minimum Thresholds do not consider GDEs and ISWs. **Please include GDEs (see comments under checklist items 8-20) in this section and whether the minimum thresholds and interim milestones will help achieve the potential sustainability goal as it pertains to the environment.**
- Section 4.4.1.5 (p. 4-14) states that "Interconnected surfaces waters are not considered present in the Subbasin are; therefore, no further discussion will occur on this indictor in terms of MTs". However, the GSP fails to provide any monitoring data, analysis or other information to substantiate this position. Based on the inconsistencies in groundwater levels presented previously in the GSP and this letter, and the unknowns associated with the extent and location of shallow and/or perched zones in the upper aquifer, it is possible that rivers, streams and GDEs may be hydraulically connected to the regional aquifer system. Minimum thresholds must be established for ISWs and GDEs unless and until sufficient data are provided to eliminate them from consideration. **Please modify this section of the GSP to 1) develop minimum thresholds for possible ISWs, including GDEs, and 2) include a statement that a data gap exists related to the interconnectedness of the of the Tulare Lakebed, rivers / streams, and shallow groundwater zones.**

[Section 4.4.4 Potential Effects to Beneficial Uses and Users (p. 4-17 to 4-18)]

- The evaluation of minimum thresholds completely disregards consideration of environmental beneficial users, such as ISWs, GDEs or the species they support. Effects to beneficial uses and users is focused on well capacity, pumping costs, extraction, and impacts from subsidence on infrastructure. There is no mention about potential impacts to GDEs or ISWs that could be affected by lowering of the

shallow portions of the unconfined or semi-confined portions of the upper aquifer since a continuity / discontinuity between the two is a data gap. Although there are many data gaps associated with ISWs and GDEs, it must be assumed that potential significant and unreasonable impacts to these beneficial users could occur. As such, they should be addressed in the evaluation of minimum thresholds. Section 4.4.4 should be modified to address how potential ISWs and GDEs would be affected by further lowering of groundwater levels. **Please address how 1) potential ISWs and GDEs would be affected by further lowering of groundwater levels, 2) these beneficial users will be protected / managed in the interim until data gaps are filled, and 3) what measures will be employed to protect GDEs and ISWs that are confirmed after data gaps are filled.**

- This Section does not include the required analysis of how the selected minimum thresholds for decline in groundwater levels could affect potential ISWs and GDEs within and near the GSP area. **Please include an analysis of the potential effect of the established minimum thresholds on ISWs and GDES within and near the GSP area, particularly in adjacent wildlife preserves / refuges.**
- Although agricultural and domestic water quality concerns have been articulated, similar concerns were not identified for environmental users. Degradation of water quality can impact terrestrial and aquatic wildlife that live in or near these ecosystems during at least part of the year even if the water is not a concern from an agricultural or municipal standpoint. **Please include a discussion about GDEs and water quality and whether the minimum thresholds and interim milestones will help achieve sustainability for environmental users.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 4.3 Undesirable Results (pp. 4-6 to 4-12), and Subsection 4.3.3 Potential Effects to Beneficial Uses and Users (pp. 4-11 to 4-12)]

- The GSP states that there are no ISWs; however, this is largely based on assumptions and there are no monitoring data, analyses or other information to support this statement. In addition, the GSP indicates that 1) streams and rivers are the primary source of recharge; 2) a connection may exist between shallow and perched groundwater, but the extent and location of perched groundwater is unknown; and 3) surface and groundwater may be periodically connected in Tulare Lake. Furthermore, GDEs may exist within and near the GSP area. This is a data gap that needs to be identified and rectified by employing a monitoring network to verify the status of ISWs prior to complete dismissal of ISWs from the GSP. **Please modify this section of the GSP to include:**
    1) **A statement that there are potential ISWs and GDEs, unless adequate data can be provided to dismiss them.**
    2) **An assessment of the nature of potential undesirable results to ISWs and GDEs.**
    3) **A statement that the aquifers will be managed such there will be no depletion of ISWs that results in a significant and unreasonable impacts to ISWs or GDEs.**

4) **Data gaps and specific steps to verify the presence or absence of ISWs and GDEs with monitoring wells screened at the appropriate depths.**

- This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses / users that could be adversely affected by chronic groundwater level decline or depletion of ISWs. **Please add "possible adverse impacts to potential GDEs and ISWs" to the list of potential undesirable results.**
- The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within and near the GSA. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture. An example screen shot of GDEs near Lemoore, California from the GDE Pulse tool is presented under Checklist items 16 to 20 above.
    - **For each potential GDE unit with supporting hydrological datasets please include the following:**
        - Plot and provide hydrological datasets for each GDE.
        - Define the baseline period in the hydrologic data.
        - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater.
        - Explore cause-and-effect relationships between groundwater changes and GDEs.
    - **For each identifiable GDE unit without supporting hydrological datasets please describe data gaps and / or insufficiencies.**
    - **Compile and synthesize biological data from CDFW's CNDDB, USFWS' ECOS Mapper, NC dataset, and / or the GDE Pulse tool (as applicable) for each GDE unit by:**
        - Characterizing biological resources for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.
        - Describing data gaps / insufficiencies.
    - **Describe possible effects on potential ISWs, GDEs, land uses, and property interests, including:**
        - Cause-and-effect relationships between potential ISWs and GDEs with groundwater conditions.
        - Impacts to potential ISWs and GDEs that are considered to be "significant and unreasonable".
        - Report known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities.
        - Land uses should include recreational uses (e.g., fishing/hunting, hiking, boating).
        - Property interests should include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.

- This section discusses water quality with respect to agricultural and municipal use but does not include a discussion of potential undesirable results for GDEs and ISWs. **Please modify this section to address how degraded water quality could affect vegetation and wildlife species that rely on GDEs and ISWs. Although arsenic is mentioned in this GSP, please consider adding a statement that over-pumping and dewatering of aquitards has been identified as a potential source of elevated arsenic concentrations above drinking water standards in San Joaquin Valley aquifers.** The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": https://www.nature.com/articles/s41467-018-04475-3

Checklist Items 47-49 – Monitoring Network (23 CCR §354.34)

[Chapter 5 Monitoring Network (pp. 5-1 to 5-3), and Section 5.1 Description of Monitoring Network (pp. 5-3 to 5-15)]

- The GSP describes groundwater monitoring locations and states that groundwater monitoring in areas de-designated by the Tulare Lake Basin Plan amendment and associated aquifer zones is not proposed as decided by the GSAs. Although these areas (designated Management Area A and B) are not designated for municipal and agricultural uses in the Basin Plan, the groundwater could still potentially be used or is being used for livestock, crops with a higher tolerance to salt, domestic supply, public supply, and potentially other uses in the future. Since it is currently unclear how withdrawals within the unconfined aquifer will affect the perched and shallow areas of the aquifer (as associated with the A-Clay and C-Clay layers), Management Areas A and B still need to be monitored to assess effects to the unconfined aquifer as a whole. As stated above in the comments for other Checklist Items, **please reconcile data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells, GDE and ISW responses to groundwater levels) along rivers, creek and the Tulare Lakebed in this section of the GSP to improve ISW and GDE mapping in future GSPs**.
- It is not acceptable to completely disregard these Management Areas based purely on a de-designation from municipal and agricultural uses only when there are still current and potential environmental uses of this groundwater. In addition, there is much uncertainty how the shallow aquifers are interacting with GDEs and ISWs. **Please add Representative Monitoring Sites (RMS) for these areas in order to better understand the interaction of the A-Clay and C-Clay layers with the unconfined aquifer, and potential GDEs and ISWs.**
- This section lists the proposed facilities for monitoring groundwater levels, storage and quality, and subsidence on pp. 5-9 through 5-15. This section proposes to use groundwater level monitoring to assess potential groundwater level and storage declines, existing programs to monitor water quality, and monitored surface conditions to evaluate land subsidence. It may acceptable to use groundwater level [in combination with assessment of vegetation response, for example by remote sensing] as a proxy for assessing potential effects on ISWs and GDEs, but the data gaps associated with the A-Clay, C-Clay, and shallow water tables need to be addressed. A set of representative wells have been selected to monitor the upper

and lower aquifer (Figures 5-1 to 5-3). There are only five wells that represent the "Above A-Clay and Shallow Groundwater Levels (i.e., Zone A)", and there are three data gaps areas identified (Figure 5-1). **Please describe 1) how these five wells are considered representative of the entire GSP Area, 2) how those data gap areas were selected, and 3) what methodologies would be used to extrapolate results to other areas where there are no wells or identified data gaps.**

- Many of the monitoring wells are not screened in the upper portion of the unconfined aquifer, where environmental beneficial users would obtain the groundwater on which they rely. Finally, there are currently no plans to monitor groundwater level declines to assess the potential for significant and unreasonable impacts to ISWs or GDEs in response to groundwater level declines. **Please modify the description of the new well network in the Proposed Facilities Section (Sections 5.1.4, p. 5-9) and Groundwater Levels Section (Section 5.1.4, p.5-9 to 5-11) to provide methodologies, data and other information to support the monitoring of GDEs and ISWs so as to assess and prevent potential significant and unreasonable impacts. This modification should include 1) locating new wells that are appropriately screened to detect connectivity of GDEs and ISWs with the unconfined aquifer and 2) identifying or installing additional stream gages in areas where there is potential for ISWs and GDEs. In addition, monitoring GDE responses to groundwater level declines should be included. GDE Pulse represents an example of how remote sensing can be used to achieve this objective. Please expand on the discussion of how the new well, stream and other data will be used to improve ISW mapping and inform an adequate analysis, and how the data will be used to verify possible GDEs and their sensitivity to groundwater level declines.**

[Section 5.1.1 Monitoring Network Objectives (p. 5-6)]

- The monitoring objectives listed include developing data to evaluate impacts to beneficial uses and users of groundwater but does not include filling data gaps as they specifically pertain to environmental users of groundwater. **Please expand this list to include monitoring to inform data gaps associated with groundwater use by potential GDEs, ISWs and the species that they support.**

[Section 5.4.1.4 Site Selection (p. 5-23)]

- This section includes the scientific rationale for the groundwater level monitoring network and the rationale used to add new wells to the monitoring system. However, evaluation and monitoring of potential GDEs and ISWs were not considered in new well site selection. **Please modify the site selection criteria to include the potential to install new wells that will provide information to support the investigation of GDEs and ISWs. This modification should include locating new / existing wells that are appropriately screened to detect connectivity of GDEs and ISWs with the shallow zones of the unconfined**

aquifer, and 2) expanding information on the extent and location of shallow / perched areas within the unconfined aquifer.

[Section 5.5 Data Storage and Reporting (pp. 5-31 to 5-32)]

- The data management system (DMS) described in this section allows for upload and storage of information related to the development and implementation of the GSP. The types of information that will be stored in the DMS are listed. Other than groundwater elevations, quality, and site information, there is no information being stored specific to the monitoring and evaluation of GDEs or ISWs. **We recommend adding remote sensing information to this list to evaluate possible correlations of ecosystem response to potential declines in groundwater level or quality due to pumping. This can be accomplished by incorporating the GDE pulse tool, Sentinel data, evapotranspiration, or leaf area index.**

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Chapter 6 Projects and Management Actions to Achieve Sustainability (pp. 6-1 to 6-21)]

- **This chapter should identify the specific actions and schedules proposed to address data gaps in the hydrogeologic conceptual model, water budget and monitoring network.**

[Section 6.3 Projects (pp. 6-4 to 6-17)]

- This section identifies many important types of projects, including conveyance facilities modifications and construction of new facilities, above-ground surface water storage, intentional recharge basins, on-farm recharge, and aquifer storage and recovery through injection. However, the descriptions of Measurable Objectives for these projects only identifies benefits to water level and storage through changes in allocation, imports, surface water diversions, pumping allowances; and adding recharge projects or water banking. Since maintenance or recovery of groundwater levels, or construction of recharge facilities, may have potential environmental benefits it would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.
    - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
    - If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting potential ISWs.**
    - Storage and recharge projects can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local HCPs and NCCPs, more fully recognizing the value of the habitat that they provide and the species they support. On-farm recharge may benefit waterfowl during migration, and recreational hunting and birdwatching depending on the time of year that fields are flooded. For

recharge projects, **please consider identifying if there is habitat value incorporated into the design and how the recharge ponds can be managed as multiple-benefit projects to benefit environmental users. Grant and funding opportunities for SGMA-related work may be available for multi-benefit projects that can address water quantity as well as provide environmental benefits. Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

- The GSP states that recharged water typically remains in the unconfined aquifer, above the A-Clay, C-Clay and E-Clay; and that existing wells in the area will be used for extraction of stored water. There appear to be many unknowns as to the extent and location of perched and shallow areas in the unconfined aquifer, and the connectivity of those areas with the aquifer. In addition, there are currently only five wells that will be used to monitor shallow zones throughout the entire GSP area. There remains a fair amount of uncertainty as to how this would operate or affect potential GDEs and ISWs. **Please acknowledge these uncertainties and address 1) how these recharge operations could affect environmental beneficial users, 2) how ecosystems that could be affected by recharge in the unconfined aquifer, particularly above the A- and C-Clay layers will be monitored if there are only five wells.**
- For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 6.5 GSA Sustainable Methods (pp. 6-18 to 6-21)]

- The Subbasin potentially includes GDEs and ISWs (see our comments under Checklist Items 8-10 and 16-20 above) that are beneficial uses and users of groundwater and may include sensitive and protected resources. Protection of these environmental users and uses should be considered in establishing project priorities. In addition, and consistent with existing grant and funding guidelines for SGMA-related work, **priority should be given to multi-benefit projects that can address water quantity and quality as well as providing environmental benefits or benefits to disadvantaged communities.**

Attachment C

Freshwater Species Located in the Tulare Lake Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located within the Tulare Lake Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[5]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[6] as well as on TNC's science website[7].

		Legally Protected Status		
Scientific Name	**Common Name**	**Federal**	**State**	**Other**
BIRDS				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	BCC	SSC	BSSC - First priority, BLM
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail

IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[8] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[9]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

[8] *NC Dataset Online Viewer:* https://gis.water.ca.gov/app/NCDatasetViewer/

[9] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[10]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[11] on the Groundwater Resource Hub[12], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

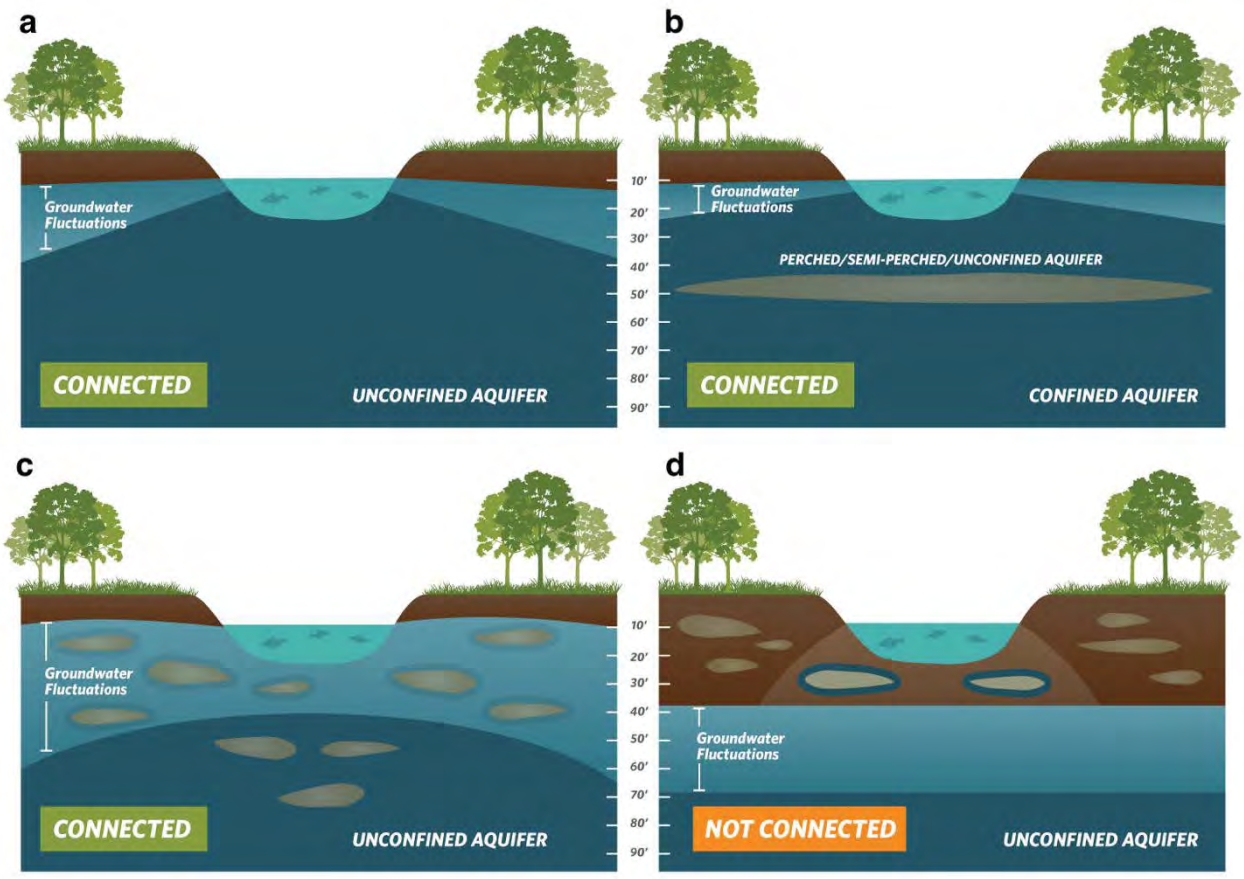

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[13] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[14] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[15] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[16]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

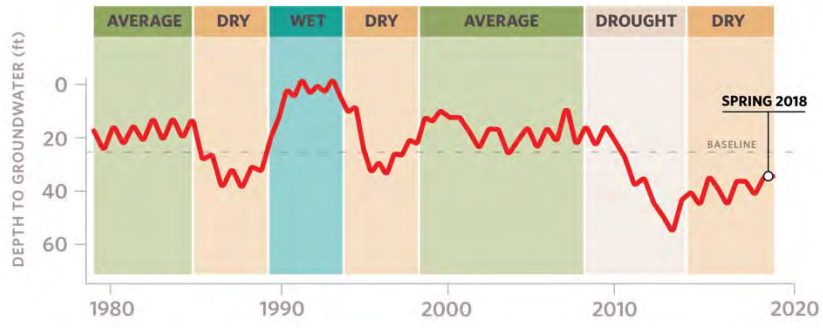

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[13] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[14] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[15] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[16] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[17], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

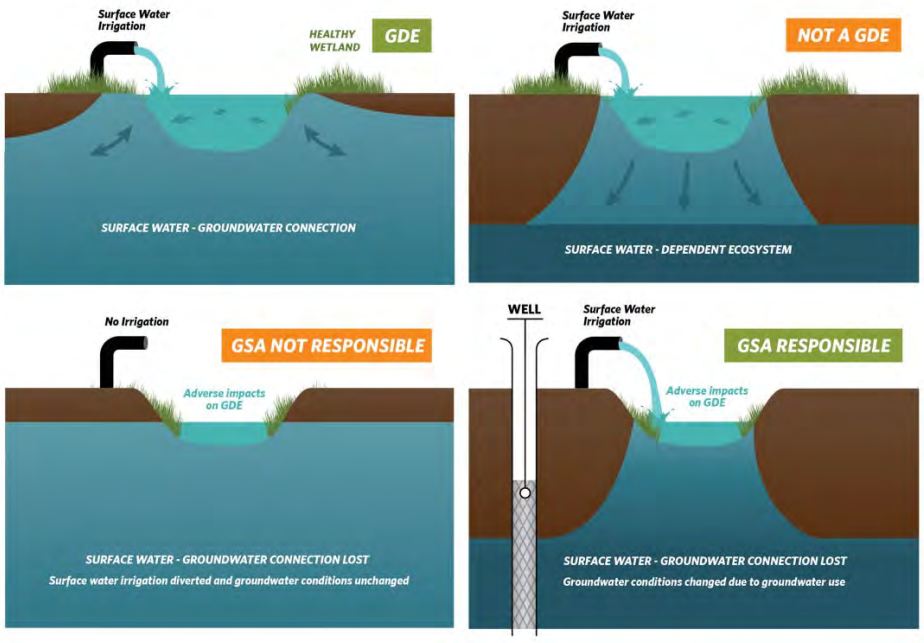

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[17] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

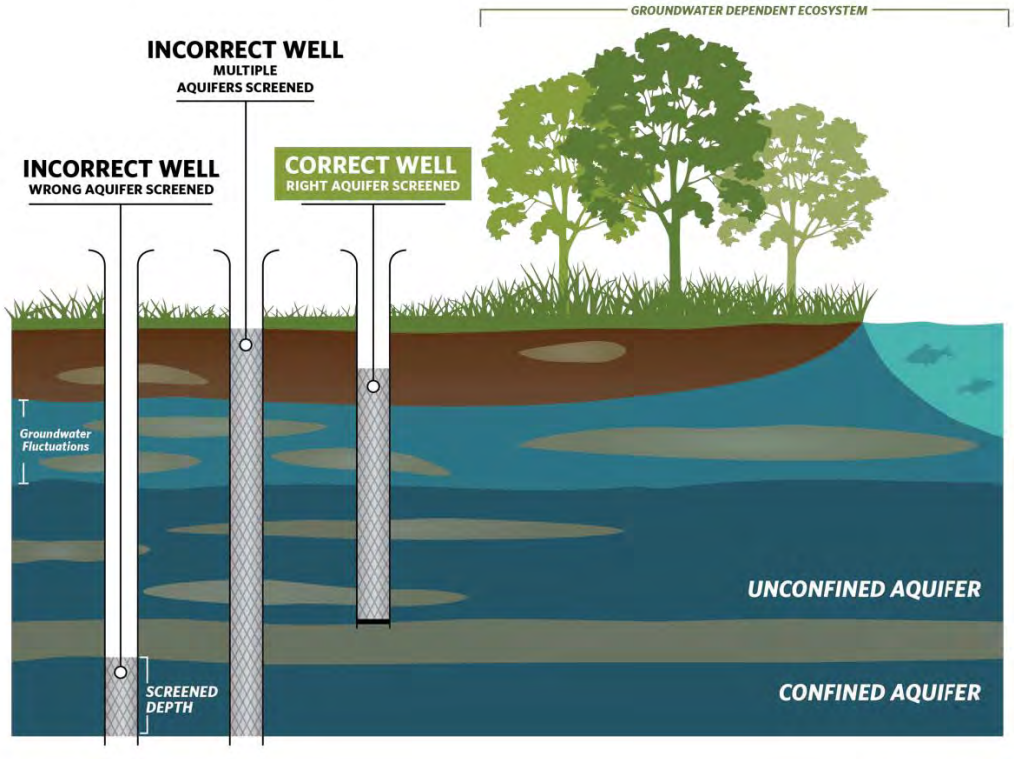

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[18] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

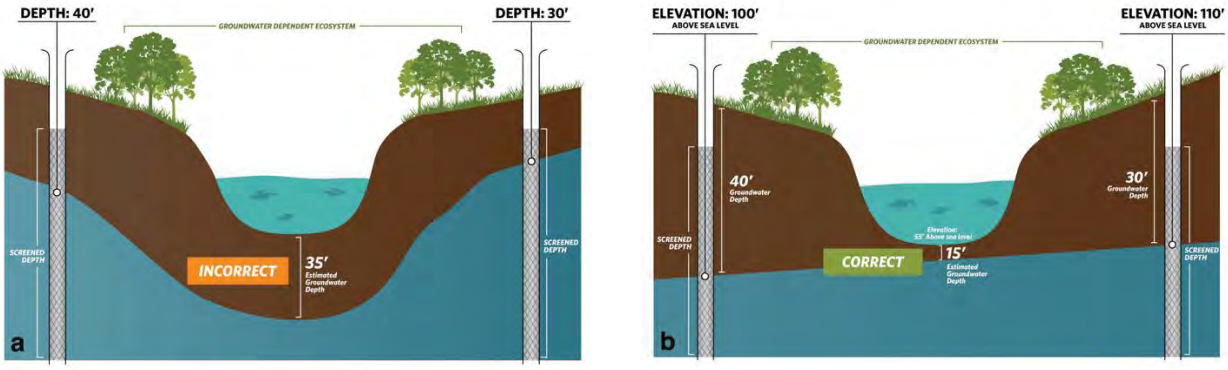

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

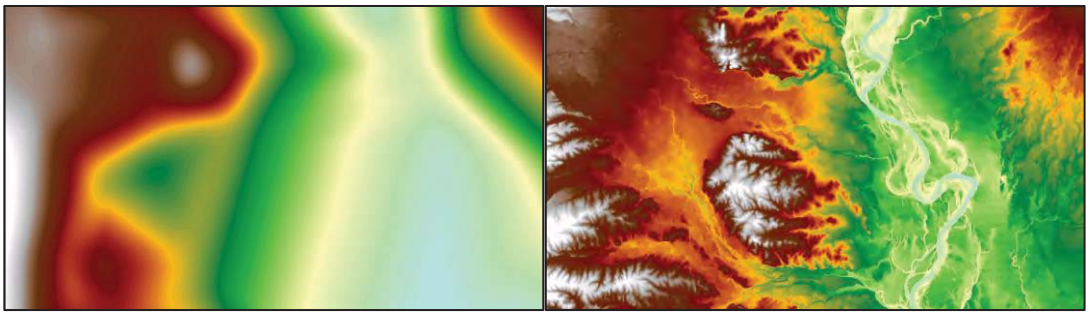

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[18] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[19]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[20]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Re: Tulare Lake Subbasin GSP

Dear Board Members:

The California Poultry Federation ("CPF") appreciates the opportunity to comment on the draft Tulare Lake Subbasin Groundwater Sustainability Plan (the "Draft GSP"). CPF is the trade association for California's diverse and dynamic poultry industry. Our members include growers, hatchers, breeders, and processors that work with chickens, turkeys, ducks, game birds, and squab. Water is essential for all of them—both for nutrition and for maintaining sanitary conditions. CPF therefore supports effective measures to assure reliable water supplies.

In this regard, CPF recommends that each Tulare Lake Subbasin Groundwater Sustainability Agency ("GSA") make supply augmentation its top priority. We were encouraged to see that the Draft GSP incorporated storage, recharge, and conveyance projects and that Table 7-1 listed consideration of incentives as a means of encouraging participation in augmentation. Additional extraction rights in particular would be an excellent method of increasing landowner support for supply projects.

But we are concerned that the Draft GSP also emphasized substantial demand management without explaining precisely how that would be done. The listed management actions are "conceptual" (Draft GSP page 6-2) and Appendix E, which is to contain GSA appendices, is blank. Nor does the Draft GSP appear to set out any principles—which should include minimizing economic impact, maintaining established water rights, and incentivizing investment in water supply infrastructure—for developing demand management measures. The public will need to have meaningful opportunities to participate in the development of any specific demand management measures, which means that there must be sufficient time to evaluate supporting information and submit written comments. That is especially important in light of the finding (at Draft GSP page 7-7) that "[a]t this time there is not sufficient information to develop a financial

EXECUTIVE COMMITTEE MEMBERS AND OFFICERS

BILL MATTOS, CALIFORNIA POULTRY FEDERATION - PRESIDENT

impact due to demand reduction." CPF expects all the Subbasin GSAs to do their best to ameliorate economic impacts by adopting implementation measures that are cost-effective.

One other point about public comment deserves mention. It was difficult to ascertain when written comments on the Draft GSP were due and where they should be sent. The Subbasin GSAs should establish, utilize, and publicize one central clearinghouse available through the Internet for disseminating information about further proposed actions in the Subbasin and receiving written comments.

Please contact me if you need any further information about these comments.

Very truly yours,

Bill Mattos

Re: Comments on Draft Groundwater Sustainability Plan for Tri County Water Authority Tulare Lake Groundwater Basin

To Whom It May Concern,

On behalf of the above-listed organizations, we would like to offer the attached comments on the draft Groundwater Sustainability Plan for the Tri County Water Authority Tulare Lake Groundwater Basin. Our organizations are deeply engaged in and committed to the successful implementation of the Sustainable Groundwater Management Act (SGMA) because we understand that groundwater is a critical piece of a resilient California water portfolio, particularly in light of our changing climate. Because California's water and economy are interconnected, the sustainable management of each basin is of interest to both local communities and the state as a whole. This letter adopts by reference the comments and recommendations submitted by The Nature Conservancy on this draft plan.

Our organizations have significant expertise in the environmental needs of groundwater and the needs of disadvantaged communities.

- The Nature Conservancy, in collaboration with state agencies, has developed several tools[1] for identifying groundwater dependent ecosystems in every SGMA groundwater basin and has made that tool available to each Groundwater Sustainability Agency.
- Local Government Commission supports leadership development, performs community engagement, and provides technical assistance dealing with groundwater management and other resilience-related topics at the local and regional scales; we provide guidance and resources for statewide applicability to the communities and GSAs we are working with directly in multiple groundwater basins.
- Audubon California is an expert in understanding wetlands and their role in groundwater recharge and applying conservation science to develop multiple-benefit solutions for sustainable groundwater management.
- Clean Water Action and Clean Water Fund are sister organizations that have deep expertise in the provision of safe drinking water, particularly in California's small disadvantaged communities, and co-authored a report on public and stakeholder engagement in SGMA[2].

[1] https://groundwaterresourcehub.org/

[2] https://www.cleanwater.org/publications/collaborating-success-stakeholder-engagement-sustainable-groundwater-management-act

Because of the number of draft plans being released and our interest in reviewing every plan, we have identified key plan elements that are necessary to ensure that each plan adequately addresses essential requirements of SGMA. A summary review of your plan using our evaluation framework is attached to this letter as Appendix A. Our hope is that you can use our feedback to improve your plan before it is submitted in January 2020.

This review does not look at data quality but instead looks at how data was presented and used to identify and address the needs of disadvantaged communities (DACs), drinking water and the environment. In addition to informing individual groundwater sustainability agencies of our analysis, we plan to aggregate the results of our reviews to identify trends in GSP development, compare plans and determine which basins may require greater attention from our organizations.

Key Indicators

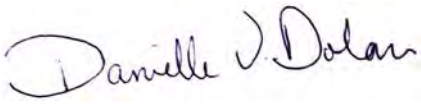
Appendix A provides a list of the questions we posed, how the draft plan responds to those questions and an evaluation by element of major issues with the plan. Below is a summary by element of the questions used to evaluate the plan.

1. Identification of Beneficial Users. This element is meant to ascertain whether and how DACs and groundwater-dependent ecosystems (GDEs) were identified, what standards and guidance were used to determine groundwater quality conditions and establish minimum thresholds for groundwater quality, and how environmental beneficial users and stakeholders were engaged through the development of the draft plan.
2. Communications plan. This element looks at the sufficiency of the communications plan in identifying ongoing stakeholder engagement during plan implementation, explicit information about how DACs were engaged in the planning process and how stakeholder input was incorporated into the GSP process and decision-making.
3. Maps related to Key Beneficial Uses. This element looks for maps related to drinking water users, including the density, location and depths of public supply and domestic wells; maps of GDE and interconnected surface waters with gaining and losing reaches; and monitoring networks.
4. Water Budgets. This element looks at how climate change is explicitly incorporated into current and future water budgets; how demands from urban and domestic water users were incorporated; and whether the historic, current and future water demands of native vegetation and wetlands are included in the budget.
5. Management areas and Monitoring Network. This element looks at where, why and how management areas are established, as well what data gaps have been identified and how the plan addresses those gaps.
6. Measurable Objectives and Undesirable Results. This element evaluates whether the plan explicitly considers the impacts on DACs, GDEs and environmental beneficial users in the development of Undesirable Results and Measurable Objectives. In addition, it examines whether stakeholder input was solicited from these beneficial users during the development of those metrics.
7. Management Actions and Costs. This element looks at how identified management actions impact DACs, GDEs and interconnected surface water bodies; whether mitigation for impacts to DACs is discussed or funded; and what efforts will be made to fill identified data gaps in the first five years of the plan. Additionally, this element asks whether any changes to local ordinances or land use plans are included as management actions.

Conclusion

We know that SGMA plan development and implementation is a major undertaking, and we want every basin to be successful. We would be happy to meet with you to discuss our evaluation as you finalize your Plan for submittal to DWR. Feel free to contact Suzannah Sosman at suzannah@aginnovations.org for more information or to schedule a conversation.

Sincerely,



Jennifer Clary

Appendix A
Review of Public Draft GSP

Groundwater Basin/Subbasin: Tulare Lake Subbasin (DWR 5-22-12)
GSA: Five GSAs (Mid-Kings River, South Fork Kings, Southwest Kings, El Rico, and the Tri-County Water Authority GSAs)
GSP Date: August 2019 Public Review Draft

1. Identification of Beneficial Users

Were key beneficial users identified and engaged?

Selected relevant requirements and guidance:
GSP Element 2.1.5, "Notice & Communication" (§354.10):
(a) A description of the beneficial uses and users of groundwater in the basin, including the land uses and property interests potentially affected by the use of groundwater in the basin, the types of parties representing those interests, and the nature of consultation with those parties.
GSP Element 2.2.2, "Groundwater Conditions" (§354.16):
(d) Groundwater quality issues that may affect the supply and beneficial uses of groundwater, including a description and map of the location of known groundwater contamination sites and plumes.
(f) Identification of interconnected surface water systems within the basin and an estimate of the quantity and timing of depletions of those systems, utilizing data available from the Department, as specified in Section 353.2, or the best available information.
(g) Identification of groundwater dependent ecosystems within the basin, utilizing data available from the Department, as specified in Section 353.2, or the best available information.
GSP Element 3.3, "Minimum Thresholds" (§354.28):
(4) How minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests.

Review Criteria		Yes	No	N/A	Relevant Info per GSP	Location (Section, Page[1])
1. Do beneficial users (BUs) identified within the GSP area include:	a. Disadvantaged Communities (DACs)	X			From Table 2-4, DACs include Armona, Home Garde, Hardwick, Community of Stratford, Kettleman City, and City of Corcoran.	Table 2-4, Page 94
	b. Tribes	X			"The only Native American Tribe within the Tulare Lake Subbasin boundary is the Santa Rosa Rancheria Tachi-Yokut Tribe. The Tachi-Yokut Tribe was invited to participate in GSP development via a letter sent on June 28, 2016 by the then Upper Tulare Lake GSA MOU Group (now known as the South Fork Kings GSA). A copy of the letter is included in the Appendix A of the Tulare Lake Subbasin GSAs' Communication & Engagement Plan. The Tribe's EPA director attended one of the South Fork Kings GSA's board meetings, and has been on their Interested Parties List since April 2017, receiving regular updates about GSP development within the SFKGSA and the Tulare Lake Subbasin. In addition, a Sacred Lands File & Native American Contacts List Request was also sent to the Native American Heritage Commission."	Appendix B, Page 373
	c. Small community public water systems (<3,300 connections)	X			Public water systems such as Armona CSD and Home Garden CSD are included in Table 2-4. It is not clear from the GSP which systems have fewer than 3,300 connections.	Table 2-4, Page 94
2. What data were used to identify presence or absence	d. DWR DAC Mapping Tool[2]		X		Data source is not clear from the GSP.	
	i. Census Places		X			

[1] Page numbers refer to the page of the PDF.
[2] DWR DAC Mapping Tool: https://gis.water.ca.gov/app/dacs/

	of DACs?	ii. Census Block Groups		X			
		iii. Census Tracts		X			
		e. Other data source		X			
3.	Groundwater Conditions section includes discussion of:	f. Drinking Water Quality	X			"Currently, as described in Section 5.4.3, groundwater quality in the northern portion of the Subbasin encompassing the Mid-Kings River GSA and South Fork Kings GSA is generally excellent for irrigation and satisfactory for municipal and industrial use (KCWD 2011). South of Stratford and Corcoran, groundwater quality diminishes, and portions of the Tulare Lakebed have been undesignated from being suitable for municipal, domestic, agricultural irrigation, and stock watering supply. Shallow groundwater contamination from fuel hydrocarbons, agricultural chemicals, or solvents are localized in the urbanized areas of Lemoore and Hanford and some smaller communities. Limited regional data is available for determining current nutrient concentrations based on groundwater depth and location. As discussed in Section 3.2.5, shallow groundwater can have elevated concentrations of nitrates and TDS, but the majority of the region is generally below Maximum Contaminant Levels (MCLs)."	4.4.1.4, Page 248
		g. California Maximum Contaminant Levels (CA MCLs)[3] (or Public Health Goals where MCL does not exist, e.g. Chromium VI)		X		See above. MCLs are only briefly discussed.	4.4.1.4, Page 248
4.	What local, state, and federal standards or plans were used to assess drinking water BUs in the development of Minimum Thresholds (MTs)?	h. Office of Environmental Health Hazard Assessment Public Health Goal (OEHHA PHGs)[4]		X			
		i. CA MCLs[3]	X			"The basic authority of the GSAs is to locally determine the sustainable amount of groundwater that can be pumped and to manage the transition from the current groundwater usage to a groundwater usage that is sustainable. Also, GSAs do not have the authority to modify surface water rights. Federal and state agencies provide direct oversight of quality and set their own appropriate thresholds such as Maximum Contaminant Levels for drinking water. These will be utilized by the Subbasin for MOs and MTs. For these reasons, the local GSAs will focus on water quality issues that are related to groundwater pumping rather than on issues related to contamination." "MTs will follow the state, federal, and local standards related to the relevant sustainability indicators set by the coalitions."	4.2.4, Page 239 4.4.2.4, Page 249

	l. County and/or City General Plans, Zoning Codes and Ordinances[6]		X			

Summary/ Comments
It is recommended that the GSP clearly identify the data sources that were used to identify the presence of DACs, and include as maps showing the locations of DACs. The representative monitoring networks should be shown on maps that include the location of DACs so that one can assess the networks' ability to monitor potential impacts to these sensitive beneficial users.

The GSP should provide much more thorough information on what the water quality MTs/MOs are and what standards were used in the development of MTs/MOs. Such information is crucial to the drinking water beneficial users in the subbasin.

[6] OPR General Plan Guidelines: http://www.opr.ca.gov/planning/general-plan/

2. Communications Plan

How were key beneficial users engaged and how was their input incorporated into the GSP process and decisions?

Selected relevant requirements and guidance:
GSP Element 2.1.5, "Notice & Communication" (§354.10):
Each Plan shall include a summary of information relating to notification and communication by the Agency with other agencies and interested parties including the following:
(c) Comments regarding the Plan received by the Agency and a summary of any responses by the Agency.
(d) A communication section of the Plan that includes the following:
(1) An explanation of the Agency's decision-making process.
(2) Identification of opportunities for public engagement and a discussion of how public input and response will be used.
(3) A description of how the Agency encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin.
(4) The method the Agency shall follow to inform the public about progress implementing the Plan, including the status of projects and actions.

DWR Guidance Document for GSP Stakeholder Communication and Engagement[7]

Review Criteria	Yes	No	N/A	Relevant Info per GSP	Location (Section, Page)
1. Is a Stakeholder Communication and Engagement Plan (SCEP) included?	X			Appendix B: Stakeholder Communication and Engagement Plan (no date)	Appendix B, Page 368
2. Does the SCEP or GSP identify that ongoing engagement will be conducted during GSP implementation?	X			"During the implementation phase, communication and engagement efforts focus on educational and informational awareness of the requirements and processes for reaching groundwater sustainability as set forth in the submitted GSP. Active involvement of all stakeholders is encouraged during implementation, and public notices are required for any public meetings, as well as prior to imposing or increasing any fees. Public outreach is also completed by the individual GSAs with collaborative efforts when target audiences span more than one GSA boundary."	2.5.1, Page 73
3. Does the SCEP or GSP specifically identify how DAC beneficial users were engaged in the planning process?	X			"Communication and educational outreach efforts with disadvantaged communities (DAC) and severely disadvantaged communities (SDAC) was needed for the development and implementation of the Tulare Lake Subbasin's GSP according to the Department of Water Resources' Best Management Practices. Information used to communicate to and engage the DACs in the GSP process, included an explanation of SGMA and soliciting feedback. GSA representatives regularly communicated with DACs and gave presentations on SGMA to community representatives, while gathering their feedback and input. By including DACs and SDACs in communication efforts during the development, public review and implementation phases of the GSP, residents were more likely to participate and provide feedback that could be crucial to long-term solutions for groundwater sustainability within their communities.	Appendix B, Page 374, 377

[7] DWR Guidance Document for GSP Stakeholder Communication and Engagement
https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/Guidance-Document-for-Groundwater-Sustainability-Plan---Stakeholder-Communication-and-Engagement.pdf

				Any feedback received from DAC/SDAC residents was reviewed and evaluated by the Tulare Lake Subbasin GSAs during the GSP development and public review phases." "For outreach to DACs/SDACs, fliers were available in both English and Spanish languages."	
4. Does the SCEP or GSP explicitly describe how stakeholder input was incorporated into the GSP process and decisions?	X			"As active stakeholders, members of the Boards of Directors and Stakeholder/Advisory Committees are direct representatives of their districts, communities and industries, and they continually gather feedback/input, and the concerns/needs of their constituents and report back to their respective meetings. Any stakeholder input received was reviewed by the GSA and Subbasin technical teams and taken into consideration during GSP development." "Stakeholder input was utilized during the GSA formation phase, as beneficial users and stakeholders with interests in groundwater usage within the GSAs' boundaries were notified via public meeting notices as soon as the process began." "With the goal of having the draft GSP before the end of the third quarter in 2019, 2018 was primarily the technical development of the plan, while working with GSA Boards of Directors, technical teams/committees, and GSA management at the subbasin level, as well as stakeholders for feedback and input. During the last quarter of 2018, the first round of public outreach meetings and interaction with stakeholder groups and other community organizations and entities was held with the purpose of educating and informing stakeholders about SGMA and the GSP process, while also soliciting feedback and input from these groups to consider and possibly include feedback and input into the GSP. Public outreach for this phase was completed by the individual GSAs." "Once the draft of the GSP was completed in September 2019, the public review process began. A 90-day comment period was held, with the GSP draft posted on the Tulare Lake Subbasin GSAs' websites for all stakeholders to conveniently download and review and provide comments. Outreach meetings were held during this phase both on subbasin-wide level, as well as by individual GSAs. These meetings focused on an overview of the GSP content, while giving stakeholders a public forum to provide their feedback and comments." Outreach tracking is also presented in tables by each GSA in Appendix D.	Appendix B, Page 370
Summary/ Comment It is important that stakeholder engagement be maintained through the development of future projects and management actions and other SGMA compliance and implementation steps.					

3. Maps Related to Key Beneficial Uses

Were best available data sources used for information related to key beneficial users?

Selected relevant requirements and guidance:
GSP Element 2.1.4 "Additional GSP Elements" (§354.8):
Each Plan shall include a description of the geographic areas covered, including the following information:
(a) One or more maps of the basin that depict the following, as applicable:
(5) The density of wells per square mile, by dasymetric or similar mapping techniques, showing the general distribution of agricultural, industrial, and domestic water supply wells in the basin, including de minimis extractors, and the location and extent of communities dependent upon groundwater, utilizing data provided by the Department, as specified in Section 353.2, or the best available information.

GSP Element 3.5 Monitoring Network (§354.34)
(b) Each Plan shall include a description of the monitoring network objectives for the basin, including an explanation of how the network will be developed and implemented to monitor groundwater and related surface conditions, and the interconnection of surface water and groundwater, with sufficient temporal frequency and spatial density to evaluate the affects and effectiveness of Plan implementation. The monitoring network objectives shall be implemented to accomplish the following:
(c) Each monitoring network shall be designed to accomplish the following for each sustainability indicator:
(1) Chronic Lowering of Groundwater Levels. Demonstrate groundwater occurrence, flow directions, and hydraulic gradients between principal aquifers and surface water features by the following methods:
(A) A sufficient density of monitoring wells to collect representative measurements through depth-discrete perforated intervals to characterize the groundwater table or potentiometric surface for each principal aquifer.
(4) Degraded Water Quality. Collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues.
(6) Depletions of Interconnected Surface Water. Monitor surface water and groundwater, where interconnected surface water conditions exist, to characterize the spatial and temporal exchanges between surface water and groundwater, and to calibrate and apply the tools and methods necessary to calculate depletions of surface water caused by groundwater extractions. The monitoring network shall be able to characterize the following:
(A) Flow conditions including surface water discharge, surface water head, and baseflow contribution.
(B) Identifying the approximate date and location where ephemeral or intermittent flowing streams and rivers cease to flow, if applicable.
(C) Temporal change in conditions due to variations in stream discharge and regional groundwater extraction.
(D) Other factors that may be necessary to identify adverse impacts on beneficial uses of the surface water.
(f) The Agency shall determine the density of monitoring sites and frequency of measurements required to demonstrate short-term, seasonal, and long-term trends based upon the following factors:
(3) Impacts to beneficial uses and users of groundwater and land uses and property interests affected by groundwater production, and adjacent basins that could affect the ability of that basin to meet the sustainability goal.

Review Criteria		Yes	No	N/A	Relevant Info per GSP	Location (Section, Page)
1. Does the GSP Include Maps Related to Drinking Water Users?	a. Well Density		X		No maps are provided. Page 47 indicates that there are 75 public supply wells in the Subbasin and the total number of wells is about 3,871.	Section 2, Page 47
	b. Domestic and Public Supply Well Locations & Depths		X		The GSP does not appear to include information on domestic and public supply well locations and depths.	
	i. Based on DWR Well Completion Report Map Application[8]?			X		

[8] DWR Well Completion Report Map Application: https://www.arcgis.com/apps/webappviewer/index.html?id=181078580a214c0986e2da28f8623b37

	ii. Based on Other Source(s)?				X		
2. Does the GSP include maps of monitoring networks?	a. Existing Monitoring Wells		X			Existing monitoring wells for subsidence and water quality can be found in Figure 5-4 and 5-5.	Figure 5-4, Page 301 Figure 5-4, Page 302
	b. Existing Monitoring Well Data sources:	i. California Statewide Groundwater Elevation Monitoring (CASGEM)	X			"Groundwater levels are measured in the various networks and types of wells including: […] CASGEM Wells: DWR collects groundwater levels reported by local agencies and reports them through the CASGEM program. There are currently 17 CASGEM wells in the Subbasin."	5.1.5, Page 276
		ii. Water Board Regulated monitoring sites	X			"Water quality data will be obtained from the below-mentioned coalitions: […] RWQCB - Regional Water Quality Control Board" "Though water quality has been periodically analyzed within the Subbasin for irrigation suitability, monitoring programs are generally not in place with defined temporal and spatial distribution, except for municipal water suppliers, RWQCB sites with WDRs, and monitoring at evaporation ponds."	4.4.2.4, Page 250 5.4.3, Page 291
		iii. Department of Pesticide Regulation (DPR) monitoring wells	X			"The California Department of Pesticide Regulation (DPR) maintains a Surface Water Database (SURF) containing data from a wide variety of environmental monitoring studies designed to test for the presence or absence of pesticides in California surface waters. As part of DPR's effort to provide public access to pesticide information, this database provides access to data from DPR's SURF (DPR 2019)."	2.4.3.3, Page 68
	c. SGMA-Compliance Monitoring Network		X			Figure 5-1 to Figure 5-5	Figure 5-1 to Figure 5-5, Page298-302
	i. SGMA Monitoring Network map includes identified DACs?			X		DACs are not included. However, public water systems are shown on the maps.	
	ii. SGMA Monitoring Network map includes identified GDEs?			X		GDEs are not included.	

Summary/ Comments

The draft GSP does not provide maps showing "The density of wells per square mile, by dasymetric or similar mapping techniques, showing the general distribution of agricultural, industrial, and domestic water supply wells in the basin, including de minimis extractors, and the location and extent of communities dependent upon groundwater, utilizing data provided by the Department, as specified in Section 353.2, or the best available information" as required by 23 CCR § 354.8.(a)(5). The GSP should include the density, location and depths of all domestic and public supply wells in the GSA area using the best available information, and present this information on maps along with the proposed SGMA-compliance monitoring network so that the public can evaluate how well the monitoring network addresses these key beneficial users.

Providing maps of the monitoring network overlaid with location of DACs, GDEs, and any other sensitive beneficial users will also allow the reader to evaluate adequacy of the network to monitor conditions near these beneficial users.

4. Water Budgets

How were climate change projections incorporated into projected/future water budget and how were key beneficial users addressed?

Selected relevant requirements and guidance:
GSP Element 2.2.3 "Water Budget Information" (Reg. § 354.18)
Each Plan shall include a water budget for the basin that provides an accounting and assessment of the total annual volume of groundwater and surface water entering and leaving the basin, including historical, current and projected water budget conditions, and the change in the volume of water stored. Water budget information shall be reported in tabular and graphical form.

*Projected water budgets shall be used to estimate future baseline conditions of supply, **demand**, and aquifer response to Plan implementation, and to identify the uncertainties of these projected water budget components. The projected water budget shall utilize the following methodologies and assumptions to estimate future baseline conditions concerning hydrology, water demand and surface water supply availability or reliability over the planning and implementation horizon:*
(b) The water budget shall quantify the following, either through direct measurements or estimates based on data:
(5) If overdraft conditions occur, as defined in Bulletin 118, the water budget shall include a quantification of overdraft over a period of years during which water year and water supply conditions approximate average conditions.
(6) The water year type associated with the annual supply, demand, and change in groundwater stored.
(c) Each Plan shall quantify the current, historical, and projected water budget for the basin as follows:
*(1) Current water budget information shall quantify current inflows and outflows for the basin using the most recent hydrology, water supply, **water demand**, and land use information.*

DWR Water Budget BMP[9]
DWR Guidance for Climate Change Data Use During GSP Development and Resource Guide[10]

Review Criteria	Yes	No	N/A	Relevant Info per GSP	Location (Section, Page)
1. Are climate change projections explicitly incorporated in future/ projected water budget scenario(s)?	X			"The projected water budget for the Subbasin represents a hypothetical forecast for the 54-year period from 2017 through 2070 based on an assumed "normal hydrology" period and estimated future climate change impacts."	3.3.7, Page 141
2. Is there a description of the methodology used to include climate change?	X			"In a climate period analysis, climate change is modeled as a shift from a baseline condition, usually historically observed climate where every year or month of the simulation it is shifted in a way that represents the climate change signal at a future 30-year climate period. Climate period analysis provides advantages in this situation because it isolates the climate change signal independent of the monthly variability signal. In a climate period analysis, monthly variability is based on the reference period from which change is being measured, meaning that all differences between the future	3.3.7.3, Page 142-143

[9] DWR BMP for the Sustainable <management of Groundwater Water Budget:
https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/BMP-4-Water-Budget.pdf

https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/Climate-Change-Guidance_Final.pdf

						simulation and the reference period are the result of the climate change signal alone. Climate period analysis was utilized to modify the 54-year forecast of "normal hydrology" to account for future climate change. The 2017-2070 forecast incorporates climate period analysis using the 2030 and 2070 monthly change factors (CNRA 2018) for each forecast analog month (Figure 3-52). The 2030 monthly change factors were applied to the forecast months January 2017 through December 2030. The 2070 monthly change factors were applied to the forecast months January 2031 through December 2070. There is a notable increase in magnitude of the 2070 change factors compared to the 2030 change factors."	
3. What is used as the basis for climate change assumptions?	a. DWR-Provided Climate Change Data and Guidance[11]		X			"The DWR provides guidance on how to incorporate climate change into hydrology forecasts. There are two basic approaches that have been used to simulate climate change in water resource modeling: 1) transient analysis; and 2) climate period analysis (DWR 2018)."	3.3.7.3, Page 142
	b. Other			X			
4. Does the GSP use multiple climate scenarios?				X			
5. Does the GSP quantitatively incorporate climate change projections?			X			Based on the information presented in Figure 3-53, the GSP appears to have quantitatively incorporated climate change projections. However, no descriptions or tables are provided regarding the quantitative results of the climate change projections.	Figure 3-53, Page 219
6. Does the GSP explicitly account for climate change in the following elements of the future/projected water budget?	a. Inflows:	i. Precipitation	X			"The climate change factors were also applied to 54-year forecasts of monthly inflows (effective precipitation, surface water deliveries, lake bottom storage, and canal and river seepage) and outflows (agricultural demand) for the "normal hydrology" forecast."	3.3.7.4, Page 143
		ii. Surface Water	X				
		iii. Imported Water	X				
		iv. Subsurface Inflow	X				
	b. Outflows:	i. Evapotranspiration	X				
		ii. Surface Water Outflows (incl. Exports)			X		
		iii. Groundwater Outflows (incl. Exports)	X				
7. Are demands by these sectors (drinking water users) explicitly included in the future/projected	a. Domestic Well users (<5 connections)		X			"Municipal and domestic groundwater pumping are estimated upward based on projected population growth at an annual rate of 0.03%." It is not clear from the GSP if demands by some or all of these community and non-community water systems were considered. The GSP also does not identify the number of connections of the various	3.3.7.4, Page 143
	b. State Small Water systems (5-14 connections)			X			
	c. Small community water systems (<3,300 connections)			X			

[11] DWR Guidance Document for the Sustainable Management of Groundwater Guidance for Climate Change Data Use During GSP Development: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/Climate-Change-Guidance_Final.pdf
DWR Resource Guide DWR-Provided Climate Change Data and Guidance for Use During GSP Development: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/Resource-Guide-Climate-Change-Guidance_v8.pdf

water budget?	d. Medium and Large community water systems (> 3,300 connections)		X		public water systems present in the basin.	
	e. Non-community water systems		X			

Summary/ Comments

Given the uncertainties of climate change, the GSP should include and analyze the effects of multiple climate change scenarios.

The GSP should present the results of the projected water budget in a tabulated, transparent format. The GSP should also clearly identify and quantify water demands of all drinking water users in the projected water budget, including the small and large public water systems. Such information is necessary for the public to assess whether drinking water demands were fully and appropriately considered in the GSP.

5. Management Areas and Monitoring Network

How were key beneficial users considered in the selection and monitoring of Management Areas and was the monitoring network designed appropriately to identify impacts on DACs and GDEs?

Selected relevant requirements and guidance:
GSP Element 3.3, "Management Areas" (§354.20):

(b) A basin that includes one or more management areas shall describe the following in the Plan:
(2) The minimum thresholds and measurable objectives established for each management area, and an explanation of the rationale for selecting those values, if different from the basin at large.
(3) The level of monitoring and analysis appropriate for each management area.
(4) An explanation of how the management area can operate under different minimum thresholds and measurable objectives without causing undesirable results outside the management area, if applicable.
(c) If a Plan includes one or more management areas, the Plan shall include descriptions, maps, and other information required by this Subarticle sufficient to describe conditions in those areas.

CWC Guide to Protecting Drinking Water Quality under the SGMA[12]
TNC's Groundwater Dependent Ecosystems under the SGMA, Guidance for Preparing GSPs[13]

Review Criteria	Yes	No	N/A	Relevant Info per GSP	Location (Section, Page)
1. Does the GSP define one or more Management Area?	X			"In order to facilitate implementation of the GSP, management areas have been created for the Subbasin. There are five Primary Management Areas and two Secondary Management Areas."	3.4, Page 144 Figure 3-54, Page 220
2. Were the management areas defined specifically to manage GDEs?		X		"Primary Management Areas have been formed from each of the five GSAs." "Two Secondary Management Areas have been formed for the Subbasin. These two Secondary Management Areas are different from the Primary Management Areas and each other due to distinctly different groundwater conditions in each area."	3.4, Page 144
3. Were the management areas defined specifically to manage DACs?		X			
a. If yes, are the Measurable Objectives (MOs) and MTs for GDE/DAC management areas more restrictive than for the basin as a whole?			X		
b. If yes, are the proposed management actions for GDE/DAC management areas more restrictive/ aggressive than for the basin as a whole?			X		
4. Does the GSP include maps or descriptions indicating what DACs are located in each Management Area(s)?	X			Table 2-4 describes DACs in each GSA area.	Table 2-4, Page 94
5. Does the GSP include maps or descriptions indicating what GDEs are located in each Management Area(s)?	X			Figure 3-38. Distribution of Wetlands and Phreatophyte Vegetation	Figure 3-38, Page 198

[12] CWC Guide to Protecting Drinking Water Quality under the SGMA: https://d3n8a8pro7vhmx.cloudfront.net/communitywatercenter/pages/293/attachments/original/1559328858/Guide_to_Protecting_Drinking_Water_Quality_Under_the_Sustainable_Groundwater_Management_Act.pdf?1559328858
[13] TNC's Groundwater Dependent Ecosystems under the SGMA, Guidance for Preparing GSPs: https://www.scienceforconservation.org/assets/downloads/GDEsUnderSGMA.pdf

Summary/ Comments
It is recommended that the GSP includes maps of the identified DACs located within each Management Area.

Care should be taken so that the management areas and the associated monitoring network are designed to adequately assess and protect against impacts to all beneficial users, including GDEs and DACs.

6. Measurable Objectives, Minimum Thresholds, and Undesirable Results

How were DAC and GDE beneficial uses and users considered in the establishment of Sustainable Management Criteria?

Selected relevant requirements and guidance:
GSP Element 3.4 "Undesirable Results" (§ 354.26):
(b) The description of undesirable results shall include the following:
(3) Potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results

GSP Element 3.2 "Measurable Objectives" (§ 354.30)
(a) Each Agency shall establish measurable objectives, including interim milestones in increments of five years, to achieve the sustainability goal for the basin within 20 years of Plan implementation and to continue to sustainably manage the groundwater basin over the planning and implementation horizon.

Review Criteria	Yes	No	N/A	Relevant Info per GSP	Location (Section, Page)
1. Are DAC impacts considered in the development of Undesirable Results (URs), MOs, and MTs for groundwater levels and groundwater quality?		X		The impacts to DACs are not explicitly considered. Water Level URs: "Exceedance of MTs leading to undesirable results related to groundwater level in the Subbasin would cause a diminished level of groundwater supplies for agricultural and municipal needs. Groundwater levels are anticipated to continue to decrease at current rates in the next several years before implemented programs have a positive effect on the stabilization of groundwater levels based on the variability of hydrology and availability of flood water. As stated above, agriculture is the main economic enterprise of the Subbasin, so effective management of groundwater for sustainable future use is critical to the continuation of current economic interests, which add value to the Subbasin's communities. Decreases in groundwater levels will continue to increase the cost of energy for pumping. If MT levels are reached or exceeded, wells have the potential to go dry and require deepening to reach the lowered water table. Alternatively, pumps may be lowered if the existing well casing is sufficiently deeper. However, once the Subbasin reaches sustainability in the future, the depth of the wells will be known and can be designed to meet those depths to prevent future wells from becoming dry." Water Level MTs: "Due to the timely process of infrastructure development and program implementation, and variability in hydrology and the availability of flood water, groundwater levels are expected to continue to decrease in the next several years before programs have a positive effect on the stabilization of groundwater levels. Decreases in groundwater levels will continue to increase the cost of energy for pumping. If MT levels are reached, there may be some wells that go dry and require deepening to reach the water table. Alternatively, pumps may be lowered if the existing well casing is sufficiently deeper. However, once the Subbasin reaches sustainability in the future, the design depth for wells will be known and will be used in planning of future	4.3.3, Page 245 4.4.4, Page 251

					well construction to minimize future wells from becoming dry." Water Quality MTs: "If water quality is allowed to deteriorate to levels set by MTs, agricultural producers may experience a decrease in crop yield and/or crop quality. Poor water quality would cause a buildup of salts and nitrates in the surface layers of soil. The best way to treat nutrient build up is by leaching or over-irrigating enough to push soluble contaminants through the soil column."	
2.	Does the GSP explicitly discuss how stakeholder input from DAC community members was considered in the development of URs, MOs, and MTs?		X		The GSP does not explicitly discuss how stakeholder input from DACs was considered.	
3.	Does the GSP clearly identify and detail the anticipated degree of water level decline from current elevations to the water level MOs and MTs?		X		The GSP does not clearly identify the anticipated degree of water level decline. However, current water levels and MOs/MTs are presented in Table 4-1. Based on this if water levels reach MTs, this will represent an average decline of approx. 100 feet below 2017 conditions, and over 200 feet below current conditions in some parts of the subbasin (i.e., wells SFK_B_1920E19A001M, SFK_C_20S20E07H001M, and SFK_C_LEM_12). Even MOs represent over 100 feet of decline below 2017 water levels in many areas of the Subbasin.	Table 4-1, Page 262
4.	If yes, does it include:	a. Is this information presented in table(s)?	X			
		b. Is this information presented on map(s)?	X			
		c. Is this information presented relative to the locations of DACs and domestic well users?	X			
		d. Is this information presented relative to the locations of ISW and GDEs?	X			
5.	Does the GSP include an analysis of the anticipated impacts of water level MOs and MTs on drinking water users?		X		"Due to the timely process of infrastructure development and program implementation, and variability in hydrology and the availability of flood water, groundwater levels are expected to continue to decrease in the next several years before programs have a positive effect on the stabilization of groundwater levels. Decreases in groundwater levels will continue to increase the cost of energy for pumping. If MT levels are reached, there may be some wells that go dry and require deepening to reach the water table. Alternatively, pumps may be lowered if the existing well casing is sufficiently deeper. However, once the Subbasin reaches sustainability in the future, the design depth for wells will be known and will be used in planning of future well construction to minimize future wells from becoming dry." Impacts on drinking water users are not explicitly considered. Based on the water level declines identified above, it would be expected that such impacts could be significant.	4.4.4, Page 251
6.	If yes:	a. On domestic well users?	X			
		b. On small water system production wells?	X			
		c. Was an analysis conducted and clearly illustrated (with maps) to identify what wells would be expected to be partially and fully dewatered at the MOs?	X			
		d. Was an analysis conducted and clearly illustrated (with maps) to identify what wells would be expected to be partially and fully dewatered at the MTs?	X			
		e. Was an economic analysis performed to assess the increased operation costs associated with increased lift as a result of water level decline?	X			
9.	Does the sustainability goal explicitly include drinking water and nature?		X		"This GSP aims to manage groundwater resources to continue to provide an adequate water supply for existing beneficial uses and users in accordance with counties and cities general plans while meeting established measurable objectives (MO) to maintain a sustainable yield. This goal aims to continue to provide adequate water supply for existing beneficial uses and users while ensuring the future, sustainable use of groundwater. Additionally, the sustainability goal works as a tool for managing groundwater, basin-wide, on a long-term basis to protect quality of life through the continuation of existing economic industries in the area including but not limited to agriculture."	1.3.1, Page 40 Table 2-4, Page 94

				Table 2-4. Beneficial Uses and Users by GSA The sustainability goal does not include nature.	

Summary/ Comments

Based on the presented information, impacts to DACs are not explicitly considered in the discussion of URs, MOs, and MTs. More detail and specifics regarding DACs, including those that rely on smaller community drinking water systems and domestic wells, is necessary to demonstrate that these beneficial users were adequately considered. It is recommended that the GSP present a thorough and robust analysis, supported by maps, that identifies: (1) what domestic wells are likely to be impacted (including partially dewatered) at the MTs and at the MOs and (2) the location of the likely impacted wells with respect to DACs and other communities and systems dependent on groundwater.

Based on the information presented in Table 4-1 of the draft GSP, if water levels reach MTs, this will represent an average decline of approx. 100 feet below 2017 water levels, and over 200 feet below current conditions in some parts of the subbasin (i.e., wells SFK_B_1920E19A001M, SFK_C_20S20E07H001M, and SFK_C_LEM_12). Even MOs represent an average decline of over 50 feet below current conditions and over 100 feet of decline in many areas of the Subbasin. The GSP needs to explain how such water level declines represent sustainable conditions and are protective of beneficial uses and users in the Subbasin.

A proactive assistance program should be developed for potentially impacted beneficial users, including DACs, small water systems, and domestic wells, to mitigate potential future adverse impacts.

The GSP should also explicitly demonstrate whether and how the stakeholder input from DACs was considered in the development of URs, MOs, and MTs.

We recommend that the sustainability goal explicitly includes environmental beneficial uses of groundwater.

7. Management Actions and Costs

What does the GSP identify as specific actions to achieve the MOs, particularly those that affect the key BUs, including actions triggered by failure to meet MOs? What funding mechanisms and processes are identified that will ensure that the proposed projects and management actions are achievable and implementable?

Selected relevant requirements and guidance

GSP Element 4.0 Projects and Management Actions to Achieve Sustainability Goal (§ 354.44)

(a) Each Plan shall include a description of the projects and management actions the Agency has determined will achieve the sustainability goal for the basin, including projects and management actions to respond to changing conditions in the basin.

(b) Each Plan shall include a description of the projects and management actions that include the following:

(1) A list of projects and management actions proposed in the Plan with a description of the measurable objective that is expected to benefit from the project or management action.

Review Criteria	Yes	No	N/A	Relevant Info per GSP	Location (Section, Page)
1. Does the GSP identify benefits or impacts to DACs as a result of identified management actions?		X		The impacts to DACs are not explicitly discussed in the GSP. Recharge projects are noted in the GSP as expected to improve water quality.	6.3.3, Page 323
2. If yes: a. Is a plan to mitigate impacts on DAC drinking water users included in the proposed Projects and		X			

		Management Actions?					
	b.	Does the GSP identify costs to fund a mitigation program?		X			
	c.	Does the GSP include a funding mechanism to support the mitigation program?		X			
3.	Does the GSP identify any demand management measures in its projects and management actions?		X			Section 6.3 and 6.4 provide potential P/MAs options that may be utilized by the GSAs. Table 6-1 to 6-4 in Section 6.5 list the P/MAs chosen for each GSA.	6.3, Page 317-330 6.4, Page 330-331 6.5, Page 331-334
4.	If yes, does it include:	a. Irrigation efficiency program		X			
		b. Ag land fallowing (voluntary or mandatory)	X			Fallowing programs are identified by Mid-Kings River GSA, El Rico GSA, and South Fork Kings GSA. "The Subbasin may adopt a policy to incentive farmers to permanently fallow land. Policy will solicit volunteers first then look towards mandatory fallowing based on percentage reductions possibly on a rotation basis."	
		c. Pumping allocation/restriction	X			Groundwater allocation is listed as a potential management action in Section 6.4.	
		d. Pumping fees/fines	X			Pumping fees for groundwater allocation exceedances and groundwater extractions are listed as potential management actions in Section 6.4.	
		e. Development of a water market/credit system	X			Groundwater marketing and trade is listed as a potential management action in Section 6.4.	
		f. Prohibition on new well construction		X			
		g. Limits on municipal pumping		X		It is not clear if there would be limits on municipal pumping.	
		h. Limits on domestic well pumping		X		It is not clear if there would be limits on domestic well pumping.	
		i. Other	X			"Require new developments (non-de minimis extractors) to prove sustainable water supplies if land use conversion is not a conservation measure"	
5.	Does the GSP identify water supply augmentation projects in its projects and management actions?		X			Section 6.3 and 6.4 provide potential P/MAs options that may be utilized by the GSAs. Table 6-1 to 6-4 in Section 6.5 list the P/MAs chosen for each GSA.	6.3, Page 317-330 6.4, Page 330-331 6.5, Page 331-334
6.	If yes, does it include:	a. Increasing existing water supplies	X			"Each GSA is proposing to use their existing contract and rights for surface water as access to import more surface water into the Subbasin."	
		b. Obtaining new water supplies		X			
		c. Increasing surface water storage	X			Storage projects are identified by South Fork Kings GSA, El Rico GSA, and Tri-County Water GSA.	
		d. Groundwater recharge projects – District or Regional level	X			Recharge projects are identified by Mid-Kings River GSA and South Fork Kings GSA.	
		e. On-farm recharge	X			On-Farm Improvements project is identified by South Fork Kings GSA.	
		f. Conjunctive use of surface water	X			The recharge projects also involve conjunctive use of surface water.	
		g. Developing/utilizing recycled water		X			

	h. Stormwater capture and reuse		X			
	i. Increasing operational flexibility (e.g., new interties and conveyance)	X			The Mid-Kings River GSA plans to pursue improvement to conveyance systems and expanded surface water delivery system.	
	j. Other		X			
7. Does the GSP include plans to fill identified data gaps by the first five-year report?		X			Section 5.4.1.3 discusses plans to fill data gaps in groundwater level monitoring network, including plans to collect well completion reports, perform a video inspection of wells to obtain construction information, construct a dedicated monitoring well, and replace monitor point with another alternate private well. Some P/MAs in Table 7-1 are also noted in the GSP as expected to help fill data gaps, including (1) Flood Flows (Spills into the Subbasin), include, Tule River, Deer Creek, Cross-Creeks and Kings River; (2) Registration of extraction facilities; (3) Require self-reporting of groundwater extraction, water level, and water quality data; and (4) Require well meters, sounding tubes, and water quality sample ports.	5.4.1.3, Page 286 Table 7-1, Page 343
8. Do proposed management actions include any changes to local ordinances or land use planning?		X			"Require new developments (non-de minimis extractors) to prove sustainable water supplies if land use conversion is not a conservation measure"	6.4, Page 330
9. Does the GSP identify additional/contingent actions and funding mechanisms in the event that MOs are not met by the identified actions?			X		"This section identifies the proposed project and management action targets envisioned to achieve sustainability. These preliminary amounts will be reevaluated, and conditions monitored while efforts are implemented. This will allow the GSA to compare the anticipated versus resulting change in groundwater levels as well as other sustainability criteria to determine if additional measures need to be employed to achieve sustainability." However, the GSP does not provide details on what projects and management actions will be implemented as additional measures.	6.5, Section 331
10. Does the GSP provide a plan to study the interconnectedness of surface water bodies?			X		"As discussed in Section 3.2.8, Interconnected Surface Water and Groundwater Systems, the Subbasin does not contain interconnected surface and groundwater systems based on review of groundwater potentiometric surface maps. Groundwater contours indicate the Kings River, Cross Creek, and Mill Creek are losing streams that directly recharge groundwater. Groundwater is not in contact with these streams and cannot contribute any base flow to them. Due to the lack of connected water systems, interconnected surface water will not be monitored or considered when making management decisions."	4.2.5, Page 240
11. If yes:	a. Does the GSP identify costs to study the interconnectedness of surface water bodies?			X		
	b. Does the GSP include a funding mechanism to support the study of interconnectedness surface water bodies?			X		

Summary/ Comments

The GSP should identify the potential impacts of the proposed projects or management actions on DACs. If impacts are expected, the GSP should include plans to monitor for, prevent, and/or mitigate against such impacts, provide the estimated costs, and identify the funding sources.

The GSP does not appear to include any plans to address impacts to domestic well users if water quality in these wells is degraded in the future. The GSP should include plan to

monitor for and mitigate impacts to DAC drinking water users.

Subject: Tulare Lake Subbasin Draft Groundwater Sustainability Plan

Dear Southwest Kings GSA Group:

Westlands Water District ("Westlands GSA") appreciates the opportunity to provide comments on the Tulare Lake Subbasin Draft Groundwater Sustainability Plan ("Draft GSP"). The Westlands Groundwater Sustainability Agency ("GSA") respectfully submits the following comments.

Finding 1 (Page 3-27): Figures 3-26 and 3-27, Table 3-6, and Section 3.2.2 of the GSP states with respect to groundwater flow in the unconfined aquifer that, "[i]n general, groundwater flowed into the Subbasin from the Kings, Kaweah, and Tule Subbasins and out of the Subbasin to the Westside Subbasin." This statement is supplemented by contours of unconfined potentiometric head developed by DWR from 1990 through 2016.

Westlands' Comment: The unconfined water level data are used to make inferences about general groundwater flow directions. As stated in Section 3.2.3 of the GSP, vertical gradients can exceed 50 feet per 100 feet suggesting that flow directions can be heavily dependent on the depth horizons that are selected and therefore, change considerably with depth. Model results provided in Appendix D also highlight how groundwater flow directions vary with depth.

DWR does not provide groundwater contours for the majority of the boundary shared between the Westside and Tulare Lake Subbasin. In fact, contours from 2005, 2010 and 2016 provide almost no overlap with the shared Subbasin boundary. As a result, there is no substantial evidence to support the statements regarding groundwater flows "out of the Subbasin to the Westside Subbasin."

The spatial information for wells used to develop the DWR water level contours are readily available for 2016 (DWR, 2019). Review of these data reveals that the majority of wells used by DWR to develop contours of unconfined potentiometric head within the Westside Subbasin are screened in the Lower Aquifer (**WWD Attachment: Figure 1**). Given that groundwater level readings can vary considerably between the Upper Aquifer and Lower Aquifer, water levels from the Lower Aquifer are unlikely to be representative of unconfined water levels (even in the Spring) and should not be used to support the GSP conclusions of subsurface flow in the unconfined aquifer between the Westside and Tulare Lake Subbasins.

Therefore, the analysis is not supported by substantial evidence and we respectfully disagree with the conclusion set forth in the GSP relating to groundwater conditions in the unconfined aquifer.

Finding 2 (Page 3-87): Figures 3-28b, 3-28c and 3-28d display wells within the Tulare Lake Subbasin with long term hydrographs.

Westlands' Comment: Figures 3-28b to 3-28d shows long term hydrographs for wells within the Tulare Lake Subbasin. Unfortunately, the data displayed by the hydrographs is pixelated, therefore unreviewable. Westlands GSA recommends revising the mentioned figures to display hydrographs using a higher resolution to allow the public to review.

Finding 3 (Page 3-93): Figures 3-30 through 3-32, and Section 3.2.5 describes groundwater quality data in the Tulare Lake and Westside Subbasins. With respect to TDS, the GSP cites reports from Davis et al., 1956 and Hansen et al., 2018.

Westlands Comments: Both reports highlight how depth significantly influences TDS concentrations. However, Figure 3-30 does not report the depth of the wells or the aquifer the TDS sample represents which can substantially influence how data is interpreted. Furthermore, none of the maps shows the time period being represented. With respect to the concentration of arsenic in groundwater, neither the most recent nor the maximum arsenic concentration in the data available from GeoTracker is as high as those shown in Figure 3-31 (**WWD Attachment: Figure 2 and 3**). Furthermore, the density of wells with available arsenic data in the Geotracker GAMA database is substantially less than that shown in Figure 3-31.

The concentration of nitrate in groundwater is shown in Figure 3-32. This map shows nitrate concentration exceeding the MCL in four locations adjacent to the Westside Subbasin boundary. A review of data available from Geotracker GAMA show that samples exceeding the MCL were measured in the mid to late-1980's and likely do not reflect the current ambient nitrate concentration at these locations.

We recommend that the draft GSP be revised to accurately convey groundwater quality data by aquifer and by the timeframe the data represents. In addition, we recommend that the groundwater quality data be reviewed for accuracy.

Finding 4 (Page 3-87): Figures 3-34 displaying historical subsidence in the San Joaquin Valley from 1949 – 2005.

Westlands' Comment: Figures 3-34 contains a legend that is incomplete and is unable to be reviewed. Westlands GSA recommends applying the corresponding color scheme to the vertical displacement legend to allow readers to be able to review the presented information.

Finding 5 (Page 4-18): Section 4.5.1.1 introduces the following sustainable management criteria for Groundwater Levels paraphrased as follows: The Sustainable Management Criteria for Groundwater Level (Section 4.5.1.1) proposes the Measurable Objective to be set at a groundwater level using Method 4, which forecasts water levels to 2035 and sets the 2035 water level as the Measurable Objective. Minimum Thresholds were based on assumed stability of groundwater levels between 2035 and 2040 and are designed to be a last-resort warning before more severe measures must be taken to protect groundwater resources. Section 4.4.3 (Selection Process of Minimum Thresholds to Avoid

Undesirable Results) establishes the Minimum Thresholds as "one standard deviation of all observed head data in compliance wells or modeled forecasted data." Figure 4-2 through 4-6 describe establishment of the Minimum Thresholds as "one standard deviation or 50 feet, whichever is greater."

Westlands' Comment: Sustainable Management Criteria, which includes the measurable objectives and the minimum thresholds, allows groundwater levels in the aquifer to decline past the Westside Subbasin's Measurable Objectives and Minimum Thresholds, set at 2015 groundwater levels, and may negatively impact the Westside Subbasin's ability to achieve sustainability by reducing net inflow into the Westside Subbasin and/or reversing the groundwater flow direction. More specifically, the proposed decline of groundwater levels in the Southwest Kings GSA may alter the groundwater conditions near the boundary between the Westside Subbasin and the Kings Subbasin and result in a lowering of groundwater levels in the Westside Subbasin. This action would have the effect of shifting the burden of SGMA compliance from the Southwest Kings GSA to Westlands GSA. This is not permissible. The GSP is devoid of substantial evidence and any explanation as to how the Minimum Thresholds will avoid a significant and unreasonable reduction in groundwater storage and significant and unreasonable land subsidence contributing to the impairment of surface uses within the Westside Subbasin.

Water Code section 10733, subdivision (c) provides in relevant part:

> "The department shall evaluate whether a groundwater sustainability plan adversely affects the ability of an adjacent basin to implement their groundwater sustainability plan or impedes achievement of sustainability goals in an adjacent basin"

Further, we respectfully call your attention to Code of Regulations, title 23, section 355.4, subdivision (b)(7):

> "When evaluating whether a Plan is likely to achieve the sustainability goal for the basin, the Department shall consider . . . whether the Plan *will adversely affect the ability of an adjacent basin to implement its Plan or impede achievement of its sustainability goal.*" (emphasis added)

and Code of Regulations, title 23, section 354.28, subdivision (b)(3):

> "The description of minimum thresholds shall include . . . how minimum thresholds have been selected to *avoid causing undesirable results in adjacent basins or affecting the ability of adjacent basins to achieve sustainability goals*." (emphasis added)

Moreover, the implementation of SGMA and a GSP cannot be used to override the protections afforded common law water rights. Overlying and appropriative uses of groundwater within the Westside Subbasin are entitled to legal and equitable protection against infringement by an action that deprives them of their historical subsurface inflows. (*City of Lodi v. East Bay Municipal Utility District* (1936) 7 Cal.2d 316, 344 [protecting groundwater levels against lowering from another party's pumping]; *Trussell v. City of San Diego* (1959) 172 Cal.App.2d 593, 611 [enjoining a party for lowering water table by interrupting surface flow].)

Practically speaking, proposing a continued decline of groundwater levels in the Lower Aquifer is not supported by substantial evidence because the GSP acknowledges that it does not have enough data to support its finding that there will be no impact to historical boundary flow conditions between the

Subbasins. The potential for curtailing historic underflow into the Westside Subbasin may be a substantial factor in contributing to significant and unreasonable subsidence and frustrate the Westlands' GSA ability to achieve the sustainability goal.

Finding 6 (Page 4-21): Section 4.5.33 Land Subsidence references Table 4-2: *Lemoore-Average Land Subsidence Interim Milestones based on Measurable Objectives for the Subbasin,* which displays modeled subsidence rates and interim milestones for those subsidence rates. The Tulare Lake Subbasin also proposes a minimum threshold of 16 ft by 2040 in Section 4.4.1.3.

Westlands' Comment: Westlands GSA is concerned that allowing subsidence rates as proposed may impact critical infrastructure such as roads, railroads, and may increase flood risks to existing land uses, especially near Corcoran where subsidence rates are critical, in the Westside Subbasin and other neighboring subbasins. Westlands GSA strongly recommend selecting Measurable Objectives and Minimum Thresholds to subsidence rates that will not negatively impact infrastructure in neighboring subbasins. The GSP fails to reference any substantial evidence that the minimum threshold will avoid significant and unreasonable land subsidence that impairs surface uses in the Westside Subbasin.

Finding 7 (Appendix D): The information provided in the GSP suggests a conceptual error leading to flows between the Westside Subbasin and Tulare Lake Subbasin to be misrepresented in the numerical model and GSP. Figure D5-5 in Appendix D shows the average model simulated net lateral subsurface flow of 158,405 AFY from the Lower Aquifer to the general head boundary (GHB) in the Westside Subbasin. Contours of simulated Lower Aquifer groundwater levels from 2015 in Figure D5-3 show a cone of depression along the GHB in the Westside Subbasin. Figure D5-5 shows pumping from the Lower Aquifer is a net positive suggesting that intraborehole flow from the Upper Aquifer to the Lower Aquifer is greater than the amount extracted from wells, suggesting the GHB is driving the flow across the boundary between the Westside and Tulare Lake Subbasins and out of the Westside Subbasin.

Westlands' Comment:
Lower Aquifer contours developed from water level data at the end of the 2014 irrigation year (one year before the simulated contour data provided) do not show a cone of depression in the location of the GHB (**WWD Attachment: Figure 4**). These contours also cannot be interpreted to suggest that groundwater flow is from the Tulare Lake Subbasin to the Westside Subbasin. Furthermore, it is unclear what physical process would cause a localized cone of depression to form in this location, especially considering that the groundwater model simulates positive net pumping from the Lower Aquifer in the Westside Subbasin.

The analysis is not supported by substantial evidence and for the reasons set forth above, Westlands recommends reanalyzing the water level contour data from the numerical model and GSP.

Lastly, the Westlands GSA identified the following reporting discrepancies within the text of the GSP and Appendix D that should be reviewed:

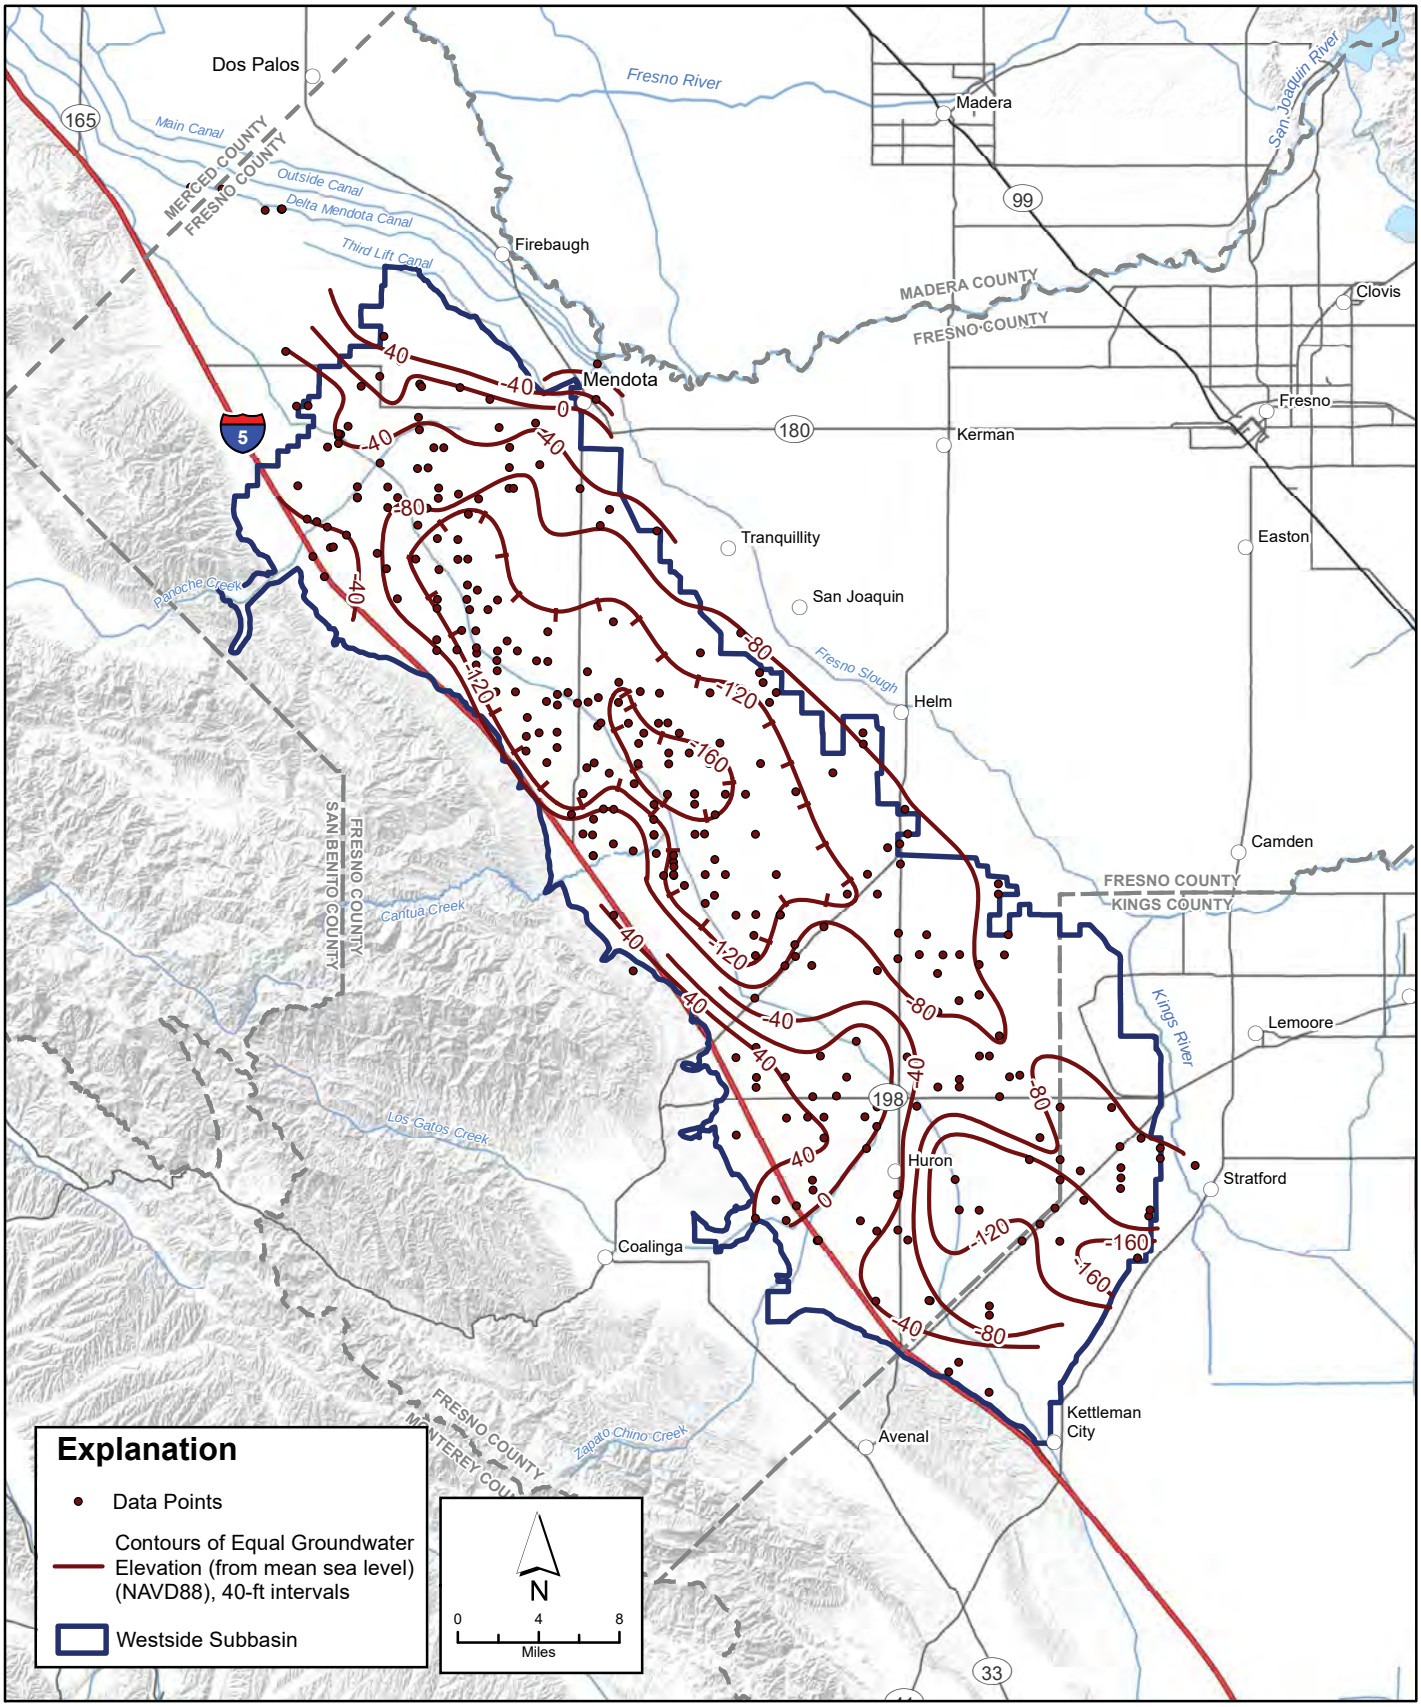
1. Total lateral subsurface inflow into the Westside Subbasin shown in Figure D5-5 averages 72,296 AFY (67,347 from the Tulare Lake Subbasin and 4,948 AFY from the Kings Subbasin). Table 3-6 of the GSP shows average annual subsurface flow from the Tulare Lake Subbasin to the Westside Subbasin of 41,390. What is the source of this discrepancy?

2. In the graphic depicting aquifer specific fluxes in Figure D5-5, the sum of the "Net GW Flux" (which presumably is lateral subsurface flow between adjacent subbasins) totals 4,936 AFY while the total in the table shown in Figure D5-5 is 72,296 AFY. What is the source of this discrepancy?

3. Figure numbers in the Appendix D text do not correspond to the correct figures. Figure D5-10 is titled "Simulated Subsidence 1990-2016". Figure D5-8 shows "Groundwater Mass Balance Tule Subbasin".

Westlands' General Comment: The GSP Regulations include a provision authorizing GSAs in adjacent basins to enter into interbasin agreements. The interbasin agreements can "establish compatible sustainability goals" and be included in GSPs to "support a finding that implementation of the Plan will not adversely affect an adjacent basin's ability to implement its Plan or impede the ability to achieve its sustainability goal." (Code Regs., tit. 23, § 357.2.)[1] The interbasin agreements may also address: (1) "an estimate of groundwater flow across basin boundaries;" (2) how the GSAs will reconcile differing minimum thresholds and measurable objectives in the basins to avoid undesirable results; and (3) a process for resolving conflicts between the GSAs. (*Id.*) Given the potential reduction of historical cross-boundary flow attributable to the planned operation with the Tulare Lake Subbasin Draft GSP, Westlands strongly recommends that we meet and confer at the earliest opportunity to determine whether an interbasin agreement can be reached. Our intention is to reach a cooperative resolution of these important issues that will enable coordinated sustainable management in our GSAs.

If you have any questions or concerns, regarding these comments, please contact Kiti Campbell by email at kcampbell@wwd.ca.gov or by phone at (559) 241-6226. Thank you for the opportunity to provide comments on the Tulare Lake Subbasin Draft GSP.



Sincerely,

Russ Freeman

Subject: Tulare Lake Subbasin Draft Groundwater Sustainability Plan

Dear South Fork Kings GSA Group:

Westlands Water District ("Westlands GSA") appreciates the opportunity to provide comments on the Tulare Lake Subbasin Draft Groundwater Sustainability Plan ("Draft GSP"). The Westlands Groundwater Sustainability Agency ("GSA") respectfully submits the following comments.

Finding 1 (Page 3-27): Figures 3-26 and 3-27, Table 3-6, and Section 3.2.2 of the GSP states with respect to groundwater flow in the unconfined aquifer that, "[i]n general, groundwater flowed into the Subbasin from the Kings, Kaweah, and Tule Subbasins and out of the Subbasin to the Westside Subbasin." This statement is supplemented by contours of unconfined potentiometric head developed by DWR from 1990 through 2016.

Westlands' Comment: The unconfined water level data are used to make inferences about general groundwater flow directions. As stated in Section 3.2.3 of the GSP, vertical gradients can exceed 50 feet per 100 feet suggesting that flow directions can be heavily dependent on the depth horizons that are selected and therefore, change considerably with depth. Model results provided in Appendix D also highlight how groundwater flow directions vary with depth.

DWR does not provide groundwater contours for the majority of the boundary shared between the Westside and Tulare Lake Subbasin. In fact, contours from 2005, 2010 and 2016 provide almost no overlap with the shared Subbasin boundary. As a result, there is no substantial evidence to support the statements regarding groundwater flows "out of the Subbasin to the Westside Subbasin."

The spatial information for wells used to develop the DWR water level contours are readily available for 2016 (DWR, 2019). Review of these data reveals that the majority of wells used by DWR to develop contours of unconfined potentiometric head within the Westside Subbasin are screened in the Lower Aquifer (**WWD Attachment: Figure 1**). Given that groundwater level readings can vary considerably between the Upper Aquifer and Lower Aquifer, water levels from the Lower Aquifer are unlikely to be representative of unconfined water levels (even in the Spring) and should not be used to support the GSP conclusions of subsurface flow in the unconfined aquifer between the Westside and Tulare Lake Subbasins.

Therefore, the analysis is not supported by substantial evidence and we respectfully disagree with the conclusion set forth in the GSP relating to groundwater conditions in the unconfined aquifer.

Finding 2 (Page 3-87): Figures 3-28b, 3-28c and 3-28d display wells within the Tulare Lake Subbasin with long term hydrographs.

Westlands' Comment: Figures 3-28b to 3-28d shows long term hydrographs for wells within the Tulare Lake Subbasin. Unfortunately, the data displayed by the hydrographs is pixelated, therefore unreviewable. Westlands GSA recommends revising the mentioned figures to display hydrographs using a higher resolution to allow the public to review.

Finding 3 (Page 3-93): Figures 3-30 through 3-32, and Section 3.2.5 describes groundwater quality data in the Tulare Lake and Westside Subbasins. With respect to TDS, the GSP cites reports from Davis et al., 1956 and Hansen et al., 2018.

Westlands Comments: Both reports highlight how depth significantly influences TDS concentrations. However, Figure 3-30 does not report the depth of the wells or the aquifer the TDS sample represents which can substantially influence how data is interpreted. Furthermore, none of the maps shows the time period being represented. With respect to the concentration of arsenic in groundwater, neither the most recent nor the maximum arsenic concentration in the data available from GeoTracker is as high as those shown in Figure 3-31 (**WWD Attachment: Figure 2 and 3**). Furthermore, the density of wells with available arsenic data in the Geotracker GAMA database is substantially less than that shown in Figure 3-31.

The concentration of nitrate in groundwater is shown in Figure 3-32. This map shows nitrate concentration exceeding the MCL in four locations adjacent to the Westside Subbasin boundary. A review of data available from Geotracker GAMA show that samples exceeding the MCL were measured in the mid to late-1980's and likely do not reflect the current ambient nitrate concentration at these locations.

We recommend that the draft GSP be revised to accurately convey groundwater quality data by aquifer and by the timeframe the data represents. In addition, we recommend that the groundwater quality data be reviewed for accuracy.

Finding 4 (Page 3-87): Figures 3-34 displaying historical subsidence in the San Joaquin Valley from 1949 – 2005.

Westlands' Comment: Figures 3-34 contains a legend that is incomplete and is unable to be reviewed. Westlands GSA recommends applying the corresponding color scheme to the vertical displacement legend to allow readers to be able to review the presented information.

Finding 5 (Page 4-18): Section 4.5.1.1 introduces the following sustainable management criteria for Groundwater Levels paraphrased as follows: The Sustainable Management Criteria for Groundwater Level (Section 4.5.1.1) proposes the Measurable Objective to be set at a groundwater level using Method 4, which forecasts water levels to 2035 and sets the 2035 water level as the Measurable Objective. Minimum Thresholds were based on assumed stability of groundwater levels between 2035 and 2040 and are designed to be a last-resort warning before more severe measures must be taken to protect groundwater resources. Section 4.4.3 (Selection Process of Minimum Thresholds to Avoid

Undesirable Results) establishes the Minimum Thresholds as "one standard deviation of all observed head data in compliance wells or modeled forecasted data." Figure 4-2 through 4-6 describe establishment of the Minimum Thresholds as "one standard deviation or 50 feet, whichever is greater."

Westlands' Comment: Sustainable Management Criteria, which includes the measurable objectives and the minimum thresholds, allows groundwater levels in the aquifer to decline past the Westside Subbasin's Measurable Objectives and Minimum Thresholds, set at 2015 groundwater levels, and may negatively impact the Westside Subbasin's ability to achieve sustainability by reducing net inflow into the Westside Subbasin and/or reversing the groundwater flow direction. More specifically, the proposed decline of groundwater levels in the South Fork Kings GSA may alter the groundwater conditions near the boundary between the Westside Subbasin and the Kings Subbasin and result in a lowering of groundwater levels in the Westside Subbasin. This action would have the effect of shifting the burden of SGMA compliance from the South Fork Kings GSA to Westlands GSA. This is not permissible. The GSP is devoid of substantial evidence and any explanation as to how the Minimum Thresholds will avoid a significant and unreasonable reduction in groundwater storage and significant and unreasonable land subsidence contributing to the impairment of surface uses within the Westside Subbasin.

Water Code section 10733, subdivision (c) provides in relevant part:

> "The department shall evaluate whether a groundwater sustainability plan adversely affects the ability of an adjacent basin to implement their groundwater sustainability plan or impedes achievement of sustainability goals in an adjacent basin"

Further, we respectfully call your attention to Code of Regulations, title 23, section 355.4, subdivision (b)(7):

> "When evaluating whether a Plan is likely to achieve the sustainability goal for the basin, the Department shall consider . . . whether the Plan *will adversely affect the ability of an adjacent basin to implement its Plan or impede achievement of its sustainability goal.*" (emphasis added)

and Code of Regulations, title 23, section 354.28, subdivision (b)(3):

> "The description of minimum thresholds shall include . . . how minimum thresholds have been selected to *avoid causing undesirable results in adjacent basins or affecting the ability of adjacent basins to achieve sustainability goals.*" (emphasis added)

Moreover, the implementation of SGMA and a GSP cannot be used to override the protections afforded common law water rights. Overlying and appropriative uses of groundwater within the Westside Subbasin are entitled to legal and equitable protection against infringement by an action that deprives them of their historical subsurface inflows. (*City of Lodi v. East Bay Municipal Utility District* (1936) 7 Cal.2d 316, 344 [protecting groundwater levels against lowering from another party's pumping]; *Trussell v. City of San Diego* (1959) 172 Cal.App.2d 593, 611 [enjoining a party for lowering water table by interrupting surface flow].)

Additionally, proposing a continued decline of groundwater levels in the Lower Aquifer is not supported by substantial evidence because the GSP acknowledges that it does not have enough data to support its finding that there will be no impact to historical boundary flow conditions between the

Subbasins. The potential for curtailing historic underflow into the Westside Subbasin may be a substantial factor in contributing to significant and unreasonable subsidence and frustrate the Westlands' GSA ability to achieve the sustainability goal.

Finding 6 (Page 4-21): Section 4.5.33 Land Subsidence references Table 4-2: *Lemoore-Average Land Subsidence Interim Milestones based on Measurable Objectives for the Subbasin,* which displays modeled subsidence rates and interim milestones for those subsidence rates. The Tulare Lake Subbasin also proposes a minimum threshold of 16 ft by 2040 in Section 4.4.1.3.

Westlands' Comment: Westlands GSA is concerned that allowing subsidence rates as proposed may impact critical infrastructure such as roads, railroads, and may increase flood risks to existing land uses, especially near Corcoran where subsidence rates are critical, in the Westside Subbasin and other neighboring subbasins. Westlands GSA strongly recommend selecting Measurable Objectives and Minimum Thresholds to subsidence rates that will not negatively impact infrastructure in neighboring subbasins. The GSP fails to reference any substantial evidence that the minimum threshold will avoid significant and unreasonable land subsidence that impairs surface uses in the Westside Subbasin.

Finding 7 (Appendix D): The information provided in the GSP suggests a conceptual error leading to flows between the Westside Subbasin and Tulare Lake Subbasin to be misrepresented in the numerical model and GSP. Figure D5-5 in Appendix D shows the average model simulated net lateral subsurface flow of 158,405 AFY from the Lower Aquifer to the general head boundary (GHB) in the Westside Subbasin. Contours of simulated Lower Aquifer groundwater levels from 2015 in Figure D5-3 show a cone of depression along the GHB in the Westside Subbasin. Figure D5-5 shows pumping from the Lower Aquifer is a net positive suggesting that intraborehole flow from the Upper Aquifer to the Lower Aquifer is greater than the amount extracted from wells, suggesting the GHB is driving the flow across the boundary between the Westside and Tulare Lake Subbasins and out of the Westside Subbasin.

Westlands' Comment:
Lower Aquifer contours developed from water level data at the end of the 2014 irrigation year (one year before the simulated contour data provided) do not show a cone of depression in the location of the GHB (**WWD Attachment: Figure 4**). These contours also cannot be interpreted to suggest that groundwater flow is from the Tulare Lake Subbasin to the Westside Subbasin. Furthermore, it is unclear what physical process would cause a localized cone of depression to form in this location, especially considering that the groundwater model simulates positive net pumping from the Lower Aquifer in the Westside Subbasin.

The analysis is not supported by substantial evidence and for the reasons set forth above, Westlands recommends reanalyzing the water level contour data from the numerical model and GSP.

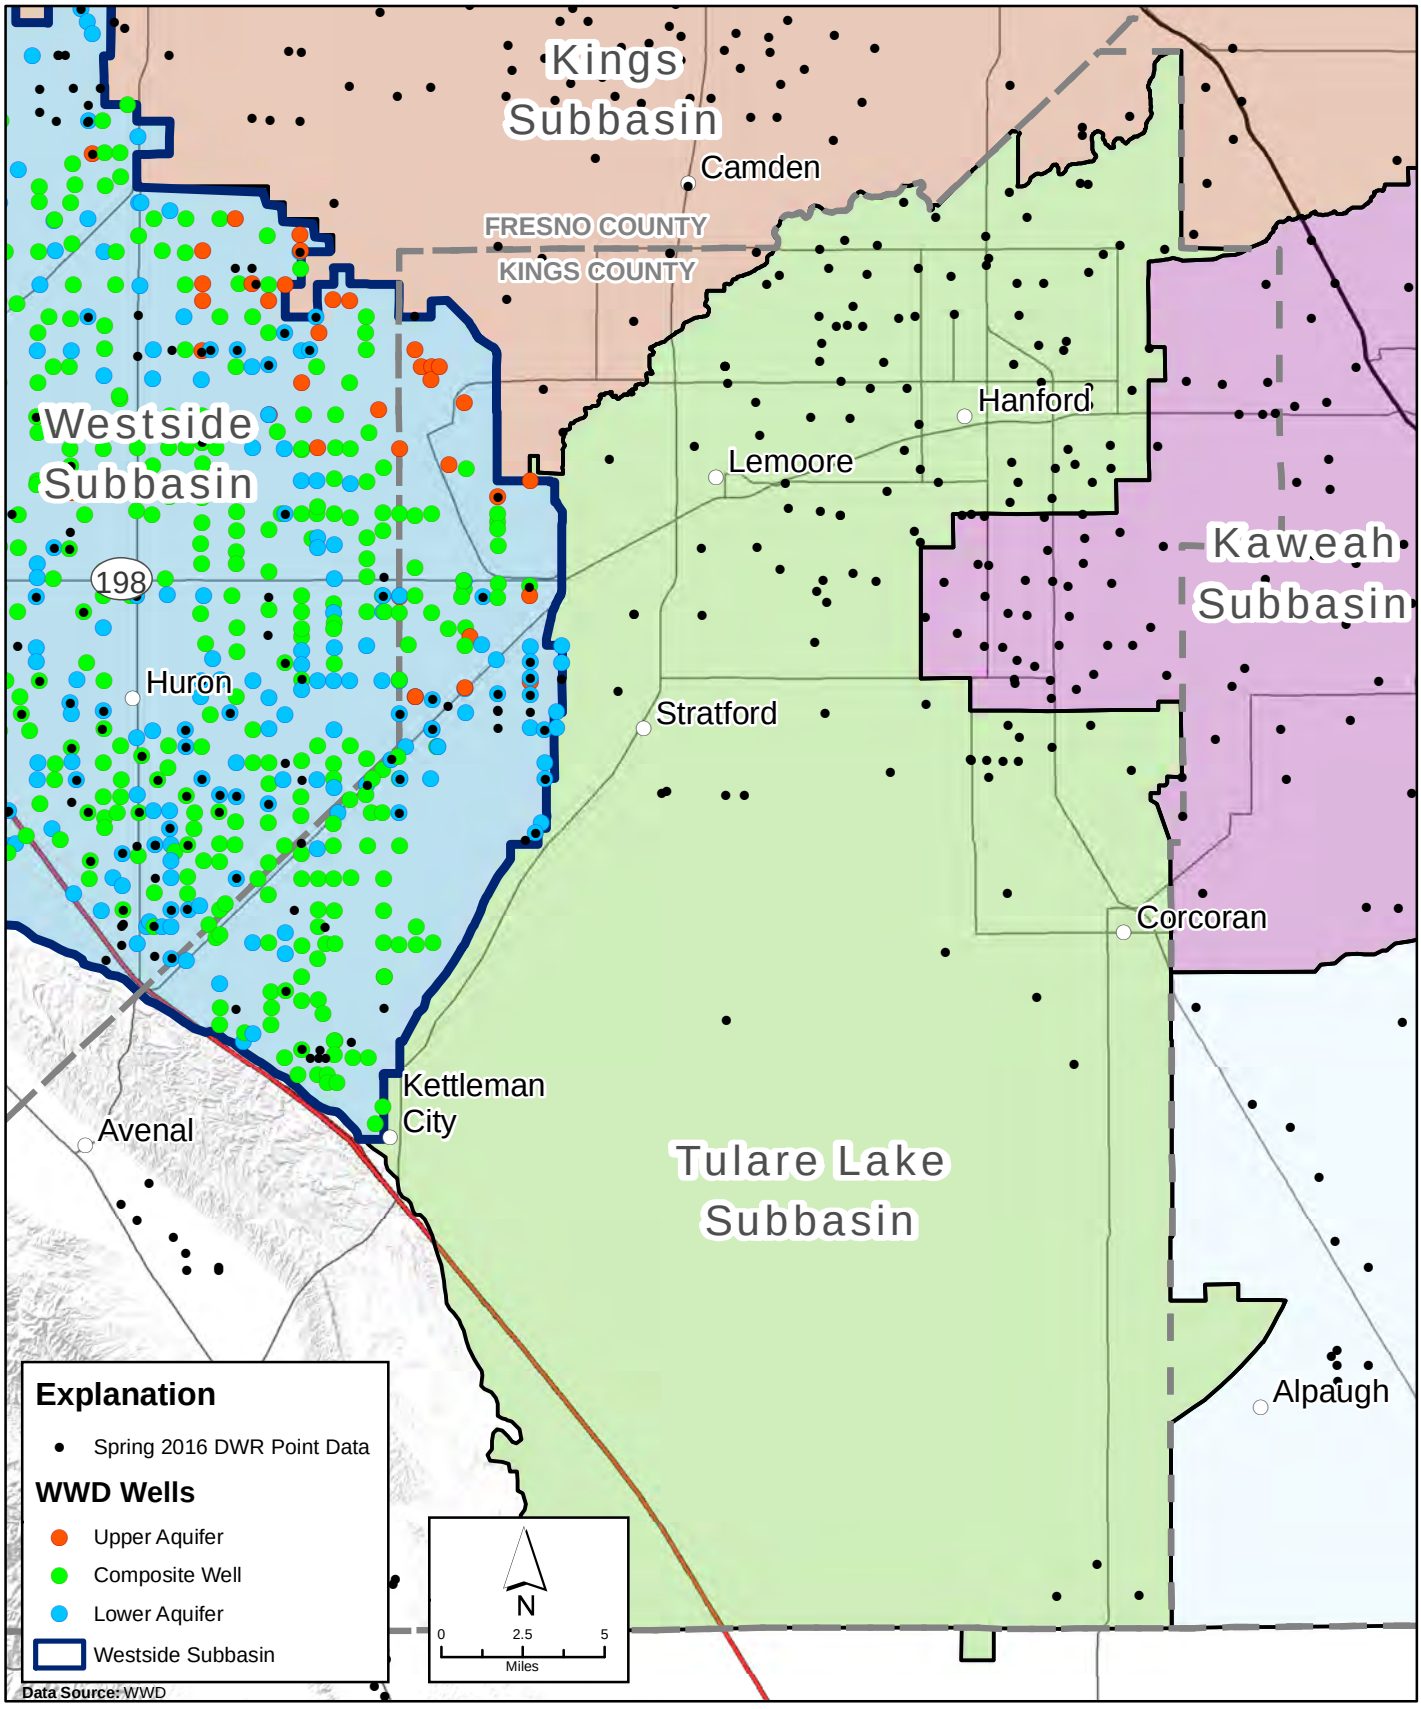
Lastly, the Westlands GSA identified the following reporting discrepancies within the text of the GSP and Appendix D that should be reviewed:

1. Total lateral subsurface inflow into the Westside Subbasin shown in Figure D5-5 averages 72,296 AFY (67,347 from the Tulare Lake Subbasin and 4,948 AFY from the Kings Subbasin). Table 3-6 of the GSP shows average annual subsurface flow from the Tulare Lake Subbasin to the Westside Subbasin of 41,390. What is the source of this discrepancy?

2. In the graphic depicting aquifer specific fluxes in Figure D5-5, the sum of the "Net GW Flux" (which presumably is lateral subsurface flow between adjacent subbasins) totals 4,936 AFY while the total in the table shown in Figure D5-5 is 72,296 AFY. What is the source of this discrepancy?

3. Figure numbers in the Appendix D text do not correspond to the correct figures. Figure D5-10 is titled "Simulated Subsidence 1990-2016". Figure D5-8 shows "Groundwater Mass Balance Tule Subbasin".

Westlands' General Comment: The GSP Regulations include a provision authorizing GSAs in adjacent basins to enter into interbasin agreements. The interbasin agreements can "establish compatible sustainability goals" and be included in GSPs to "support a finding that implementation of the Plan will not adversely affect an adjacent basin's ability to implement its Plan or impede the ability to achieve its sustainability goal." (Code Regs., tit. 23, § 357.2.)[1] The interbasin agreements may also address: (1) "an estimate of groundwater flow across basin boundaries;" (2) how the GSAs will reconcile differing minimum thresholds and measurable objectives in the basins to avoid undesirable results; and (3) a process for resolving conflicts between the GSAs. (*Id.*) Given the potential reduction of historical cross-boundary flow attributable to the planned operation with the Tulare Lake Subbasin Draft GSP, Westlands strongly recommends that we meet and confer at the earliest opportunity to determine whether an interbasin agreement can be reached. Our intention is to reach a cooperative resolution of these important issues that will enable coordinated sustainable management in our GSAs.



If you have any questions or concerns, regarding these comments, please contact Kiti Campbell by email at kcampbell@wwd.ca.gov or by phone at (559) 241-6226. Thank you for the opportunity to provide comments on the Tulare Lake Subbasin Draft GSP.

Sincerely,

Russ Freeman

Re: Comments on the Tulare Lakes Subbasin Groundwater Sustainability Plan

Dear Messrs. and Madams:

I am writing as a duly elected Supervisor for the County of Kings (the "County") and not on behalf of the Board of Supervisors. I am also writing on behalf of the other signatories to this letter, who care as deeply as I do about the issues raised in the Tulare Lakes Subbasin Groundwater Sustainability Plan (the "GSP") that has been proposed and is subject to this public hearing. I am submitting my comments and proposed changes in writing so that they may be incorporated into the GSP prior to its submission to the State Department of Water Resources ("DWR") by January 31, 2020.

Procedural Defects

The Groundwater Sustainability Agencies addressed above ("GSAs") issued a notice on September 3, 2019 for the December 2, 2019 public hearing to comment on the GSP. The narrative part of the GSP – approximately 500 pages – was not issued until three days later, on September 6, 2019. The Appendix D to the GSP – the Water Modeling Report – and the Water Model itself were not released to the public for review until October 17th, 2019, a month and half later. Even though the County requested to, and did, coordinate with the GSAs on Wednesday, November 6th, the GSAs' delay in getting the complete GSP out for the full 90-day review period set out in Section 10728.4 of the Water Code impeded any serious review and feedback on the GSP.

Under Section 10728.4, you were required to provide the County – and, consequently, the public – with at least 90-days written notice of the public hearing at which you planned to adopt the GSP. When the GSAs were told their "notice" was inadequate because of the lengthy delay in issuing the entire GSP, the responses have typically been two-fold: First, they claim the statute is ambiguous as to what it meant by "notice" of the public hearing. In other words, the statute does not say with specificity that the GSP had to be released at the same time as the notice. The second response has been, "Well, you'll get to comment at the State level once the GSP is lodged with the State in January, so it shouldn't matter whether you had adequate opportunity to comment now." Neither of these responses excuses the GSAs from giving the County and its water users a full opportunity to review and comment on the draft GSP.

For public notice to be effective, it must satisfy the requirements of administrative due process. Federal and California courts have ruled over the last half-century that adequate notice must be "reasonably calculated, under all the circumstances, to apprise the interested parties of the pendency of the action and afford them an opportunity to present their objections . . . ." (*Mullane v. Cent. Hanover Bank & Trust Co.* (1950) 339 U.S. 306, 314.) Furthermore, the notice must "convey the required information" within "a reasonable time for those interested" to be heard "at a meaningful time and in a meaningful manner." (See *id;* see also *Mathews v. Eldridge* (1976) 424 U.S. 319, 333.) From these cases and others, it is clear that the September 3rd notice needed to include at least 90-days written notice of the date, time, and location of the public hearing, as well as service of the entire GSP.

Second, regardless of whether the County or anyone else has an opportunity to comment to the State on the final GSP submission, it was the legislature's intent that all interested parties have a meaningful opportunity to comment *before* it was submitted to the State. At least the legislature believed that the GSAs should be given the benefit of substantive input on the GSP before they submitted it. Unfortunately, the GSAs' delay in getting the draft GSP prepared in time for any substantive review, feedback and opportunity to revise the draft GSP in response to the public's comments has compromised the successful adoption and implementation of the GSP.

Project Vagueness

One of the most important parts, in my view, of a successful GSP is convincing the State that the GSAs are committed to creating a sustainable source of groundwater for the region and that they can be trusted to implement an approved GSP. I am concerned that the purported "projects" set out in the GSP are too vague and non-committal and, consequently, won't convince the State to defer to the GSAs when it comes to groundwater sustainability. If the State rejects the GSP as being too vague – or for any other reason – the Sustainable Groundwater Management Act ("SGMA") makes clear that the State will take over our groundwater management and local control of that essential water resource will be history.

I attended the October 22nd, 2019, Board of Supervisors meeting when Dennis Mills addressed the Board and stated openly that the GSAs had made a judgment decision to keep the description of the GSP's proposed projects vague; he said the GSAs didn't want to commit to any specific projects in case, on further review, it was determined a project was not viable. I was also part of the delegation from the County that met with the GSAs on November 6th to consult on the draft GSP. As we discussed whether the GSAs had considered certain elements of certain projects,

such as CEQA requirements, Dennis stated that none of the GSA Boards had committed to any of the projects in the GSP. The fact that the GSA Boards haven't committed to doing anything (other than perhaps a groundwater monitoring program) as part of the GSP process is not going to instill confidence in the State and I'm concerned it could lead to the State's rejection of the GSP. The "projects" that have been proposed in the GSP should be firmed up as much as possible before the plan is submitted in January.

Land Fallowing Project

Finally, and most importantly, I am very concerned about the GSP proposal to fallow significant amounts of land within the County so as to cut agricultural demand for groundwater by at least 25 percent in 12 years. When we spoke with the GSAs during the November 6th consultation meeting, Jeof Wyrick confirmed that the GSP model incorporated an assumption that two percent (2%) of the land in the subbasin – not even spread out over the entire County – would be fallowed each year until we met the 2040 compliance deadline. If that is pursued, it would result in approximately 220,000 acres of agricultural land being fallowed. A good portion of that fallowed land would have to be permanent tree crops, which would result in the destruction of a significant amount of the value of the land (as they have to be irrigated every year) as well as the County's tax base.

During our consultation meeting, Jeof said that the water model consultants had erroneously incorporated the two percent (2%) assumption into the model, thus, overstating the amount of land to be fallowed as a result of GSP implementation. He said the GSP was going to be revised to incorporate an assumption of one percent (1%) per year fallowing that would result in "only approximately 100,000 acres" in the GSAs' boundaries being fallowed. I have no idea whether that has been done already or if it actually will be done before the GSP is submitted to the State. That amount of fallowed land is certainly less by half than what was previously projected, but when there are only approximately 420,000 acres of agricultural land within the GSAs' boundaries, that is an unacceptable level of fallowing both to the farmers whose land would be fallowed and, I believe, to the residents of the County. This 25 percent of total agricultural land fallowing is consistent with representations that the GSAs made publicly at the public outreach meeting in Lemoore, California, on October 15, 2019.

I was also surprised when Jeof said at our consultation meeting that implementation of the GSP was really "farmer versus farmer warfare" and that what was going to happen is "private adjudication of water rights in a public forum" (*i.e.*, before the GSAs). We all know what's going to happen when the few large farm and agricultural interests in the County go after the small, family-owned farms: The small farms are going to lose. I'm going to do everything in my power as a member of the Board of Supervisors to make sure that doesn't happen.

For this reason alone, the GSP should be revised to clarify that land fallowing in Kings County will be deployed only as a last resort after every other possible means of demand reduction and water recharge have been fully implemented and only at the minimal levels absolutely necessary to achieve sustainability. It is important to have survivability for the small farmer so that he can be competitive with the large corporate famers when it comes to ground water pumping. The Tulare Lake Subbasin will never achieve sustainability if the exported ground water from the subbasin to surrounding areas in the region is left unaddressed.

I am available to answer questions and discuss these concerns.

Sincerely,

DOUG VERBOON

Memorandum

To:	Tulare Lake Subbasin GSAs' Managers and Technical Team
From:	Trilby Barton, Public Outreach Coordinator, Provost & Pritchard
Subject:	Tulare Lake Subbasin GSAs' Groundwater Sustainability Plan Public Hearing Comments
Date:	December 2, 2019

December 2, 2019 Draft GSP Public Hearing Recap

The Tulare Lake Subbasin Groundwater Sustainability Agencies (GSAs) held a public hearing on the Draft Groundwater Sustainability Plan (GSP) on December 2, 2019. The hearing was held in the County of Kings Board of Supervisors' Chambers, and was called to order at 10:01 a.m. by Mid-Kings River GSA Manager, Dennis Mills.

Mr. Mills introduced himself and the other four GSA managers: Deanna Jackson with Tri-County Water Authority, Dale Melville with Southwest Kings GSA, Jeof Wyrick with El Rico GSA, and Charlotte Gallock with South Fork Kings GSA. Mr. Mills also introduced Trilby Barton, public outreach consultant with Provost & Pritchard Consultant Group. Mr. Mills and Ms. Barton explained the process for the public hearing, and Mr. Mills opened the floor for public comments.

Twenty stakeholders were in attendance, and one public comment was provided:

- **Bill Toss, Grower in Mid-Kings River GSA**
  "Reading through the plan that is available, the only thing that really struck out to me was the 25 percent set aside for reduction. That of course is most likely very damaging, and would not be sustainable economically here for Kings County or for us as growers. I hope that there is a change to that, and to make sure that is not the status quo."

Upon seeing that no other stakeholders wanted to provide oral comments, Mr. Mills thanked everyone for attending and closed the public hearing at 10:06 a.m.

1.0 Introduction

Wood Environment & Infrastructure Solutions, Inc. (Wood), has been retained by the Mid-Kings River Groundwater Sustainability Agency to prepare and document a hydrologic flow model of the Tulare Lake Subbasin (Subbasin) to aid local agencies in compliance with the Sustainable Groundwater Management Act of 2014 (SGMA). The Subbasin is located primarily in Kings County, within the Tulare Lake Hydrologic Region of the San Joaquin Valley, California (Figure D1-1). This project is a cooperative effort among five Groundwater Sustainability Agencies (GSAs) within the Subbasin including: Mid-Kings River GSA (MKR GSA), El Rico GSA (ER GSA), South Fork Kings GSA (SFK GSA), Southwest Kings GSA (SWK GSA), and Tri-County Water Authority GSA (TCWA GSA). Although the Subbasin is the primary focus of this modeling study, the modeling effort encompasses portion of adjacent California Department of Water Resources (DWR)-defined groundwater subbasins including the Kings, Kaweah, Tule, Kern, and Westside subbasins.

1.1 Background

Included as part of SGMA was a requirement that the DWR identify groundwater basins and subbasins in conditions of critical overdraft. As defined by DWR, overdraft occurs where the average annual amount of groundwater extraction exceeds the long-term average annual supply of water to the basin. Effects of overdraft can include land subsidence, groundwater depletion, and/or chronic lowering of groundwater levels. DWR Bulletin 118 defines critical overdraft as "when continuation of present water management practices would probably result in significant adverse overdraft-related environmental, social, or economic impacts."

Based on this criterion and a formal evaluation of groundwater basins across the state, the DWR found much of the Tulare Lake Hydrologic Region to be one of the most critically over-drafted regions of the state. The Subbasin sits at the lowest point of the Tulare Lake Hydrologic Region and receives both surface water inflows from several rivers and streams (including Kings River, Kaweah River, Tule River, and Deer Creek) and the State Water Project (SWP), but also irrigation return flows (tailwater) draining from irrigated lands. Nonetheless, in most years, especially during frequent drought cycles, agricultural water demand exceeds the surface water inflows, leading to the drilling of wells to develop the groundwater resources to fulfill that unmet demand. In fact, under recent historical conditions, the average annual demand on groundwater resources significantly exceeds the average existing recharge to the groundwater system, leading the DWR to declare the Subbasin critically over drafted, triggering the need to develop a Groundwater Sustainability Plan (GSP) by January 31, 2020, per SGMA requirements.

The Tulare Lake Subbasin Hydrologic Model (TLSBHM) developed for this project provides a quantitative tool for development and evaluation of alternative water management scenarios considered for the GSP. Additional model development and calibration will occur throughout the implementation of the GSP as additional data are collected.

1.2 Modeling Objectives

The objectives of the current modeling efforts were to:

1. Prepare a three-dimensional numerical surface water/groundwater flow model of the Subbasin and portions of adjoining subbasins.

2. Calibrate the surface water/groundwater flow model for the period 1990-2016, with a focus on the "normal hydrology" period 1998 through 2010, for initial calibration using available groundwater elevation observations and stream flow observations.
3. Provide a Baseline Forecast from 2017-2070 assuming continued recent land use and continued 1998 through 2010 "normal hydrology" conditions modified to account for climate change. This forecast was utilized to establish Critical Thresholds (CT) and Monitoring Objectives (MO) throughout the Subbasin.
4. Provide a Projects Forecast from 2017-2070 assuming continued recent land use, continued 1998 through 2010 "normal hydrology" conditions as modified to account for climate change, and additional Surface Water Supply and Aquifer Recharge resulting from several projects assumed to be implemented throughout the Subbasin and adjoining subbasins.
5. Compare the Baseline and Projects forecasts and estimate what additional projects and management actions (such as land fallowing) may be required to obtain sustainability by 2040 and thereafter.

2.0 Hydrogeologic Conceptual Model

A hydrogeologic conceptual model (HCM) is a simplified description of the groundwater flow system, frequently in the form of a block diagram or cross-section with an accompanying narrative description of the function and interaction of the various components that comprise the hydrogeologic system (Anderson et al., 2015). The nature of the HCM determines the dimensions of the numerical model and the design of the grid, the distribution of the hydrogeologic properties, and the definition and distribution (over space and time) of external and internal stresses and boundary conditions. The purpose of the HCM is to establish an initial understanding of the groundwater system and organize the associated data and information so that the system can be analyzed more effectively.

Figure D2-1 presents block diagrams that schematically represents key aspects of the HCM for the TLSBHM under both pre-development and current conditions. Details related to this HCM for the project include: (1) description of the model domain, (2) delineation of the hydrostratigraphic units within the model domain, (3) definition of sources and sinks and estimation of the water budget, and (4) narrative description of the flow system. Each of these items are discussed in the following subsections.

2.1 Basin Location and Study Area

The Subbasin is located primarily in Kings County in the Tulare Lake Hydrologic Region of the San Joaquin Valley, California (Figure D2-2). The Subbasin covers an area of approximately 535,869 acres or about 837 square miles (DWR, 2016b). The Subbasin in bounded by the Kings Subbasin to the north, the Kaweah Subbasin to the northeast, the Tule Subbasin to the southeast, the Kern Subbasin to the south, the Kettleman Plain Subbasin to the southwest, and the Westside Subbasin to the northwest.

As shown on the figure, the study area extends beyond the official Subbasin boundaries (as delineated by the DWR) from 3 to 6 miles into adjacent subbasins to better evaluate interactions with groundwater in those adjacent areas. The study area includes approximately 151,880 acres (~237.3 square miles) of the Kaweah Subbasin, approximately 119,360 acres (~186.5 square miles) of the Kings Subbasin, approximately 126,600 acres (~197.8 square miles) of the Tule Subbasin, approximately 81,760 acres (~127.8 square miles) of the Westside Subbasin, and approximately 78,000 acres (~121.8 square miles) of the Kern Subbasin.

The vertical extent of the study area is the freshwater hydrogeologic system, based on the United States Geological Survey (USGS) Central Valley Hydrologic Model (CVHM; Faunt et al., 2009), and modified to be consistent with the findings of Tulare Lake Bed de-designation studies (RWQCB, 2017). The depth zones that comprise the freshwater hydrogeologic system extend to a depth of about 3,000 feet below ground surface (bgs), but not reaching down into the deeper confined saline groundwater below.

2.2 Topography

The Subbasin and surrounding area is generally located in the lowest portion of the San Joaquin Valley (Figure D2-3). Ground surface gently rises to the northeast from about 180 feet above mean sea level (msl) at the Tulare Lake bottom to about 300 feet above msl near Kingsburg. To the southwest, ground surface rises rapidly from the Tulare Lake bottom to about 500 feet near the Kettleman Hills. To the south, ground surface gently rises from the lake bottom to about 220 above msl at the Kern County line.

2.3 Geology

The Subbasin is located in the south-central portion of the greater San Joaquin Valley. The valley was formed generally as a structural trough subsiding between two uplifts: the tectonically driven tilted block of the Sierra Nevada and the thrust belts of the Coast Ranges created by crustal shortening east of the San Andreas fault.

Episodic intrusion of the Pacific Ocean through land gaps along the northern and southern boundaries of the San Joaquin Valley occurred during Miocene and Pliocene times, allowing deposition of marine sediments to accumulate in the subsiding shallow sea environment of the San Joaquin basin. These deposits were subjected to deformation as the Sierra Nevada rose on the east and Coastal Range rose to the west and the valley trough subsided. The marine deposits are exposed in the west-side thrust belts, which typically reach elevations of 2,000 feet or less. Beneath the San Joaquin Valley, the top of the marine deposits are typically 3,000 feet or more below the valley floor, rising on the southeastern portion of the valley to cap the igneous rocks of the uplifted Sierra foothills.

As the land gaps closed in the mid-Pliocene, the continued uplift of the Sierra Nevada and Coast Ranges shed continental deposits to the San Joaquin Valley. These continental deposits, typically assigned to the Plio-Pleistocene Tulare Formation, have filled the valley trough in places with more than 3,000 feet of sediments. Where Pleistocene geologic features periodically cut off the route of major rivers and tributaries to the sea, wide spread and sometimes extreme thicknesses of lacustrine sediments were deposited. Significant examples of these lacustrine deposits are the Tulare Lake Bed clays, the Buena Vista clays, and the Corcoran Clay (sometimes referred to as the E-Clay or modified E-Clay).

2.3.1 Tulare Formation – Continental Deposits

Various investigators in the San Joaquin Valley have assigned ages and names to what they have identified as formations in their respective study areas. The Plio-Pleistocene Tulare Formation, which has its type section on the eastern slope of the North Dome of the Kettleman Hills (Woodring et al., 1940), has been correlated stratigraphically with other valley formations such as the Laguna Formation in the northeast portion of the valley (Woodring et al., 1940) and Kern River formations in the southeast portion of the valley (Bartow, 1991).
In the Subbasin, the primary stratigraphic units containing usable groundwater include the Tulare Formation, older alluvium, and younger alluvium. The Tulare Formation is by far the thickest of these three. The bottom of the Tulare Formation has been defined by Woodring et al. (1940) as occurring just above the Mya interval of the primarily marine San Joaquin Formation, over which it conformably lies on

the North Dome, just northwest of the Tulare Lake bed. The Tulare Formation/San Joaquin Formation contact dips steeply eastward from the Kettleman Hills, lying more than 3,000 feet beneath the trough in the Tulare Lake area (Croft and Gordon, 1968). Woodring et al. (1940) have defined the Tulare as the uppermost continental deposits deformed by the folding associated with the Kettleman Hills. However, as noted by Davis et al. (1959), the upper contact of the Tulare Formation with younger continental deposits (older and younger alluvium) is not easily discerned because "at many places along the valley border the dips increase westward so gradually that only a rough separation can be effected between the valley alluvium and the Tulare Formation. Separation of the alluvium from the Tulare Formation beneath the valley is virtually impossible because of their lithologic similarity."

2.3.2 Lacustrine, Marsh, and Flood Deposits

In the Subbasin, Croft & Gordon (1968) identified a number of lacustrine clays in the subsurface that they correlated to lacustrine clays identified by Woodring et al. (1940) in the Tulare Formation in Kettleman Hills. Croft & Gordon (1968) identified these in geophysical logs and named them the A- through F-Clays, with the E-Clay being equivalent to the diatomaceous Corcoran Clay. Though the A- through D-Clays may be important locally in restricting downward movement of groundwater, by far the most important is the EC-Clay, which has been identified as a spatially extensive (about 3,500 square miles, Croft, 1972) and thick clay that separates regionally confined and unconfined groundwater zones in the southern San Joaquin Valley (Figure D2-4). The E-Clay has been age-dated as mid-Pleistocene and is considered part of the Tulare Formation (Croft & Gordon, 1968). Beneath the Tulare Lake bed, there is a thick, nearly homogeneous deposit of lacustrine clays from ground surface to the San Joaquin Formation, including the E-Clay. However, the E-Clay extends far beyond the shoreline of Tulare Lake (Croft, 1972).

2.3.3 Older and Younger Alluvium

The other continental deposits that have been identified in published reports as containing groundwater are the older and younger alluvium (Croft & Gordon, 1968). In the Tulare Lake area, these deposits are primarily Sierran in origin, being deposited by the major stream channels emanating from the Sierra Nevada. Some sediments may have Coast Range origin, but the axis of Tulare Lake bed is close to the Kettleman Hills, which leaves little room for Coast Range sediment deposition on the west side. The older alluvium is widespread throughout the San Joaquin Valley and in other areas represents deposition from both the Coast Ranges on the west side of the valley and the Sierra on the east. It typically overlies the Tulare Formation, though as mentioned earlier, there is no way to differentiate between the two in the subsurface. It is considered Pleistocene to Recent in age. Most of the groundwater withdrawn from the Subbasin comes from the older alluvium/Tulare Formation complex.

The younger alluvium is generally thinner than the older alluvium and is present in current stream channels and as a veneer over the older alluvium as the deposits stretch to the west. The younger alluvium is primarily arkosic and contains groundwater only ephemerally or where underlying clays tend to restrict downward movement of recharging water. It is considered of Recent age.

2.3.4 Tulare Lake Bed

The Tulare Lake bed is the prominent sedimentary feature in the Subbasin. It was a natural lake bed fed by streams from the east and south. Its elongate shape to the northwest reflects the subsidence of the valley trough east of the Kettleman Hills. Geologic cross sections through the Tulare Lake bed (Croft, 1972; Croft & Gordon, 1968; Davis et al., 1959) illustrate the thick and continuous nature of the clay deposits beneath the lake bed (Figure D2-5).

Cross-section A-A' (Plate 4, Croft & Gordon, 1968) indicates uninterrupted lacustrine deposits from the surface to at least 2,200 feet bgs beneath the central portion of the lake. Cross-sections B-B' and C-C' (Plates 5 and 6, Croft & Gordon, 1968) illustrate the interfingering of the coarser sediments and the thinner clay zones along the periphery of the lake with the thick clay deposits beneath the lake. Though Croft & Gordon (1968) did not carry the E-Clay through the lake deposits, Davis et al. (1959, Plate 10, Section G-G', Diatomaceous Clay) and Croft (1972, Plate 3, Section G-G', E-Clay) felt they had enough evidence to map it beneath the lake. Davis et al. (1959) show it as being warped downward along the axis of the lake with a maximum thickness of 150 to 175 feet. These cross sections indicate the Tulare Lake deposits form a clay "plug" across the center of the San Joaquin Valley that may be 15 miles wide, 8 miles long, and over ½ mile deep at its maximum dimensions.

2.4 Hydrogeology

The hydrogeology of the Subbasin is complex in that the only physical boundaries are the Kings River and the Kettleman Hills on the southwest edge of the Subbasin. The remaining edges of the Subbasin are based on political and water management areas. The Corcoran Clay under lies most of the Subbasin, and essentially subdivides the Subbasin into two aquifer systems: an unconfined to semi-confined aquifer system above the Corcoran Clay and a confined aquifer system below the Corcoran Clay.

The Kings River appears to be a natural groundwater divide separating the Subbasin and Kings Subbasin. The Kings River is also the primary source of surface water diversion into the Subbasin. As such, the Kings River hydrologic year has a significant influence on groundwater levels in the Subbasin. In the unconfined aquifer, groundwater outflow from the Kings Subbasin into the Subbasin is primarily due to leakage from the Kings River. However, this groundwater predominantly flows along the course of the Kings River and therefore does not remain exclusive to the Subbasin. In the confined aquifer, groundwater outflow from the Kings Subbasin into the Subbasin is also due to leakage from the Kings River in the northeast portion of the Subbasin where the Corcoran Clay is not present. This groundwater has a strong downward vertical component which creates steep southward hydraulic gradients beneath the Corcoran Clay. This groundwater tends to remain resident in the Subbasin confined aquifer.

The groundwater flow system for these two aquifer systems is summarized in the following subsections.

2.4.1 Unconfined Aquifer

The unconfined and semi-confined upper portion of the regional fresh-water aquifer are found above the Corcoran Clay. This upper portion of the regional freshwater aquifer is generally comprised of coarse- to medium-grained sediments (i.e., sand and gravel) with silt and clay interbeds.

Groundwater beneath the Subbasin and surrounding areas is typically found between depths from 30 to 250 feet bgs, depending on location and time. A review was conducted of available DWR groundwater elevation contour maps of the unconfined aquifer from 1960 to 2010 and briefly described below (DWR, 2018). The maps show a persistent, large data gap beneath the Tulare Lake bed where there are few observations of groundwater levels due to a lack of wells.

- In 1990, a dry hydrologic year on the Kings River, groundwater was at an elevation of about 260 feet msl near Kingsburg, decreasing toward the Tulare Lake bottom (Figure D2-6a). Groundwater elevations beneath Hanford were about 170 feet msl, and about 140 feet msl near Corcoran. There were several cones of depression in the water table near Hanford, north and south of Corcoran, and around Alpaugh. The Kings River appears to be a natural groundwater

divide. In general, the potentiometric surface map indicates that groundwater was flowing into the Subbasin from the Kern, Kings, Kaweah, and Tule subbasins and out of the Subbasin to the Westside Subbasin.

- In 1995, a wet hydrologic year on the Kings River, groundwater was at an elevation of about 260 feet msl near Kingsburg, decreasing toward the Tulare Lake bottom (Figure D2-6a). Groundwater elevations beneath Hanford were about 150 feet msl and about 110 feet msl near Corcoran. The cone of depression in the water table between Hanford and Corcoran has merged into a single large depression. The Kings River continues to be a natural groundwater divide. In general, the potentiometric surface map indicates that groundwater was flowing into the Subbasin from the Kern, Kings, Kaweah, and Tule subbasins and out of the Subbasin to the Westside Subbasin.

- In 2000, an average hydrologic year on the Kings River, groundwater was at an elevation of about 250 feet msl near Kingsburg, decreasing toward the Tulare Lake bottom (Figure D2-6a). Groundwater elevations beneath Hanford were about 150 feet msl and less than 100 feet msl near Corcoran. The Kings River continues to be a natural groundwater divide. In general, the potentiometric surface map indicates that groundwater was flowing into the Subbasin from the Kings, Kaweah, and presumably the Kern subbasins and out of the Subbasin to the Tule and Westside subbasins.

- In 2005, a wet hydrologic year on the Kings River, groundwater was at an elevation of about 260 feet msl near Kingsburg, decreasing toward the Tulare Lake bottom. Groundwater elevations beneath Hanford were about 140 feet msl, about 10 feet lower than in 2000 (Figure D2-6b). Throughout the Subbasin, groundwater levels were about 10 or more feet lower than in 2000. The Kings River continues to be a natural groundwater divide. In general, the potentiometric surface map indicates that groundwater was flowing into the Subbasin from the Kings, Kaweah, and Tule subbasins and out of the Subbasin to the Westside Subbasin.

- In 2010, an average hydrologic year on the Kings River, groundwater was at an elevation of about 250 feet msl near Kingsburg, decreasing toward the Tulare Lake bottom. Groundwater elevations beneath Hanford were about 130 feet msl and less than 10 feet msl near Corcoran (Figure D2-6b). Throughout the Subbasin, groundwater levels were about 10 or more feet lower than in 2005. The Kings River continues to be a natural groundwater divide. In general, the potentiometric surface map indicates that groundwater was flowing into the Subbasin from the Kings, Kaweah, Tule, and presumably the Kern subbasins and out of the Subbasin to the Westside Subbasin.

- In 2016, a dry hydrologic year on the Kings River, groundwater was at an elevation of about 230 feet msl near Kingsburg, decreasing toward the Tulare Lake bottom. In the Hanford area, groundwater levels were about 110 feet msl, about 20 feet lower than in 2010. Cones of depression in the water table west, north, and southeast of Corcoran are still present and becoming deeper (-40 feet msl). The Kings River no longer is a natural groundwater divide. In general, the potentiometric surface map indicates that groundwater was flowing into the Subbasin from the Kings and Kaweah subbasins and out of the Subbasin to the Kern, Tule, and Westside subbasins.

2.4.2 Confined Aquifer

The sediments below the Corcoran Clay comprise the lower confined portion of the regional fresh-water aquifer. This lower portion of the regional freshwater aquifer is generally comprised of clay, silt, sandy silt and clay, sand, silty/clayey sand, gravel, and sandy, silty and clayey gravel (Page, 1983).

There are few available maps showing groundwater elevations in the confined aquifer beneath the Subbasin and surrounding areas (Harder, 2017). In fall 1998 and spring 1999, a wet hydrologic year on the Kings River, groundwater was at an elevation of about 100 feet msl near Corcoran, decreasing to the south towards an apparent pumping center near Alpaugh. In general, the potentiometric surface map (Harder, 2017) indicates that groundwater was flowing into the Subbasin from the Kaweah Subbasin and out of the Subbasin to the Tule Subbasin.

In fall 2010, an average hydrologic year on the Kings River, groundwater was at an elevation of about -50 feet msl near Corcoran, decreasing towards an apparent pumping center southwest of Corcoran. In general, groundwater was flowing into the Subbasin from the Kaweah and Tule subbasins.

2.4.3 Subsidence

Land subsidence due to groundwater drawdown associated with heavy groundwater pumping has affected large areas of the San Joaquin Valley since the 1920s, including the Subbasin (AFW, 2018). Between 1926 and 1970, there was approximately 4 feet of cumulative subsidence near Corcoran, 4 to 6 feet of subsidence near Hanford, and as much as 12 feet of subsidence near Pixley (Figure D2-7). Following the completion of the SWP and Central Valley Project (CVP), surface water became readily available and groundwater extraction was reduced and subsidence due to groundwater drawdown was temporarily slowed or stopped.

In the past 10 to 25 years, groundwater pumping has once again been increasing, with associated resumption and acceleration of groundwater drawdown and associated subsidence. The subsidence was exacerbated during a moderate to severe drought from 2007 through 2009, and a severe to exceptional drought from 2012 through 2016. A Jet Propulsion Laboratory study of subsidence between June 2007 and December 2010 (JPL, 2012) indicated subsidence rates were as high as 8.5 inches per year in the vicinity of Corcoran (Figure D2-7). A more recent study by Jet Propulsion Laboratory (JPL, 2017) indicted that subsidence rates accelerated in some areas during the recent drought, with annual subsidence rates of 1 to 1.5 feet near Corcoran in 2015-2016 (Figure D2-8). Groundwater pumping and drawdown, and consequent subsidence, are anticipated to continue into the future at least until sustainable groundwater pumping is achieved. Due to inelastic soil behavior, subsidence is mostly irreversible even if groundwater pumping decreases and groundwater level recovers.

2.5 Surface Water Occurrence

Historically, river runoff from the Sierra Nevada collected in terminal lakes on the basin floor in the San Joaquin Basin creating vast regions of Tule marshes and woodland wetlands (Figure D2-9a). Tulare Lake, the largest terminal lake, received runoff from four major rivers, the South Fork Kings, Kaweah, Tule, and Kern Rivers (ECORP, 2007). These rivers formed broad deltaic and alluvial fans as they emerged from the Sierra foothills forming multiple channels and sloughs that shifted periodically especially during flooding events (ECORP, 2007). The natural hydrology of the Tulare Lake Basin has been extensively altered over the last 130 years for flood control, irrigation, land reclamation, and water conservation. Concerns about water supplies led to the construction of large dams and reservoirs on each of the four major rivers and channelization of the rivers for flood control and water banking have further modified the Tulare Basins

hydrography (ECORP, 2007). The surface water sources that supply the Subbasin are primarily from man-made canals and diverted rivers.

2.5.1 Tulare Lake

Tulare Lake was the largest freshwater lake west of the Mississippi River estimated to encompass 790 square miles at its highest overflow lever of 216 feet in 1862 and 1868 (Figure D2-9a) (ECORP, 2007). The lake was very shallow and had no natural outlet when the water levels was below 207 feet (ECORP, 2007). However, at 207 feet, the water could flow north into the San Joaquin River Basin. Increased diversion of water from the rivers and tributaries that previously flowed into Tulare Lake resulted in the lake drying up in the late 1800s except when occasionally flooded.

2.5.2 Kings River

The Kings River is a 133-mile-long river, the largest river draining the southern Sierra Nevada. The Kings River has three main tributaries, the North Fork, Middle Fork and South Fork, with the North and Middle forks flowing north to the San Joaquin River and the South Fork flowing south to the old Tulare Lake bed. Significant water development structures including the Pine Flat Dam were constructed in the last century to control and modified the rivers flow. The Kings River lies along the boundary between the Subbasin and Kings Subbasin, a portion of the boundary between the Subbasin and Westside Subbasin, and a portion of the boundary between the Subbasin and Kaweah Subbasin (Figure D2-9b). Leakage of water from the Kings River and distributary canals provides significant groundwater recharge in the Kings, Kaweah, Westside, and Tulare Lake subbasins, resulting in complex groundwater flow patterns between the subbasins.

2.5.3 Kaweah River

The Kaweah River is a 100-mile-long river in Tulare County and drains the southern Sierra Nevada (Figure D2-9a). The Kaweah River begins as four forks in Sequoia National Park, then flows in a southwest direction to Lake Kaweah – the only major reservoir on the river – and into the San Joaquin Valley, where it diverges into multiple channels across an alluvial plain around Visalia. The lower course of the river and its many distributaries – including the St. John's River and Mill Creek – form the Kaweah Delta, a productive agricultural region in the Kaweah Subbasin. Before the diversion of its waters for irrigation, the river flowed into Tulare Lake.

2.5.4 Tule River

The Tule River is a 71-mile-long river in Tulare County and drains the southern Sierra Nevada (Figure D2-8c). The Tule River has three main tributaries, the North Fork, Middle Fork and South Fork, that in the past flowed into Tulare Lake. Currently, water in the Tule River now flows into Lake Success, a reservoir constructed in 1961 near Porterville, California, and only in times of above normal precipitation or snow melt is water released onto the dry Tulare Lake bed.

2.5.5 Canals and Pipelines

There are 34 rivers, streams, canals, and diversions entering and within the Subbasin that deliver surface water to the Subbasin (Figures D2-9b-d).

Water is imported into the Subbasin using facilities of the SWP located west of the Subbasin and the CVP. Water can also be exported out of the Subbasin using the SWP and CVP facilities in combination with facilities developed by local water districts (ECORP, 2007). The CVP imports San Joaquin River water into

the Subbasin through the Friant-Kern Canal and Delta water through the Delta-Mendota and San Luis Canals.

The Friant-Kern Canal is operated and maintained by the Friant Water Authority and is used to convey water from the San Joaquin River to Kern County. The canal originates at the Friant Dam, which is operated by the United States Bureau of Reclamation. The Friant-Kern Canal flows southeasterly along the western flank of the Sierra Nevada foothills through Fresno, Tulare, and Kern counties. The Friant-Kern Canal has a capacity of approximately 5,300 cubic feet per second or about 10,510 acre-feet per day (AF/D), which decreases to about 2,500 cubic feet per second or about 4,960 AF/D as demand decreases toward its end in the Kern River, near Bakersfield, California (AFW, 2018).

2.6 Climate

The climate in the Subbasin is semi-arid characterized by hot, dry summers and cool moist winters and is classified as Mediterranean steppe climate (Köppen climate classification). The wet season occurs from November through March with 80 percent (%) of precipitation falling during this time frame (ECORP, 2007). The valley floor often receives little to no rainfall in the summer months. Precipitation typically occurs from storms that move in from the northwest off the Pacific Ocean and occasionally storms from the southwest that contain warm sub-tropical moisture can produce heavy rains especially during El Nino episodes.

Historical annual precipitation at the Hanford weather Station from 1899 to 2017 (Hanford, 2017) has ranged from a low of 3.37 inches in 1947 to a maximum of 15.57 inches in 1983 (Table D2-1). Monthly precipitation in the area ranges between 0 and 6.69 inches per month and averages about 8.28 inches per year. This results in an estimated 2 inches per year of infiltration into the unconfined aquifer. Figure D2-10 provides a chart of the annual precipitation at the Hanford station from 1940 to 2017.

2.7 Land Use

Land use in the Subbasin and surrounding areas is predominately agricultural with smaller urban areas. Land use was evaluated using DWR land use maps for 1990 through 2006 (DWR, 2016a) and annual CropScape maps from 2006 through 2016 (USDA, 2016). These maps were provided in Geographic Information System formats, allowing for aggregation of similar land uses (i.e., crop types) to simplify analysis (Figure D2-11a-d). A total of 33 land uses were identified and evaluated (Table D2-2). Of these land uses, 27 were assumed to be irrigated, while 6 land uses (open water, forests, etc.) were assumed to only receive precipitation.

The Subbasin covers an area of approximately 535,869 acres or about 837 square miles (DWR 2016b). Between 1990 and 2016, the Subbasin had an average of approximately 310,800 acres of crops, 7,110 acres of riparian or open water, 137,110 acres of fallow or non-developed land, and 22,130 acres of urban and industrial development (Table D2-2, Appendix D1). The mix of crops grown and fallow lands has changed over time as agricultural practices changed in response to agricultural markets and drought conditions. A chart of area by land use shows that fallow acreage increased significantly during the 2010-2016 drought, while riparian, cotton, and pasture acreage all decreased during the drought (Figure D2-12). Cotton showed the most change with a decrease of over 85,000 acres between 1995 and 2016. The data also show that the was an overall increase in permanent crops over time, with increases in young and mature almonds from approximately 7,680 acres in 1995 to 42,300 acres in 2016. The total acreage of pistachios also increased from 4,700 to 26,900 acres between 1995 and 2016; however, there was a loss of 4,220 acres of mature pistachios with a concurrent increase of 26,400 acres of young pistachios.

Annualized tables and charts of land use for the Subbasin GSAs and the portions of the Westside, Kings, Kaweah, Tule, and Kern subbasins within the model domain are presented in Appendix D1.

2.8 Basin Water Budget

The basin water budget describes the inflows to and outflows from the Subbasin hydrogeologic system. Inflow and outflow can occur from the hydraulic boundaries of the system, from various sources within the model domain such as rainfall, lakes, and leakage from rivers and canals, and from the exit points or sinks such as wells or drainage systems. The boundaries, sources, and sinks identified within the model domain are discussed below.

2.8.1 Inflows

Inflows consist of precipitation, surface water diversions for irrigation, imported groundwater for irrigation, intentional recharge, and leakage from streams and conveyances.

2.8.1.1 Precipitation

Precipitation can be a significant source of water to the Subbasin and surrounding area. Given the large areal extent of the Subbasin and surrounding area, it was determined that using a single weather station to estimate precipitation would be inadequate to represent the entire Subbasin. Instead, the Parameter-elevation Regression on Independent Slopes Model (PRISM) database maintained by the Oregon State University was used to estimate monthly precipitation from January 1990 through December 2016 across the model domain (PRISM, 2017). The PRISM database contains monthly total precipitation for the entire United States using a 4-kilometer grid. The monthly precipitation values are statistically derived values based on local weather stations and corrections for topographic variations. A total of 304 PRISM data sets were downloaded for the model domain. The monthly precipitation data were summed by Subbasin area to estimate the potential annual precipitation volume for each subbasin (Figure D2-13a). Maps of average monthly rainfall across the model domain for the months of January, March, May, July, September, and November shows that precipitation also varies spatially across the model domain (Figure D2-13b).

Not all rainfall is available for use by crops – some fall on impervious surface, some is taken up by dry soils, some is intercepted by foliage and on evaporates before it can infiltrate, and some deep percolates and recharges groundwater. Monthly effective precipitation was estimated by multiplying the monthly PRISM data sets by the Precipitation / Effective Precipitation ratios presented in FAO 56 (Chapter 3, Table 6; Allen et al., 1998) and shown on Figure D2-14. A table and chart summarizing annual effective precipitation by subbasin within the model domain is presented on Figure D2-15. This shows that between 1990 and 2016, effective precipitation provided as little as 9,320 acre-feet (AF) in a dry year (2013) to 501,030 AF in a wet year (2010) and averaged approximately 214,720 acre-feet per year (AF/Y) of water across the model domain.

2.8.1.2 Surface Water Diversions

Surface water diversion from external sources are the most significant source of water to the Subbasin and surrounding area. There are 34 rivers, streams, canals, and diversions entering and within the Subbasin that have recorded diversions (Figure D2-9a-c). Two primary data sources were employed for the surface water inflows and deliveries to the farms within the model domain:

- For lands within the Subbasin itself, surface water delivery and diversion records were obtained by via direct contacts with the various GSAs (and member water management agencies within the

GSAs) within the Subbasin proper (Table D2-3). Those records were relatively complete from 1990 through 2016 for diversions off the Kings system and SWP. As shown on Table D2-3, during the period 1998 through 2010, the Kings River had six below normal water years, four average water years, and three above average water years. Over the 1998-2010 period is Kings River water years average 96% of normal, making this a "normal hydrology" period.

- For deliveries to lands located within the model buffer area (between the boundaries of the Subbasin as defined by the DWR and the TLSBHM model domain boundaries), a combination of data gathered for GSAs whose footprint extended into the Subbasin proper, and data mined from the C2VSIM (Brush et al., 2016) model for those GSAs and water management districts that lay completely outside the official Subbasin boundary were utilized. The C2VSIM model surface water data covered from the beginning of the TLSBHM model period through the end of 2011 and was extended through the end of 2016 by correlation of those inflows with Kings River deliveries at Peoples weir. In general, inflows into this area from Kaweah and Tule Rivers, and Deer Creek were reconstructed from a variety of disparate data.

A table and chart summarizing annual surface water diversions by subbasin within the model domain is presented on Figure D2-16. Monthly surface water diversions by subbasin by GSA and subbasin are provide in Appendix D2. This shows that between 1990 and 2016, surface water diversions provided an average of 948,370 AF/Y of water across the model domain and as much as 1,696,540 AF of water in wet years.

The surface water diversions are not delivered uniformly across the model domain spatially or temporally (Figure D2-17). During the 1990-2016 period, there are several areas that historically have not received any surface water diversions or have received intermittent deliveries of surface water (Figure D2-17).

2.8.1.3 Imported Groundwater Supply

One unique feature of the Subbasin is the importation of groundwater supplies from adjacent subbasins. The ER GSA and TCWA GSA operated well fields in the adjacent Tule Subbasin and import the pumped groundwater into the Subbasin as an additional water supply. Between 1990 and 2016, ER GSA operated up to 52 wells in the Creighton Ranch well field, which delivered up to 68,730 AF in a dry year (2014) and as little as 0 AF in wet years (1996-1999) and averaged approximately 39,320 AF/Y in non-wet years (Table D2-4). The TCWA GSA operated up to 51 wells in the Angiola Water District (WD) well field, which delivered groundwater to TCWA GSA lands in both the Subbasin (about 60%) and Tule Subbasin (about 40%). Between 1990 and 2016, the Angiola WD well field delivered up to 23,100 AF in a dry year (2009) and as little as 0 AF in wet years (1996-1999) and averaged approximately 15,950 AF/Y in non-wet years (Table D2-4).

2.8.1.4 Lake Bottom Water Storage

Another unique feature of the Subbasin is the utilization of certain portions of the historical lake bottom for storage of the excess surface water inflows that were not diverted by others. This stored surface water is later used as an irrigation supply. In some years, sufficient water can be stored in the lake bottom to eliminate the need for supplemental groundwater pumping to meet the irrigation demand.

As observed in historical aerial imagery, the area occupied and the locations of water storage changes from year to year, although certain areas to the south appear to be more regularly utilized by storage (Figure D2-18). This can result in significant volumes of stored water in some years. Permanent lakebed storage facilities have the capacity to store approximately 70,000 AF at any given time. During flood events,

as an example of conjunctive use, some fields can be flooded allowing for the storage of significant volumes of water, in some years up to 450,000 AF in the ER GSA management area (Figure D2-18). When available, the storage water is typically utilized to supplement surface water deliveries in lieu of groundwater pumping. The importance of this conjunctive management capability is illustrated by the fact that the cumulative excess inflow stored in the lake bottom allowed lake bottom farmers to completely turn off their groundwater well fields between January 1995 and June 1999 (Table D2-4).

2.8.1.5 Intentional Recharge

Groundwater recharge in the Subbasin also occurs from intentional percolation of surface water in infiltration ponds and water banks. The Corcoran Irrigation District (CID) has operated nine intentional recharge basins covering approximately 2,760 acres since the 1980s (Figure D2-19). Aerial photograph analysis shows that only one or two basins are typically utilized each year between March and September when surface water is available, percolating an estimated average of 23,500 AF/Y of surface water. The other ponds are typically dry except in extremely wet years such as 2005-2006, 2010-2011, and 2017 when as much as 147,700 AF of water has been estimated to be percolated. During the 1990-2016 simulation period, the CID Ponds percolated an estimated 616,100 AF of excess surface water.

Kings County Water District (KCWD) has been infiltrating Kings River flood waters along the Old Kings River channel since the 1940s (referred to as Condition 8). Condition 8 water is surface water that naturally would have infiltrated along the Old Kings River channel during high river flow years had the river not been diverted for irrigation. Between 1990 and 2016, Condition 8 recharge has ranged from as little as 0 AF in most years and as much as 36,800 AF in flood years (1995) and averaged approximately 30,370 AF/Y in wet years (Figure D2-20).

In addition, KCWD operates 25 recharge basins totaling about 720 acres within the MKR GSA and also began operating a water bank on the Old Kings River Channel in 2002. Since 2002, approximately 73,600 AF of water has been recharged via percolation through approximately 50 acres of ponds through the water bank, and approximately 48,500 AF has been recovered utilizing five recovery wells. This leaves a positive balance of approximately 25,100 AF in the unconfined aquifer system as of 2016.

In the Chamberlain Ranch area of the ER GSA, 640 acres has been utilized for percolation basins. In 2017, approximately 5,000 AF was recharged. Immediately adjacent to the eastern boundary of the ER GSA in the Tule Subbasin, there are recharge basins that are operated by ER GSA landowners.

2.8.1.6 River and Canal Seepage

Seepage losses from river and canals provide another source of water to the Subbasin and surrounding areas. There are over 290 miles of major streams and canals within the Subbasin, in addition to many more miles of small distribution ditches on individual farms (Figures D2-9b-d). Most to the stream and canals are unlined and can have significant seepage losses. Ownership of canal and river seepage is to be determined. There was little available information on seepage losses in the Subbasin, although anecdotal reports indicate the Old River Channel, Peoples Ditch, and Lakeland Canal all have substantial losses near the head gates at Peoples Weir (personal communication, Dennis Mills).

2.8.2 Outflows

Outflows consist of evapotranspiration, agricultural pumping, municipal pumping, and agricultural drains.

2.8.2.1 Evapotranspiration

Crop evapotranspiration (ETc) or crop demand use is the largest outflow of water from the Subbasin. ETc data are based on spatial distributions of different types of crops, as well as estimated rates of evapotranspiration for the Subbasin area. Crop data comes from DWR data sets for the counties of Fresno, Kern, Kings, and Tulare (surveyed intermittently between 1990-2006) and from CropScape datasets (surveyed annually from 2007-2016). Monthly ETc varies by crop type and by season, typically peaking during the summer months. ETc rates were estimated from published ITRC rates (ITRC, 2003) under normal year conditions for the region (Table D2-5).

Annual crop demand was calculated for each crop type on a 40-acre basis as follows:

Annual Crop Acres (Acres) * *Annual Crop ETc* (Feet/Acre) = *Irrigated Crop Demand* (AF/Y)
(Table D2-2) (Table D2-5) (Table D2-6)

Note: some crop types do not receive irrigation water and thus have zero irrigated crop demand.

Between 1990 and 2016, the total irrigated crop demand in the Subbasin ranged from 564,120 AF in 2015 to 1,072,440 AF in 2007 and had an average irrigated crop demand of approximately 879,020 AF/Y (Table D2-6).

The mix of crops grown and fallow lands has changed over time as agricultural practices changed in response to agricultural markets and drought conditions. A chart of annual crop acreage shows that total crop acreage has generally decreased since 2010 (Figure D2-12). Crop demand shows a similar pattern, generally decreasing from 2009 through 2015 (Table D2-6). Cotton showed the most change with a decrease of crop demand over 50% between 1995 and 2016. The data also show that during the 2011-2016 drought, there was an overall increase in row crop demand including tomatoes, peppers, small vegetables, onion, garlic, grain, and hay. In addition, the data show a large increase in ETc demand from almonds, pistachios, and stone fruits. Annualized tables and charts of crop demand for the Subbasin GSAs and the portions of the Westside, Kings, Kaweah, Tule, and Kern subbasins within the model domain are presented in Appendix D3.

2.8.2.2 Specified Agricultural Well Field Pumping

Agricultural pumping is typically not recorded over much of California, including the Subbasin. However, there are 455 wells with reported production in 6 agricultural well fields within the model domain. A wellfield consists of a group of wells generally located in the same area and operated a single entity to provide a reliable groundwater supply. The agricultural wellfields include: ER GSA (99 wells), Creighton Ranch (52 wells), CID (98 wells), Angiola Water District (51 wells), Westlands Water District (150 wells), and Apex Ranch (5 wells) (Figure D2-21). The ER GSA and CID well fields service local areas in the Subbasin. The Creighton Ranch and Angola Water District well fields, located in the Tule Subbasin, service the Tule Subbasin and also export significant amounts of groundwater to the Subbasin. The Westlands Water District well field only services the Westside Subbasin. The specified pumping from the agricultural well fields has varied significantly over time, ranging from 23,470 AF (1998) to 370,880 AF (2016) and averaging about 202,750 AF/Y (Figure D2-22). The reduction in annual pumping coincides with the availability of surface flood waters (Figure D2-18). Appendix D4 presents an annualized summary of reported pumping by agricultural well fields within the model domain.

2.8.2.3 Specified Municipal Well Field Pumping

Municipal pumping of groundwater occurs in the Subbasin by the cities of Hanford, Lemoore, Stratford, and Corcoran (Figure D2-21). Specified pumping from the 30 identified municipal well fields has been slowly increasing over time but has remained relatively consistent (Figure D2-22). Between 1990 and 2016, reported municipal pumping has ranged from 9,110 AF (1991) to 26,700 AF (2002) and averaged 14,910 AF/Y over this 26-year period. The municipal pumping demand varies seasonally, peaking in the summer months. As noted in Section 2.4, municipal pump has created persistent cones of depression in the potentiometric surface near the cities of Hanford and Corcoran. Appendix D4 presents an annualized summary of pumping by municipal wells within the model domain as reported by the cities.

2.8.2.4 Estimated Agricultural Pumping

As noted above, agricultural pumping is typically not recorded over much of California, including the Subbasin. However, agricultural pumping by subbasin can be estimated using a simple water balance approach where:

Irrigated Crop Demand (AF/Y)- *Effective Precipitation* (AF/Y) */ Irrigation Efficiency* (%) = *Farm Demand* (AF/Y)

and

Farm Demand (AF/Y) – *Surface Water Supplies* (AF/Y) = *Estimated Agricultural Pumping Demand* (AF/Y) (Figure D2-23)

Note: Surface Water Supplies include Surface Water Deliveries, imported groundwater, and lake bottom water storage

Although this simple water balance approach does not account for subtleties in the areal distribution of effective precipitation, irrigation efficiency, and surface water deliveries, it does provide a reasonable gross estimate of agricultural pumping on the subbasin scale. Based on this analysis, gross agricultural pumping demand in the Subbasin from 1990 through 2016 has ranged from 24,730 AF (1995) to 785,260 AF (1991) and averaged approximately 469,560 AF/Y (Figure D2-23).

2.8.2.5 Agricultural Drains

Agricultural drains are used in several areas across the model domain to keep soil from becoming waterlogged in the root zone. Typically, a tile or French drain system is used, with tiles buried approximately 4 to 6 feet bgs draining to sumps. Subsurface drainage collected in the sumps is pumped via pipeline to evaporation basins. Figure D2-24 shows the approximate location of known subsurface drains within the Subbasin.

3.0 Simulation Code

In order to meet the model objectives discussed in Section 1.3, the groundwater flow model code must meet the following criteria:

- be able to simulate three-dimensional groundwater flow within the model domain,
- be well documented and verified against analytical solutions for specific flow scenarios,
- be accepted by regulatory agencies,
- be readily understandable and usable by others for simulation of future groundwater conditions, and
- have a readily available technical support structure.

The groundwater flow model codes MODFLOW2005-NWT (Niswonger et al., 2011) and MODFLOW-OWHM (Hanson et al., 2014) are two distinct versions from the well-known MODFLOW family of groundwater simulation codes. These codes were used to develop the Subbasin model.

MODFLOW is a modular, finite-difference computer code developed by the USGS to simulate three-dimensional groundwater flow (McDonald and Harbaugh, 1988, Harbaugh, A. W., 2005). The use of the MODFLOW family of codes is well documented in technical literature and is a de facto standard for groundwater flow modeling worldwide.

MODFLOW2005-NWT is a particular version of MODFLOW that implements the Newton method for handling non-linearities in flow equations, which allows for very efficient solution of the flow equation including complexities such as unsaturated zone flow, eliminated the cell draining and re-wetting problems of earlier versions of MODFLOW (Niswonger et al., 2011). MODFLOW-OWHM is a relatively new version of MODFLOW (still under development) specifically developed to provide a flexible and robust approach to simulate conjunctive management of surface water and groundwater resources in an agricultural crop production setting (Boyce et al., 2016).

3.1 Model Code Selection

Once the decision was made to develop a model using the MODFLOW family of codes, the initial plan was to develop both a MODFLOW2005-NWT model and a MODFLOW-OWHM model to provide independent, yet complementary, methods for model development. This was planned due to the fact that both codes will share many of the same input files, only differing in how the farm irrigation pumping is specified. For the NWT model, the farm irrigation pumping requirement would be calculated externally in a de-coupled modeling approach, whereas with OWHM, the farm irrigation pumping is calculated internally as a dynamic component.

The MODFLOW-NWT ("MF-NWT") code would be employed to develop a "de-coupled" model of conjunctive surface water – groundwater management in the Subbasin. In the de-coupled approach, the following four-step procedure is used to build surface boundary processes (irrigation, crop water use, return flows, etc.), build the irrigation well pumping file, and run the model to simulate system response:

- the crop ETc demand calculated externally on a model cell-by-cell basis based on cropping patterns, crop coefficients, and reference ETc;
- effective precipitation and specified surface water deliveries are also calculated on a model cell-by-cell basis, irrigation pumping demand is calculated as the ETc demand – effective precipitation - surface water supplies;
- the resulting cell-by-cell irrigation pumping demand is subsequently summed by area, and assigned to a hypothetical pumping well in the center of the area in the de-coupled model; and
- the model is run to simulate groundwater-system response (drawdown, loss of storage, subsidence) to the stresses (including municipal and irrigation pumping, natural recharge, intentional artificial recharge, recharge from stream and canal leakage, recharge from irrigation return flows.

The MODFLOW-OWHM ("MF-OWHM") code was investigated as a tool to dynamically simulate conjunctive management of surface water and groundwater resources in the Subbasin. The MF-OWHM model employs basically the same input data sets used to calculate the ETc and irrigation pumping

demands externally for the de-coupled MF-NWT model, but the MF-OWHM simulations are dynamic in the sense that the ETc and irrigation pumping are calculated internally within the model allowing for "feedback loops" between these two key stressors on the groundwater system. The MF-NWT de-coupled model does not address these types of feedback loops that actually can be occurring in the field.

The MF-OWHM, the code is currently undergoing enhancements (from to its capabilities and numerical methods. In January 2019, the USGS indicated that updated version of the model code (OWHM v2) would be available in March 2019. The most recent communication with the USGS indicated that the updated model code might not be ready until the end of October 2019, too late for the GSP schedule. Thus, further development of the OWHM was suspended at the end of March and efforts were directed at completing the de-coupled MF-NWT model for the Subbasin within the project schedule. The remainder of this report focusses on the de-coupled model development, application, and results.

3.2 Code Assumptions and Limitations

There are certain model code assumptions and limitations that must be considered when developing, applying, and interpreting a numerical model. Some key assumptions and limitations that may affect the site models are briefly discussed below.

Porous Media: The MODFLOW family of codes is limited simulation of saturated and unsaturated flow in porous media. It does not simulate flow through fractures or relatively impermeable bedrock.

Layer Continuity: MODFLOW requires that all layer extend from edge-to-edge of the model domain. This limits the ability to explicitly simulate formation pinch-outs or unconformities. Instead these features may be simulated using a hydraulic conductivity contrast.

Unsaturated Flow: The MODFLOW Unsaturated Zone Flow (UZF1) package can simulate flow in the unsaturated zone using an approximation to Richards' equation to simulate vertical unsaturated flow. The approach is limited in that unsaturated flow occurs in response to gravity, and there must be uniform hydraulic properties in the unsaturated zone for each vertical column of model cells. This limits the ability of the MODFLOW to simulate different properties of the thick unsaturated zone. The Brooks-Corey function is used to define the relation between unsaturated hydraulic conductivity and water content. Variables used by the UZF1 Package include initial and saturated water contents, saturated vertical hydraulic conductivity (Kv), and an exponent in the Brooks-Corey function. Residual water content is calculated internally by the UZF1 Package on the basis of the difference between saturated water content and specific yield (Sy).

The UZF1 Package is also substitution for the Recharge (RCH) and Evapotranspiration (ET) Packages of MODFLOW-2005. The UZF1 Package differs from the RCH Package in that an infiltration rate is applied at land surface instead of a specified recharge rate directly to ground water. The applied infiltration rate is further limited by the saturated Kv. The UZF1 Package differs from the ET Package in that evapotranspiration losses are first removed from the unsaturated zone above the evapotranspiration extinction depth, and if the demand is not met, water can be removed directly from ground water whenever the depth to ground water is less than the extinction depth. The UZF1 Package also differs from the ET Package in that water is discharged directly to land surface whenever the altitude of the water table exceeds land surface. Water that is discharged to land surface, as well as applied infiltration in excess of the saturated Kv, may be routed directly as inflow to specified streams or lakes if these packages are active; otherwise, this water is removed from the model similar to the Drain (DRN) Package.

Stress Periods: MODFLOW requires that temporally variable data be consistent within each stress period. This results in some temporally averaging of data. For example, stream flow or municipal pumping may vary hourly or daily in response to demand, while agricultural well field may pump nearly continuously for several months in a row. The averaging of transient stress into consistent monthly stress period tends to smooth out the hydraulic impacts of the transient stresses.

3.3 Graphic Pre/Post-Processor

To facilitate the preparation and evaluation of each model simulation, Wood utilized the graphics pre/post processor GWVistas® Version 7 (GWV) by Environmental Simulations, Inc. (ESI, 2017). GWV is a Windows® program that utilizes a graphic user interface (GUI) to build and modify a database of model parameters. The model grid, hydraulic properties, and boundary conditions are input using the GUI, and then GWV creates the necessary MODFLOW and MT3DMS data input files. The input files generated by GWV are generic (standard) files compatible with USGS MODFLOW-NWT and MT3DMS. Wood also utilized some in-house utilities and Microsoft EXCEL spreadsheets to generate standard MODFLOW data input files for selected simulations and for post-processing simulation results. For example, PYTHON scripts were utilized to add and subtract the large matrices containing 27 years of monthly data worth of effective precipitation, surface water deliveries, and crop demand to estimate agricultural pumping. Similarly, an Excel spreadsheet was created to allocate the estimated agricultural pumping demand to hypothetical wells, and export file formatted for importation into GWV.

GWV was also utilized to post-process the model simulations. GWV can display the simulated head results as plan views and cross-sections. In plan view, the contour intervals and labels specified by the user and dry cells are denoted by a different color. In cross-section view, the water table surface is also plotted. Most outputs to the screen can be saved in a number of formats (DXF, WMF, PCX, SURFER, etc.) for utilization in other graphics programs.

4.0 Model Design

The following sections describe the numerical groundwater flow model for the TLSBHM. The model construction was based on the HCM presented in Section 2.0, with each of the key features described in that Section represented numerically in the TLSBHM. This modeling effort is a revision to the preliminary groundwater model of the Subbasin (Kings Model) developed in 2016-2018 on behalf of the Kings County Community Development Agency (AFW, 2018).

4.1 Model Domain/Grid

As described in Section 2.1, the TLSBHM model domain is centered on the Subbasin and extends beyond the Subbasin several miles, overlapping adjacent subbasins within the Tulare Lake Hydrologic Region (Figure D2-2). The model domain was extended beyond the Subbasin so that model boundary conditions are sufficiently far away the area of interest in the Subbasin; these areas beyond the extent of the Subbasin henceforth are referred to as the "buffer areas" (Figure D2-2). The buffer areas extend approximately 3 miles beyond the DWR-defined Subbasin boundaries on the north, south, and east sides; on the west and southwest sides, however, a large buffer area is not included because the alluvial groundwater basin is truncated by low-permeability geologic units on those side. The active model grid covers an area of approximately 1,091,320 acres (about 1,705 square miles) and is orientated due north to align the model grid with the predominant direction State Plane coordinate system of Township/Range/Sections.

The preliminary Kings Model (AFW, 2018) exhibited some boundary condition interference along the eastern edge of the model. Hence the TLSBHM model grid was extended further east approximately

2.5 miles. In addition, some of the active model grid edges were modified to yield straighter lines to simplify specified boundary conditions. The resulting TLSBHM model grid consists of 281,750 active cells with uniform dimensions of 1,320 x 1,320 feet (¼ mile x ¼ mile, or 40-acres) (Figure D4-1). The complete model grid consists of 230 rows, 175 columns, and 7 layers.

4.2 Model Layers

The purpose of model layers is to represent the hydraulic influence of stratigraphy at a scale appropriate to the model objectives. One way to think of "hydraulic influence" is how finer-grained deposits present resistance to flow, both laterally and vertically, and it is only through multiple model layers that one can simulated the vertical resistance to flow. It is understood that stratigraphic variations occur at scales that are both smaller and larger than that characterized for this model.

- Those hydrostratigraphic variations that are of the same scale or larger than the numerical grid cell size, for example the Corcoran Clay, are captured explicitly in model property variations.
- Those hydrostratigraphic variations that are much smaller than the model cell size are not treated explicitly in the model, but rather their effect is incorporated into the model via appropriate assignment of large scale "effective" properties for the model cell as described above in Section 2.1.1. For example, say three 1- to 2- foot thick clay layer or lenses extend across a large portion of the 1,320-foot x 1,320-foot plan view area of a 50-foot thick model cell. To capture the hydraulic effect of those layers in the 50-foot thick model cell requires significantly reducing the Kv as guided by this conceptual model and application of the harmonic average as a lower bracket for significantly reducing Kv compared to what is in the CVHM model data that was provided to the TLSBHM modeling team by the USGS.

In addition to direct import of the CVHM hydraulic conductivity fields (based on the USGS sediment texture study) as the starting point for the model, refinements to the conceptual and numerical models of the site were based on consideration of several types of information. Supplement information considered included both recent and older USGS literature (Croft, 1972; Page, 1986), monitoring well perforation intervals in sub-areas of the site, and qualitative and quantitative information obtained directly from the GSAs.

The initial basis for the TLSBHM model layering scheme was based on a modified version of the CVHM (AFW, 2018). The modified CVHM model had 13 layers including 5 layers above the Corcoran Clay, 3 layers representing the Corcoran Clay, and 5 layers below the Corcoran Clay. The TLSBHM layering scheme was reduced from 13 layers to 7 layers to simplify the model and make it more consistent with the 3- to 4-layer models being developed for the Tule and Kaweah subbasins. The TLSBHM layer count was reduced by combining several thin layers into a single, thicker layer. For example, the 3 layers representing the Corcoran Clay in the CVHM model were combined into a single layer in the TLSBHM. Layer elevations and thicknesses were also modified in some areas based on local information. The resulting Cross-sections showing the model layering scheme and initial hydraulic conductivity distribution are shown on Figures D4-2 and D4-3.

4.3 Model Duration and Stress Periods

The TLSBHM simulates the period from 1990 through 2016 using 324 monthly stress periods (Table D4-1). The model simulates the period from 1990 to 1995 as a "run-up" period to stabilize the model hydraulics

prior to the 1998-2010 focused calibration period. The model continues from 2010 through 2016 to bring the model up to date with current hydraulic conditions as required under SGMA.

4.4 Model Hydraulic Parameters

The initial hydraulic properties assigned to the TLSBHM were extracted from CVHM. The hydraulic parameters were only modified as necessary during the model calibration process to improve the fit between simulated and observed heads. As such, the model contains no more complexity than is justified by the available data, the model objectives, and the model results to date. Section 4.4.1 briefly describes how the USGS used textural information from thousands of boring logs to develop three-dimensional maps of the hydraulic properties.

The range of final hydraulic properties, hydraulic conductivity, Kv, storage, Sy, and porosity used as a result of the calibration process are briefly summarized in the following subsections.

4.4.1 Hydraulic Conductivity

Geologically speaking, the Central Valley is a large structural trough filled with sediments of Jurassic to Holocene age. These sediments reach thicknesses on the order of 15,000 feet in the San Joaquin Valley, and as much as 30,000 feet in the Sacramento Valley. In general, the Sacramento Valley is predominantly fine-grained and reflects more fine-grained volcanic-derived sediments, and in the San Joaquin Valley the areas of coarse-grained texture are more widespread than the areas of fine-grained texture and occur along the major rivers, especially on the eastern side.

The texture (particle size) of these sediments and how that texture varies spatially strongly impacts how groundwater flows in response to recharge and discharge stresses on the system. Therefore, the textural distribution of the basin-fill sediments was used to define the initial vertical and lateral hydraulic conductivity and storage property distributions for the TLSBHM domain.

To characterize the Central Valley basin-fill deposits, scientists from the USGS developed a geologic texture model to describe the coarseness or fineness of basin-fill materials that make up the hydrogeologic system, and then used it to estimate hydraulic properties (hydraulic conductivity and storage properties) for every cell in the model grid. To create a sediment texture model for the Central Valley, the USGS compiled and analyzed data and information from approximately 8,500 drillers' logs of boreholes ranging in depth from 12 to 3,000 feet below land surface (Faunt el al., 2009). The textural characterization focused on the variability and spatial distribution of the fraction of coarse sediments (f_c) over 50-foot depth intervals. Figure D4-4 presents the f_c for several of the model layers, and Figure D4-5 presents an oblique view of f_c for the San Joaquin Valley, with the TLSBHM study area outlined in red. In general, there are two key aquifer systems, the upper unconfined and semi-confined aquifer and the deeper confined aquifer system, separated by the Corcoran Clay aquitard. On Figures D4-4 and D4-5, the Corcoran Clay horizon is found in model layers 6 through 8, with the unconfined and semi-confined shallow aquifer system in model layers 1 through 5 and the deeper confined aquifers in model layers 9 through 13.

The USGS generated estimates of hydraulic properties from their texture model developed for the CVHM. These values were imported directly into the TLSBHM to use as initial values prior to beginning model calibration. The initial hydraulic conductivity distribution utilized in the TLSBHM is shown on Figure D4-6.

Beneath the Subbasin study area, previous studies have identified extensive deposits of fine-grained materials consisting of lacustrine and marsh sediments (Croft and Gordon, 1968; Croft, 1972; Page, 1986, Williamson et.al., 1989). A cumulative thickness of as much as 3,000 feet of these fine- grained deposits have been identified and include laterally extensive clay layers (A – F Clays). The A-, C-, and E-Clays (i.e., Corcoran Clay) cover much of the TLSBHM domain. During the calibration process, these studies and input from the GSAs were utilized to adjust hydraulic properties derived from the USGS texture model to be more representative of the Tulare Lake bed and surrounding area (Figure D4-7). The following subsections provide a summary of the hydraulic properties for each of these depth intervals.

4.4.1.1 Unconfined and Semi-Confined Aquifer Zones above the Corcoran Clay

Above the Corcoran Clay is the unconfined to semi-confined upper portion of the regional fresh-water aquifer. This upper portion of the regional freshwater aquifer is generally comprised of coarse- to medium-grained sediments (i.e., sand and gravel) with silt and clay interbeds.

According to the USGS CVHM, the grid-block-scale horizontal hydraulic conductivity (K_h), ranges from 8 to 75 feet per day (ft/d). These values span the lower range of a "good aquifer" as defined by Bear (1972). Figure D4-4 presents the K_h distribution derived from the USGS texture study for selected model layers. On Figure D4-4 (as well as Figure D4-6), a broad swath of lower permeability (low sand fraction) deposits is evident that run from the northwest side of the model domain trending to the southeast toward the southeast corner of the model domain. In this zone, the hydraulic conductivities derived from the CVHM are in the 5 to 25 ft/d range, which is closer to the range of a "poor aquifer" (Bear, 1972), and which appear to be lower than values obtained from pumping tests in these areas (P&P, 2009). In fact, the averaging of sediment texture (f_c) over 50-foot depth intervals leads to "smoothing out" of permeability contrasts.

As described previously, it is important to recognize that even in the zones with a higher fraction of coarse textured sediments, clayey layers and lenses are found throughout the profile. This is especially important for estimating effective horizontal-to-vertical anisotropy of hydraulic conductivity for a numerical model layer thickness of 50 feet, which is the scale of vertical averaging that the USGS employed in their sediment texture study. For example, say the fraction of coarse-materials over a 50-foot depth interval is 90%; if the remaining 10% consists of a fine fraction that is concentrated in a few clay layers on the order of a foot thickness, then the effective K_v should tend toward the harmonic average of a clay and a sand (Freeze and Cherry, 1979). If the sand has a K_h of 90 ft/d and the clay layers have a K_h of 0.01 ft/d, then the effective K_v for that grid cell could be estimated using a layer-thickness weighted harmonic average as:

$$K_v \approx [50 / ((5/0.01) + (45/90))] = [50/500.5] \approx 0.1 \text{ ft/d}$$

The effective K_h can be estimated as the layer-thickness weighted arithmetic average:

$$K_h \approx [(45x90) + (5x0.01)] / 50 \approx 90* (45/50) = 81 \text{ ft/d}$$

These simple calculations indicate that it would be reasonable to expect very high anisotropy ratios (very low effective K_v), and indeed that is what was found during the model calibration process (see Section 5.0).

The storage properties above the Corcoran Clay do not vary nearly as much as the hydraulic conductivity in this portion of the aquifer. The S_y of the sediments above the Corcoran Clay (Layers 1 through 3) range from 0.08 to 0.3, while the specific storage (S_s) ranges between 1.5x10-5/feet and 7.3x10-3/feet.

4.4.1.2 Corcoran Clay Aquitard

The lateral extent and thickness of the Corcoran Clay are shown on Figure D2-4. While it is sometimes considered a continuous layer of low permeability sediments spanning across the San Joaquin Valley, in fact comparing these figures to the CVHM hydraulic conductivity maps for model layers 4 through 10 (Figures D4-4 through D4-6) clearly shows that the Corcoran Clay grades into coarse materials laterally, as well as above and below. They also show that some clay lenses exist above and throughout areas characterized as relatively "coarser" in the USGS texture study. Recognizing that the texture maps were developed from averaging f_c over 50-foot depth intervals, this impacts the effective Kv used in the TLSBHM as described in the previous section.

This is consistent with recent investigations by the USGS in the San Joaquin Valley, which indicate that the groundwater conditions grade from unconfined, or water-table, at the shallowest depths to semi-confined with increasing depth, eventually grading into fully confined conditions beneath the Corcoran Clay. Geophysical well logs indicate that the Corcoran Clay, although probably the largest single confining bed, constitutes only a small percentage of the total cumulative thickness of clay layers in the fresh-water bearing unconsolidated sediments in the Subbasin. Thus, it is more accurate to consider the confinement as the result of numerous overlapping clay lenses and beds. Further, the difference in hydraulic head directly above and below the Corcoran Clay is relatively small when compared to head differences between larger intervals of the deeper parts of the aquifer system. Again, rather than to explicitly simulate each of these thin clay layers and lenses discretely in the model, their impact on the flow system is simulated through the high anisotropy in hydraulic conductivity (very low Kv).

Hydraulic conductivity (K_h) values of the Corcoran Clay cells in the model domain from the USGS CVHM range from 0.5 to 10 ft/d, which is rather high for an aquitard material, and especially high considering that the harmonic average should be the guide for effective K_v. As mentioned in Section 4.4.1, hydraulic conductivity values at the depth horizon of the Corcoran Clay were adjusted during model calibration to improve the fit between the simulated and observed hydraulic heads over time.

In addition, as discussed in Section 2.3.4, Croft & Gordon (1968) identified uninterrupted lacustrine (clay) deposits from the surface to at least 2,200 feet bgs beneath the central portion of the Tulare Lake bed (Figure D2-5). These lacustrine deposits interfinger with coarser sediments and the thinner clay zones along the periphery of the lake with the thick clay deposits beneath the lake bed itself. The Corcoran Clay (E-Clay) has been identified as extending beneath the lake bed (Davis et al., 1959). show it as being warped downward along the axis of the lake with a maximum thickness of 150 to 175 feet. These cross sections indicate the Tulare Lake deposits form a clay "plug" across the center of the San Joaquin Valley that may be 15 miles wide, 8 miles long, and ½ mile deep at its maximum dimensions. This was incorporated into the TLSBHM (Figure D4-7).

Again, the storage properties do not vary as much as the hydraulic conductivity, with S_s of the Corcoran Clay and other sediments in this depth horizon ranging between 4.5x10-4/feet and 1.2x10-3/feet, with the S_y ranging from 0.10 to 0.15 where unconfined. Storage values were adjusted during model calibration to improve the fit between the simulated and observed hydraulic heads over time.

4.4.1.3 Confined Aquifer Beneath the Corcoran Clay

Hydraulic conductivities initially assigned to the model layers beneath the Corcoran Clay horizon were derived from the USGS CVHM. Conductivity values generally ranged from 20 to 40 ft/d, except for two broad regions of lower permeability. One of the areas with a predominance of low-K_h materials at depth is in the Westside Subbasin to the west, and the other is beneath the southeast buffer areas near where Deer Creek

enters the model domain. Again, the storage properties do not vary as much as the hydraulic conductivity, with Ss of the sediments below the Corcoran Clay ranging between $6.8x10^{-4}$/feet and $1.5x10^{-3}$/feet. Storage values were adjusted during model calibration to improve the fit between the simulated and observed hydraulic heads over time.

The TLSBHM groundwater model was initially assigned variable K_h values that ranged between $4.0x10^{-4}$ ft/d for aquitard clay units to 91 ft/d for aquifers, with the spatial distribution of the properties derived from the CVHM. These values were modified as necessary during the calibration process to improve the model fit to observed groundwater elevations (Figure D4-7).

4.4.2 Storage

The TLSBHM groundwater model was initially assigned S_s values from the USGS CVHM. Initial S_s values ranged between $1.5x10^{-5}$ to $7.3x10^{-3}$ feet-1. These values are within the published range of values for the silty to sandy sediment types (Spitz and Moreno, 1996). S_s values were modified over a limited range during the model calibration process.

4.4.3 Specific Yield

The TLSBHM groundwater model was initially assigned S_y values from the USGS CVHM. Initial S_y values ranged between $7.9x10^{-2}$ to $3.0x10^{-1}$. These values are within the published range of values for the silty to sandy sediment types (Spitz and Moreno, 1996). S_y values were modified over a limited range during the model calibration process.

4.4.4 Porosity

The TLSBHM groundwater model was initially assigned porosity values from the USGS CVHM. Initial porosity values ranged between $9.1x10^{-2}$ to $2.9x10^{-1}$. These values are within the published range of values for the silty to sandy sediment types (Spitz and Moreno, 1996). Porosity values were modified over a limited range during the model calibration process.

4.5 Model Boundary Conditions

Significant hydraulic boundaries (sources and sinks) within the model domain that must be considered in the site numerical model include the inflows and outflows from surrounding subbasins, inflows and outflows of surface water, return flows and intentional recharge, and groundwater pumping. These boundaries are discussed in the following subsections.

4.5.1 General Head Boundaries

The MODFLOW General Head Boundary (GHB) package was utilized to simulate the north, south, and east edges of the model domain and represent the aquifer system beyond the model domain (Figure D4-8). For the TLSBHM, the GHBs were developed based on historical water level observations in well located within 2 miles of the model domain boundary. Figure D4-8 shows the locations of wells evaluated to develop the GHB boundary conditions. The GHBs were developed as a series of 20 GHB reaches. The GHB heads at the ends of each reach were interpolated on a monthly basis from the available hydrograph data. The GHB heads for each cell within a reach were then linearly interpolated between the end points. This resulted in a relative smooth variation in GHB heads along the length of each reach.

The GHB conductance term, which governs how much water can flow through the GHB, was calculated as:

Conductance = KLW/M in square feet per day (ft^2/d), where:

K is the hydraulic conductivity of the sediments (assumed to be 25 ft/d),
L is the GHB length or distance to the head value (assumed to be 1,320 feet),
W is the GHB width (assumed to be 1,320 feet), and
M is the saturated thickness of GHB layer (assumed to be 100 feet).

4.5.2 River and Canal Boundaries

As noted above, several rivers and streams deliver surface water to irrigated lands within the model domain. The most important of these is the Kings River, which enters the model domain on the northeast side, and it flows westward near the top of the model domain before turning southwest then southward in the western portion of the model domain. Other major surface water inflows are provided by the Kaweah River, the Tule River, Deer Creek, and Poso Creek. Figure D4-9 shows the locations of each of these surface water features; also shown are the major distributary canals that take the deliveries from the streams and rivers and distribute that water to the irrigation farmlands.

The MODFLOW River (RIV) package was utilized to simulate all the stream and canals that deliver water to irrigated lands. The streams were developed as a series of 23 RIV reaches, where each RIV reach is composed on many model cells. The RIV package is a head dependent boundary and will allow water to enter groundwater via seepage (losing stream) or exit groundwater (gaining stream) based on river stage (Head) and a steam bed conductance term:

Conductance = KLW/M in ft^2/d, where:

K is the hydraulic conductivity of the sediments (assumed to be 1 to 10 ft/d),
L is the length of the river reach (variable in feet),
W is the river width (assumed to be 10 to 40 feet), and
M is the thickness of the river bed (assumed to be 10 feet).

The rivers were assumed to leak anytime there were surface water diversions down a particular river reach. Throughout the Subbasin, almost all river are disconnected from groundwater and are losing rivers. Appendix D2 presents an annualized summary of river flow by reach within the model domain.

4.5.3 Agricultural Drains

The MODFLOW Drain (DRN) package was utilized to simulate the agricultural drains within the model domain (Figure D2-24). The DRN package is a head dependent boundary condition that only collects groundwater above a specified elevation. Similar to GHBs, the rate of removal is governed by a conductance term:

Conductance = KLW/M in ft^2/d, where:

K is the hydraulic conductivity of the sediments (assumed to be 100 ft/d),
L is the length of the drain (assumed to be 1,320 feet),
W is the width of the drain (assumed to be 1,320 feet), and
M is the thickness of the drain bed (assumed to be 1 foot).

In areas where drains were simulated, if simulated groundwater rose to within 4 feet of ground surface, then groundwater was collected by the drains and assumed to be discharged to evaporation basins where it evaporated and was removed from the model domain.

4.5.4 Groundwater Extraction

Groundwater extraction for municipal, industrial, and agricultural demand was simulated using the MODFLOW Multi-Node Well (MNW2) package. The MNW2 package is a powerful enhancement to the original MODFLOW well package in that it allows for simulation of wells screened across multiple model layers (aquifers). Thus, the MNW2 package will calculate inflows from each model layer within the screened interval as well as the calculating flow within the well casing, including flows from one layer to another when the well is not being pumped. In addition, the MNW2 package will automatically increase pumping from deeper intervals as shallower aquifers become dewatered until the pumping level in the well approaches a specified elevation (such as a pump setting).

4.5.4.1 Specified Pumping Wells

As discussed in Sections 2.8.2.2 and 2.8.2.3, there are 485 known municipal, industrial, recovery, and agricultural wells that have data on well construction as well as reported pumping rates over time (Figure D2-21). The pumping rates were specified for the municipal wells based on monthly historical pumping data obtained from the cities of Corcoran, Hanford, Lemoore, and Stratford (Table D2-3), or reported monthly pumping data from irrigation districts such as CID, ER GSA, Westlands Water District, and reported pumping from well fields like Creighton Ranch and Angiola well fields (Table D2-6).

4.5.4.2 Hypothetical Agricultural Irrigation Wells

As discussed in Section 2.8.2.4, agricultural pumping is not typically recorded throughout most of the Subbasin. As such agricultural pumping had to be estimated based on available cropping data using a water balance method. Recognizing that many more wells exist in the Subbasin than those 485 known wells, an additional 1,091 hypothetical irrigation wells were uniformly distributed across the model domain on approximately 1-mile centers for those areas with unknown well completion intervals, resulting in the final well distribution as shown on Figure D4-10. The hypothetical wells were specified to be screened in the upper (above Corcoran) or lower (below Corcoran) aquifer zones based on statistics of well completions for 238 known irrigation wells in the Subbasin. In addition, approximately 25% of the hypothetical irrigation wells were specified to be completed across the Corcoran, producing groundwater from permeable intervals both above and below the aquitard, consistent with the completion statistics for the 238 known irrigation wells in the Subbasin.

Crop Evapotranspiration Rates

Field crops (alfalfa, row crops, corn, cotton, etc.) are assigned on an annual basis in the model. For example, if the annual DWR crop survey/CropScape data (DWR, 2016a) indicate that corn was present in a particular model cell, then it was assumed that corn was the only crop within that cell for the full calendar year (12 stress periods). The applied evapotranspiration rates for that cell were assigned based on the monthly ETc rates for corn.

Permanent crops including vineyards, almonds, pistachios, pomegranates, and stone fruit (tree crops) are assumed to be fully mature at the beginning of the simulation in 1990 (based on 1994-1996 DWR crop data). As the model progresses forward in time, the available crop data changed, and the spatial distribution of crops also changed, with a recent trend to more permanent tree crops being planted. As the permanent crop grows from seedling to full maturity, the evapotranspiration rate was assumed to

increase as well. The presence of a crop within a specific space in a cell was tracked over time by assigning crop IDs that reflect the number of years of maturity for each tree crop and using the intersect tool in ArcMap to see specific areas of overlap between year n tree crops and year n+1 tree crops. If an intersected area of the domain has almonds in year n and in year n+1, it is assumed that the almonds have matured in that particular portion of the cell.

The crop data for the Subbasin indicates that there was a substantial increase in the number of acres planted in tree crops during the 2010-2016 period (Section 2.8.2.1, Table D2-2). Rather than assuming full maturity and peak evapotranspiration rates for these new areas of tree crops, the ET rates for these areas are assumed to be a fraction of the mature ET rates.

For example, almonds are assumed to mature over a 5-year period, so the first year that almonds are present in a portion of a model cell they are assigned ET rates that are 1/5th of the mature rate. If those almonds are still in the same area the next year, then they are assigned an ET rate of 2/5^{ths} of the mature rate, and so on. If almonds are in the same spot for 5 years, they are assumed to have the full ET rates of a mature almond tree. Anything beyond 5 years, up to 25 years, uses the full maturity ET rates. For instances where almonds have been in a portion of a cell more than 25 years, the almond trees are assumed to have been replanted, and start over at the 1-year, 1/5th mature ET rates.

Almonds were assumed to mature over a 5-year period and were assumed to be replanted after 25 years. Pistachios were assumed to mature over a 13-year period and are assumed to remain in place for 100 years once they are planted. Pomegranates were assumed to mature over a 19-year period and were assumed to be replanted after 44 years. Stone fruits were assumed to mature over a 5-year period and were assumed to be replanted after 25 years.

Irrigated Areas/Irrigated Fractions

Area fractions within cells were used to compute an area-weighted average for crop ET values within each cell and to determine the irrigated areas of each cell for use with surface water delivery matrix processing. The crop distributions for each stress period were intersected with the active domain grid in ArcMap. Each cell containing crops was subdivided into multiple pieces, one for each crop type within the cell. The areas of each crop type within the cells were calculated for each stress period. The ET demand for a single cell is computed as the area of the crop type times the rate of ET for that crop, divided by the total area of the cell.

Irrigated areas also play a part in the surface water delivery preprocessing. Surface water deliveries were assumed to be spread evenly across the entire irrigated area of each GSA Area (or farm). Not all cells within a GSA may be fully irrigated; there may be a portion of a cell which is fallow, or contains non-irrigated land uses (winter wheat, native vegetation, urban areas). Therefore, the irrigated area of a cell can be used as a weighting factor against the full area of the cell to adjust the effective rates of surface water delivered within a specific cell in a GSA.

For example, if a GSA has a surface water delivery of 30,000 AF in the month of September and the total irrigated area of the GSA is 10,000 acres, then the nominal rate of surface water delivery is 30,000 AF / 30 days = 1,000 AF/D over an irrigated area of 10,000 acres. Going a step further, this becomes (1,000 AF/D) / (10,000 acres) = 0.1 ft/d rate of surface water delivery. For a cell where only half of the area is irrigated, the weighted surface water delivery rate for that cell would be 0.05 ft/d.

Agricultural Irrigation Pumping Demand

Monthly pumping rates for the hypothetical irrigation wells were computed based on crop ETc demand (Section 2.8.2.1) minus the sum of effective precipitation (Section 2.8.1.1), surface water deliveries (Section 2.8.1.2) and Lake Bottom Water Storage (Section 2.8.1.3). The logic behind the calculation of the hypothetical irrigation well pumping rates is summarized below.

For each monthly stress period and each 40-acre model cell:

- Area Weighted Crop Acreage (acres) x Crop ETc (feet per month [ft/m]) = ET Demand (acre-feet per month [AF/M])
- [-ET Demand (AF/M) + Effective Precipitation (ft/m)] / Irrigation Efficiency = -Farm Demand (AF/M)

  (*Note: over most of the model domain, Irrigation Efficiency was assumed to be 75% from 1990 to 2000 and then increase to 85% from 2000 through 2016. Irrigation Efficiency from the lake bottom area was assumed to be 95% from 1990 through 2016. Approximately 50% of excess Effective Precipitation was assumed to infiltrate and 50% was assumed lost to evaporation. Farm Demand is the volume of water needed to irrigate a field and meet crop demand due to inefficiencies in irrigation methods*)
- -Farm Demand (AF/M) + Surface Water Deliveries (AF/M) + Lake Bottom Storage Water (AF/M) = -Unmet Demand (AF/M) and +Tailwater Flow (AF/M)

  (Note: monthly Surface Water Deliveries were summed by GSA and applied to irrigated areas within each GSA. Lake Bottom Water Storage typically occurred only during and following very wet years and was an additional water supply for the ER GSA and TCWA GSA)
- -Unmet Demand (AF/M) + Avg Tailwater Flow/GSA (AF/M) = -Ag Pumping Demand (AF/M) and +Excess Applied Water (AF/M)

  (Note: Tailwater Flows were assumed to stay within each GSA. The monthly Average Tailwater Flow/GSA (AF/M) = Sum of Tailwater flow per GSA (AF/M) divided by GSA irrigated area. Approximately 75% of excess Applied Water was assumed to infiltrate and 25% was assumed lost to evaporation.)

Typically, each hypothetical agricultural irrigation well was assigned a service area (or farm) consisting of 16 model cells totaling 1-square mile (Figure D4-11). The sum of the monthly Ag Pumping Demand (AF/M) for the 16 model cells was assigned to each hypothetical agricultural irrigation well. For some hypothetical agricultural irrigation well the cell count was more or less than 16 model cells due to boundaries no-flow boundaries or to eliminate hypothetical wells servicing only 1 or 2 cells.

In addition, there are several large areas (ER GSA, CID, SWK GSA, TCWA GSA, and Westlands Water District) that were assumed to be operated as single service areas (or farms) with equal access to surface water and pumped groundwater within the service area. Several of the service areas supplied groundwater by wells located within the service area and/or by external well fields outside of the service area. For example, ER GSA is supplied groundwater from wells within the GSA and by the Creighton Ranch well field in the Tule Subbasin. Likewise, both SWK GSA and TCWA GSA are supplied groundwater from a few wells inside the GSAs and by the Angiola well field in the Tule Subbasin. CID and Westlands Water District are assumed to be supplied groundwater from the wells within each service area.

4.5.5 Deep Percolation and Intentional Recharge

Groundwater recharge occurs within the Subbasin from deep percolation of applied water and intentional recharge. Intentional recharge occurs at specific locations including Apex Ranch, CID ponds, and the Old Kings River (Section 2.8.1.4). Deep percolation of applied water occurs almost everywhere in the TLSBHM where there is active irrigation due to inefficient irrigation practices. There are three components to deep percolation including Farm Demand, Excess Applied Water, and Intentional Recharge. Deep percolation is estimated for each monthly stress period and each 40-acre model cell or farm as follows:

- [+Farm Demand (AF/M) / (1-1/Irrigation Efficiency)] + Excess Applied Water (AF/M) + APEX/CID/Condition 8 Intentional Recharge (AF/M) = Deep Percolation (AF/M)

  (*Note: over most of the model domain 75% of Excess Applied Water was assumed to percolate and 25% was assumed to evaporate*)

Deep percolation is applied to the TLSBHM for each stress period and each model cell using the RCH Package.

4.5.6 Subsidence

Land subsidence due to extraction of groundwater was simulated using the MODFLOW Subsidence (SUB) package. The SUB Package simulates elastic (recoverable) compaction and expansion, and inelastic (permanent) compaction of compressible fine-grained beds (interbeds) within the aquifers. The compaction of the interbeds is caused by head or pore-pressure changes (changes in effective stress) within the interbeds. If the stress is less than the pre-consolidation stress of the sediments, the deformation is elastic; if the stress is greater than the pre-consolidation stress, the deformation is inelastic.

The SUB package parameters of:

Sk_e skeletal storage elastic,

Sk_i skeletal storage in elastic,

b_{equiv} combine thickness of delay interbeds within a model layer, and

n_{equiv} combine thickness of non-delay interbeds within a model layer

were derived from CVHM and modified during calibration to approximate observed subsidence during the simulation period.

5.0 Model Calibration

Calibration of a groundwater flow model is a process through which the model is demonstrated to be capable of simulating the field-measured heads and flows that comprise the calibration targets. Calibration is accomplished by selecting a set of model parameters, boundary conditions, and stresses that produce simulated heads and fluxes that match field measurements within a pre-established range of error. Because of the multiplicity of parameters involved in the calibration process, a unique solution (e.g., one set of parameters) cannot be achieved. A brief discussion of the calibration of the groundwater flow model for the site is presented in the following subsections.

5.1 Model Calibration Criteria

The quantitative fit of the model to observed water level measurements is conducted through statistical analysis of the residuals, (the difference between observed and simulated water levels or heads) at specified observation locations, and in the case of transient calibration, with time. The residual is calculated as the observed value minus the simulated value; thus, a positive residual indicates that the simulated head value is less than the observed value, and vice-versa. The principal statistical measures of the residuals of all data points combined include the following:

- the mean of the residuals,
- the mean of the absolute value of the residuals,
- the standard deviation of the residuals,
- the sum of the square of the residuals (SSR),
- the root mean square (RMS) error of the residuals,
- the min and max of the residuals,
- the range of the observed values, and
- normalized root mean square error (NRMS) (e.g., the root mean square error divided by the range of observed values or the standard deviation divided by the range in observed values).

There is no industry standard for determining when a numerical model is adequately calibrated. However, a commonly used rule of thumb criterion for acceptable calibration is a normalized RMS error of less than 10% (Anderson et al., 2015). The RMS is the square root of the SSR divided by the number of observations throughout the model divided by the range of observed water level measurements. In addition, a plot of observed versus computed head values should track close to a 45-degree line and generally fall within one standard deviation of the mean error.

A common qualitative (visual) measure of goodness of fit in numerical modeling is a comparison of observe and simulated values using hydrographs for individual wells. In addition, a map view plot of the average residuals may be used to help identify targets or areas where the residuals in the model domain are largest. Clusters or patterns of gradation of positive or negative residuals may suggest areas where model parameters need to be adjusted further.

5.2 1990-2016 Transient Model Calibration

The transient TLSBHM simulated the period January 1990 through December 2016 using 324 monthly stress periods (Table D4-1). The TLSBHM was calibrated to two data sets, one data set covering the 1990-2016 period and a second data set limited to the 1998-2010 “normal hydrology” period.

The 1990-2016 calibration period included 16,468 groundwater level observations collected from 593 observation wells across the model domain. The 1998-2010 “normal hydrology” calibration period included 7,028 groundwater level observations collected from 544 observation wells across the model domain. Most of the observation wells had little or no completion interval information, making it difficult to assign the observations to a particular model layer. Wells with known completion intervals includes 81 wells above the Corcoran Clay and 69 wells below the Corcoran Clay. The other observation wells were assigned to model layers based on the similarity of observations with nearby known wells. Although additional observation wells with groundwater elevation measurements are available, many were

determined to have too short a record, too many spurious observations, or uncertain completion intervals and hence were not utilized.

Numerous model iterations were needed to calibrate the TLSBHM model. Various hydraulic parameters (K_h, K_v, S_s, S_y) and boundary conditions (RCH, GHB heads, RIV conductance) were incrementally modified using the manual trial and error method.

The calibration statistics for the entire 1990-2016 historical simulation period include a residual mean of -4.98 feet, a RMS error of 50.85 feet, a range of 575.33 feet, and a NRMS of 8.84 %, meeting the calibration criteria of a NRMS of <10% (Figure D5-1a). A scattergram of observed and simulated values shows that many values fall within one standard deviation of the perfect 45-degree fit. A residual distribution chart shows that the residual error approximates a gaussian distribution with a slight bias to over predicting heads.

The calibration statistics for 1998-2010 "normal hydrology" calibration period include a residual mean of 2.26 feet, a RMS error of 46.26 feet, a range of 545.16 feet, and a NRMS of 8.50 %, slightly better than for the 1990-2016 period, and meeting the calibration criteria of a NRMS of <10% (Figure D5-1b). A scattergram of observed and simulated values shows that most values are closer to the perfect 45-degree fit compared to the 1990-2016 period. A residual distribution chart shows that the residual error approximates a gaussian distribution with a slight bias to over predicting heads.

A qualitative comparison of observed and simulated heads in selected monitoring wells using hydrographs shows a reasonable fit for several wells, and poor fits for others (Figures D5-2a through D5-2g). In general, the hydrographs show that simulated heads are slightly under predicted above the Corcoran Clay (Figures D5-2a to D5-2c). Within the Corcoran Clay, the hydrographs show that simulated heads tend to start out lower than observed during the ramp-up period but end up with a relatively good fit after 1998 (Figure D5-2d). Below the Corcoran Clay, the hydrographs show that simulated heads are generally on trend with the observed, although seasonal variations are not simulated very well (Figures D5-2e to D5-2g). Observed and simulated heads in selected all monitoring wells used for model calibration are provided in Appendix D5.

Simulated potentiometric surface maps with groundwater flow vectors from above and below the Corcoran Clay show how the general direction of groundwater flow between the subbasins for December 2015 (Figure D5-3). In general, above the Corcoran Clay, simulated groundwater flow is entering the Subbasin from the north, east, and south, and leaving the Subbasin to the west. Below the Corcoran Clay, simulated groundwater flow is also entering the Subbasin from the north. The simulation results also show consistent cones of depression above the Corcoran Clay around pumping centers beneath the cities of Hanford, Lemoore, and Corcoran. There is also a large, persistent cones of depression beneath CID and lake bottom well fields southeast of the City of Corcoran and along the border between the Tulare Lake and Tule subbasins.

The maps also show that there is a large area in the lake bottom area where groundwater appears to be mounding slightly and the groundwater flow vectors show little movement of groundwater above and below the Corcoran Clay (Figure D5-3). This area has been described as being under lain by an extensive sequence of lacustrine and marsh deposits (i.e., Tulare Lake bed "clay plug") which are relatively impervious. Thus, the apparent mounding may result from a zone of residual high heads that are draining more slowly than surrounding areas as groundwater levels are being drawn down due to pumping, recharge to the lake bottom, or it could result as a combination of both.

5.3 1990-2016 Water Balance Calculations

The calibrated transient TLSBHM was used to estimate the groundwater flows that occur between the Subbasin and the adjoining subbasins (Figure D2-2). The following subsection present water balances 1990-2016 simulation period and the 1998-2010 "normal hydrology" period for the Subbasin itself, as well as for each adjoining subbasin, and net flows between the Subbasin can be extracted from these results. Note that the protrusion of the Kaweah Subbasin boundary into the Subbasin and the presence of large wellfields near subbasin boundaries complicate the assessment of inter-basin flows.

5.3.1 Tulare Lake Subbasin

The 1990-2016 annualized net water balance for the Subbasin shows that overall there is a long-term net outflow of groundwater from the Subbasin to the Kings, Kaweah and Tule subbasins (Table D5-1, Figure D5-4), while there is a long-term net inflow of groundwater from the Westside and Kern subbasins. These overall results can be disaggregated to subbasin interactions above and below the Corcoran Clay. Above the Corcoran Clay, there is a net outflow of groundwater from the Subbasin to the Kings, Kaweah, and Tule subbasins, and a net inflow of groundwater from the Westside and Kern subbasins. Below the Corcoran Clay, there is a net outflow of groundwater from the Subbasin to the Westside, Kings, Kaweah and Tule subbasins and a net inflow of groundwater from the Kern Subbasin. The inflows and outflows of groundwater from below the Corcoran Clay are greater than those from above the Corcoran Clay.

The change in storage in the Subbasin has varied from year to year depending on the water year type. Between 1990 and 2016, the estimated change in storage has ranged from -392,280 AF (2015) to 361,230 AF (2011) and averaged -85,690 AF/Y. During 1990-2016, the estimated cumulative change in storage was about -2,313,740 AF. During the 1998-2010 "normal hydrology" period, the estimated change in storage has ranged from about -220,650 AF (2006) to -296,280 AF (2008) and averaged -73,770 AF/Y. During the 1998-2010 period, the estimated cumulative change in storage was about -958,940 AF.

5.3.2 Westside Subbasin

Annualized net water balance for the portions of the Westside Subbasin within the model domain shows that there is a long-term net outflow from the Westside Subbasin to the Tulare Lake and Kings subbasins (Figure D5-5). In general, the long-term outflow from the Westside Subbasin to the Subbasin is greater than that from the Kings Subbasin above the Corcoran Clay, while the long-term inflow to the Westside Subbasin from the Subbasin is less than that from the Kings Subbasin below the Corcoran Clay. The potentiometric surface maps (Figure D5-3) show that the outflow of groundwater from the Subbasin is due to both pumping in the Westside Subbasin and leakage from the South Fork of the Kings River.

The change in storage for the portions of the Westside Subbasin within the model domain has varied from year to year depending on the water year type. Between 1990 and 2016 the estimated change in storage has ranged from -425,290 AF (1990) to 103,573 AF (1998) and averaged -84,070 AF/Y. During 1990-2016 the estimated cumulative change in storage was about -2,269,800 AF. During the 1998-2010 "normal hydrology" period the estimated change in storage has ranged from -177,600 AF (2008) to 103,573 AF (1998) and averaged about -47,080 AF/Y. During the 1998-2010 period the estimated cumulative change in storage was about -612,040 AF.

5.3.3 Kings Subbasin

Annualized net water balance for the portions of the Kings Subbasin within the model domain shows that there is a long-term net groundwater inflow to the Kings Subbasin from the Tulare Lake, Westside, and

Kaweah subbasins (Figure D5-6). In general, the groundwater inflow to the Kings Subbasin from the Tulare Lake and Kaweah subbasins is from both above and below the Corcoran Clay, while there is a net outflow from the Kings Subbasin to the Westside Subbasin below the Corcoran Clay. The potentiometric surface maps (Figure D5-3) show that above the Corcoran Clay, the outflow of groundwater from the Subbasin is primarily due to leakage from the Kings River. Below the Corcoran Clay, the outflow of groundwater from the Subbasin to the Kings Subbasin is due to leakage from the Kings River (where the Corcoran Clay is not present).

The change in storage for the portions of the Kings Subbasin within the model domain has varied from year to year depending on the water year type. Between 1990 and 2016, the estimated change in storage has ranged from -229,310 AF (2015) to 74,030 AF (1998) and averaged -68,220 AF/Y. During 1990-2016, the estimated cumulative change in storage was about -1,841,980 AF. During the 1998-2010 "normal hydrology" period, the estimated change in storage has ranged from -162,950 AF (2004) to 74,030 AF (1998) and averaged about -66,520 AF/Y. During the 1998-2010 period, the estimated cumulative change in storage was about -864,720 AF.

5.3.4 Kaweah Subbasin

Annualized net water balance for the portions of the Kaweah Subbasin within the model domain shows that there is a long-term net groundwater inflow to the Kaweah Subbasin from the Tulare Lake and Tule subbasins and a long-term net groundwater outflow to the Kings Subbasin (Figure D5-6). In general, the groundwater outflow from the Tule Subbasin is greater than that from the Subbasin above the Corcoran Clay, while the outflow from the Subbasin is greater than that from the Tule Subbasin below the Corcoran Clay. The potentiometric surface maps (Figure D5-3) show that a portion of the Kaweah Subbasin protrudes into the Subbasin. This complicates the calculation of inter-basin groundwater flow because there is both inflow and outflow between the Tulare Lake and Kaweah subbasins through this area. In addition, there is outflow of groundwater from the Kaweah Subbasin to the Subbasin due to well field pumping in the area near the City of Corcoran.

The change in storage for the portions of the Kaweah Subbasin within the model domain has varied from year to year depending on the water year type. Between 1990 and 2016, the estimated change in storage has ranged from -317,310 AF (2014) to 31,300 AF (2011) and averaged -156,640 AF/Y. During 1990-2016, the estimated cumulative change in storage was about -4,229,350 AF. During the 1998-2010 "normal hydrology" period, the estimated change in storage has ranged from -239,860 AF (2004) to -2,110 AF (1998) and averaged about -128,390 AF/Y. During the 1998-2010 period, the estimated cumulative change in storage was about -1,669,020 AF.

5.3.5 Tule Subbasin

Annualized net water balance for the portions of the Tule Subbasin within the model domain shows that there is a log-term net groundwater inflow to the Tule Subbasin from the Tulare Lake and Kern subbasins and a log-term net groundwater outflow from the Tule Subbasin to the Kaweah Subbasin (Figure D5-8). In general, the flow from the Subbasin is greater than that from the Kaweah Subbasin both above and below the Corcoran Clay, with greater groundwater flow below the Corcoran Clay. The potentiometric surface maps (Figure D5-8) show that the outflow of groundwater from the Subbasin is primarily due to pumping wellfields southeast of the City of Corcoran and a pumping center east of the model domain in the vicinity of the City of Pixley.

The change in storage for the portions of the Tule Subbasin within the model domain has varied from year to year depending on the water year type. Between 1990 and 2016, the estimated change in storage has ranged from -247,850 AF (1990) to -1,820 AF (2011) and averaged -143,770 AF/Y. During 1990-2016, the estimated cumulative change in storage was about -3,881,750 AF. During the 1998-2010 "normal hydrology" period, the estimated change in storage has ranged from -224,920 AF (2008) to -46,570 AF (2006) and averaged about -140,900 AF/Y. During the 1998-2010 period, the estimated cumulative change in storage was about -1,831,680 AF.

5.3.6 Kern Subbasin

Annualized net water balance for the portions of the Kern Subbasin within the model domain shows that there is a long-term net groundwater outflow from the Kern Subbasin to the Tulare Lake and Tule subbasins (Figure D5-9). In general, the outflow from the Kern Subbasin to the Subbasin is greater than that to the Tule Subbasin both above and below the Corcoran Clay, with greater groundwater flow below the Corcoran Clay. The potentiometric surface maps (Figure D5-3) show that the outflow of groundwater above the Corcoran Clay from the Subbasin to the Kern Subbasin. Starting in the mid-2000s, the groundwater flow filed above the Corcoran Clay reversed and there was a net inflow from the Kern Subbasin to the Subbasin. Below the Corcoran Clay, the water balance charts and potentiometric surface maps show a general decline in the outflow of groundwater from the Subbasin to the Kern Subbasin.

The change in storage for the portions of the Kern Subbasin within the model domain has varied from year to year depending on the water year type. Between 1990 and 2016, the estimated change in storage has ranged from -97,940 AF (2013) to 64,860 AF (2011) and averaged -17,490 AF/Y. During 1990-2016, the estimated cumulative change in storage was about -472,140 AF. During the 1998-2010 "normal hydrology" period, the estimated change in storage has ranged from -84,350 AF (2008) to 64,860 AF (1999) and averaged about -10,950 AF/Y. During the 1998-2010 period, the estimated cumulative change in storage was about -141,330 AF.

5.3.7 Groundwater Storage

The change in storage in the Subbasin has varied from year to year depending on the water year type. Between 1990 and 2016, the estimated change in storage has ranged from -392,280 AF (2015) to 361,230 AF (2011) and averaged -85,690 AF/Y. During the 26-year 1990-2016 simulation period, the estimated cumulative change in storage was about -2,313,740 AF (Table D5-1, Figure D5-4). During the 1998-2010 "normal hydrology" period, the estimated change in storage has ranged from about -220,650 AF (2006) to -296,280 AF (2008) and averaged -73,770 AF/Y. During the 13-year 1998-2010 "normal hydrology" period, the estimated cumulative change in storage was about -958,940 AF.

The simulated groundwater mass balance data were used to estimate the change in groundwater storage in the Subbasin on an annual basis for the simulation period. The simulation results indicate that between 1990 and 2016, the estimated annual change in storage averaged -85,690 AF/Y while during the 1998-2010 "normal hydrology" period, the estimated annual change in storage averaged -73,770 AF/Y or about 14 % less than the 1990-2016 period. Likewise, the estimated net cumulative change in storage for the 26-year 1990-2016 period was about -2,313,740 AF while the estimated net cumulative change in storage for the 13-year 1998-2010 period was about –958,940 AF or almost 60% less than during the 1990-2016 period. Note that following the wet years of 1995-1998, 2005-2006, and 2010-2011, there was a small net increase in groundwater storage in the Subbasin (Table D5-1, Figure D5-4). This indicates that the Subbasin is relatively sensitive to water year type, and that during wet years, there can be a significant

increase in the amount of groundwater in storage. Likewise, as shown on Figure D5-4, extended drought periods (like 2011-2016) can results in a significant loss of groundwater in storage.

5.3.8 Subsidence

Simulated cumulative land subsidence due to extraction of groundwater was simulated for the period 1990-2015 (Figure D5-10). Throughout most of the Subbasin, simulated cumulative subsidence was less than 2 feet. However, in the vicinity of the wellfields southeast of Corcoran in the Tule Subbasin, simulated subsidence was over 9 feet. The simulation results also indicate up to 4 feet of subsidence in the Westside, Kaweah, and Kern subbasins. Charts of simulated subsidence over time was also calculated for the major municipal and agricultural wellfields in the TLSBHM (Figure D5-11). These charts show that there was 1 to 2 feet of cumulative subsidence in the vicinity of Hanford, Lemoore, and Stratford, while there was about 5 feet of subsidence at Corcoran, and up to 9 feet of subsidence at the Angiola and Creighton Ranch well fields in Tule Subbasin. The charts also show a small seasonal pattern of elastic subsidence rebound. During the early simulation period (1990-1992), the simulated subsidence occurred at all locations and then stabilized from 1993 through 2001. Simulated subsidence at that time started to increase again after 2002 in a series of steps. Additional calibration of the model to subsidence is needed as more data are collected.

6.0 Sensitivity Analysis

A sensitivity analysis was conducted to evaluate the sensitivity of the model to a change in the estimated hydraulic conductivity and storage parameters. These values in the model were systematically modified over the plausible range of values for the sediment types present beneath the site, and the model was re-run. The sensitivity model run results were compared to the calibration model result to estimate the change in model calibration due to the change in the model parameter.

The sensitivity analysis results indicate that the aquifers above and below the Corcoran Clay are relatively sensitive to changes in K_h, while the Corcoran Clay is not sensitive, as shown by the change (delta) in the sum of square residual (Figure D6-1). The results indicate that little improvement in calibration could be expected by modifying the K_h parameters.

The model sensitivity is reversed with respect to K_v, with the Corcoran Clay heads relatively sensitive to changes in K_v, while the aquifers above and below the Corcoran Clay are relatively insensitive (Figure D6-1). The results indicate that a small improvement in calibration could be obtained by decreasing the K_v above the Corcoran Clay.

The sensitivity analysis results indicate that the model is also relatively sensitive to changes in aquifer S_s, with the change in sum of squares error increasing with lower values of storage (Figure D6-1). A small improvement in calibration could be obtained by decreasing the S_s above the Corcoran Clay.

The sensitivity analysis results indicate that the model is also relatively in sensitive to changes in the Sy of the unconfined aquifer above the Corcoran Clay, with the change in sum of squares error decreasing with lower values of S_y (Figure D6-1).

7.0 Predictive Simulations

The calibrated groundwater flow model was modified to develop two 54-year transient predictive simulations from 2017 through 2070: (1) a Baseline Forecast to evaluate potential undesirable impacts from maintaining the recent land use under “normal hydrology” conditions (i.e., the status quo); and

(2) a Projects Forecast to evaluate potential impacts of implementing alternative land uses and projects to obtain groundwater sustainability. Both forecast models consist of 649 monthly stress periods starting with December 2016 and ending with December 2070. The SGMA requires that any forecast model start with current conditions. The models were started in December 2016 to permit the importation of the calibration simulations results as the start for the forecast models. The forecast models assume multiple repeating 14-year cycles of "normal hydrology" (e.g., precipitation, stream flow, surface water deliveries, and boundary conditions) from 1998 to 2010 (Figure D7-1), starting with using 2011 hydrology as an analog for 2017, which was a wet year. A summary of the forecast year and associated "normal hydrology" analog year is presented on Table D7-1. The forecast models were developed as described in the following subsections.

7.1 Baseline Forecast Scenario

The TLSBHM Baseline Forecast model represents conditions that assume land use recovering from the 2010-2015 drought conditions to "normal hydrology" conditions in the first few years of the simulation and maintaining these "normal hydrology conditions for the duration of the simulations. The Baseline Forecast model were developed as described below.

7.1.1 Baseline Forecast Land Use

A review of historical land use shows that major cropping acreage patterns have changed significantly over the past decades (Table D2-6, Figure D2-12). Acreage of cotton, pasture, and dairy fodder decreased, especially during the 2011-2016 drought. During this same period, acreage of almonds, pistachios, pomegranates, and fallow land increased. Note that the more recent plantings of almonds, pistachios, pomegranates have not yet reached maturity and associated increased water demand (Section 4.5.4.2).

During this early Baseline Forecast stress period, the acreage of corn and cotton that had been fallowed during the drought was assumed to be replanted, except for the acreage that had been converted to permanent crops. In addition, the water demand of more recently planted acreage of almonds, pistachios, and pomegranates was assumed to increase as the trees matured as discussed in Section 4.5.4.2.

For crop maturation, tree crops are assumed to continue to mature on a 25-year cycle (except for pistachios which can produce for over 100 years) and continuously mature forward in time. All other crops/land use is assumed to revert to whatever the land use was in the seed year for that particular forecast year. For example, assume there is a new patch of almonds planted in 2016 (crop zone 201). In 2021, it will be in its sixth year of existence, so it's assigned the ET rate of 6-year old almonds (crop zone 206). The other crops around this patch of almonds will revert to whatever was planted there in 2001, since 2001 is the seed year for the forecast year 2021. Three years from then, the patch of almonds is now mature and assigned an ET rate for mature almonds (crop zone 209), while the nearby crops are represented by seed year 2004 (corresponding to 2024). Further into the forecast, the almonds will be in their 25th year of existence in 2041 (crop zone 225), while the surrounding crops will be represented by seed year 2007. That same patch of almonds will be replaced, cycle back to being represented by 1st year almond ET rates (crop zone 201), and since it is 2042, the other crops are represented by whatever was planted in 2008. A chart of Baseline Forecast crop acreage is presented on Figure D7-2. Note that the crop acreage chart shows a repeating cycle of replanting of permanent tree crops.

7.1.2 Baseline Forecast Municipal Pumping

Baseline Forecast municipal water demand for the cities of Hanford, Lemoore, and Corcoran were assumed to vary seasonally at the average of 2011-2015 pumping rates. Municipal pumping was assumed

to increase slowly with populations growth at a rate of 0.35% per year from about 25,060 AF (2017) to about 30,160 AF (2070).

7.1.3 Baseline Forecast Hypothetical Irrigation Pumping

As discussed in Section 4.5.4.2, the calibration model utilized the available groundwater pumping data for the individual wells and well fields servicing the ER GSA, CID, SWK GSA, TCWA GSA, and Westlands Water District, which allowed these areas to be treated as individual service area or "farms" (Figure D4-11). In the rest of the model domain, the agricultural pumping demand was calculated on approximately 40-acre spacing and assigned to hypothetical agricultural wells on approximately a 1-miles spacing. A similar process was utilized for the forecast models with a few modifications as described below.

For the forecast models, the service area or "farm" concept was extended throughout model domain by dividing the model by subbasin and GSAs into 10 services areas or "farms" (Figure D7-3). For each service area, the monthly agricultural pumping demand was calculated as follows:

- Service Area Weighted Crop Acreage (acres) x Crop ETc (ft/m) = Service Area ET Demand (AF/M)
- [-Service Area ET Demand (AF/M) + Effective Precipitation (ft/m)] / Irrigation Efficiency = -Service Area Farm Demand (AF/M)

  (*Note: over most of the model domain, Irrigation Efficiency was assumed to be 85% from 2017 to 2070. In the lake bottom area Irrigation Efficiency from was assumed to be 95% from 2017 through 2070. Approximately 50% of excess Effective Precipitation was assumed to infiltrate and 50% was assumed lost to evaporation).*
- -Service Area Farm Demand (AF/M) + Service Area Surface Water Deliveries (AF/M) + Service Area Lake Bottom Storage Water (AF/M) +Service Area Project Water (AF/M) = -Service Area Ag Pumping Demand (AF/M)

  (Note: when monthly Service Area water supplies exceeded monthly Service Area Farm Demand the excess water supply was assumed to carry over as available water supply in the following month).

The resulting service area agricultural pumping demand was then divided equally amongst the wells and well fields suppling groundwater to each servicing area. However, pumping from the Westlands Water District, CID, ER GSA, Creighton Ranch, and Angiola wells fields was limited to the maximum historical pumping from each well field (although not necessarily for each well). While this approach many not replicate the individual historical pumping from each well in a service area, it does provide a reasonable approach to allocate forecast groundwater agricultural pumping in each service area and thus a reasonable estimate of groundwater system demand.

7.1.4 Baseline Forecast GHBs

As shown on Table D7-1, the Baseline Forecast uses historical years as analogs for the hydrology conditions in the forecast. For example, 2019 is assumed to have hydrology similar to 1999. However, the GHB heads in 1999 are many feet higher than those in 2016 when the Baseline Forecast model starts. To correct for this head discrepancy, the general head boundaries for the Baseline Forecast model were developed by calculating the difference in monthly heads for each stress period of the calibration simulation, and then adding that difference to the forecast GHB head from the previous month. This allows the Baseline Forecast GHBs to have a similar change in heads between stress periods as the calibration model, but from a different initial (2016) elevation. For example, the Baseline Forecast GHB

heads for simulation year 2019 are based on the heads difference for the analog year 1999. If the head difference for GHB cell 1001 between December 1998-January 1999 was 0.55 feet in the calibration model, then 0.55 feet was added to the GHB cell 1001 head for the December 2018 to yield the January 2019 GHB head. Thus the resulting Baseline Forecast GHBs exhibit a change in heads similar to that for the calibration model analog year, but from a different initial condition.

7.1.5 Baseline Forecast of Climate Change

The SGMA guidelines require that climate change be considered in any forecasts of future land uses. The California Natural Resources Association (CNRA) has developed a set of tools that can apply change factors to historical precipitation, ET demand, and surface water delivery data to make historical data consistent with forecasted conditions under climate change. The CNRA has developed two climate change factor data sets, one for 2030 and one for 2070.

7.1.5.1 Effective Precipitation

The Baseline Forecast monthly effective precipitation data set was processed through the CNRA python script/ArcGIS tool. The tool takes monthly data and processes it using change factors, which vary temporally and spatially. For model cells that cross multiple change factor grid cells, an area-weighted average change factor is applied. The change factors for a 2030 forecast were used for the forecast period January 2017-Dececember 2030 (stress periods 2 – 169) while the change factors for a 2070 forecast were used for the forecast period January 2031-December 2070 (stress periods 170 – 649).

7.1.5.2 Crop Evapotranspiration

The Baseline Forecast monthly ETc data set was processed through the CNRA python script/ArcGIS tool. The tool takes monthly data and processes it using change factors, which vary temporally and spatially. Since the "normal hydrology" Baseline Forecast scheme rotates through a series of years from 1997 to 2010 (with a 2011-based year for 2017), each ET distribution for the Baseline Forecast is unique when accounting for tree crop maturation. For model cells that cross multiple change factor grid cells, an area-weighted average change factor is applied. The change factors for a 2030 forecast were used for the forecast period January 2017-December 2030 (stress periods 2 – 169) while the change factors for a 2070 forecast were used for the forecast period January 2031-December 2070 (stress periods 170 – 649).

7.1.5.3 Surface Water Deliveries

The Baseline Forecast surface water delivery data set incorporates a reduction in historical surface water allocations to SWK GSA and TCWA GSA due the sale of water rights. The Baseline Forecast surface water delivery data set all GSAs outside of the Subbasin were not modified. CNRA change factors for surface water deliveries do not vary spatially, and are simply a multiplier applied to the historical surface water delivery volume. Different change factors are available for 2030 and 2070 climate change forecasted conditions. Like the effective precipitation and ETc data sets, the 2030 change factors were used for the forecast period January 2017-December 2030 (stress periods 2 – 169) while the change factors for a 2070 forecast were used for the forecast period January 2031-December 2070 (stress periods 170 – 649).
The Baseline Forecast of surface water deliveries is shown on Figure D7-4.

7.1.6 Baseline Forecast Simulation Results

A comparison of simulated potentiometric surface maps from above and below the Corcoran Clay for December 2015 (Figure D5-3) with simulated Baseline Forecast potentiometric surface maps from above and below the Corcoran Clay for June 2040 (Figure D7-5) show that the groundwater elevations beneath

the Subbasin above and below the Corcoran clay are projected to decline about 25 feet and 50 feet, respectively during the 25-year simulation period. Dewatered areas in the upper aquifer on the east side of the model domain (mostly in the Kaweah and Tule subbasins) are projected to expanded and migrate into deeper intervals. The cones of depression above and below the Corcoran Clay in the Lemoore, Creighton Ranch, and Angiola Water District well field areas are projected to become more pronounced.

Simulated Baseline Forecast potentiometric surface maps from above and below the Corcoran Clay for December 2070 (Figure D7-6) show that the groundwater elevations beneath the Subbasin above and below the Corcoran clay are projected to decline about 50 feet and 150 feet, respectively, during the 54-year simulation period. Dewatered areas in the upper aquifer in the Kaweah and Tule subbasins are projected to expanded significantly and migrate into deeper intervals. The cones of depression above and below the Corcoran Clay in the Westside Subbasin, Creighton Ranch, and Angiola well field areas are projected to become much more pronounced.

Simulated Baseline Forecast hydrographs for selected compliance wells in the vicinity of the cities of Corcoran, Hanford, and Lemoore show a continued gradual decline in groundwater elevations in the unconfined aquifer above and below the Corcoran Clay, with seasonal variations much greater below the Corcoran Clay (Figure D7-7). Over the 54-year simulation period, the hydrographs above the Corcoran Clay show approximately 100 feet of decline in the Corcoran area, about 90 feet of decline in the Hanford area, and about 100 feet of decline in the Lemoore area. Over the same period, the hydrographs below the Corcoran Clay show about 100 feet of decline in the Corcoran area, about 100 feet of decline in the Hanford area, and about 100 feet of decline in the Lemoore area.

The Baseline Forecast simulation results indicate that subsidence will continue over the next 54 years under continued existing conditions. A map of cumulative subsidence from 2017-2040 shows that the is about 0 to 4 feet of additional subsidence over most of the Subbasin, with up to 6 feet of additional subsidence in the Lemoore area and Angiola and Creighton Ranch wells fields in the Tule Subbasin (Figure D7-8). Baseline Forecast subsidence in the lake bottom area are minimal. A map of cumulative subsidence from 2017-2070 shows that the is about 0 to 8 feet of additional subsidence over most of the Subbasin, with up to 10 feet of additional subsidence in the Lemoore area and over 10 feet of subsidence in the Angiola and Creighton Ranch wells fields in the Tule Subbasin (Figure D7-8).

Simulated Baseline Forecast subsidence hydrographs for continuous GPS compliance point near the cities of Corcoran and Lemoore wells show that under continued existing conditions, subsidence rate remain consistent during the forecast period (Figure D7-8). The minimum threshold for subsidence was specified as 11.5 feet, which was the maximum simulated subsidence within the TLSBHM domain in 2070.

The Baseline Forecast simulation groundwater mass balance data were used to estimate the change in groundwater storage in the Subbasin on an annual basis for the 54-year forecast simulation period (Figure D7-9). Similar to the 1998-2010 “normal hydrology” period in the calibration model, the period 2040-2048 represents a “normal” or “hydrologically balanced” period in the forecast model. Under the Baseline Forecast assumptions described above, the 2040-2408 “hydrologically balanced period” annual change in groundwater storage averaged about -149,430 AF/Y. During the 2017-2070 period, the annual change in groundwater storage averaged about -142,990 AF/Y, and as much as -7.72 million AF of cumulative storage depletion from the Subbasin.

In summary, the Baseline Forecast simulation results indicate continued overdraft conditions in the Subbasin, with chronic lowering of groundwater levels, continued reduction of groundwater in storage,

continued land subsidence, and possibly degraded groundwater quality. Thus, the Baseline Forecast indicates that sustainable groundwater conditions in the Subbasin cannot be achieved without changes in groundwater usage and management.

7.2 Forecast Project Simulations

Multiple Projects Forecast simulations were created iteratively by modifying the Baseline Forecast and incorporating various potential projects and management actions developed by the GSAs for the Subbasin and surrounding subbasins (see Section 7.6) (Figure D7-10). The objectives of the projects and management actions are to obtain groundwater sustainability (defined as stable groundwater elevations with minimal changes in storage, land subsidence, and water quality degradation over time) by 2040 through a combination of increase water supplies and demand reduction.

Potential projects and management actions considered include:

- Above ground surface water storage projects,
- Intentional recharge basins,
- On-Farm Recharge,
- Aquifer Storage and Recovery (ASR), and
- Agricultural pumping limits in surrounding subbasins.

The combined projects were assumed to provide an annual average of 40,500 AF/Y of increases water supply and 38,000 AF/Y of groundwater recharge for a total of about 78,500 AF/Y of new water supply (Table D7-2, Figure D7-11). This is slightly more than the average overdraft (-73,760 AF/Y) observed during the 1998-2010 "normal hydrology" period and about 92% of the 1990-2016 average overdraft (-85,690 AF/Y). In addition, land use changes resulting from construction of the projects are anticipated to reduce agricultural demand by approximately 26,900 AF/Y. In total, the proposed project may yield an average of up to 104,400 AF/Y of additional water supply to the Subbasin. The proposed projects are described below by Subbasin GSAs.

Mid-Kings River Groundwater Sustainability Agency

The Mid-Kinks River GSA has proposed constructing several 40-80 acre groundwater recharge facilities in the GSA. For modeling purposes, the proposed recharge facility was assumed to be constructed on about 1,500 acres of land in the northeast portion of the GSA (Figure D7-10). The simulated facility was implemented in four 5-year phases starting in 2020. Full build out would be completed in 2035. Due to conversion of irrigated crop land to recharge basins, the recharge facility construction is estimated to result in a permanent annual agricultural demand reduction of about 4,500 AF once completed. The facility was assumed to recharge Kings River flood waters with an assumed percolation rate of approximately 1-foot per day for a 150-day period from March through July when flood waters are typically available based on the historical hydrology cycles used to construct the forecast (Figure D7-11). Flood water were assumed to be available about every 6 to 7 years. Total recharge capacity would increase in 5-year phases from an initial 50,000 AF to an estimated 200,000 AF during flood years when fully built out. Annual average project yield is estimated to be about 38,000 AF/Y over the simulation period, and about 44,440 AF/Y over the hydrologically balanced 2040-2048 period (Table D7-2). Intentional recharge was simulated in the Projects Forecast using the RCH package.

El Rico Groundwater Sustainability Agency

The ER GSA has proposed constructing an intermittent surface water storage facility to store Kings River flood water when available (Figure D7-10). The proposed surface water storage facility was assumed to be constructed by 2030 using raised 6-foot berms to enclose approximately 6,400 acres of land. The land would continue to be farmed during non-flood years, so the net average agricultural demand reduction is estimated to be about 8,400 AF/Y. The surface water storage facility was assumed to store approximately 40,000 AF of Kings River flood waters at a rate of about 8,000 AF/M during a 150-day period from March through July when flood water are typically available based on the historical hydrology cycles used to construct the forecast (Figure D7-11). Because of the clayey nature of the Lake Bottom sediments, infiltration of storage water was assumed to be de minimis. Annual average project yield is estimated to be about 8,780 AF/Y over the simulation period, and 8,890 AF/Y over the hydrologically balanced 2040-2048 period (Table D7-2). This additional surface water supply was added to the Baseline Forecast surface water deliveries for the ER GSA.

South Fork Kings Groundwater Sustainability Agency

The SFK GSA has proposed a number of small projects including aquifer storage and recovery (ASR) wells, new surface water storage facilities, and land fallowing. The potential projects for SFK GSA were very conceptual in nature. The location of the potential ASR well field(s) and potential recharge and recovery rates has not been identified. The locations of potential surface water storage facilities and land fallowing areas were also undefined. Hence, for forecast modeling purposes, a single large surface water storage facility was assumed to be constructed in the southeast portion of the GSA (Figure D7-11). The simulated surface water storage facility was assumed to be constructed by 2030 using raised 6-foot berms to enclose approximately 10,000 acres of land. Approximately half of this land was assumed to already be fallow, so the net agricultural demand reduction is estimated to be about 15,000 AF/Y after 2030. Because of the clayey nature of the sediments in this area, infiltration of storage water was assumed to be de minimis. The surface water storage facility was assumed to store approximately 60,000 AF of Kings River flood waters at a rate of about 12,000 AF/M from March through July when flood water are typically available based on the historical hydrology cycles used to construct the forecast (Figure D7-11). Annual average project yield is estimated to be about 13,170 AF/Y over the simulation period, and 13,330 AF/Y over the hydrologically balanced 2040-2048 period (Table D7-2). This additional surface water supply was added to the Baseline Forecast surface water deliveries for the SFK GSA.

Tri-County Water Authority Groundwater Sustainability Agency

The TCWA GSA has proposed constructing a new surface water storage facility over the middle portion of the GSA (Figure D7-11). The simulated surface water storage facility was assumed to be constructed by 2030 using raised 6-foot berms to enclose approximately 13,340 acres of fallow land, so there was no net agricultural demand reduction. Because of the clayey nature of the sediments in this area, infiltration of storage water was assumed to be de minimis. The surface water storage facility was assumed to store approximately 80,000 AF of Kings River flood waters at a rate of about 16,000 AF/M from March through July when flood water are typically available based on the historical hydrology cycles used to construct the forecast (Figure D7-11). Annual average project yield is estimated to be about 17,561 AF/Y over the simulation period, and 17,780 AF/Y over the hydrologically balanced 2040-2048 period (Table 7-2). This additional surface water supply was added to the Baseline surface water deliveries for the TCWA GSA and SWK GSA.

Surrounding Subbasins Projects

As shown on Figure D2-2, the Subbasin is surround by the Westside, Kings, Kaweah, Tule, and Kern subbasins. It was assumed that these surrounding subbasins would also implement projects similar in scope and yield as those proposed for the Subbasin in order to obtain groundwater sustainability. Since all the surrounding subbasins were developing potential projects as part of their GSPs, there was insufficient time to coordinate with the surrounding subbasins and implement their proposed projects into the TLSBHM Projects Forecast model. Therefore, for simplicity, it was assumed that each surrounding subbasins would implement projects that would yield additional surface water supplies similar to what is proposed for the Subbasin, or approximately 75% of the 1990-2016 annual average change in storage estimated for that portion of each subbasin within the TLSBHM (Figures D5-4 through D5-9). It was further assumed, for simplicity, that the surrounding subbasin projects would be implement outside of the TLSBHM model domain and that the additional water supply would be imported into the TLSBHM domain as addition surface water deliveries. The assumed surrounding subbasin additional water supplies include:

- Westside Subbasin 60,330 AF/Y
- Kings Subbasin 50,960 AF/Y
- Kaweah Subbasin 114,400 AF/Y
- Tule Subbasin 104,220 AF/Y
- Kern Subbasin 35,720 AF/Y

This additional surface water supply was added to the Baseline surface water deliveries for each of the surrounding subbasins.

Surrounding Subbasins Pumping Limits

Another management option under consideration by the surrounding subbasins is a limitation of groundwater pumping to a prescribed number of acre-feet per acre of irrigated land. Based on review of draft GSPs and discussions with other GSA the pumping limits under consideration include:

Subbasin	GSA	Irrigated Acres in Model	Pumping Limit (af/ac)	Agricultural Pumping (AF/Y)
Kaweah	All	127,870	2.00	255,740
Kings	Central Kings	16,170	1.13	18,275
Kings	Kings River East	15,800	0.73	11,530
Kings	North Fork Kings	41,864	1.10	46,050
Kern	--	36,190	1.00	36,190
Tule	--	79,920	0.54	43,160
Westside	--	62,920	0.60	37,750

The prescribed pumping limit volumes were assumed to be uniformly distributed between all agricultural wells in each subbasin within the model domain.

7.2.1 Projects Forecast Land Use

Land use under the Projects Forecast is identical to that used in the Baseline Forecast with the exception that lands utilized for most of the Subbasin projects was assumed to go out of production as the projects are built out over time, resulting in a step-wise decrease in agricultural demand (Figure D7-10).

Land fallowing in the surrounding subbasins resulting from implementation of pumping limits was not explicitly simulated in the model. Only the reduction in agricultural pumping was specified in the forecast model.

7.2.2 Projects Forecast Municipal Pumping

The Project Forecast municipal water demand for the cities of Hanford, Lemoore, and Corcoran is identical to that used in the Baseline Forecast. Municipal pumping was assumed to increase slowly with populations growth at a rate of 0.35% per year from about 25,060 AF (2017) to about 30,160 AF (2070).

7.2.3 Projects Forecast Hypothetical Irrigation Pumping

The Projects Forecast of agricultural irrigation pumping was calculated in an identical manner as for the Baseline Forecast, assuming increased surface water deliveries from the projects and pumping limits in the surrounding subbasins. The available surface water supplies were increased by the proposed project yields as described in Section 7.2.1. During flood events, additional stored surface water was assumed to be available to supplement surface water deliveries the month following storage, less evaporative losses. For example, the volume of water stored in the proposed SFK GSA surface water pond during March 2031 (about 1.2 feet over 10,000 acres) would be available to be redistributed as additional surface water supply to SFK GSA in April 2013 minus open water evaporation for March (about 0.38 feet). This assumption allows the proposed project surface water storage to be depleted in a timely manner by both evaporation and re-use.

7.2.4 Projects Forecast GHBs

The Projects Forecast GHBs were calculated in an identical manner as for the Baseline Forecast with one modification. As described in Section 7.1.4, the general head boundaries for the Baseline Forecast model were developed by calculating the difference in monthly heads for each stress period of the calibration simulation, and then adding that difference to the forecast GHB head from the previous month. This allows the forecast GHBs to have a similar change in heads between stress periods as the calibration model, but from a different initial (2016) elevation. This same process was used for the Projects Forecast GHBs with the addition of a head change factor that assumes projects were implemented in the subbasins surrounding the Subbasin resulting in a gradual stabilization (or "soft landing") of heads around 2040. The head change factor had a value of 100% from 2017 through 2026, and then decreased by 5% per year until 2040 where the head change factor was fixed at 25% for the duration of the simulation. The resulting Projects Forecast GHBs show a more gradual decrease in the rate of decline compared to the Baseline GHBs (Figure D7-12).

7.2.5 Projects Forecast of Climate Change

The SGMA guidelines require that climate change be considered in any forecasts of future land uses. The same CNRA climate change factor data sets for 2030 and 2070 used in the Baseline Forecast were applied to the Projects Forecast ET demand, and surface water delivery data. The CNRA corrected effective precipitation results remained identical to the Baseline Forecast.

7.2.6 Projects Forecast Simulation Results

As discussed in Section 7.2, multiple Projects Forecast simulations were created iteratively by modifying the Baseline Forecast and incorporating various potential projects and management actions developed by the Subbasin GSAs and surrounding subbasins. The Projects Forecast scenarios evolved as follows:

1. Projects Forecast Scenario 1: The Baseline Forecast was modified by added projects and associated land fallowing in the Subbasin only (discussed below). The simulation results showed a continued lowering of groundwater levels, reduction of groundwater in storage, continued land subsidence, and increased outflow to surrounding subbasins.
2. Projects Forecast Scenario 2: The Projects Forecast was further modified with GHBs that caused an asymptotic flatting (i.e., soft landing) of the GHB heads in 2040, representing the effects of assumed projects in other subbasins. The modification of the GHBs simulation results showed only a slight reduction of groundwater level declines compared to Projects Forecast Scenario 1, with continued reduction of groundwater in storage, continued land subsidence, and continued outflow to surrounding subbasins.
3. Projects Forecast Scenario 3: The Projects Forecast was further modified by assuming each surrounding subbasin implemented projects that would yield additional surface water supplies similar to what is proposed for the Subbasin, or approximately 75% of the 1990-2016 annual average change in storage estimated for that portion of each subbasin within the TLSBHM. The simulation results showed a substantial reduction of groundwater level declines over time compared to Projects Forecast Scenarios 1 and 2, but with continued declining groundwater levels, reduction of groundwater in storage, continued land subsidence, and continued outflow to surrounding subbasins, after 2040.
4. Projects Forecast Scenario 4: The Projects Forecast was further modified by implementing agricultural pumping limits in the surrounding subbasins. The simulation results showed a substantial reduction of groundwater level declines over time compared to Projects Forecast Scenarios 1 through 3, resulting in stable groundwater elevations throughout most of the Subbasin and surrounding subbasins, with significantly reduced reduction of groundwater in storage, and significantly reduced land subsidence. These results are presented below.

A comparison of simulated potentiometric surface maps from above and below the Corcoran Clay for the Baseline Forecast for June 2040 (Figure D7-5) with simulated Projects Forecast Scenario 4 (hereafter referred to simply as the Projects Forecast) potentiometric surface maps from above the Corcoran Clay for June 2040 (Figure D7-13) show that the simulated groundwater elevations beneath the Subbasin above the Corcoran Clay are about 10 feet higher under the Projects Forecast compared to the Baseline Forecast. Simulated groundwater elevations in the surrounding subbasins are substantially higher with groundwater elevation increases ranging from 20 to 30 feet in Kaweah, Kings, and Tule subbasins. The Westside Subbasin showed groundwater elevations increases in the 10 to 20 foot range, while there was little increase in the Kern Subbasin.

Simulated groundwater elevations for June 2040 beneath the Subbasin below the Corcoran Clay are about 20 to 30 feet higher under the Projects Forecast compared to the Baseline Forecast. In the Kaweah and Kings subbasins, simulated heads are 20 to 40 feet higher compared to the Baseline Forecast. In the Tule Subbasin in Creighton Ranch and Angiola well field areas, simulated heads are as much as 130 feet higher compared to the Baseline Forecast. The Westside Subbasin showed groundwater elevations increases in the 40- to 100-foot range, while the heads in the Kern Subbasin increased as much as 50 feet.

A comparison of simulated potentiometric surface maps from above and below the Corcoran Clay for the Baseline Forecast for December 2070 (Figure D7-5) with simulated Projects Forecast potentiometric surface maps from above the Corcoran Clay for December 2070 (Figure D7-14) show that the simulated groundwater elevations beneath the Subbasin above the Corcoran Clay are about 10 to 30 feet higher under the Projects Forecast compared to the Baseline Forecast. Simulated groundwater elevations in the surrounding subbasins are substantially higher with groundwater elevation increases ranging from 20 to 40 feet in Kaweah and Kings subbasins, and as much as 80 feet in the Tule Subbasin. The Westside Subbasin showed groundwater elevations increases in the 10 to 20 to 60 foot range, while the heads in the Kern Subbasin increased as much as 40 feet.

Simulated groundwater elevations for December 2070 beneath the Subbasin below the Corcoran Clay are about 30 to 40 feet higher under the Projects Forecast compared to the Baseline Forecast. In the Kaweah and Kings subbasins, simulated heads are 30 to 60 feet higher compared to the Baseline Forecast. In the Tule Subbasin in Creighton Ranch and Angiola well field areas, simulated heads are as much as 160 feet higher compared to the Baseline Forecast. The Westside Subbasin showed groundwater elevations increases in the 50-to 130-foot range, while the heads in the Kern Subbasin increased as much as 90 feet.

Simulated Projects Forecast hydrographs for selected compliance wells in the vicinity of the cities of Corcoran, Hanford, and Lemoore show a gradual stabilization of groundwater elevations in the unconfined aquifer above and confined below the Corcoran Clay, with seasonal variations much greater below the Corcoran Clay (Figure D7-15). Over the 54-year simulation period, the hydrographs above the Corcoran Clay show approximately 15 feet of decline in the Corcoran area, about 25 feet of decline in the Hanford area, and about 60 feet of decline in the Lemoore area. Over the same period, the hydrographs below the Corcoran Clay show about 30 feet of decline in the Corcoran area, about 25 feet of decline in the Hanford area, and about 20 feet of decline in the Lemoore area.

The Projects Forecast simulation results indicate that subsidence will continue over the next 54 years under the assumed forecast conditions. A map of cumulative subsidence from 2017-2040 shows that the is about 0 to 2 feet of additional subsidence over most of the Subbasin, with up to 2 feet of additional subsidence in the Lemoore area (Figure D7-16). Subsidence in the Angiola and Creighton Ranch wells fields in the Tule Subbasin is significantly less compared to the Baseline Forecast (Figure D7-7). Projects Forecast subsidence in the lake bottom area in minimal. A map of cumulative subsidence from 2017-2070 shows that the is about 2 to 4 feet of additional subsidence over the northern portion of the Subbasin, with up to 2 feet of additional subsidence in the Angiola and Creighton Ranch wells fields in the Tule Subbasin (Figure D7-16).

Simulated Projects Forecast subsidence hydrographs for continuous GPS compliance point near the cities of Corcoran and Lemoore wells show that under project conditions, the subsidence continues to occur (Figure D7-17), but at significant reduced rates compared to the Baseline Forecast (Figure D7-8).

The Projects Forecast simulation groundwater mass balance data were used to estimate the change in groundwater storage in the Subbasin on an annual basis for the 54-year forecast simulation period (Figure D7-18). Under the Projects Forecast assumptions described above, between 2017 and 2070, there would continue to be an annual average of about -36,200 AF/Y of groundwater storage depletion (a reduction of 75% compared to the Baseline Forecast), and as much as -7.72 million AF of cumulative storage depletion from the Subbasin. Most of the remaining overdraft in the Subbasin appears to result from the continued outflow of groundwater to the surrounding subbasins, which average approximately -58,610 AF/Y over the 2017-2070 simulation periods (Figure D7-18).

As discussed in Section 7.2, for simulation purposes it was assumed that the surrounding subbasins would implement projects and management actions that would increase surface water supply and decrease agricultural demand. However, until the magnitude and timing of actual projects and management actions to be implemented in the surrounding subbasins can be incorporated into the TLSBHM, the model forecasts will have a degree of uncertainty regarding future water balance and overdraft estimates.

In summary, the Projects Forecast simulation results indicate that overdraft conditions in the Subbasin will be mostly eliminated, with stable groundwater levels by 2040. While there continues to be some reduction of groundwater in storage, the forecast that groundwater levels remain relatively stable through 2070 indicates that the continued reduction in groundwater in storage is also sustainable. Likewise, although some land subsidence will continue over time, the forecast that groundwater levels remain relatively stable through 2070 indicates that the continued subsidence is also sustainable. Thus, the Projects Forecast indicates that sustainable groundwater conditions in the Subbasin can be achieved by 2040 with implementation of the proposed projects and management actions in the Subbasin and assumed projects and management actions in the surrounding subbasins.

7.2.7 Historical vs. Projects Forecast Simulation Comparison

A comparison of the 1990-2016 historical model, 2017-2070 Baseline Forecast, and 2017-2070 Projects Forecast was made using the annual average groundwater balance data for each simulation (Table D7-3). The Baseline and Projects forecast models both assume that land fallowed during the 2011-2016 drought would be put back into production, and that overall crop demand would increase due to the maturation of permanent crop as described in Section 7.1.1. The increase in ET demand was also exacerbated by climate change. Furthermore, the forecasts also assume that groundwater levels would continue to decline at historical rates for 10 or more years prior to project implementation. As a result, for the even though the Baseline Forecast 2017-2070 average annual pumping, recharge, and river leakage are similar to the Calibration 1990-2016 average values, the net change in storage increased from -85,690 AF/Y to -142,990 AF/Y because there was more interbasin outflow from the Subbasin into the surrounding subbasins. The annual average values for 1998-2010 and 2040-2048 "normal hydrology" periods have similar results, where the net change in storage increased from -73,760 AF/Y to -149,430 AF/Y.

The Projects Forecast shows a different trend. With implementation of the projects, the 2017-2070 average annual pumping decreases, groundwater recharge increases, and interbasin flow decreases. As a result, the net change in storage decreased from -85,690 AF/Y to -36,200 AF/Y (nearly a 60% decrease). The results are similar for the 1998-2010 and 2040-2048 "normal hydrology" periods, where the net change in storage decreased from -73,760 AF/Y to -19,390 AF/Y.

The results of the Projects forecast simulation indicate that under the assumed forecast conditions, implementation of the proposed projects to increase surface water supply and recharge coupled with agricultural demand reductions in the surrounding subbasins can significantly reduce overdraft to sustainable levels in the Subbasin as evidenced by the stabilization of groundwater levels throughout most of the subbasins (Figure D7-15, GSP Appendix G) and the reduction of subsidence (Figure 7-17).

8.0 Data Limitations

Groundwater models are designed to estimate changes over time in groundwater levels, flow directions, and storage given a set of inflows (precipitation, surface water, under flow in, etc.) and outflows (evapotranspiration, pumping, underflow out, etc.). Prior to the SGMA there were no requirements to manage or report groundwater usage. As a result, most GSAs do know the location, construction, and

pumping history of many pumping wells within their GSAs. Furthermore, most GSAs often do not have a good historical accounting of which parcels have received surface waters and at what rates. Hence, these inputs and outputs need to be approximated by other means than direct measurement.

The data utilized for construction and calibration of the TLSBHM were provided by various private parties, public agencies, and data extracted from existing numerical models of the area including DWR's 2014 release of C2VSim in the Coarse Grid version, USGS CVHM, the Kaweah Delta Water Conservation District model (Fugro West, 2005), and the preliminary Tule Subbasin and Westside Subbasin models. Other numerical models adjacent to and/or covering portions of the TLSBHM are known to exist, but were unavailable for this effort. The data gathering effort also occurred before many GSAs were organized, so it is likely that some data were unavailable at the time the model was developed. It is anticipated that as the TLSBHM is reviewed and utilized that some corrections of input data will be necessary and that additional data, unavailable at the time, will need to be incorporated into the model.

Much of the hydrologic data used to construct and calibrate the TLSBHM are based on estimates or inferred from multiple data sources. As noted above, most GSAs do not know the historical delivery of surface water to various parcels within the GSAs. Hence it was necessary to assume that all irrigated parcels received some surface water allotment. Likewise, the location, construction, and pumping history of most of the irrigation wells in the TLSBHM domain are not known. Hence hypothetical irrigation well locations were assumed to be distributed with relatively uniform spacing across the model domain. The hypothetical irrigation wells were also assumed to have completion intervals and frequency similar to that of a small subset of wells with known constructions. Hypothetical irrigation wells pumping was estimated based on a water balance method using estimated agricultural demand based on reported crop type minus the assumed distribution of surface water supplies. While these simplifying assumptions and estimates are reasonable given the sparseness of measurements, they add uncertainty to the model.

Overtime, under the SGMA, more accurate spatial and temporal groundwater pumping, and surface water delivery data should be collected and utilized to construct and update groundwater models of the Subbasin. As the models are populated with actual measurement instead of estimate, the models will become more useful tool for managing groundwater in the Subbasin.

9.0 Summary of Model Reliability and Peer Review

The TLSBHM is an approximation of existing conditions beneath and in the vicinity of the Subbasin. It covers a large area with very dynamic hydrologic conditions that have significant changes over the simulation period. Due to a lack of historical data, much of the data utilized to construct the model had to be inferred from alternative data sets. Given the uncertainty of these estimates, the model can approximate on average, but not completely reproduce, all observations across the entire site area under all conditions. Overall, the TLSBHM can reliably predict groundwater elevations in response to various hydrologic conditions within the calibration period based on the available data and estimates. However, forecast simulations with extreme ranges in hydrologic conditions (i.e., severe drought conditions or extreme flooding) may produce less reliable results.

The TLSBHM was submitted for peer review to Dr James T McCord of GeoSystems Analysis, Inc. Dr. McCord has over 30 years of experience in hydrology, hydrogeology, and water resource investigations, with emphasis on characterization of groundwater and surface water systems, numerical modeling of hydrologic systems. He has authored numerous consulting reports and technical peer-reviewed papers, and co-authored the textbook, Vadose Zone Processes (CRC Press, 1999). He has served as an Adjunct Professor of Earth Science at New Mexico Technical University since 1991, as well as Adjunct

Professor of Civil Engineering at the University of New Mexico and of Civil and Environmental Engineering at New Mexico Tech since 2007. Dr. McCord's per review in include in Appendix D6.

Table D2-3
Historical Kings River Diversions

Tulare Lake Subbasin Hydrologic Model
Kings County, California

Notes:
1. Values highlighted have been modified.
2. Values with "0" indicate no surface water delivery to the best of our knowledge.
3. Values with "-" have no verified data.
4. Total flow from Peoples Canal is split 60% to Mid-Kings, 40% to Melga.
5. Last Chance Diversion is split 50% between Mid-Kings and El Rico.
6. Blakeley has added State Water from Lateral A for Southwest.
7. Total flow from Deer Creek split 30% to El Rico, 70% to Tri-County.
8. Tule River for El Rico includes the total of Elk Bayou and TID Spill.
9. SWP from TLBWSD Split Through out Tri-County and Southwest Kings.
10. Kings River water in Tri-County was subtracted from the total in Empire Weir No. 2. 1976 and 2010 are 0 for Empire Weir No. 2 because of negative values.
11. Lakeside is a portion of Kaweah River, Reduced Total Kaweah River between Mid-Kings and El Rico.
12. Additional Tule River flow data added for Tri-County.
13. Empire Westside Irrigation District total from SWP reduce annual totals by 10%.
14. Dudley Ridge Water District reduce annual totals by 10%.
15. Lateral A (T200) & Lateral B (T206) reduce annual totals by 18% for El Rico & Tri-County.
16. Modifications to Peoples Canal and Last Chance as a result of discussions with Mid-Kings River GSA on 2/14/19.

Re: Kings County – Tulare Lake Subbasin GSP Project: Groundwater Model Peer Review

As requested, I performed a technical peer review of the Tulare Lake Subbasin Hydrologic Model (TLSBHM) and associated report developed by Wood Environment & Infrastructure Solutions, Inc. ("Wood"). This model has been and is continuing to be utilized as a tool for evaluation of hydrologic impacts of future water management scenarios being considered as part of the Groundwater Sustainability Plan (GSP) for the Tulare Lake Subbasin (TLSB) as part of the required Sustainable Groundwater Management Act (SGMA) implementation for that planning region. My review focused of four aspects of the model, specifically:

- the model objectives,
- the Hydrogeologic Conceptual Model (HCM) of the TLSB,
- the development and documentation of numerical groundwater model as a predictive simulation tool based on the HCM, and
- documentation of model development and application in a report that is included as an appendix as part of the final GSP report.

Each of these topics is discussed in separate subsections below.

Model Objectives

Model objectives are clearly stated in Section 1.2, and importantly the stated objectives are consistent with model requirements define in the SGMA (Sustainable Groundwater Management Act of 2014) regulations. Specifically, as required by SGMA, the stated objectives include development of a model capable of forecasting groundwater management actions over a 50-year planning horizon (Cal. Water Code §10727.2(c)), establishment of measurable objectives and critical / minimum thresholds (Cal. Code of Regulations, "CCR," §354.29 and CCR §354.30), and development of a numerical model to quantify and evaluate projected water budget conditions (CCR §354.18).

Hydrogeologic Conceptual Model

A hydrogeologic conceptual model (HCM) is the fundamental basis upon which a numerical model of groundwater flow is based. The HCM is basically a narrative description of the physical system, including:

- the areal extent of the model (typically referred to as the model domain)
- the hydrostratigraphic units within the model domain, including a description of the spatial distribution (area covered, depth, continuity, and thickness)
- the water sources and sink, also referred to as the inflows and outflows, within the model domain
- a description of the flow system functioning, and a preliminary water budget.

Section 2 of the Wood report covers the HCM, utilizing block diagrams to illustrate key flow components under both pre-development and developed conditions. The report section on the HCM covers all items listed above, including a narrative description of the evolution and chronology of hydrogeologic conditions in the basin / study area since development began. The conceptual model describes all recharge sources and surface water sources available and applied to meet water demands in the study area. Land subsidence due to groundwater withdrawal is explicitly described in the HCM, setting the stage for explicit simulation of subsidence in the TLSB numerical model. The HCM section also includes a separate subsection on the basin water budget, citing ranges of values for each of the inflow and outflow components. It is recommended that a table be added that summaries the preliminary water budget documented in the HCM section.

Development and Documentation of Numerical Groundwater Model

As previously noted, CCR §354.18 requires the development of a model to quantify and evaluate projected water budget conditions for the GSP. While a simple spreadsheet model can be employed for development of historical water budgets based on available data, a more quantitative approach is need for predict basin sustainability into future conditions. A numerical model is the most common tool employed for quantitative predictions of basin response to future stresses. Per SGMA requirements, the numerical model must: include publicly available supporting documentation; be based on field or laboratory measurements and calibrated against site specific field data; and developed using public domain, open-source software (CCR §352.4(f)(1-3)) As part of the model documentation, the Wood (2019) groundwater model report notes that the model was developed using the MODFLOW-2005-NWT code, and cites publicly available background documents related to this code, its mathematical development, capabilities, and user guide. The Wood (2019) report also describes the preliminary application of the MODFLOW-OWHM code, and explains why that code ultimately was not utilized for this current phase of the TLSB GSP project. The "Model Design" section of the Wood (2019) report provides a detailed description of each of the key model inputs and data sources for assigning/developing input values, including all the boundary conditions used. The methodology employed to develop agricultural pumping estimates are well-described, as well as the methodology for accounting for in-basin storage and management of excess surface inflows in wet years (for subsequent irrigation when surface inflow supplies are insufficient to meet demands).

The model calibration section describes in detail calibration criteria employed, as well as a description of the calibration data. It appears that that significant effort was invested in gathering and compiling whatever calibration data could be obtained from public sources, as well as from stakeholders / participants in the GSP process. For example, the 1990 – 2016 calibration period included 16,621 groundwater level observations collected from 593 observation wells across the model domain. The 1998 – 2010 "normal hydrology" calibration period included 7,028 groundwater level observations collected from 544 observation wells across the model domain. Wood (2019) also note that additional data was available and reviewed as part of the calibration process, but ultimately was not used due to data uncertainty / data quality concerns. The trial & error calibration procedure is well described, and plots are presented showing "goodness-of-fit for wells employed in the calibration process. The final calibration statistics are presented, showing that the final calibrated model generally meets defined criteria for an adequately calibrated model (e.g., Normalized Root Mean Squared Error < 10%).

Detailed water balance results are presented for the calibrated model, including for interactions between the TLSB and adjacent subbasins in the southern San Joaquin Valley. The calibration model simulated subsidence is also presented, although Wood (2019) notes that additional calibration of the model to observed subsidence is needed.

Consistent with good model practice, a model parameter sensitivity analysis is presented to show that the sensitivity of the model results to changes in hydraulic conductivity and storage parameters. The sensitivity analysis showed the calibrated model to be quite robust to changes in model parameters, and the importance of the Kv parameter of the Corcoran Clay layer, and Kh for the shallow and deeper aquifers (above and below the Corcoran, respectively).

Finally, the Wood (2019) report summarizes forecast models to predictive TLSB hydrologic condition 50 years into the future under two future scenarios:

- a Baseline Forecast scenario projecting current cropping patterns into the future, a slow growth rate in municipal pumping(0.3% per year) with a 50-year hydrology driver that accounts for climate change following the guidelines of the California Natural Resources Association (CNRA) for applying "change factors" to historical precipitation, ET demand, and surface water delivery data to make historical data consistent with forecasted conditions under climate change.
- multiple Project Forecast simulations; that involved by modifying the Baseline Forecast and incorporating various potential projects and management actions developed by the GSAs for the TLSB and surrounding subbasins. Potential projects and management action considered include: (i) Above ground surface water storage projects, (ii) Intentional recharge basins, (iii) On-Farm Recharge, (iv) Aquifer Storage and Recovery (ASR), and (v) Agricultural demand reductions.

The results for the Forecast model results include projected water budgets into the future, as well as piezometric levels and changes to basin storage (both elastic and inelastic) for the Baseline and Sustainability Project scenarios. The forecast model results are also presented for water level hydrographs for selected Compliance Wells (which were identified in the main body of the GSP report) in Figures 7-6 and 7-15 and predicted subsidence for Subsidence Compliance

Monitoring points (Figures 7-8 and 7-17). Identification of and calculation of responses at designated Compliance Monitoring points meets the SGMA requirement that the model be able to quantify Sustainability Indicators (23 CCR §354.28(b)), which are clearly defined in Chapter 4 of the GSP report.

Summary

The TLSB groundwater model developed to support groundwater sustainability planning for the TLSB was reviewed and evaluated against explicit needs and requirements for basin sustainability planning under SGMA. Based on this Peer Review of the model, it was found that the model was developed following good groundwater modeling practice in terms of compilation and integration of historical available data and information, groundwater calibration criteria, sustainability analyses, forecasts of future conditions under Baseline and implementation of sustainability Projects, and clear documentation of model development and application. As required under SGMA, the model develops a rigorous groundwater budget under the historical calibration period as well as under the two future Forecast scenarios (Baseline and Project). In addition, it also quantifies groundwater response at key monitoring points in the basin in the context of sustainability criteria and thresholds identified in Chapter 4 of the GSP.

If you have any questions, please do not hesitate to contact me. As always, we appreciate this opportunity to work with the Wood – Provost & Pritchard team.

Best Regards,

James T. McCord

Article 5. Plan Contents, Subarticle 2. Basin Setting				
354.14.(a-b)	10727.2	Hydrogeologic Conceptual Model (HCM), descriptive text	a. Hydrogeologic Conceptual Model and maps of the physical components and interaction of the surface water and groundwater systems in the basin. b. The HCM will include: 1. Regional geologic and structural setting of the Subbasin, as well as surrounding areas 2. Lateral basin boundaries including major geologic features 3. Definable bottom of the basin 4. Principal aquifers and aquitards including: a. formation names b. physical properties of aquifers and aquitards c. structural properties of the Subbasin that restrict groundwater flow within the aquifers d. General water quality of principal aquifers e. identification of primary uses of each aquifer including domestic, irrigation, municipal water supplies f. Identification of data gaps and uncertainty in the HCM	a. Section 3.1 (p. 3-2) and Appendix D b. HCM summarized in written descriptions within: 1. Sects 3.1.1 to 3.1.3 (p. 3-2) 2. Section 3.1.6 (p. 3-14) 3. Section 3.1.7 (p. 3-17) 4a. Section 3.1.8 (p. 3-20) 4b. Section 3.1.8 (p. 3-20) 4c. Section 3.1.8 (p. 3-20) 4d. Section 3.2.5 (p. 3-33) 4e. Section 3.1.11 (p. 3-27) 4f. Section 3.1.12 (p. 3-28)

GSP Regulation Section	Water Code Section	Requirement	Description	Section(s) and Page Number(s) in the GSP
354.14.(c-d)	10733.2	HCM, Maps	c. Include at least 2 cross section maps of the HCM that depict major stratigraphic and structural features of the Subbasin d. Map(s)pf physical characteristics of the Subbasin 1. Topographic information 2. Surficial geology (by USGS or other applicable agency) 3. Soil characteristics (by NCRS or other applicable agency) 4. Delineation of existing recharge areas, potential recharge areas, and discharge areas 5. Surface water bodies 6. Source and point of delivery for imported water supplies	c. Figures 3-14a to 3-14c d1. Figure 3-7 d2. Figure 3-12 d3. Figures 3-9 to 3-11 d4. Figure 3-22 d5. Figure 3-5 d6. Section 3.1.1.6 (p. 3-8)
354.16	10733.2	Groundwater Conditions	a. Groundwater elevation data 1. Groundwater elevation contour maps (depict groundwater table or potentiometric surface) 2. Hydrographs for long term groundwater elevations, historic levels, and hydraulic gradients b. Estimate of groundwater storage (graph). Graph must include annual and cumulative change in the volume of groundwater in storage between seasonal high groundwater conditions including annual use and water year type c. Seawater intrusion conditions (including maps and cross sections for each principal aquifer) d. Groundwater quality issues including locations of known groundwater contamination sites and plumes e. Extent, cumulative total, and annual rate of land subsidence (including map of total subsidence based on data from DWR)	a1. Figures 3-24 to 3-27 a2. Figures 3-23 through 3-28d and Appendix D b. Figures 3-29a,b,c c. Section 3.2.4 (p. 3-32) d. Section 3.2.5 (p. 3-33) e. Section 3.2.6 (p. 3-35) f. Section 3.2.8 (p. 3-37) g. Section 3.2.8.1 (p. 3-38)

GSP Regulation Section	Water Code Section	Requirement	Description	Section(s) and Page Number(s) in the GSP
			f. Identification of interconnected surface water systems and estimate of quantity and timing of the depletions using DWR data g. Identification of groundwater-dependent ecosystems (using data from DWR)	
354.18.(a-b)	10733.2	Water Budget Information	a. Water budget that provides an assessment of total annual volume of groundwater and surface water entering and leaving the Subbasin (including historic, current, and projected) b. The water budget shall quantify the following through estimates or direct measurements: 1. Total surface water entering and leaving the Subbasin (by water source type) 2. Inflow to the groundwater system by water source type 3. Outflows from the groundwater system by water use sector 4. Change in annual volume of groundwater in storage 5. Quantification of overdraft over a period of years including water year and water supply conditions compared to average conditions 6. Water year type associated with annual supply, demand, and change in groundwater 7. Estimate of sustainable yield	a. Section 3.3 (p. 3-40) b1. Section 3.3.1 (p. 3-41) b2. Section 3.3.1 (p. 3-41) b3. Section (3.3.1 p. 3-41) b4. Section 3.3.2 (p. 3-49) b5. Section 3.3.3 (p. 3-50) b6. Section 3.3.4 (p. 3-51) b7. Section 3.3.4 (p. 3-51)
354.18.(c)	10733.2	Quantification of Water Budget	c. Each Plan shall quantify the current, historic, and projected water budget including: 1. Current water budget information including current inflows and outflows 2 Historical water budget must include the following:	1. Section 3.3.5 (p. 3-52) 2. Section 3.3.6 (p. 3-52) 3. Section 3.3.7 (p. 3-54)

GSP Regulation Section	Water Code Section	Requirement	Description	Section(s) and Page Number(s) in the GSP
			• Quantitative evaluation of availability/reliability of historical surface water supply (by water source type and water year type) *must be based on the most recent 10 years of data • Quantitative evaluation of historic water budget to project the future water budget information and future aquifer response to GSP implementation • Description of how historical conditions have impacted GSA ability to create sustainable yield 3. Projected water budget to estimate future baseline conditions for GSP implementation and identify uncertainties. This section should include the following: • Projected hydrology must include 50-year historical precipitation, evapotranspiration, and streamflow information as the baseline *climate change must also be incorporated • Projected water demand will utilize the most recent land use, evapotranspiration, and crop coefficient data. Projected changes in local land use planning, pop growth and climate must be included • Projected surface water supply will use most recent data and also consider historical surface water supply	
354.18 (d)	10733.2	Water Budget Data Source	d. The Agency shall utilize the following information provided by the DWR (or other comparable data) to develop the Water Budget 1 .Historical water budget information: use mean annual temperature, mean annual precipitation, water year type, and land use 2. Current water budget information for temperature, water year type, evapotranspiration, and land use	d. Section 3.3 (p. 3-40) 1. Section 3.3.6 (p. 3-52) 2. Section 3.3.5 (p. 3-52) 3. Section 3.3.7 (p. 3-54)

GSP Regulation Section	Water Code Section	Requirement	Description	Section(s) and Page Number(s) in the GSP
			3. Projected water budget information for population, population growth, climate change.	
354.18 (e, f)	10733.2	Water Budget	e. Must use a numerical groundwater and surface water model or the Plan must identify and describe an alternate method f. DWR will provide the Ca Central Valley Groundwater-Surface Water Simulation Model and the Integrated Water Flow Model for GSA use. (GSA can also select an alternate method but must be called out by type)	e. Appendix D f. Noted
354.20	10733.2	Management Areas	a. Define management areas and if they will have different measurable objectives (MOs) and minimum thresholds (MTs) b. Describe the following on Management areas: 1. Reason for creation of each management area 2. MO/MTs for each management area and why those values were selected if vary from Subbasin 3. Level of monitoring and analysis in each management area 4. Why MO/MTs can differ without causing undesirable results c. GSP must include descriptions and maps of management areas.	a. Section 3.4 (p. 58) b1. Section 3.4 (p. 58) b2. Section 3.4 (p. 58) b3. Section 3.4 (p. 58) b4. Section 3.4 (p. 58) c. Section 3.4 (p. 58)
Article 5. Plan Contents, Subarticle 3. Sustainable Management Criteria				
354.24	10733.2	Sustainability Goal	Description of the Sustainability Goal	Section 4.1.1 (p. 4-2)
354.26	10733.2, 10721, 10723.2, 10727.2, 10733.2, 10733.8	Undesirable Results	a-b. Description of Undesirable Results, including: 1. Cause of Groundwater Conditions that would lead to Undesirable Results 2. Criteria used to define Undesirable Results for each sustainability indicator	a-b. Section 4.2 (p. 4-4) 1. Causes of undesirable results are discussed in Section 4.2.1 (p. 4-4)

GSP Regulation Section	Water Code Section	Requirement	Description	Section(s) and Page Number(s) in the GSP
			3. Potential effects of Undesirable Results on beneficial uses and users of groundwater c. Evaluation of multiple MTs and monitoring sites to determine undesirable results	2. Criteria to define undesirable results are discussed in Section 4.2.2 (p. 4-10) 3. Potential effects of undesirable results are discussed in Section 4.2.2 (p. 4-10) c. Section 4.3 (p. 4-11)
354.28 (a-b)	10723.2, 10727.2.(d).1, 10727.2.(d).2,	Minimum Thresholds	a-b. Description of each MT and how they were established for each sustainability indicator, including numeric values. 1. Information and criteria that establish and justify the MTs for each sustainability indicator 2. Relationship between MTs for each sustainability indicator 3. How MTs have been selected to avoid undesirable results for each sustainability indicator 4. How MTs may affect the interest of beneficial uses and users of groundwater 5. How state, federal, or local standards relate to the relevant sustainability indicator 6. How each MT will be quantitatively measured	a-b. Section 4.3 (p. 4-11) describes each MT 1. Section 4.3.1 (p. 4-12) 2. Section 4.3.1 (p. 4-12) 3. Section 4.4.1 (p. 4-12) 4. Section 4.3.1 (p. 4-12) 5. Section 4.3.1 (p. 4-12) 6. Section 4.3.2 (p. 4-16)
354.28 (c-d)	10733.2	Minimum Thresholds	c. Definition of MTs for each sustainability indicator: 1. Chronic lowering of groundwater levels a. Rate of groundwater elevation decline based on historical trends, water year type, and projected use b. Potential effects on other sustainability indicators 2. Reduction of groundwater storage	c. Section 4.3 (p. 4-11) 1. Section 4.3.1.1 (p. 4-12) a. Section 4.3.1.1 (p. 4-12) b. Section 4.3.1.1 (p. 4-12) 2. Section 4.3.1.2 (p. 4-14) 3. N/A

APPENDIX F

INTERIM OPERATING AGREEMENT

Interim Operating Agreement for the Tulare Lake Subbasin to Develop and Implement a Groundwater Sustainability Plan

THIS INTERIM OPERATING AGREEMENT FOR THE TULARE LAKE SUBBASIN TO DEVELOP AND IMPLEMENT A GROUNDWATER SUSTAINABILITY PLAN (this “Agreement") is effective September 1, 2017, among the MID-KINGS RIVER GROUNDWATER SUSTAINABILITY AGENCY, SOUTH FORK KINGS GROUNDWATER SUSTAINABILITY AGENCY, EL RICO GROUNDWATER SUSTAINABILITY AGENCY, SOUTHWEST KINGS GROUNDWATER SUSTAINABILITY AGENCY, TRI-COUNTY WATER AUTHORITY, and ALPAUGH IRRIGATION DISTRICT. The signatories to this Agreement are hereinafter referred to collectively as the "Parties" or individually as "Party".

RECITALS

WHEREAS, the Parties are all located within the Tulare Lake Hydrologic Region, San Joaquin Valley Groundwater Basin, Tulare Lake Subbasin, a groundwater subbasin recognized by the California Department of Water Resources ("DWR") Bulletin 118 (2016) as Groundwater Basin No. 5-22.12 (hereinafter “Subbasin”) and a depiction of the Subbasin is attached hereto as Exhibit "A" and incorporated herein by this reference; and

WHEREAS, the State of California has classified the entire Subbasin as an Economically Distressed Area and each community within the Subbasin as a Disadvantaged Community; and

WHEREAS, all lands within the Subbasin are included within one of the six groundwater sustainability agencies (“GSAs”) that are the Parties to this Agreement, and each Party has been or are in the process of being determined an “exclusive” GSA by DWR; and

WHEREAS, the Sustainable Groundwater Management Act ("SGMA") requires the development and establishment of groundwater sustainability plans ("GSPs"), which are designed to ensure the sustainability of groundwater basins and subbasins; and

WHEREAS, DWR has identified the Subbasin as a critically overdrafted subbasin; and

WHEREAS, SGMA allows local agencies or a combination of local agencies overlying a groundwater basin to serve as a GSA to develop and implement a GSP over an entire basin, subbasin, or a portion of a basin; and

WHEREAS, pursuant to Water Code §10727, SGMA allows for the preparation of a GSP by three methods: (a) a single GSP covering the entire basin/subbasin developed and implemented by one GSA, (b) a single GSP covering the entire basin/subbasin developed and implemented by multiple GSAs, or (c) multiple GSPs implemented by two or more GSAs that are subject to a single Coordination Agreement that covers the entire basin/subbasin; and

WHEREAS, Water Code §10727.6 requires that if multiple GSPs will be implemented within a subbasin, then a Coordination Agreement must be prepared to ensure that the GSPs utilize the same data and methodologies within that subbasin for the following items: (a) groundwater elevation data, (b) groundwater extraction data, (c) surface water supply, (d) total water use, (e) change in groundwater storage, (f) water budget, and (g) sustainable yield; and

WHEREAS, the Parties acknowledge that multiple GSAs have been formed within the Subbasin and those GSAs currently seek to explore the possibility of developing and implementing a single GSP. The Parties also acknowledge the desire to have a single GSP may not be achievable, but regardless of whether one or more GSPs are developed for the Subbasin, an interim agreement is beneficial to the Parties in proceeding to initially develop and coordinate the data and methodologies required by SGMA for the Subbasin; and

WHEREAS, the Parties acknowledge that the GSAs need to do further data collection prior to making decisions with regard to GSP preparation and implementation, but the Parties agree that in the future a Coordination Agreement or an amendment to or replacement of this Agreement will be necessary based on the additional information obtained and decisions made by the Parties under this Agreement; and

WHEREAS, the purpose of this Agreement is to provide a framework among the Parties for a cooperative means of gathering the initial data and information for a single GSP, applying for grant funding, selecting consultants, and coordinating on other SGMA-related issues for the Subbasin.

NOW, THEREFORE, in consideration of the mutual promises, covenants, and conditions hereinafter set forth and the above Recitals, which are hereby incorporated herein by this reference, it is agreed by and among the Parties hereto as follows.

SECTION 1. DEFINITIONS

1.1 "Tulare Lake Subbasin" or "Subbasin" refers to that subbasin identified and described in California Department of Water Resources Groundwater Bulletin 118 as part of the Tulare Lake Hydrologic Region, San Joaquin Valley Groundwater Basin, Tulare Lake Subbasin, also identified as Groundwater Basin No. 5-22.12, and is depicted in Exhibit “A” of this Agreement.

1.2 "Groundwater Sustainability Agency" or "GSA" means one or more local agencies that implement the provisions of SGMA as defined by Water Code §10721(j).

1.3. "Groundwater Sustainability Plan" or "GSP" means a plan of one or more GSAs proposed or adopted under SGMA as defined in Water Code §10721(k).

1.4 "Coordination Agreement" shall be the agreement (whether one or more GSPs are developed within the Subbasin) to ensure coordination of the data and methodologies used by each GSA in developing the GSP(s) within the Subbasin for the following assumptions: (a) groundwater elevation data, (b) groundwater extraction data, (c) surface water supply, (d) total water use, (e) change in groundwater storage, (f) water budget, and (g) sustainable yield (Water Code §10721(d); 10727.6).

SECTION 2. PURPOSES AND GOALS

2.1 The Parties are entering into this Agreement to perform the following:

(a) Set forth their mutual intent to work towards the development of a single GSP for the Subbasin.

(b) Authorize research and collection of the data required for the GSP according to a mutually agreeable timeline.

(c) The Parties agree to utilize their best efforts in selecting and fully cooperating with the consultants gathering the information, preparing grant applications, and preparing the GSP.

(d) The Parties agree that after they gather data and determine an appropriate governance structure, they will either (1) amend or replace this Agreement to reflect specifics required to finalize a GSP or (2) if a single GSP is not to occur, prepare and enter into a Coordination Agreement setting forth appropriate assumptions based on information gathered and developed as a result of this Agreement.

SECTION 3. COST SHARING AND GOVERNANCE

3.1 The Parties agree that if grant funds are available for grant applications, efforts necessary to develop a GSP(s), facilitation and/or consultant costs, and similar efforts to develop a GSP(s) for the Subbasin, then the Parties have the authority to and shall act jointly in applying for and seeking to obtain such grant funds. Any grant funds received on behalf of the Subbasin and/or all of the Parties, shall first be applied to eligible costs incurred after July 1, 2017; should any funds then remain, the Parties may develop a method for reimbursing relevant costs incurred by the Parties prior to the effective date of this Agreement.

3.2 The Parties agree to the following formula, identified in the table below, for sharing costs to develop and implement the actions taken within the confines of this Agreement. As shown below, after combining the El Rico GSA and Alpaugh Irrigation District, one-half the costs shall be allocated one-fifth to each of the participants and one-half of the costs shall be allocated in proportion to the relative acreage of each Party. The overall proportionate cost of each Party is shown as the Total Cost Allocation in the table below.

GSA	Acres	Acreage Portion	Participant Portion	Total Cost Allocation
Mid-Kings River GSA	97,384.6	0.09084	0.1	0.19084
South Fork Kings GSA	71,310.9	0.06652	0.1	0.16652
El Rico GSA/Alpaugh ID	228,653.4	0.21328	0.1	0.31328
Southwest Kings GSA	90,037.1	0.08398	0.1	0.18398
Tri-County WA	48,656.5	0.04538	0.1	0.14538
Totals	536,042.5	0.50000	0.5	1.00000

3.3 All decisions related to implementing or amending this Agreement shall require a unanimous vote of the authorized representatives of each of the five (5) entities[1] identified in the table shown in Section 3.2 of this Agreement; a quorum is represented by any four (4) authorized representatives of these five (5) entities. Decisions may include, but are not limited to hiring experts or consultants to prepare and draft documents associated with this Agreement that would exceed $100,000, developing the Coordination Agreement (if necessary), applying for grant funding, and/or developing all or portions of a GSP(s).

SECTION 4. GENERAL PROVISIONS

4.1. Term. This Agreement shall become effective on the date first above written and shall remain in effect until superseded by amendment to this Agreement or another agreement among the Parties which shall address more specifics that are not available at this time for the final development and implementation of the GSP(s).

4.2 Withdrawal. Any Party shall have the right to withdraw from this Agreement by giving each of the other Parties written notice at least 30 days prior to its date of withdrawal ("Withdrawal Date"). The withdrawing Party shall be responsible for its share of any costs incurred under this Agreement up to its Withdrawal Date. Except as set forth in the preceding sentence, and except for the withdrawing Party's obligations under Section 5 hereof relating to confidential information, effective as of the Withdrawal Date, the withdrawing Party shall be

[1] For purposes of cost sharing and voting, the El Rico GSA and Alpaugh ID are to be considered as one entity; it shall be up to those two GSAs to determine their internal cost-sharing and voting process.

relieved and released of all obligations under this Agreement.

4.3 Construction of Terms. This Agreement is for the sole benefit of the Parties and shall not be construed as granting rights to or imposing obligations on any person other than the Parties.

4.4 Good Faith. Each Party shall use its best efforts and work in good faith for the completion of the purposes and goals of this Agreement and the satisfactory performance of its terms.

4.5 Rights of the Parties and Constituencies. This Agreement does not contemplate the Parties taking any action that would (a) adversely affect the rights of any of the Parties or (b) adversely affect the constituencies of any of the Parties.

4.6 Counterparts. This Agreement may be executed in counterparts and the signed counterparts shall constitute a single instrument. The signatories to this Agreement represent that they have the authority to sign this Agreement and to bind the Party for whom they are signing.

4.7 Governing Law. This Agreement and all documents provided for herein and the rights and obligations of the Parties hereto shall be governed in all respects, including validity, interpretation and effect, by the laws of the State of California (without giving effect to any choice of law principles).

4.8 Waiver. The failure of any Party to insist on strict compliance with any provision of this Agreement shall not be considered a waiver of any right to do so, whether for that breach or any subsequent breach. The acceptance by any Party of either performance or payment shall not be considered to be a waiver of any preceding breach of the Agreement by any other Party.

4.9 Recitals and Exhibits. The Recitals and Exhibits are incorporated into the Agreement.

SECTION 5. CONFIDENTIALITY PROVISIONS

5.1 Confidential Information. The confidential information to be disclosed under this Agreement ("Confidential Information") includes data, information, modeling, projections, estimates, plans, that are not public information and in which each Party has a reasonable expectation of confidentiality, regardless of whether such information is designated as Confidential Information at the time of its disclosure.

5.2 Duty to Protect. In addition to the above, Confidential Information shall also include, and the Parties shall have a duty to protect, other confidential and/or sensitive information which is (a) disclosed in writing and marked as confidential (or with other similar designation) at the time of disclosure; and/or (b) disclosed in any other manner

and identified as confidential at the time of disclosure or is summarized and designated as confidential in a written memorandum delivered within thirty (30) days of the disclosure.

5.3 Limited Use. The Parties shall use the Confidential Information only for the purposes set forth in this Agreement.

5.4 Limited Disclosure. The Parties shall limit disclosure of Confidential Information within its own organization to its directors, officers, partners, members and/or employees having a need to know and shall not disclose Confidential Information to any third party (whether an individual, corporation, or other entity) without prior written consent of all the Parties. The Parties shall satisfy their obligations under this paragraph if they take affirmative measures to ensure compliance with these confidentiality obligations through their employees, agents, consultants and others who are permitted access to or use of the Confidential Information.

5.5 Allowable Disclosure. This Agreement imposes no obligation upon the Parties with respect to any Confidential Information (a) that was possessed before receipt; (b) is or becomes a matter of public knowledge through no fault of receiving Party; (c) is rightfully received from a third party not owing a duty of confidentiality; (d) is disclosed without a duty of confidentiality to a third party by, or with the authorization of the disclosing Party; or (e) is independently developed.

IN WITNESS WHEREOF, the Parties hereto have executed this Agreement to be effective as of the date first above written.

Chapter Groundwater Sustainability Plan

Prepared for:

Prepared by:

December 2019

This page intentionally left blank.

Table of Contents

Executive Summary **ES-1**
Section 1.0 Agency Information, Plan Area, and Communication **1-1**
1.1 Compliance Information 1-1
1.2 Introduction and Agency Information 1-3
1.2.1 Relationship to the Umbrella GSP and Other Subbasin GSAs 1-3
1.2.2 WKWD Background 1-4
1.2.3 WKWD GSA Contact Information 1-5
1.2.4 Management Structure 1-5
1.2.5 Legal Authority 1-5
1.3 Plan Area 1-5
1.3.1 Plan Area Definition 1-6
1.3.2 Plan Area Setting 1-6
1.3.3 Existing Surface Water Monitoring Programs 1-35
1.3.4 Existing Groundwater Monitoring Programs 1-36
1.3.5 Existing Water Management Programs 1-38
1.3.6 Permitting New or Replacement Wells 1-44
1.3.7 Conjunctive Use Programs in the Subbasin 1-44
1.3.8 Plan Elements from California Water Code Section 10727.4 1-44
1.4 Outreach and Engagement 1-45
1.4.1 Decision Making process 1-45
1.4.2 Public Engagement, Stakeholder Involvement, and GSP Implementation Progress 1-45
1.5 References 1-46
Section 2.0 Basin Settings: Hydrogeologic Conceptual Model **2-1**
2.1 Compliance Information 2-1
2.2 Introduction 2-1
2.3 Hydrogeologic Conceptual Model Definition 2-2
2.4 Useful Terms 2-2
2.5 Regional Geologic and Structural Setting 2-3
2.5.1 Geologic History 2-4
2.5.2 Geologic Formations/Stratigraphy 2-5
2.6 Faults and Structural Features 2-13
2.6.1 Synclines and Anticlines 2-13
2.6.2 Major Faults 2-18
2.6.3 Bakersfield Arch 2-19
2.6.4 Outcrops of Bedrock Inside the GSA area 2-19
2.7 Basin Boundaries 2-19
2.7.1 Lateral Boundaries 2-19

2.7.2 Boundaries with Neighboring Subbasins 2-20
2.7.3 Bottom of the Subbasin in the GSA Area 2-20
2.8 Principal Aquifers and Aquitards 2-20
2.8.1 Aquifers 2-21
2.8.2 Aquitards 2-22
2.8.3 Aquifer Properties 2-22
2.9 Natural Water Quality Characterization 2-24
2.10 Topography, Surface Water and Recharge 2-25
2.10.1 Topography 2-25
2.10.2 Surface Water Bodies 2-25
2.10.3 Groundwater Discharge, and Areas of Recharge and Potential Recharge 2-29
2.10.4 Soils 2-29
2.11 Hydrogeologic Conceptual Model Data Gaps 2-29
2.12 References 2-35
Section 3.0 Basin Settings: Groundwater Conditions 3-1
3.1 Compliance Information 3-1
3.2 Introduction 3-1
3.3 Groundwater Trends 3-2
3.3.1 General Groundwater Elevation Hydrographs 3-2
3.3.2 Hydrographs 3-5
3.3.3 Vertical Gradients 3-11
3.3.4 Groundwater Elevation Contour Maps 3-11
3.4 Historical Change in Storage 3-12
3.5 Groundwater Quality 3-12
3.6 Land Subsidence 3-14
3.7 Interconnected Surface Water Systems 3-15
3.8 Groundwater Dependent Ecosystems 3-16
3.9 References 3-19
Section 4.0 Water Budget 4-1
4.1 WKWD and the Basinwide Coordinated Water Budget 4-1
4.2 Compliance Information 4-1
4.3 Introduction 4-2
4.4 Water Budget Information 4-3
4.5 Definitions and Assumptions 4-4
4.6 North and South Project Management Areas: Historical Water Budget Estimates 4-8
4.6.1 Land System Water Budget 4-8
4.6.2 Surface Water System Water Budget 4-8
4.6.3 Groundwater System Water Budget 4-9
4.6.4 North and South Management Areas: Water Budget Components 4-9

4.7 Western Management Area Water Budget....4-2
4.8 Lake Management Area Water Budget....4-2
4.9 Treated Produced Water....4-3
4.10 References....4-4
Section 5.0 Undesirable Results Statements....5-1
5.1 Compliance Information....5-1
5.2 Introduction....5-1
5.3 Sustainability Goal....5-2
5.4 Chronic Lowering of Groundwater Levels....5-3
5.4.1 Description of Undesirable Results....5-3
5.4.2 Identification of Undesirable Results....5-3
5.4.3 Potential Causes of Undesirable Results....5-3
5.4.4 Description of Potential Effects of Undesirable Results....5-3
5.5 Reduction of Groundwater Storage....5-3
5.5.1 Identification of Undesirable Results....5-4
5.5.2 Potential Causes of Undesirable Results....5-4
5.5.3 Description of Potential Effects of Undesirable Results....5-4
5.6 Seawater Intrusion....5-4
5.7 Degraded Water Quality....5-4
5.7.1 Description of Undesirable Results....5-4
5.7.2 Identification of Undesirable Results....5-4
5.7.3 Potential Causes of Undesirable Results....5-5
5.7.4 Description of Potential Effects of Undesirable Results....5-5
5.8 Land Subsidence....5-5
5.8.1 Description of Undesirable Results....5-5
5.8.2 Identification of Undesirable Results....5-5
5.8.3 Potential Causes of Undesirable Results....5-5
5.8.4 Description of Potential Effects of Undesirable Results....5-6
5.9 Depletions of Interconnected Surface Water....5-6
5.10 Evaluation of the Occurrence of Undesirable Results....5-6
Section 6.0 Monitoring Networks....6-1
6.1 Compliance Information....6-1
6.2 Introduction....6-3
6.3 Monitoring Network Objectives....6-3
6.4 Existing Monitoring Used....6-3
6.4.1 Groundwater Level Monitoring....6-3

ES-1 Executive Summary

ES-1.1 Compliance Information

The West Kern Water District (WKWD) Groundwater Sustainability Agency (GSA) has prepared this *Chapter Groundwater Sustainability Plan* (Chapter GSP) in compliance with the Sustainable Groundwater Management Act (SGMA) as specified in Part 2.74, Division 6 of the California Water Code, beginning with Section 10720. Table ES-1 summarizes the California Department of Water Resources' (DWR's) *Preparation Checklist for GSP Submittal* items that are covered in this Executive Summary. For the complete *Preparation Checklist for GSP Submittal*, see Appendix A.

Table ES-1. Applicable Preparation Checklist Items

GSP Regulation Section	Water Code Section	Description	GSP Section
Article 5. Plan Contents, Subarticle 1. Administrative Information			
Section 354.4	General Information	Executive Summary	Executive Summary

This Chapter GSP meets the requirements of DWR's emergency GSP regulations. The structure of this Chapter GSP also generally follows the order that the regulations provide, with some minor exceptions, to facilitate efficient review by DWR. Each section is written so that it can be reviewed without extensive cross-reference to other Chapter GSP sections.

ES-1.2 Introduction

In 2014, the California legislature enacted SGMA in response to continued overdraft of California's groundwater resources. The Kern County Groundwater Subbasin (Subbasin) is one of 21 basins and subbasins identified by DWR as being in a state of critical overdraft. SGMA requires preparation of a GSP to address measures necessary to attain sustainable conditions in the Subbasin. Within the framework of SGMA, sustainability is generally defined as the conditions that result in long-term reliability of groundwater supply, and the absence of undesirable results.

In 2016, in response to SGMA, the WKWD GSA was formed. The WKWD GSA was created on June 28, 2016 when WKWD's Board of Directors adopted Resolution 16.03, electing to become a GSA in the Subbasin and included the WKWD service area. During GSP development, the GSA boundary has expanded to include undistricted areas in and around the WKWD service boundary that were not previously part of another GSA. KCWA is one of several members of the Kern Groundwater Authority (KGA), a joint powers agency created to enhance coordination among agencies in the Subbasin.

The majority of KGA member agencies are in the KGA GSA's jurisdiction; four member agencies have formed their own GSAs, and are participating fully with the KGA's coordination, including the WKWD GSA, the Pioneer GSA, the Cawelo GSA and the Semitropic GSA.

Each KGA member agency has prepared a Chapter GSP that provides information, data, and descriptions of groundwater conditions on a localized scale. Each Chapter GSP supports the Umbrella GSP that is being developed by the KGA GSA. Chapter GSPs will supplement the Umbrella GSP where detailed local information is needed. In turn, the Umbrella GSP will supplement Chapter GSPs when a broader,

Subbasin-wide approach is more appropriate. The Umbrella GSP is also being coordinated with other GSPs under development by other GSAs that are not member agencies of the KGA GSA.

This Chapter GSP is now available for public review and comment. SGMA requires the WKWD GSA to develop a GSP that achieves groundwater sustainability in the Subbasin by 2040. Although SGMA references 2015 as a basis for groundwater planning, SGMA does not require a GSP to address undesirable results that occurred before 2015. This Chapter GSP outlines the current and historical sustainable management of groundwater in the WKWD GSA area through a balanced water budget and operation. Additionally, this Chapter GSP highlights the need for continued coordination within the KGA and neighboring regions, and for continued groundwater monitoring.

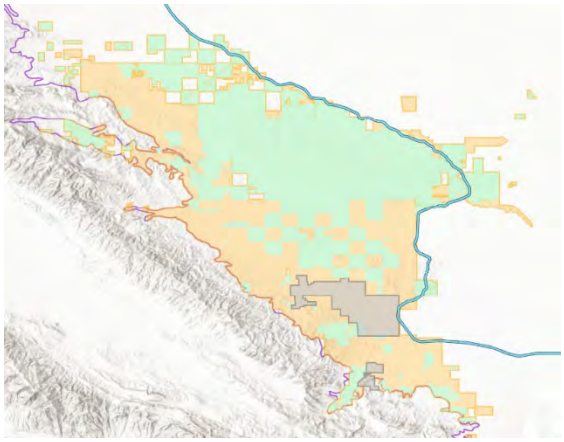

Figure ES-1. WKWD GSA Boundary

ES-1.3 Plan Area

The WKWD GSA jurisdictional area is defined by the WKWD service boundary with some addition proximal parcels owned and operated by oil production companies and other private landowners. The WKWD GSA boundary lies within the Kern County Subbasin, as shown in Figure ES-1.

ES-1.4 Subbasin Setting

The Subbasin is located toward the southern end of the San Joaquin Valley in Central California. The WKWD GSA is located along the western edge of the Subbasin, encompassing the cities of Taft and Maricopa. The GSA boundary is comprised of 299 square miles as shown in Figure ES-2. The WKWD GSA is bordered by the KGA GSA and Buena Vista Water Storage District GSA to the north, and the Henry Miller Water District GSA and the KGA GSA to the east.

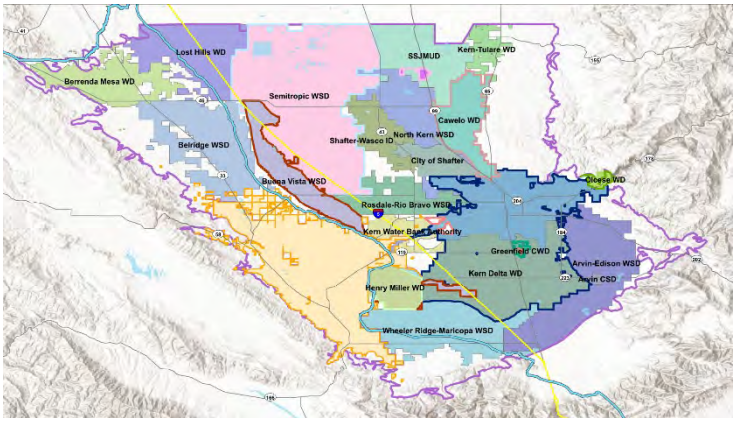

Figure ES-2. WKWD GSA Boundary

WKWD GSA formed four management areas, namely the North Project, South Project, Lake and Western management areas. Groundwater pumping in any large scale is undetectable via remote sensing, and the only pumping known in the area considered de minimis domestic use; in general, yields of water in this area are unsuitable for domestic or industrial use. As a result, no management or monitoring actions have been established in the Western Management Area. Management actions in this Chapter GSP focus on the North Project, South Project

and Lake management areas in the GSA, where groundwater pumping occurs above de minimis amounts and yields water that is acceptable for domestic and industrial use.

The hydrogeology in the WKWD GSA's area is well understood in the North, South, and Lake management areas. The North Management Area has two primary aquifers, above and below Corcoran or E clay. Corcoran or E clay is absent in both the South and Lake management areas. The unconfined aquifer extends to a depth of approximately 200 to 300 feet below the ground surface and consists of interbedded silts, sands, and some clay. Both the North and South wellfields are screened within the semi-confined to unconfined aquifer, with the South wellfield being exclusively within the unconfined to semi-confined aquifer. The confined aquifer system exists in the GSA's North Project Management Area and ranges from approximately 600 to 800 feet below the ground surface.

ES-1.5 Existing Groundwater Conditions

ES-1.5.1 Groundwater Levels

Groundwater levels in WKWD GSA's North and South Project management areas generally fluctuate with climactic cycles and reached a historical low in 2015 (ES-3). Groundwater levels in these management areas recovered significantly from 2015 to 2018. Change in storage has generally matched climactic trends as well, and subsidence has not occurred in the WKWD GSA area. Groundwater-dependent ecosystems are limited to the Western Management Area and are not present in the other management areas.

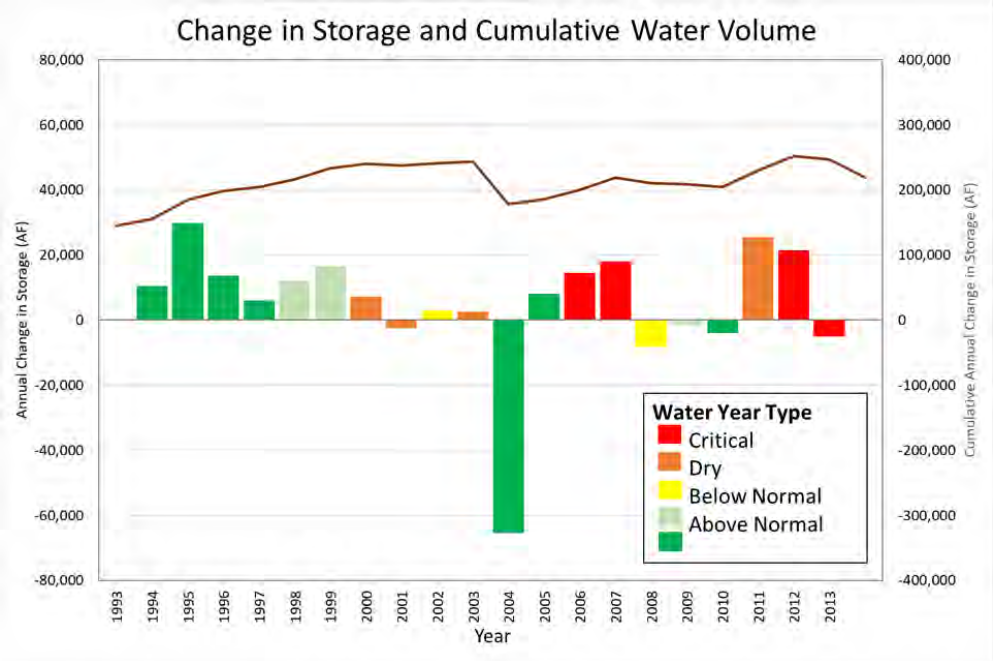

Figure ES-3. Change in storage by Year, Water Year Type, and Cumulative Water Volume

ES-1.5.2 Groundwater Quality

Overall, groundwater quality in the North and South Project management areas is excellent and meets all federal and state drinking water health standards. The only COCs detected during routine annual testing are arsenic and antimony. While both were detected at concentrations below their MCL for drinking water, WKWD took a proactive approach to manage any concerns; those actions are discussed below. Groundwater quality within the GSA area degrades toward the Western Management Area, where groundwater is generally unusable due to high salinity levels.

ES-1.6 Subsidence

Although groundwater pumping has caused land subsidence elsewhere in the southern San Joaquin Valley, data indicate that the Kern Fan aquifer behaves elastically in response to groundwater banking operations.

ES-1.7 Undesirable Results

Undesirable results are conditions that cause significant and unreasonable reduction in the long-term viability of domestic, agricultural, municipal, or environmental uses of the Subbasin's groundwater. SGMA identifies six defined areas for classification of undesirable results, as shown in the adjacent callout. The one undesirable result that does not impact the Subbasin is seawater intrusion.

Undesirable Results Categories

- Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply if continued over the planning and implementation horizon
- Significant and unreasonable reduction of groundwater storage
- Significant and unreasonable seawater intrusion (does not apply in the Subbasin)
- Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies
- Significant and unreasonable land subsidence that substantially interferes with surface land uses
- Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water

Due to the WKWDs sustainable banking practices, overall groundwater levels and storage do not trigger undesirable results conditions. As shown in Figure ES-3 and additional recent data, cumulative water storage in the WKWD GSA Area has experienced a net increase over the last 20 years with approximately 10 years of drought reserve stored currently. Through this sustainable management, degradation of groundwater quality and land subsidence have not adversely impacted the WKWD GSA.

ES-1.8 Sustainability

SGMA introduces several terms to measure sustainability, including the following:

- **Sustainability Goals** – These goals are the culmination of conditions resulting in an absence of undesirable results within 20 years.
- **Undesirable Results** – Undesirable results are the significant and unreasonable occurrence of conditions that adversely affect groundwater use in the Subbasin.
- **Sustainability Indicators** – Sustainability indicators refer to any of the adverse effects caused by groundwater conditions occurring throughout the Subbasin that, when significant and unreasonable, cause undesirable results, including the following:
  - Lowering groundwater levels
  - Reduction of groundwater storage
  - Seawater intrusion (does not apply in the Subbasin)
  - Degraded water quality
  - Land subsidence
  - Depletion of interconnected surface water
- **Minimum Thresholds** – Minimum thresholds are a numeric value for each sustainability indicator and are used to define when undesirable results occur, including if minimum thresholds are exceeded in a percentage of sites in the Subbasin's monitoring network.
- **Measurable Objectives** – Measurable objectives are a specific set of quantifiable goals for the maintenance or improvement of groundwater conditions. They will be included in the adopted Chapter GSP and will help the WKWD GSA achieve their sustainability goal.

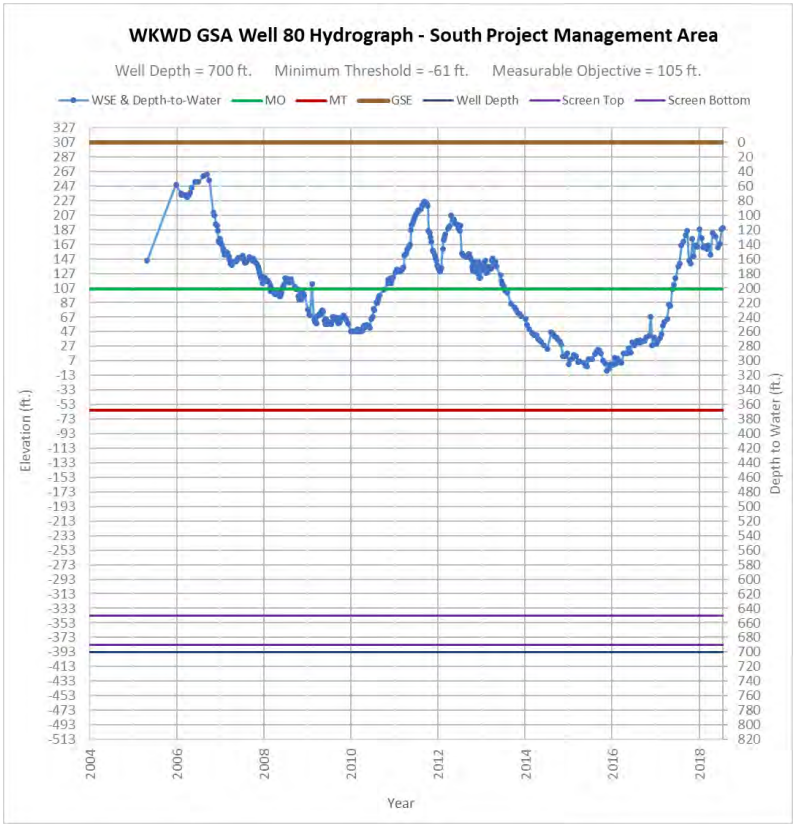

Figure ES-4. Sample Relationship Between Minimum Threshold and Measurable Objective

The method prescribed by SGMA to measure undesirable results involves setting minimum

thresholds and measurable objectives for a series of representative wells. Because of the similar groundwater conditions in both the North Project and South Project management areas, the strategies used to apply minimum thresholds and measurable objectives was consistent across both and were applied to all representative wells.

Minimum thresholds and measurable objectives were set to allow for an appropriate margin of operation flexibility to allow for normal operations and transfers of water as regularly conducted and sustainable operation by WKWD. Through coordination efforts, neighboring GSAs' minimum thresholds and measurable objectives were also taken into

consideration. Figure ES-4 shows an example of a monitoring well hydrograph with the minimum threshold and measurable objective.

ES-1.9 Water Budgets

Water budgets for the Subbasin were developed considering historical, current and projected conditions, and were developed at the Subbasin scale. This Subbasin water budget prepared for this Chapter GSP will also be provided as part of the Umbrella GSP, where each participating GSA has contributed data relevant to their respective areas.

ES-1.10 Monitoring Networks

This Chapter GSP describes the monitoring networks for the four sustainability indicators that apply in the Subbasin. The objective of these monitoring networks is to monitor conditions across the Subbasin and detect trends toward undesirable results. Specifically, the monitoring network was developed to do the following:

- Monitor impacts to the beneficial uses or users of groundwater
- Monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds
- Demonstrate progress toward achieving measurable objectives described in this Chapter GSP

The monitoring networks were designed by evaluating data sources provided by DWR, including information from the California Statewide Groundwater Elevation Monitoring (CASGEM) Program, the U.S. Geological Survey, participating agencies. The monitoring network consists of wells that are already being used for monitoring in in the WKWD GSA Area. Historically, both DWR and USGS have monitored wells in the Pioneer GSA, but their monitoring efforts have been discontinued. All monitoring is currently conducted by the WKWD.

ES-1.11 Data Management System

The WKWD GSA's Data Management System incorporates current and historical data from all available sources including WKWD, DWR, the CASGEM Program, USGS, and other local sources.

ES-1.12 Projects and Management Actions

Maintaining sustainability in the WKWD GSA and contributing to sustainability efforts in the larger Subbasin requires implementation of management actions and, if demonstrated to be feasible, projects that will increase water supply. These include:

- Automatic meter reading project
- Participation in Delta Conveyance Facility
- Buena Vista Aquatic Recreation Area water supply management coordination
- Continued balanced pumping and recharge
- Implementation of the water shortage response plan
- Continued participation in Subbasin-wide coordination

Adaptive management strategies include the following:

- Taft recycled water program
- Shifting balance of pumping between the North and South wellfields
- Implementing permanent demand management measures if necessary

ES-1.13 GSP Implementation

Plan implementation is the execution of activities described in this Chapter GSP for sustainable operation of the GSA area of the Subbasin. Some of these activities include the following:

- Continued groundwater level monitoring
- Coordinating among GSAs in the Subbasin
- Installing additional monitoring equipment
- Updating the GSP

ES-1.14 Funding

WKWD GSA operations and implementation would incur costs and would be funded by the GSA. Four primary activities that would incur costs are as follows:

- Implementing the GSP
- Implementing GSP-related projects and management actions
- Developing annual reports
- Developing five-year evaluation reports

- These activities would be funded by WKWD normal operations and would be carried out by WKWD staff. Additional funding sources such as grants and water market trading may also help fund activities in the future.

Section 1.0 Agency Information, Plan Area, and Communication

Table 1-1 summarizes the California Department of Water Resources' (DWR's) *Preparation Checklist for GSP Submittal* items that are covered in this section. For the complete *Preparation Checklist for GSP Submittal*, see Appendix A.

1.2 Introduction and Agency Information

This section describes the West Kern Water District (WKWD) Groundwater Sustainability Agency (GSA), its authority in relation to the Sustainable Groundwater Management Act (SGMA), its relationship to other GSAs within the Kern County Subbasin (Subbasin), and the purpose of this *Groundwater Sustainability Plan* (GSP).

This Chapter GSP meets regulatory requirements established by the California Department of Water Resources (DWR) as shown by the completed *Preparation Checklist for GSP Submittal* (Appendix A). Additionally, this Chapter GSP shows that the WKWD GSA area is managed sustainably, imports more water into the Subbasin than is consumptively used by the GSA area, is adequately monitored to enable sustainable management in the future, and is coordinated with other GSAs and GSPs in the Subbasin.

On June 28, 2016, WKWD held a public hearing to consider the decision to serve as a GSA within the Subbasin. Following the hearing, WKWD's Board of Directors adopted Resolution No. 16.03, electing to become a GSA to the extent of its service boundaries. During the GSP development processes, the GSA boundary was expanded to include areas in and around the WKWD service boundary that were not previously part of any other GSA. Neighboring agencies and GSAs were consulted throughout GSP development, and these additional parcels were incorporated to provide greater coverage of the Subbasin.

In late 2019, the WKWD GSA discovered groundwater use in the Little Santa Maria Valley (LSMV), and coordinated with local landowners to add LSMV as a Management Area to the WKWD GSA area. Appendix H contains the SGMA-required information for inclusion in this Chapter GSP. During the five-year update to the GSP, the LSMV Management Area will be fully integrated into the GSA and Chapter GSP/

1.2.1 Relationship to the Umbrella GSP and Other Subbasin GSAs

The Subbasin is the southern portion of the San Joaquin Valley Groundwater Basin. Several GSAs have been formed in the Subbasin as follows:

- Buena Vista Water Storage District GSA
- Cawelo GSA
- Kern Groundwater Authority (KGA) GSA
- Greenfield County Water District GSA
- Henry Miller Water District GSA
- Kern River GSA
- Pioneer GSA
- Semitropic Water Storage District GSA
- WKWD GSA

The KGA GSA is a joint powers agency created to enhance coordination among water-related agencies in the Subbasin. Member agencies of the KGA are listed below.

- Arvin Community Services District
- Arvin Edison Water Storage District
- Cawelo Water District
- City of Shafter
- Kern County Water Agency
- Kern-Tulare Water District
- North Kern Water Storage District
- Rosedale-Rio Bravo Water Storage District
- Semitropic Water Storage District
- Shafter Wasco Irrigation District
- South San Joaquin Municipal Utilities District
- Tejon-Castaic Water District
- West Kern Water District
- Westside Water District Authority
- Wheeler Ridge-Maricopa Water Storage District

The majority of KGA's member agencies are covered under the KGA GSA's jurisdiction. However, the WKWD GSA, Pioneer GSA, Cawelo GSA, and Semitropic GSA have become their own GSAs, and are participating fully with the KGA GSA as it develops the Umbrella GSP for the Subbasin. The Umbrella GSP encompasses areas in the KGA and is being coordinated with other GSPs under development in the Subbasin. As a single document, the Umbrella GSP also complies with California Water Code (CWC) under SGMA regulations.

As the Umbrella GSP is being developed, each member agency of the KGA is preparing a Chapter GSP that provides information, data, and descriptions on a localized scale. Data from these Chapter GSP will be integrated into the Umbrella GSPs, and the Chapter GSPs will then be attached to the Umbrella GSP. Chapter GSPs supplement the Umbrella GSP where detailed information is needed, while the Umbrella GSP supplements Chapter GSPs when a broader, Subbasin-wide approach is more appropriate.

Development of the Umbrella GSP is also being coordinated with other GSAs in the Subbasin who are not members of the KGA. These non-member groups are also developing their own GSPs.

1.2.2 WKWD Background

WKWD is an industrial and municipal water provider in the southern San Joaquin Valley in western Kern County and encompasses the cities of Taft and Maricopa. WKWD's mission is "to provide its customers a reliable supply of excellent quality water in a planned, efficient, cost effective and environmentally

responsible manner, while promoting public awareness of water issues." (WKWD, 2014). WKWD was formed by election in 1959 and encompasses a roughly 300 square miles area with approximately 7,600 metered accounts. WKWD does not supply water for agricultural uses and imports water which it uses to recharge groundwater in the areas of its wellfields.

1.2.3 WKWD GSA Contact Information

WKWD GSA contact information is shown below:

- WKWD General Manager/GSA Director: Greg Hammett
- Phone Number: 661-763-3151
- Email: ghammett@wkwd.org
- Mailing Address: P.O. Box 105 800 Kern Street, Taft, CA. 93268
- Website: http://www.wkwd.org/

1.2.4 Management Structure

WKWD is governed by a five-member Board of Directors that meets monthly. The General Manager manages day-to-day operations of WKWD, with support provided by the administration, finance, and operations departments. The operations department includes four groups; engineering, field services, production, and transmission and distribution.

1.2.5 Legal Authority

Per CWC Section 10723.8(a), WKWD gave notice of its decision to form a GSA in the Subbasin (Basin 5-22.14 per DWR's Bulletin 118) (DWR, 2003). This notice is in Appendix B.

1.3 Plan Area

This section describes the WKWD GSA area, including the following:

- Major streams
- Institutional entities
- Agricultural and urban land uses
- Locations of groundwater wells and state lands
- Geographic boundaries of surface water runoff areas

This section also describes existing surface water and groundwater monitoring programs, and water management plans in the GSA area. Information in this section was gathered from publicly available sources and may not reflect all information that will be used for Chapter GSP technical analysis.

1.3.1 Plan Area Definition

The WKWD GSA was formed on June 28, 2016 by adoption of Resolution 16-03 by WKWD's Board of Directors (DWR, 2018e). The GSA area includes the WKWD boundary and adjacent oilfield properties owned by corporate and independent operators that have requested coverage under the WKWD GSA, as well as State land and privately owned parcels. The GSA area covers roughly 287 square miles of the Subbasin's southwestern region (Figure 1-1).

The GSA area includes four management areas as follows (Figure 1-2):

- Lake Management Area
- North Project Management Area
- South Project Management Area
- Western Management Area

Due to the lack of groundwater use in the Western Management Area, the Chapter GSP and monitoring networks focus primarily on the North Project, South Project, and Lake management areas.

1.3.2 Plan Area Setting

The Subbasin encompasses roughly 3,040 square miles of the southernmost San Joaquin Valley Groundwater Basin portion of the Tulare Lake Hydrologic Region. The San Joaquin Valley Groundwater Basin is a structural trough up to 200 miles long and 70 miles wide that represents the southern portion of the Great Central Valley of California (DWR, 2006).

The Subbasin is bounded by the Sierra Nevada foothills on the east, the Tehachapi and San Emigdio Mountains and White Wolf Subbasin on the south, the Temblor Range on the west, and portions of the KGA jurisdictional boundary to the north. The Kettleman Plain, Tulare Lake and Tule subbasins border the KGA jurisdictional line to the north. The GSA area overlies the southwestern portion of the Subbasin, along the western edge of Kern County, roughly 30 miles west of metropolitan Bakersfield and 100 miles north of Los Angeles. The incorporated cities of Maricopa and Taft and the communities of Fellows, Derby Acres, and McKittrick are located along the western edge of the GSA area along California State Route (Route) 33. The communities of Ford City, South Taft, Valley Acres, and Dustin Acres are in the northeast to southcentral portion of the GSA along Route 119. The community of Tupman is located on the northeast border of the GSA area adjacent to the California Aqueduct. Figure 1-3 shows key geographic features in the GSA area.

This page intentionally left blank.

As described in Section 1.2.1, 11 GSAs have been formed to manage groundwater sustainability in the Subbasin (Figure 1-4). In Figure 1-4, white areas indicate areas the KGA GSA was originally responsible for that were originally under Kern County jurisdiction. However, Kern County has withdrawn from the KGA GSA, leaving these areas unmanaged. Some of the white areas have been incorporated into the GSAs, but other white areas remain unmanaged.

Figure 1-4 shows the WKWD GSA and neighboring GSAs. Table 1-1 lists the Subbasin GSAs. As mentioned above, Kern County has withdrawn from the KGA; no agency with authority over white areas in the figure are identified at this time.

Table 1-2. Subbasin GSAs

GSA Name	Member Agencies
Buena Vista Water Storage District (BVWSD)	BVWSD
Cawelo Water District (WD)	Cawelo WD
City of McFarland	City of McFarland
Greenfield County WD	Greenfield County WD
Henry Miller WD	Henry Miller WD
Kern Groundwater Authority	Arvin Community Services District (CSD), Arvin-Edison Water Storage District (WSD), City of Shafter, Kern County, Kern-Tulare WD, Kern Water Bank Authority (KWBA), North Kern WSD, Rosedale-Rio Bravo WSD, Shafter Wasco Irrigation District (ID), Southern San Joaquin Municipal Utility District, Tejon-Castaic WD, Westside District Water Authority, Wheeler Ridge-Maricopa WSD
Kern River	Kern County Water Agency Improvement District 4, Kern Delta WD, City of Bakersfield, East Niles CSD, Oildale Mutual Water Company
Olcese WD	Olcese WD
Pioneer	Kern County Water Authority (KCWA)
Semitropic WSD	Semitropic WSD
West Kern WD	WKWD

The southern portion of the San Joaquin Valley in the Tulare Lake Hydrologic Region is divided into seven subbasins (Figure 1-5). Portions of the White Wolf Subbasin are separated into the South Lahontan Hydrologic Region by the White Wolf fault. The San Andreas, Poso Creek, and White Wolf faults are active faults bordering the Subbasin (DWR, 2006) (Figure 1-6).

Kern County has the largest jurisdiction in the Subbasin, covering approximately 286.5 square miles, or 99.8 percent of the GSA area (Figure 1-7). The remaining 0.5 square miles along the midwestern edge fall under San Luis Obispo County jurisdiction. Because the primary GSP focus areas (i.e., North Project, South Project, and Lake management areas) are within Kern County, and the small portion of San Luis Obispo County has no land use or water use systems, San Luis Obispo County elected to not participate in the Chapter GSP development process.

Most lands within the WKWD GSA area are covered by native grasses and vegetation. Although not shown in Figure 1-8, oil production is the majority of developed land use and thus does not utilize onsite groundwater pumping. Roughly 80 percent of WKWD's water supply is delivered to industrial companies, primarily for oil development and power plants. Domestic water sales account for the remaining 20 percent of WKWD's annual sales, and is split between residential and commercial customers (WKWD, 2016). There is a small field of alfalfa adjacent to Taft that is irrigated exclusively with treated effluent from the local wastewater treatment plant.

This page intentionally left blank.

Information about domestic, production, and municipal wells identified in the GSA area was downloaded from DWR's *Well Completion Report Map Application*. CWC Section 13752 allows for the release of copies of well completion reports; this application allows government agencies and the public to review these data as well density information per the Public Land Survey System (PLSS) section (DWR, 2019).

Figure 1-9 through Figure 1-11 show the total number of domestic, production, and public wells in each square mile of the WKWD GSA area contained in DWR's well completion database. DWR's well designations are based on information contained in well completion reports and have not been modified for this Chapter GSP section. In February 2018, wells in the GSA area were identified using aerial imagery to establish whether active groundwater pumping was occurring. A small number of homes and a golf course were identified in the database as using wells for irrigation; however, WKWD provides water service to these areas, and they do not rely on a local groundwater well.

Figure 1-12 shows an example assessment for PLSS Section M30S24E20. The aerial imagery shows no evidence of groundwater production from any of the wells identified in the DWR database.

WKWD's *Kern County Groundwater Subbasin Boundary Modification Request Technical Report* states there is a low density of wells west of the California Aqueduct (WKWD, 2018). Table 1-3 lists the wells identified from DWR's well completion database and the PLSS sections examined to validate groundwater production. Since large production wells were not identified during the assessment, WKWD has determined that there is not significant groundwater use in the area. WKWD will re-evaluate wells in the western area as part of its 5-year GSP update, and determine if use has increased or management is required to maintain sustainability. The analysis appears to agree with the findings in the Subbasin Modification report, that there are very few wells in the Western Management Area. Figures 1-13 through 1-15 describe the remaining wells that are above de minimis use.

Figure 1-13 shows the approximate number and average depth of verified domestic wells in the GSA area. There are approximately 11 wells in the GSA area with well completion depth ranging from 300 feet in the Lake Management Area to 1,000 feet in the North Project Management Area.

Figure 1-14 shows the approximate number and average depth of verified production wells in the GSA area. There are approximately 27 wells in the GSA area with well completion depth ranging from 310 feet in the South Project Management Area to 1,140 feet in the Lake Management Area.

Figure 1-15 shows the approximate number and average depth of verified public wells in the GSA area. There are approximately five wells in the GSA area with well completion depth ranging from 560 to 818 feet in the South Project Management Area.

The Bureau of Land Management manages most of the protected lands within the GSA area primarily along the boundary and central portion of the Western Management Area. The California Department of Fish and Wildlife (CDFW) also manages lands within the Western Management Area including the Carrizo Plain National Monument. The U.S. Fish and Wildlife Service (USFWS) Wildlands Conservancy's Wind Wolves Preserve is adjacent to the southeastern boundary of the GSA area. Figure 1-16 shows the public lands in and around the GSA area.

The GSA area is split between the Middle Kern-Upper Tehachapi-Grapevine and Tulare Lake Bed Regional Watersheds. All streams in the GSA area are ephemeral and only flow during heavy precipitation events, with most flow originating outside the GSA area. Ephemeral surface water flow into the GSA area is not actively captured or banked, but rather infiltrates or flows out of the GSA area. Figure 1-17 shows the regional watersheds overlying and around the GSA area.

This page intentionally left blank.

Numbers in the township and range grid correspond to the average depth of the wells within that grid.
Grids with no number have no associated well depth data.
Average well depth is given in feet below the ground surface.

1.3.3 Existing Surface Water Monitoring Programs

Because of the regional arid climate, there are no surface water bodies in the GSA area. Ephemeral streams do exist; however, flows are rare and only occur during large storm events. Surface water used in the GSA area is imported via the California Aqueduct as part of the State Water Project (SWP), or from rare high flow events on the Kern River (WKWD, 2016). Except for direct industrial water deliveries from the California Aqueduct to the La Paloma Power Facility, surface water imported by WKWD is recharged and later recovered to meet in-district demands (See Section 1.3.7). Historical and current surface water monitoring in the GSA area is described below.

Natural Water Courses

United States Geological Survey (USGS) National Water Information System (NWIS). While no active monitoring of natural water courses is currently performed in the GSA area, the USGS did monitor flows in several ephemeral streams from 1959 to 1969. Metadata for those monitoring sites are summarized in Table 1-4. These gages are maintained by the USGS and data were reported to the NWIS database (USGS, 2019).

Table 1-4. Surface Flow Gages in the GSA area

Reporting Agency	Gage Number	Location	Status	Years of Record
USGS	11195150	Bitterwater Creek Near Maricopa CA	Inactive	1962-1969
USGS	11195000	Oil Creek Near Taft CA	Inactive	1959-1969
USGS	11194800	Shale Creak Near Fellows CA	Inactive	1959-1973
USGS	11194500	Sand Creek Near McKittrick CA	Inactive	1959-1968

Source: (USGS, 2019)

Surface Water Conveyance

- **Kern Water Bank Canal**. SWP and other surface water supplies can be delivered to WKWD recharge ponds through the Kern Water Bank Canal. Water delivered to WKWD from the Kern Water Bank Canal is measured by the Kern County Water Agency (KCWA) and BVWSD through a rated gate structure or a rated weir structure called “Second Measurement Point on the Kern River” (Second Measurement Point). Second Measurement Point was established by the Miller-Haggin Agreement of 1888 to measure and apportion river flows and document water deliveries to downstream rights holders.
- **Cross Valley Canal.** SWP and other surface water supplies can be delivered to the South Management Area using WKWD’s capacity rights in the Cross Valley Canal. The Cross Valley Canal is operated by the KCWA and deliveries from the Cross Valley Canal to WKWD are fully metered.
- **Eastside Canal.** SWP and other surface water supplies can be delivered to the North Project Management Area from the Eastside Canal. The Eastside Canal is owned and operated by BVWSD. Deliveries to the North Management Area from the Eastside Canal are fully metered.

- **California Aqueduct.** DWR and downstream SWP contractors maintain groundwater pump-in guidelines to protect water quality downstream of banking programs in the California Aqueduct. These guidelines are meant to reduce the need for additional treatment by downstream users (State of California, 2016). The pump-in guidelines were developed based upon existing or background water quality in the California Aqueduct and taking into consideration current state and federal drinking water standards. One pump-in monitoring site is in the GSA area near Cole's Levee at milepost 241.02, and is sampled annually between November to December.

1.3.4 Existing Groundwater Monitoring Programs

Existing groundwater monitoring in the GSA area is performed by various local, state and federal agencies. Groundwater monitoring in areas adjacent to the WKWD GSA is primarily the responsibility of the Kern Water Bank Authority (KWBA). Existing monitoring programs in the GSA area collect data related to groundwater elevation (GWE), groundwater quality, and subsidence on a routine basis. These monitoring programs are summarized below.

GWE Monitoring Programs

Through various state, regional, and local monitoring programs, groundwater levels throughout the GSA area are typically measured in spring and fall, as well as at regular intervals during periods of groundwater recovery (State of California, 2016).

- **DWR Water Data Library (WDL)**. DWR's WDL contains information about GWE measurements from 52 wells in the GSA area that have reported periodically from 1930 through 2018. KCWA, DWR, Wheeler Ridge-Maricopa WSD, Kern County Land Company, and Tenneco-West reported data to the WDL during this time period (DWR, 2018d).
- **USGS NWIS**. The USGS's NWIS contains extensive water data, including manual measurements of depth to water in wells throughout California. In the GSA area there is one active groundwater monitoring well reporting data from 2018. There are 38 inactive wells; of those inactive wells, 19 of the 38 reported data from 1953 through 1961 (USGS, 2018b).
- **DWR California Statewide Groundwater Elevation Monitoring (CASGEM) Program**. The CASGEM Program collects monitoring data about seasonal and long-term GWE trends in collaboration with local monitoring entities. WKWD participates in the Kern River Fan Group of the CASGEM Program. The Kern River Fan Group provides groundwater level data to the state for the Kern Fan region. There are 28 CASGEM Program wells and 24 additional voluntary wells in the GSA area; these wells have reported data from 1930 to 2018 (DWR, 2018a).
- **Kern Fan Monitoring Committee Groundwater Level Monitoring**. Through a Memorandum of Understanding (MOU), local adjoining entities formed the Kern Fan Monitoring Committee (KFMC) to monitor and manage groundwater operations on the Kern Fan. Seven WKWD wells are included in the KFMC monitoring network. Water level measurements are collected at least twice a year during spring and fall, with measurements taken more frequently during periods of groundwater recovery. Additionally, WKWD monitors its wells continuously using data loggers. Well data for the KFMC monitoring project are provided to both the DWR and KCWA groundwater-level databases (State of California, 2016).

Groundwater Quality Monitoring Programs

Groundwater quality in the vicinity of the WKWD wellfields is excellent (WKWD, 2016). WKWD regularly monitors groundwater conditions using dedicated monitoring wells, and water quality is tested in accordance with protocols developed by the California Department of Public Health (CDPH) for drinking water. WKWD water met all United States Environmental Protection Agency (EPA) and State drinking water health standards in 2018 (WKWD, 2018).

- **DWR WDL**. DWR's WDL contains groundwater quality data from 1909 through 1983 for 67 wells in the GSA area (DWR, 2018d). Most wells are not regularly sampled, and many have only one or two recorded sampling events with large time periods in between. Constituents most frequently reported include dissolved chloride, sodium, calcium, boron, magnesium, and sulfate. Field measurements taken include conductance, pH, total alkalinity, and hardness.
- **GeoTracker Groundwater Ambient Monitoring and Assessment (GAMA) Program**. Established in 2000, the GAMA Program collects groundwater quality monitoring data throughout California. The GAMA Program's goal is to create a comprehensive groundwater monitoring program throughout California and increase public availability and access to groundwater quality and contamination information (State Water Resources Control Board [SWRCB], 2018).
- **USGS NWIS**. The USGS' NWIS is a collection of groundwater monitoring data including chemical, physical, and biological properties in water supply wells. This system covers the GSA area, and data are uploaded on a quarterly basis to GeoTracker, a data management system operated by the California State Water Resource Control Board. In the GSA area there is one active groundwater monitoring well with historical water quality data from 1957 and there are data available for 11 of 38 inactive wells from 1954 through 2015 (USGS, 2018b).
- **KWBA**. KWBA conducts extensive monitoring to establish baseline groundwater quality and ensure constituents of concern (COCs) do not degrade water quality. This monitoring consists of two elements: regular sampling of 57 dedicated monitoring wells for potential constituents of concern, and sampling of all recovery wells. Monitoring wells are sampled according to a protocol developed by the KFMC. Recovery wells are sampled according to a monitoring schedule developed by the CDPH. Results are provided to DWR and are used to establish non-project water delivery criteria for the California Aqueduct (KWBA, 2018).
- **KCWA Groundwater Quality Monitoring Database**. Well networks in the Subbasin primarily consist of production and dedicated monitoring wells. Most production wells are sampled once or twice a year for COCs as required by Title 22 of the California Code of Regulations, and in accordance with protocols developed by CDPH for testing public drinking water supplies. Monitoring wells are typically sampled more frequently for general water quality parameters and sampled annually for Title 22 COCs. The KCWA database includes data collected from 1,953 wells (monitoring and production), many of which are sampled as part of the Kern Water Bank Groundwater Monitoring Program and for Kern Fan Water Banking Program monitoring.

- **California Department of Pesticide Regulation (CDPR) Data.** CDPR's well inventory dataset is used to monitor pesticides and compile sample data as part of its Groundwater Protection Program. The goal of this program is to improve understanding of the environmental impact and behavior of pesticides and develop pesticide-use practices that reduce threats to groundwater. There are seven wells in the GSA area with data reported by the CDPR from 1985 through 2016 (CDPR, 2018).

Subsidence Monitoring Programs

In the GSA area, subsidence monitoring is performed using continuous global positioning system (GPS) stations maintained by the University NAVSTAR Consortium's (UNAVCO) Plate Boundary Observatory (PBO) program. The National Aeronautics and Space Administration (NASA) Jet Propulsion Laboratory (JPL) also provides interferometric synthetic aperture radar (InSAR) data for the Kern County region. There are no known extensometers in the GSA area.

- **UNAVCO PBO.** The UNAVCO PBO network consists of nearly 1,100 continuous GPS and meteorology stations in the western United States that monitor subsidence. There is one monitoring station in the vicinity of the GSA area east of the city of Taft that has reported ground elevation data from 2000 through 2018 (UNAVCO, 2019).
- **NASA JPL InSAR.** This dataset represents measurements of vertical ground displacement rates derived from InSAR data that are collected by the European Space Agency (ESA) Sentinel-1A satellite and that are processed by the NASA JPL, under contract with DWR. The data covers March 2015 through September 2016 (California Natural Resources Agency, 2018).

1.3.5 Existing Water Management Programs

KFMC Operations and Monitoring Program

The KFMC was established through an MOU among Kern Fan entities. Participants include KWBA participants and adjoining entities (i.e., those entities whose lands and/or banking projects are adjacent to the KWB). As part of the MOU, the KFMC operations and monitoring program was established to measure recharge, recovery, and water levels in wells, collect samples of surface water to be recharged, and collect groundwater quality samples. The KFMC monitors operations and groundwater account balances of projects on the Kern Fan and assesses project impacts. It also monitors the activities of surrounding groundwater districts (KFMC, 2012). WKWD GSA's North, South and Lake management areas are included in the KFMC's routine monitoring and reporting.

KFMC Operations and Monitoring Program's Influence on Water Demand and Chapter GSP Goals

KFMC's purpose is to monitor groundwater banking program management activities on the Kern Fan and monitor those of adjoining entities to ensure long-term sustainability of local groundwater resources. Sustainability is achieved through a collaborative effort across the Kern Fan Subregion to maintain GWEs and water quality that benefit the area. WKWD has a surplus of banked groundwater in excess of 200,000 acre-feet (AF) with an average annual demand of about 20,000 AF per year (AFY). WKWD will continue to bank water excess to maintain this operational buffer and provide sustainability well into the future. WKWD will continue to participate in the KFMC, and the wells monitored by the KFMC will be

incorporated into the broader GSP monitoring network. Data from this program will also be incorporated into the Umbrella GSP.

GSP's Influence on KFMC's Monitoring Program

Successful implementation of this Chapter GSP will help ensure that WKWD continues to manage groundwater sustainably. By continuing to participate in the KFMC monitoring program, WKWD will receive groundwater level data routinely that are related to its recharge and recovery activities. Implementation of this Chapter GSP will also establish a more robust and extensive groundwater-level monitoring network for WKWD, increasing the amount of data available.

WKWD Groundwater Management Plan

On November 29, 1995, WKWD's Board of Directors authorized preparation of a *Groundwater Management Plan* (GMP) and adopted the final plan in February 1997 (WKWD, 2016). The GMP's objectives were to protect the quality of WKWD's groundwater supply, promote and improve existing monitoring activities, and enable WKWD to identify and implement necessary means to preserve and enhance their groundwater resources.

WKWD currently monitors water levels in all wells and measures the total production at each production well on a monthly basis. Water levels from wells in the vicinity of WKWD's wellfield are monitored in a joint effort with the KCWA.

Water quality samples at these wells are collected as required by federal and state drinking water standards. General mineral, general physical, inorganic chemical, volatile organic, and synthetic organic chemical analyses are conducted once every three years. Radiological testing is conducted at each well once every four years for four consecutive quarters. Raw water well samples are also collected on a monthly basis from each operating well for bacteriological analysis.

The GMP also identified nine action items to increase the frequency and efficiency of monitoring efforts. These action items, although over 20 years old, are consistent with the goals set forth by this Chapter GSP.

These GMP action items are listed below, and a full copy of the GMP can be found in the WKWD *Urban Water Management Plans* (UWMPs) at http://www.wkwd.org/menus/urban-water-management-plan.html.

- Develop groundwater management program
- Assess hydrogeologic basin
- Develop conjunctive use program
- Evaluate wellfield
- Identify monitoring plan
- Manage groundwater contamination
- Protect wellhead and aquifer

- Develop well construction and abandonment plan
- Coordinate with land use and regulatory agencies

WKWD GMP's Influence on Chapter GSP Goals

WKWD's GMP suggests its current water management directly complements this Chapter GSP groundwater resource goals. GMP objectives include promoting monitoring activities, protecting groundwater quality, and preserving the groundwater resource. The GMP's action items (above) will be incorporated into this Chapter GSP, and its established monitoring networks and will be considered for development in future Chapter GSP updates, as appropriate.

GSP Influence on WKWD's GMP

Successful implementation of this Chapter GSP will help maintain WKWD's sustainable groundwater management practices. While some of the GMP's action items have already been implemented, development of this Chapter GSP and WKWD's monitoring networks will consider all the identified GMP action items to increase the frequency and efficiency of monitoring efforts, as needed.

WKWD Urban Water Management Plan

The WKWD UWMP describes the GSA area's water system, supplies and demands, reliability of water resources, and existing and planned water conservation measures to ensure that adequate water supplies are available to meet existing and future water needs. Per California Urban Water Management Planning Act requirements, the UWMP is prepared every five years to support WKWD's long-term resource planning (WKWD, 2016).

The UWMP also addresses Senate Bill X7-7 requirements. Enacted in November 2009, Senate Bill X7-7 requires a statewide per capita water use reduction of 20 percent by the year 2020. WKWD's 10-year baseline water use is 237 gallons per capita per day (gpcd), with a goal of 213 gpcd by 2015 and 189 gpcd by 2020. The actual per capita consumption in 2015 was 174 gpcd, which is below the 2020 target.

WKWD UWMP's Influence on GSP Goals

WKWD's UWMP stated goals are to "ensure adequate water supplies are available to meet existing and future water needs," which directly complements Chapter GSP objectives. The UWMP not only promotes efficient use of water supply but strengthens the Chapter GSPs goals of providing a long-term sustainable supply of groundwater for beneficial uses.

GSP Influence on WKWD's UWMP

Successful implementation of the GSP will help maintain WKWD's sustainable groundwater management program. Implementation of this Chapter GSP and its related monitoring networks will provide more robust and comprehensive data for WKWD with a focus on the North Project, South Project, and Lake management areas. Chapter GSP implementation will also promote the efficient use of water to promote sustainable supply, ensuring WKWD further meets or exceeds its water use reduction goal.

Tulare Lake Basin Portion of Kern County's 2011 Integrated Regional Water Management Plan

Kern County's *Integrated Regional Water Management Plan* (IRWMP) provides an overview of the water system for Kern County including water supply, water quality, interface with land use planning, and potential climate change impacts. The IRWMP describes monitoring, data reporting, identifies data gaps, and describes monitoring plan performance in Kern County. The IRWMP also provides a matrix of 26 water management strategies, divided into six categories. The IRWMP identifies which strategies are most applicable and appropriate for the nine subregions throughout the IRWMP region. According to the IRWMP, all 26 water management strategies apply to the Kern Fan subregion where WKWD is located. These strategies are listed below (KCWA 2011).

- Reduce water demand
  - Agricultural water use efficiency
  - Urban water use efficiency
- Improve operational efficiency and transfers
  - Conveyance – Sacramento-San Joaquin River Delta (Delta), and regional/local
  - System reoperation
  - Water transfers
- Increase water supply
  - Conjunctive management and groundwater storage
  - Desalination – brackish\seawater
  - Precipitation enhancement
  - Recycled municipal water
  - Surface storage – CALFED Bay-Delta Program (CALFED) and regional/local (now the Delta Stewardship Council)
- Improve water quality
  - Drinking water treatment and distribution
  - Groundwater/aquifer remediation
  - Matching quality to use
  - Pollution prevention
  - Salt and salinity management
  - Urban runoff management
- Practice resource stewardship
  - Agricultural lands stewardship
  - Economic incentives (loans, grants, water pricing)
  - Ecosystem restoration
  - Forest management
  - Land use planning and management

  - Recharge area protection
  - Urban land use management
  - Water-dependent recreation
  - Watershed management
- Improve flood management
  - Flood risk management

2011 Tulare Lake Basin Portion of Kern County IRWMP's Influence on Water Demand and Chapter GSP Goals

The 2011 Tulare Lake Basin portion of Kern County's IRWMP water management strategies and associated proposed projects for the Kern Fan subregion complement this Chapter GSP's strategies for beneficial use and conservation of groundwater resources. The primary objective of the IRWMP's strategies is to achieve sustainable yield and management of groundwater throughout the subregion, which directly aligns with the sustainability goals of this Chapter GSP.

Chapter GSP Influence on the 2011 Tulare Lake Basin Portion of Kern County IRWMP

Successful implementation of this Chapter GSP will help maintain WKWD's sustainable management of groundwater resources. Many of the strategies identified in the IRWMP were incorporated into this Chapter GSP during development, and all strategies will be considered during both project implementation and future Chapter GSP updates.

Kern County General Plan

Because of the interrelationship between water supplies, land use, conservation, and open space, the Land Use, Conservation, and Open Space Element sections of the *Kern County General Plan* are the most relevant elements for development of this Chapter GSP. These plan elements provide for a variety of land uses for future economic growth while also assuring the conservation of Kern County's agricultural and natural resources.

Relevant Kern County General Plan Goals and Policies

The following *Kern County General Plan* Land Use, Conservation, and Open Space Element goals and policies related to groundwater use would potentially influence implementation of this Chapter GSP (Kern County, 2009):

- Goal 1.4.5: Ensure that adequate supplies of quality water (appropriate for intended use) are available to residential, industrial, and agricultural users in Kern County.
- Policy 1.4.2: The efficient and cost-effective delivery of public services and facilities will be promoted by designating areas for urban development which occur in or adjacent to areas with adequate public service and facility capacity.
- Policy 1.4.2.a: Ensure that water quality standards are met for existing users and future development.
- Goal 1.6.6: Promote the conservation of water quantity and quality in Kern County.

- Goal 1.6.7: Minimize land use conflicts between residential and resource, commercial, and industrial land uses.
- Policy 1.6.11: Provide for an orderly outward expansion of new urban development so that it maintains continuity of existing development, allows for the incremental expansion of infrastructure and public service, minimizes impacts on natural environmental resources, and provides a high-quality environment for residents and businesses.
- Policy 1.9.10: To encourage effective groundwater resource management for the long-term economic benefit of the county, the following shall be considered:
- Policy 1.9.10.a: Promote groundwater recharge activities in various zone districts.
- Policy 1.9.10.c: Support the development of groundwater management plans.
- Policy 1.9.10.d: Support the development of future sources of additional surface water and groundwater, including conjunctive use, recycled water, conservation, additional storage of surface water and groundwater and desalination.
- Goal 1.10.1: Ensure that the county can accommodate anticipated future growth and development while maintaining a safe and healthful environment and a prosperous economy by preserving valuable natural resources, guiding development away from hazardous areas, and assuring the provision of adequate public services.
- Policy 1.10.6.39: Encourage the development of the county's groundwater supply to sustain and ensure water quality and quantity for existing users, planned growth, and maintenance of the natural environment.
- Policy 1.10.6.40: Encourage utilization of community water systems rather than the reliance on individual wells.
- Policy 1.10.6.41: Review development proposals to ensure adequate water is available to accommodate projected growth.

Kern County General Plan's Influence on Water Demand and Chapter GSP Goals

Relevant *Kern County General Plan* goals and policies about future land use development and conservation complement Chapter GSP use and conservation of groundwater resource goals. The *Kern County General Plan* explicitly encourages development of the county's groundwater supply to ensure that existing users have access to high quality water, and states that future growth should be accommodated only while ensuring that adequate high-quality water supplies are available to existing and future users.

Chapter GSP Influence on Kern County's General Plan Goals and Policies

Successful implementation of this Chapter GSP will help maintain WKWD's sustainable groundwater management program. Given the small portion of the GSA area that is the focus of Chapter GSP management, and since the Western Management Area is predominantly barren or oil fields, it is anticipated that Chapter GSP implementation will have little to no effect on the *Kern County General Plan*'s goals related to sustainable land use development in Kern County.

1.3.6 Permitting New or Replacement Wells

WKWD will default to the existing permitting processes utilized by Kern County, but requests that all wells designed to pump above de minimis levels be reviewed by WKWD GSA staff. This will provide the option to incorporate the well into the DMS system and ensure that water pumped or injected via the new or replacement well is recorded in the water budget. Details on the process to permit wells with Kern County are available at: https://kernpublichealth.com/water-wells/.

1.3.7 Conjunctive Use Programs in the Subbasin

WKWD has been banking water in the Kern Fan subregion area since 1966. All surface water deliveries to WKWD are transported through the California Aqueduct and other surface water conveyance facilities, where it is banked and later recovered from WKWD's wellfield or delivered directly to industrial customers.

By agreement, BVWSD takes direct delivery of WKWD's SWP Table A water and, in exchange, BVWSD delivers a like amount of Kern River supplies for recharge on WKWD's North Project and South Project management areas.

As of 2018, WKWD has banked approximately 200,000 AF of water. Through banking and exchange programs, other agencies owe WKWD an additional 24,000 AF. Therefore, WKWD's total banked water assets are approximately 224,000 AF. Currently, WKWD has maintained a positive balance in the banking program, and has approximately a 10-year supply currently banked (WKWD, 2016).

1.3.8 Plan Elements from California Water Code Section 10727.4

The plan elements from CWC Section 10727.4 require GSPs to address the components listed in Table 1-5. Each component is coordinated at the Subbasin level, and is addressed in the Umbrella GSP.

Table 1-5. Plan Elements from CWC Section 10727.4

Element	Location
(a) Control of saline water intrusion.	Umbrella GSP
(b) Wellhead protection areas and recharge areas.	Umbrella GSP
(c) Migration of contaminated groundwater.	Umbrella GSP
(d) A well abandonment and well destruction program.	Umbrella GSP
(e) Replenishment of groundwater extractions.	Umbrella GSP
(f) Activities implementing, opportunities for, and removing impediments to, conjunctive use or underground storage.	Umbrella GSP
(g) Well construction policies.	Umbrella GSP
(h) Measures addressing groundwater contamination cleanup, groundwater recharge, in-lieu use, diversions to storage, conservation, water recycling, conveyance, and extraction projects.	Umbrella GSP

Table 1-5. Plan Elements from CWC Section 10727.4

Element	Location
(i) Efficient water management practices, as defined in Section 10902, for the delivery of water and water conservation methods to improve the efficiency of water use.	Umbrella GSP
(j) Efforts to develop relationships with state and federal regulatory agencies.	Umbrella GSP
(k) Processes to review land use plans and efforts to coordinate with land use planning agencies to assess activities that potentially create risks to groundwater quality or quantity.	Umbrella GSP
(l) Impacts on groundwater dependent ecosystems.	Umbrella GSP

1.4 Outreach and Engagement

The KGA conducted outreach and engagement efforts at the Subbasin scale. These efforts are documented in the Umbrella GSP. These efforts include:

- A description of beneficial uses and users
- A list of public meetings
- GSP comments and responses
- Decision-making process
- Public engagement
- Encouraging active involvement
- Informing the public on GSP implementation progress

WKWD is the only user of groundwater above de minimis levels within the GSA area. Outreach performed by the KGA, as documented in the KGA's Umbrella GSP was intended to reach stakeholders within the WKWD GSA area. Because WKWD is the only user of groundwater above de minimis levels within the GSA area, Chapter GSP comments and responses were conducted through Subbasin coordination and with the Umbrella GSP.

1.4.1 Decision Making process

The WKWD GSA is governed by a board of directors who also serve as the board of directors for the WKWD. Decisions are made by majority at a meeting of the board where a quorum is present.

1.4.2 Public Engagement, Stakeholder Involvement, and GSP Implementation Progress

WKWD is the only user of groundwater above de minimis levels within the agency area. Outreach performed by the KGA, as documented in the KGA's Umbrella GSP was intended to reach stakeholders within the WKWD GSA area.

WKWD held a public workshop on July 22, 2019 to review the components of the WKWD Chapter GSP.

Section 2.0 Basin Settings: Hydrogeologic Conceptual Model

2.1 Compliance Information

Table 2-1 summarizes DWR's *Preparation Checklist for GSP Submittal* items that are covered in this section. For the complete *Preparation Checklist for GSP Submittal*, see Appendix A.

Table 2-1. Applicable Preparation Checklist Items

GSP Regulation Section	Water Code Section	Description	GSP Section
Article 5. Plan Contents, Subarticle 1. Administrative Information			
354.4	General Information	List of references and technical studies	Section 2.12
Article 5. Plan Contents, Subarticle 2. Basin Setting			
354.14	Hydrogeologic Conceptual Model	Description of the Hydrogeologic Conceptual Model	Section 2.0
		Two scaled cross sections	Umbrella GSP
		Map(s) of physical characteristics: topographic information, surficial geology, soil characteristics, surface water bodies, source and point of delivery for imported water supplies	Section 1.0 Section 2.5 Section 2.10
354.14(c)(4)	Map of Recharge Areas	Map delineating existing recharge areas that substantially contribute to the replenishment of the basin, potential recharge areas, and discharge areas	Section 2.10
	Recharge Areas	Description of how recharge areas identified in the plan substantially contribute to the replenishment of the basin	Section 2.10 and Umbrella GSP

2.2 Introduction

Basin settings information is composed of three Chapter GSP sections as follows:

- **Hydrogeologic Conceptual Model (HCM)**—this HCM section (Section 2.0) provides the geologic information needed to understand the framework that water moves through the Basin. It focuses on geologic formations, aquifers, structural features, and topography.
- **Groundwater Conditions**—The groundwater conditions section (Section 3.0) describes groundwater trends, levels, hydrographs and level contour maps, estimates, and changes in groundwater storage. It also identifies groundwater quality issues, and addresses subsidence and surface water interconnection.

- **Water Budget**—The water budget section (Section 4.0) provides information about the data used for water budget development and discusses how the water budget was calculated.

2.3 Hydrogeologic Conceptual Model Definition

This section describes the HCM for the GSA area. The HCM has a specific role in understanding the GSA area, and according to the DWR GSP requirements specified in the *Hydrogeologic Conceptual Model BMP*, the HCM provides the following (DWR 2016):

- Provides an understanding of the general physical characteristics related to regional hydrology, land use, geology geologic structure, water quality, principal aquifers, and principal aquitards of the basin setting
- Provides the context to develop water budgets, mathematical (analytical or numerical) models, and monitoring networks
- Provides a tool for stakeholder outreach and communication

This HCM was developed to understand and convey information about the physical conditions by which water moves through the GSA area. The HCM is also used elsewhere in this Chapter GSP to understand the distribution and movement of water within the GSA area, which will support the development of water budgets.

2.4 Useful Terms

This HCM section includes descriptions of the geologic formations and structures, aquifers, and properties of geology related to groundwater, among other related components. A glossary of pertinent technical terms is below. The glossary is intended to guide readers through this subsection, and is not a definitive definition of any term:

- **Aquifer**—An aquifer is an underground reservoir of water stored within the pores and fractures of rocks and sediments.
- **Aquitard**—An aquitard is a layer of strata that has a low conductivity that groundwater flows very slowly through. Aquitards can be regional, such as the Corcoran Clay in the Central Valley, where it prevents flow from upper strata to lower strata across the western side of the valley, or it can be localized, which is common in most alluvial settings. Localized aquitards restrict vertical flows in a small region of an aquifer, and water will generally move laterally around localized aquitards as it flows by gravity toward the bottom of the aquifer.
- **Basement complex**—The basement complex is comprised of the oldest and deepest rocks in the subsurface. Basement rocks are typically crystalline and metamorphic or igneous in origin, and groundwater generally only moves through fractures in the rock instead of pore spaces like in sedimentary rocks. No sedimentary layers are found below basement rocks.

- **Confined aquifer**—A confined aquifer is an aquifer that has an impermeable layer above it, and is pressurized by the weight of water pushing down into the aquifer. Confined aquifers are measured by measuring their potentiometric surface, which is the elevation that water rises to in a well due to pressure in the aquifer.
- **Formation**—A formation, or geologic formation, is a unit of rock of similar properties, such as grain size, mineral composition, or depositional environmental. Geologic formations are distinct from surrounding rock types and are large enough to be mapped regionally. If a formation contains a dominant rock type, such as sandstone, it may be included in the name of the formation.
- **Hydraulic conductivity**—Hydraulic conductivity is defined as the "measure of a rock or sediment's ability to transmit water," typically measured in feet or meters per unit of time (day, hour, minute) (DWR, 2003). Rocks and sediments with high conductivity values, such as gravels or coarse sands, can sustain groundwater flow better than rocks and sediments with low conductivity values. Rocks and sediments with near zero values of hydraulic conductivity, such as very fine-grained sandstones, shale, or granites, do not transmit groundwater and are considered barriers to flow. Conductivity values are used in a groundwater model to determine how quickly formations transmit groundwater and where barriers to groundwater flow (i.e., formations with very low conductivity values) exist.
- **Primary aquifer**—GSP regulations require that primary aquifers are identified, and the GSP must identify which aquifers require specific monitoring and management. Primary aquifers are regionally extensive and are sources groundwater used for beneficial uses.
- **Unconfined aquifer**—An unconfined aquifer is an aquifer that does not have an impermeable layer above it (such as a clay layer). An unconfined aquifer has an upper water surface defined as the water table and is at atmospheric pressure. Water seeps from the ground surface directly into the aquifer, as there are no impermeable layers to prevent water from entering the aquifer.
- **Water bearing formation**—A water bearing formation is a rock formation that is saturated and contains water within the pores or fractures of the unit. One or more water bearing formations compose an aquifer.

2.5 Regional Geologic and Structural Setting

The GSA area lies within the Central Valley of California, which runs approximately 400 miles north to south and approximately 50 miles inland from the Pacific Ocean. The Central Valley comprises about 20,000 square miles (Page, 1986). The Central Valley can be subdivided into the Sacramento Valley to the north and the San Joaquin Valley to the south where the GSA area is located. The San Joaquin Valley is a geosynclinal trough of low relief bounded by the Sierra Nevada Ranges to the east and the Diablo, Temblor, and San Emigdio mountains of the Coast Ranges to the west. The geosyncline is asymmetrical, with the western flank steeper than the relatively eastern flank. The eastern side of the San Joaquin Valley, which is the western portion of the Sierra Nevada fault block, is characterized by tension faults and gently folded anticlines (Hoots et al., 1954). In contrast, the western side of the San Joaquin Valley is steeply tilted, overturned, and cut by thrust faults originating from compressional forces driven by orogenic processes and lateral movement along the San Andreas fault during the Pleistocene (Hoots et al., 1954). The western side of the San Joaquin Valley is rich in oil and petroleum reservoirs, another effect of the folding and faulting activities that resulted in unconformities between geologic formations

(particularly of Cretaceous age or older), creating stratigraphic traps for oil and petroleum (Hoots et al., 1954). This environment has resulted in the San Joaquin Valley being one of the most important oil-producing areas in California (Wood and Davis, 1959).

The trough of the San Joaquin Valley is cut through the igneous and metamorphic crystalline rocks of the Sierra Nevada and Tertiary age marine rocks of the Coast Ranges, and is filled by sediments of deep marine, shallow marine, deltaic, and continental origin (Faunt et al., 2009). The fill deposits range in thickness from zero (i.e., sea level) on the eastern edge of the San Joaquin Valley to more than 50,000 feet on the western edge (Faunt et al., 2009). The continental sediments consist of basin-fill and/or lake deposits of sand and gravel interbedded with fine-grained materials, such as clay and silt and were delivered to the valley trough by major streams and tributaries (Faunt et al., 2009).

The San Joaquin Valley is characterized by four distinct geomorphic units: dissected uplands, low plains and fans, river flood plains and channels, and overflow lands and lake bottoms (Wood and Davis, 1959). The GSA area is located within regions of the dissected uplands (i.e., Elk Hills, Buena Vista Hills, and Little Signal Hills) and the river flood plains and channels. Generally, the land surface has low relief interrupted by low hills that reflect local anticlines (Hoots et al., 1954).

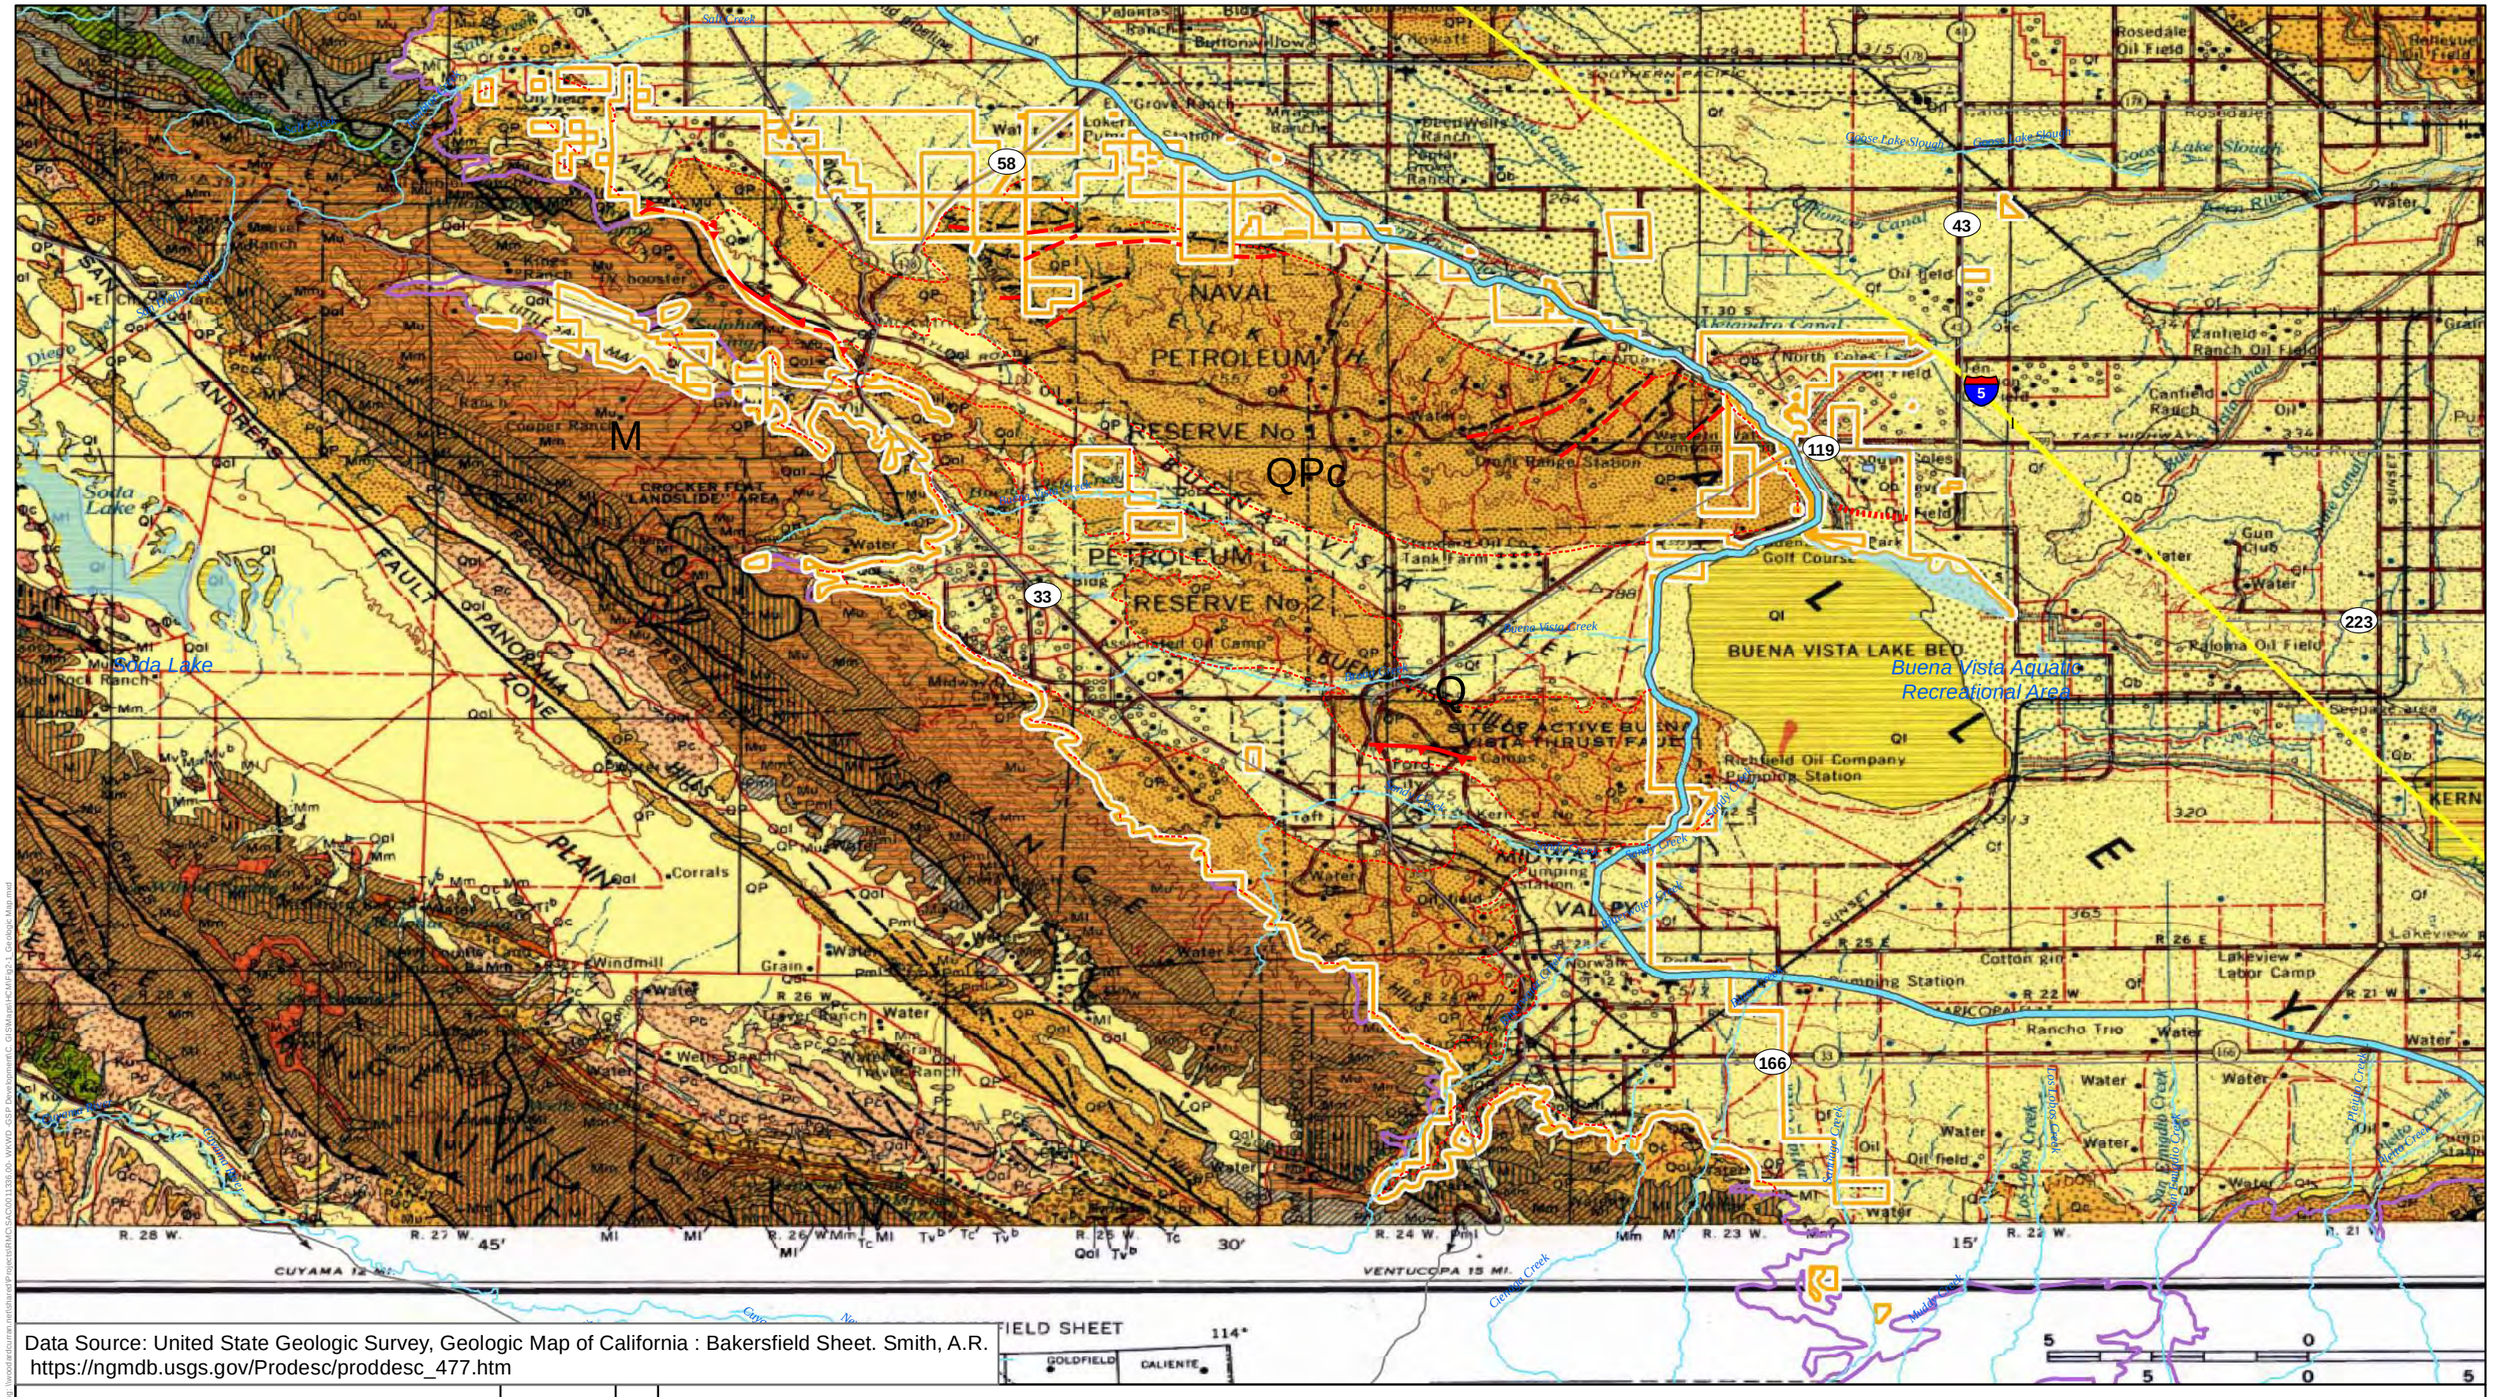
2.5.1 Geologic History

The southern San Joaquin Valley has been developed through periods of deformation and deposition, influenced by tectonic subsidence and cycles of marine transgression and regression. The deepest sediments in the GSA area were deposited within a marine environment associated with an inland sea that inundated the San Joaquin Valley between 200 million years ago (Jurassic Period) and 2 million years ago (end of the Tertiary Period) (Croft, 1972). Thick deposits of coarse-grained sediments at depths ranging from 300 to about 3,000 feet accumulated where the streams of the alluvial fan dropped most of their remaining load as they entered lakes and marshes around the Tulare Lake Bed (Croft, 1972). Deeper marine sediments are overlain by approximately 2,400 feet of nonmarine continental deposits associated with an alluvial environment (Planert and Williams, 1995). Throughout the depositional history of the Basin, sediment was supplied by the rising Coast Ranges, Transverse Ranges, and the Sierra Nevada.

Detailed geologic cross sections of the Kern County Subbasin are provided in the Umbrella GSP.

2.5.2 Geologic Formations/Stratigraphy

Geologic formations present within the GSA include unconsolidated to partly consolidated continental sedimentary deposits of Tertiary and Quaternary age overlying consolidated Tertiary-age marine sedimentary rocks on top of pre-Tertiary crystalline gabbro bedrock (Croft, 1972). The primary water-bearing units in the Subbasin are two-fold: fresh water is found in the coarse, unconsolidated, and oxidized continental deposits and alluvium, while brackish to saline water is found in the Tertiary age marine and continental sedimentary rocks (Croft, 1972). These units are described in further detail in Section 2.8.1. Two nearly impermeable clay layers, known as the A and E clays, impede groundwater flow in the GSA's North Project Management Area, dividing the unconfined, freshwater aquifer from the brackish, confined to semi-confined aquifer, all while dividing the alluvial sequences into separate aquifers (Croft, 1972). The E clay is not present within the GSA's South Project Management Area. Individual geologic units found in the Subbasin in the GSA area are described in detail below, in order of youngest to oldest in deposition. Geologic units mapped at the surface are shown in Figure 2-1.



Stratigraphic Units of the Subbasin Aquifers in the GSA area

Stratigraphic units in this section are presented in order from youngest to oldest. Generally, water-bearing formations are limited to continental fill-deposits. The stratigraphic column highlights the clay lenses present throughout the subsurface and the variable thicknesses of the geologic units, roughly thickening to the east.

Recent Alluvium and Flood Basin Deposits

The youngest deposit in the Subbasin in the GSA area is the recent alluvium and flood basin deposits of the Kern River Fan complex; they are Holocene in age (DWR, 2006). These flood basin deposits are difficult to distinguish from the underlying fine-grained alluvium; as a result, they are grouped stratigraphically together (DWR, 2006). The Recent Alluvium is composed of unconsolidated valley and stream deposits with interstratified and discontinuous beds of clay, silt, sand, and gravel (Smith, 1964). The alluvium fines to the southwest where it grades into the fine-grained flood basin deposits underlying the historical lake beds. The flood basin deposits include silt, silty clay, sandy clay, and clay interbedded with poorly permeable sand layers. The deposits are sourced primarily from the western Coast Ranges and, to a lesser extent, from the eastern Sierra Nevada Ranges. Sediment sources can be differentiated by degree of reduction; oxidized deposits represent subaerial deposition while reduced deposits represent a subaqueous deposition (Croft, 1972). A contact between the oxidized and reduced deposits transgresses the alluvial deposits sourced from the Sierra Nevada (Croft, 1972). Since the Coast Ranges consist mainly of marine shale and sandstone, its derived sediments are composed of very fine-grained sediments (Dale et al., 1966).

The Recent Alluvium and flood basin deposits are widespread throughout the GSA area, and are exposed throughout the low plains and stream channels between the hills. The thickness and character of the alluvium and flood basin deposits vary throughout the Subbasin, but at maximum, the total thickness reaches 1,000 feet (DWR, 2006). The Younger Alluvium and flood basin deposits are permeable; however, they are not the major source of groundwater in the GSA area.

Older Alluvium

Older Alluvium, which includes stream and terrace deposits, are composed of loosely consolidated to cemented lenticular deposits of clay, silt, sand, and gravel (DWR, 2006). These deposits are exposed at the subbasin margins. The unit is Pliocene to Pleistocene nonmarine sedimentary deposits, consisting mainly of slightly consolidated and dissected fan deposits (Smith, 1964). The deposits are composed of generally poorly sorted silty materials containing lenticular bodies of sand and gravel derived from the Coast Ranges that were deposited by streams. Arkosic sand and gravel are derived from the Sierra Nevada Range, while clay and mudstones are sourced from the Coast Ranges (Dale et al., 1966).

Older Alluvium is one of the principal water-bearing formations in the Subbasin and yields large quantities of water due to its moderately to highly permeability (DWR, 2006). The Older Alluvium and stream and terrace deposits, along with the Tulare Formation, compose the principal aquifer in the Subbasin (DWR, 2006). The Older Alluvium unconformably overlies the Tulare Formation.

A Clay

The A clay is a shallow aquitard locally present throughout the Subbasin. The A clay is a fine-grained lacustrine or paludal (i.e., marsh) deposit composed of plastic silty sandy gypsiferous highly organic clay (Croft, 1972). The A clay ranges in color from blue, olive brown or dark greenish gray (Croft, 1972). In some areas, the clay is interbedded with stringers of fine to medium sand and/or several thin clay layers separated by thin beds of sand. The A clay layer is typically less than 60 feet thick and occurs at shallow depths ranging from 10 to 60 feet below ground surface (bgs) (Croft, 1972). The A clay is considered Pleistocene and Holocene in age (Croft, 1972). The presence of A clay is limited to the southeasternmost edge of the GSA area, near the Buena Vista Lake bed and intersection of Route 119 and the California Aqueduct. This unit is not present in the wellfields of the GSA's North or South Project management areas.

Tulare Formation

The Pliocene to Pleistocene-aged Tulare Formation consists of alternating beds of sand and mudstone and includes the Corcoran Clay member. The Tulare Formation is highly variable in thickness and composition throughout the San Joaquin Valley and has an eastern facies equivalent known as the Kern River Formation. Generally, the Tulare Formation is a continental deposit of unconsolidated to poorly consolidated continental units that are predominantly silty sediments with lenses and stringers of poorly sorted coarse sand and gravel predominantly sourced from the Coast Range (Wood and Davis, 1959). Locally, the Tulare Formation includes thin beds of argillaceous limestone, marl, diatomaceous clay, marly silt, and shale (Smith, 1964; Wood and Davis, 1959). Near Elk Hills, the Tulare Formation is a varying combination of gypsiferous mudstone, sand, sandstone, siltstone, and shale (Provost & Pritchard Consulting Group [Provost & Pritchard], 2019). Spatially, the sandy and gravelly coarse-grained

sediments underlie the northern, eastern, and southern portions of the Tulare Formation at depths greater than 1,800 feet, while most of the silty and clayey sediments are found at depths below 1,400 feet in the western and central parts of the Tulare Formation. Below 1,400 feet, fine-grained sediments are widespread and represent the base of the formation at 2,400 to 2,800 feet bgs (Page, 1983). The base of the Tulare Formation is defined as the layer just above the upper Mya zone of the San Joaquin Formation, which represents a gradual transition from marine to lacustrine environments (Dale et al., 1966). The Tulare Formation lies conformably above the San Joaquin Formation. The Buena Vista, Elk, and Little Signal hills are composed of deformed and folded Tulare Formation (Provost & Pritchard, 2019). To the south and west of the GSA area, the Tulare Formation truncates oil bearing rocks. Coarse sediments in the Tulare Formation are moderately permeable and yield water.

Corcoran Clay Member

The lower member of the Tulare Formation includes the Corcoran Clay member, which is a regionally extensive lacustrine clay that serves as a confining layer separating the shallow semi-confined to unconfined aquifer system from a deeper confined aquifer system. Locally, an alluvial deposit of rhyolitic ash overlies the Corcoran Clay layer (Croft, 1972). Within the GSA area, the Corcoran Clay member is present in the North Project Management Area, where WKWD wells are screened above the Corcoran Clay member. The Corcoran Clay member is not present in the South Project Management Area, which allows wells to extend to greater depths.

E Clay

The E clay is the principal aquitard in the Subbasin and throughout the San Joaquin Valley (Croft, 1972). The E clay includes the Corcoran Clay member of the Tulare Formation and is the most extensive hydrologic confining layer in the San Joaquin Valley (Croft, 1972). This confining layer is composed of silty clay, clayey silt, and sand, silt, and clay and is typically found at depths of approximately 700 to 800 feet bgs in the North Project Management Area (Croft, 1972). The characteristically blue color of E clay has earned it the nickname “blue clay.” Within the GSA area, E clay is blue silty, sandy, clay and is typically less than 75 feet thick (Croft, 1972). The layer is fossiliferous and contains marine fossils of middle to late Pleistocene age.

The E clay stratum is highly warped and creates an asymmetric, northwesterly trending syncline of which the axis lies south of the present San Joaquin Valley trough. The E clay bifurcates into an upper and lower stratum that contain thin beds of moderately yellowish-brown silt and fine sand, representing the early transgression of Corcoran Lake. Based on the age of fossil diatom assemblages found in the stratum, the E clay layer is Pleistocene in age.

The E clay is not regionally present in the GSA area; from west to east, it first appears at the eastern foothills of Elk Hills at depths of 100 feet bgs and extends east toward the East Side Canal (Croft, 1972). The E clay is present within the GSA’s North Project Management Area but not within the South Project Management Area.

Santa Margarita Formation

The Santa Margarita Formation is a well shorted gray and white sandstone interbedded with gravel and shale and ranges in thickness from 100 to 400 feet thick (Croft, 1972). Locally, the formation includes very coarse fanglomerate and granitic breccia near the Temblor and Caliente ranges, along the western margin of the GSA area. The formation is upper Miocene in age and represents the final phase of marine sedimentation and sea transgression (Lagoe, 1981). The Santa Margarita Formation is not exposed at the surface within the GSA area, but is exposed directly west of the Subbasin boundary in the Temblor Range.

The Santa Margarita Formation is highly permeable and is a source of water in confined aquifers in the western and eastern margins of the Subbasin, including within the GSA area, where the groundwater is of suitable water quality (Croft, 1972).

Olcese Formation

The Olcese Formation consists of unconsolidated sandstone with interbedded pebble and siltstone beds (Smith, 1964). The formation is both continental and marine in origin, representing a sea level regression from east to west during the Miocene age (DWR, 2006). The Olcese Formation ranges in thickness from 100 to 450 feet (DWR, 2006). In the northeastern portion of the Subbasin, outside of the GSA area, the Olcese Formation is a source of drinking water in confined aquifers. The highly saline sands in the Olcese Formation result in groundwater that is more saline than aquifers in formations overlying and underlying the Olcese Formation. The saline difference separates aquifers into upper and lower sources of drinking water, based on the salinity content. Sands in the Olcese Formation are more saline along the western margin of the Subbasin and the GSA area (Gillespie et al., 2017). The Olcese Formation is not exposed within the GSA area but does outcrop directly west of the GSA's jurisdiction in the Temblor Range. The Olcese Formation underlies the Etchegoin Formation.

Stratigraphic Units Below the Subbasin Aquifer in the GSA Area

San Joaquin Formation

The San Joaquin Formation consists of blue and green fine-grained silty sands, silt, and clay (Foss and Blaisdell, 1968). The San Joaquin Formation was formed during the late Pliocene to early Pleistocene age, when the Central Valley was an inland sea. The San Joaquin Formation is predominantly marine in origin and a suite of marine fauna, including mollusks, Pecten, Mya, and gastropods, are commonly found within the coarser grained sand, sandstones, and conglomerate layers (Foss and Blaisdell, 1968). There is only one recognizable member of the San Joaquin Formation, the Cascajo Conglomerate, which is located at the base of the formation and is characterized by fossil and lithic components (Foss and Blaisdell, 1968). The San Joaquin Formation ranges in thickness from 1,500 to 4,200 feet (Foss and Blaisdell, 1968; USGS, 1996). The Midway-Sunset and Kettleman Hills oil production wells are found in the San Joaquin Formation (Foss and Blaisdell, 1968). The San Joaquin Formation is conformably overlain by the Tulare Formation and underlain by the Etchegoin Formation.

Etchegoin Formation

The Etchegoin Formation consists of marine blue and brown sandstones, poorly sorted blue or blueish gray shales, and pebble conglomerates (Foss and Blaisdell, 1986). Sands within the formation contain oil and gas. Strata of the Etchegoin Formation contain a mix of fresh and marine water molluscan assemblages and is mid to early Pliocene in age (Foss and Blaisdell, 1986). The Etchegoin Formation occurs mainly on the west side of the San Joaquin Valley and is up to 4,360 feet thick (Foss and Blaisdell, 1968). The Etchegoin Formation includes middle sand, lower shale, and basal sand members, respectively known as the Jacalitos, Bitterwater Creek, and Panorama Hills Formations. The Bitterwater Creek Formation is a semi-siliceous shale up to 3,000 feet thick that grades to the northwest into a marine sandstone (Foss and Blaisdell, 1968). The Jacalitos Formation contains diatomite shale and sand and is often referred to as the "Lower Etchegoin" (Foss and Blaisdell, 1968). The Panorama Hills Formation is a non-marine pebble gravel layer in the Lower Etchegoin and grades into the Bitterwater shale to the southeast, adjacent to the San Andreas Fault (Foss and Blaisdell, 1968). To the east, the Etchegoin Formation grades into the Kern River Formation (Foss and Blaisdell, 1968). The Etchegoin Formation lies unconformably on the Santa Margarita Formation (Croft, 1972).

The upper portion of the Etchegoin Formation was the most productive oil-bearing bed and dry-gas zone within the Elk Hills production zone in 1932 (Woodring et al., 1932).

Monterey Shale

The Monterey Shale is a brown, organic, bituminous, siliceous shale with some local thin limestone beds (Jennings and Strand, 1969). The Monterey Shale represents a period of sea level regression and a depositional environment like the Etchegoin Formation (Woodring et al., 1932). It is also known and mapped as Maricopa Shale in the Santa Margarita Formation. The Monterey Shale is divided into a lower part, principally of mud and siliceous shales and diatomite, and an upper part consisting of soft, punky diatomite and coarse detrital deposits (Woodring et al., 1932). The Monterey Shale hosts several fossil species, including diatoms, radiolarians, sponge spicules, and other foraminifera (Woodring et al., 1932). In the southwest portion of the GSA area near the city of Maricopa, the Monterey Shale is up to 4,800 feet thick and increases in thickness further south (Woodring et al., 1932). The Monterey Shale unconformably underlies the Etchegoin Formation along the western mountain front.

The Monterey Shale is regarded as the source of oil in the western portion of the San Joaquin Valley and is within the two petroleum reserves in the GSA area, in Elk Hills and Buena Vista Hill (Woodring et al., 1932).

Sierra Nevada Batholith (Basement Complex)

The basement complex in the Subbasin and in the GSA area is composed of plutonic and metamorphic rocks, commonly referred to as the Sierra Nevada batholith (Croft, 1972). The surface of the basement complex slopes approximately 3 to 5 degrees southwest from the base of the foothills toward the San Joaquin Valley floor (Croft, 1972). In the southeast portion of the GSA area near the Buena Vista Lake bed, the basement complex is buried more than 20,000 feet deep by younger marine and continental rocks of the Cretaceous, Tertiary, and Quaternary ages (Croft, 1972). Though fractures and joints in the

basement complex may produce groundwater, no wells reach this depth, and the unit is not considered an important part of the groundwater aquifer (Dale et al., 1966).

2.6 Faults and Structural Features

The GSA area contains a number of tectonic features including faults, synclines, anticlines, and a major arch (Figure 2-2), which are described below.

2.6.1 Synclines and Anticlines

There are a number of fold structures present in the older sediments in the GSA area, including the Buena Vista Syncline and several anticlines. In general, these fold structures trend and plunge from the northwest to southwest across the GSA area (Gillespie et al., 2017). Several known anticlinal folds in the GSA area and Subbasin restrict movement of groundwater.

Synclines

Synclines are structural folds where the youngest formations are located closest to the trough of the fold. Formations underlying the youngest formation presumably follow the basic law of geochronology where they increase in age of deposition.

Buena Vista Syncline

The Buena Vista Syncline runs approximately 25 miles through the GSA area, parallel to western edge of the Buena Vista Hills through Midway Valley. Development and deepening of the syncline occurred during the uplift of the Elk and Buena Vista hills (Woodring et al., 1932). The syncline is not believed to restrict the movement of groundwater.

Unnamed Syncline

An unnamed syncline is mapped within the extent of the GSA area and cuts through the North Project Management Area. The syncline trends roughly northwest to southeast throughout the GSA area (Jennings, 2010).

Anticlines

Anticlines are structural folds where the oldest formations are located at the core of the fold and younger formations drape over in sequential order.

Elk Hills-North Coles Levee Anticline

The Elk Hills, located in the eastern margin of the GSA area, are a surficial expression of a large subsurface anticline, known as the Elk Hills-North Coles Levee anticline. The anticline consists of two main anticlinal folds, a western and eastern fold, arranged en echelon (Woodring et al., 1932). The anticline, as expressed at the surface at Elk Hills, strikes to the northwest, roughly parallel to the axis of the San Joaquin Valley, and plunges to the southeast (Hoots et al., 1954). The anticline is approximately 17 miles long and 6 miles wide. The anticline is the result of folding that occurred during the early Pliocene age, consistent with regional uplift (Wood and Davis, 1959). The anticlines were first noted in 1910 after observing gypsum deposits on the upgradient side of the anticline, similar to gypsum deposits at the Lost Hills anticline (located northeast of the GSA area) (Hess, 1910; Provost & Pritchard, 2019).

In addition, there are a series of narrow anticlines that interrupt the slope of the hills and almost surround them (Woodring et al., 1932). The anticlines in the Elk Hills have been eroded primarily by streams to varying depths, and often serve as drainage features to the hills (Woodring et al., 1932). The anticline transverses the length of the Elks Hills, which are the topographic expression of anticlinal structures. Structurally, the Elk Hills are broad and flat-topped, with steeper dips along the edge that are deformed by narrow, flat-topped anticlines (Woodring et al., 1932). The crest of the eastern anticline consists of a number of terracelike steps that funnel anticlinal noses down the north slope of the hills; four faults are expressed in between the terraced anticlines (as shown in Figure 2-2) (Woodring et al., 1932). More information about the Elk Hills faults is provided in Section 2.6.2.

The Elk Hills-North Cole Levee anticline is an important petrologic structure within the GSA area and has developed a major oil field underlying the Elk Hills. The Bakersfield arch, described in Section 2.6.3, further contributes to structural deformity and uplift. The anticlines play an important role in capturing oil within the permeable rock units, and in trapping oil below impermeable layers.

The western anticline in Elk Hills is believed to divert the movement of groundwater south through the Buena Vista Valley toward the Buena Vista Lake (Page, 1986). The shallow and eastern anticlines are considered “shallow wrinkles” and not regarded as having significant impacts to groundwater or oil in the area (Woodring et al., 1932).

Buena Vista Hills Anticline

The Buena Vista Hills are in the center of the GSA area in the Subbasin and are a topographic expression of anticlinal structures. Three anticlines compose the anticline series in the Buena Vista Hills; two are located at the northern corner, and one is in the south-central portion of the hills. At the northern end of the Buena Vista Hills, a double plunging anticline is mapped plunging to the northwest and southeast. Another anticline is mapped at the northern end of the hills plunging to the southeast. The third anticline trends northwest to southeast across the Buena Vista Hills, and curves to the east near the eastern edge of

the GSA area. Past the boundary of the GSA area, this syncline becomes concealed and plunges to the east.

The Buena Vista Hills are an important oil resource in the GSA area, with a major oil field underlying the hills. The anticlines play an important role in capturing oil within the permeable rock units and trapping oil below impermeable layers.

The anticlines were first noted in 1910 after observing gypsum deposits on the upgradient side of the anticline, similar to gypsum deposits at the Lost Hills anticline (located northeast of the GSA area) (Hess, 1910; Provost & Pritchard, 2019). The axis of the anticlines strikes roughly parallel to the axis of the San Joaquin Valley and plunges to the southeast. The Buena Vista Hills anticline is believed to restrict the movement of groundwater flowing from the Buena Vista Valley (Page, 1986).

Little Signal Hill Anticlines (Unnamed)

Three unnamed anticlines are mapped by Jennings within the extent of the Little Signal Hills (Jennings, 2010). These anticlines run generally northwest to southeast along the extent of the Little Signal Hills, approximately 12 miles in total length. The unnamed anticlines are located on the western margin of the Subbasin and GSA area.

Unnamed Anticlines

There are several unnamed anticlines located in the GSA area that are not associated with a hill series. These anticlines are primarily concentrated in the west to northwest quadrant of the GSA area and roughly trend from northwest to southeast and plunge to the southeast. The anticlines are both exposed and concealed, and range in length from approximately 3 to 10 miles.

2.6.2 Major Faults

There are several faults in the GSA area as mapped in Figure 2-2. Most notable is the Buena Vista Fault, in addition to several unnamed faults in the Elk Hills that have been documented as historically active in the GSA area.

Buena Vista Fault

The Buena Vista fault is the most extensively studied fault in the area, with studies dating back to 1933 (Smith, 1984). Though little seismic activity has been recorded in the GSA area, creep activity along the Buena Vista fault has been reported as far back as the 1910s, where numerous oil-well casing failures were recorded at depths of 630 to 800 feet below sea level (Smith, 1984). The average strike of the fault is North, 75°W (Smith, 1984). Between 1933 and 1957, approximately 1.7 feet of displacement occurred, while in a two-hour period in 1970, 13.4 millimeters of creep occurred (Smith, 1984). It is suggested that slip on the Buena Vista Fault may be caused by oil withdrawal rather than tectonic forces (Smith, 1984). It was assumed by Smith (1984) that groundwater flow is not impacted by the fault.

Elk Hills Faults

As described in Section 2.6.1, a series of four faults are in the Elk Hills, lying between terraced anticlines. These faults are not expressed at the surface and are mapped within the mudstone at the base of the upper part of the Tulare Formation (Woodring et al., 1932). These four faults, named Faults 1 through 4, are thrust and normal faults that position buff-colored mudstone of the upper Tulare Formation against olive-gray mudstones of the lower Tulare Formation (Woodring et al., 1932). Faults 1 through 4 have the same trend as surface faults and subsurface faults known to displace oil-bearing beds in the Subbasin (Woodring et al., 1932). Fault 1 has the greatest maximum surface displacement of 160 feet and lies at the western edge of the Elk Hills (Woodring et al., 1932). Faults 2 through 4 are normal faults that dip toward the northwest and displace the subsurface at a range of 65 to 220 feet (Woodring et al., 1932). Additionally, there are a series of unnamed Quaternary age faults on the northern margin of Elk Hills. Little is known about these faults.

Unnamed Thrust Fault

An unnamed thrust fault is located along the western margin of the GSA area, along the boundary between alluvium and the Tulare Formation (Jennings, 2010). The fault runs approximately 5 miles parallel to the GSA boundary, from northwest to southeast.

2.6.3 Bakersfield Arch

Arches are subsurface regional and geologic features that naturally capture and accumulate oil and gas. The Bakersfield Arch, located in the southern end of the San Joaquin Valley and the GSA area, is a major west to southwest plunging structural bow (Hoots et al., 1954). The Bakersfield Arch is responsible for the northeast to southwest trending concentration of oil fields in the Subbasin and the GSA area. The Arch is aligned generally with the Elk Hills-North Coles Levee anticlinal trend (Hoots et al., 1954). The Bakersfield Arch is also a boundary separating northern folds aligned in a northwesterly direction (such as the Elk Hills-North Coles Levee) from southern folds aligned in a westerly direction (Hoots et al., 1954).

2.6.4 Outcrops of Bedrock Inside the GSA area

There are no known outcrops of bedrock in the GSA area.

2.7 Basin Boundaries

2.7.1 Lateral Boundaries

The GSA area is politically and topographically bounded in the Subbasin. To the north, east, and southeast, the GSA area is politically bounded by neighboring GSAs, directly abutting the Belridge Water Storage District GSA, the BVWSD GSA, the KWBA GSA, the Henry Miller Water District GSA, and the Wheeler Ridge-Maricopa Water Storage District GSA. To the south and west, the GSA area is defined by the western boundary of the Subbasin, which is bounded by the bedrock of the Temblor Range. The Temblor Range bedrock is a geologic groundwater divide that juxtaposes permeable sedimentary materials with impermeable bedrock. DWR defines this type of boundary as “Impermeable bedrock with

lower water yielding capacity. These include consolidated rocks of continental and marine origin and crystalline/or metamorphic rock" (DWR, 2003).

2.7.2 Boundaries with Neighboring Subbasins

The GSA area does not share a boundary with a neighboring subbasin.

2.7.3 Bottom of the Subbasin in the GSA Area

The bottom of the Kern County Subbasin has been determined during coordination with the KGA. The KGA's Umbrella GSP states the following about the bottom of the subbasin:

"An aquifer may not be suitable for beneficial use if:

a) is not currently serving as a source of drinking water,
b) it has commercially producible minerals or hydrocarbons, or
c) it is not expected to supply a public water system and
- is either economically or technologically infeasible for treatment or recovery now or in the future for domestic, agricultural, or industrial use.

The purpose of this plan is not to exempt aquifers, nor is it to define the maximum depth or water quality concentration at which groundwater is economically recoverable or treatable now or in the future. However, by applying the criteria of 40 CFR §144.3 and 40 CFR §146.4, active oil and gas aquifers and exempted aquifers are not a part of the groundwater basin for beneficial use. The following whichever is shallowest, are the lateral and vertical boundaries of the groundwater Subbasin:

a) depth to producible minerals or hydrocarbons or primacy productive limits,
b) depth to exempted aquifers,
c) depth that makes recovery of water for domestic, commercial, or industrial purposes no longer economically or technologically feasible, or
d) the depth at which groundwater cannot now or in the future serve as a source of drinking water. For example, water bearing zones below the depth to producible hydrocarbons are not within the groundwater basin; likewise, water bearing zones below an exempted aquifer are not within the groundwater basin"

2.8 Principal Aquifers and Aquitards

The primary use of water in the unconfined and confined aquifers in the WKWD GSA area is municipal. A portion of the municipal supply in the WKWD GSA is also used to generate energy, and water is also used to maintain Buena Vista Lake levels.

2.8.1 Aquifers

There are two principal aquifer systems in the GSA area, an upper semi-confined to unconfined aquifer and a deeper confined aquifer. These aquifers are defined by nearly impermeable clay layers (i.e., the Corcoran member) that impede vertical flow of groundwater. The primary, fresh water-bearing deposits in the Subbasin in the GSA area are coarse, unconsolidated, oxidized deposits of continental and alluvial deposits (i.e., the Tulare Formation and overlying alluvium), which correspond to the most permeable beds (Croft, 1972). Nearly all water wells are pumped from the unconsolidated to loosely consolidated water-bearing deposits of continental origin (Wood and Davis, 1959). The semi-confined and unconfined aquifer are primarily of the Recent and Older alluvium, in addition to the Tulare Formation. The confined aquifer is within the Tulare Formation. Water bearing intervals range in depth from 10 to 700 feet (Croft, 1972; Meiller et al., 2008).

Groundwater in the GSA area is produced from continental sedimentary deposits from the North and South wellfields, located approximately 15 to 18 miles northeast of the City of Taft, and the Buena Vista Lake area east of the City of Taft. The North and South wellfields correlate to the GSA's North and South Project management areas. Though groundwater exists within the basement complex and marine deposits, these units are typically non-water bearing in the GSA area and are not considered a part of the GSA area's aquifer system (Kennedy Jenks Consultants [Kennedy Jenks, 2010]). Rocks older than the Tulare Formation are generally considered either non-water bearing or have low yields with water quality that is too poor for municipal uses.

Semi-Confined to Unconfined Aquifer

A semi-confined to unconfined aquifer system exists within the alluvial fan complex in the GSA area, which is composed of unconsolidated to partly consolidated sand, silt, clay and gravel that yield fresh groundwater. The uppermost part of the aquifer, considered to be entirely unconfined, extends to a depth of approximately 200 to 300 feet bgs and consists of interbedded silts, sands, and some clay (Meiller et al., 2008; Kenneth D. Schmidt and Associates [Schmidt & Associates], 2001). Both the North and South wellfields are screened within the semi-confined to unconfined aquifer, with the South wellfield being exclusively within the unconfined to semi-confined aquifer.

The unconfined aquifer is separated from a middle, semi-confined aquifer by lower permeability sediments and spatially discontinuous occurrences of Corcoran Clay. The clay layers are responsible for creating semi-confined aquifer conditions within this middle aquifer (Meiller et al., 2008). The unconfined to semi-confined aquifer is separated from the deeper confined aquifer by a regionally extensive Corcoran Clay layer that is an impermeable layer acting to impede groundwater flow.

Confined Aquifer

A deeper confined aquifer system also exists in the GSA's North Project Management Area. The confined aquifer is separated from the overlying semi-confined and unconfined aquifer by an impervious layer of E clay (including Corcoran Clay) at a depth ranging from 200 to 650 feet bgs (Schmidt & Associates, 2001; Dee Jaspar & Associates, Inc. [Jaspar & Associates], 2010). The confined aquifer is primarily located

within the Tulare Formation. The lower, confined aquifer extends to a depth of approximately 600 to 800 feet bgs (Meiller et al., 2008; Provost & Pritchard, 2016).

2.8.2 Aquitards

As described in Section 2 of the Umbrella GSP, nearly impermeable flood-basin, lacustrine, and marsh deposits are widespread throughout the San Joaquin Valley. In the San Joaquin Valley, there are six differentiated clay tongues, designated A through F, that are extensively found at the base of the unconsolidated deposits. Within the extent of the GSA area, the E clay acts as the major aquitard in the Subbasin, along with the A clay to a lesser extent. These lacustrine clay tongues create a nearly impermeable layer that divides the alluvium and water-bearing strata into several aquifers that range from unconfined to semi-confined to confined.

E Clay

E clay is the principal confining bed in the Subbasin (Croft, 1972). E clay includes the Corcoran Clay member of the Tulare Formation, and is the most extensive hydrologic confining layer in the San Joaquin Valley (Croft, 1972). This confining stratum is composed of silty clay, clayey silt, and sand, silt, and clay and is typically found at depths of approximately 600 to 650 feet bgs in the GSA's North Project Management Area (Croft, 1972; Jaspar & Associates, 2010). E clay defines the base of the unconfined aquifer in the Subbasin and is responsible for the semi-confined properties of the middle aquifer due to the spatially discontinuous presence of clay. Though E clay has been mapped during earlier investigations in the GSA's South Project Management Area, it is generally absent in this portion of the GSA area.

A Clay

Water level data indicate that A clay is a confining bed throughout the Subbasin. Within the GSA area, A clay is locally discontinuous and is unlikely to act as a confining bed, though it may create semi-confined aquifer conditions. Historical studies and water-level records throughout the southern portion of the San Joaquin Valley indicate that a shallow water body occurs in the strata overlying A clay, particularly in irrigated areas (Croft, 1972). A clay is generally absent in the GSA area, except for the southeastern most part, near the South Project Management Area. Monitoring wells along the eastern edge of the WKWD near the intersection of the Kern River and Interstate 5 contain large amounts of clay (Provost & Pritchard, 2016).

2.8.3 Aquifer Properties

Hydraulic Conductivity

DWR defines hydraulic conductivity as the "measure of a rock or sediment's ability to transmit water" (DWR, 2003). Conductivity data are limited throughout the GSA area. DWR estimated hydraulic conductivity values for the GSA area during development of their San Joaquin Valley groundwater model. The average hydraulic conductivity for the unconfined aquifer, shallower than 300 feet deep, was estimated to be 880 gallons per day per square foot (gpd/ft) (Schmidt & Associates, 2001). No estimates of hydraulic conductivity were located for the confined aquifer.

Specific Yield

DWR defines specific yield as the "amount of water that would drain freely from rocks or sediments due to gravity and describes the portion of groundwater that could actually be available for extraction" (DWR, 2003). Specific yield is a measurement specific to unconfined aquifers, which includes the primary aquifer in the GSA area. Sediments that compose the shallow to intermediate depth water-bearing deposits in the Subbasin are primarily continental deposits of Tertiary and Quaternary age. From youngest to oldest, deposits in the unconfined aquifer include Recent Alluvium and flood deposits, Older Alluvium and stream deposits, and the Tulare Formation.

Specific yield values for the unconfined aquifer are estimated using data compiled from two sources, DWR's San Joaquin District office and the DWR groundwater model for the Subbasin (DWR, 2006). DWR's San Joaquin District office estimates that the specific yield values for the unconfined aquifer range from 5.3 to 19.6 percent and average 11.8 percent for the interval from surface to 300 feet bgs (DWR, 2006). DWR's 1977 groundwater model of Kern County estimates the specific yield to range from 8.0 to 19.5 percent, with an average of 12.4 percent, representing an interval thickness of 175 to 2,900 feet (DWR, 2006). The highest specific yield values for the entire Subbasin are associated with sediments of the Kern River Fan west of Bakersfield (DWR, 2006).

Specifically, in the WKWD's South Wellfield, Schmidt & Associates estimated specific yield for the upper, unconfined to semi-confined aquifer to be approximately 18 percent, which is a value near the upper range of DWR's estimate (Schmidt & Associates, 2001).

Specific Capacity

Specific capacity is defined as "the yield of the well, in gallons per minute, divided by the pumping drawdown, in feet" (Singer and Swarzenski, 1970). There is a lack of specific capacity data specific to the GSA area. However, a study performed by Wood and Davis in 1959 estimated specific capacities for irrigation wells in the Avenal-McKittrick area that includes portions of the GSA area. The study found specific capacities ranged from 2 to 120 gallons per minute per foot of drawdown in irrigation wells screened in depths from 100 to 1,700 feet (Wood and Davis, 1959). Specific capacities in the GSA area are likely to fall within the range calculated by Wood and Davis.

Pump tests and historical values for wells in the North Project Management Area and surrounding area estimate the specific capacity of the confined aquifer range from 50 to 126 gallons per minute per foot in wells screened from 250 to 600 feet bgs (Jaspar & Associates, 2010).

Transmissivity

DWR defines transmissivity as the "aquifer's ability to transmit groundwater through its entire saturated thickness" (DWR, 2003). Generally, transmissivity values are estimated to be higher in the confined aquifer than the unconfined aquifer.

In 2001, Schmidt & Associates calculated transmissivity values for the unconfined aquifer in the WKWD's South Wellfield. Transmissivity values were calculated using Darcy's law, and were estimated to be approximately 72,000 gpd/ft for strata around 160 feet deep located within the upper unconfined

aquifer (Schmidt & Associates, 2001). For overlying strata, at depths between 30 and 160 feet deep, transmissivity values were calculated using hydraulic conductivity estimates from DWR's model, and were estimated to be 114,000 gpd/ft (Schmidt & Associates, 2001). For strata deeper than 160 feet (and up to 300 feet in depth), a transmissivity value of 72,000 gpd/ft was estimated (Schmidt & Associates, 2001). Total transmissivity was estimated at 186,000 gpd/ft by Schmidt & Associates in 2001. Total transmissivity values were also calculated for areas neighboring the WKWD wellfield and generally increased to the north, up to 642,000 gpd/ft, northwest (212,000 gpd/ft), and to the west (up to 364,000 gpd/ft) (Schmidt & Associates, 2001).

Transmissivity values for the confined aquifer in the GSA's North Project Management Area were estimated to be approximately 225,000 gpd/ft based on pump tests (Jaspar & Associates, 2010). A 2009 GEI Consultants, Inc. (GEI) report states historical transmissivity values for the North Project Management Area to range from 128,000 gpd/ft up to 212,000 gpd/ft (GEI, 2009). Overall, the transmissivity of the North Project Management Area is modeled to be 202,000 gpd/ft (GEI, 2009).

2.9 Natural Water Quality Characterization

Within the GSA area's North and South Project management areas wellfields, groundwater quality is described as "excellent," according to the WKWD 2016 *Draft Urban Water Management Plan*. Groundwater quality within the wellfield is representative of water recharged by the Kern River, which is typically calcium sodium bicarbonate type and low in TDS (WKWD, 2016). The groundwater is typically a sodium bicarbonate water, although the upper portion of the aquifer contains a thin interval of calcium bicarbonate water wells (WKWD, 2016). Kern River water recharges the aquifer, and groundwater transitions from calcium sodium bicarbonate to sodium bicarbonate after undergoing an ion exchange process as it infiltrates the deeper parts of the aquifer (WKWD, 2016). TDS concentrations within the wellfield average 400 mg/L (Jaspar & Associates, 2010).

The major COC in the GSA's wellfield is arsenic, which is naturally occurring in local lacustrine deposits in the region (WKWD, 2016). WKWD has taken wells offline due to arsenic concentrations exceeding the MCL of 10 micrograms per liter (Kennedy Jenks, 2010).

Additional constituents of concern include elevated concentrations of naturally occurring TDS, sulfate, chloride, uranium, and fluoride. Schmidt & Associates reports ranges in concentration of the following constituents in wellfield groundwater as shown below (Schmidt & Associates, 2001):

- TDS: 800 to 1,300 mg/L
- Uranium: 20 – 30 mg/L
- Sulfate: > 250 mg/L
- Chloride: > 250 mg/L
- Manganese: > 0.05 mg/L

Outside of the GSA's wellfield areas, groundwater is highly saline in some areas. Groundwater in sediments derived from the marine sedimentary rocks of the Coast Range is more saline than groundwater

derived from continental sediments. Spatially, the western portion of the Subbasin and GSA area has higher TDS and salinity concentrations than the eastern portion due to the increased presence of marine sediments. In particular, groundwater within the marine Olcese sand is more saline than aquifers above or below the occurrence of the Olcese Formation (Gillespie et al., 2017). The nonmarine Tulare Formation is typically a USDW source with TDS concentrations less than 10,000 mg/L, while underlying marine formations are more saline, such as the Olcese Formation with TDS concentrations greater than 10,000 mg/L (Gillespie et al., 2017).

Wells screened within the Tulare Formation contain concentrations of TDS ranging from 3,000 to 10,000 parts per million (ppm) at depths less than 2,000 feet (Gillespie et al., 2017). The Buena Vista Oilfield has a salinity gradient that increases with depth, and the USDW occurs at approximately 1,000 feet. (Gillespie et al., 2017).

2.10 Topography, Surface Water and Recharge

This section describes the topography, surface water, soils, and groundwater recharge potential in the Subbasin.

2.10.1 Topography

The GSA area ranges from 2,531 to 269 feet above mean sea level. The GSA area generally slopes to the southeast from the Temblor Range to the valley floor, with east-west trending ridges (Figure 2-3).

2.10.2 Surface Water Bodies

Surface water bodies in the GSA area flow from west to east, and are ephemeral streams including Bitter, Cienega, Bitterwater, Sandy, Broad, and Buena Vista creeks. These creeks are present in the Western Management Area, and have no known flow requirements. The California Aqueduct flows along and inside the eastern boundary of the GSA area, and the Buena Vista Aquatic Recreational Area is present to the south of the Lake Management Area (Figure 2-4).

2.10.3 Groundwater Discharge, and Areas of Recharge and Potential Recharge

Groundwater discharge takes place in the area of springs. Figure 2-5 shows the locations of springs near the GSA area; there are no springs in the GSA area. Figure 2-6 shows that areas of potential recharge lie generally within the flatlands of the GSA area as identified by the Soil Agricultural Groundwater Banking Index (SAGBI). SAGBI provides an index for groundwater recharge for agricultural lands by considering deep percolation, root zone residence time, topography, chemical limitations, and soil surface condition. SAGBI considers the open flatlands throughout the GSA area to be Excellent or Good. SAGBI considers the Elk Hills and Buena Vista Lake areas of the GSA area to be Poor or Very Poor.

Most recharge within the GSA area occurs from via surface flows from the California Aqueduct. Wells in both the North Project and South Project management areas conduct recharge from this surface water supply to bank water in the aquifer.

Recharge is conducted in two locations in the WKWD GSA and are delineated as management areas. The North Project Management Area is shown in Figure 1-2 and has recharge ponds that recharge into the shallow aquifer in that region. The South Project Management Area has recharge ponds that recharge into the unconfined aquifer in that region.

2.10.4 Soils

Figure 2-7 shows soils by hydrologic soil group. Hydrologic soil groups were calculated by the National Resource Conservation Service (NRCS) on a county-by-county basis. In general, hydrologic soil groups are sorted by permeability, with class A being the most permeable and class D being the least permeable. Figure 2-7 shows that, in general, most of the soils in the GSA area have lower permeabilities and are listed as class C or D, with higher permeabilities located on the north end of the GSA area and near streams and rivers. Notably, there is a change in categorization between the northwest part of Kern County and the southwest part of Kern County. Each part was likely analyzed by a different NRCS study, and as a result there are reported discrepancies.

Soils in the GSA area were categorized by the NRCS. The GSA area is comprised mostly of fine- to coarse-loamy soils (NRCS, 2018). As shown in Figure 2-8, the GSA area’s flatlands are primarily fine-loamy soils, while the GSA area’s hills are primarily eroded complexes.

2.11 Hydrogeologic Conceptual Model Data Gaps

There are no significant data gaps for the HCM in the WKWD GSA area.

		Identification of groundwater-dependent ecosystems	Section 3.8

3.2 Introduction

This section describes historical and current groundwater availability, groundwater quality, and groundwater distribution in the GSA area to define measurable objectives, identify sustainability indicators, and establish undesirable results. As defined by the GSP regulations this groundwater conditions section is intended to:

- Describe current and historical groundwater conditions
- Describe the distribution, availability, and quality of groundwater
- Identify interactions between groundwater, surface water, groundwater dependent ecosystems, and subsidence

- Establish a baseline of quality and quantity conditions that will be used to monitor changes in the groundwater conditions relative to measurable objectives and minimum thresholds
- Support the GSPs monitoring to demonstrate that the GSP is achieving sustainability goals

3.3 Groundwater Trends

3.3.1 General Groundwater Elevation Hydrographs

Groundwater elevations in the Subbasin are dynamic by nature and have been affected over time by climatic variations, land use, and the development of surface water supplies and recharge facilities. Since 1970, regional GWEs in the Subbasin have risen and fallen in two complete cycles. Groundwater banking operations in the GSA area began in 1978 when conjunctive use began. By 2000, groundwater levels equaled those that were observed in 1970 (Bureau of Land Management, 2013). Proactive conjunctive use programs have allowed the GSA to maintain a positive balance in their groundwater banking operations. This proactive approach provided a reliable water supply and allowed the GSA to meet demands during the recent drought (WKWD, 2016). GWE levels have increased in each of the management areas since January 1, 2015.

Figure 3-1 shows the North Project Management Area well hydrographs. The hydrographs show an overall decline of GWEs during the 2012-15 drought and a steady recovery of GWEs to near pre-drought conditions from 2015 to present. GWEs in production wells are more sensitive to this cyclic effect than GWEs in monitoring wells because of the localized cone of depression created during pumping. Because of this, GWE data reported from the monitoring wells better represent local groundwater conditions within the GSA area over the same time.

Figure 3-2 shows South Project Management Area well hydrographs. Like the North Project Management Area, the hydrographs show an overall decline of GWEs during the 2012-15 drought and a steady recovery of GWEs to near pre-drought conditions from 2015 to present. GWEs in production wells are more sensitive to this cyclic effect than GWEs in monitoring wells because of the localized cone of depression created during pumping. Again, GWE data reported from the monitoring wells better represent local groundwater conditions within the GSA's South Management Area over the same time.

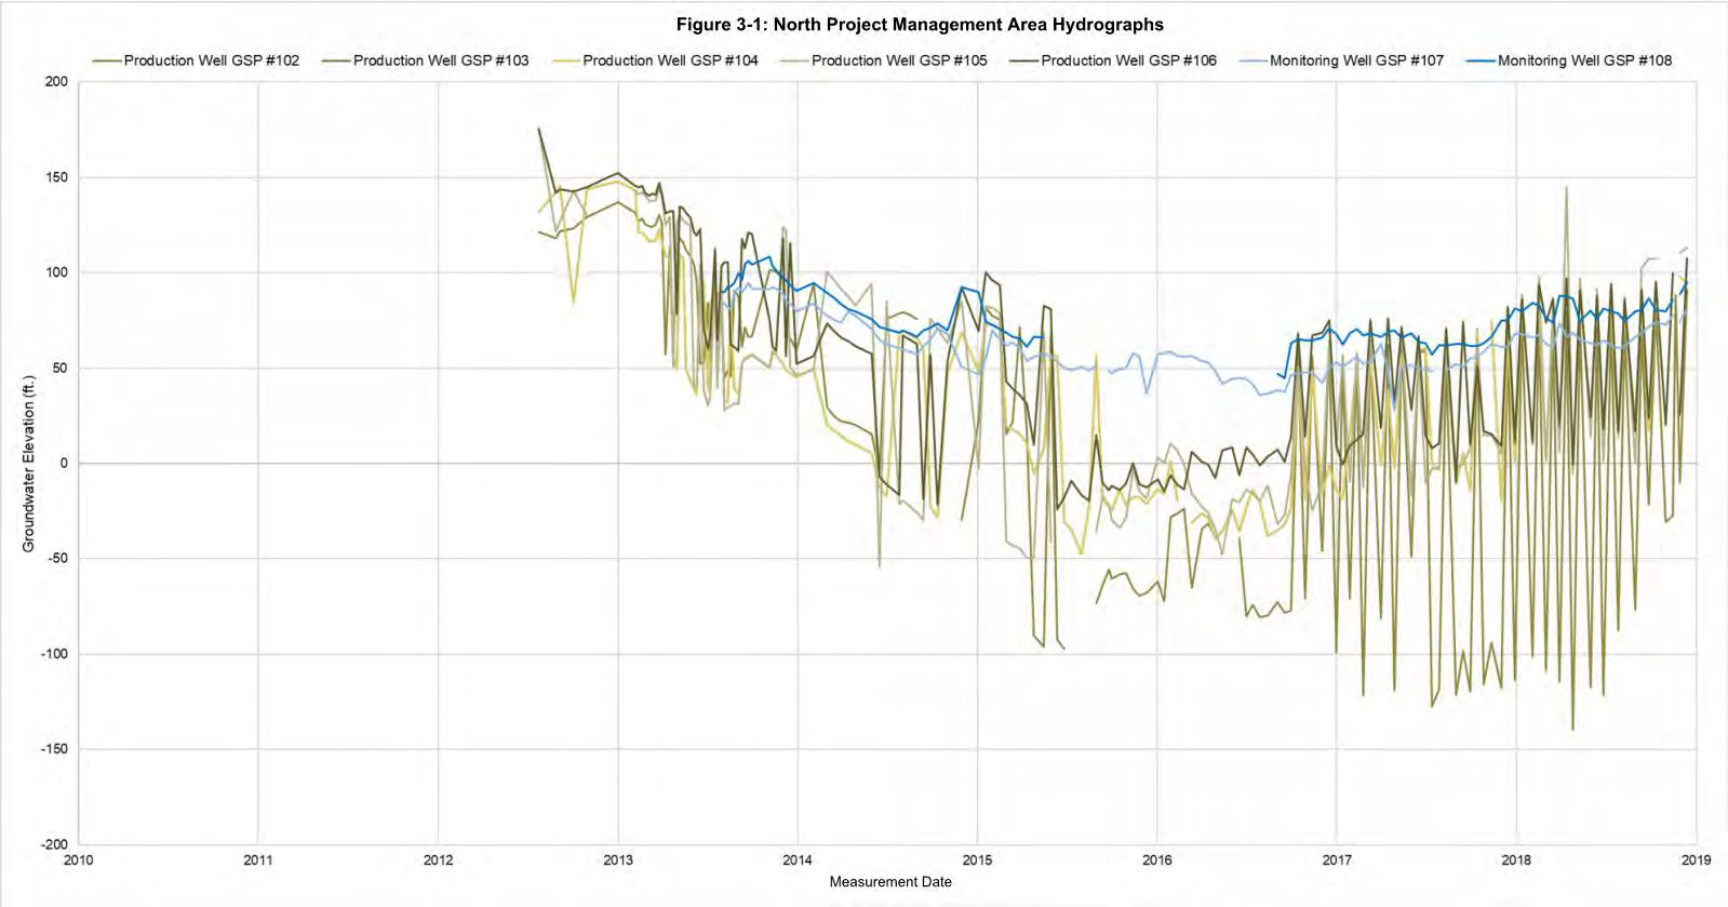

Figure 3-1. North Project Management Area Hydrographs

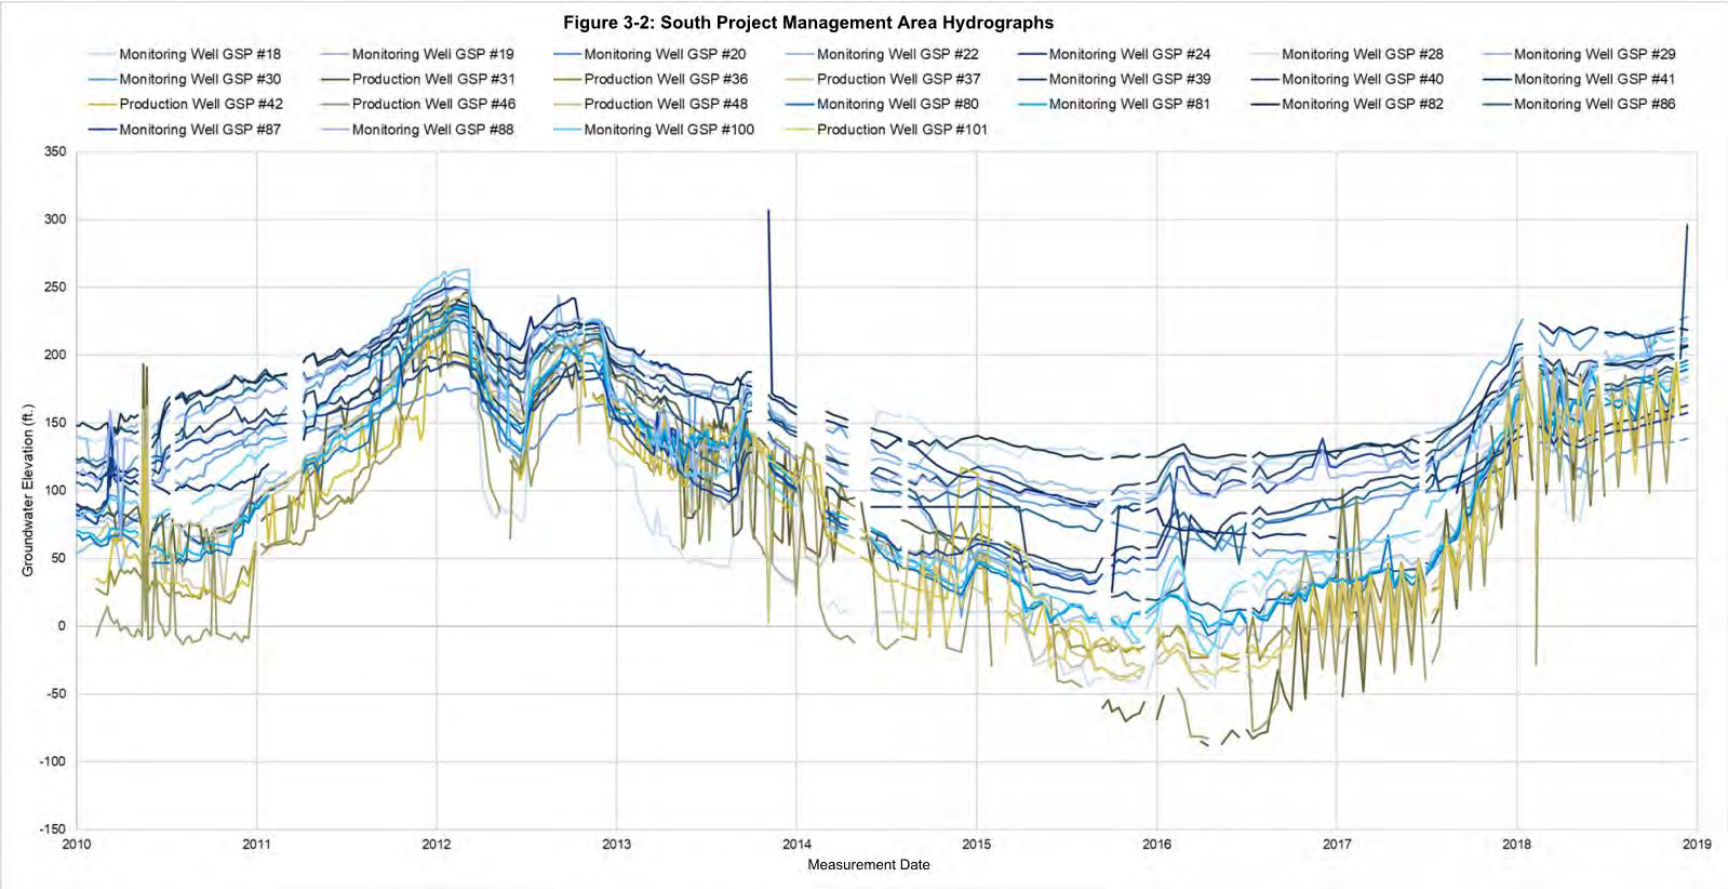

Figure 3-2. South Project Management Area Hydrographs

Little or no pumping occurs in the Western Management Area and there is no current GWE data available for the Lake Management Area.

3.3.2 Hydrographs

Figure 3-3 shows the locations of GSA monitoring network wells. Hydrographs were prepared for each well shown, and are included in Appendices C and D. Well construction information is shown in Section 6.0 of this Chapter GSP in Table 6-4. One well was selected from the North and South Project management areas to show example GWE conditions in those areas.

Figure 3-4 shows a hydrograph for Well 107, a dedicated monitoring well located in the North Project Management Area. This hydrograph shows that the GWE decreased by approximately 40 feet from 2013 to 2016 and recovered 30 feet from 2016 to 2018.

Figure 3-5 shows a combined hydrograph for a multi-completion well that was completed at three specific depths (i.e., Wells 18, 19, and 20) in the South Project Management Area. This hydrograph shows GWEs from 2000 to 2018 for each completion. In general, groundwater levels declined and recovered in all three completions in a similar manner to that in the North Project Management Area from 2013 to 2018.

The remaining hydrographs in Appendices C and D show GWE trends similar to Wells 18, 19, 20, and 107.

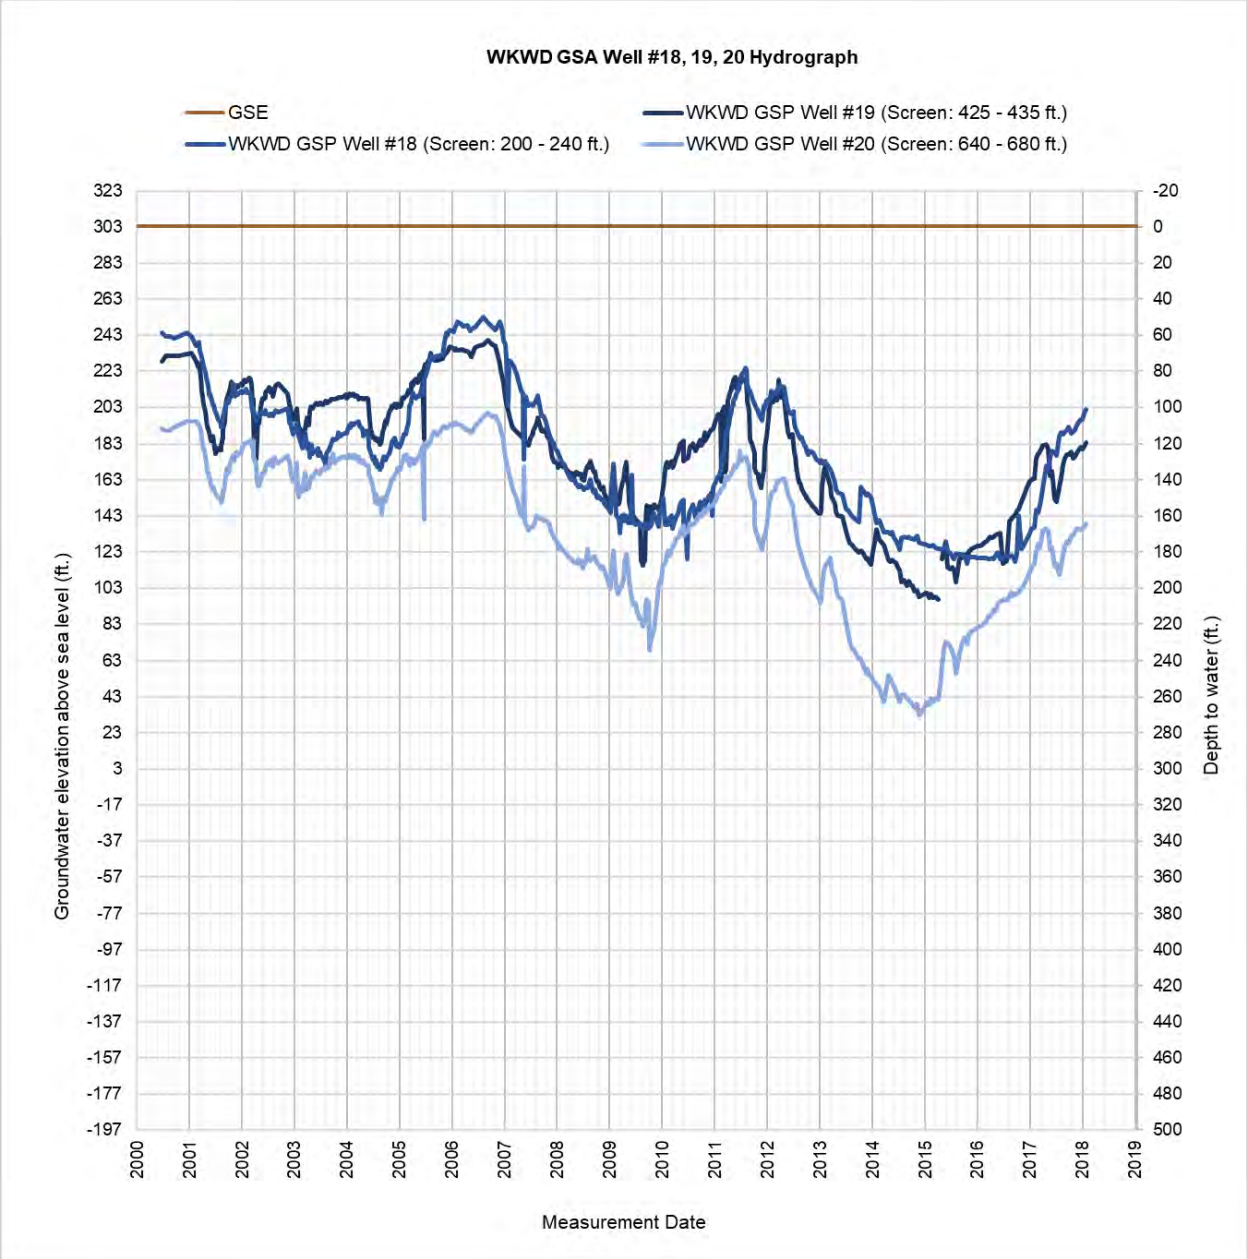

Figure 3-5. Combined Hydrograph of WKWD GSA Multiple Completion Wells 18, 19, and 20

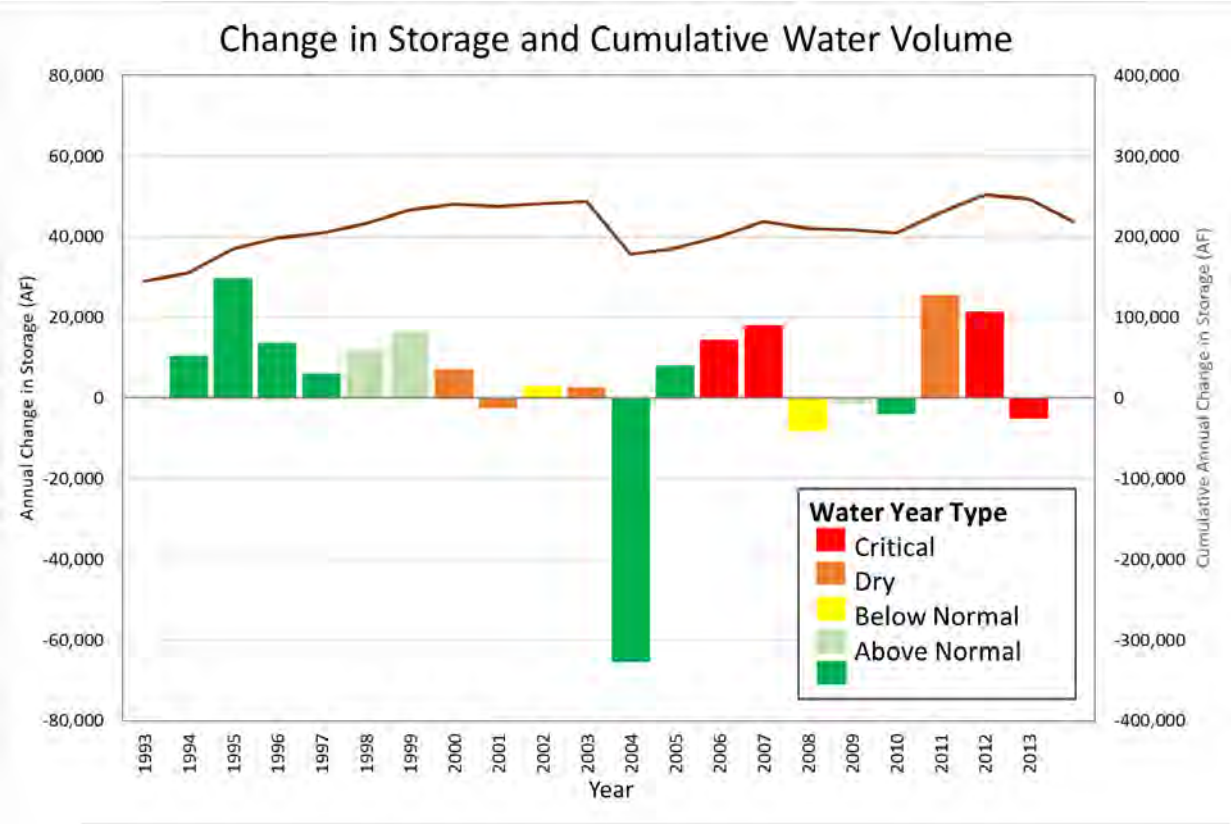
3.3.3 Vertical Gradients

A vertical gradient describes the movement of groundwater perpendicular to the ground surface. Vertical gradient is typically measured by comparing GWE readings in a well with multiple completions located at different depths. If GWEs in the shallower completions are higher than in the deeper completions, groundwater is moving down into the ground and is referred to as a downward gradient. This would occur when there is more water percolating down through the soil toward the aquifer. If GWEs in the shallower completions are lower than in the deeper completions, groundwater is upwelling toward the surface and is referred to as an upward gradient. This would occur when a significant amount of groundwater pumping is shallower in the aquifer, causing an upwelling of water toward the well screens, or in special cases, a confined aquifer may provide an upward gradient if it were leaky. If GWEs are similar throughout the completions, there is no vertical gradient. Vertical gradients were analyzed at each of the GSA area's monitoring network wells. Each of the wells showed a downward vertical gradient. This proves the GSA area's sustainable management because it shows a trend of groundwater recharge into the Subbasin. Recharge of groundwater in GSA area percolation ponds creates a larger hydraulic head at the surface that percolates downward over time, reporting higher water levels in shallower well completions, and lower water levels in well completions deeper in the Subbasin. Figure 3-3 shows the locations of the GSA monitoring network wells.

Appendix C shows hydrographs for the North Project Management Area representative network wells. The two monitoring network wells in the North Project Management Area are single wells; therefore, only a single depth to water measurement is collected at this location. Two new multiple completion wells have been installed, but they do not have enough recorded, usable data to calculate vertical gradients. Since vertical gradient analysis requires measurements to be taken from at least two different depths (i.e., completions), there are no vertical gradients presented for the North Project Management Area.

Appendix D shows hydrographs for the South Project Management Area representative network wells. Five of the seven representative wells are multi-completion and show a downward vertical gradient through the reported GWE data. Each of the multi-completion wells show higher GWEs for the shallowest completion and the lowest GWE for the deepest completions. Water flows from high elevation to low elevation, meaning water is flowing downward in the South Project Management Area.

3.3.4 Groundwater Elevation Contour Maps



Contour maps for the South Project Management Area for January 2015 and 2018 are included in Appendix E and described in this section. January was chosen to reflect GWE under SGMA baseline condition and under current conditions. Pumping in the Western Management Area is considered de minimis; therefore, no GWE monitoring occurs and no contour maps were prepared the area.

Figures C-3 and C-4 in Appendix C show January 2015 and 2018 GWEs for the South Project Management Area. The surface elevation in the South Project Management Area fluctuates by 11 feet (i.e., 303 to 314 feet), meaning horizontal gradients are the result of groundwater management and do not occur naturally with surface elevations. Groundwater levels have risen over 100 feet in many portions of this area from 2015 to 2018.

3.4 Historical Change in Storage

Historical change in storage in the GSA area is tied to two factors: climate cycles and availability of water for import. Note: WKWD transferred 100,000 AF to Rosedale Rio Bravo WSD in 2004

Figure 3-6 shows the change in storage by year, water year type, and cumulative water volume for the last 20 years. Change in storage was calculated by comparing imported water and consumptively used water in the GSA area. Average annual use over the 20-year period was 20,154 AF. In general, groundwater rises in years that are wetter, and declines in years that are dryer.

Note: WKWD transferred 100,000 AF to Rosedale Rio Bravo WSD in 2004

Figure 3-6. Change in Storage by Year, Water Year Type, and Cumulative Water Volume

3.5 Groundwater Quality

Overall, groundwater quality in the North and South Project management areas is excellent and meets all federal and state drinking water health standards (WKWD, 2018). While arsenic and antimony were detected at concentrations below their MCL for drinking water, WKWD took a proactive approach to manage any concerns; those actions are discussed below. Groundwater quality within the Western Management Area portion of the GSA is generally unusable due to high salinity levels. There is little or no groundwater production in the Western Management Area, so water quality in that area is not discussed in this section.

WKWD monitors water quality at each of its production wells. Appendix F includes WKWD's water quality monitoring results for each well from 2012 through 2019. Monitoring results indicate there are very few instances where samples exceed the MCL for any constituents, except for antimony (discussed below), and that no constituents are consistently above the MCL in any well. Groundwater quality was consistent over the measurement period, including through the drought and the historically low groundwater levels of 2015, which indicates that groundwater quality does not degrade with decreased groundwater elevations in the WKWD GSA.

Antimony

Antimony is a trace component of many rocks and minerals common to the GSA area. Like arsenic, it occurs in groundwater through contact with rocks and sediments in the subsurface and through industrial process and other human activities.

During the January 1 to December 31 sampling period for the 2017 WKWD *Annual Water Quality Report*, one of WKWD's 13 wells reported concentrations that exceeded the 6 mg/L MCL for antimony. All other production wells did not detect antimony. To address the issue for drinking water standards, WKWD implemented a blending operation and began a trend monitoring program for four consecutive quarters beginning in June 2017. Laboratory analytical data showed WKWD's blending operations were effective at reducing the antimony concentration in water delivered to WKWD's customers to 0 mg/L.

The antimony detection is localized to a single well and is not indicative of a long-term regional trend. No further actions to address antimony are required in this Chapter GSP.

Oil and Gas Production

The GSA area overlies a petroleum producing area. Impacts to WKWD's groundwater supply by these operations, both actual and potential, are continuously monitored and evaluated. WKWD takes a proactive approach in addressing and correcting any contamination threats to its groundwater supply. To date, no significant threat to groundwater quality has occurred because of local oil and gas operations. No further actions to address oil and gas production are required in this Chapter GSP.

Water produced water in western Kern County is typically managed by either recycling it for enhanced oil recovery (EOR) operations, such as steam/cyclic steam flooding, or by permitted disposal under the regulatory oversight of the Department of Oil and Gas (DOGGR). It is important to clarify that the type of EOR described here is not hydraulic fracturing.

- **Reinjection—**Produced water used for steam or water flood EOR is reinjected under permit into the same geologic zone it was produced from in order to help maintain oil reservoir pressures and sweep residual oil towards planned extraction wells. In this way, produced water can potentially be used through several cycles of production and reinjection. During this process, a portion of the water that is reused in this way is inevitably lost to the geologic formation or to the process of steam generation etc. Because of the loss of reused water to the geologic formation, water is purchased from WKWD to be added to the water reused, called "make up water" in oil production circles is used depending on field conditions.

- **Disposa—**Disposal of brackish and saline oil field produced water in western Kern County has typically employed two methods (1) evaporation ponds or (2) reinjection into exempt aquifers identified by DOGGR. Due to water quality concerns, many of the produced water disposal ponds in Kern County have been closed. Consequently, reinjection into exempt aquifers has become the primary method of produced water disposal.

In summary, a significant percentage of the oil field produced water in the WKWD GSA's western management area is either recycled into the same geologic zones it was produced from, or is sequestered in deeper zones that are isolated from sources of drinking water. This water is supplemented by water purchased from WKWD, which indicates that very little water is disposed of, since purchasing fresh water is more expensive than recycling water.

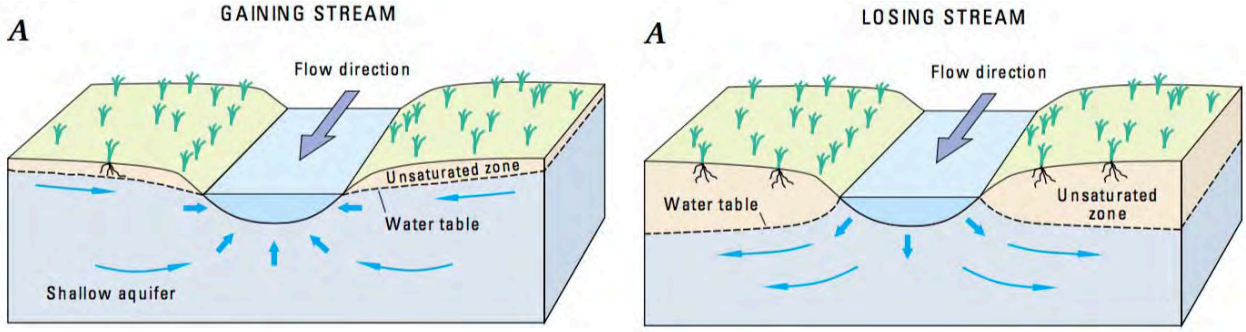
Because the regulation of oil produced water under SGMA is not fully clear at this time, WKWD GSA will reevaluate this evaluation of oil produced water during the first five-year update of its Chapter GSP. WKWD GSA will also coordinate with oil producers to identify approaches to enhance water quality monitoring and reporting of oil produced water to ensure that groundwater quality is protected.

EnviroStor and GeoTracker Databases

The Kern County GSA reviewed the SWRCB GeoTracker website, the California Department of Toxic Substances Control's EnviroStor website, and the EPA's National Priorities List for locations of potential groundwater impacts throughout the Subbasin. Figure 2-25 of the Umbrella GSP shows no regional plumes of contaminants are associated with sites in the GSA area.

Sites of interest identified in Figure 2-26 of the Umbrella GSP indicate that they are sites related to oil production and include percolation ponds and underground injection control. These sites are in the far western portion of the Western Management Area and cannot affect water management activities in other WKWD GSA management areas.

3.6 Land Subsidence



Although groundwater pumping has caused subsidence elsewhere in the southern San Joaquin Valley, data indicate that the Kern Fan aquifer behaves elastically in response to groundwater banking operations. Figures 2-27 and 2-28 in the Umbrella GSP show Subbasin subsidence rates from 2007 to 2011, and from 2015 to 2016 respectively. The data show the impact of subsidence due to groundwater pumping on ground surface elevation in the GSA area has been minimal, and over time, the average land surface elevation risen approximately 0.8 feet (KWBA, 2018).

While water entrained in oil as oil is extracted from the ground is properly excluded from the Water Budget, DWR's Water Budget BMP directs the GSA to consider whether such produced water will cause undesirable results. Subsidence can be caused by a variety of factors and will be appropriately monitored throughout the basin. Several processes contribute to land subsidence in the subbasin and include, in order of decreasing magnitude: aquifer compaction by overdraft, hydrocompaction (shallow or near-surface subsidence) of moisture deficient deposits above the water table that are wetted for the first time since deposition, petroleum reservoir compaction due to oil and gas withdrawal, and subsidence caused by tectonic forces (Ireland et al., 1984).

Subsidence Subbasinwide is fully discussed in the KGA's Umbrella GSP.

3.7 Interconnected Surface Water Systems

Interconnected surface waters are water features that are hydraulically connected by a saturated zone to the groundwater system—in other words, where water table elevations and surface water features intersect at the same elevations and locations. Interconnected surface waters are classified as either gaining or losing; the surface water feature is either gaining water from the aquifer system or losing water into the aquifer system as shown in Figure 3-7.

(Source: USGS, 2018)

Figure 3-7. Gaining and Losing Streams

There are no interconnected surface water systems in the North or South Project management areas. Intermittent streams are identified in the Western Management Area. These streams are non-jurisdictional waters of the United States, and only flow during heavy precipitation events; therefore, management of interconnected surface water is not necessary. The Buena Vista Aquatic Recreational Area (BVARA) does lie partly in the GSA area; however, Buena Vista Lake itself is not within the GSA boundary.

3.8 Groundwater Dependent Ecosystems

Groundwater dependent ecosystems (GDEs) are defined in the GSP regulations as "ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface." A working group comprised of DWR, California Department of Fish and Wildlife, and The Nature Conservancy reviewed publicly available state and federal agency datasets that mapped California vegetation, wetlands, springs, and seeps, and conducted a screening process to identify types and locations commonly associated with groundwater. The results were compiled into the Natural Communities Commonly Associated with Groundwater database, and two habitat classes were defined. The first class includes wetland features commonly associated with the surface expression of groundwater under natural, unmodified conditions. The second class includes vegetation types commonly associated with the sub-surface presence of groundwater (i.e., phreatophytes). Figure 3-8 shows potential locations of GDEs in the GSA area (CNRA, 2018). All GDEs identified by the working group are in the Western Management Area where, the likelihood of groundwater emerging from the aquifer or occurring near the surface is highly unlikely.

Section 4.0 Water Budget

4.1 WKWD and the Basinwide Coordinated Water Budget

All GSAs in the Subbasin coordinated and collaborated on the development of a groundwater model to evaluate historical, baseline and projected groundwater conditions. The GSAs entered into a Cost Share Agreement with the Kern River GSA who took the lead and contracted with Todd Groundwater to develop the model on behalf of the Subbasin. The contract required that Todd Groundwater use the C2VSim model provided by DWR. Considerable effort and resources were expended to update the C2VSim model with local data to better represent Subbasin conditions. The process Todd Groundwater used to update C2VSim is more fully described in the Historical and Projected Future Water Budget Development (see Attachment H in Umbrella GSP). Basinwide water budget results from the model are provided in Attachment H and show the Subbasin, as a whole, has a total storage deficit of approximately 324,326 AFY over the baseline period.

The Subbasin's dynamic conjunctive use programs, water banking operations, and water transfers/exchanges made it necessary to coordinate a GSA level water accounting system (Checkbook) using Subbasin specific values for supply, demand and net results. The Model results reflect Subbasin-wide conditions and do not allocate water shortages/surpluses, nor do the results allocate the "ownership" of water. As a result, the GSAs, through a coordinated effort, developed the Checkbook that estimates current conditions for each GSA that are generally consistent with the Model results under baseline condition. The Checkbook and Model budgets are based upon best available information, recognizing however, each estimate includes data gaps and has varying degrees of accuracy and/or reliability in the interest of developing a Subbasin coordinated approach.

To ensure the individual water budgets reflected actual conditions, the KGA members developed the Checkbook budget and coordinated water accounting methodology. The result of that effort indicates a current baseline shortage/deficit for KGA members of approximately-256,281 AFY.1 This reflects the difference between a total demand for KGA members of 1,939,409 AFY, and a total supply of 1,683,128 AFY. Of the shortage/deficit of the KGA, West Kern's portion of the KGA shortage/deficit is -2,421 AF. Or a difference in demand of 36,077 AF and a water supply of 33,656 AF.

As is mentioned above, each estimate includes data gaps and has varying degrees of accuracy and/or reliability. The Checkbook is complimentary to the Model and reflects the allocation of water supply benefits and obligations independent of geographic constraints within the Subbasin. This was important to recognize and ensure the coordination of the various groundwater banking projects and water management programs amongst the various GSA's within the groundwater basin.

4.2 Compliance Information

Table 4-1 summarizes DWR's *Preparation Checklist for GSP Submittal* items that are covered in this section. For the complete *Preparation Checklist for GSP Submittal*, see Appendix A.

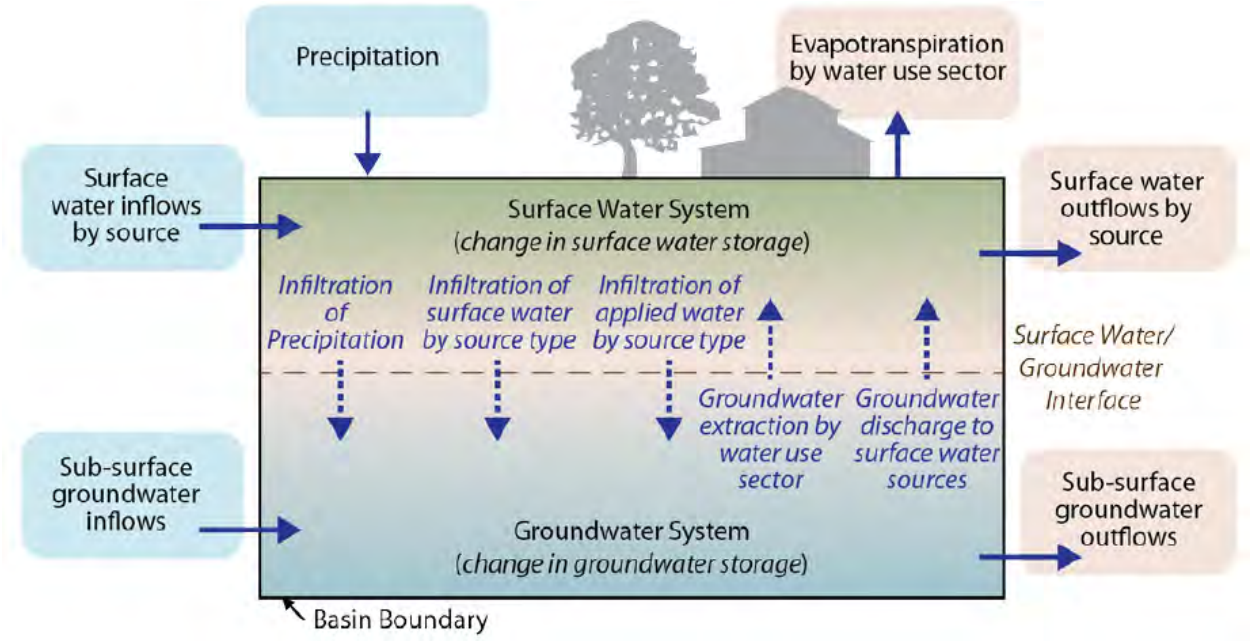
4.3 Introduction

This Chapter GSP section includes information about the water budget. This water budget information also supports the Subbasin-scale water budget as presented in the Umbrella GSP. This water budget information meets Section 354.18 of the SGMA regulations.

In general, water budgets quantify the following:



- Total surface water entering and leaving a basin by water source type
- Inflow to the groundwater system by water source type
- Outflows from the groundwater system by water source type
- Outflows from the groundwater system by water use sector
- The change in annual volume of groundwater in storage between seasonal high conditions
- If overdraft occurs, water budgets quantify overdraft over a period of years during which water year and water supply conditions approximate average conditions
- The water year type associated with annual supply, demand, and change in groundwater stored
- An estimate of sustainable yield for the Subbasin

Water budgets for the Subbasin were developed considering historical, current and projected conditions, and were developed at the Subbasin scale. This section describes WKWD data used to support and develop the historical Subbasin water budget. Current and future condition water budgets were developed based on broader, basin-wide assumptions, and are presented in the Umbrella GSP.

4.4 Water Budget Information

The Umbrella GSP's water budgets were developed to provide a quantitative accounting of water entering and leaving the Subbasin. Generally, water entering the Subbasin includes water entering on the surface and through the subsurface, and water leaves in a similar manner. Water entering and leaving does so through precipitation, streamflow, and through human activities such as recovery and recharge of surface supplies for irrigation (DWR, 2016). Figure 4-1is a diagram in cross section that shows the various water balance components used when developing a water budget.

Values presented in this Subbasin water budget describe historical, current, and projected conditions as they relate to hydrology, water demand, water supply, land use, population, climate change, sea-level rise (which does not apply in the Subbasin), groundwater and surface water interaction, and subsurface groundwater flow. This information can help the WKWD GSA manage water resources in the Subbasin by identifying, among other things, the scale of different water uses and potential opportunities to improve water supply conditions while highlighting potential risks.

(Source: DWR Water Budget Best Management Practice)

Figure 4-1. Generalized Water Budget Diagram

Water budgets can be developed on different spatial scales. For agricultural use, water budgets may be limited to the root zone in soil, with the goal of improving irrigation efficiencies by estimating crop evapotranspiration and the downward movement of applied water through the shallow subsurface. For groundwater, a water budget may be limited to assessing the behavior of water flow in the subsurface.

Global climate models simulate water budgets that incorporate elements such as atmospheric water, allowing for simulation of climate change conditions. Consistent with SGMA requirements, the water budget for the Umbrella GSP describes both surface water and groundwater systems in the Subbasin.

Water budgets can also be developed at different temporal scales. Daily water budgets may be used to demonstrate how evaporation and transpiration increase during the day and decrease at night. Monthly water budgets may be used to demonstrate how groundwater pumping increases in dry, hot summer months and decreases in the cool, wet winter months. In this section, also consistent with SGMA requirements, the water budget focuses on a full water year (i.e., 12 months spanning from October of the previous year to September of the current year), with some consideration of monthly variability.

SGMA requires that annual water budgets are based on historical, current, and projected conditions. The water budget for the Subbasin was developed to capture typical conditions during these time periods. Typical conditions were developed by averaging hydrologic conditions over time that incorporate droughts, wet periods, and normal periods. By incorporating these varied conditions, analysis of the groundwater system under certain hydrologic conditions such as drought can be performed, along with an analysis of long-term averages. The following subsections discuss the Kern County implementation of the C2VSim model, the associated data used to develop the water budget for this Chapter GSP, and how this information supports coordination with the Umbrella GSP's water budgets.

4.5 Definitions and Assumptions

According to SGMA, water budgets are "an accounting of the total groundwater and surface water entering and leaving a basin, including the changes in the amount of water stored." In the case of the Subbasin, the water budget zone is the area of interest extending from the land surface to the bottom of the Subbasin. WKWD GSA has prepared its water budget for coordination with the KGA in a 'checkbook' format, where water imported by agencies in the WKWD GSA is compiled with other factors and consumptive use. In the WKWD GSA area, the water budget zone is a compilation of information from the four management areas: the North Project, the South Project, the Western, and the Lake management areas (Figure 4-2).

This page intentionally left blank.

An accounting of water budget inflow and outflow components is based on both measured and estimated data. The accounting of water can be divided into three systems as follows:

- Land system
- Surface water system
- Groundwater system

The total water budget is a consolidation of inflows and outflows from each of these three systems, and the resulting water budget depicts inflows and outflows from the water budget zone. The primary surface water features in the Subbasin are Kern River and Poso Creek.

The land system water budget is an analysis of inflows to and outflows from the land surface in a water budget zone, including any change in storage in the land surface and unsaturated zone. It accounts for the exchange of water over a land surface, as well as the following:

- Exchange of water between surface and groundwater systems resulting from various native and managed land use activities (e.g., urban, agricultural, and managed wetlands)
- Movement of water through the unsaturated zone including infiltration into and past the root zone,
- Evaporation
- Evapotranspiration recharge from streams

A groundwater budget is an analysis of inflows to and outflows from the groundwater system in a water budget zone, including the amount of change in groundwater storage.

Inflows to a groundwater system include the following:

- Subsurface groundwater flow
- Seepage from surface water conveyance systems
- Recharge of applied water
- Migration of precipitation through the unsaturated zone
- Managed aquifer recharge from dedicated recharge facilities

Outflows from a groundwater system include the following:

- Groundwater extraction
- Losses to the surface water system
- Subsurface groundwater flow

Additional outflows from a groundwater system may also occur due to shallow groundwater discharge from seeps, wetlands, springs, and evapotranspiration.

4.6 North and South Project Management Areas: Historical Water Budget Estimates

The following components are included in each of the three system water budgets for the Subbasin.

4.6.1 Land System Water Budget

The Subbasin's land system water budget considers the following:

- Inflows
  - Precipitation
  - Applied water
- Outflows
  - Evapotranspiration
    - Agriculture
    - Native vegetation
  - Domestic water use
  - Deep percolation
    - From precipitation
    - From applied water
- Runoff
  - Stream seepage to groundwater
  - Flow out of Subbasin

4.6.2 Surface Water System Water Budget

The Subbasin's surface water system water budget considers the following:

- Inflows
  - Surface water inflow
  - Bypasses
  - Stream gain from groundwater
- Outflows
  - Evaporation
  - Surface water diversions
  - Return flow and runoff
  - Stream loss to groundwater

4.6.3 Groundwater System Water Budget

The Subbasin's groundwater system water budget considers the following:

- Inflows
  - Infiltration from precipitation
  - Infiltration from applied water
  - Recharge from local rivers and streams
  - Managed aquifer recharge (i.e., groundwater banking)
  - Boundary inflows from adjacent, non-alluvial areas
  - Subsurface inflows from adjacent basins

- Outflows
  - Evapotranspiration by water use sector
  - Groundwater production by water use sector
  - Discharge to local rivers and streams
  - Subsurface outflows to adjacent subbasins
  - Change in storage

Components of the water budgets listed above are presented at the Subbasin scale in the Umbrella GSP. The following discussion about WKWD North and South management areas' water budgets focus on the data used to support development of the Subbasin-scale water budgets.

4.6.4 North and South Management Areas: Water Budget Components

All groundwater recharge and water use in the North and South Project management areas is metered and operated by WKWD. WKWD has a contract with the KCWA to deliver water from the SWP. A portion of the SWP supply is delivered to BVWSD in exchange for BVWSD's water from the Kern River. Kern River water is physically recharged on the wellfields in the North and South Project management areas. A total of 5 percent of recharged water is considered a non-recoverable loss to benefit the Subbasin, leaving 95 percent of this water available for recovery and use in and outside WKWD.

WKWD participates in a number of water exchanges in addition to direct operations of its recharge activities, imports and pumping. BVWSD also sends additional water to WKWD in exchange for future deliveries. These exchanges are tracked as "WKWD Non-SWP recharge" in the water balance. During some water years, the WKWD groundwater banking program also conducts physical exchanges with other neighboring agencies such as the Kern Water Bank and Irrigation District (ID) 4. These are considered "Transfers In" in the water balance. WKWD also maintains a balance of "additional assets" that are tracked separately from the rest of the banked water. These additional assets consist of water exchanges with other agencies including the Rosedale-Rio Bravo Water Storage District, the North Kern Water Storage District, and the Palmdale Water District. The balance of additional assets is accounted for separately from WKWD's groundwater balance, as it includes both physical and paper exchanges.

The North and South Project management areas contain wells used to recover banked groundwater. Water recharged in these areas is extracted for both in-district use and to support exchange programs with other local water districts. Absent pumping to meet demands at BVARA, WKWD maintains a positive banked water balance in these areas and has banked water reserves in excess of 200,000 AF.

WKWD's remaining SWP supply is delivered directly through a turnout off the California Aqueduct for use by the La Paloma Power Facility. Groundwater pumping in the Western Management Area is considered de minimis. Municipal and industrial (M&I) demands are met by recovering banked water from the North and South projects. Approximately 80 to 85 percent of the water recovered is used to meet industrial demands, and the remaining 15 to 20 percent is used to meet residential demands. The Lake Management Area does not have any managed water supplies and no measured data are currently available. Evapotranspiration demands for the Lake Management Area are included in the Kern C2VSim model, and results are presented in the Umbrella GSP. The water budget information presented below pertains primarily to the sources and uses for water in WKWD.

Table 4-2 shows the balance of inflows and outflows from the WKWD for the period from 1994 to 2014. Water balance components listed in Table 4-1 are defined in more detail below.

- California Aqueduct Inflow for Direct Use—SWP water diverted and used for the La Paloma Power Facility
- California Aqueduct Inflow for Recharge—SWP exchange with BVWSD that is recharged and credited to WKWD
- WKWD Non-SWP Recharge—Other recharge credited to WKWD, typically through exchanges with BVWSD
- WKWD Transfers In—Transfers from other agencies that are credited to the total WKWD balance
- Additional Assets In—Other transfers into WKWD that are tracked separately from the WKWD groundwater balance
- WKWD Native Yield—3,000 AFY that is credited to WKWD each year.
- Total In—Sum of all inflows, not including prescriptive right or not accounting for losses
- WKWD Pumping—Net pumping from the WKWD North and South projects
- Additional Assets Out—Transfers out that are tracked separately from WKWD groundwater balance
- Direct use of California Aqueduct Water—California Aqueduct Water used for La Paloma Power Facility
- Total Out—Sum of all outflows, not accounting for losses
- WKWD Total Assets—Total Inflows with losses minus total outflows. A 5 percent loss factor is applied to California Aqueduct inflow for recharge and WKWD non-SWP recharge

Between 1965 when WKWD began banking water, and 1993 when the water balance table begins, WKWD built a surplus balance of 144,692 AF.

Tables 4-2 through 4-3 list average water supplies and demands for the wellfields and district area separately, and then show them consolidated into a total supply chain.

Notes:
[a] Effluent from the local sanitation district is used to irrigate non-edible fodder crops in the WKWD service area and are not accounted for here.

Table 4-5. North and South Project Management Areas: Water Balance

Component	Historical (1994-2014) Average Annual Volume (AF)
Surface Water Sources	
California Aqueduct for Direct Use	2,256
California Aqueduct for Recharge	16,717
Groundwater Pumping	
WKWD Distribution System	18,711
Exports to California Aqueduct	413
Exports to Cross Valley Canal	401
Demands	
Urban residential and M&I use within the district	18,711
La Paloma Power Facility	2,256

This 1994 to 2014 historical water balance for WKWD shows that, on average, 18,973 AF of water are diverted off the California Aqueduct and recharged or delivered directly into the WKWD GSA. Historically, 2,256 AFY of SWP deliveries are sent directly to the La Paloma Power Facility, and the remaining 16,717 AFY are recharged in the wellfields in the North and South Project management areas. Except for a small amount of water delivered for agricultural purposes, all water delivered in WKWD's service area meets M&I demands. The cities of Taft and Maricopa account for most urban residential demand in the GSA area. Water exported through the California Aqueduct and Cross Valley Canal to support occasional transfer and exchange programs is considered another outflow from the system. Additional recharge from non-SWP sources account for 4,500 AFY of inflow. WKWD also receives 3,170 AFY of transfers and 4,013 AFY of additional assets. A total of 30,230 AF of water enters WKWD each year.

Average annual demand in the WKWD GSA is 20,967 AFY. This demand is met by 2,256 AFY of SWP deliveries and 18,711 AFY coming from recovery of banked groundwater supplies. Groundwater is pumped from the North and South Project management area wellfields and conveyed through WKWD's distribution system. In addition to in-district use, water from the wellfields is also pumped and exported out of WKWD for various exchange and transfer programs. These programs are part of WKWD's overall water management strategy. In addition to in-district use, WKWD also has outflows that occur as part of groundwater transfers. Excluding pumping for BVARA, an average of 6,851 AFY leaves the WKWD as part of transfers. A total of 27,819 AFY of leaves WKWD.

WKWD maintains a positive banked water balance through established banking programs dating back to 1965. From 1965 through 1993, WKWD built banked groundwater reserves of 144,692 AF. Between 1994 and 2014, WKWD had an average annual inflow of 30,230 and an average outflow of 27,819. The net difference between inflows and outflows is 2,411 AFY, WKWD tracks a balance of assets each year and manages its water supply so supplies are never depleted. When tracking the balance of the banked groundwater reserves, groundwater recharged from the SWP or other sources are assigned a 5 percent loss factor. Groundwater transfers already account for a loss factor. Between 1994 and 2014, WKWD increased its groundwater balance from 144,692 to 219,353 AF.

Historically, WKWD has managed its operations to maintain a surplus water supply. Groundwater pumped from the North and South projects draw upon previously banked supplies that are managed so that an overdraft condition will not occur. Similarly, groundwater transfers build upon previously established balances and are managed so that overdraft does not occur. Information about surface water deliveries, groundwater recharge and recovery, and exported supply information was incorporated into the Kern County C2VSim model for development of the overall basin water budgets.

4.7 Western Management Area Water Budget

As discussed in Section 4.6.4 any groundwater use in the Western Management Area is de minimis and therefore is not monitored or managed by the WKWD GSA.

4.8 Lake Management Area Water Budget

The Lake Management Area is pumped by Kern County to provide water supplies to BVARA, specifically to Lake Webb. BVARA is in and adjacent to the WKWD GSA area. The 1,585-acre BVARA is home to two manmade lakes, Lake Webb and Lake Evans, boating facilities, playgrounds and volleyball courts, camp sites, and picnic areas. The lakes lie outside of the GSA area but the park facilities such as picnic areas, restrooms, and parking areas are within the GSA area. When constructed, the lakes had a combined storage capacity of over 6,800 AF. Shoreline camping and picnic areas are landscaped with grass and are irrigated during the dry season (County of Kern Parks and Recreation Department, 2019). With no outlet, water from the lakes either evaporates or percolates into the groundwater basin. Kern County pumps groundwater from wells located within the GSA area to supplement losses at the lake. Water demand from BVARA has been estimated to be approximately 8,000 AF per year, as identified by ITRC study used in the KGA's Umbrella GSP.

Water pumped into the lake is considered overdraft at this time, and is being addressed through Project 3, described in Section 8.7.3. Table 4-6. Pumping in the Lake Management Area shows pumping into the lake per year.

Table 4-6. Pumping in the Lake Management Area

Year	Pumping (AF)
2009	8,526
2010	8,565
2011	3,461
2012	11,052
2013	7,460
2014	10,616
2015	10,706
2016	10,250
2017	3,965
2018	7,210

4.9 Treated Produced Water

Treated produced water in western Kern County is typically managed by either recycling it for enhanced oil recovery (EOR) operations, such as steam/cyclic steam flooding, or by permitted disposal under the regulatory oversight of the Department of Oil and Gas (DOGGR). It is important to clarify that the type of EOR described here is not hydraulic fracturing.

- **Reinjection—**Produced water used for steam or water flood EOR is reinjected under permit into the same geologic zone it was produced from in order to help maintain oil reservoir pressures and sweep residual oil towards planned extraction wells. In this way, produced water can potentially be used through several cycles of production and reinjection. During this process, a portion of the water that is reused in this way is inevitably lost to the geologic formation or to the process of steam generation etc. Because of the loss of reused water to the geologic formation, water is purchased from WKWD to be added to the water reused, called “make up water” in oil production circles is used depending on field conditions.
- **Disposal—**Disposal of brackish and saline oil field produced water in western Kern County has typically employed two methods (1) percolation ponds or (2) reinjection into exempt aquifers identified by DOGGR. Due to water quality concerns, many of the produced water disposal ponds in Kern County have been closed. Consequently, reinjection into exempt aquifers has become the primary method of produced water disposal.

In summary, a significant percentage of the oil field produced water in the WKWD GSA's western management area is either recycled into the same geologic zones it was produced from, or is sequestered in deeper zones that are isolated from sources of drinking water.

Oilfield produced water is produced from sediments and formations that are below the bottom of the basin as defined in Section 2.7.3.

354.26	Undesirable Results	Description of undesirable results	Section 5.0
		Cause of groundwater conditions that would lead to undesirable results	
		Criteria used to define undesirable results for each sustainability indicator	
		Potential effects of undesirable results on beneficial uses of users of groundwater	

5.2 Introduction

This section presents information about undesirable results, and descriptions as follows:

- A set of the coordinated undesirable results statements for the Subbasin
- A description of how undesirable results are identified in the WKWD GSA
- A description of how undesirable results may be caused
- A discussion of what would happen if undesirable results were to occur

Undesirable results statements are a key component of a GSP and are used to set quantitative thresholds for specific monitoring points that indicate when an undesirable result either has occurred or may occur. Additionally, undesirable results are used to establish monitoring protocols.

Undesirable results are defined in the SGMA regulations as one or more of the following effects caused by particular groundwater conditions occurring throughout a basin:

- "Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply if continued over the planning and implementation horizon. Overdraft during a period of drought is not sufficient to establish a chronic lowering of groundwater levels if extractions and groundwater recharge are managed, as necessary, to ensure that reductions in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods.
- Significant and unreasonable reduction of groundwater storage.
- Significant and unreasonable seawater intrusion.
- Significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies.
- Significant and unreasonable land subsidence that substantially interferes with surface land uses and critical infrastructure
- Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water."

Undesirable results related to seawater intrusion are not present in the WKWD GSA.

The information in this section was developed based on the Water Code,[1] on related regulations adopted by DWR, BMPs developed by DWR, physical conditions, and through coordination with other Subbasin GSAs.

5.3 Sustainability Goal

The goal of the WKWD GSA's Chapter GSP is coordinated with the KGA. The coordinated sustainability goal for the KGA is:

The sustainability goal of the Kern County Subbasin is to:

- Achieve sustainable groundwater management in the Kern County Subbasin through the implementation of projects and management actions at the member agency level of each GSA
- Maintain its groundwater use within the sustainable yield of the basin through as demonstrated by monitoring and reporting groundwater conditions
- Operate within the established sustainable management criteria, which are established based on the collective technical information presented in the GSPs in the Subbasin.
- Collectively bring the Subbasin into sustainability and to maintain sustainability over the implementation and planning horizon.

Further, the Subbasin sustainability goal includes a commitment to monitor and report groundwater conditions, as required by SGMA, and to continue coordination among the KGA member agencies and all other GSA's in the Subbasin to identify the potential for, or presence of, undesirable results and actions to

[1] https://leginfo.legislature.ca.gov/faces/codes_displayText.xhtml?lawCode=WAT&division=6.&title=&part=2.74.&chapter=6.&article=

prevent undesirable results. The coordination process established in the development of this GSP and memorialized in the Coordination Agreement will ensure that the Subbasin is managed as a shared groundwater resource and that the districts within the Subbasin work collaboratively towards achieving and maintaining sustainable groundwater use.

5.4 Chronic Lowering of Groundwater Levels

5.4.1 Description of Undesirable Results

The undesirable result for chronic lowering of water levels is the point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

5.4.2 Identification of Undesirable Results

An undesirable result would occur when the minimum threshold for groundwater levels are exceeded in at least three adjacent management areas that represent at least 15 percent of the Subbasin, or that represent greater than 30 percent of the Subbasin (as measured by each management area; see Section 7.0 for more information about Subbasin management areas). Each GSAs will set minimum thresholds by each of Chapter GSP that participates in the KGA

5.4.3 Potential Causes of Undesirable Results

WKWD has a history of successful groundwater management. Potential causes of future undesirable results from the chronic lowering of groundwater levels would likely be tied to outside forces, such as reduced deliveries of water from the SWP.

Undesirable results driven by local water use, such as increased use of water, or other local changes in the hydrologic system, such as an increase in impervious surfaces are possible, but neither are likely under projected land and water use estimates.

5.4.4 Description of Potential Effects of Undesirable Results

Should groundwater levels reach established minimum thresholds and trigger an undesirable result, one potential impact could include dewatering of a subset of the existing groundwater infrastructure, starting with the shallowest wells. This would affect pumping capacity, water quality, and may lead to costly equipment repairs. This may also potentially impact WKWD’s ability to meet water demands.

5.5 Reduction of Groundwater Storage

The undesirable result for reduction of groundwater storage is the point at which significant and unreasonable impacts, as determined by the amount of groundwater in the Subbasin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended drought period.

5.5.1 Identification of Undesirable Results

Storage in the Subbasin is monitored by proxy using groundwater levels. An undesirable result would occur when the volume of storage (i.e., above the groundwater level minimum thresholds) was depleted to an elevation lower than the groundwater level minimum threshold in at least three adjacent management areas that represent at least 15 percent of the Subbasin or represent greater than 30 percent of the Subbasin (as measured by the acreage of each management area).

5.5.2 Potential Causes of Undesirable Results

WKWD has a history of successful groundwater management. Potential causes of future undesirable results for the reduction of groundwater storage would be the same as for the chronic lowering of groundwater levels. These levels would likely be tied to outside forces, such as reduction in deliveries of water from the SWP. Undesirable results driven by local water use, such an increase in the consumptive use of water, or other local changes in the hydrologic system such an increase in impervious surfaces are possible, but neither are likely under projected land and water use estimates.

5.5.3 Description of Potential Effects of Undesirable Results

If groundwater levels were to reach levels indicating undesirable results, potential effects could include the potential dewatering of a subset of the existing groundwater infrastructure, starting with the shallowest wells. Additionally, reaching undesirable results for groundwater levels potentially could adversely affect current and projected municipal uses, which rely on groundwater in the GSA area. See Section 5.4.4 above.

5.6 Seawater Intrusion

Seawater intrusion is not an applicable sustainability indicator in the Subbasin, because seawater intrusion is not present and is not likely to occur in the Kern Subbasin due to the distance between the basin and the Pacific Ocean, bays, deltas, or inlets.

5.7 Degraded Water Quality

5.7.1 Description of Undesirable Results

The undesirable result for degraded water quality is the point at which significant and unreasonable impacts over the planning and implementation horizon, as caused by water management actions, that affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

5.7.2 Identification of Undesirable Results

In the Subbasin, degraded water quality is monitored by proxy using groundwater levels. This is determined when the minimum threshold for a groundwater quality COC is exceeded in at least three adjacent management areas, and which represent at least 15 percent of the Subbasin, or represent greater than 30 percent of the designated monitoring points in the Subbasin. Minimum thresholds are set by each of Chapter GSP that participates in the KGA.

5.7.3 Potential Causes of Undesirable Results

WKWD has a history of successful sustainable groundwater management. Potential causes of future undesirable results for degraded groundwater quality likely would be tied to potential significant increases in groundwater production, resulting in upconing of deeper saline water present in the aquifer below the fresh water aquifer accessed for water supply. The potential causes of substantial increases in groundwater production are the same as those previously described in Section 5.4 above. Additionally, degraded groundwater quality may also be caused by unforeseen point source contamination issues. These changes could occur either naturally or might result from human activity.

5.7.4 Description of Potential Effects of Undesirable Results

If groundwater quality were degraded to reach undesirable results levels, the effect could potentially cause a reduction in usable supply delivered to groundwater users, including impacting municipal suppliers. Municipal suppliers might then have to install treatment systems or seek alternate water supplies. Water quality degradation could cause adverse effects to property values and have other economic effects.

5.8 Land Subsidence

5.8.1 Description of Undesirable Results

The undesirable result for land subsidence is the point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the Subbasin, affects the surface land uses or critical infrastructure.

5.8.2 Identification of Undesirable Results

An undesirable result is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin-wide coordinated GSP subsidence monitoring plan. This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan.

5.8.3 Potential Causes of Undesirable Results

WKWD has a history of successful groundwater management. Historically, successful management has prevented subsidence from occurring in the GSA area. Potential causes of future undesirable results for land subsidence likely would be tied to significant increases in groundwater pumping, resulting in dewatering of compressible clays in the subsurface. The potential causes of substantial increases in groundwater pumping are the same as those previously described in Section 5.4 above.

5.8.4 Description of Potential Effects of Undesirable Results

If land subsidence conditions were to reach undesirable results levels, the adverse effects could potentially cause damage to infrastructure, including water conveyance facilities and flood control facilities. This could impact the ability to deliver surface water, resulting in increased groundwater use, and by extension this could have adverse effects to property values.

5.9 Depletions of Interconnected Surface Water

Depletions of interconnected surface water are not an applicable sustainability indicator for the WKWD GSA area, because the three active GSA management areas (i.e., the North Project, South Project, and Lake management areas) do not have overlying surface water. Streams overly the Western Management Area, but no pumping occurs in this area over de minimis levels. If groundwater pumping were to increase above de minimis levels in the Western Management Area, the GSA would consider revising management of this sustainability indicator at the five-year GSP update interval.

5.10 Evaluation of the Occurrence of Undesirable Results

As shown in Section 6, no monitoring points are currently below the minimum threshold. This indicates that undesirable results are not occurring in the WKWD GSA area.

6.2 Introduction

This section of the Chapter GSP discusses the planned monitoring networks needed to guide or maintain the WKWD GSA portion of the Subbasin toward groundwater sustainability. Monitoring networks need to be established for each sustainability indicator either directly or via monitoring through a proxy.

Additionally, this section also addresses the requirements set out in SGMA regulations, and discusses monitoring network objectives, the existing monitoring networks used to develop each network, and describes a monitoring network for each sustainability indicator. Data gaps, and a plan to fill data gaps if they are present, are provided for each monitoring network.

6.3 Monitoring Network Objectives

This section describes Subbasin monitoring networks for the five sustainability indicators that apply in the Subbasin. The objective of these monitoring networks is to detect undesirable results as described in Section 5 using the sustainability thresholds described in Section 7 of this Chapter GSP. The SGMA regulations also define other related monitoring network objectives; they are listed below.

- Demonstrate progress toward achieving measurable objectives described in the GSP
- Monitor impacts to the beneficial uses or users of groundwater
- Monitor changes in groundwater conditions relative to measurable objectives (MOs) and minimum thresholds (MTs)
- Quantify annual changes in water budget components

The monitoring networks described in this section were designed by evaluating data provided by the WKWD, DWR, and USGS. Wells used for monitoring are included here and were considered based on criteria described below.

WKWD and Kern County are the only users of groundwater that exceeds de minimis amounts of water in the WKWD GSA area. Therefore, the monitoring networks presented in this section are selected to be able to monitor conditions that would adversely affect WKWD and Kern County.

6.4 Existing Monitoring Used

This section discusses current groundwater level monitoring in the GSA area of the Subbasin.

6.4.1 Groundwater Level Monitoring

This section describes groundwater level monitoring conducted by agencies and other groups in the GSA area.

DWR Statewide Dataset/CASGEM

The State of California has several water-related database portals that are accessible online as follows:

- CASGEM Program
- WDL
- Groundwater Information Center Interactive Map Application

Data for these portals are organized and saved in one master database; each portal accesses and displays the intended data depending on the search criteria and portal used.

Although all groundwater production pumping in the GSA area is conducted by WKWD, analysts accessed State's database was to ensure other production wells were not missed during analysis. Analysis results indicated that monitoring wells included in the State's dataset in the GSA area were wells managed and operated by WKWD, and either had discontinued measurements, or took groundwater level measurements in an area that does not have any production pumping.

USGS

USGS data can be accessed through online portals for the National Ground-Water Monitoring Network, the Groundwater Watch, and the NWIS.

USGS online data portals provide approved data that have been quality assured and confirmed fit to be published, and provisional data that are unverified and subject to revision. To obtain all available data, researchers used the USGS URL Generation Tool to download all provisional and approved data in the GSA area.

Data processing results indicate that wells in the GSA area were either part of WKWD's existing network, were abandoned or destroyed, or monitored groundwater levels in areas with no production pumping.

WKWD

WKWD manages 72 production, monitoring, completion wells in its service boundary. Some of the data for these wells are included in DWR and USGS datasets. Figure 6-1 shows these well locations.

This page intentionally left blank.

6.4.2 Subsidence Monitoring

Subsidence is the sinking or downward settling of the earth's surface and is often the result of over-extraction of subsurface water. Subsidence can be measured in a few different methods such as with InSAR, continuous GPS, extensometers, and spirit leveling.

There are no continuous GPS stations in the GSA area. Other continuous GPS stations in the Subbasin are positioned too far from the GSA area to provide informative or applicable data.

Other subsidence methods used in the Kern Basin include extensometers (as shown in Figure 2-26 of the Umbrella GSP) and InSAR (as shown in Figures 2-27 and 2-28 in the Umbrella GSP). One extensometer located approximately 1 mile from the GSA area provides data representative of subsidence conditions in the GSA. Additionally, InSAR data do cover the GSA area. Further discussion about the data is provided in Section 6.10.

6.4.3 Surface Water Monitoring

The GSA area does not have any consistent natural surface water flows, and while a small portion of the Kern River channel is in the northeastern corner of the GSA area, this portion of the Kern River is dry in most years. As such, flows in that portion of the Kern River are not monitored within the GSA boundary. A gage is present on the Kern River where it flows into the South Management Area. No other surface gages exist in the GSA area.

6.5 Monitoring Rationales

This section discusses the reason why certain monitoring networks were selected. The selected monitoring networks were developed to ensure they can detect changes in Subbasin conditions. With this information, the GSA can manage the portion of the Subbasin used by WKWD to ensure sustainability goals are met, and to ensure no undesirable results are present after 20 years of sustainable management.

The monitoring networks were selected specifically to detect short-term, seasonal, and long-term trends in groundwater conditions. The monitoring networks were selected to include an adequate amount of temporal frequency, spatial density, hydraulic gradients, flow directions, and for use in estimating the annual change in groundwater storage. These factors help evaluate information about groundwater conditions, which in turn are necessary to evaluate the effectiveness of projects and management actions undertaken by the GSA.

This Chapter GSP does not include water quality, water in storage, seawater intrusion, depletions of interconnected surface water, or subsidence monitoring performed by the GSA, and therefore does not include monitoring protocols for those sustainability indicators. WKWD GSA will coordinate with the KGA to modify these as necessary in the future.

6.6 Groundwater Level Monitoring Network

Groundwater level monitoring is conducted through a groundwater well monitoring network. This section describes the following:

- How the level monitoring network was developed
- Criteria for selecting representative wells
- Monitoring frequency
- Spatial density
- Monitoring protocols
- Data gap identification and strategies to fill data gaps

6.6.1 Management Areas

There are four management areas in the GSA area: the North Project, the South Project, the Lake, and the Western management areas. Figure 6-2 shows management area locations.

6.6.2 Monitoring Wells Selected for Monitoring Network

Monitoring wells were selected based on their construction. All dedicated monitoring wells in the WKWD GSA were selected to be used for the monitoring network, and production wells were not selected for the monitoring network. In the South Project Management Area, there is one aquifer, and in the North Project Management Area there are two aquifers. Figure 6-3 shows these wells' locations.

Most of the monitoring network wells are in the North and South Project management areas because these are the only management areas that actively pump water above de minimis levels. The Lake Management Area has pumping, but currently does not have monitoring, and the Western Management Area does not have any pumping. All wells that are currently operational and managed by WKWD are incorporated into the monitoring network.

6.6.3 Monitoring Frequency

DWR's *Monitoring Networks and Identification of Data Gaps Best Management Practices* (DWR, 2016) provide guidance about monitoring frequency based on discussion presented in the *National Framework for Ground-water Monitoring in the United States* (National Water Quality Monitoring Council, 2013). Table 6-2 lists guidance based on aquifer properties and degree of use.

The guidance described above recommends that initial characterization of monitoring locations use frequent measurements to establish the dynamic range at each monitoring site and to identify external stresses affecting groundwater levels. An understanding of these conditions based on professional judgment should be reached before normal monitoring frequencies are followed.

Table 6-2. Monitoring Frequency Based on Aquifer Properties and Degree of Use

Aquifer Type	Nearby Long-Term Aquifer Withdrawals		
	Small Withdrawals	Moderate Withdrawals	Large Withdrawals
Unconfined Aquifer			
Low recharge (<5 inches/year)	Quarterly	Quarterly	Monthly
High recharge (>5 inches/year)	Quarterly	Monthly	Daily
Confined Aquifer			
Low hydraulic conductivity (<200 feet/day)	Quarterly	Quarterly	Monthly
High hydraulic conductivity (>200 feet/day)	Quarterly	Monthly	Daily

Monitoring frequency for groundwater levels is coordinated Subbasin-wide through the Umbrella GSP. The Umbrella GSP requires Chapter GSPs to report monitoring twice per year, one taken at a time from January 15 through March 30, and one taken at a time from September 15 to November 15. More information about monitoring frequency is provided in the Umbrella GSP.

During normal operations, WKWD samples monitoring and production wells on a monthly schedule and will use data collected on this schedule to meet reporting requirements of the Umbrella GSP. WKWD will continue to monitor on this schedule to comply with the Umbrella GSP and to provide additional data for GSA planning and monitoring purposes.

6.6.4 Spatial Density

The goal of the groundwater level monitoring network is to provide adequate coverage of the aquifer in the GSA area. Adequate coverage includes the ability to monitor and identify GWE changes across the basin over time.

The *Monitoring Networks and Identification of Data Gaps Best Management Practices* published by DWR provide different sources and condition-dependent densities to guide monitoring network implementation (Table 6-3) (DWR, 2016). This information was adapted from the *CASGEM Groundwater Elevation Monitoring Guidelines* (DWR, 2010). While these estimates provide guidance about monitoring well site spatial densities, monitoring points should primarily be influenced by local geology, groundwater use, and GSP-defined undesirable results. Finally, professional judgment is essential for determine if the chosen wells are adequate.

Table 6-3. Recommended Well Densities

Reference	Monitoring Well Density (per 100 square miles)
Heath (1976)	0.2-10
Sophocleous (1983)	6.3
Hopkins (1994)	
Basins pumping more than 10,000 AFY per 100 square miles	4.0
Basins pumping between 1,000 and 10,000 AFY per 100 square miles	2.0
Basins pumping between 250 and 1,000 AFY per 100 square miles	1.0
Basins pumping between 100 and 250 AFY per 100 square miles	0.7

The GSA area covers 287 square miles. Based on Hopkins' well density estimate guidelines, the Subbasin should have four monitoring wells per 100 square miles, or 11.5 wells in the GSA area. According to Sophocleous, the Subbasin should have 6.3 monitoring wells per 100 square miles, or 18 wells in the GSA area. According to Heath, the Subbasin should have between 0.2 and 10 monitoring wells per 100 square miles, or 5.7 to 28.7 wells in the GSA area.

The GSA area is unique in that nearly all recovery is concentrated in the three relatively small management areas (i.e., the North Project, South Project and Lake management areas), and only de minimis pumping occurs in the largest management area, the Western Management Area. Because of this unique circumstance, all active monitoring wells in the North Project, South Project, and Lake management areas will be incorporated into the monitoring network, despite their relatively close proximity to one another. Table 6-4 includes information about well density per management area and indicates that the density of monitoring wells in the North and South Project management areas is significantly above recommended density.

Table 6-4. Monitoring Network Groundwater Level Well Density

Management Area	Monitoring Network Wells	Monitoring Network Well Density (per 100 square miles)
North Project Management Area	2	207 wells
South Project Management Area	17	1,223 wells
Lake Management Area	0	0 wells
Western Management Area	0	N/A
Total WKWD GSA Area	**19**	**603 wells**

6.6.5 Groundwater Level Monitoring Network

The groundwater level monitoring network is comprised of 19 monitoring wells in the GSA area. All wells are considered representative wells. Overall well density is 603 wells per 100 square miles. Figure 6-3 shows the locations of the groundwater level monitoring network monitoring wells and representative wells. Table 6-5 includes the wells in the groundwater level monitoring network and their associated metadata.

WKWD will continue to monitor groundwater levels monthly. This monitoring frequency will capture short-term, seasonal, and long-term trends in groundwater levels. These wells will also provide useful information for determining flow directions, hydraulic gradients, and change in storage calculations. This information will be used in future water budgeting efforts in portions of the Subbasin with significant land use.

6.6.6 Representative Monitoring

SGMA specifies two categories of wells as follows:

- **Representative Wells**—These wells would be used to monitor sustainability in a basin. MTs and MOs would also be calculated for these wells.
- **Monitoring Well**—Other monitoring wells would be included in the monitoring network to provide redundancy for representative wells, and to maintain a robust network for evaluation as part of five-year GSP updates.

Representative wells are wells that represent conditions in the Subbasin; representative wells are in locations that allow monitoring on the well to indicate long-term, regional changes in its vicinity.

Considering the spatial distribution of wells in the Subbasin, knowledge of local geology, and a long-documented history of operating wells in the GSA area, all monitoring network wells are considered representative for the purposes of this Chapter GSP.

This page intentionally left blank

6.6.7 Monitoring Protocols

Monitoring protocols for the groundwater level monitoring network are included in the Umbrella GSP. WKWD will continue ongoing monitoring using the protocols currently in use until coordination of the monitoring protocols in the Umbrella GSP are completed.

6.6.8 Data Gaps

Research performed to develop this section of the Chapter GSP indicates a data gap for the Lake Management Area and, although active recovery occurs in this management area, there is no information available about pumping volumes or groundwater levels. A minimum of one well would be needed to adequately monitor this management area and fill this data gap.

6.6.9 Plan to Fill Data Gaps

WKWD uses in-house staff to monitor its well network. WKWD will coordinate with Kern County to establish monitoring protocol for the Lake Management Area.

6.7 Groundwater Storage Monitoring Network

Groundwater levels can be used as a proxy for determining changes in groundwater storage. Therefore, the WKWD GSA will use information collected from its groundwater level monitoring network described above to monitor for changes in storage.

6.8 Seawater Intrusion Monitoring Network

The GSA area is geographically and geologically isolated from the Pacific Ocean, and any other large source of saline water. As a result, the Subbasin is not at risk for seawater intrusion.

6.9 Degraded Groundwater Quality Monitoring Network

As discussed in Section 3.5, groundwater quality was consistent throughout its measurement period, including through the drought period and historically low groundwater levels of 2015, indicating that groundwater quality does not degrade with decreased groundwater elevations in the GSA. Therefore, monitoring of groundwater quality is not necessary when groundwater levels are sustainably managed.

Due to the relationship of undesirable results for water quality and the causal nexus of groundwater quality, Chapter GSP actions, and groundwater levels, no additional groundwater quality monitoring network is needed. Groundwater levels will be used as a proxy for the management of degraded groundwater quality in the GSA area.

6.10 Land Subsidence Monitoring Network

6.10.1 Management Areas

Land subsidence often occurs over large areas of land, and may be the result of dynamic groundwater levels, oil and gas extraction, or natural processes. Due to these factors, subsidence is monitored for the entire GSA, area and is not monitored in the separate management areas.

6.10.2 Monitoring Sites Selected for Monitoring Network

Currently, there are no subsidence monitoring stations in GSA area. However, there is an extensometer 1 mile north of the North Project Management Area that is operated by the KWBA. This extensometer provides adequate data about conditions in the GSA area.

6.10.3 Monitoring Frequency

Subsidence monitoring frequencies should capture long-term and seasonal fluctuations in ground level changes. DWR's *Monitoring Networks and Identification of Data Gaps Best Management Practices* does not provide specific monitoring frequency or interval guidance (DWR, 2016). Additionally, the extensometer that the WKWD GSA will use is operated by the KWBA in a neighboring GSA and has been monitored monthly since 1994.

6.10.4 Spatial Density

Figure 6-4 shows the extensometer used as a subsidence monitoring station for the WKWD GSA. DWR's *Monitoring Networks and Identification of Data Gaps Best Management Practices* does not provide specific spatial density guidelines for subsidence monitoring networks, and thus relies on professional judgment for site identification (DWR, 2016). Data from InSAR imagery and the extensometer data provided by Kern Water Bank provide adequate subsidence monitoring for the GSA area.

6.10.5 Monitoring Protocols

This Chapter GSP does not include subsidence monitoring protocols because subsidence monitoring is not conducted by the WKWD GSA. The WKWD GSA will coordinate with the KGA to modify these as necessary in the future.

6.10.6 Data Gaps

Current monitoring stations outside of the GSA area, in addition to InSAR spatial coverage provided by the Umbrella GSP, provide adequate data for monitoring subsidence in the GSA area. No data gaps for the WKWD GSA have been identified; however, subsidence monitoring is identified as a data gap in the Umbrella GSP. The KGA has prepared a Technical Memorandum regarding subsidence monitoring which is included in Appendix I.

6.11 Depletions of Interconnected Surface Water Monitoring Network

There is little surface water in the GSA area. All streams are ephemeral, and there are currently no surface stream or river gages in the GSA area. The Kern River also flows through a small part of the GSA area. However, the Kern River is a subsurface flow except during high flow events. The Kern River is also fully adjudicated. Due to these natural and legal characteristics, surface water monitoring is not conducted in the GSA area.

7.2 Introduction

This section of the Chapter GSP defines the sustainability criteria the WKWD GSA will use to avoid undesirable results during GSP implementation. SGMA requires the application of MTs, MOs, and interim milestones (IMs) to all representative monitoring sites identified in a GSP. These values will guide the WKWD GSA and groundwater users in the Subbasin as they identify sustainable values for sustainability indicators and progress indicators over the 20-year GDP implementation period.

7.3 Management Areas

WKWD GSA defined four management areas to allow areas with similar conditions to be grouped together so that MO, MT, and MI values could be calculated. Many of the management area boundaries were defined using established WKWD project boundaries. Management areas are shown in Figure 6-2.

The following subsections discuss the strategies used to calculate MOs, MTs, and IMs for each management area.

North Project Management Area

The North Project Management Area is a small plot of land to the northeast of the main WKWD service area. This plot of land is approximately 472 acres with 18 monitoring and production wells. GWEs in this area range from approximately -150 to 150 feet above sea level but are heavily dependent on pumping conditions.

South Project Management Area

The South Project Management Area lies to the east of the main WKWD service area along the Kern River and Interstate 5. This management area is a small plot of land of approximately 898 acres with 45 production and monitoring wells, including several multi-completion wells. Groundwater elevations in this area have ranged from approximately -50 to 250 feet above sea level but are heavily dependent on pumping conditions.

Lake Management Area

The Lake Management Area lies to the east of the main WKWD service area along the north bank of Buena Vista Lake. Wells in this management area are used to fill the lake for recreational purposes and are managed by Kern County. The lake is also used by agricultural water districts as a regulating reservoir.

Western Management Area

The Western Management Area comprises the majority of the WKWD service area and includes the cities of Taft and Maricopa. This management area does not currently have any active wells that pump above de minimis volumes. This management area also contains several parcels owned and operated by oil companies. Since this area does not have significant pumping, this management area is not monitored, nor does it have sustainability thresholds assigned to it.

7.4 Chronic Lowering of Groundwater Levels

The undesirable result for chronic lowering of water levels is the point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

Groundwater conditions, as discussed in Section 3.0, vary across the Subbasin and the GSA area. These conditions are influenced by geographic, geologic, and land uses overlying the Subbasin and GSA area. Because of the variety of conditions, threshold regions, in the form of the management areas described above, were used to establish the appropriate sustainability criteria for each region.

7.4.1 MTs, MOs, and IMs

WKWD is the only user of groundwater that exceeds de minimis amounts of water in the WKWD GSA area. Therefore, the thresholds presented in this section affect the beneficial use of groundwater by WKWD and may cause WKWD to enact projects and management actions described in Section 8 if groundwater levels approach minimum thresholds.

The following subsections describe the methods used to calculate MTs, MOs, and IMs in the four management areas.

North Project Management Area

MTs and MOs were set in the North Project Management Area to allow for an appropriate margin of operational flexibility that would allow for recovery of water as regularly conducted during normal WKWD operations. Through coordination efforts, neighboring GSAs' MTs and MOs were also taken into consideration.

The MT were calculated by finding the maximum and minimum historical values for each well; 20 percent of the difference between these elevations was calculated, and then subtracted from the minimum historical value to obtain the numerical MT value.

The MO was calculated by finding three years of drought usage/storage above the MT. Three years of drought usage/storage represents three years of normal water use and pumping done by WKWD during drought conditions. This was found by identifying the groundwater decline through a drought period and applying that decline-time ratio over three years.

Based on the available monitoring data (presented in Section 6), a drought condition existed in the North Project Management Area from approximately 2013 to 2016. Using these data, analysts found the maximum elevation between January 1, 2012 and December 31, 2014 and the minimum elevation between January 1, 2015 and December 31, 2017. Analysts then used the dates of these measurements to determine the number of days between each of those measurements. This provided a drought decline ratio of elevation decline over time.

To determine drought usage/storage over three years, the following formula was used:

$$\frac{D}{T} = \frac{X}{Y}$$

$$X = \frac{(D * Y)}{T}$$

where:

D = Decline of elevation over known drought period

T = Time between maximum value (from 2012 to 2014) and minimum value (from 2015 to 2017)

X = Three years drought storage/decline, *unknown*

Y = Three years in days = 365.25*3 = 1,095.75

Since all representative wells are currently above the MO, IMs were not set for this area.

Levels will be measured using the frequency of measurement and monitoring protocols documented in Section 6.

South Project Management Area

Because groundwater conditions and well use in the North Project Management Area are like those in the South Project Management area, the same MT, MO, and IM strategies were used in the South Project Management Area.

MTs and MOs were set in the South Project Management Area to allow for an appropriate margin of operational flexibility that would allow for recovery of water as regularly conducted during WKWD's normal operations. Through coordination efforts, neighboring GSAs' MTs and MOs were also taken into consideration.

Lake Management Area

Although WKWD and WKWD GSA know the location of production wells in the Lake Management Area, there are currently no available groundwater level monitoring data for these wells. Kern County owns and operates the production wells in this area, and, to date, been unable to provide groundwater level data sufficient for developing MTs, MOs, or IMs. As outlined in Section 6, this management area is identified as a data gap. When data become available for this area, the GSA will apply MTs, MOs, and IMs in the five-year GSP update.

Western Management Area

The Western Management Area does not use groundwater and does not have any active wells; as a result, no MOs, MTs, or IMs were calculated.

7.4.2 Selected MTs and MOs, Figures, and Tables

This section summarizes data about MTs and MOs used for each representative well. Figure 7-1 is an example hydrograph with the applied MT and MO, and Table 7-2 summarizes data for each of the wells. Hydrographs with MTs and MOs are included in Appendix G.

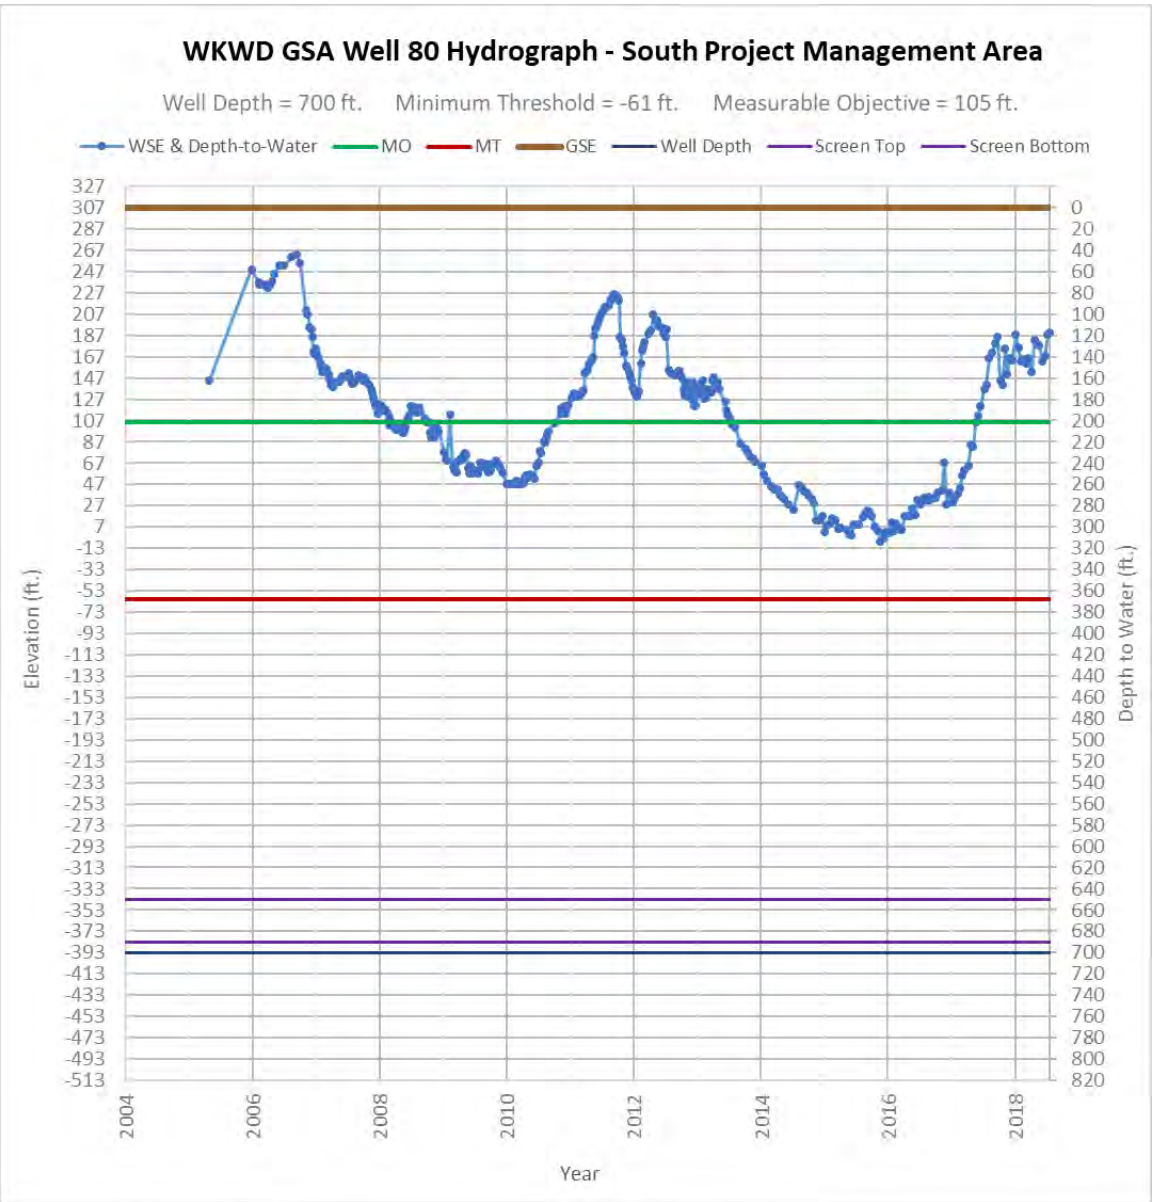

Figure 7-1. WKWD Example Hydrograph with Thresholds

Table 7-2. MTs, MOs, and IMs for WKWD GSA Representative Wells

Representative Well Number	MT (feet above mean sea level)	MO (feet above mean sea level)

88	23	166
100	-82	125
107	14	70
108	32	99

7.5 Reduction of Groundwater Storage

The undesirable result for reduction of groundwater storage is the point at which significant and unreasonable impacts, as determined by the amount of groundwater in the Subbasin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended drought period.

Reduction of groundwater storage is not a concern for the WKWD GSA. Based upon current demands and banked water records, WKWD GSA's banked water supply is sufficient to meet demand for nearly 10 years. Groundwater level data show that this proactive approach to banking has increased local water levels and provided a net benefit to the Subbasin.

7.5.1 Proxy Monitoring

Section 354.26(d) of the DWR Emergency Regulations permits the use of groundwater levels as a proxy sustainability indicator to monitor whether an undesirable result, due to a reduction in groundwater storage, has occurred. Additionally, there are no state, federal, or local standards that regulate groundwater storage. As described above, storage capacity is not a concern for the Subbasin, and any benefits to groundwater storage are expected to coincide with groundwater level management.

7.6 Seawater Intrusion

Due to the WKWD GSA's location, the effect of seawater intrusion is not a concern; as a result, it is not necessary to establish criteria for undesirable results, as supported by Section 354.26(d) of the DWR Emergency Regulations.

7.7 Degraded Water Quality

SGMA regulations specify that "minimum thresholds for degraded water quality shall be the degradation of water quality, including the migration of contaminant plumes that impair water supplies or other indicator of water quality as determined by the Agency that may lead to undesirable results."

The undesirable result for degraded water quality is the point at which significant and unreasonable impacts over the planning and implementation horizon, as caused by water management actions, that affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

7.7.1 Management Areas

As a domestic water purveyor, WKWD is required to monitor groundwater quality in its wells on a routine basis. As a result, no management areas were used to establish water quality sustainability thresholds.

7.7.2 Proxy Monitoring

WKWD delivers disinfected groundwater for domestic and industrial use that must meet Title 22 drinking water standards. Through the successful management of their water sources and groundwater levels, WKWD has continuously provided high quality water to its customers since 1959. Groundwater quality in the vicinity of WKWD's wellfields is of very high quality and requires minimal disinfection to meet drinking water standards. Any degradation to groundwater quality that may occur will be identified during required routine water quality monitoring, would be considered an undesirable result by nature, would and trigger a management action to determine the cause.

As discussed in Section 3.5, groundwater quality was consistent throughout its measurement period, including through the drought period and historically low groundwater levels of 2015, indicating that groundwater quality does not degrade with decreased groundwater elevations in the GSA. Therefore, groundwater levels thresholds are protective of Division of Oil, Gas, and Geothermal Resources (DOGGR).

7.7.3 MTs, MO, and IMs

As described above, groundwater levels may be used as a proxy for determining the cause of degraded water quality in a GSA area; as such, the MOs, MTs, and IMs established for degraded water quality are the same as those described in Section 7.4.

7.8 Subsidence

The undesirable result for land subsidence is the point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.

7.8.1 Management Areas

Subsidence monitoring is conducted on a Subbasin-wide level; as a result, no management areas were used to establish subsidence criteria. Figure 6-4 shows subsidence monitoring locations in the GSA.

7.8.2 Representative Monitoring

As discussed in Section 6, the extensometer located north of the North Project Management Area is the only representative monitoring point used for this Chapter GSP. Detrimental impacts of subsidence include groundwater storage reduction, and potential damage to critical infrastructure such as large scale linear infrastructure, and canals. Portions of the California Aqueduct that lie within the GSA area have shown no negative impacts due to subsidence, and there is no groundwater pumping in these areas.

Ground surface elevations in the GSA area of the Subbasin are rising and have risen from approximately 0.5 to 0.8 feet since 1994, as shown in Section 3. Currently, there are no state, federal, or local standards that regulate subsidence rates.

7.8.3 MTs, MOs, and IMs

Although several factors can affect subsidence rates, including geologic processes, soils, oil extraction, and groundwater pumping, these factors have not induced subsidence in the GSA area. Because subsidence has not impacted local infrastructure, and the fact that surface elevations have increased since 1994, an MT rate for subsidence of 2 inches per year (as measured at Kern Water Bank Extensometer 30S/25E16L) is reasonable for warranting a management action to investigate the cause. This magnitude of subsidence, when compared to that in other areas of the San Joaquin Valley that approach 1 foot per year, is considered unlikely to cause a significant or unreasonable impact to local infrastructure over the planning and implementation horizon of this Chapter GSP.

Groundwater recovery can have a direct impact on the rate of subsidence; however, those impacts can be managed proactively by maintaining GWEs that control subsidence. As a result, the MO for subsidence in the WKWD GSA will be to maintain groundwater water elevations at levels to where no subsidence occurs.

IMs are not needed for this subsidence sustainability indicator because the current rate of subsidence is above the MO.

Subsidence rates will be measured via the frequency of measurement and monitoring protocols documented in Section 3.

7.9 Depletions of Interconnected Surface Water

SGMA regulations define the MT for interconnected surface water as "… the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on the beneficial uses of the surface water and may lead to undesirable results."

Currently, there are no beneficial uses of surface water in the GSA area, as all surface flows infiltrate into the groundwater system except during the most extreme flash flood events. It should be noted that BVARA is operated by Kern County, is adjacent to the Lake Management Area, and is a surface water source that may influence groundwater within the GSA area. Although BVARA is outside of the GSA boundary, the lake is maintained through groundwater pumping from wells in the GSA area. There are no data currently available regarding BVARA operations at this time; however, it is assumed that water loss from the lake results from evaporation and infiltration into the groundwater system.

7.9.1 Proxy Monitoring

Although the lake within BVARA (an interconnected surface water) is outside of the GSA area, the remainder of the BVARA property is within the GSA area, and beneficial uses of that water must be considered under SGMA regulations. The effect of depletions of interconnected surface waters in the GSA area will use groundwater levels as a proxy for determining sustainability, as permitted by Section 354.26(d) of the DWR Emergency Regulations.[2] Additionally, there are currently no state, federal, or local standards that regulate the depletions of interconnected surface waters.

As addressed in Section 6, the Lake Management Area has been identified as a data gap. Section 8 provides a strategy for the GSA to develop additional groundwater level monitoring in this management area in the future. This monitoring will be used to establish groundwater level sustainability thresholds that consider beneficial uses of interconnected surface water. Current groundwater level thresholds are set to be protective of conditions for the remaining areas of the GSA and are expected to provide protection of the Lake Management Area until more data are collected.

8.2 Introduction

This section of the Chapter GSP includes projects, management actions, and adaptive management information, and satisfies the requirements found in Sections 354.42 and 354.44 of the SGMA regulations.[3] The projects resulting from this Chapter GSP and their benefits will help achieve WKWD GSA's sustainable management goals in the GSA area. This section of the Chapter GSP also identifies the following:

- Projects and management actions that will help move the GSA area toward sustainability
- Adaptive management strategies that may be implemented if resulting projects and management actions do not move the Subbasin toward sustainability at a sufficient pace
- Adaptive management strategies that may be implemented if monitoring demonstrates undesirable results

8.3 Addressing Sustainability Indicators

Sustainability indicators are described in Section 7. Groundwater levels are being used either directly or as a proxy for determining status of the relevant sustainability indicators, which are as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

As described in Sections 8.7, 8.8, and 8.9, each of the projects, management actions, and adaptive management strategies are designed to reduce or balance sustainable groundwater pumping. This will help to reduce or avoid declines in groundwater levels, thereby contributing to sustainability in the GSA area as measured by the relevant sustainability indicators. Management actions respond to non-groundwater related conditions (e.g., drought), and the adaptive management strategies respond to changes in groundwater conditions (e.g., local declines in GWEs).

The management actions and adaptive management strategies described here will allow the WKWD GSA flexibility to respond to changing conditions.

[3] https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/GSP_Emergency_Regulations.pdf

8.4 Overdraft Mitigation

The GSA area is not known to be in overdraft because WKWD balances its recharge and pumping. However, the Subbasin, which partially underlies the WKWD GSA, is in overdraft conditions as a whole, according to WKWD's *2015 Urban Water Management Plan* (2015 UWMP) (WKWD, 2016). Further, annual groundwater pumping for BVARA is unknown, and represents potential localized overdraft near the BVARA. Projects, management actions, and adaptive management strategies described in this section contribute to protecting GWEs, and emphasize balancing recharge and pumping, offsetting potable demands, or creating new supplies.

Projects, management actions, and adaptive management strategies therefore all serve to mitigate overdraft.

8.5 Water Balance Management for Drought Preparedness

Under existing management operations, WKWD banks surplus water supplies for use during drought or other shortages. As described in its 2015 UWMP, WKWD's supplies during normal water years exceed demand by 4,900 to 11,250 AFY. This surplus has consistently been banked by WKWD, with approximately 200,000 AF currently stored in the Subbasin. Since WKWD began groundwater banking in the 1960s, it has experienced multiple droughts. The current surplus is sufficient to meet approximately 10 years of WKWD demand as the sole supply. The success of current practices, as seen by the large volume of water currently stored in the groundwater bank, demonstrate that WKWD is an experienced manager of its water balance for drought preparedness. The projects and management actions described here each contribute to WKWD's ability to continue to bank groundwater in years with surplus supply, and reduce demands on banked supplies during drought, allowing the Subbasin to recover more quickly from drought.

8.6 Projects, Management Actions, and Adaptive Management Strategies

The GSA has identified a series of projects and management actions that will support the GSA's sustainability goals. Additionally, WKWD GSA has identified adaptive management strategies that may be implemented if monitoring indicates groundwater levels are approaching the MT (and as a result may be at risk for undesirable outcomes). Table 9-2 summarizes projects and actions described in this section along with their status and timing.

Table 8-2. Project and Action Status and Timing

Project/Management Action/ Adaptive Strategy	Status	Implementation Timing	Accrual of Benefits[a]
Project 1: Automatic Meter Reading Project	Planning	Near-term	Within a few months
Project 2: Participation in Delta Conveyance	Planning	Long-term	Immediately following water deliveries

Table 8-2. Project and Action Status and Timing

Project/Management Action/ Adaptive Strategy	Status	Implementation Timing	Accrual of Benefits[a]
Facility			
Project 3: Buena Vista Recreation Area Water Supply Management Coordination	Ongoing	Now	After supplemental water management project/action is implemented
Management Action 1: Continued Balanced Pumping and Recharge	Ongoing	Now	Now
Management Action 2: Implement Water Shortage Response Plan	Ongoing, As Needed	Now; as needed	Within a few months
Management Action 3: Continued Participation in Basin-Wide Coordination	Ongoing	Now	Now
Adaptive Management Strategy 1: Taft Recycled Water Program	Pre-planning	Long-term	Immediately following water deliveries
Adaptive Management Strategy 2: Shift Balance of Pumping between North and South Wellfields	Untriggered	As needed	Within a few months
Adaptive Management Strategy 3: Implement Permanent Demand Management Measures	Untriggered	As needed	Within a few months

Notes:
[a] GWEs are expected to react to project and action benefits in a timeframe of a few weeks to a few months after direct project and action benefits are realized.

8.7 Projects

This section describes projects selected by WKWD GSA that will help achieve sustainability goals for the portion of the Subbasin that lies within WKWD GSA's boundaries.

8.7.1 Project 1: Automatic Meter Reading (AMR) Project

In 2015, WKWD began installing AMR systems for all industrial and outlying customers. To further achieve sustainability goals, WKWD would install AMR systems on the remainder of its primarily residential customer meters. The AMR system selected by WKWD for its industrial and outlying customers uploads data every 24 hours to a website where customers can access their accounts and view water use data, compare their current water use to their historical water use, and receive leak alerts.

AMR can be used by WKWD and its customers to identify potential leaks and encourage water use reductions by providing near-real-time data, using a webtool that provides water use in 15-minute intervals. Volume reductions will vary depending on initial water use, frequency of leak detection pre-

AMR system, and whether the AMR is coupled with a user-friendly interface that motivates voluntary water use reduction. AMR can also improve water conservation by providing detailed data that can be used to improve overall system management.

Public Notice and Outreach

WKWD would conduct public outreach to inform customers of their upgraded meters and provide instruction on using the website interface to track water use and identifying potential leaks. Outreach would likely include bill inserts and website updates and may include other forms of outreach such as flyers in public libraries, informational meetings, or radio ads, depending on the methods deemed most appropriate by WKWD staff at the time the project is implemented.

Permitting and Regulatory Processes

Implementation of this project is not subject to permits or additional regulation because it is part of WKWD's normal system operation, maintenance and upgrades. It would require approval by WKWD's Board of Directors.

Project Benefits

AMR provides potential water savings through early leak detection and increased awareness of water use among customers. Upgrading meters also reduces unaccounted-for losses related to accuracy degradation in older meters. WKWD estimates that AMR will save an average 8 percent of water for each metered connection, based on savings experienced by nearby agencies. The City of Sacramento had an average 4 percent water savings based on a pilot AMR project, while the Golden Hills Community Services District realized 12 percent in average savings (WKWD, 2014). WKWD's 2015 UWMP shows residential water use ranges between 2,169 AF in 2015 to a projected high of 2,597 AF in 2040, and applying the projected 8 percent conservation, anticipated water savings from this project is estimated to be 173 to 208 AFY (WKWD, 2016). Conservation achieved by the AMR project would be measured by the reduction in water deliveries to customers with AMR meters.

Increasing water conservation would reduce demands for potable water, thereby reducing the volume of water pumped from the Subbasin.

This project would benefit the MO of protecting GWEs, and supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Project Implementation

Implementation of this project would require approval by WKWD's Board of Directors and provision in the budget to fund this effort. No design or substantial engineering would be required. WKWD would purchase the meters and necessary appurtenances and perform the installation.

Project Status and Timing

The circumstance of implementation for this project would be current conditions, once funding is secured or committed and the project approved by WKWD's Board of Directors, it could be implemented. Once completed, this project would be limited to maintenance of the system and ongoing outreach as necessary. The circumstance of implementation would end at the end of the system's life or if another system is selected in the future.

This project could be implemented in the near future because it is an expansion of work WKWD has already completed for some of its customers. WKWD has already selected a meter and has the software system operating in its system. Customers are anticipated to be supportive of the project because it has been partially implemented already and would likely require less outreach to solicit public support than a project that was new to the area. WKWD installed the initial 484 meters in the original AMR project in about 2.5 months. This project would involve installing 5,900 meters; assuming a similar rate of installation, it would take approximately two and a half years to complete installation of all meters. It is likely that meter installation for residential customers could be done faster because staff would be gaining installation experience over the life of the project, and meters are located closer together, reducing travel time between work sites. This Chapter GSP assumes all meters could be installed within three years. Although it would likely take some time for customers to adjust to using the data provided by new meters to motivate behavioral changes and to calibrate meters and understand baseline water use, benefits are expected to accrue quickly once the learning curve is overcome. Benefits, particularly conservation from early leak detection, are expected to be maintained over the life of the project.

Supply Reliability

The AMR project is a conservation project and would not rely on out-of-basin supplies for successful implementation. The project would reduce potable water demands, thereby reducing groundwater pumping and allow for increased groundwater recharge in years with a surplus of supply.

Legal Authority

This project is within the normal operational authority of WKWD, who owns and operates all customer meters within its system. The project would only be implemented within WKWD's potable water system and requires no additional legal authority.

Project Costs

WKWD's cost to install AMR on 484 industrial meters and implement the necessary system upgrades was approximately $599,088, or an average per-meter cost of $1,237 (WKWD, 2014). However, the 2015 AMR project primarily served industrial customers, which generally have larger, and therefore more expensive meters than most residential customers. Adjusting costs to reflect the use of smaller meters

results in a projected cost of $690 per residential meter. WKWD has 5,900 residential connections; at a project cost of $690 per meter, the total cost would be approximately $4.1 million. Revised project costs would be determined during the planning stages of this project and are expected to vary from this estimate based on the exact number of meters for each size, potential economy of scale, cost changes since 2015, and evolution of AMR technology. Operational costs for WKWD may reduce after installation because staff will no longer need to manually read each meter, saving time and transportation costs. WKWD successfully secured grant funding to cover a portion of AMR implementation for its industrial and outlying customers. Based on grant funding obtained for this project, costs to WKWD and customers would decrease.

Technical Justification

WKWD has already experienced the benefit of AMR through installation with its industrial customers. It is difficult to quantify the water savings associated with AMR in the WKWD because demands from both industrial and residential customers have declined since the installation of AMR. However, as described in the Project Benefits section, WKWD reviewed multiple case studies that demonstrate the water saving potential of AMR (WKWD, 2014). Any reduction in potable demands allows WKWD to bank an equivalent amount of water in years with surplus supply and reduce groundwater recovery by an equivalent volume in dry years.

Subbasin Uncertainty

Water conservation achieved through AMR is largely independent of overall supply reliability and uncertainty because the primary water savings realized comes from the ability to detect leaks in real-time. Savings attributable to AMR vary depending on baseline water use and customer behaviors. Overall, AMR will help to reduce the effects of uncertainty in the Subbasin by reducing demands for water that could be used for other purposes.

California Environmental Quality Act (CEQA)/National Environmental Policy Act (NEPA) Considerations

Installation of water meters and AMR systems do not require review under CEQA. The project would only trigger NEPA if WKWD pursued federal funding for the project. Based on the WKWD's experience securing federal grant funds to install AMR for industrial customers, impacts under NEPA would be minimal.

8.7.2 Project 2: Participation in Delta Conveyance Facility

Delta Conveyance Facility is intended to address the challenges of pumping water from the Delta by diverting water upstream of the current diversion points and conveying it to existing pump stations for the SWP and the Central Valley Project (CVP). Under current operation, the SWP and CVP are unable to consistently deliver state and federal water contractors their full contract supplies. Delta Conveyance Facility is intended to address some of the conditions that impact the ability to export water from the Delta.

SWP delivers water to 23 SWP contractors, which retail or wholesale water to customers and other agencies. KCWA is the SWP contractor for the region, and directly contracts with WKWD for a SWP supply. Each year, DWR determines the amount of water available to contractors based on the hydrology for a given water year. Regulatory actions to protect fish and manage water quality in the Delta have reduced the overall reliability of supplies from the SWP. Delta Conveyance Facility is intended to increase the reliability of supplies, thereby increasing the amount of SWP water delivered to SWP contractors annually.

WKWD will participate in Delta Conveyance Facility to increase water supply reliability for its customers. While the exact increase in water supply from the Delta Conveyance Facility remains uncertain until final design, approvals, and agreements are in place, WKWD anticipates that any water supply benefits from the project would be allocated in proportion to its level of participation.

Public Notice and Outreach

Participation in Delta Conveyance Facility is anticipated to require the approval of WKWD's Board of Directors at a publicly noticed meeting. Delta Conveyance Facility itself has a substantial public outreach effort designed to inform stakeholders about the need for and benefit of the project, as well as provide information about the project components, how it works, and its benefits to the people of California. Because WKWD is not an SWP contractor itself, it is likely that participation in Delta Conveyance Facility would also require approval from KCWA's Board of Directors at a publicly noticed meeting.

Permitting and Regulatory Processes

Participation in Delta Conveyance Facility would not require WKWD to secure any permits or implement additional regulatory compliance actions. All required permits and regulatory processes would be undertaken by DWR and the Delta Conveyance Design and Construction Joint Powers Authority (i.e., DWR's designated administering agency), which together are implementing Delta Conveyance Facility (DWR, 2018a). If WKWD's cost to participate in Delta Conveyance Facility results in a need to adjust customer rates, WKWD would prepare a rate study and approve water rate adjustments in accordance with applicable laws and policies.

Project Benefits

The primary benefit of this project would be the increased reliability of imported water supplies and to expand groundwater banking opportunities to meet customer demands. Additional supplies could be 1) banked in WKWD's recharge facilities, 2) used for GWE protection if monitoring shows unexpected declines in elevation, or 3) transferred to neighboring agencies to help offset groundwater pumping in the Subbasin.

Delta Conveyance Facility is still in the planning and design stages, and project details are subject to change; therefore, quantification of project physical benefits remain uncertain. To provide context, an estimate of potential water supply benefit provided by Delta Conveyance Facility is below. These benefits are based on the current project description, recent analyses provided by DWR, and assume each participating SWP contractor will receive its pro rata share of the water supply benefits through Delta Conveyance Facility.

Potential Delta Conveyance Facility Water Supply Benefits

Benefits from the Delta Conveyance Facility are generalized because details of the Delta Conveyance Facility are still under development.

Overall, SWP contractors have contracted with the SWP for 4,172,786 AF annually. KCWA's SWP contract supply for 2019 is 982,730 AF. This represents the amount of SWP water available to KCWA if DWR allocates 100 percent of its contracted supplies (DWR, 2019). Of this amount, WKWD is entitled to 31,500 AF; therefore, WKWD anticipates receiving a minimum of 0.75 percent of any water supply benefit available to SWP contractors from Delta Conveyance Facility. This assumes all SWP contractors and KCWA member units participate in the project based on their full contracted supplies.

A 2018 economic analysis of Delta Conveyance Facility estimated that the project, assuming full SWP and CVP participation, would result in an additional 685,000 AFY of water on average, with 60 percent and 40 percent of the supply allocated to SWP and CVP contractors, respectively. Additional water would be available to SWP contractors if the CVP does not fully participate (DWR, 2018b). Based on WKWD's contracted SWP supply, which is 0.75 percent of the total contract supply of the SWP, participation in Delta Conveyance Facility could increase WKWD supplies by approximately 3,100 AFY. The exact water supply benefit will vary from year to year and will be affected by elements such as changes to the final project, project participation, and annual variations in hydrology. Benefits for the GSA and WKWD via participation in Delta Conveyance Facility would be evaluated based on metered deliveries and overall increase in groundwater storage once the project is completed.

The benefit of participation would be measured via the volume of water delivered from the SWP (including SWP supplies available through Delta Conveyance Facility).

Increasing availability of imported water through participation in Delta Conveyance Facility would allow WKWD to recharge additional water, directly contributing to groundwater level sustainability. This project would also improve reliability of SWP supplies, reducing the need to withdraw water from the banked groundwater supplies, which supports sustainable groundwater levels.

This project would benefit the MO of protecting or increasing GWEs, supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Project Implementation

Project implementation would require WKWD to participate in Delta Conveyance Facility and obligate itself to pay for its share of the project. Because all Delta Conveyance Facility facilities would be constructed by DWR and the Delta Conveyance Design and Construction Joint Powers Authority, and existing SWP facilities are sized for full SWP delivery, no additional local or regional infrastructure would be required to receive additional water made available by Delta Conveyance Facility.

Project Status and Timing

The circumstance of implementation for this project would be approval of Delta Conveyance Facility by the State of California. Once implemented, this project would remain until the end of the useful life of the Delta Conveyance Facility portion of the SWP.

The timing of this project is beyond the control of the GSA, because Delta Conveyance Facility would be implemented by the State. As of March 2019, Delta Conveyance Facility had completed the CEQA process and secured some permits but is still in the planning phase. Project changes are anticipated that may require additional CEQA documents. Once planning is complete, permitting, design, and construction are anticipated to take 17 years, with deliveries beginning around year 18 (Delta Conveyance Facility, 2019). Benefits would begin accruing following the start of water deliveries from the project. Participation in Delta Conveyance Facility participation could be approved relatively quickly at a WKWD Board meeting, depending on public support for this project.

Supply Reliability

Water made available using Delta Conveyance Facility facilities would come from sources north of the Delta including, among others, the Sacramento River and its tributaries. Water delivered using these facilities is considered more reliable than the water currently available to the SWP from the Delta, because it is less impacted by water quality standards and regulatory actions to protect fish, both of which impact existing SWP facilities ability to divert water. Actual annual water supply benefits are difficult to quantify and will vary depending on hydrology.

Legal Authority

Participation in Delta Conveyance Facility is within the authority of KCWA as an SWP contractor, and its decision to participate would require coordination with its member units. Some negotiations may be required if certain KCWA member units do not elect to participate in Delta Conveyance Facility. Regardless of overall member unit participation, WKWD's participation in Delta Conveyance Facility would require agreements with KCWA to coordinate wheeling of WaterFix supplies to WKWD.

Project Costs

Because of certain project uncertainties such as design changes and ultimate participation by SWP and CVP contractors, it is difficult to quantify WKWD's Delta Conveyance Facility fixed obligation. WKWD anticipates that the cost to participate would be proportional to the water supply benefit and incremental yield received. Per DWR's 2018 economic analysis, estimated costs to SWP contractors would be approximately $12.17 billion (in present value costs, combined urban and agricultural), assuming no

federal grants were received (DWR, 2018b). This analysis estimated that the incremental water supply made available by Delta Conveyance Facility to urban SWP contractors would cost $686 per AF. Assuming an additional $550 per AF for conveyance and treatment, total cost of water from Delta Conveyance Facility for urban suppliers would be $1,236 per AF.

Costs associated with participation in Delta Conveyance Facility would be funded through WKWD's water rates and sales of excess water to other agencies.

Technical Justification

The statewide benefits of Delta Conveyance Facility are identified and described by DWR in numerous reports and publications. Direct benefits to WKWD will be primarily increased water supplies and reliability. The purpose of Delta Conveyance Facility is to increase water supply reliability and provide ecosystem benefits and enhancements in the Delta (DWR, 2016a). If the project cannot achieve this objective, it will not be implemented. DWR completed a water supply analysis using the CALSIM II model, which was developed by DWR and the United States Department of the Interior's Bureau of Reclamation (Reclamation) to evaluate SWP and CVP deliveries under a variety of hydrologic conditions, and is considered the best available planning model for system-wide evaluations of these imported water systems (DWR, 2016b). Modeling outcomes and methods are described in detail in Delta Conveyance Facility's *Environmental Impact Report/Environmental Impact Statement* (EIR/EIS) (DWR, 2016c).

Subbasin Uncertainty

This project would help to address uncertainty in the Subbasin by providing new, additional supplies and improved reliability of SWP deliveries. Delta Conveyance Facility will provide additional water supply benefits and allow WKWD to recharge more water for use in dry years when surface supplies are limited due to drought, disaster, or other factors.

CEQA/NEPA Considerations

Delta Conveyance Facility is a project subject to both CEQA and NEPA. The EIR/EIS has been certified by DWR (Delta Conveyance Facility, 2017). Due to project changes, it is anticipated that Subsequent EIRs, Addendums to the EIR, or other additional CEQA documentation may be necessary. Such documentation would be prepared and certified by DWR. Securing NEPA compliance will be the responsibility of DWR in coordination with the appropriate lead federal agency. WKWD's participation in Delta Conveyance Facility would not require construction of any additional facilities or projects and would not entail additional CEQA or NEPA compliance beyond that already being undertaken by DWR.

8.7.3 Project 3: Buena Vista Aquatic Recreation Area Water Supply Management Coordination

BVARA is in and adjacent to the WKWD GSA area. The 1,585-acre BVARA is home to two manmade lakes, Lake Webb and Lake Evans, boating facilities, playgrounds and volleyball courts, camp sites, and picnic areas. The lakes lie outside of the GSA area but the park facilities such as picnic areas, restrooms, and parking areas are within the GSA area. When constructed, the lakes had a combined storage capacity of over 6,800 AF. Shoreline camping and picnic areas are landscaped with grass and are irrigated during

the dry season (County of Kern Parks and Recreation Department, 2019). With no outlet, water from the lakes either evaporates or percolates into the groundwater basin. Kern County pumps groundwater from wells located within the GSA area to supplement losses at the lake. Supplemental water delivered to the lakes is not metered and is not included in WKWD GSA's water balance.

There is need for Kern County to replenish the lake losses from evaporation and percolation because of a contractual responsibility between the County and BVWSD. Since the "minimum pool" level is a measure of Kern County's responsibility, any proposed variation from that water surface elevation should be considered by BVWSD.

Due to uncertainty regarding BVARA water demands, and the condition of the Subbasin near the extraction wells, this project requires ongoing coordination between the GSA and Kern County to understand BVARA's water management needs and related impacts to the GSA area. Together, the WKWD GSA and Kern County would develop an appropriate project to address the BVARA's water needs in a manner that could be accommodated without triggering an undesirable result as described in this Chapter GSP. Some projects that may be considered by WKWD GSA and Kern County include the following:

- Metering groundwater pumped for supplemental water, and charge Kern County a pump tax on the amount recovered
- Reducing pumping for supplemental water and manage the lakes at a lower level
- Acquiring supplemental water from other sources, such as the North Project Management Area, South Project Management Area, the County's Willow Springs Groundwater Bank, other water districts, or from direct diversions from the California Aqueduct

WKWD GSA and Kern County may identify other projects as appropriate.

Public Notice and Outreach

Public notice and outreach would be necessary for any project ultimately implemented that affects the public's use of the BVARA and lakes. For example, if the project results in the need to increase use fees at the BVARA to cover the cost of purchasing supplemental water, or the lakes are managed at a lower volume of water, some outreach would be necessary to inform the public of the changes and why they are necessary. Outreach would likely include informational signs or flyers available at the recreation area's information and entrance booths as well as information posted on the Kern County's Parks and Recreation website. Any decisions made as a result of this project that require approval from either WKWD's Board of Directors or the County Board of Supervisors would be made in a public meeting.

Permitting and Regulatory Processes

Specific permitting and regulatory processes would depend on which project or management action is decided upon as a result of this project. All final project decisions would likely require approval from WKWD's Board of Directors and the Kern County Board of Supervisors. WKWD or Kern County would acquire any applicable permits and consult with the appropriate regulatory bodies necessary to implement the selected project.

Project Benefits

Managing water supply for the BVARA would include a focused effort on monitoring pumping in that portion of the GSA area, and identifying which projects or management actions are needed to eliminate undesirable results in the Subbasin. Securing additional supplemental supplies would reduce the potential impacts to groundwater levels, storage, and water quality for this portion of the GSA area. Improved management of the BVARA water supply would also support ongoing use of the BVARA, a popular recreation area. The project does not have a directly measurable benefit unless implementation actions arise from these meetings.

This project would benefit the MO of protecting GWEs near the BVARA, supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Project Implementation

Implementation of this project would include ongoing coordination meetings between WKWD GSA and Kern County to discuss 1) the quantity of water needed by BVARA, 2) current condition of the groundwater Subbasin in the vicinity of BVARA, and 3) potential projects to improve how supplemental water for BVARA is acquired and used. These coordination meetings would be held in person and via teleconference as necessary, with in-person meetings held at critical decision-making junctions. Once a project or management strategy is agreed upon for the BVARA's supplemental water, an implementation plan would likely be developed, depending on the type of project or management strategy identified.

Project Status and Timing

Implementation of this project is already underway and is likely to remain an ongoing project until such time as the BVARA no longer requires water from the GSA area.

BVARA water supply management efforts are in the initial stages. WKWD GSA has met with Kern County to discuss groundwater use as supplemental supply for the lakes. Coordination between the two agencies will continue until a project or management action is identified and implemented. This Chapter GSP assumes it will take a full year to understand BVARA's supplemental water needs and identify a preliminary list of potential projects or management actions that could be implemented. Selection of the preferred project or management action may take an additional six to twelve months, depending on the alternatives being considered. Implementation of the selected project or management action may take months or years depending on the activity. Once implemented, benefits are expected to be realized immediately.

Supply Reliability

This project would address supply uncertainties for BVARA by preventing continued potential overdraft in the vicinity of BVARA. Whichever project is ultimately decided upon by WKWD GSA and Kern County, a reliable and sustainable supply will be paramount. For example, if WKWD GSA and Kern County decide to purchase banked water from WKWD, the supply would be considered highly reliable due to WKWD's relatively large banked groundwater reserves.

Legal Authority

Kern County's Parks and Recreation Department owns and operates BVARA. Substantial changes to how BVARA is managed may require approval from the Kern County Board of Supervisors. The groundwater wells currently used to pump supplemental water to BVARA are owned and operated by Kern County; changing how much water is pumped using these wells is within the authority of the County. If an alternative supply source is identified as the preferred project for management of BVARA's supplemental water, the managing entity for that supply would need to agree to provision of service, such as WKWD or other water districts.

Project Costs

Coordination costs between WKWD GSA and Kern County would primarily involve staff time and would not represent an additional capital expenditure. These costs would be covered by the general operating budgets for both agencies. Implementation costs will vary depending on the project or management action selected. WKWD has estimated a cost of as much as $500 per AF to provide a supplemental supply through groundwater pumping. Estimating costs at this early planning stage has proven difficult. Costs may be higher depending on the water source and if additional infrastructure is required.

Technical Justification

The water management needs of BVARA are unknown and currently unquantified. This project would improve WKWD GSA's understanding of these needs and identify data gaps before an appropriate project or management action could be identified to manage BVARA's supplemental water supply. Technical justification would be a consideration when evaluating potential projects and management actions to address BVARA's water supply needs. Projects and actions that are not technically sound or not likely to achieve desired results would not be implemented.

Subbasin Uncertainty

This project would address the existing uncertainty over how supplemental water for BVARA is managed, as well as provide clarification and understanding about groundwater use and conditions in the vicinity of BVARA. Coordination between WKWD GSA and Kern County would allow both agencies to share information about potential changes or concerns regarding the targeted area and reduce potential impacts from water supply uncertainties in the Subbasin. Subbasin uncertainties would be a consideration when determining the preferred project or management action to implement for BVARA's supplemental water.

CEQA/NEPA Considerations

Coordination meetings between WKWD GSA and Kern County do not constitute a project that would trigger CEQA or NEPA. Should this project's coordination meetings result in a project or management action found to be a project under CEQA or NEPA, the appropriate environmental analysis and corresponding CEQA and NEPA documentation would be prepared prior to implementation.

8.8 Management Actions

Management actions are those decisions that could be made to affect groundwater conditions without the need for additional capital projects or approval beyond the appropriate governing board.

8.8.1 Management Action 1: Continued Balanced Pumping and Recharge

Continued balanced pumping of groundwater and recharge of imported supplies has and will continue to be the operational norm for WKWD. Under this management action, recharge and recovery activity will continue to be monitored closely by WKWD to maintain balanced conditions.

The only water management agency within the WKWD GSA is WKWD, whose supplies include groundwater and imported water. The Subbasin is naturally recharged by the Kern River, primarily through seepage from the stream channel and occasional flood flows. Imported water comes from the SWP, which is ultimately sourced from the Sacramento River and the Delta. According to the 2015 UWMP, WKWD has rights to 31,500 AFY imported water from the SWP in total, with the potential to receive an additional 10,000 AFY during wet years. A portion of WKWD's SWP allocation is delivered directly to WKWD's customer, La Paloma Power Facility, as raw water, with the remainder of imported water recharged into the Subbasin and later extracted. When additional supplies are available, WKWD practices groundwater banking, storing excess water in the Subbasin.

WKWD's 2015 UWMP reports that WKWD had 200,000 AF of banked water supplies, and an additional 24,000 AF owed to WKWD by other agencies.

Public Notice and Outreach

This management action does not require public notice and outreach because it does not represent a change in how WKWD manages its water supplies. WKWD provides annual water quality reports to its customers and engages in a variety of public outreach efforts, such as classroom educational programs, to encourage responsible water use. Responsible water use is an important component of the continued sustainability of current water management practices. Important announcements are provided in both English and Spanish to increase dissemination of information.

Permitting and Regulatory Processes

Continuing sustainable operation of groundwater recharge and pumping requires maintaining existing permits and continued compliance with applicable regulations. WKWD's operations are subject to the terms of its drinking water permit (Permit No. 1510022) and wellfield operations permit (Permit No. 03-

12-09P-001), which are issued by the SWRCB. No additional permits would be required to implement this management action.

Management Action Benefits

This management action would allow WKWD to continue operating groundwater recharge and recovery in balance, resulting in a long-term net-zero balance in the Subbasin for the areas under WKWD's control. As demonstrated in WKWD's 2015 UWMP, historically WKWD has operated its groundwater banking efforts with a net positive volume of stored water for recovery during times of supply shortages, such as drought. WKWD expects that demand for groundwater will decrease as the oilfields in its jurisdiction reduce pumping (and therefore, related associated water demands); it also expects changes in SWP supply reliability. As a result, WKWD does not anticipate a long-term negative balance in its groundwater banking. The full benefits of this management action would be evaluated through water accounting of recharge volumes compared to pumping. All the wells in WKWD's jurisdiction are metered, so a full accounting of water recovered is available, and all water recharged is accounted for by WKWD's metered turnouts from the California Aqueduct and known purchases of SWP water used for recharge.

Continuing the practice of balanced pumping and recharge would benefit the MO of protecting GWEs, supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Management Action Implementation

This management action would be accomplished by continuing existing groundwater recharge and recovery operations. Surplus water would continue to be banked, while groundwater would be recovered to supplement supplies in years where imported water shortages are projected.

Management Action Status and Timing

The circumstance of project implementation would be current conditions and would remain unless conditions indicated a different management approach was needed to achieve sustainability indicators.

This management action continues WKWD's current operation of its system to bank surplus water and balance pumping with recharge and is already being implemented. The benefits of Management Action 1 are currently being realized and are reflected in WKWD's existing 200,000 AF of banked groundwater.

Supply Reliability

This management action depends on continued access to SWP supplies. The long-term reliability of SWP supplies is estimated at 61 percent in WKWD's 2015 UWMP. With an allocation of 31,500 AFY from the SWP, WKWD expects a long-term average delivery of SWP supplies to be 19,215 AFY. Additional

water is secured through transfers or exchanges with neighboring agencies, including BVWSD, Rosedale-Rio Bravo Water Storage District, and the Kern Tulare Water District, with long-term transfer of water from BVWSD expected at 6,500 AFY. Water available through individual years' transfers and exchanges are expected to vary from a low of 6,500 AF to as high as 12,450 AF from a combination of these sources.

Per the 2015 UWMP, these volumes will result in a surplus of supplies in average water years; in accordance with current management practices, this surplus is expected to be banked for use during dry years. During multiple dry years, SWP supplies are expected to drop to as low as 8 percent of normal, and imported supply shortfalls would be met using banked groundwater, projected to range between 6,300 and 12,700 AF in multiple dry years with low SWP availability. Given that WKWD has 200,000 AF of banked groundwater, this banked supply should be sufficient to serve approximately 10 years of demand without entering deficit, even when no other supplies, including imported or surface water, are available.

Legal Authority

The sole water supplier in the WKWD GSA is WKWD. WKWD owns and operates the only groundwater recovery wells in the North and South management areas. A small number of wells are operated by Kern County to maintain the BVARA, and no other private wells can be used in the GSA area. WKWD operates its groundwater recovery wellfields under a permit issued by the SWRCB's Division of Drinking Water (Permit No. 03-12-09P-001) and is an authorized public water supplier. Groundwater banking operations are undertaken in partnership with BVWSD. Continued operation of both the groundwater bank and the groundwater recovery wells falls within WKWD's authority, and as a result, within the boundary of the WKWD GSA.

Management Action Costs

The cost of continued balanced operation of groundwater recharge and recovery would remain within normal WKWD operating costs. These costs are expected to increase over time due to inflation, but do not represent an additional capital investment. WKWD's operating costs include natural gas, electricity, customary fees associated with conveying water in canals, and facility maintenance. Costs to implement this management action would be met through WKWD's standard rate structure, with rate changes implemented as necessary to address inflation and rising costs described above.

Technical Justification

Existing groundwater banking operations have been monitored since WKWD inception in the early 1960s. The volume of water recharged and available for recovery is calculated to be 90 percent of the water volume entering the North and South Project management areas. The 10 percent decrease assumes a 6 percent water loss due to evaporation and a 4 percent water loss due to groundwater migration. These losses were calculated based on groundwater scenario modeling, the siting and design of recharge ponds below the near-surface fine grained sands (which have lower infiltration potential), and the experience of other groundwater banking operations in the region (WKWD, 2010).

Subbasin Uncertainty

WKWD currently manages water supplies to address uncertainty by banking groundwater during wet years for use during years with SWP and surface water shortages. WKWD's current management practices have resulted in approximately 200,000 AF banked groundwater. This is despite high variability in available supplies for recharge since initiation of WKWD's groundwater banking activities, including times of severe drought, such as the 2012-16 drought. WKWD's 2015 UWMP indicates that the existing banked supplies are adequate as the sole source of supply for 10 years, if SWP deliveries are decreased to 0 AFY. While dry years may result in drawdown of banked groundwater, normal and wet years will result in increases to banked groundwater. Because dry years are the only years where surplus water could not be banked, the long-term net forecast for dry, normal, and wet years would result in maintenance of groundwater levels or an increase in banked groundwater. Existing banked supplies demonstrate that current groundwater management can provide sufficient reserves to act as a buffer for uncertainty in the GSA area.

Subbasin uncertainty identified in the Basin Setting sections of this Chapter GSP is not anticipated to substantially affect WKWD's ability to implement this management action or the overall effectiveness of this management action given the substantial water supply reserves already banked.

CEQA/NEPA Considerations

No additional CEQA or NEPA documentation or compliance measures would be required to implement this management action because it does not require implementation of a project as defined by CEQA or NEPA.

8.8.2 Management Action 2: Implement Water Shortage Response Plan

WKWD's *Water Shortage Response Plan* (WSRP) is incorporated into the 2015 UWMP and includes triggers for when the WSRP would be implemented. The WSRP describes management actions and use restrictions that would be implemented if water shortages were declared. Because current operation of groundwater recharge and recovery in the GSA area has shown a long-term increase in banked groundwater, and normal water years are projected to have a surplus of supply that can be banked, it is not expected that the WSRP would go into effect during normal or wet years. During extended dry periods, groundwater pumping would increase, and WKWD would use banked supplies to meet demands in excess of available imported and surface water supplies. The WSRP might be implemented to address statewide conservation requirements, such as during the 2012-16 drought, or when supplies are restricted, or for other reasons that may require a reduction in demand.

In the WSRP, demand on imported and surface water is reduced as a result of customer conservation and increased pumping from the groundwater bank. The WSRP has four stages, which are implemented following a Response Level declaration by WKWD's Board of Directors. Table 8-3 lists those Response Levels, the conservation required, and the groundwater bank pumping needed.

Table 8-3. WSRP Response Levels

Response Level	Conservation Target (Percent)	Customer Conservation (AF)	Groundwater Bank Pumping (AF)
Level 1 – Water Awareness	0 to 10	0	2,800
Level 2 – Water Restrictions	20	2,750	2,750
Level 3 – Critical/Water Reduction	30	4,150	4,150
Level 4 – Emergency/Water	50	6,900	6,900

Notes:
[a] Groundwater bank reserves will make up for any part of the Response Level 1 conservation not met
[b] Adapted from Table 8-1 in WKWD's 2015 UWMP

For Response Levels 2 through 4, a variety of water use restrictions would be implemented using a mix of voluntary and mandatory restrictions, depending on the Response Level and at the discretion of WKWD's Board of Directors. Restrictions may include limits on when landscape irrigation may occur, time limits for repairing leaks, and measures to avoid excess runoff and water waste, among other measures. Enforcement of WSRP violations would include warnings, fees, and potential discontinuation of service per WKWD's 2015 UWMP.

The WSRP includes triggers for when WKWD's Board of Directors may declare a Response Level, though only Response Level 1 has hard triggers. Response Level 1 may be declared if the following three conditions are met:

- Consecutive three-year state-wide drought
- Significant reduction in groundwater levels, as deemed by the Board of Directors
- Significant reduction in groundwater storage, as deemed by the Board of Directors

Response Level 1 may also be declared if facility or infrastructure issues result in a significant reduction of water supplies.

According to WKWD's 2015 UWMP, Response Levels 2 through 4 do not have hard triggers, but are declared by the Board of Directors after declaration of a water shortage emergency and upon consideration of the following factors:

- Local drought conditions
- General statewide drought conditions
- Groundwater depths, including recent changes
- Total banked groundwater storage, including recent changes
- Changes in well capacity due to groundwater level declines
- Recent allocation of surface water
- Short-term ability to purchase water from other sources

- Water quality issues impacting water supply
- Infrastructure issues (such as well failure, pipeline failure, or aqueduct breach) that could significantly reduce water supplies

Although Response Levels 2 through 4 are more subjective than Response Level 1, the circumstances that trigger them can generally be described as needing to reduce water use due to drought or other restriction in supply (Response Level 2), needing to increase cutbacks due to continued drought or disaster (Response Level 3), and requiring reduced demand so that WKWD has sufficient water supply to meet basic needs (Response Level 4).

Public Notice and Outreach

At all four Response Levels, WKWD implements public outreach to encourage water conservation and notify customers of voluntary and mandatory water use restrictions per the 2015 UWMP. Declaration of a Response Level by WKWD's Board of Directors takes place at public Board meetings, which are publicly noticed.

For each violation of a Response Level requirement, a customer would receive written notice of the violation and information about the consequences of continued violation. WKWD's 2015 UWMP, including the WSRP, underwent public review and was noticed in accordance with the *Final 2015 Urban Water Management Plan Guidebook for Urban Water Suppliers* and California Water Code Sections 0642 and 10608.26 (DWR, 2016c).

Permitting and Regulatory Processes

As previously mentioned, implementation of the WSRP requires WKWD's Board of Director approval through a Response Level declaration. Implementation of the water use restrictions following declaration would not require any additional permitting or regulatory action.

Management Action Benefits

The WSRP is designed to reduce customers' overall water use by implementing restrictions on when and how water may be used. As a result, implementation of this management action would reduce overall demand, which offsets demand for imported water and groundwater. Each Response Level is designed to help achieve a specific conservation target, and would reduce overall demands between 0 and 6,900 AF (i.e., 0- to 50 percent conservation) (Table 8-3). Conservation achieved by this management action would be measured by the reduction in metered water deliveries after this management action is implemented.

Increasing water conservation would reduce demands for potable water, thereby reducing the volume of water pumped from the Subbasin.

This management action would benefit the MO of protecting GWEs from excess pumping during years with supply shortages, supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Management Action Implementation

Implementation of the WSRP requires declaration of a Response Level from WKWD's Board of Directors, at which time WKWD staff would begin outreach efforts with customers and explain restrictions that would be implemented for a given Response Level. WKWD staff would be responsible for enforcement of the restrictions described in the WSRP, and for changes to pumping volumes from the groundwater bank. Individual customers would be responsible for complying with water use restrictions, and WKWD would penalize violations in accordance with the WSRP.

Management Action Status and Timing

The circumstance of implementation for this project would be times of water shortage, supply interruption, or drought, as declared by WKWD's Board of Directors. Implementation would cease when shortages are no longer being experienced, and as approved by the WKWD's Board of Directors.

The WSRP is not actively being implemented, but it is available for implementation should the WKWD Board of Directors initiate a Response Level declaration. The WSRP was activated during the 2012-16 drought, and while water supply conditions have since improved and restrictions have been lifted, the WRSP is ready to be activated at any moment. Once activated, water use restrictions in the WSRP would apply immediately or in the near future, pending the terms of the Board of Director's declaration activating the Response Level. Water conservation benefits would begin accruing immediately after these water use restrictions were implemented, though it may take a short period of time for customers to learn about and adjust to the restrictions before full benefits are realized. The enforcement actions available to WKWD through the WSRP would help achieve full benefits relatively quickly.

Supply Reliability

This management action includes conservation, which does not depend on supplies for successful implementation, and groundwater pumping from banked resources. The groundwater pumped during implementation of the WSRP would come from the surplus banked groundwater and is considered 100 percent reliable for the short-term because WKWD has 200,000 AF currently stored, which is enough to meet the normal-year demand as the sole source of water for a period of 10 years.

Legal Authority

As the sole water supplier in the WKWD GSA area, WKWD has the authority to implement the WSRP at the discretion of its Board of Directors and in accordance with the process described in the WSRP.

Project Costs

Some additional costs associated with public outreach and enforcement of the WSRP Response Levels may be incurred when the WSRP is implemented. Further, as a result of conservation encouraged or required by the WSRP, WKWD's revenue stream is anticipated to decrease when this management action is implemented. However, groundwater is WKWD's lowest cost water supply, so supply-related costs would decrease compared to years when the WSRP is not implemented, which will help offset potential costs for enforcement of the WSRP and reduction of revenue. According to the 2015 UWMP, potential revenue deficiencies created by implementation of this management action could be covered by WKWD's operating funds.

Technical Justification

The WSRP includes water use reduction measures that are commonly implemented in similar plans across the state, including reduction in irrigation volumes, limits on when irrigation may occur and for how long, and prohibitions on excess water use, among other measures. These restrictions provide direct water savings.

Subbasin Uncertainty

Implementation of the WSRP is triggered by changes in the basin setting, specifically drought status and availability of supplies. Successful implementation of the WSRP relies on customer behavior and availability of reliable water supply from banked groundwater. Should customers not achieve conservation targets described in the WSRP, or should they not comply with mandatory restrictions in place for a given Response Level, the WSRP includes measures to penalize customers who are in violation, including the ability to shut off water service to repeat offenders.

CEQA/NEPA Considerations

Implementation of the WSRP is not a project as defined by CEQA and NEPA, and therefore does not require CEQA or NEPA compliance to implement.

8.8.3 Management Action 3: Continued Participation in Basin-Wide Coordination

The WKWD GSA is one of 11 GSAs in the Subbasin. Coordination among these GSAs is necessary for sustainable management of the Subbasin as a whole and has been ongoing during development of their respective GSPs. Coordination during GSP development has included regular in-person meetings and calls to discuss sustainability thresholds, potential projects and management actions, and to discuss specific issues and concerns. As described in this Chapter GSP, the KGA is developing an Umbrella GSP for the Subbasin, while the other GSAs in Kern County are developing Chapter GSPs.

The KGA was established in 2014 as a joint powers agency to develop and implement a groundwater management plan in the Subbasin and in the neighboring Tulare Lake Groundwater Basin (KGA, 2017). The KGA currently serves as a forum for coordinating groundwater management activities.

Other nearby entities that WKWD GSA would coordinate with under this management action include the following:

- Kern Water Bank
- Kern River GSA
- Henry Miller GSA
- Pioneer GSA
- Buena Vista GSA

WKWD GSA is adjacent to Kern Water Bank, the Henry Miller GSA, and the Buena Vista GSA. As such, WKWD GSA would engage more frequently with these GSAs because their activities are likely to have a greater potential effect on WKWD GSA, and vice versa.

This management action would involve attending KGA manager meetings and coordination meetings, which are already held monthly, and KGA stakeholder meetings, which are held as needed. Quarterly coordination meetings would be held with Buena Vista GSA, the Henry Miller GSA, and the Kern River GSA, while annual coordination meetings would be held with the Pioneer GSA. These meetings would be an opportunity to discuss progress toward meeting sustainability goals, potential changes in overall groundwater levels and quality, and potential management actions and projects to address common concerns. Coordination of five-year updates to GSPs in the Subbasin would also occur as part of this management action (see Section 9.0).

Public Notice and Outreach

This management action involves internal coordination between GSA managers, and does not require public participation in the meetings themselves. KGA stakeholder and Board of Director meetings are publicly noticed, with agendas and meeting materials posted online. This management action assumes that decisions made in these meetings would be presented at an appropriate Board of Directors meeting or stakeholder meeting.

Permitting and Regulatory Processes

No permits or regulatory approvals would be required to implement this management action because it involves coordination meetings rather than physical projects. Actions or projects resulting from decisions based on coordination meeting outcomes would be subject to the appropriate permitting and regulatory processes if implemented.

Management Action Benefits

This management action would continue existing coordination activities among GSA managers, helping to build and maintain relationships with neighboring GSAs. Potential conflicts between GSAs regarding groundwater management would be reduced because GSAs would better understand the challenges experienced in each GSA area, and how these challenges are being addressed. Coordination meetings will also provide an opportunity for GSAs to inform each other of potential issues that may require intra-Subbasin coordination to address, and to notify neighboring GSAs of management actions or projects that might affect a decision made by another GSA.

Coordination among GSAs would help identify potential threats to groundwater levels and develop projects or actions to address them, which would benefit the MO of protecting GWEs, supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Management Action Implementation

This management action would be accomplished through continued attendance at existing KGA coordination meetings and arranging periodic coordination meetings with the Kern Water Bank, the Kern River GSA, the Henry Miller GSA, the Buena Vista GSA, and the Pioneer GSA. WKWD GSA would designate one or more representatives to participate in these coordination meetings; representatives may include the GSA manager or their staff. Decisions made in coordination meetings would not be binding until approved by the appropriate authority, such as the WKWD GSA manager or WKWD's Board of Directors.

Management Action Status and Timing

The circumstance of implementation for this project is ongoing.

This management action is currently being implemented and may decrease in frequency following completion of GSPs, as GSAs move toward implementation of their GSPs. Timing of coordination meetings are expected to generally align with the frequency described above, as appropriate. Benefits from continued coordination are being realized; WKWD GSA has identified a previously unknown use of groundwater to supplement BVARA lake levels because of coordination activities in the Subbasin. As coordination continues, benefits are expected to continue.

Supply Reliability

This management action does not involve physical water supplies; as a result, supply reliability is does not apply to this management action.

Legal Authority

WKWD GSA is the agency responsible for sustainable management of the GSA area. It has the authority to designate staff to meet with staff from other GSAs and share information as appropriate.

Management Action Costs

Costs associated with this management action would include staff time (salary), transportation costs for in-person meetings, and potential costs associated with reserving facilities, if meetings are not hosted at a GSA member agency's facility. WKWD is a member of the KGA and pays an annual fee to participate. This cost is included in WKWD's annual budget.

Technical Justification

This management action does not involve capital project funding or changes to operations. Direct benefits of this action are not physical. As such, no technical justification is required.

Subbasin Uncertainty

This management action would help address uncertainty in the Subbasin by maintaining communication among groundwater management entities and use existing forums for information sharing. This will help WKWD GSA and its neighbors better understand, anticipate, and plan for uncertain conditions in the Subbasin.

CEQA/NEPA Considerations

This management action does not include implementation of a project as defined by CEQA or NEPA.

8.9 Adaptive Management Strategies

Adaptive management strategies would only be considered for implementation if designated trigger events for that strategy occur. Triggers for each adaptive management strategy are described below. Triggering events would be based on monitoring results and data and are set in relation to undesirable results as described in this Chapter GSP's Section 7.0.

8.9.1 Adaptive Management Strategy 1: Taft Recycled Water Program

The Taft Recycled Water Program would create up to 423 AFY of tertiary recycled water suitable for Title 22-approved applications for recycled water. This project would be implemented in partnership between WKWD, the City of Taft, and the Ford City-Taft Heights Sanitation District (FCTHSD). WKWD provides water within the WKWD GSA area, but sanitation services are provided by the City of Taft and FCTHSD, which jointly own the Taft Wastewater Treatment Facility (WWTF). The Taft WWTF currently produces undisinfected secondary effluent that is suitable for and applied to feed crops, specifically alfalfa. This effluent is not suitable for wider recycled water use, but through upgrade to tertiary treatment, it could be used more widely for non-potable applications, such as landscape irrigation, which currently use potable water to meet demands (WKWD, 2018).

While the *2018 Administrative Draft Recycled Water Project Report* (2018 Feasibility Study) included four subalternatives for tertiary recycled water, this Chapter GSP assumes the Taft Recycled Water Program would install the most comprehensive of these subalternatives, Subalternative 4 (WKWD, 2018).

The project would accomplish the following:

- Install a 1.5-million gallon per day capacity tertiary treatment train that uses direct microfiltration and chlorine disinfection
- Construct a recycled water conveyance and distribution system to serve the identified use sites
- Construct pump stations, booster stations, and pressure reducing stations
- Construct a 1.5-million gallon covered storage facility for tertiary treated recycled water

Secondary effluent not needed for tertiary recycled water production would bypass the tertiary treatment train and would either be used for alfalfa irrigation (or similar approved use) or would be disposed of via spray fields. If Harrington Farms, the current (and only) user of secondary effluent, finds it is infeasible to use excess secondary effluent not needed for tertiary recycled water production, the City of Taft and FCTHSD would resume effluent spray disposal operations. These operations would require some equipment updates and ongoing maintenance of both the spray field and equipment.

Adaptive Management Trigger

This strategy would be triggered if regulatory requirements increase the feasibility of recycled water above the costs, if public demands for recycled water are sufficiently high to offset the cost of implementation, if implementation costs decrease sufficiently that recycled water becomes the preferred alternative, or if a future evaluation of recycled water otherwise determines it to be the preferred alternative.

Public Notice and Outreach

Public outreach would be necessary to bolster public support for the project, as well as to encourage potential customer participation. As identified in the 2018 Feasibility Study, most potential use sites are public parcels, such as schools, sports fields, and parks, though some privately owned sites with large irrigation needs were included in the study as potential customers. Public outreach could help identify additional potential customers or could lead to recommended changes in the project to accommodate anticipated future demands or address potential concerns raised by the public.

Public outreach is also necessary under the CEQA process. The degree of outreach required would depend on the appropriate CEQA document needed for the project. Outreach required by CEQA ranges from public noticing and posting of documents to public meetings at different stages of CEQA document development. Common types of CEQA-related outreach include sending mailers, posting website announcements, and publishing newspaper notices.

Permitting and Regulatory Processes

In addition to construction-related permits, the project partners (WKWD, City of Taft, and FCTHSD) would need to develop a *Title 22 Engineering Report* for approval under the SWRCB's General Waste Discharge Requirement permit (Order WQ 2014-0090-DWQ) that authorizes certain non-potable recycled water uses consistent with Title 22. The existing Taft WWTF is operated under an individual Waste Discharge Requirement permit (Order 5-00-080 and National Pollutant Discharge Elimination System Permit CA0080161), which specifies the quality of effluent from the Taft WWTF, and where and how this effluent may be discharged or used. Modification to the Waste Discharge Requirement permit is also expected to be required before tertiary recycled water could be used.

Moving forward with project implementation would also require an agreement between the three project partners regarding the preferred project alternative and a cost and revenue sharing structure, as well as agreements with potential customers to provide recycled water service. While not required, this project would also benefit from coordination with Harrington Farms, the current user of secondary effluent from the Taft WWTF.

Adaptive Management Strategy Benefits

The project would create up to 423 AFY of tertiary recycled water, offsetting an equal volume of potable water (WKWD, 2018). Available and unused potable water is currently banked for future use during imported and surface water supply shortages. This project would both reduce demand for groundwater pumping during dry years and allow for additional water to be banked during wet years. Tertiary recycled water would be a local supply with high supply reliability, even during drought years. The volume of water offset by this project would be measured by quantifying the amount of tertiary recycled water both produced and delivered.

Offsetting demand for potable water, thereby reducing the volume of water pumped from the Subbasin, would benefit the MO of protecting GWEs, supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Adaptive Management Strategy Implementation

This project would be implemented through an agreement between WKWD, the City of Taft, and FCTHSD. Construction of the project components would involve soliciting bids for design and construction, while delivery of water would involve outreach to and coordination with potential customers and use sites. Once construction is complete and sites are converted for delivery of tertiary recycled water, the treatment component of the Taft Recycled Water Project would be operated by City of Taft and FCTHSD as part of normal Taft WWTF operations, while recycled water conveyance and delivery

systems would be maintained and operated by WKWD. WKWD would also be responsible for billing recycled water customers for deliveries.

Adaptive Management Strategy Status and Timing

The circumstance of implementation for this strategy is reaching one of the triggers described above.

The Taft Recycled Water Program would take longer to implement than the other adaptive management strategies listed here. It is not currently the preferred use of treated wastewater from the Taft WWTF due to the cost of the project and current use of secondary effluent from the Taft WWTF for irrigation, so no further planning for this strategy will take place until a triggering event is reached. This strategy is included here because the WKWD GSA anticipates it will become a more viable project as the State continues to move toward increased water reuse, and as regulations change. Planning, design, permitting, CEQA compliance, and construction of a tertiary recycled water system would take multiple years. Once implemented, benefits will begin to accrue immediately after delivery of tertiary water begins, because it will directly offset demands for potable water.

Supply Reliability

Tertiary recycled water is sourced from wastewater flows, which can vary depending on water conservation efforts, but a minimum baseflow always exists due to basic health and safety-related uses of water. For this reason, tertiary recycled water is reliable and minimally affected by drought.

Legal Authority

Implementation of this project would require coordination between the water supplier (WKWD) and the owners of the Taft WWTF (City of Taft and FCTHSD). Such coordination would most likely be laid out in an MOU similar to the MOU implemented for the 2018 Feasibility Study between the City of Taft, WKWD, West Side Recreation and Park District, and West Side Cemetery District.

For a successful project, a mechanism to guarantee the use of the tertiary recycled water would also be necessary. This may take the form of formal requests for service, MOUs with customers, or mandatory use ordinances. Formal requests for service and MOUs with customers would only require agreements between the project partners (WKWD, City of Taft, and FCTHSD) and the customer, while mandatory use permits would require WKWD or the City of Taft to pass an ordinance.

WKWD is a member of the WKWD GSA and would be able to implement this project in coordination with project partners if it becomes feasible to do so.

Project Costs

The 2018 Feasibility Study estimated capital costs to construct a tertiary treatment and distribution system would be $14,455,000, with annual O&M costs of $415,000. Annualized total cost for the full tertiary recycled water project is $1.51 million, with a recycled water cost of $5,000 per AF. As of 2018, the cost of the proposed project was too high to make it a preferred alternative over the no-project alternative (WKWD, 2018). However, it is anticipated that tertiary recycled water use will increase in value in the future due to increased costs of imported water, changes in regulations, and culture regarding water use.

The cost of the project is expected to be borne by recycled water customers. Costs to individual customers would be determined by which components of the project are required to provide customers service, and how much recycled water is expected to be used. Project costs and costs to individual customers are anticipated to vary from those provided in the 2018 Feasibility Study depending on how many customers participate, potential changes to the project, and when the project might be implemented.

Technical Justification

Design and engineering of the project would comply with applicable standards and regulations, and the project would be designed to meet Title 22 regulations and other applicable recycled water use regulations and permits. Tertiary recycled water is commonly used throughout California and is a known technology with proven safety standards. Any tertiary water used by customers would directly offset potable water demands by physically replacing it with recycled water for irrigation purposes.

Subbasin Uncertainty

Recycled water itself is a reliable supply and is not substantially subject to Subbasin uncertainty. The project would help address uncertainty in the Subbasin by reducing demands for other supplies, allowing for potable water to be used for other purposes such as groundwater banking, sales to other agencies, and to meet other potable demands. Offsetting demands for potable water acts as a buffer against fluctuations in supply and overall Subbasin uncertainty.

CEQA/NEPA Considerations

This project would require CEQA compliance due to the type and size of the project. One of the project partners would be the lead agency under CEQA and would prepare an *Initial Study* to determine the appropriate CEQA document for the project. The other project partners would be responsible agencies under CEQA. Unless the project partners pursue federal funding for the project, NEPA is unlikely to be required as the project in unlikely to require federal actions that would trigger NEPA.

8.9.2 Adaptive Management Strategy 2: Shift Balance of Pumping between North and South Project Management Areas Wellfields

In 2010, WKWD's North Wellfield (wells within the North Project Management Area) was constructed in response to falling groundwater levels at the South Wellfield (wells within the South Project Management Area). Despite a surplus of banked groundwater, local levels at the South Wellfield showed a trending decline associated with groundwater recovery activities. A single wellfield for recovery activities also limited WKWD's operational flexibility. To combat these two management challenges, the North Wellfield was constructed along with additional recharge basins. Under current operation of the two wellfields, 11,300 AFY are pumped from the South Wellfield and 12,700 AFY are pumped from the North Wellfield. The North Wellfield has an annual pumping capacity of 24,000 AFY (WKWD, 2010).

This adaptive management strategy entails WKWD increasing the proportion of groundwater pumped at the wellfield that is experiencing the least decline in groundwater levels. This strategy would allow local recovery of groundwater levels in the other wellfield.

Adaptive Management Triggers

This adaptive management strategy would be considered if groundwater levels in either wellfield fell below baseline groundwater levels. As banked water is extracted, groundwater levels are expected to temporarily decline. Assuming equivalent aquifer hydraulic properties, the greatest decline would be localized around the wellfield pumping the most water. These temporary declines in groundwater levels are generally planned, such as during years when large water transfers occur. This trigger would only apply when declines in groundwater levels are not associated with planned events.

This trigger would be activated at the discretion of the WKWD's General Manager or their designee. The decision to activate this trigger would be based on a trend of declining GWEs (i.e., more than 20 percent of the historical GWE range below the historical minimum for each well, exclusive of declines attributable to a planned management decision).

Alternatively, WKWD may choose to implement an adaptive management zone which would serve as the trigger for considering adaptive management strategies. An adaptive management zone would establish a range of GWEs; if monitoring finds groundwater levels are within the adaptive management zone, the trigger would be activated.

Public Notice and Outreach

The decision to adapt groundwater pumping between the two wellfields is an internal management decision and does not require public notice or outreach. Changes to wellfield production would be reported using standard reporting methods, consistent with current management processes.

Permitting and Regulatory Processes

Pumping volumes are limited in the North Project Management Area wellfield to 12,700 AFY and are not limited on the South Project field. Operation of both wellfields are regulated by their respective permits. If pumping at each wellfield remains within its permitted capacities, and are in accordance with applicable agreements, no additional permits would be required to implement this adaptive management strategy.

Adaptive Management Strategy Benefits

This adaptive management strategy would reduce groundwater pumping in a localized area, allowing water levels in that area to recover or to decline less sharply during times of drought. Minimizing groundwater level declines reduces the potential for localized subsidence and long-term decrease in groundwater storage capacity. It also helps to maintain well efficiency, allowing for improved wellfield longevity. Local recovery of GWEs would be determined by standard monitoring activities that are part of regular wellfield management. Local groundwater level recovery from this strategy would be measured by monitoring of groundwater levels in the vicinity of the two wellfields.

This adaptive management strategy would help local recovery of groundwater levels, which would benefit the measurable objective of protecting GWEs, supporting the four sustainability indicators relevant to the WKWD GSA:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Adaptive Management Strategy Implementation

This adaptive management strategy would be implemented by WKWD staff by changing how much water is pumped from each wellfield as an operational change. It would not require infrastructure improvements or additional investment, nor would it require any additional permits or budgetary changes.

Adaptive Management Strategy Status and Timing

The circumstance of implementation for this adaptive management strategy would be if the trigger as described above is reached.

Implementation would require easy-to-implement operational changes and could be implemented quickly once triggered. Benefits of this strategy are expected to begin accruing immediately after it is implemented, though some time may be required before monitoring shows related changes in groundwater levels.

Supply Reliability

WKWD has a surplus of banked groundwater available to recover. This adaptive management strategy would address potential long-term reliability issues with recovery of this banked groundwater that may arise if localized groundwater levels decline too far. The North Wellfield was constructed specifically to address supply reliability concerns that arose at the South Wellfield, where local GWEs had fallen to the point where there were concerns about impacts to overall well capacity. By balancing pumping between the two wellfield operations, and if unplanned localized declines are identified, WKWD would proactively protect wellfield reliability and long-term access to its banked groundwater supplies.

Legal Authority

WKWD is a member of the GSA and has full control over the North and South wellfields. WKWD makes operational decisions associated with both wellfields, and all management decisions within the legal limits of applicable permits. Additionally, all agreements are within the authority of WKWD.

Project Costs

This adaptive management strategy does not change the total volume of water recovered by WKWD; it adjusts how much water is pumped in each wellfield. Costs associated with this adaptive management strategy include energy demands for pumping and conveyance. Because energy demands for both wellfields are met with the same supply, and total pumping would remain consistent with regular demand,

and cost differences associated with shifting pumping volumes are expected to be negligible. Some cost savings may be realized by adjusting the balance of pumping between the wellfields because energy demands for pumping increase as groundwater levels decline.

Technical Justification

In the absence of water use restrictions, water demands within the GSA area are independent of available supply. Demands originally served by only the South Wellfield are now served using a combination of the two wellfields, decreasing the intensity of overall pumping at the South Wellfield. Long-term GWE data from both two wellfields are anticipated to support the use of the North Wellfield to allow groundwater levels in the South Wellfield to recover or maintain GWEs. The North Wellfield was constructed at the beginning of the 2012-16 drought. As a result of imported water supply shortages during the drought, groundwater levels in both wellfields declined. Benefits to the South Wellfield from construction of the North Wellfield are expected to be realized as the region recovers from drought. For more information, see WKWD's 2015 UWMP.

Subbasin Uncertainty

This adaptive management strategy would be implemented in response to unplanned changes in the GSA area, specifically changes in groundwater levels that would impact long-term ability to pump banked groundwater at either of the two wellfields. Pumping volumes for each wellfield would be determined by WKWD staff and may be adjusted during implementation of this adaptive management strategy as appropriate, depending on demand and recovery of GWEs in response to the changes.

CEQA/NEPA Considerations

The South Wellfield was constructed in the late 1960s and predates both CEQA and NEPA. As such, it was not subject to CEQA and NEPA review when constructed. The North Wellfield achieved CEQA compliance in 2010, under the WKWD Groundwater Banking Project's *2010 Final Environmental Impact Report* (WKWD, 2010). It was not subject to NEPA review because it did not require discretionary approval from a federal agency. Operation of the North Wellfield is covered by its CEQA and NEPA compliance documentation. Implementation of this adaptive management strategy would not trigger CEQA or NEPA because it falls within the operational boundaries established for the two wellfields and is not a project under CEQA or NEPA.

8.9.3 Adaptive Management Action 3: Implement Permanent Demand Management Measures

According to the 2016 WSRP, Response Level 1 is ongoing, and all water use restrictions are strictly voluntary. These actions only become mandatory if a Response Level 2 is declared, which requires a declaration by the WKWD's Board of Directors. This adaptive management strategy would convert the Response Level 1 actions in the WSRP from voluntary to mandatory. These water restrictions would require a 25 percent reduction in large landscape watering from 2007 levels, prohibit water waste, and reduce non-contracted industrial water use by 15 percent from 2007 levels. WKWD may choose to implement these or a different set of permanent demand management measures as appropriate at the time this adaptive management strategy is approved.

Adaptive Management Strategy Triggers

This adaptive management strategy would be considered for implementation if GWEs meet the following two thresholds:

- Groundwater elevations are within 10 percent of the minimum threshold
- Groundwater elevations are not trending toward the interim milestone or measurable objective

This adaptive management strategy may also be triggered if GWEs that were in the margin of operational flexibility dip below the MT for unplanned reasons, or when groundwater levels fall within the adaptive management zone. If these triggers are met, the GSA would notify WKWD and request that WKWD's Board of Directors approve and implement this adaptive management strategy.

Public Notice and Outreach

Implementation of permanent demand management measures would involve a public outreach campaign similar to that which would be implemented during a Response Level 2 water shortage scenario. Implementation of the action would require WKWD Board of Director approval and would occur at a publicly noticed meeting.

Permitting and Regulatory Processes

The process for implementing this action is WKWD Board of Directors approval, to be held at a public meeting as part of the Board's agenda for that meeting. Upon approval of the Board of Directors, WKWD would be authorized to implement enforcement consistent with the measures in the WSRP. No additional regulatory or permitting processes would be required for implementation.

Adaptive Management Strategy Benefits

Project benefits are expected to be like those achieved under Management Action 2 (Implement WSRP), though they will have long-term benefits because they are permanent measures rather than temporary ones under the WSRP. Conservation achieved by this management action would be measured by the reduction in metered water deliveries after this management action is implemented.

Like Management Action 2, increasing water conservation would reduce demands for potable water, thereby reducing the volume of water pumped from the Subbasin. This project would benefit the MO of protecting GWEs, supporting the four sustainability indicators relevant to the WKWD GSA as follows:

- Chronic lowering of groundwater levels (direct)
- Reduction in groundwater storage (proxy)
- Degraded water quality (proxy)
- Subsidence (proxy)

Adaptive Management Strategy Implementation

Implementation of this adaptive management strategy would involve approval from WKWD's Board of Directors, public outreach to inform customers about the new permanent conservation measures, and enforcement of those measures by WKWD staff. Approval from WKWD's Board of Directors would include clarification on the specific activities that would be prohibited, as well as the penalties for violations. This Chapter GSP assumes that enforcement of this adaptive management strategy would be consistent with enforcement of Response Level 2 of the WSRP.

Adaptive Management Strategy and Timing

The circumstance of implementation for this adaptive management strategy would be if the trigger as described above is reached.

Permanent demand management measures are not currently implemented by WKWD and may require additional time to determine the specific demand management measures to make permanent. It is anticipated that it would require some time to finalize the demand management measures and an enforcement structure before implementation and enforcement. Benefits of this adaptive management strategy are expected to begin accruing immediately after the strategy is implemented, though it may require some additional time before monitoring shows related changes in groundwater levels.

Supply Reliability

This adaptive management strategy is a conservation action and does not depend on a given water supply to implement. Supply reliability therefore does not apply to this adaptive management strategy.

Legal Authority

As the water supplier within the GSA, WKWD has the legal authority to limit non-essential water use. A resolution from WKWD's Board of Directors would be necessary to implement this strategy, but additional approvals would not be necessary.

Project Costs

Like Management Action 2 (Implement WSRP), costs for this adaptive management strategy would be funded by WKWD's normal operating budget. According to the 2015 UWMP, the WSRP shows that implementation of Response Level 2 would reduce WKWD's revenues by $2,746,000, which would be offset by reduced costs associated with not supplying the conserved water and would not require monetary adjustments by WKWD. Implementation of this adaptive management strategy is expected to cost a similar amount and is expected to be funded in the same way.

Technical Justification

Reduction in irrigation water volumes, limits on when irrigation may occur and for how long, and prohibitions on excess water use, among other measures, are commonly used mechanisms for reducing water demand. As when restrictions are implemented under the WSRP, these restrictions provide direct water savings, and were found to be effective during the 2012-16 drought.

Subbasin Uncertainty

This adaptive management strategy would be implemented in response to uncertainty about water supply in the GSA area, and is intended to help reduce that uncertainty by offsetting overall water demands.

CEQA/NEPA Considerations

This adaptive management strategy is not a project under CEQA or NEPA and therefore does not require any CEQA or NEPA compliance.

Article 8. Interagency Agreements			
357.4	Coordination Agreements - Shall be submitted to the Department together with the GSPs for the basin and, if approved, shall become part of the GSP for each participating Agency.	Coordination Agreements shall describe the following:	Umbrella GSP
		A point of contact	
		Responsibilities of each Agency	
		Procedures for the timely exchange of information between Agencies	
		Procedures for resolving conflicts between Agencies	
		How the Agencies have used the same data and methodologies to coordinate GSPs	
		How the GSPs implemented together satisfy the requirements of SGMA	
		Process for submitting all Plans, Plan amendments, supporting information, all monitoring data and other pertinent information, along with annual reports and periodic evaluations	
		A coordinated data management system for the basin	
		Coordination agreements shall identify adjudicated areas within the basin, and any local agencies that have adopted an Alternative that has been accepted by the Department	

9.2 Introduction

As discussed in Section 8.0, several projects, management actions, and adaptive management strategies will or may be implemented by the WKWD GSA. These include the following:

- GSP implementation
- Management actions
- Project implementation
- Adaptative management strategies

Plan implementation is the execution of activities described in this Chapter GSP for sustainable operation of the GSA area of the Subbasin. Some of these activities include the following:

- Continued groundwater level monitoring
- Coordinating among GSAs in the Subbasin
- Installing additional monitoring equipment
- Updating the GSP

Management action implementation activities consist of continued balancing of water recharge and pumping within the GSA area and implementation of the WSRP, as needed.

Project implementation activities are additional projects identified in this Chapter GSP that reduce water demands or increase water supplies within the GSA area. These projects are as follows:

- AMR Project
- Participation in Delta Conveyance Facility
- Buena Vista Lake Project

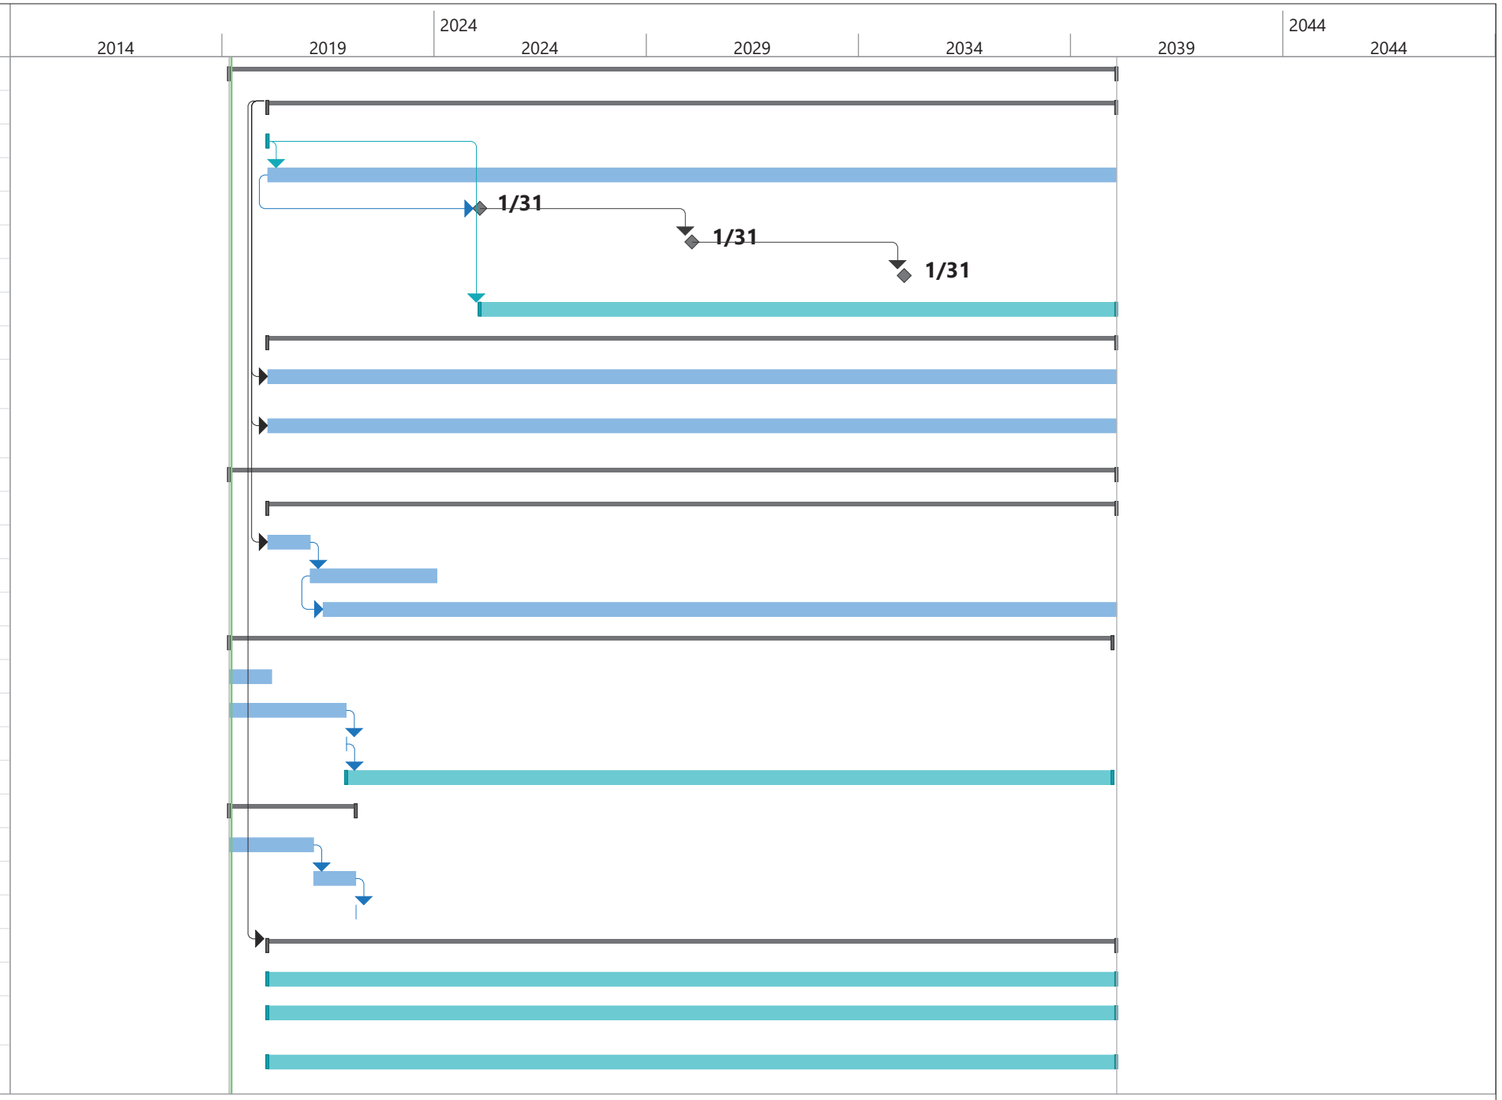
Adaptive management actions are strategies that would be implemented to support WKWD GSA in achieving sustainability as needed. These include the following:

- Taft Recycled Water Program
- Pump balancing and shifting
- Implementing permanent demand management measures

9.3 Implementation Schedule

Figure 9-1 illustrates this Chapter GSP's implementation schedule. Included in the chart are activities necessary for ongoing GSP monitoring and updates, as well as tentative schedules for projects and management actions. More detailed descriptions of the timing and duration of each activity is provided in the respective sections of this Chapter GSP.

Certain GSP implementation activities occur continuously through the planning horizon, and others occur periodically, such as the evaluation of interim targets, which occur every five years (i.e., five-year GSP updates). In Figure 9-1, management actions occur throughout the planning horizon because they are either already being implemented or may be implemented at any time during the Chapter GSP's duration. The implementation schedule for projects is tentative, but the timelines for implementation are intended to provide context for how long it would likely take to implement a project and when benefits could potentially be realized. For the AMR Project, benefits would begin to accrue as meters were installed and customers were added to the online system. For other projects, benefits would begin to be realized after completion of construction. Adaptive management strategies do not have a schedule or duration because they would be implemented only if triggered.



9.4 GSA and GSP Implementation Costs and Funding Source

GSA operations and GSP implementation will incur costs, which will require funding by the GSA. The five primary activities that will incur costs are listed below.

- Implementing the GSP
- Implementing GSP-related projects and management actions
- GSA operations
- Developing annual reports
- Developing five-year GSP updates

The following sections describe these primary activities and discuss potential funding sources.

ID	Task Name	Duration	Start	Finish
1	**WKGSP Implementation**	**5458 days?**	**Mon 3/4/19**	**Wed 2/1/40**
2	**Plan Implementation**	**5218 days**	**Fri 1/31/20**	**Tue 1/31/40**
3	Plan submittal to the State	1 day	Fri 1/31/20	Fri 1/31/20
4	Monitoring	5218 days	Fri 1/31/20	Tue 1/31/40
5	Interim Target Evaluation 1	0 days	Fri 1/31/25	Fri 1/31/25
6	Interim Target Evaluation 2	0 days	Thu 1/31/30	Thu 1/31/30
7	Interim Target Evaluation 3	0 days	Wed 1/31/35	Wed 1/31/35

Figure 9-1: Implementation Schedule

This page intentionally left blank.

9.4.1 GSP Implementation Costs

Costs associated with GSP implementation include the following:

- Performing well monitoring
- Performing management tasks
- Developing annual reports
- Developing five-year GSP updates
- Implementing projects
- Implementing management actions
- Implementing adaptive management strategies

Monitoring of WKWD GSA's current well network is conducted as part of normal WKWD operations. The cost to monitor the current well monitoring network is approximately $25,000 annually and is funded through WKWD's service fee.

WKWD has also undertaken initial management of the WKWD GSA and covered those costs through normal service fees. GSA management is anticipated to cost approximately $100,000 annually, which includes support staff services, GSA General Manager services, and costs for GSA coordination within the Subbasin.

The anticipated cost for developing an annual and a five-year GSP update are $50,000 and $200,000, respectively.

Management actions are generally covered by WKWD's normal operating costs because they represent activities already being undertaken by WKWD. Management Action 3 (continued participation in GSA coordination) would be covered by WKWD GSA's operating costs and is part of GSA management.

Project implementation would incur costs only when implemented and would vary by project activity. Implementation of the actual costs may change depending on when the project is implemented and final design of projects. Installation of AMR systems is projected to cost $4.1 million, though O&M would be included in WKWD's normal operating costs. Participation in Delta Conveyance Facility is expected to cost $1,236 per acre-foot of water received, though costs are expected to change as the State continues to refine the project. Coordination activities to manage water supply at BVARA would be included in WKWD GSA's management activities, though any projects or management decisions that come out of this project could have additional costs that would be determined during evaluation of those projects.

Adaptive management strategies would only be implemented if triggered, and their costs would be incurred only when triggered. The Taft Recycled Water Program is projected to cost $14.5 million, with annual O&M costs of approximately $415,000. The relatively high cost is why this program is an adaptive management strategy rather than a project, though costs are expected to change as technology advances and as planning and design is finalized if triggered. The other two adaptive management strategies would be incorporated into WKWD or WKWD GSA's normal operating costs, because if

implemented, they would be management actions that would not incur additional capital costs, and they would not incur substantial staff costs.

Cost information for GSP implementation is provided in Table 9-2. Individual project, management action, and adaptive management strategy costs are detailed in Section 8.0 of this Chapter GSP.

Table 9-2. Implementation Costs

Implementation Activity	Estimated Cost
Monitoring	$25,000 per year
Management Tasks	$100,000 per year
Annual Reporting	$50,000 per year
Five-Year GSP Updates	$200,000 every five years
Project 1: Automatic Meter Reading Project	$4.1 million ($690/meter)
Project 2: Participation in Delta Conveyance Facility	$1,236 per AF water received
Project 3: BVARA Water Supply Management Coordination	Included in Management Tasks; implementation of projects identified by this Project would have variable costs
Management Action 1: Continued Balanced Pumping and Recharge	Included in WKWD operating costs
Management Action 2: Implement Water Shortage Response Plan	Included in WKWD operating costs
Management Action 3: Continued Participation in Subbasin-Wide Coordination with other GSAs	Included in Management Tasks
Adaptive Management Strategy 1: Taft Recycled Water Program	$14.5 million construction; $415K O&M. Annualized cost $1.51M
Adaptive Management Strategy 2: Shift Balance of Pumping between North and South Wellfields	Included in Management Tasks
Adaptive Management Strategy 3: Implement Permanent Demand Management Measures	Included in WKWD operating costs

9.4.2 GSP Implementation Funding

Initial GSP development and GSA management costs are covered by WKWD through service fees, paid by its customers. WKWD will continue to provide management and funding of GSA and GSP activities, but may seek other funding sources in the future, such as grants, pumping fees, or acreage-based fees. Some GSP-identified projects and management actions, such as monitoring of groundwater wells are already incorporated into WKWD's routine operations and funded through services fees to customers. This method of funding may continue in the future. Costs associated with GSP-identified projects and management actions not previously undertaken by WKWD may be funded through the service fees or through other potential funding sources noted above.

9.5 Annual Reports

Per DWR's Emergency Regulations, GSAs must submit annual reports by April 1 of each year, following GSP adoption.[4] Annual reports must include three key sections described below.

9.5.1 General Information

Annual reports will contain an executive summary that summarize the content of the report and provide information about Subbasin condition. This section will also describe sustainability goals, describe GSP projects and their progress, and describe a general implementation schedule paired with a map of the GSA. Key components of this section required by regulation include the following:

- Executive Summary
- Map of the GSA

9.5.2 Basin Conditions

Annual reports will contain a basin conditions section will describe how conditions have changed in the Subbasin over the past year. Additionally, this section will evaluate GWEs and compare newly collected groundwater data against historical data. The GSA's water extraction volumes and practices will also be described in this section. Information about extraction data, surface water flows, total water use, and groundwater storage will also be included. Key components of this section required by regulation include the following:

- Groundwater elevation data from the monitoring network
- Hydrographs of elevation data
- Groundwater extraction data
- Surface water supply data
- Total water use data
- Change in groundwater storage, including maps

9.5.3 Plan Implementation Progress

In the annual report's plan implementation section, the GSA's progress toward implementing Chapter GSP projects and management actions will be evaluated. This includes evaluating and comparing data about sustainability indicators, including IMs and Subbasin progress toward or maintaining sustainability. Descriptions of the project schedules and funding options will also be provided.

[4] https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/GSP_Emergency_Regulations.pdf

The plan implementation section of the annual report will also describe GSA management actions and may include the following:

- Schedule of management actions
- Management action description
- Management action review of success or progress
- Management action effectiveness helping the GSA reach sustainability per the California Code of Regulations.

If applicable, this section will also evaluate the GSA's adaptive management strategies to help it achieve the sustainability goals. Key components of this section required by regulation include the following:

- Plan implementation progress
- Sustainability progress

9.6 Five-Year Chapter GSP Update

WKWD GSA is required by SGMA to evaluate the progress of their GSP in reaching approved sustainability goals at least every five years, or whenever the GSP is amended. These five-year updates will result in an update of the original GSP, and must include additional information as follows:

- Descriptions of management actions taken
- Reviews of additional data or information about the Subbasin
- Reviews and assessments of monitoring networks
- Descriptions of progress toward addressing data gaps

The components of a five-year GSP update are described below.

9.6.1 Sustainability Evaluation

This section of a five-year GSP update will describe current groundwater conditions for each applicable sustainability indicator and will discuss progress toward sustainability by evaluating current conditions along with IMs, MTs and MOs.

A re-evaluation of wells located in the Western Management Area will be conducted to ensure that groundwater is not produced in the area beyond de-minimis users. Should non-de-minimis use be determined to be occurring, WKWD GSA will consider development of sustainable management criteria for portions of the Western Management Area where non-de-minimis use is occurring.

9.6.2 Plan Implementation Progress

This section of a five-year GSP update will provide information about the progress GSP implementation components, discuss projects that have been implemented, projects that are in the process of being implemented, and projects still on the planning horizon, with an approximate implementation timeline. GSP implementation components include projects, management actions, and adaptive management strategies.

9.6.3 Reconsideration of GSP Elements

Upon submission of a five-year GSP update, DWR may reconsider GSP elements, including basin settings, management areas, undesirable results, MOs, MTs, and IMs. Information that may impact these GSP elements include the following:

- Data collected through the monitoring network
- Changes in water use or water supply
- Changes to water resources through projects and plan implementation

9.6.4 Monitoring Network Description

Per the requirements of DWR Emergency Regulations Section 356.4. (e),[5] the monitoring network will be described, and its function will be assessed. The five-year GSP update will also analyze data collected to date. This section of a five-year GSP update will also re-identify data gaps, and identify actions required to improve the monitoring network. If data gaps are identified, this section will also describe a program for addressing those data gaps, provide a time line for closing data gaps, and describe how data will be incorporated into a five-year GSP update.

9.6.5 New Information

A five-year GSP update will provide new information that has become available since publishing the last GSP annual report, and more specifically, will discuss how this information may impact the Chapter GSP or Subbasin. This section could include information about impacts to the Subbasin setting, MOs, MTs, IMs, or criteria that help define undesirable results.

9.6.6 Regulations or Ordinances

A five-year GSP update will describe any regulations or ordinances implemented by the GSA.

9.6.7 Legal or Enforcement Actions

A five-year GSP update will describe any legal or enforcement actions taken by the GSA during implementation of the GSP to attain the sustainability goals.

[5] https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/GSP_Emergency_Regulations.pdf

9.6.8 Plan Amendments

Any amendments to a GSP will be described in the five-year GSP update.

9.6.9 Coordination

A five-year GSP update will summarize coordination efforts that have occurred among the GSA, other GSAs, and other agencies. This section may include a summary of meetings and discussions held with these groups or may include information about joint projects or data collection efforts.

Re: **NOTICE OF THE WEST KERN WATER DISTRICT'S INTENT TO BECOME A GROUNDWATER SUSTAINABILITY AGENCY**

Dear Mr. Nordberg:

Per Section 10723.8(a) of the California Water Code, the West Kern Water District ("West Kern") gives notice of its decision to form a Groundwater Sustainability Agency ("GSA") for the portion of its jurisdictional boundaries that overly the Kern County Subbasin (Basin Number 5-22.14, DWR Bulletin 118) within the San Joaquin Valley Groundwater Basin.

West Kern's jurisdictional boundaries are depicted in **Exhibit A**.

On June 28, 2016, the West Kern Board of Directors held a public hearing to consider the decision to serve as a GSA. In accordance with Section 10723(b) of the California Water Code, and Section 6066 of the California Government Code, a notice of public hearing was published in a newspaper of general circulation. Proof of publication is shown as **Exhibit B**.

Following the public hearing, West Kern's Board of Directors adopted Resolution No. 16-03, enclosed as **Exhibit C**, electing to become a GSA to the extent of the boundaries depicted in Exhibit A. West Kern is not proposing any new bylaws, ordinances, or other new authorities associated with this GSA formation.

Other agencies that are managing or proposing to manage groundwater within the Kern County Subbasin include: the Kern Groundwater Authority, Buena Vista Water Storage District, Kern River Groundwater

West Kern Water District · 800 Kern St., P. O. Box 1105 · Taft, California 93268-1105 · 661 763-3151 · FAX 661 765-4271

Sustainability Agency, the County of Kern, and the Greenfield County Water District.

As required by Water Code section 10723.8(a)(4), West Kern established and is maintaining a list of interested parties that West Kern will amend as necessary during the GSA formation process and Groundwater Sustainability Plan (GSP) development process. As required by SGMA, West Kern will consider all classes of beneficial users and users of groundwater within the Basin, as well as those responsible for developing GSPs. An initial list of stakeholders and interested party classes includes:

(a) Holders of overlying groundwater rights

(1) Agricultural users
- None known at this time.

(2) Domestic well operators
- Aera Energy, LLC
- California Resources Corporation

(b) Municipal well operators
- City of Taft
- City of Maricopa

(c) Public Water Systems
- West Kern Water District
- Wheeler Ridge-Maricopa Water Storage District

(d) Local land use planning agencies
- County of Kern

(e) Environmental users of groundwater
- None known at this time.

(f) Surface water users
- None known at this time

(g) Federal Government agencies
- Federal Bureau of Prisons (Taft Federal Correctional Institution)

(h) California Native American Tribes
- None known at this time

(i) Disadvantaged communities
- None known at this time

West Kern Water District • P. O. Box 1105 • Taft, California 93268-1105 • 661 763-3151 • FAX 661 765-4271

(j) Entities monitoring and reporting groundwater elevations in all or a part of the groundwater basin
- Kern Groundwater Authority
- Kern Water Bank Authority
- Arvin-Edison Water Storage District
- Deer Creek & Tule River Authority
- Kern County Water Agency Improvement District 4
- Kern-Tulare Water District
- North Kern Water Storage District
- Semitropic Water Storage District
- Shafter-Wasco Irrigation District
- Kern Fan Authority

West Kern is committed to working with all interested parties, across the basin, to develop a GSP that achieves sustainable groundwater management.

By this notice, West Kern has provided DWR with all applicable information required by Water Code section 10723.8(a). If any further information is required, please contact West Kern's general manager, Harry Starkey, at Harry@wkwd.org.

Sincerely,

Harry Starkey
General Manager

RESOLUTION NO. 16-03

RESOLUTION ELECTING TO ESTABLISH THE WEST KERN WATER DISTRICT AS A GROUNDWATER SUSTAINABILITY AGENCY FOR THOSE PORTIONS OF THE KERN COUNTY SUBBASIN OF THE SAN JOAQUIN VALLEY GROUNDWATER BASIN

WHEREAS, the California Legislature passed a statewide framework for sustainable groundwater management, known as the Sustainable Groundwater Management Act (California Water Code § 10720 et seq.) pursuant to Senate Bill 1168, Senate Bill 1319, and Assembly Bill 1739, which was approved by the Governor and Chaptered by the Secretary of State on September 16, 2014; and

WHEREAS, the SGMA went into effect on January 1, 2015; and,

WHEREAS, the SGMA requires all high- and medium-priority groundwater basins, as designated by the California Department of Water Resources (DWR) Bulletin 118, to be managed by a Groundwater Sustainability Agency (GSA) or multiple GSAs; and,

WHEREAS, the Kern County Groundwater Sub-basin has been designated by DWR as a high-priority basin and in critical groundwater overdraft; and,

WHEREAS, the SGMA authorizes a local public agency overlying groundwater sub-basin to elect to become a GSA; and,

WHEREAS, the West Kern Water District (the "District") is a local public agency as defined under the SGMA and is therefore eligible to serve as a GSA; and,

WHEREAS, Section 10723.2 of the SGMA requires that a GSA consider the interests of all beneficial uses and users of groundwater, as well as those responsible for implementing groundwater sustainability plans; and,

WHEREAS, Section 10723.8 of the SGMA requires that a local public agency electing to be a GSA to notify the DWR of its election and intention to undertake sustainable groundwater management within a sub-basin; and,

WHEREAS, the District is committed to sustainable management of its groundwater resources; and,

WHEREAS, pursuant to Government Code Section 6066, notices of a public hearing regarding whether to adopt a Resolution to elect to become a GSA were published on June 14, 2016 and June 21, 2016 in the Taft Daily Midway Driller; and,

WHEREAS, the District held a public hearing on June 28, 2016, after publication of notice pursuant to Government Code section 6066 to consider adoption of this Resolution; and,

WHEREAS, the District wishes to exercise the powers and authorities of a GSA granted by the SGMA;

NOW, THEREFORE, BE IT RESOLVED that this Board of Directors of the West Kern Water District hereby elects to become a GSA for those portions of Kern County subbasin shown in the map attached hereto as Exhibit A; and,

BE IT FURTHER RESOLVED that the District authorizes the General Manager to, within 30 days from the date of this Resolution, provide notification of this election to the DWR, including a copy of this Resolution and additional information required by Water Code Section 10723.8, in the manner required by law; and,

BE IT FURTHER RESOLVED that the District directs the General Manager to begin preliminary negotiations concerning the resolution of potential overlapping GSA boundaries, and to report back about the potential options to resolve any overlapping boundaries.

All the foregoing being upon the motion of Director Morris, seconded by Director Niblett and carried by the following vote:

AYES:	President Barry M. Jameson Vice President David A. Wells Director Gary J. Morris Director Scott Niblett Director Roger Miller
NOES:	None
ABSENT:	None
ABSTAIN:	None

ADOPTED, SIGNED, AND APPROVED this 28th day of June 2016.

Barry M. Jameson,
President of the Board of Directors of
WEST KERN WATER DISTRICT

SECRETARY'S CERTIFICATE

I, Harry O. Starkey, being the appointed secretary of the **West Kern Water District**, do hereby certify that the above and foregoing **Resolution No. 16-03** was duly adopted by the Board of Directors of said District at a legally convened meeting of said Board held on the **28th day of June 2016,** that the above and foregoing is a full, true, and correct copy of **Resolution No. 16-03**, and that the same has not been amended or repealed.

ATTEST:

Harry O. Starkey,
Secretary of the Board of Directors of
WEST KERN WATER DISTRICT

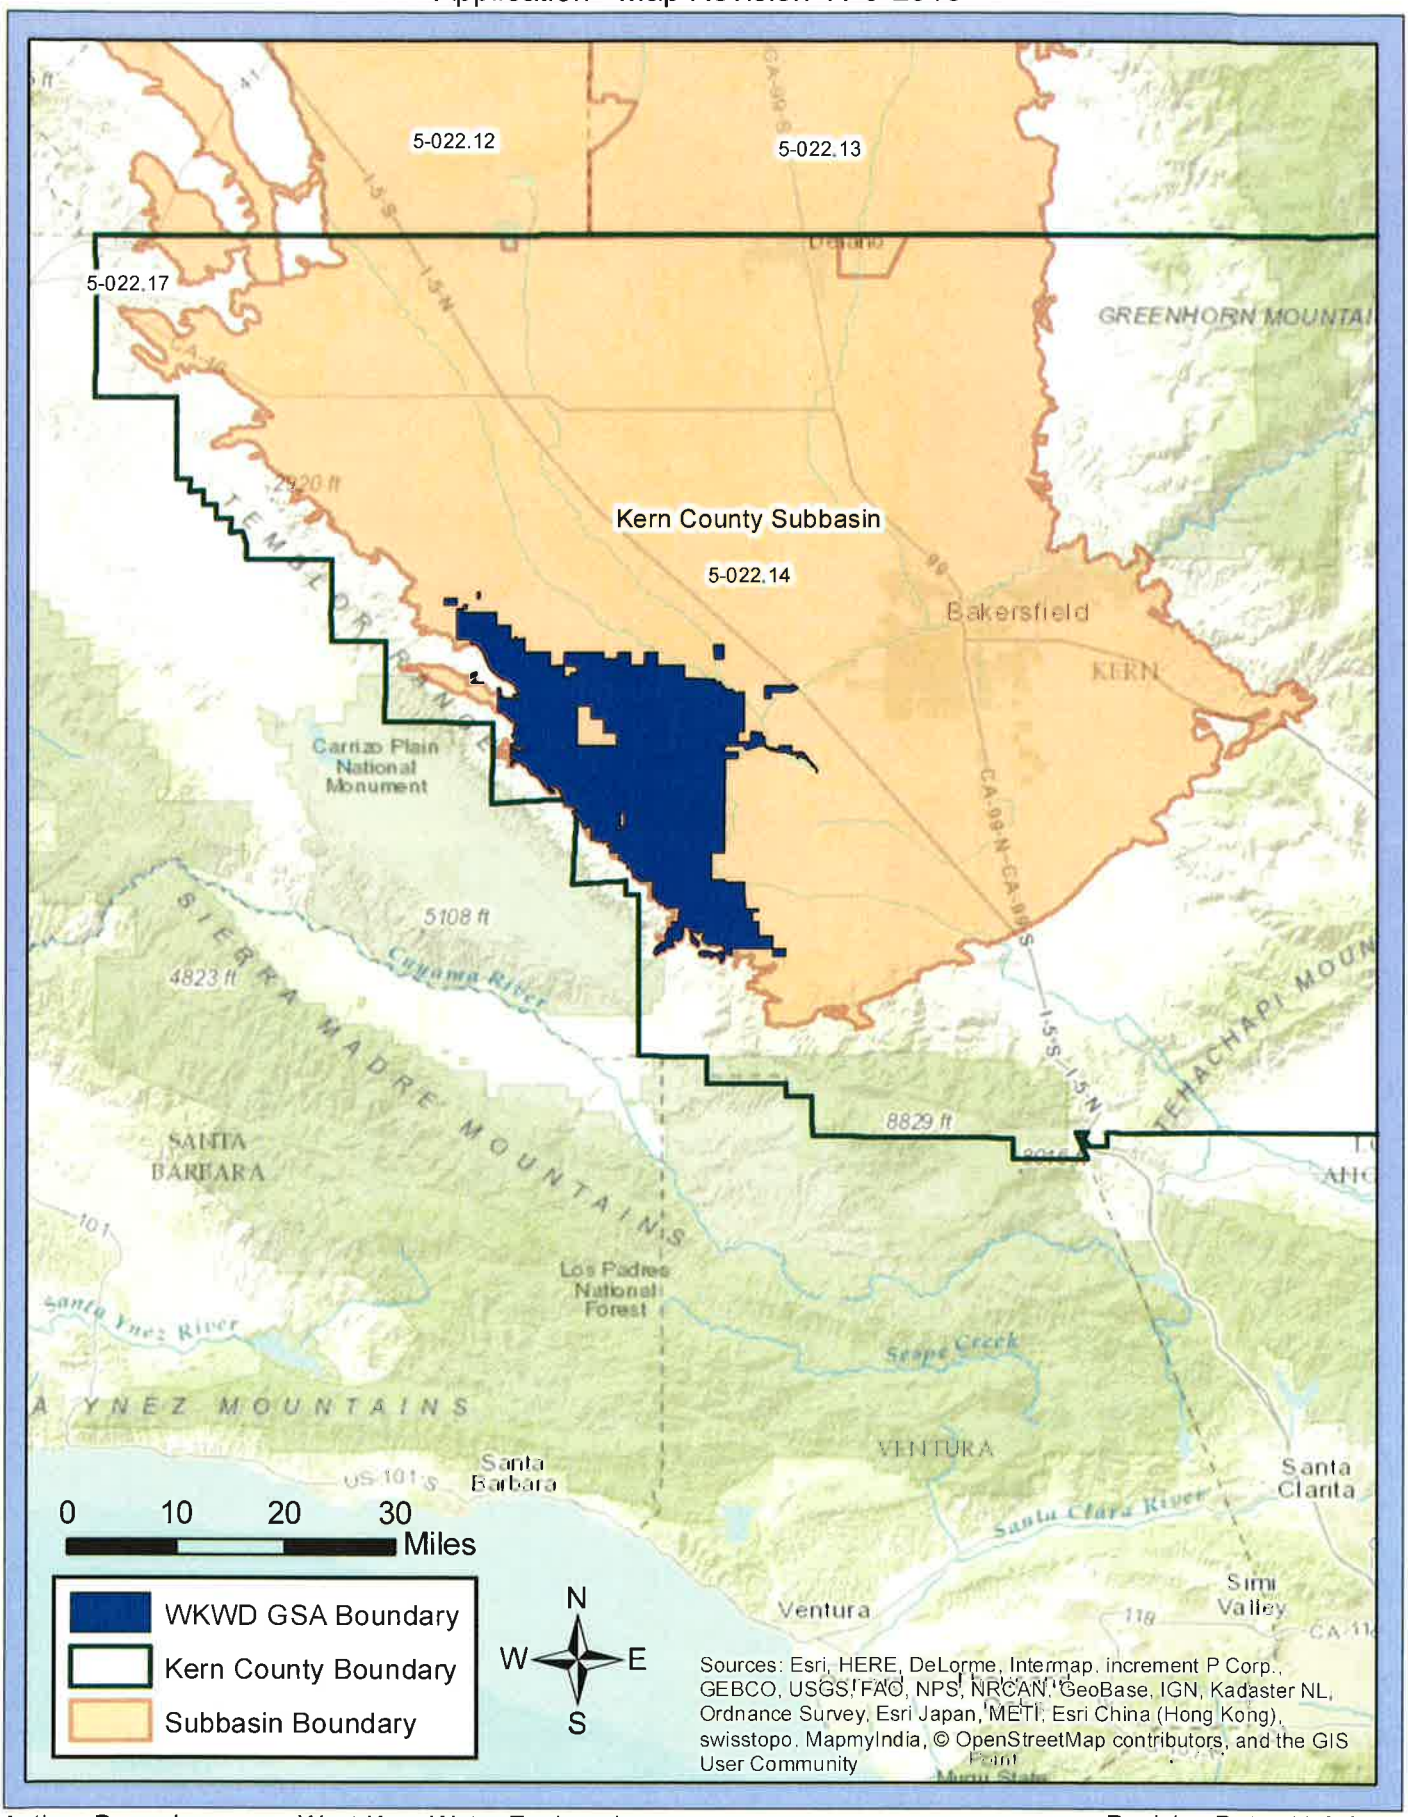
Mr. Mark Nordberg,

West Kern Water District wishes to modify our desired GSA area in order to allow another local agency to potentially be formed and to adjust for the subbasin revisions recently made available to us.
Attached, please find a .pdf map outlining the requested revision. I have also included an ESRI shape file of the revised WKWD-GSA desired area for your use.



Thank You.
