1.0 Introduction

On November 9, 2015, the Kern County Board of Supervisors approved revisions to the Kern County Zoning Ordinance – 2015 (C), focused on Oil and Gas Local Permitting and certified an Environmental Impact Report (SCH #2013081079). Staff was directed to provide an annual update to the Board regarding the process.

1.1 Reporting Period

This report marks the first year of Oil and Gas processing under the new revisions to the Zoning Ordinance. The reporting Period began on December 9, 2015, the first day after the Ordinance was enacted, and goes through November 30, 2016.

1.2 Topics to be Discussed

Staff has proposed the following topics to be discussed in this and each subsequent Report to your Board:

Accounting of Annual Permits

- Oil and Gas Conformity Review
- Minor Activity Review

Accounting of Annual CEQA Mitigation Fees Collected

- Roads Mitigation
- Fire equipment Mitigation
- Rural Crimes Task Force Mitigation
- Biological Habitat Replacement Mitigation
- Air Quality Emission Reduction Agreement Mitigation
- Agricultural Land Replacement Mitigation
- Paleontological Mitigation
- Notice of Exemption Clerk Posting Fee

County Produced Permit Assistance

- Accela Automation
- Oil and Gas Handbook
- Small Producers Handbook

Continued Coordination

- Online Permitting System
- Other County Departmental Reporting
- Emission Reduction Agreement Reporting
- Re-use of Produced Water

2.0 Accounting

2.1 Annual Permits

During the reporting period, the Planning and Natural Resources Department received and processed the following number of permits:

Permit Type	Applied	Issued	Closed
Oil and Gas Conformity Review	1202	1122	125
Minor Activity Review	77	72	20

In the first year of the new program, County Staff has successfully reviewed 100% of applications within the mandated 7-day and 3-day review time frames. With an average 7-day review being completed within 5 days.

2.2 Annual CEQA Mitigation Fees Collected

During the reporting period, the Planning and Natural Resources Department collected the following CEQA mitigation fees:

Mitigation Measure	FEE CODE	AMOUNT
4.16-1	POG050 - Roadway Maintenance/Improvements	$388,700.00
4.14-1	POG051 - Firefighting Equipment	$162,450.00
4.5-3	POG052 - Paleontological Resource	$10,300.00
4.14-2	POG053 - Rural Crimes Unit	$432,225.00
4.2-1	POG054 - Mitigation of Agricultural Land Replacement	$30,996.00
4.3-8	POG055 - Air Quality Impacts	$3,329,332.87
4.3-8	POG057 – SJVAPCD Fee	$138,722.20
4.4-16	POG056 - Biological Resources Mitigation	$60,502.50

3.0 County Produced Permit Assistance

3.1 Accela Automation

Beginning shortly after the project was approved by your Board, Staff began working to create a new permitting process. This process entailed the development of computer aided permitting software, designed to assist in meeting the review periods set out by the adoption of the revisions to the Zoning Ordinance. Accela Automation, the program currently used by the County for processing of grading and building permits by the Public Works Department was selected as the most compatible. Staff worked to design a module capable of handling oil and gas permits. The program was successfully launched at the start of the permitting process and has allowed Staff to input each oil and gas review permit into a database. Benefits of this program include: consistent processing times, accurate fee and mitigation estimates, and has allowed for reporting of permitting types for production of annual reports.

3.2 Oil and Gas Handbook

In January 2016, Staff released the Oil and Gas Handbook. This handbook is designed as an introduction to oil and gas permitting. The handbook can be utilized by oil and gas companies or

by citizens in Kern County to help with understanding the rules and regulations of the local permitting process. A copy of the handbook can be found on the Kern County Website, located: http://www.co.kern.ca.us/planning/pdfs/oil_gas/kern_oil_gas_permitting_handbook.pdf

3.3 Small Producers Handbook and Permitting Software

County Staff released the first version of the Small Producers Handbook in November. This handbook differs from the Oil and Gas handbook, in that it provides a step-by-step tutorial for any company to begin the permitting process. Along with the handbook, Staff worked with a private consultant to create an online permitting tool. This wizard driven program can be used by any company wishing to create a detailed site plan and checklist for mitigation monitoring and reporting. The program, along with the handbook, allows companies to walk through each of the requirements of the Zoning Ordinance and produce a package that can be submitted to County Staff for review.

4.0 Continued Coordination

4.1 Online Permit Submission

Staff is currently developing tools to allow for the online submission of oil and gas permits through the Accela Automation program, known as Citizen Access. Applicants will be able to submit the application package, including site plans, mitigation compliance, and fees completely from their office. They will also have the ability to check the status of their permit and print the necessary permit documents, once a permit has been issued. Staff believes this process will dramatically increase the efficiency of the permitting process and save applicants time and money. Another feature of Citizen Access will be the ability for any member of the public to view past and current permits online. Staff estimates this online feature will be available in January 2017.

4.2 Other County Departmental Reporting

Two mitigation measures approved with the revisions to the Ordinance require other County Departments to file annual reports with your Board. These Mitigation Measures are MM 4.14-2 (Rural Crimes) and MM 4.16-1 (Roads). The Sheriff's Department provided the Board of Supervisors during budget hearings in July and august the staffing levels for the Rural Crimes Unit and is utilizing these funds to keep the unit operational. The Roads Commissioner has determined that the amount of the funding should increase through the first quarter next year before expenditures begin. Projects eligible for the funding were identified in the Final EIR and Public Works is beginning an evaluation of priorities.

4.3 Emission Reduction Agreement Reporting

On August 18th, 2016, the San Joaquin Air Pollution Control (APCD) Board approved the final Emission Reduction Agreement (ERA) between the APCD and the County for mitigation of air impacts as outlined in the Final EIR. County Staff is currently working with the APCD to setup processing for coordination of review with respect to the project selection and approval process and transfer of funds.

4.4 Re-use of Produced Water

Mitigation Measure 4.17-2 states the following:

> Applicant shall increase the re-use of produced water, and reduce its use of municipal and industrial-quality ground or surface water use to the extent feasible. By the end of 2016, the Applicants shall work with the County to review water use data submitted to Division of Oil Gas and Geothermal Resources under Senate Bill 1281 and identify the five biggest oil industry users of municipal and industrial water by volume. The five biggest oil industry users of municipal and industrial water shall work together to develop and implement a plan identifying new measures to reduce municipal and industrial water use by 2020. The plan shall address the following activities, as appropriate: steam generation; drilling and completions (including hydraulic fracturing); dust control; compaction activities related to construction; and landscaping. Through the KernFLOWS initiative or other efforts (e.g., Groundwater Sustainability Agency), the five biggest oil industry users of municipal-and-industrial water shall also work with local agricultural producers and water districts to identify new opportunities to increase the use of produced water for agricultural irrigation and other activities, as appropriate. Any produced water treated and used for agricultural irrigation or other activities shall be tested and monitored to assure compliance with applicable standards for such agricultural irrigation or other uses.

Industry representatives have submitted a memorandum identifying the five biggest industry users of municipal and industrial water by volume. These companies are: Chevron, Freeport-McMoRan Oil & Gas, Aera Energy, LINN Energy, and California Resources Corporation. The estimated amount of combined M&I water injected was 8,000 acre-feet/year. The industry has committed to working together to identify new measures to reduce M&I water by 2020. Staff will continue to update the report as necessary.

1.0 Introduction

On November 9, 2015, the Kern County Board of Supervisors approved revisions to the Kern County Zoning Ordinance – 2015 (C), focused on Oil and Gas Local Permitting and certified an Environmental Impact Report (SCH #2013081079). Staff was directed to provide an annual update to the Board regarding the process.

1.1 Reporting Period

This report marks the second full year of Oil and Gas processing under the revisions to the Zoning Ordinance. The reporting Period began on December 1, 2016, the first day after last year's annual report, and goes through November 30, 2017.

1.2 Topics to be Discussed

Staff has proposed the following topics to be discussed in this and each subsequent Report to your Board:

Accounting of Annual Permits

- Oil and Gas Conformity Review
- Minor Activity Review

Accounting of Annual CEQA Mitigation Fees Collected

- Roads Mitigation
- Fire equipment Mitigation
- Rural Crimes Task Force Mitigation
- Biological Habitat Replacement Mitigation
- Air Quality Emission Reduction Agreement Mitigation
- Agricultural Land Replacement Mitigation
- Paleontological Mitigation
- Notice of Exemption Clerk Posting Fee

County Produced Permit Assistance

- Accela Automation
- Oil and Gas Handbook
- Small Producers Handbook

Continued Coordination

- Online Permitting System
- Other County Departmental Reporting
- Emission Reduction Agreement Reporting
- Re-use of Produced Water

2.0 Accounting

2.1 Annual Permits

During the reporting period, the Planning and Natural Resources Department received and processed the following number of permits:

Permit Type	Applied		Issued		Closed	
	2016	2017	2016	2017	2016	2017
Oil and Gas Conformity Review	1202	1943	1122	1891	125	252
Minor Reworks *	N/A	424	N/A	399	N/A	4
Minor Activity Review	77	118	72	105	20	38

* Permitting initiated in May 2017

In the second year of the program, County Staff has successfully reviewed 100% of applications within the mandated 7-business day and 3-business day review time frames. With an average 7-business day review being completed within 5-business days.

2.2 Annual CEQA Mitigation Fees Collected

During the reporting period, the Planning and Natural Resources Department collected the following CEQA mitigation fees:

Mitigation Measure	FEE CODE	AMOUNT	
		2016	2017
4.16-1	POG050 - Roadway Maintenance/Improvements	$388,700.00	$1,444,500.00
4.14-1	POG051 - Firefighting Equipment	$162,450.00	$380,700.00
4.5-3	POG052 - Paleontological Resource	$10,300.00	$37,950.00
4.14-2	POG053 - Rural Crimes Unit	$432,225.00	$1,065,050.00
4.2-1	POG054 - Mitigation of Agricultural Land Replacement	$30,996.00	$20,817.00
4.3-8	POG055 - Air Quality Impacts	$3,329332.87	$14,443,711.93
4.3-8	POG057 – SJVAPCD Fee	$138,722.20	$584,744.32
4.4-16	POG056 - Biological Resources Mitigation	$60,502.50	$349,985.29

3.0 County Produced Permit Assistance

3.1 Accela Automation

Beginning shortly after the project was approved by your Board, Staff began working to create a new automated permitting process. This process entailed the development of computer aided permitting software, designed to assist in meeting the review periods set out by the adoption of the revisions to the Zoning Ordinance. Accela Automation, the program currently used by the County for processing of grading and building permits by the Public Works Department was selected as the most compatible. Staff

worked to design a module capable of handling oil and gas permits. The program was successfully launched at the start of the permitting process and has allowed Staff to input each oil and gas review permit into a database. Benefits of this program include: consistent processing times, accurate fee and mitigation estimates, and has allowed for reporting of permitting types for production of annual reports.

3.2 Oil and Gas Handbook

In January 2016, Staff released the Oil and Gas Handbook. This handbook was designed as an introduction to oil and gas permitting. The handbook can be utilized by oil and gas companies or by citizens in Kern County to help with understanding the rules and regulations of the local permitting process. A copy of the handbook can be found on the Kern County Website, located:
http://www.co.kern.ca.us/planning/pdfs/oil_gas/kern_oil_gas_permitting_handbook.pdf

3.3 Small Producers Handbook and Permitting Software

County Staff released a Small Producers Handbook in November of 2016. This handbook differs from the Oil and Gas handbook, in that it provides a step-by-step tutorial for any company to begin the permitting process. Along with the handbook, Staff worked with a private consultant to create an online permitting tool. This wizard driven program can be used by any company wishing to create a detailed site plan and checklist for mitigation monitoring and reporting. The program, along with the handbook, allows companies to walk through each of the requirements of the Zoning Ordinance and produce a package that can be submitted to County Staff for review.

4.0 Continued Coordination

4.1 Online Permit Submission

In January of 2017 Staff completed development of a tool to allow for the online submission of oil and gas permits through the Accela Automation program, known as Citizen Access. Applicants now are able to submit an application package, including site plans, mitigation compliance, and fees completely from their office. They also have the ability to check the status of their permit and print the necessary permit documents, once a permit has been issued. This process has dramatically increased the efficiency of the permitting process and saved applicants time and money. Another feature of Citizen Access is the ability for any member of the public to view past and current permits online.

4.2 Other County Departmental Reporting

Two mitigation measures approved with the revisions to the Ordinance require other County Departments to file annual reports with your Board. These Mitigation Measures are MM 4.14-2 (Rural Crimes) and MM 4.16-1 (Roads). The Sheriff's Department provided the Board of Supervisors during budget hearings in July and August the staffing levels for the Rural Crimes Unit and is utilizing these funds to keep the unit operational. The Roads Commissioner has determined that the amount of the funding should increase through the first quarter next year before expenditures begin. Projects eligible for the funding were identified in the Final EIR and Public Works is beginning an evaluation of priorities.

4.3 Emission Reduction Agreement Reporting

On August 18th, 2016, the San Joaquin Air Pollution Control (APCD) Board approved the final Emission Reduction Agreement (ERA) between the APCD and the County for mitigation of air impacts as outlined

in the Final EIR. County Staff continues to work with the APCD on the coordinated review of projects to facilitate their consideration and the subsequent transfer of funds upon approval.

4.4 Re-use of Produced Water

Mitigation Measure 4.17-2 states the following:

> Applicant shall increase the re-use of produced water, and reduce its use of municipal and industrial-quality ground or surface water use to the extent feasible. By the end of 2016, the Applicants shall work with the County to review water use data submitted to Division of Oil Gas and Geothermal Resources under Senate Bill 1281 and identify the five biggest oil industry users of municipal and industrial water by volume. The five biggest oil industry users of municipal and industrial water shall work together to develop and implement a plan identifying new measures to reduce municipal and industrial water use by 2020. The plan shall address the following activities, as appropriate: steam generation; drilling and completions (including hydraulic fracturing); dust control; compaction activities related to construction; and landscaping. Through the KernFLOWS initiative or other efforts (e.g., Groundwater Sustainability Agency), the five biggest oil industry users of municipal-and-industrial water shall also work with local agricultural producers and water districts to identify new opportunities to increase the use of produced water for agricultural irrigation and other activities, as appropriate. Any produced water treated and used for agricultural irrigation or other activities shall be tested and monitored to assure compliance with applicable standards for such agricultural irrigation or other uses.

Industry representatives have submitted a memorandum identifying the five biggest industry users of municipal and industrial water by volume. These companies are: Chevron, Freeport-McMoRan Oil & Gas, Aera Energy, LINN Energy, and California Resources Corporation. The estimated amount of combined M&I water injected was 8,000 acre-feet/year. The industry has committed to working together to identify new measures to reduce M&I water by 2020. Staff will continue to update the report as necessary.

1.0 Introduction

On November 9, 2015, the Kern County Board of Supervisors approved revisions to the Kern County Zoning Ordinance – (2015C), focused on Oil and Gas Local Permitting and certified an Environmental Impact Report (SCH #2013081079). Staff was directed to provide an annual update to the Board regarding the process.

History of Oil and Gas Zoning Amendment

On January 22, 2013, your Board directed Staff to proceed with identifying changes to the Zoning Ordinance that would provide streamlined permitting for oil and gas operations with full California Environmental Quality Act (CEQA) coverage and address surface owners concerns in split estate (surface and minerals owned by different entities) situations. The costs were directed to be fully funded by the oil industry, but as with other development applications, managed by Staff as an objective review and proposal that balanced the needs of business with critical environmental protection and quality of life issues for all of Kern County. The revisions to Title 19 of the Kern County Zoning Ordinance included updated procedures, implementation standards, and conditions for future oil and gas exploration, development, and production activities in unincorporated Kern County. The project required consideration of environmental impacts under the California Environmental Quality Act (CEQA) with an Environmental Impact Report (EIR), which was certified by your Board.

Specifically, the Zoning Ordinance revisions addressed oil and gas exploration and operation activities by:

- Establishing updated implementation standards, conditions and mitigation measures to address environmental impacts of pre-drilling exploration, well drilling, and the operation of wells and other oil and gas production-related equipment and facilities, including exploration, production, completion, stimulation, reworking, injection, monitoring, and plugging and abandonment; and by,

- Establishing new "Oil and Gas Conformity Review" and "Minor Activity Review" ministerial permit (7 day review time) procedures for future well drilling and operations to ensure compliance with the updated implementation standards, mitigation measures, and conditions and provide for ongoing tracking and compliance monitoring.

- Incorporating a 120 day pathway and additional notice and monitoring requirements for projects on split estate that do not have surface owner signature on the site plan application for Oil and Gas Conformity Review in some areas to encourage surface and mineral owner dialogue and resolution of issues.

- Implementing a Mitigation Measure Monitoring Program in compliance with the California Environmental Quality Act, which includes all mitigation measures included in a comprehensive Environmental Impact Report prepared for the project.

The unincorporated valley portion of Kern County was broken up into five Tiers. Tier 1 consisting of land primarily used for oil and gas exploration. Tier 2 consisting of property zoned for agricultural use. Tier 3 consisting of industrial zoned lands. Tier 4 consisting of residential and commercial zones and Tier 5 consisting of Special Planning Areas.

Two types of permits are now required for oil and gas exploration. An Oil and Gas Conformity Review is required for all new wells (exploration, production, observation and injection), re-works of existing wells, and SB4 – regulated activities. A Minor Activity Review is required for other new ground disturbing

activities such as: pipelines, tanks, and treatment facilities that are not associated with an Oil and Gas Conformity Review.

Departmental Structure

On December 9, 2015, oil and gas companies began submitting applications for oil and gas permits. Your Board authorized Staff to develop a system for receiving and processing these permits under a new Departmental Division known as: Energy/Permitting. Currently, the Division is managed by one Division Chief (filled), and one Supervising Planner (filled), three Planners (2 vacant), three Permit Specialists (filled), one Oil Compliance Officer (vacant), and one Office Services Technician (vacant). As permitting levels were low at the beginning of the process Staff has held positions open to ensure adequate processing fees are collected prior to filling vacant positions. Staff has identified the need for a fiscal support position to manage aspects of the reconciliation required by the Auditor. Staff will continue to monitor permitting levels and processing times, as well as process improvement, prior to consultation with the CAO to request and fill vacant positions.

1.1 Reporting Period

This report marks the third full year of Oil and Gas processing under the revisions to the Zoning Ordinance. The reporting Period began on December 1, 2017, the first day after last year's annual report, and goes through November 30, 2018.

During this reporting year, several parties filed lawsuits challenging the adequacy of the certified EIR, and the cases were consolidated before Judge Eric Bradshaw of the Kern County Superior Court (Vaquero Energy, Inc. et al. v. County of Kern et al., King 7 Gardiner Farms LLC v. County of Kern en al., and Committee for a Better Arvin et al. v. County of Kern et al., Kern County Superior Court Case No. BCV-15-101645, consolidated with Case Nos. BCV-15-101666 and BCV-15-101679). On April 20, 2018, the Court issued a judgment (Judgment) that upheld the EIR in its entirety except for requiring supplemental analysis under the California Environmental Quality Act (CEQA) for two (2) issues: (i) impacts to rangeland/grazing land, and (ii) impacts from road paving as a potential future means of mitigation to reduce designated air emissions. The Judgement did not vacate any portion of the Ordinance or the EIR. Pursuant to the Judgment, the Court issued a writ of mandate (Writ) to the County.

In response to the Court's ruling Staff prepared a Supplemental Environmental Impact Report (SEIR) and revisions to the Kern County Zoning Ordinance to address the potential impacts from oil and gas operations to rangeland/grazing land. The Kern County Planning Commission on November 8, 2018 considered and recommended the Board of Supervisors to certify the Supplemental Environmental Impact Report (SEIR) and adopt an ordinance amending various chapters of the Kern County Zoning Ordinance, relating to site development standards and permitting procedures for oil and gas exploration, extraction, operation, and production activities in unincorporated Kern County. The Kern County Board of Supervisors considered the SEIR and project on December 11, 2019 and approved the SEIR and related ordinance. The SEIR and approvals will be submitted back to the Superior Court for review in January, 2019. An appeal to the State of California Appeals Court is pending for consideration sometime in 2019 -2020.

1.2 Topics to be Discussed

Staff has proposed the following topics to be discussed in this and each subsequent Report to your Board:

Accounting of Annual Permits

- Oil and Gas Conformity Review
- Minor Activity Review

Accounting of Annual CEQA Mitigation Fees Collected

- Roads Mitigation
- Fire equipment Mitigation
- Rural Crimes Task Force Mitigation
- Biological Habitat Replacement Mitigation
- Air Quality Emission Reduction Agreement Mitigation
- Agricultural Land Replacement Mitigation
- Paleontological Mitigation
- Notice of Exemption Clerk Posting Fee

County Produced Permit Assistance

- Accela Automation
- Oil and Gas Handbook
- Small Producers Handbook

Continued Coordination

- Online Permitting System
- Other County Departmental Reporting
- Emission Reduction Agreement Reporting
- Re-use of Produced Water

2.0 Accounting

This topic discusses the details of the permitting process in terms of permits processed and mitigation fees collected.

2.1 Annual Permits

During the reporting period, the Planning and Natural Resources Department received and processed the following number of permits:

Permit Type	Applied			Issued			Closed		
	2016	2017	2018	2016	2017	2018	2016	2017	2018
Oil and Gas Conformity Review	1,202	1,943	1,114	1,122	1,891	1,055	125	252	42
Minor Reworks *	N/A	424	925	N/A	399	903	N/A	4	93
Minor Activity Review	77	118	159	72	105	151	20	38	26

* Permitting initiated in May 2017
Source: Accela

In the third year of the program, County Staff has successfully reviewed 100% of applications within the mandated 7-business day and 3-business day review time frames. With an average 7-business day review being completed within 5-business days. Staff notes that the Division of Oil Gas and Geothermal Resources (DOGGR) will not issue the necessary permits unless the applicant has obtained a Kern County permit.

Section 19.98.100 of the Zoning Ordinance has provisions for the processing of an Oil and Gas Conformity Review when there is split mineral and surface ownership. When the applicant cannot obtain a signature from the surface owner, the 120 day permit process is activated. During this reporting period, the

Department has processed and approved three (3) permits under this pathway which include video surveillance, but none have yet to be finaled.

2.2 Annual CEQA Mitigation Fees Collected

The following CEQA mitigation fees were collected during the reporting period. The requirements for the expenditure of each collected amount is detailed in the individual mitigation measures and where appropriate, funds are managed by the County Administrative Office (CAO) to be expended by the responsible entity for specific uses.

Mitigation Measure	FEE CODE	AMOUNT		
		2016	2017	2018
4.16-1	POG050 - Roadway Maintenance/Improvements	$388,700.00	$1,444,500.00	$2,805,000.00
4.14-1	POG051 - Firefighting Equipment	$162,450.00	$380,700.00	$299,550.00
4.5-3	POG052 - Paleontological Resource	$10,300.00	$37,950.00	$61,800.00
4.14-2	POG053 - Rural Crimes Unit	$432,225.00	$1,065,050.00	$1,427,575.00
4.2-1	POG054 - Mitigation of Agricultural Land Replacement	$30,996.00	$20,817.00	$66,247.67
4.3-8	POG055 - Air Quality Impacts	$3,329332.87	$14,443,711.93	$32,268,388.27
4.3-8	POG057 – SJVAPCD Fee	$138,722.20	$584,744.32	$1,301,032.45
4.4-16	POG056 - Biological Resources Mitigation	$60,502.50	$349,985.29	$431,815.40

Source: Accela

The Public Service Mitigation Measure (MM 4.14-1) established a total funding goal in the amount of $850,000.00 for acquisition of industrial firefighting and rescue equipment. Each applicant for an Oil and Gas Conformity Review permit is required to contribute $150.00 per each well for this Special Revenue Fund until the funding goal of $850,000.00 has been met. As of the date of this report the balance of this account has reached $846,925.00. The entire $850,000.00 will be collected by the end of 2018. The Fire Department has ordered the construction of the Combination Walk in/Non-Walk-in Industrial Firefighting Vehicle which will take a year to build.

3.0 County Produced Permit Assistance

3.1 Accela Automation

Subsequent to when the project was approved by your Board, Staff began working to create a new automated permitting process. This process entailed the development of computer aided permitting software, designed to assist in meeting the review periods set out by the adoption of the revisions to the Zoning Ordinance. Accela Automation, the program currently used by the County for processing of grading and building permits by the Public Works Department was selected as the most compatible. Staff worked to design a module capable of handling oil and gas permits. The program was successfully launched at the start of the permitting process and has allowed Staff to input each oil and gas review permit into a database. Benefits of this program include: consistent processing times, accurate fee and mitigation estimates, and has allowed for reporting of permitting types for production of annual reports.

3.2 Oil and Gas Handbook

In January 2016, Staff released the Oil and Gas Handbook. This handbook was designed as an introduction to oil and gas permitting. The handbook can be utilized by oil and gas companies or by citizens in Kern County to help with understanding the rules and regulations of the local permitting process. A copy of the handbook can be found on the Kern County Website, located:
https://psbweb.co.kern.ca.us/planning/pdfs/oil_gas/kern_oil_gas_permitting_handbook.pdf

3.3 Small Producers Handbook and Permitting Software

County Staff released a Small Producers Handbook in November of 2016. This handbook differs from the Oil and Gas handbook, in that it provides a step-by-step tutorial for any company to begin the permitting process. Along with the handbook, Staff worked with a private consultant to create an online permitting tool. This wizard driven program can be used by any company wishing to create a detailed site plan and checklist for mitigation monitoring and reporting. The program, along with the handbook, allows companies to walk through each of the requirements of the Zoning Ordinance and produce a package that can be submitted to County Staff for review. A copy of the handbook can be found on the Kern County Website, located:
https://psbweb.co.kern.ca.us/planning/pdfs/oil_gas/kern_oil_gas_small_producers_handbook.pdf

4.0 Continued Coordination

The success of the permitting program continues to be based on close coordination with State agencies including: DOGGR (Division of Oil, Gas, and Geothermal Resources), State Water Board, RWQCB (Regional Water Quality Control Board), SJVAPCD (San Joaquin Valley Air Pollution control Board), CDFW (California Department of Fish and Wildlife). Every week, a CD with all permits issued and materials submitted are sent so that these agencies, who can then utilize Kern County's enforcement of the permit requirements and EIR as a basis for the issuance of their permits.

Working proactively with the private sector, Staff identified areas for support in the permit process.

- Five individual mitigation measures discuss the need for a Worker Environmental Awareness Program (WEAP) to be in place for each company, prior commencement of any work associated with the oil and gas ordinance. Two private companies (Association of Builders and Contractors and Bruce Hoyt Safety) have become certified as WEAP trainers. This allows any oil company to send their employees to a training class in lieu of developing their own company based WEAP training. For smaller companies, this can equate to a few thousand in savings.

- As part of the processing for an Oil and Gas Conformity Review in a Tier II area, on split estate, the operator must provide for monitoring of all construction activity. As part of the Ordinance, a video surveillance plan may be used in lieu of having an on-site monitor. During the reporting period, three permits have been issued but have not been finaled. The video surveillance plan established will setup cameras on-site and record data during the construction period. Each evening, the video data will be uploaded to the Department for review. This process will continue to allow Staff to quickly review the files and will not require the use of County Staff time to be present for 8-10 hours a day on the job sites. To-date, two of these type of permits have been issued and completed.

- In order to process large quantities of permits with some of the larger oil companies, Staff has worked with the industry to offer fund transfer accounts by establishing a

workorder. The Department holds on retainer a sum of money, deposited by individual companies, and bills against this deposit as permits are issued. This allows the more regular companies to submit permits without the need to issue a check for each one.

As noted above, Staff is continuing to work on the Online Permitting System for all applicants. The System was fully operational in the middle of 2017. The online system allows the public the ability to view permitting activity.

4.1 Online Permit Submission

In January of 2017 Staff completed development of a tool to allow for the online submission of oil and gas permits through the Accela Automation program, known as Citizen Access. Applicants now are able to submit an application package, including site plans, mitigation compliance, and fees completely from their office. They also have the ability to check the status of their permit and print the necessary permit documents, once a permit has been issued. This process has dramatically increased the efficiency of the permitting process and saved applicants time and money. Another feature of Citizen Access is the ability for any member of the public to view past and current permits online.

Along with the handbook(s), Staff worked with a private consultant to create an online permitting tool. This wizard driven program can be used by any company wishing to create a detailed site plan and checklist for mitigation monitoring and reporting. The program, along with the handbook, allows companies to walk through each of the requirements of the Zoning Ordinance and produce an electronic package that can be submitted to Staff for review. These four tools have allowed Staff to continue to meet all processing times, along with providing applicants with helpful ways to learn about the new process and create applications.

4.2 Other County Departmental Reporting

Two mitigation measures approved with the revisions to the Ordinance require other County Departments to file annual reports with your Board. These Mitigation Measures are MM 4.14-2 (Rural Crimes) and MM 4.16-1 (Roads).

The Public Service Mitigation Measure (MM 4.14-2) established that each applicant for an Oil and Gas Conformity Review permit is required to contribute $425.00 per each well for this Special Revenue Fund for the Sheriff's Rural Crime Unit to fund personnel. As of the date of this report the fees collected during this reporting period reached $1,427,575.00. As part of this mitigation measure, the Sheriff's Department is charged with annually reporting to your Board on the expenditure of funds for the Rural Crimes Unit, including incident reports and response times.

The Public Service Mitigation Measure (MM 4.16-1) established that each applicant for an Oil and Gas Conformity Review permit is required to contribute $1,500.00 per each well for this Special Revenue Fund to be expended by the Roads Commissioner for roadway maintenance and related improvements to address wear and tear on roads caused by oil and gas industry traffic. As of the date of this report the fees collected during this reporting period reached $2,805,000.00. As part of this mitigation measure, the Kern County Public Works Department shall annually report to your Board on the expenditure of funds from the Oil and Gas Roadway Maintenance fee.

4.3 Emission Reduction Agreement Reporting

On August 18, 2016, the San Joaquin Air Pollution Control (APCD) Board approved the final Emission Reduction Agreement (ERA) between the APCD and the County for mitigation of air impacts as outlined

in the Final EIR. County Staff continues to work with the APCD on the coordinated review of projects to facilitate their consideration and the subsequent transfer of funds upon approval.

The Kern County Planning and Natural Resources Department is in receipt of the San Joaquin Valley Air Pollution Control District 2018 Annual Report for Indirect Source Review Program for July 1, 2017 to June 30, 2018 which can be reviewed at the following link:

http://www.valleyair.org/ISR/Documents/2018-Annual-Report.pdf

District Rule 9510 Indirect Source Review (ISR), was adopted by the District's Governing Board to reduce the impacts of growth in emissions resulting from new land development in the San Joaquin Valley. Developers of projects subject to Rule 9510 must reduce a portion of the emissions occurring during construction and operational phases through on-site measures, or pay off-site fees.

For 2019 the District has established the emission reductions cost effectiveness fee at $9,090 per ton of emissions reduced. The Kern County Planning and Natural Resources Department Fee Well Emissions and Related Fee Schedule for the year 2019 to take effect January 1, 2019.

4.4 Re-use of Produced Water

Mitigation Measure 4.17-2 states the following:

> Applicant shall increase the re-use of produced water, and reduce its use of municipal and industrial-quality ground or surface water use to the extent feasible. By the end of 2016, the Applicants shall work with the County to review water use data submitted to Division of Oil Gas and Geothermal Resources under Senate Bill 1281 and identify the five biggest oil industry users of municipal and industrial water by volume. The five biggest oil industry users of municipal and industrial water shall work together to develop and implement a plan identifying new measures to reduce municipal and industrial water use by 2020. The plan shall address the following activities, as appropriate: steam generation; drilling and completions (including hydraulic fracturing); dust control; compaction activities related to construction; and landscaping. Through the KernFLOWS initiative or other efforts (e.g., Groundwater Sustainability Agency), the five biggest oil industry users of municipal-and-industrial water shall also work with local agricultural producers and water districts to identify new opportunities to increase the use of produced water for agricultural irrigation and other activities, as appropriate. Any produced water treated and used for agricultural irrigation or other activities shall be tested and monitored to assure compliance with applicable standards for such agricultural irrigation or other uses.

Industry representatives have submitted a memorandum identifying the five biggest industry users of municipal and industrial water by volume. These companies are: Chevron, Freeport-McMoRan Oil & Gas, Aera Energy, LINN Energy, and California Resources Corporation. The estimated amount of combined M&I water injected was 8,000 acre-feet/year. The industry has committed to working together to identify new measures to reduce M&I water by 2020. Staff will continue to update the report as necessary.

1.0 Introduction

On November 9, 2015, the Kern County Board of Supervisors approved revisions to the Kern County Zoning Ordinance – (2015C), focused on Oil and Gas Local Permitting and certified an Environmental Impact Report (SCH #2013081079). Staff was directed to provide an annual update to the Board regarding the process.

History of Oil and Gas Zoning Amendment

On January 22, 2013, your Board directed Staff to proceed with identifying changes to the Zoning Ordinance that would provide streamlined permitting for oil and gas operations with full California Environmental Quality Act (CEQA) coverage and address surface owners concerns in split estate (surface and minerals owned by different entities) situations. The costs were directed to be fully funded by the oil industry, but as with other development applications, managed by Staff as an objective review and proposal that balanced the needs of business with critical environmental protection and quality of life issues for all of Kern County. The revisions to Title 19 of the Kern County Zoning Ordinance included updated procedures, implementation standards, and conditions for future oil and gas exploration, development, and production activities in unincorporated Kern County. The project required consideration of environmental impacts under the California Environmental Quality Act (CEQA) with an Environmental Impact Report (EIR), which was certified by your Board.

Specifically, the Zoning Ordinance revisions addressed oil and gas exploration and operation activities by:

- Establishing updated implementation standards, conditions and mitigation measures to address environmental impacts of pre-drilling exploration, well drilling, and the operation of wells and other oil and gas production-related equipment and facilities, including exploration, production, completion, stimulation, reworking, injection, monitoring, and plugging and abandonment; and by,

- Establishing new "Oil and Gas Conformity Review" and "Minor Activity Review" ministerial permit (7 day review time) procedures for future well drilling and operations to ensure compliance with the updated implementation standards, mitigation measures, and conditions and provide for ongoing tracking and compliance monitoring.

- Incorporating a 120 day pathway and additional notice and monitoring requirements for projects on split estate that do not have surface owner signature on the site plan application for Oil and Gas Conformity Review in some areas to encourage surface and mineral owner dialogue and resolution of issues.

- Implementing a Mitigation Measure Monitoring Program in compliance with the California Environmental Quality Act, which includes all mitigation measures included in a comprehensive Environmental Impact Report prepared for the project.

The unincorporated valley portion of Kern County was broken up into five Tiers. Tier 1 consisting of land primarily used for oil and gas exploration. Tier 2 consisting of property zoned for agricultural use. Tier 3 consisting of industrial zoned lands. Tier 4 consisting of residential and commercial zones and Tier 5 consisting of Special Planning Areas.

Two types of permits are now required for oil and gas exploration. An Oil and Gas Conformity Review is required for all new wells (exploration, production, observation and injection), re-works of existing wells, and SB4 – regulated activities. A Minor Activity Review is required for other new ground disturbing

activities such as: pipelines, tanks, and treatment facilities that are not associated with an Oil and Gas Conformity Review.

Departmental Structure

On December 9, 2015, oil and gas companies began submitting applications for oil and gas permits. Your Board authorized Staff to develop a system for receiving and processing these permits under a new Departmental Division known as: Energy/Permitting. Currently, the Division is managed by one Division Chief (filled), and one Supervising Planner (filled), one Planner (filled), three Permit Specialists (filled), one Oil Compliance Officer (vacant), and one Office Services Technician (vacant). As permitting levels were low at the beginning of the process Staff has held positions open to ensure adequate processing fees are collected prior to filling vacant positions. A fiscal support technician has been assigned to the Energy/Permitting Division to manage aspects of the reconciliation required by the Auditor. Staff will continue to monitor permitting levels and processing times, as well as process improvement, prior to consultation with the CAO to request and fill vacant positions.

1.1 Reporting Period

This report marks the third full year of Oil and Gas processing under the revisions to the Zoning Ordinance. The reporting Period began on December 1, 2018, the first day after last year's annual report, and goes through November 30, 2019.

During the previous reporting year there were several parties that filed lawsuits challenging the adequacy of the certified EIR, and the cases were consolidated before Judge Eric Bradshaw of the Kern County Superior Court (Vaquero Energy, Inc. et al. v. County of Kern et al., King 7 Gardiner Farms LLC v. County of Kern en al., and Committee for a Better Arvin et al. v. County of Kern et al., Kern County Superior Court Case No. BCV-15-101645, consolidated with Case Nos. BCV-15-101666 and BCV-15-101679). On April 20, 2018, the Court issued a judgment (Judgment) that upheld the EIR in its entirety except for requiring supplemental analysis under the California Environmental Quality Act (CEQA) for two (2) issues: (i) impacts to rangeland/grazing land, and (ii) impacts from road paving as a potential future means of mitigation to reduce designated air emissions. The Judgement did not vacate any portion of the Ordinance or the EIR. Pursuant to the Judgment, the Court issued a writ of mandate (Writ) to the County.

In response to the Court's ruling Staff prepared a Supplemental Environmental Impact Report (SEIR) and revisions to the Kern County Zoning Ordinance to address the potential impacts from oil and gas operations to rangeland/grazing land. The Kern County Planning Commission on November 8, 2018 considered and recommended the Board of Supervisors to certify the Supplemental Environmental Impact Report (SEIR) and adopt an ordinance amending various chapters of the Kern County Zoning Ordinance, relating to site development standards and permitting procedures for oil and gas exploration, extraction, operation, and production activities in unincorporated Kern County. The Kern County Board of Supervisors considered the SEIR and project on December 11, 2018 and approved the SEIR and related ordinance. The SEIR and approvals were submitted back to the Superior Court and the SEIR was certified as valid. No challenges remain to the Final EIR in Superior Court. An appeal to the State of California Appeals Court is pending for consideration as three cases. The first case heard in the State Appeals Fifth Appellate District was Vaquero Energy, Inc. v County of Kern (BCV-15-101645) which was decided in favor of the county and applicants on November 19,2019 as a published opinion. The remaining cases are scheduled for oral briefing in January 2020.

1.2 Topics to be Discussed

Staff has proposed the following topics to be discussed in this and each subsequent Report to your Board:

Accounting of Annual Permits

- Oil and Gas Conformity Review
- Minor Activity Review

Accounting of Annual CEQA Mitigation Fees Collected

- Roads Mitigation
- Fire equipment Mitigation
- Rural Crimes Task Force Mitigation
- Biological Habitat Replacement Mitigation
- Air Quality Emission Reduction Agreement Mitigation
- Agricultural Land Replacement Mitigation
- Paleontological Mitigation
- Notice of Exemption Clerk Posting Fee

County Produced Permit Assistance

- Accela Automation
- Oil and Gas Handbook
- Small Producers Handbook

Continued Coordination

- Online Permitting System
- Other County Departmental Reporting
- Emission Reduction Agreement Reporting
- Re-use of Produced Water

2.0 Accounting

This topic discusses the details of the permitting process in terms of permits processed and mitigation fees collected.

2.1 Annual Permits

During the reporting period, the Planning and Natural Resources Department received and processed 2,483 permits and since the inception of the Ordinance 7,166 have been processed (See Table 1 for a breakdown of permit types).

In the fourth year of the program, County Staff has successfully reviewed 100% of applications within the mandated 7-business day and 3-business day review time frames. With an average 7-business day review being completed within 5-business days. Staff notes that the Division of Oil Gas and Geothermal Resources (DOGGR) will not issue the necessary permits unless the applicant has obtained a Kern County permit.

Section 19.98.100 of the Zoning Ordinance has provisions for the processing of an Oil and Gas Conformity Review when there is split mineral and surface ownership. When the applicant cannot obtain a signature from the surface owner, the 120 day permit process is activated. During this reporting period, the Department has processed thirteen (13), approved four (4) and finaled one (1) permit(s) under this pathway which include video surveillance.

Table 1 Permit Issuance

Permit Type	Applied				Issued				Closed			
	2016	2017	2018	2019	2016	2017	2018	2019	2016	2017	2018	2019
Oil and Gas Conformity Review	1,202	1,943	1,114	1,323	1,122	1,891	1,055	1,208	125	1,090	276	49
Minor Reworks *	N/A	424	925	952	N/A	399	903	880	N/A	322	306	50
Minor Activity Review	77	118	159	208	72	105	151	177	20	64	70	20

*Permitting initiated in May 2015
Source: Accela

2.2 Annual CEQA Mitigation Fees Collected

The following CEQA mitigation fees were collected during the reporting period. The requirements for the expenditure of each collected amount is detailed in the individual mitigation measures and where appropriate, funds are managed by the County Administrative Office (CAO) to be expended by the responsible entity for specific uses.

Mitigation Measure	FEE CODE	AMOUNT				
		2016	2017	2018	2019	Totals
4.16-1	POG050 - Roadway Maintenance/Improvements	$388,700.00	$1,444,500.00	$2,805,000.00	$2,769,000.00	$7,407,200.00
4.14-1	POG051 - Firefighting Equipment	$162,450.00	$380,700.00	$299,550.00	$47,026.00	$889,726.00
4.5-3	POG052 - Paleontological Resource	$10,300.00	$37,950.00	$61,800.00	$59,200.00	$169,250.00
4.14-2	POG053 - Rural Crimes Unit	$432,225.00	$1,065,050.00	$1,427,575.00	$1,312,975.00	$4,237,825.00
4.2-1	POG054 - Mitigation of Agricultural Land Replacement	$30,996.00	$20,817.00	$66,247.67	$28,242.00	$146,302.67
4.3-8	POG055 - Air Quality Impacts	$3,329332.87	$14,443,711.93	$32,268,388.27	$38,896,506.00	$88,937,939.07
4.3-8	POG057 – SJVAPCD Fee	$138,722.20	$584,744.32	$1,301,032.45	$1,554,270.00	$3,578,768.97
4.4-16	POG056 - Biological Resources Mitigation	$60,502.50	$349,985.29	$431,815.40	$505,495.00	$1,347,798.19

Source: Accela

The Public Service Mitigation Measure (MM 4.14-1) established a total funding goal in the amount of $850,000.00 for acquisition of industrial firefighting and rescue equipment. Each applicant for an Oil and Gas Conformity Review permit is required to contribute $150.00 per each well for this Special Revenue Fund until the funding goal of $850,000.00 has been met. The total fee of $850,000.00 has been received and the firefighting equipment has been purchased, therefore this fee is no longer collected.

3.0 County Produced Permit Assistance

3.1 Accela Automation

Subsequent to when the project was approved by your Board, Staff began working to create a new automated permitting process. This process entailed the development of computer aided permitting software, designed to assist in meeting the review periods set out by the adoption of the revisions to the Zoning Ordinance. Accela Automation, the program currently used by the County for processing of grading and building permits by the Public Works Department was selected as the most compatible. Staff worked to design a module capable of handling oil and gas permits. The program was successfully launched at the start of the permitting process and has allowed Staff to input each oil and gas review permit into a database. Benefits of this program include: consistent processing times, accurate fee and mitigation estimates, and has allowed for reporting of permitting types for production of annual reports.

3.2 Oil and Gas Handbook

In January 2016, Staff released the Oil and Gas Handbook. This handbook was designed as an introduction to oil and gas permitting. The handbook can be utilized by oil and gas companies or by citizens in Kern

County to help with understanding the rules and regulations of the local permitting process. A copy of the handbook can be found on the Kern County Website, located:
https://psbweb.co.kern.ca.us/planning/pdfs/oil_gas/kern_oil_gas_permitting_handbook.pdf

3.3 Small Producers Handbook and Permitting Software

County Staff released a Small Producers Handbook in November of 2016. This handbook differs from the Oil and Gas handbook, in that it provides a step-by-step tutorial for any company to begin the permitting process. Along with the handbook, Staff worked with a private consultant to create an online permitting tool. This wizard driven program can be used by any company wishing to create a detailed site plan and checklist for mitigation monitoring and reporting. The program, along with the handbook, allows companies to walk through each of the requirements of the Zoning Ordinance and produce a package that can be submitted to County Staff for review. A copy of the handbook can be found on the Kern County Website, located:
https://psbweb.co.kern.ca.us/planning/pdfs/oil_gas/kern_oil_gas_small_producers_handbook.pdf

4.0 Continued Coordination

The success of the permitting program continues to be based on close coordination with State agencies including: DOGGR (Division of Oil, Gas, and Geothermal Resources), State Water Board, RWQCB (Regional Water Quality Control Board), SJVAPCD (San Joaquin Valley Air Pollution control Board), CDFW (California Department of Fish and Wildlife). Every week, a CD with all permits issued and materials submitted are sent so that these agencies, who can then utilize Kern County's enforcement of the permit requirements and EIR as a basis for the issuance of their permits.

Working proactively with the private sector, Staff identified areas for support in the permit process.

- Five individual mitigation measures discuss the need for a Worker Environmental Awareness Program (WEAP) to be in place for each company, prior commencement of any work associated with the oil and gas ordinance. Two private companies (Association of Builders and Contractors and Bruce Hoyt Safety) have become certified as WEAP trainers. This allows any oil company to send their employees to a training class in lieu of developing their own company based WEAP training. For smaller companies, this can equate to a few thousand in savings.

- As part of the processing for an Oil and Gas Conformity Review in a Tier II area, on split estate, the operator must provide for monitoring of all construction activity. As part of the Ordinance, a video surveillance plan may be used in lieu of having an on-site monitor. During the reporting period, three permits have been issued but have not been finaled. The video surveillance plan established will setup cameras on-site and record data during the construction period. Each evening, the video data will be uploaded to the Department for review. This process will continue to allow Staff to quickly review the files and will not require the use of County Staff time to be present for 8-10 hours a day on the job sites. To-date, two of these type of permits have been issued and completed.

- In order to process large quantities of permits with some of the larger oil companies, Staff has worked with the industry to offer fund transfer accounts by establishing a work order. The Department holds on retainer a sum of money, deposited by individual companies, and bills against this deposit as permits are issued. This allows

the more regular companies to submit permits without the need to issue a check for each one.

As noted above, Staff is continuing to work on the Online Permitting System for all applicants. The System was fully operational in the middle of 2017. The online system allows the public the ability to view permitting activity.

4.1 Online Permit Submission

In January of 2017 Staff completed development of a tool to allow for the online submission of oil and gas permits through the Accela Automation program, known as Citizen Access. Applicants now are able to submit an application package, including site plans, mitigation compliance, and fees completely from their office. They also have the ability to check the status of their permit and print the necessary permit documents, once a permit has been issued. This process has dramatically increased the efficiency of the permitting process and saved applicants time and money. Another feature of Citizen Access is the ability for any member of the public to view past and current permits online.

Along with the handbook(s), Staff worked with a private consultant to create an online permitting tool. This wizard driven program can be used by any company wishing to create a detailed site plan and checklist for mitigation monitoring and reporting. The program, along with the handbook, allows companies to walk through each of the requirements of the Zoning Ordinance and produce an electronic package that can be submitted to Staff for review. These four tools have allowed Staff to continue to meet all processing times, along with providing applicants with helpful ways to learn about the new process and create applications.

4.2 Other County Departmental Reporting

Two mitigation measures approved with the revisions to the Ordinance require other County Departments to file annual reports with your Board. These Mitigation Measures are MM 4.14-2 (Rural Crimes) and MM 4.16-1 (Roads).

The Public Service Mitigation Measure (MM 4.14-2) established that each applicant for an Oil and Gas Conformity Review permit is required to contribute $425.00 per each well for this Special Revenue Fund for the Sheriff's Rural Crime Unit to fund personnel. As of the date of this report the fees collected during this reporting period reached $1,312.975.00. As part of this mitigation measure, the Sheriff's Department is charged with annually reporting to your Board on the expenditure of funds for the Rural Crimes Unit, including incident reports and response times.

The Public Service Mitigation Measure (MM 4.16-1) established that each applicant for an Oil and Gas Conformity Review permit is required to contribute $1,500.00 per each well for this Special Revenue Fund to be expended by the Roads Commissioner for roadway maintenance and related improvements to address wear and tear on roads caused by oil and gas industry traffic. As of the date of this report the fees collected during this reporting period reached $2,769,000.00. As part of this mitigation measure, the Kern County Public Works Department shall annually report to your Board on the expenditure of funds from the Oil and Gas Roadway Maintenance fee.

4.3 Emission Reduction Agreement Reporting

On August 18, 2016, the San Joaquin Air Pollution Control (APCD) Board approved the final Emission Reduction Agreement (ERA) between the APCD and the County for mitigation of air impacts as outlined in the Final EIR. County Staff continues to work with the APCD on the coordinated review of projects to facilitate their consideration and the subsequent transfer of funds upon approval.

The Kern County Planning and Natural Resources Department is in receipt of the San Joaquin Valley Air Pollution Control District 2019 Annual Report for Indirect Source Review Program for July 1, 2018 to June 30, 2019, which can be reviewed at the following link:

https://www.valleyair.org/ISR/Documents/2019-Annual-Report.pdf

District Rule 9510 Indirect Source Review (ISR), was adopted by the District's Governing Board to reduce the impacts of growth in emissions resulting from new land development in the San Joaquin Valley. Developers of projects subject to Rule 9510 must reduce a portion of the emissions occurring during construction and operational phases through on-site measures, or pay off-site fees.

The District has not yet established the emission reductions cost effectiveness fee for 2020 yet however when the 2020 fee is adopted the Kern County Planning and Natural Resources Department Fee Well Emissions and Related Fee Schedule for the year 2020 will be prepared and will take effect January 1, 2020 .

4.4 Re-use of Produced Water

Mitigation Measure 4.17-2 states the following:

> Applicant shall increase the re-use of produced water, and reduce its use of municipal and industrial-quality ground or surface water use to the extent feasible. By the end of 2016, the Applicants shall work with the County to review water use data submitted to Division of Oil Gas and Geothermal Resources under Senate Bill 1281 and identify the five biggest oil industry users of municipal and industrial water by volume. The five biggest oil industry users of municipal and industrial water shall work together to develop and implement a plan identifying new measures to reduce municipal and industrial water use by 2020. The plan shall address the following activities, as appropriate: steam generation; drilling and completions (including hydraulic fracturing); dust control; compaction activities related to construction; and landscaping. Through the KernFLOWS initiative or other efforts (e.g., Groundwater Sustainability Agency), the five biggest oil industry users of municipal-and-industrial water shall also work with local agricultural producers and water districts to identify new opportunities to increase the use of produced water for agricultural irrigation and other activities, as appropriate. Any produced water treated and used for agricultural irrigation or other activities shall be tested and monitored to assure compliance with applicable standards for such agricultural irrigation or other uses.

Industry representatives have submitted a memorandum identifying the five biggest industry users of municipal and industrial water by volume. These companies are: Chevron, Freeport-McMoRan Oil & Gas, Aera Energy, LINN Energy, and California Resources Corporation. The estimated amount of combined M&I water injected was 8,000 acre-feet/year. The industry has committed to working together to identify new measures to reduce M&I water by 2020. Staff will continue to update the report as necessary.

Executive Summary

This management area plan was written to represent the efforts of Southern San Joaquin Municipal Utility District (SSJMUD) to comply with the California state regulated Sustainable Groundwater Management Act (SGMA) of 2014. According to SGMA, groundwater basins in California that have been classified as high or medium priority must correct current overdraft conditions in order to reset the balance of groundwater input/output as an effort to reach sustainability by the year 2040. This plan was written in conjunction with and in support of a basin-wide Groundwater Sustainability Plan (GSP) drafted on behalf of the Kern Groundwater Authority (KGA). The KGA represents 16 member agencies within the boundary of the Kern County Subbasin (Subbasin) which are joined together by the adoption of a Joint Powers Agreement (JPA). While the District will be coordinating with the KGA to comply with SGMA, it will write its own management area plan. This management area plan follows the California Code of Regulations and discusses background information of the District and its corresponding management area; current practices and existing plans; management structure and actions; and current groundwater conditions and future sustainability management practices required to comply with SGMA.

SSJMUD is located within the Tulare Lake Region of the Central Valley. Beneficial users serviced within the District boundaries consist of agricultural; municipal and domestic; and industrial. Groundwater is used in this region to support agricultural production and industrial practices that support the economic viability of local communities. This management area plan includes a detailed overview of the Districts' historical, current, and projected groundwater conditions, including groundwater storage, water quality, and land subsidence.

This plan provides the required elements of a GSP and identifies an initial path for sustainable management in the Districts' portions of the Subbasin. As documented in this management area plan, the goal for the District is to balance the average inflow and outflows of water in the District so that a negative change in groundwater storage does not occur; thus, preventing the lowering of average groundwater levels beyond 2040 through the actions of the District. This goal is expected to maintain groundwater levels as well as prevent water quality degradation and land subsidence. To reach the sustainability goal by 2040, the District will implement projects and management actions over time by increasing supply or reducing demand. Once fully implemented, project and management actions are expected to reduce the groundwater pumping for the District to avoid undesirable results

This Page Left Blank Intentionally

1. Introduction

1.1 General Information

1.1.1 *Purpose of Management Area Plan*

To comply with the requirements of SGMA, SSJMUD has contracted with GEI Consultants, Inc. (GEI) for the preparation of this management area plan for inclusion in the KGA GSP. This management area plan serves to do the following:

- Define and describe the geographic and geologic conditions of the SSJMUD area in the Subbasin.
- Identify and describe the sustainability goal for the Subbasin and the SSJMUD jurisdictional area.
- Identify and describe the six undesirable results set forth in SGMA, as they pertain to the Subbasin and the SSJMUD jurisdictional area.
- Identify and describe the specific minimum thresholds and measurable objectives required for SSJMUD to achieve the sustainability goal of the Subbasin.
- Define and identify projects and management actions proposed by SSJMUD to achieve the sustainability goal.

1.2 Agency Information

Agency's Name:	Southern San Joaquin Municipal Utility District
Agency's Address:	11281 Garzoli Ave, Delano CA 93215
Agency's Phone Number:	(661) 725-0610
Agency's Website:	http://www.ssjmud.org/
Contact Person:	Roland Gross
Contact Person's Title:	General Manager, SSJMUD

SSJMUD was formed in 1935, under the Municipal Utility District Act of the Public Utility Code of California, with the purpose to obtain and provide a supply of water for lands located within the boundaries of the District. Although the District includes the cities of Delano and McFarland, the District only provides agriculture water services. SSJMUD first entered into a 9(e) Water Services Contract with United States Bureau of Reclamation (USBR) in 1945. In 2011, this Water Service Contract was converted to a permanent 9(d) Repayment Contract with the USBR, which now has the benefit of being a perpetual contract for the existing amounts of contracted water supply, thus securing the District's water supply from the Central Valley Project (CVP).

1.2.1 *Legal Authority of Agencies*

On May 27, 2014 the agencies and districts listed in Table 1-1 below and the County of Kern entered into a JPA agreement to form the KGA. To facilitate the implementation of the KGA GSP, the Agency's jurisdictional area is divided into management areas formed by the portion of the Subbasin that underlies the boundaries of each general member agency. Under this JPA agreement, the KGA was granted the authority to serve as the Groundwater Sustainability Agency (GSA) for all of its member agencies. This JPA Agreement was amended and restated on March 22, 2017. The amended and restated JPA agreement is included in Appendix A of the KGA GSP.

Table 1-1: Kern Groundwater Authority Member Agencies

Arvin Community Services District	Rosedale-Rio Bravo Water Storage District
Arvin-Edison Water Storage District	Semitropic Water Storage District
Cawelo Water District	Shafter-Wasco Irrigation District
City of Shafter	Southern San Joaquin Municipal Utility District
Kern County Water Agency – Pioneer Project	Tejon-Castaic Water District
Kern-Tulare Water District	West Kern Water District
Kern Water Bank Authority	Westside District Water Authority
North Kern Water Storage District	Wheeler Ridge-Maricopa Water Storage District

SSJMUD entered into a cooperative agreement with the City of Delano and the City of McFarland for the purposes of coordinating SGMA compliance and the development and implementation of a management area plan under the KGA. Per the terms of the KGA's JPA agreement, the Districts maintain authority over their own internal matters, including but not limited to, their respective surface water supplies, their respective groundwater supplies, facilities, operations, water management, and water supply matters.

Nothing in this Management Chapter or in the related Groundwater Sustainability Plan determines or alters surface water rights or groundwater rights under common law, any provision of law that determines or grants surface water rights, or otherwise. (See, California Water Code section 10720.5(b)). This Management Chapter and the related Groundwater Sustainability Plan shall be construed consistent with Section 2 of Article X of the California Constitution and nothing provided in this Chapter modifies rights or priorities to use or store groundwater except as expressly stated in California Water Code section 10720.5(a). SSJMUD reserves and retains all rights to the use of water to the extent provided by law.

1.3 Management Area Plan Implementation Costs

SSJMUD, on behalf of its customers and landowners, will incur costs to implement its management area plan and maintain the plan via five-year updates, both on their own and as members of the KGA. These costs and sources of funding are described below.

1.3.1 *Costs Generated by Management Area Plan Implementation*

Table 1-2 presents a description and an estimate of the costs associated with the implementation of the SSJMUD management area plan and measures associated with SGMA compliance.

Table 1-2: Estimated Costs for Management Area Plan Implementation

Item	Description	Estimated Cost
Monitoring	Improvement of in-district monitoring network for SGMA compliance. Coordination of groundwater level, groundwater quality, and land subsidence monitoring activities for annual reporting and Five-Year Updates	$400,000 for the first 5 years
Projects	Implementation of projects that have been identified in this plan. This estimate is for the duration of the 20-year SGMA implementation period.	$70,000,000
Management	Administration of management actions and SGMA implementation measures.	$65,000 per year
Annual Report	Reporting of data collected in-district for inclusion in the Subbasin's Annual Report to DWR.	$25,000 per year
5-Year Management Area Plan Update and Report	Development of plan updates, based upon the ongoing evaluation of groundwater conditions, changes to monitoring network, and developments of new projects and management actions for SGMA implementation.	$500,000 every 5 years

These costs are an estimate based on known requirements for SGMA compliance and on projects that have been identified at this time. They are subject to change as SGMA is implemented both at the district-level and throughout the Subbasin.

1.3.2 *Management Area Plan Implementation Funding*

Under the JPA Agreement, the KGA may impose reasonable fees, charges, assessments, and other levies to implement its management area plan. However, the KGA shall have no authority to impose any such fees, charges, assessments, or other levies on any of its members or within a management area without the express consent and approval of the affected member(s). SSJMUD

retains its own authority, within its own jurisdiction, to impose fees, changes, assessments, or other levies as defined in their respective Rules and Regulations, pursuant to the Water Code.

1.4 Description of Plan Area

The KGA's jurisdictional area is entirely within the Subbasin, as defined in the California Department of Water Resources (DWR) Bulletin 118, South of the Tulare Lake hydrologic region of the San Joaquin Valley groundwater basin. The Subbasin is bound by the Kern County – Tulare County line to the north, the Sierra Nevada Mountains to the east, the Tehachapi Mountains to the south, and the Temblor range to the west. The Kern River flows from the Sierra Nevada Mountains, to the southwest, thence north, to its terminus at the Tulare Lakebed.

SSJMUD is bound by the northern Subbasin boundary between the Tule Subbasin and Kern County Subbasin (coincidental with the Kern-Tulare County line), and Semitropic Water Storage District (SWSD) to the west, North Kern Water Storage District (NKWSD) and the Cawelo Water District (CWD) to the south, and Kern-Tulare Water District (KTWD) and undistricted lands within Kern County to the east. California State Highway 99 roughly bisects the areas covered by SSJMUD's jurisdictional area. The Friant-Kern Canal (FKC, CVP) flows through SSJMUD, from Millerton Dam on the San Joaquin River, running south and terminating at the Kern River, east of Highway 99.

1.4.1 *Geographic Areas Covered*

As shown in Figure 1-1, this management area plan covers SSJMUD's jurisdictional area and the cities of Delano and McFarland. This area represents approximately 3% of the area within the Subbasin. The boundaries are coincidental with the boundaries of the Subbasin, SWSD, NKWSD, CWD, KTWD, and undistricted lands in the unincorporated portion of Kern County. The district is located entirely within the Subbasin. There are no adjudicated areas within SSJMUD.

The incorporated cities of Delano and McFarland lay almost entirely within SSJMUD's jurisdictional area, with the exception of the land annexed into the City of McFarland for its wastewater treatment plant (which is located in the NKWSD's jurisdictional area), as shown in Figure 1-1. There are also several *de minimis* domestic water users and multi-parcel water systems located within the SSJMUD jurisdictional area, which will be covered by this management area plan.

1.4.2 *Plan Area Setting*

The total service area of SSJMUD is approximately 66,000 acres, with an irrigated acreage of approximately 51,000 acres. While the total irrigated acreage remains consistent, the actual parcels receiving water from each of the districts varies from year to year, based on decisions made by the landowners for which properties are to be irrigated and which crops are being grown. Land use mainly consists of vineyards, deciduous fruits and nut crops, and citrus, as

shown in Figure 1-2. Field crops, pasture, and grain and hay crops are located mainly in the western portion of the district, west of Highway 99. The majority of land within the limits of the cities of Delano and McFarland is classified as urban, with some land in deciduous crops or idle.

Figure 1-3 shows the areas of SSJMUD that currently receive surface water and the areas that are dependent on groundwater only. The cities of Delano and McFarland are groundwater dependent, while the service area covered by SSJMUD has access to both groundwater and surface water supplies.

Based on the data available from DWR, the jurisdictional area of SSJMUD has domestic water supply well density ranging from 1 to 22 wells per sq. mi., as shown in Figure 1-4. The area outside the City of Delano has a domestic well density of 15 to 22 wells per sq. mi.

The density of water production wells for agricultural use generally range from 0 to 6 wells per sq. mi., as shown in Figure 1-5. Most of the areas with higher well densities are in the western portion of the District. The density of water production wells for municipal use is generally 0 to 2 sq. mi. for areas around the cities of Delano and McFarland as shown in Figure 1-6.

There are scattered multi-parcel and state small water systems throughout the western portion of the District in proximity to the cities of Delano and McFarland. As shown in Figure 1-3, these include the two incorporated cities, the unincorporated communities, and the state small systems owned and operated by Cal Water. The *de minimis* domestic water users and multi-parcel water systems located within the SSJMUD's jurisdictional area are also groundwater dependent.

1.4.3 *Existing Plans in Plan Area*

There are existing groundwater management plans (GMP) within the Plan Area: the 2007 Poso Creek Integrated Water Management Plan (IRWMP) and the SSJMUD 2015 Agricultural Water Management Plan (AWMP), which is discussed in further detail in the basin setting section (Section 2) of this management area plan. A copy of the SSJMUD AWMP is included in Appendix B.

Adopted in July 2007, the Poso Creek IRWMP was created to address short and long-term water supply challenges at a regional scale. The IRWMP was developed by the Poso Creek Regional Management group comprised of seven agricultural districts, of which the SWSD was the lead agency. Groundwater goals within the IRWMP included:

- Maintain groundwater levels at economically viable pumping lifts
- Protect the quality of groundwater and enhance where practical
- Enhance monitoring activities to meet groundwater levels and water quality goals

Of the highest priority to the IRWMP was facilitating proper groundwater management. In addition to the requirements of the Districts' water management plans and the Poso Creek IRWMP, there are other federal, state, local, and regional programs that monitor groundwater

levels, groundwater and surface water quality, surface water inflow, weather and precipitation, and land subsidence. A description of these existing monitoring programs is provided in the basin setting and monitoring network sections of this management area plan.

In addition to these regional and district plans, the City of Delano has adopted an Urban Water Management Plan (UWMP); the City of McFarland is exempt from the requirement for an UWMP because its annual groundwater usage is less than 3,000 acre-feet per year (AFY). In addition to the required GMP, both Delano and McFarland have adopted General Plans. For the areas not within the limits of the incorporated cities, the Kern County General Plan applies. The General Plans for the cities and the General Plan for the County each have land use elements which address water usage. These elements are to be considered in this management area plans.

1.4.3.1 City of Delano General Plan

The City of Delano's General Plan (adopted in December 2005) includes an open space and conservation element. This element of the General Plan describes that groundwater is the primary source of domestic water supply for the city, as well as the sources of groundwater recharge. One of the objectives stated in the General Plan is "to protect natural resources including groundwater, soils, and air quality, to meet the needs of present and future generations."

The policies and standards adopted in the General Plan which deal specifically with groundwater are:

Policy #1: Protect areas of natural groundwater recharge from land uses and disposal methods, which would degrade groundwater quality. Promote activities, which combine stormwater control, and water recharges.

Policy #2: Expand programs that enhance groundwater recharge in order to maintain the groundwater supply, including the installation of detention ponds in new growth areas.

1.4.3.2 City of McFarland General Plan

The City of McFarland's General Plan (adopted in September 1991, updated in December 2015) includes an open space, conservation, and recreation element, which contains a description of the sources of the city's water supply. The current version of the open space, conservation, and recreation element does not address groundwater objectives, nor does it currently provide the policies or measures to meet those objectives.

1.4.3.3 Kern County General Plan

The Kern County General Plan contains provisions within the Land Use, Open Space and Conservation Element that relate specifically to groundwater resource management. These provisions, found in the Resource Policies of the Land Use, Open Space, and Conservation Element, are:

Policy #10: To encourage effective groundwater resource management for the long-term economic benefit of the County the following shall be considered:

a. Promote groundwater recharge activities in various zone districts
b. Support for the development of Urban Water Management Plans and promote Department of Water Resources grant funding for all water providers
c. Support the development of GMPs
d. Support the development of future sources of additional surface water and groundwater, including conjunctive use, recycled water, conservation, additional storage of surface water and groundwater and desalination

Under the General Provisions of the General Plan, there is a section which deals specifically with surface and groundwater. This section includes a policy statement which states that the County will "encourage the development of the County's groundwater supply to sustain and ensure water quality and quantity for existing users, planned growth, and maintenance of the natural environment" and that "new high consumptive water uses, such as lakes and golf courses, should require evidence of additional verified sources of water other than local groundwater. Other sources may include recycled stormwater or wastewater."

The implementation measures listed in the General Provisions which are directly related to groundwater are:

Measure U: The Kern County Environmental Health Services Department will develop guidelines for the protection of groundwater quality which will include comprehensive well construction standards and the promotion of groundwater protection for identified degraded watersheds.

Measure X: Encourage effective groundwater resource management for the long-term benefit of the County through the following:

i. Promote groundwater recharge activities in various zone districts
ii. Support for the development of Urban Water Management Plans and promote Department of Water Resources grant funding for all water providers
iii. Support the development of GMPs
iv. Support the development of future sources of additional surface water and groundwater, including conjunctive use, recycled water, conservation, additional storage of surface water and groundwater and desalination

Measure Z: General Plan Amendments subject to environmental review and not otherwise subject to California Water Code Section 10910 shall demonstrate through a water supply assessment that a long-term water supply for a 20-year timeframe is available. The water assessment shall include, but not limited to, the following:

i. Source and quantity of historical water use on the site.

ii. Estimated water consumption of the proposed development.

iii. Estimated storage, if any, in meeting the projected need.

iv. Recommendations for additional sources of water to address demand shortage. Such measures may include, but not limited to, development of future sources of additional surface water and groundwater, including water transfers, conjunctive use, recycled water, conservation, and additional storage of surface water, groundwater, and desalination.

Written acknowledgement that water will be provided by a community or public water system with an adopted Urban Water Management Plan shall constitute compliance with this requirement.

1.4.4 *Plan Elements from CWC Section 10727.4*

A. Control of Saline Water Intrusion

Seawater intrusion is not considered an issue in the Subbasin. The coastal range provides a barrier, preventing seawater from coming into contact with groundwater flow in the Subbasin.

B. Wellhead Protection Areas and Recharge Areas

Permits are issued by the Kern County Public Health Services Department (KCPHSD) Water Well Program to construct, reconstruct, and destroy water wells. The Districts assist their landowners through this process to comply with the wellhead protection area program. This program was implemented through the Safe Drinking Water Act and aims to prevent contamination in public water systems. The Districts also manage recharge areas throughout their jurisdictional boundaries and with adjacent water district recharge programs such as for the Kern Water Bank and Pioneer Project.

C. Migration of Contaminated Groundwater

There is one identified contamination plume of concern within SSJMUD's boundaries. Refer to Section 2.3.4 for further details.

D. Well Abandonment and Well Destruction Program

The KCPHSD issues permits to destroy water wells. The process consists of completing a water well permit through the county. All state and county regulations must be followed during the destruction process. According to the Kern County Ordinance Code 14.08, any wells that are abandoned or wells with inadequate water supply must be destroyed. Furthermore, any abandoned wells on the site of an active new well construction permit must be destroyed prior to construction.

E. Replenishment of Groundwater Extractions

To manage the groundwater basin within its boundaries, the Districts actively participate in conjunctive use or underground storage programs (see Section 2.7.2). In addition to these efforts, the Districts will work to implement additional projects to bring more water into the basin to maintain sustainable groundwater conditions.

F. Conjunctive Use or Underground Storage

The Districts actively participate in conjunctive use and underground storage programs to manage the groundwater basin within its boundaries. These projects aim to reduce demand on local groundwater resources. Projects include land fallowing, expansion of recharge facilities, and water banking on behalf of the Districts (see Section 2.7.2).

G. Well Construction Policies

The KCPHSD, Environmental Health Division, issues permit to construct, deepen, or replace water wells. The permitting process consists of a county water well permit and the SGMA implemented Overdraft Supplemental Well Application accompanied by detailed site maps.

H. Groundwater contamination cleanup, groundwater recharge, in-lieu use, diversions to storage, conservation, water recycling, conveyance, and extraction projects

Regarding groundwater contamination cleanup, there are five contamination plumes in Pond and Delano. Potential contaminants at the sites include gasoline, tetrachloroethylene (PCE), pesticides, fumigants, and herbicides. Since there are no nearby impacted wells or municipal wells (within 1,500 feet of the sites), these sites are not impacting groundwater quality. SSJMUD is not taking an active role in the remediation effort that is managed by the Department of Toxic Substance Control (DTSC).

Through its water management practices, the District is constantly pursuing water conservation. Efficient water management practices are described in each District's GMP. For information regarding in-lieu use, water recycling, and extraction projects, see Section 2.7.2.

I. Efficient Water Management Practices

The existing GMPs the Districts currently follow are their own GMP's as well as the Poso Creek IRWMP. These plans were implemented to approach short and long-term water supply challenges throughout the region. These challenges were combatted with increased recharge capacities, improved conveyance, and coordinated operation of the water management programs.

J. Relationships with State and Federal Regulatory Agencies

The District coordinates with other state and federal agencies as needed to manage its water supplies; construct and implement water management projects; monitor and report local water conditions; and coordinate and provide input to local, regional and state water policy matters.

K. Land use plans and efforts to coordinate with land use planning agencies to assess activities that potentially create risks to groundwater quality or quantity

Documents pertaining to land use plans and coordination between planning agencies are included in Section 1.4.3 of this management area plan. The Districts will continue to coordinate with the KGA and other GSAs in the Subbasin as the SGMA implementation process proceeds.

L. Impacts on Groundwater Dependent Ecosystems

The presence of GDE's has not been identified. Section 2.3.7 of this management area plan provides an overview of the available information regarding GDEs in the Districts.

1.5 Notice and Communication

Per Section 354.10 of the GSP emergency regulations, the following sections discuss the notice and communication processes conducted by the Districts with other agencies and interested parties. A list public outreach meetings and workshops for the Districts' beneficial users and other interested parties are provided along with a brief overview of their respective purpose.

1.5.1 *Participating Agencies*

The following agencies were engaged in the public outreach activities related to the development of this management area plan:

- City of Delano
- City of McFarland
- Kern Groundwater Authority

1.5.2 *Beneficial Uses and Users*

As required by Section 354.10(a) of the GSP emergency regulations, beneficial use and users in the Districts' portions of the Subbasin have been identified. The beneficial uses of groundwater in the management area plan, consistent with the uses identified in DWR Bulletin 118, are:

- Agricultural;
- Municipal and Domestic;
- And Industrial.

Users of groundwater have been identified as landowners, agricultural operations (including farms, dairies, and food processors), businesses, rural residents, and urban residents of

incorporated communities and unincorporated communities. These beneficial users of groundwater have been identified as stakeholders for public outreach activities in the plan area.

1.5.3 *Public Meetings*

Throughout the development of this management area plan, SSJMUD has conducted a series of public meetings to educate and engage the beneficial users within the District boundaries regarding the planning and implementation of SGMA. The Districts have also encouraged its beneficial users to participate in public meetings held by the KGA. A list of all meetings conducted by the Districts are provided in Table 1-3.

Following the enactment of SGMA in 2014, the Districts began conducting public outreach meetings and workshops to educate its beneficial users on SGMA implementation and to open the lines of communication for the development of this management area plan. Active participation was encouraged for all beneficial users in order to accurately reflect the diverse social, cultural, and economic elements of the beneficial users represented in this management area plan.

In addition to their regularly scheduled board meetings, which are publicly noticed on the District website (see Section 1.2), SSJMUD facilitated a publicly-noticed stakeholder outreach meeting on April 29, 2019 to discuss the Districts' joint efforts to develop a management area plan under the KGA. This meeting was then followed-up with smaller, landowner-focused meetings on May 2, 2019. SSJMUD also held publicly-noticed quarterly landowner meetings.

The sign-in sheets, agendas, and minutes from these meetings are included in Appendix C. Feedback received was taken under consideration and used in the development of this management area plan. The GSA Board, along with the General Manager and Consultant, considered feedback to formulate a plan that accurately captures all beneficial use/users and their interests with a goal to achieve groundwater sustainability by 2040.

Table 1-3: SSJMUD Public Meetings and Workshops

Date	Meeting	Purpose
Monthly	KGA Stakeholder Coordination Meetings	Review development of SGMA management area plan with KGA member agencies and coordinate on efforts for development.
Monthly	Board Meetings	Review development of SGMA management area plan.
August 21, 2018	Management Area Plan Development Meeting	Meeting with growers in the district and representatives from Wonderful Orchards, Westchester Group, and Yurosek Farms to discuss plan progress and development of Sustainable Management Criteria and Projects and Management Actions to be included in the management area plan.
February 21, 2019	Management Area Plan Development Meeting	Overview of SGMA plan development and coordination with the cities of Delano and McFarland and the district managers.
April 29, 2019	Stakeholder Outreach Meeting	Review presentation of SGMA; participants; and overview of Plan development and sustainable management criteria.
May 2, 2019	Stakeholder Outreach Meeting	Review and follow up to discuss April 29 meeting materials.
May 14, 2019	KGA Open House	Presentation of member agencies' GSPs/plans development with representatives from state agencies in attendance.
June 12, 2019	Management Area Plan Development Meeting	Discussion of Plan administrative draft with representatives from the cities of Delano and McFarland.
September 24, 2019	Management Area Plan Review	Meeting with representatives from the cities of Delano and McFarland to provide them an opportunity to ask questions or make comments on the Public Draft of the District's Management Area Plan.
September 26, 2019	KGA Open House	Presentation of member agencies' GSPs/plans development with representatives from state agencies in attendance.
October 8, 2019	Stakeholder Outreach Meeting	Presentation to review the contents of the District's management area plan, including the water budget, Sustainable Management Criteria, Projects, and Management Actions.

1.5.4 Comments Received

In addition to the district-level and GSA-level outreach efforts, SSJMUD provided an opportunity for the public to review and comment on its management area plan during the 90-day Public Comment period facilitated by KGA. This management area plan was made available

to the public on the KGA's website and SSJMUD's website during the comment period. During the comment period, which commenced on August 30, 2019 and ended on November 29, 2019, SSJMUD received three letters pertaining to its management area plan and two letters via the KGA with comments pertinent to SSJMUD's management area plan. These comment letters and a summary table responding to the comments in these letters has been included in Appendix D of this plan.

The SSJMUD Board of Directors met on December 11, 2019 to review the revisions made to the Public Draft of the District's Management Area Plan. Upon review and approval of the revisions made, the Board adopted Resolution 19-14 to adopt and implement the SSJMUD Management Area Plan. A copy of this resolution is included in Appendix E of this plan.

1.5.5 Management Area Plan Organization

This management area plan includes the following information, pertinent to SSJMUD's jurisdictional area:

- Basin Setting elements, pertaining to the groundwater conditions and sustainability indicators of the portions of the Subbasin located within the jurisdictional area of SSJMUD (Section 2),
- The sustainability goal and undesirable results, adopted at the Subbasin, and applied to the management areas within SSJMUD, along with the sustainable management criteria for all sustainability indicators within SSJMUD that have been identified as applicable to the Subbasin (Section 3),
- The identification of existing monitoring networks for the evaluation of sustainable management criteria and monitoring of sustainability indicators identified in the management area plan (Section 4), and
- The identification of projects and management actions proposed by the District to reach the sustainability goals identified in this management area plan (Section 5).

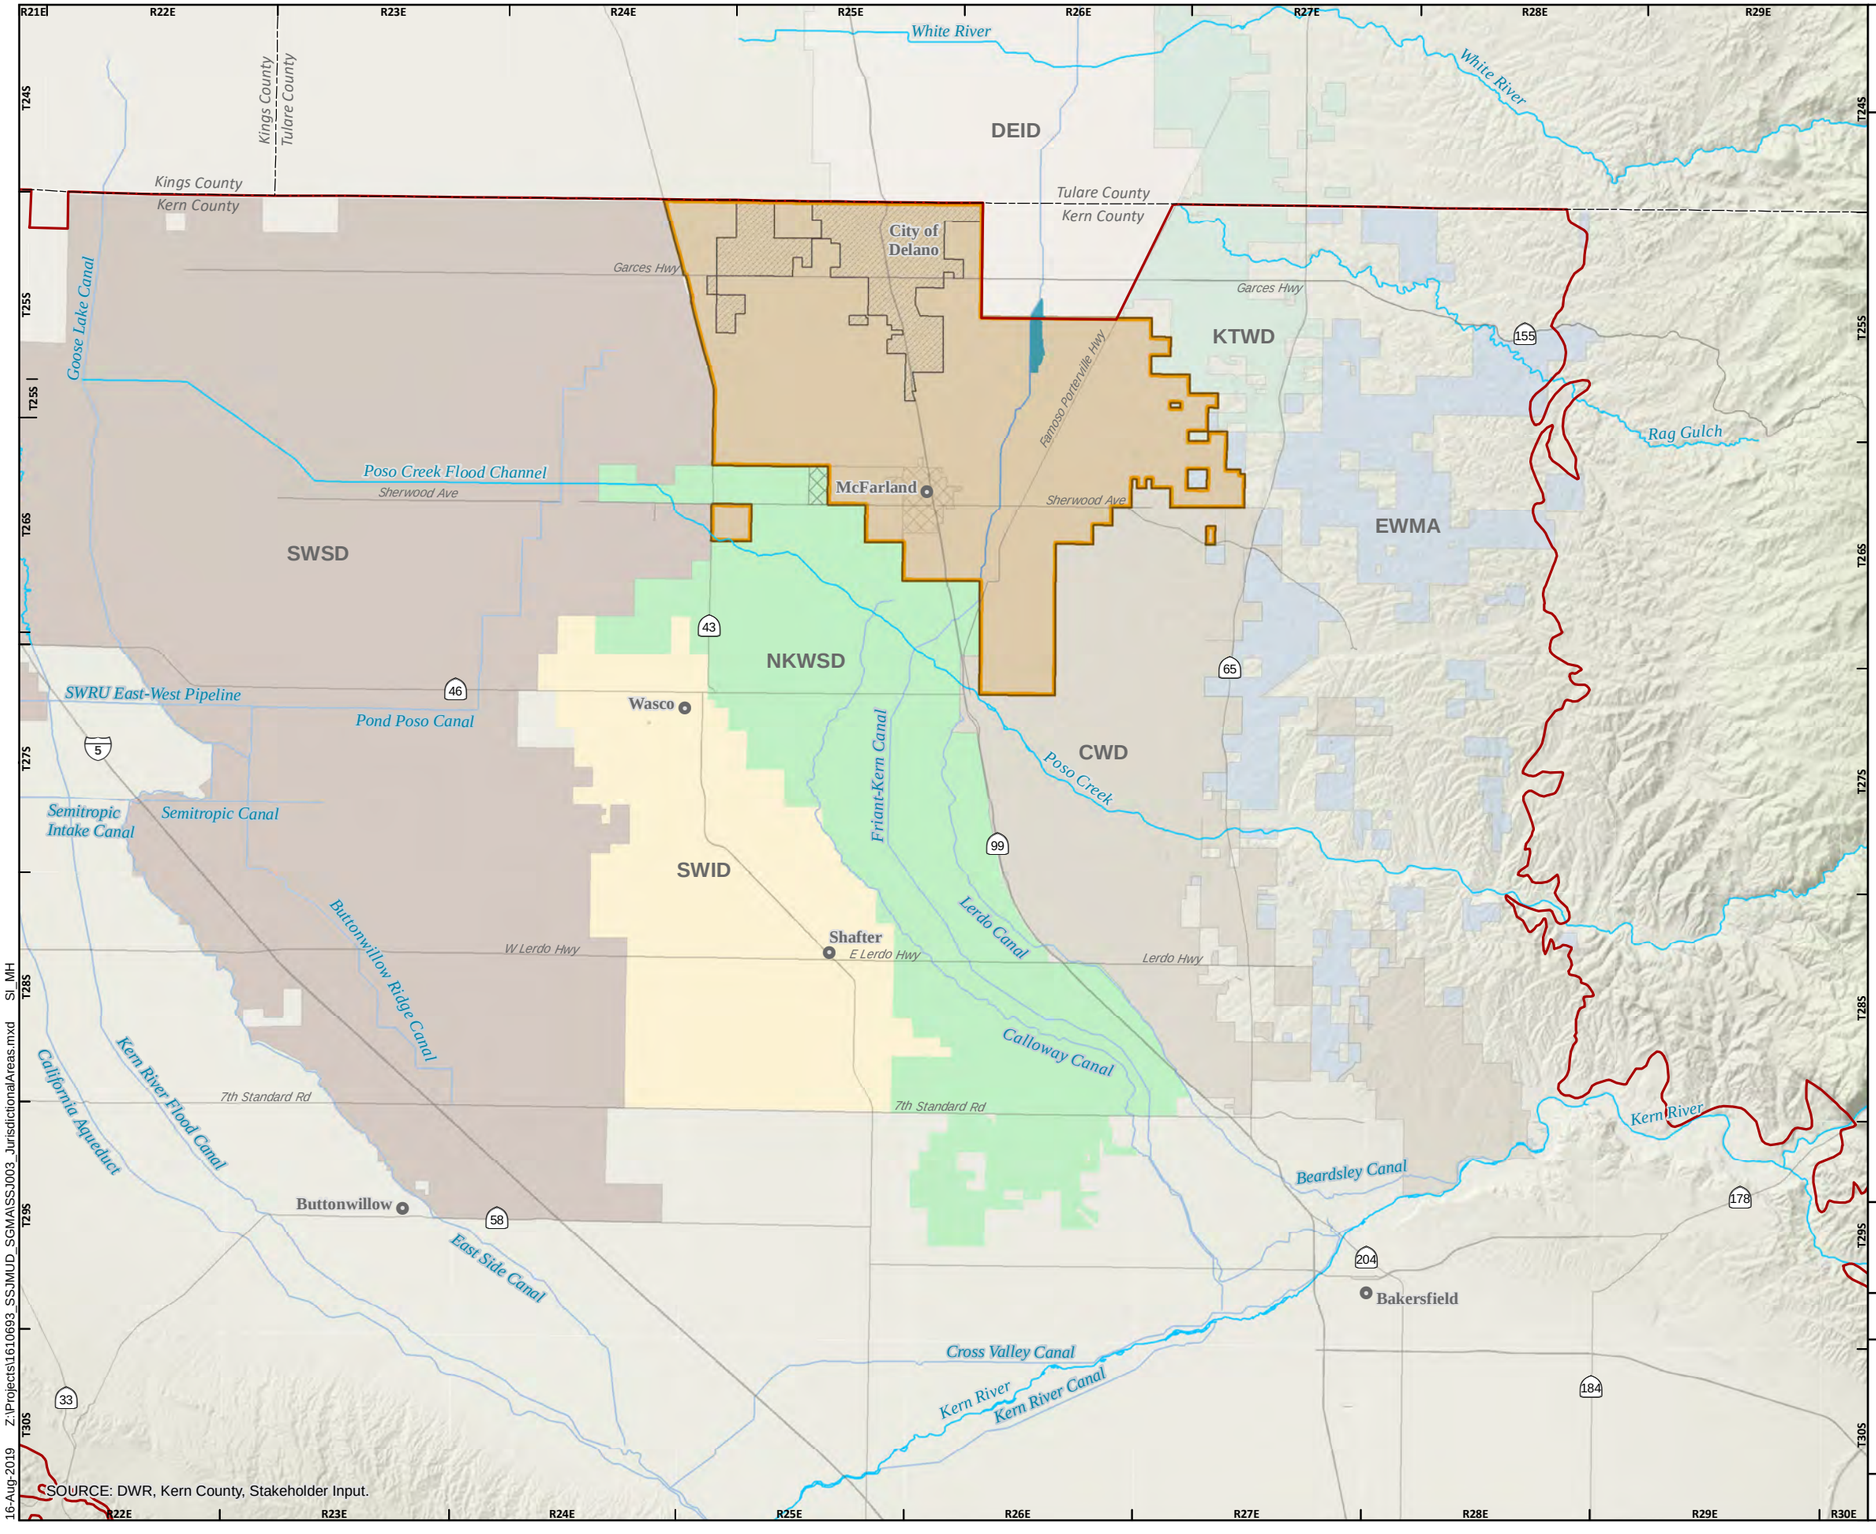
2. Basin Setting

The Basin Setting is made up of the hydrogeologic conceptual model (HCM), the current and historical groundwater conditions, the water budget components of the Subbasin, and the description of Subbasin management areas. This section provides the local and regional details of the HCM and groundwater conditions as context for defining and assessing sustainable management criteria and projects and management actions for SSJMUD.

2.1 Introduction

Regional details for the entire Subbasin basin setting are included in the KGA GSP basin setting chapter; whereas, most of the discussion provided in this section focuses on the extent of SSJMUD boundaries and the immediate vicinity. Pertinent details related to the entire Subbasin that apply to SSJMUD, such as the definition of the vertical and lateral extents of the groundwater Subbasin and the regional geology, regional structural setting, and aquifer hydrostratigraphy are presented in this section.

Details of this study come from SSJMUD's 2012 *Agricultural Water Management Plan* (SSJMUD, 2012), and the *Geologic Study of the Southern San Joaquin Municipal Utility District* (USBR, 1948). These studies are referenced herein. Figure 2-1 presents the current extent of SSJMUD's jurisdictional area and its proximity to other agencies within the Subbasin.



2.2 Hydrogeologic Conceptual Model

The hydrogeologic conceptual model characterizes the physical components and interaction of the surface water and groundwater systems in the study area. A brief description of the regional geology and structural setting of the area in and around SSJMUD, including the vertical and lateral extents of the groundwater Subbasin, groundwater flow, aquifer characteristics, and other physical characteristics are presented in this section.

2.2.1 *Subbasin Regional Setting*

As described in the KGA GSP basin setting, the Kern County Subbasin is located in the southern San Joaquin Valley, known as the Tulare Lake Region of the Central Valley. The Tulare Lake Region encompasses the Central Valley subbasins from just north of Fresno to the Tehachapi Mountains and San Emigdio Mountains at the southern end of the valley; with the Sierra Nevada Mountains (Sierra Nevada) to the east, and the Coast Ranges to the west (Figure 2-2). SSJMUD is situated in the north eastern portion of the Subbasin. For additional information on the regional geologic and structural setting for the entire Subbasin, please refer to Section 2 of the KGA GSP Basin Setting chapter (Chapter 2 of the KGA GSP).

Figure 2-2: Central Valley Hydrologic Regions - Tulare Lake Region

2.2.1.1 Sediment Deposition

The southern San Joaquin Valley (and most of the Central Valley), was a large basin with marine deposition occurring from Late Jurassic and Cretaceous Periods into the Tertiary Period. Thereafter, continental deposition of alluvial, fluvial, and lacustrine sediments occurred along the margins and into the center of the valley. These younger sediments were derived from the surrounding mountain ranges (Planert and Williams, 1995). Sand, silt, and clay deposits were deposited in the study areas in a complex sequence by the Kern River and Poso Creek (Kern River Formation), flowing from the Sierra Nevada Mountains to the east, and to a lesser extent, by streams along the Coast Range to the west. The terminus for these flows in the geologic past was Tulare Lake (Tulare Formation) (NKWSD, 2012).

A conceptual block diagram below (Figure 2-3) is provided as a general example of the sequence of deposition in the valley and shows the source of most fresh water into the basin originates from the Sierra Nevada mountains.

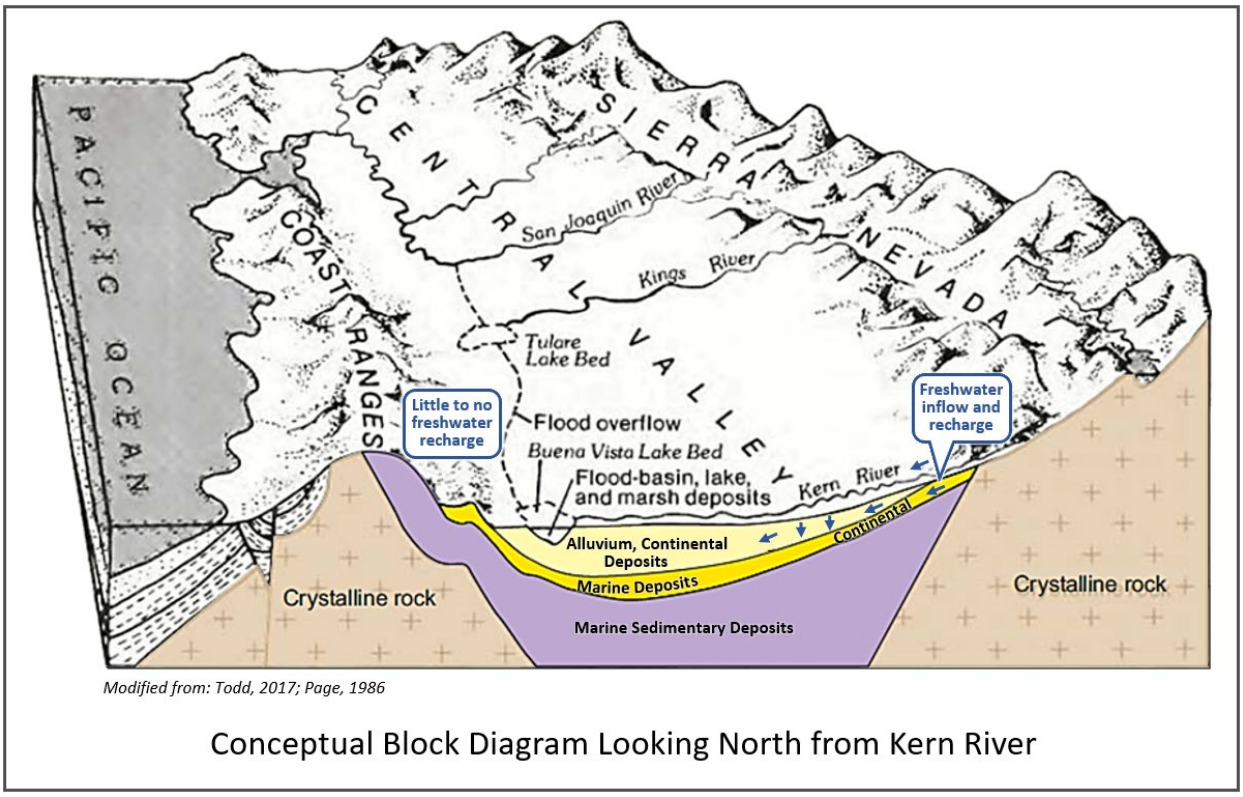

Figure 2-3: Conceptual Block Diagram from Kern River (Looking North)

2.2.2 *Groundwater Subbasin Lateral and Vertical Boundaries*

Within SSJMUD, jurisdictional boundaries limit the lateral extent of groundwater pumping, while natural boundaries delineate the vertical extent of groundwater with beneficial use. The KGA GSP provides context for the discussion of lateral and vertical extents of groundwater in the Subbasin. By applying California Water Code §10723.2, the bottom of the groundwater Subbasin includes groundwater that can be applied to beneficial use. The KGA GSP basin setting references criteria from the state and federal code for defining the extent of groundwater with beneficial use in the Subbasin. For details on these criteria, refer to the KGA GSP. In general, the groundwater Subbasin extent, where no exemptions or commercially producible hydrocarbons or minerals exist, likely ranges between 3,000 mg/l and 10,000 mg/l total dissolved solids (TDS) depending on the feasibility of treatment and recovery of the groundwater for beneficial use. The definition below provides context for the groundwater boundaries discussion in the Subbasin.

2.2.2.1 Datasets with Lateral and Vertical Distribution of Groundwater in the Subbasin

As described above, the KGA GSP basin setting discusses criteria for defining the bottom of the groundwater Subbasin. This section and subsections present datasets with general vertical distribution of groundwater ranging from 2,000 to 10,000 mg/l TDS.

Page's 1973 depth to fresh groundwater with a TDS of 2,000 mg/l is presented on Figure 2-4. There are other definitions for fresh groundwater (Heath, 1983), but for this discussion, Page's dataset is used because it is a commonly known and is a published dataset in the Central Valley. Page's (1973) base of fresh water is not however, the defined bottom of the groundwater Subbasin.

The depth to groundwater with a TDS of 10,000 mg/l (one of the criteria for the definition of an Underground Source of Drinking Water, or USDW), is presented on Figure 2-5. This dataset was recently developed by research in the Subbasin based on geochemical analysis of water samples and geophysical log analysis (Gillespie et al., 2017), and provides further insight of the distribution of groundwater that may be within the range for potential beneficial use.

Both the lateral and bottom boundaries of the groundwater in the Subbasin are constrained by the primacy productive limits with depths to hydrocarbons, and aquifer exemptions with corresponding depths. However, within SSJMUD's management area, there are no aquifer exemptions or active oil fields within the District. The oil field depths to hydrocarbons are below the base of 10,000 mg/l TDS. The base of 10,000 mg/l TDS may underlie the depth to hydrocarbons of the oil fields in proximity to the District; where applicable, the shallowest of the two is considered the bottom of the Subbasin.

2.2.2.2 Conceptual profile of the Groundwater Basin underlying SSJMUD

Figure 2-6 is a conceptual profile of the groundwater basin in SSJMUD, the groundwater basin is laterally continuous until reaching structural highs at the margins where a lot of the sediments begin to pinch out. The vertical extents are defined by the base of fresh water and the USDW. Both the base of fresh water and the base of USDW dip to the east. At about the middle of NKWSD, the base of freshwater levels out and decreases in depth toward CWD and SSJMUD. Although the conceptual profile does not illustrate the oil fields, as stated above, there are no primacy limits or aquifer exemptions within the vertical groundwater Subbasin boundaries of SSJMUD.

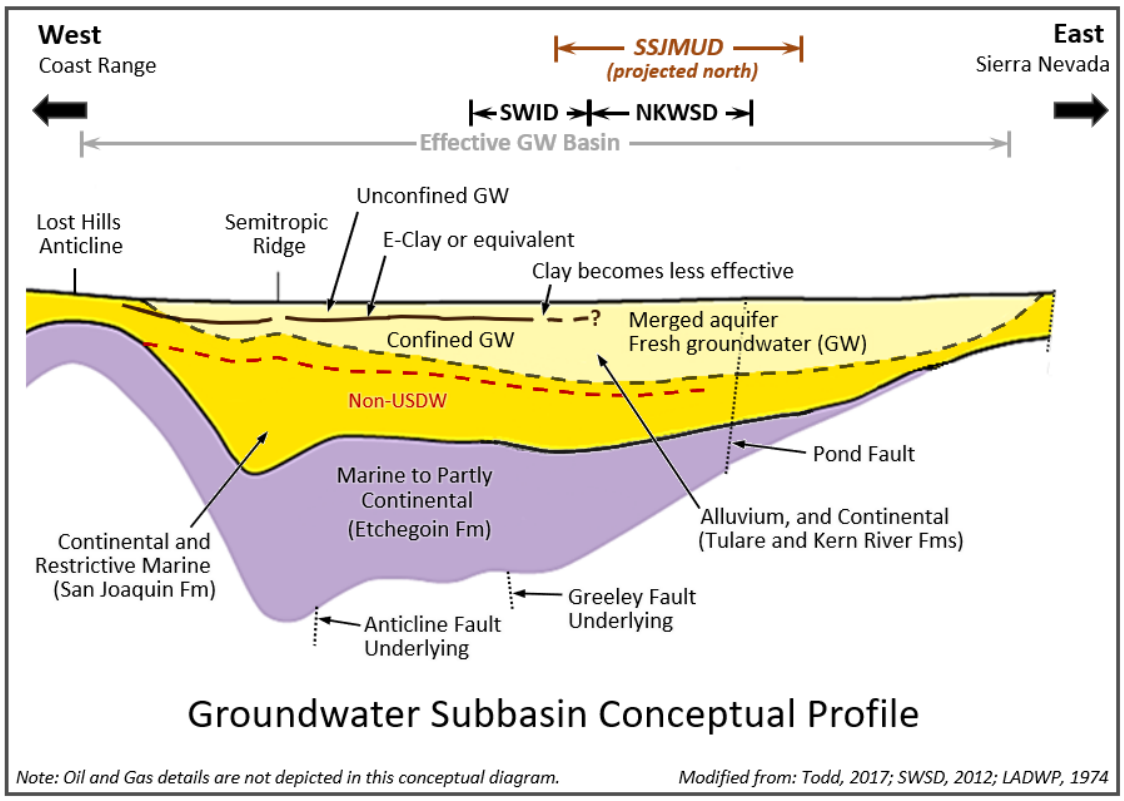

Figure 2-6: Conceptual Profile of Subbasin

2.2.2.3 SSJMUD Setting and Lateral Boundaries

SSJMUD's jurisdictional area lies in the north central portion of the Subbasin and encompasses a surface area of approximately 64,700 acres (101 square miles), plus an additional 320 acres of undistricted lands adjacent to SSJMUD's eastern boundary. The lateral boundaries of SSJMUD's jurisdictional area, shown in Figure 2-1, also include the incorporated cities of Delano and McFarland and the unincorporated community of Pond, and both the North Kern and Kern Valley State Prisons. As described above, SSJMUD is bordered by Delano-Earlimart Irrigation District (DEID) and Tulare County to the north, Kern-Tulare Water District (KTWD) undistricted lands to the east, Cawelo Water District (CWD) and North Kern Water Storage District (NKWSD) to the south, and Semitropic Water Storage District (SWSD) to the west.

2.2.2.4 SSJMUD Subbasin Vertical Boundaries

From Page's data (Figure 2-4), the base of 2,000 mg/l TDS "fresh water" ranges in SSJMUD from approximately -1,600 ft msl (~1,850 ft bgs) in the western portion of the District near T25SR25E and -2,000 ft msl (~2,400 ft bgs) in the southern central portion of SSJMUD near T26SR26E. The base of 2,000 mg/l TDS water is approximately -1,200 ft msl (~1,650 ft bgs) in the eastern portion of the District near T25SR27E.

While the data from Gillespie et al. (2017) (Figure 2-5), does not cover the entire District, the base of 10,000 mg/l TDS is estimated to range from -1,750 ft msl (~2,100 ft bgs) in the western portion of the District near T25SR25E and -2,500 ft msl (~2,800 ft bgs) in the southeastern portion of the District, near T27SR26E.

2.2.2.5 General Observations of Base of Fresh Water

Just south of SSJMUD is the Pond-Poso Fault, which marks the northern end of the deep northwest-trending trough of fresh groundwater between Bakersfield and Wasco. This trough of fresh groundwater (-2400 ft msl) lies between the concealed Poso Creek fault to the northeast and the concealed, pre-Quaternary Greeley fault system on the southwest. Historical displacement on the Greeley Fault and historical and recent displacement on the Pond Fault may have led to this depression of Quaternary sediments that accommodate this trough of fresh groundwater. Slightly trending more northerly than the Pond Fault, is a trough to the east of SSJMUD underlying KTWD (-2800 ft msl). This trough represents the depth to fresh groundwater in the Santa Margarita and Olcese Formations and does not represent a structural and lithologic low in continental deposits as observed in the trough to the south of Pond Fault. Cross sections from KTWD confirm the depths to the Santa Margarita and Olcese Formation and Page's Base of Freshwater (KTWD, 2016). Additionally, the shallowing of the base of fresh water to -1200 ft msl underlying some parts of SSJMUD, is the transition of water quality at the base of continental deposits approaching Pliocene Marine deposits.

2.2.3 *Principal Aquifers and Aquitards*

Groundwater underlying SSJMUD is a part of a regional alluvial aquifer system that is heterogeneous in texture and occurs under a variety of conditions, including upper unconfined zone and lower confined zone in the western half of the district. On the eastern half of the district, the Corcoran Clay thins and loses confinement to the east, where the aquifer is unconfined to semiconfined with depth. Water quality further differentiates the alluvial groundwater system of the Subbasin with lower concentrations of TDS on the eastern side and higher TDS in the upper zone on the western side.

The production horizons (confined unconfined zones in the eastern half) of the Subbasin aquifer are generally thick and consist of interbedded layers of gravel, sand, silt, and clay of the continental deposits of the Kern River (USBR, 1948). Much of the district is underlain by alluvium of the coalesced Poso Creek Fan and Rage Gulch Alluvial Fan Below this is the Kern River Formation which interbeds with fluvio-lacustrine deposits in the western half of the district, characterized by finer grained deposits. Groundwater wells extend to depths of greater than 1,200 feet (Page, 1986; Lofgren and Klausing, 1969), and the maximum thickness of freshwater deposits ranges from roughly 1,700 ft to 2,100 ft on the east side, gradually deepening to the south and west side of SSJMUD.

2.2.3.1 Formation Names and Descriptions within Aquifers

The aquifers underlying the study area are made up of alluvium, the Kern River Formation, and clay beds associated with lakebed deposits. For more details throughout the Subbasin, including the Santa Margarita and Olcese formations to the east of SSJMUD, refer to the KGA GSP Basin Setting chapter.

USBR (1948) describes the aquifer of SSJMUD to be made up of the "Kern River series" which overlies older marine deposits. The Kern River series is made up of a lower blue bed which is rich in silt, diatoms, and fine-grained sediment likely representative of fluvio-lacustrine conditions, and the intermediate Kern River Formation and upper "Delano Beds" or older alluvium, which are essentially identical and were deposited by coalescing alluvium derived from the weathering of the nearby highlands and Sierra to the east. USBR (1948) describes the process of deposition as "beds of sand, sandy clay, and clay [that were] laid down in a complex assemblage of discontinuous lenses, stringers, and pockets. The streams (flowing westward from the Sierra) swept back and forth across the valley floor building great alluvial fans, which grew until they coalesced and reached farther and farther out into the valley". This coalescing of discontinuous and lensoidal alluvium is what forms most of the aquifer system underlying SSJMUD. Grain sizes fine westward as the distal edges of these fans are approached.

The Kern River Formation is between 300 and 550 feet thick underlying SSJMUD (USBR, 1948). This formation consists mostly of poorly sorted fluvial sandstone and conglomerate with interbeds of siltstone or mudstone that becomes finer grained northward and westward (Bartow and Pittman, 1983). Some of the thicker siltstone or mudstone interbeds may represent deposits of small ephemeral lakes or ponds (Bartow and Pittman, 1983). The Kern River Formation is coarsest in its easternmost exposures, generally the area south of the Kern River, where the composition includes a cobble conglomerate with boulders near the base and pebbly sandstone (Bartow and Pittman, 1983).

The modified E-clay of the Corcoran Clay member has been mapped by Page (1986) in the western half of the district. Below is a brief description of the Tulare Formation for which likely only the Corcoran Clay Member is present in SSJMUD. In general, the Tulare Formation is located west of SSJMUD, near the western half of SWSD.

The Tulare Formation is Plio-Pleistocene in age, and in conjunction with the Kern River Formation (Mio-Pliocene to possibly early Pleistocene), represents west-east facies change across the Subbasin. The Tulare and Kern river formations are moderately to highly permeable and are major freshwater sources within the Subbasin (Page, 1986; SWSD, 2012).

The Tulare Formation (western Subbasin) contains up to 2,200 feet of interbedded, oxidized to reduced sands, gypsiferous clays, and gravels derived primarily from Coast Range sources. The permeable deposits of the Tulare Formation are divided into upper and lower units, separated by the Corcoran Clay member of the formation. Groundwater beneath the Corcoran Clay is typically

confined to semiconfined (Page, 1986; SWSD, 2012). In addition to its confining properties, laboratory tests indicate that the clay is highly susceptible to compaction (Faunt, et al., 2009).

The Corcoran Clay occurs laterally in the north Subbasin (~34 miles wide in extent) from Delano to Lost Hills (Figure 2-7) and narrows to the south just to the west of the Kern River banking facilities to about 3.5 miles wide. Within the central area of the Subbasin between the Kern River and Highway 46, the depth to the Corcoran Clay varies from 300 to 450 feet. Further north to the county line, the depth varies from 200 feet to the east and 750 feet to the west. The Corcoran Clay, most notably the modified E-clay (Page, 1986) is generally very fine grained; however, isolated, coarser zones are possible, particularly where the clay is less than 20 feet thick. The thickness of the clay is as much as 100 feet in a small area of the southern Subbasin but typically varies between 20 and 40 feet. In the northern Subbasin, the clay might be as thick as 60 to 80 feet in isolated areas, but the thickness typically varies between 10 and 30 feet. The Corcoran Clay is also not present in the eastern/northeastern part of the Subbasin from the cities of McFarland and Bakersfield, to Edison (Faunt et al., 2009).

Older alluvium or the "Delano Beds" overly the Tulare and Kern River formations. These deposits also make up a portion of SSJMUD's aquifer. They are composed from 150 to 300 feet of Pleistocene-age lenticular deposits of clay, silt, sand, and gravel that are loosely consolidated to cemented (USBR, 1948 and DWR, 2006). These deposits are moderately to highly permeable and yield sufficient water to wells. They are often indistinguishable from the underlying Tulare and Kern River formations (DWR, 2006).

The Holocene-age younger alluvium is not saturated underlying the district (USBR, 1948). According to USBR, the younger alluvium differs from older alluvium in that the former is not oxidized or cemented and is usually loose.

2.2.3.2 Physical Properties of Each Aquifer and Aquitard

Aquifer parameters within the Subbasin are available for both well pumping tests and calibrated groundwater models. For details on aquifer parameters estimated for the Subbasin-level, refer to the KGA GSP Basin Setting. Aquifer properties reported herein include hydraulic conductivity which is a function of an aquifer's ability to move or transmit water (transmissivity) through an aquifer of a given saturated thickness, and the specific yield (unconfined systems) and storage coefficient (confined systems), which are functions of an aquifer's ability to store and release water from storage (storativity).

Table 2-1: Aquifer Parameters for Kern County Subbasin

This Page Left Blank Intentionally

Pumping test data within SSJMUD were not available at a district-level; however, aquifer test data derived from pumping tests in the Subbasin, some of which are in proximity to SSJMUD, are briefly described below. Pumping test data were taken from two sources: 1) relatively short (1.5- to 5-hour) pumping tests by the USGS at irrigation wells during the late 1950s and 1960 (McClelland, 1962), and 2) from constant rate pumping tests from engineering consultants in the 2000's (Todd, 2018). The depth of these test wells varied from 98 to 1,500 feet below ground surface (bgs) (median: 650 ft bgs), and pumping rates varied from 44 to 4,480 gpm (median: 2,500 gpm). The analysis included the use of water level recovery data from pumping wells and water levels from observation wells. From these tests, the hydraulic conductivity was estimated at ranges from 3 to 250 feet per day (ft/d; median: 60 ft/d), which is consistent with published ranges for clean, medium- to coarse-grained sand (Heath, 1983), or for a fine sand to coarse gravel (Schwartz & Zhang, 2003). These values also fall within the range of the groundwater models that were partially calibrated with these data (C2VSim; CVHM; Todd, 2018; Todd, 2017).

Estimates of specific capacities observed from pumping in SSJMUD have been reported by USGS (McClelland et. al., 1962), and are included in Table 2-2 below. These data have been used for various Transmissivity estimates in the past and may prove useful for future work.

Table 2-2: SSJMUD Specific Capacity

SSJMUD Specific Capacity	
Township Range	Estimated Specific Capacity (gpd/ft)
T25R25	35,000
T25R26	36,000
T26R25	85,000
T26R26	68,000
Source: McClelland et al, 1962	

Corcoran Clay

The Corcoran Clay Member of the Tulare Formation is most commonly known for its fine-grained beds; however, lithology does vary from fine (clay and silt) to coarse (sand) texture (Page, 1986; Faunt et al., 2009). Faunt et al., (2009) compiled and estimated horizontal hydraulic conductivities within the range of 0.0024 to 33 ft/d, which is within the range of silt to fine/medium sand (Heath, 1983). A range of vertical hydraulic conductivity was estimated from permeameters and field tests between 6.6 x 10-6 ft/d to 1.5 x 10-3 ft/d (Faunt et al., 2009), representing a potential vertical anisotropy range of 3.6 x 102 to 2.2 x 104. As noted by Faunt et

al., (2009) laboratory permeameter tests may have underestimated the hydraulic conductivity while field testing may have overestimated hydraulic conductivity due to potential for intra-borehole flow across the clay. Additionally, recent inelastic compaction of the Corcoran Clay in areas of subsidence may have further reduced vertical hydraulic conductivity (Faunt et al., 2009).

Specific Yield and Storage

Storage of an aquifer is primarily described and quantified by the storativity or the volume of water released from storage per unit surface area of the aquifer per unit decline in hydraulic head. It is important to note that while storativity applies to both confined and unconfined systems, it can be further simplified for these two systems. Storativity accounts for aquifer compression and water expansion (specific storage components), which are the primary factors for estimating storage in confined systems; thus, for confined systems, the specific storage or storage coefficient is most often reported. In contrast, for unconfined systems, the specific yield or effective porosity (gravity-driven dewatering of an aquifer) better represents storativity because aquifer compressibility and water expansion are somewhat negligible in unconfined systems. For unconfined systems, specific yield is most often reported, and is a function of porosity and specific retention.

For confined systems, the aquifer compressibility of the storage coefficient can be further defined as elastic and inelastic skeletal specific storage, where inelastic storage will be lost once compression and dewatering occur. It is estimated that in the Central Valley, the inelastic specific storage typically is 30 to several hundred times larger than the elastic skeletal specific storage (Faunt et al., 2009; Ireland et al., 1984). Where fine-grained deposits with inelastic storage are thick in the aquifer system, water released could be a major source of water, but could also result in a permanent loss in storage capacity of fine-grained sediments.

Specific yield underlying SSJMUD was estimated by USBR (1948). The estimates were only meant to be a preliminary characterization; nonetheless, they are presented herein. They were evaluated based on soil type from well logs at or just below the water table at the time of the study. The average estimated specific yield in SSJMUD (from the Kern County line to Poso Creek) is roughly 7.6 percent (USBR, 1948). The yield is as high as 13 percent along Poso Creek. Just north of SSJMUD in the Rag Gulch channel, the yield was estimated at 14 percent (USBR, 1948). Underlying the western half of the district, the yield was estimated as low as 5 percent (USBR, 1948). USBR's mapped specific yield data is included in Appendix F.

2.2.3.3 Geologic Features that Significantly Affect Groundwater Flow

The large, asymmetrical, northwestward-trending trough of the Central Valley, and consequently the southern Tulare Lake Basin, is the principal structure controlling the occurrence and movement of groundwater in the area. Groundwater within the Subbasin is laterally bounded to east, south, southwest, and west by the surrounding highlands (Sierra Nevada, Tehachapi, and San Emigdio Mountains, and Coast Ranges, respectively) and crystalline basement rock. Groundwater flows from higher elevation recharge areas of the highlands from tributary rivers

and streams toward the center axis/trough of the valley and then northward outside of the Subbasin (Page, 1986), except where fault barriers and extensive recharge zones cause local variation in groundwater flow changes such as in the center of the Subbasin along the Kern River. Sediments are several thousand feet thick in the central portions and western side of the basin but considerably thinner where deposited on and draped over the Bakersfield Arch which extends from the southeast of Edison to the northwest of Shafter (Figure 2-8) (Bartow, 1991). In general, most of the confinement of ground water occurs near the axis of the valley because of more extensive confining beds of the Tulare Formation, such as the Corcoran Clay (Page 1986). Figure 2-7 presents the extent, depth, and approximate thickness of the Corcoran Clay as estimated by the USGS (Page, 1986).

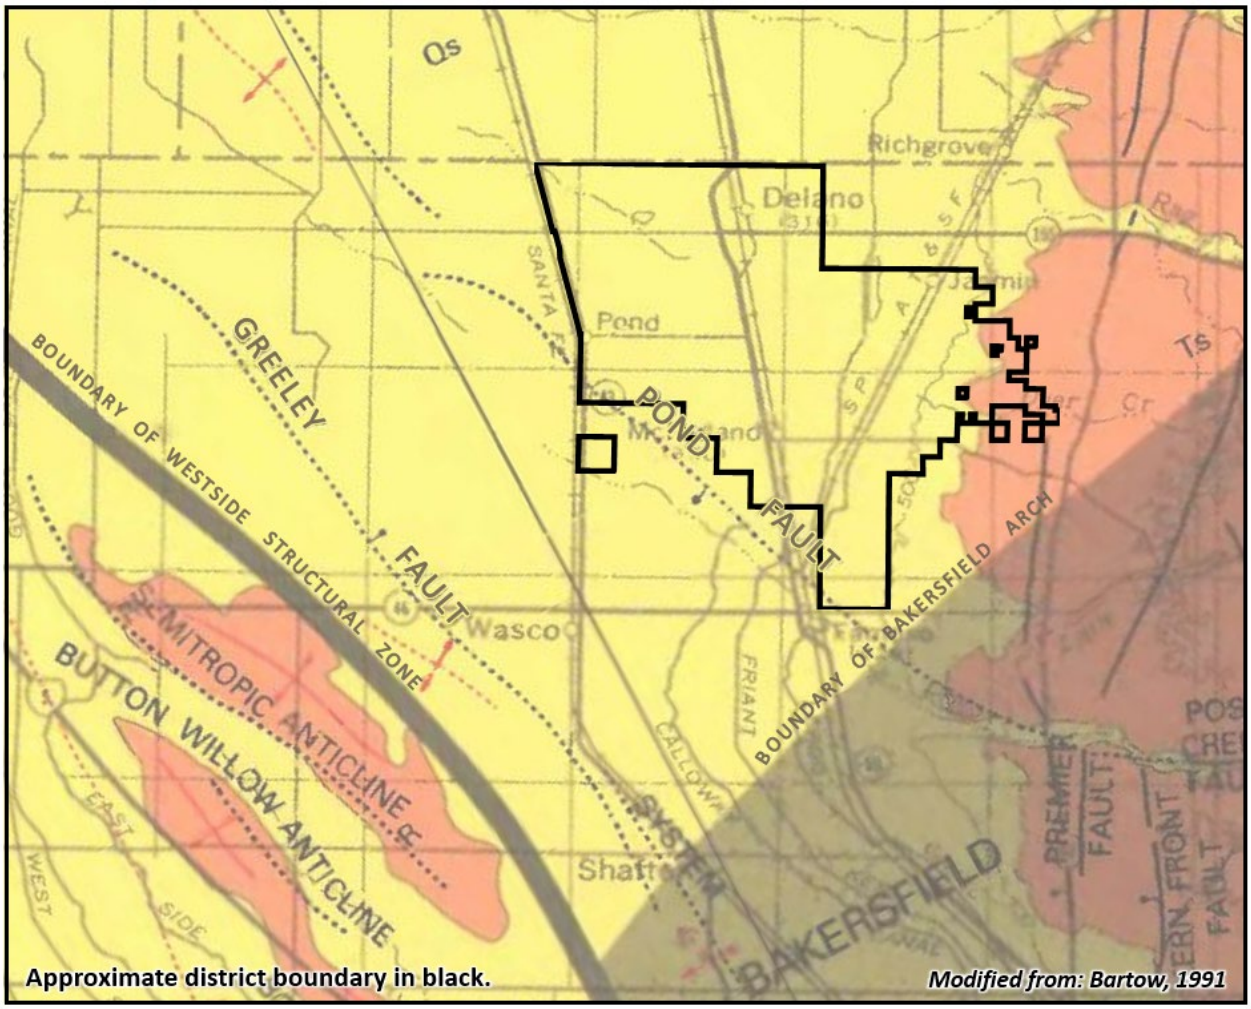

Figure 2-8: Geologic Map (Bartow, 1991)

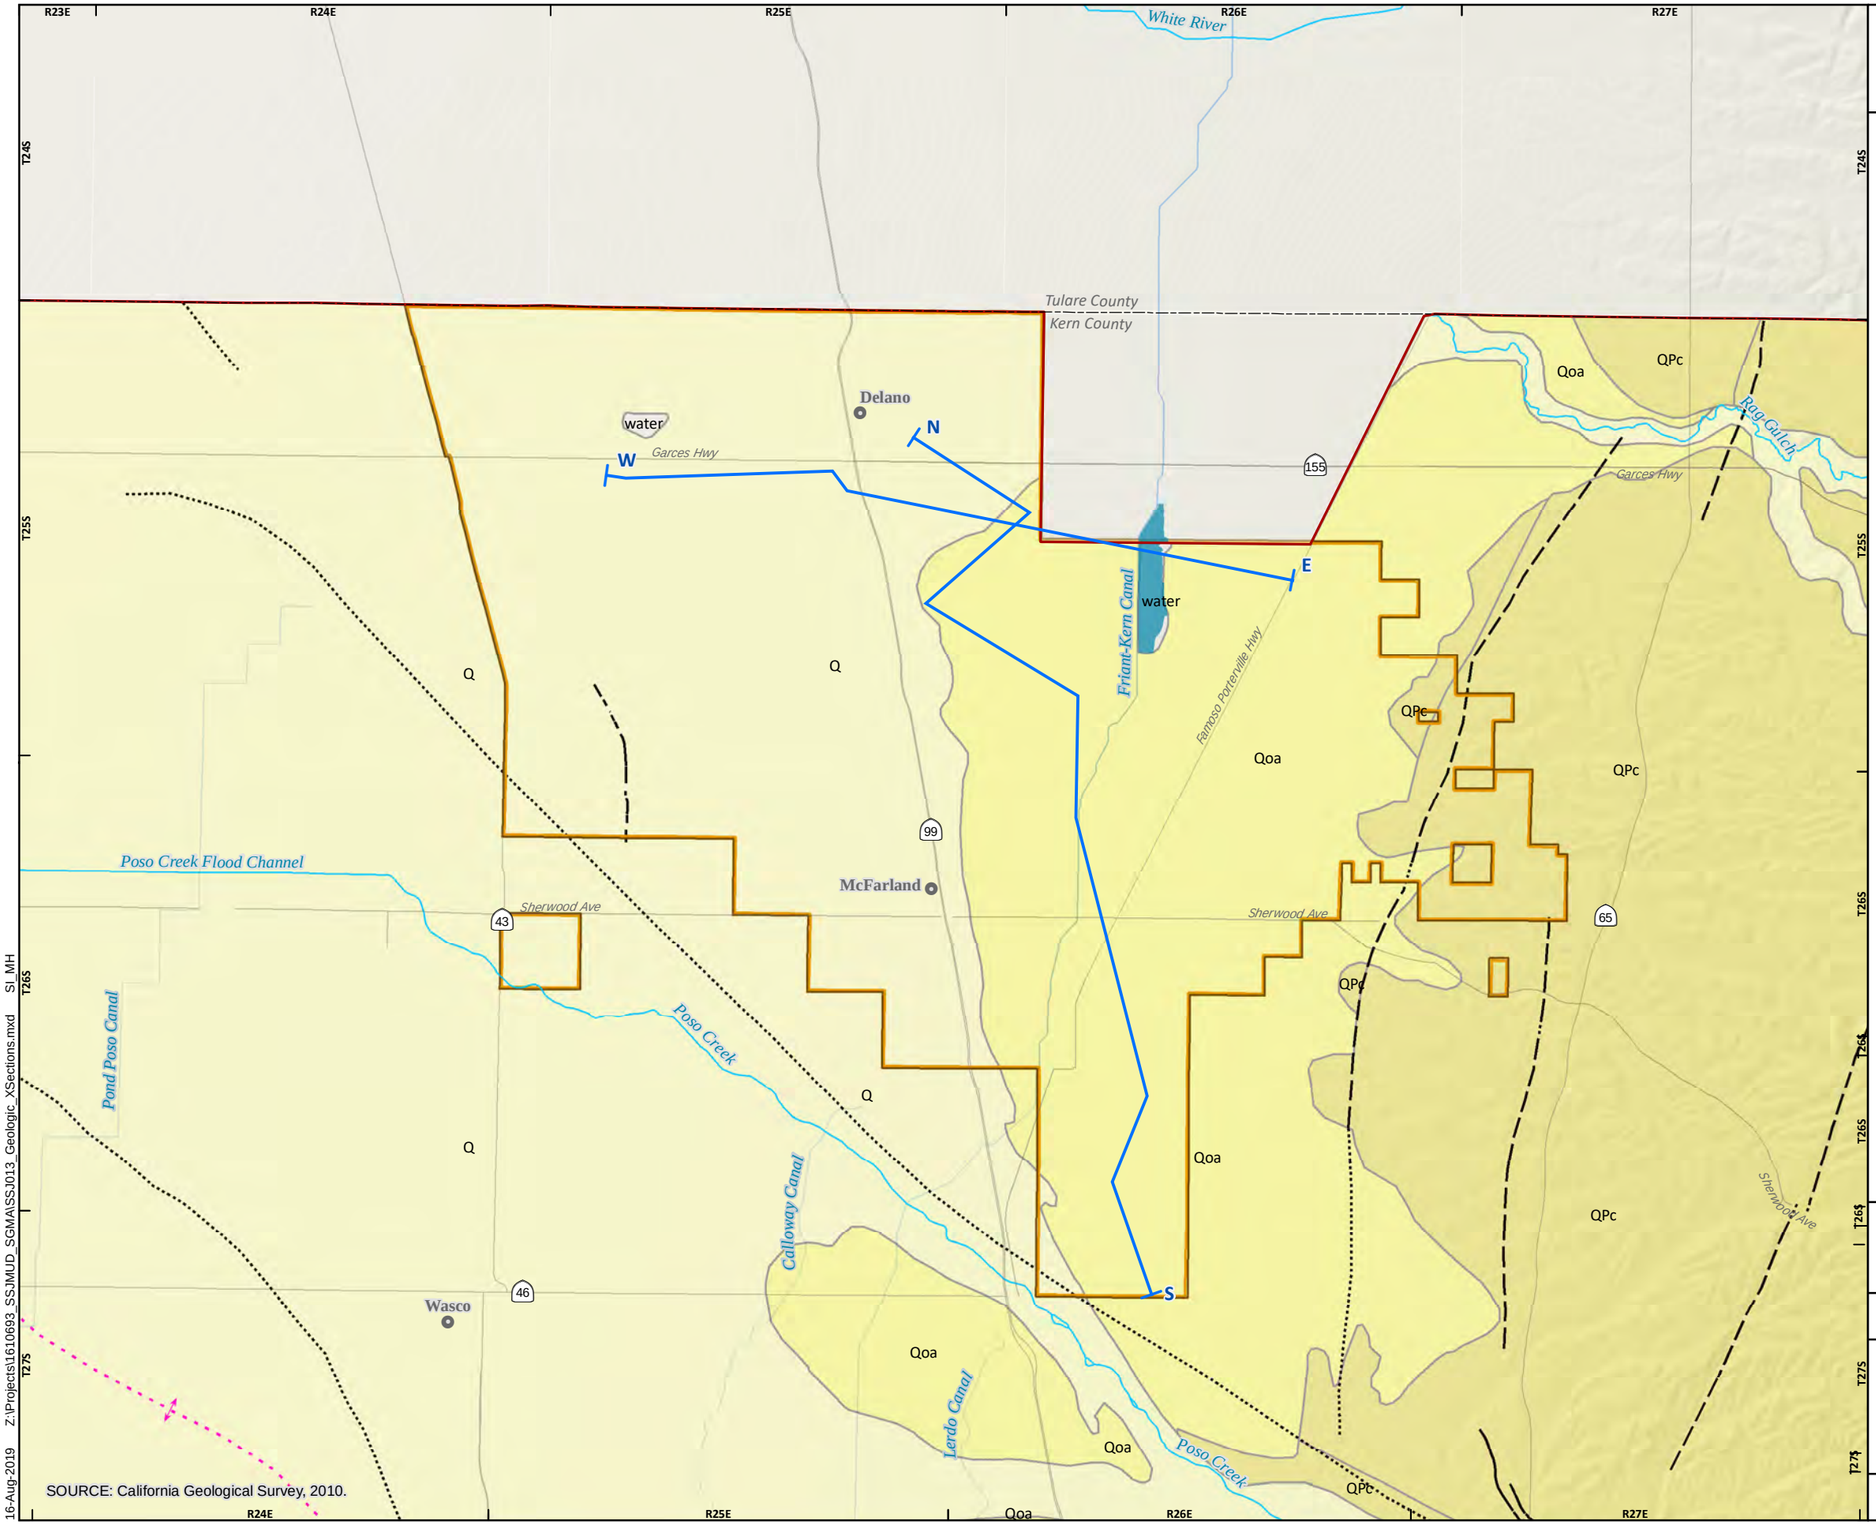
Faults



Numerous faults are mapped within the Subbasin and have been grouped by age of displacement (Figure 2-9, CGS, 2010a; and Figure 2-8). Most of the active faults within the Subbasin are located on the east, south, and southeastern sides of the Subbasin. Many of the faults are oriented

toward the northwest, parallel to the San Andreas Fault, while several faults are oriented northeasterly. The Pond-Poso Fault reportedly alters groundwater flow in the valley (DWR, 2006). Existing literature is not clear about the number of the faults in the Subbasin that are barriers to groundwater flow, although Faunt et al., (2009) included four northwest-trending "potential horizontal flow barriers" in the groundwater Central Valley Hydrologic Model (CVHM) near Semitropic Ridge and Buttonwillow Ridge and east toward Pond-Poso Fault. Although these faults are reported in regional datasets, LADWP (1974), indicates that Semitropic anticline fault system and Greeley fault system do not show displacement in sediments shallower than 10,000 feet (well below the base of USDW); therefore, they are not directly impactful to groundwater flow in the Subbasin.

The Pond-Poso Fault System reportedly affects groundwater flow. This system is a zone of four subparallel breaks/faults 2/3 mile in width, which extends from just east of Trico anticline (T25S-R24E) southeasterly approximately 48 miles through the Poso Creek oil field to the base of the Sierra Nevada (LADWP, 1974). Based on seismic reflection lines and vibratory seismic profile lines, the Pond-Poso Fault dips southwesterly at 50 to 70 degrees. LADWP (1974) and Holzer (1980) documented approximately 30 to 65 feet of difference in water levels across the fault zone, respectively from 1974 and 1978 studies. Holzer (1980) observed that fault offset of groundwater levels was greater during dry years when the lowest seasonal water level low occurred. The Pond-Poso Fault System is also documented to offset sediment in the subsurface. This vertical offset of sediment ranges from approximately 20 to 80 feet in the upper 1,000 feet of the subsurface (LADWP, 1974 and PGA, 1991), and the displacement decreases northwesterly along the fault system (LADWP, 1974). Exploratory trenches documented offset of 9 inches at 10 feet depth, and slickensides in the trenches show near vertical, oblique slip movement (LADWP, 1974). Coincidentally, Holzer (1980) concluded that 9 inches of offset had occurred along the Pond-Poso Fault System since the 1950s. Holzer (1980) observed fault movement from February 1977 to March 1979 during seasons of water level decline.

2.2.3.4 Cross Sections with Structures that Affect Groundwater Flow in SSJMUD

The purpose of developing cross sections for this management area plan was to identify prevailing conditions that affect groundwater flow and groundwater quality in the study area, and not to focus on correlating detailed stratigraphy. Furthermore, sediments underlying the study area are highly lenticular and, although some locally continuous clays are present, the eastern extent of the E-clay or other equivalent confining beds is debatable (Logan, 1992); thereby making accurate correlations difficult. However, to provide context for groundwater flow within the study area, a brief discussion of correlated stratigraphy in the literature is provided below, with the understanding that developed cross sections for this management area plan do not fully attempt to correlate stratigraphy across the study area.

GEOLOGIC MAP INDEX *(CGS, 2010)*

Regional Cross Section

Geologic Features

Historical Cross Sections

Historical cross sections are included in Appendix G. A few observations from the historical cross sections are provided below:

- Lofgren and Klausing (1969; B-B' Hydrologic Section and Geologic Section) provide some detail on the transition from an upper and lower aquifer zone in western SSJMUD to one aquifer zone with the absence of the Corcoran E-Clay in the southern and eastern portion of the district. The upper zone is likely unconfined to semiconfined while the lower zone is confined. In the south and east the aquifer system is semiconfined to confined with depth.

- Few wells are installed in the upper zone where water quality is poorer than below the Corcoran (C-C' Hilton et al, 1963; and H-H' Davis et al, 1959).

- The base of freshwater deepens eastward from SWSD and reaches an elevation of -1700 ft msl west of Delano at which point it begins to shallow eastward likely due to the proximity of the contact with Pliocene marine strata. The San Joaquin Formation is present under the westside of the district and likely becomes thin to nonexistent on the eastern side of the district, where the Etchegoin Formation is the upper contact of Pliocene marine deposits (Schierer et al, 2007). East of SSJMUD, the base of fresh water may be mixed into the Pliocene marine strata, due to proximity to recharge areas in foothills and prominent aquifers underlying the marine strata, such as the Santa Margarita and Olcese Formations (B-B'; Lofgren and Klausing, 1969).

- The trough of fresh water in central SSJMUD deepens southward into NKWSD (H-H' Croft, 1972); likewise, oxidized deposits associated with alluvial fans are thicker in the central portion of SSJMUD and progressively toward the south (Croft, 1972; B-B' geologic section of Lofgren and Klausing, 1969).

- PGA (1991; C-C') documented the displacement of bedding across the Pond Fault as observed in seismic and down hole geophysics. PGA's magnitude of displacement across the fault is consistent with LADWP (1974) (20 to 80 of displacement), except that LADWP reported the fault zone dipping to the southwest.

- Additional historical cross sections of lithology are included in Appendix G from the USBR (1948) investigation.

Current Cross Sections

Cross sections for SSJMUD are provided as Figure 2-10 and Figure 2-11 of this management area plan (north to south and east to west trending). The cross sections include general lithology from well drilling logs (DWR, 2017a), surficial geology along with folds and faults by the California Geological Survey (CGS, 2010a, b), the base of fresh groundwater (Page, 1973), the E-Clay confining layer (DWR, 2018a), groundwater elevations for the upper and lower aquifer

zones, and general interpretations of faults and folds underlying SWSD. The E-Clay data on the cross sections represent the C2VSim Corcoran model layer. The C2VSim Corcoran model layer was compared with the CVHM model layer (USGS, 2018a) and mapped Page (1986) modified "E" clay extent and was found to be in general agreement. The C2VSim Corcoran layer was chosen because C2VSim fine-grid model is the basis for the Subbasin's groundwater model. The cross sections also include a representation of general well construction across the study area. Logged fine-grained deposits in well logs are depicted to provide an interpretation of dipped bedding in the subsurface, as observed from seismic data correlations from PGA (1991), and cross sections by B-E (1968).

2.2.3.5 General Water Quality of Principal Aquifers

A general summary of water quality variation both laterally (from west to east across the Subbasin) and vertically (shallow–deep within the Subbasin) is provided in the table at the beginning of Section 2.2.2. In general, water quality is poor in the western third of the Subbasin and in shallow perched zones, generally above shallow beds of the Corcoran Clay. Groundwater is progressively fresher below the Corcoran Clay, toward the center of the basin, and eastern half of the Subbasin. Water quality within the Subbasin is described in more detail in Section 2.3.4 herein.

2.2.3.6 Primary Use of Each Principal Aquifer

The unconfined zone to the east of the Corcoran Clay and the production zone beneath and outside the extent of the Corcoran Clay are the key zones within the Subbasin aquifer system that provide the bulk of water production for beneficial use. The primary uses of the Subbasin's aquifer system include agricultural, municipal, domestic, and storage for the banking of surface water.

2.2.3.7 Summary of Beneficial Uses and Users of Groundwater

Land use in SSJMUD is 70 percent agriculture, 9 percent urban/industrial/residential, and 21 percent open space. According to the 2014 SGMA legislation, beneficial users of groundwater and property interests potentially affected by the use of groundwater include:

- Agricultural Users
- Domestic Users
- Municipal Well Operators
- Public water systems
- Local Land Use Planning Agencies, and
- Environmental Users

According to DWR well completion reporting and the CASGEM program, groundwater wells are constructed for a variety of uses including:

- Domestic / Residential
- Irrigation
- Stock
- Municipal / Public
- Monitoring / Observation
- Industrial
- Cathodic Protection
- Other / Unknown

2.2.4 *Data Gaps and Uncertainty in the Hydrogeologic Conceptual Model*

The primary data gaps in the hydrogeologic conceptual model include:

- Groundwater characterization on the eastern and western flanks of the Subbasin as further presented in Section 2.3 Groundwater Conditions, and

- Groundwater quality of the primary aquifer zones and confined zones on the eastern and western flanks of the Subbasin, from wells screened solely in a single aquifer zone.

2.2.5 *Mapped Physical Characteristics*

2.2.5.1 Topographic Information

Figure 2-12 presents a topographic map of SSJMUD's administrative area and local proximity. The east side of the district is rolling upland with steep-sided gulches due to natural drainage and topographic relief (USBR, 1948). The central portion of the district is marked by a belt of westerly slopes 30 to 40 feet per mile with recent alluvial fans (Poso and Rag Gulch fans) that have coalesced to the west. Elevation ranges from 700 feet msl on the eastern edge to 250 feet msl on the very northwestern edge of the district. Poso creek is located just south of the district. The FKC cuts through the center of the district, with the cities of Delano and McFarland along Highway 99 running west of FKC. North Kern State Prison and Kern Valley State Prison are located west of Delano.

2.2.5.2 Surficial Geology (Including Location of Geologic Sections)

Surficial geology of the Subbasin has been documented in a variety of previous investigations and is presented on Figure 2-8 and Figure 2-9 (Bartow, 1991 and CGS, 2010). According to the CGS (2010b), the western part of the district consists mainly of Pleistocene to Recent unconsolidated and semi-consolidated alluvial (Q of Figure 2-9) lake, playa, and terrace deposits. USBR (1948) reports that groundwater does not occur in the young alluvium underlying the district. Older Pleistocene alluvium (Qao) is present in the eastern portion of the district on top of

Pliocene-Pleistocene deposits (QPc) of sandstone, shale and gravel deposits, including the Kern River Formation.

As described by USBR (1948), the surficial geology does control some of the topographic features of the district. The rolling upland topographic area on the east is developed by erosion in Pliocene to Pleistocene alluvial fan and flood plain sediments. The broad west-sloping valley floor is situated on the medial and distal portions of the alluvial fans.

Bartow (1991) provides a similar map (Figure 2-8) as the CGS map but refers to Quaternary alluvial and lacustrine sediments (Qs) on the valley floor and Tertiary sedimentary rocks (TS) in the very eastern edge of the district. The map shows the location of the Bakersfield Arch to the southeast as well as the boundary of the westside structural zone to the southwest of the district and the Pond Fault trending along the southeast border of the district. As mentioned in the previous sections, the Pond Fault displaces bedding and has been documented to affect horizontal groundwater flow, although it is not considered a significant barrier to flow.

Page (1986) provides a somewhat different interpretation of the surficial geology, as discussed in the KGA GSP Basin Setting. Most of the valley is made up of Miocene to recent continental deposits (QTc) – a heterogenous mixture of gravel, sand, silt, and clay with some layers of conglomerate, sandstone, siltstone, and claystone. The western half of the district is made up of Recent flood basin deposits (Qb) – clay, silt, and some sand.

2.2.5.3 Soil Characteristics

Soils within the Subbasin have two general origins that are approximately delineated by the trough of the valley, which also mirror depositional patterns as mapped in surficial geology. The eastern alluvial fans were deposited primarily by runoff from the Sierra Nevada, Tehachapi, and Transverse mountain ranges. These soils are of igneous and metamorphic origin; are typically well drained, very low in salinity, and ideal quality for agriculture. The northwestern alluvial fans originated from Coast Range sedimentary rock formed on the sea bottom. This northwest region tends to have more areas with poorly drained soils of relatively marginal quality (Provost & Pritchard, et al., 2015).

Figure 2-13 and Figure 2-14 present the soil distribution within the Subbasin as defined by U.S. Dept. of Agriculture (USDA), National Resources Conservation Service, Soil Survey Geographical Database (SSURGO) as obtained from the DWR SGMA Data Viewer website (DWR, 2018b). More detailed soil survey data can be found in four USDA reports on various portions of the Subbasin: Soil Survey of Kern County, California (USDA, 1981, 1988, 2007, and 2009), including recent online updates.

2.2.5.4 Hydrologic Soils Groups

For the purposes of SGMA, a useful index of a soil's capacity to infiltrate precipitation and applied irrigation water is the NRCS Hydrologic Soils Group classification. Hydrologic Soils Groups typical of the Study area are defined below and are displayed on Figure 2-13 was developed using data from the NRCS' Soil Survey Geographic Database (SSURGO).

- Hydrologic Group A – "Soils in this group have low runoff potential when thoroughly wet. Water transmitted freely" (NRCS, 2009). Group A soils have a high infiltration rate due to well drained sands or gravelly sands giving the group the highest potential for contributing to groundwater recharge.

- Hydrologic Group B – "Soils in this group have moderately low runoff potential when thoroughly wet. Water transmission is unimpeded" (NRCS, 2009). Group B soils are moderately well drained due to moderately fine to coarse textures and have the second highest potential permeability and potential for contributing to groundwater recharge. These soils are present on the east, west, and south sides of the valley floor.
- Hydrologic Group C – "Soils in this group have moderately high runoff potential when thoroughly wet. Water transmission is somewhat restricted" (NRCS, 2009). This group has limited potential to contribute to groundwater recharge. Group C soils have a low infiltration rate due to their fine texture or because of a layer that impedes downward movement of water. These soils are present along the valley floor, along the eastern highlands, and at various locations along the northwestern side of the Study area.

- Hydrologic Group D – "Soils in this group have high runoff potential when thoroughly wet. Water transmission is very restricted" (NRCS 2009). This group has a very limited capacity to contribute to groundwater recharge. These soils have a very slow infiltration rate due to the presence of clay and are located primarily along the northern boundary of the Study area.

2.2.5.5 Taxonomic Soil Orders

Figure 2-14 displays taxonomic soil orders for the study area north of the Kern River, as defined by the Soil Survey Geographic Database (SSURGO) mapping obtained from the DWR SGMA Data Viewer website (NRCS, 2018). This figure shows six soil orders with the most prominent being Aridisols and Entisols and Inceptisols along the eastern highland mixed with Alfisoils, Mollisols, and Vertisols. Based on the NRCS publication Keys to Soil Taxonomy (NRCS, 12th edition, 2014), the following characteristics are associated with each of these soil types:

- Ardisols are dry soils characterized by a low humus, light colored surface horizon with a subsurface accumulation of soluble salts, silicate clays, and possibly a cemented layer of calcium carbonate, calcium sulfate (gypsum) or silica.

- Entisols are characterized by the absence of soil horizons due to recent deposition or active erosion under extreme wet or dry conditions.

- Inceptisols exhibit a weak appearance of soil horizons overlying a weathering-resistant parent material.

- Alfisols are characterized by well-developed soil horizons enriched with aluminum- and iron-bearing (Al/Fe) minerals but depleted of calcium carbonate. Translocated clays typically form a layer with relatively high amounts of mineral nutrients (calcium, magnesium, sodium, and potassium).

- Mollisols are characterized by a thick, dark surface horizon of humus, which typically originates from native grass vegetation with mineral nutrients present in most horizons.

- Vertisols are clay-rich soils (>30%) with significant cracking during the dry season due to the shrink-swell response of the clay minerals during the dry and wet seasons. The shrink-swell action produces significant vertical mixing of the soil.

2.2.5.6 Natural Recharge, Direct Recharge Areas, and Potential Recharge Areas

Direct recharge, potential recharge, and in-lieu recharge are differentiated in this section from natural recharge.

- Natural recharge occurs by groundwater underflow from adjacent sources, precipitation exceeding evapotranspiration to allow deep percolation in a subbasin, or from deep percolation of natural surface waters flowing into the Subbasin.

- Direct recharge is either planned or unplanned deep percolation of surface water from unlined conveyance, field application, managed recharge, and spreading operations.

- In-lieu recharge refers to instances where surface water is applied to lands that otherwise would have been irrigated using groundwater. Imported surface water for in-lieu recharge to the study area is conveyed through the same pipelines and canals as contracted imported water. These conveyances are described in the surface water bodies section of this management area plan. In-lieu recharge will be further discussed in the water budget section of this management area plan because it is an accounting aspect of water input to the basin. It represents the application of surface water for use to meet water demands and does not represent direct recharge to the subsurface for the purposes of replenishing aquifers, although it benefits the aquifer system by alleviating groundwater pumping demand.

2.2.5.7 Natural Recharge

As discussed in the KGA GSP Basin Setting, natural recharge to the Subbasin occurs mainly by underflow or surface recharge from the eastern and southern highlands (Sierra Nevada and

Tehachapi Mountains). The surface water bodies as a source of recharge are discussed in the next section.

Fresh water primarily recharges the aquifer underlying the district, from the east and southeast where the E-Clay or other beds are not effective confining units. These areas of recharge extend from the Kern River and Poso Creek through the fans of alluvium spreading out from these tributaries.

In general, natural recharge by precipitation is minimal in the study area, and may only occur in extreme wet years, because typically evapotranspiration exceeds the amount of natural precipitation to the Subbasin (Provost and Pritchard et. al., 2015).

2.2.5.8 Direct Recharge

In SSJMUD, direct recharge to groundwater occurs from infiltration through unlined canals and application of irrigation water more than the total ET of farmland that migrates below the root zone. Direct recharge is planned in the future for SSJMUD via spreading grounds.

2.2.5.9 Potential Recharge Areas

As described in the KGA GSP Basin Setting, the Soil Agricultural Groundwater Banking Index (SAGBI), may further estimate groundwater recharge suitability; however, the dataset may be limited to the shallow subsurface at or just below the root zone (O'Geen et al, 2015). The California Soil Resource Lab at University of California Davis has developed an online application (https://casoilresource.lawr.ucdavis.edu/sagbi/) to present the SAGBI, which estimates groundwater recharge suitability based on five major factors: deep percolation, root zone residence time, topography, chemical limitations, and soil surface condition. Areas of Natural and Direct Recharge are shown on Figure 2-15.

UC Davis mapping coverage of the SAGBI indicates a moderately good to excellent rating for the Poso Creek alluvial fan area near SSJMUD. SAGBI ratings are moderately poor to very poor along the western portions of the district. In addition to the areas identified in the KGA GSP Basin Setting, SSJMUD commissioned its own groundwater recharge feasibility study in 2018 to identify the locations of potential direct recharge projects.

2.2.5.10 Surface Water Bodies and Supplies

Figure 2-16 shows the location of surface water bodies near SSJMUD according to the National Hydrography Dataset (NHD). The federal FKC, as well as Poso Creek, and other significant ephemeral streams that flow from the mountains. Although the Kern River doesn't flow through the District, it is the most important local source of surface water to Kern County and to NKWSD, which is to the south of SSJMUD. The Kern River has been regulated by the Isabella Dam and Reservoir since 1954. The dam and reservoir are operated by the U.S. Army Corps of Engineers and the distribution of water is administered by the Kern River Watermaster. Poso Creek and the Kern River provide local surface water during the wet season and during above

normal and wet water years. Irregularly occurring flows are captured, to the degree possible, by spreading grounds and recharge facilities as described above in each district.

2.2.5.11 Source and Point of Delivery for Imported Water Supplies

SSJMUD uses both groundwater and surface water from local and imported sources. In the Subbasin, the Kern River is the primary source of local supply. However, Poso Creek and other minor streams contribute occasionally.

Imported water is supplied to SSJMUD by the CVP from the Friant Division. The FKC is a feature of the CVP. The canal diverts water from Millerton Reservoir, created by Friant Dam on the San Joaquin River, and extends southward a distance of 152 miles through Fresno, Tulare, and Kern counties to its terminus at the Kern River near Bakersfield. Water districts along the east side of the San Joaquin Valley entered into long-term water supply contracts with the Bureau of Reclamation, which provide for the delivery of three types of water; Class 1, Class 2, and Section 215. SSJMUD holds a contract for Friant Division for both Class 1 and Class 2 water. Figure 2-17 shows the FKC and indicates where water from this canal is delivered to SSJMUD.

Section 215 Water

Section 215 Water is available in exceptionally large water supply years and in infrequent and otherwise unmanaged flood flows of short duration. This category of water is not storable for project purposes (i.e., for meeting contract obligations for Class 1 and Class 2 water). Section 215 water can be made available under temporary contracts to districts who are not long-term Friant contractors, a mechanism some districts in the North of the River area that are not Friant contractors have exercised. The historical allocation priorities for section 215 water are as follows:

1. Long-term contractors;
2. Cross
3. Other parties within the Friant Division service area with direct delivery capabilities;
4. CVP contractors outside of the Friant Division service area; and
5. Other parties.

SSJMUD has purchased Section 215 water in the past when it has been available, and the District has the ability to either bring it in-district with available capacity in the FKC or the ability to bank the water through agreements with entities in the Subbasin (e.g. NKWSD) or outside of the Subbasin (e.g. Kaweah Delta Water Storage District).

2.3 Current and Historical Groundwater Conditions (Reg. § 354.16)

2.3.1 *Groundwater Trends*

Annual groundwater elevation contour maps covering much of SSJMUD have been prepared by KCWA in Water Supply Reports since before the 1990s. These maps provide seasonal high groundwater level conditions from spring water level data prior to most of the active groundwater pumping during peak evapotranspiration (ET) and growing season conditions.

Below is a generalized diagram of groundwater flow in the Subbasin (Figure 2-18). In the absence of pumping or significant barriers, groundwater naturally flows from high elevation points of recharge to lower elevation points with less recharge. Based on a review of the 1995 to 2017 Schmidt and Associates maps and historical groundwater data from USGS and KCWA (Page, 1986; and KCWA, 2018), groundwater generally flows westward from the Sierra Nevada and Kern River. Groundwater flows from natural and managed recharge points along the Kern River, which is situated on the Bakersfield Arch and has a broad topographical rise that gradually dips to the north and south of the river; thus, the rough alignment of the river effectively splits the Subbasin into Northern and Southern groundwater flow regimes. To the North of the river, groundwater flows from the uplands along the east margins of the Subbasin toward the west and northwest until it leaves the Subbasin as subsurface underflow or is captured by pumping wells for irrigation or potable consumption. Figure 2-18 below presents the approximate location of the San Joaquin Valley (Buttonwillow) Syncline. The syncline likely negates the potential flow of saline connate water of the westside from significantly impacting groundwater in the main production zone of the Subbasin.

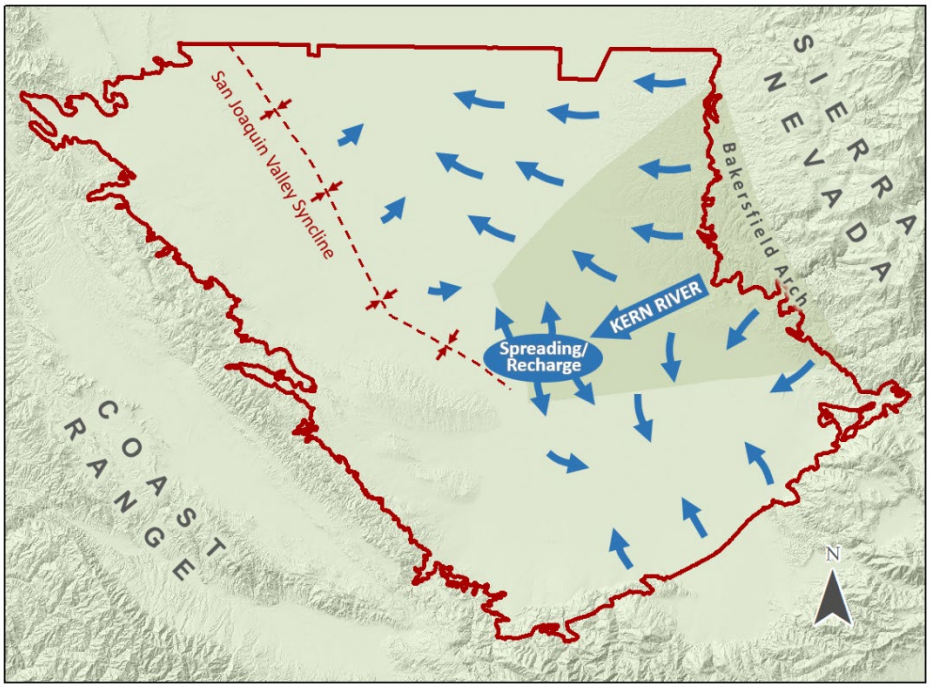

Figure 2-18: Generalized Groundwater Flow in Kern County Subbasin

As observed in cross sections Figure 2-10 and Figure 2-11, the seismic form correlations confirm the general flow direction of groundwater and the general topographic high of the Bakersfield Arch with bedding gradually dipping northerly on the northside of the Arch, and southerly on the south side of the Arch. Cross sections also depict some of the highs of the anticlines and the low of the Buttonwillow Syncline. In general, groundwater elevations near the river tend to respond to flow in the river channel and the management of groundwater banking projects located near the river, whereas, groundwater elevations further away from the river show more pronounced seasonal responses from pumping and recharge.

The following sections include the discussion of groundwater elevation contours, hydrographs, and other details to present the historical and current groundwater conditions within SSJMUD.

2.3.1.1 Elevation and Flow Directions (Groundwater Contour Map for Each Principal Aquifer)

Groundwater elevation contour maps were prepared for Spring 2015 (seasonal high) (Figure 2-19) as well as Fall 2015 (seasonal low) (Figure 2-20) to provide relatively current groundwater flow trends across the Subbasin since the inception of SGMA. Groundwater contour maps were prepared for the main production zone. In general, flows were consistent with historical trends, with groundwater flowing from the uplands on the east and around Poso Fan, and from the south along Kern River Fan along the natural flow direction to the northwest and toward pumping well discharge points. Groundwater elevations during Spring 2015 from less than minus 100 ft msl on the west to greater than 150 ft msl on the southeast. Groundwater elevation data for the Fall 2015 were limited in availability due to the high demand for pumping; therefore, the data range is incomplete and represents only a partial dataset; however, general groundwater flow trends are consistent with historical trends. Groundwater elevation data for the Fall 2015 in the main production zone of the aquifer system ranged from less than minus 150 ft msl to greater than 100 ft msl. In addition to recent mapping, the KCWA historical maps are provided in Appendix G.

2.3.1.2 Hydrographs

Hydrographs provided in Appendix I present groundwater elevations versus time with corresponding water years. In general, groundwater levels decline during dry years and increase during wet years based on the availability of imported surface water supplies. As a reference for recent surface supply water years, the below Table 2-3 presents the water year indexes from 1995 to 2017 for both the Sacramento Valley Index (typically representative of the State Water Project (SWP) allocations), and the San Joaquin Valley Index (typically representative of the FKC allocations). The 23-year period (1995-2017) started with six years of wet to above-normal years followed by 12 of the final 17 years as below normal to critically dry years. The implementation of SGMA (2015) began with critically-dry and dry years midway through a historic 5-year drought period.

A complete set of hydrographs for data in the data management system (DMS) is contained in Appendix I. A select group of representative hydrographs with a summary table of well data are included in the Appendix I and are discussed below. These representative hydrographs were selected from CASGEM, neighboring district-owned supply wells, and private wells that are made available for SSJMUD water level monitoring.

Group 1. T26S-R26E and T27S-R26E:

Hydrographs represent wells in the southern portion of the study area just northwest of Poso Creek. The magnitude in seasonal drawdown and rise and fall of water levels between wet and dry years indicate is fairly small compared with Group 2. Potentially indicating that Group 1 wells are closer to natural recharge along the Kern and Poso Fans.

Group 2. T25S-R24E to T26S-R26E:

Hydrographs represent wells in central SSJMUD. The magnitude in seasonal drawdown and rise and fall of water levels is larger than Group 1, because it is further downgradient from natural recharge, appears to exhibit more semi-confinement which is consistent with the presence of the Corcoran Clay near these wells and possibly due to greater amounts of fine-grained units in the subsurface as indicated in historical cross sections from USBR, 1948).

Group 3. T24S-R26E and T25S-R26E:

Hydrographs in the north-central area of SSJMUD exhibit less seasonal drawdown in some wells and a smaller response in water level change between dry years and wet years. These trends may indicate more unconfined conditions. Water level elevations are higher in Group 3 than in Groups 1 and 2.

Overall, for all areas of SSJMUD, water levels are declining in dry years, and stabilizing or increasing in wet years.

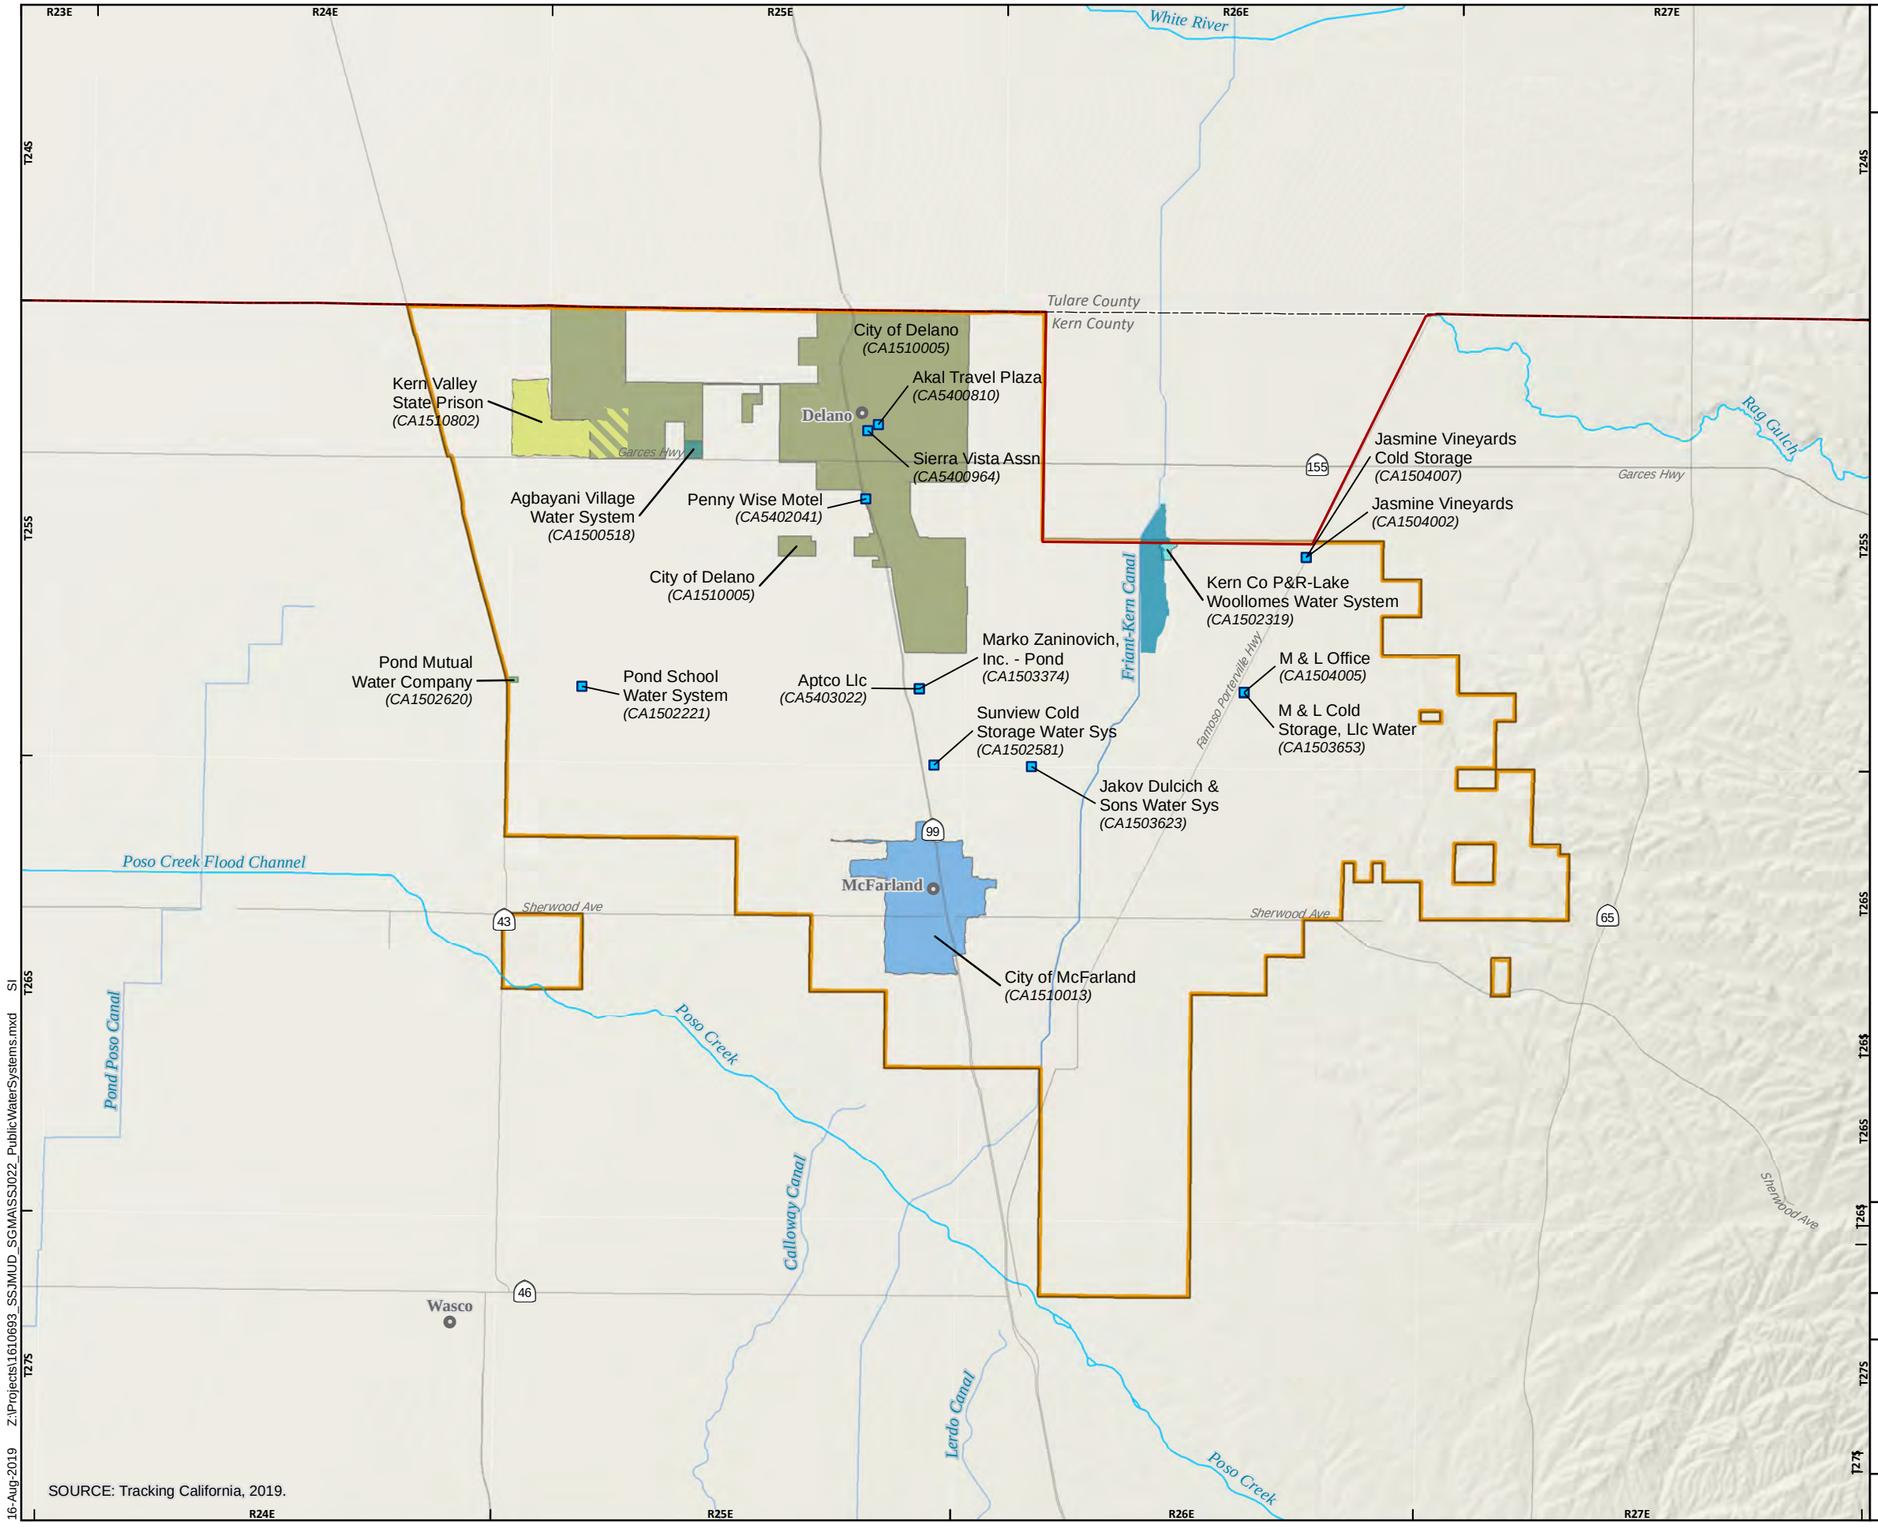
2.3.2 *Change in Groundwater Storage*

Change in groundwater storage is estimated in the KGA GSP Basin Setting. Included with the description are graphs of the change in groundwater storage over the study period of 1995 through 2015.

Historical changes in groundwater elevation maps for SSJMUD are documented in Appendix G. As observed with the change in elevation maps and hydrographs, groundwater storage is reduced during "dry" water years when imported surface water deliveries are limited, resulting in greater reliance on pumping groundwater to meet water demands.

2.3.3 *Seawater Intrusion*

Seawater intrusion is not applicable to Subbasin. The Coast Range are a barrier to groundwater flow that separates seawater from the Subbasin.



2.3.4 *Groundwater Quality*

The purpose of this groundwater quality section is to discuss groundwater quality issues that may affect the supply and beneficial uses of groundwater as stated under CCR §354.16. This section includes a discussion of water quality standards used and information relevant to capturing the groundwater quality in SSJMUD boundaries.

Public Water Systems

While land use within SSJMUD is predominately agricultural, there are 18 public water systems that are located within the District's service area identified through the Groundwater Ambient Monitoring and Assessment Program (GAMA). Six of these water systems are classified as community water systems, meaning that there are at least 15 service connections, or 25 year-round residents are served. The remaining public water systems are either Non-Transient Non-Community (NTNC) or Transient Non-Community water systems (TNC). These classifications are generally designated for businesses who supply water to their employees, or a transient (pass through) population. Table 2-4 lists the public water systems with a brief description, classification and estimated population served. Figure 2-21 shows where they are located within SSJMUD boundaries.

Water quality data from regulated drinking water systems is available through the State Drinking Water Information System (SDWIS). NTNC water systems are required to test for most

Existing Water Quality Monitoring Programs

SSJMUD does not own any wells within their district. Therefore, there is no direct monitoring of groundwater quality within their service area. This evaluation was conducted using public water system data.

Domestic Wells

Domestic wells are used exclusively to supply general household needs of the property owner and are typically constructed to a shallower depth than municipal or agricultural wells. Therefore, domestic wells are more commonly impacted by surface contaminants leaching into the groundwater.

Currently, information about domestic wells is limited. There is an effort being led by the SWRCB, as well as multiple other agencies, to explore the best sources of information and conduct a Needs Assessment of domestic wells in contaminated groundwater basins. An effort that is specific to SSJMUD is being conducted by the Tulare Kern Funding Area Disadvantaged Community Involvement Program that anticipates its study will be completed by the end of 2019. This study is seeking to quantify the number of domestic wells in the funding area. These studies will also gather information on the disadvantaged communities (DAC) and domestic well owners and explore potential remedies for contaminated wells.

Water Quality Standards

Federal and State Drinking Water Standards are predominantly referenced when discussing water quality standards. However, the predominant use of land in SSJMUD is for agricultural purposes and drinking water salinity limits are not protective enough for agriculture. For this reason, the SWRCB's Agricultural Water Quality Goals (Ag Goals) is also referenced for evaluation of groundwater quality in this area. The most applicable standard, Drinking Water Standard or Ag goals will be used as a reference point when discussing each constituent.

Water quality constituents that have the potential to impact the groundwater quality of SSJMUD are: arsenic, hexavalent chromium, nitrate, chloride, sodium, boron, 1,2,3-trichloropropane (TCP) and dibromochloropropane (DBCP). The list of these constituents along with their corresponding standards are listed in Table 2-5. In the Subbasin, arsenic, hexavalent chromium, and boron are predominately naturally occurring. Constituents related to salinity - chloride and sodium - are also naturally occurring but concentrated by surface activities. Nitrate is predominately anthropogenic. DBCP and TCP are manmade chemicals and are completely anthropogenic.

Table 2-5: List of Constituents and Standards

Constituent	Units*	Drinking Water Standard	Agricultural Water Quality Goal
Arsenic	ppb	10	100
Boron	ppb	1,000	700
Chloride	ppm	250	106
Dibromochloropropane (DBCP)	ppt	2	n/a
Hexavalent Chromium	ppb	n/a	n/a
Nitrate	ppm	10	n/a
Sodium	ppm	n/a	69
1,2,3-Trichloropropane (TCP)	ppt	5	n/a

*ppt = parts per trillion
ppb = parts per billion
ppm = parts per million

Land Use

Multiple sources were used to determine the land and crop land uses within SSJMUD. Ideally one single source would be used; however, none of the single sources cover the entire extent of Kern County. Using the combination of sources, land use for the entire county is accounted for.

The sources that were used in priority order are: 2014 data from Land IQ, 2016 Kern County Data from Department of Agriculture and Measurement Standards, and 2006 data from Department of Water Resources (DWR).

Land IQ was contracted by DWR to assist in obtaining land use data. In addition, Land IQ works in partnership with many other water districts within Kern County and uses satellite data to obtain the land and crop records. Given that water districts have worked closely with Land IQ to develop the data, this dataset was given the highest priority of the three sources to develop the land and crop land uses within SSJMUD.

Data from Land IQ also covers much of the crop land in the county and it was determined that crop patterns have been consistent within the last ten years. 2016 Kern County data was then used to fill in any spatial gaps of missing data from Land IQ. The last source, 2006 DWR data, was used to fill in any missing gaps from the two other sources. Despite DWR data being older than Land IQ and Kern County data, much of the missing land data filled by DWR are generally riparian and native vegetation land. Geographic Information System software (GIS) was used to merge shapefiles from all three data sources together.

When evaluating water quality, it is important to know what the land uses are in the area. Often, the land use activities may impact the groundwater quality. SSJMUD has a combined land acreage of 64,711.66. Of the total land within SSJMUD, about 81 percent is dedicated to agricultural land. From the agricultural land data, about 91 percent of it was determined from the use of Land IQ data, 4 percent from Kern County data, and 5 percent from DWR data. The next largest percentage of land use within both districts is urban at about 8 percent. Urban land use is predominately located in the central and north central portions of the District. Table 2-6 provides a breakdown of these land uses within SSJMUD. Figure 2-22 shows the land use distribution.

Table 2-6: Land Uses within SSJMUD

Land Use	Acres	Percentage (%)
Agriculture	52,527.02	81.17
Industrial	516.71	0.80
Commercial	665.16	1.03
Native Vegetation	3,612.65	5.58
Urban	5,388.70	8.33
Urban Landscape	19.80	0.03
Residential	282.65	0.44
Vacant	818.58	1.26
Surface Water	880.39	1.36
Total	64,711.66	100

Data Used

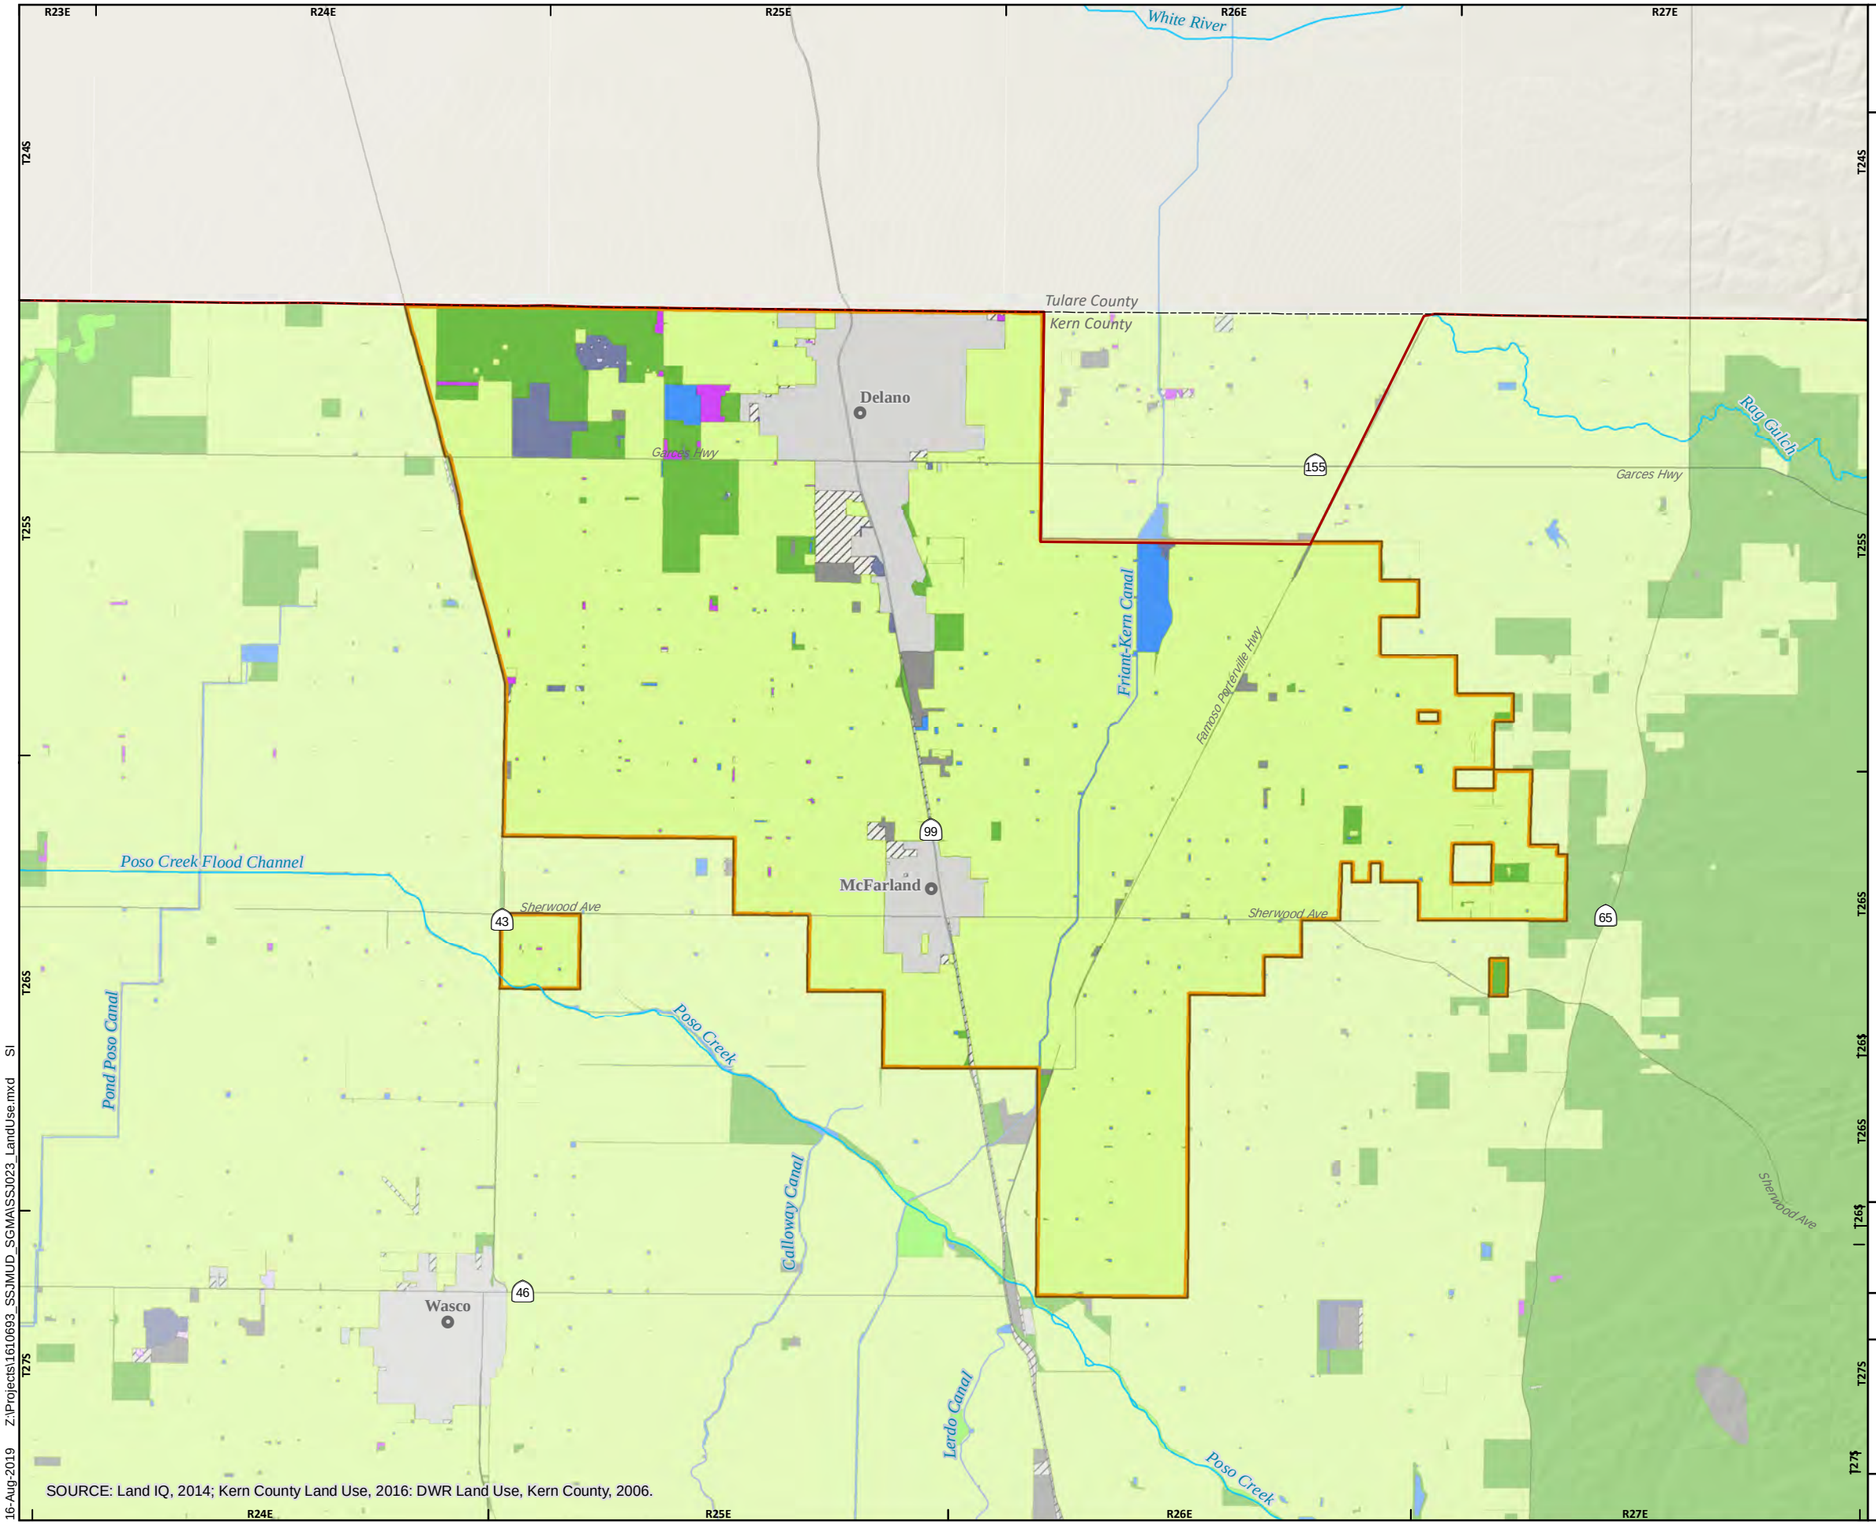
Public Water System Wells

Public water systems were identified through GAMA and water quality data was extracted from SDWIS. Since most of the water systems identified are businesses, monitoring requirements are sometimes less extensive than municipalities serving residential communities. Consequently,

there are some water systems with no data or only one result available for the identified constituents of concern in this region. Since SSJMUD does not own any groundwater wells and water quality data was not available, municipal well data was used for representation. Of the 18 public water systems identified, 33 wells were evaluated, and water quality data was trended from 2008 to current. In addition to the water quality data, the cities of Delano and McFarland provided well construction details.

Water level data and well construction details were not available for public supply wells, which has been challenging in determining where wells are perforated within the aquifer. This information is helpful for understanding what the water quality trends mean in relation to the aquifer. Water level data is also of value to determine if water quality trends are related to fluctuation in wet and dry water years. When examining the data, depths where constituents are more prevalent in the aquifer should be considered. Knowing this can help determine if water levels and well construction have an impact on water quality conditions.

Water Quality Evaluation



Groundwater conditions in SSJMUD was conducting using public water system data. All available water quality data was evaluated to identify constituents of concern, as identified in Table 2-5. Not all constituents that are commonly found in the Subbasin are found at concerning concentrations in SSJMUD. Therefore, only TCP, arsenic, chloride, and sodium are addressed as constituents of concern.

Sodium and Chloride

Since land use within SSJMUD is predominately agricultural, the SWRCB's Ag goals are referenced as the appropriate value rather than drinking water standards. Sodium and chloride have an Ag goal of 69 and 106 ppm, respectively. Drinking water does not apply a limit for sodium. The recommended limit for chloride is 250 ppm and the upper limit is 500 ppm.

Ag goals were published by the Food and Agriculture Organization of the United Nations in 1985. The criteria are protective of various agricultural uses of water, including irrigation of various types of crops and stock watering. At or below the thresholds presented in the Water Quality Goals database, agricultural uses of water should not be limited.

Both sodium and chloride show similar trends in the wells evaluated; therefore, for this discussion, they will be collectively referred to as salinity levels. Since sodium concentrations is an important measurement to crop yield, the focus of salinity level discussion will be on sodium. Table 2-7 summarizes sodium concentrations for the public water systems included in this analysis.

When compared against Ag goals, data indicates that there are 12 wells with no trends available. Only one sodium result was available for those wells. For the remaining wells, no discernable trends were observed. Wells with elevated sodium levels were located throughout the District's service area. More data such as well construction information will be necessary to determine if elevated sodium areas are in a certain part of the aquifer. If sodium levels continue to increase, this will cause an adverse effect on the Ag industry due to sodium hazard concern to crops mentioned earlier.

TCP

TCP is a newly regulated synthetic organic chemical. The SWRCB reports that contamination in the Central Valley is predominately from legacy pesticide applications of certain soil fumigants. The drinking water MCL is 5 ppt; there is no Ag goal.

While TCP contamination is widespread throughout the Subbasin, there appears to be less occurrence where the Corcoran Clay is present. Detections in SSJMUD are relatively intermittent and appear to only occur above the 5 ppt detections limit when wells are perforated in the upper aquifer, or when a nearby wells is serving as a conduit between the upper and lower aquifers.

Of the public supply wells tested, 36 percent of the wells have detections above the MCL of 5 ppt. Table 2-8 shows the water systems and the number of wells that are impacted by TCP. Noncommunity water systems are not required to monitor for TCP. There are four of these water systems, which are identified in Table 2-8 with no data. The table confirms that TCP is a

contaminant of concern for SSJMUD given that 36 percent of the wells in the region exceed the MCL.

Arsenic

In terms of drinking water quality, arsenic is the primary contaminant of concern in SSJMUD. There is a primary drinking water standard of 10 ppb for arsenic. The Ag goal is 100 ppb. All water quality data in SSJMUD indicates that arsenic is below the Ag goal.

The most common source of arsenic is from natural geochemical processes that leach metals from the sediments, particularly in the lakebed areas and where dark clay deposits occur. Studies conducted by USGS found that arsenic is in an easily exchangeable state where oxidizing geochemical conditions, caused by groundwater containing higher oxygen content, dissolve the pyrite (a mineral which can contain arsenic) and release arsenic into the groundwater. Smith et. al. (2018) found that over-pumping in the San Joaquin Valley has led to land subsidence due to compaction of the lakebed deposits (clay layers) that then releases the high arsenic pore water from the clay layers into the groundwater. In SSJMUD, the Corcoran Clay is in the northwest portion of the District.

About 33 percent of the wells evaluated exceed the drinking water limit. Elevated arsenic levels are predominately located in the confined aquifer, which is in the north east portion of the District. Tables 2-9 shows the number of municipal wells within the District and their respective arsenic concentration levels.

Because arsenic is believed to be naturally occurring in the Subbasin and leaching from dark clay deposits is the local sources of contamination, arsenic concentrations greater than 10 ppb are most commonly found in wells that are screened across pyrite sediments. Higher concentrations are generally found in very deep wells.

When comparing arsenic levels to a well's depth, there was an observed trend. For wells in the City of Delano, which are within the Corcoran Clay, wells at 1,200 feet or greater are above the arsenic MCL compared to shallower wells. Figure 2-23 shows this observation, which coincides with studies conducted in the Subbasin that arsenic concentrations tend to be elevated in the deeper part of the aquifer.

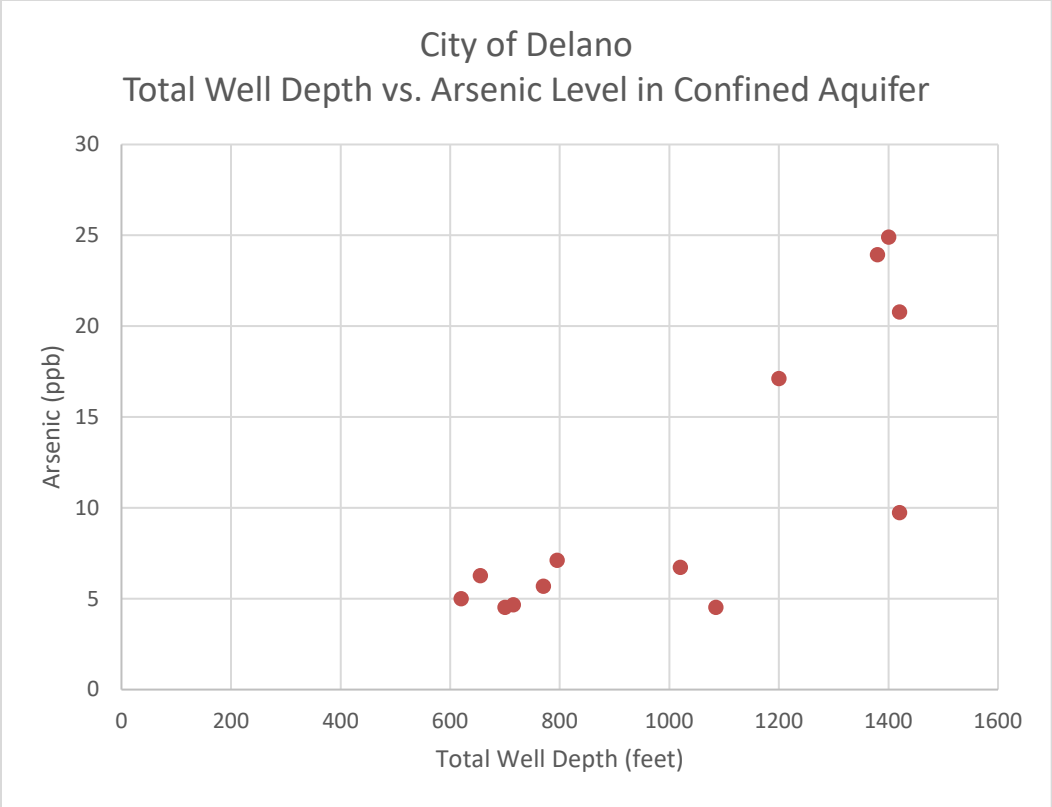

Figure 2-1: City of Delano - Relationship between Total Well Depth and Arsenic Levels

Even though a similar trend of deeper wells having elevated arsenic levels is seen outside of the Corcoran Clay, there was not enough data at the time of evaluation to conclude that arsenic is not generally found in the shallow aquifer. Well construction details are necessary to make this determination. This similar trend of elevated arsenic levels in deeper wells was noted in City of McFarland wells, which are east of the Corcoran Clay. Figure 2-24 shows that with deeper wells, arsenic levels are elevated. Even though the arsenic levels do not exceed the MCL like the wells within the Corcoran Clay, it is observed that the arsenic levels in the deeper wells are higher compared to shallower wells. The deeper wells also have lower screened intervals, therefore are drawing water from the deeper part of the aquifer where there is less dilution. For the wells within the City of McFarland, wells deeper than 1,200 feet have higher arsenic levels compared to shallower wells, which is similar to City of Delano.

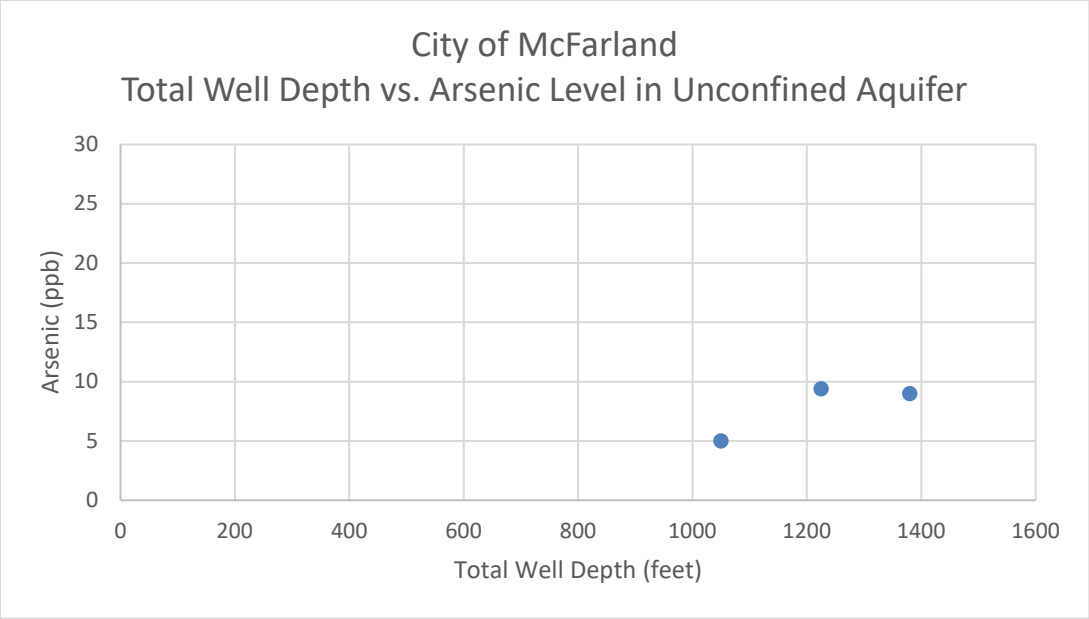

Figure 2-2: City of McFarland - Relationship between Total Well Depth and Arsenic Levels

No discernable trends were observed when comparing arsenic levels to water levels. When analyzing the wells together, there was no clear relationship. However, when looking at some wells individually, certain relationships were observed. Since the correlation was not consistent for most of the wells, no discernable trend can be stated.

Nitrate

Nitrate contamination is a significant concern in rural communities, particularly where agriculture is the predominant land use. However, a significant source of nitrate also comes from septic systems that are used in these rural communities. Since municipal services (drinking water or wastewater collection systems) are not available in rural communities, all domestic and public wastewater disposal is through onsite septic systems.

Even though nitrate is not a concern in terms of the percentage of wells with elevated levels, more data is necessary to determine if there are observable trends. Nitrate can be naturally present at low concentrations in groundwater, typically less than 2 ppm. Moderate and high concentrations generally occur because of human activities. Septic systems typically contribute moderate concentrations between 5 and 15 ppm of nitrate as nitrogen. Typically, higher concentrations (greater than 20 ppm) are associated with applying fertilizers to crops. Nitrate contamination is a significant public health concern because it has acute health effects. High concentrations of nitrate are typically found in shallow groundwater, such as those in the unconfined aquifer. About 24 percent of the municipal wells exceed the drinking water MCL for nitrate. Table 2-10 shows the number of wells at different concentration levels.

The location of elevated nitrate concentrations tends to be in rural areas where municipal services are not available. Despite most of the land use being agricultural, there are rural communities as well. As previously mentioned, since there are no municipal services, these communities rely on septic systems to manage their wastewater. Septic tanks are known to have failures such as leakage and are not as well maintained as a municipal sewer system. The failing septic tanks leak contaminants, such as nitrate, which eventually enter the groundwater. This is especially concerning if there is a groundwater well downgradient of the septic tank. Elevated nitrate levels in a groundwater well is typically due to surface contamination and have been more prevalent in shallower wells or in areas where a confined aquifer is not present. To better understand the nitrate trends, more data such as well construction information would be beneficial.

Contamination Plumes

A search of contamination plumes within SSJMUD was conducted using both GeoTracker and EnviroStor databases. The criteria outlined in the KGA GSP Basin Setting was applied during this review. Based on the criteria, five facilities in Pond and Delano, were identified and are being overseen by the Central Valley Regional Water Quality Control Board and Department of Toxic Substances. Table 2-11 identifies the facilities and the potential contaminants of concern. Other sites were acknowledged, but no nearby impacted wells or municipal wells within 1,500 feet of those sites were identified. Since there are no nearby affected wells and remediation efforts have begun, those sites are not impacting the groundwater quality, therefore not presented in Table 2-11.

Table 2-11: Contamination Sites within SSJMUD

Global ID#	Potential Contaminants of Concern	Status
T0602900113	Gasoline	Open – Remediation as of 7/6/16
SL185724257	Pesticides, other chlorinated hydrocarbons, TCP, synthetic organic carbons, other solvent, Nitrate+Nitrite as N	Open – Verification monitoring as of 4/20/10
60001327	Tetrachloroethylene (PCE)	Active as of 8/4/10
60002270	Tetrachloroethylene (PCE)	Associated with 60001327
60002268	Tetrachloroethylene (PCE)	Associated with 60001327
60002269	Tetrachloroethylene (PCE)	Associated with 60001327

The main contamination plume to be concerned with is the city-wide PCE plume in Delano. There are three dry cleaners that have been identified so far. Three City of Delano wells were within 225 feet of the plume and were destroyed in July 1995. City of Delano Well 22 is the closest active well to the plume; however, none of the city's wells have had any PCE detections so far. It is unknown if there are any other domestic wells within the plume. PCE has been detected as high as 420 ppb in one of the monitoring wells near the site. Groundwater samples have been collected between 105 to 250 feet below ground surface and levels have generally decreased with depth, except for one sample. Studies conducted so far at this site show that PCE is generally not detected above reporting limits at depths greater than 230 feet below ground surface or in samples collected more than a quarter mile downgradient of the potential source area. A Geosyntec report dated August 8, 2018 indicates that the Corcoran Clay is approximately 250 feet below ground at the site and believes that PCE, if present in a dense non-aqueous phase, would sink in groundwater but not below the clay. This still needs to be confirmed since a lower confining unit has not been encountered yet. Investigative work is still in progress and includes further groundwater investigation work and more monitoring well installations to better define the lateral and vertical limits of the plume. Figure 2-25 shows the locations of these contamination sites.

Groundwater Quality Findings

Based on data evaluated in this groundwater characterization, sodium is the primary constituent of concern for SSJMUD. Salinity is strictly an agricultural concern and arsenic is strictly a drinking water concern. All other constituents that were evaluated are not as great of concern since the concentrations and overall impact to this region are low.

Overall, sodium is of great concern for the District. 64 percent of the municipal wells are over the sodium Ag limit. Since the land use in SSJMUD is about 81 percent agricultural, the focus of the water quality evaluation for salinity, was sodium due to its impact the agricultural industry. High sodium levels pose a sodium hazard to crops. Sodium levels were observed to be elevated throughout the District. Management actions will need to be established to limit the impact to the agricultural industry from increasing sodium levels.

Following sodium, TCP and arsenic are of concern. TCP was elevated in about 36 percent of the municipal wells within the District. Elevated TCP wells are located throughout the District's

service area. Arsenic was elevated in about 33 percent of the wells. High arsenic wells are predominately located in the northwestern portion of the District's service area where the Corcoran Clay is present. For wells within the Corcoran Clay, it was observed that wells deeper than 1,200' had arsenic levels at or above the MCL. This same trend was observed for wells outside the clay.

Overall, nitrate was not seen as a concern. About 24 percent of the wells exceeded the MCL. Since nitrate is a surface contaminant, it is expected for wells with shallow screened intervals or annular seals to typically show the highest levels of contamination. More data, such as well construction information will be valuable to determine if there are any trends observed. To comply with the Human Right to Water, nitrate levels will need to be closely monitored and management actions will need to be in place to comply with the nitrate drinking water standard.

Contamination plumes were identified using the GeoTracker and EnviroStor databases. Of the plumes identified, the main one of concern to the District is the city-wide plume in Delano. So far, no drinking water wells have been impacted. However, much work still needs to be completed to determine the extent of the plume, both laterally and vertically.

From this water quality evaluation, sodium, TCP, and arsenic are the constituents of concern for SSJMUD's service area. These constituents will impact both the agriculture industry and public health. More information such as well construction information and water level data are necessary to determine if there are any relationships with constituent levels. All other constituents that were evaluated are not as great of a concern since the concentrations and overall impact to this region are low. Public health related constituents, TCP and arsenic already has an impact to public water systems that are already exceeding the respective MCLs but unable to provide treatment for the wells. There are disadvantaged communities among the District and it is anticipated that the Needs Assessment study will capture the domestic wells within Kern County to better understand the water quality impacts to these communities. If sodium levels continue to elevate or become more prominent in the area, it will become detrimental to the agricultural industry. This can greatly impact this industry since it is one of the primary economic livelihoods for the county.

2.3.5 *Land Subsidence*

As described in the KGA GSP Basin Setting, inelastic (irrecoverable) land subsidence (subsidence) is a potential concern in areas of active groundwater extraction with underlying fine-grained sediment, such as in the study area. Increased potential for Undesirable Results may occur due to subsidence. Undesirable Results of subsidence may include, but are not limited to, flood risk in low lying areas; well casing damage or collapse; canal and infrastructure damage or collapse; and reduced groundwater storage (LSCE, 2014).

According to DWR (2014), the Kern County Subbasin was rated at a high potential for future subsidence, due to 1) most of the wells monitored with water levels at or below historical lows; 2) documented historical subsidence; and 3) documented current subsidence. Moreover, greater

amounts of subsidence are occurring to the north of Kern County boundaries in the Tulare Subbasin. The amount of future subsidence will depend on whether future water levels decline below previous low levels and remain low for a considerable amount of time. Maintaining water levels above the previous low water levels may limit the risk of future subsidence.

Several processes contribute to subsidence in the Subbasin and include, in order of decreasing magnitude: aquifer compaction by overdraft, hydro compaction (shallow or near-surface subsidence) of moisture deficient deposits above the water table that are wetted for the first time since deposition, petroleum reservoir compaction due to oil and gas withdrawal, and subsidence caused by tectonic forces (Ireland et al., 1984).

Inelastic compaction (subsidence) typically occurs in the fine-grained beds of aquifers and in the aquitards. The fine-grained beds contain water in the pore spaces between the clay particles at the time of deposition and this water supports the clay particles which contributes to the thickness of the fine-grained bed. During dry conditions when surface water supplies are diminished, over-pumping of groundwater may cause a one-time release of water from the clay (dewatering). This one-time release is also referred to as the inelastic skeletal specific storage of clay. Once the clays dewater, the volume released from inelastic storage results in permanent realignment of the clay particles and the collapse of the clay layer structure, or permanent land subsidence. Although space within the overall aquifer is reduced by an amount equivalent to subsidence of the land surface (due to reduced thickness of the clay layers), this storage reduction does not substantially decrease usable storage for groundwater in the aquifer because the clay layers do not typically store significant amounts of recoverable, usable groundwater (LSCE, 2014). However, Ojha et. al. (2019), references recent studies suggesting that subsidence between 2007-2015 in the Central Valley (primarily San Joaquin Valley) resulted in losses of 0.4% to 5.25% storage capacity in the aquifer system. Although much this capacity mostly represents fine grained layers, this loss may impact the overall aquifer system by increasing the replenishment time of the aquifer which could pose further challenges to water management (Ojha et. al., 2019).

The one-time release of water compaction has been substantial in some areas of the Central Valley; and it is estimated that by the mid-1970s, about one-third of the volume of water pumped from storage in areas such as Los Banos-Kettleman City, came from compaction of fine-grained beds (Poland et al, 1975; Faunt et al, 2009); therefore, water budget projections may need to consider the one-time release of water from compaction as an irrecoverable water source for future projections. Although the largest body of fine-grained beds is the Corcoran Clay, a relatively insignificant volume of water has been released from storage in the Corcoran Clay (Faunt et al, 2009). However, aquifer water quality could be impacted by poor quality water released from the dewatering of clays, as postulated for an increase in arsenic (Smith et. al, 2018). The surface displacement of subsidence represents the reduced thickness of the impacted clay layers and this vertical displacement, if significant enough, may cause damage to wells and structures.

Groundwater overdraft is considered to be the primary driver of historical land subsidence in the Central Valley (Faunt et. al., 2009). USGS estimates that about 75 percent of the subsidence occurred in the 1950s and 1960s, corresponding to extensive groundwater development (Galloway, et al., 1999), prior to implementation of the SWP, CVP, and other development of surface water resources.

2.3.5.1 Subsidence Results and Methodology in the Study Area.

Results of subsidence estimates are summarized in the Table 2-12 below and on Figure 2-26 through Figure 2-30. In addition, time-series charts of subsidence are provided in Appendix J. Results were compiled from historical leveling surveys, recent GPS data, extensometer data, and satellite- and aircraft-based remote sensing.

Historical Results

Within the study area, historical subsidence has been documented from leveling surveys by the National Geodetic Survey at up to 6.5 feet from 1926 to 1970 (Ireland et al., 1984). Compaction data by the extensometers were plotted against the DWR water year indices. Greater rates of compaction generally correlated with low water year indices (critical, dry, or below normal) while compaction rates were lower during high water year indices (wet, and above normal).

In general, Figure 2-26 shows that centers of historical subsidence occurred northeast of SSJMUD and propagated outward to the south into SSJMUD.

CGPS

Recent subsidence studies of the Central Valley, and the Kern County Subbasin have utilized continuous GPS (CGPS) station data. The following CGPS stations are located in or near the study area: P544 (Twisselman Road), P545 (Lerdo Highway), P563 (Buttonwillow Rest Area), P564 (Wasco), and P565 (Delano), respectively located west of SWSD along I-5 and Twisselman Road, southwest of SWSD (along I-5 just north of Lerdo Highway), south of SWSD along I-5 at the Buttonwillow Rest Area, within SWID at Wasco Airport, and to the north of NKWSD at Delano Municipal Airport. These CGPS stations are monitored as a part of Unmanned Aerial Vehicle Synthetic Aperture Radar's (UNAVCO) Plate Boundary Observation (PBO). Day-to-day CGPS height solutions vary by as much as about 35 mm, likely due to variable atmospheric conditions, random walk noise, and other effects not directly related to land-surface-elevation change (Zerbini and others, 2001; Williams and others, 2004; Langbein, 2008) and, for this reason, short-term day-to-day comparisons of CGPS data to characterize land subsidence in the Central Valley is not ideal. Based on the time-series charts in Appendix J, CGPS data are more meaningful in characterizing land subsidence when looking at quarterly and annual trends. Therefore, cumulative subsidence and rates of subsidence were calculated by taking averages of the dataset for each water year. Note: For CGPS data plotted with InSAR data (Figure 2-27 through Figure 2-30), cumulative subsidence and rates were by daily averages.

In general, CGPS data show subsidence in the SSJMUD region with relatively modest declines (P544, P545, P563) and much higher decline (P564 and P565) in Wasco and Delano.

Ojha et. al. (2019) incorporated many of these CGPS points in a regional Central Valley-wide study of subsidence and were able to estimate skeletal storage of the aquifer system at CGPS points in the Valley. This skeletal storage could then be used to estimate the loss in storage of the aquifer based on CGPS subsidence estimates. Ojha et. al (2019) found that elastic subsidence recovered after 10 to 20 months from when groundwater levels begin to recover.

Extensometer

SSJMUD does not currently have any subsidence monitoring points with its plan area. However, it is appropriate to consider monitoring on a basin-wide level because subsidence occurs on a regional scale. This would include the use of monitoring points in neighboring management areas. Semitropic currently maintains an extensometer (25S/22E-35B001) for monitoring compaction in the subsurface. This extensometer was completed to a depth of 900 feet below ground surface in 2006. The benefit of an extensometer over other datasets such as CGPS or Interferometric Synthetic Aperture Radar (InSAR), is that an extensometer measures a discrete subsurface interval, or typically the interval of the ground surface to the total depth of the extensometer. On the other hand, CGPS and InSAR monitor overall change in ground surface relative to a datum such as sea level, regardless of the depth interval. Moreover, InSAR provides information over a wide area.

Ideally, an extensometer should be installed below the base of the compacting aquifer system (Galloway et. al, 1999), to monitor the entire compaction zone. Although Page's base of freshwater and nearby supply wells to the southeast suggest the lower aquifer zone extends below the extensometer, the upper 900 feet that the extensometer monitors is a very active depth interval of groundwater production.

Extensometer data have been collected over time, and a consistent dataset from December 2013 to present is provided in the table below. Time-series (Appendix J) data show that between December 2013 and October 2016, the rate of subsidence recorded by 25S/22E-35B001 extensometer was nearly 1.0 inch per year. This rate is within the range of rates reported for CGPS points in the area (0.1 to 2.8 inches per year) and is consistent with the interpretation that higher rates of subsidence are northeast of SWSD and inside the northeast boundary of SWSD, while lower rates are observed in central SWSD, to the south and to the west.

Time-Series Data

Time-series data (Appendix J) present cumulative subsidence from approximately 2006 to 2017 with corresponding water level elevation hydrographs observed from nearby wells. Below normal to "critical dry" water years are shaded in yellow, while above normal to "wet" water years are shaded in gray. All wells are within the lower zone or main production groundwater zone unless noted with "upper zone".

Variation in subsidence on the time-series is a function of:

- elastic subsidence to inelastic subsidence as well as the lag time of subsidence after the main pumping season,

- the distribution of fine-grained sediments in the subsurface,
- the amount of water pumped from fine-grained units, and
- potential near-surface factors such as shrinking and swelling of some soil types due to precipitation or other factors.

All the factors mentioned above may introduce additional signals or noise to the CGPS data; however, general broad trends are discernible when plotting data with water year type and nearby water levels. In the future, more water level monitoring and pumping data in areas near these CGPS stations may provide finer resolution of data to interpret lag times, elastic changes, and other short-term signals.

Based on the attached time-series, residual subsidence persists after each pumping season (especially in dry years) for relatively long periods of time (several months to over a year). Researchers note that delayed or residual subsidence response may occur in the Central Valley for years after pumping (USGS, 2018b).

The following observations were derived from the time-series data:

- P544 (Twisselman Road) shows increasing subsidence associated with dry years. Subsidence may lag up to 6 months after pumping season, while long-term residual subsidence and elastic rebound is observed from 6 to 18 months. No water level data in nearby pumping zones were available. Only water levels from shallow monitoring piezometers are plotted on this chart.

- P545 (Lerdo Highway) shows increasing subsidence associated with dry years and water level decline in the lower zone. Water levels and some elastic subsidence may recover/rebound within a month of the beginning of a wet water year; however, both elastic and inelastic subsidence lags for at least 6 to 18 months or longer after a dry year. Subsidence rates trend more with lower zone water levels than upper zone water levels. The included upper zone well is located in Buena Vista Water Storage District (BVWSD), is in the upper zone above the "E" Clay or equivalent and may vary over time because of groundwater production in the upper zone that occurs in BVWSD.

- P563 (Buttonwillow Rest Area) data are similar to P545, with subsidence associated with dry years and the rebound from elastic subsidence due to wet year conditions and stabilization of water levels. The subsidence time lag is evident in the elastic recovery from April 2011 to summer 2012. Similar to P545, changes in subsidence rates do not correlate significantly with upper zone water levels. Subsidence rates are associated with decline in water level from the lower zone.

- Data for SWSD Extensometer 25S22E35B001M are collected monthly to quarterly rather than daily, so any small-scale noise, rebound, or recovery aren't seen in the data. Consequently, subsidence may be more apparent in the extensometer data while water levels are variable during each year. Continued monitoring may confirm the

consequences of residual drawdown during sequential wet years. In general, subsidence or compaction occurs during dry years, and a decrease in the rate of subsidence is observed during wet years.

- P564 (Wasco) within SWID. In general, rates of subsidence increase during dry years and decrease during wet years. Between 2009 to 2011, elastic rebound (recovery) appears to outgain inelastic subsidence. On the other hand, between the wet year 2016 to 2017, subsidence continued but at a low rate even after some recovery of water levels. Note: P564 subsidence data are plotted on a smaller vertical scale (from -2 to 18 inches) than P545 and P563. As a result, smaller monthly changes in subsidence observed in the latter, aren't as apparent in P564

- P565 (Delano) within SSJMUD, also plots subsidence on a smaller vertical scale. P565 shows a lesser rate of subsidence between 2006 and 2009 in comparison to P564 but shows a similar rate of decline between 2011 and 2016. Overall, subsidence at P565 increases during dry years and decreases in wet years. A slight elastic rebound is observed in wet years. This plot is consistent with overall regional trends of declining water levels during the drought.

Remote Sensing

Recent investigations of land surface subsidence include Satellite-based Interferometric Synthetic Aperture Radar (InSAR), aircraft-based L-band SAR or Unmanned Aerial Vehicle Synthetic Aperture Radar (UAVSAR). The data from these remote sensing techniques have been processed by the National Aeronautics and Space Administration (NASA) Jet Propulsion Laboratory (JPL). Reported data have been published in a subsidence study commissioned by the California Water Foundation (LSCE, 2014), and by JPL via the DWR SGMA Data Viewer (DWR, 2018b) and the DWR website (Farr et al, 2015, Farr et al, 2016). The InSAR data were processed from a group of satellites including but not limited to: Japanese PALSAR, Canadian Radarsat-2, and European Space Agency's (ESA) satellite-borne Sentinel-1A. Data reported herein are from 2006 to 2017 with a gap from 2011 to 2014 when satellite outage occurred before the launch of the ESA's Sentinel satellites in 2014.

Ojha et. al. 2019, compared InSAR vertical displacement time series against CGPS and extensometer data by averaging the value of InSAR pixels within 200 m of each GPS and extensometer station. They found a good agreement between InSAR measurements and CGPS and extensometer data. The average standard deviation of the difference between InSAR and GPS was 0.9 inch, and between InSAR and extensometer data was 0.6 inch (Ojha et. al, 2019). The agreement of InSAR with extensometer measurements indicates that the majority of the compaction measured by InSAR occurs in the same depth intervals as extensometers and that any change or compaction in the subsurface below the average extensometer depth (1300 feet) is negligible.

DWR is currently evaluating the remote sensing data with in-field measurements, such as from CGPS stations, as a means of "ground truthing" the remote sensing data (Mardock, 2018). This plan does not intend to validate the InSAR data, but only to present it as best available regional data. Data gaps are undoubtedly present, and therefore, the discussion below is a qualitative interpretation of the data. Nonetheless, cumulative subsidence and rates of subsidence, based on InSAR data, are also provided in the table below and in the attached figures.

Along with InSAR data, the CGPS data for P564 and P565 are plotted as cumulative subsidence on Figure 2-27 and Figure 2-28. Evaluating spatial distribution of land subsidence. Data from 2007 to 2011 show subsidence of 1.7 inches in CGPS points within SSJMUD and 0 to ~1.2 inches for InSAR data within SSJMUD. Data from 2015 to 2016 show subsidence of 3.7 inches in CGPS points within SSJMUD, and 0 to ~8 inches for InSAR data within SSJMUD.

Discussion of Results

Overall, the subsidence data indicate that centers of greatest decline, both historically and recently, occur north of the study area in the adjacent subbasin and propagate outward to the south, west, and southwest into Kern. As a qualitative observation, the CGPS, extensometer, and InSAR data agree with the trends as stated above. From a quantitative standpoint, the magnitude of subsidence reported from InSAR from 2015 to 2016 is much higher than surrounding CGPS and extensometer data points. In the future, additional monitoring points would be beneficial to corroborate the highest subsidence rates detected by InSAR in northwest SSJMUD.

Based on time-series data, subsidence appears generally to trend with water levels from lower zone wells – deeper wells with screens below confining clays ("E" clay or equivalent), which are more likely to dewater fine-grained beds below the confining units. Consequently, recent subsidence does not trend as closely with upper zone water levels.

Continued monitoring of water levels, pumping, and subsidence, as well as more detailed subsurface lithologic characterization may provide a better dataset for future projection of subsidence. At this time, the calculated rates of subsidence have been posted on the results table and the time-series charts. These historical rates present an estimate of possible future subsidence rates if groundwater extraction continues at the current rate.

Table 2-12: Subsidence Results

District Area	Date Range	Approximate Cumulative Subsidence (inches)	Approximate Annual Rate of Subsidence (inches/year)	Source
North of SSJMUD boundary (Historical)	1926 to 1970	0 to 150	0 to 3.4	Ireland, 1984. Topographic Maps and Leveling Data

North of SSJMUD boundary		1.1 to 16	0.8 to 12.3	

Future Data Availability and Subsidence

According to USGS, the ESA's Sentinel satellites collect InSAR data at an approximate weekly rate, and data are available for download and interpretation (personal communication, USGS). These InSAR data are available but will require users support for the interpretation and distribution of the information. Likewise, CGPS data will likely to be available for future use. DWR is currently evaluating the remote sensing data with in-field measurements such as from CGPS stations, as a means of "ground truthing" the data (Mardock, 2018). Continued improvements in data interpretation and processing will benefit remote subsidence monitoring along with continued collection of CGPS and extensometer data. Figure 2-31 shows the locations

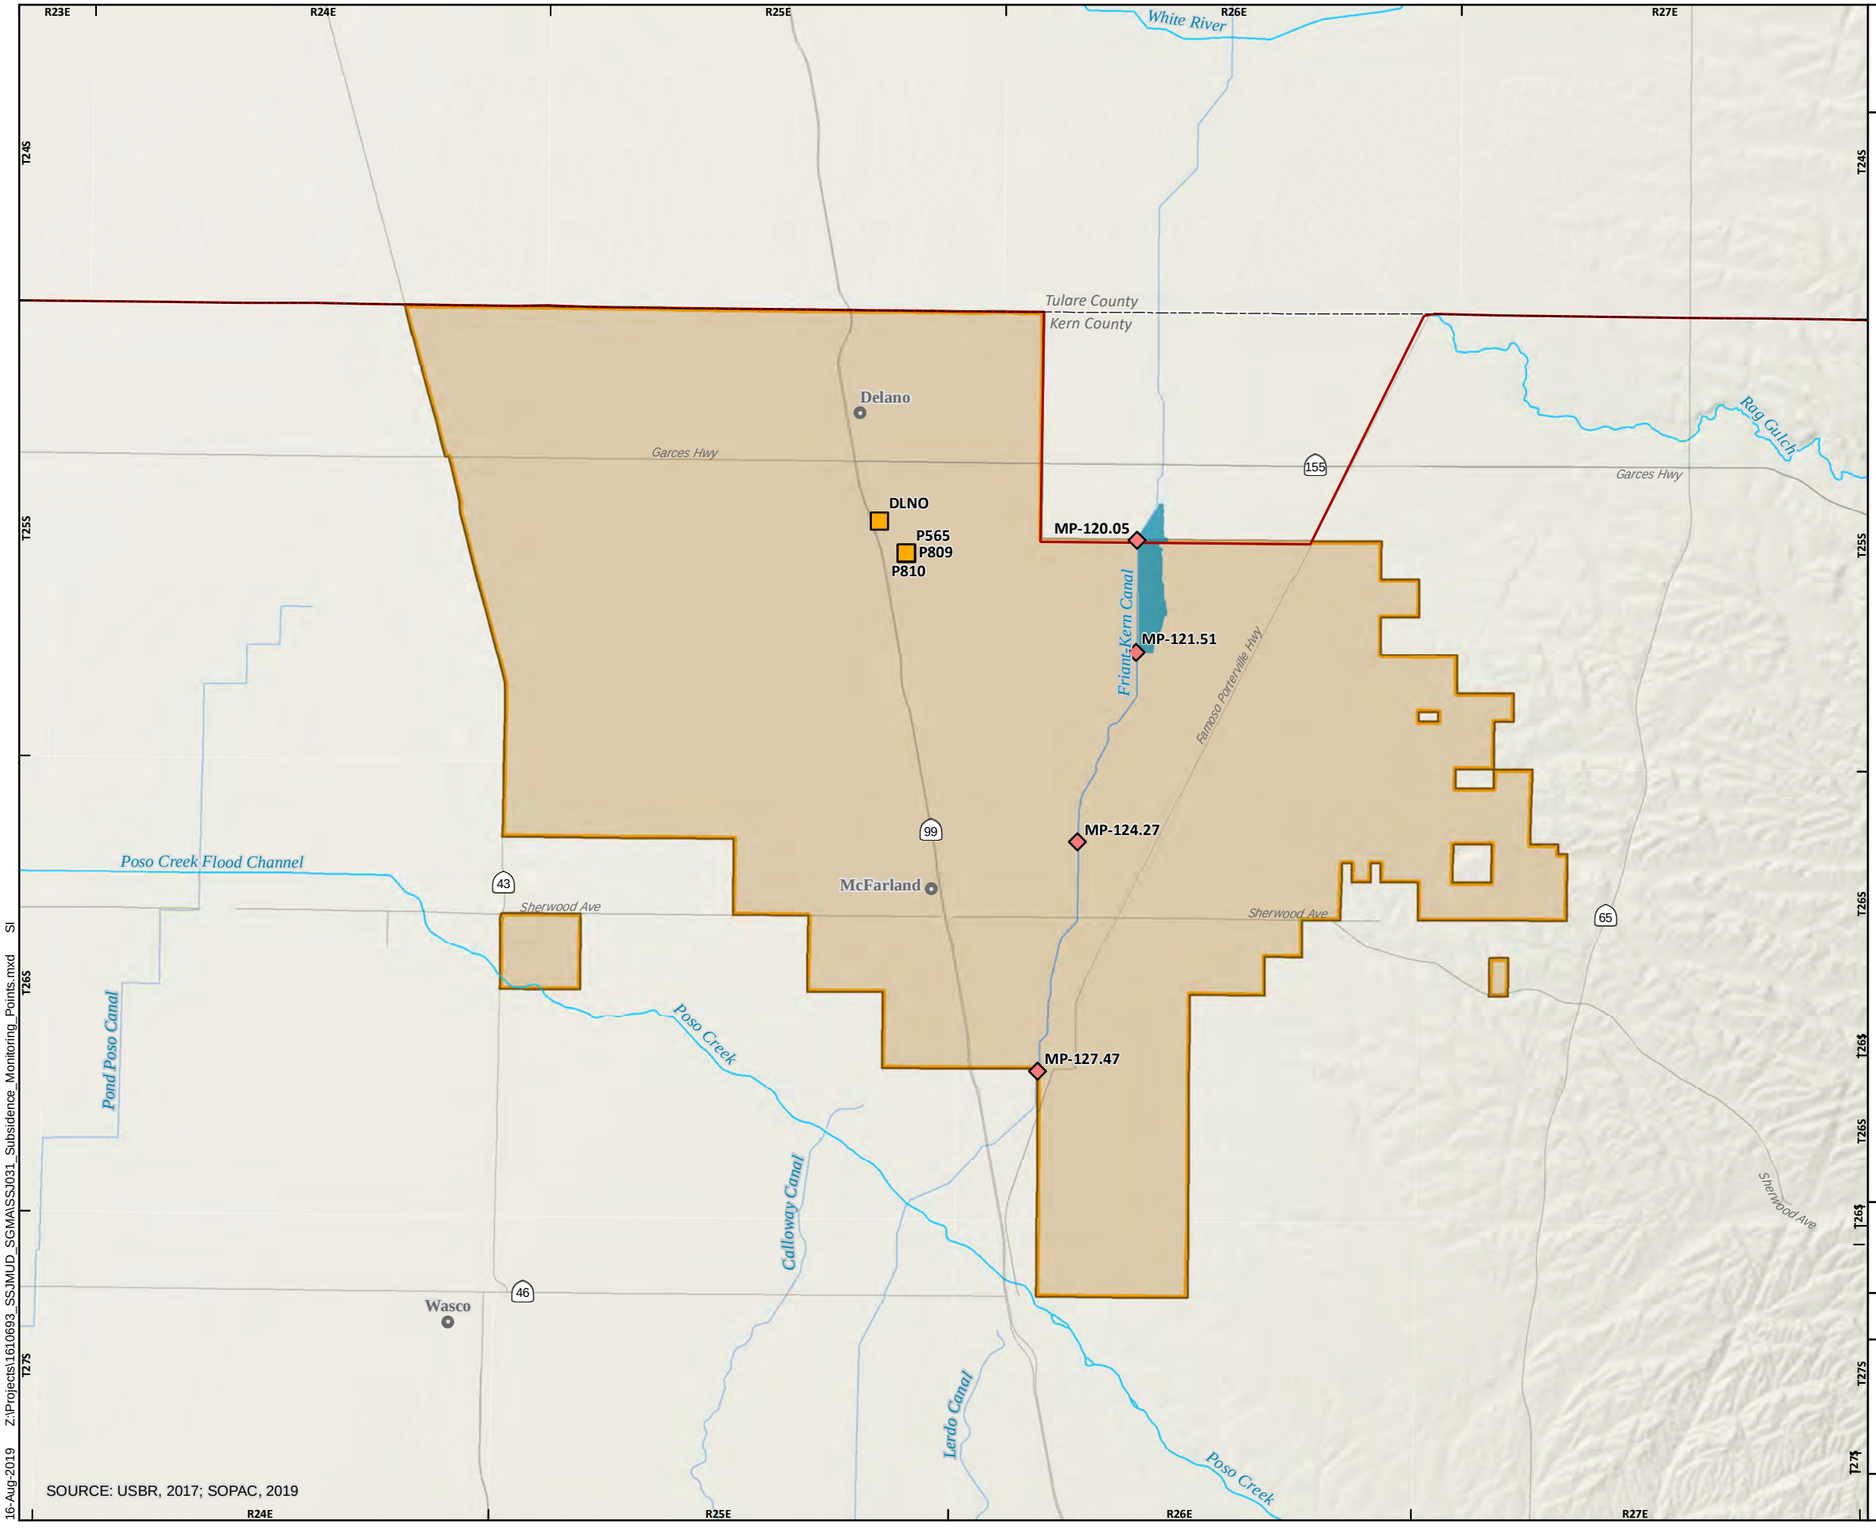
of CGPS locations and FKC Benchmark survey locations within SSJMUD that will be used for future subsidence monitoring. Further discussion of subsidence monitoring will be addressed in the Monitoring Networks section of this report.

2.3.6 *Interconnected Surface Water Systems*

Interconnected surface water systems are surface waters that are hydraulically connected by a continuous saturated zone to an underlying aquifer. There are no known natural interconnected surface water systems near SSJMUD since the subsequent impoundment and regulation of flow of the Kern River and groundwater pumping.

Apart from managed surface water to natural drainages in the study area, Poso Creek channel is the only channel that experiences natural recharge from the surrounding highlands. However, Poso Creek is ephemeral and only flows during limited "wet" months of some "wet" years.

2.3.7 *Potential Groundwater Dependent Ecosystems*



SGMA defines a Groundwater Dependent Ecosystem (GDE) as ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. SGMA states that a GSP shall include impacts on GDEs but does not explicitly state the requirements that warrant a GDE to be eligible for protection.

The first step in evaluating a potential GDE is to identify vegetation communities that are typically associated with groundwater, and secondly, to confirm the presence of shallow groundwater that could support potential GDEs. Lastly, is to evaluate any active groundwater pumping that could lead to shallow groundwater level change in the vicinity of potential GDEs.

In SSJMUD, there are no known GDEs. Many of the vegetation communities that could be potential GDEs are likely to be associated with managed wetlands and riparian areas that are supported by a combination of groundwater and imported surface water. In addition, other potential habitats include ephemeral wetlands covered by water seasonally but supported by irrigation deliveries and precipitation, and groundwater recharge basins that are artificially flooded with surface water.

Currently, the best available dataset for evaluating the occurrence of vegetation communities that are typically associated with groundwater is the Natural Communities Commonly Associated with Groundwater (NCCAG) dataset (DWR, 2018c). DWR has stated that use of the NCCAG dataset is not mandatory and does not represent DWR's determination of a GDE. Rather, NCCAG can provide a starting point for the identification of GDEs within a groundwater basin (DWR, 2018c).

The NCCAG dataset maps vegetation in the northwest part of SSJMUD. There are no known natural or surface water features that support shallow groundwater in SSJMUD. KCWA has not mapped shallow groundwater in SSJMUD. Therefore, further investigation may be warranted to understand the NCCAG dataset mapped in the district.

Below is a discussion of the NCCAG dataset. For reference, the NCCAG vegetation and wetlands data are presented in Figures 2-32 and 2-33, respectively. Distribution of mapped NCCAG vegetation occurs in the natural lowlands along Poso Creek.

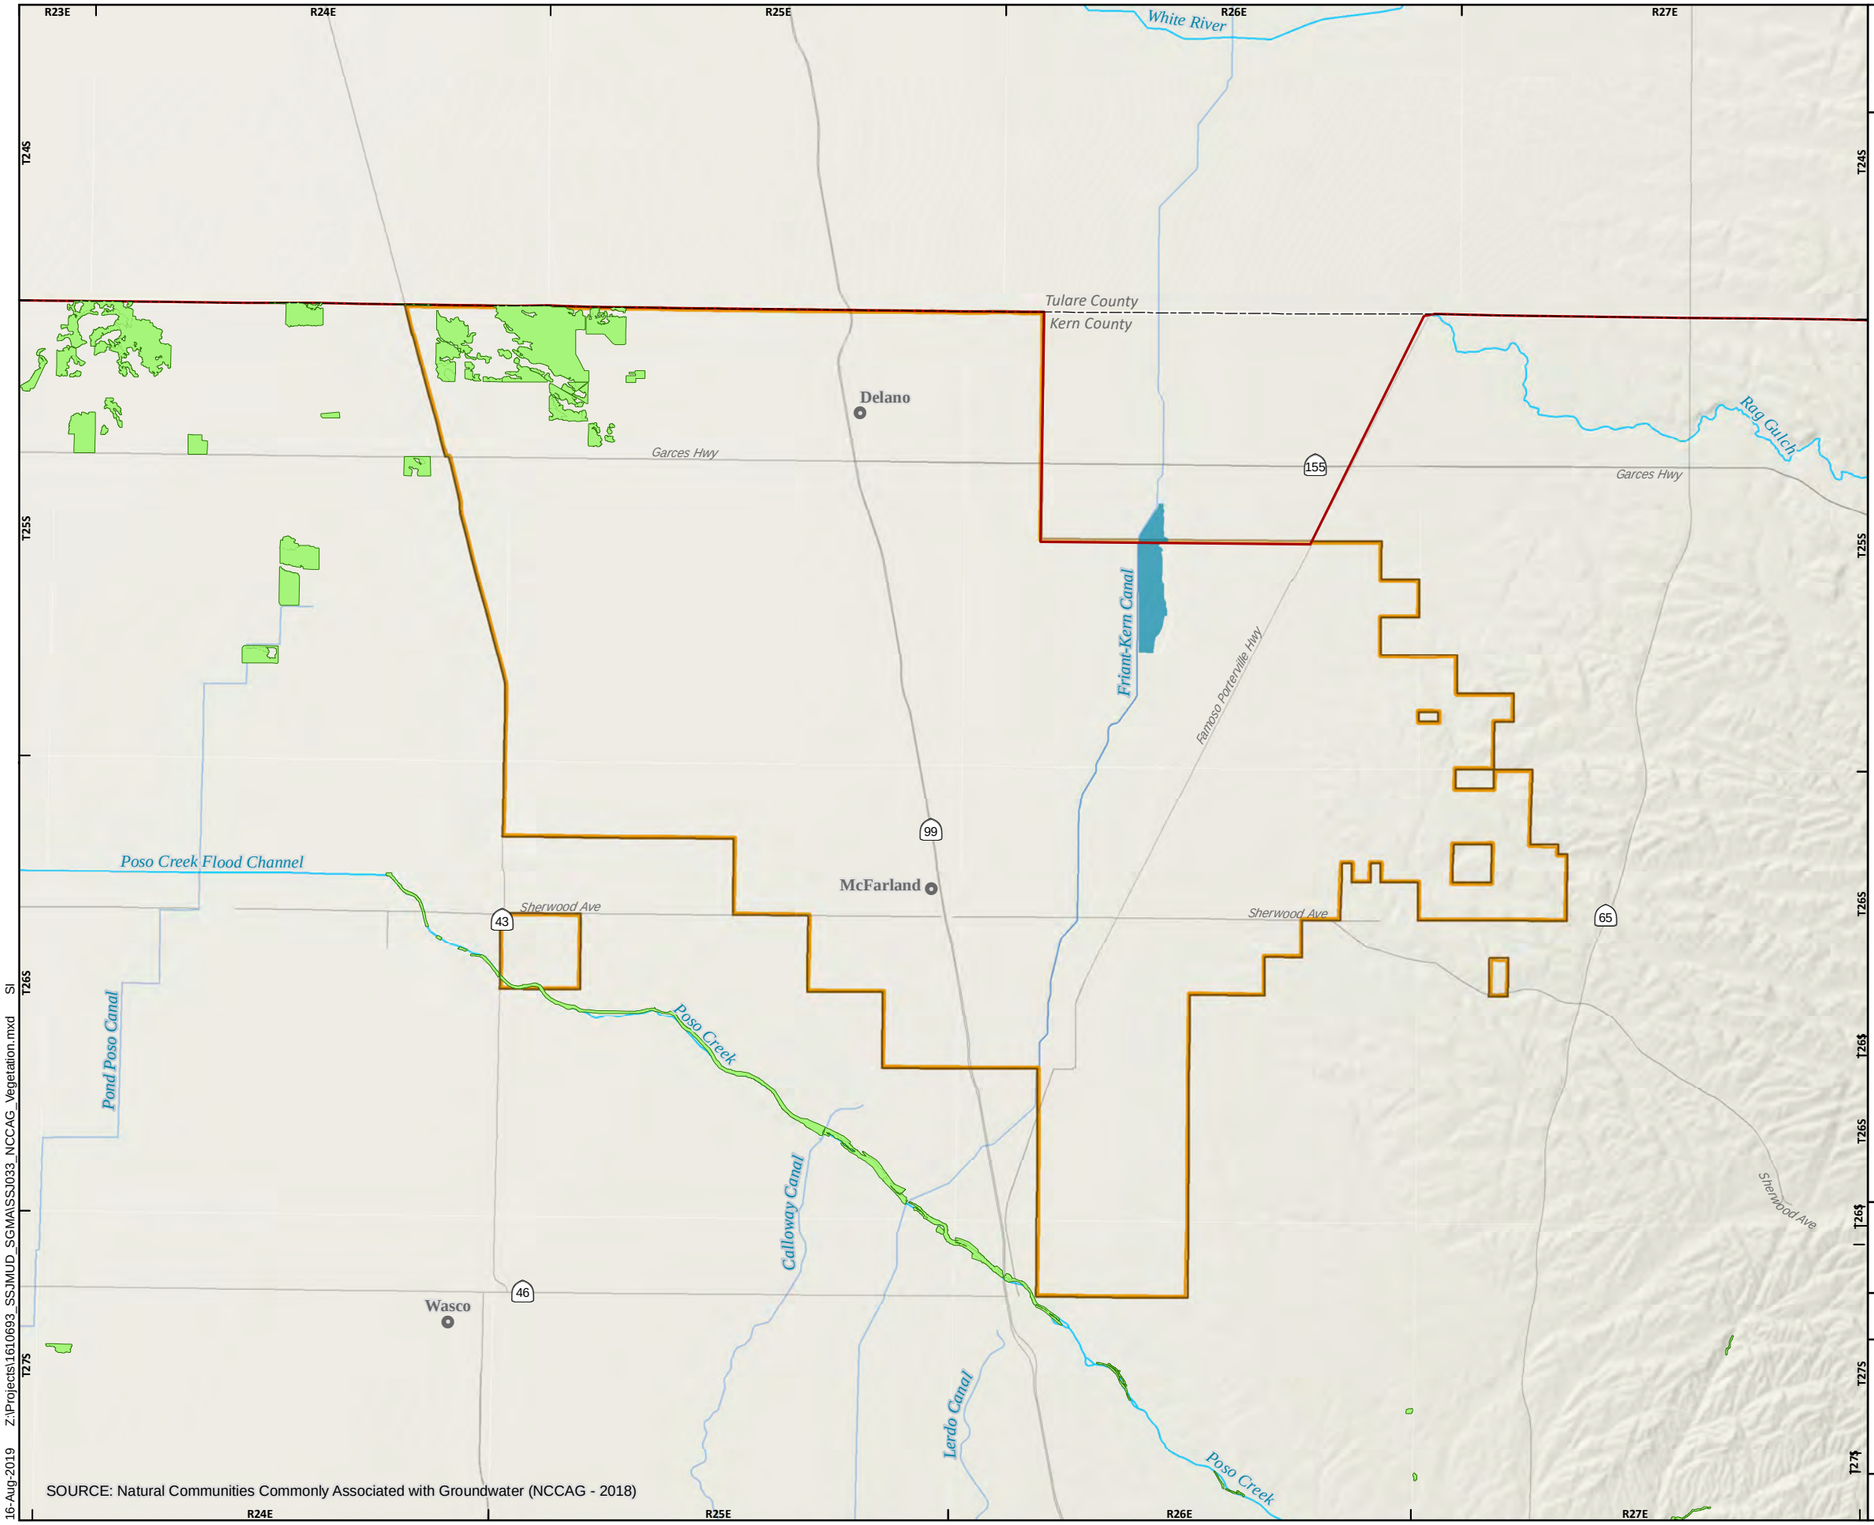
2.3.7.1 Review of NCCAG Dataset Components

The NCCAG dataset was compiled based on 48 layers of publicly available data sets developed by state or federal agencies that map vegetation, wetlands, springs, and seeps in California (DWR 2019). A technical working group with representatives from DWR, California Department of Fish and Wildlife (CDFW), and TNC reviewed the datasets compiled to assemble the NCCAG. This dataset attempts to extract mapped vegetation and wetland features that have indicators suggesting dependence on groundwater. The data presented in NCCAG display vegetation polygons that have indicators of GDEs based on published and/or field observations of phreatophytic vegetation characteristics in California, flooding frequency, or areas classified as perennial hydrologic features. A phreatophyte is defined as a "deep-rooted plant that obtains water that it needs from the phreatic zone (zone of saturation) or the capillary fringe above the phreatic zone" (TNC 2018). The dominance of phreatophytic plant species in a mapped vegetation type is a primary indicator of GDEs. A list of plant species considered to be phreatophytes based on review of peer-reviewed scientific literature on rooting depths, published lists of phreatophytes, expert field observations, and vegetation alliance descriptions is publicly available (Klausmeyer et al. 2018, TNC 2018).

While developing the NCCAG dataset of areas with indicators of GDEs, the technical working group attempted to exclude vegetation and wetland types and polygons that are less likely to be associated with groundwater (Klausmeyer et al. 2018). For example, riparian vegetation along perennial mountain streams is generally not in the NCCAG dataset, because although these communities contain species that can act as phreatophytes, vegetation at those sites is generally sustained by surface waters that are not locally interconnected with shallow groundwater aquifers. The working group also attempted to remove any polygons that are not likely to be GDEs where they occurred in areas where they are more likely supported by alternate artificial water sources (e.g. local seepage from agricultural irrigation canals), or where appropriate available data indicated the shallow groundwater depth is located well below the rooting zone (Klausmeyer et al. 2018).

The Vegetation Classification and Mapping Program (VegCAMP) and National Wetland Inventory (NWI) are the vegetation mapping datasets that cover the water districts of interest and a discussion of each dataset follows below.

The VegCAMP dataset is the primary vegetation base layer used for the NCCAG dataset. Fish and Game code Section 1940 directed CDFW to develop and maintain a standardized vegetation dataset for the state of California, which conforms to the U.S. National Vegetation Classification Standards, and to produce a hierarchical classification of vegetation types. VegCAMP is the product of the Survey of California Vegetation (SCV). Vegetation polygon attributes are assigned to the alliance taxon level in the hierarchical classification system, when possible. An



"alliance" is a lower taxonomic rank that is based on plant species composition as compared to higher taxon levels that more broadly define the life form (tree, shrub, or herbaceous) and ecological drivers (e.g., climate, regionalism). The alliance-level taxon is a group of diagnostic plant species that repeat across a landscape reflecting regional to sub-regional climate, substrate, hydrology, moisture/nutrient factors, and disturbance regimes. The VegCAMP data also includes polygons of group-level, which are higher level and less specific than alliance level descriptions. Alliances are defined and described in detail by A Manual of California Vegetation (Sawyer et al. 2009).

The VegCAMP vegetation maps are geospatially registered polygons that are digitized on base imagery that meets or exceeds the National Agricultural Imagery Program (NAIP) resolution standards of 1-meter ground sample distance. VegCAMP is considered the highest resolution data source for California vegetation mapping and is therefore used as the basis of the NCCAG dataset. The minimum map unit (MMU) of VegCAMP data is typically 1–2 acres, with a maximum of 10 acres; wetlands identified in VegCAMP have an MMU of 0.25 acre with the minimum polygon width of at least 10 meters (DWR 2018c). Accuracy Assessments are conducted in-field as a form of quality control, to correct any specific and systematic errors prior to map finalization and release. SCV requires every map to be verified and to meet a standard of at least 80 percent overall accuracy between map units and spot checks, and the maps typically exceed this standard. Data gaps and overlaps are ideally eliminated through geodatabase quality checking of each map (CDFW 2018).

The National Wetland Inventory (NWI) created by the U.S. Fish and Wildlife Service (USFWS) is a mapping tool that identifies wetlands by type, based on the Cowardin classification (Cowardin et al. 1979), and distribution throughout the United States. NWI relies on trained image analysts to digitize wetland habitats, which are identified based on vegetation, visible hydrology and geography. Mapping is completed at 1:24,000 scale (1-inch equals 2000 feet). A margin of error is inherent in the identification of wetlands on imagery; thus, detailed on-the-ground inspection of any site may result in revision of the wetland boundaries or classification established through image analysis (USFWS 2018). In the continental United States, NWI uses a target MMU of 0.5 acre (USFWS 2015). Certain types of "farmed wetlands" and submerged aquatic vegetation found in intertidal and subtidal zones of estuaries are specifically excluded from the NWI dataset.

2.3.7.2 Conclusions

As state in the introduction of this section, there are no known GDEs in SSJMUD. Although NCCAG data are mapped within the Poso Creek channel and in the northwest corner of the District, persistent shallow groundwater has not been documented in either location. Poso Creek is ephemeral and rarely flows west of SR-99. Based on the data gaps discussed in the above description, a field survey may be warranted to identify some of the NCCAG species listed in the Poso Creek area and in the northwestern portion of the District. In addition, field investigation of any potential shallow water table within the Poso Creek channel may be informative.

FIGURE 2-33

2.4 Management Areas within SSJMUD

This management area plan covers the jurisdiction of SSJMUD as shown in Figure 2-34. Management areas for the districts described in this management area plan are defined as follows:

2.4.1 *SSJMUD District Management Area*

The "District" management area consists of the land located within the boundaries of SSJMUD, including those undistricted "islands" that are entirely within SSJMUD and lands within the limits of the cities of Delano and McFarland. These areas are subject to the sustainable management criteria, projects, and management actions defined by SSJMUD in this plan.

2.4.2 *SSJMUD Undistricted Management Area*

The "Undistricted" management area consists of the land located adjacent to SSJMUD's boundaries which are to be covered for SGMA compliance with the District's management area plan. In 2019, Kern County withdrew from membership in the KGA, which resulted in undistricted lands of the Subbasin no longer being covered under the KGA's GSP. In order to give landowners a method by which they could comply with SGMA, the Member Agencies of the KGA engaged with landowners to establish agreements by which the landowner would be covered by the sustainable management criteria, projects, and management actions of a district without annexation into that district. SSJMUD has entered into agreements with landowners who represent 320 acres of undistricted land.

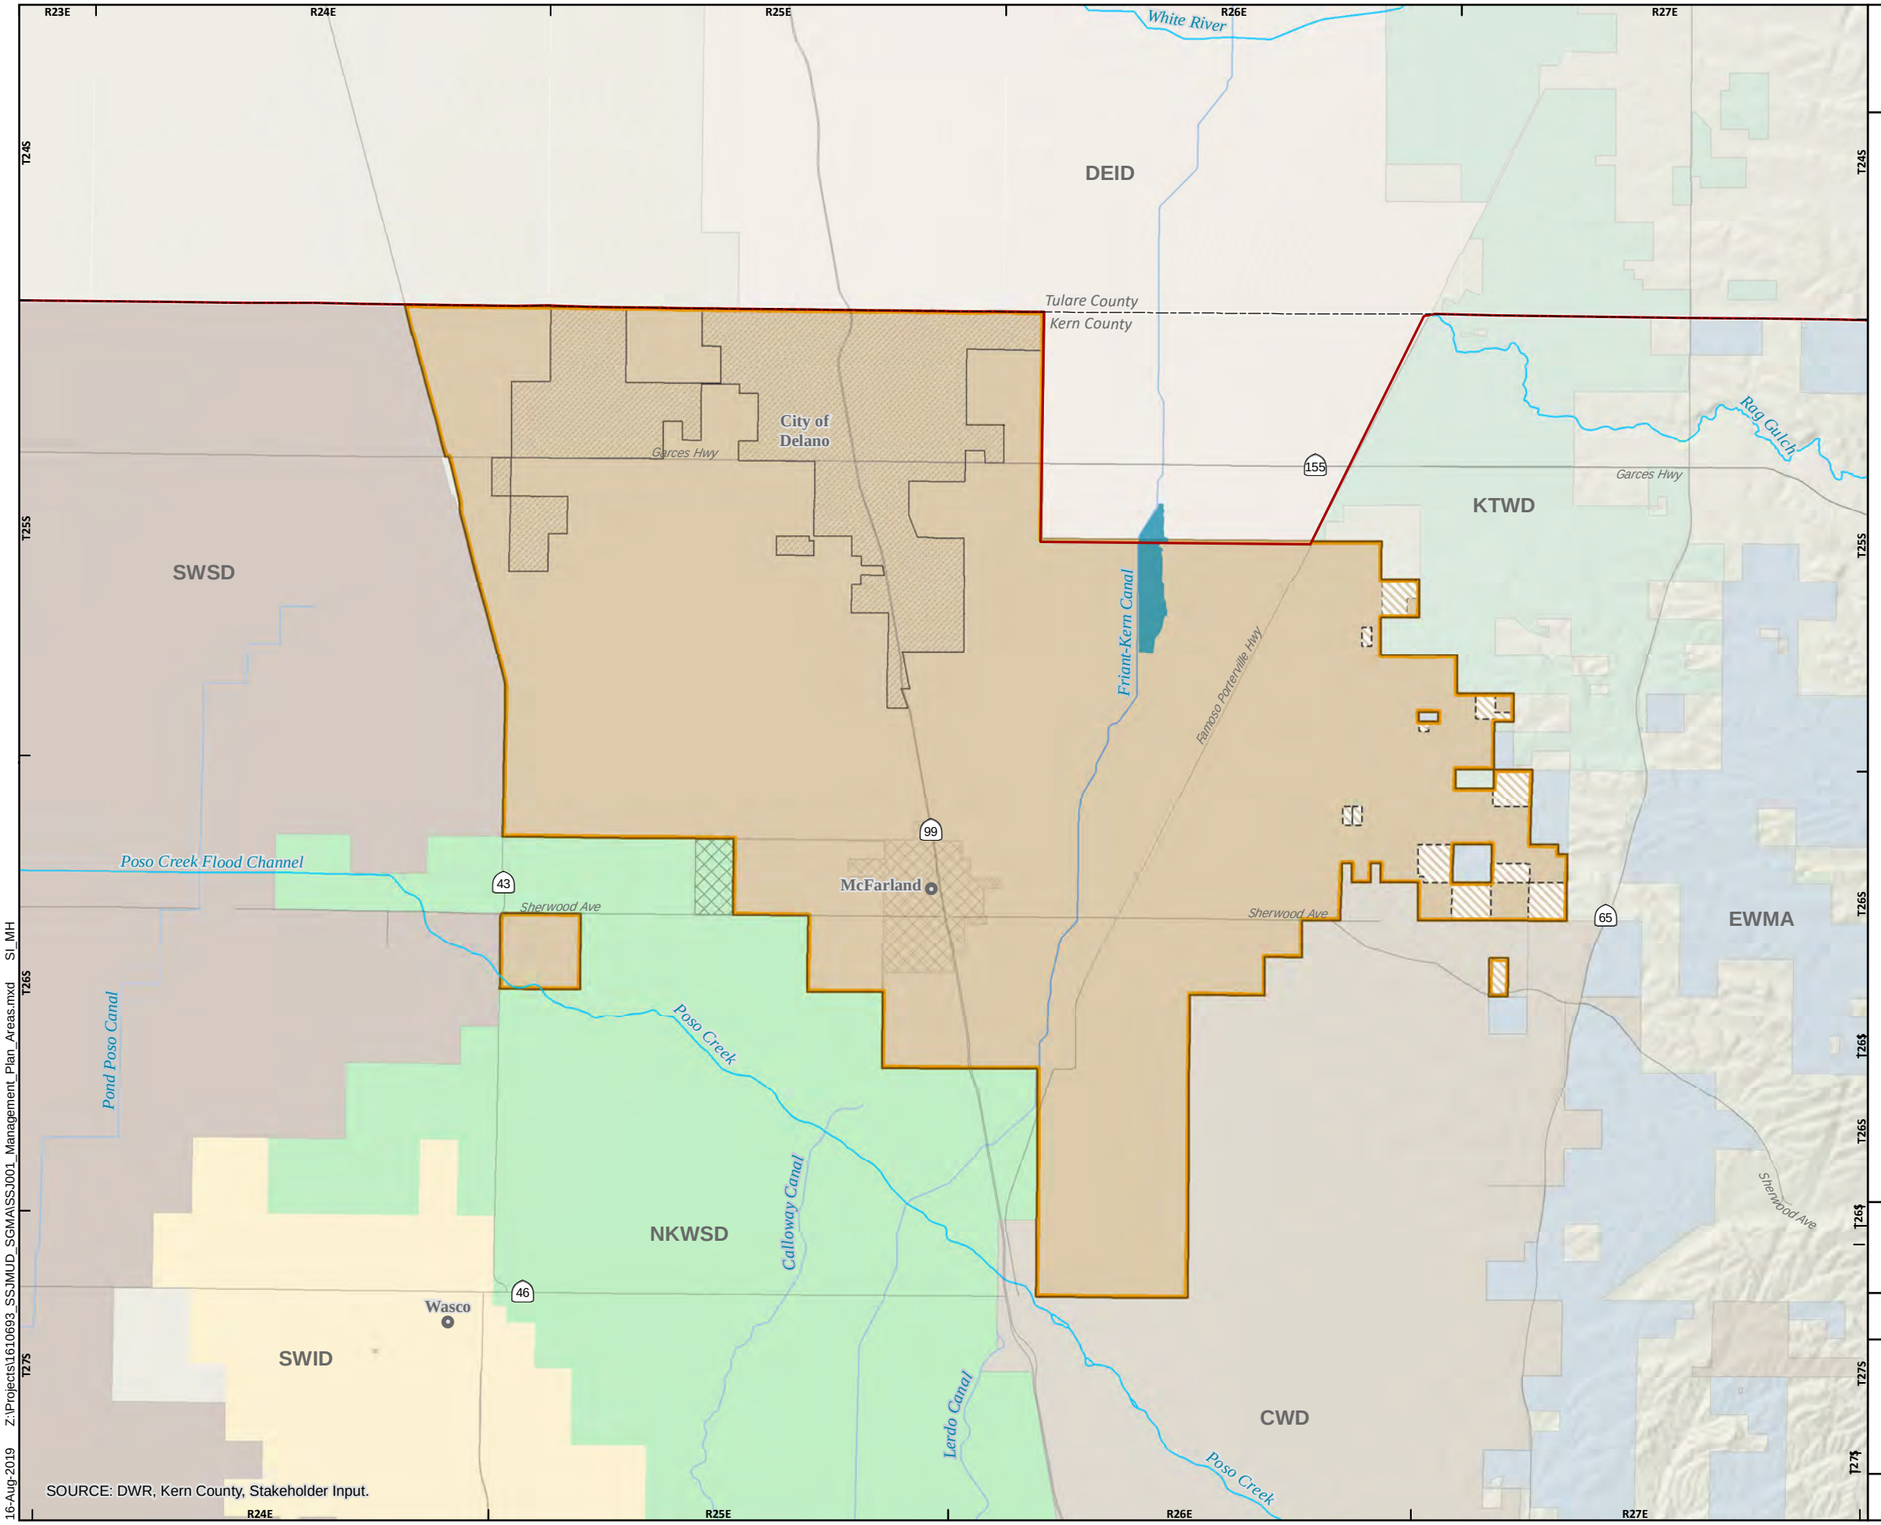
2.5 District Water Budget

All GSAs in the Kern County Subbasin coordinated and collaborated on the development of a groundwater model (Model) to evaluate historical, baseline and projected groundwater conditions. The GSAs entered into a Cost Share Agreement with the Kern River GSA who took the lead and contracted with Todd Groundwater to develop the Model on behalf of the Subbasin. The contract required that Todd Groundwater use the C2VSim model provided by DWR. Considerable effort and resources were expended to update the C2VSim model with local data to better represent Subbasin conditions. The process Todd Groundwater used to update C2VSim is more fully described in the Historical and Projected Future Water Budget Development (see Attachment H in Umbrella GSP). Basin-wide water budget results from the Model are provided in Attachment H and show the Subbasin has a total storage deficit of approximately 277,100 AFY over the baseline period.

The Subbasin's dynamic conjunctive use programs, water banking operations, and water transfers/exchanges made it necessary to coordinate a GSA level water accounting system (Checkbook) using Subbasin specific values for supply, demand and net results. The Model results reflect Subbasin-wide conditions and do not allocate water shortages/surpluses, nor do the results allocate the "ownership" of water. As a result, the GSAs, through a coordinated effort, developed the Checkbook that estimates current conditions for each GSA that are generally

consistent with the Model results under baseline condition. The Checkbook and Model budgets are based upon best available information, recognizing however, each estimate includes data gaps and has varying degrees of accuracy and/or reliability in the interest of developing a Subbasin coordinated approach.

To ensure the individual water budgets reflected actual conditions, the KGA members developed the Checkbook budget and coordinated water accounting methodology. The result of that effort indicates a current baseline shortage/deficit for KGA members of approximately 256,300 AFY. This reflects the difference between a total demand for KGA members of 1,939,400 AFY and a total supply of 1,683,100 AFY. Of the shortage/deficit of the KGA, SSJMUD's portion of the KGA deficit is 16,557 AFY, which represents a difference in demand of 149,835 AFY and a water supply of 133,278 AFY.



The water supplies available to each KGA member from the Pioneer and Kern Water Bank banking programs are incorporated into the listed total available supplies in the KGA's Checkbook water budget. Both programs only store surface supplies, and do not have consumptive demands that contribute to the shortages identified in the Checkbook water budget. For more detail on these banking programs, please see their respective management area plans.

As is mentioned above, each estimate includes data gaps and has varying degrees of accuracy and/or reliability. The Checkbook water budget is complimentary to the Model and reflects the allocation of water supply benefits and obligations independent of geographic constraints within the Subbasin only for the purposes of developing this management area plan and the KGA's GSP. As stated previously in this management area plan, this is not an allocation of water rights. This was important to recognize and ensure the coordination of the various groundwater banking projects and water management programs amongst the various GSA's within the groundwater basin.

2.5.1 *Planning Budgets*

In addition to the KGA Checkbook water budget, SSJMUD has developed a district-level historical water budget, as well as current and future projection water budgets for their use in implementing SGMA to meet the Sustainability Goal of the Subbasin. The following section describes, in detail, the estimation of the planning water budgets for the SSJMUD management area. These water budgets were developed to quantify the inflows and outflows within the District, based on water supply availability, water demand, and land use information for a historical, current, and future time periods.

Historical water budget was estimated for the time period between water year 1993 and 2015, consistent with the hydrologic base period selected for the Subbasin Model. This time period was selected as it includes varying conditions of water years affected by changes in water supply availability and changes to water demand. This period was also selected as reliable data is available for the district and includes enough variability to quantify and evaluate district responses.

This Page Left Blank Intentionally

The current conditions water budget uses the historical period averages as a baseline and adds the projects and management actions that have been implemented in the years from 2015 to 2019.The projected water budget uses a representative period of 1970 to 2009 to project the SSJMUD CVP contract supply to determine the average long-term hydrology. Other supply and demand components are determined from components of the historical budget.

Sections 2.5.1 and 2.5.2 outline data for the historical water budget for 1993 to 2015, relying on the inflow into the districts and the outflow out of the districts to determine the representative change in storage. The data is summarized in yearly format with approximations made to some data sources based on best judgement.

2.5.2 *Water Budget Components*

The following section describes in detail various components of the water budget, methodology and data sources used in estimation of these water budget components.

2.5.2.1 Demand

Total demand for the District's management area is estimated as the sum of -

- Evapotranspiration (ET) of irrigated acreage,
- surface water outflow, and
- subsurface outflow.

ET was estimated for the total irrigated acres within the District. Urban areas were excluded in this demand estimation as urban water demand was included in the cities' pumping data in Section 2.5.2.11. Land use outside of the irrigated acres and urban areas rely on water supplies other than groundwater pumping and were therefore not considered in this demand estimation.

2.5.2.2 Evapotranspiration

Irrigated acres were estimated based on the 2014 land use data developed by Land IQ, on behalf of DWR. SSJMUD's management areas comprise of approximately 65,000 acres. Land use data collected by SSJMUD indicated that irrigated acreage remained relatively constant over the years ranging from 51,639 acres in 1993 to 42,572 acres in 2016. The irrigated acreage estimated by Land IQ in 2014 was estimated as 44,787 acres, which falls in this range. This land use distribution for SSJMUD's jurisdictional area is shown in Figure 2-22.

ET data is used to estimate the districts historical groundwater pumping requirements. ET for agricultural lands was estimated based on the Irrigation Training and Research Center (ITRC) ET data from 1993 to 2015 based on the corresponding Land IQ irrigated land use data. ITRC estimates ET data based on satellite imagery. As explained previously, irrigated acreage remained relatively constant over the years. However, ET data varied due to the changing crop patterns.

Table 2-13 shows the estimated ET for SSJMUD based on the corresponding irrigated acreages from 1993 to 2015. SSJMUD's ET varied from 101.2 thousand acre-feet (TAF) in 2015 to 141.5 TAF in 2013 with an average ET of 121.6 TAF.

Table 2-13: SSJMUD Historical ET Data, in TAF

Year	Total ET (ITRC)
1993	124.5
1994	130.2
1995	127.0
1996	140.6
1997	122.3
1998	116.4
1999	108.5
2000	114.9
2001	128.4
2002	126.5
2003	124.5
2004	137.8
2005	113.7
2006	109.3
2007	121.2
2008	117.5
2009	117.4
2010	111.8
2011	113.7
2012	127.6
2013	141.5
2014	119.5
2015	101.2
Minimum	**101.2**
Maximum	**141.5**
Average 1993-2015:	**121.6**

ET for non-agricultural lands such as riparian vegetation is not included in this estimation as it was assumed that the precipitation over the non-agricultural land will result in a net zero demand. ET in urban areas is also excluded, as it is accounted for in the cities' pumpage estimation.

2.5.2.3 Surface Outflows

In addition to participating in transfer and exchange programs, SSJMUD also periodically participates in banking services and return water to other agencies. In the period of 1993 to 2015, SSJMUD participated in such a groundwater bank with KTWD. A summary of SSJMUD's historical outflows to KTWD is shown in Table 2-14. These outflows range from zero to a maximum of 2.17 TAF in 2000. The average outflow to KTWD was 0.5 TAF over the hydrologic base period of 1993 to 2015.

The deliveries made to districts in the Subbasin participating in the transfer and exchange programs, over a long period of time, is expected to net zero change in groundwater storage. This is reflected in the surface outflow components in the projected future water budget for SSJMUD.

2.5.2.4 Subsurface Outflows

At this time, there is insufficient data to determine the exact volume of subsurface outflow from SSJMUD. Therefore, for the purposes of this management area plan, it is assumed that subsurface outflows into the Kern County Subbasin net zero change in groundwater storage. This has been identified as a data gap and will be addressed in future plan updates.

Table 2-14: SSJMUD Surface Outflows, in AF

Year	Total Outflow from District
1993	0
1994	0
1995	0
1996	0
1997	0
1998	0
1999	2,081
2000	2,168
2001	40
2002	0
2003	1,898
2004	0
2005	1,969
2006	1,541
2007	188
2008	0
2009	1,879
2010	0
2011	0
2012	0
2013	0
2014	0
2015	0
Minimum	**0**
Maximum	**2,168**
Average 1993-2015:	**511**

2.5.2.5 Sustainable Yield

The sustainable yield is the expected amount of water each district is allowed to pump from the Subbasin without seeing significant impacts or undesirable results. The sustainable yield can be used as a way for each district to manage its performance in reaching groundwater sustainability. While the thresholds, objectives, and milestones of each sustainability indicator are the metric by which the Subbasin will be evaluated, the districts may use the sustainable yield as one way to ensure that they maintain their objectives as described in this plan.

There are two components to sustainable yield: native yield and surface water supply. Native yield is the sum of subsurface flow, runoff, and precipitation. For the purposes of this management area plan, subsurface flow and runoff are assumed to be between 0.15 AF per acre and 0.30 AF per acre in the Subbasin. With the implementation of SGMA and further refinement of the Kern County Subbasin Model, this range is subject to change in future management area plan updates. An assumed precipitation volume of 0.42 AF/acre for irrigated lands is also a component of sustainable yield for the Subbasin. The summation of these components provides a native yield range of 0.57 AF per acre to 0.72 AF per acre for irrigated lands. Because precipitation is only accounted for over irrigated acreage, the native yield assigned to other land uses for the purposes of this plan ranges from 0.15 AF per acre to 0.30 AF per acre. The sustainable yield for land with access to surface water supply is the native yield, plus whatever surface water is available.

2.5.2.6 Water Supply

SSJMUD primarily receives water through supplemental water sources. Native sources such as streambed infiltration are considered minimal. Supplemental water sources for SSJMUD include water received from the CVP contract and surplus water, when it is available.

Native sources are available from precipitation, subsurface flow, and runoff. Precipitation over non-agricultural lands is estimated as a net zero change in groundwater storage as it was assumed that the ET for these non-agricultural lands balances out the precipitation. As a result, only precipitation over agricultural lands is used to estimate water supply into the District. For the purposes of developing these water budget components for SGMA planning, an assumed precipitation value of 0.42 AF per irrigated acre is used.

Subsurface flow and runoff are components of native yield that are estimated to be in the range of 0.15 AF per acre to 0.30 AF per acre and is attributed to all lands within the Subbasin. The summary of SSJMUD's water supply is presented in Table 2-15.

2.5.2.7 CVP Water

The CVP is the primary source of surface water available to SSJMUD and provides water via the Friant-Kern Canal from Millerton Lake (Friant Reservoir). SSJMUD, through its contract with the USBR, receives 97 TAF of Class 1 and 45 TAF of Class 2 water per year. This water is used to supplement ET demand. In addition, the District receives recaptured Class 1 and Class 2, 16B, and other water when available from the CVP. The non-Class 1 and non-Class 2 water are typically "surplus water" made available during periods of forecasted spill on the Friant Dam. On average, SSJMUD receives 96.0 TAF of deliveries via the Friant-Kern Canal (1993-2015) as shown in Table 2-15.

2.5.2.8 Precipitation

Precipitation is a source of inflow into the District. However, precipitation is only considered for the irrigated acreage. Areas outside irrigated acreage such as native vegetation is assumed to net

zero in the water budget analysis as it was assumed that the demand is met by the precipitation. Similarly, rural areas were also estimated to net zero in the water budget and were estimated to be of minimal use.

Through the coordination with all the member agencies of KGA, it was estimated that the average precipitation for the area is 0.42 AF per acre per year. This value is applied as an annual value to the irrigated acreage and is observed in Table 2-15.

2.5.2.9 Inflow to the Groundwater System

For the purposes of developing the water budgets for this plan, an assumed zero net change in groundwater storage is used. This assumption is made in the absence of reliable data. This has been identified as a data gap and will be addressed in subsequent plan updates.

2.5.2.10 Agricultural Pumping

Groundwater pumping in the District is estimated as the volume of water required to supplement surface water supplies to cover the total ET for the irrigated lands. Agricultural pumping is estimated as:

$$AP = CD - SWc - Pr$$

where: AP = Agricultural Pumping

CD = Agricultural Crop Demand

SWc = Surface Water Crop Delivery

Pr = Total Precipitation

Total pumping is dependent on the amount of surface water available to the District which varies annually. During wet years, the District requires less pumping due to excess surface water imports; similarly, during dry years the District would require more pumping due to decreased surface water imports.

The volume of groundwater pumping (change in storage) within the SSJMUD from 1993 to 2015 are shown in Table 2-16. It was observed that SSJMUD has an average change in storage ranging from 2.5 TAF per year to 12.3 TAF per year of net surplus based on the 0.15 AF per acre to 0.30 AF per acre of native inflow range. The negative values in the change in storage columns represent the years in which the District had to pump groundwater in order to meet the ET demand of irrigated acreage.

Using the native inflow range over the period of 1993 to 2015, it is estimated that the largest volume that the District had to pump was 85.2 TAF in 2014. The largest surplus of water in the District over this same period, using the native yield range, is an estimated 50.5 TAF in 2011. While the District shows an average surplus condition, operational conditions during drought (as observed in the 2012 – 2015 period) severely limit the amount of surface water delivered into SSJMUD. As a result, the District had to rely heavily on groundwater to meet ET demand.

Table 2-15. Summary of SSJMUD Water Supply

Year	Friant-Kern Canal Deliveries[1]	Avg Rainfall[2]	Native Inflow (0.15 AF/acre)[3]	Native Inflow (0.30 AF/acre)[4]	Total Water Supply (0.15 AF/acre)[5]	Total Water Supply (0.30 AF/acre)[6]

2.5.2.11 Urban Pumping

City of Delano and City of McFarland do not have detailed urban pumping data available at this time for the entire hydrologic base period of 1993 to 2015. Groundwater pumping for the cities was estimated for 2005, 2010 and 2015 in the City of Delano's 2015 Urban Water Management Plan (UWMP) and in City of McFarland's 2015 General Plan Amendment Environmental Impact Report (EIR). This data does not include the demand from either of the prisons in SSJMUD's jurisdictional area as neither of the cities provide water to the prisons. The cities of Delano and McFarland have provided actual groundwater pumping volumes for use in the historical water budget for SSJMUD and to develop projected water budgets for this management area plan.

This combination of estimated and actual data was used to estimate the 2005, 2010 and 2015 urban pumping for SSJMUD. Table 2-17 provides a summary of City of Delano and City of McFarland urban pumping for 2005, 2010, and 2015, which represents the urban pumping for SSJMUD's management area. As shown in the below table, it was observed that urban pumping decreased in 2015 when compared to 2005 and 2010. This decrease in demand can be attributed to the historical drought the State of California experienced between 2011 and 2015 which enacted water restrictions on urban users and promoted conservation of urban water.

Table 2-16: SSJMUD Estimated Urban Pumpage, in TAF

City	2005	2010*	2015*
Delano	9.8	9.3	8.1
McFarland	1.6	1.7	1.8
Total	11.4	11.0	9.9

* Values in UWMP updated to actual Production values

2.5.2.12 Urban Recovery

The City of Delano has a wastewater treatment plant (WWTP) located in SSJMUD. The effluent from the WWTP is applied to agricultural land for beneficial reuse as irrigation water for permanent tree crops or pasture and hay crops in proximity to the WWTP. The historic wastewater flows are shown in Table 2-18. The effluent provided for beneficial reuse ranging from 3.7 TAF to 4.9 TAF, with an average of 4.5 TAF and an average recovery rate of 49.2%.

The McFarland WWTP is located outside of SSJMUD's jurisdictional area, in NKWSD. Like Delano's WWTP, the effluent from the McFarland WWTP is provided for beneficial reuse in irrigation of tree crops, pasture, or for groundwater recharge. At this time, the effluent from McFarland's WWTP is credited to NKWSD's water budget because it is used outside of SSJMUD.

Table 2-18: Delano WWTP Effluent Volumes, in TAF

	2005	2010 [1]	2015 [1]	Average
Groundwater Pumped	9.8	9.3	8.1	**9.0**
% of Supply	50%	52%	45%	**49.2%**
Recycled	4.9	4.8	3.7	**4.5**

(1) Values updated to reflect actual city effluent volumes.

2.5.3 *Historical Water Budget*

The historical water budget for SSJMUD's jurisdictional area, presented in Table 2-19, represents the average conditions for the hydrologic base period of 1993 to 2015. This water budget includes the average change in groundwater storage to do agricultural groundwater pumping, imported water supplies, and urban groundwater pumping. The coordinated subsurface inflow range of 0.15 AF per acre to 0.30 AF per acre and the assumed precipitation of 0.42 AF per irrigated acre is included in Table 2-19. Over this assumed range, the average change in groundwater storage for SSJMUD's jurisdictional area ranges from 4.0 TAF overdraft to 5.7 TAF surplus.

Table 2-19: SSJMUD Historical Water Budget (1993-2015), in TAF

This Page Left Blank Intentionally

2.5.4 *Current Water Budget*

While the historical base period used in the previous section is consistent with the base period selected for the Subbasin groundwater model, it does not capture the current conditions within the District. Since 2015, projects and management actions have been implemented as part of the District's response to the 2006-2016 drought. The following section will describe the water budget components used to determine the water budget for SSJMUD under current conditions. Some of the water budget components developed in the historical water budgets are used in the current water budget.

2.5.4.1 Agricultural Demand

The average historical ET data from 2013 to 2015 (described in the previous section) is used in the "current conditions" water budget for SSJMUD. This shortened historical period is most representative of the current land use and crop types in the District's management areas. As with the historical water budget, ET for undeveloped land is assumed to net zero change in groundwater storage because it is assumed that the ET is balanced with precipitation. ET from urban land is also not counted in the calculation of agricultural demand because those lands are supplied by the urban groundwater pumping. The average of 2013 through 2015 ET is 120.7 TAF and is used in Table 2-20.

2.5.4.2 Urban Demand

Groundwater pumping data from 2009 to present for the cities of Delano and McFarland, were used to develop the current conditions water budget, as it closely reflects the current urban water use. The City of Delano currently pumps 8.1 TAF to meet its urban demand; the City of McFarland pumps 1.8 TAF.

2.5.4.3 Water Supply

The average current water supply conditions are based on the long-term average supply for the CVP. As with the historical water budgets, exchanges and transfers between SSJMUD and other districts are expected to be a net zero change in groundwater storage for the districts. Water that is "banked" is recognized as the 10% of leave behind water, the remainder of the water is considered temporary storage which is not included in the water accounting for the current conditions.

To account for subsurface inflow and runoff, SSJMUD is using the KGA range of 0.15 AF per acre to 0.30 AF per acre for the gross acreage of its jurisdictional area. In addition to the subsurface inflow and runoff and precipitation, the effluent from the Delano WWTP averages 3.7 TAF for beneficial reuse under current conditions.

As shown in Table 2-20, SSJMUD received an average surplus flow of 2.8 TAF under current conditions. The district has also taken advantage of available surplus supply made available to

Friant contractors, bring this supply into the District or banking it in NKWSD for in-district delivery during dry periods. This has led to the current conditions water budget reflecting an average change in groundwater storage for SSJMUD that is net positive 6.3 TAF to 16.1 TAF over the assumed native inflow range of 0.15 AF per acre to 0.30 AF per acre. The addition of the City of Delano Spreading Grounds (in pilot phase), SSJMUD added 500 AFY of recharge capacity. This, in addition to the adoption of emergency drought measures by the cities, has led to the current conditions with projects in SSJMUD having a net positive change in groundwater storage of 6.9 TAF per year to 16.6 TAF per year over the assumed native inflow range.

Table 2-20: SSJMUD Current Water Budget, in TAF

2.5.5 *Projected Water Budget*

A projected water budget is prepared to estimate a baseline condition of supply, demand, and plan implementations. This projected water budget accounts for conditions for 2030 and 2070, using data on projected available supplies, projected changes in demand due to changes in land use. The projected water budget, consistent with the Subbasin groundwater model, also accounts for climate change factors that affect the water budget inflow and outflow components. Projects and management actions, which are described in Section 5, are not accounted for in this baseline projected water budget.

2.5.5.1 Agricultural Demand

As shown in Section 2.2.3.7, land use has not varied greatly historically, as a result it was assumed that the crop demand will remain similar in the future. However, overall irrigated acreage will decrease as urban land use increases within the cities' limits and spheres of influence. For the purposes of this projected water budget, crop types within the District are assumed to remain the same. Current water demands for agriculture are based off the most recent crop demand (2013 to 2015 ITRC based ET) and have been adjusted to account for the climate change factors used in the Subbasin groundwater model.

The projected agricultural demand for average 2030 conditions is estimated to be 119.2 TAF. The projected agricultural demand for average 2070 conditions is estimated to be 125.0 TAF. The increase in ET is due to the irrigated acreage and crop types in the District remaining the mostly unchanged from 2030 to 2070. Agricultural to urban land use conversion is anticipated to be relatively small from 2030 to 2070.

2.5.5.2 Urban Demand

Urban water demand is expected to increase as shown in Table 2-21. These volumes are subject to further reduction, due to mandatory indoor water use reductions (described further in Section 5 of this plan).

Table 2-21: SSJMUD Projected Urban Demand, in TAF

City	2015*	2030	2070
Delano	8.1	11.5	21.5
McFarland	1.8	2.3	3.6
Total	9.9	14.8	25.1

* Current Average Production values

2.5.5.3 Water Supply

WWTP Effluent

As identified in the historical and current water budgets, the City of Delano's WWTP is anticipated to continue providing effluent for beneficial reuse. The estimated volumes are based on the population growth projections in each city's respective General Plans. The Delano WWTP

is anticipated to provide 11.5 TAF of effluent for beneficial reuse in 2030; that volume is projected to increase to 21.5 TAF by 2070.

Table 2-22: Projected Effluent Volumes from Delano WWTP, in TAF

	2015 [1]	2030	2070
Groundwater Pumped	8.1	11.5	21.5
% of Supply	46%	43%	59%
Recycled	3.7	4.9	12.6

(1) Values updated to reflect actual city effluent volumes.

Precipitation

As described during the historical water budget estimation, precipitation for project water budget is also estimated as 0.42 AF per irrigated acre, with adjustments to account for the climate change factors used in the Subbasin groundwater model. These adjusted volumes are shown in Table 2-23.

CVP Water

Projected water supply from the CVP for SSJMUD is based on "Future Friant Supplies Model". This model estimated SSJMUD supplies from CVP based on Class 1, Class 2, Other, 16B, Recapture Class 1, and Recapture Class 2 categories. It is expected due to restriction, regulations, and climate change the Districts will receive a lower than historical amount of water from the CVP. City recycled water is expected to increase as shown in Table 2-23.

SSJMUD's other surface water supplies are assumed to net zero with the District demand over long term periods and are left out of the projected water budgets. SSJMUD, at its current baseline conditions, shows a positive storage in 2030 for the assumed native inflow range, adjusting for climate change factors used in the Subbasin groundwater model and accounting for reduction of irrigated acreage due to urban use conversion. At 0.15 AF per acre for 2030 conditions, SSJMUD has an estimated surplus of 400 AF. The District has an estimated surplus of 10.2 TAF for 2030 conditions at 0.30 AF per acre.

For 2070 conditions, SSJMUD shows a baseline of 8.6 TAF to 18.4 TAF net overdraft, when accounting for climate change factors used in the Subbasin groundwater model, CVP model data for Friant, and the cities' projected increase in urban demand. These volumes reflect a baseline condition which does not account for the proposed projects and management actions that are conceptual and yet to be implemented by the District.

The projects and management actions to be implemented to reach sustainability by 2040 are outlined in Section 5. The District will implement projects and management actions to reach sustainability and the projected impact of the projects and management actions are summarized in Section 5.

Table 2-23: SSJMUD Projected Baseline Water Budget for 2030 and 2070, in TAF

Data Type, Water Year and Hydrologic Condition (1)	Total Surface Inflow + (2)	Total Surface Outflow - (3)	Total Rainfall + (4)	Total ET (ITRC) - (5)	Δ Storage (Irrigated Lands) = (6)	City of Delano Demand - (7)	City of McFarland Demand - (8)	City of Delano Recycled Water + (9)	Native Inflow (0.15 AF/acre) + (10)	Native Inflow (0.30 AF/acre) + (11)	Δ Storage w/NY and City Data (0.15 AF/acre) = (12)	Δ Storage w/NY and City Data (0.30 AF/acre) = (13)
CVP Model Data Long-Term Average												
2015.c (Current)	104.8	-	18.8	120.7	**2.8**	8.1	1.8	3.7	9.8	19.5	**6.3**	**16.1**
2015.c (Current with Current Projects)	105.3	-	18.8	120.7	**3.4**	8.1	1.8	3.7	9.8	19.5	**6.9**	**16.6**
2030.c	100.0	-	18.8	119.2	**(0.4)**	11.5	2.3	4.9	9.8	19.5	**0.4**	**10.2**

2.6 Existing Monitoring Programs

The purpose of this section is to identify and discuss existing water resource monitoring programs as required under §354.8(c). This section specifically focuses on water level and groundwater quality monitoring within the District's boundaries.

2.6.1 *Existing Water Level Monitoring*

The umbrella level GSP describes existing water level monitoring networks at a generalized regional scale. These networks include the Kern Fan Monitoring Committee (KFMC), Kern County Water Agency (KCWA) groundwater monitoring, and water level data reported to CASGEM. These regional networks benefit data collection and inform SSJMUD on water level changes occurring in the Subbasin. The umbrella level GSP provides details on the KFMC, KCWA, CASGEM networks, and an approximate number of wells and locations of monitoring throughout the Subbasin. This section focuses on groundwater monitoring at the local-level, and provides a brief description of the monitoring network, well types, well construction, participants in local monitoring, and figures with locations.

2.6.1.1 Groundwater Level Monitoring

SSJMUD uses water level monitoring data from supply wells in the district to report on local and regional groundwater level conditions. Historically, water levels in supply wells have been measured twice a year, in both the "spring" and "fall", with the timing of these measurements intended to coincide with the annual water level high and low, respectively.

The district uses 66 supply wells for monitoring purposes. These locations of these wells are shown on Figure 1 of Appendix J. The district coordinates with the private well landowners for well access.

The wells are classified as interim monitoring wells for SGMA purposes because they are actively used as water supply wells for domestic and agricultural use. As such, there are limitations on the ability to collect data when they are in operation, the wells are not designed for monitoring, and well construction data are limited.

In the future, improvements to the District's infrastructure will likely include completion of dedicated monitoring wells to replace interim wells in the monitoring network. The locations of these wells are to be determined as part of the development of the District's management area plan.

2.6.1.2 Semitropic Water Storage District Water Banking Project Monitoring Committee

In addition to local monitoring, SSJMUD also participated in the monitoring committee for the Semitropic Water Storage District Water Banking Project. The Semitropic Water Banking Monitoring Committee is made up of Semitropic Water Storage District, Southern San Joaquin Municipal Utility District, Cawelo Water District, Shafter-Wasco Irrigation District, North Kern

Water Storage District, Rosedale-Rio Bravo Water Storage District, and Buena Vista Water Storage District, with KCWA and Department of Water Resources working alongside the monitoring committee. The committee submits biennial monitoring reports which first began in 1995 and have continued to the present. The reports include groundwater elevation maps, discussion of groundwater flow trends, groundwater quality, land subsidence, and time series data on hydrographs. A summary is presented in Table 2-24 below.

Table 2-24: Summary of Monitoring Committee

Monitoring Network	Number of Wells Monitored	Date Range	Source
SWSD Water Banking Monitoring Committee	29 SWSD monitoring wells ~ 65 supply wells SWSD, ~53 wells NKWSD, ~8 wells in BVWSD, ~ 11 wells in SWID, a few wells RRBWSD, and a few in SSJMUD	1995 to present	Biennial Groundwater Monitoring Report for the Semitropic Water Storage District Water Banking Project.

Locations of wells in the monitoring network are included in the figure in Appendix K.

The benefit of the monitoring committee is in coordination of water level data collection and reporting, which provides more understanding of water levels at the boundaries between SSJMUD and neighboring districts. Data that are a result of this coordination, including groundwater contour maps, hydrographs, and subsidence data, are presented in the Groundwater Conditions section of this report.

Many of the wells in the committee's monitoring network are included in the future monitoring network for this Groundwater Sustainability Plan.

2.6.2 *Existing Land Subsidence Monitoring*

The umbrella level GSP describes existing land subsidence monitoring networks at a generalized regional scale. These networks include Borehole Extensometers, Continuous GPS (CGPS), Leveling Surveys, and Remote Sensing. These regional networks benefit data collection and inform SWSD on land subsidence changes occurring in the Subbasin. The KGA GSP and the Groundwater Conditions section of this report provide details on these networks and status of data usability and collection. This section focuses on land subsidence monitoring at the local-level. Details on data availability and locations are provided below.

2.6.2.1 Local Land Subsidence Monitoring

As a part of the Semitropic Water Banking Monitoring Committee, land subsidence has been monitored and data reported in the biennial reports prepared by Schmidt and Associates. The monitoring network includes SWSD's borehole extensometer, as well as nearby continuous GPS points P545, P563, and P564 (Table 2-18). In addition, P565 near the Delano Airport is also monitored through UNAVCO and Scripps Orbit and Permanent Array Center (SOPAC) (Table 2-18). All of these GPS stations are maintained, and data are processed and reported, by affiliates of UNAVCO (https://www.unavco.org/instrumentation/networks/status/pbo) and SOPAC (http://sopac-csrc.ucsd.edu/index.php/sopac/). A location map of the existing land subsidence monitoring network is included in Appendix K.

Figure 2-35: Monument Survey by GPS Methods

Details including data for the CGPS points and extensometer, and benefits and frequency of the data, are further discussed in the Groundwater Conditions of this report. In general, CGPS points record daily to sub-daily frequency, while the extensometer is currently set up for manual measurements that require periodic visits to record data values. While CGPS points record near continuous data, their limitations are in that they measure land surface deformation referenced to a datum but cannot measure discrete intervals in the subsurface. On the other hand, the borehole extensometer can measure a discrete interval from the bottom of the extensometer to ground surface, thus providing a more accurate approximation of compaction in the intervals subject to groundwater pumping.

Details of the data collected from these monuments is included in the Groundwater Conditions section of this report.

2.6.2.2 USBR Friant-Kern Canal

Recently USBR and Friant Water Authority have worked together to collect elevation survey data along the Friant-Kern Canal from Tulare County to Kern County.

Surveys were taken at construction benchmark points that were measured during construction in the 1940s and 1950s. SSJMUD is coordinating with USBR to consider future monitoring at these points along the canal within the district. These points are listed as mile postings along the canal (Table 2-18).

2.6.2.3 Remote Sensing Land Subsidence Monitoring

In addition to CGPS and level surveying along infrastructure such as the Friant-Kern Canal, NASA and DWR have collected remote sensing data (INSAR and UAVSAR) on a regional scale to better understand the lateral and temporal extent of subsidence within the study area. The

methodology and approach for collecting and processing the data has varied over the last decade as refinements have been made. NASA and DWR are working together to field calibrate these remote sensing data with CGPS points to better understand the quantitative estimates of land subsidence that have been reported.

The existing monitoring data are available for some date ranges and therefore are discussed further in the Groundwater Conditions of this report. In addition, the umbrella level GSP also provides details on INSAR and UAVSAR reporting and availability. As remote sensing data continue to be available, it will be used for the monitoring network of this management area plan.

2.6.2.4 Summary Land Subsidence Monitoring

Table 2-25 below shows the current available land subsidence monitoring for the study area.

Table 2-25: Summary of Land Subsidence Monitoring in Study Area

Type	Stations	Range of Available Data	Source
Continuous GPS Stations	P544, P545, P563, P564, P565	Varies. 2000 to present 2005 to present	UNAVCO PBS www.unavco.org Access data from: Instrumentation > Network Monitoring > Plate Boundary Observatory (PBO).
InSAR / UAVSAR	Remote Satellite Imagery	Recent. Range of freely accessible data: 2007 to 2011 2014 to present	Areal extent varies depending on dataset. Not always extensive across the Subbasin. Post-processed data available from (Farr, et. al., 2016), JPL, and USGS.
Survey Monuments	MP-116.94, MP-120, MP-124, MP-127,	1959-2017, 2017-present	USBR, Friant-Kern Canal. (Coverage: SSJMUD and Tulare).

2.6.3 *Existing Groundwater Quality Monitoring*

SSJMUD does not directly monitor groundwater quality in its management area. However, it uses the data collected by the Public Water systems (PWS) within its District boundary to monitor the groundwater quality. A summary of each of the Districts' local and regional efforts programs are discussed in this section.

Groundwater quality in the District is currently monitored by a network of domestic wells. Table 2-26 summarizes the types of monitoring program implemented within the District.

Table 2-26: Types of Monitoring Program Implemented within the District

Well Type	Number of Wells	Monitoring Program	
		AB 3030	Title 22
Public Water system Wells	24		X

The monitoring programs previously described are implemented through sampling a combination of the District's network of wells. This network is described in detail below.

2.6.3.1 SSJMUD's Water Quality Monitoring Program

As discussed earlier, SSJMUD does not directly monitor groundwater quality in its management area. However, it uses the data collected by the municipalities within its District boundary to monitor the groundwater quality. The public water systems within SSJMUD are included in Table 2-27 below.

2.6.3.2 Kern County Subbasin Water Quality Monitoring Efforts

SSJMUD, with the objective of identifying and implementing specific programs as needed to reflect changing conditions in the basin, established a Groundwater Monitoring Committee that includes Semitropic W.S.D (as the lead agency), and five other neighboring water districts. The KCWA and DWR are interested parties and periodically participate in the Committee activities. One of the committee's key objectives is to control degradation of groundwater quality and enhance quality where practicable. Since its inception in 1994, this committee has been preparing a biennial monitoring report that provides a comprehensive study of the underlying groundwater with the objective of identifying and implementing specific programs as needed to reflect changing conditions in the basin. The biennial report characterizes the groundwater quality based on the collected data from Semitropic's monitoring network, and the five neighboring water districts.

Additionally, the District is an active member of multiple regional groundwater quality monitoring programs. These programs are briefly described below. Groundwater quality data from these programs will be used by the District for SGMA monitoring purposes.

2.6.3.3 Irrigated Lands Regulatory Program

The Irrigated Lands Regulatory Program (ILRP) was initiated in 2003 with a focus on protecting surface waters; groundwater regulations were added in 2012. The Kern River Watershed Coalition Authority (KRWCA) implements the ILRP program in the Subbasin. Data collected and reported as a part of ILRP are provided to the SWRCB and are available in the GeoTracker database for download and use. The KRWCA's primary group is made up of 10-member agencies representing approximately 1.5M acres of irrigated land, out of which 4% of the irrigated acreage is under the district's jurisdiction.

2.6.3.4 California Drinking Water Information System Database (SDWIS)

Routine water quality monitoring data is also available from the eight Public Water Systems (PWS) within SSJMUD boundaries. These systems are required to routinely sample for Title 22 regulated constituents. These water systems were identified through the Groundwater Ambient Monitoring and Assessment (GAMA) database. Water quality data is available through SDWIS. This program provides data for an additional 12 wells. Table 2-27 summarizes the public water systems identified within SSJMUD boundaries.

Table 2-17: Public Water Systems within SSJMUD

Water System Number	Water System Name	District	Type	# Connections	Population Served	Service Area	# Wells
CA1500518	Agbayani Village Water System	SSJMUD	C	5	NT=12; R=26	Residential	1 well
CA5400810	Akal Travel Plaza	SSJMUD	NC	3	200	Restaurant	1 Well

*C = Community water system
NTNC = Nontransient non-community water system
TNC = Transient non-community water system
NT = Nontransient
T = Transient
R = Residential

2.7 Existing Water Resource Programs

This section identifies and discusses current water resources programs the District participates in. Expanding off Section 1.4.3, this section provides an in-depth overview of each program and District involvement.

2.7.1 *Management Plans*

The State of California has pre-SGMA programs for the management of groundwater supply and quality. These programs are managed at various levels of government by existing public agencies, either individually or collaboratively with neighboring agencies within the same groundwater basin. The following section provides an overview of these programs and the elements addressed in each.

2.7.1.1 Groundwater Management Plans

In 1992, the State of California passed the Groundwater Management Act (AB 3030). This legislation provided guidelines for the agencies and districts to provide planned and coordinated monitoring, operation, and administration of groundwater basins with the goal of long-term sustainability. There are several types of GMPs.

Pre-SB 1938 Plans:

These plans, typically adopted before 2002, could be prepared by a local agency in a Bulletin 118-desginated basin on a voluntary basis. The voluntary components of these plans include:

- The control of saline water intrusion.
- Identification and management of wellhead protection areas and recharge areas.
- Regulation of the migration of contaminated groundwater.
- The administration of a well abandonment and well destruction program.
- Mitigation of conditions of overdraft.
- Replenishment of groundwater extracted by water producers.
- Monitoring of groundwater levels and storage.
- Facilitating conjunctive use operations.
- Identification of well construction policies.
- The construction and operation by the local agency of groundwater contamination cleanup, recharge, storage, conservation, water recycling, and extraction projects.
- The development of relationships with state and federal regulatory agencies.
- The review of land use plans and coordination with land use planning agencies to assess activities which create a reasonable risk of groundwater contamination.

SB 1938 Plans:

These plans were generally adopted during or after 2002, incorporating the elements of the Pre-SB 1938 Plans. With the passage of SB 1938, the following components were required as part of any GMP:

- Basin Management Objectives: The GMP shall include Basin Management Objectives relating to the monitoring and management of groundwater levels within the groundwater basin, groundwater quality degradation, inelastic land surface subsidence, and changes in surface flow and surface water quality that directly affect groundwater levels or quality or are caused by groundwater pumping in the basin.
- Agency Cooperation: The local agency shall prepare a plan to involve other agencies that enables the local agency to work cooperatively with other public entities whose service area or boundary overlies the groundwater basin.
- Mapping: The local agency shall prepare a map that details the area of the groundwater basin, as defined in DWR's Bulletin 118, and the area of the local agency, that will be subject to the GMP, as well as the boundaries of other local agencies that overlie the basin in which the agency is developing a GMP.
- Monitoring Protocols: The local agency shall adopt monitoring protocols that are designed to detect changes in groundwater levels, groundwater quality, inelastic surface subsidence (in basins for which subsidence has been identified as a potential problem), and flow and quality of surface water that directly affect groundwater levels or quality or are caused by groundwater pumping in the basin.
- Located outside Bulletin 118 Groundwater Basins: Plans located outside DWR Bulletin 118 alluvial groundwater basins will incorporate the above components and shall use geologic and hydrologic principles appropriate to those areas.

AB 359 Plans:

When AB 359 was enacted in 2013, it required additional technical components related to groundwater recharge areas and modification to several of the existing GMP adoption procedures in place as part of SB 1938. The additional technical components are as follows:

- The groundwater projects to which these requirements apply include projects that are part of an integrated regional water management program or plan.
- Groundwater projects require a description of how recharge areas identified in the plan substantially contribute to the replenishment of the groundwater basin and a map identifying the recharge areas, as defined, for the groundwater basin to be included in a GMP for purposes of the state funding requirements.
- Require the local agency to provide the map of the recharge areas to local planning agencies and notify the department and other interested persons when a map is submitted to those local planning agencies.

SSJMUD adopted a Pre-SB 1938 GMP in 1993. This GMP was also included in SSJMUD's Agricultural Water Management Plan in 2012.

2.7.1.2 Agricultural Water Management Plans

The Water Conservation Act of 2009 (SB X7-7) requires that agricultural water suppliers serving more than 25,000 irrigated acres adopt and submit to DWR an Agricultural Water Management Plan (AWMP). These plans include reporting on implementation status of Efficient Water Management Practices (EWMPs) within the supplier's service area. Areas which are served by recycled water deliveries only are excluded from the total amount of irrigated acreage. In the Emergency Drought Measures enacted by the State of California in 2015, agricultural water suppliers serving 10,000 irrigated acres or more were required to prepare and submit an AWMP to DWR. The Emergency Drought Measures also included requirements for information beyond the requirements of SB X7-7. SSJMUD prepared its first draft of its AWMP in 2010; the final draft was submitted to the US Bureau of Reclamation and approved in May 2012.

2.7.1.3 Urban Water Management Plans

The Urban Water Management Planning Act requires that urban water suppliers with a usage of over 3,000 AFY or that serve more than 3,000 urban connections must adopt an Urban Water Management Plan (UWMP). This plan is to ensure that the urban water supplier adequate addresses water supplies for existing and future demands. These plans were first required in 2005, with updates to be prepared and submitted by urban water suppliers every five (5) years. Based upon its historic and current water usage of less than 3,000 AFY, the City of McFarland is not required to prepare and implement a UWMP. The City of Delano, however, prepared and submitted its 2010 UWMP in 2011, with a subsequent update prepared in 2015.

2.7.1.4 Integrated Regional Water Management Plans

In 2002, the Regional Water Management Planning Act (SB 1672) created the Integrated Regional Water Management (IRWM) Program. The IRWM Program is used as a collaborative effort to identify and implement water management solutions on a regional scale that increase regional self-reliance, reduce conflict between agencies and users, and manage water to concurrently achieve social, environmental, and economic objectives. By collaborating on projects, participants in the IRWM Program can provide these benefits and meet their water supply and quality goals. In the Kern County Subbasin, there are two IRWM Plans: the Poso Creek IRWM Plan and the Kern County IRWM Plan. SSJMUD is a participant in the Poso Creek IRWM Plan, which was adopted in 2007.

2.7.1.5 Irrigated Lands Regulatory Program

The Tulare Lake Basin General Order (Order R5-2013-0120) was passed by the RWQCB in 2006. This order requires that any irrigated land having the potential to discharge to surface water or groundwater must comply with the requirements set by the RWQCB. Compliance

includes membership in a Coalition or obtaining coverage through an Individual Order from the RWQCB. SSJMUD is a member of the Kern River Watershed Coalition Authority, which was formed in 2011.

2.7.1.6 Groundwater Export Ordinance

Kern County adopted a groundwater export ordinance in 1998, which requires a Conditional Use Permit (CUP) for export of water to areas both outside the County and within watershed areas of underlying aquifers in the County. The ordinance applies only to the southeastern drainage of the Sierra Nevada and Tehachapi mountains in the South Lahonten Hydrologic Region in eastern Kern County.

2.7.1.7 Title 22 Drinking Water Program

The Division of Drinking Water regulates public drinking water systems, which include municipal and state small water systems. In addition to the cities of Delano and McFarland, there are several state small systems and multi-parcel/multi-connection systems in SSJMUD's jurisdiction. These systems are required to comply with the standards set forth in Title 22 of the California Code of Regulations. For single parcel/single-connection systems, Kern County Environmental Health Services provides regulation and oversight to meet the requirements of Title 22.

2.7.2 *Conjunctive Use Programs*

Conjunctive use or "the coordinated use of surface water and groundwater" has been used for many years in Kern County, for the benefit of water users, to allow for flexibility in the way water is delivered, whether climatic conditions allow for imported surface water, or if groundwater is needed in any given year. Conjunctive use is further described by the Water Education Foundation with the following: "In its passive form, also called in-lieu conjunctive use, surface water is used in wet years and groundwater is used in dry years. In active conjunctive use, surface water is directly injected into aquifers and wells to be used as needed as part of groundwater banking" (Water Education Foundation, 2019).

SSJMUD has participated in conjunctive use programs, for both in-lieu and direct recharge banking activities to enhance the flexibility of water supplies to meet the water demands of SSJMUD stakeholders.

3. Sustainable Management Criteria

3.1 Sustainability Goals

SGMA requires that a sustainability goal be defined for the basin (CWC §10727(a)) and the GSP emergency regulations further clarify that the sustainability goal be defined on a basin-wide basis. SSJMUD, working with the KGA and other GSAs in the Subbasin have developed the following sustainability goals for the Subbasin:

> *Sustainable management in the Kern County Subbasin will result from the implementation of projects and management actions at the member agency level of each GSA to maintain its groundwater use to the sustainable yield of the basin, operate at or above established measurable objectives, and above established minimum thresholds. The sustainable yield, measurable objectives, and minimum thresholds in the Subbasin have been established based on the technical information presented in the Basin Setting of this KGA GSP and the technical information developed by each member agency and presented in their management area plans.*
>
> *The projects and management actions proposed by the member agencies of the KGA include a variety of water supply development and demand management actions that collectively will bring the Subbasin sustainability over the 20-year implementation period.*
>
> *The Subbasin will continuously monitor groundwater conditions, as required by SGMA, and will continue coordination among the KGA member agencies and all other GSA's in the Subbasin to identify the potential for or presence of undesirable results. The coordination process established in the development of the this GSP and memorialized in the coordination agreement will ensure that the Subbasin is managed as a unit and that the districts within the Subbasin work collaboratively towards sustainability.*

3.2 Undesirable Results

Undesirable results for each sustainability indictor have been developed through a collaborative process with all GSAs in the Subbasin, compliant with GSP emergency regulations, which states that undesirable results are to be defined consistently throughout the basin (23-CCR § 354.20). The definitions of undesirable results provide flexibility for each management area within the Subbasin to define minimum thresholds that constitute significant and unreasonable impacts to the beneficial uses and users of groundwater within the specific management areas.

The definitions of undesirable results for the Subbasin are described in the KGA GSP and are repeated here with additional information regarding causes and effects of each sustainability indicator for the SSJMUD management area.

3.2.1 Undesirable Results for Chronic Lowering of Groundwater Levels

The basin-wide definition of undesirable results for chronic lowering of groundwater levels is as follows:

> *The point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users.*
>
> *This is determined when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each management area). Minimum thresholds shall be set by each of the management areas through their respective management area plans and Groundwater Sustainability Plans.*

Within the Subbasin, a management area will be considered an undesirable results watch area for lowering of groundwater levels when it exceeds its minimum threshold criteria, as determined by each management area. The SSJMUD management area will be considered an undesirable results watch area when 51% of the representative monitoring sites in a management area violate their minimum threshold for groundwater levels. If multiple undesirable results watch areas meet the criteria for a Subbasin undesirable result, as defined above, the Subbasin would be considered to be experiencing an undesirable result.

3.2.1.1 Potential Cause of Undesirable Results

A potential cause of the undesirable result of chronic lowering of groundwater levels in the SSJMUD management area is a continued or increased reliance on groundwater pumping due to the reduction of imported water supplies. As the primary use of groundwater in SSJMUD is for agriculture, increased groundwater pumping could also occur if new land is put into agricultural production or if water use per acre on existing irrigated land increases. Volume of water pumped by municipal and industrial users is relatively minimal when compared to the volume of water used for agricultural production. No significant development is anticipated in SSJMUD based on the review of the current General Plans.

3.2.1.2 Potential Effects of Undesirable Results

The primary potential effect of the chronic lowering of groundwater levels on the beneficial uses and users of groundwater in SSJMUD may include groundwater well dewatering and increased pumping lift. Well dewatering is detrimental to wells as it can lead to increased maintenance costs (e.g., well rehabilitation/redevelopment and pump lowering) and reduced well lifespan due to corrosion of well casings and screens. Increased pumping lift results in more energy use necessary per unit volume of groundwater pumped and corresponding higher pumping costs, as well as increased wear and tear on well pump motors, and reduced well efficiency.

3.2.2 Undesirable Results for Reduction of Groundwater Storage

The basin-wide definition of undesirable results for reduction of groundwater storage is as follows:

> *The point at which significant and unreasonable impacts, as determined by the amount of groundwater in the basin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended 10-year drought period.*
>
> *This is determined when the volume of storage (above the groundwater level minimum thresholds) is depleted to an elevation lower than the groundwater level minimum threshold in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by the acreage of each management area). Minimum thresholds shall be set by each of the management areas through their respective management area plans and Groundwater Sustainability Plans.*

Within the Subbasin, a management area will be considered an undesirable results watch area for reduction in storage when it exceeds its minimum threshold criteria, as determined by each management area. The SSJMUD management area will be considered an undesirable results watch area for reduction in groundwater storage when 51% of the representative monitoring sites in a management area violate their minimum threshold for groundwater levels, since water elevations serve as a proxy for reduction of groundwater storage. If multiple undesirable results watch areas meet the criteria for a Subbasin undesirable result, as defined above, the Subbasin would be considered to be experiencing an undesirable result.

3.2.2.1 Potential Cause of Undesirable Results

Reduction of groundwater storage is generally correlated to chronic lowering of groundwater levels. Therefore, the potential causes of undesirable results due to reduction in groundwater storage are generally the same as the potential causes listed above for the undesirable results due to chronic lowering of groundwater levels.

3.2.2.2 Potential Effects of Undesirable Results

SSJMUD has defined the undesirable result of reduction of groundwater storage as the reduction of available groundwater volumes needed to support a 10-year drought period, similar to that experienced over the 2006 to 2016 period. The volume of groundwater storage needed to support a 10-year drought is above the minimum threshold for chronic lowering of groundwater levels, therefore groundwater elevations below this minimum threshold would have the same effects on beneficial uses and users in SSJMUD as chronic lowering of groundwater levels.

3.2.3 Undesirable Results for Degraded Water Quality

The basin-wide definition of undesirable results for degraded water quality is as follows:

The point at which significant and unreasonable impacts over the planning and implementation horizon, as caused by water management actions, that affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

This is determined when the minimum threshold for a groundwater quality constituent of concern is exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the designated monitoring points within the basin. Minimum thresholds shall be set by each of the management areas through their respective management area plans and Groundwater Sustainability Plans.

Within the Subbasin, a management area will be considered an undesirable results watch area for degraded water quality when it exceeds its minimum threshold criteria, as determined by each management area. The SSJMUD management area will be considered an undesirable results watch area for degraded water quality when 51% of the representative monitoring sites in a management area violate their minimum threshold for groundwater levels, since groundwater levels serve as a proxy for degraded water quality. If multiple undesirable results watch areas meet the criteria for a Subbasin undesirable result, as defined above, the Subbasin would be considered to be experiencing an undesirable result.

3.2.3.1 Potential Cause of Undesirable Results

As described in Section 2.3.4, groundwater within the SSJMUD management area plan's boundaries is high quality that meets nearly all existing standards, including the SWRCB's Water Quality Goals. Based on the available data and trend analysis, TCP, arsenic and salinity are the primary constituents of concern. Potential cause of undesirable results for these constituents are:

- **TCP:** no undesirable results related to groundwater levels or management. TCP is a chlorinated hydrocarbon that is highly soluble in water with a low soil sorption coefficient, meaning that it easily migrates in groundwater. The half-life of TCP in groundwater is reported from one to two hundred years (reference: State Water Board, Groundwater Information Sheet, TCP https://www.waterboards.ca.gov/gama/docs/coc_tcp123.pdf). Additionally, the California Water Boards reports that drinking water sources impacted with TCP in the Central Valley are attributed to past application of soil fumigants containing TCP (1,3-D soil fumigants), which were applied between 1950 and the late 1970's. By the early 80's these fumigants were believed to be completely out of the market. Because of the nature and source of TCP contamination, water management activities do not influence groundwater contamination from TCP.
- **Arsenic:** potential causes of undesirable results related to arsenic and lowered water levels are unknown at this time because arsenic is naturally occurring in the groundwater. Where the Corcoran clay is present, arsenic leaches into the groundwater from the pyrite sediments contained within the clay deposits. Consequently, arsenic occurrence is a

function of contact with these deposits. If lowered water levels minimize contact with the clay deposits, less arsenic will be present in the groundwater.

Outside of the Corcoran clay, arsenic is also found in very deep portions of the basin. Data analysis shows that elevated arsenic levels are predominately located in the confined aquifer, which is in the north east portion of the District. Trends were observed with very deep wells showing higher arsenic concentrations. There were clear trends indicating that lowered water levels contributed to increased arsenic levels.

- **Salinity:** potential causes of undesirable results related to salts and lower water levels are unknown at this time. No discernable trends were observed. Wells with elevated sodium levels are located throughout the District's service area. Studies and management plans conducted through CV-SALTS are expected to have a greater impact on salt loading/management than groundwater levels.

The extent and impact that groundwater levels have had historically, and may have in the future, should continue to be analyzed and addressed in future updates of this plan. It is proposed to monitor the interaction of water management actions with groundwater levels, and in turn the interaction of groundwater levels with water quality, over the next five years to determine if a correlation exists. With respect to point source contamination issues, GeoTracker and EnviroStor databases should be routinely monitored for any updates or new contamination sites.

3.2.3.2 Potential Effects of Undesirable Results

Potential effects of an undesirable result for sodium depends on the beneficial users. Salinity levels are unlikely to increase to levels that exceed the drinking water limits. Therefore, agricultural users are the most impacted. Effects of levels above the SWRCB Ag goals could potentially reduce crop yield.

While it is important for SSJMUD and KGA to closely monitor the correlation between groundwater levels and contaminant concentrations, other water quality regulatory programs are expected to have a greater impact. The ILRP and the Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS) program both focus on managing the increasing salinity and nitrate levels in the Central Valley. ILRP is contributing to reducing nitrate loading through its nitrate management plans. By 2022, CV-SALTS will require waste discharge permittees to establish and participate in management zones that are focused on supporting the Human Right to Water and provide replacement drinking water where nitrate exceeds the MCL of 10 ppm.

Because degraded water quality could potentially reduce the amount of usable supply delivered to groundwater users or require the need for treatment systems, which could potentially have a negative economic effect, SSJMUD and KGA intend to cooperate with regulatory programs focused on studying, mitigating, and managing nitrates and salts in the groundwater.

3.2.4 Undesirable Results for Land Subsidence

The basin-wide definition of undesirable results for land subsidence is as follows:

> *The point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.*
>
> *This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan.*

It is generally recognized that land subsidence is occurring within the Subbasin and also within SSJMUD. However, within SSJMUD management area described in this management area plan, no impacts to critical infrastructure have been identified. The lowering of groundwater levels within the SSJMUD area could potentially contribute to subsidence, as can the groundwater pumping from neighboring areas. As no impacts to critical infrastructure have been identified and because it is not clearly understood how groundwater pumping in different areas of the basin affects subsidence, SSJMUD has identified land subsidence as a data gap. As a result, no minimum thresholds are established for land subsidence at this time. SSJMUD will work cooperatively with the KGA and other GSAs in the Subbasin to collect additional data and develop a better understanding of the causes (amount and locations of groundwater pumping) and impacts to critical infrastructure. Minimum thresholds will be adopted by SSJMUD at such time that a clear understanding of the causes and effects can be developed.

3.2.4.1 Potential Cause of Undesirable Results

Land subsidence can be caused by several mechanisms, but the mechanism most relevant to sustainable groundwater management is the depressurization of aquifers and aquitards due to lowering of groundwater levels, which can lead to compaction of compressible strata and lowering of the ground surface. Therefore, the potential causes of the undesirable results of land subsidence are generally the same as the potential causes listed above for undesirable results due to chronic lowering of groundwater levels.

3.2.4.2 Potential Effects of Undesirable Results

Potential effects of land subsidence include damage to critical infrastructure including pipelines, roads, building, water conveyance systems, and flood control facilities. Damage to these systems could impact water delivery to surface water, resulting in increased groundwater use. Of primary concern to the District, is the impact of subsidence to the FKC. Subsidence affecting the canal is from groundwater pumping to the north of the Subbasin.

3.2.5 Undesirable Results for Seawater Intrusion

The location of the Subbasin, as it is described in the KGA GSP's basin setting and the basin setting of this management area plan demonstrates that seawater intrusion is not under

consideration for this management area or for the Subbasin at large because the Kern County Subbasin is located more than 60 miles from the nearest body of seawater. This separation precludes the possibility of seawater intrusion.

3.2.6 Undesirable Results for Interconnected Surface Streams

Due to the historic groundwater pumping in the Subbasin and the Tulare Lake Basin, in general, the groundwater elevations have lowered such that interconnected surface streams no longer exist in the KGA portions of the Subbasin. This information is presented in the KGA GSP basin setting and the basin setting in this management area plan.

3.3 Minimum Threshold

The following section sets the minimum threshold for each of the sustainability indicators applicable to the SSJMUD management area. Thresholds are discussed as a proposed minimum groundwater elevation that would exhibit undesirable results if groundwater elevations fall below the proposed thresholds for any sustainability indicator. Of the six sustainability indicators, seawater intrusion and interconnected surface water are not issues within the District, as indicated in the Basin Setting.

In accordance to §354.28 (d), the District thresholds with respect to groundwater elevations are used as a proxy for identifying undesirable results in groundwater storage, groundwater water quality, and land subsidence. Although groundwater storage in the basin is plentiful, it becomes uneconomical to obtain groundwater at certain depths. Therefore, SSJMUD has elected to maintain approximately 10-years of groundwater storage (by volume) above the minimum threshold for groundwater elevation to manage a 10-year operational drought, similar to the 2006-2016 historical period. With respect to water quality, water levels cause changes in concentration of constituents at different depths of water level per location. Subsidence is known to be caused by the dewatering clay layers (from water level decline) and can be represented by groundwater levels.

The minimum threshold values are determined by separating the basin underlying the SSJMUD management area into different hydrogeologic zones (HZs), areas with similar hydrologic and geologic conditions. The creation of the HZs was closely coordinated with those districts adjacent to the SSJMUD management area. Figures in Appendix H shows the distribution of HZs across the District and its neighboring management areas. Spring water level data spatially representative of individual HZs were plotted together and a linear trend was projected from 2006 to 2016 (historic 10-year drought period). Within the District's, all HZ groundwater elevation plots show a declining groundwater slope during the 2006-2016 period. This 10-year period was then projected to 2040 with a unique equal slope for each HZ to estimate the resulting groundwater level if the 2006-2016 conditions persisted for the 20-year implementation period from 2020 through 2040. This methodology was chosen as it would represent a worst-case condition and present a case which could be evaluated by the District's stakeholders to

understand what level of impact would be considered significant and unreasonable to individual stakeholder within each HZ. As previously stated, this methodology represents a worst-case scenario in terms of imported water supply deliveries and local hydrology. Figure 3-1 shows the change in groundwater elevation from 2015 to 2040 for North of the Kern River.

The 2040 conditions are set as the minimum threshold value. Figure 3-2 shows the estimated minimum thresholds in the SSJMUD management area. The projected 2040 water levels indicate the expected change to groundwater level with hydrology maintaining the 2006 to 2016 trend through 2040. This trend represents a worst-case scenario in which the District does not implement any management actions, or projects to mitigate pumping beyond what currently exists and is the case landowners/stakeholders were presented to determine which impacts would be significant and unreasonable. Through a series of workshops and individual meetings between the District's staff and landowners, the results of this projected future condition were reviewed with District's stakeholders. Based on the review and feedback from landowners and stakeholders, the District adopted the minimum thresholds and measurable objectives described in the following section.

3.3.1 The Chronic Lowering of Groundwater Levels

Minimum threshold values for chronic lowering of groundwater levels in SSJMUD are shown on Table 3-1. The minimum threshold values vary within the management area (and throughout the Subbasin) due to hydrology and the projected decreases in water levels, determined in each HZ. The management area contains multiple minimum thresholds depending on the hydrologic gradients and spatial distribution of the representative monitoring sites as shown in the table below.

SSJMUD believes that the proposed minimum groundwater elevation will not cause undesirable results in the basin. The District will reevaluate the threshold based upon the District's ability to implement projects and management actions and, if necessary, will adjust the minimum threshold if they are able, to prevent causing an undesirable result in the basin.

In determining the minimum threshold, the impact of lowering water levels to the proposed minimum threshold was analyzed by using available well construction data for agriculture, municipal, and domestic wells. The well impact analysis of the equivalent minimum threshold average values (represented as depth to water values) for each HZ was used to determine that a portion of the existing wells are impacted to varying extents. Most wells are expected to be operational (even with a decrease in efficiency) as the bottom of the screens remain in the water. This can be observed in Figure 3-3 for agricultural wells, Figure 3-4 for domestic wells, and Figure 3-5 for municipal wells.

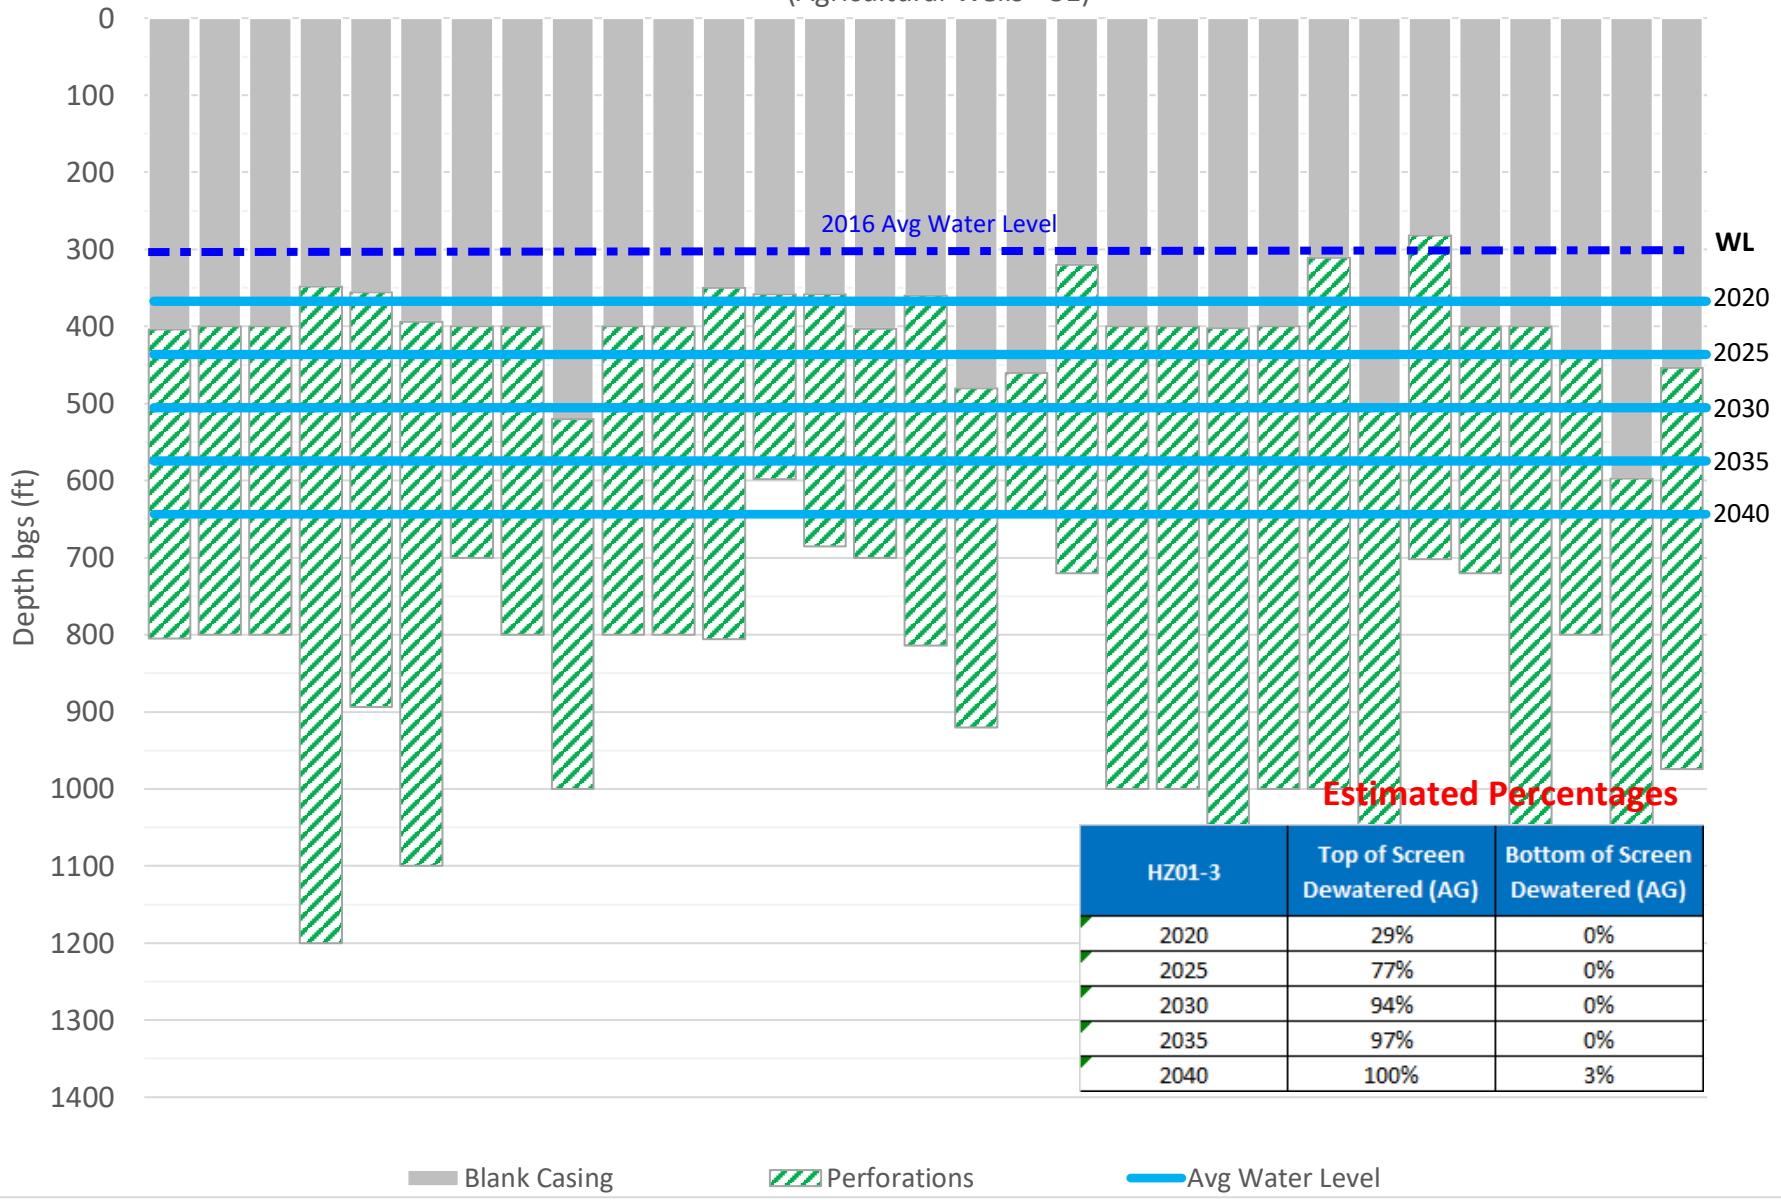
Although the data presented is a subset of the total wells in the Districts' management areas, it is reasonable to assume that many wells will maintain operation even at the proposed minimum threshold values. The projected minimum threshold depths to water were reviewed with landowners within SSJMUD, along with the well impact analysis, to determine if it would be economical to mitigate the impacts of agricultural, domestic, and municipal wells.

It was determined that at the average 2040 water levels, impacts to agricultural wells could and would be mitigated by landowner to the extent that declining groundwater levels was created by localized actions by those landowners. It was determined that none of the identified agricultural

water wells within the SSJMUD management area would be dewatered, however in many instances water levels near the minimum threshold would require lowering of pump bowls.

It was also identified that if water levels were to fall to levels near the minimum threshold then mitigation would be necessary to address the impacts to the few impacted domestic wells in the area. Any further decrease in water level below the established minimum threshold would create a significant and unreasonable impact to overlying groundwater users and would cause an undesirable result. In normal operating conditions, the extent of impact to wells is expected to be less as water levels are expected to be at higher elevations than the minimum threshold. However, the analysis determined it is possible for the District to drop water levels to the established minimum threshold values and not have undesirable results that cannot be mitigated.

3.3.2 Groundwater Storage



The minimum threshold for groundwater storage was set in conjunction with the minimum threshold for the groundwater level. In this Subbasin groundwater storage is not a significant issue regarding water supply since there is enough storage in the Subbasin to use beyond the set minimum threshold, but access is reduced based on what is economical to currently extract. The minimum thresholds impact to groundwater users for reduction of groundwater storage are the same as those for the chronic lowering of groundwater based on the ability to economically access the water and the proposed water levels are not expected to cause an undesirable result.

3.3.3 Degraded Water Quality

Minimum thresholds are not set for degraded water quality because the data analysis conducted does not indicate that water quality is degraded by lowered water levels. Data trending was performed on several representative wells in the management area plan's boundaries to evaluate contaminant concentration changes and identify correlations to groundwater levels. This trending indicated that no discernable trends can be stated since the correlation between groundwater levels and arsenic levels was not consistent for most of the wells. TCP trending indicates that contaminant concentrations also did not correlate to water level changes. Sodium levels also could not be correlated with water levels due to lack of data.

Based on these findings, groundwater levels will be used as a proxy for degraded water quality as the District, in coordination with the other members of the KGA, continues to analyze groundwater level and water quality trends. Even though SGMA does not require a GSA to comply with Federal and state drinking water standards, the various monitoring programs overseen by regulatory agencies (as discussed in Section 2.6.3.3) were incorporated into this management area plan by reference. Existing regulatory programs include Title 22 (Regulations Related to Drinking Water), ILRP, and CV-SALTS. While managing groundwater levels, the District and KGA will work cooperatively with entities implementing these regulatory programs to share facilities, data, and (when applicable) management actions to protect all users and beneficial uses of groundwater.

This Page Left Blank Intentionally

As defined in Section 4: Monitoring Network, water quality sampling coincides with groundwater levels. This approach is expected to provide clear correlations between water quality and groundwater levels. Monitoring sites and parameters were strategically selected to inform on future degradation of water quality.

3.3.4 Subsidence

The minimum threshold for land subsidence is set equivalent to the chronic lowering of groundwater levels minimum threshold. Land subsidence currently occurs and is expected to continue with lowering of groundwater levels. The proposed water levels are unknown to cause an undesirable result regarding subsidence. In the future, when more consistent and better calibrated data is available, it may be necessary to adjust the minimum threshold dependent on what new information is available. Information needed are specifically the magnitude of subsidence around facilities and infrastructure, which are areas that may cause a significant economic problem affecting water users and others. In the future, minimum thresholds will be derived from monitoring programs implemented to increase the available data in suspected critical areas and to calibrate spatial data available.

Current data available for the Subbasin indicates that subsidence varies throughout the Subbasin. Within the jurisdictional area of SSJMUD, higher rates of subsidence occur in the northwestern portion of SSJMUD increasing North towards the Tule Basin and West to SWSD. While these rates of subsidence are higher than the rest of the area covered in this management area plan, they have not been identified as significant or unreasonable.

3.4 Measurable Objectives and Interim Milestones

The measurable objective is established in accordance to regulation §354.30 (d), groundwater elevations can serve as the value for multiple sustainability indicators where the representative value is a reasonable indicator for multiple measurable objective. As with the minimum threshold, measurable objective values were not established for depletion of interconnected surface water and sea water intrusion as these are not applicable to the basin.

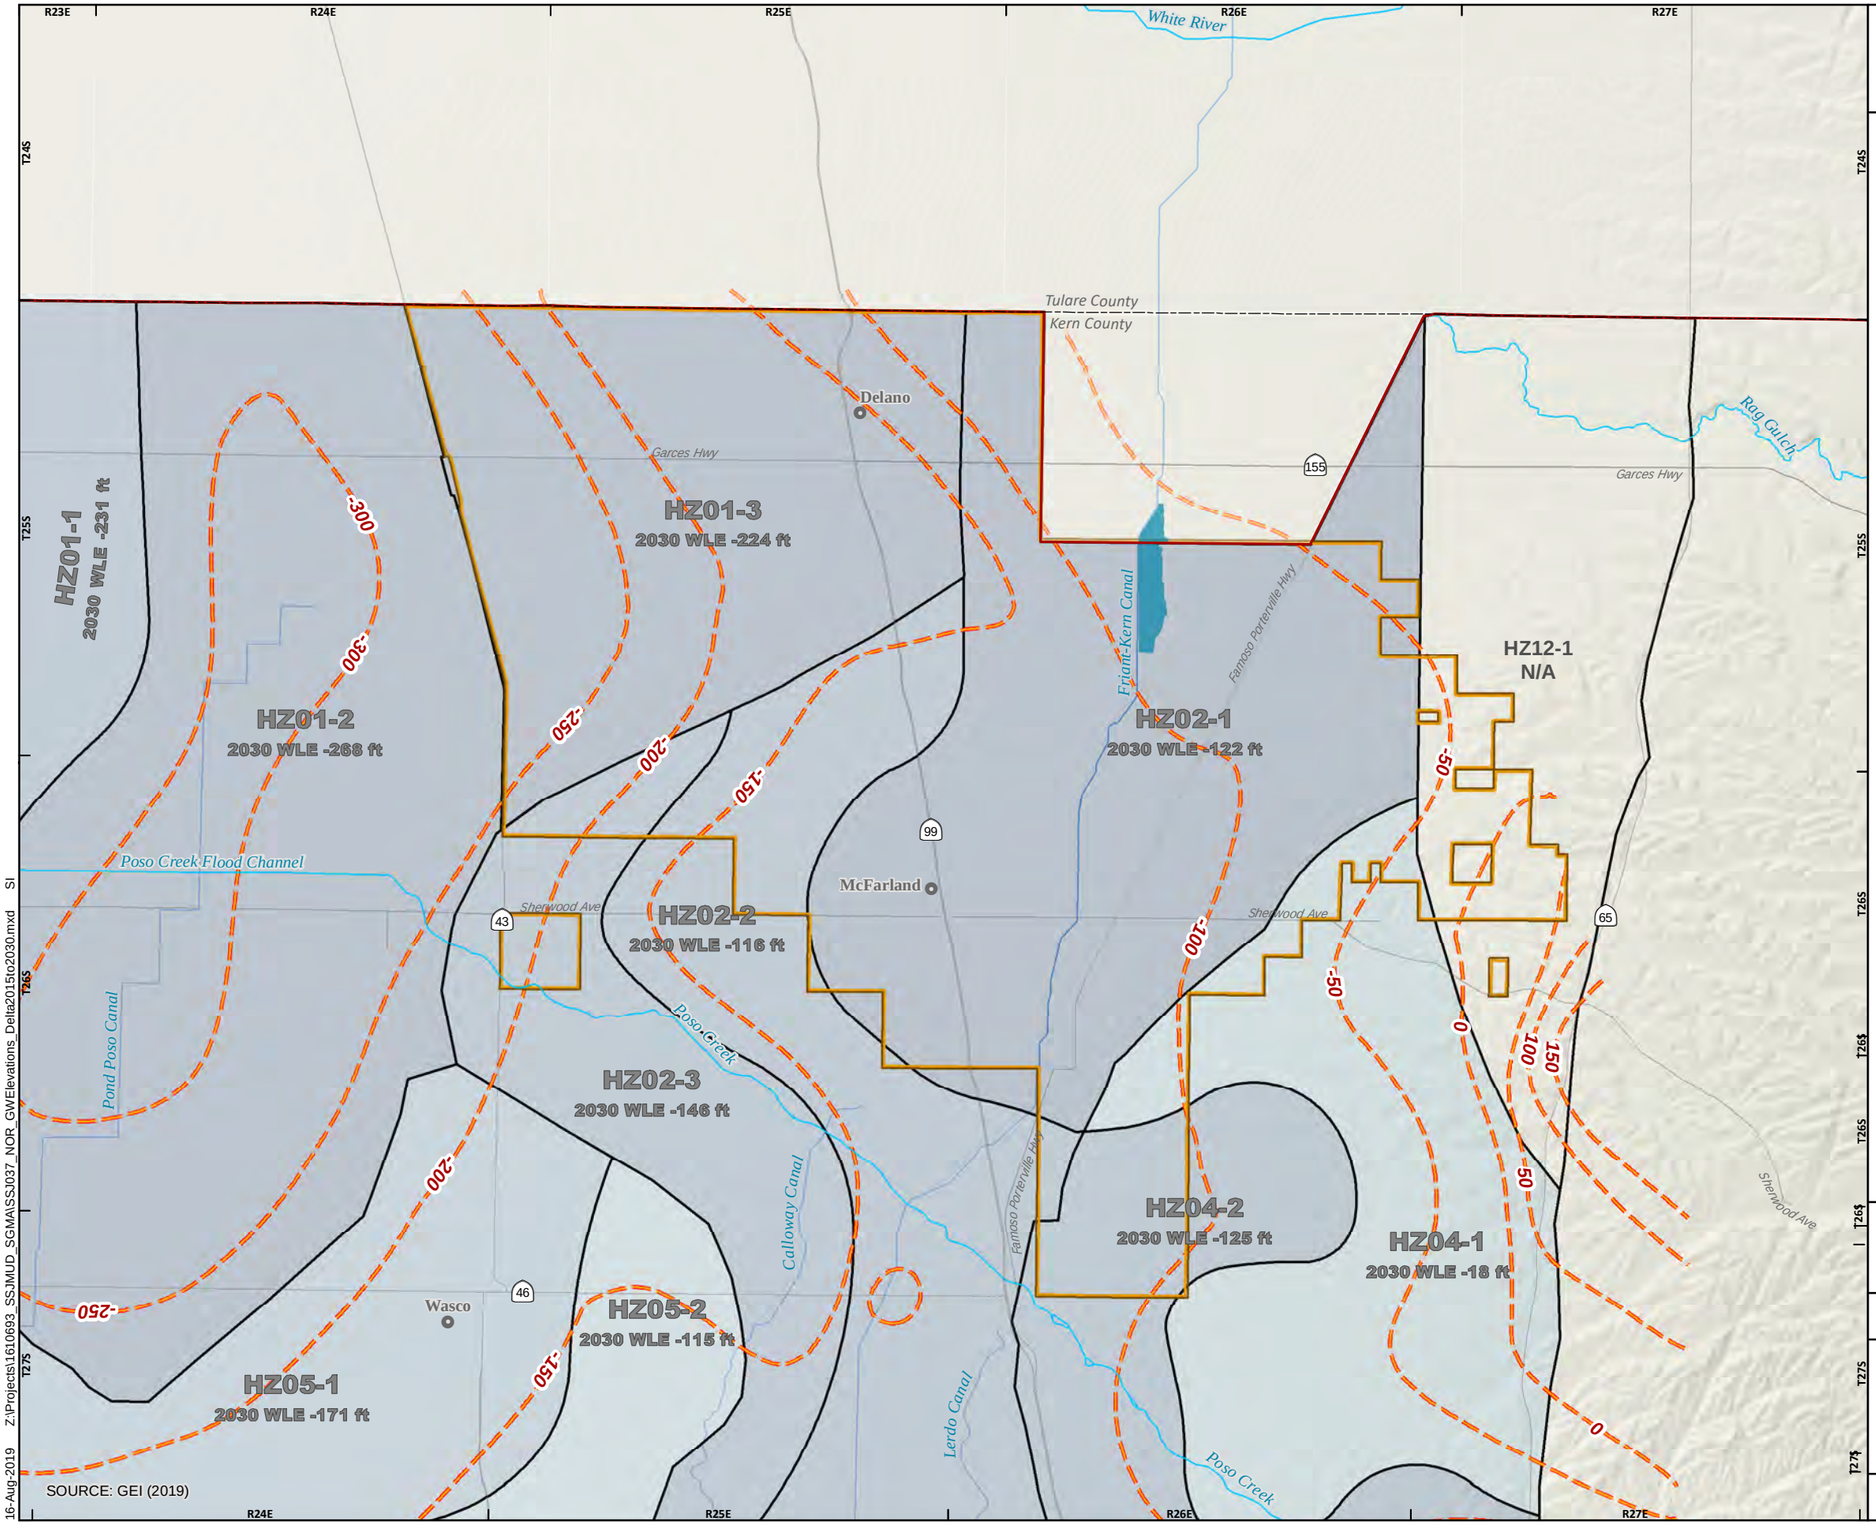
The measurable objective values are determined in the same manner as explained in Section 3.3 for the minimum threshold with the exception that the measurable objective is set at 2030 water levels per the methodology described above. For the SSJMUD management area, the measurable objective is the adopted goal to maintain groundwater levels at or above the interpolated 2030 water levels. The measurable objective is a ten-year rolling average of the groundwater elevation at any given monitoring site, that represents the proposed groundwater elevation at which SSJMUD plans to maintain for sustainability.

Figure 3-6 shows the change in groundwater elevations from 2015 to 2030 for North of the Kern River. Setting the measurable objective at the 2030 water level was determined based on the margin of safety giving the District's an approximate storage of 10-years (may vary

significantly) of water supply in the instance the District is faced with a similar water supply situation as experienced during the 2006 to 2016 drought.

The interim milestones are the points at which the District plans to set their water level to reach the sustainability goal at the district level within 20 years of the plan implementation. The milestones are set every five years and are based on a linear trend to reach the measurable objective values by 2040, as shown in Figure 3-7 for the SSJMUD management area. The District will implement projects and management actions to maintain a path along the interim milestones and to meet the measurable objectives. The time frame for implementation of management actions and projects are discussed in this section.

3.4.1 The Chronic Lowering of Groundwater Levels



The measurable objective for the chronic lowering of groundwater levels is set at projected 2030 water levels and are monitored at the specific monitoring points. The measurable objective in each management area are monitored at various location. The established measurable objective values are determined from the 2030 water level contours and are shown for each representative monitoring point as shown in Table 3-2 for the SSJMUD management area. Figure 3-7 shows the measurable objectives along with minimum thresholds in the SSJMUD management area.

The proposed measurable objective will allow the District to operate in a worst-case scenario drought condition (2006 to 2016 conditions) and maintain operation before approaching the minimum threshold for an approximated 10 years. Prior to 10 years, the District would have the ability to implement projects or perform emergency actions to reduce pumping.

The measurable objective, like the minimum threshold values vary within the management area (and the basin) due to hydrology and the projected decrease in water level determined in each HZ subzone. The Management area contains multiple measurable objectives dependent on hydrologic gradients and spatial distribution.

The interim milestones were determined trending a linear trend to reach the measurable objective by 2040. The steps to reach the measurable objectives will be set by the interim milestones which are checked every five years during the plan's implementation. At these points, projects and management actions will be taken to reduce the reliance on groundwater supply. Section 5 contains details of the projects and management actions which will be used to achieve the interim milestones every five- years. A linear interpolation between the 2015 spring groundwater levels and the measurable objective (2030 water level projections) are used in setting the interim milestones.

3.4.2 Groundwater Storage

The measurable objective for the reduction in groundwater storage is based on the measurable objective for the chronic lowering of groundwater levels. In setting the measurable objective at the 2030 projection and the minimum threshold at the 2040 water level projection (based on the historical drought), approximately 10 years of storage is available to the District before reaching the minimum threshold, this was set as a factor of safety. A linear interpolation between the 2015 spring groundwater levels and the measurable objective (2030 water level projections) are used in setting the interim milestones.

3.4.3 Degraded Water Quality

For similar reasons as defined in Section 3.3.3 (Minimum Threshold for Degraded Water Quality), the measurable objective for the lowering groundwater levels will be used as a proxy for the measurable objective for degraded water quality. A linear interpolation between the 2015 spring groundwater levels and the measurable objective (2030 water level projections) are used in setting the interim milestones. As defined in Section 4: Monitoring Network, water quality sampling coincides with groundwater levels. This approach is expected to provide clear correlations between water quality and groundwater levels.

3.4.4 Land Subsidence

The measurable objective for land subsidence at this time is based on the measurable objective of chronic lowering of groundwater levels. As mentioned in Section 2.3.5,3.3.4 the magnitude and severity of subsidence is unknown, and data is needed to be collected to ensure the set reasonable

measurable objective and minimum threshold. The data will be reviewed at the five-year intervals. A linear interpolation between the 2015 spring groundwater levels and the measurable objective (2030 water level projections) are used in setting the interim milestones.

3.5 Margin of Operational Flexibility

The margin of operational flexibility between the measurable objectives and the minimum thresholds is a designated 10-year drought water supply. The flexibility in the system is the amount of time to implement projects to bring in additional surface water supply or to reduce groundwater demand to maintain groundwater levels above the minimum thresholds. Table 3-3 shows example of the District's operational flexibility to maintain above the minimum thresholds through voluntary management actions, such as a fallowing or land retirement program.

Table 3-3: Example District Operational Flexibility

Sustainability Component	Categories of Projects & Management Actions
Water Demand	Incentives of pumping reduction
	Fees for landowner excess pumping
	Water Market Response
	Buy Back Program
Water Supply	Import Water Supply
	Recharge Projects
	Surface Water Capture
	Other Projects

In instances where voluntary programs are not being utilized or are proven to be ineffective in the reduction of groundwater demand, more drastic measures will be taken. These measures may include mandatory pumping reduction and land fallowing. In instances where neighboring management areas differ on their sustainable management criteria, having a greater difference between the measurable objective and the minimum threshold will allow for more operational flexibility within the District so they may take action prior to reaching the minimum threshold and/or potentially negatively affecting adjacent management areas. In addition, neighboring management areas which approach their minimum thresholds may have less impact on the Districts' management area due to the larger range between the measurable objective and the minimum threshold for a given representative monitoring site, which allows for approximately 10-years of water level decline.

3.6 Potential Effects beyond Management Area

The setting of the minimum thresholds and measurable objectives described in this management area plan is coordinated with neighboring Districts to maintain a similar water level gradient as

2015 conditions. It is not expected to severely affect areas outside of the District in terms of significantly changing the surrounding water levels either lower, or higher, than conditions of neighboring Districts' plans. Also, the change in groundwater storage is correlated with the change in groundwater levels and is not expected to cause severe impact to neighboring Districts or GSAs.

Subsidence is a potential impact to neighboring Districts, GSAs, and subbasins. This extent is currently unknown, and more data needs to be collected to determine where the impacts may occur and what is contributing to these impacts.

Water quality data used to characterize groundwater conditions does not indicate that water quality degrades when groundwater levels decline. Regardless, a sampling program has been established to monitor changes in water quality related to water levels. No minimum threshold or measurable objective is set because degradation has not been observed.

Degraded water quality within SSJMUD is defined as an increasing trend in salinity (sodium and chloride) that potentially threatens agriculture viability within the district; or concentrations of nitrate, arsenic or hexavalent chromium exceeding the respective drinking water standard, because of declining water levels. While these constituents are present throughout the district, the overall trends indicate lower concentrations with lower water levels. In contrast, higher concentrations are typically observed with higher water levels.

This Page Left Blank Intentionally

4. Monitoring Networks

This chapter describes the objectives, design, rationale, monitoring protocols, and data reporting requirements of the monitoring network to be implemented. This chapter discusses any data gaps, and a plan for assessment and future improvement to the monitoring network to fill data gaps.

The monitoring network and protocols are designed to collect data of sufficient quality, frequency, and distribution to characterize the groundwater and change in storage of the District, along with water budget components in SSJMUD, and to evaluate changing conditions due to water management actions and future water supply projects.

4.1 Monitoring Network Objectives

The monitoring network in the District is designed to meet the following monitoring objectives of this plan:

- Monitor impacts of groundwater pumping on beneficial uses and users of groundwater,
- Monitor progress toward measurable objectives of this plan relative to minimum thresholds,
- Collect data to quantify annual changes in water budget components of the study area, and
- Monitor changes in groundwater conditions relative to the pertinent sustainability indicators:
    - Groundwater Potentiometric Surfaces, or Groundwater Levels,
    - Groundwater Storage,
    - Groundwater Quality, and
    - Land Subsidence

4.1.1 *Water Level Monitoring as a Key Sustainability Indicator*

As described in the Section 3 of this management area plan, groundwater elevation is the key sustainability indicator for undesirable results in the Subbasin because lowering of groundwater levels leads to:

- Increased groundwater well pumping costs,
- decrease in groundwater storage,
- increased land surface subsidence most notably where fine-grained units and active groundwater overdraft are present, and

- potential changes in groundwater quality.

The groundwater level monitoring network is key to informing the progress of the management area plan's objectives for all sustainability indicators. While water levels are the key sustainability indicator for which minimum thresholds have been established, the monitoring network continues to include data collection stations for water quality, land subsidence, and other water budget components such as water demand and water supply inputs. The following sustainability indicators are not pertinent to this management area plan: seawater intrusion and depletions of interconnected surface water. Seawater intrusion is anticipated to not be a problem since the District is several miles from the ocean. For details on depletions of interconnected surface water, please refer to Section 2.3.6.

4.1.2 *Monitoring Progress toward Measurable Objectives*

The monitoring network will inform progress of sustainable management to reach interim milestones and measurable objectives. As described in Section 3.3 of this management area plan, groundwater levels are the primary indicator for which minimum thresholds have been set, and for which interim milestones and measurable objectives will be compared. However, all sustainability indicators identified in this management area plan and in the KGA Umbrella GSP are included in the monitoring network. As groundwater level monitoring progresses, effects on other indicators can be evaluated. Tracking the progress of water levels as well as other indicators will inform the effectiveness of water management actions and implemented projects. The details for how the measurable objectives and minimum thresholds were developed for groundwater levels are described in Section 3 of this Plan.

Monitoring the progress toward reaching interim milestones and measurable objectives will provide information needed to evaluate whether adjustments to management actions and the monitoring networks are required. Tables 3-1 and 3-2 show the minimum threshold and measurable objective for each monitoring site included as part of this Management Area Plan's network. As stated in §354.34(g)(3), minimum thresholds, measurable objectives, and interim milestones will be established at each monitoring site or representative monitoring site. Where needed, interim milestones for groundwater levels or other sustainability indicators may be adjusted in the five-year updates in order to maintain the objectives of this management area plan.

4.1.3 *Potential Impacts to Beneficial Uses and Users of Groundwater*

The monitoring network to be implemented will provide data to monitor the impacts of sustainable groundwater management on beneficial uses and users of groundwater, as well as secondary impacts such as land subsidence. A summary of potential impacts is included below in Table 4-1.

Table 4-1. Potential Impacts of Overdraft with Corresponding Monitoring

User Group	Potential Impacts	Monitoring and Data Collection
Irrigated Agriculture	• Increased pumping costs and maintenance • Decrease in groundwater storage	• Water level monitoring • Incorporate data into the Subbasin model to monitor storage outlooks with interim milestones
	Increased salinity in the upper and migration into the lower zone	Water quality monitoring
Industrial, Commercial, and Residential Wells	• Increased pumping costs and maintenance • Well Dewatering • Decrease in groundwater storage	• Water level monitoring • Incorporate data into the Subbasin model to monitor storage outlooks with interim milestones
	Increased Arsenic	Water quality monitoring
	Increased TCP and Nitrates	Water quality monitoring in lower aquifer zone
Public Facilities	Damaged infrastructure	Land subsidence monitoring
Groundwater Dependent Ecosystems (Preliminary NCCAG mapped dataset).	• Decline in shallow groundwater levels • Reductions in shallow groundwater storage due to groundwater pumping	• Water level monitoring • Confirm NCCAG mapped areas by field survey and evaluation • If applicable, compare pumping in the upper and lower zone with water levels in the shallow zone

4.1.4 *Monitoring Network for Water Budget Components*

One of the objectives of the monitoring network is to monitor the water budget components in order to quantify the change in water budget over time. This aspect of the network will rely on local monitoring stations for water levels, but also regional weather stations and remote sensing methods for consumptive use. In addition, water supply and exports accounting are required to monitor the water budget components. These aspects of the network are briefly described below.

4.1.4.1 Water Inflow to the Subbasin

As described in the water budget section of the report, water inflow to the Subbasin within the Districts includes:

- Surface water supplies (both imported and natural), that satisfies consumptive use, or becomes managed or unmanaged direct recharge to the Subbasin
- Precipitation
- Subsurface inflow

Surface Water Supplies

SSJMUD monitors all water received via the Friant-Kern Canal, and neighboring districts, at conveyance interties. The District performs monitoring using metering, or other gauging methods.

All imported surface water into the Districts, whether it is contracted and will be used for direct consumptive use, other exchanges, in-lieu banking, oil produced water, or direct recharge counts as water inflow to the Subbasin. Surface water diversions and imports are monitored by the Districts and are available annually to be incorporated in data evaluation.

Precipitation

Depending on the water year, precipitation may account for recharge as well as consumptive use in the Subbasin. It is a component of water budget accounting that is monitored by weather stations. The following weather stations (Table 4-2**Error! Reference source not found.**) may be used for monitoring purposes in or near the Subbasin. Online weather station data are updated daily to monthly.

Table 4-2. Weather Stations within the Vicinity.

Station Name	ID	Latitude	Longitude	Elevation (feet msl)	Other
Shafter	CIMIS 5	35.532556	-119.281790	360	
Delano	CIMIS 182	35.8330	-119.255960	300	Just north of Subbasin.

Source: https://cimis.water.ca.gov/Stations.aspx

Subsurface Inflow

Historical quantities of groundwater inflow to the Subbasin underlying the study area have been estimated in various regional models, calculated in local studies by Darcian Law, and may be estimated in the future by water budget accounting.

As a model of the study area is refined, groundwater inflow calculations may become more accurate. In addition, annual water budget accounting as well as semiannual water elevation monitoring, contouring and gradient estimating, will continue to provide data to support estimates of groundwater inflow.

4.1.4.2 Water Out of the Subbasin

As described in the water budget section of the report, water outflow or removal from the Subbasin within the District includes:

- Consumptive use from crop demand, other vegetation, evaporation, and other beneficial use such as water recreation, domestic use, municipal or industrial use, etc.

- Exported water or “Pump Back”
- Subsurface outflow

Consumptive Use

Sources of water for consumptive use include diverted surface water, precipitation, and groundwater. As described in the water budget section of this plan, consumptive use from crop demand, other vegetation, and evaporation has been calculated from remote sensing techniques (GEI, 2017; ITRC-METRIC) with periodic ground truthing. The District continues to use remote sensing methodology to further quantify consumptive use within the study area for monitoring (Land IQ, 2019). The Subbasin will continue to coordinate techniques and methodology for monitoring consumptive use to update water budget components for the Subbasin.

Exported Water, “Pump back” Water

The District monitors water that leaves the study area for banking partners or exchanges by metering or other gauging methods. These data are included in annual accounting of the water budget and will continue to be available in the future.

Subsurface Outflow

Historical quantities of groundwater outflow to the Subbasin underlying the study area have been estimated in various regional models, calculated in local studies by Darcian Law, and estimated by water budget accounting.

As the model of the study area is refined, groundwater outflow calculations may become more accurate. In addition, annual water budget accounting as well as semiannual water elevation monitoring, contouring and gradient estimating, will continue to provide data to support estimates of groundwater outflow.

4.2 Monitoring Network Design

The monitoring network design considers the use of existing monitoring networks, and the coverage required to monitor areas within the District with current and projected groundwater use. The network to be implemented is also designed to have new locations installed for data collection to fill pertinent data gaps in groundwater conditions.

The monitoring network is designed to collect data with respect to the applicable sustainability indicators in the study area: groundwater levels and reduction of groundwater storage, degraded water quality, and land subsidence. Seawater intrusion and interconnected surface waters are not applicable sustainability indicators in the study area, as described in the basin setting of this report, and are therefore, not included in the design of this monitoring network. A brief summary of the network design is introduced below. Details are provided in the sections on the monitoring of sustainability indicators.

4.2.1 *Monitoring Frequency Design*

The monitoring frequency is outlined in the protocols for monitoring sustainability indicators. In general, monitoring will occur semiannually for groundwater and monthly for land subsidence with co-located groundwater gauging. This frequency provides sufficient short-term, seasonal, and long-term data to evaluate the effectiveness of management actions.

4.2.2 *Spatial Density Design*

The spatial density of the monitoring network design accounts for general representative distribution in the district. The District's management area includes agricultural land, as well as the Cities of Delano and McFarland.

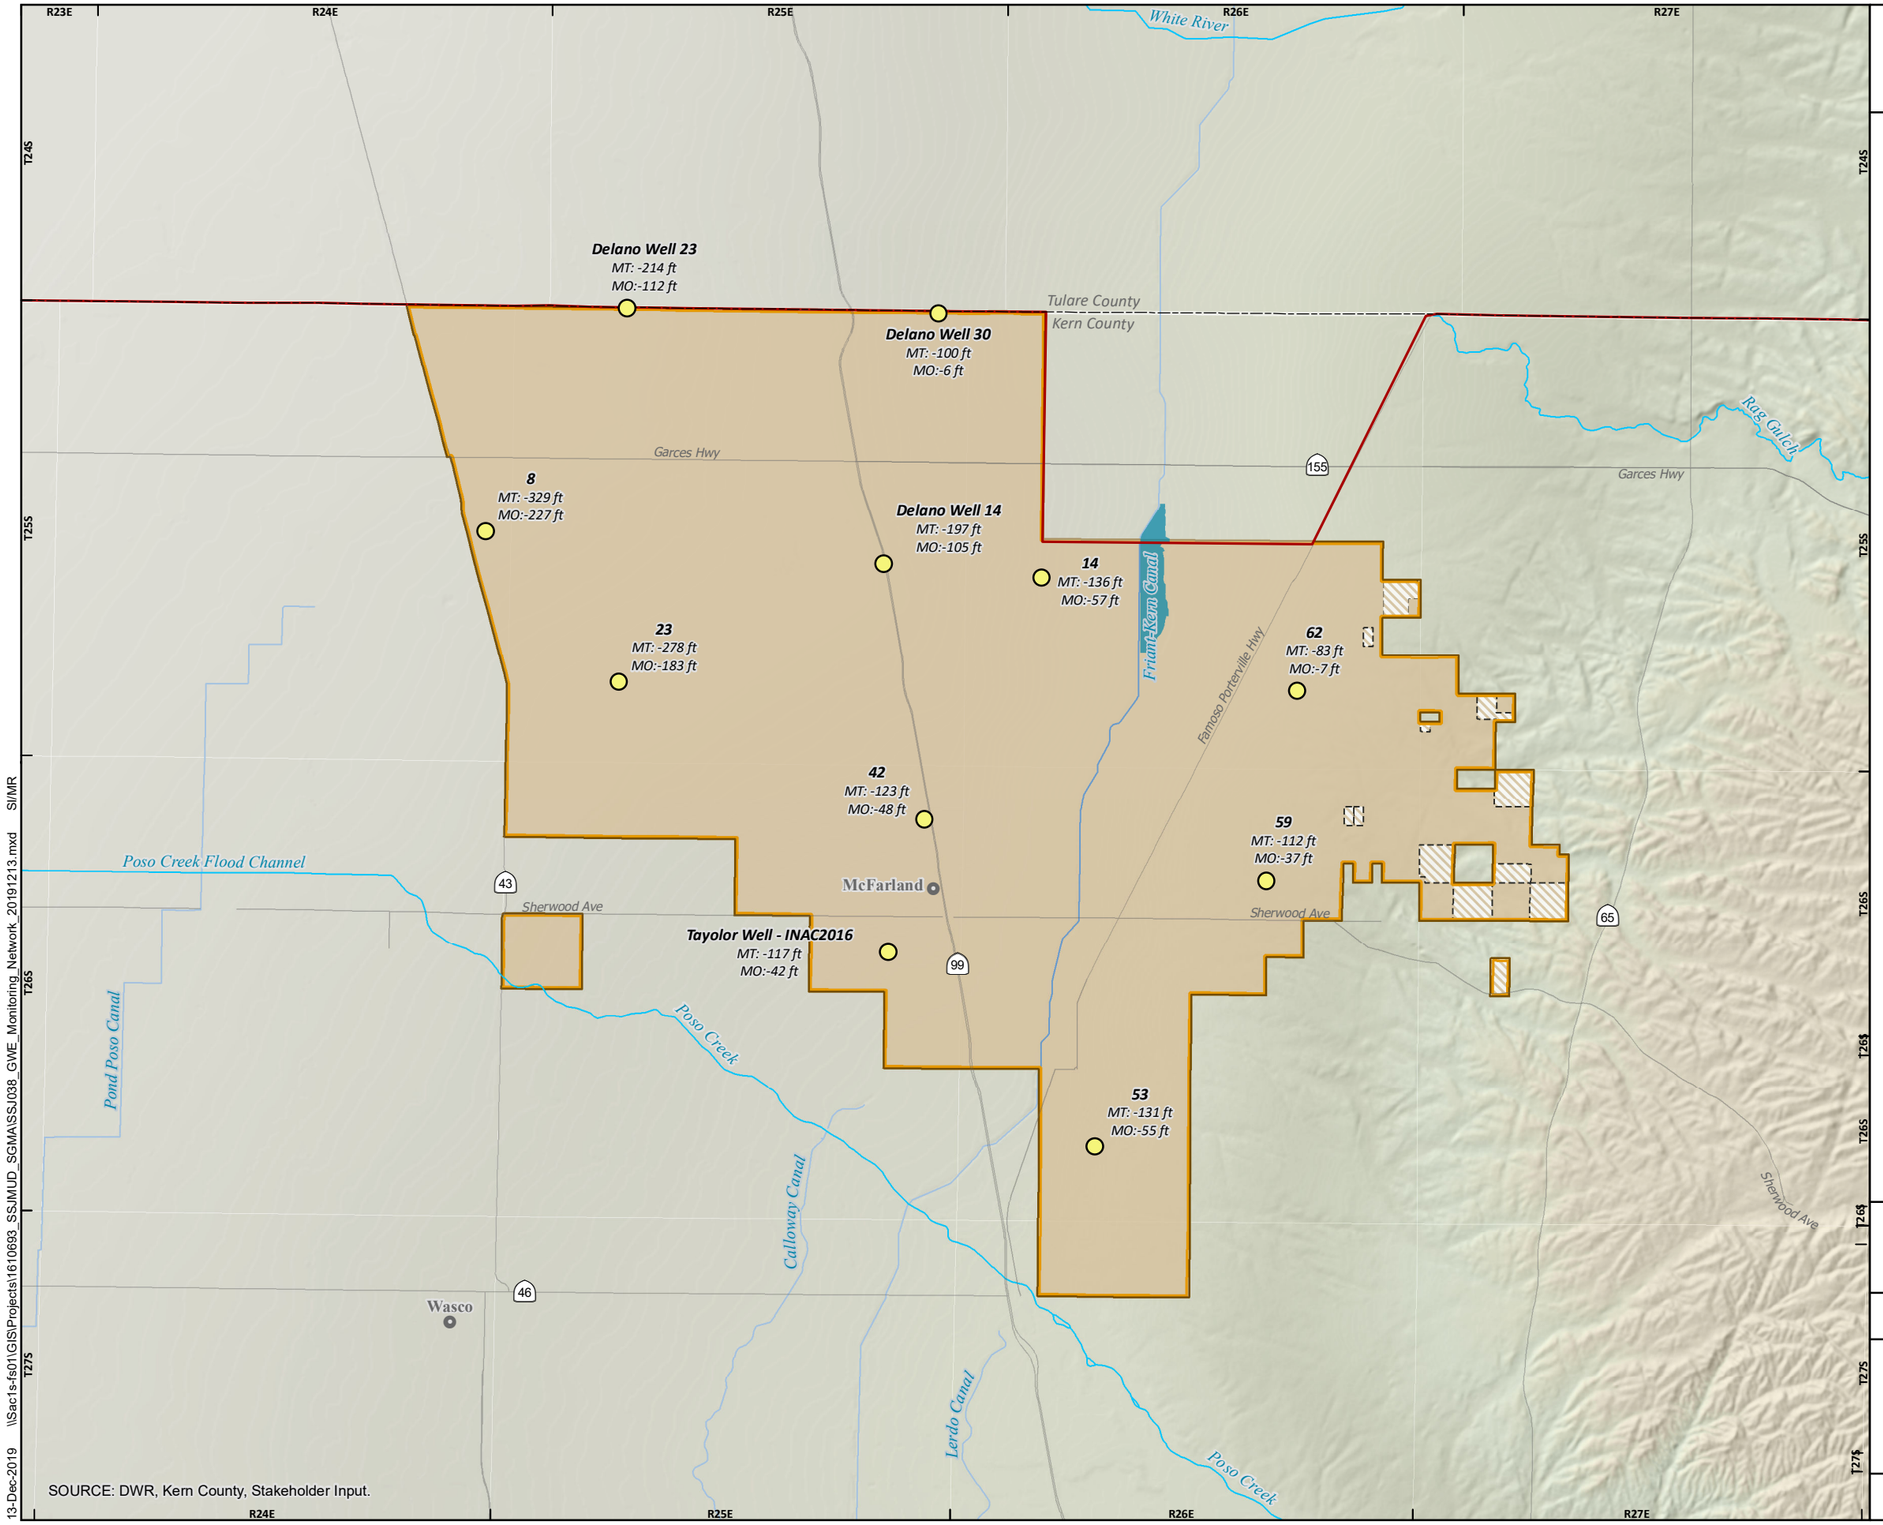
The spatial distribution of the water level monitoring sites is presented on Figure 4-1. For additional details on the spatial density for each of the monitoring sites, refer to the sections below on the monitoring of sustainability indicators.

4.2.3 *Rationale for Design*

Rationale regarding the design of the monitoring network is provided in the sections below dedicated to each sustainability indicator. In general, monitoring stations were chosen based on the following scientific rationale:

- Aquifer representation – Per DWR guidelines §354.34, monitoring wells were chosen to represent each underlying aquifer under the jurisdiction of the District
- Potential impacts to beneficial users of groundwater
- Availability of site-specific historical data and technical information
- Spatial and vertical representation
- Site accessibility

Additionally, monitoring stations were chosen based on providing suitable spatial density and representation of both agricultural and urban areas. Groundwater contour maps, hydrographs, land subsidence, and groundwater quality maps in the basin setting provide the background for current hydrogeologic conditions and where data gaps are located. Further discussion of data gaps is provided in the sections on sustainability indicators below.



4.3 Monitoring Network

4.3.1 *Chronic Lowering of Groundwater Levels and Reduction of Groundwater Storage*

SSJMUD network of wells for monitoring water levels, water quality, and groundwater storage changes are included on Table 4-3**Error! Reference source not found.** and Figure 4-1. Table 4-

3 provides about the well type, reference point elevation, etc. The wells selected are predominately CASGEM wells which will

be used as interim well sites for monitoring which will be gauged at a minimum frequency of two times per year (Spring and Fall). This frequency will capture the seasonal high and seasonal low conditions, per §354.34.

4.3.1.1 Rationale

The District's monitoring network design and site selection for monitoring the groundwater levels was based on the same rationale outlined in section 4.3.1 of this chapter. Since the District owns both agricultural production wells, and monitoring wells, an additional column has been added in the table to indicate the level of compliance with the DWR Best Management Practices guidelines for monitoring networks (DWR, 2016). The level of compliance has been categorized as Interim wells.

Interim wells (originally designed and constructed as agricultural production wells) were selected for the network to provide adequate spatial distribution until a permanent dedicated monitoring well can be installed. These interim wells generally have water level gauging data reported historically; however, not all of them have available well construction data. Interim wells selected were chosen based on spatial location to fill gaps in the monitoring network.

The monitoring network for each respective aquifer zone was considered where active groundwater production occurs and where aquifer zones are present. For example, as described in the basin setting of this chapter, no pumping for beneficial uses occurs in the upper zone and is therefore classified as de minimis; consequently, the monitoring network does not include any monitoring of this zone (refer to the basin setting of this chapter for details on extent of the Corcoran clay). Therefore, congruous to the pumping occurring in the aquifer zones, all wells included in this monitoring network will monitor the lower zone.

4.3.1.2 Monitoring Frequency

The monitoring network will be capable of collecting sufficient data to demonstrate seasonal, short-term (1 to 5 years) and long-term (5 to 10 years) trends in groundwater and related surface conditions and yield representative information about groundwater conditions as necessary to evaluate plan implementation. In general, water level monitoring will be seasonal to evaluate groundwater elevations during spring time (seasonal high prior to summer irrigation demands) and fall (seasonal low after the summer irrigation demands).

4.3.1.3 Spatial Density

In general, the monitoring network well density follows the recommendation of 4 to 10 wells per 100 square miles (DWR, 2016), in active groundwater production zones. Table 4-4 below lists the well density for the network with interim wells and with future installation of monitoring wells. The well density is listed in relation to the three management areas.

Table 4-4. Monitoring Network Well Density per Management Area (approximate)

Management Area	Area (Sq. miles)	Corresponding minimum number of wells recommended in DWR BMP	Monitoring wells included as part of the network
SSJMUD	101	4	11

4.3.1.4 Data Gaps

While the monitoring network provides a good spatial coverage of the entire District, the interim wells identified lack well construction details and require confirmation of perforation intervals. As referenced in § 352.4 of the regulations, *"If an Agency relies on wells that lack casing perforations, borehole depth, or total well depth information to monitor groundwater conditions as part of a Plan, the Agency shall describe a schedule for acquiring monitoring wells with the necessary information, or demonstrate to the Department that such information is not necessary to understand and manage groundwater in the basin."*

All supply wells included in the monitoring network lack well construction details and require confirmation of perforation intervals and annular seal details. The extents of the Corcoran clay (shown in the Basin Setting) was primarily used to determine where upper and lower aquifers exist and does not indicate with absolute certainty that a shallower aquifer does not exist in the central and east portions of SSJMUD. The description of steps to fill this data gap has been identified in section 4.5 below.

4.3.2 *Degraded Water Quality*

The District proposes to utilize the same network of wells that were identified as part of the groundwater level monitoring network.

4.3.2.1 Rationale

Since the District's monitoring network comprises wells for both water quality and water level monitoring, the same rationale elaborated in Section 4.3.1.1 applies here.

4.3.2.2 Spatial Density

As described in section 4.3.1.3 and evidenced in Table 4-4, the monitoring network well density follows DWR's BMP recommendation of 4 to 10 wells per 100 square miles, in active groundwater production zones.

4.3.2.3 Data Gaps

The data gaps identified in section 4.3.4.3 are also applicable here.

4.3.3 *Seawater Intrusion*

Seawater intrusion is not applicable to this management area plan.

4.3.4 *Land Subsidence*

The network of land subsidence monitoring is included on Table 4-5. The monitoring stations include those from the existing regional subsidence network, as discussed in the existing monitoring of the basin setting and umbrella section of the KGA GSP.

Table 4-5. Land Subsidence Monitoring

Type	Stations	Well Pair	Frequency	Source
Continuous GPS Stations	P564 Wasco P565 Delano Airport	26S-24E-36P 25S-25E-23	Daily to Monthly	UNAVCO PBS www.unavco.org Access data from: Instrumentation > Network Monitoring > Plate Boundary Observatory (PBO).
InSAR / UAVSAR	Remote Satellite Imagery		Monthly to Annually	Areal extent varies depending on dataset. Not always extensive across the Subbasin. Post-processing is required to use the data.
Survey Monuments	MP-116.94, MP-120, MP-124, MP-127		Event-specific	USBR, Friant-Kern Canal. (Coverage: SSJMUD and Tulare).

4.3.4.1 **Rationale**

Discrete monitoring stations are paired with water level monitoring points to record changes in land subsidence over time with respect to groundwater. The monitoring network is designed to take advantage of available data from CGPS and remote sensing sources. Most importantly, as the network consistently collects data for several years, an understanding of the long-term effects of groundwater extraction on local land subsidence will improve.

4.3.4.2 **Land Subsidence Spatial Density**

The District currently utilizes for monitoring, one CGPS station near Delano (P565), and one CGPS station located ~4 miles southwest of the District near Wasco (P564).

In addition, InSAR data has been used to evaluate land subsidence in between these monitoring points. However, the InSAR data historically has had large gaps over the District during certain time periods (example seen in the Basin Setting Figure 2-22).

In addition to the CGPS and InSAR data, benchmark locations along the Friant-Kern Canal exist in the northern, central and southeastern portions of the District where the Friant-Kern Canal and Poso creek intersect.

Future coordination with other Subbasin stakeholders will be critical to provide input on regional basin-wide remote sensing surveys to continue to provide coverage between subsidence monitoring points.

4.3.4.3 Data Gaps

The western and eastern portions of the District do not have discrete point stations for monitoring subsidence, rather InSAR regional data has been used. Based on InSAR data, these areas appear to experience greater subsidence relative to adjacent portions of the District where subsidence point stations are located. If deemed appropriate, in the future, installation of discrete point stations such as National Geodetic Survey (NGS) type concrete survey monuments or CGPS stations, may be useful control points to compare with InSAR data in the District.

4.3.5 *Depletion of Interconnected Surface Water*

Depletion of interconnected surface water is not applicable to the basin.

4.4 Monitoring Protocols and Reporting Standards

The District monitoring protocols for collection of groundwater levels and water quality samples will generally follow the Groundwater Monitoring Protocols, Standards, and Sites BMP produced by DWR (DWR, 2016a). The protocols and standards for monitoring and reporting requirements are provided below. For detailed description of monitoring protocols and reporting standards, please refer to the KGA GSP.

4.5 Monitoring Network Improvement Plan

A monitoring network improvement plan with an assessment of improvements is required every five years. This improvement plan contains areas of data gaps in the initial monitoring network, in which additional data or monitoring sites are needed.

The network assessment conforms with § 354.38 and is required for every five-year update. It includes:

- An evaluation of uncertainty of the data and whether there are data gaps including in the number of monitoring sites, the frequency of monitoring, and whether the monitoring stations comply with the minimum standards of a monitoring network.
- A description of the location and reason for data gaps in the network, and any local issues and circumstances that limit or prevent monitoring.
- A description of how data gaps will be filled before the next five-year assessment, including the location and purpose of newly added or installed monitoring sites.

- Plans for network revisions to adjust the monitoring frequency and density of monitoring sites to better assess the effectiveness of management actions, if there are:
    - Minimum threshold exceedances,
    - Highly variable spatial or temporal conditions,
    - Adverse impacts to beneficial uses and users of groundwater, or
    - The potential to adversely affect the ability of an adjacent basin to implement its Plan or impede achievement of sustainability goals in an adjacent basin.

4.5.1 *Assessment of Network Improvements*

An assessment of the monitoring network is provided below to discuss future improvements.

4.5.1.1 Water Level, Groundwater Storage, and Water Quality Monitoring Network Assessment Plan

As indicated previously in the data gaps section, construction details of the interim wells need to be determined to improve on the monitoring network. This will be mitigated by conducting downhole well surveys and desktop surveys to fill in the well construction details gap.

Within the next 5 years, the plan to fill data gaps in the water level monitoring network include:

- Coordinate with cities for access to use wells in monitoring network.
- Assess if interim wells are compliant with monitoring well standards.
- Assess the feasibility of a future permanent well installation to fill the data gaps in the management area coverage.
- Rank or prioritize future installation sites and reject any redundant monitoring sites if any.
- Assess the need to increase coverage of the future monitoring network, further than currently recommended.
- Finalize future monitoring network and develop a schedule for station installation.
- Continue evaluating the monitoring network for data gaps.

4.5.1.2 Land Subsidence Network Assessment Plan

As described in the data gaps section of the land subsidence network, the western portion of the District does not currently have discrete point stations for monitoring subsidence. Rather, InSAR regional data has been used to provide coverage between discrete monitoring stations. Additional monitoring of subsidence in the west is needed to better evaluate land subsidence as a sustainability indicator.

Based on InSAR data, the data near the CGPS point appears relatively similar for an analysis of one time period and is missing data for another, seen in Basin Setting. If deemed appropriate, in

the future, installation of discrete point stations such as NGS-type concrete survey monuments or CGPS stations, may be useful control points to compare with InSAR data in the west and east parts of the District.

Alternatively, as described in the Basin Setting, various groups have or are comparing InSAR data with monitoring point stations (CGPS and extensometer) to evaluate the effectiveness of using InSAR in lieu of monitoring stations. A better understanding and continued monitoring of subsidence by remote sensing such as InSAR and point station data are needed to further this evaluation.

It is anticipated that the Friant-Kern Canal benchmarks may also be useable as interim monitoring stations with coordination between the District, Friant Water Authority, and USBR.

As described in the Basin Setting, reduction in storage as potentially an undesirable result, has been documented from land subsidence in the San Joaquin Valley. In order to evaluate potential changes in storage, water level data with subsidence data from stations such as CGPS are needed. This evaluation requires reliable co-located groundwater monitoring stations within the vicinity of the subsidence stations.

Plan to fill Data Gaps

Within the next 5 years, the plan to fill data gaps in the subsidence monitoring network include:

- Coordinate with Friant Water Authority and USBR on the use of the Friant-Kern Canal benchmarks as interim monitoring sites.
- Evaluate future benchmark monitoring sites co-located with the future well monitoring network, especially in the western portion of the District, where monitoring stations are not currently present.
- Assess the adequacy of nearby interim wells and future monitoring wells as co-located water level monitoring stations with CGPS, to better evaluate water levels with subsidence monitoring data. Collect data and evaluate the need for installing a well closer to CGPS station.
- Continue to collect data to evaluate InSAR data in relation to discrete point stations, to assess the feasibility of using InSAR or other remote sensing data as a supplement for data gaps in the monitoring station network.

This Page Left Blank Intentionally

5. Projects, Management Actions, and Adaptive Management

5.1 Sustainability Goal

The sustainability goal of the District is to balance the average annual inflow and outflow of water in the district so that a negative change in groundwater storage does not occur; thus, preventing the lowering of groundwater levels beyond 2040. This section describes projects and management actions to meet this sustainability goal for SSJMUD in a manner that can be maintained over the planning and implementation horizon. The projects and management actions presented here represent the best available engineering and analysis completed to-date. This list will be updated throughout the planning and implementation period to reflect analyses and new emerging opportunities.

5.2 Projects and Management Actions Processes

The following sections describe the processes required for projects and management actions to be implemented, the sustainability indicator(s) addressed and an overview of the expected benefits. A summary list of the projects and management actions considered by SSJMUD are provided in Table 5-1 at the end of this Section.

5.2.1 *Goals and Objectives*

Per Section 354.44 of the GSP emergency regulations, plans are to include projects and management actions to address any existing or potential undesirable result for the identified relevant sustainability indicators. SSJMUD plans to implement projects and management actions that will meet the measurable objectives of the following sustainability indicators: (1) chronic lowering of groundwater levels, (2) reduction of groundwater storage, (3) degraded water quality, and (4) land subsidence.

Implementation of each project and management action will address the chronic lowering of groundwater levels. Since groundwater levels are used as proxy for identifying undesirable results in groundwater storage, groundwater quality, and land subsidence, each project and management action may also address the other three sustainability indicators. Tables 5-1 provides an indication of the sustainability indicators that may be addressed by the proposed management action.

5.2.2 *Circumstances for Implementation*

Given the circumstances of conditions described in the basin setting of this management area plan, SSJMUD has already begun implementation of certain projects and management actions. Projects and management actions will be implemented as seen fit by the District and certain

management actions will be implemented as early as 2020 following the adoption of this management area plan. Other management actions will be implemented following the development of the appropriate plans to be approved by the SSJMUD Board of Directors.

When feasible, the District will construct projects to bring in supplemental water to the Subbasin and implement management actions to reduce pumping of groundwater. Table 5-1 provides a timeline for each management action's implementation and the circumstances for which each will be implemented.

5.2.3 *Public Notice*

The public notice and outreach processes for the District consist of notified public board meetings, discussion with landowners within the District's boundaries, and the CEQA process each project and management action may undergo before implementation. SSJMUD provides public noticing by posting all board meeting notices, agendas, and minutes on its website (see Section 1.2) according to the Brown Act.

5.2.4 *Permitting and Regulatory Processes*

Permitting and regulatory requirements vary for the different projects and management actions SSJMUD plans to implement. While these requirements are similar for the District's project and management actions, specific requirements will depend on the type of project, which could be recharge and infrastructure projects as well as administrative actions that incentivize reduced groundwater pumping. The following is a list of the types of permitting at the federal, state, and county level that could apply, but not necessarily, to all management actions:

- Federal
    - If federal grants are used, National Environmental Policy Act (NEPA) documentation is required
    - National Pollution Discharge Elimination System (NPDES) stormwater program permit
- State
    - California Environmental Quality Act (CEQA) documentation is required for all project and management actions.
        - These documents include one or more of the following: Initial Study, Categorical Exemption, Negative Declaration, Mitigated Negative Declaration, and Environmental Impact Report;
- Regional
    - San Joaquin Valley Air Pollution Control District (SJVAPCD) permit and regulations

Table 5-1
Proposed list of Projects and Management Actions for Southern San Joaquin MUD

P/MA Number	P/MA Name	Summary Description	Relevant Sustainability Indicators Affected			Cirumstance for Implementation	Public Noticing Process	Permitting and Regulatory Process Requirements	Status	Timetable / Circumstances for Initiation	Timetable for Completion	Timetable for Accural of Expected Benefits	Expected Benefits				Source(s) of Water, if Applicable	Legal Authority Required	Estimated Costs		
													Primary		Secondary						
			Goundwater Levels and Storage	Goundwater Quality	Land Subsidence								Water Supply Augmentation	Water Demand Reduction	Water Quality Improvement	Water Management Flexibility / Efficiency			One-time Costs	Ongoing Costs (per year)	Potential Funding Source(s)
1	City of Delano Spreading Grounds	Improvements to existing 16-acre stormwater retention basin for use as a spreading basin. Improvement to adjacent 32-acre site for expansion of spreading grounds.	•		•	Pilot phase operation underway. Permanent implementation upon completion of CEQA.	SSJMUD Meetings & Webiste	NPDES, Dust Control Plan, CEQA	Initiated	2020	2021	Through 2040	500 AFY		TBD	TBD	CVP Contract Water and Surplus Water	District / SGMA authorities	$ 450,000	TBD	Grant/ District/ City of Delano
2	In-District Spreading and Recovery Facility	80-acre spreading ponds and 2 recovery wells	•		•	Implementation upon Acquisition of Land and completion of CEQA	SSJMUD Meetings & Webiste	NPDES, Dust Control Plan, CEQA	Initiated	2020	2022	Through 2040	2,800 AFY				CVP Contract Water	District / SGMA authorities	$ 1,664,491	TBD	Grant/ District
3	Schuster Intertie	Construction of pipeline between Semitropic and SSJMUD to proivide operational flexibility and allow SSJMUD to import more supplies to the Subbasin.	•		•	Upon completion of development	SSJMUD Meetings & Webiste	CEQA, County LUP, Road Encroachments, NEPA (if federal	Conceptual	2020	2022	Through 2040	1,811 AFY		TBD	TBD	CVP Contract Water	District / SGMA authorities	$ 2,500,000	TBD	Grant/ District
4	SSJMUD & Cawelo WD Intertie	Construction of pipeline between Cawelo and SSJMUD to proivide operational flexibility and allow SSJMUD to import more supplies to the Subbasin.	•		•	Upon completion of development	SSJMUD Meetings & Webiste	CEQA, County LUP, Road Encroachments	Conceptual	2022	2025	Through 2040	500 AFY		TBD	TBD	CVP Contract Water	District / SGMA authorities	$ 5,000,000	None	Grant/ District
5	SSJMUD & NKWSD 9-28 Intertie	Construction of pipeline to connect SSJMUD's existing system to NKWSD to provide opertational flexibility to absorb delivered surface water	•		•	Upon completion of development	SSJMUD Meetings & Webiste	CEQA, County LUP, Road Encroachments	Conceptual	2022	2025	Through 2040	4,284 AFY		TBD	TBD	CVP Contract Water and Surplus Water	District / SGMA authorities	$ 2,000,000	TBD	Grant/ District
6	Souteast Delano Spreading Grounds	Conversion of land to permanent spreading grounds, up to 320 acres, to facilitate groundwater recharge in proximity to the City of Delano to the benefit of both the district and the city.	•		•	Implementation upon Acquisition of Land and completion of CEQA	SSJMUD Meetings & Webiste	NPDES, Dust Control Plan, CEQA	Initiated	2020	2022	Through 2040	2,640 AFY		TBD	TBD	CVP Contract Water and Surplus Water	District / SGMA authorities	$ 8,000,000	TBD	Grant/ District/ City of Delano
7	Pond Road Spreading Grounds	Conversion of land to permanent spreading grounds, up to 220 acres in proximity to the FKC, to capture and utilize excess surface water deliveries.	•		•	Implementation upon Acquisition of Land and completion of CEQA	SSJMUD Meetings & Webiste	NPDES, Dust Control Plan, CEQA	Conceptual	2020	2025	Through 2040	1,840 AFY		TBD	TBD	CVP Contract Water and Surplus Water	District / SGMA authorities	$ 6,000,000	TBD	Grant/ District
8	In-District Spreading Grounds	Conversion of land to permanent spreading grounds, up to 800 acres, to facilitate groundwater recharge. This project would consist of multiple locations throughout SSJMUD identified as potential recharge sites.	•		•	Implementation upon Acquisition of Land and completion of CEQA	SSJMUD Meetings & Webiste	NPDES, Dust Control Plan, CEQA	Conceptual	2020	2030	Through 2040	9,600 AFY		TBD	TBD	CVP Contract Water and Surplus Water	District / SGMA authorities	$ 44,000,000	TBD	Grant/ District
9	Conversion of Dairy to Recharge Facility	Conversion of land previously used for dairy operations into permanent recharge facilities.	•		•	Implementation upon Completion of Feasibilty Study, Acquisition of Land and completion of CEQA	SSJMUD Meetings & Webiste	NPDES, Dust Control Plan, CEQA	Conceptual	2020	2030	Through 2040	TBD		TBD	TBD	CVP Contract Water and Surplus Water	District / SGMA authorities	TBD	TBD	Grant/ District
10	"Surface Water First" Incentive Program	Implementation of fees for groundwater use when surface water is available.	•		•	Upon adoption of this plan and development of District program	SSJMUD Meetings & Webiste	Board Approval	Conceptual	2020	2020	Through 2040	None	1,800 AFY	TBD	TBD	Existing surface water supply	District / SGMA authorities	None	None	None
11	On-Farm Efficiency/Deficit Irrigation Practices Incentive Program	Improvements to individual farming operations that address water use efficiency and/or groundwater protection through incentive programs.	•		•	Upon adoption of this plan	SSJMUD Meetings & Webiste	SB 7, AB 1668, and SB 606	Conceptual	2020	2025	Through 2040	None	TBD	None	None	No additional supply required	District / SGMA authorities	TBD	TBD	District
12	Refinement of Water Budget Components	Improvement of monitoring and measurements to refine the accuracy of measurement or calculation of inflow and outflow components of district-level water budget. Will also refine Subbasin Model and water budget.	•			Ongoing	SSJMUD Meetings & Webiste	None	Ongoing	Ongoing	TBD	Through 2040	TBD	TBD	TBD	TBD	No additional supply required	District / SGMA authorities	TBD	TBD	District
13	Conversion of Agricultural Land to Urban Use	Conversion of agricultural land to urban use within the limits of each city to reduce groundwater use due to the decreased demand.	•		•	Ongoing	SSJMUD Meetings & Webiste	County zone change, CEQA	Ongoing	Ongoing	TBD	Through 2030	None	1750 AFY	TBD	TBD	No additional supply required	District / SGMA authorities	TBD	TBD	Landowners and Cities

- Local/County
    - Encroachment permits;
    - Kern County grading permit;
    - Kern County well permit;
    - Kern County supplemental well permit.

5.2.5 *Implementation and Timetable Status*

The current status of each project and management action is included in Table 5-1. Since most projects and management actions are in the conceptual phase of development, timeline for implementation is estimated and subject to change depending on project need and supplemental water availability. SSJMUD will begin to implement management actions to reduce groundwater extractions as soon as 2020 and will continue to implement based on their estimated timeline.

The status of each project and management action is also provided in Table 5-1. Each project and management action are designated as follows:

Conceptual: The project or management action is identified but has not undergone significant planning, engineer or feasibility analyses.

Not yet started: This project or management action as undergone some initial evaluations but has advanced to an implementation phase. The management action will likely require additional feasibility analyses.

Initiated: The project or management action has undergone initial planning and feasibility assessments and being advanced to implementation.

Ongoing: The project or management action is part of an ongoing effort by the District and will continue to be implemented to meet the sustainability goals of the District.

5.2.6 *Expected Benefits*

Table 5-1 provide the estimated benefits for each project and management action the Districts plan to implement. As previously stated, most of the proposed actions are in their conceptual phase of development; therefore, a range has been provided for the estimated benefits each action is expected to yield.

5.2.7 *Source and Reliability of Water Outside of SSJMUD*

SSJMUD will bring in supplemental water from outside the District to support projects and management actions. While not all projects and management actions require source water from outside the district, there are several that do. As discussed in Section 2 of this management area plan, SSJMUD's primary source of water is supplied by the CVP which will help support existing and future projects and management actions in the District. In addition, the District will be seeking other sources of water and will continue to participate in various surface water

transfer and exchange programs as well as explore purchasing markets in the Central Valley to support their effort to achieve groundwater sustainability by 2040.

5.2.8 *Legal Authority Required*

SSJMUD is a member agency under the KGA GSA. Under the JPA with KGA, each district maintains its authority over in-district services and projects. Thus, SSJMUD has the legal authority to implement projects and management actions in order to achieve groundwater sustainability.

5.2.9 *Estimated Costs and Funding*

As previously stated, most of the projects and management actions are in their conceptual phase of development; therefore, costs may not be available. Where costs have been estimated, they are subject to change as the project or management action undergoes more detailed analysis.

With regard to funding, the District has been successful in securing grants through various government agencies for past projects. The District will continue these efforts and apply for various funding sources at all levels of government in order to implement project and management actions.

5.3 SSJMUD Projects Planned Regardless of Conditions

Given the circumstances of conditions described in the basin setting, the District may implement projects as early as 2020. SSJMUD has identified the following projects to accomplish groundwater sustainability:

- In-District Spreading and Recovery Facility
- SSJMUD and Semitropic Schuster Intertie
- SSJMUD and CWD Intertie Pipeline
- SSJMUD and North Kern WSD 9-28 Intertie Pipeline
- Southeast Delano Spreading Grounds
- City of Delano Spreading Grounds
- Pond Road Spreading Grounds
- In District Spreading Grounds
- Conversion of Dairy to Recharge Facility

5.3.1 *City of Delano Spreading Grounds*

SSJMUD proposes identifying and evaluating potential land suitable for developing recharge basins, with possible purchase with private and/or public partnering agencies within the City of Delano. The purpose of this project is to capture surface water deliveries that are delivered

through the FKC. Excess available surface supply, or those flows beyond the quantity of water that satisfies immediate water demand within a service area, typically occurs in wet years when precipitation in contributing watersheds is large enough to induce surface water available above Friant Class 1 contract supplies. Potential flows to capture consists of water which is currently discharged during wet years, during flood conditions and for water that needs to be delivered due to changes in timing to meet environmental water management goals for the San Joaquin River Restoration.

Any purchased land holdings under this project would be converted to dedicated spreading ponds, used to hold recharge delivered water into the groundwater basin. To that extent, conveyance from the Friant-Kern Canal to any spreading ponds will be constructed using pipe and/or canal systems, as well as conveyance pumping stations.

5.3.2 *In-District Spreading and Recovery Facility*

This project will include construction of 80-acres of spreading ponds and the installation of two recovery wells within district boundaries. The proposed recharge ponds have an anticipated annual capacity of 3,240 AFY. SSJMUD will realize an estimated recoverable volume of 2,800 AFY from this project. Prior to this project, the district has not had any in-district direct recharge facilities. Implementation of this project will allow SSJMUD the opportunity to capitalize on wet period storage of CVP supplies and allow them to bypass less favorable out-of-district banking agreements to store water that would increase the District's and the Subbasins water reliability and drought resiliency.

5.3.3 *SSJMUD and Semitropic Schuster Intertie*

The proposed project is to construct an intertie in coordination with SWSD. This pipeline will allow for SSJMUD to bank or return water to SWSD previously delivered to SWSD's groundwater banking program. SSJMUD would be able to deliver wet period water from the FKC for groundwater banking to SWSD and able to return water to SSJMUD for irrigation purposes during dry years.

This Project removes the need to involve a third-party in an agreement with SWSD for banking since it establishes a direct connection to return water to SSJMUD from SWSD, thereby increasing operational flexibility and reliability to deliver previously stored water from groundwater storage at times of drought. If federal funding is secured for this project, NEPA will also need to be considered as part of the permitting and regulatory process.

5.3.4 *SSJMUD and CWD Intertie Pipeline*

SSJMUD and CWD propose to construct a bidirectional intertie connecting their respective water conveyance systems. This pipeline is a regional opportunity to improve flexibility, reliability, and conjunctive use of water supplies.

A primary benefit is the improved access each District will have to each other's contract supply. The pipeline will allow SSJMUD, a CVP water contractor, and CWD, a Kern River and SWP water contractor, to more easily exchange contract surface supplies to meet their immediate agricultural demand. With the increasing uncertainty of surface supplies, the ability to efficiently exchange and obtain supplies from different sources has also become increasingly important. Benefits provided by the intertie are further shared with nearby districts, as other water management strategies occur such as multi-district water transfers and groundwater banking. If federal funding is secured for this project, NEPA will also need to be considered as part of the regulatory and permitting process.

5.3.5 *SSJMUD and North Kern WSD 9-28 Intertie Pipeline*

Project proposal includes the construction of the 9-28 Intertie pipeline with NKWSD. This pipeline will allow for the return of CVP Class I, Class II, and surplus floodwater that was previously delivered to the District's groundwater banking partner (NKWSD) from the FKC for groundwater banking or irrigation purposes during wet years. The pipeline is the conveyance mechanism for return of previously stored water to the District during dry years.

This project removes the need to involve a third-party in an agreement with North Kern for banking since it established a direct connection to return water to SSJMUD from NKWSD, thereby increasing operational flexibility and reliability to deliver previously stored water from groundwater storage during times of drought. If federal funding is secured for this project, NEPA will also need to be considered as part of the regulatory and permitting process.

5.3.6 *Southeast Delano Spreading Grounds*

SSJMUD proposes the purchasing of land holdings, with possible partnering agencies (to be identified later), in and around the eastern most portion of the District. The District is currently exploring the potential for capturing excess surface water deliveries in the FKC. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand, typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class I contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.

Any purchased land holdings under this project would be converted to dedicated spreading ponds, used to hold recharge delivered water into the groundwater basin. To that extent, conveyance from the FKC to any spreading ponds will be constructed using pipe and/or canal systems, as well as conveyance pumping stations.

Implementation of this project has the potential for contributing water supplies to SSJMUD, the City of Delano (which qualifies as a DAC), and Poso Creek IRWM water users. Specifically, SSJMUD will use a portion of these captured flows to offset their groundwater use in dry years by moving the surplus water to this banking facility using either the FKC or other existing infrastructure. Wet year water supplies captured in the spreading grounds and storage locations

will be utilized by SSJMUD, City of Delano, and potentially other Poso Creek stakeholders, during years where other water supplies are limited. Depending upon the scale of the project, the anticipated benefits range from 247 AFY for a 30-acre site to 2,640 AFY for a 320-acre site.

5.3.7 *Pond Road Spreading Grounds*

SSJMUD proposes identifying and evaluating potential land holdings to be purchased, with possible private and/or public partnering agencies. The District is currently exploring the potential for capturing excess surface water deliveries in the Friant-Kern Canal. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand, typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class 1 contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.

Any purchased land holdings under this project would be converted to dedicated spreading ponds, used to hold recharge delivered water into the groundwater basin. To that extent, conveyance from the FKC to any spreading ponds will be constructed using pipe and/or canal systems, as well as conveyance pumping stations.

5.3.8 *In-District Spreading Grounds*

SSJMUD proposes identifying and evaluating potential land holdings to be purchased, with possible private and/or public partnering agencies. The District is currently exploring the potential for capturing excess surface water deliveries in the FKC. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand, typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class 1 contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.

Any purchased land holdings under this project would be converted to dedicated spreading ponds, used to hold recharge delivered water into the groundwater basin. To that extent, conveyance from the FKC to any spreading ponds will be constructed using pipe and/or canal systems, as well as conveyance pumping stations.

5.3.9 *Conversion of Dairy to Recharge Facility*

SSJMUD proposes identifying and evaluating potential purchase of a dairy, with possible private and/or public partnering agencies. The District is currently exploring the potential for capturing excess surface water deliveries in the FKC. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand, typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class 1 contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.

Any purchased land holdings under this project would be converted to dedicated spreading ponds, used to hold recharge delivered water into the groundwater basin. To that extent, conveyance from the FKC to any spreading ponds will be constructed using pipe and/or canal systems, as well as conveyance pumping stations. Before eventual conversion to spreading grounds, the dairy facility will be replaced by alfalfa fields, with the view of removing nitrates from the soil and improving infiltration with the alfalfa root system.

In addition to the development of the a CEQA document, the use of former dairy waste discharge ponds may require review and approval by the Central Valley RWQCB to ensure that degradation of groundwater quality in the proposed project area does not occur. A soils and groundwater sampling plan, report of findings and analysis, and a remediation plan and report may be required prior to the use of the former dairy site for groundwater recharge.

5.4 Management Actions Planned for Groundwater Sustainability

Per Section 354.4 of the GSP emergency regulations, the following sections details the managements actions SSJMUD will take to achieve groundwater sustainability by 2040. The district has identified the following management actions:

- In-Lieu Recharge Incentive Program
- On-Farm Efficiency/Deficit Irrigation Practices Incentive Program
- On-Farm Recharge Activities Incentive Program
- Conversion of Agricultural Land to Urban Use
- Urban Water Conservation Program
- In-District Allocation Structure
- Voluntary Land Fallowing
- Pumping Restrictions

5.4.1 *In-Lieu Recharge Incentive Program*

SSJMUD has access to imported surface water to supply its jurisdictional area. However, there are instances in which growers have historically opted to pump groundwater, rather than receiving deliveries of surface water from the district which services their properties. When this occurs, the district must either use that water for groundwater recharge or enter into exchanges with other districts (either in this Subbasin or in another basin).

While this may be an economic decision for the grower, it has the potential to cause local impacts to groundwater in the district over the long-term. To prevent local impacts to groundwater due to the use of groundwater over available surface water, the districts may explore a fee structure in which growers with access to surface water may be assessed for the use

of groundwater when surface water is available for use. The fees collected for such activities would be applied to the expansion of existing recharge projects or the development of new recharge projects to accommodate the additional surface water that would be brought into the district to replace the additional groundwater pumped.

The adoption of an incentive program would require approval of a district's Board of Directors. No additional permitting would be required for this management action because it does not change existing uses of land or infrastructure within the district.

5.4.2 *On-Farm Efficiency/Deficit Irrigation Practices Incentive Program*

As an agricultural water service provider, SSJMUD complies with all provisions of SB 7 (amending Division 6, Part 2.55 of the Water Code) passed into law in November 2009 regarding agricultural water conservation and management. Efficient management practices in the law, related to SGMA objectives, include volumetric water pricing, incentives for conjunctive use and increased groundwater recharge, and development of an overall water budget. AB 1668 and SB 606 passed in 2018 did not materially add to these objectives, save for those districts serving between 10,000 and 25,000 acres who must now prepare water management plans under the newer laws.

While these new laws do not require water use objectives or savings thresholds, they do encourage more efficient use of water by the agricultural sector and its suppliers. SSJMUD will encourage improvements to individual farming operations that address water use efficiency and/or groundwater protection through incentive programs.

5.4.3 *Refinement of Water Budget Components*

In addition to the implementation of this management area plan, and the monitoring and measurement described herein, the districts may consider additional improvements to refine the accuracy of the measurement or calculation of inflow and outflow components of their water budgets. The scope of these improvements is yet to be determined, but it may include improved ET measurement to further refine the calculation of consumptive water use, improved weather data to provide more accurate precipitation volumes, refinement of subsurface flow volumes using groundwater level data and local hydrogeologic data, and improved estimation of surface runoff. These efforts would culminate in the improvement of the Kern County Subbasin Model, which is used as a coordinated subbasin-wide water budget. This management action is conceptual; a volume of water associated with this management action has not been calculated.

5.4.4 *Land Conversion from Agricultural Use to Urban Use*

As described in the General Plans for the cities of Delano and McFarland, anticipated population growth is expected to lead to changes in land use within the limits of each city and in the Sphere of Influence for each city. The conversion of land use from agricultural to urban use generally leads to an overall reduction in groundwater use due to the decreased demand, in terms of

volume per unit area. The City of Delano and the surrounding areas have a projected increase of 2,100 acres in urban use; the City of McFarland and its surrounding areas have a projected increase of 1,100 acres.

While these areas are described as part of each city's Sphere of Influence in their respective General Plans, the lands which are anticipated to convert from irrigated agricultural use to urban use are still zoned for Agricultural use in either the city or county zoning. In order to develop these lands for urban use, the land would have to be re-zoned for the proposed, non-agricultural use.

The conversion of land use from agricultural to urban is an ongoing process, the pace of which is determined by external factors such as the demand for land based on each city's growth and need for additional housing and/or property to support business, industrial, or municipal use. The projected growth for each city is based upon the current General Plans and may be subject to change when the cities update their respective plans.

5.4.5 *Urban Water Conservation Program*

As referenced in the Umbrella Basin Setting (Chapter 2), urban water usage in the future is expected to comply with the conservation mandates contained in SB 606 and AB 1668, both bills signed into law in May 2018. Based on that legislation, indoor residential use is to be capped at 55 gpcd in 2019 and ramp down to 50 gpcd by 2030, and outdoor residential use is to be capped in the future based on local climate and size of landscaped areas. Standards for outdoor usage are to be defined in a SWRCB rule-making process to be completed by June 2022.

Urban water conservation compliance currently derives from SB 7X-7 passed in 2009 (Water Conservation Act of 2009), and the UWMP for Delano, along with associated ordinances, reflect that Act's mandates of a 20% reduction in urban per capita water usage by 2020. While McFarland is not currently required to prepare a UWMP, projected population growth and expansion of its service area will require the preparation and implementation of an SB 7X-7 compliant plan. Future achievements in urban conservation will be as derived from the passage of AB 1668 and SB 606 in 2018. Future amendments to UWMPs and modified ordinances of both cities will eventually embody these recent laws.

5.4.6 *Mitigation Program for Potential Impacts to Domestic Wells*

In the use of projected groundwater elevation contours to establish SMCs based on recent hydrologic conditions, the districts using this method observed that there are potential impacts to shallow domestic wells resulting from the establishment of SMCs which allow for groundwater levels to fall below the historically lowest elevations. To mitigate these impacts the Districts, in coordination with other KGA members, will develop a mitigation program to offer financial assistance for the replacement of domestic wells which are impacted by groundwater management to the proposed SMCs. The KGA members will also develop eligibility criteria for the proposed mitigation program which would help determine if the impacts are a result of the

plan's implementation or have some other cause. Since this management action is conceptual, a volume of water associated with this management action has not been calculated. The implementation of this management action is dependent upon the coordination of the elements of the program, including the funding mechanism, and the approval of the districts' respective boards.

5.4.7 *In-District Allocation Structure*

At the time of this draft of the District's management area plan, SSJMUD does not have an established allocation structure and fee schedule for groundwater extraction. As SGMA is implemented throughout the Subbasin, the districts are required to manage to the sustainable management criteria established in Section 3 of this management area plan. One of the ways to manage for the sustainable management criteria (SMC) is to allocate the Sustainable Yield for their respective districts to the landowners within their districts. The allocation structure would allow for the transfer of groundwater pumping credits within each district's jurisdiction, provided that it does not lead to localized impacts to at the representative monitoring sites defined in Sections 4 of this management area plan.

While the specifics of such an allocation structure may vary between the districts, a baseline groundwater extraction volume would be allocated to each parcel based on its size and the Sustainable Yield for the district. If a landowner were to extract more water than the baseline volume for that parcel or for the aggregate of all of their parcels within the district, they would be required to pay an extraction fee which would be applied toward projects and programs implemented by the district to reach and/or maintain sustainability.

5.4.8 *Voluntary Land Fallowing*

In the event of a drought, the District may not be able to entirely meet in-district demand by increasing the volume of imported water. The combination of decreased availability in surface water to supply to the district and decreased recharge from other sources in the Subbasin has the potential to lead to violations of sustainable management criteria at the representative monitoring sites, in the absence of decreased demand. To facilitate the district's ability to maintain sustainability at its monitoring sites, the district will develop and implement a voluntary land fallowing program.

The District will be required to develop the guidelines for eligibility and the terms of the program, prior to submitting them to the board for adoption. This will also include the determination of funding and for the program and in-district outreach.

5.4.9 *Pumping Restrictions*

In the event that the districts or the entire Subbasin are nearing a condition where they are at risk of triggering an undesirable result, even with the implementation of the projects and management actions described in this Plan, it may be necessary for the district to limit groundwater pumping.

The volume of groundwater extraction permitted under this Management Action would be determined by the district based on the Sustainable Yield for the district and the SMC at the Representative Monitoring Sites.

5.5 Summary

A summary list of the projects and management actions considered by SSJMUD is provided in Table 5-1.

Appendix A

Joint Powers Authority Agreement

KERN GROUNDWATER AUTHORITY
FOR THE TULARE LAKE BASIN PORTIONS OF KERN COUNTY
AMENDED AND RESTATED JOINT POWERS AGREEMENT

THIS AMENDED AND RESTATED AGREEMENT ("Agreement") is made and effective as of March 22, 2017, pursuant to the Joint Exercise of Powers Act (Government Code Sections 6500, *et seq.*) by and between the public agencies listed on the attached Exhibit A.

This Agreement is made with reference to the following facts and understandings.

A. Each of the parties to this Agreement (the "Members") provides water service to landowners and/or residents and/or provides water to retail water entities within its respective service area and the County of Kern has various oversight and active roles relative to water resources within the County, including, but not limited to, flood control, police powers, and water service.

B. Pursuant to a Joint Powers Agreement dated as of May 27, 2014 (the "Original Agreement"), the Kern Groundwater Authority (the "Authority") was created to carry out the purposes of Part 2.75 of Division 6 (commencing at Section 10750 of the California Water Code) and develop, adopt and implement a groundwater management plan that would be available to those lands within the boundaries of the Authority's members and within the Tulare Lake Groundwater Basin.

C. On August 29, 2014, the California Legislature passed comprehensive groundwater legislation contained in SB 1168, SB 1319 and AB 1739. Collectively, those bills, as subsequently amended, enacted the "Sustainable Groundwater Management Act" ("SGMA"). Governor Brown signed the legislation on September 16, 2014 and it became effective on January 1, 2015. In adopting SGMA, the Legislature intended "[t]o provide local groundwater agencies with the authority and technical and financial assistance necessary to sustainably manage groundwater." (California Water Code Section 10720(d).)

D. SGMA anticipates that each affected groundwater basin or subbasin will be regulated separately by one or more Groundwater Sustainable Agencies (each, a "GSA"). A local agency or combination of local agencies may elect to be the GSA for a basin or sub-basin. SGMA generally provides that a combination of local agencies may form a GSA through a joint powers agreement, memorandum of understanding or other legal agreement. (California Water Code Section 10723.6)

E. Groundwater sustainability under SGMA is to be achieved through Groundwater Sustainability Plans ("GSPs"). Under SGMA, a GSP can be a single plan developed by one or more GSAs, or multiple coordinated plans within a basin or subbasin by multiple GSAs (California Water Code Section 10727).

F. The Members, individually and collectively, have the goal of cost-effective, sustainable groundwater management in the Kern County Subbasin that considers the interests and concerns of the Members and other stakeholders.

G. As used in this Agreement "Kern County Subbasin" means such basin as defined in Department of Water Resources Bulletin 118, as its boundaries may be modified from time to time through the procedures described in California Water Code Section 10722.2.

H. The intent of the Members under this Agreement is to provide each Member with the sole right and responsibility to implement SGMA within its respective boundaries and/or Management Areas, as defined herein, in a manner determined by the Member, whether through the Authority or as a GSA. To facilitate coordination within the Kern County Subbasin, the Members desire for the Authority to have the authority to serve as a GSA for some or all of the Members within the Kern County Subbasin in a manner that allows the Members (individually or collectively) to directly implement SGMA and a GSP within their respective Management Areas as defined herein, while the Authority serves primarily a coordinating and administrative role in order to provide for sustainable groundwater management through the subbasin. The Members expressly intend that the Authority will not have the authority to limit or interfere with the respective Members' rights and authorities over their own internal matters, including, but not limited to, a Member's surface water supplies, groundwater supplies, facilities, operations, water management, and Water Supply Matters, as defined herein. Nothing in this Agreement is intended to modify or limit Members' police powers.

I. The Members expressly intend that neither SGMA, nor this Agreement, nor any GSP adopted by the Authority shall be construed as authorizing the Authority, or any dispute resolution process contained herein, to:

(i) determine or alter surface water rights or groundwater rights (California Water Code Section 10720.5 (b));

(ii) make binding determinations of the water rights of any person or entity (California Water Code Section 10726.8 (b)); or

(iii) supersede the existing land use authority of cities or counties, including the city or county general plan, within the overlying basin (California Water Code Section 10726.8 (f)).

J. In light of the enactment of SGMA together with the goals and intent described above, the Members wish to amend and restate the Original Agreement in its entirety as provided herein.

THEREFORE, in consideration of the mutual promises, covenants and conditions herein set forth, it is agreed by and among the Members that the Original Agreement is hereby amended and restated to read in its entirety as follows:

Article I: Definitions

As used in this Agreement, unless the context requires otherwise, the meaning of the terms hereinafter set forth shall be as follows:

(a) "Associate Members" shall mean those Members of the Authority admitted in accordance with the terms and provisions of this Agreement that are not General Members. The Board of Directors may from time to time admit Associate Members on terms and conditions

consistent with SGMA and as determined by the Board. Representatives of Associate Members may not serve on the Board and/or Board Committees. Likewise, while the Board of Directors welcomes their input, the representatives of Associate Members shall be non-voting, their presence shall not be counted in determining whether a quorum is present, and they shall not be permitted in closed sessions of the Board of Directors.

(b) "Authority" shall mean the Kern Groundwater Authority, being the separate entity created pursuant to the provisions of Government Code sections 6500 *et seq.* by this Agreement.

(c) "Board of Directors" or "Board" shall mean the governing body of the Authority as established by Section 3.01 of this Agreement.

(d) "Committee" shall mean any committee established pursuant to Section 3.03 of this Agreement.

(e) "Fiscal Year" shall mean that period of 12 months established as the Fiscal Year of the Authority pursuant to Section 4.01 of this Agreement.

(f) "General Members" shall mean those Members of the Authority more particularly identified as General Members on Exhibit A, and any parties which shall hereafter become General Members in accordance with the terms and provisions of this Agreement. A local agency as defined by SGMA may participate as a General Member on its own behalf or join with one or more agencies as a single General Member. Multiple agencies which elect to coordinate their representation as one General Member shall, for purposes of this Agreement, be treated as one General Member.

(g) "GSA" shall mean Groundwater Sustainability Agency as defined in SGMA.

(h) "GSA Notice Date" shall mean March 1, 2017.

(i) "Kern County Subbasin" means the groundwater subbasin described in Recital G of this Agreement.

(j) "GSP" shall mean Groundwater Sustainability Plan as defined in SGMA.

(k) "Management Area" shall mean the area within the boundaries of a Member or group of Members to be managed by that Member or group of Members under any GSP adopted by the Authority.

(l) "Members" shall mean the General Members and Associate Members.

(m) "SGMA" shall mean the Sustainable Groundwater Management Act.

(n) "Special Activities" shall mean activities that are consistent with the purpose of this Agreement, but which are undertaken by fewer than all the Members in the name of the Authority pursuant to Section 3.07.

(o) "Water Supply Matters" shall mean a Member's surface water supplies, groundwater supplies, facilities, operations, water management, water supply projects and financial affairs.

Article II: Creation of Authority

Section 2.01 – Creation.

The Members hereby reaffirm that, pursuant to their joint exercise of powers under the provisions of Government Code sections 6500 *et seq*., they have created a public entity to be known as the "Kern Groundwater Authority."

Section 2.02 – Term.

This Agreement is an amendment of the Original Agreement and shall therefore become effective, including without limitation on General Members not executing it, upon its execution by at least 75% of the General Members and will remain in effect until terminated by agreement of a majority of then participating General Members. Notwithstanding the above, once the Authority has adopted and approved a GSP for some or all of the Kern County Subbasin, this Agreement shall not be terminated except by agreement of 75% of the General Members (as described in Section 3.05 below). Unless it is terminated, this Agreement shall remain in effect and be binding upon the Members and upon all future Members for such a period as the Authority engages in any activities under this Agreement, except as to any party which withdraws or is terminated from its participation in the Authority in accordance with this Agreement. This Agreement shall supersede the Original Agreement and the Interim Funding Agreement effective 2013. Any monies collected pursuant to the Interim Funding Agreement which have not been expended as of the date of this Agreement shall be credited towards each Member's financial commitment as identified herein.

Section 2.03 – Purpose.

(a) The purposes of this Agreement are to:

(i) provide for the joint exercise of powers common to each of the Members and powers granted pursuant to SGMA (subject to the restrictions contained in this Agreement), through the Authority, to cooperatively carry out the purposes of SGMA and develop, adopt and implement a legally sufficient GSP covering those portions of the Kern County Subbasin that are within the jurisdictional boundaries of the Members, subject to the limitations set forth herein; and

(ii) provide a mechanism for the coordination of groundwater management activities by and among the Members, in accordance with SGMA.

(b) Each of the General Members (or group of General Members) shall have the sole and absolute right, in its sole discretion, to:

(i) become a GSA individually or collectively within the General Member's boundaries or the Management Area managed in whole or in part by such General Member;

(ii) approve the portion, section or chapter of the GSP adopted by the Authority as applicable within the General Member's boundaries or the Management Area managed in whole or in part by such General Member, as provided for in Section 7.01 of this Agreement; and

(iii) implement SGMA and the GSP adopted by the Authority within the General Member's boundaries or the Management Area managed in whole or in part by such General Member.

(c) Except to the extent requested by a General Member with respect to the lands within its boundaries, the Authority shall serve primarily a coordinating and administrative role in order to provide for sustainable groundwater management of the Kern County Subbasin in a manner that does not limit any Member's rights or authority over its own water supply matters, including, but not limited to, a Member's Water Supply Matters. Subject to the provisions, limitations and restrictions contained in this Agreement, activities unrelated to coordinating and administrative tasks necessary for groundwater management and sustainability shall not be undertaken by the Authority.

(d) Notwithstanding any other provision of this Agreement, the Authority shall not seek status as a GSA or approve a GSP prior to the GSA Notice Date.

(e) Not later than the GSA Notice Date, or such later date as determined by the Board of Directors, each Member shall provide the Authority with written notice that such Member will:

(i) continue as a Member and request the Authority to act as the GSA within such Member's boundaries or for the Management Area managed in whole or in part by such Member pursuant to a separate agreement between the Authority and the Member setting forth the terms and conditions of the Authority's role as the GSA within such Member's boundaries or for the Management Area managed in whole or in part by such Member;

(ii) continue as a Member and confirm that it will implement the GSP adopted by the Authority within such Member's boundaries or for the Management Area managed in whole or in part by such Member continue as a Member;

(iii) continue as a Member but seek GSA status within its boundaries or within the Management Area managed in whole or in part by such Member in order to implement SGMA and the GSP adopted by the Authority therein; or

(iv) seek GSA status within its boundaries or within the Management Area managed in whole or in part by such Member and adopt its own GSP, in which case such Member shall be deemed to have withdrawn from the Authority pursuant to Article VI but will endeavor in good faith to develop and execute a coordination agreement with the Authority in accordance with SGMA. Such Member may still be eligible to become an Associate Member pursuant to Section 6.02 (a).

The County of Kern may form a separate GSA or be part of a GSA for areas not within the boundaries of other Members and also be a GSA or participate in a GSA formed pursuant to this Agreement.

Section 2.04 – Powers.

(a) Subject to the limitations and restrictions contained within this Agreement, the Authority shall have the power to take any action, for the benefit of its Members, to carry out the purposes of this Agreement, including, but not limited to, applying for loans and grants, becoming a GSA for any or all of the Kern County Subbasin except the portions thereof for which Members become the GSA, and developing, adopting and implementing a GSP, subject to the paramount right of Members to become GSAs as specified in Section 2.03. The Authority shall have the power to sue and be sued. Notwithstanding the foregoing, the Authority shall not have the power to control, limit or empower a Member's rights and authorities over its own Water Supply Matters. Likewise, unless a Member requests it, the Authority shall have no power to interfere with (i) the Member's rights, use or management of the Member's water or water supply or (ii) the rights of individual landowners within the Member's boundaries to utilize, apply, store, or otherwise use surface or groundwater. Subject to the limitations and restrictions contained in this Agreement, the Authority is authorized, in its own name, to do all acts necessary for the exercise of said powers provided that said acts are duly adopted by the then seated Board of Directors and are consistent with this Agreement. Except as provided in Section 4.05, the Authority may not levy assessments on its Members. In accordance with California Government Code Section 6509, the foregoing powers shall be subject to the restrictions upon the manner of exercising such powers pertaining to the Cawelo Water District.

(b) Notwithstanding anything to the contrary in this Agreement, the Authority shall not (i) undertake any activities within any Member's boundaries, or within a Management Area managed in whole or in part by such Member, unless the Member formally and expressly requests, consents to and agrees, in writing, to the activity proposed in accordance with Section 7.4 or (ii) acquire or seek to acquire by eminent domain any property of a Member. Nothing in this Agreement shall modify or limit the police powers of Members, if any.

Article III: Internal Organization

Section 3.01 – Governing Body.

(a) The Authority shall be governed by a Board of Directors which is hereby established and which shall be initially composed of representatives of the General Members, as shown on Exhibit A. Without amending this Agreement, the Board of Directors composition shall be altered from time to time to reflect the termination and/or admission of any new General Members.

(b) Each General Member's governing board shall select a representative from its governing body or the governing body of one of the agencies within the General Member to serve as their Board member. A General Member may designate from its governing body or the governing body of one of the agencies within the General Member to serve as its alternative Director. The role of each alternate Director shall be to assume the duties of the Director appointed by his/her Member entity in case of the absence or unavailability of such Director, including without limitation such Director's duties as a member of any Committee established pursuant to Section 3.03. The Directors and alternates so named shall continue to serve until their respective successors are appointed.

(c) Nothing in this Agreement shall preclude a future amendment of this Agreement to reconfigure the Board of Directors into a smaller body comprised of representatives of General Members or other individuals, all as defined in such amendment.

Section 3.02 – Officers.

The Board shall select a Chair from among the Board of Directors who shall be the presiding officer of the Board meetings. The Board shall select a Vice Chair from among the Board of Directors who shall serve as the presiding officer in the absence of the Chair. The Board shall also select a Secretary, who need not be a member of the Board of Directors. The terms of such Officers shall be established by the Board of Directors from time to time and as necessary.

Section 3.03 – Committees.

There shall be established such Committees as the Board of Directors shall determine from time to time. Each such Committee shall be comprised of representatives of General Members, shall exist for the term specified in the action establishing the Committee, shall meet as directed by the Board of Directors, and shall make recommendations to the Board of Directors on the various activities of the Authority. The Board of Directors may delegate authority to the Committee to administer and implement the various activities of the Authority, subject at all times to the limitations on the Authority set forth in this Agreement; provided, that no power to enforce any aspect of SGMA or the GSP adopted by the Authority shall be delegated to a Committee.

Members shall be give reasonable advance notice of all Committee meetings, including without limitation ad hoc Committee meetings, all of which meetings shall be open to Members and their representatives.

Section 3.04 – Seal; Bylaws.

The Board may (but need not) adopt an official seal for the Authority and adopt such bylaws as it may deem necessary to regulate the affairs of the Authority in accordance with this Agreement. The bylaws may be amended from time to time by a majority vote of the Board of Directors as it may deem necessary.

Section 3.05 – Voting; Quorum.

(a) Subject to Section 3.05(c), each member of the Board of Directors shall be entitled to a vote determined as follows:

(i) Each member of the Board shall have one (1) vote on matters with respect to which such member is entitled to vote.

(ii) Voting on actions related to Special Activities shall be weighted as determined by each Special Activity agreement.

(b) Directors holding two-thirds of the voting power on the entire Board of Directors on a matter shall constitute a quorum for the transaction of Authority business. Any Board member abstaining from a vote shall be counted for purposes of determining the existence of a quorum, but shall not be deemed to be voting.

(c) A Director (including a Director serving as a member of a Committee) shall be entitled to vote on any matter or action (i) that would affect the General Member represented by such Director, (ii) relating to the general business or administration of the Authority, or (iii) that would impact any land or landowners within the boundaries of the General Member represented by such Director or the Management Area managed in whole or in part by such General Member.

(d) Examples of matters and actions on which a Director shall be entitled to vote include without limitation matters or actions relating to the implementation of SGMA within the boundaries of the General Member represented by such Director, amounts to be paid by the General Member represented by such Director to the Authority, the imposition of fees or charges within the boundaries of the General Member represented by such Director, the adoption or amendment of the Authority's GSP.

(e) In the event of a disagreement as to whether a Director is entitled to vote on a matter or action coming before the Board or a Committee, such Director shall be entitled to vote on the matter or action unless 75% of the Directors present at the meeting determine that such Director is not so entitled.

(f) Except as otherwise provided in this Agreement, any action by the Board of Directors shall require a two-thirds vote of the Directors entitled to vote thereon that are present at the meeting. Any amendment of this Agreement shall be governed by Section 8.01.

(g) Two-thirds of the members of a Committee entitled to vote thereon shall constitute a quorum for a matter or action before the Committee. All questions and matters of any nature whatsoever coming before any Committee shall be determined, provided a quorum is present, by the concurrence of 75% of the members of such Committee entitled to vote thereon present and voting on such matter. Any Committee member entitled to vote thereon abstaining from a vote shall be counted for purposes of determining the existence of a quorum, but shall not be deemed to be voting.

(h) This Section 3.05 shall not apply to matters affecting implementation of SGMA within a particular Management Area. Such matters shall be governed by the Member or

Members implementing SGMA within that Management Area, except to the extent otherwise agreed upon by such Member(s) pursuant to 2.04(b) or in a Special Activity agreement.

Section 3.06 – Meetings.

Meetings of the Board of Directors and any Committee (to the extent applicable) shall be conducted in accordance with the Ralph M. Brown Act, California Government Code Sections 54950, *et seq.*

Section 3.07 - Special Activities.

With the prior approval of the entire Board of Directors, Members may undertake Special Activities in the name of the Authority. All Members shall be given the opportunity to participate in each Special Activity of the Authority unless the Special Activity is an action described in Section 7.04. Prior to undertaking a Special Activity, the Members electing to participate in the Special Activity shall enter into an activity agreement. Such activity agreement shall provide that (i) no Special Activity undertaken pursuant to such agreement shall conflict with the terms of this Agreement and (ii) the Members to the activity agreement shall indemnify, defend and hold the Authority, and the Authority's other Members, harmless from and against any liabilities, costs or expenses of any kind arising as a result of the Special Activity described in the activity agreement. All assets, rights, benefits, debts, liabilities and obligations attributable to a Special Activity shall be assets, rights, benefits debts, liabilities and obligations solely of the Members that have entered into the activity agreement for that Special Activity, in accordance with the terms of the activity agreement, and shall not be the assets, rights, benefits, debts, liabilities and obligations of those Members that have not executed the activity agreement. Members not electing to participate in the Special Activity shall have no rights, benefits, debts, liabilities or obligations attributable to such Special Activity.

Article IV: Financial Provisions

Section 4.01 – Fiscal Year.

The Fiscal Year of the Authority shall be from January 1 through December 31 of each year.

Section 4.02 – Funds; Accounts.

(a) The North Kern Water Storage District shall serve as the Fiscal Agent and Treasurer for the Authority unless otherwise determined by the entire Board. The Fiscal Agent shall be responsible for all money of the Authority from whatever source. The Board may compensate the fiscal agent for services rendered.

(b) All funds of the Authority shall be strictly and separately accounted for and regular reports shall be rendered of all receipts and disbursements at least quarterly during the Fiscal Year. The books and records of the Authority shall be open to inspection by the Members.

(c) The Authority shall contract with a certified public accountant to make an audit or review of the accounts and records of the Authority which shall be conducted in compliance with Section 6505 of the California Government Code. The Fiscal Agent shall have the right to reject

any proposed certified public accountant. All costs associated with this Audit will be the full responsibility of the Authority.

Section 4.03 – Property; Bonds.

The Board of Directors shall from time to time designate the officers and persons, in addition to those specified in Section 4.02 above, who shall have charge of, handle, or have access to any property of the Authority. Each such officer and person shall file a bond in an amount designated by the Board of Directors.

Section 4.04 – Budget.

By a date set by the Board of Directors each Fiscal Year, the Board of Directors shall adopt a budget for the Authority for the ensuing Fiscal Year; provided, that except as provided in Section 4.05, the Authority shall not impose assessments or other charges on Members. Notwithstanding the foregoing, by its execution of this Agreement, each Member confirms that it has authorized its Director and Alternate Director to approve actions and expenditures by the Authority over and above the approved annual budget of the Authority for a Fiscal Year that do not create a fiscal obligation greater than $5,000 on such Member without further action of such Member.

Section 4.05 – Payments To The Authority.

(a) Except as otherwise provided, all fees, costs and expenses incurred by the Authority for general administrative services, such as legal, preparation of audits, and other general administrative functions shall be funded (i) from permissible contributions from third parties and (ii) assessments on the General Members, levied from time to time by the Board of Directors to carry out the activities of the Authority generally applicable to all General Members, which shall be equal per General Member, as initially shown on Exhibit A.

(b) No Member shall be bound, financially or otherwise, by any obligation, contract or activity undertaken by the Authority unless and except to the extent agreed upon by the Member, except that each Member shall be obligated to fund its then current annual share of the general basic budget of the Authority, provided such budgets are otherwise approved as provided herein. Funding of other matters shall be through Special Activity agreements or as otherwise agreed to by the Members in writing.

Section 4.06 – GSP Fees.

The Authority may impose reasonable fees, charges, assessments and other levies to implement its GSP and/or SGMA; provided, that the Authority shall have no authority to impose any such fees, charges, assessments or other levies on any of its Members or within a Management Area without the express consent and approval of the affected Member(s), or the Member or Member implementing the Authority's GSP and SGMA within such Management Area.

Article V: Management

Section 5.01 – Management.

In addition to, or in lieu of, hiring employees, the Authority may engage one or more General Member(s) or third party(ies) to manage any or all of the business of the Authority on terms and conditions acceptable to the Board of Directors. Any General Member or third party so engaged shall have such responsibilities as are set forth in the contract for such General Member's or third party's services.

Article VI: Relationship of Authority And Its Members

Section 6.01 – Separate Entity; Property.

In accordance with California Government Code Sections 6506 and 6507, the Authority shall be a public entity separate and apart from the parties to this Agreement. Unless, and to the extent otherwise agreed herein, the debts, liabilities and obligations of the Authority shall not be debts, liabilities or obligations of the Member entities. The Authority shall own and hold title to all funds, property and works acquired by it during the term of this Agreement.

Section 6.02 – Admission, Withdrawal and Termination of Members.

(a) Additional qualified parties may join in this Agreement and become General Members upon the approval of the entire Board of Directors, subject to terms and conditions as may be established by the Board of Directors. Associate Members may be admitted on terms and conditions established by the entire Board of Directors. Prior to being admitted as a new Member, an entity shall execute an agreement to be bound by the terms of this Agreement and any other terms and conditions established by the Board of Directors.

(b) Notwithstanding anything herein to the contrary, any Member may withdraw from this Agreement by giving 30 days written notice of its election to do so, which notice shall be given to the Board of Directors and to each of the other parties.

(c) Upon withdrawal, the Member shall not be relieved of all obligations for assessments to pay costs or liabilities of the Authority which were incurred prior to the date of the withdrawing Member's notice of withdrawal, but shall remain responsible for all obligations for assessments to pay costs or liabilities of the Authority which were incurred prior to the date of the withdrawing Member's notice of withdrawal.

(d) Subject to any contrary provisions of SGMA, a Member may be terminated by a three-fourths vote of the Directors representing Members not subject to the termination vote if such Member is then in breach of this Agreement and the breach is identified in the vote of the Board of Directors. Upon termination, the breaching Member shall no longer be a Member of the Authority; provided, that such termination shall become effective no earlier than 90 days after such vote of the Board of Directors and shall only be effective if the breach identified in the vote of the Board of Directors has not be cured by the effective date for the termination.

(e) Upon termination, the Member shall be entitled to a reimbursement for all assessments collected within 12 months prior to the termination vote and they shall be relieved

of all ongoing obligations for assessments to pay costs or liabilities of the Authority which were incurred prior to the date of the termination.

(f) Upon withdrawal or termination as a Member, the provisions of Section 2.04(b) shall remain applicable to any such withdrawing or terminated Member. The withdrawing or terminated Member will also be entitled to copies of all documents, information, and material developed by the Authority and paid for in whole or in part by the Member prior to the Member's withdrawal or termination.

(g) Upon withdrawal or termination as a Member, whether occurring before or after the GSA Notice Date and/or the date the Authority becomes a GSA as provided for in SGMA, or whether occurring before or after June 30, 2017, it is contemplated the withdrawing or terminated Member would concurrently become (or designate) a GSA for the lands within its boundaries (or a Management Area managed in whole or in part by such Member), so that such lands of the withdrawing or terminated Member would continue to be subject to a GSA and if applicable a GSP and the powers of such withdrawing Member within its boundaries would not be limited by this Agreement. In such event the Authority and its remaining Members shall (i) not object to or interfere with the lands in the withdrawing or terminated Member's boundaries (or a Management Area managed in whole or in part by such Member) being in a GSA, as designated by such withdrawing or terminated Member, (ii) facilitate such transition to the extent reasonably necessary, and (iii) in cooperation with the withdrawing or terminated Member, withdraw from managing the Kern County Subbasin as a GSA (if it has already elected to be a GSA) for that portion of the Basin within the boundaries of the withdrawing or terminated Member and so notify the Department of Water Resources..

Section 6.03 – Disposition Of Property Upon Termination Or Determination By Board Of Directors Of Surplus.

(a) Upon termination of this Agreement or upon determination by the Board of Directors that any surplus money is on hand, such surplus money shall be returned to the Members of the Authority. The distribution of said surplus shall be proportionate to the current year percentages as shown in Exhibit A, or as modified after the inclusion of new Members.

(b) The Board of Directors shall first offer any surplus properties, works, rights and interests of the Authority for sale to the Members and the sale shall be at the Authority's actual cost unless otherwise required by law. If no such sale is consummated, then the Board of Directors shall offer the surplus properties, works, rights and interests of the Authority for sale in accordance with applicable law to any governmental agency, private entity or persons for good and adequate consideration.

Section 6.04 –Liability For Debts.

The Members do not intend hereby to be obligated either jointly or severally for the debts, liabilities or obligations of the Authority, except as may be specifically provided for in California Government Code Section 895.2 as amended or supplemented. Provided, however, if any General Member(s) of the Authority are, under such applicable law, held liable for the acts or omissions of the Authority caused by negligent or wrongful act or omission occurring in the performance of this Agreement, such parties shall be entitled to contribution from the other Members so that after said contributions each General Member shall bear an equal share of such liability, as shown on the then-current Exhibit A. This Section 6.04 does not apply to acts or omissions of a Member in implementing the GSP adopted by the Authority within such

Member's boundaries or a Management Area managed in whole or in part by such Member.

Section 6.05 – SGMA-Related Expenses Incurred by Members.

Expenses incurred by a Member, or group of Members, for the implementation of the SGMA within a Management Area shall be borne solely by that Member or group of Members. Neither the Authority nor its other Members shall be liable for such expenses.

Article VII – Implementation of SGMA

Section 7.01 – Development of GSP.

Any Member or group of Members may create its or their own chapter or provisions governing SGMA implementation within their respective boundaries or a Management Area managed in whole or in part by such Member(s) for inclusion by the Authority into the Authority's GSP. The Authority shall promptly review the proposed chapter or provisions for consistency with the Authority's GSP and to determine that it meets the requirements of SGMA. If the Authority determines by a vote of 75% of the Directors that a Member's proposed chapter or provisions is/are consistent with SGMA and the Authority's GSP, it shall incorporate such chapter or provisions into the Authority's GSP. Such chapter or provisions may include operating conditions and criteria for groundwater banking projects that have previously been negotiated with other Members or agencies within the Basin and/or are contained within approved environmental documents, and in reviewing a Member's chapter the Authority shall not reject or fail to approve a Member's chapter based solely upon such operating conditions and criteria. The Authority shall not adopt a GSP that will be implemented within any Member's boundaries or Management Area without the prior approval of the Member.

Section 7.02 – Authorization to Carry Out the Terms of the GSP.

The Authority is authorized to carry out any of the following powers for the benefit of its Members that are included in the GSP adopted by the Authority without any further approval of the Board of Directors, subject at all times to the limitations and restrictions contained within this Agreement:

(a) Collection and maintenance of water extraction information and other technical data.

(b) Coordination of actions within, and reporting by, a Management Area.

(c) Carrying out studies and other technical investigations.

(d) Establishment and administration of conjunctive use and land fallowing programs.

(e) Requiring permitting of water extraction facilities.

(f) Requiring installation of meters.

(g) Buy, sell, exchange, recharge, and/or store water if the benefits thereof are made available to all General Members.

(h) Fix and collect rates for replenishment and other activities as a regulatory or service fee provided for at Water Code Sections 10730 through 10731.

Section 7.03 – Actions Requiring Additional Approval.

Subject to the limitations of this Agreement, the Authority shall not do any of the following without the approval of 75% of the voting power of the Board of Directors:

(a) Restrict or otherwise limit extraction of native groundwater other than through economic incentives and disincentives.

(b) Fund capital construction projects.

Notwithstanding any other provision of this Agreement, the Authority shall not restrict or otherwise limit the extraction of water stored (whether through direct recharge or in lieu deliveries) in the Kern County Subbasin as a part of any banking or recharge project or program, or otherwise seek to regulate the operation any such project or program.

Section 7.04 – Management Areas.

Any General Member (or group of General Members) may request that the Authority directly assume the responsibility of implementing SGMA and the Authority's GSP within its Management Area by giving written notice to the Authority, which notice may be given at any time. Where the service areas of multiple Members overlap a Management Area, the Members within the Management Area shall unanimously join the request. The Board of Directors shall take action to accept or reject such request. If the Authority accepts such request, the Authority and the requesting General Member(s) shall develop a mutually acceptable agreement describing the respective roles and responsibilities of the Authority and the requesting General Member(s) with respect to such implementation.

Except as otherwise expressly provided, the Authority's role within a Management Area, unless otherwise unanimously requested by the Member(s) managing such Management Area, shall be primarily coordinating and administrative. In particular, the roles and responsibilities for implementing SGMA and the GSP within a Management Area shall be the subject of a Special Activity agreement between the Member(s) and the Authority.

Article VIII: Miscellaneous Provisions

Section 8.01 – Amendment.

This Agreement may be amended from time to time by the concurrence of 75% of the General Members. To provide non-concurring parties an opportunity to withdraw from the Authority as provided herein, an amendment shall be binding on all parties 60 days after the required concurrence has been obtained.

Section 8.02 – Severability And Validity Of Agreement.

Should the participation of any party to this Agreement, or any part, term or provision of this Agreement be decided by a courts or the Legislature to be illegal, in excess of that party's authority, in conflict with any law of the State of California, or otherwise rendered unenforceable or ineffectual, the validity of the remaining portions, terms or provisions of this Agreement shall

not be affected thereby and each party hereby agrees it would have entered into this Agreement upon the remaining terms and provisions.

Section 8.03 – Assignment.

Except as otherwise provided in this Agreement, the rights and duties of the parties to this Agreement may not be assigned or delegated without the advance written consent of the Authority (as evidenced by a majority vote of the Board of Directors), and any attempt to assign or delegate such rights or duties in contravention of this section shall be null and void. Any assignment or delegation permitted under the terms of this Agreement shall be consistent with the terms of any contracts, resolutions or indentures of the Authority then in effect, including without any Special Activity agreement to which the assigning or delegating Member is a party. This Agreement shall inure to the benefit of and be binding upon the successors and assigns of the parties hereto. This section does not prohibit a party from entering into an independent agreement with another agency regarding the financing of that party's contributions to the Authority or the disposition of proceeds which that party receives under this Agreement so long as such independent agreement does not affect, or purport to affect, the rights and duties of the Authority or the parties under this Agreement.

Section 8.04 – Execution In Parts Or Counterparts.

This Agreement may be executed in parts or counterparts, each part or counterpart being an exact duplicate of all other parts or counterparts, and all parts or counterparts shall be considered as constituting one complete original and may be attached together when executed by the parties hereto. Facsimile or electronic signatures shall be binding.

Section 8.05 – Notices.

Notices authorized or required to be given pursuant to this Agreement shall be in writing and shall be deemed to have been given when mailed, postage prepaid, or delivered during working hours to the addresses set forth for each of the parties hereto on Exhibit "A" of this Agreement, or to such other changed addresses communicated to the Authority and the Member entities in writing, and to such other entities that become Members.

Section 8.06 – Dispute Resolution.

(a) A dispute resolution group shall be established by the Board of Directors to resolve disputes and/or controversies through mediation relating to the interpretation, construction, performance, termination, breach of, or withdrawal from this Agreement (the "Dispute Resolution Group"). The Dispute Resolution Group shall meet with the parties involved no later than 30 days following notification of the dispute or controversy. Thereafter, the Dispute Resolution Group will have 90 days to endeavor to resolve the dispute.

(b) Following conclusion of the dispute resolution process as herein provided, any Member may pursue any judicial or administrative remedies otherwise available. Notwithstanding this Section 8.06, a Member may seek a preliminary injunction or other interlocutory judicial relief if necessary to avoid irreparable damages or to preserve the status quo.

FIVE YEAR UPDATE

AGRICULTURAL WATER MANAGEMENT PLAN

SOUTHERN SAN JOAQUIN
MUNICIPAL UTILITY DISTRICT

MAY 2012

BEFORE THE BOARD OF DIRECTORS OF THE
SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT

IN THE MATTER OF: **RESOLUTION NO. 12-09**

ADOPTING A FIVE YEAR UPDATE
OF THE DISTRICT'S WATER MANAGEMENT PLAN

WHEREAS, a five year update to the Southern San Joaquin Municipal Utility District's WATER MANAGEMENT PLAN, has been prepared, presented to and discussed by the Board of Directors of the Southern San Joaquin Municipal Utility District which defines water management, control and policies of the Southern San Joaquin Municipal Utility District:

THEREFORE, BE IT RESOLVED that the WATER MANAGEMENT PLAN prepared by the staff of the Southern San Joaquin Municipal Utility District is adopted as presented and discussed at a noticed meeting scheduled for this date, is deemed acceptable and the Board of Directors finds that adoption of the same is in the best interest of the Southern San Joaquin Municipal Utility District and its landowners.

RESOLVED FURTHER, that William R. Carlisle, Manager-Secretary, is hereby authorized and directed to file said WATER MANAGEMENT PLAN on behalf of the Southern San Joaquin Municipal Utility District with the U. S. Bureau of Reclamation as deemed acceptable to this Board of Directors and to execute such other documents as may be necessary to carry out the intent of the above resolution.

The foregoing Resolution was adopted at a regular meeting of the Board of Directors of Southern San Joaquin Municipal Utility District held at the District Office on the 14th day of May, 2012, upon a motion of Director Regan and seconded by Director Morris, was authorized by the following vote:

AYES: Fisher, Dulcich, Regan, Zaninovich and Morris

NOES: None

ABSENT: None

I HEREBY CERTIFY that I am the duly appointed Secretary of the SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT and that the foregoing resolution was adopted by the Board of Directors of said District at a meeting held on the 14th day of May 2012, at which meeting a quorum was present at all times and acting.

IN WITNESS WHEREOF, I have set my hand this 14th day of May, 2012.

William R. Carlisle
WILLIAM R. CARLISLE, Secretary

Web Address

A. History

1. Date district formed: 1935 *Date of first Reclamation contract*: 10/18/1945
Original size (acres): 61,000 *Current year (last complete calendar year)*: 2009

The Southern San Joaquin Municipal Utility District (District) under its present name was organized in 1935, in accordance with the provisions of California laws pertaining to the formation and operation of municipal utility districts. The District was formed for the purpose of entering into a contract for purchase and distribution of water from the Central Valley Project (CVP). Portions of the area now included in the District formerly were part of the Poso Irrigation District, formed in 1888 and of the Kern and Tulare Irrigation District, formed in 1890. These early districts were short lived because of financial difficulties and lack of water. Prior to completion of the Southern Pacific Railroad through the vicinity in 1873, land in the area was used principally for livestock grazing.

With improved transportation facilities and development of large capacity water wells, irrigated agriculture superseded livestock production in the area. In subsequent years, intensive pumping had resulted in a serious lowering of the groundwater table underlying the District. This had necessitated drilling deeper wells with large increases in costs for installation and operation. At present, the District's only source of irrigation water is their surface supply from the Central Valley Project.

2. Current size, population, and irrigated acres

	(2009)
Size (acres)	64,000
Population served	48,442
Irrigated acres	44,627

The Cities of Delano and McFarland are located entirely within the District's service area boundary. The District does not, however, make any direct deliveries to either cities and is therefore not an urban water provider. The cities, however, do rely on the local groundwater supply, which is naturally recharged. The District provides a small amount of recharge to the groundwater reservoir supply through on-farm, in-lieu recharge efforts and recharge efforts through District reservoirs. A portion of this recharge would accrue to the benefit of the urbanized areas.

3. Water supplies received in current year

Water Source	*AF*
Federal urban water (Tbl 1)	
Federal agricultural water (Tbl 1)	121,259
State water (Tbl 1)	
Other Wholesaler (define) (Tbl 1)	
Local surface water (Tbl 1)	
Upslope drain water (Tbl 1)	
District ground water (Tbl 2)	
Banked water (Tbl 1)	
Transferred water (Tbl 6)	
Recycled water (Tbl 3)	
Other (define) (Tbl 1)	
Total	121,259

"Other" District water is defined as delivered non-Project water made available through exchanges between the District and other Friant-Division CVP contractors that have local water sources in addition to their CVP supply.

4. Annual entitlement under each right and/or contract

	AF	*Source*	*Contract #*	*Availability period(s)*
Reclamation Urban AF/Y				
Reclamation Agriculture AF/Y	97,000	Friant Division CVP – Class 1	Ir1-1460D	All year
Reclamation Agriculture AF/Y	50,000	Friant Division CVP – Class 2	Ir1-1460D	All year
Other AF/Y				

5. Anticipated land-use changes

There are no anticipated land-use changes.

6. Cropping patterns (Agricultural only)

List of current crops (crops with 5% or less of total acreage) can be combined in the 'Other' category.

Original Plan (1998)		*Previous Plan (2004)*		*Current Plan*	
Crop Name	*Acres*	*Crop Name*	*Acres*	*Crop Name*	*Acres*
Almonds	13,344	Alfalfa	3,536.5	Almonds	13,170
Grapes	10,656	Almonds	11,885	Table, Grapes	10,992
Cotton	10,080	Citrus	4,647	Navel Oranges	4,250
Alfalfa	5,664	Table Grapes	12,901	Pistachios	4,130
Citrus	2,928			Alfalfa	2,796
				Grapes	2,740
Other (<5%)	5,328	*Other (<5%)*	10,923.5	*Other (<5%)*	6,549
Total	48,000	*Total*	43,893	*Total*	44,627

(See Planner, Chapter 2, Appendix A for list of crop names)

The total acreage of 44,627, listed in the table above, is the current cropped portion of the total irrigated acres (45,765) listed in Section 1.A.2. and in Section 5, Table 5. The remaining 1,138 acres were idle/fallow during the current year.

7. Major irrigation methods (by acreage) (Agricultural only)

Original Plan (1998)		*Previous Plan (2004)*		*Current Plan*	
Irrigation Method	*Acres*	*Irrigation Method*	*Acres*	*Irrigation Method*	*Acres*
Row	17,897	Row	16,724	Flood	18,453
Flood	15,501	Flood	14,485	Drip	16,265
Drip	5,355	Drip	5,004	Micro Sprinkler	4,849
Sprinkler	5,261	Sprinkler	4,916	Fan Jet	3,243
Misters	2,959			Furrow	1,409
				Sprinkler	408
Other		*Other*	2,764	*Other*	0
Total	46,973	*Total*	43,893	*Total*	44,627

(See Planner, Chapter 2, Appendix A for list of irrigation system types)

The total acreage of 44,627, listed in the table above, is the current cropped portion of the total irrigated acres (45,765) listed in Section 1.A.2. and in Section 5, Table 5. The remaining 1,138 acres were idle/fallow during the current year.

B. Location and Facilities

See **Attachment A** for points of delivery, turnouts (internal flow) and outflow (spill) points, measurement locations, conveyance system, storage facilities, operational loss recovery system, wells and water quality monitoring locations.

The Southern San Joaquin Municipal Utility District (District) is located in Kern County, California, approximately 75 miles southeast of Fresno and 30 miles northwest of Bakersfield. The District includes lands in the southeastern San Joaquin Valley and the adjacent low foothills of the Sierra Nevada mountains. Its northern boundary is the Kern-Tulare Counties line, from which it extends southward about 13 miles. Its greatest width east and west is also about 13 miles. The general location of the District is shown on Plate 1. The principal town and location of the District's headquarters is Delano, located in the north-central part of the District. The community of McFarland is also in the District and is located about six miles south of Delano.

The distribution system is designed for a capacity of one (1) cubic foot per second for each 80 acres, with a delivery pressure of 10 feet of head available at the highest point in each 160 acres. The portion of the District lying below the Friant-Kern Canal is served by a

combination gravity and pumping system, with the pumping being confined to the first sub-lateral. The portion of the District lying above the canal is served by pumping through three (3) pumping stations on the canal and two re-lift plants on each of the three (3) laterals. The District has eleven (11) regulating reservoirs in total. Each has an area of approximately two (2) acres. Their locations within the distribution system are shown in **Attachment A**.

The District's system consists of 158 miles of pipelines. The original pipelines, completed in the early 1950's, were made of concrete. Portions of the pipelines were of non-reinforced pipe with mortar joints, while portions were of reinforced concrete pipe with rubber gasketed joints.

The District has 539 active deliveries at the present time and approximately 30 that are not currently in use. All deliveries are metered. Older meters are being replaced by a propeller type meter that indicates the flow and records the total flow that is supplied to the user.

The District does not own any groundwater production facilities. Landowners in the District continue to own and operate groundwater production facilities aside from the District.

1. Incoming flow locations and measurement methods

Location Name	*Physical Location*	*Type of Measurement Device*	*Accuracy*
Friant-Kern Canal & Lateral 1	FKC Mile Post 119.6	Propeller Meter	±2%
Friant-Kern Canal & Lateral 2	FKC Mile Post 122.5	Propeller Meter	±2%

Lateral 8 – S12	Regulating	1	Distribution
Lateral 8 – Reynolds S14	Regulating	14	Distribution
Lateral 9 – S16	Regulating	1	Distribution
Lateral 9 – S17	Regulating	1	Distribution
Lateral 9 – S18	Terminal Reservoir	1	Distribution

5. Outflow locations and measurement methods (Agricultural only)
Provide this information in Section 2 F.

6. Description of the agricultural spill recovery system

There are no operational spill losses experienced by the District. All water conveyed within the District's distribution system remains within the system until utilized. On-farm tailwater return systems have been constructed by those District landowners not utilizing permanent on-farm distribution systems. All deep percolation losses return to usable groundwater source and no water leaves the service area in the form of surface runoff.

7. Agricultural delivery system operation (check all that apply)

On-demand	*Scheduled*	*Rotation*	*Other (describe)*
	✓		

8. Restrictions on water source(s)

Source	*Restriction*	*Cause of Restriction*	*Effect on Operations*
USBR	Declaration	Quantity of Snowfall	Reduced Deliveries
FKC	Capacity	Subsidence/Siphons	Reduced Deliveries

9. Proposed changes or additions to facilities and operations for the next 5 years

Since the District is fully developed, the only anticipated changes to the District's distribution system are continued efforts to replacing older pipelines. The District is also scheduled to build Reservoir S-21 along Lateral 8 in 2010, and plans to expand the Lateral 8 – Reynolds S14 reservoir in 2012.

C. Topography and Soils

1. Topography of the district and its impact on water operations and management

The general relief of the District gently slopes predominantly from the southeast to the northwest, with the topography becoming smoother and more level to the west. The topography of lands varies in elevation from a high of 650 feet on the eastern boundaries to a low of 240 feet at the western boundaries. The average slope is about 21 feet per mile and the average elevation is about 310 feet above sea level.

The District may be divided topographically into three types of terrain: (1) low foothills on the eastern boundary of the District, (2) an intermediate belt averaging 6 miles wide, sloping 30 to 40 feet per mile westerly with small isolated areas of poor drainage and (3), in the western portion, a zone with relatively flat slopes that originate from a series of alluvial fans, of which those of Poso Creek and Rag Gulch are pre-eminent. Farther west these fans merge into an area of very flat slopes marked by saline soils.

2. District soil association map (Agricultural only)

See **Attachment B**, District Soils Map

Soils of the District can be divided into three (3) different major categories. The foothill area is distinguished by hardpan and other compact subsoil layers which allow for limited

development into vineyards and truck crop areas. The transition zone and the majority of the valley floor area consists of deep permeable soils. The soil in this area is extremely productive and well suited for any crop that fits the existing weather conditions. On the western limits of the District, the soil contains areas of saline type material which require specific reclamation actions to become productive.

In February of 1948, the United States Bureau of Reclamation made a semi-detailed land classification of the District, as detailed in Land Use Study of the Southern San Joaquin Municipal Irrigation District. The land classes assigned to District lands represent varying degrees of suitability for irrigation and were determined by evaluation of the factors of soil, topography and drainage in relationship to adapted crops, productivity and land management.

The first soil region contains soils mainly on alluvial fans, alluvial plains, basin rims and flood plains in the eastern part of the San Joaquin Valley. The Garces soil series is deep, nearly level, saline-alkali, well-drained silt loam and clay loams soils. With the Garces soils, typically, the surface layer is silt loam. The subsoil is clay loam and loam. The substratum is loam and fine sandy loam. In some areas, the substratum is stratified and contains a brittle layer of weakly to moderately cemented material. These soils are moderately to strongly saline-alkali.

The Kimberlina soil series is deep, nearly level, well drained fine sandy loam and sandy loam soils. Also present, to a minor extent, are Cajon soils which are deep and somewhat excessively drained. The surface soil of the Kimberlina soils is fine sandy loam. The upper part of the underlying material is fine sandy loam, and the lower part is silt loam.

The McFarland soil series is a deep, nearly level, well drained loam soil. These soils are formed in alluvium and derived from granite rock. The surface layer and underlying material are loam.

The second soil region included within the District contains soils on terraces in the eastern part of the San Joaquin Valley. The Delano soil series is deep, nearly level to hilly, well

drained sandy loam and clay loam soils. These soils are formed in alluvium and derived from granite rock. The surface layer of Delano soils is sandy loam. The subsoil is clay loam, sandy clay loam and sandy loam. The substratum is sandy loam.

3. Agricultural limitations resulting from soil problems (Agricultural only)

Soil Problem	*Estimated Acres*	*Effect on Water Operations and Management*
Salinity	None	None
High-water table	None	None
High or low infiltration rates	None	None
Other (define)	None	None

D. Climate

1. General climate of the district service area

The climate of the District is typical of the San Joaquin Valley, being semiarid and characterized by mild winters and hot, dry summers. Mean annual temperature at Delano is 62.9 degrees Fahrenheit. The average annual minimum and maximum temperatures are 48.4 and 78.5 degrees, respectively.

The average yearly rainfall for the District area is 6.97 inches, based on records published for the California Irrigation Management Information System (CIMIS) station number 182 at Delano, for the 8-year period of 2002-2010, inclusive. Rain falls principally during the period November to April.

Many of the crops in this area are crops that are particularly sensitive to frost. The most favored areas for citrus and other frost-sensitive crops are the tops and slopes of some of the foothills where there is better air drainage. The area is in a thermal belt, but there are cold areas in some of the low lands and depressions.

The climatological normals for the District area presented in the preceding tables were obtained from the CIMIS station number 182 at Delano, for the 8-year period of 2002-2009,

inclusive. The climatological extremes for the District area were obtained from the CIMIS station number 182 at Delano, for the period of 2002-2009, inclusive.

Weather station ID CIMIS #182 *Data period: Year* 2002 *to Year* 2009

Average wind velocity 3.2 mph *Average annual frost-free days:* 280

2. Impact of microclimates on water management within the service area

Demand exists for water during the winter months for frost protection purposes. This demand is independent of the evapotranspiration demand.

E. Natural and Cultural Resources

1. Natural resource areas within the service area

Name	*Estimated Acres*	*Description*
N/A	None	N/A

2. Description of district management of these resources in the past or present

Not Applicable

3. Recreational and/or cultural resources areas within the service area

Name	*Estimated Acres*	*Description*
N/A	None	N/A

F. Operating Rules and Regulations

1. Operating rules and regulations

See **Attachment C**, District Rules and Regulations (water related)

2. Water allocation policy (Agricultural only)

See **Attachment C**, Section C, Page C-5

General: Any Water User of lands within the District designated non-excess (or otherwise made eligible to receive water) who has otherwise complied with these Rules and Regulations and policies of the Board, including having timely submitted an application for water service, is entitled to water service made available to the District under the Contract with the Bureau. Provided, however, no Schedule B lands shall be eligible to receive any share of the District's contract entitlement until all applications for Schedule A lands are fulfilled.

3. Official and actual lead times necessary for water orders and shut-off (Agricultural only)

See **Attachment C**, Section B (9), Page C-4

Water delivery changes are made six (6) days a week with no changes on Sundays. Water Users desiring water shall place their water orders a minimum of 24-hours in advance. Water orders are taken between the hours of 7:00 A.M. to 3:30 P.M. Monday through Friday and 7:00 A.M. to 9:00 A.M. on Saturday. No orders are taken on Sunday and orders for Monday changes must be in by 9:00 A.M. Saturday. All orders are compiled by the Dispatcher in order to place the District water order for the next day deliveries.

4. Policies regarding return flows (surface and subsurface drainage from farms) and outflow (Agricultural only)

See **Attachment C**, Section B (11), Page C-4

The District reserves the right to turn off Water deliveries in those instances of a Water User not taking care of his water and flooding roads or neighboring lands.

5. Policies on water transfers by the district and its customers

See **Attachment C**, Section B (5), Page C-3

Water may be transferred from one parcel to another parcel provided the parcels are owned or leased by the same person(s) or company. No landholder or Water User can transfer or exchange water outside the District service area.

Exchanges of water with other Friant-Division, CVP contractors are permitted with Board approval.

G. Water Measurement, Pricing, and Billing

1. Agricultural Customers

a. Number of farms 225

b. Number of delivery points (turnouts and connections) 640

c. Number of delivery points serving more than one farm 4

District delivery points serving more than one farm exist when an individual landowner divides a parcel and sells off the divided portion of his/her land to another party. When this occurs, water conveyed to each parcel is accomplished through the existing turnout and meter. When payment for the water is due to the District, the original landowner, whose name is on the District account, pays the District water bill. The original landowner then receives payment from the secondary landowner based on his share of the delivery.

In order to comply with the current Guidelines, all farm deliveries must be provided with measurement capability meeting the established minimum accuracy requirements. For the referenced (4) deliveries, the District will design, construct and place into operation, new metered turnouts with appropriate rating capabilities and sized to meet the requirements of each delivery. The installations will be completed during Fall 2012. The budget estimate to complete all four (4) installations is $12,000.

d. Number of measured delivery points (meters and measurement devices) 640

e. Percentage of delivered water that was measured at a delivery point 100

f. Delivery point measurement device table (Agricultural only)

Measurement Type	*Number*	*Accuracy (+/- %)*	*Reading Frequency (Days)*	*Calibration Frequency (Months)*	*Maintenance Frequency (Months)*
Orifices					
Propeller meter	640	±6%	Daily	Upon Request	As needed
Weirs					
Flumes					
Venturi					
Metered gates					
Acoustic doppler					
Other (define)					
Total					

The District's water tracking software performs a day by day comparison of what is ordered versus the amount recorded as delivered through each individual meter. When a consistent difference occurs, the District installs a temporary clock mechanism within the meter and proceeds to repair, recalibrate and reinstall the existing clock. In the case where the clock is not repairable, the District installs a new clock. As it relates to District underground line meters, which can no longer be repaired, the District replaces the entire meter. In the event that the District receives a complaint from a water user, the District automatically installs a temporary clock and repairs, recalibrates and reinstalls the clock in question, unless a new clock is warranted. This program is performed on an on-going basis.

2. Urban Customers

This section was intentionally left blank because the District does not have urban customers.

a. *Total number of connections* N/A

b. Total number of metered connections N/A

c. Total number of connections not billed by quantity N/A

d. Percentage of water that was measured at delivery point N/A

e. Percentage of delivered water that was billed by quantity N/A

f. Measurement device table

Meter Size and Type	*Number*	*Accuracy (+/-percentage)*	*Reading Frequency (Days)*	*Calibration Frequency (Months)*	*Maintenance Frequency (Months)*
5/8-3/4"					
1"					
1 ½"					
2"					
3"					
4"					
6"					
8"					
10"					
Compound					
Turbo					
Other (define)					
Total					

3. Agriculture and Urban Customers

a. Current year agriculture and /or urban water charges - including rate structures and billing frequency

The current-year water rate is $49.93 per acre foot. Water users are billed on a monthly basis with payments due on or before the 20th of each month for water used the prior month.

b. Annual charges collected from customers (current year data)

Fixed Charges			
Charges ($ unit)	*Charge units ($/acre), ($/customer) etc.*	*Units billed during year (acres, customer) etc.*	*$ collected ($ times units)*
$44.70	$/Acre	49,900 Acres	$2,230,530

Volumetric Charges			
Charges ($ unit)	*Charge units ($/AF), ($/HCF), etc.*	*Units billed during year (AF, HCF) etc.*	*$ collected ($ times units)*
$49.93	$/Acre Foot	115,323 AF	$5,758,077

Lift Charges			
Charges ($ unit)	*Charge units ($/AF), ($/HCF), etc.*	*Units billed during year (AF, HCF) etc.*	*$ collected ($ times units)*
$11.00	$/lifts per account	117,848 Lifts	$1,296,330

See **Attachment D**, District Sample Bill

c. Water-use data accounting procedures

The District record management system is kept on a Dell Server Computer System. The District utilizes True Point Solutions Software for water accounting which interfaces with Sage Software for invoicing and financial accounting. More than forty years of records are archived at the District office and available to customers for their reference.

H. Water Shortage Allocation Policies

1. Current year water shortage policies or shortage response plan - specifying how reduced water supplies are allocated

See **Attachment C**, Section C (2), Page C-5

The District's annual entitlement of Class 1 and Class 2 water shall be distributed according to requests taken from water applications. During dry years, requests may be allocated proportionately to all applicants on the basis of the acreage entitled to receive water.

2. Current year policies that address wasteful use of water and enforcement methods

See **Attachment C**, Section B (11), Page C-4

The District reserves the right to turn off water deliveries in those instances of a Water User not taking care of his water allocation and flooding roads or neighboring lands. Prior to turning off such a delivery, an attempt will be made to reach by phone the responsible party causing the wasting of water.

Section 2: Inventory of Water Resources

A. Surface Water Supply

1. Acre-foot amounts of surface water delivered to the water purveyor by each of the purveyor's sources

2009 Month	Federal Ag Water (acre-feet)	Federal non-Ag Water. (acre-feet)	State Water (acre-feet)	Local Water (acre-feet)	Other Water (Non-Proj) (acre-feet)	Upslope Drain Water (acre-feet)	Total (acre-feet)

November	0	0
December	0	0
TOTAL	0	34,482

*normally estimated

2. Ground water basin(s) that underlies the service area

Name	*Size (Square Miles)*	*Usable Capacity (AF)*	*Safe Yield (AF/Y)*
Kern County Basin (5-22.14)	3,040	11,200,000	37,000[(1)]
SSJMUD	100	59,000[(2)]	15,800[(3)]

[(1)] *Bureau of Reclamation Water Needs Analysis Summary, March, 1988.*
[(2)] *Groundwater pumping quantity based on continued delivery of contract supply leading to a period of stable groundwater levels. Ref. USBR Needs Assessment, February 14, 2000.*
[(3)] *Safe yield. Quantity independent of imported water deliveries. Ref. USBR Water Supply Study, February, 1948.*

3. Map of district-operated wells and managed ground water recharge areas

See **Attachment F**, District Map of Ground Water Facilities

As stated previously, the District does not own or operate any groundwater extraction wells. A map indicating the District's groundwater facilities (limited to regulation reservoirs) and its proximity to Poso Creek is included as **Attachment F**.

4. Description of conjunctive use of surface and ground water

The main contributions to the recharge of the groundwater reservoir underlying the District are from any percolation from the 12 regulating reservoirs, Poso Creek runoff and other smaller adjacent foothill drainage areas to the east. Historically, the District has primarily achieved its groundwater recharge goals through an in-lieu surface water delivery program. When surface water supplies are available and can be delivered to the District, the surface water supplies are utilized "in lieu" of groundwater pumping. The District will continue this program whenever surface supplies are available and will augment deliveries whenever supplemental supplies can be purchased at a reasonable cost and ordered for delivery by growers. The District continues to evaluate available and developing banking programs.

5. Ground Water Management Plan

See **Attachment G**, Groundwater Management Plan

The District, through its Groundwater Management Plan, entitled *Groundwater Management Program, Under California Water Code, Sections 10750 Et Seq.*, dated May 12, 1993, meets the AB 3030 requirements for management of groundwater related resources.

6. Ground Water Banking Plan

The District does not participate in any groundwater banking projects.

C. Other Water Supplies

1. "Other" water used as part of the water supply

2009 Month	Federal Ag Water (acre-feet)	Federal non-Ag Water. (acre-feet)	State Water (acre-feet)	Local Water (acre-feet)	Other Water (Non-Proj) (acre-feet)	Upslope Drain Water (acre-feet)	Total (acre-feet)
Method							
January	1664	0	0	0	0	0	1,664
February	5659	0	0	0	0	0	5,659
March	2613	0	0	0	0	0	2,613
April	7006	0	0	0	0	0	7,006
May	17165	0	0	0	0	0	17,165
June	19853	0	0	0	0	0	19,853
July	23566	0	0	0	0	0	23,566
August	18227	0	0	0	0	0	18,227
September	12234	0	0	0	0	0	12,234
October	8511	0	0	0	0	0	8,511
November	4094	0	0	0	0	0	4,094
December	667	0	0	0	0	0	667
TOTAL	121,259	0	0	0	0	0	121,259

As stated previously in Section 1.A.3, "Other" District water is defined as delivered non-Project water made available through exchanges between the District and other Friant-Division CVP contractors that have local water sources in addition to their CVP supply.

D. Source Water Quality Monitoring Practices

1. Potable Water Quality (Urban only)

Not Applicable

2. Agricultural water quality concerns: *Yes* _____ *No* ✓
(If yes, describe)

3. Description of the agricultural water quality testing program and the role of each participant, including the district, in the program

Individual landowners are signator to the Kern Sub-watershed of the Southern San Joaquin Valley Water Quality Coalition. The District is not a participant as it has no agricultural related discharges.

4. *Current water quality monitoring programs for surface water by source (Agricultural only)*

There are currently two (2) water quality sampling and monitoring programs conducted on waters related to the District. The first of these is a four-entity program conducted on waters in the Friant-Kern Canal. A sample is taken monthly, year-round, on which tests are run to determine suitability and treatability. The second program is run by Reclamation District No. 770 on waters of the Kaweah River and the Tule River. Tests are run at least annually to provide a base related to pumping into the Friant-Kern Canal for flood water management purposes. The tests are designed to insure that any waters pumped into the canal meet Title 22, CAC, standards.

Current water quality monitoring programs for groundwater by source (Agricultural only)

Water quality monitoring programs on groundwater are conducted by the cities of Delano and McFarland based on criteria established by the State Department of Health Services.

E. Water Uses within the District

1. Agricultural

See Water Inventory Tables, Table 5 - Crop Water Needs

2009 Crop Name	Area (crop acres)	Crop ET (AF/Ac)	Leaching Requireme (AF/Ac)	Cultural Practices (AF/Ac)	Effective Precipitation (AF/Ac)	Appl. Crop Water Use (acre-feet)
Alfalfa	2,796	3.50	0.022	-	0.20	9,288

3. *Urban use by customer type in current year*

Not Applicable.

4. *Urban Wastewater Collection/Treatment Systems serving the service area – current year*

Not Applicable.

5. *Ground water recharge/management in current year (Table 6)*

None.

6. *Transfers and exchanges into or out of the service area in current year (Table 6)*

The District did not participate in any transfers and/or exchanges with other entities during the current year.

7. *Trades, wheeling, wet/dry year exchanges, banking or other transactions in current year (Table 6)*

None.

8. *Other uses of water in current year*

None.

F. Outflow from the District (Agricultural only)

Districts included in the drainage problem area, as identified in "A Management Plan for Agricultural Subsurface Drainage and Related Problems on the Westside San Joaquin Valley (September 1990)," should also complete Water Inventory Table 7 and Appendix B (include in plan as Attachment L)

See Facilities Map, **Attachment A**, for the location of surface and subsurface outflow points, outflow measurement points, outflow water-quality testing locations

1. *Surface and subsurface drain/outflow in current year*

The District did not have any surface and/or subsurface drainage/outflow during 2009.

2. *Description of the Outflow (surface and subsurface) water quality testing program and the role of each participant in the program*

Not Applicable.

3. *Outflow (surface drainage & spill) Quality Testing Program*

Not Applicable.

Outflow (subsurface drainage) Quality Testing Program

Not Applicable.

4. *Provide a brief discussion of the District's involvement in Central Valley Regional Water Quality Control Board programs or requirements for remediating or monitoring any contaminants that would significantly degrade water quality in the receiving surface waters.*

Individual landowners are signator to the Kern Sub-watershed of the Southern San Joaquin Valley Water Quality Coalition. The District does not participate in the ILRP as it has no irrigated lands based discharges.

G. Water Accounting (Inventory)

1. *Water Supplies Quantified*

   a. *Surface water supplies, imported and originating within the service area, by month (Table 1)*

   See Section 5, Table 1.

   b. *Ground water extracted by the district, by month (Table 2)*

   See Section 5, Table 2.

   c. *Effective precipitation by crop (Table 5)*

   See Section 5, Table 5.

   d. *Estimated annual ground water extracted by non-district parties (Table 2)*

   See Section 5, Table 2.

   e. *Recycled urban wastewater, by month (Table 3)*

   See Section 5, Table 3.

   f. *Other supplies, by month (Table 1)*

   See Section 5, Table 1.

2. *Water Used Quantified*

   a. *Agricultural conveyance losses, including seepage, evaporation, and operational spills in canal systems (Table 4) or Urban leaks, breaks and flushing/fire uses in piped systems (Table 4)*

   See Section 5, Table 4.

   b. *Consumptive use by riparian vegetation or environmental use (Table 6)*

   See Section 5, Table 6.

   c. *Applied irrigation water - crop ET, water used for leaching/cultural practices (e.g., frost protection, soil reclamation, etc.) (Table 5)*

   See Section 5, Table 5.

   d. *Urban water use (Table 6)*

   See Section 5, Table 6.

   e. *Ground water recharge (Table 6)*

   See Section 5, Table 6.

   f. *Water exchanges and transfers and out-of-district banking (Table 6)*

   See Section 5, Table 6.

   g. *Estimated deep percolation within the service area (Table 6)*

   See Section 5, Table 6.

   h. *Flows to perched water table or saline sink (Table 7)*

   See Section 5, Table 7.

   i. *Outflow water leaving the district (Table 6)*

   See Section 5, Table 6.

   j. *Other* - None

3. Overall Water Inventory
a. Table 6

See Section 5, Table 6.

H. Assess Quantifiable Objectives:

Identify the Quantifiable Objectives that apply to the District (Planner, chapter 10) and provide a short narrative describing past, present and future plans that address the CALFED Water Use Efficiency Program goals identified for the District.

The District has been identified as having lands within its boundary that are subject to quantifiable objectives. The identified quantifiable objectives address increasing the water supply for beneficial uses by providing long-term diversion flexibility to benefit Pixley National Wildlife Refuge, to provide improved long-term diversion flexibility to increase the water supply for beneficial uses and to decrease flows to salt sinks to increase the water supply for beneficial uses.

The District currently has no plans in place that would make water available to the Pixley National Wildlife Refuge. The District does not have any habitat preservation or restoration sites which could be the candidate areas for conserved water supply diversions. District growers have improved on-farm irrigation systems to the extent that in excess of 55 percent of these systems are permanent, low volume systems. This has resulted in reduced losses to the soil mantle outside of the root zone. Resultant water savings have first been dedicated to improving crop yields with the periodic residual being the negotiating tool to allow the District to deal with reduced water supplies resulting from settlement of the San Joaquin River litigation.

Section 3: Best Management Practices (BMPs) for Agricultural Contractors

A. Critical Agricultural BMPs

1. *Measure the volume of water delivered by the district to each turnout with devices that are operated and maintained to a reasonable degree of accuracy, under most conditions, to +/- 6%*

Number of turnouts that are unmeasured or do not meet the standards listed above: 4

Number of measurement devices installed last year: 0

Number of measurement devices installed this year: 2

Number of measurement devices to be installed next year: 4

In order to comply with the current Guidelines, all farm deliveries must be provided with measurement capability meeting the established minimum accuracy requirements. For the referenced (4) deliveries to be installed next year, the District will design, construct and place into operation, new metered turnouts with appropriate rating capabilities and sized to meet the requirements of each delivery. The installations will be completed during Fall 2012 and reported in the subsequent annual report to this Plan. The budget estimate to complete all four (4) installations is $12,000.

Types of Measurement Devices Being Installed	*Accuracy*	*Total Installed During Current Year*
Propeller meter	±6%	2

2. *Designate a water conservation coordinator to develop and implement the Plan and develop progress reports*

Name: Bill Carlisle *Title:* Secretary/General Manager

Address: P.O. Box 279 or 11281 Garzoli Avenue, Delano, CA 93216

Telephone: (661) 725-0610 *E-mail:* gm@ssjmud.org

3. Provide or support the availability of water management services to water users

See **Attachment H**, Notices of District Education Programs and Services Available to Customers.

a. On-Farm Evaluations

1) On farm irrigation and drainage system evaluations using a mobile lab type assessment

	Total in district	*# surveyed last year*	*# surveyed in current year*	*# projected for next year*	*# projected 2nd yr in future*
Irrigated acres	44,627	80	240	2,232	2,232
Number of farms	225	2	3	12	12

The District is supplied with color brochures from the North West Kern Resource Conservation District, which are sent out to each landowner at the beginning of each water year. These brochures supply information as it pertains to these evaluations.

2) Timely field and crop-specific water delivery information to the water user

See **Attachment H**, Notices of District Education Programs and Services Available to Customers.

Each week, the Friant Water Authority issues a reproduction of crop coefficients to all of its contractors which are compiled by the Kings River Conservation District and made available by the District to its growers. The table lists the daily average for the previous seven (7) days and estimate of the average for the subsequent seven (7) days of crop coefficients. District water delivery information is provided to each water user, each month in which delivery to a water user is made. This information can then be used by a water user to manage water used by field and crop.

b. Real-time and normal irrigation scheduling and crop ET information

See **Attachment H**, Notices of District Education Programs and Services Available to Customers.

Each week, the Friant Water Authority issues a reproduction of crop coefficients and CIMIS evapotranspiration rates to all of its contractors which are compiled by the Kings River Conservation District and made available by the District to its growers. The crop coefficients table lists the daily, average for the previous seven (7) days and an estimate of the average for the subsequent seven (7) days, while the CIMIS evapotranspiration rates table lists data for twelve (12) CIMIS stations located within the Friant Division, CVP service area and details daily, total for the previous seven (7) days, normal previous seven (7) days, variance percentage from normal and normal next seven (7) days, evapotranspiration rates.

Most normal year information pertaining to irrigation scheduling and crop evapotranspiration (ET), such as CIMIS data and crop coefficients, is available to the landowner/grower through many agencies or services. The following are examples of services and information that are available to growers:

- The office of Water Use Efficiency (OWUE), through the Department of Water Resources (DWR) provides CIMIS data free of charge to the public for the use in estimating crop water use for irrigation scheduling. This information can be found through the OWUE's CIMIS website at www.cimis.water.ca.gov;
- During the growing season, crop ET information is published in the local newspapers and broadcast daily over the radio for reference and use by any water user;
- The U.S. Weather Service currently provides real-time CIMIS ET data and forecasts on their local weather channels and on the NOAA website.

The examples listed above provide crop specific ET data that is based on real-time. In an effort to assist District landowners in the understanding of crop coefficient and evapotranspiration rates, and how to develop water use for a specific crop, calculated examples will be published within the on-farm water conservation tools and strategies found in the Water Conservation Information Bulletins, as described in Section 3.3.d. of this report.

c. Surface, ground, and drainage water quantity and quality data provided to water users

The District, upon request, will provide surface water quality data, which is provided to the District by the Friant Water Authority, to District landowners/growers. The District, however, does not participate in in-district water quality testing. As per the District's Rules and Regulations for Water Service; "The District's water supply is in a raw, untreated condition, and as a result is considered to be unfit for human consumption without treatment. The District does not warrant the quality of water delivered and is under no obligation to construct or furnish water treatment facilities or maintain or better the quality of water."

d. Agricultural water management educational programs and materials for farmers, staff, and the public

Program	*Co-Funders (If Any)*	*Yearly Targets*
Water Conservation Information Bulletins	Keller/Wegley Consulting Engineers Client Group Provost & Pritchard Consulting Group	Quarterly Publications.Mailings
Friant Water Authority	Friant Division Contractors	Monthly Publications

See **Attachment H** for samples of provided materials and notices

The Water Conservation Information Bulletins will be provided to the District to inform both the District and its growers of on-farm water conservation tools and strategies. This educational program is being sponsored by both Keller/Wegley Consulting Engineers and Provost & Pritchard Consulting Group. The program is scheduled to release its first publication in late Spring/early Summer 2012.

e. other

None

4. Pricing structure - based at least in part on quantity delivered
Describe the quantity-based water pricing structure, the cost per acre-foot, and when it became effective.

The District's pricing structure is that of three (3) forms, all which are values set on an annual basis. Fixed charges are based on a per acre basis and applied to all eligible lands at a value of $44.70. Volumetric charges are based on a per acre-foot basis and can be adjusted as water supply allocations from Reclamation change. The cost per acre-foot for 2009 was $49.93. The Friant-Kern Canal bifurcates the District. The lands that are supplied surface water via the District's gravity system are west of the Friant-Kern Canal. All lands located east of the Friant-Kern Canal are supplied surface water through a pressurized system. Water delivered through this system is charged the third form of pricing, known as lift charges. Lift charges are based on a per lift basis at a cost of $11.00.

5. Evaluate and describe the need for changes in policies of the institutions to which the district is subject.

The District is currently looking into water quality issues and policies as they relate to pump-back and pump-in capability involving the Friant-Kern Canal.

6. Evaluate and improve efficiencies of district pumps
Describe the program to evaluate and improve the efficiencies of the contractor's pumps.

As stated previously, the District does not own or operate any groundwater pumping facilities. The District does operate distribution system lift stations and includes those facilities in the District preventative maintenance program including efficiency performance tests.

B. Exemptible BMPs for Agricultural Contractors

(See Planner, Chapter 2, Appendix C for examples of exemptible conditions)

1. Facilitate alternative land use

Drainage Characteristic	*Acreage*	*Potential Alternate Uses*
High water table (<5 feet)	0	Not Applicable[1]
Poor drainage	0	Not Applicable[1]
Ground water Selenium concentration > 50 ppb	0	Not Applicable[1]
Poor productivity	0	Not Applicable[1]

[1]Not applicable as all lands are put to beneficial use.

Describe how the contractor encourages customers to participate in these programs.

2. Facilitate use of available recycled urban wastewater that otherwise would not be used beneficially, meets all health and safety criteria, and does not cause harm to crops or soils

Sources of Recycled Urban Waste Water	*AF/Y Available*	*AF/Y Currently Used in District*
No non-recycled sources of urban wastewater exist within the District	N/A	N/A

3. Facilitate the financing of capital improvements for on-farm irrigation systems

The District maintains a listing of potential funding sources and has an established policy to provide assistance in completing funding application documents. The District is a member of the Farm Service Agency (FSA), formerly known as the Agricultural Stabilization and Conservation Service, which is part of the United States Department of Agriculture. The FSA administers programs concerning on farm conservation and grants loans to farms, through a 50 percent cost-share program for conservation related improvements. The District also financially participates in on-farm efficiency evaluations.

4. Incentive pricing

Structure of incentive pricing	*Related goal*
Off-Peak water usage	Energy Savings
Discounted weekend water rates (program has been discontinued due to no noticeable change in delivery pattern).	Water Availability/Energy Savings were the program goals

5. a) Line or pipe ditches and canals

Not applicable. The District's distribution system is a closed pipeline system.

b) Construct regulatory reservoirs

Regulatory reservoirs required for proper system operation have previously been constructed. No additional facilities are currently required for efficient operation. Funds are budgeted to maintain existing reservoir facilities.

6. Increase flexibility in water ordering by, and delivery to, water users

The District has, over the past few years, been replacing several miles of its distribution system, which was clay mortar joint pipe, which severely leaked, causing a loss in potential delivered supply to the growers. By replacing the old clay mortar joint pipe with new, more efficient and modern pipe, the District has been able to increase its percentage of supply delivered to approximately 98 percent.

The District's water tracking software, which performs a day-by-day comparison of what is ordered versus the recorded delivered volume through each individual meter, allows the District to manage, at high accuracy, the amount of water delivered at each turnout. This level of tracking allows the District to maximize flexibility in water ordering and water accounting based on available system characteristics.

The District does not have a 'water order form.' Water orders are currently submitted to the District by landowners on their own template, via fax, email or in-person at the District office.

7. Construct and operate district spill and tailwater recovery systems

None. There are no District spills.

8. Plan to measure outflow.

This is not applicable to the District, due to the District not having any outflow other than a shallow leaching fraction from applied water.

Total # of outflow (surface) locations/points 0
Total # of outflow (subsurface) locations/points 0
Total # of measured outflow points 0
Percentage of total outflow (volume) measured during report year Not Applicable

Identify locations, prioritize, determine best measurement method/cost, submit funding proposal

Location & Priority	*Estimated cost (in $1,000s)*				
	2009	*2010*	*2011*	*2012*	*2013*
Not Applicable					

9. Optimize conjunctive use of surface and ground water

Historically, the District has primarily achieved its groundwater recharge goals through an in-lieu surface water delivery program. When surface water supplies are available and can be delivered to the District, the surface water supplies are utilized "in lieu" of groundwater pumping. The District will continue this program whenever surface supplies are available and will augment deliveries whenever supplemental supplies can be purchased at a reasonable cost

and ordered for delivery by growers. The District continues to evaluate available and developing banking programs.

10. Automate canal structures

The District utilizes a closed piped system. Automation of structures is currently limited to the District delivery points from the Friant-Kern Canal, which are automated and controlled by the Friant Water Authority. The District has taken the first steps toward total system automation by replacing all main gate control devices and constructing low volume bypass piping and valves at each large diameter system control location. A trial SCADA element is currently in-place, the success or failure of which will be published during this Plan's annual updates.

11. Facilitate or promote water customer pump testing and evaluation

See **Attachment H**, Notices of District Education Programs and Services Available to Customers.

The District has and will continue to provide information to the growers relative to the availability of pump testing and efficiency services provided by the serving utility or local pump companies. The involvement of the District with private pump efficiencies is related to water conservation and overall resource management. The fact that a farmer may apply a given amount of water to a field with a pump which is operating at a less than optimum efficiency does affect the application time and the total quantity of water which is being demanded by the crop. In May, 2012, the District has plans to initially distribute and continuously make available a memorandum informing landowners of the Center for Irrigation Technology's Agricultural Pumping Efficiency Program and a listing of local participating pump test companies.

12. Mapping

GIS maps	*Estimated cost (in $1,000s)*				
	2009	*2010*	*2011*	*2012*	*2013*
Layer 1 – Distribution system	0	0	0	0	0
Layer 2 – Drainage system	N/A	N/A	N/A	N/A	N/A
Suggested layers:					
Layer 3 – Ground water information	0	0	0	0	0
Layer 4 – Soils map	0	0	1	0	0
Layer 5 – Natural & cultural resources	N/A	N/A	N/A	N/A	N/A
Layer 6 – Problem areas	N/A	N/A	N/A	N/A	N/A

C. Provide a 3-Year Budget for Implementing BMPs

1. Amount actually spent during current year.

BMP #		*BMP Name*	*Actual Expenditure (not including staff time)*	*Staff Hours*
A	*1*	*Measurement*	*$0*	*0*

RULES AND REGULATIONS
FOR WATER SERVICE
SOUTHERN SAN JOAQUIN
MUNICIPAL UTILITY DISTRICT

Adopted January 11, 1989, Revised September 13, 1989, February 13, 1991, February 10, 1993, January 12, 1994, March 1, 1994; Effective March 1, 2002.

A. GENERAL

(1) Authority:

Article 4, Section 11885 of the Municipal Utility District Act states as follows:

The Board shall supervise and regulate every utility owned and operated by the District including the fixing of rates, rentals, charges, and classification, and the making of rules, regulations, contracts, practices, and schedules for or in connection with any service product or commodity owned or controlled by the District.

(2) Applicable Contracts with United States of America:

The District receives its surface water supply by Contract I1r-1460-LTR1, with the United States from the Central Valley Project and delivers its supply through a pipeline distribution system constructed by the United States under Contracts 175r-1434 and Supplementary Contract 14-06-200-6660.

(3) Definitions:

The following definitions shall be applicable to these Rules and Regulations:

Board: The Board of Directors of the Southern San Joaquin Municipal Utility District.

Bureau: Bureau of Reclamation of the United States Department of Interior.

District: Southern San Joaquin Municipal Utility District

Schedule A Lands: Those lands within the District's boundaries, as of March 1, 2001 which are presently connected to the District's distribution system and which either (a) have received a surface water supply from the District during the five (5) years immediately preceding March 1, 2001, or (b) which were designated excess land according to Federal Reclamation Law in effect prior to October 12, 1982, but which have become eligible prior to March 1, 2002.

Schedule B Lands: Those lands within the District's boundaries as of March 1, 2001, or as subsequently annexed to the District, not defined as Schedule A lands.

Water User: The individual or entity who either owns, leases or in a wholesale capacity distributes water to property within the District and makes application with the District for water service, and is responsible for ordering, controlling, using and paying for water received from the District.

Water Year or Year: March 1 through the last day of February.

B. DELIVERY OF WATER

1) District Water Supply – General: The District sells water as a commodity only and not as a guaranteed service and will not be liable for defective quality of water, shortage of water, either temporary or permanent, or for failure to deliver water or delay in doing so. The District assumes no liability for damages to persons or property occasioned through defective works.

The District's water supply is in a raw, untreated condition, and as a result is considered to be unfit for human consumption without treatment. The District does not warrant the quality of water delivered and is under no obligation to construct or furnish water treatment facilities or maintain or better the quality of water.

(2) Applications: Each year prior to February 15, Water Users shall file on a form provided by the District, an "Application for Water" for the forthcoming Water Year. Said application shall contain the following:

(a) Name and address of the Water User.

(b) Telephone number of the Water User and telephone number of the local individual who manages or irrigates the farm or distributes water.

(c) Farm or operation delivery numbers, with legal descriptions, Assessor's parcel numbers, assessed acreage, ownership and Schedule A or B land designation, crop, type of irrigation method and requested quantity of water, for each delivery.

(d) If the Water Application is for leased land, the Landowner must also sign the Water Application along with the Lessee.

Unless previously paid, the Water Application shall be accompanied with a deposit of 18.00 per irrigable acre. However, if in the judgement of the General Manager, the applicant for water is a poor risk, an additional sum may be required to guarantee payment of water bills. The deposit does not represent any particular quantity of water and will be returned when the Landholder ceases to operate the lands served by the outlet. Existing deposits held by the District are considered grandfathered until the land is either sold or assessed per D(2)(a). All deposits paid after March 1, 2002 shall be made in the amount of $18.00 per irrigable acre.

The water year begins on March 1. Applications received after the above deadline may result in a delay of water service while the application is reviewed. In any case, water deliveries will be delayed a minimum of 48 hours after the forms are received.

(3) Bureau Forms: The Water Application must also be accompanied by the proper Bureau Certification or Verification forms for the forthcoming Water Year (unless previously submitted). Such forms must be completed by the Landowner, and where the property is leased, by the lessee. No water will be delivered until the forms, properly completed, are in the District office. Forms may be obtained in the District office.

District staff will review the forms for completeness but are not responsible for errors not found. The District is not responsible for deliveries made to landholders filing forms with incorrect information or if no forms have been filed. The landholder is responsible for filing timely and correct forms.

(4) Land Sales: If, during a year in which water is allocated, a parcel of land is sold, the remaining water, if any, allocated to that land will be assigned to the new owners. However, if the seller has used all of the water allocated to the land, the new owner will not have a water allocation until the next Water Year.

Upon sale of the land, change in a lease or other operating arrangement, both parties must notify the District within 15 days (verbally or by letter) and file new Certification forms within 30 days. However, no water will be delivered to newly acquired land until the proper forms are filed with the District. Landholders not notifying the District of a change in status will be responsible for any charges incurred until such notification is given.

If the proper forms are not filed within 30 days, any water that may have been delivered may be charged at "Full Cost" from the date of the change of status until the forms are filed.

(5) Excess Supplies/Pools: A Water User who retains his allocation with the intent to use in the current Water Year will pay for such water. A Water User who releases his remaining allocation prior to August 15 will not be charged for the water. Water released on or after said deadline, will be charged to the landholder except for the water which can be disposed of by the District.

Prior to February 15 each year, Water Users must apply on the Application for Water form provided by the District for water allocated to the District by the United States Bureau of Reclamation. In the event

requests exceeds allocation, Water Users requests shall be pro-rated to each eligible acre of land within the District proportionally based on the total eligible acreage within the District.

Unused requested and/or pro-rated water will be billed after the last day of February of the same Bureau water year. Unused water will be billed and not eligible to be carried over. Water may be transferred from one parcel to another parcel provided the parcels are owned or leased by the same person(s) or company. No landholder or Water User can transfer or exchange water outside the District service area.

Prior to but not later than August 15 each year, Water Users having reserved water greater than they can use on eligible land owned or leased by them will be allowed to assign their excess water to a common pool. Pool water will be made available on a first come, first served basis to other Water Users for use on eligible lands in the District. Either Board policy or the General Manager, depending on existing circumstances, will determine the disposition of water remaining in the common pool at the end of the irrigation season.

(6) M & I Deliveries: No Water User is eligible to be delivered water for municipal or industrial uses, as defined in the District's contract with the Bureau, until it has complied with the District's M&I water policy and procedures.

(7) Excess Lands: Water received through District delivery outlets shall not be used to irrigate or provide water to excess lands as determined by the Bureau. Violators are subject to a cut off of water delivery until the situation is rectified and may be assessed the full-cost rate, plus interest, for any such water delivered.

(8) Place of Use: Water received under the District contracts with the United States shall not be used to irrigate or provide water to lands outside of District boundaries, except in certain circumstances as determined by the Bureau and the Board. Violators are subject to cut off of water delivery and other penalties which may be prescribed by law.

(9) Turn Ons and Turn Offs: All adjustments and turning on and off of water deliveries, gates and pumps are performed by District personnel. Unauthorized individuals tampering with District facilities are subject to a Misdemeanor charge as prescribed by the California Penal Code.

Water delivery changes are made six (6) days a week with no changes on Sundays. Water Users desiring water shall place their water orders a minimum of 24-hours in advance. For example, to have water turned on or off on Tuesday morning, the water order must be placed with the District Dispatcher (phone 725-0610) by 9:00 A.M. Monday morning. Water orders can also be faxed to 725-2110 or emailed. Water orders are taken between the hours of 7:00 A.M. to 3:30 P.M. Monday through Friday and 7:00 A.M. to 9:00 A.M. on Saturday. No orders are taken on Sunday and orders for Monday changes must be in by 9:00 A.M. Saturday. All orders are compiled by the Dispatcher in order to place the District water order for the next day deliveries. Water orders should not be called into the Ditchrider's homes as those orders may not be accepted by the Dispatcher the following morning.

The District has an employee designated for standby to handle emergencies during off-duty hours. During holidays and off-duty hours, Water Users must call 725-0610 and choose option 5 to report an emergency. Please do not use this emergency service for a non-emergency use. An emergency is a broken pot, ruptured pipeline or similar failure, not an error in scheduling water. Excessive use of emergency service may result in a service charge of up to $50.00 per call.

(10) Access: To operate the system, it is necessary to have access to valves, meters, etc. No delivery of water will be made to a Water User who blocks access to his delivery or provides an unsafe condition for District personnel.

(11) Runoff Prohibited: In addition to the reasons stated above, the District reserves the right to turn off Water deliveries in those instances of a Water User not taking care of his water and flooding roads or neighboring lands. Prior to turning off such a delivery an attempt will be made to reach by phone the responsible party causing the flooding.

(12) Carryover/Preuse: To the extent permitted by the Bureau in administering the water supply contract between the District and Bureau, the District may carryover water allocated or acquired from the prior Water Year or to preuse water to be allocated the next Water Year, as the case may be, but carryover or preuse will not be permitted for individual water users.

(13) Responsibility After Delivery: The District assumes no responsibility for water after it passes through its meter and into a Water User's pipeline or ditch. As a condition for water service, Water User shall indemnify and shall assume the defense of and hold harmless the District and its officers, agents and employees for any and all loss, damage, liability, claims or cause of action of every nature whatsoever, for damage to or destruction of property, including the District's property or for injury to or death of persons, in any manner arising out of or incidental to the control, carriage, handling, use, disposal or distribution of water once it has passed the District's meter.

(14) Subdivided Parcels – Additional Turnouts: Water Services shall only be provided to a single parcel through a turnout designated to serve that parcel only, the water user of which is eligible to receive water upon such lands. After April 13, 1994, the District shall not provide water service to any parcel which does not have a turnout designated to serve that single parcel, unless, and only so long as, the Manager determines that multiple parcels served by a single turnout are under common ownership and/or control. Accordingly, for any land after such date which is further sub-divided, the owners of such land must make arrangements at their sole cost and expense for the District to install additional turnout(s), such that each sub-divided parcel has its own turnout, together with any necessary easements across other landowner's land so that water service can be provided for from a turnout located within the District's existing right-of-way. Notwithstanding the foregoing, the General Manager may, at District expense, provide for the District installing additional turnouts such that multiple parcels being served by a single turnout prior to April 13, 1994, are thereafter served by separate turnouts.

C. ALLOCATION OF WATER

(1) General: Any Water User of lands within the District designated nonexcess (or otherwise made eligible to receive water) who has otherwise complied with these Rules and Regulations and policies of the Board, including having timely submitted an application for water service, is entitled to water service made available to the District under the Contract with the Bureau. Provided, however, no Schedule B lands shall be eligible to receive any share of the District's contract entitlement until all applications for Schedule A lands are fulfilled.

(2) Allocation of Class I and Class II Water: The District's annual entitlement of Class I and Class II water shall be distributed according to requests taken from water applications. During dry years, requests may be allocated proportionately to all applicants on the basis of the acreage entitled to receive water (i.e. designated nonexcess or otherwise entitled to service under reclamation law). Provided, however, no Schedule B lands shall be eligible to receive any share of the District's Class I entitlement until all applications for Schedule A lands are fulfilled.

In any year in which the District's water supply under its contract with the Bureau is adequate to supply all applications for Schedule A lands, but not all Schedule B lands, the Schedule B lands shall share in such a shortage on a proportionate acreage basis.

(3) Allocation of Other Water from Bureau: Notwithstanding the foregoing, water made available by the Bureau beyond the District's contract providing for Class I and Class II water will be allocated to meet the demands of any Schedule A lands within the district, and secondly shall be allocated equally on a per acre basis to owners or operators of Schedule B lands within the District requesting service. Such water shall include, but not be limited to, water which is unstorable or flood flows.

(4) Allocation of Water Other than from the Bureau: In spite of the foregoing, water which the District acquires from sources other than the Bureau shall be marketed within the District to Water Users at a price which reflects the cost of acquiring such additional supplies, and shall be allocated on a "first come, first served" basis.

(5) Allocations of System Capacity: At times that there is inadequate capacity upon a particular lateral to meet the request of all Water Users requesting water service at that particular time, the District shall first reduce the quantity of water provided to each Water User's turnout to the capacity for which the system was originally designed, which was 3.74 acre-feet per day per 160-acre parcel (approximately 5.29 gallons per minute per acre), and then in the event that there is still inadequate capacity upon a particular lateral, the District shall prorate the quantity provided to each Water User requesting service at that particular time on an equal basis per acre. The Board may provide specific exceptions to the foregoing where landowners in a particular service area have funded enhancements of the system to provide a greater level of service, such as the East System Improvement Project.

D. PAYMENT

(1) Tolls and Charges: Payments required to be paid in order for a Water User to be eligible to receive water from the District include the following:

(a) Standby charges, annually fixed by the Board on a per acre basis for the availability of water and/or groundwater benefits, assessed to all "irrigated lands," regardless of whether eligible or capable of receiving water from the District, and collected by the County of Kern along with property taxes.

(b) Water tolls, annually fixed by the Board on a per acre-foot basis, and paid for by Water Users in the manner set forth following. The Board shall fix a basic Water Toll to cover District costs attributable to providing water service to all Water Users, including, but not limited to, the following costs: Water, District operation and maintenance, administration, debt service (to the extent not covered by the standby charge) and reserve accounts. In addition thereto, Water Toll surcharges shall be charged for each lift through a District pumping plant based on the estimated power cost to pump an acre-foot of water through each plant.

(c) Bureau charges, including cost of service charges, Friant surcharge, restoration fund payments, and full-cost charges where applicable, fixed by the Bureau and added to water tolls as applicable, and paid by Water Users in the manner set forth following. The District may impose an administrative charge in addition to such Bureau charges.

(d) Non-contract water, such as water purchased from outside the District or groundwater put into the District's distribution system, will not be charged the charges in (b) and (c) above. However, a service charge will be fixed to cover District costs attributable to delivering such water, including, but not limited to, the following costs: District operation and maintenance, administration, debt service, Bureau of Reclamation charges for use of federal facilities and surcharges for each lift through District pumping plant based on the estimated power cost to pump an acre-foot of water through each plant. The District reserves the right to deny any request for delivery of such water if it may create capacity, water quality problems, endangering public safety or during a bona fide emergency event.

(2) Payment Schedule: The water service contract with the Bureau requires the District to prepay for all water prior to delivery to the District and, therefore, the following regulations will apply:

(a) Payments of monthly water bills are due and payable on or before the 20th of each month for water used the prior month. Payments not received on or before the 20th will be assessed a 10% penalty plus interest at 1-1/2% per month, and if not paid by 8:30 A.M. on the 26th of the month, the water will be shut off on the 27th of the month, and no water orders will be accepted until payment is made in full. An additional deposit totaling $28.00 per assessed acre will be required before water service is resumed if a bill is delinquent sixty (60) days after date of penalty. If the aforementioned steps have been imposed on a Water User and the General Manager believes noncompliance will persist, that Water User may, at the discretion of the General Manager, be required to submit a monthly schedule for water delivery and pay for said water by cash or cashier's check thirty (30) days in advance of delivery.

(b) Lands or parties which are in arrears in payment to the District of any assessments, standby charges, water tolls, penalties or interest, will not receive District water until payment in full is made as set forth above. Water will be delivered in accordance with Contract I1r-1460-LTR1 with the United States… "The Contractor shall not furnish water made available pursuant to this contract for lands or parties which are in arrears in the advance payment of water rates levied or established by the Contractor." (Art. 22(b))

(3) Means of Payment: For payment of bills by check, other than those signed by the Water User and applicant, the District requires the name of the account being paid. Checks which do not identify the account being paid will be returned. When paying two or more accounts, the District requires a separate check for each account being paid in order that a true and exact audit trail can be made. Checks received paying for more than one account will be returned. Penalties and interest will be assessed if the account becomes delinquent.

(4) NSF Checks: Checks returned for non-sufficient funds will be charged an additional $50.00 service charge. All accounts paid by such check will be delinquent and assessed penalties as above.

(5) Delinquencies: As prescribed by California Public Utilities Code Section 12811.1, any fees, tolls, rates or other charges which become delinquent, together with interest and penalties thereon, shall become a lien on the real property within the District for which the services were provided upon the District filing a certificate with the County Recorder, which lien shall have the same force, effect and priority as a judgment lien. This remedy is in addition to other remedies provided by law. In order to partially recover the District's costs incurred in processing said lien, added to said lien will be a service charge of $100.00.

E. ENFORCEMENT OF RULES AND REGULATIONS – APPEALS – AMENDMENTS

(1) The General Manager of the District is authorized to perform all acts necessary and proper to enforce these Rules and Regulations. Failure of a Water User to comply with any of these Rules and Regulations shall be sufficient cause for the termination of water service, and water service will not again be furnished to such Water User until full compliance has been made with all the requirements as herein set forth; PROVIDED, HOWEVER, that Water User in no way be relieved of any responsibility for payment of any charge or obligations by reason of such termination of water service. When it is practicable to do so, advance notice of any such termination of water service will be furnished to Water User. In no event shall any liability accrue against the District or any of its officers, agents or employees, for damage, direct or indirect, arising from such terminations of water service. Non-enforcement of any provision of these Rules and Regulations does not constitute a waiver of the District's right of enforcement at any time.

(2) In the event a Water User disagrees with a decision made by the General Manager in carrying out the enforcement of these Rules and Regulations, he/she shall have the right of appeal to the Board. Appeals should be submitted in writing no less than five (5) days prior to a regular meeting of the Board in order to be considered at that meeting, and shall specifically set forth the decision being appealed and shall give the reasons for said appeal.

(3) These Rules and Regulations shall become effective March 1, 2002, and may be added to, amended or repealed at any time by resolution of the Board of the District.

HELPFUL INFORMATION

- Water Applications and RRA Forms are due in the Office by February 15 each year. (pages 3 & 4)
- Return of excess water is due by August 15 each year. (pages 4 & 5)
- Payments are due by the 20th of each month. (Page 10)
- To place an order for water. (page 6)
    - By Phone: 725-0610 between 7 a.m. & 3:30 p.m. Monday through Saturday.
    - By Fax: 725-2110
    - By email.
    - In person.
- To report an emergency, call 725-0610, choose option 5. (page 6)

ATT.: Mr. Bill Carlisle

Re: Groundwater Management Plan Update

Dear Bill,

As requested, Cornerstone Engineering has reviewed the current groundwater management plan and compared it against applicable provisions in the California Water Code as revised by AB 3030. This report summarizes AB 3030 requirements for groundwater plans, the condition of SSJMUD's existing groundwater plan and the provisions of the plan requiring action.

AB 3030 requirements

As stated on the Department of Water Resources groundwater web page,

The Groundwater Management Act, commonly referred to as AB 3030, was signed into law on September 26, 1992, and became effective on January 1, 1993. The legislation is designed to provide local public agencies with increased management authority over groundwater resources in addition to those existing groundwater management capabilities. AB 3030 was developed in response to Environmental Protection Agency's Comprehensive State Groundwater Protection Programs...Action is voluntary not mandatory.

Attached is a copy of the applicable Water Code Sections 10750-10756.

The purpose of the legislation was to encourage local agencies to work cooperatively to manage groundwater resources within their jurisdictions to ensure the safe production and quality of groundwater.

The water code states groundwater management plans may include elements relating to all of the following:

1. The control of saline water intrusion.

2. Identification and management of wellhead protection areas and recharge areas.
3. Regulation of the migration of contaminated groundwater.
4. The administration of a well abandonment and well destruction program.
5. Mitigation of conditions of overdraft.
6. Replenishment of groundwater extracted by water producers.
7. Monitoring of groundwater levels and storage.
8. Facilitating conjunctive use operations.
9. Identification of well construction policies.
10. The construction and operation by the local agency of groundwater contamination cleanup, recharge, storage, conservation, water recycling, and extraction projects.
11. The development of relationships with state and federal regulatory agencies.
12. The review of land use plans and coordination with land use planning agencies to assess activities which create a reasonable risk of groundwater contamination.

As stated by the Department of Water Resources,

Each component would play some role in evaluating or operating a ground water basin so that ground water can be managed to maximize the total water supply while protecting ground water quality.

Department of Water Resources' Bulletin 118-80 (page 9) defines ground water basin management as including planned use of the ground water basin yield, storage space, transmission capability, and water in storage. Ground water basin management includes:

1. *Protection of natural recharge and use of intentional recharge;*
2. *Planned variation in amount and location of pumping over time;*
3. *Use of ground water storage conjunctively with surface water from local and imported sources; and,*
4. *Protection and planned maintenance of ground water quality.*

The 12 components listed in Section 10753.7 of the Ground Water Management Act (AB 3030) form a basic list of data collection and operation of facilities that may be undertaken by an agency operating under this act.

Data collection will provide information to evaluate the water resources in the basin within the boundaries of the district. The construction of facilities will allow operation of the basin to protect ground water quality and to maximize the water supply by means of recharge of surface water and extraction of ground water at appropriate times and locations."

Included in the attachments are details of applicable elements from the Department of Water Resources that may be of use to SSJMUD.

Additionally, the legislation as defined in the water code contains provisions with regard to adoption of rules and regulations to implement and enforce the plan including the imposition of

fees and assessments, land annexation into the district, and coordination of the plan with adjacent districts.

Existing Groundwater Management Plan

The following summarizes the action points of the existing plan:

- Meet and coordinate groundwater plans with other agencies who share the San Joaquin Valley basin such as North Kern Water Storage District and Delano-Earlimart Irrigation District
- Preserve water rights and contracts respecting surface water supplies
- Integrating the conjunctive use of surface and groundwater supplies to achieve the optimal use of each by surface delivery in lieu of groundwater pumping, transfers and exchanges with neighboring areas, and groundwater banking
- Pricing surface water at rates which induce water users to buy surface water when available, rather than pumping groundwater
- Groundwater data collection and monitoring for the purpose of documenting accomplishments of the Management Program and to identify and implement specific programs to reflect changing conditions of the basin. This includes for example, continuance of spring and fall collection of water level data, utilization of water quality monitoring wells to sample and test water quality, and hydrologic data collection.
- Monitoring of the districts financial ability to implement the groundwater plan and if necessary, implementing groundwater replenishment assessments as well as water extraction fees

Recommended Action

The Department of Water Resources has no formal Groundwater Management Plan review procedure. Details of groundwater management plan elements are discretionary, as applicable to the specific needs of each managing district.

The existing SSJMUD Groundwater Management Plan appears to meet the basic intent of AB 3030 even though it was enacted pursuant to AB-255, which has been superseded by AB 3030. At this juncture, the recommended course of action is to apply district groundwater management policies already in place. An evaluation and prioritization should be made of the twelve AB 3030 suggested plan elements mentioned above. This information will be helpful in executing the action points of the existing groundwater plan.

For clarification purposes, it is recommended the existing plan basis be changed from the current AB 255 basis to an AB 3030 reference. All other provisions in the plan appear satisfactory.

Despite the fact AB 3030 is more advisory rather than regulatory, a well-monitored groundwater management plan will greatly benefit SSJMUD and help to preserve this vital resource.

It should be noted Mr. Carl Hauge of the Department of Water Resources was very helpful in providing assistance in our research. He can be reached at (916) 327-8861 or chauge@water.ca.gov.

If you have any questions, please contact Mark Dawson at this office at (661) 325-9474.

Respectfully,

CORNERSTONE ENGINEERING, INC.

[i] California Department of Water Resources, May 22, 1998
[ii] Ibid., December 29, 1999

BEFORE THE BOARD OF DIRECTORS OF
THE SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT

IN THE MATTER OF: RESOLUTION NO. 93-11

RESOLUTION OF THE BOARD OF DIRECTORS OF THE
SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT
TO ADOPT A GROUNDWATER MANAGEMENT PROGRAM PURSUANT
TO PART 2.5 OF DIVISION 6 OF THE CALIFORNIA WATER CODE

WHEREAS, pursuant to Resolution No. 92-10, adopted December 9, 1992, this Board set the date of a public hearing pursuant to Water Code section 10753 to consider a proposed groundwater management program;

WHEREAS, as prescribed by Water Code section 10753, the Board provided notice of that hearing on the question of adopting a groundwater management program; and

WHEREAS, on July 14, 1993, as prescribed by the above-referenced notice, this Board of Directors conducted hearings on the proposed groundwater management program; and

WHEREAS, no written protest to adoption of the plan has been filed; and

WHEREAS, having fully considered all testimony received at the hearing, this Board finds that it is in the best interest of the District and its landowners to adopt a resolution to implement the District Groundwater Management Program attached hereto.

NOW, THEREFORE, BE IT RESOLVED, by this Board of Directors that said Board declares the adoption of the attached District Groundwater Management Program attached hereto;

BE IT FURTHER RESOLVED, that the secretary-manager is directed to provide copies of the adopted District Groundwater Management Program to any interested persons who may request a copy of said program.

ALL THE FOREGOING, being on motion of Director Shick, and seconded by Director Peck, was authorized by the following vote:

AYES: Directors Antonell, Hiett, Clement, Peck & Shick

NOES: None

ABSENT: None

ABSTAIN: None

I HEREBY CERTIFY that the foregoing is the resolution of said District as duly passed and adopted by said Board of Directors on this 10th day of August 1993.

WITNESS my hand and seal of said Board of Directors this 10th day of August 1993.

Secretary of the Board of Directors

(SEAL)

SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT
PHONE DELANO 725-0610
P.O. BOX 279 DELANO, CALIF. 93216

June 16, 1993

To All Water Users and Landowners:

Enclosed for your information is a copy of a proposed Groundwater Management Plan which is being considered by the District. The Board of Directors will hold a public hearing on the Plan at 2:00 P. M. on July 14, 1993 in the District office.

This plan is being proposed pursuant to Part 2.5 of Division 6 of the Water Code. The District Board of Directors believes that it is in the best interest of the District and its landowners to adopt such a plan and thereby reduce the opportunity for the State or others to attempt to impose groundwater management in the future.

Your attention is called to page 7 of the plan which explains the procedure for adopting a plan.

The powers of the District under the plan are explained on page 6. Under any plan adopted, the District would have the authority to levy and collect groundwater replenishment fees and extraction fees. However, we do not intend to do so at this time. Furthermore, any fees would have to be approved by the District voters.

If you have any questions, please call.

Sincerely yours,

STANLEY T. NELSON, JR.
General Manager

PROCEDURES FOR ADOPTION OF PROGRAM	7

SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT
GROUNDWATER MANAGEMENT PROGRAM
MAY 12, 1993

The Southern San Joaquin Municipal Utility District (District) desires to formalize its existing Groundwater Management Program to provide for the continuance of local management, and to enhance existing monitoring activities so as to position itself to identify and implement modifications to its ongoing program that may be required to preserve and enhance the groundwater resource. Accordingly, the District is proposing to organize its existing Groundwater Management Program under provisions of California Water Code 10750 et seq., which were added through enactment of AB-255 and became effective January 1, 1992. With adoption of Resolution 92-10 on December 9, 1992, the District commenced procedures to enact a Groundwater Management Plan pursuant to AB-255.

Preservation and enhancement of the groundwater resource is vital to sustaining the local economies which have been built up in reliance, in whole or in part, on this resource. Physically, the District's objective is to preserve the utility of the groundwater resource, both in terms of quantity and quality. Further, enhancement or augmentation of the resource is necessary to mitigate the present level of overdraft in the overall groundwater basin and the attendant long-term decline in groundwater levels. Economically, the District's objective is to accomplish the stated physical objectives at least cost to minimize or reduce any duplication of agencies by establishing a local management program.

MANAGEMENT AREA

The previously cited provisions of the California Water Code provide for the development of a management program within the boundaries of the District. The District's underlying groundwater basin is part of the larger basin which is part of the south San Joaquin Valley basin. It is proposed that the management area for the District's Program may include agreements with adjacent areas which would encompass the area of influence of groundwater activities. The adjacent areas would include lands in the North-Kern Water Storage District, and Delano-Earlimart Irrigation District.

PROGRAM ELEMENTS

The objective of the Groundwater Management Program is to preserve and maximize the utility of the groundwater resource through conjunctive use with available surface water, all with the view of obtaining an adequate water supply of satisfactory quality and quantity at the least possible cost to sustain the agriculture production in the District and an adequate supply for towns and cities within the District. Elements have been formulated to achieve the objectives and are presented in the sections which follow. Necessarily, the subsequent discussion includes a description of management activities which are presently in place.

SURFACE WATER SUPPLY

Groundwater management in California is rooted in the conjunctive us of surface and groundwater resources. Simply, water supplies from the two sources are integrated to accomplish the optimum utilization of each. In this regard, the District's primary source of surface water supply is imported Central Valley Project water (originating i Millerton Lake on the San Joaquin) under long-term contract with the United States. Also, the District makes short-term and year-to-year arrangements to secure additional Central Valley Project (CVP) and other supplies. The District has conjunctively utilized CVP waters and groundwater since 1951. The District has in place and operates an extensive system of conveyance and distribution facilities throughout its service area to make use of the surface supplies as available.

Under the subject Program, the District will seek to preserve the water rights and contracts respecting its surface water supplies. Further, the District will pursue opportunities to supplement these supplies. Additional opportunities could include the purchase of additional CVP or ''Section 215 water'' and any other water which may be available in the future at reasonable cost.

GROUNDWATER BASIN CHARACTERISTICS

The physical characteristics of the groundwater basin substantially shape the Groundwater Management Program. In particular, the manner in which groundwater is replenished is directly affected by surface and subsurface characteristics, such as the permeability of the overlying and subsurface soils. Replenishment of the groundwater resource is more particularly discussed in the section following.

GROUNDWATER REPLENISHMENT

The replenishment of groundwater underlying the District occurs naturally and through deliberate, controlled means (artificial). The District's groundwater replenishment is achieved indirectly through the delivery of surface water, when available, to lands otherwise relying on the groundwater resource (also referred to as in-lieu recharge, i.e., delivery of surface water in lieu of groundwater pumping). The importation of CVP water has totaled over 4.3 million acre-feet over the last 42 years for both surface delivery and groundwater replenishment activities. Additionally, irrigation water not consumed by evapotranspiration of cropped lands returns to the underlying groundwater system.

Under the Management Program, the District will make every effort to preserve the presently available in-lieu recharge capabilities, and will consider enhancement of these capabilities as well as the development of additional facilities. Delivery of surface water in lieu of groundwater pumping will continue, limited only by the availability of surface water and distribution facilities.

CONJUNCTIVE USE OF SURFACE AND GROUNDWATER

As discussed previously, groundwater management is the conjunctive use of surface water and groundwater supplies where conjunctive use refers to integrating the two sources of supply to achieve the optimal use of each. The District's conjunctive use program reflects available facilities, groundwater basin characteristics, and the nature of the surface water supplies respecting availability and institutional considerations. In particular, the District's conjunctive use program includes surface delivery in lieu of groundwater pumping, transfers and exchanges with neighboring areas. Further, it depends on available groundwater storage capacity and, conversely, it depends on groundwater in storage when needed to supplement available surface supplies.

Surface delivery in lieu of groundwater pumping motivated the District to enter into a long-term contract with the United States in 1945 for the importation of a supplemental surface water supply from the Friant Unit of the CVP. This aspect of the District's program relies on its extensive system of irrigation distribution facilities.

Water transfers and exchanges, in various forms, are also a part of the District's conjunctive use program. Under the Management Program, the District will seek to preserve and enhance its conjunctive use activities. Enhancement of conjunctive use activities could include the development of groundwater banking arrangements with other agencies utilizing their storage capacity or the groundwater storage capacity within this District.

MANAGEMENT OF GROUNDWATER EXTRACTIONS

Effective groundwater replenishment necessarily involves both the management of water supply to the basin and the management of the extractions from the basin. Extractions within the management area are by private wells and those wells owned and operated by the City of Delano and Mcfarland Mutual Water Company for municipal and industrial purposes. It is expected that management of groundwater extractions in the District can be achieved through economic inducement rather than regulating extractions. This has been achieved and would continue to be implemented by pricing surface water at rates which induce water users to buy surface water when available, rather than pumping groundwater. The District also attempts to assist water users to qualify for delivery of surface water, but Federal Reclamation Law and Regulations as to eligibility and pricing often inhibit these efforts.

MONITORING

Optimal use of the groundwater resource is dependent on obtaining good basic data respecting both geology and hydrology. The purpose of this element of the Program is to characterize the conditions within the groundwater basin, both to document the accomplishments o the Management Program and to identify and implement specific programs, as needed, to reflect changing conditions in the basin. Monitoring includes gathering the basic data and analyzing these dat to characterize the basin and would be subject to modification, as needed, to reflect changes or additions in the programs implemented under the Management Program. Monitoring is considered critical to future management decisions. Accordingly, the District's present activities in this regard may be expanded.

WATER LEVELS

Data respecting water levels are used to evaluate groundwater flow and storage conditions. Maps showing contours of equal water level elevation indicate the direction of groundwater movement and can be used to quantify estimates of groundwater under flow entering and leaving the management area. Maps of depth to groundwater can provide insight into the distribution of pumping lifts (and so assist in estimating pumping cost). Maps showing changes in groundwater levels (when used in conjunction with data on specific yield) can be used to estimate changes in groundwater storage. In addition to these water level maps, hydrographs of water levels in selected wells provide information on seasonal and long-term variations in water levels.

The District routinely measures water levels in both the spring and fall. The present monitoring network will be reviewed in order to provide sufficient areal coverage to prepare representative water level evaluation and depth contour maps. Measurement of water levels will continue to be performed in both spring and fall in order to show seasonal variations in water levels. Using the same wells for monitoring over a long-term period will facilitate the preparation of meaningful water level change maps and hydrographs.

WATER QUALITY

Water quality monitoring, including water sampling and testing, will identify the suitability of groundwater for various uses. A network of water quality monitoring wells has been established to provide sufficient data to allow preparation of water quality contour maps. The same wells can be sampled each year, allowing long-term water quality trends to be identified. It is envisioned that supplemental water quality sampling would also be performed at other wells, as needed to better define localized areas of impaired water quality. Water quality testing may typically include standard agricultural-type analyses, but may also include additional testing (e.g., Title 22) as required.

WATER SUPPLY AND WATER SUPPLY USE

Data related to the hydrologic inventory of the basin will be collected annually. These data will allow quantification of the various elements of the hydrologic inventory, and will support further analysis of the impact of various elements of the Program. Principal components of the inventory to be considered include amounts of water replenished and quantities of groundwater pumped.

ANALYSIS

Documentation, in the form of a monitoring report, will be prepared as required to present the results of the monitoring element of the District's Program. The contents of the monitoring report could include:

1. Maps showing spring and fall water elevations;

2. Maps showing spring and fall depths to water;

3. Map showing change in water levels from spring to the current year to spring of previous year;

4. Estimate of change in groundwater storage computed using specific yield data and maps of change in groundwater levels;

5. Assess effectiveness of management activities.

INSTITUTIONAL CONSIDERATIONS

The Groundwater Management Program requires a public body, endowed with appropriate powers, to carry out the Program. California Water Code Sections 10750 et seq. provide the necessary powers. Prior to enactment of these provisions of the Water Code, the vehicle best suited to the management of groundwater was the water replenishment district. Many of the powers granted a Water Replenishment District are granted to the agency organizing its program under the cited provisions of the Water Code.

The District would (upon adoption of the Program) have the authority to levy and collect general groundwater replenishment assessments, as well as water extraction fees based on the amount of groundwater extracted from the aquifier. However, these fees must be ''ratified'' by a majority vote in an election governed by the election rules applicable to the District. At the present time the Board does not intend to invoke such powers, intending instead to rely on water charges and standby charges to pay for district costs. However, changing Federal and State regulatory actions and water conditions may cause the District's entire financial program to be reassessed in the future.

Powers granted to a district which adopts a Groundwater Management Program include the powers of a Water Replenishment District (Part 4, of Division 18, of the Water Code), to the extent not already possessed by a district, including, but not limited to the following:

a. Acquire and operate facilities, waters and rights needed to replenish the groundwater supplies;

b. Store water in groundwater basins, acquire water rights, import water into the District, and conserve water;

c. Participate in legal proceedings as required to protect and defend water rights, and water supplies, and to prevent unlawful exportation of water from the District;

d. Under certain conditions to exercise the right of eminent domain;

e. Act jointly with other entities in order to economically perform required activities;

f. Carry out investigations required to implement the program;

g. Fix rates for water for replenishment purposes; and

h. Fix the terms and conditions of contracts for use of surface water in-lieu of groundwater.

PROCEDURE FOR ADOPTION OF PROGRAM

At the conclusion of the May 12, 1993 public hearing, the Board of Directors approved a draft of the Groundwater Management Program and adopted the Resolution of Intention to Adopt and Implement the Program. Copies of the Groundwater Management Plan will be sent to each owner of a water extraction, storage, or distribution facility within the District, and upon written request, to any other interested person. The Board of Directors also fixed the time, date and place for a second hearing to be held by the Board of Directors for the purpose of considering protests to the implementation of the Groundwater Management Program (a notice of the second hearing will be appended to the Groundwater Management Program). Furthermore, notice of said public hearing shall also be published in accordance with the provisions of California Government Code Section 6066.

At any time prior to the conclusion of the second public hearing, any landowner within the District may file a written protest or withdraw a protest previously filed. A protest by a landowner shall include the landowner's signature and description of the land owned sufficient to identify the land. A public agency owning land is deemed to be a landowner for the purpose of making a written protest.

If at the conclusion of the second public hearing the Board of Directors finds that a ''majority protest'' exists, the Groundwater Management Program shall be abandoned and no new program shall be considered by the Board for a period of one (1) year. If a ''majority protest'' have not been filed, the Board of Directors, within thirty-five (35) days after the conclusion of the hearing, may adopt a resolution to implement the Groundwater Management Program. A ''majority protest'' shall be determined to exist if the Board of Directors of the District finds that protests filed and not withdrawn prior to the conclusion of the second public hearing represent more than fifty percent (50%) of the assessed value of the land within the Southern San Joaquin Municipal Utility District. (Water Code Section 10757).

As part of the Groundwater Management Program, the Board of Directors reserves the right to subsequently amend the program or adopt another type of groundwater management program after following procedures required by law in order to repond to changing conditions.

RE: AGRICULTURAL PUMP EFFICIENCY TESTING

This memorandum is being distributed to inform Landowners within the Southern San Joaquin Municipal Utility District (SSJMUD) of the Center for Irrigation Technology's Agricultural Pumping Efficiency Program (Program) funded by the Pacific Gas and Electric Company's (PG&E) Advanced Pumping Efficiency Program through 2012 using the Public Purpose Programs Fund under the auspices of the California Public Utilities Commission. The program offers 2,300 subsidized pump efficiency tests per year and cash incentives for 300 pump retrofit projects per year. Below is a listing of local participating pump test companies and other local companies that can provide pump testing services. For more information on the Program and a full complete listing of all participating pump testing companies, please visit the Center for Irrigation Technology's website at http://www.pumpefficiency.org.

This memorandum contains information on a program that is supplemental to the normal pump efficiency service information provided by the District. That information is provided on the memorandum which is attached.

FRIANT WATER AUTHORITY

April 2011

Volume 23, No. 206

FRIANT Waterline

Big Runoff Begins But Is Under Control

Bureau's Restoration Water Decision Boosts Friant Use

Peak snowmelt and runoff have begun with remaining snowpack water content within the San Joaquin River watershed double what it should normally be on May 1.

U.S. Bureau of Reclamation and Friant Water Authority water managers, however, are not particularly worried. A well-planned strategy of aggressive Friant Dam releases, coupled with cooler than average spring temperatures to date, has carved out a great deal of welcomed storage space in Millerton Lake.

STORAGE CUT IN HALF

As of May 2, the reservoir behind Friant Dam contained 223,674 acre-feet of water, less than half of what was in storage on March 26 during a late winter and early spring stretch of potent storms.

With the San Joaquin River's full natural flow and actual Millerton inflow remaining at least a few thousand cubic feet per second less than releases on each

Accident victim John Collins, former Bakersfield College President, is reached on his partially submerged car in the Arvin-Edison Canal April 13 by a Bakersfield emergency staff member suspended from a helicopter following a harrowing accident.

Arvin, Friant Staffs Help Save Driver

Friant Water Authority and Arvin-Edison Water Storage District canal operations staff members assisted with quick and effective emergency water management actions during a dramatic April 13 rescue of former Bakersfield College President John Collins, driver of a car that veered into the Arvin-Edison Canal in Bakersfield.

The car driven by the 93-year-old Collins drifted across Truxton Avenue, through a fence and into the canal not far below its headworks from the Friant-Kern Canal.

SNAGGED BY CABLE

By good fortune, the car landed backwards in the canal, its trunk sprung open. Although the rushing current rapidly pushed the car nearly a half mile downstream, the trunk lid jammed into a safety cable where the vehicle wedged in place.

Had the vehicle not been snagged, the car might have been swept further down the

SAN JOAQUIN RIVER RESTORATION PROGRAM

Draft Environmental Study Issued

An 8,000-page environmental blueprint that is to guide San Joaquin River Restoration Program (SJRRP) planners and designers has been released for public review and comment.

The long-awaited series of documents – a draft federal program environmental impact statement and state environmental impact report (PEIS/R) was released April 22 by the U.S. Bureau of Reclamation and the California Department of Water Resources (DWR).

'UNAVOIDABLY' DELAYED

For the first time in so public a manner, the Bureau acknowledged that the program that is to restore flows and a salmon fishery to all San Joaquin River reaches between Friant Dam and the Merced River has run into delays.

"Reclamation recognizes that some actions required by the Settlement are unavoidably behind schedule," the Bureau stated in a news release. "This includes certain channel and structural improvement projects that may be beneficial for

New Deputy Resources Chief Meral Meets Friant Leaders

Jerry Meral, Governor Brown's new State Resources Agency Deputy Director, has had a first-hand look at key San Joaquin River Restoration Program locations and has received a primer on Friant Division water issues, needs, programs and hopes explained by numerous Friant water leaders.

Meral's April 7 view of the central San Joaquin Valley was marked by heavy rain and flood releases that swelled the San Joaquin River's flows and obscured evidence of critically dry conditions which had prevailed until this winter's big storm events.

VIEWS SWOLLEN RIVER

Friant Water Authority leaders conducted a tour of portions of west valley reaches of the San Joaquin River and its associated flood control bypass channels.

"We had planned to show some of the in-channel challenges being faced by the

HOUSE WATER AND POWER SUBCOMMITTEE

Hearing In Fresno Airs Valley Water Frustration

San Joaquin Valley water supply frustrations were the focus of an April 11 House Water and Power Subcommittee field hearing at Fresno City Hall.

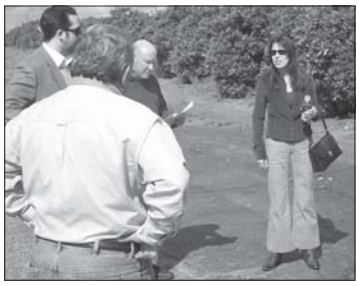
The hearing's published theme – "Creating Jobs by Overcoming Man-Made Drought: Time for Congress to Listen and Act" – set the tone that one speaker after another followed.

One Friant Water Authority board member, Kaweah-Delta Water Conservation District Vice President Mark Watte, testified during the well-attended hearing.

Those attending armed themselves with signs linking water supply curtailments – such as those that plagued the valley in the years before the current above-average precipitation – with job losses, economic woes, social problems, higher food costs and environmental difficulties.

FEDS BLAMED

The overwhelming mood was one of placing blame on federal government agencies, bureaucrats, regulations and court decisions for the grief caused in cutting Central Valley Project water supplies in the west valley to as low as 5% in 2009. That resulted in thousands of job losses, hundreds of thousands of idle acres and millions of dollars in economic damage.



Water and Power Subcommittee Chairman Tom McClintock (*R-Elk Grove*) blamed the political left for advocating what he termed "politically motivated junk science."

"The House and Senate must act now," said a valley Congressman, Rep. Devin Nunes (*R-Visalia*) in commenting on the valley's water crisis and Delta pumping restraints. "The time for studying and talking is over."

Rep. Jim Costa (*D-Fresno*) told an interviewer after the hearing, "I think anytime you can continue to find greater awareness to the problems we're facing here. That's helpful."

One of the few dissenting voices was that of Larry Collins, Pacific Coast Federation of Fishermen's Associations Vice President, who defended

AROUND FRIANT

TULE RIVER

Corps Says No To Testing Higher Storage In Lake Success

Lake Success on the Tule River will remain less than half full in the wake of a U.S. Army Corps of Engineers decision to scrap a data gathering test this spring that would have increased permitted storage .

Had the plan been approved, the lake's maximum water surface elevation would have been increased 10 feet.

Storage in Lake Success has been restricted by the Corps since 2004 due to seismic safety concerns.

The surface level now is normally allowed no higher than 630 feet above sea level, or 40,000 acre-feet. That is 10 feet higher than the initial restriction.

The reservoir's as-built capacity is 82,300 acre-feet.

Corps officials for several years have been working on a solution to concerns that the dam's foundation and structure might be susceptible to failure in a major earthquake. The test had been intended to help the Corps find the highest safe level for water storage.

The Corps felt the risk was too high to undertake such a test..

Increased storage would have been beneficial to Tule River water users, and would have enhanced recreation.

Favoring the test were the Porterville Irrigation District, Tulare County, City of Porterville, Lower Tule River Irrigation District and Vandalia Irrigation District.

President Obama's 2012 budget includes funds to begin purchasing land below the dam, including a mobile home park. No funding is in place for replacing Success Dam. Published reports indicate the project cost is now estimated to be more than $450 million.

KERN RIVER

Isabella Dam Plans Expected

The U.S. Army Corps of Engineers is expected to conduct public meetings during May to explain how it believes problems with Isabella Dam can best be resolved.

The facility is now ranked among the Corps' most at-risk dams.

Seepage below the auxiliary dam, concerns over an earthquake fault running through the site and fears of insufficient spillway size have dogged the facility and led to restrictions on water storage.

A bigger auxiliary spillway will be proposed to be part of the solution so a greater spill could be handled without overtopping the earth-fill dams.

Lawsuit Will Challenge New Take Limits

State's Salmon Fishermen Are Gleeful Over 2011 Prospects, Long Season

While commercial salmon fishermen are ecstatic over prospects for what they believe could be their best season in years, a lawsuit is being prepared against two agencies over this season's expanded take limits.

A complaint was expected to be filed in early May (after WATERLINE press time) on behalf of the San Joaquin River Group Authority, of which the Friant Water Authority is a member, against the National Marine Fisheries Service (NMFS) and Pacific Fishery Management Council (PFMC).

The San Joaquin River Group Authority (SJRGA) is a joint powers authority that includes irrigation and water districts in the San Joaquin River Basin.

TAKE LIMITS QUESTIONED

The lawsuit, expected to be filed in a U.S. District Court, will seek a court determination that the agencies were arbitrary in their permitting of this season's salmon take limits, and requiring that the agencies start over.

At the heart of the suit is an allegation that the large amount of ocean take of salmon to be allowed by the new limits will cause species recovery programs in California rivers to suffer, resulting in even fewer fish in the future.

With the salmon season opening, the lawsuit is not expected to be of much help to the SJRGA this year.

"There is nothing we can do to put a stop to the current fishing season. Federal law does not allow that," a SJRGA statement said. "The best we can do is hope that over harvesting salmon is not permitted again in the future."

The lawsuit will reportedly seek to show that the PFMC's forecasting model is flawed and that hatcheries are having too much harmful influence. The plaintiff believes hatchery fish are increasing in the proportion of the fall-run Chinook salmon stock, leading to progressively less genetic diversity, less species resilience, and greater vulnerability to catastrophic occurrences such as poor ocean conditions that existed from 2007-09.

SALMON RECOVERY

Ronald D. Jacobsma, Friant Water Authority General Manager, said the SJRGA, as well as many other state and federal agencies, is working hard to promote recovery of fall-run Chinook and spring-run Chinook salmon in the San Joaquin basin.

Spring-run is a "threatened" species under the Endangered Species Act. It was extirpated from the basin, but there are substantial on-going efforts now to reintroduce spring-run.

A major part of that effort is to be the San Joaquin River Restoration Program in which Friant Division contractors of Central Valley Project water are involved deeply. The SJRGA's Vernalis Adaptive Management Program is also aimed in restoring salmon in the San Joaquin River Basin.

Fall-run salmon are not listed, but are an ESA candidate species.

AGENCIES TARGETED

SJRGA officials point out that the same state agency – the Department of Fish and Game (DFG) – and federal agencies (NMFS and U.S. Fish and Wildlife Service [USFWS]) authorizing a substantial commercial harvest of salmon this year have acted in past years to stop or critically reduce Delta water export pumping from the Delta to, in part, protect spring and winter-run salmon.

"The amount of fishing those agencies are allowing this year will kill many, many times more salmon than the Delta pumps ever did," the SJRGA said in a statement. The same state and federal agencies continually demand higher flows and more water released from reser-

Please see **Lawsuit**, Page 3

Arvin-Edison Water Storage District

Even with lower post-rescue flows, water still poured over the car.

Rescue: Water Cut To Help Victim Escape From Canal

Continued from front page

canal to where its cold and rushing waters fall into a siphon that carries Arvin-Edison's water under the Kern River.

Collins was also able to open the car's sunroof and stand on a seat as the car filled with cold water.

Four Arvin-Edison Water Storage District staff members responded immediately as did Bakersfield police and fire rescuers, who initially reported having trouble locating the car in the high rushing water.

FWA STAFF CUTS FLOWS

Once at the scene, rescuers got a life vest to Collins that he put on but could not secure. With the water moving too fast to put a swimmer in the water, Arvin-Edison asked the Friant Water Authority staff for an emergency cutoff of flows from the Friant-Kern Canal.

Friant's staff was able to quickly reduce the diversion by 485 cubic feet per second to greatly ease the rescue effort.

A helicopter was used to lift Collins out of the vehicle and onto a gurney. He was rushed to a Bakersfield hospital. Collins was cold but not injured. The car was then lifted by crane from the canal.

Eric Quinley, Friant Water Authority Maintenance Manager, said the Authority coordinated with the City of Bakersfield and river operators but no spill into the Kern River from the Friant-Kern Canal's Terminal Check was necessary during the 45 minutes that water was cut off from the Arvin-Edison Canal.

Hearing: Fresno Frustration

Continued from Page 2

the government's role in salmon protection by saying, "The more water you take out of [the Delta], the more you guarantee the death spiral of my industry." Collins blamed "corporate billionaire agribusinesses" for the troubles of fishermen, an assertion that was aggressively challenged by Nunes.

BAKERSFIELD MEETING

Meanwhile, a Bakersfield meeting was held April 27 by Kern County farmers, the Kern County Water Agency and Rep. Kevin McCarthy to seek solutions to the water supply crisis, including easing Endangered Species Act restrictions to curtail water deliveries.

Means of resolving Delta problems, including new water conveyance facilities such as a user-financed canal or tunnel, were discussed.

"We are not asking the government to pay for it, we are just asking to find common sense regulations so we can get it into the ground and get it moving," said McCarthy.

Frustration was also expressed over difficulties in separately meeting similar state and federal regulations.

Delta Bypass Study Hits A Snag In Court

A San Joaquin County judge has thrown a monkey wrench into state plans to drill and take soil samples for a water conveyance bypass tunnel or canal through or around the Delta.

The court ruled access to private lands proposed by the state Department of Water Resources under the Bay Delta Conservation Plan is a taking of land.

The ruling is a major problem for the facility's planners but was cheered around Stockton where a modern-day version of the Peripheral Canal is strongly opposed.

State officials said they may appeal but will work toward obtaining access by using eminent domain.

The state wants to take core samples at hundreds of locations for facility planning and design.

Lawsuit: Salmon Actions Targeted

Continued from Page 2

voirs to preserve and enhance the salmon fishery.

A state and federal goal of doubling natural production of Chinook salmon "will not be achieved if high levels of salmon fishing are allowed to continue," the SJRGA said.

SALMON RETURNS UP

Meanwhile, it is estimated this year's Chinook salmon run will be the best since 2007, with an estimated 730,000 Chinook now expected to return to the Sacramento River.

In 2009, a record-low 39,500 Chinook returned to the river to spawn. The commercial salmon season is to last through September. California's salmon fishing season in recent years has been cancelled or greatly curtailed.

SAN JOAQUIN RIVER RESTORATION

Reclamation Names New Program Manager

The San Joaquin River Restoration Program has a new U.S. Bureau of Reclamation manager.

Alicia (Ali) Forsythe, who has been the Acting Program Manager since January 2011, was named earlier this spring to head the complex planning and implantation effort.

"Ali is a great selection to head the Restoration Program," said Friant Water Authority General Manager Ronald D. Jacobsma. "She is uniquely qualified and experienced to deal with the multi-faceted challenges the program is already facing. We look forward to working with her as the Program Manager."

IMPLEMENTATION

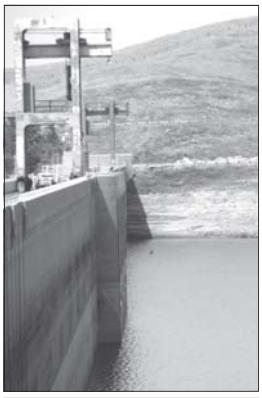
The Restoration Program is being implemented as a result of the San Joaquin River litigation Settlement agreed to nearly five years ago by the lawsuit's environmental plaintiffs, led by the Natural Resources Defense Council (NRDC); Friant Division water agencies; and the U.S. government.

Restoration of flows and fishery habitat, with an objective of restoring a salmon fishery between Friant Dam and the Merced River, are program objectives along with a co-equal Water Management Goal. Under the Settlement, the Settling Parties agreed to strive to return all or much of the water given up by Friant districts for river restoration.

The Bureau's Regional Director, Donald Glaser, said Forsythe "has been involved with San Joaquin River issues for many years and has gained the respect of the organizations and individuals who are working together to implement this important restoration program."

COORDINATION

Forsythe is to coordinate with:



- The other SJRRP Implementing Agencies (U.S. Fish and Wildlife Service, National Marine Fisheries Service, California Department of Water Resources, California Department of Fish and Game).
- The Settling Parties (NRDC and Friant Water Authority).
- The Restoration Administrator (selected jointly by NRDC and FWA to provide recommendations regarding specific elements of the Settlement).
- Downstream landowners and water districts, and many other entities.

BACKGROUND

Forsythe has managed various National Environmental Policy Act, California Environmental Quality Act, water rights and restoration projects in both the public and private sectors.

She began her federal career with Reclamation in 2009 on the SJRRP staff. Forsythe led the program's interim flow activities and three on-going site-specific channel and structural improvements projects, oversaw the program's budget and schedule, and helped establish and implement SJRRP policies and direction. Prior to joining the Mid-Pacific Region, she was a project manager with CH_2M Hill.

Forsythe holds Bachelor of Science degrees in Environmental Studies and Hydrologic Sciences from the University of California, Santa Barbara.

Friant Water Authority

Millerton Lake's level, which looked low in mid-April, has dropped even more since then.

Runoff: Millerton Storage Makes Room For Snowmelt

Continued from front page

day for well over a month, reservoir storage has continued to decline. Flood releases into the river, which briefly were near the channel capacity of 8,000 c.f.s., have been reduced as demands have increased and reservoir storage has dropped. Nearly all of that flood release water has flowed to the ocean.

Friant districts were slow to step up water orders, for irrigation or groundwater recharge purposes, because all local streams have also been handling flood release flows. Until recently, spring rains had made many fields too wet for cultural work or irrigation.

RECOVERED WATER

A help in creating demand in early April was a decision by the U.S. Bureau of Reclamation to make available 460,000 acre-feet of Recovered Water Account (RWA) water credits for Friant Division long-term contractors under the San Joaquin River Restoration Program's Water Management Goal.

RWA water is available at a cost of $10 per acre-foot to all Friant Division long-term contractors who experience a reduction in water deliveries due to the flows called for in the Settlement to restore the San Joaquin River.

"These advanced RWA water credits are being made available to take advantage of this year's unusually wet hydrologic conditions for the purpose of reducing or avoiding future water supply impacts," a Bureau statement said. "The additional 460,000 acre-feet of RWA water credits is based on projections of anticipated future water supply impacts as a direct result of the flows called for in the Settlement."

FULL SUPPLY FOR NOW

In addition, the current Friant "uncontrolled season" water supply conditions – featuring full supplies of Class 1 and Class 2 water – are to continue throughout May and possible into June, according to Michael Jackson, Reclamation's Area Director in Fresno.

Deliveries of "Section 215" (unstorable) water to non-Central Valley Project contractors will continue until demands fill the Madera and Friant-Kern canals, Bureau staff member Ed Salazar said. He explained that even with the big storage reduction, a huge snowpack remains and more water needs to be moved out of fairly small Millerton Lake.

The May 1 snow surveys of nine San Joaquin River watershed courses show snowpack water content that is 199% of the May 1 average, and 163% of what is considered normal for April 1, the date upon which snow conditions are assumed to peak.

San Joaquin River runoff is currently expected to be 164% of average in the April-through-July peak period, or 2,060,000 acre-feet.

Corps Faces Lawsuit Over Rules For Levees

At a time when one federal agency after another is striving for improved riparian and fishery habitats along and in California rivers, another agency is demanding that vegetation vanish from Central Valley levees.

The U.S. Army Corps of Engineers in 2007 began imposing a clear-off-the-levees policy across the nation.

Now, two environmental organizations have served notice they will sue the Corps for violating the Endangered Species Act (ESA).

The Sacramento *Bee* reported that the Corps' rules do not state implicitly that all trees and vegetation – except for grass – must be eliminated but such is the practical effect.

Should levee operators not comply and a damaging flood were to occur, federal aid would not be forthcoming.

The Corps has suspended the rules from taking effect within the Central Valley until 2012.

ALLEGATIONS

Friends of the River and Defenders of Wildlife plan to sue against the rules. They allege the Corps failed to consult as required with other federal agencies to ensure the rules would not cause environmental harm. Nor did the Corps study environmental consequences, as required by the ESA, the organizations say.

Friant Water Authority / J. Randall McFarland

As the flood release-swollen San Joaquin River flows by at Sand Slough, north of Dos Palos, Friant Water Authority Water Resources Manager Stephen Ottemoeller points to a map to show state Deputy Resources Secretary Jerry Meral key locations in the San Joaquin River Restoration Program between Friant Dam and Merced River.

Study: Restoration's Impacts

Continued from front page

successful reintroduction of salmon." The latter is currently scheduled to occur by the end of 2012.

The schedule and projects were included in the Settlement of 18-year litigation reached several years ago by the plaintiffs – an environmental coalition led by the Natural Resources Defense Council – on one hand and the U.S. government along with the FWA and many of its member Friant Division districts on the other.

The Bureau says it "will promptly initiate consultation with the parties to the [San Joaquin River] Settlement to develop a new schedule based upon the PEIS/R that assures implementation of the Restoration Program in a manner that addresses the requirements of the Settlement for expeditious action while meeting the requirements of the legislation to minimize impacts on third party interests."

FOUR HEARINGS IN MAY

Four public hearings and open houses of 2½ hours each have been scheduled in valley locations during May to explain the PEIS/R, which took three years to compile, as part of a 60-day public comment period. (*Please see story, lower left.*)

Federal and state officials say the joint document describes direct, indirect and cumulative impacts of implementing the SJRRP. Agencies involved include Reclamation, the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, the California Department of Fish and Game and DWR.

General Manager Ronald D. Jacobsma said the Friant Water Authority's first task is to coordinate review and comment responsibilities among Authority and member district staff members. Comments on the massive document are due June 21.

The PEIS/R is required under federal and state laws, and is considered crucial to implementing the comprehensive, long-term effort to restore flows to the San Joaquin River below Friant Dam to restore a self-sustaining Chinook salmon fishery in the river. The SJRRP is also to reduce or avoid adverse water supply impacts from restoration flows.

Four Hearings Set On Restoration's Environmental Plan

Four public hearings will be held from May 24-26 around the Central Valley as the U.S. Bureau of Reclamation and California Department of Water Resources solicit input on the San Joaquin River Restoration Program's newly released draft program environmental impact statement and environmental impact report.

Each public hearing will include an open house portion during which the Restoration Program staff will be available to talk with public. Formal public hearings will follow to gather comments.

The meetings will be held:

In Visalia

- Tuesday, May 24, 10 a.m. - 12:30 p.m., Lampliter Inn, 3300 West Mineral King Avenue.

In Fresno

- Tuesday, May 24, 6 p.m. - 8:30 p.m., Piccadilly Inn-University, 4961 North Cedar Avenue.

In Los Banos

- Wednesday, May 25, 6 p.m. - 8:30 p.m., Merced County Fairgrounds, 403 F Street.

In Sacramento

- Thursday, May 26, 1:30 p.m. - 4 p.m., Holiday Inn-Capitol Plaza, 300 J Street.

Meral: Visits River, Friant

Continued from front page

Bureau of Reclamation and Department of Water Resources in implementing river restoration, but most of what we'd hoped to see was under water from the flood releases," said Ronald D. Jacobsma, Friant Water Authority General Manager.

STORAGE NEED

The extremely soggy condition had an upside, Jacobsma added, including an opportunity to view local West Side seepage under levees and resulting field-flooding problems, caused by high groundwater, of the sort that have occurred during early San Joaquin River Restoration Program interim flows.

"It also gave us a great opportunity to show the need for more storage – on the surface and underground – to capture high runoff flows when they are occurring, reduce flooding threats and gain longer-lasting water supply benefits for the environment and Friant users who are providing the river restoration flows," he said.

Meral in the past has expressed reservations on the need for new surface water storage projects.

The San Joaquin River has one proposed new reservoir project – Temperance Flat in the upper end of the CVP's Millerton Lake, northeast of Fresno.

'MUCH IN TOUCH'

Jacobsma noted that Meral, who served as Department of Water Resources Deputy Director during Brown's first administration from 1975-83, is well known for his support and involvement in the environment and its issues.

"Jerry Meral is also very much in touch with the practical problems and real needs that California water providers have to deal with for their customers," Jacobsma said.

> **'He was keenly interested in everything we showed him and points of view we presented'**
> —RONALD D. JACOBSMA

"He was keenly interested in everything we showed him and points of view we presented on surface water storage development, infrastructure needs, Delta solutions and conveyance, groundwater issues and river restoration."

TULARE MEETING

During a luncheon meeting later in Tulare hosted by the Friant Water Authority and Tulare Irrigation District, Meral listened intently as directors and managers from several Friant Division contractors of Central Valley Project water spoke.

They outlined past and present programs, along with future plans and desires.

All of the projects they discussed have been aimed at further improving beneficial water delivery and on-farm use efficiency, and the region's already extensive system of groundwater storage and water banking.

DELTA OVERSIGHT

Meral is in charge of the Bay-Delta Conservation Program, which is charged with finding solutions to the Delta's many infrastructure, environmental, water quality and water supply problems.

Meral, former Planning and Conservation League Executive Director, is again on the front line in debate over whether to build alternative water conveyance through or around the Delta. Even while many in the environmental community were opposing such a plan, Meral pushed for the construction of a controversial Peripheral Canal that was ultimately defeated by California voters in November 1982.

A renewed plan is now focusing increasingly on development of a large tunnel to bypass the fragile Delta in order to move north state water to the CVP and state Water Project pumps near Tracy.

Friant Water Authority / J. Randall McFarland

Harvey Bailey, Friant Water Authority Chairman and Orange Cove Irrigation District President, explains the importance of San Joaquin River water delivered to Orange Cove growers and city residents through the Friant-Kern Canal (background). Fifty-five participants in the Water Education Foundation's San Joaquin Valley tour also visited Friant Dam, the San Joaquin River and many other valley water features April 12-15.

Sustainable Groundwater Management Act Stakeholder Workshop

Topic: SGMA – SSJMUD Management Area Plan under the Kern Groundwater Authority's (KGA) Groundwater Sustainability Plan (GSP)

When: Tuesday, October 8, 2019 @ 10:00 am – 12:00 pm

Where: Hyatt Place Delano, 1200 Garzoli Ave, Delano CA 93215

You are invited by the Southern San Joaquin Municipal Utility District (SSJMUD) to attend a SGMA workshop at the Hyatt Place Delano (1200 Garzoli Ave, Delano CA 93215) on Tuesday, October 8, 2019 from 10:00 am to 12:00 pm.

We will provide an update on the district's development of a Management Area Plan under the KGA's GSP, including the development of Sustainability Management Criteria for groundwater conditions and proposed Projects and Management Actions to be undertaken by the District during the implementation of SGMA.

If you are planning to attend this workshop, please RSVP to Grace Martin (GEI Consultants) at 661.716.3010 or gemartin@geiconsultants.com by Friday October 4, 2019 so we can get a head count to ensure adequate seating.

Thank you and we look forward to seeing you at the workshop.

Regards,

Roland Gross
Southern San Joaquin M.U.D.

Southern San Joaquin Municipal Utility District Management Area Plan

Kern Groundwater Authority
Groundwater Sustainability Plan

Tuesday, October 8, 2019

GEI Consultants

Management Area Plan

- The District's Plan incorporates the cities of Delano and McFarland
- Includes undistricted lands adjacent to the District that signed agreements for coverage under the Plan
- Part of Kern Groundwater Authority Groundwater Sustainability Plan (KGA GSP)

GEI Consultants

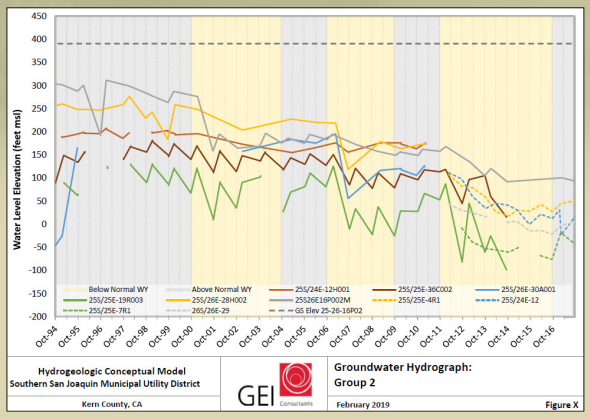
Management Area Plan

- Includes:
  - Introduction
  - Basin Setting
  - Sustainable Management Criteria
  - Monitoring Network
  - Projects and Management Actions

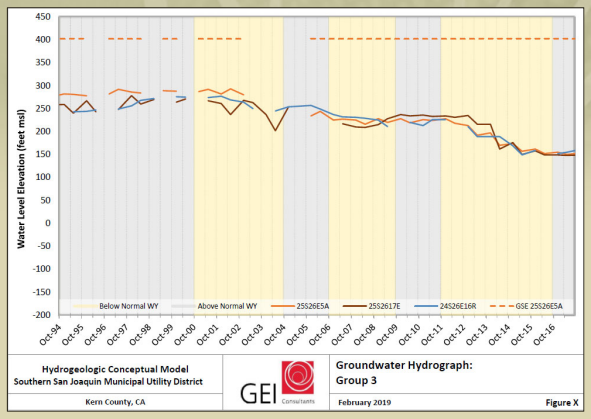
GEI Consultants

Introduction

- Section includes:
  - Contact Info
  - General Description of the Plan Area
    - Existing land use
    - Sources of water
  - Existing Plans
    - Agricultural Water Management Plan
    - Urban Water Management Plan for Delano
    - General Plans for the Cities and Kern County



GEI Consultants



Basin Setting

- Consistent with KGA GSP Basin Setting Chapter
- Includes:
  - Hydrogeologic Conceptual Model
    - Hydrogeologic conditions of the Plan area
  - Existing conditions in the Plan area
    - Sustainability Indicators
  - Water Budget
    - Historical Budget
      - average conditions from 1993-2015
    - Current Water Budget
      - changes within the district post-2015
    - Projected Water Budget
      - estimated changes in demand and supply for 2030 and 2070 conditions

GEI Consultants

Existing Conditions

GEI Consultants

Historical Water Budget

- Demand
  - Agricultural Demand
    - Based on ITRC ET data from 1993 through 2015
    - ET for undeveloped land and land in urban use not considered part of ag demand
  - Urban Demand
    - Based on a combination of data from the cities General Plans, Delano's UWMP, and actual pumping data available from the cities of Delano and McFarland
- Supply
  - CVP Supply, Delano WWTP Effluent, Precipitation, and Native Inflow
  - Through coordination with KGA agreed upon the following assumptions:
    - 0.42 AF/irrigated acre for precipitation
    - Range of Native Inflow of 0.15 AF/acre to 0.30 AF/acre for the gross acreage of the district

GEI Consultants

Current Water Budget

- Demand
  - Agricultural Demand
    - Based on 2013 to 2015 data for irrigated lands
  - Urban Demand
    - Based on actual pumping data from 2013 to 2015 (no ET demand)
- Supply
  - CVP Supply, Delano WWTP Effluent, Precipitation, and Native Inflow
  - Through coordination with KGA agreed upon the following assumptions:
    - 0.42 AF/irrigated acre for precipitation
    - Range of Native Inflow of 0.15 AF/acre to 0.30 AF/acre for the gross acreage of the district

GEI Consultants

Historical and Current Water Budget TAF

Water Year and Hydrologic Condition	Total Surface Inflow	Total Surface Outflow	Total Rainfall*	Total ET (ITRC)	Δ Storage (Irrigated Lands)	City of Delano Demand	City of McFarland Demand	City of Delano Recycled Water	Δ Storage (Irrigated Lands and City)	Native Inflow Range (0.15 AF/acre to 0.30 AF/acre)	Δ Storage with City and Native Inflow Range

Projected Kern River Supply											
2030.c	100.0	0	18.8	119.2	**(0.4)**	11.5	2.3	4.9	(11.9)	9.8 to 19.5	0.4 to 10.2
2070.c	90.8	0	18.6	125.0	**(15.6)**	21.5	3.6	12.6	(28.1)	9.8 to 19.5	(18.4) to (8.6)

*This is a BASELINE budget (no projects or management actions)
**Reflects assumed precipitation at 0.42 AF/irrigated acre, adjusted with climate change factors used in Subbasin model

GEI Consultants

Sustainable Management Criteria

- Sustainability Goal and Undesirable Results
  - Defined at the Subbasin level
  - Adopted by KGA and the other GSAs in the Subbasin
  - Consistent with the Umbrella KGA GSP

GEI Consultants

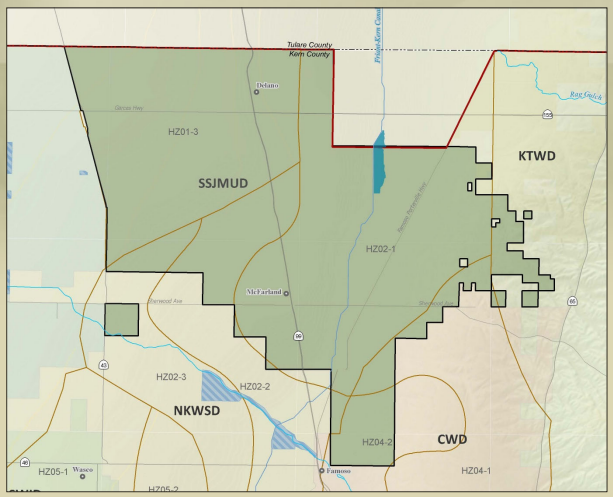
Sustainability Indicators

- Kern County Subbasin Sustainability Indicators :
  - Chronic lowering of groundwater levels
  - Reduction of groundwater storage
  - Degradation of groundwater quality
  - Land Subsidence
- Sustainability Indicators not of concern:
  - Seawater Intrusion
  - Depletion of interconnected surface water

GEI Consultants

Sustainable Management Criteria

- Addresses four Sustainability Indicators
- Defines Undesirable Results
- Provide
  - Minimum Thresholds
  - Measurable Objectives
  - Interim Milestones

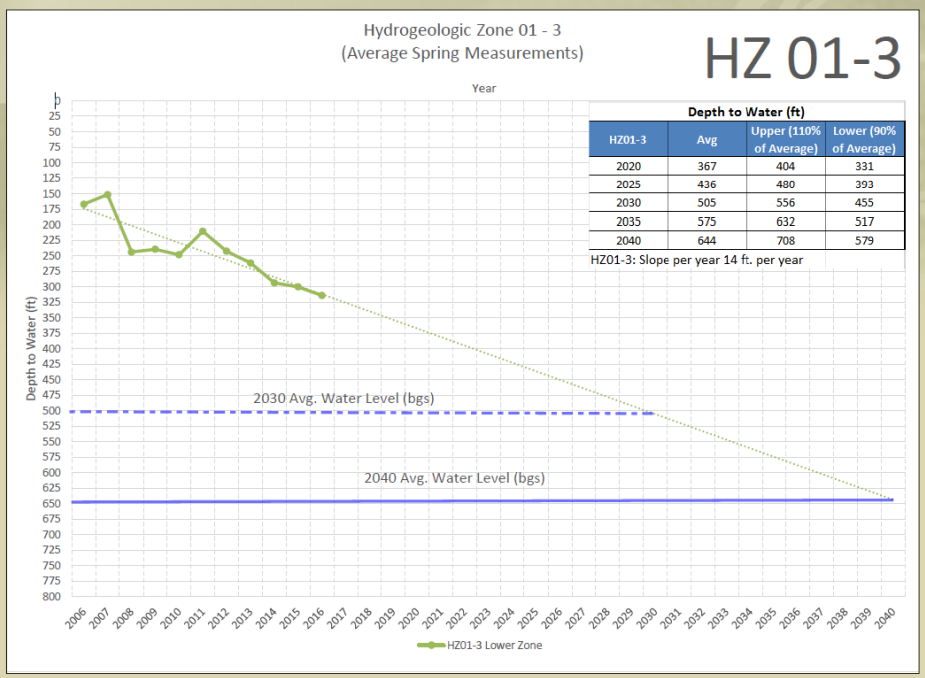


GEI Consultants

Sustainable Management Criteria

- (Subbasin) Chronic Lowering of Groundwater Levels Undesirable Result Definition:
  - The point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

    This is determined when the Minimum Threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each Management Area). Minimum Thresholds shall be set by each of the management areas through their respective Groundwater Sustainability Plans.

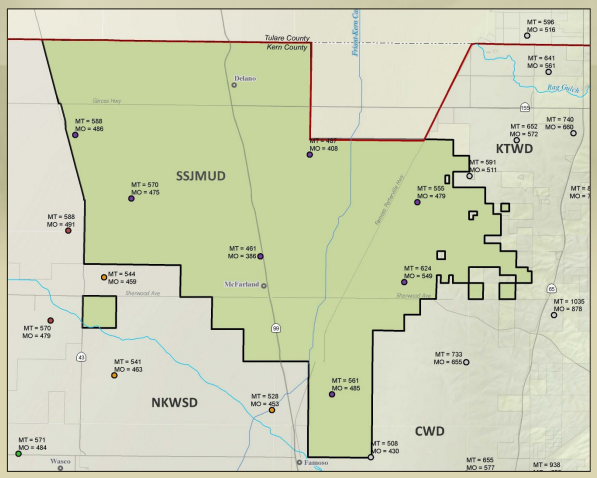


GEI Consultants

The Hydrogeologic Zones (HZs) were established using the following data:

- Spring 2015 Groundwater Contours
- USGS Extents of the Corcoran Clay
- Hydrographs for the period from 2006 to 2016

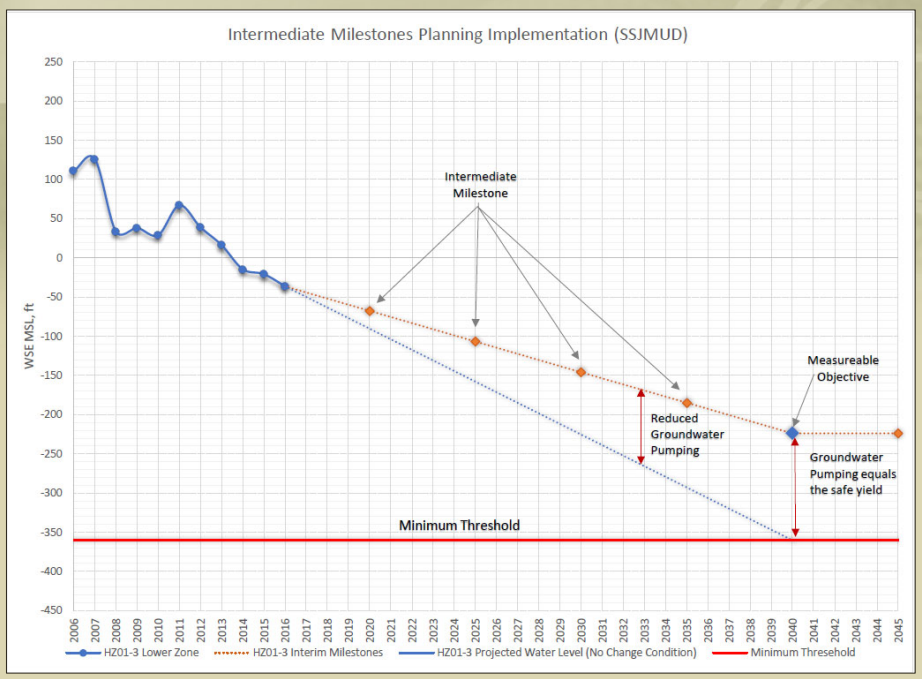
GEI Consultants



Depth to Water (ft)

HZ01-3	Avg	Upper (110% of Average)	Lower (90% of Average)
2020	367	404	331
2025	436	480	393
2030	505	556	455
2035	575	632	517
2040	644	708	579

HZ01-3: Slope per year 14 ft. per year



GEI Consultants

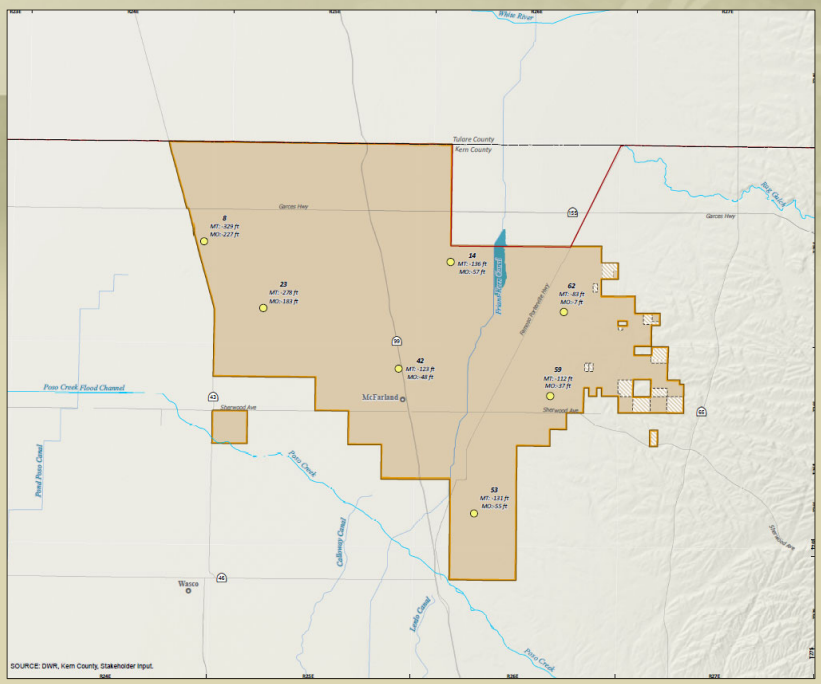
The Minimum Thresholds (MTs) are set based on the projected 2040 GWLs at each Representative Monitoring Site.

The Measurable Objectives (MOs) are set at each Representative Monitoring Site, based on the projected 2030 GWLs.

GEI Consultants

GEI Consultants

Sustainable Management Criteria



- Groundwater Levels are a proxy for
  - Change in Groundwater Storage
  - Degradation of Groundwater Quality
- Further data is required before setting numerical SMCs for Water Quality and Land Subsidence.
  - Qualitative minimum thresholds and measurable objectives

GEI Consultants

Monitoring Network

- Representative monitoring sites for Sustainability Indicators
- Identifies
  - Existing Programs
  - Monitoring Sites
  - Data Gaps
    - Plan for how data gaps will be addressed during implementation of SGMA

GEI Consultants

GEI Consultants

Projects & Management Actions

- Projects - "supply side" of sustainability
  - SSJMUD Projects includes
    - expansion of existing projects
    - development of new projects
- Management Actions -"demand side" of sustainability
  - addresses the data gaps identified in the Basin Setting and Monitoring Network sections

GEI Consultants

Projects & Management Actions

- For each Project and Management Action, SGMA requires the identification of:
  - Permitting & regulatory process
  - Source & reliability of water
  - Costs & source of funding
  - CEQA/NEPA Considerations

GEI Consultants

Projects

Project Name	Status	Water Savings or Supply Increase (AFY)
City of Delano Spreading Grounds	Initiated	500
In-District Spreading & Recovery Facility	Initiated	2,800
Cawelo Intertie	Conceptual	500
Schuster Intertie (Semitropic)	Conceptual	1,810
NKWSD Intertie	Initiated	4,280
SE Delano Spreading Grounds	Conceptual	2,640
Pond Spreading Grounds	Conceptual	1,840
	ESTIMATED TOTAL	**14,370**

GEI Consultants

Management Actions

Management Action	Status	Demand Decrease (AFY)
In-Lieu Recharge Incentive Program	Planning	1,800
Ag to Urban Land Conversion	Planning	1,750
Urban Water Conservation Program	Planning	4,000
	TOTAL DEMAND DECREASE	**7,550**

GEI Consultants

Schedule for GSP Completion

Milestone	Start Date	End Date
SSJMUD Board Review and Approval of GSP	August 21	August 21
KGA Board Approval of Chapter GSPs	August 28	August 28
Public Review (90 Days)	**August 30**	**November 29**
Response to Public Comments	November 29	December 20
Preparation of Final GSP	December 20	January 17

GEI Consultants

Questions?

GEI Consultants

Chapter Groundwater Sustainable Plan (GSP) for Kern Groundwater Authority

Southern San Joaquin Municipal Utility District

Wednesday, July 10, 2019

GEI Consultants

Chapter GSP Development

- The following sections have been reviewed by the district managers and revised by GEI in preparation for submittal to the KGA:
  - Introduction
  - Basin Setting
  - Sustainability Goal and Undesirable Results
  - Monitoring Network
  - Sustainable Management Criteria
  - Projects & Management Actions
  - Communication & Outreach

GEI Consultants

Introduction

- The introduction includes the following information:
  - Contact Info for the Districts
  - A general description of the area covered by the chapter, including existing land use, sources of water, and plans already implemented by the districts and municipalities covered in the Chapter GSP
    - AWMP for SSJMUD
    - UWMP for Delano
    - General Plans for the Delano, McFarland, and Kern County

GEI Consultants

Basin Setting

- Hydrogeologic Conceptual Model
  - Describes existing conditions in the SSJMUD plan area, including the Sustainability Indicators that must be addressed in the GSP.
  - Consistent with the Umbrella KGA Basin Setting chapter.
- Historical & Projected Water Budgets for SSJMUD.
  - Historical Budget uses average conditions over the period from 1993-2015.
  - Projected Budgets account for estimated changes in supply and demand at 2030 and 2070.

GEI Consultants

Basin Setting

Water Year	Irrigation Demand (TAF)	Delano Urban Demand (TAF)	McFarland Urban Demand (TAF)	Delano WWTP Effluent (TAF)	Imported Supply (TAF)	Native Supply* (TAF)	Change in Storage (TAF)
Historic Avg	120.7	9.3	1.7	4.5	104.8	19.4	-3.0
Current	120.7	8.1	1.8	3.7	108.9	19.4	1.4
2030	120.7	11.5	2.3	4.9	116.3	19.4	6.1
2040	120.7	16.3	2.9	6.8	118.1	19.4	4.4

* Reflects a Native Yield Range of 0.15 AF/ac – 0.30 AF/ac (precipitation + subsurface flow)

The Native Yield numbers are subject to change, based on the coordination discussions with the KGA managers.

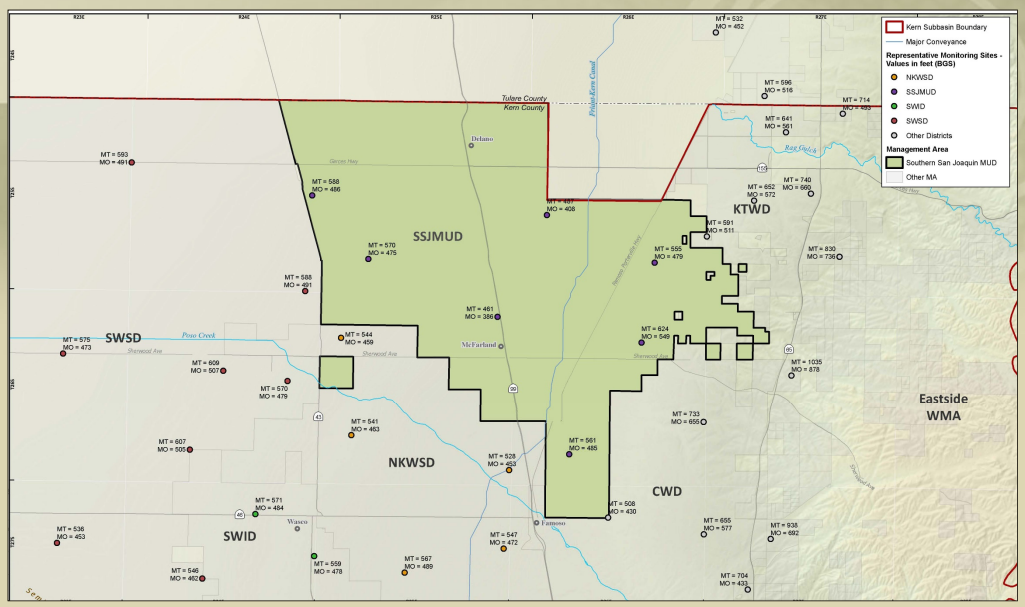
GEI Consultants

Sustainability Goal & Undesirable Results

- Defined at the subbasin level and adopted by KGA and the other GSAs in the subbasin.
  - This section of the Chapter GSP is consistent with the Umbrella KGA document.
  - Four of the Six Sustainability Indicators defined by SGMA are addressed in the Undesirable Results.
    - Declining Groundwater Levels
    - Change in Groundwater Storage
    - Degradation of Water Quality
    - Land Subsidence

GEI Consultants

Monitoring Network & SMCs



- The Monitoring Network section identifies the existing programs and monitoring sites for the district.
  - Also identifies data gaps and provides a plan for how the data gaps will be addressed during the implementation of SGMA.
  - Representative Monitoring Sites within the districts are identified for the Sustainability Indicators addressed in the Undesirable Results section of the Chapter GSP.

GEI Consultants

Monitoring Network & SMCs

- The SMCs section addresses the four Sustainability Indicators for which Undesirable Results were defined.
  - Provides Minimum Thresholds, Measurable Objectives, and Interim Milestones for Groundwater Levels at the Representative Monitoring Sites identified in the Monitoring Network section.
  - GWLs are a proxy for Change in Groundwater Storage.
  - Further data is required before setting numerical SMCs for Water Quality and Land Subsidence. Qualitative thresholds and objectives have been described for the 2020 Plans.

GEI Consultants

GEI Consultants

Projects & Management Actions

- Projects address the "supply side" of sustainability for the district.
  - Describes both expansion of existing projects and the development of new projects.
  - For each project, SGMA requires that we identify:
    - The permitting & regulatory process
    - Source & reliability of water
    - Costs & source of funding
    - CEQA/NEPA Considerations
  - The ability to use Projects to reach/maintain sustainability is dependent on the availability of water to supply those Projects.

GEI Consultants

Projects & Management Actions

Project Name	Status	Capacity Increase (AFY)
In-District Spreading & Recovery Facility	Planning	2,800
Schuster Intertie (SWSD)	Conceptual	1,811
Cawelo Intertie	Conceptual	5,00
NKWSD 9-28 Intertie	Planning	4,300
Southeast Delano Spreading Grounds	Planning	2,640
City of Delano Spreading Grounds	Planning/Implementation	580
Pond Rd Spreading Grounds	Planning	1,840
In-District Recharge Basins	Planning	24,000
	TOTAL CAPACITY INCREASE	**38,470**

GEI Consultants

Projects & Management Actions

- Management Actions address the "demand side" of sustainability and/or address the data gaps identified in the Basin Setting and Monitoring Network sections.
  - For each Management Action, SGMA requires that we identify:
    - The permitting & regulatory process
    - Source & reliability of water
    - Costs & source of funding
    - CEQA/NEPA Considerations
  - In the absence of Projects, Management Actions are a way for the district to reach/maintain sustainability.

GEI Consultants

Projects & Management Actions

Management Action	Status	Demand Decrease (AFY)
Surface Water First Program	Conceptual	1,800
On-Farm Recharge Program	Conceptual	1,200
Ag to Urban Land Conversion	Planning	1,750
Urban Water Conservation Program	Planning	3,600
	TOTAL DEMAND DECREASE	**8,350**

GEI Consultants

Communication & Outreach

- July 30, 2019
  - Completion of Internal Draft Chapter
  - Submittal of Draft Chapter to KGA for preparation of Admin Draft (internal)
- Week of August 5, 2019
  - SWSD Committee Review of SWSD Chapter and KGA Umbrella GSP
- August 14, 2019
  - SWSD Board approval of Draft Chapter for public review
- August 28, 2019
  - KGA Approval and release of Draft Kern Groundwater Authority GSP
- August 28 to November 29
  - District and KGA public review period
  - Two public workshops during review period

Sustainable Groundwater Management Act Stakeholder Workshop

Topic: SGMA – Sustainable Management Criteria and Minimum Thresholds

When: Monday, April 29, 2019 @ 10:00 am – 12:00 pm

Where: Hyatt Place Delano, 1200 Garzoli Ave, Delano CA 93215

You are invited by the Southern San Joaquin Municipal Utility District (SSJMUD) to attend a SGMA workshop at the Hyatt Place Delano (1200 Garzoli Ave, Delano CA 93215) on Monday, April 29, 2019 from 10:00 am to 12:00 pm.

We will provide an update on the district's development of a Groundwater Sustainability Plan and the development of Sustainability Management Criteria, including Minimum Thresholds for groundwater conditions.

If you are planning to attend this workshop, please RSVP to Grace Martin (GEI Consultants) at 661.716.3010 or gemartin@geiconsultants.com by Friday April 26th, 2019 so we can get a head count to ensure adequate seating.

Thank you and we look forward to seeing you at the workshop.

Regards,

Roland Gross
Southern San Joaquin M.U.D.

Sustainable Groundwater Management Act (SGMA) Stakeholder Outreach

Southern San Joaquin Municipal Utility District

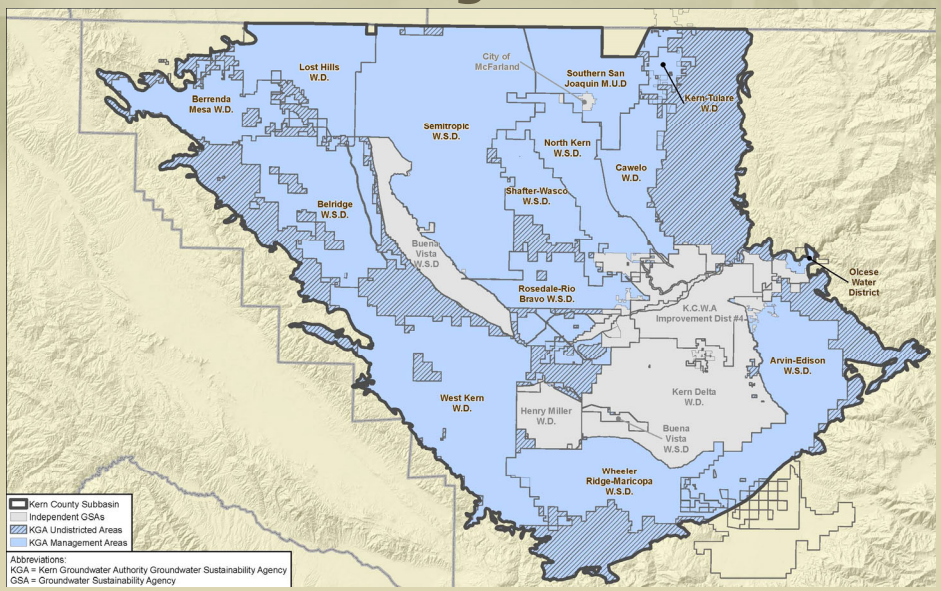
12000 Garzoli Ave – Delano, CA

Monday, April 29, 2019

GEI Consultants

Sustainable Groundwater Management Act

- State Legislation passed in **September 2014**, effective **January 2015**
- Provides tools and authorities to Groundwater Sustainability Agencies to manage groundwater (Semitropic is a GSA)
- Requires a Groundwater Sustainability Plan in January 2020
- Requires groundwater basins to be managed "**sustainably**" by 2040



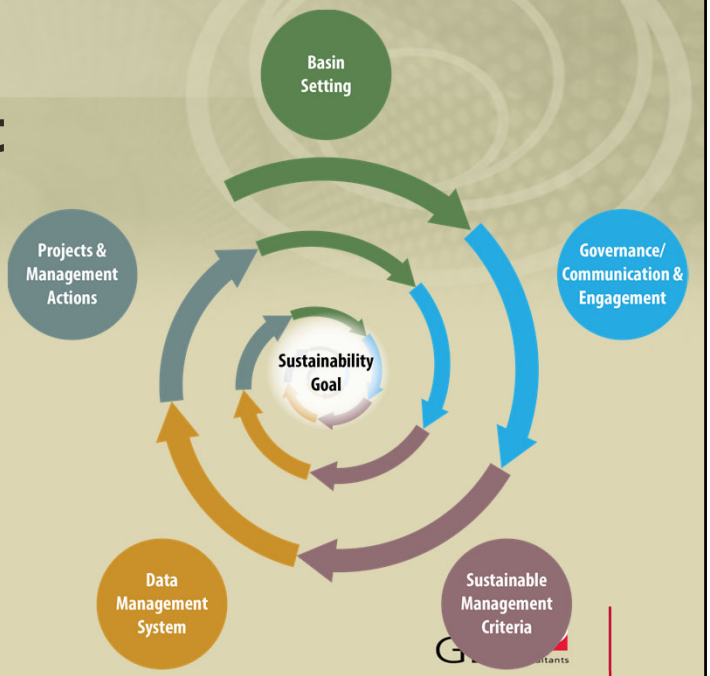
GEI Consultants

Who is Doing What in Kern Basin?

GEI Consultants

Who is Doing What in Kern Basin?

GEI Consultants



Who Is Doing What in the Kern Basin?

- Kern Groundwater Authority
  - Developing Umbrella GSP for all members
  - Developing guidance for development of "Chapter GSPs"
  - Ensuring Coordination between KGA members and other GSAs (Kern River GSA)
  - Point of Contact to DWR for GSP submittal, updates and annual reporting.

GEI Consultants

SSJMUD GSP Development

- Communication & Engagement
  - *Reaching out to local landowners and stakeholders*
- Sustainable Management Criteria
  - *Establishing target groundwater levels*
- Project and Management Actions
  - *How the GSA can mitigate reduced groundwater pumping*
- Prepare a GSP
  - *Consistent with KGA Umbrella GSP*

Communication and Engagement

- Identify stakeholders
  - *Anyone affected/impacted by groundwater in and around basin*
  - *Beneficial uses and users*
  - *Interested parties within and around basin*
  - *Keep landowners/stakeholders informed*
  - *Seek input on key SGMA elements:*
    - Minimum Thresholds and Measurable Objectives
    - Projects and Management Actions
- Stakeholder Communication & Engagement
  - *SSJMUD Board Meetings*
    - 2nd Wednesday of the Month
  - *Landowner Meetings*
  - *KGA Meetings*

GEI Consultants

Communication and Engagement

WWW.KERNGWA.COM

GEI Consultants

8

Sustainable Management Criteria

- Identify which of the six Sustainability Indicators apply within the Basin and the Shafter-Wasco Management Areas, now or in the future.
- Define preliminary definitions for:
  - *Undesirable Results*
    Conditions you don't want to see in the groundwater basin
  - *Minimum Thresholds*
    The level that you never want to go below or exceed
  - *Measurable Objectives*
    Where you want to be operating most of the time

GEI Consultants

9

Sustainable Management Criteria

- Undesirable Results
  - *These have been defined at the subbasin level and adopted at by the KGA.*
  - *The occurrence of an Undesirable Result indicates that the subbasin is not being managed sustainably*
  - *Triggered by the violation of Minimum Thresholds in a significant portion of the subbasin*

Chronic Lowering of Water Levels
Groundwater Storage
Degraded Groundwater Quality Trends
Land Subsidence Trends
Surface Water Depletion
Seawater Intrusion

GEI Consultants

10

Sustainable Management Criteria

Chronic Lowering of Water Levels

The point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users

This is determined when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent Management Areas that represent at least 15% of the subbasin or greater than 30% of the subbasin (as measured by each Management Area).

GEI Consultants

11

Sustainable Management Criteria

Groundwater Storage

The point at which significant and unreasonable impacts, as determined by the amount of groundwater in the basin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended drought period. (10-years?).

This is determined when the volume of storage (above the groundwater level minimum thresholds) is depleted to an elevation lower than the groundwater level minimum threshold in at least three (3) adjacent Management Areas that represent at least 15% of the subbasin or greater than 30% of the subbasin (as measured by each Management Area).

GEI Consultants

12

Sustainable Management Criteria

Degraded Groundwater Quality Trends

The point at which significant and unreasonable impacts over the planning and implementation horizon, as caused by water management actions, that affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

This is determined when the minimum threshold for a groundwater quality constituent of concern is exceeded in at least three (3) adjacent management areas that represent at least 15% of the subbasin or greater than 30% of the designated monitoring points within the basin.

GEI Consultants

13

Sustainable Management Criteria

Land Subsidence Trends

The point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.

This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan.

Sustainable Management Criteria

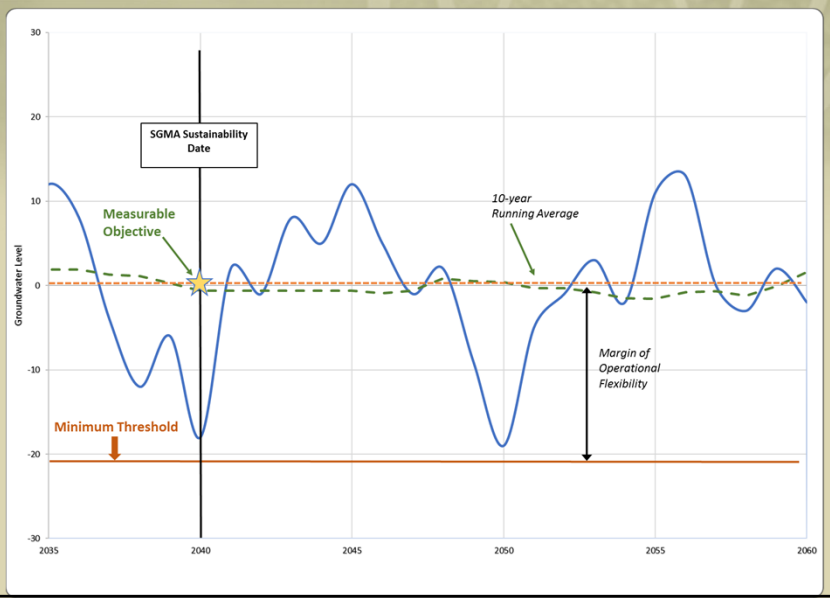
- Identify which of the six Sustainability Indicators apply within the Basin and SSJMUD's Management Areas, now or in the future.
- Define preliminary definitions for:
  - *Undesirable Results*
    Conditions you don't want to see in the groundwater basin

Chronic Lowering of Water Levels --- YES
Groundwater Storage --- YES
Degraded Groundwater Quality Trends --- NO
Land Subsidence Trends --- Maybe, need more data

GEI Consultants

17

Sustainable Management Criteria



- Identify which of the six Sustainability Indicators apply within the Basin and SSJMUD's Management Areas, now or in the future.
- Define preliminary definitions for:
  - *Minimum Thresholds*
    The level that you never want to go below or exceed
  - *Measurable Objectives*
    Where you want to be operating most of the time

GEI Consultants

18

Sustainable Management Criteria

19

Sustainable Management Criteria

Minimum Threshold
- The level that you never want to go below or exceed
- Violation of Minimum Threshold is an indication that a Management Area is not being managed sustainably
- Local call to action

Starting Point:
- Project 2006 – 2016 groundwater conditions to 2040
- Period represents a "worse case" scenario (hydrology and regulatory)

Adjust the Starting Point (if needed)
- Assess impacts to beneficial uses
  - Wells (Ag, domestic and municipal)
  - Water quality
  - Subsidence
  - Storage

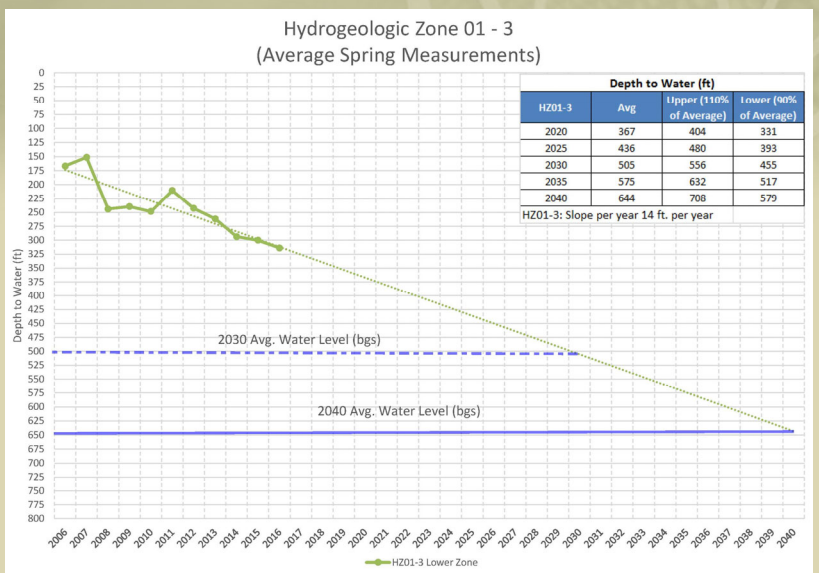
2020	0%	0%
2025	7%	0%
2030	36%	0%
2035	43%	0%
2040	43%	0%

Sustainable Management Criteria

Measurable Objectives
- Where you want to be operating most of the time
- Represents a long-term average, not annual values



Starting Point:
- Provide a Margin of Operational Flexibility to protect against prolonged droughts – 10 years?

Adjust the Starting Point (if needed)
- Assess impacts to beneficial uses
  - Wells (Ag, domestic and municipal)
  - Water quality
  - Subsidence
  - Storage

Sustainable Management Criteria

28

Projects & Management Actions

- Determine deficiency, if any, in groundwater supply (sustainable yield) basinwide
- Formulate, investigate, and implement desired projects and management actions to eliminate the deficiency in groundwater supply and achieve the sustainability goals
- Iterate as necessary to reach ensure the correct mix of projects and management actions
- Update projects and management actions every 5-years for GSP required update

Sustainable Management Criteria

Next Steps for Setting Minimum Thresholds

- Work with landowners/stakeholders within discrete areas to review 2040 projections and impacts to wells and groundwater production costs
- Based on input revise Minimum Thresholds as appropriate
- *REMINDER: This is the Point of Avoidance!*

Next Steps for Setting Measurable Objective

- Work with landowners/stakeholders within discrete areas to set the normal operating groundwater elevations
- Based on input revise Measurable Objective.
- *REMINDER: This is the Point of Management!*

Coordination with Kern subbasin neighbors

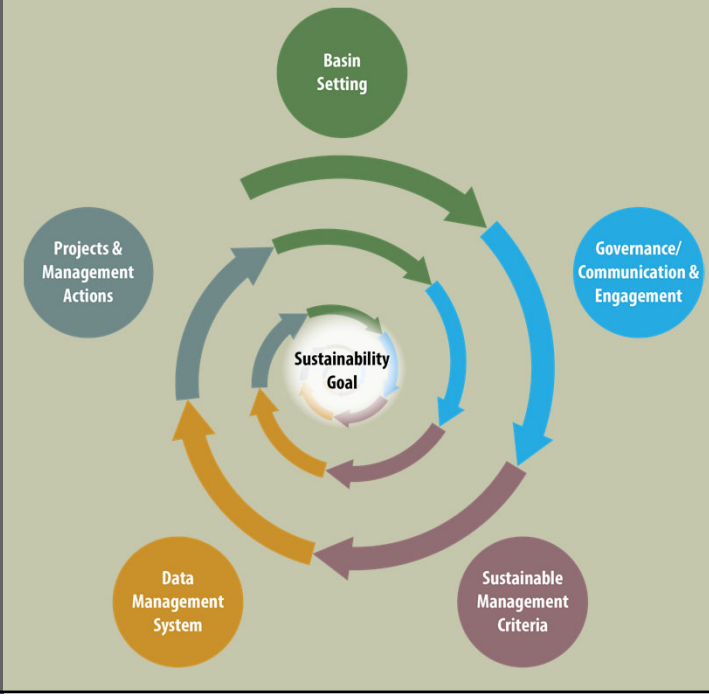
GSP DEVELOPMENT PROCESS

GEI Method and Approach

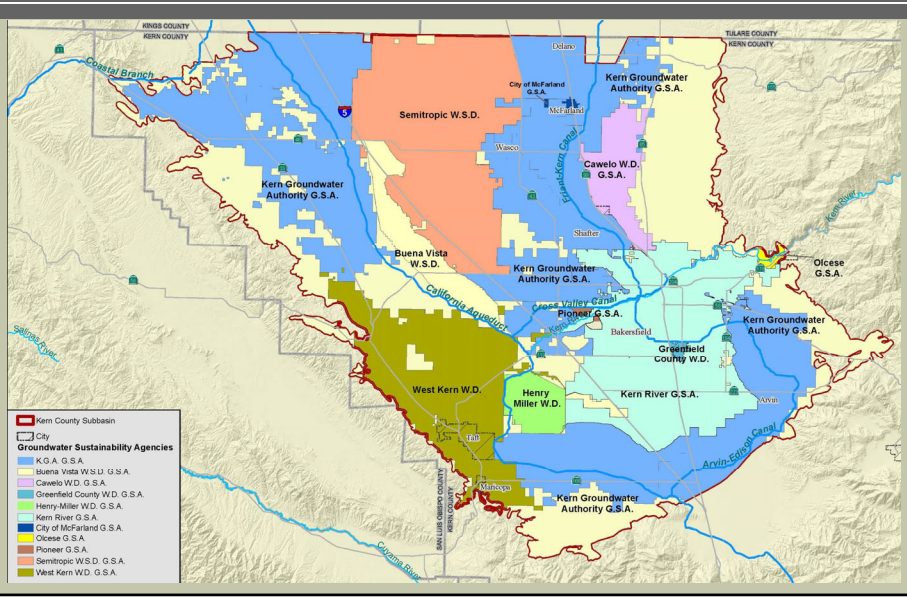
July 24, 2018



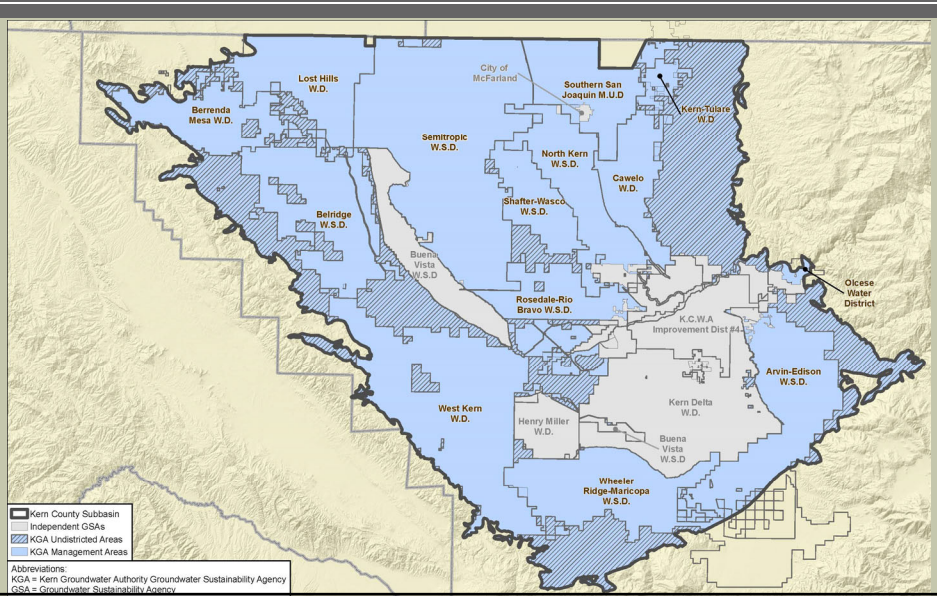
Presented by:
Michelle Ricker
Larry Rodriguez

GEI Consultants

ITERATIVE PROCESS

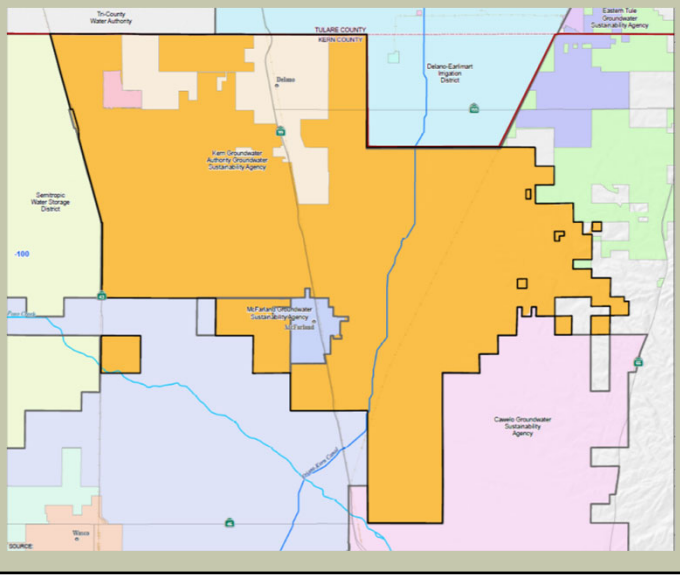


- GSP development is not a linear process
- Steps may be taken in parallel
- Steps may iterate until conclusion is reached
- Process is continuous
- GSAs work toward increased sustainability, adaptively managing and responding to changes over time
- GSPs submitted to DWR will not all be equal



GSP DEVELOPMENT – KERN SUB-BASIN

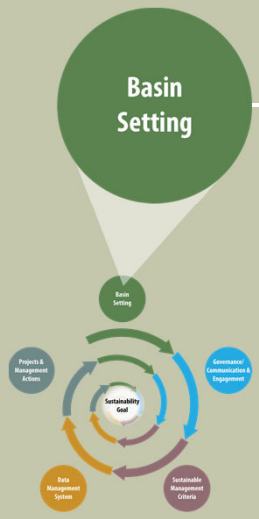
- The Kern Groundwater Authority (KGA) is preparing an "Umbrella GSP" for all of its members.
  - *North Kern WSD and Shafter-Wasco Irrigation District are members of the KGA*
  - *The KGA is also developing guidance for each of its members to develop "Chapter GSPs"*
- The KGA is also ensuring coordination between its members and other GSAs within the basin (e.g. Kern River GSA)
- The KGA is the point of contact to DWR for GSP submittal, updates, and annual reporting



GSP DEVELOPMENT – KERN SUB-BASIN

GSP DEVELOPMENT – KERN SUB-BASIN

GSP DEVELOPMENT – SSJMUD



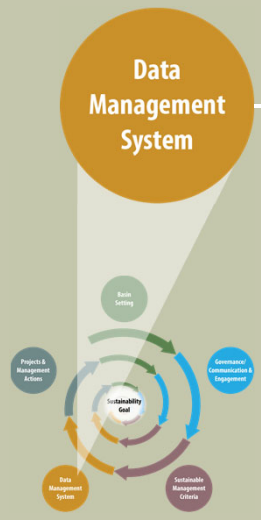
GSP Participants

- **GSA Leadership**
  - *Local water managers and leaders with decision-making responsibilities*
- **Technical Experts**
  - *Local water managers, subject matter experts (local staff), consultants*
- **Stakeholders**
  - *Beneficial users of groundwater, interested parties, impacted parties within and adjacent to the basin*

BASIN SETTING

- Develop basin description and state of the basin
- Develop hydrogeologic conceptual model (HCM)
- Outline what impacts are already happening
- Develop basin numerical model
- Identify structures and costs (i.e. important structures/wells/types of wells/current and future pumping costs, etc.)
- Identify gaps in knowledge
- Develop plan to eliminate data gaps when necessary
- Identify areas where there is disagreement about the basin setting

GOVERNANCE AND COMMUNICATION & ENGAGEMENT



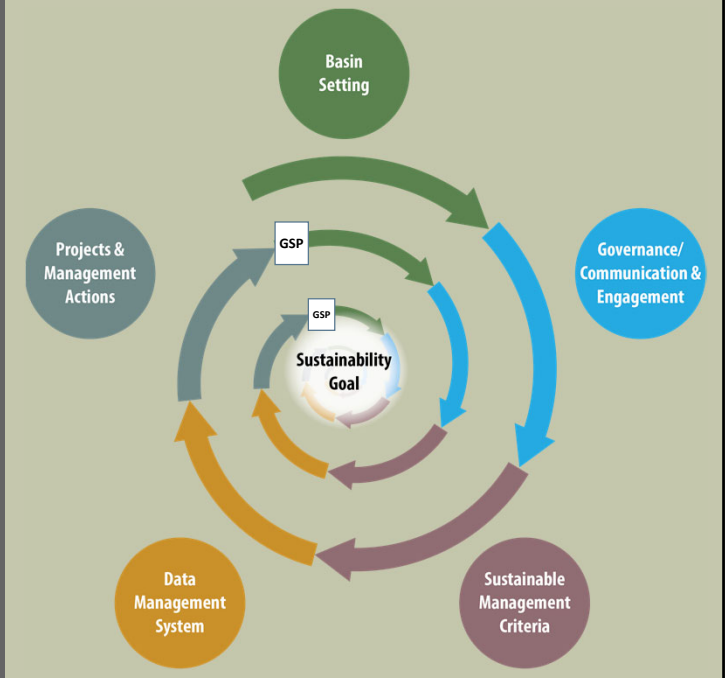
- Identify stakeholders
  - *Anyone affected/impacted by groundwater in and around basin*
  - *Beneficial uses and users*
  - *Interested parties within and around basin*
- Identify technical experts
  - *GSA leadership*
  - *Consultants*
  - *Technical leads*
- Define governance structure
  - *Who makes the decisions for the basin*
  - *How conflicts will be resolved*
  - *How GSA will interact with adjacent basins*
- Develop Stakeholder Communication & Engagement Plan

SUSTAINABLE MANAGEMENT CRITERIA

- Identify which of the six Sustainability Indicators (SI) are possible in the basin, now or in the future.
- Define impacts those SIs are having, and potential future impacts.
- Define a basin level Undesirable Results for each SI.
- Define Minimum Thresholds, Measurable Objectives and Interim Milestones for each SI (could be more than one per SI)
- Begin outreach communications in your basin.
- Identify Representative Monitoring Sites (RMS)

DATA MANAGEMENT SYSTEM

- Establish monitoring program
- Develop DMS – data will be reported to DWR
- Use DMS to track which RMS is monitoring which SI



PROJECTS AND MANAGEMENT ACTIONS

- Determine deficiency, if any, in groundwater supply (sustainable yield) basinwide (§354.18(b)(7).
- Iterate as necessary to adjust sustainable management criteria
- Formulate, investigate, and implement desired projects and management actions to eliminate the deficiency in groundwater supply and achieve the GSAs goals
- Iterate as necessary to ensure the correct mix of projects and management actions to work toward sustainability
- Update projects and management actions every 5 years for required GSP updates

SUMMARY

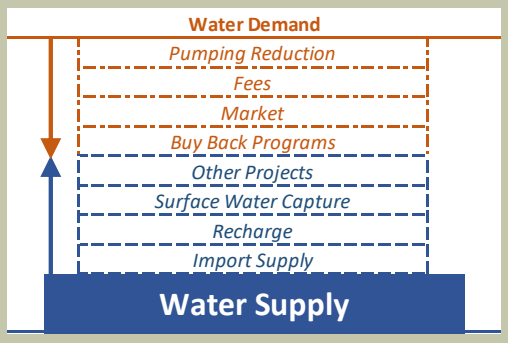
- Iteration required
- Record gaps or disputed data/decisions so can be addressed in GSP
- GSAs will work through these activities differently – some may make many iterations before the first GSP, others may not
- GSPs submitted to DWR will not all be equal or at the same level of sustainability or completeness of information

Sustainable Management Criteria

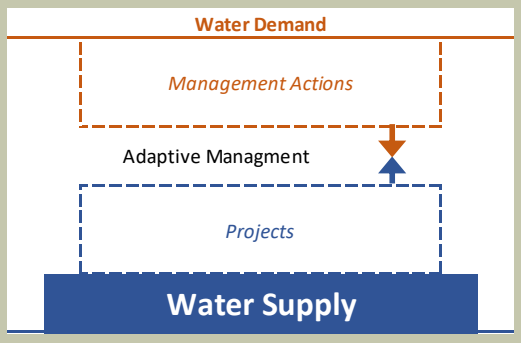
SUSTAINABLITY

GEI Consultants

- Managing and using groundwater in a way that can be sustained over a long period of time
- Sustainable yield is the amount of groundwater that can be withdrawn without causing undesirable results



Sustainable Management Criteria



SUSTAINABILIITY

GEI Consultants

Project and Management Actions

Adaptive Management to Difference Between Supply and Demand

Adaptive Management

HOW TO BECOME INVOLVED

- SSJMUD Board Meetings – GSP Development Update Each Month
- Public Workshops
  - *KGA Board Meetings*
  - *KGA-sponsored Workshops and Meetings*

GEI Consultants

Set Basinwide

- Undesirable Results
- Sustainability Goals

Set by Management Area

- Minimum Thresholds
- Measurable Objectives
- Interim Milestones

Sustainable Management Criteria

SUSTAINABILIITY GOALS

GEI Consultants

Chronic Lowering of Groundwater Levels

Maintain groundwater levels that continue to support agricultural viability and sustainable communities

Reduction of Groundwater Storage

Maintain groundwater volumes in storage to sustain agriculture and communities during prolonged drought conditions

Degraded Water Quality

Avoid degradation of groundwater quality that would impact sustainable agriculture and communities

Land Subsidence

Reduce or prevent land subsidence that causes impacts to critical infrastructure

Depletions of Interconnected Surface Water

Prevent impacts to groundwater dependent ecosystems

Seawater Intrusion

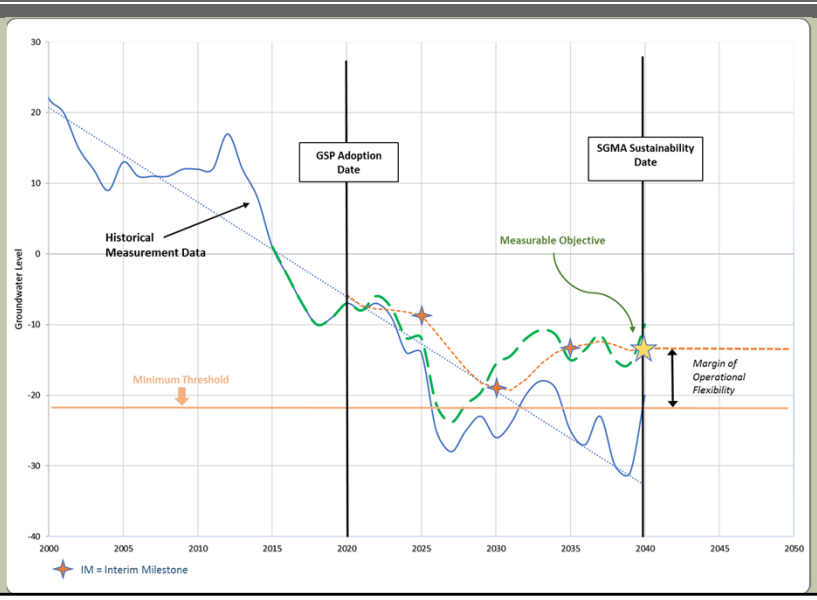
Not applicable

Sustainable Management Criteria

SUSTAINABILIITY GOALS

GEI Consultants

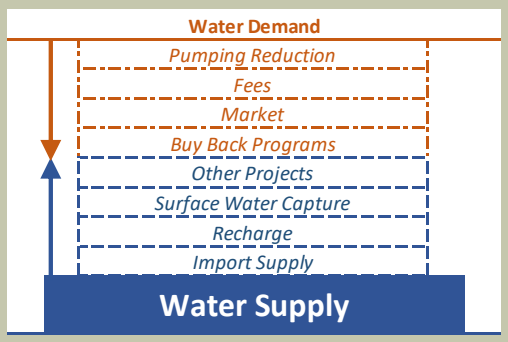
- Undesirable Results:
  - *High level definition, applicable to the entire sub-basin*
- Example Definitions:
  - *Water Levels*
    - *GW levels that impact >10% of domestic and municipal wells*
    - *Violation of Minimum Thresholds in >10% of the sub-basin (by area)*
  - *Storage – Storage Amounts Equivalent to Double the Volume Needed for Operational Flexibility*
  - *Seawater Intrusion – Not Applicable*
  - *Water Quality – No Migration of Identified Plumes Resulting in new MCL Exceedances*
  - *Subsidence – No Subsidence to Critical Infrastructure Resulting in 2% Loss in Performance*
  - *Depletion of Interconnected Streams – Streamflow Depletion Limited to Less than 1% or Less than 2% Impact to Area of Riparian Impacts*



Sustainable Management Criteria

SUSTAINABILIITY GOALS

GEI Consultants



- Minimum Thresholds:
  - *Quantitative value that, when exceeded, can cause Undesirable Results*
  - *Measurable Objective is goal that represents the normal or average groundwater condition*
- Measurable Objectives:
  - *Quantitative goals that reflect the desired groundwater condition of the management area while maintaining a volume of operational flexibility*
  - *A Measurable Objective is a goal that represents the average or normal groundwater condition (GW elevations based on trends, WQ based on discrete values)*
- Interim Milestones:
  - *Trend line values that represent the projected changes in groundwater conditions based on implementation of projects and management actions*

Developing Minimum Thresholds

Developing Minimum Thresholds

NEXT STEPS

- Sub-Basin Level (August)
  - *Set Undesirable Results at the Sub-Basin level*
  - *Develop basic guidance for development of Minimum Thresholds, Measurable Objectives and Interim Milestones*
- GSA Level (Late August - October)
  - *Preliminary cut at Minimum Thresholds, Measurable Objectives and Interim Milestones*

Appendix D

Public Comments Received by SSJMUD

Commentor	Ref #	Comment	Response
Southern San Joaquin Municipal Utility District Received Comments			
Farmland Reserve		"Though not specifically addressed, we are concerned that overlying right to extract groundwater will be allocated among all District landowners based on gross acreage…it ignores accepted principles of law intended to more fairly allocate this right among those who have historically used groundwater for irrigation purposes -- and made substantial investments based on that use."	We have discussed adding language to the Water Budget section of the plan to address the fact that there is currently no in-district allocation of water to the landowners. The language in the Projects & Mgmt Actions section, dealing with in-district allocation as a mgmt action has been revised to address this, as well.
Farmland Reserve		"These numbers should not be seen as establishing a precedent or used to establish some legal right. Therefore, a statement emphasizing the above points should be made."	The discussion on native yield in the Water Budget section of the plan addresses this.
Farmland Reserve		"The Chapter could address the possibility of a market for the exchange or transfer of groundwater credits."	At this time, such a discussion is premature. There is no framework within the districts or the basin at large to allow for the exchange or transfer of groundwater credits. We cannot reasonably address this in the plans for 2020 submittal.
Wonderful Orchards		"The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource."	The districts have identifed as a management action the coordinated effort to further refine water budget components in the Kern County Subbasin Model. The Model and water budget components will continue to be refined in coordination with the KGA and other GSAs in the basin.
Wonderful Orchards		"In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. Appendix J of the GSP indicates the subbasin native yield is approximately 0.144 acre-feet per acre. It is our understanding that subsequent to the release of the draft GSP, all MAPs and other GSPs in the basin agreed to utilize the same number for their water budgets. If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights. Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross or net area."	The discussion on native yield in the Water Budget section of the plan addresses this already. Further emphasis on the "planning budget" role of the Native Yield estimate has been added to the final draft of the plan. In terms of native yield allocation to the parcel/landowner level, there is no framework currently in place to do so. The development the policies and framework necessary to implement such an allocation cannot be completed in time for the 2020 plan submittal.
Wonderful Orchards		"Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next."	At this time, such a discussion is premature. There is no framework within the districts or the basin at large to allow for the exchange or transfer of groundwater credits. We cannot reasonably address this in the plans for 2020 submittal.
Wonderful Orchards		"Wonderful understands that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled)."	As described in the Management Actions subsection of the Management Area Plan, policies for instituting pumping restrictions have not been developed for the 2020 plan submittal. This has been identifed as a potential management action, should the districts or the basin in general find that it cannot maintain it path to sustainability through the projects and other management actions to be implemented.
Wonderful Orchards		"GSAs must develop clear policies and conditions that protect existing investment in groundwater banking and banked inventory, and without interference with existing rules and regulations. GSAs must also find a way to incentivize additional investment, such as on-farm recharge, and allow flexibility for recharged or banked water to be freely transferrable (subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results). Where possible, GSPs should also identify management areas that may benefit from additional recharge and banking. We also recommend that GSAs work to develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.)."	At this time, the framework to offer such incentives does not exist and would require the districts' boards to develop & adopt policy to put it in place. In the time required to prepare the 2020 submittal of the plan, we cannot develop the structure and policy required to implement this. However, this is discussed in the Projects & Mgmt Actions section of the plan and will be considered for implementation after the 2020 plan submittal, when the districts have an opportunity to develop the policy and framework necessary for such programs.
Wonderful Orchards		"GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	A coordinated DMS is already being developed. However, that effort is currently focused at the district/MA level due to the precision of the data being used. Parcel-level allocation is not at this time being done in the subbasin. It is premature to consider a basin-wide water market, as the data available does not allow for that level of allocation to be done. For consideration in the 2020 plan submittal, we do not have adequate time or resources for the development of such a framework.
Westchester Group Investment Mgmt		The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water and not associated with a given gross or net area. In the event that allocations are to be made at a landowner or property level, WGIM encourages the KGA and other GSAs in the basin to initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations that are coordinated across the basin.	The discussion on native yield in the Water Budget section of the plan addresses this already. More language can be added to emphasize the "planning budget" role of the Native Yield estimate.
Westchester Group Investment Mgmt		GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked water inventory, and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	At this time, the framework to offer such incentives does not exist and would require the districts' boards to develop & adopt policy to put it in place. In the time required to prepare the 2020 submittal of the plan, we cannot develop the structure and policy required to implement this. However, this is discussed in the Projects & Mgmt Actions section of the plan and will be considered for implementation after the 2020 plan submittal.

Commentor	Ref #	Comment	Response
Westchester Group Investment Mgmt		GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	A coordinated DMS is already being developed. However, that effort is currently focused at the district/MA level due to the precision of the data being used. Parcel-level allocation is not at this time being done in the subbasin. It is premature to consider a basin-wide water market, as the data available does not allow for that level of allocation to be done. For consideration in the 2020 plan submittal, we do not have adequate time or resources for the development of such a framework.
Westchester Group Investment Mgmt		"WGIM supports use of efficient and accurate systems to determine groundwater use. GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water."	This is already included in the Projects and Management Actions section and is part of the larger action of refining data for the calculation of Water Budget components in future plan updates.
Leadership Council		"The Draft GSP is incomplete and must include additional information for the public to evaluate the GSP. The Draft GSP omits critical data regarding the consideration of drinking water impacts on disadvantaged communities and protected groups, sustainable management criteria that consider all beneficial users, and projects and management actions that address significant and unreasonable impacts to beneficial users."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with the statement, as the information that Leadership Council claims is missing from the GSP is actually included in the management area plans, as appropriate to each respective management area.
Leadership Council		"The KGA is responsible for the disproportionate and disparate impacts that its policies and activities will have on disadvantaged communities belonging to protected groups."	This comment is directed to the KGA GSP and will be addressed by KGA. While the KGA is the GSA entity submitting the plan on behalf of its members, the JPA forming the KGA is such that each member is responsible for the implementation of SGMA within their respective plan areas. The KGA GSP and its management area plans were developed in consideration of all beneficial uses of water and the beneficial users of the groundwater in the subbasin.
Leadership Council		"The Coordination Agreement does not "explain how the plans, implemented together, satisfy the requirements of the Act."	This comment is directed to the KGA GSP and will be addressed by KGA.
Leadership Council		"The GSP was not crafted in a way that adequately considered the input of disadvantaged communities, either at the GSA level or the member agency level."	This comment is directed to the KGA GSP and will be addressed by KGA, pertaining to the KGA level engagement. With respect to the member level engagement, SGMA leaves the manner and frequency of public outreach and engagement to the discretion of the GSA. As described in the introduction of the management area plan, SSJMUD holds monthly publicly-noticed meetings which serve as an opportunity for members of the public to provide feedback to the districts regarding the plan's development and implementation. Furthermore, the districts were active participants in the KGA-level outreach activities as well as hosts of their own workshops, which were publicly-noticed, and coordination with the cities of Delano and McFarland on the development of the plan.
Leadership Council		"The Kern Subbasin Undesirable Results do not comply with existing law."	The definitions for undesirable results were developed in coordination with the other GSAs and take into consideration "significant and unreasonable" impacts to the groundwater which affect all beneficial users. Such beneficial uses include agriculture, domestic, and municipal & industrial.
Leadership Council		"It is not clear what the impacts from reaching this undesirable result will be on beneficial users, and instead seems to be an arbitrary determination of what is "significant and unreasonable."	The impact analysis performed by the GSAs in the subbasin contributed to the development of the undesirable results for declining groundwater level.
Leadership Council		"Like the proposed definition of undesirable results for groundwater levels, the proposed definition of undesirable results for degraded water quality are 'when the minimum threshold for when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each management area)."	The comment letter cites an incorrect definition. The definition for the undesirable result for water quality is "when the minimum threshold for a groundwater quality constituent of concern is exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the designated monitoring points within the Subbasin."
Leadership Council		"The GSP's minimum thresholds and measurable objectives were not established in a way that considered the interests of beneficial users including domestic well owners and disadvantaged communities."	The KGA GSP outlines the methods used by its members to establish the Sustainable Management Criteria (SMCs) within their respective plan areas. For the SSJMUD management plan area, projected groundwater levels based on recent historical hydrology were used to analyze the impact to known agricultural, domestic, and municipal wells. While impacts were identified at the minimum thresholds in some management areas, these impacts were determined to not meet the definition of "significant and unreasonable".
Leadership Council		"As in the case of groundwater levels, it is clear that the GSA has not considered the potential impact on drinking water users, in particular disadvantaged communities who are less able to afford solutions to treat contaminated drinking water."	As with the groundwater level SMCs, the KGA GSP outlines the methods used by its members to establish the Sustainable Management Criteria (SMCs) within their respective plan areas. Based on the analysis in the Basin Setting subsection on existing water quality conditions, it was deemed appropriate to use groundwater levels as a proxy for water quality, in addition to water quality and water level measurement at the representative monitoring sites.
Leadership Council		"GSAs must monitor impacts to groundwater for drinking water beneficial users,54 including disadvantaged communities on domestic wells, and must avoid disparate impacts on protected groups pursuant to state law. The GSA's monitoring network does not comply with SGMA regulations, and fails to capture drinking water impacts to disadvantaged communities and domestic wells[...] To ensure the monitoring network adequately captures impacts to all beneficial users, the GSA must ensure the following: Ensure the proposed monitoring network contains representative monitoring wells in or near all disadvantaged communities and clusters of domestic wells in the GSA area; Ensure that monitoring wells and representative monitoring wells in or near disadvantaged communities and clusters of domestic wells are able to measure the groundwater levels at the depth at which the drinking water wells are screened; Explicitly describe any future representative monitoring wells and identify the proposed locations. When assessing the monitoring network data gaps, the GSP must prioritize installing new monitoring wells in locations where disadvantaged communities, small water systems, and domestic well users reside."	The coordinated basin-wide monitoring network was developed using the DWR BMP on SGMA Monitoring Networks, which discusses recommended well density and what constitutes a "SGMA compliant" representative monitoring site. It also allows for (and encourages) GSAs to use existing monitoring programs already in place for collecting data on the Sustainability Indicators identified in a basin's plan. Domestic wells are typically shallow or in the first occurence of groundwater and are, therefore, not representative of the groundwater conditions of the basin as a whole. Further, there are existing programs with which domestic wells and community wells must comply. These have been identified in the Basin Setting and Monitoring Network sections in the discussions of existing programs. In areas of the basin where the well density does not meet the standards used in the plan, proposed well locations have been identified. Per discussion and comments from the cities of Delano and McFarland, four additional wells have been added to the monitoring network within the SSJMUD management area.

Commentor	Ref #	Comment	Response
Leadership Council		The groundwater quality monitoring network does not adequately capture impacts on drinking water users.[…] First, measuring for Arsenic (as in Arvin-Edison WSD) only once a year does not provide the member agency or the GSA with frequent enough information to respond to severe drinking water contamination in a reasonable amount of time. If the member agency's management actions, projects, or decisions to let groundwater decline increase drinking water contamination for families in the management area, the member agency could go a whole year without detecting these impacts. [...] Second, only measuring for compliance with arsenic measurable objectives and minimum thresholds does not protect against increases in other contaminants that exist in other parts of the management area (boron, nitrates, TDS, 123-TCP, iron and manganese). These contaminants could extend, move or increase due to groundwater management activities and pumping patterns. [...] However, avoiding monitoring contaminated areas defeats the purpose of groundwater quality monitoring under SGMA, which is to measure the concentration and spread of contaminant plumes to ensure that groundwater management activities and pumping do not aggravate existing contamination.	The monitoring of water quality for the basin will include the use of data from existing programs (e.g. Title 22, ILRP, CV-SALTS) and sampling coincidental with groundwater level measurements at the representative monitoring sites. As such, the water quality data collected through SGMA will be more frequent than once a year. The constituents of concern to be tested in the water quality sampling at representative monitoring sites vary between the management areas. Therefore, the constituents analyzed will differ according to the management area plan. The selection of representative monitoring sites discouraged the use of wells with existing MCL exceedances because of the nature of the definition of undesirable results for degradation of groundwater quality. The occurence of an increase in concentration for constituents of concern in a representative monitoring site will, by virtue of it being a representative site, will be indicative of the migration of existing contamination.
Leadership Council		The projects and management actions set forth in the Draft GSP do not demonstrate a path towards achieving sustainability goals in the plan, and do not adequately account for the needs of disadvantaged communities pertaining to protected groups under state law. The GSA has allowed member agencies like the Arvin-Edison WSD to use a "glidepath" approach that increases surface water and groundwater recharge before demand reduction measures are implemented. This places the majority of the plan's success on surface water resources, which are variable and may not be able to be procured. The GSA should instead ensure that member agencies implement demand reduction strategies from the beginning so that groundwater levels do not plummet. A critical problem with the structure of the GSA is that member agencies cannot share the cost or responsibility for critical GSA-wide projects. Many more financially powerful agricultural and water banking member agencies could and should be part of a strategy to protect drinking water resources in the GSA area, especially given that they use much larger quantities of groundwater and their continued pumping will likely lead to dry wells and groundwater contamination issues for the most vulnerable homes in the GSA area.	The KGA and its members have the authority under SGMA to prioritize projects and management actions, as they see fit, to demonstrate that the basin can reach sustainability by 2040. The prioritization of projects to increase imported supply for use by districts' customers or for water banking projects protects groundwater for beneficial use in the basin by facilitiating in-lieu banking (where surface water is used whenever it is available, replacing groundwater pumping) or by maintaining groundwater levels through replenishment with banking projects. These projects do not run contrary to the mandate to protect groundwater quality. In fact, with groundwater levels as a proxy Sustainability Indicator for water quality, these projects achieve both the maintenance of groundwater levels and water quality. The agricultural and water banking agencies in the basin, as the customers paying for water deliveries and funding projects via land assessments in their respective districts, can and should be a beneficiary of the projects which they are funding.
Leadership Council		"The KGA GSA should implement or incentivize recharge basins or other recharge activities throughout the subbasin wherever DACs and clusters of domestic wells exist. The GSA should encourage these kinds of recharge projects with health co-benefits over on-farm recharge, which is likely lead to accelerate groundwater contamination."	It is at the discretion of the KGA's member agencies to identify projects to fund, as well as opportunities to collaborate with DACs. SSJMUD is already collaborating with the City of Delano to develop in-district recharge facilities which will be made available to the city when there is capacity available. Conversely, Delano will allow the district to utilize an existing stormwater catch basin as a spreading basin, when it is not in use to manage storm flows. Future projects and management actions which deal specifically with the DACs and domestic wells may be considered for subsequent updates to the GSP and management area plans.
Leadership Council		"For areas vulnerable to declining water levels and loss of production capacity, the KGA GSA should adopt management actions that establish geographical protection areas (buffer zones) by establishing bans, pumping limitations or community-specific management areas around disadvantaged communities and domestic well clusters."	The development of these buffer zones would be predicated on the development of a shallow-zone specific monitoring network and SMCs. As discussed in the response to the Monitoring Network comments, these shallow zones are not representative of groundwater conditions throughout the basin. Furthermore, the framework necessary to implement pumping restrictions or bans does not exist within the KGA or its members. Such policy would not be developed or implemented in time for the 2020 submittal.
Leadership Council		"We also strongly recommend against a groundwater market in the KGA GSA area. The GSP includes potential groundwater market and trading programs. Groundwater markets raise concerns from the perspective of domestic well users and disadvantaged communities."	At this time, the framework to establish a groundwater market in the basin does not exist. The policies and framework that would need to be developed by the KGA and its members is too complex to be completed in time for consideration in the 2020 submittal. Additionally, any groundwater market developed by the KGA or its members would have to comply with SGMA (i.e. prevent localized impacts to the Sustainability Indicators in its implementation).
Leadership Council		"The GSAs should implement and incentivize multi-benefit projects such as wetlands restoration or stormwater drainage ponds that would eliminate flooding and increase groundwater recharge in disadvantaged communities."	It is at the discretion of the KGA's member agencies to identify projects to fund. Future projects and management actions which provide benefits beyond SGMA may be considered for subsequent updates to the GSP and management area plans.
Leadership Council		"Although there are multiple short-term funding sources to leverage for SGMA-related projects, the GSA's and member agencies' operating budgets must be a reliable source of funding over the long-term of GSP implementation, and the GSA and member agencies cannot rely on grant funding for long-term projects and programs that benefit disadvantaged communities. The GSA and member agencies must be responsible for addressing the drinking water issues caused by their policy decisions and activities."	It is entirely appropriate that the KGA's members, when working in collaboration with DACs on a project to benefit groundwater quantity and quality in the basin, seek funding for such projects through state and federal grant funding programs. Grant funding, where the districts are eligible, is applied for to defray the cost of projects (which often far exceed the award amount). The remaining costs of projects and management actions are to be funded with the districts' operating budgets or through special assessments.
Leadership Council		"the Draft GSP allows continued overdraft above the safe yield of the basin, such that drinking water wells (especially domestic wells) will continue to go dry, infringing on the rights of overlying users of groundwater. The GSP must be revised to protect the rights of residents of disadvantaged communities and/or low-income households who hold water rights to groundwater."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with the statement, as the KGA GSP and its included management area plans have demonstrated, the combination of projects, management actions, and established SMCs will bring the basin into balance with its groundwater management by 2040.
Leadership Council		"The reasonable and beneficial use doctrine applies here given the negative impacts of the Draft GSP on groundwater supply and quality, which are likely to unreasonably interfere with the use of groundwater for drinking water and other domestic uses. As the Draft GSP authorizes waste and unreasonable use, it conflicts with the reasonable and beneficial use doctrine and the California Constitution."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with Leadership Council's statement regarding the plan's authorization of "waste and unreasonable use". The beneficial uses of water in the basin include other uses beyond domestic consumption. As such, it is entirely appropriate and in the authority of the GSAs that impacts to groundwater be analyzed in consideration of all beneficial uses identified in the plan.
Leadership Council		"The "public trust" doctrine has recently been applied to groundwater where there is a hydrological connection between the groundwater and a navigable surface water body. In Environmental Law Foundation , the court held that the public trust doctrine applies to "the extraction of groundwater that adversely impacts a navigable waterway" and that the government has an affirmative duty to take the public trust into account in the planning and allocation of water resources. The court also specifically held that SGMA does not supplant the requirements of the common law public trust doctrine. In contrast to these requirements, the Draft GSP does not consider impacts on public trust resources, or attempt to avoid insofar as feasible harm to the public's interest in those resources."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with Leadership Council's position in that the Basin Setting of the KGA GSP and its management area plans have adequately demonstrated that there are no interconnected surface waters in the basin and that this is the existing condition of the basin.

Appendix E

SSJMUD Board Resolution to Adopt Management Area Plan

BEFORE THE BOARD OF DIRECTORS OF
SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT

IN THE MATTER OF: **RESOLUTION NO. 19-14**

RESOLUTION APPROVING MANAGEMENT AREA PLAN FOR SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT MANAGEMENT AREA PLAN

WHEREAS, the Kern Groundwater Authority (the "Authority") is duly formed and existing under and pursuant to that certain Second Amended and Restated Agreement Joint Powers Agreement (the "JPA"), for the purposes of carrying out the Sustainable Groundwater Management Act (Water Code § 10720 *et seq.*) (SGMA), including the development, adoption and implementation of a Groundwater Sustainability Plan (GSP) for lands within the boundaries of the Authority's members and elsewhere within the Tulare Lake Groundwater Basin;

WHEREAS, the District is a member of the Authority;

WHEREAS, pursuant to Section 7.01 of the JPA, the District has exercised its option under the JPA to develop a chapter governing SGMA implementation within the boundaries of the District for inclusion in the Authority's GSP, which is titled *Southern San Joaquin Municipal Utility District Management Area Plan* (the "SSJMUD Chapter"); and,

WHEREAS, the District has conducted public outreach, solicited public input on, and, as appropriate, has responded or will respond to public comments on, the SSJMUD Chapter as required under SGMA; and

WHEREAS, following such outreach, solicitation and response, the District's Board of Directors reviewed and evaluated the SSJMUD Chapter.

NOW, THEREFORE, THE BOARD OF DIRECTORS OF THE SOUTHERN SAN JOAQUIN MUNICIPAL UTILITY DISTRICT does hereby resolve, declare and order as follows:

1) Each of the matters set forth above is true and correct and the Board so finds and determines.

2) The Board finds that the SSJMUD Chapter is consistent with the requirements of SGMA, and pursuant to Section 2.03(b) of the JPA approves the Chapter for inclusion in the Authority's GSP.

3) The Board hereby authorizes District staff to undertake such actions as are necessary and appropriate to transmit the SSJMUD Chapter to the Authority and to present the SSJMUD Chapter to the Authority's Board of Directors for consideration of inclusion in the Authority's GSP.

All the foregoing being on motion of Director, seconded by Director, and authorized by the following vote, to wit:

AYES: Fisher, Dulcich, Regan, Zaninovich, Morris

NOES: None

ABSTAIN: None

ABSENT None

I HEREBY CERTIFY that the foregoing resolution is the resolution of said District as duly passed and adopted by said Board of Directors on the 11 day of December 2019.

WITNESS my hand and seal of said Board of Directors this 11 day of December 2019.

Roland Gross, Secretary
of the Board of Directors

GEOLOGIC CROSS SECTION LOOKING NORTH

LOCATION MAP

This profile was prepared from well logs which were either copied from the records of drillers or made by geologists from samples obtained from drillers. The accuracy of the logs varies with the individual and is often open to considerable question. Thus conspicuous and rapid changes in sediment character, from well to well along the profiles are only in part actual, i.e. due to lensing and channeling during deposition. To an indeterminate extent they are merely a result of inconsistancies in the use of descriptive terms by the several drillers.

The 1921 water levels were taken from The California Department of Public Works Ground-water map for that year, and the 1946 water levels were taken from a map by The Bureau of Reclamation.

Sodium sulfate water; dissolved solids average above 1,500-4,000 ppm and percent sodium about 50

Sodium sulfate, sulfate chloride, and chloride water; dissolved solids average about 2,000 to 7,000 ppm and percent sodium about 50 to 75

Sodium bicarbonate water; dissolved solids average about 150 ppm and percent sodium about 80

Sodium and calcium chloride sulfate water; dissolved solids average about 400 to 800 ppm and percent sodium about 40

Sodium bicarbonate and bicarbonate sulfate water; dissolved solids average about 300 ppm and percent sodium about 75

Diatomaceous clay

Sea level

Position of perforated casing, where known, is indicated by heavy-line segment. The chemical-character symbol is based on the analysis of water from the pump discharge. The uppermost number indicates dissolved solids in parts per million. No parentheses indicates total solids were determined by weighing. Parentheses indicate dissolved solids calculated as the sum of determined constituents; figure includes silica if determined. Asterisk (*) indicates dissolved solids estimated from electrical conductivity or from empirical formula (Mendenhall and others, 1916, p. 81). The number immediately above the line is the percent sodium. The numbers below the line, reading downward, represent the bicarbonate plus carbonate, sulfate, and chloride content, in equivalents per million

See plate 3 for well locations

EXPLANATION

Appendix J

Land Subsidence

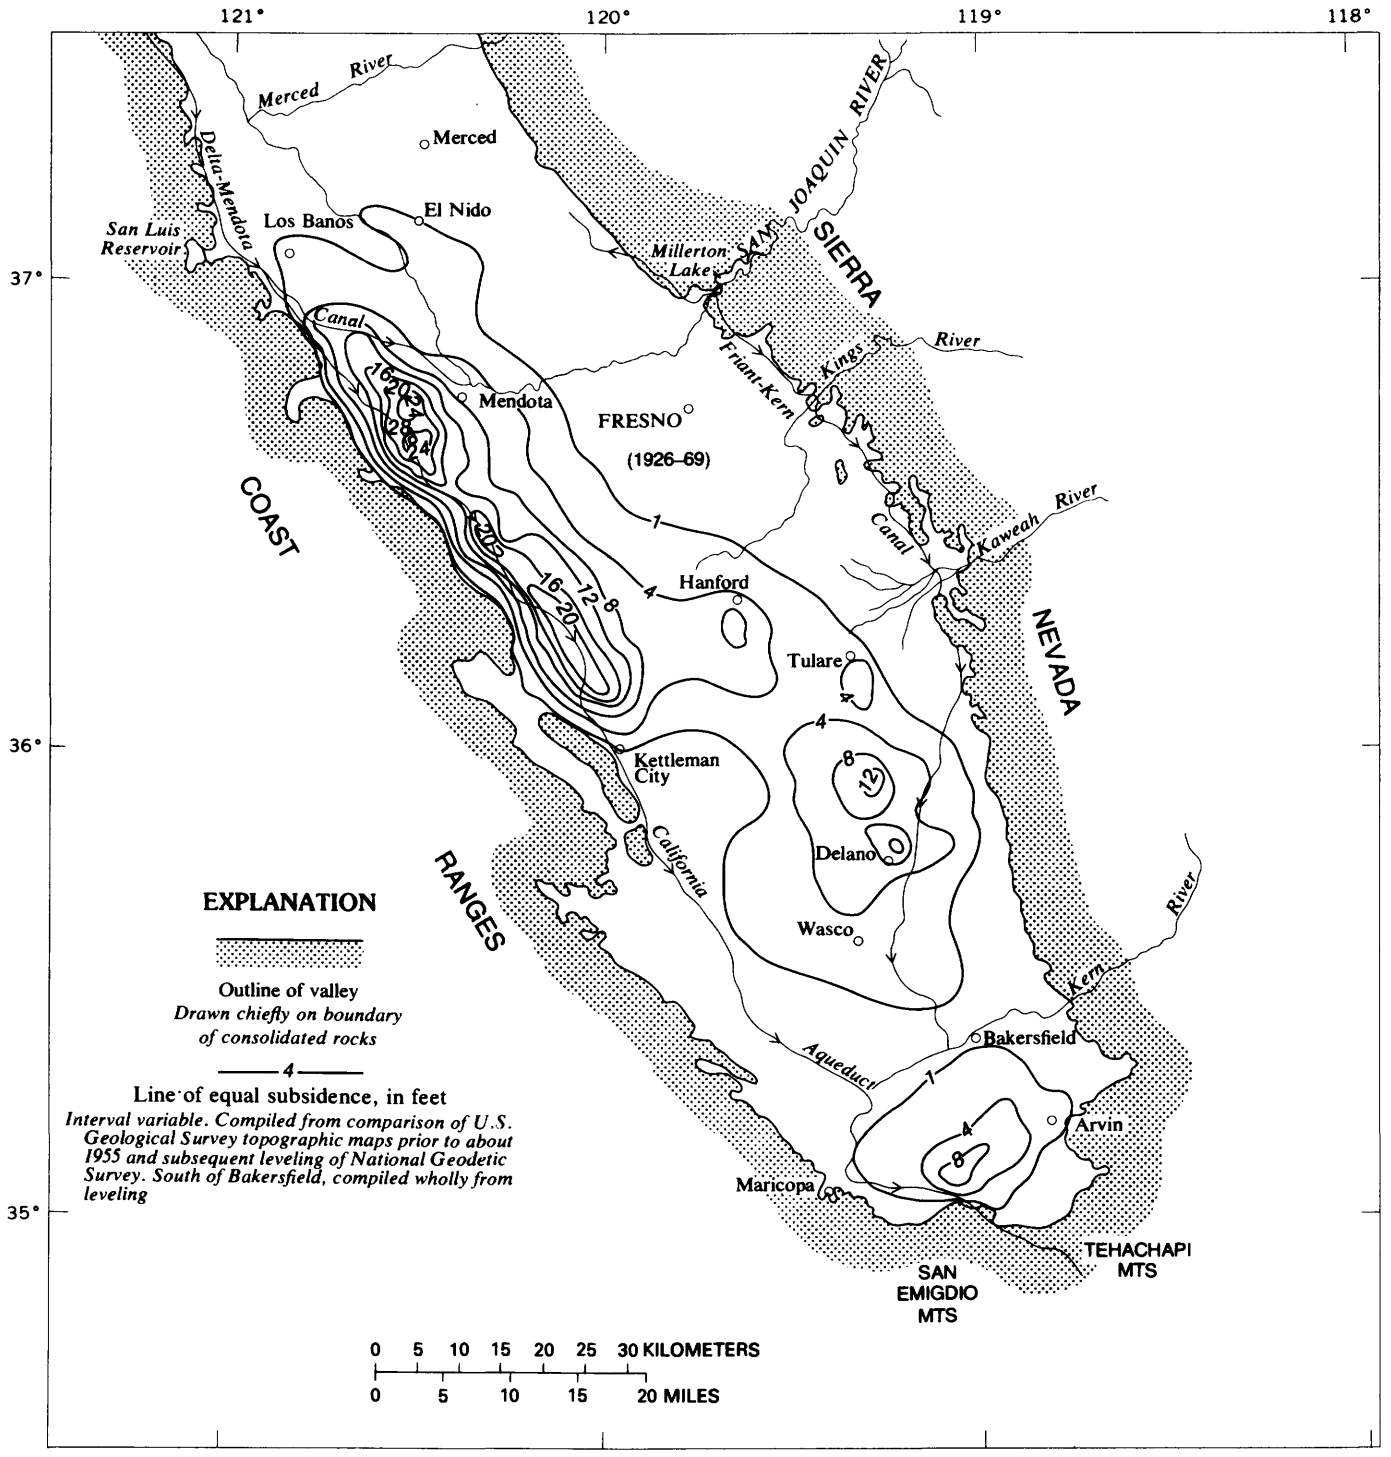

FIGURE 2.—Land subsidence in the San Joaquin Valley, California, 1926–70. Base from U.S. Geological Survey, 1:1,000,000, State of California map, 1940.

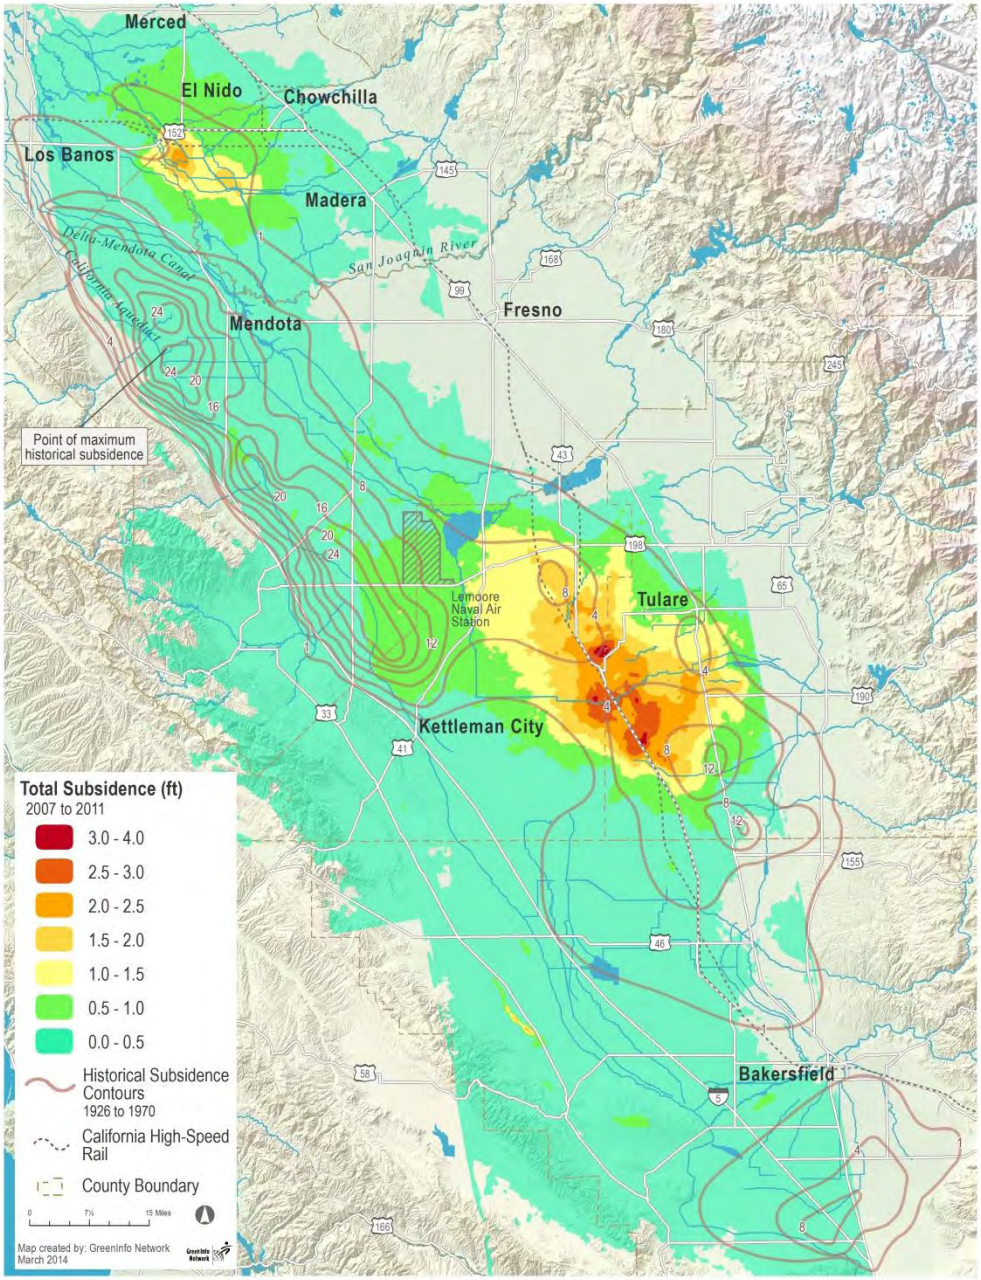
Ireland et al, 1984.



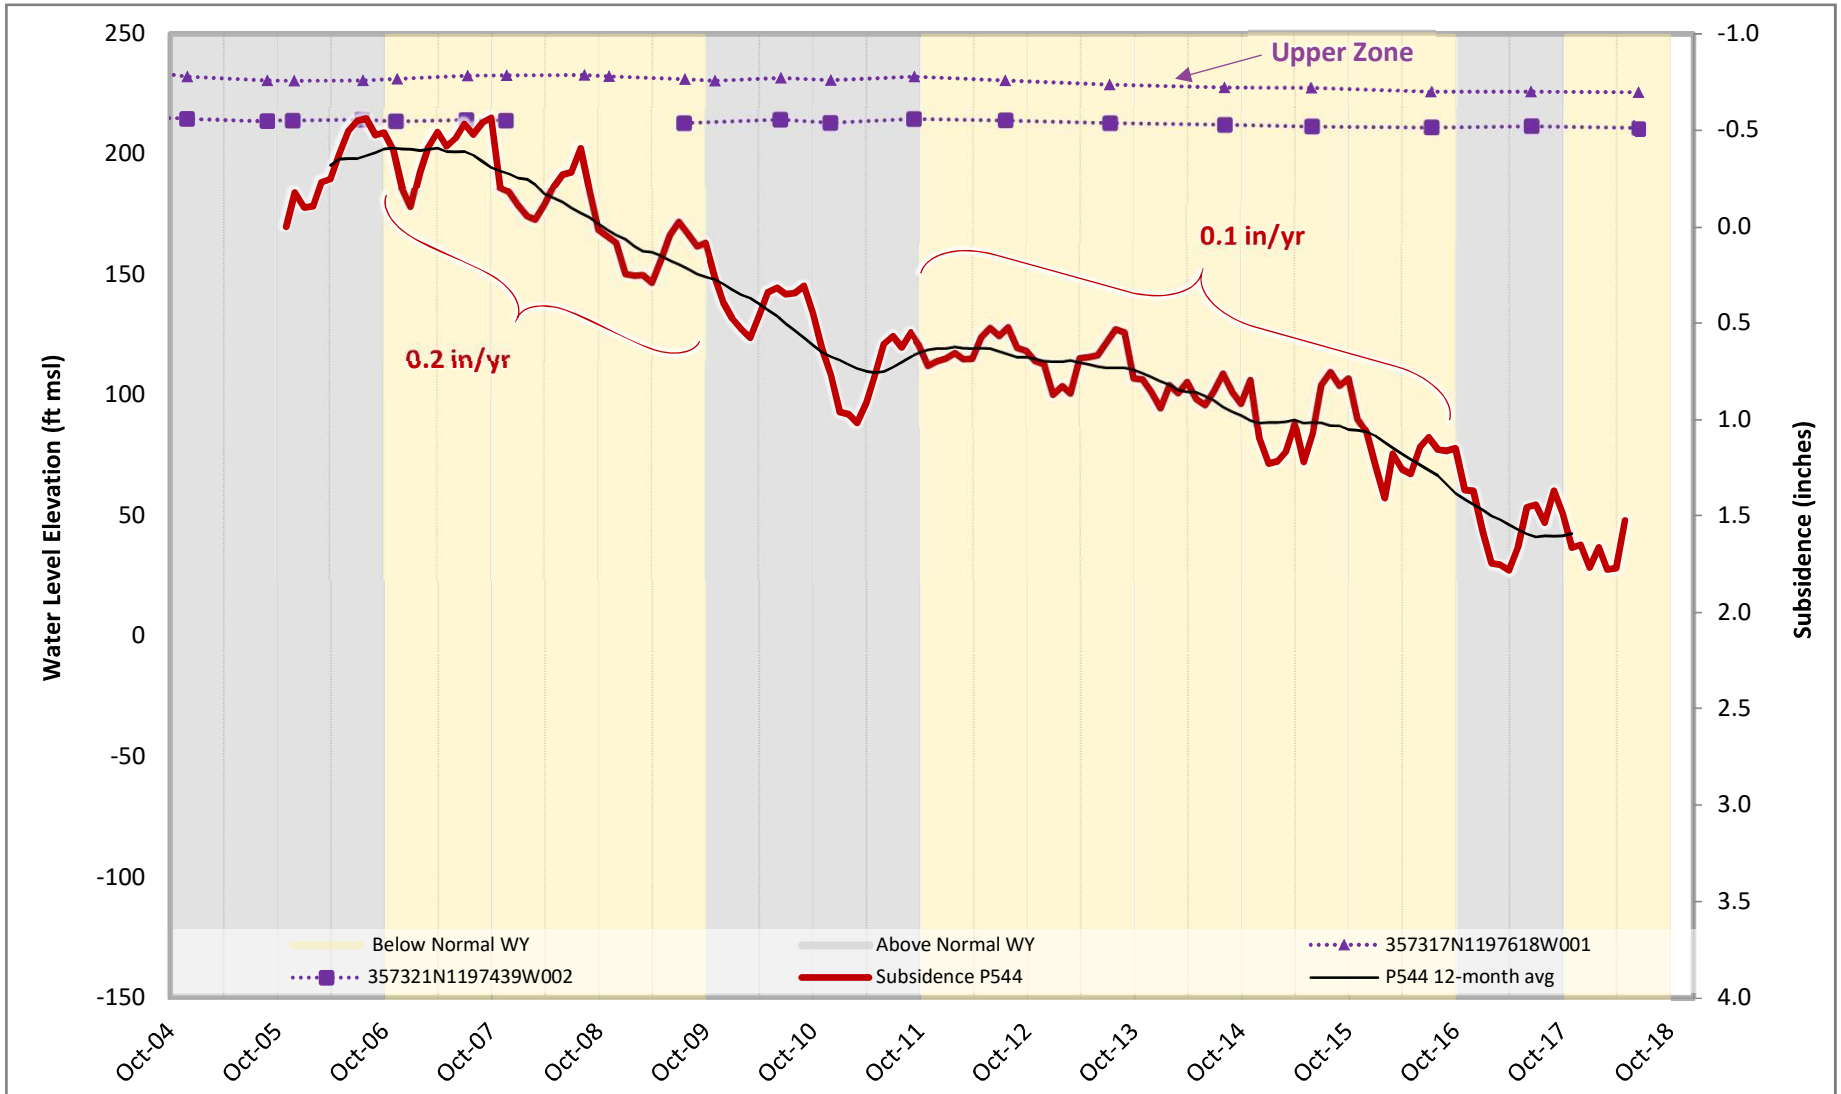


Figure 4-8. Recent subsidence in the in San Joaquin Valley January 2007-March 2011 shown as shaded regions compiled from Interferometric Synthetic Aperture Radar (InSAR) analysis. (InSAR derived subsidence data were provided as preliminary unpublished data courtesy of NASA-JPL.) Subsidence data were composited from three separate interferograms—eastern part of the area, 1/2007-7/2010; central part, 6/2007-6/2010; and western part, 1/2007-3/2011.). Brown contours are lines of equal magnitude of historical land subsidence, in feet, during 1926-1970 (Ireland et al., 1984). The proposed alternative alignments of the California High-Speed Rail system are shown as dotted lines.

Re: Recommendations for DWR and SWRCB Action Regarding the Kern Groundwater Authority Groundwater Sustainability Plan

Dear Department of Water Resources and State Water Resources Control Board,

Leadership Counsel for Justice and Accountability works with low-income communities of color in the San Joaquin Valley and the Eastern Coachella Valley. We have been engaged in the Sustainable Groundwater Management Act (SGMA) implementation process because most of the communities we work with are wholly dependent on groundwater for their drinking water supplies, and many have already experienced groundwater supply and quality issues. The communities where we work have not been adequately included in decision-making about their precious water resources, and their needs are not prioritized in such decisions.

Disadvantaged communities in the Kern Groundwater Authority GSA have the most to gain and the most to lose from SGMA implementation in the region. Communities like Arvin are majority

Latino and depend on small community water systems and/or domestic wells for their drinking water supply. Because residents in disadvantaged communities do not typically have the financial means to dig deeper wells or to install, operate and maintain drinking water treatment infrastructure, they are more likely to be severely impacted by lowering groundwater levels and groundwater contamination.

As a particularly vulnerable group, the critical drinking water needs of disadvantaged communities and low-income households must be considered and protected by the Groundwater Sustainability Plan (GSP). The Kern Groundwater Authority GSA has not adequately done so in this GSP. As described below, the GSP will likely allow drinking water to be contaminated by existing contaminant plumes, is likely to allow wells to go dry, and has no clear plan to help prevent and mitigate drinking water impacts.

The Department of Water Resources (DWR) and the State Water Resources Control Board (SWRCB) must evalue GSPs according to the Human Right to Water, and ensure that the GSPs comply with SGMA, the GSP regulations, and state and federal civil rights law, among other laws and regulations. In 2012, California recognized the Human Right to Water, codifying "the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."[1] Under the Human Right to Water law, DWR and the State Water Resources Control Board must consider the Human Right to Water on review of GSPs.[2] In order to comply with this obligation, the Department and Board must ensure that GSPs do not cause or allow further drinking water crises that interfere with residents' access to an adequate supply of safe drinking water. In coordination with the Community Water Center and Self-Help Enterprises, we have developed a Human Right to Water Scorecard that contains elements necessary for state review of GSPs to comply with the Human Right to Water.[3] We urge DWR and the SWRCB to use this scorecard in evaluating this GSP.

Additionally, SGMA requires GSAs to include disadvantaged communities in decision-making, and create GSPs in a transparent and inclusive way. DWR and the SWRCB must ensure that GSPs do not cause "significant and unreasonable impacts" to the beneficial uses and users of groundwater in the subbasin, that they encourage the participation of a diverse variety of stakeholders,[4] and that they "consider the interests of" an enumerated list of all types of beneficial users, including disadvantaged communities on domestic wells and community water

[1] Water Code § 106.3(a)

systems.[5] Furthermore, state law provides that no person shall, on the basis of race, national origin, ethnic group identification, and other protected classes, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state.[6] The state's Fair Employment and Housing Act guarantees all Californians the right to hold and enjoy housing without discrimination based on race, color, or national origin.[7] DWR and the SWRCB must evaluate GSPs in accordance with all of these and other relevant legal obligations.

Unfortunately, the Kern Groundwater Authority GSA did not protect the drinking water resources relied upon by disadvantaged communities or low-income households, or avoid disparate impacts, and the GSP is incomplete and does not comply with SGMA and other applicable state laws. As noted above, we reviewed the Kern Groundwater Authority GSP according to our Human Right to Water Scorecard. Our review shows that the GSP does not contain all of the information required under SGMA, does not adequately evaluate "significant" and "unreasonable" impacts to beneficial uses including the drinking water needs of disadvantaged communities, will create a disparate impact on protected classes unless significantly modified, and does not comply with the Human Right to Water statute.

For the reasons discussed in these comments, and in prior written and oral comments provided to the GSA, DWR must not approve the GSP.[8]

~ ~ ~ ~ ~ ~

A. The GSP Does Not Comply with SGMA Because It Lacks Required Information

The GSP must contain all of the elements set forth in the GSP regulations. However, this GSP omits critical data and information to comply with the GSP regulations. As discussed below, the GSP lacks required information and analyses, including among other things critical data regarding the consideration of drinking water impacts on disadvantaged communities and protected groups, sustainable management criteria that consider impacts on all beneficial users, and projects and management actions that address significant and unreasonable impacts to beneficial users. The GSP also fails to demonstrate how its proposed policies and activities will achieve its sustainability goal, which SGMA requires.[9] Therefore, the GSP fails to "include[] the information required by [SGMA] and [its accompanying regulations]," and is thus inadequate.[10] These inadequacies prevent DWR from being able to determine that the GSP will likely achieve its sustainability goal.[11] Given these deficiencies, we ask DWR not to approve the plan.

B. DWR Cannot Approve The GSP Because It Will Cause Disproportionate And Disparate Negative Impacts On Protected Classes.

The Kern Groundwater Authority GSA and DWR must ensure that the GSP does not cause disparate impacts on protected groups, and must prioritize drinking water as an essential pillar of their groundwater sustainability plan. The GSP does not comply with these requirements.

State law provides that no person shall, on the basis of race, national origin, ethnic group identification, and other protected classes, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by any state agency.[12] In addition, the state's Fair Employment and Housing Act guarantees all Californians the right to hold and enjoy housing without discrimination based on race, color, or national origin.[13]

---

[9] Water Code sec. 10727.2(b)(2)
[10] 23 CCR § 355.4(a)(2).
[11] Water Code § 10733(a); 23 CCR § 355.4(b).
[12] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].
[13] Gov. Code § 12900 et seq.

The GSP will have disparate impacts on protected classes, including negative and discriminatory impacts on the basis of race, color, ancestry, national origin, and ethnic group identification. "Low-income communities and communities of color in the Central Valley rely disproportionately on private wells because adequate public services were not developed in those communities."[14]As a result, "low-income households, people of color, and communities already burdened with environmental pollution suffered the most severe impacts [from drought]" and dry wells.[15] Similarly, communities of color in the Central Valley are disproportionately impacted by groundwater contamination.[16]

Consistent with these studies, this GSP will cause disproportionate negative impacts on communities of color reliant on small water systems and domestic wells. There are at least 105 disadvantaged unincorporated communities (DUCs) within Kern County, many of which will be impacted by this GSP.[17] Approximately 55% of the population of Kern County DUCs are people of color, slightly higher than the approximately 51% of the population of the County overall who are people of color. Many of the communities we work with and that are most susceptible to falling groundwater levels and groundwater pollution, however, are nearly 100% Latino. For example, according to the most recent American Communities Survey data, Lamont is 95% Hispanic or Latino.[18]

As discussed below, the GSP's determinations and policy decisions will result in many more dry wells, and will not prevent increased drinking water contamination from groundwater activities, particularly for disadvantaged communities reliant on small water systems and domestic wells. This will cause severe harm to residents' health and daily lives, as well as permanent impacts on residents' finances and living situations. Additionally, the GSP contains no measures to mitigate these impacts. Therefore, because the GSP is likely to have significant negative impacts on households reliant on small water systems and domestic wells, and because the people reliant on small water systems and domestic wells are disproportionately people of color, the GSP is likely

to cause disparate impacts on protected classes.

C. The GSP Does Not Adequately Evaluate Whether Adverse Impacts Are "Significant And Unreasonable" Or Consider Beneficial Uses And Users.

Under SGMA, DWR must find that a GSP is likely to achieve its sustainability goal before DWR may approve the plan.[19] "'Sustainability goal' means the existence and implementation of one or more groundwater sustainability plans that achieve sustainable groundwater management by identifying and causing the implementation of measures targeted to ensure that the applicable basin is operated within its sustainable yield."[20] "'Sustainable groundwater management' means the management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results."[21] An "undesirable result" occurs when a GSP allows a "significant and unreasonable" adverse impact to one of six sustainability indicators, including groundwater levels, groundwater storage, groundwater quality, and land subsidence.[22]

If a GSP is unlikely to achieve its sustainability goal, DWR cannot approve the plan.[23] DWR must also independently determine whether or not the GSP is likely to avoid "significant and unreasonable" adverse impacts with regard to each sustainability indicator, and if not then DWR cannot approve the plan. If a GSP will allow an undesirable result even if implemented effectively, then the GSP cannot achieve sustainable groundwater management.[24] Likewise, a plan that cannot achieve sustainable groundwater management has failed to set a valid sustainability goal, in violation of SGMA.[25] If a GSP does not contain a valid sustainability goal, DWR cannot determine that the GSP is "likely to achieve the sustainability goal for the basin," and DWR cannot approve it.[26]

In addition to defining undesirable results, GSPs must quantify benchmarks for groundwater conditions, or "minimum thresholds," that may cause undesirable results if exceeded.[27] GSPs must include "an explanation of how the Agency has determined that basin conditions at each minimum threshold will avoid undesirable results for each of the sustainability indicators."[28] A GSP's determination of when an undesirable result will occur must be based on analysis of when

[19] Water Code § 10733(a).
[20] Water Code § 10721(u).
[21] Water Code § 10721(v).
[22] Water Code § 10721(x).
[23] Water Code § 10733(a).
[24] Water Code § 10721(v).
[25] Water Code § 10721(u).
[26] Water Code § 10733(a); *see also* 23 CCR 354.24 ("Each Agency shall establish in its Plan a sustainability goal for the basin that culminates in the absence of undesirable results within 20 years of the applicable statutory deadline.").
[27] 23 CCR 354.28(a).
[28] 23 CCR 354.28(b)(2).

adverse impacts become "significant" and "unreasonable."[29]

In all of its actions, a GSA must "consider the interests of" all categories of beneficial users, including express requirements to consider disadvantaged communities on domestic wells and community water systems.[30] Failure to consider the interests of a category or categories of beneficial users is itself grounds for DWR to decline to approve a plan.[31] DWR regulations also establish that a failure to consider all beneficial uses and users of groundwater undermines the likelihood that a basin will reach its sustainability goal.[32]

We note that an impact on drinking water that persists for even a relatively short period of time (e.g., months or years rather than decades) may have permanent and irreversible impacts on households and communities. A household is not habitable without access to an adequate supply of safe drinking water, and failed wells thus may have irreparable impacts on community cohesion. These impacts are inconsistent with the very concept of sustainable groundwater management.

As explained below, the GSA has not based their policy determinations on an analysis of what impacts are "significant" and "unreasonable," and have not considered the interests of disadvantaged communities or low-income households reliant on small water systems or domestic wells.

D. DWR Cannot Approve The GSP Because It Was Developed With Inadequate Transparency, Accessibility, Consideration Of Public Input And Representation.

As public agencies, GSAs are subject to the requirements of the Brown Act, which requires transparency of public agencies through notice of meetings and prior posting of agendas, posting of meeting minutes after meetings, and public access to meeting materials upon request by a member of the public.[33] GSAs are also subject to the requirements of the Bilingual Services Act, which requires a public agency to provide interpretation and translate materials into all languages for which there is a "substantial" number of people who it serves who speak that language.[34]

---

[29] Water Code § 10721(x); 23 CCR 354.28(b); *see also* Cal. Dep't Water Res., *Draft Best Management Practices for the Sustainable Management of Groundwater* 6 (Nov. 2017) ["GSAs must consider and document the conditions at which each of the six sustainability indicators become significant and unreasonable in their basin, including the reasons for justifying each particular threshold selected."]; *id.* 8 ["The GSP must include an analysis and written interpretation of the information, data, and rationale used to set the minimum threshold."].

[30] Water Code § 10723.2.

[31] Water Code § 10723.2; 23 CCR 355.4(b) ["The Department shall evaluate a Plan … to determine whether the Plan … complies with the Act …."].

[32] 23 CCR 355.4(b)(4).

[33] California Gov. Code § 54954.1

[34] Bilingual Services Act, Gov. Code, §§ 7293, 7295.

In addition, GSAs must also adhere to the specific public participation and inclusivity requirements laid out in SGMA. As discussed above, SGMA requires that a GSA "shall consider the interests of all beneficial uses and users of groundwater," which expressly includes "[h]olders of overlying rights" and "[d]isadvantaged communities, including, but not limited to, those served by private domestic wells or small community water systems."[35] The emergency regulations similarly require that a GSP summarize and identify "opportunities for public engagement and a discussion of how public input and response will be used."[36] GSAs thus must engage "diverse social, cultural, and economic elements of the population within the basin."[37] The regulations recognize that failure to engage adequately with a diverse cross-section of the public undermines the likelihood that a GSP will avoid undesirable results and meet its sustainability goal.[38]

The GSA did not adequately consider the input of disadvantaged communities, either at the GSA level or the member agency level. First, the GSA itself did not adequately engage residents of disadvantaged communities in the GSP creation process. The KGA GSA held regular GSA meetings at times that were not accessible to residents working during the day, so many beneficial user groups could not be adequately represented.

The GSA held several public workshops, but the feedback from these workshops, from meetings and from written comments was not incorporated into the GSP. We submitted a comment letter to the KGA GSA in June 2019 and presented this same letter verbally to the KGA board on June 26, 2019. At this meeting we expressed our initial concerns about GSP development and shared recommendations to ensure the protection of vulnerable water users. Among other things, we asked for the GSP to set protective sustainable management criteria to protect drinking water access in disadvantaged communities, ensure the GSP development process be reflective of all beneficial users by monitoring all primary drinking water contaminants, and to engage with DAC residents. These comments were not incorporated into the GSP or the GSP development process. We repeated these same concerns and recommendations in our comment letter on the final public draft of the GSP.

The GSA had a communications plan and an online Stakeholder Survey that was available most of the GSP development period, but the survey was only in English and was only available online, thereby limiting the opportunity for diverse input from non-English speakers and those without regular access to the internet. The survey was also not promoted outside the KGA agencies' existing networks in an authentic and intentional way to reach all beneficial users including disadvantaged communities. While the GSA worked with Self-Help Enterprises to

[35] Water Code § 10723.2.
[36] 23 CCR 354.10(d).
[37] Guidance Document for Groundwater Sustainability Plan; Stakeholder Communication and Engagement, p. 1.
[38] 23 CCR 355.4(b)(4).

provide interpretation at workshops, it did not provide interpretation at its board meetings. It also did not provide translated materials at its meetings.

Additionally, the decision-making structure of the GSA created barriers to public engagement. Instead of being able to learn about GSP development and provide feedback at GSA meetings, stakeholders also had to engage with a myriad of local member agencies, which all had separate meetings, to fully understand GSP development. The KGA GSP states that, "[t]o capture the intent of SGMA as legislation better served under local control, KGA member agencies played a vital role in the development of this GSP. This process included communication and outreach at the local level, with each KGA member agency engaging with its beneficial users to gather vital input, data, and feedback to ensure the success of this GSP and individual management area plans."[39] However, this decision-making structure meant attending member agency meetings and GSA meetings to understand GSP development, which is overly burdensome to most stakeholders who do not have adequate time in their schedules to attend so many regular meetings.

This burdensome process is compounded by the fact that GSA meetings were held during work hours, and member agencies' websites did not provide adequate notice or agendas for GSP-related meetings. The GSP states that "each KGA member agency engag[ed] with its beneficial users to gather vital input, data, and feedback to ensure the success of this GSP and individual management area plans."[40] However, our organization and residents we work with in Arvin had serious barriers to actively participating in GSP development through their local member agency.

The member agency that has jurisdiction over residents we work with in the GSA area, the Arvin-Edison Water Storage District ("Arvin-Edison WSD"), states in its Management Plan, a chapter of the GSP, that it considered disadvantaged communities by engaging representatives of the Arvin CSD, which contains disadvantaged community residents; by creating a Stakeholder Communication and Engagement Plan; and by "welcom[ing] public participation" at stakeholder workshops, Arvin-Edison WSD board meetings, Arvin CSD board meetings, KGA GSA events and meetings, a stakeholder survey, letters to landowners, and small or one-on-one meetings with individual stakeholders.[41] However, as a community-based organization working directly with residents in the GSA area, we were not included in these conversations until August 15, 2019 when we attended the Arvin- Edison WSD Board meeting where they presented their GSP chapter to its board for approval. Residents we work with did not have any knowledge of the GSP development process in the Arvin-Edison Management Area. We have collaborated with many GSAs to develop more effective outreach materials and procedures for ensuring

[39] Kern Groundwater Authority GSP, p. 37, dated January 2020.
[40] Kern Groundwater Authority GSP, p. 37, dated January 2020.
[41] Arvin-Edison Water Storage District Management Area GSP, p. 3-4, dated December 2019.

disadvantaged community involvement, but it was very difficult to follow the structure of KGA. This made it difficult to relay accurate and complete information to community residents and properly engage them with the topic.

Additionally, during GSP implementation the Arvin WSD's website contained no information on SGMA or GSP meetings. We understand from conversations with staff that the agency sent notices to its list serv, but there was no way to sign up for the list serv on the website, and without knowing when and where meetings are occuring the public could not go to a meeting to sign up and be added to the interested parties list serv. A representative from Arvin CSD brought regular updates to a community meeting, but no meeting notices or agendas about GSP development meetings were published in any publicly available format. This public process did not comply with the Brown Act, the Bilingual Services Act, or the requirements under SGMA.

After we submitted our comments on the draft GSP, including the Arvin-Edison Management Area chapter of the GSP, representatives from Arvin CSD reached out to us to discuss our concerns about their public process and the substance of their portion of the GSP. The representatives from Arvin CSD expressed their commitment to public participation and drinking water needs of the residents of Arvin, and agreed to consider our feedback on improved public participation practices. Since then, Arvin WSD huas updated its website and included a link to sign up for its interested parties listserv. But these efforts, taking place after GSP development was largely complete, did not inform the GSP.

The GSA's public participation process and its choice to delegate GSP development to member agencies did not ensure a transparent and inclusive process for developing the GSP. The public engagement process for this GSP was therefore inadequate. At a minimum, an adequate process must include the following elements, which were not present here:

1. **Notice:**[42] Ensure that the GSA provided clear notice to the public about GSA meetings to develop the GSP, posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.[43]

[42] Government Code § 54954(a).

[43] Government Code sec. 7296.2: Dymally-Alatorre Bilingual Services Act, stating that local agencies providing services to the public must provide translated materials and interpretation when it serves a substantial number of non-English-speaking people. The law defines a "substantial number of non-English-speaking people" as "members of a group who either do not speak English, or who are unable to effectively communicate in English because it is not their native language, and who comprise 5 percent or more of the people served by the statewide or any local office or facility of a state agency." This is because "effective maintenance and development of a free and democratic society depends on the right and ability of its citizens and residents to communicate with their government and the right and ability of the government to communicate with them."

2. **Translation of materials:**[44] Ensure that the GSA translated materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.
3. **Interpretation:**[45] Ensure that the GSA provided interpretation services at board meetings, committee meetings and workshops for all languages spoken by at least 5 percent of the public served by the agency, to allow those who do not speak English or are unable to effectively communicate in English to effectively participate.
4. **Meaningful DAC representation on advisory committee:** Ensure that the GSA developed the GSP with an advisory committee that contained representatives from DACs, such that DAC representatives' voices were not drowned out by the overwhelming majority of another interest group.
5. **DAC representation on GSA boards and Coordination Committee:** Ensure that the GSA developed the GSP with GSA boards and a Coordination Committee that contained representatives from DACs.
6. **Incorporation of stakeholder input:** Ensure that the GSP explicitly describes how stakeholder input was incorporated into the GSP process and decisions, including sustainable management criteria and all projects and management actions.

E. The GSP's Sustainable Management Criteria for Groundwater Levels Are Not Adequate

The sustainable management criteria for groundwater levels must be made after considering the interests of all beneficial user groups, including disadvantaged communities reliant on domestic wells and community water systems,[46] and must be based on an analysis of what are "significant" and "unreasonable" impacts.[47] These policy decisions must also avoid disparate impacts on protected groups pursuant to state and federal law.[48] As discussed below, the GSP does not meet these requirements.

a. The Undesirable Result for Groundwater Levels are Inadequate

Undesirable results are the point at which groundwater conditions cause "significant and unreasonable" impacts on beneficial users. The SGMA regulations require GSAs to justify their undesirable results by including the "[p]otential effects on the beneficial uses and users of

[44] Government Code sec. 7296.2.
[45] Government Code sec. 7296.2.
[46] Water Code § 10723.2.
[47] Water Code § 10721(x); 23 CCR 354.28(b); *see also* Cal. Dep't Water Res., *Draft Best Management Practices for the Sustainable Management of Groundwater* 6 (Nov. 2017) ["GSAs must consider and document the conditions at which each of the six sustainability indicators become significant and unreasonable in their basin, including the reasons for justifying each particular threshold selected."]; *id.* 8 ["The GSP must include an analysis and written interpretation of the information, data, and rationale used to set the minimum threshold."].
[48] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).

groundwater."[49] GSAs must also describe the "processes and criteria relied upon to define undesirable results."[50] These determinations must be made based on an analysis of when decreasing groundwater levels will cause results that are either "significant" or "unreasonable" in light of the context of the basin and the real-world circumstances on the ground. The undesirable results determination does not comply with these requirements because it is unsupported by analysis, it is too vague, and it does not show how the GSA considered the interests of beneficial users in shaping its conclusions.

The KGA GSP defines undesirable results for groundwater levels as "when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each management area)."[51] Neither the KGA GSP nor the Kern Subbasin Coordination Agreement contain an analysis of how what the concrete impacts would be on beneficial users from reaching these undesirable results, including how many wells could go dry, or a process by which beneficial users were consulted in order to determine whether these potential impacts were "significant and unreasonable."

The undesirable result could allow for more than 30% of the territory in the subbasin to exceed its minimum thresholds for groundwater levels before this undesirable result is triggered. This standard allows localized impacts across the subbasin area, which would cause significant and unreasonable impacts to beneficial users of groundwater for drinking and other domestic purposes. There is no justification for dividing the GSA area up into arbitrary management areas and then defining undesirable results as occurring only where three ***adjacent*** management areas exceed minimum thresholds. In short, the GSP allows domestic and small community wells to be dewatered.

Because the undesirable result for groundwater levels allows significant and unreasonable impacts, the GSP is inadequate.

b. The Measurable Objectives for Groundwater Levels are Inadequate

The SGMA regulations require the GSA to set measurable objectives that "achieve the sustainability goal for the basin within 20 years of Plan implementation and...continue to sustainably manage the groundwater basin over the planning and implementation horizon."[52]

The GSA has not demonstrated that it evaluated how the proposed measurable objectives would contribute to the overall sustainable yield of the Kern Subbasin, which is approximately 324,326

[49] 23 CCR § 354.26.
[50] 23 CCR § 354.26.
[51] Kern Groundwater Authority GSP, p. 170, adopted January 2020.
[52] 23 CCR § 354.30(a)

acre-feet per year, according to the GSP,[53] or maintain sustainability over the implementation and planning horizon.

c. The Minimum Thresholds for Groundwater Levels are Inadequate

The groundwater levels sustainable management criteria set by a GSA must be the point that, "if exceeded, may cause undesirable results."[54] SGMA requires GSAs to analyze both the significance and reasonableness of proposed minimum thresholds,[55] and minimum thresholds must have the purpose of avoiding "significant and unreasonable" impacts on beneficial users.[56] The GSA's determination of what is "significant and unreasonable" must consider the impacts on all types of beneficial users, including disadvantaged communities.[57] For groundwater levels specifically, GSAs must place minimum thresholds for each monitoring site at the level "that may lead to undesirable results."[58] Under DWR regulations, the GSA must provide a description of "the information and criteria relied upon to establish minimum thresholds," an explanation of how the proposed minimum thresholds will "avoid undesirable results," and "how minimum thresholds may affect the interests of beneficial uses and users of groundwater."[59]

The GSP's minimum thresholds were not established in a way that considered the interests of beneficial users including domestic well owners and disadvantaged communities, and the resulting minimum thresholds cause significant and unreasonable impacts on the most vulnerable beneficial users. The GSA delegated the task of creating the sustainable management criteria to member agencies, and in the process, did not ensure that the resulting policies complied with the law. The resulting impact from the proposed sustainable management criteria will likely lead to disparate impacts on protected groups pursuant to state and federal law.

The KGA GSA did not ensure that minimum thresholds created by member agencies considered the interests of all beneficial user groups, or prioritize the security of drinking water in the subbasin, in developing minimum thresholds. For example, the Arvin-Edison Management Area GSP did not consider the impact on drinking water users in setting its minimum thresholds. The AEWSD Management Area Draft GSP details how it calculated historical water lows and divided the Management Area into four "Sustainability Criteria Zones" based on historical low groundwater levels and agency jurisdiction, and how it adjusted the minimum thresholds to protect the canal that brings surface water to farmers.[60] However, it did not evaluate or consider

[53] Kern Groundwater Authority GSP, p. 151, dated January 2020.
[54] 23 CCR § 354.28.
[55] Water Code § 10721(x); 23 CCR 354.26(a). (b), 354.28(b); see also Cal. Dep't Water Res., Draft Best Management Practices for the Sustainable Management of Groundwater 6, 8 (Nov. 2017).
[56] 23 CCR § 354.26.
[57] Water Code § 10723.2.
[58] 23 CCR § 354.28.
[59] 23 CCR § 354.28.
[60] Arvin-Edison Water Storage District Management Area GSP, p. 124, dated December 2019.

how many wells could go dry from its proposed minimum thresholds, or adjust for effects on drinking water. Figures 2-5, 2-6 and 2-7 show all of the domestic wells, public supply wells, and communities dependent on groundwater in the GSA area.[61] The GSA therefore knows the number and location of all drinking water wells, but has chosen not to evaluate what the impacts will be to these wells at the minimum thresholds, and whether those impacts are significant and unreasonable. Therefore the GSA did not consider impacts on drinking water beneficial users, or ensure the protection of drinking water as the highest beneficial use of water, despite having all the information it needed to conduct such a drinking water impact analysis.

The GSP does not show that the impact to beneficial users was evaluated. It lays out the process by which the minimum thresholds and measurable objectives were approved, states that the GSA had workshops about the sustainable management criteria and that these items "appeared as discussion items" at the GSA board meetings, but does not show that the GSA considered the impacts on beneficial users.[62] The GSP contains no evaluation of impacts on beneficial users from reaching these sustainable management criteria, and the GSA's decisions regarding sustainable management criteria were not based on an evaluation of the impacts to beneficial users' access to groundwater resources.

The groundwater levels sustainable management criteria for this GSP are therefore inadequate. At a minimum, adequate groundwater levels sustainable management criteria must include the following elements, which are not present here:

1. **Evaluate the drinking water impact:** Ensure that the GSP includes an analysis of how many drinking water wells (municipal wells, community water system wells, and domestic wells) might go fully or partially dry if groundwater levels reach the undesirable results,[63] measurable objectives and minimum thresholds,[64] including a map of wells that will go fully and partially dry at the measurable objectives and minimum thresholds. Ensure that the GSP includes estimates of the increased pumping costs from additional lift needed to pump water from lower elevations if the undesirable results, measurable objectives and minimum thresholds were to be reached.
2. **Avoid significant and unreasonable impacts to drinking water users in creating sustainable management criteria:**[65] The GSA must analyze "when significant and unreasonable effects ... are caused by groundwater conditions occurring throughout the basin," taking into account the beneficial users of groundwater and the basin's specific circumstances.[66] Therefore the GSP must explicitly state how the GSA considered

[61] Kern Groundwater Authority GSP, pg. 26-28, dated January 2020.
[62] Kern Groundwater Authority GSP, p. 177, dated January 2020.
[63] 23 CCR § 354.26(c)
[64] 23 CCR § 354.28(b)(4)
[65] Water Code § 10723.2
[66] 23 CCR § 354.26.

drinking water impacts in shaping undesirable results, measurable objectives and minimum thresholds for groundwater levels; for example, the GSP could state how its well impact analysis supported setting stricter measurable objectives and minimum thresholds near at-risk communities.

3. **Incorporate new drinking water data into sustainable management criteria:**[67] Ensure that the GSP includes a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data.
4. **Implement DAC and drinking water user input into sustainable management criteria:**[68] Ensure that the GSP discusses how stakeholder input from DAC community members was considered in the development of undesirable results, measurable objectives and minimum thresholds. For example, the GSP could state how they took the results of the well impact assessment to the public through meetings, workshops, or Advisory Committees, and together with stakeholders decided how to change sustainable management criteria to protect drinking water, or other programs to implement to mitigate these impacts.
5. **Avoid disparate impact:**[69] Ensure that the measurable objectives and minimum thresholds for groundwater levels are established in such a way that prevents a disparate impact from occurring on protected classes in the GSP area. For example, the GSP should ensure that the same minimum threshold methodology across the GSP area will not lead to disproportionately more wells going dry for residents of color than for white residents.

F. The GSP Fails To Adequately Address Groundwater Quality Through Its Sustainable Management Criteria for Groundwater Quality

GSA activities and policies could cause increased contamination in many ways. For example, the proposed timeline for implementation of demand reduction may allow for continued pumping which may create an increase in naturally occurring contaminants and/or migration of contaminant plumes.[70] Recharge projects could also have severe impacts on groundwater quality by facilitating water percolation on land contaminated with years of pesticide, herbicide, fungicide, and fertilizer application and/or by releasing natural contaminants like uranium into groundwater.[71] A groundwater market is also likely to cause geographic concentrations of

[71] See Fakhreddine et al., Protecting Groundwater Quality In California, Management Considerations For Avoiding Naturally Occurring And Emerging Contaminants (2019), available at https://www.edf.org/sites/default/files/documents/groundwater-contaminants-report.pdf ["Recharging water, even clean water, into a previously uncontaminated aquifer can potentially alter the existing geochemistry and hydrology

pumping that increases the likelihood of contaminant plume migration, putting drinking water resources at risk. Oil and gas impacts on groundwater should also be analyzed, since Kern County is one of the largest producers of oil and gas, and reports show oil and gas activities can severely impact groundwater quality.[72]

SGMA charged GSAs with the responsibility to protect water quality from further degradation due to groundwater management practices, and requires GSAs to establish sustainable management criteria to prevent degraded groundwater quality,[73] based on a determination of what is a "significant and unreasonable" impact on all beneficial users, including domestic well users and disadvantaged communities.[74] This GSP only monitors and regulates one contaminant of concern despite its express knowledge that many other more harmful drinking water contaminants exist in its GSP area, which could be impacted by groundwater usage and activities. The GSA's sustainable management criteria for groundwater quality are inadequate.

b. The Undesirable Results Determination for Groundwater Quality Is Inadequate

Undesirable results are the point at which "significant and unreasonable" impacts on beneficial users caused by degraded groundwater quality. The SGMA regulations require GSAs to justify their undesirable results by including the "[p]otential effects on the beneficial uses and users of groundwater."[75] GSAs must also describe the "processes and criteria relied upon to define undesirable results."[76] The undesirable result cannot have a disparate impact on protected groups pursuant to state civil rights law.

Like the undesirable result for groundwater levels, the proposed definition of undesirable results for degraded water quality are "when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the

---

and subsequently cause the release of geogenic contaminants from soils and sediments."]; Jurgens, Bryant C., et al. [74] Water Code §§ 10727.2(d)(2); 10721(x)(4)

[75] 23 CCR § 354.26.

[76] 23 CCR § 354.26.

Subbasin or greater than 30% of the Subbasin (as measured by each management area)."[77] As with the groundwater levels undesirable results, it is not clear what the impacts from reaching this undesirable result will be on beneficial users, and neither the KGA GSP nor the Kern Subbasin Coordination Agreement contain an analysis of how what the concrete impacts would be on beneficial users from reaching these undesirable results, including how many wells could go dry. Instead of being formed through a process in which beneficial users were consulted in order to determine whether these potential impacts were "significant and unreasonable," the process of defining undesirable results in the Kern subbasin seems to be an arbitrary determination of what is "significant and unreasonable."

The water quality undesirable results will allow significant and unreasonable impacts in localized areas and/or for short to medium periods of time. Given that more than 30% of the territory in the subbasin will be allowed to exceed its minimum thresholds for groundwater quality before this undesirable result is triggered, the GSP allows drinking water users to be impacted by drinking water contamination caused by GSA policies and activities. The definition of undesirable results therefore sets a very low inadequate bar for plan failure, and must be modified to ensure that drinking water is protected within the basin.

Because the undesirable results for groundwater quality allow significant and unreasonable impacts on sources of drinking water, DWR cannot approve the GSP.

b. The Minimum Thresholds and Measurable Objectives for Groundwater Quality Are Inadequate

GSAs must place groundwater quality minimum thresholds for each monitoring site at the level "that may lead to undesirable results."[78] Under the SGMA regulations, the GSP must provide a description of "the information and criteria relied upon to establish minimum thresholds," an explanation of how the proposed minimum thresholds will "avoid undesirable results," and "how minimum thresholds may affect the interests of beneficial uses and users of groundwater."[79] Measurable objectives must lead to compliance with the GSA's sustainable yield by 2040.

The GSP briefly states that each member agency established the minimum thresholds and measurable objectives for their management area, mentions that in many cases groundwater levels serve as a proxy for groundwater quality, lists the minimum thresholds and measurable objectives established by each member agency in Table 3-1, and states that more information can be found in the management area GSPs.[80] For several management areas, Table 3-1 does not list which contaminants are being monitored for compliance with the proposed minimum thresholds

[77] Kern Groundwater Authority GSP, p. 172, dated January 2020.
[78] 23 CCR § 354.28.
[79] 23 CCR § 354.28.
[80] Kern Groundwater Authority GSP, p. 179, dated January 2020.

and measurable objectives. Many management areas have used groundwater levels as a proxy for groundwater quality.

Groundwater levels are not a proxy for groundwater quality, and failure to set adequate minimum thresholds or measurable objectives to protect against discharge of all primary and secondary drinking water contaminants during recharge activities and/or activities that cause shifting contaminant plumes renders the GSP inadequate.

As in the case of groundwater levels, it is clear that the GSA has not considered the potential impact on drinking water users, in particular disadvantaged communities that are less able to afford solutions to treat contaminated drinking water. This has resulted in minimum thresholds and measurable objectives like those in the Arvin GSP, which will only be monitoring for compliance with sustainable management criteria in one well location, and has set the minimum threshold at the drinking water MCL for the contaminant, and the measurable objective at 75% of the MCL. The member agency is only monitoring for compliance with arsenic standards, despite the agency's knowledge of the existence of "nitrate...total dissolved solids (TDS), boron, iron and manganese...within or near the Arvin-Edison Management Area above drinking water standards and/or agricultural water quality goals."[81]

The lack of sufficient groundwater quality sustainable management criteria in areas like Arvin means that the GSP allows drinking water pollution that will be disproportionately felt by disadvantaged communities that are less able to afford treatment solutions. This significant and unreasonable impact is not adequate under SGMA or state and federal law prohibiting policy from resulting in disparate impact. The GSA has not conducted an analysis of how the minimum thresholds and measurable impacts could impact critical drinking water resources, and therefore has not considered the interests of all beneficial user groups, particularly drinking water users.

The GSA has also not specified what actions will be taken if water contamination approaches minimum thresholds, or how minimum thresholds will be triggered. Member agencies such as the Arvin-Edison WSD have not specified this in their plans. The GSA should ensure that minimum thresholds will be triggered after one test shows a violation of an MCL or a trend toward an MCL. The GSA must require that member agencies specify what actions they will take if groundwater quality approaches minimum thresholds, what point or measurement will trigger this action, and how impacted residents will be informed. The GSA must also ensure GSA-wide consistency on when minimum thresholds are triggered and what actions are taken in response, in order to protect drinking water across the GSA area.

[81] Arvin-Edison Water Storage District Management Area Plan, p. 80, dated December 2019.

Because the minimum thresholds and measurable objective fail to consider all beneficial users and cause significant and unreasonable impacts, the GSP is inadequate and DWR cannot approve it.

The groundwater quality sustainable management criteria for this GSP are therefore inadequate. At a minimum, adequate groundwater quality sustainable management criteria must include the following elements, which are not present here:

1. **Ensure that the GSP sets measurable objectives and minimum thresholds at all representative monitoring wells for all of the following contaminants:**[82]
    a. Contaminants with primary drinking water standards,
    b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health, AND
    c. Contaminants like uranium, arsenic and nitrate which are known to increase due to groundwater management practices.
2. **Ensure that the GSP triggers a violation of a minimum threshold after *one* test shows that there has been an increase in contamination since January 1st, 2015**. Once the minimum threshold is reached, the GSA must start the evaluation of whether groundwater management activities or groundwater pumping have caused the increase, or whether the increase was caused by other factors such as natural fluctuation, testing inaccuracy, or activities outside the purview of the GSA. If the increase was caused by groundwater management activities or groundwater pumping, the GSA must immediately stop increasing the contamination and remediate.
3. **Immediately remediate any contamination caused by groundwater conditions since 2015:** The GSA must immediately remediate any increased contamination caused by groundwater management policies or activities (including lack of adequate regulation of pumping) since 2015. The GSA must begin remediation immediately upon establishing causation. The GSA must remediate contamination within two years, or as soon as technologically and hydrologically possible, whichever is faster. Design and implementation of remediation measures must be done in partnership with all groundwater users, primarily disadvantaged communities. The GSA must also clearly identify funding sources for remediation, and identify a timeline for procuring those funds.
4. **Strive to remediate existing drinking water contamination:** Ensure that the GSA will strive to remediate drinking water contaminants that exceeded the MCL before 2015 wherever feasible, through projects, management actions and policies.
5. **Evaluate the drinking water impact:** Ensure that the GSP includes an analysis of how drinking water wells (municipal wells, community water system wells, and domestic

[82] 23 CCR § 354.34(b)(2) and (f)(3)

wells) are likely to be be affected by the undesirable results,[83] measurable objectives and minimum thresholds.[84]

6. **Implement DAC and drinking water user input into sustainable management criteria:**[85] Ensure that the GSP discusses how stakeholder input from DAC community members was considered in the development of undesirable results, measurable objectives and measurable objectives.
7. **Incorporate new drinking water data into sustainable management criteria:**[86] Ensure that the GSP includes a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data.
8. **Avoid disparate impact:**[87] Ensure that the minimum thresholds for groundwater quality are established in such a way that prevents a disproportionately negative impact on communities of color in the GSP area. For example, the GSP should ensure that the same minimum threshold methodology across the GSP area will not lead to disproportionately more wells going dry for residents of color than for white residents.

G. The Monitoring Network is Inadequate With Respect to Groundwater Levels and Groundwater Quality

GSAs must monitor impacts to groundwater for drinking water beneficial users,[88] including disadvantaged communities on domestic wells,[89] and must avoid disparate impacts on protected groups pursuant to state law.[90]

As discussed below, The GSA's monitoring network does not comply with SGMA regulations, and fails to capture drinking water impacts to disadvantaged communities and domestic wells. Specifically, the GSP lacks representative monitoring wells in areas of the subbasin where drinking water users may be particularly vulnerable to groundwater supply and quality issues, leaving the GSA with no ability to measure and avoid significant and unreasonable impacts to those users. The monitoring wells are also monitored two infrequently to timely detect and prevent falling groundwater levels and/or contamination.

[83] 23 CCR § 354.26(c)
[84] 23 CCR § 354.28(b)(4)
[85] 23 CCR § 354.10(d); DWR Guidance Document for Groundwater Sustainability Plans: Stakeholder Communication and Engagement, p.1.
[86] 23 CCR § 354.38(e)(3)
[87] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[88] 23 CCR § 354.34
[89] Water Code § 10723.2.
[90] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).

The lack of adequate monitoring will make it impossible for the GSA to monitor drinking water to detect and prevent undesirable results, undermining the likelihood that the basin will achieve sustainable groundwater management.

The insufficiency of the representative monitoring network renders the GSP inadequate.

a. Groundwater Level Monitoring

The SGMA regulations state that monitoring networks must include a "sufficient density of monitoring wells to collect representative measurements through depth-discrete perforated intervals to characterize the groundwater table or potentiometric surface for each principal aquifer."[91] The GSA must also make decisions about the monitoring network in a way that considers the interests of all beneficial users.[92]

The GSP here presents a map of its groundwater levels monitoring wells,[93] but does not show what aquifers the wells are monitoring, and where monitoring wells are in relation to disadvantaged communities on domestic wells and small community water systems. As such, it is not possible for the public or DWR to determine whether there is a sufficient density of wells to collect representative measurements and detect and prevent significant and unreasonable impacts on beneficial users.

The monitoring network for groundwater levels is therefore inadequate and will not detect significant and unreasonable impacts to disadvantaged communities. At a minimum, an adequate groundwater levels monitoring network must include the following elements, which are not present here:

1. **Ensure accurate detection of impacts on drinking water users and DACs:**[94] Ensure that the groundwater level monitoring network includes *representative* monitoring wells *in or near DACs*, and placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area. If new monitoring wells are required, ensure that the GSP contains a concrete plan to fund and construct new representative monitoring wells within the first year of GSP implementation to ensure that vulnerable communities' drinking water resources are monitored. The plan to improve the monitoring network should include testing of domestic wells in the interim as wells are constructed.
2. **Clearly show representative monitoring well locations in relation to DACs:**[95] Ensure that the representative monitoring wells (RMWs) for groundwater levels are presented on maps and in tables that identify which set of minimum thresholds and measurable

[91] 23 CCR § 354.34(c)(1)(A)
[92] 23 CCR § 354.34(b)(2)
[93] Kern Groundwater Authority GSP, Figure 3-3, p. 186-189, dated January 2020.
[94] 23 CCR § 354.34(b)(2) and (f)(3)
[95] 23 CCR § 354.34(b)(2) and (f)(3)

objectives will be applied to which RMWs, and that these maps clearly identify the locations of DACs, small water systems and other sensitive users.

3. **Identify and address other drinking water data gaps:**[96] Ensure that the GSP clearly identifies any other gaps in data regarding impacts to drinking water users, and that the GSP contains a clear plan to fill data gaps regarding impacts to drinking water users. The GSP explains how it will fill some monitoring data gaps, but does not ensure that these gaps will capture impacts on all drinking water users, particularly disadvantaged communities.

b. Groundwater Quality Monitoring

SGMA regulations require that GSPs create a groundwater quality monitoring network that will "collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues."[97]

The groundwater quality monitoring network does not adequately capture impacts on drinking water users. For example, in the case of the Arvin GSP, the member agency will only monitor for compliance with its minimum threshold and measurable objective for arsenic once a year in one well, ACSD Well #14, which is one of the wells that provide drinking water to the community of Arvin.[98]

First, measuring for Arsenic only once a year does not provide the member agency or the GSA with frequent enough information to detect and respond to severe drinking water contamination in a reasonable amount of time. If the member agency's management actions, projects, or decisions to let groundwater decline increase drinking water contamination for families in the management area, the member agency could go a whole year without detecting these impacts. Meanwhile, it will not be responsive to the drinking water impacts from other contaminants which it may have moved or increased from its activities. Instead, the member agency must measure for all contaminants of concern every month.

Second, only measuring for compliance with arsenic measurable objectives and minimum thresholds does not protect against increases in other contaminants that exist in other parts of the management area (boron, nitrates, TDS, 123-TCP, iron and manganese). These contaminants could extend, move or increase due to groundwater management activities and pumping patterns. The Arvin GSP does plan to monitor for these contaminants in seven other wells outside of Arvin,[99] but has not set minimum thresholds and measurable objectives for these wells, and does

[96] 23 CCR § 354.38(e)(3)
[97] 23 CCR § 354.34(c)(4)
[98] Arvin-Edison Water Storage District Management Area Plan, p. 144, dated December 2019.
[99] Arvin-Edison Water Storage District Management Area Plan, p. 144-145, dated December 2019.

not have plans to do so. Without standards against which to compare detected levels of contaminants, and concrete commitments to preventing increased contamination, inclusion of these monitoring networks are meaningless.

Furthermore, Arvin is currently experiencing 123-TCP contamination that threatens the health of Arvin residents, so the GSP must monitor for compliance with 123-TCP standards in particular. In order to ensure that member agencies are detecting new contaminant plumes that could impact drinking water quality, the GSA must ensure that these representative monitoring wells monitor for all contaminants with primary drinking water standards, as well as contaminants known to increase with groundwater management activities such as uranium.[100] The GSA must also ensure that all representative monitoring wells are held to minimum thresholds and measurable objectives, measure the extent and spread of known contaminant plumes, and are able to measure the groundwater levels at the depth at which the drinking water wells are screened.

Third, the well that was chosen, ACSD Well #14, was chosen because it does not have contaminants that are known to exist in wells in the northern part of the management area, which are not currently in use by Arvin CSD, according to our conversation with Arvin-Edison WSD staff at the Kern Subbasin Open House on September 26th, 2019. Avoiding monitoring contaminated areas is inappropriate and fails to ensure that groundwater management activities and pumping do not aggravate existing contamination. The GSA should ensure that the member agency instead monitors for all existing contaminants at minimum throughout the area and especially in areas where contamination is known to exist, and sets minimum thresholds and measurable objectives that apply to all monitoring wells.

The groundwater quality monitoring network for this GSP is therefore inadequate. At a minimum, an adequate groundwater quality monitoring network must include the following elements, which are not present here:

1. **Ensure that the GSP plans to measure the following contaminants at all representative monitoring wells:[101]**
    a. Contaminants of concern with primary drinking water standards
    b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health
    c. Contaminants like uranium, arsenic and nitrate which are known to increase due to groundwater management practices

[100] Smith et al., "Overpumping Leads to California Arsenic Threat," Nature Communications (June 2018) [arsenic discharge from clay correlated with overpumping]; Jurgens et al., "Effects of Groundwater Development on Uranium" (November 2010) [strong correlation between high bicarbonate irrigation and recharge water and leaching of uranium from shallow sediments to groundwater].
[101] 23 CCR § 354.34(b)(2) and (f)(3)

2. **Clearly describe how the GSA will monitor for drinking water impacts:** Ensure that the GSP includes a description of how the GSA(s) will monitor groundwater contamination that could affect drinking water in the GSA area. Ensure that the representative monitoring wells (RMWs) for groundwater quality are presented on maps and in tables, and that the maps of RMWs clearly identify the locations of DACs, small water systems and other sensitive users.
3. **Ensure that the GSP plans to measure the following contaminants at all representative monitoring wells:**[102]
    a. Contaminants of concern with primary drinking water standards
    b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health
    c. Contaminants like uranium, arsenic and nitrate which are known to increase due to groundwater management practices
4. **Clearly describe how the GSA will monitor for drinking water impacts:** Ensure that the GSP includes a description of how the GSA will monitor groundwater contamination that could affect drinking water in the GSA area. Ensure that the representative monitoring wells (RMWs) for groundwater quality are presented on maps and in tables, and that the maps of RMWs clearly identify the locations of DACs, small water systems and other sensitive users.
5. **Ensure accurate detection of impacts on drinking water users and DACs:**[103] Ensure that the groundwater level monitoring network includes *representative* monitoring wells *in or near DACs*, and placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area. If new monitoring wells are required, ensure that the GSP contains a concrete plan to fund and construct new representative monitoring wells within the first year of GSP implementation to ensure that vulnerable communities' drinking water resources are monitored. The plan to improve the monitoring network should include testing of domestic wells at least as an interim measure as wells are constructed.
6. **Identify baseline contaminant levels:** Ensure that the GSP identifies the current contaminant levels, minimum thresholds and measurable objectives at each RMW, so that it is clear to the public how the contamination could change at each RMW site.
7. **Frequent testing:** Ensure that the groundwater quality monitoring network tests for contaminants of concern frequently, in a way that avoids persistent drinking water contamination. Testing should be done monthly.
8. **Collaboration with other agencies:**[104] Ensure that the GSP explains how the GSA will share data with and collaborate with other groundwater quality regulatory programs, such as ILRP, IRWM, and CV SALTS, and nonregulatory programs such as SB 200, the

[102] 23 CCR § 354.34(b)(2) and (f)(3)
[103] 23 CCR § 354.34(b)(2) and (f)(3)
[104] 23 CCR § 354.34(e)

SWRCB's needs assessment and the GAMA program, in order to build better regional understanding of groundwater quality issues, commit to clear roles, and better respond to groundwater quality impacts caused by groundwater management.

H. Projects and Management Actions Are Inadequate

The GSA must consider the interests of all beneficial users including domestic well owners and disadvantaged communities[105] and avoid disparate impacts on protected groups.[106] The GSP must also concretely outline how each objective and the overall sustainability goal will be achieved.[107] The projects and management actions set forth in the GSP do not demonstrate a plan for achieving sustainability goals, and do not adequately account for the needs of disadvantaged communities pertaining to protected groups under state law. This undermines the likelihood that the basin will reach its sustainability goal by 2040, as required by SGMA.[108]

a. The Projects and Management Actions are Inadequate, Do Not Protect Drinking Water for Disadvantaged Communities, and Will Likely Cause Disparate Impacts.

The projects and management actions set forth in the GSP does not demonstrate a path towards achieving sustainability goals in the plan. The GSA has not demonstrated how they have considered the interests of beneficial users including domestic well owners and disadvantaged communities.[109] The resulting impact from the proposed sustainable management criteria will likely lead to disparate impacts on protected groups pursuant to state and federal law.[110]

The GSA has allowed member agencies like the Arvin-Edison WSD to rely heavily on increasing use of surface water.[111] This places the majority of the plan's success on surface water resources, which are variable and may not be able to be procured. The GSA must ensure that member agencies implement demand reduction strategies from the beginning to ensure that the

---

[105] Water Code § 10723.2.
[106] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[107] Water Code § 10727.2(b)(2).
[108] Water Code § 10727.2(b)(1).
[109] Water Code sec. 10723.2.
[110] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].
[111] Arvin-Edison Water Storage District Management Area Plan, p. 153-154, dated December 2019.

GSP is on a path to sustainability within the statutory time period. The GSA will not achieve its sustainability goals if water use is not limited through fully-implemented demand reduction requirements immediately. The chosen management actions undermine the likelihood that the basin will reach its sustainability goal by 2040, as required by SGMA.[112]

Despite the fact that drinking water wells may go dry at the GSP's groundwater levels minimum thresholds, and the fact that drinking water contamination is likely to occur because of changing pumping patterns and recharge activities, the GSA does not have a plan for preventing or mitigating these impacts. Furthermore, the GSA's description of projects does not include a description of any potential negative impacts on beneficial uses of water, such as groundwater contamination, and how such impacts will be mitigated and monitored.

A critical problem with the structure of the GSA is that member agencies are not required to share the cost or responsibility for critical GSA-wide projects. Many more financially powerful agricultural and water banking member agencies could and should be part of a strategy to protect drinking water resources in the GSA area as a whole, especially given that they use much larger quantities of groundwater and their continued pumping will likely lead to dry wells and groundwater contamination issues for the most vulnerable homes in the GSA area. Given that California has recognized drinking water as a human right, and the importance of drinking water that we all experience in our own lives, the GSA member agencies should collectively come together to ensure that no family has to go days, months or years without safe tap water in their home. The Arvin GSP contains two projects for treating water quality in Arvin, but these projects were already under way and fully funded so should not be included in the GSP. The GSP has no overall drinking water protection program to protect residents against dry wells and contaminated drinking water from its policies and groundwater management activities.

b. Minimum Requirements for Projects and Management Actions

The projects and management actions for this GSP are inadequate. At a minimum, adequate projects and management actions must include the following elements, which are not present here:

1. **Include a Drinking Water Well Impact Mitigation Program:** Ensure that the GSP contains a drinking water protection program to prevent impacts to drinking water users and mitigate the drinking water impacts that occur. Please reference the Framework for a Drinking Water Well Impact Mitigation Program that our organization developed with the Community Water Center and Self-Help Enterprises for more details, a draft of which is attached as part of the Human Right to Water Scorecard in Exhibit B.

[112] Water Code § 10727.2(b)(1).

2. **Establish a clear and proactive plan for demand reduction.** Demand reduction should be implemented immediately.
3. **Describe the potential drinking water impacts of each project or management action.**
4. **Include management actions to measure groundwater extraction using the most scientifically accurate method.** From our conversations with scholars, it is clear that metering is the most accurate way of measuring groundwater extraction. Metering should be required for all users, particularly large agricultural pumpers.
5. **Ensure that the GSP's projects and management actions will not cause a disparate impact:**[113] Ensure that the GSP's projects and management actions, taken as a whole, prevent a disproportionately negative impact on communities of color in the GSP area. Projects and management actions may not cause, or fail to prevent, disproportionately more dry wells and contaminated water for residents of color than for white residents in the GSP area.

I. Plan Implementation Section is Inadequate

GSPs must include a planning and implementation horizon[114] and must show how the sustainability goal will be achieved by 2040.[115] GSP implementation must continue to consider the interests of all beneficial user groups and engage a diversity of stakeholders. The GSP's plan implementation section is insufficient in regards to public engagement/outreach and does not contain adequate information regarding annual reporting or the potential to make amendments to the GSP. Absent this information, DWR cannot evaluate when and whether the plan is likely to achieve sustainable groundwater management, so DWR cannot approve the plan.[116]

The GSA's Communications and Engagement plan states that "[d]uring the implementation phase, communication and engagement efforts will be shifted to educational and informational awareness of the requirements and processes for reaching groundwater sustainability. Active involvement of all stakeholders is encouraged during this phase, and public notices are required for any public meetings and prior to imposing, and later increasing, any fees."[117] It is concerning that this statement communicates that the public will not be engaged in decisions about projects and management actions, annual reports, five year updates, or potential modifications to the sustainable management criteria and monitoring network. The public must be engaged in in all decisions about GSA policies and activities, to ensure that impacts to all beneficial users are considered.

[113] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[114] Water Code § 10727.2.(c)
[115] Water Code § 10727.2(b)(1).
[116] Water Code § 10733(a); 23 CCR 355.4(b).
[117] Kern Groundwater Authority GSP, Appendix E, pg. I-6, dated January 2020.

The GSA does not include commitments to provide translated, accessible notice about agency meetings and decisions. The GSA does not commit to providing interpretation and translated materials at workshops and board meetings, or creating an Advisory Committee with representation from disadvantaged communities. The GSP also lacks a commitment to working with local community-based organizations to ensure effective outreach and engagement of disadvantaged communities.

The plan implementation section for this GSP is therefore inadequate. At a minimum, an adequate plan implementation section must include the following elements, which are not present here:

1. **Description of DAC engagement:** Ensure that the GSP describes how ongoing engagement will be conducted during GSP implementation, including but not limited to engagement regarding: decisions about projects, management actions, modifying sustainable management criteria, changes to monitoring networks, and conducting GSP updates.
2. **Notice:**[118] Ensure that the GSP states that ongoing engagement will include clear notices about GSA meetings and workshops that are posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.[119]
3. **Translation of materials:**[120] Ensure that the GSP states that ongoing engagement will include translation of materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.
4. **Interpretation:**[121] Ensure that the GSP states that ongoing engagement will include. interpretation services provided at board meetings, committee meetings and workshops into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.
5. **Accessible workshops:** Ensure that the GSP states that ongoing engagement will include workshops held at accessible times and locations for disadvantaged community residents.
6. **DAC representation on advisory committee and board:** Ensure that the GSP states that ongoing engagement will include an advisory committee and a GSA Board containing representatives from DACs. The GSA must include representatives on the the GSA board, and should include representatives from DACs on all advisory committees such that their voices can be as strong as other beneficial user groups.

[118] Government Code § 54954(a).
[119] Government Code sec. 7296.2.
[120] Government Code sec. 7296.2.
[121] Government Code sec. 7296.2.

7. **Partnership with local community based organizations:** Ensure that the GSP states that ongoing engagement will include partnership between the GSA and community based organizations and nonprofits.
8. **Engagement on key decisions:** Ensure that the GSP states that ongoing engagement will include strategies to keep the public informed and engaged during and prior to critical decisions about the GSP, including but not limited to the five year GSP review, modification of sustainable management criteria, design and adoption of any projects and management actions, and development and adoption of the programs to assist with impaired wells.
9. **Engagement on financial issues:** Ensure that the GSP states that it will conduct meaningful outreach to DACs and incorporate feedback before approving operating budgets and enacting groundwater fees.

J. The GSP Does Not Comply With California Water Law.

a. The GSP Conflicts With Water Code § 106.3.

As noted above, California codified access to an adequate supply of safe and affordable drinking water as a human right in 2012. Water Code § 106.3(a) provides as follows:

> It is hereby declared to be the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes.

It is often incorrectly stated that this section is not binding. This is a misnomer for several reasons. First, § 106.3(b) expressly states in that "[a]ll relevant state agencies, including the department, the state board, and the State Department of Public Health, ***shall*** consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria when those policies, regulations, and criteria are pertinent to the uses of water described in this section." (emphasis added.) The use of the mandatory "shall" rather than a permissive "may" indicates that the requirement of subsection (b) to consider the Human Right to Water is a mandatory duty of DWR and the SWRCB.

Moreover, there is nothing in § 106.3 that indicates that either a GSA or a state agency may take an action that conflicts with the human right of all Californians to access safe and affordable drinking water. Rather, the section and its requirements are subject to only three narrow exceptions. First, subsection (c) states that "[t]his section does not expand any obligation of the state to provide water or to require the expenditure of additional resources to develop water infrastructure beyond the obligations that may exist pursuant to subdivision (b)." This exception

applies only to the "state," and does not apply to GSAs. Further, it speaks only to the obligation to provide water or to require development of water infrastructure, not to any obligation to manage groundwater resources in a way that protects existing access to drinking water.

Second, subsection (d) states that "[t]his section shall not apply to water supplies for new development." It is silent regarding water supplies for existing households.

Third, subsection (e) states that "[T]he implementation of this section shall not infringe on the rights or responsibilities of any public water system." As a GSA is not a public water system, this exception is not relevant here.

Given that none of the three exceptions contained in § 106.3 apply to the development and implementation of the GSP, it must be consistent with the Human Right to Water, and separately, DWR must consider the human right on review of GSP. Because the GSP conflicts with § 106.3 by interfering with access to safe and affordable drinking water, DWR cannot approve it.

b. The GSP Threatens to Infringe Upon Water Rights

In enacting SGMA, the legislature found and declared that "[f]ailure to manage groundwater to prevent long-term overdraft infringes on groundwater rights."[122] The text of SGMA further notes that "[n]othing in this part, or in any groundwater management plan adopted pursuant to this part, determines or alters surface water rights or groundwater rights under common law or any provision of law that determines or grants surface water rights."[123] As discussed in detail above, the GSP allows continued overdraft above the safe yield of the basin, such that drinking water wells (especially domestic wells) will continue to go dry, infringing upon the rights of overlying users of groundwater. DWR cannot approve the GSP until it is revised to protect the rights of residents of disadvantaged communities and/or low-income households who hold overlying rights.[124]

c. The GSP Conflicts with the Reasonable And Beneficial Use Doctrine

The "reasonable and beneficial use" doctrine is codified in the California Constitution. It requires that "the water resources of the State be put to beneficial use to the fullest extent of which they are capable, and that the waste or unreasonable use or unreasonable method of use of water be prevented, and that the conservation of such waters is to be exercised with a view to the

[122] AB 1739 (2014).
[123] Water Code § 10720.5(b).
[124] *See also* Water Code § 10723.2 [The groundwater sustainability agency shall consider the interests of all beneficial uses and users of groundwater… [including] Domestic well owners."].

reasonable and beneficial use thereof in the interest of the people and for the public welfare."[125] The doctrine applies to all water users, regardless of basis of water right, and all water rights and methods of diversion.[126] A determination of reasonableness of a use "cannot be resolved in vacuo isolated from statewide considerations of transcendent importance."[127]

DWR and the Water Board must ensure that GSP's water allocations are consistent with the reasonable and beneficial use doctrine.[128] In doing so, DWR and the Board must follow the Legislature's directive to prioritize domestic use of water resources over irrigated agriculture[129] and ensure that SGMA implementation furthers the human right to safe and affordable drinking water[130] — both statewide considerations of transcendent importance. In other words, a GSP that allows use of water for irrigation at the expense of use of water for domestic purposes is not consistent with the reasonable and beneficial use doctrine.

The reasonable and beneficial use doctrine applies here given the negative impacts of the GSP on groundwater supply and quality, which are likely to unreasonably interfere with the use of groundwater for drinking water and other domestic uses. As the GSP authorizes waste and unreasonable use, and indeed does not even analyze the reasonable and beneficial use doctrine at all, it conflicts with the reasonable and beneficial use doctrine and the California Constitution. As a result, DWR cannot approve the GSP as presently drafted.

d. The GSP Conflicts with the Public Trust Doctrine

The public trust doctrine applies to the waters of the State, and establishes that "the state, as trustee, has a duty to preserve this trust property from harmful diversions by water rights holders" and that thus "no one has a vested right to use water in a manner harmful to the state's waters."[131]

[129] Water Code § 106 ["It is hereby declared to be the established policy of this State that the use of water for domestic purposes is the highest use of water and that the next highest use is for irrigation"]; *United States v. State Water Resources Control Board* (1986) 182 Cal.App.3d 82, 103 .

[130] Water Code § 106.3.

[131] *United States v. State Water Resources Control Bd.* (1986) 182 Cal.App.3d 82, 106; *see also Nat'l Audubon Soc'y v. Superior Court* (1983) 33 Cal.3d 419, 426 ["before state courts and agencies approve water diversions they should consider the effect of such diversions upon interests protected by the public trust, and attempt, so far as feasible, to avoid or minimize any harm to those interests."].

The public trust doctrine has recently been applied to groundwater where there is a hydrological connection between the groundwater and a navigable surface water body.[132] In *Environmental Law Foundation v. State Water Resources Control Board* ("*ELF*"), the court held that the public trust doctrine applies to "the extraction of groundwater that adversely impacts a navigable waterway" and that the government has an affirmative duty to take the public trust into account in the planning and allocation of water resources.[133] Under *ELF*, the Public Trust doctrine imposes an affirmative and independent obligation to consider the public trust that applies to DWR's decisions regarding submitted GSPs, imposing a legal duty on DWR to not only consider the potential adverse impacts of groundwater extractions on navigable waterways but also "to protect public trust uses whenever feasible."[134] The court also specifically held that SGMA does not supplant the requirements of the common law public trust doctrine.[135]

Notably, the public trust doctrine applies to both currently navigable surface water bodies and surface water bodies that were historically navigable at the time of statehood.[136]

In contrast to these requirements, the GSP does not consider impacts on public trust resources, or attempt to avoid insofar as feasible harm to the public's interest in those resources. DWR cannot approve the GSP without evaluating impacts to public trust resources and protecting public trust uses whenever feasible. Specifically, DWR must (1) identify any public trust resources within the basin; (2) identify any public trust uses within the basin; (3) identify and analyzing potential adverse impacts of groundwater extractions on public trust resources and uses; and (4) determine the feasibility of protecting public trust uses and protect such uses whenever feasible.

~ ~ ~ ~ ~ ~ ~ ~ ~

DWR cannot approve the GSP because it fails to protect beneficial users and access to drinking water. We welcome the opportunity to further discuss our concerns with the Department of Water Resources and the State Water Resources Control Board. Furthermore, we urge DWR to review this and all other GSPs according to the Human Right to Water Scorecard, as we have done in this letter.[137] We hope to successfully work with the GSA, communities, DWR and the SWRCB to ensure that groundwater management is equitable and sufficiently protective of vital drinking water resources. Going forward, we ask DWR to ensure that the GSP adhere to the

Re: Reviewing Groundwater Sustainability Plans In Accordance With State Agency Obligations to Consider the Human Right to Drinking Water

Our collective organizations write to express our concern regarding implementation thus far of the Sustainable Groundwater Management Act (SGMA), specifically with respect to its treatment of (or lack of consideration for) safe drinking water in many of the most vulnerable California communities -- and to urge the Department and Board to review Groundwater Sustainability Plans in accordance with state agency obligations to consider California's Human Right to Water law.

We have engaged in the SGMA implementation processes throughout the state because many of the communities with whom we work are dependent on groundwater for their drinking water supplies, and have already experienced groundwater quality and supply issues. We have participated in meetings, commented on dozens of groundwater plans, and supported engagement of residents from several communities in the development of Groundwater Sustainability Plans (GSPs). But despite our engagement and the engagement of disadvantaged community residents, most GSPs do not adequately address threats to drinking water quality or reliability for disadvantaged communities.

Historically, many of the communities most impacted by depleted and tainted groundwater sources have been excluded from the decision-making tables that determined where water would flow and what infrastructure would be laid. But California took historic steps forward with the recognition of the Human Right to Water as a state-wide goal in 2012 and with the passage of SGMA in 2014 which included requirements for a transparent and inclusive process and consideration of vulnerable communities. Specifically, decision-making processes related to groundwater management must include disadvantaged communities, and groundwater management plans must respond to the unique vulnerabilities of disadvantaged communities,[1] consider their drinking water needs,[2] and avoid causing disproportionately negative impacts on low income communities of color.[3]

Unfortunately, many of the draft GSPs released to date pose a significant threat to safe drinking water access in low-income communities. Few account for drinking water impacts on local communities dependent on groundwater— the vast majority of small communities in the San Joaquin Valley. When

[1] Water Code § 10723.2
[2] Water Code § 106.3
[3] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].

implemented, these GSPs have the potential to threaten severe and irreparable harm to drinking water supplies and the communities dependent on those supplies. As such, many of the recently approved draft GSPs undermine Governor Newsom's vision of a California where everyone has safe drinking water and run counter to California's Human Right to Drinking Water (AB 685).

With these grave concerns in mind, we urge the state to abide by the mandate the Human Right to Water demands.

The Human Right to Drinking Water in GSP Evaluation and Approval

The human right to safe and affordable water for drinking and sanitation was codified by AB 685 in 2012, which modified Water Code section 106.3 to include: "it is...the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."[4] The law obligates "all relevant state agencies" to "consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria...pertinent to" drinking water purposes.[5] The law specifically names the Department of Water Resources (DWR) and the State Water Resources Control Board (SWRCB).

The Human Right to Water has catalyzed and facilitated several new state initiatives. The State Water Resources Control Board has created a Human Right to Water Portal on its website which shows drinking water quality in all public water systems in the state and passed a resolution aligning State Board priorities and values with the Human Right to Water. The human right to water has also been used as underpinning for two successful legislative campaigns: AB 401 (2015) and the Safe and Affordable Drinking Water Fund, or SB 200 (2019). The former mandated a state-wide study of the best mechanism for delivering affordable drinking water in all publicly regulated water systems; the latter created a state-wide fund for installing, operating and maintaining drinking water infrastructure for disadvantaged communities and schools suffering from water quality and water supply issues. Governor Newsom played a strong role in the passage of the Safe and Affordable Drinking Water Fund as part of his personal commitment to securing safe water for all Californians.

These initiatives represent clear steps forward towards achieving safe and affordable drinking water for all Californians, but the state remains far from achieving the law's goal of guaranteeing "safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes" to "every human being" in the state of California.[6] In the San Joaquin Valley alone, tens of thousands of vulnerable families, including those with whom we work, suffer from contaminated drinking water, unaffordable drinking water costs, and the impacts of inadequate water supply such as dry wells and water pressure problems. As many as 350,000 people lack access to potable water in the San Joaquin Valley alone, and Hispanic communities are disproportionately impacted: while Hispanics make up just under half, or 49 percent, of the total population of the San Joaquin Valley, they represent more than two-thirds of residents in these unincorporated communities and 57 percent of all residents served by out-of-compliance water systems.[7] This number does not account for those unincorporated communities

[4] Water Code sec. 106.3(a)
[5] Water Code sec. 106.3(b)
[6] Water Code sec. 106.3(a)
[7] The Struggle for Water Justice in California's San Joaquin Valley: A Focus on Disadvantaged Unincorporated Communities, London & Fencl et al., University of California Davis, February 2018.

on private domestic wells, many of which also have contaminated water which goes unmonitored and unregulated.

Groundwater management practices have historically aggravated drinking water issues in the San Joaquin Valley by allowing agribusiness and other actors to pump unrestricted amounts of groundwater, leaving local communities with dry wells, and unreliable drinking water supplies. Moreover, there has been limited regulation on agricultural impacts to groundwater quality, leading to contamination of drinking water for communities in the San Joaquin Valley. Low-income families living in disadvantaged communities do not have the financial means to replace or deepen wells, install costly treatment mechanisms, or transition to alternative water supplies such as surface water.

SGMA created both an unprecedented and quite possibly a last opportunity to avoid further encroachment on the basic human right to water, yet our review of GSPs in the San Joaquín, Salinas and Coachella Valleys indicates that GSAs have not leveraged this opportunity. Rather, the GSPs we have reviewed rarely account for impacts on local communities dependent on groundwater, and prioritize the continued economic viability of agriculture at the expense of drinking water for low income communities. For example, some Central Valley GSPs have established minimum thresholds—or failure points—that, if reached, would allow up to 85% of domestic wells to go fully or partially dry within the GSP area. Overall, a technical review that the Community Water Center and Self-Help Enterprises commissioned of drinking water impacts of 13 GSPs in the San Joaquin Valley shows more than 8,000 wells will be dewatered in the area covered by the GSPs. Draft GSPs allow continued groundwater quality degradation in excess of water quality objectives, violating the Porter-Cologne Water Quality Control Act (Water Code sec. 13000 et seq.), the antidegradation policy, and the non-point-source policy. Even worse, some GSPs ignore water quality impacts entirely.

DWR and the SWRCB are now tasked with evaluating and deciding whether to approve GSPs. The agencies must determine whether to approve policies in these documents that set out the level to which GSAs will allow groundwater levels to decline, the extent to which GSAs will protect local drinking water users from contamination resulting from groundwater management activities, and which projects and management actions the GSA will implement to impact local groundwater resources. All of these decisions have vast drinking water implications for communities within each GSP area. As such, evaluation and approval of GSPs falls squarely within the category of "revising, adopting, or establishing policies, regulations, and grant criteria...pertinent to" drinking water purposes.[8] DWR and the State Water Resources Control Board must therefore "consider this state policy"[9] "that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes"[10] in their review of each GSP. In order to comply with this obligation, the Department and Board must ensure that GSPs do not cause or allow further drinking water crises.

Implementing the Human Right to Drinking Water in GSP Evaluation and Approval

We have compiled and attached a "Human Right to Drinking Water GSP Scorecard" which identifies the elements that must exist in GSPs in order for GSPs to adequately protect the Human Right to Drinking Water. We urge the Department of Water Resources and the State Water Resources Control Board to integrate this analysis into their review of GSPs, and to require that each GSP contain these elements

[8] Water Code § 106.3(b)
[9] Water Code § 106.3(b)
[10] Water Code § 106.3(a)

before it grants approval of the GSP. This scorecard could also be adapted to create a general evaluation rubric that is used by the two agencies as part of a drinking water review protocol for all drinking water-related activities. Additionally, we encourage DWR to use this letter and scorecard to develop a "Human Right to Water"/"Protecting Drinking Water" Best Management Practices guidance document for GSAs to consider when developing, updating and implementing GSPs. Additionally, the Scorecard references a framework that we have developed to show what an effective drinking water protection program would look like, which we have also attached.

We look forward to discussing this Human Right to Water Scorecard with you, and supporting implementation of such a scoring methodology in GSP evaluation and approval. Please do not hesitate to contact Amanda Monaco (amonaco@leadershipcounsel.org), Deborah Ores (deborah.ores@communitywatercenter.org), or Liesbet Olaerts (olaerts@selfhelpenterprises.org) with any follow-up questions or for more information.

Framework and Guidance for Developing a Drinking Water Well Impact Mitigation Program (Working Draft)..……..…..p. 15-24

Human Right To Water Scorecard for the Review of Groundwater Sustainability Plans

Review Criteria *(All Indicators Must be Present in Order to Protect the Human Right to Water)*		Yes/No
A	**Plan Area**	
1	**Does the GSP identify, describe, and provide maps of all of the following beneficial users in the GSA area?**[11] a. Disadvantaged Communities (DACs). b. Tribes. c. Community water systems d. Private well communities.	
2	**Land use policies and practices:**[12] Does the GSP review all relevant policies and practices of land use agencies which could impact groundwater resources? These include but are not limited to the following: a. Water use policies General Plans and local land use and water planning documents b. Plans for development and rezoning c. Processes for permitting activities which will increase water consumption	
B	**Basin Setting (Groundwater Conditions and Water Budget)**	
1	Does the **groundwater level conditions** section include past and current drinking water supply issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities?	

[11] 23 CCR § 354.8(a) and (b)
[12] 23 CCR § 354.8(f)

2	Does the **groundwater quality conditions** section include past and current drinking water quality issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities, including public water wells that had or have MCLs exceedances?[13]	
3	Does the **groundwater quality conditions** section include a review of all contaminants with primary drinking water standards known to exist in the GSP area, as well as hexavalent chromium, and PFOs/PFOAs?[14]	
4	**Incorporating drinking water needs into the water budget:**[15] Does the Future/Projected Water Budget section explicitly include both the current and projected future drinking water needs of communities on domestic wells and community water systems (including but not limited to infill development and communities' plans for infill development, installation of additional services, and housing growth in disadvantaged communities), taking into account increased climate variability due to climate change ?	
C	**Sustainability Goal**	
1	Does the **sustainability goal** explicitly include considerations about the needs of drinking water users?[16]	
D	**Sustainable Management Criteria (SMC) for Groundwater Levels**	
1	**Evaluation of drinking water impact:** Does the GSP include an analysis of how many drinking water wells (municipal wells, community water system wells, and domestic wells) might go fully or partially dry if groundwater levels reach the Undesirable Results (URs),[17] Measurable Objectives (MOs) and Measurable Objectives (MTs),[18] including a map of wells that will go fully and partially dry at the MOs and MTs? Does this include Does the GSP include estimates of the increased pumping costs from additional lift needed to pump water from lower elevations if the URs,[19] MOs and MTs[20] were to be reached?	
2	**Considering drinking water impacts in creating SMC:**[21] Does the GSP explicitly state how it considered drinking water impacts in shaping URs, MOs, and MTs for groundwater levels? For example, the GSP could state how its well impact analysis supported on setting stricter MTs and MOs near at risk communities.	

[13] 23 CCR § 354.16(d)
[14] 23 CCR § 354.16(d)
[15] 23 CCR § 354.18(c)(2)(b)
[16] 23 CCR § 354.24: Sustainability goal must "culminate in the absence of undesirable results within 20 years."
[17] 23 CCR § 354.26(c)
[18] 23 CCR § 354.28(b)(4)
[19] 23 CCR § 354.26(c)
[20] 23 CCR § 354.28(b)(4)
[21] Water Code § 10723.2

3	**Incorporating new drinking water data into SMC:**[22] Does the GSP include a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data?	
4	**Implementing DAC and drinking water user input into SMC:**[23] Does the GSP discuss how stakeholder input from DAC community members was considered in the development of URs, MOs, and MTs? For example, the GSP could state how they took the results of the well impact assessment to the public through meetings, workshops, or Advisory Committees, and together with stakeholders decided how to change SMC to protect drinking water, or other programs to implement to mitigate these impacts.	
5	**Avoiding a disparate impact:**[24] Are the MOs and MTs for groundwater levels established in such a way that prevents a disproportionately negative ("disparate") impact from occurring on communities of color in the GSP area? For example, the GSP should ensure that the same MT methodology across the GSP area will not lead to disproportionately more wells going dry for residents of color than for white residents.	
E	**Sustainable Management Criteria for Groundwater Quality**	
1	**Evaluation of drinking water impact:** Does the GSP include an analysis of how drinking water wells (municipal wells, community water system wells, and domestic wells) might be affected by the Undesirable Results (URs),[25] Measurable Objectives (MOs) and Measurable Objectives (MTs)?[26]	
2	**Does the GSP set MOs and MTs at all representative monitoring wells for the following contaminants?**[27] a. Contaminants with primary drinking water standards, b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health, AND c. Contaminants like Uranium which are known to increase due to groundwater management practices.	

[22] 23 CCR § 354.38(e)(3)

[23] 23 CCR § 354.10(d); DWR Guidance Document for Groundwater Sustainability Plans: Stakeholder Communication and Engagement, p.1.

[24] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].

[25] 23 CCR § 354.26(c)

[26] 23 CCR § 354.28(b)(4)

[27] 23 CCR § 354.34(b)(2) and (f)(3)

3	**Strive to remediate:** Does the GSP state that the GSA will strive to remediate groundwater quality wherever feasible, through projects, management actions and policies?	
4	**Description of when minimum threshold is triggered:** Does the GSP trigger a violation of a minimum threshold after *one* test shows that there has been an increase in contamination since January 1st, 2015?	
5	**Implementing DAC and drinking water user input into SMC:**[28] Does the GSP discuss how stakeholder input from DAC community members was considered in the development of URs, MOs, and MTs?	
6	**Incorporating new drinking water data into SMC:**[29] Does the GSP include a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data?	
7	**Avoiding a disparate impact:**[30] Are the minimum thresholds for groundwater quality established in such a way that prevents a disproportionately negative ("disparate") impact from occurring on communities of color in the GSP area? For example, the GSP should ensure that the same MT methodology across the GSP area will lead to disproportionately more wells go dry for residents of color than for white residents.	
F	**Monitoring Network for Groundwater Levels**	
1	**Accurately detecting impacts on drinking water users and DACs:**[31] Does the groundwater level monitoring network include *representative* monitoring wells *in or near DACs*, and placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area? If not, does the GSP contain a concrete plan to fund and implement new representative monitoring wells to ensure that vulnerable communities' drinking water resources are monitored? Such a plan could include testing of domestic wells in the interim.	
2	**Clearly showing representative monitoring well locations in relation to DACs:**[32] Are the representative monitoring wells (RMWs) for groundwater levels presented on maps and in tables that identify which set of MTs/MOs will be applied to which RMWs? Do these maps clearly identify the locations of DACs, small water systems and other sensitive users?	

[28] 23 CCR § 354.10(d); DWR Guidance Document for Groundwater Sustainability Plans: Stakeholder Communication and Engagement, p.1.
[29] 23 CCR § 354.38(e)(3)
[30] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[31] 23 CCR § 354.34(b)(2) and (f)(3)
[32] 23 CCR § 354.34(b)(2) and (f)(3)

3	**Identifying and addressing other drinking water data gaps:**[33] Does the GSP clearly identify any other gaps in data regarding impacts to drinking water users? Does the GSP contain a clear plan to fill data gaps regarding impacts to drinking water users?	
G	**Monitoring Network for Groundwater Quality**	
1	**Does the GSP plan to measure the following contaminants at all representative monitoring wells?**[34] a. Contaminants of concern with primary drinking water standards b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health c. Contaminants like Uranium which are known to increase due to groundwater management practices	
2	**Clear description of effective monitoring for drinking water impacts:** Does the GSP include a description of how the GSA(s) will monitor groundwater contamination that could affect drinking water in the GSA area? Are the representative monitoring wells (RMWs) for groundwater quality presented on maps and in tables, and do the maps of RMWs clearly identify the locations of DACs, small water systems and other sensitive users?	
3	**Accurately detecting impacts on drinking water users and DACs:**[35] Does the groundwater quality monitoring network include *representative* monitoring wells (RMWs) *in or near all DACs* AND placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area, including domestic well users? If not, does the GSP contain a concrete plan to fund and implement new representative monitoring wells to ensure that vulnerable communities' drinking water resources are monitored? This plan could include testing of domestic wells in the interim.	
4	**Baseline contaminant levels:** Does the GSP identify the current contaminant levels, MTs and MOs at each RMW, so that it is clear to the public how the contamination will change at each RMW site?	
5	**Frequent monitoring:** Does the groundwater quality monitoring network test for contaminants of concern frequently, in a way that avoids persistent drinking water contamination?	
6	**Collaboration with other agencies:**[36] Does the GSP explain how the GSA(s) will share data with and collaborate with other groundwater quality regulatory programs, such as ILRP, IRWM, and CV SALTS, in order to build better regional understanding of groundwater quality issues and better respond to groundwater quality impacts caused by groundwater management?	
H	**Projects and Management Actions**	

[33] 23 CCR § 354.38(e)(3)
[34] 23 CCR § 354.34(b)(2) and (f)(3)
[35] 23 CCR § 354.34(b)(2) and (f)(3)
[36] 23 CCR § 354.34(e)

1	**Does the GSP describe the potential drinking water impacts of each project or management action?** Example of impacts are provided below: a. **Recharge and on-farm recharge projects:** Carefully designed and implemented recharge projects can simultaneously increase groundwater storage and levels, as well as dilute contaminant plumes and improve groundwater quality. However, if not properly designed, recharge projects, in particular on-farm recharge, may mobilize nitrates, pesticides, fertilizers, and naturally occurring contaminants, which can lead to the further degradation of groundwater quality, negatively impacting drinking water wells. Even relatively unpolluted water used for recharge, such as most purchased water or streamflow, may contain constituents of concern and/-or mobilize contaminants. Therefore GSAs must consider potential impacts to water quality when planning groundwater recharge projects.[37] b. **Groundwater market management action:** Groundwater markets are very likely to put drinking water resources at risk for communities and residents who do not have the financial, political and technical power to participate equally in a market. Groundwater markets have the potential to seriously aggravate existing lack of equity in access to critical groundwater resources. We therefore recommend that GSAs do not include groundwater markets as a potential management action. In particular, local groundwater markets are not a viable option where the potential impacts of trading are not well understood, where trading rules cannot sufficiently address negative externalities, or where the expected benefits of a market do not outweigh the burdens and uncertainties associated with designing and implementing it. If GSAs wish to consider groundwater markets, a well-designed trading program requires a fair and adequate allocation of groundwater for drinking water uses, an additional margin for future growth prior to allocating water for trading purposes, and trading rules that avoid undesirable results as well as avoid or mitigate potential impacts to communities and ecosystems dependent on groundwater. If these components are missing, the market can have significant negative impacts upon a community's drinking water supply and the environment. Some impacts include, but are not limited to: localized drying of community and domestic wells, increased contamination levels, or unaffordable water rates.[38] c. **Funding mechanisms/Delinquent fees management action:** Any fee and/or extraction penalties structure should take into consideration that small communities have fewer economic opportunities, have a small role in overall groundwater pumping percentage, and are burdened with lower technical, managerial, and financial capacity for operations and maintenance. Overall, small drinking water systems should be exempted from GSA's fees or financial penalties for over-use to support their efforts on providing affordable safe water according to AB 685. If exemption is not viable, the GSA should create special considerations such as discounts, reduced costs, rebates, or other to ensure	

[37] State Water Boards, Water Quality Frequently Asked Questions document: https://www.waterboards.ca.gov/water_issues/programs/gmp/docs/sgma/sgma_water_quality_faq.pdf

[38] Community Water Center et al., *Groundwater Markets: Recommendations to Ensure Drinking Water Protection for Communities* (guidance document to be published soon)

	drinking water affordability. Alternatively, small drinking water systems should receive warnings prior to financial penalties tied to an appeal process. Doing so may allow these communities to explain why the overuse occurred, providing mechanisms for transparency and support on addressing the problems. d. **Groundwater allocation management action:** Any groundwater allocation scheme must protect all current and future drinking water needs for disadvantaged communities.	
2	**Drinking water protection and mitigation program:** Does the GSP contain a drinking water protection program to prevent impacts to drinking water users and mitigate the drinking water impacts that occur? Such a program should also identify the following: a. How it will be funded. b. An estimate of how much it will cost. c. How program beneficiaries will be eligible to participate. d. How it will be designed in collaboration with impacted stakeholders. e. What type of mitigation measurements it will provide. f. Timeline for program implementation. **Please refer to the attached **Framework and Guidance for Developing a Drinking Water Well Impact Mitigation Program** for a more in-depth description of what an effective drinking water mitigation program should look like.*	
3	**Demand reduction:** Does the GSP contain robust demand reduction management actions? Plans that depend mainly on imported surface water (supply augmentation through recharge projects) do not clearly demonstrate a path towards sustainability, since climate variability puts these resources at risk.	
4	**Accurate measurement of groundwater extraction:** Does the GSP include management actions to measure groundwater extraction using the most scientifically accurate method?	
5	**Avoiding a disparate impact:**[39] Do the GSP's projects and management actions, taken as a whole, prevent a disproportionately negative ("disparate") impact from occurring on communities of color in the GSP area? Projects and management actions may not cause disproportionately more dry wells and contaminated water for residents of color than for white residents in the GSA area.	
I	**Public Participation and Transparency**	
1	Is a **Stakeholder Communication and Engagement Plan** included in the GSP?	
DAC and drinking water user engagement during GSP development[40]		

[39] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).

[40] Water Code § 10723.2; Water Code § 10727.8(a) The groundwater sustainability agency shall encourage the active involvement of diverse social, cultural, and economic elements of the population within the groundwater basin prior to and during the development and implementation of the groundwater sustainability plan.

2	**Description of DAC engagement:** Does the GSP specifically identify how DAC beneficial users were engaged in the planning process?	
3	**Notice:**[41] Did the GSA provide clear notice to the public about GSA meetings to develop the GSP, posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English? [42]	
4	**Translation of materials:**[43] Did the GSA translate materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
5	**Interpretation:**[44] Did the GSA(s) provide interpretation services at board meetings, committee meetings and workshops into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
6	**Accessible workshops:** Did the GSA(s) host workshops held at accessible times and locations for disadvantaged community residents?	
7	**DAC representation on advisory committee:** Did the GSA(s) develop the GSP with an advisory committee that contained representatives from DACs?	
8	**DAC representation on GSA board:** Did the GSA(s) develop the GSP with a Board that contained representatives from DACs?	
9	**Partnership with local community based organizations:** Did the GSA partner with community based organizations and nonprofits on outreach and engagement?	
10	**Public Comment Period:** Did the GSA provide a robust public comment period of at least 60 days, with opportunity for the public to discuss comments and proposed agency responses with staff and the GSA before GSP approval?	
11	**Incorporation of stakeholder input:** Does the GSP explicitly describe how stakeholder input was incorporated into the GSP process and decisions?	
DAC and drinking water user engagement during GSP implementation		

[41] Government Code § 54954(a).

[42] Government Code sec. 7296.2: Dymally-Alatorre Bilingual Services Act, stating that local agencies providing services to the public must provide translated materials and interpretation when it serves a substantial number of non-English-speaking people. The law defines a "substantial number of non-English-speaking people" as "members of a group who either do not speak English, or who are unable to effectively communicate in English because it is not their native language, and who comprise 5 percent or more of the people served by the statewide or any local office or facility of a state agency." This is because "effective maintenance and development of a free and democratic society depends on the right and ability of its citizens and residents to communicate with their government and the right and ability of the government to communicate with them."

[43] Government Code sec. 7296.2.

[44] Government Code sec. 7296.2.

12	**Description of DAC engagement:** Does the GSP describe how ongoing engagement will be conducted during GSP implementation, including but not limited to engagement regarding: decisions about projects, management actions, modifying sustainable management criteria, changes to monitoring networks, and conducting GSP updates?	
13	**Notice:**[45] Does the GSP state that ongoing engagement will include clear notices about GSA meetings and workshops that are posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?[46]	
14	**Translation of materials:**[47] Does the GSP state that ongoing engagement will include translation of materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
15	**Interpretation:**[48] Does the GSP state that ongoing engagement will include interpretation services provided at board meetings, committee meetings and workshops into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
16	**Accessible workshops:** Does the GSP state that ongoing engagement will include workshops held at accessible times and locations for disadvantaged community residents?	
17	**DAC representation on advisory committee and board:** Does the GSP state that ongoing engagement will include advisory committees and Boards containing representatives from DACs?	
18	**Partnership with local community based organizations:** Does the GSP state that ongoing engagement will include partnership between GSA and community based organizations and nonprofits?	
19	**Engagement on key decisions:** Does the GSP state that ongoing engagement will include strategies to keep the public informed and engaged during and prior to critical decisions about the GSP, including but not limited to the five year GSP review, modification of sustainable management criteria, design and adoption of any projects and management actions, and development and adoption of the programs to assist with impaired wells?	
20	**Engagement on financial issues:** Does the GSP state that it will conduct outreach to DACs before approving operating budgets and enacting groundwater fees?	

[45] Government Code § 54954(a).
[46] Government Code sec. 7296.2.
[47] Government Code sec. 7296.2.
[48] Government Code sec. 7296.2.

Appendix B: Framework and Guidance for Developing a Drinking Water Well Impact Mitigation Program [Working Draft]

Management Action Name:
Drinking Water Well Impact Mitigation Program

Potential Implementing Organization(s):
Groundwater Sustainability Agencies (GSAs) in partnership with project participants.

Purpose Statement:
The purpose of this document is to be utilized by GSAs to mitigate, prevent, and address any adverse effects on drinking water wells caused by pumping volume or location, conjunctive management, or any other forms of active management as part of Groundwater Sustainability Plan (GSP) implementation. By doing so, GSAs can better achieve the goals of the Sustainable Groundwater Management Act (SGMA), avoid jeopardizing access to safe water in vulnerable communities, and also avoid violating California laws that establish a state-wide Human Right to Water and that protect access to safe water. Adverse effects can include both issues with access to safe drinking water due to increased contamination, as well as issues with sustained access to water due to changes in groundwater levels.

This document provides a framework of elements to consider when GSAs are developing a drinking water well impact mitigation plan. Every community and every GSA will have to evaluate their own needs and particular considerations in order to develop a mitigation program that works best for all users. This document is broken down into the following sections:

1) Importance of drinking water well mitigation programs;
2) Framework for developing program / key elements to consider;
3) Cost considerations for short term and long term solutions and potential funding sources; and
4) Four local case studies of existing drinking water well mitigation programs.

Section 1. Importance of a Drinking Water Well Impact Mitigation Program:

How can GSP implementation impact domestic wells and small community wells?

Across the state, critically overdrafted basins have developed Groundwater Sustainability Plans (GSPs) to manage groundwater resources sustainably under the Sustainable Groundwater Management Act

(SGMA). Many GSPs have developed sustainable management criteria, including minimum thresholds (MTs) and measurable objectives (MOs), that if reached, would cause significant impacts to access to safe and affordable drinking water for vulnerable communities. GSP implementation, including management actions and projects, can cause changes in groundwater levels and groundwater quality that could lead to:

- Completely dewatered wells;
- Partially dewatered wells:
    - needing to lower the well pump,
    - needing to clean the well screen,
    - needing to drill deeper;
- An increased movement of contaminant plumes;
- An increase in the concentration or release of contaminants;
- An increase in salinity due to sea water intrusion in coastal wells;
- Higher energy costs from having to drill or pump from a deeper depth; and
- Emotional, psychological, and health impacts related to not having access to safe water.

If GSP sustainable management criteria are developed in a way that could potentially cause significant impact on drinking water users, the GSP must also include a robust drinking water well impact program to prevent and mitigate the drinking water impacts that occur. In some GSAs, up to 85% of domestic wells are at risk of being dewatered or partially dewatered. In these same GSAs, rural domestic and small water system demand does not contribute substantially to the overdraft conditions, yet the risks imposed on these drinking water users are overlooked and neglected, creating a disproportionate impact on already vulnerable communities.

What are the drinking water challenges of disadvantaged communities?

Without an adequate groundwater sustainability plan that is protective of groundwater sources near or within communities, more drinking water wells will run dry or be unable to provide safe, potable water to residents. This will further jeopardize the livelihood of California's most vulnerable communities. Vulnerable communities, including severely disadvantaged communities (SDACs), disadvantaged communities (DACs), small water systems, and domestic well owners, have limited technical, managerial, and financial capacity to respond to drinking water challenges.

Climate change further exacerbates drinking water challenges with more frequent, longer and more severe droughts and flood periods expected. Small water systems and rural communities reliant on domestic wells are, and will continue to be, the most adversely impacted and most at risk of experiencing water shortages and/ or having to rely on contaminated drinking water supplies. In order to increase water system resiliency, the golden rule is to protect current water sources— especially if the quality of the water is meeting safe drinking water standards. Other ways to increase resiliency are to secure more than one water source, assist communities with maintenance and operation costs, and ensure water affordability. A drinking water well mitigation program is key to increasing water resilience through minimizing risks of both short-term and long-term impacts. Having adequate plans and policies to support drinking water resilience in the face of climate change is essential to reducing the amount of emergency funding needed to respond to a water shortage emergency and to prevent human health crises. A carefully designed and implemented well impact mitigation program can support efforts to ensure all communities have long-term and sustainable access to clean, safe, and affordable drinking water.

How does California law prioritize drinking water?

A GSP which lacks a mitigation program to curtail the effects of projects and management actions on the safety, quality, affordability, or availability of domestic water, violates both SGMA itself and the Human

Right to Water law. The Human Right to Water (AB 685) (HR2W) was signed in 2012 and added § 106.3 to the California Water Code, declaring, "the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."[49] The HR2W applies to all state agencies, requiring that they "...shall consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria when those policies, regulations, and criteria are pertinent to the uses of water…".[50] With this passage of AB 685, relevant state agencies, including the State Water Resources Control Board (SWRCB) and the Department of Water Resources (DWR), are now required to consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria that may impact the uses of water for domestic purposes. These agencies must consider how state actions may impact the Human Right to Water. To ensure compliance with the legislature's long established position and accordance with 23 CCR §350.4, the HR2W requires that DWR must consider the effects on domestic water users when reviewing and approving GSPs.[51] The SWB should be consulted as part of GSP review as part of the Board's expertise on water quality matters.

Further, the California legislature has recognized that water used for domestic purposes has priority over all other uses since 1913.[52] Reserving top priority for domestic water use was later codified in 1943, in Water Code § 106, which declares it the, "established policy of this State that the use of water for domestic purposes is the highest use of water and that the next highest use is for irrigation."[53] Further, the passage of the Safe and Affordable Drinking Water Act by Governor Newsom[54] indicates a clear state-level commitment to providing safe and affordable drinking water to California's most vulnerable residents. Poor implementation of SGMA would threaten the success of the Safe and Affordable Drinking Water Fund and would run counter to Governor Newsom's vision of providing safe water to all.

A carefully designed and implemented Drinking Water Well Impact Mitigation Program can support a statewide goal of ensuring DACs' access to clean, safe, reliable, and affordable drinking water. Including this type of program in a GSP also helps to create a groundwater management plan that understands DACs' unique social and economic vulnerabilities, is sensitive to their drinking water needs, and avoids causing a further disparate impact on low-income communities.

Section 2. Key elements and a framework for developing a Drinking Water Well Mitigation Program:

This section provides a framework of elements to consider when GSAs are developing a drinking water well impact mitigation plan. This section is broken down into the following categories:

i. Drinking water well monitoring network;
ii. Adaptive management and trigger system;
iii. Drinking water well impact tool/model;
iv. Public outreach and education;
v. Mitigation measures;
vi. Program eligibility.

---

[49] WAT § 106.3 (a).
[50] WAT § 106.3(b).
[51] *See generally,* WAT § 106.3 (b).
[52] California Water Commission Act of 1913 § 20.
[53] WAT§ 106; This policy is also noted in the Legislative Counsel's Digest for AB 685.
[54] SB 200, Monning (2019).

i. Drinking water well monitoring network: As required by GSP Regulation, Section 354.34, GSAs must describe how potential impacts to groundwater users and uses will be monitored. It must be recognized that most public water systems have wells deeper than domestic wells, thus monitoring networks must be able to capture impacts to deeper public water system wells as well as shallow domestic wells. The following approach will allow GSAs to comply with GSP regulations and take a proactive approach to protect DACs' and domestic well owners' access to safe and affordable drinking water:

- Map and assess drinking water well vulnerabilities to better understand:
  (1) Locations and depth of drinking water wells (both domestic and public supply wells);
  (2) Whether changes in groundwater levels and quality may be exacerbated in specific areas by pumping volume or location, conjunctive management (i.e. groundwater recharge projects) or other forms of active management as part of GSP implementation;
  (3) The proximity of potentially impacted wells to nearby existing public water systems; and
  (4) If there are areas with a high density of likely impacted wells.
  Assessment should acknowledge that not all existing and utilized wells may be documented in available resources from DWR or Counties.

- Designate key monitoring wells to assess impacts to drinking water wells: Based on the drinking water well vulnerability assessment, identify which wells from the GSP proposed monitoring network are critical to assess impacts to drinking water wells caused by changes to groundwater levels and quality. Expand and improve the monitoring network to assess potential impacts in particular for groundwater conditions near DACs, areas with high density of private domestic wells, and water systems serving schools. The monitoring network needs to be representative of conditions in all aquifers in general, including the shallow aquifer upon which domestic wells rely. The water quality monitoring network needs to routinely monitor for all contaminants that could impact public health (not only nitrate, but also chromium-6, arsenic, 123-TCP, uranium, and DBCP). This will allow the GSA to better comply with GSP regulations Section 354.34, which requires GSAs to describe how potential impacts to groundwater users and uses will be monitored, and to take a proactive approach to protect DACs and domestic well owners' access to safe and affordable drinking water.

ii. Develop an adaptive management/trigger system: Develop a protective warning system, also referred to as an adaptive management approach. Such an approach can alert groundwater managers when groundwater levels and groundwater quality are dropping to a level that could potentially negatively affect drinking water users. These "triggers" are essential for groundwater management and can be adjusted to fit the needs of different management actions as well as the basin as a whole. The table below provides an example of what a warning system might look like, using green, yellow, and red light indicators or triggers, and some potential corrective actions groundwater managers can take to remedy the problem. Ultimately, this approach allows for the evaluation of current conditions in order to respond accordingly to prevent or mitigate negative impacts.

Triggers	Groundwater Status	Potential Corrective Actions
Green-light	Groundwater levels and quality are stable.	No action required
Yellow-light	Groundwater levels and quality are approaching concerning levels and impacts may occur or are occurring at a	- Undertake an analysis to pinpoint the cause; - Undertake water quality testing for selected domestic and public supply wells; - Provide immediate support to groundwater users experiencing impacts;

	low rate. Some corrective actions are needed.	- Reassess pumping allocation and pumping patterns. Consider restricting or limiting groundwater extraction near the impacted area.
Red-light	Time to stop groundwater pumping and management actions and mitigate as significant impacts are imminent or are occurring.	- Reassess pumping allocation and pumping patterns. Consider further restricting or limiting groundwater extraction near the triggered area or reevaluating minimum thresholds or measurable objectives; - Provide interim emergency solution while working with impacted groundwater users to pursue a permanent, long-term solution.

iii. Drinking water well impact tool/model: Develop a tool or model tied to the monitoring network and the adaptive management framework (trigger system) to evaluate groundwater levels and predict potential groundwater impacts to drinking water wells. Update model regularly and develop a prediction of the potential groundwater impacts to drinking water wells. Results of this assessment should be incorporated into an annual GSP progress report to domestic well owners and DACs water systems. The tool or model could be used to:

- Monitor and forecast changes in groundwater levels and quality;
- Monitor and forecast any localized areas for special attention and/or monitoring;
- Attempt to identify domestic wells or small public supply wells at risk of impacts, and;
- Determine if triggers have been met based on the adaptive management framework.

iv. Public outreach and education: Develop public outreach and educational materials to increase awareness of groundwater management activities within the GSA. This outreach could inform groundwater pumpers of the rules, restrictions, and impacts of groundwater over-pumping. This outreach could also inform residents about the potential well impacts that could occur based on groundwater management actions, describe potential options available for well mitigation, and include information for who to contact in the event their wells experience negative impacts. This outreach could take place in the form of pamphlets, mailers, additions to the public website, or radio announcements. This information can also be included in regular GSA updates. To ensure that this program can benefit S/DAC residents, information about the program must be disseminated widely, and such materials must be translated into all threshold languages. The GSA should work with local agencies, organizations and associations to spread materials about the program. The GSA should work with local agencies and organizations to ensure that residents with impacted wells are referred quickly to the GSA for assistance. GSAs should conduct regular, door-to-door outreach (in partnership with other outreach experts as needed) to ensure that communities — particularly for communities location in areas the trigger system identifies within the yellow and red-light ranges— are aware of the well mitigation program and know who to contact in times of emergency.

v. Mitigation measures: Mitigation measures should be implemented as soon as the trigger system reaches its yellow light indicator. Groundwater should be managed in a way that prevents or avoids reaching the red light indicator and before wells become unusable. This will allow communities working with the GSA to access funding and develop a long-term plan that protects community member access to drinking water. The mitigation program should be designed to be proactive, rather than reactive to public health harms. When mechanical failures or other operational problems have occurred, or are likely to occur, due to declining water levels or deteriorating groundwater quality, mitigation should be provided as described below:

- **Third Party Determination of Causality:** Work with an objective third party to establish whether their policies and actions caused the drinking water impact. Based on a field inspection and discussion with the residents impacted, define the level of mitigation that is necessary. Verify well construction information and pump setting information, if possible;
- **Interim Drinking Water Supply Solution:** Provide short-term drinking water supply while a permanent solution is pursued. Short-term interim solutions serve to address the immediate impacts and ensure access to both water suitable for consumptive and other domestic needs, such as sanitation. Short-term emergency supplies shall be provided as soon as reasonably possible and can include bottled water, bottled water paired with tanked water, or another combination. For groundwater quality issues, bottled water may be an acceptable interim solution but if the issue is lack of access to water, providing bottled water is not an adequate interim solution and would require a combination of solutions as well as a long-term sustainable plan.
- Since short-term solutions are expensive over a prolonged period of time, it would be important to quickly identify potential long-term solutions. As an example, GEI's feasibility study for East Porterville at the height of the drought in 2016 estimated tank and bottled water programs cost $633,500 per month just for East Porterville, which has an estimated population of 7,331 residents.
- Long-term water supply can include (where appropriate):
    - Providing funding to lower a well pump and/or deepen the well;
    - Financial and technical support to complete a connection to a nearby municipal and/or industrial water provider;
    - Providing an equivalent water supply from an alternate source;
    - Providing funding to replace the affected well with a deeper well;
    - Providing funding to treat contaminated water;
    - Reducing or adjusting pumping near the impacted drinking water well as necessary to avoid the impact; and/or
    - Providing other acceptable mitigation through a collaboration with the affected drinking water well users.

  Note that lowering the pump and/or deepening the well will increase operational costs of the well and may require additional monitoring to ensure the well is not dewatered again. Further, these solutions may not address water quality concerns, depending upon aquifer conditions and screen depths.
- For a long-term water supply option, connecting current domestic well users to a nearby public water system should be pursued whenever possible. In areas with a high density of domestic wells, the establishment of a new small public water system may also be feasible. Public water systems have an obligation to test water quality for water served, and although some public water systems have limited resources, they do have a greater ability to install treatment systems to address water quality impacts, recoup funds for litigated contamination such as 1,2,3-TCP, and apply for and receive grant funding for beneficial projects. Because of this, public water systems, including small community water systems, often provide a more reliable drinking water source than privately-owned domestic wells. It should be noted that once a resident is connected to a public water system, they are then subject to water bills that will likely be higher than the operation costs of the well. As these long-term solutions are being developed, the community should be engaged in the process to learn about the benefits of a public water supply in terms of water reliability and water quality, and should also be informed of why water bills may be more costly. It is possible that some residents may request some sort of stipend to assist with the monthly water bills associated with their new water connection.

xi. Eligibility: Eligible beneficiaries should include communities that quality as DAC or SDAC, and households who qualify as low income. S/DAC residents should not be required to undertake burdensome actions or overcome other barriers to entry in order to benefit from the program. For example, residents should not be required to register before impacts occur in order to benefit from the program, and beneficiaries should not be required to prove that the GSA's activities or lack of action caused impacts. Instead, the GSA should proactively identify all well locations and information. When the GSA is notified of an impacted well, it should use the well information collected to rapidly evaluate the cause of the impact and provide adequate mitigation measures. Some questions GSAs could consider when determining eligibility are:

- What is the process for determining eligibility?
- Who determines if the well is eligible?
- What documentation does the well owner need to demonstrate eligibility? Is there an unreasonable onus on the owner to demonstrate past use that would constitute a barrier to access?
- When a well is found to have been constructed in a way that is not consistent with current regulations, is it still eligible?
- If a well is poorly constructed, does the program address replacing or repairing the well rather than just deepening it?

Section 3. Costs and Potential Funding Sources:

Costs: Costs are dependent on many factors including: how protective the GSA defines its sustainability goal and related sustainability criteria, the number of vulnerable wells, the condition of the vulnerable wells, proximity to existing public water systems, the depth of the aquifer, local contractor costs, fluctuations in material costs, etc. For comparison purposes, the San Antonio well mitigation project materials include the following average costs:

- Perform well diagnostics ($2,700);
- Lower pump ($4,000);
- Drill/outfit/connect replacement well ($58,000);
- Water purveyor connection ($5,000), and close existing well ($4,500).

The table below provides examples of interim and long-term solution costs based on Self-Help Enterprises' experience in providing solutions to disadvantaged communities in the San Joaquin Valley during the 2012-2014 drought. Costs are provided for illustrative purposes only and should be considered as rough estimates.

Solution	Problem	Options	General Overview of Pros and Cons	Estimate of Costs[1]
Interim solution	Water quality	Point-of-Use (POU)	Treats water for one tap within the household. While this option does provide safe drinking water in the home, if everything is perfect, maintenance is less likely to be carried out and assistance must be provided until a long-term solution is implemented. Costs estimates include initial capital costs (installation, treatment system, monitoring system) and also ongoing operation, maintenance, routine	$1000 to $1500 / unit per home.

			monitoring, and waste disposal costs.	
		Bottled water	Bottled water provides an effective and reliable source of safe drinking water and may be the only option available depending upon contaminant concentrations. However, bottled water can be expensive over a long period of time and can come with distribution challenges.	$30 to $50 per month per house, includes delivery.
	Access to water	Water tank program with bottled water	Tank water can meet basic sanitation needs but should not be used to meet drinking water needs, as tank water is susceptible to bacteriological or other issues making it unsafe for consumptive purposes. Instead, the program must be paired with delivery of bottled water to meet drinking water needs.	- 2,600 gallon water tank and materials roughly $2100.00. - Labor and tank installation $1500.00, does not include mileage. - Electrical permit $80.00, depending on the county. - Tank water between $300 to $500 depending on delivery charge by water hauler, per load or per hour. - $30 to $50 per month per house, includes delivery.
Permanent solution	Water quality	Water treatment system	Technical, managerial, and financial capacity of the community should be considered when assessing water treatment options.	Costs vary depending on the technology, water contaminant, and number of households.
		Alternate supply source	Options include surface water, construction of a new well, and consolidation with a nearby water system.	Costs vary depending on the desired solution, technology, and number of households.
	Access to water	Lowering of well pump	Less expensive long-term solution, if conditions allow. The following factors should be taken into account: lowering of a pump in the well is limited by the depth of the well, proximity of pump to the base of the well increases energy consumption, may require more frequent screen cleaning, and water quality may be degraded due to sediments that are drawn in.	Less than $10K, maybe around 5K.
		Drill a new deeper well	A well test is necessary to assess yield capacity and water quality on deeper levels.	Build a new private well: $20k to $45k.
				Build a new well for a water systems: up to $1.5 million.

		Alternative water supply source	Options include surface water or consolidation with a nearby water system. Recommend considering consolidation when households understand and agree with the advantages and disadvantages of connecting to a local water system.	Costs vary depending on the desired solution, technology, and number of households.

Potential Funding Sources: A secure and reliable funding source and mechanism for the implementation of this type of mitigation program needs to be identified in the GSP. While grant or emergency funding could potentially be available to support a mitigation program, the availability of these funds is not certain. Therefore, the GSA should plan to establish a more secure, on-going funding mechanism that accrues funds that would be available as water levels decline in the future. Funding for these types of programs should be considered as an operational cost of the GSA and funded with other ongoing costs such as administration and monitoring and should be included in the annual budget for the GSA. The following are potential other sources of funding to consider:

- Service or land-based fee assessments using Proposition 26 or Proposition 218;
- State Water Resource Control Board programs such as Proposition 1 Groundwater Grant Program and Prop 68 Groundwater Treatment and Remediation Grant Program;
- Department of Water Resources funding programs for groundwater projects and technical assistance programs to aid SGMA implementation;
- Central Valley Basin Plan Amendment (BPA) project funding: The BPA for the regulation of salts and nitrates has been approved by the SWRCB and implementation may result in additional funding sources for nitrate contaminated aquifers. If appropriate, GSAs should consider coordinating with nitrate dischargers forming Management Zones in order to comply with the BPA in order to streamline administrative costs and leverage resources;
- United States Department of Agriculture (USDA) Rural Development Utilities funding (if available).

Note that any well mitigation projects should be coordinated with the SWRCB's Safe and Affordable Drinking Water Fund Program (which will be seeking to implement short and long-term drinking water solutions within vulnerable communities) via the SWRCB's Division of Drinking Water. Funding from the SWRCB's Safe and Affordable Drinking Water Fund Program should not be utilized to ameliorate negative impacts to safe drinking water access in vulnerable communities that are a result of implementation of the GSPs.

Mitigation measures should not put a financial burden on S/DAC residents and communities. Where feasible, coordinate with relevant agencies to procure funding for cost-effective and affordable solutions. Solicit stipends and grants from agencies where there will be an added cost on residents.
Wherever consolidation is possible, the GSA should assist in pursuit of feasibility studies and assist in negotiations with public water systems. GSAs should also assist in pursuit of grants/funds to ensure that this water is affordable. This work must be initiated with community involvement, oversight, and leadership during "yellow light" phase. GSAs play a unique role in regional groundwater management and the ability to convene multiple agencies to leverage multiple funding sources can support both long-term access to safe and affordable drinking water while also supporting sustainable groundwater management.

ABOUT THE PACIFIC INSTITUTE

The Pacific Institute envisions a world in which society, the economy, and the environment have the water they need to thrive now and in the future. In pursuit of this vision, the Institute creates and advances solutions to the world's most pressing water challenges, such as unsustainable water management and use; climate change; environmental degradation; food, fiber, and energy production; and basic lack of access to fresh water and sanitation. Since 1987, the Pacific Institute has cut across traditional areas of study and actively collaborated with a diverse set of stakeholders, including leading policymakers, scientists, corporate leaders, international organizations such as the United Nations, advocacy groups, and local communities. This interdisciplinary and independent approach helps bring diverse groups together to forge effective real-world solutions. More information about the Pacific Institute and its staff, board of directors, and programs can be found at www.pacinst.org.

ABOUT THE ENVIRONMENTAL JUSTICE COALITION FOR WATER

The Environmental Justice Coalition for Water (EJCW) works within a Community-to-Capital framework, connecting the most pressing needs of our disadvantaged community partners to our network of partners and agencies statewide. Since 1999, EJCW's work has been rooted in the communities most affected by environmental injustice. Issues and solutions are identified through regional chapters and statewide work groups. EJCW is positioned in the state capital, in order to connect communities with state agencies to bring about change multilaterally through advocacy, education, training, litigation, community organizing, and capacity-building, and by providing technical assistance. EJCW aims to effectively influence the intersections of water justice and environmental justice, community health, and human rights issues from community to global levels.

ABOUT THE AUTHORS

LAURA FEINSTEIN, *Senior Research Associate, Pacific Institute*

Laura Feinstein joined the Water Program at the Pacific Institute in 2016. Laura conducts research on aquatic ecosystems; the impacts of climate change on water resources, water, and energy; and environmental health and justice. Prior to joining the Pacific Institute, she was a research scientist and project manager with the California Council on Science and Technology. She also served as a Science and Technology Policy Fellow with the California Senate Committee on Environmental Quality and was a California SeaGrant Delta Science Fellow. Laura holds a BA in Anthropology from the University of California, Berkeley and a PhD in Ecology from the University of California, Davis.

RAPICHAN PHURISAMBAN, *Research Associate, Pacific Institute*

Rapichan Phurisamban has worked in the Pacific Institute's Water Program since 2014, focusing on economic and policy analysis relating to domestic and international water resources. Prior to joining the Pacific Institute, she was a research consultant and project coordinator at a nonprofit organization in Thailand, where she promoted sustainable food and agricultural systems. Rapichan holds a BA in Economics from the University of British Columbia and an MPP from the University of California, Berkeley.

AMANDA FORD, *Coalition Coordinator, Environmental Justice Coalition for Water*

Rev. Ford is based in Sacramento, California. In addition to being an ordained interfaith minister, she has an MA in Sustainable International Development from Brandeis University with an emphasis in Environmental Peacebuilding and Project Management. Amanda leads the development, coordination, and implementation of EJCW's environmental justice coalition efforts, programs and advocacy campaigns at a statewide level, including Human Right to Water (AB 685) implementation, pollution prevention, democratic water governance, and tribal outreach. She has worked on environmental peacebuilding and environmental justice projects in 20+ countries and still actively advises projects around the world.

CHRISTINE TYLER, *Water Policy Leadership Intern, Pacific Institute*

Christine Tyler was a Congressman George Miller Water Policy Leadership Intern with Pacific Institute in 2016. Christine holds a BA in Political Science from the University of California, Berkeley. Her research interests revolve around international development, water and resource rights, colonialism, and climate change's effect on marginalized communities. She has previously worked on wastewater management and land rights issues in Oakland and abroad.

AYANA CRAWFORD, *Water Policy Leadership Intern, Pacific Institute*

Ayana Crawford was a Congressman George Miller Water Policy Leadership Intern with Pacific Institute in 2016. Ayana holds a BA in Environmental Studies from the University of California, Santa Cruz, where she completed a number of research and conservation internships and focused her coursework on social and environmental justice. Ayana pursued these passions after graduation through her work with the Pacific Institute, which revolved around water equity and water access, and as a research intern at Food First, a food justice think tank. She is presently studying Spanish at the University of Granada in Spain.

ACKNOWLEDGMENTS

This work was supported by a grant from the TomKat Foundation. We thank them for their generosity. The Drought and Equity Advisory Committee and report authors wish to thank the many people who gave their time to assist us in writing this report. Staff of the Community Water Center (CWC) organized two meetings with impacted communities. Marina Perez and Esther Tracy from the California State Water Resources Control Board (SWRCB) joined our Advisory Committee meetings. Many people participated in interviews or shared useful data with us, including Bruce Barton, Dave Bitts, Chris Brady, Donald Brafford, Larry Collins, Lori French, Kathy Frevert, Max Gomberg, Chook-Chook Hillman, Steve Lindley, Michael O'Farrell, Mike Ricketts, and Kurt Souza. East Porterville for Water Justice (EPWJ) and la Asociación de Gente Unida por el Agua (AGUA) Coalition met with us to discuss report recommendations. Heather Cooley gave many helpful review comments, and Matthew Heberger provided input and technical support. Brendan McLaughlin copyedited our dubious prose. Finally, our communications team, Rebecca Olson and Deb Janes, helped guide this report through its final stages. The opinions expressed in this report are those of the authors and do not necessarily reflect the views of the Drought and Equity Advisory Committee or the project funder. All conclusions and errors are our own.

Acronyms and Abbreviations

ACS – American Community Survey

AGUA – Association of People United for Water (or la Asociación de Gente Unida por el Agua)

CA HSC – California Health and Safety Code

CalEPA – California Environmental Protection Agency

CBC – Cumulatively Burdened Communities

CCF – Centum Cubic Feet (100 cubic feet)

CDPH – California Department of Public Health

CUWA – California Urban Water Association

CWS – Community Water System

DAC – Disadvantaged Community

DWR – Department of Water Resources

ESA – Endangered Species Act

GAMA – Groundwater Ambient Monitoring and Assessment Program

GPCD – Gallons Per Capita Per Day

IHS – Indian Health Service

LWS EAR – Large Water System Electronic Annual Reports

MCL – Maximum Contaminant Level

MHI – Median Household Income

NOAA – National Oceanic and Atmospheric Administration

OES – Office of Emergency Services

PFMC – Pacific Fishery Management Council

PWS – Public Water System

SDWIS – State Drinking Water Information System

SSWS – State Small Water System

SWAMP – Surface Water Ambient Monitoring Program

EXECUTIVE SUMMARY

Water is essential for life, yet not everyone in California has access to safe, affordable water. Five years of drought has highlighted these inequities. Recent reviews of the impact of the ongoing drought found that cities and farms, despite feeling the effects of curtailed water supplies, demonstrated great resilience overall (Cooley et al. 2015; Hanak et al. 2015). Small water suppliers and natural systems have not fared as well. Some small systems struggled to provide safe water to their customers, thousands of household wells ran dry, and endangered fish reached the brink of extinction (Braxton Little 2016; Moyle 2014; State of California 2016). Across California, those on low or fixed incomes have struggled with the rising cost of water (Cooley et al. 2016).

In this report, we examine three major impacts of the ongoing California drought. The first two, supply shortages and rising costs, affected people's access to safe, affordable water in their homes. We also investigated the impacts of the drought on salmon and, by extension, commercial and tribal fishermen reliant on salmon for income, food, and cultural traditions. We found that low-income households, people of color, and communities already burdened with environmental pollution suffered the most severe impacts. The good news is that there are solutions to these problems, some of which are already being implemented. We conclude with a set of policy recommendations to improve our ability to cope with drought and minimize its inequitable consequences in the future.

During the drought, some small systems struggled to provide safe water to their customers, thousands of household wells ran dry, and endangered fish reached the brink of extinction.

DOMESTIC WATER SHORTAGES

Despite a great deal of public attention on drinking water shortages since the drought began in 2012, this is the first statewide summary of reported water supply vulnerabilities. Using information collected by state and local agencies, we classified water systems as "drought-impacted" if they reported actual or near shortages, received emergency drought funding, or, in the case of tribal water systems, were identified by United States Indian Health Services (IHS) as "high risk." We examined water systems serving more than 25 people year round or at least 15 connections (referred to as public water systems) and those serving fewer than 25 people year round, such as private wells (referred to as non-public water systems). We found that:

1. Most (76 percent) of the 149 drought-impacted public water systems were small, serving 1,000 connections or fewer. This is similar to the overall percentage of small water systems in California. Drought-impacted public water systems served an estimated 480,000 people—approximately equivalent to the population of Sacramento.
2. Drought-impacted public water systems were widespread, with at least one found in 39 of the state's 58 counties, but were concentrated in the San Joaquin Valley, the North Coast, and the Central Coast. There were no reports of drought-impacted systems in the easternmost portions of the state or in the San Francisco Bay Area.
3. From January 2014 through early August 2016, the state received nearly 4,000 reports of shortages from households served by small, non-public water systems. Household shortages were reported in 38 of 58 counties across the state but were concentrated in the southern San Joaquin Valley. Tulare County accounted for 42 percent of reported household water shortages.
4. A large proportion of drought-impacted public water systems and household outages were in Disadvantaged and Cumulatively Burdened Communities.[1] Of the 92 drought-impacted public water systems for which we know the location, two-thirds served a disadvantaged community, and nearly one-third served a cumulatively burdened community. Similarly, of the household shortages reported in Tulare County, two-thirds were in a disadvantaged community, and nearly 90 percent were in a cumulatively burdened community.

To improve the drought resilience of domestic water supplies, we recommend that state and local agencies enact the following measures:

1. Establish a statewide, quantitative metric for measuring water supply reliability for public water systems;
2. Require water shortage contingency plans for all public water systems and establish regional plans for non-public systems;
3. Increase oversight of new private wells;
4. Systematically collect information on water shortages for public and non-public water systems;
5. Identify areas where private wells and other non-public water systems are likely to run dry in future droughts;
6. Identify areas where water system consolidation can resolve supply problems.

DROUGHT CHARGES AND WATER AFFORDABILITY

The cost of water can go up during a drought if, for example, the water utility must purchase more expensive supplies, increase treatment for lower quality water, or pump groundwater from greater depths. Moreover, as water use declines due to mandatory or voluntary restrictions, water utilities may implement a temporary drought charge to cover their costs, most of which are fixed. Such price increases can exacerbate affordability concerns for low-income households. In examining the impact of drought charges on low-income households in 2015, we found that:

1. More than half of the utilities analyzed increased the price of water regardless of the amount a household used, resulting in price increases for all single-family households.
2. About one-fifth of the utilities levied drought charges by increasing the price of water used

1 Disadvantaged Communities have a median household income of less than 80 percent of the state median. Cumulatively Burdened Communities are those that rank in the top quarter of census tracts in the state for environmental burdens and socioeconomic vulnerability.

in excess of some threshold. While the intent was to avoid increasing prices for basic water use, even relatively efficient households with many members still experienced an increase in the price of water.

3. Approximately one-fifth of the utilities only added drought charges if a household exceeded a customized water budget based on household size, raising the price of water only for wasteful use.
4. Drought charges exacerbated affordability concerns for low-income households. Single-family households earning less than $25,000 a year paid an average of 1.8 percent of their household income for basic water service without drought charges. This amount increased to 2.1 percent with drought charges, exceeding State of California and United States Environmental Protection Agency affordability thresholds. The effect was even more extreme for households earning less than $10,000, raising costs from 4.4 to 5.3 percent of income. These households have little or no disposable income, so any increase in water costs poses a major problem.

To reduce the inequitable impact of drought charges on low-income households, we recommend the following:

1. Ensure drought surcharges are not applied to basic water use, preferably by calculating household water budgets based on the number of people in a residence;
2. Provide technical and financial assistance to water utilities, especially the smallest ones, to implement drought charges that do not unfairly burden low-income households;
3. Target water conservation and efficiency programs to low-income households by offering, for example, point-of-sale coupons, targeted education and outreach, and direct-install programs;

Source: Photographereddie

4. Develop low-income rate assistance programs within current legal constraints and reform Proposition 218 to allow greater latitude in funding such programs;
5. Wherever possible, require meters and sub-meters to allow for more equitable drought charges based on volumetric water use;
6. Develop approaches that effectively target hard-to-reach customers, such as renters and residents of multi-unit buildings, for rate assistance and conservation programs.

DROUGHT IMPACTS ON SALMON FISHERIES

Water disputes in California are sometimes framed as "fish versus people," but this perspective overlooks those who rely on fishing for their livelihoods and traditions. While the link between drought and the collapse of endangered fish stocks has been extensively documented (Hanak et al. 2015), surprisingly little research has traced

the relationship between drought, low river flows, and the health of commercial and tribal fisheries in California. Salmon populations decline during droughts because of reduced stream flows and higher water temperatures, which lead to disease outbreaks, more competition from invasive fish species, and higher risk of predation. Habitat loss from human activity has compromised their capacity to survive and rebound from droughts. There are many factors contributing to the decline of salmon, of which drought is just one.

We examined the available data and information on trends in commercial and tribal fishing over time. We found that:

1. The commercial salmon fishing fleet has declined dramatically over the last three decades, from 6,000 vessels in 1982 to just over 1,000 vessels in 2014. Many factors have contributed to the decline, including fewer salmon, income insecurity brought about by events such as the fishery closure of 2008-2009, rising costs of fishing, and loss of support infrastructure (such as fuel docks).
2. From 2014 to 2015, Sacramento winter-run Chinook salmon had the poorest survival for juvenile fish on record due to drought conditions and water diversions from the Sacramento River, resulting in an abbreviated 2016 fishing season for much of the state.
3. Extremely low flows in the Klamath River, caused by drought and water diversions for irrigation, contributed to an outbreak of fungal infections in salmon in 2014 and 2015. The subsequent poor reproduction will impact fishermen two to five years later, when eggs hatched in 2014 and 2015 return from the ocean as mature adults.
4. Declines in salmon populations, made worse by drought, have meant that tribes cannot obtain the fish that are an essential part of their diet and an integral part of their spiritual and cultural traditions.

To reduce the impact of drought on salmon fishermen, we recommend the following:

1. Expand the goal of emergency drought responses beyond preserving endangered species to include protection of commercially-fished salmon species.
2. Manage stream flows to better serve the needs of fish.
3. Restore habitat to improve salmon resilience to drought.
4. Provide income assistance and insurance protection for fishing communities during drought emergencies.
5. Create mechanisms for meaningful and timely tribal engagement with local, regional, state, and federal agencies.
6. Evaluate ways to re-operate California hatcheries to achieve parallel goals of sustaining commercial fisheries and assisting in the recovery of naturally-spawned salmon runs.
7. Assess the use and effectiveness of instream flow regulations to protect salmon populations.
8. Develop integrated, comprehensive datasets tracking salmon populations and their environment throughout the state.

Inequities in access to water in California existed before the drought began in 2012, but lack of water made the outcome of these inequities more severe. Low-income families, those who are disproportionately burdened by multiple sources of pollution, and those who depend on aquatic ecosystems for their livelihood and traditions

are highly vulnerable to problems of supply shortages, rising unaffordability, and insufficient streamflows. Unless we act, drought's impacts on these communities will become more severe as climate change progresses, given that scientists predict longer, more severe, and more frequent droughts. We offer the Drought and Equity report and the recommendations within as a tool for community members and decision-makers to improve the resilience of all Californians, including the most vulnerable, to future droughts.

INTRODUCTION

California recently suffered the driest four years in state history, and despite somewhat wetter conditions since late 2015, 75 percent of the state remains in drought conditions as of December 2016 (U.S. Drought Monitor 2016). Cities and farms, despite feeling the effects of curtailed water supplies, have by and large demonstrated great resilience (Hanak et al. 2015; Cooley et al. 2015), but small water suppliers and natural systems have not fared as well. Some public water systems struggled to deliver safe water to their customers, thousands of household wells ran dry, and endangered fish reached the brink of extinction (Moyle 2014; Braxton Little 2016; State of California 2016). And while urban water suppliers maintained clean water delivery during the drought, many of their low-income customers struggled with the rising cost of water (Cooley et al. 2016).

In this report, we examine three major impacts of the drought. The first two—shortages and price hikes—affected people's access to safe, affordable, adequate water in their homes. The third arena we investigate is salmon fishery performance during the drought, and how it affected commercial and tribal fishermen reliant on salmon for income, food, and cultural traditions. We selected these topics based on input from a diverse set of stakeholders. While we were unable to explore them in-depth in this report, the impact of drought on farmworkers, water quality, and subsistence fishermen (beyond the tribes we discuss in Section 3), are also critical issue areas that deserve further analysis.

Our goals were to synthesize available information from the state, media outlets, and non-governmental organizations (NGOs) and develop recommendations on how to mitigate the impacts of future droughts. This report is intended to provide information to community groups to advocate for their own interests, as well as to inform policymakers and other decision-makers interested in crafting more effective drought response strategies, particularly to address the needs of the state's most vulnerable communities.

This project was conceived of cooperatively by the Pacific Institute and the Environmental Justice Coalition for Water (EJCW). To oversee the project, we convened a nine-member California Drought and Equity Advisory Committee representing a range of perspectives and interests:

Sara Aminzadeh, *Executive Director, California Coastkeeper Alliance*

Colin Bailey, *Executive Director, Environmental Justice Coalition for Water*

Carolina Balazs, *Visiting Scholar, University of California, Berkeley*

Wendy Broley, *Staff Engineer, California Urban Water Agencies*

Amanda Fencl, *PhD Student, University of California, Davis Center for Environmental Policy and Behavior*

Kelsey Hinton, *Program Associate, Community Water Center*

Gita Kapahi, *Director, Office of Public Participation, State Water Resources Control Board*

Brittani Orona, *Environmental Justice and Tribal Affairs Specialist and Native American Studies Doctoral Student, University of California, Davis*

Brian Pompeii, *Lecturer, California Polytechnic State University, San Luis Obispo*

Tim Sloane, *Executive Director, Institute of Fisheries Resources*

The Advisory Committee helped determine the scope, identified project outcomes, developed recommendations, and reviewed the report. Profiles of the Advisory Committee members and their organizations are given in Appendix IA.

This report builds on previous work by the Pacific Institute and EJCW focused on the San Francisco Bay Area, which brought together eight community partners to identify drought impacts and concerns and develop a set of recommendations for addressing them. This work was summarized in a report on Drought and Equity in the San Francisco Bay Area (Cooley et al. 2016), and culminated in a day-long summit in July 2016 that brought together representatives of Bay Area community organizations, water managers, local government, and water and justice nonprofits.

The report is divided into three sections. Section 1 highlights domestic water shortages both in public and the non-public systems that serve very few people, such as private wells. Section 2 examines drought surcharges, and how they affected water affordability for low-income households. Section 3 examines the impact of the drought on commercial and tribal fishermen reliant on salmon for their livelihood and cultural traditions. We conclude each section with recommendations for mitigating impacts of future droughts for the impacted communities.

SECTION 1.
DROUGHT AND DOMESTIC WATER SHORTAGES

OVERVIEW

With the recent passage of the Human Right to Water (CA Water Code Section 106.3), California has declared that access to sufficient water for cooking, consumption, and sanitation is a basic human right. Yet, water shortages for basic household needs have been widely reported over the last several years due to the ongoing drought (Braxton Little 2016; SWRCB 2016a; Becerra 2014; Lurie 2016). Since 2012, thousands of households reported that their wells have run dry, while hundreds of public water systems have applied for financial assistance to address dwindling or contaminated supplies. The state spent $66 million on emergency drought responses related to drinking water from July 2013 to June 2016 for programs such as delivering water to households, deepening wells, and consolidating water systems (Legislative Analyst's Office 2016). Addressing the underlying vulnerabilities in domestic water supplies is all the more urgent given that droughts are likely to become longer, more frequent, and more severe due to climate change (Dettinger et al. 2011).

Despite growing public concern and several state and local programs to address water shortages, the scope and severity of the statewide problem are not well understood. Rural, low-income, primarily Latino communities in the San Joaquin Valley such as East Porterville deservedly received a great deal of media attention when families' private wells ran dry and residents had to survive without running water, often for years (Box 1-1). But outside the intense coverage of the worst-affected communities, the overall extent and severity of water shortages during the drought is not well understood. Water utilities resorted to hauling in tanks of water and delivering bottled water as stopgaps while they identified long-term solutions to water shortages, but these problems were often only reported in the local paper, if at all. Here we pull together a number of datasets to gain a statewide perspective on domestic water shortages during the ongoing drought. Where did shortages occur? What types of water systems were impacted? What were the demographic and socioeconomic characteristics of the impacted communities? Our goal is to better understand which water sources were most vulnerable to drought, so we can improve the resiliency of domestic water supplies in future dry periods.

METHODS

Categories of Water Systems

We divided water systems into seven categories based on size, type of customers, and how they are regulated. This is consistent with the approach used in a recent Department of Water Resources report, *Californians Without Safe Water and Sanitation* (DWR 2014a). A public water system is defined in

Box 1-1.

Experiences of Tulare County Residents Living With Water Shortages

On Dec. 12, 2016, California Drought and Equity report authors, and Kelsey Hinton of Community Water Center and the Drought and Equity Advisory Committee, addressed a meeting of the AGUA Coalition (la Asociación de Gente Unida por el Agua, or the Association of People United for Water). AGUA is a regional, grassroots coalition of impacted community residents and allied non-profit organizations dedicated to securing safe, clean, and affordable drinking water for the San Joaquin Valley. It works closely with the Community Water Center.

We presented a summary of the report findings and recommendations, and asked meeting attendees to add their recommendations or tell us experiences that should be documented. Here are some of the responses.

"I've lived without water for two years, seven months. It's important to point out the urgency to get long-term solutions more rapidly than we're getting them now."

"I've been to at least two meetings where people address the Board of Supervisors of Tulare county, and a Supervisor says, 'Well my well went dry too, and I had to drill a new well.' But there's a big difference between that and someone whose well went dry, and then they had to go without water for more than two years."

"Many agencies got money to help, but maybe what is missing is a group, like the AGUA coalition, that even when the money runs out, they continue to work on this issue. People have submitted applications to agencies for money, but the money has already run out, and then the organization just shuts down. People have problems where they submitted original documents to an agency that ran out of money and haven't gotten them back so they can't put in a new application. So agencies need to stick around."

"Our community has been without clean water for more than 10 years. Then who do we call? We call the county, they're closed, or they give you a different number... nobody knows who to call."

the California Health and Safety Code (CA HSC) as a system that has "15 or more service connections or regularly serves at least 25 individuals daily at least 60 days out of the year" (CA HSC § 116275). The California State Water Resources Control Board (SWRCB) oversees approximately 8,000 public water systems in the state that deliver drinking water to the vast majority of the population. The U.S. Environmental Protection Agency (U.S. EPA) regulates the 125 tribal water systems in the state.

Systems too small to meet the threshold for a public water system are referred to as non-public water systems.[1] There are three types of non-public water systems: state small water systems, local small water

1 A public water system has 15 or more service connections or regularly serves at least 25 individuals daily at least 60 days out of the year (CA Health and Safety Code Section 116275(h)). In this report, we use the term "non-public water system" to refer to any system that has fewer than 15 service connections and serves fewer than 25 individuals daily.

systems, and private domestic wells (or surface diversions). Water quality of state small water systems is regulated at the county and local level; water quality in local and private systems has relatively few regulations. Table 1-1 summarizes the seven categories of water systems.

Table 1-1. Categories of Water Systems in California

Name	Definition	Estimated Population Served (2016)[1]	Drinking Water Quality Regulating Agency	Typical Customer Type
Public Water System	15 or more service connections or serves at least 25 individuals daily at least 60 days out of the year (CA HSC § 116275(h))			
Community Water System	At least 15 service connections used by year-long residents or regularly serves at least 25 year-long residents of the area served by the system (CA HSC § 116275(i))	41,300,000	SWRCB	Residential areas; can also include non-residential areas in addition to homes
Transient Non-Community Water System	Does not regularly serve at least 25 of the same persons over six months per year (CA HSC § 116275(o))	981,000	SWRCB	Restaurants, campgrounds, parks, motels and other non-residential areas
Non-Transient Non-Community Water System	At least 25 of the same persons over six months per year (CA HSC § 116275(k))	412,000	SWRCB	Schools, workplaces
Tribal Water System	At least 15 connections or 25 people daily, serving a federally recognized tribe	224,000	U.S. EPA	Facilities on tribal land
Non-Public Water System	Fewer than 15 service connections or serves fewer than 25 individuals daily at least 60 days out of the year			
State Small Water System	At least five, but not more than 14, service connections and does not regularly serve drinking water to more than an average of 25 individuals daily for more than 60 days out of the year (CA HSC § 116275(n))	Data not available	County and local health departments	Small number of people served in any type of location
Local Water System	2-4 service connections[2]	Data not available	N/A	"
Private Domestic Well (or Surface Diversion)	1 service connection[2]	600,000 – 2,000,000 use wells; population served by surface diversions unknown	N/A	"

1. Population served figures are approximations made by the water utilities. Note that the populations served by the different types of water systems overlap. Numbers rounded to three significant figures. Data from Safe Drinking Water Information System (SDWIS) (SWRCB 2016c), except domestic wells from DWR (2013), and Tribal Water Systems from U.S. EPA(2016).
2. Definition given in "Californians Without Safe Water and Sanitation: California Water Plan Update" (DWR 2014a).

Analysis 1: Drought-Impacted Public Water Systems

We identified drought-impacted public water systems using three statewide datasets:

- Community water systems and non-transient non-community water systems serving schools that had applied for assistance from the SWRCB as of July 2016, due to drought-related impacts on drinking water supply or quality that could not be addressed with their existing funding (SWRCB 2016e);
- A SWRCB survey in December 2015 of community water systems with 15-3,000 service connections on their ability to provide water if the drought continued through 2016 (SWRCB 2016d); and
- a July 2015 assessment of tribal water systems for multiple factors linked to drought vulnerability, such as changes in supply and availability of an alternative source of water (IHS 2015).

These datasets have a number of limitations. To our knowledge there is no single, comprehensive dataset on public water system shortages during the ongoing drought. The list we compiled reflects a best effort with available data and should be viewed as a preliminary, and likely incomplete, assessment of public water systems that have experienced drought impacts that actually, or nearly, resulted in shortages. A more careful, consistent means of collecting information on drought shortages would enable a more thorough understanding of vulnerable water systems. Nonetheless, the list provides an indication of where the known problems are concentrated, as well as a minimum number of systems affected by the drought.

Once we compiled a master list of drought-impacted systems, we mapped the locations of the systems and quantified the number serving vulnerable communities. We used two definitions of a vulnerable community, following definitions used by state agencies. A Disadvantaged Community (DAC) is a census block groups with a median household income under 80 percent of the state median household income (Department of Water Resources (DWR) 2016). A Cumulatively Burdened Community (CBC) is a census tract that ranks in the top quarter of tracts in the state for environmental burdens and socioeconomic vulnerability (California Environmental Protection Agency (CalEPA) 2014).[2]

We give further details on datasets used in the analysis of drought-impacted public water systems in Appendix 1A.

Analysis 2: Water Shortages in Households Served by Non-Public Water Systems

We also looked at shortages in households served by water systems too small to be regulated as public water systems. These data are likely an undercount of the true number of household shortages.[3] But as with the data on drought-impacted public water systems, they indicate where the known problems were concentrated, as well as a minimum number of households affected. In Tulare County, we had sufficiently detailed data on household shortage locations to map them, and calculate how many were in DACs and CBCs.

2 This definition takes into account 20 factors in the categories of pollution exposure indicators, environmental effects indicators, sensitive population indicators, and socioeconomic indicators. Two of the factors relate directly to water quality: groundwater threats and drinking water contaminants.

3 Household shortages may not be included in the statewide dataset for a number of reasons, including: not all counties had reporting mechanism in place; people that are financially able to deepen or drill a new well themselves are unlikely to communicate a problem to the officials; and people may choose not to report a shortage because they prefer to avoid interaction with government officials.

RESULTS AND DISCUSSION

Drought-Impacted Public Water Systems

For our first analysis, we identified 127 community water systems with potential or actual drought impacts to their water supply between 2014 and 2016 (Table 1-2), and an additional 22 non-community water systems facing supply vulnerabilities. Most of the community water systems (72 percent) were small, serving 1,000 connections or fewer. This is consistent with the fact that 77 percent of community water systems in California are small. The drought-impacted systems in our list served approximately 480,000 people.[4] A complete list of the 149 drought-impacted systems is provided in Appendix 1B.

Drought-impacted systems were found in most California counties (Figure 1-1a). The greatest number were in Madera (24) and Tulare (12) counties. There was also a relatively large number of drought-impacted systems in Mendocino County (13). The impacts correspond roughly to

4 Population served was calculated by adding the population served listed either in SDWIS (SWRCB 2016c) or the U.S. EPA's list of tribal water systems (U.S. EPA 2016). This number is an approximation of population served, and individuals can be served by more than one system in their home versus other places they visit.

Table 1-2.

Drought-Impacted Public Water Systems in California

	A	B	C	D	E

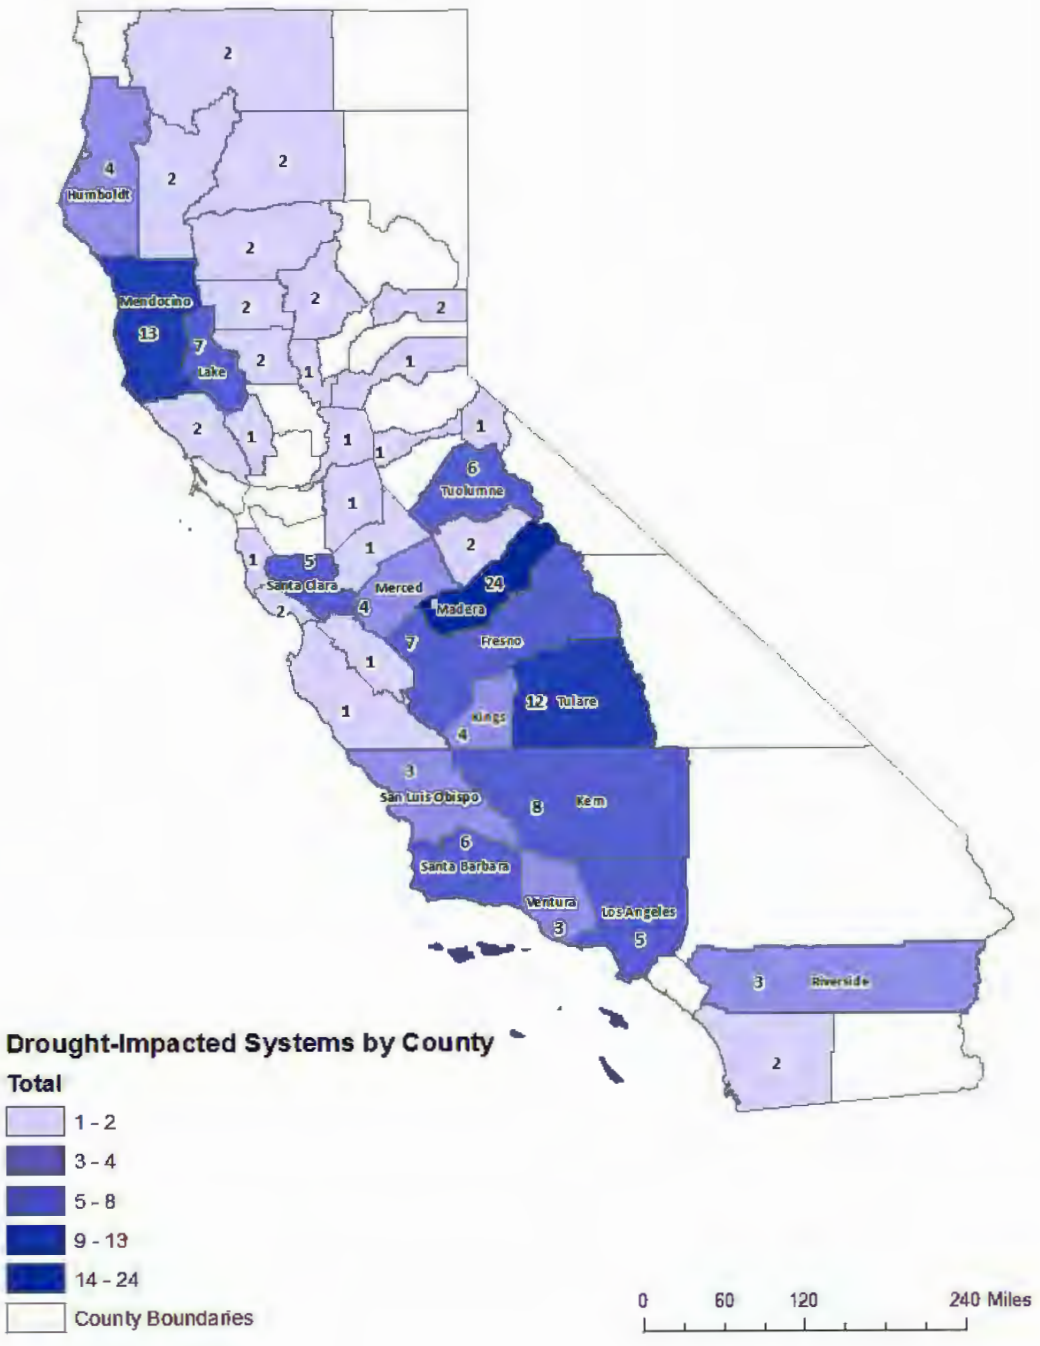
Non-Transient Non-Community	**13[1]**	**3**	**NA**	**16**	**5,550**
Transient Non-Community	**NA[2]**	**6**	**NA**	**6**	**1,660**
				Grand Total: 149	**480,000**

1. Of non-transient non-community systems, only systems serving schools were eligible for funds.
2. Transient non-community systems were not eligible to apply for funds.
3. Columns A-C do not necessarily sum to the total in Column D because duplicates appearing in both Columns A and B were eliminated.
4. Rounded to three significant figures. Figures may not sum to total due to rounding errors.



Note: Columns A-C summarize three sources of information on drought-impacted public water systems in California.

Sources: Column A based on data from SWRCB (2016e), Applications for Drought Assistance Funding. Column B based on data from SWRCB (2016d), Small Supplier Conservation Reports. Column C based on data from IHS (2015), July 2015 Drought Vulnerability and Risk Assessments for Tribal Drinking Water Systems. Column E based on SDWIS (SWRCB 2016c).

the state's hydrologic regions, with no impacted systems found in the eastern regions of North and South Lahontan, nor in the San Francisco hydrologic region. The greatest concentrations were in the San Joaquin River, Tulare, North Coast, and Central Coast hydrologic regions. The population served by impacted systems shows somewhat different patterns. The five counties

Figure 1-1a.

Number of Drought-Impacted Public Water Systems in Each County

Notes: Numbers and shading indicate drought-impacted public water system in each county, with darker colors signifying greater numbers. Blank counties had zero drought-impacted systems reported in the datasets surveyed.

Sources: Data compiled in Appendix 1B, from SWRCB (2016c), SWRCB (2016e), SWRCB (2016d), IHS (2015).

with the greatest number of people served by drought-imapcted systems were Santa Barbara (estimated 210,000 people served), Tulare (82,000), Kings (74,000), Tuolomne (23,000), and Mendocino (20,000) (Figure 1-1b).

A large proportion of drought-impacted community water systems were located in low-income and disadvantaged communities. The publicly available map of California's public water systems only gives information for some of

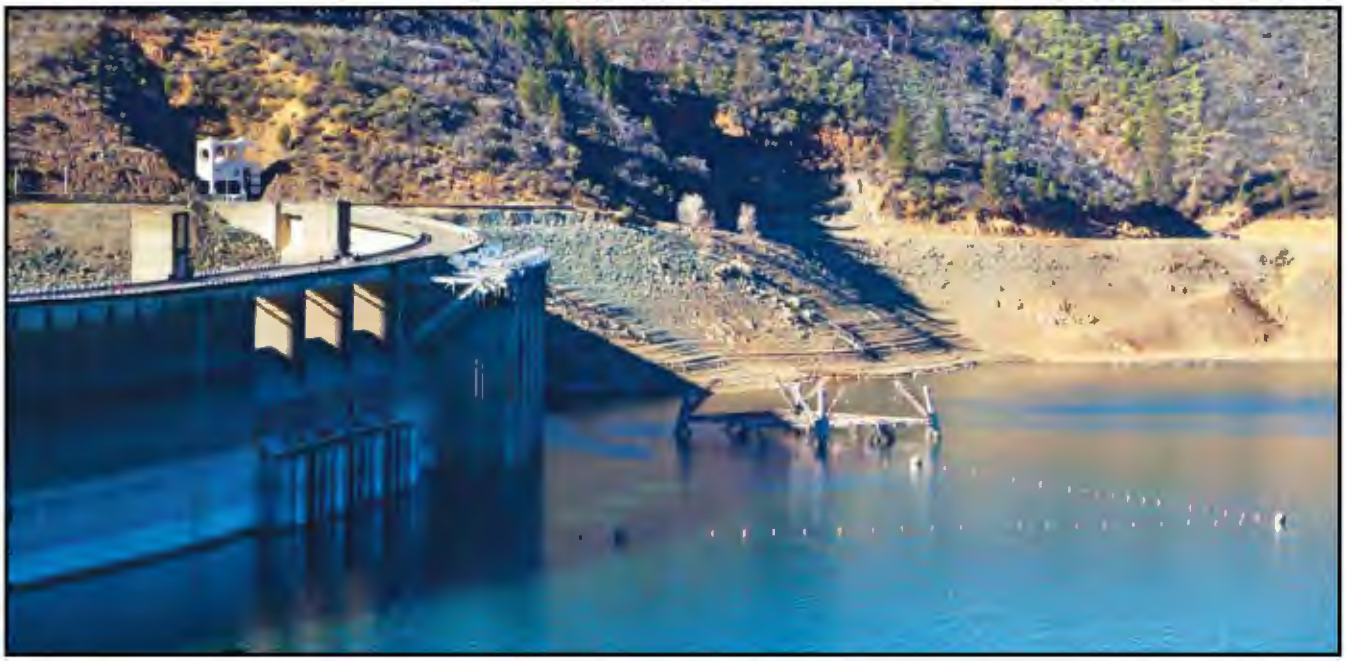


Figure 1-1b.

Population Served by Drought-Impacted Public Water Systems in Each County

Notes: Numbers and shading indicate the estimated number of persons served by drought-impacted public water system in each county, with darker colors signifying greater numbers. Blank counties had zero drought-impacted systems reported in the datasets surveyed.

Source: Slobo

the state's systems, so we were able to map only 97 of the 144 drought-impacted community water systems. Of those, 65 (67 percent) served a DAC, while 28 (29 percent) served a CBC.

Among the 122 public water systems that applied for emergency drought funding, nearly half received funding to haul in water via truck, or deliver bottled water to customers. These systems had reached acute emergencies in which they could not provide safe, sufficient tap water. In total, 52 systems fit this description: 27 received funding to haul water, 24 for bottled water, and 1 for both. The remaining funding was directed to long-term solutions to drought emergencies, such as well overhauls, new wells, new interties to neighboring systems, and new filtration devices. In most cases, whether the underlying problem was one of quality or quantity was ambiguous. In only one case did the project description explicitly mention that the water system's well had run dry. On the other hand, there were 20 project descriptions that indicated that the project intended to address quality concerns; usually the funded project included at least bottled water delivery, and sometimes a long-term solution as well, such as a new filtration device. A portion of the emergency drought assistance funds were explicitly for "contaminated drinking water supplies exacerbated by drought conditions" (CA Budget Act of 2014, Statutes of 2015). This funding was intended to address concerns that drought was causing contamination of water supplies. However, the relationship between drought and the quality of water Californians drink is complex, and we could not find evidence that the quality of drinking water in the state deteriorated because of drought (Box 1-2).

Water Shortages and Non-Public Water Systems

For our second analysis, we looked at shortages reported by households served by non-public water systems. From January 2014 through August 8, 2016, the state received 3,749 reports of shortages in households served by non-public water systems (serving under 15 connections/25 individuals). Most of the reports were concentrated in the counties that are in the San Joaquin Valley, with

Box 1-2.

Drought and Drinking Water Quality

We did not directly seek to document impacts of drought on drinking water quality in this report. However, our Advisory Committee members flagged this as a key concern for public health during droughts. Water systems can experience supply problems either because of an insufficient volume of water, or an insufficient amount of clean water. Emergency drought funding criteria include the intertwined nature of water quality and quantity, making funds available both for supply shortages and for contamination of drinking water exacerbated by drought (Assembly Bill 91, Statutes of 2015, Section 31). Here we review the available literature on the potential link between drought and declining water quality, and its impacts on DACs.

Droughts may cause significant changes in water quality and adversely impact drinking water supplies. For example, warmer surface water temperature, reduced flows, and high nutrient concentrations have resulted in algal blooms in lakes and reservoirs throughout California. These potentially toxic blue-green algae, or cyanobacteria, were the cause of poorer taste and smell of drinking water supplied to East Bay residents in 2015 (EBMUD 2015). Treatment processes can remove harmful substances, and thus these blooms have not been linked to health concerns. A major water quality problem that needs to be carefully managed during drought is the potential for salt water to intrude further into the Sacramento-Bay Delta, contaminating not only water distributed throughout the state via the State Water Project and Central Valley Project, but also water used by Delta farmers and water districts in nearby Contra Costa, Alameda, and San Joaquin counties (DWR 2014b). Other surface water quality indicators relating to the drought such as nutrient concentrations, dissolved oxygen, and organic carbon have shown mixed responses (Mosley 2015).

Communities most vulnerable to degraded water quality because of drought are likely to be those depending on non-public water systems, including private domestic wells and those served by water systems with less than 15 service connections, as these sources are not as intensively regulated or monitored. Up to two million California residents rely on private domestic wells, and unknown numbers use water from local and state small systems (SWRCB 2015b). Private domestic well owners and non-public water system operators are responsible for maintaining their water supplies and ensuring that water quality meets drinking water standards, but problems are likely to remain undetected or unaddressed due to the lack of financial and technical resources.

Drought conditions may exacerbate existing water quality problems. Given that the presence and concentration of arsenic are related to hydrologic and biogeochemical processes, higher evapotranspiration rates can increase arsenic concentrations in surface water and shallow groundwater (Beard, Fujii, and Shanks 1994; Gao, Tanji, and Bañuelos 2007). The drilling of deeper wells as a response to water shortages may cause releases of arsenic from sedimentary rocks. However, there is limited understanding of arsenic transport in sediments in all of California's key groundwater basins. Uranium, another naturally-occurring element, may also increase its concentrations in groundwater during a drought. Jurgens et al. suggested that changes in the chemistry of recharge water and increases

Box 1-2. (*Continued*)

Drought and Drinking Water Quality

in the rate of downward groundwater flow have led to uranium concentrations above drinking water standards in both domestic and public wells. Higher recharge temperatures have been found to correlate with uranium levels (Jurgens et al. 2010). Moreover, uranium contamination is linked to nitrate, which plays a role in increasing the solubility of uranium in water (Nolan and Weber 2015). This secondary uranium contamination is expected to worsen in areas with high agricultural activities and groundwater dependence.

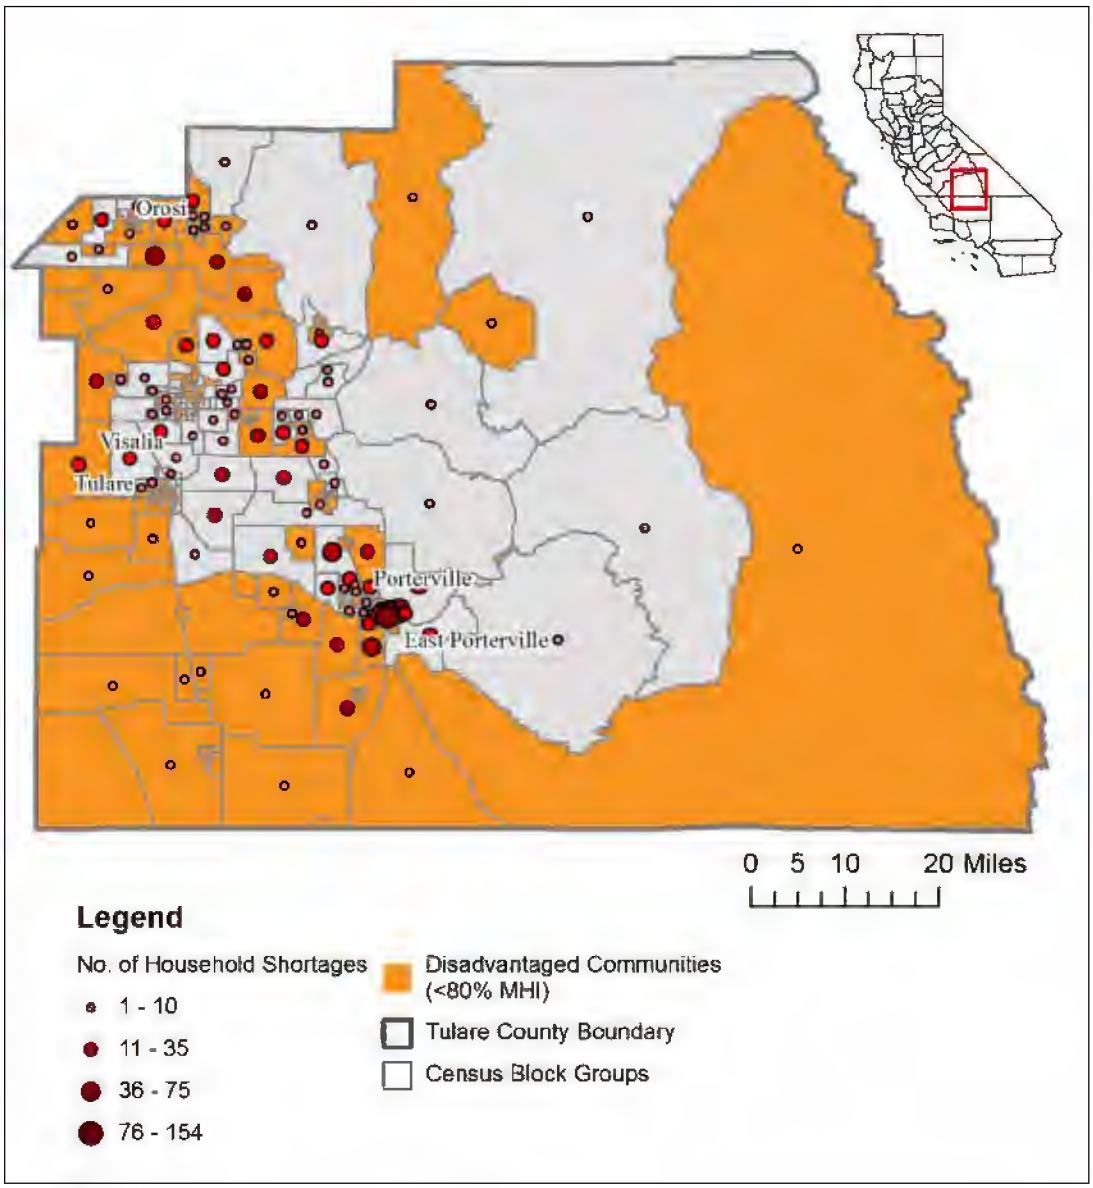
Despite some evidence of drought's negative impacts on water quality, further research is needed to document and assess the mechanisms and implications of these impacts. While drought can alter the quality of water supplies, water systems have methods to remediate the problem by treatment and mixing with higher-quality sources. Little is still known about the extent of drought impacts on the quality of water that reaches customers' taps, how many people receive lower-quality water during a drought, and how reduced water quality during drought affects minorities or socio-economically disadvantaged communities across the state. Some limited data and monitoring programs already exist. Water quality reports required under the Safe Drinking Water Act may be used to track water quality changes during the drought, but they do not include very small drinking water systems and private domestic wells. SWRCB's Surface Water Ambient Monitoring Program (SWAMP) and Groundwater Ambient Monitoring and Assessment Program (GAMA) can provide relevant resources to monitor water quality and trends. However, they also have limited temporal and geographic scopes. Data on groundwater levels are generally lacking or of poor quality, although efforts are being made under the Sustainable Groundwater Management Act (2014) to standardize and expand groundwater data collection and monitoring activities. In addition to data gaps, the complexity of hydrologic and biogeochemical processes presents another challenge in drawing clear relationships between the drought and water quality issues. More attention should be given to determining these linkages, especially in relation to drinking water supplies, to protect communities from unsafe drinking water.

Water quality issues have been shown to disproportionately affect minorities and residents of lower socio-economic status for community water systems that are subjected to federal and state drinking water regulations. (Balazs et al. 2012) found that community water systems serving predominantly low-income and socially disadvantaged groups have high arsenic levels in drinking water and are more likely to receive a Maximum Contaminant Level (MCL) violation.

1,571 (42 percent) in Tulare County alone (Figure 1-2). In Tulare County, these numbers generally reflect households that needed deliveries of bottled water and tanks of non-potable water hooked up to their plumbing. Typically, households that could resolve the problem on their own by drilling or deepening a well did not report a shortage to the county (A. Fencl, PhD Student, UC Davis, personal communication, Dec. 13, 2016). A list of all shortages by county is provided in Appendix 1C.

Figure 1-2.

Household Water Supply Outages Reported by County



Notes: Map shows cumulative reports of household water supply shortages by county from July 2014 to August 2016. Counties with "no reports" may represent zero shortages, or simply a lack of data collection and reporting. Households reported dry wells and surface water supply shortages. Figures include active outages, active supply problems, resolved outages, and outages where interim solutions have been implemented. Only eleven counties report interim and/or permanently resolved outages.

Source: Reproduced from the State of California Household Water Supply Shortage Reporting System (State of California 2016).

For Tulare County (the only county for which detailed data are available), we mapped the number of reported shortages (Figure 1-3). The outages all occurred in the western and central portion of the county. Sixty-six percent of the reported shortages occurred in a DAC, and 89 percent occurred in a CBC. Households in DACs will likely need financial assistance to resolve their water shortage. Drilling a new individual domestic drinking water well in the San Joaquin Valley is prohibitively expensive for a low-income household, costing between $25,000 to $35,000 in 2016 (Susan Atkins, Self Help Enterprises, personal communication, July 28, 2016). Median

household income in a DAC was $49,191 in 2016 (DWR 2016a). Many of these communities are already known to be sensitive populations and to be heavily burdened by other environmental problems, underscoring the urgency of resolving their water shortages, which can aggravate public health problems (CDPH and TCHHSA, 2015).

While most reported well shortages occurred in DACs and CBCs, it is unclear what drives the pattern, and whether the link is anything but a coincidence. There are a number of non-exclusive possible causes for the clustering of shortages in central Tulare County, and their overlap with DACs and CBCs. Some possible drivers for the

spatial pattern of shortages are hydrogeological. Many of these wells are quite shallow and susceptible to short-term fluctuations in the water table, or tap low-permeability fractured hard rock aquifers that are vulnerable to drought (DWR 1991; Jones 2014; DWR 2016b). The clusters of shortages may simply occur in the areas with the greatest density of wells. On the other hand, there could be systematic reasons for the correlation. Low-income communities and communities of color in the Central Valley rely disproportionately on private wells because adequate public services were not developed in those communities (Bliss 2016). The outages in domestic wells may also

be at least partially caused by rapid pumping by deeper irrigation wells.

Reporting bias could also be a factor: residents typically reported a shortage when they were seeking bottled and hauled water deliveries; those with the financial means to resolve their water shortage were less likely to report a shortage. To fully understand the drivers of household outages would require a complex study beyond the scope of this report.

Conclusions and Reccomendations

We found 149 public water systems, serving an estimated 480,000 people, reported drought-related impacts to their supplies. These systems were concentrated in the southern San Joaquin Valley, as well as the North Coast and Central Coast regions. We estimated that approximately two-thirds of these public water systems served a DAC, and one-third served a CBC. Of the nearly 4,000 shortages in households served by non-public water systems, most were concentrated in the San Joaquin Valley, with 42 percent of the reports in Tulare County. Of the shortages reported to the county, 66 percent were in a DAC, and 89 percent were located in a CBC. Our findings demonstrate that, while they were concentrated in the San Joaquin Valley, shortages in both public and non-public systems were more widespread geographically in the state than has been represented in media reports. Supply problems during the drought were frequently found in DACs and CBCs, suggesting that in many cases these systems have insufficient capacity to resolve their problems without outside technical, managerial or financial support. We recommend that the state undertake a more uniform, thorough effort to document which public and non-public systems experienced near or actual supply shortages. This data would allow an analysis of the characteristics that made systems more vulnerable to drought, and inform efforts to improve future resilience.

RECOMMENDATIONS TO IMPROVE DROUGHT RESILIENCE OF DOMESTIC WATER SUPPLIES

Mitigating Impacts of Drought on Domestic Water Supplies for Communities

1-1. Establish a Quantitative Metric for Measuring Supply Reliability in Public Water Systems

Assessing supply reliability is an important step in identifying public water systems that need improvements to prevent shortages in future dry years. The data to inform a quantitative "supply reliability" metric should be collected for all public water systems. At present, there is relatively little scrutiny on supply reliability for water systems too small to meet Urban Water Supplier[5] reporting requirements, even though smaller suppliers struggled most during the drought. Data collected and quantified should include at least the following:

- Predicted production to demand ratio in an average year, as well as droughts lasting one, three, and five years.
- Any recent shortfalls in supply that resulted in an inability to deliver enough water for consumption, cooking, and sanitation to residential customers, drops in pressure or outages, or water hauling, along with the dates of any such events, and the volume of the shortfall.

1-2. Require Water Shortage Contingency Plans of All Public, State Small[6], and Local Water Systems[7]

Small and rural communities tend to be the most vulnerable to drought, yet often lack comprehensive plans to cope with the impacts. At present, only urban water suppliers are required to prepare and file water shortage contingency plans with DWR and stress tests with the SWRCB. We recommend that the state require all public water

5 Urban Water Suppliers are defined as "providing water for municipal purposes either directly or indirectly to more than 3,000 customers or supplying more than 3,000 acre-feet of water annually." (CA Water Code Section 10617). Urban Water Suppliers report information on supply reliability under the SWRCB's Emergency Urban Water Conservation Requirements, as well as DWR's Urban Water Management Plans.

6 A State Small Water System has 5-14 service connections and does not regularly serve drinking water to more than an average of 25 individuals daily for more than 60 days out of the year.

7 A Local Water System has 2-4 service connections.

systems to file water shortage contingency plans, and that the state provide technical and financial assistance as needed in preparing the plans. At the regional level, counties should draft a water shortage contingency plan template appropriate for state small and local water systems and require the systems within their jurisdiction to modify the plan as necessary and adopt it. The IHS' California Area Office's work with tribal water systems to develop drought contingency plans can serve as a model of how to work with small water systems to develop water shortage contingency plans.

1-3. Increase Oversight of New Wells

Thousands of households reliant on private wells and surface diversions lost access to water during the drought, while those with the resources to drill deeper wells continued to pump groundwater at record-breaking rates. Counties should place restrictions on new well permits in basins where domestic water wells are at risk of outages. The Sustainable Groundwater Management Act begins to go into effect for high and medium priority basins subject to critical conditions of overdraft in 2020, and for other high and medium priority basins in 2022. Until then, counties, in collaboration with other well-permitting authorities, should exercise their authority to regulate groundwater use by issuing permits on the condition that the applicant demonstrate that water is available to serve the well.

Further Study and Data Collection on Domestic Water Shortages

1-4. Collect Information on Well Depth from Drilling Permit Applications

At present, well permits collected at the county level do not always include well depth information. Including this information would enable county officials to flag and require modifications to drilling plans for new wells likely to overdraft an aquifer that supplies domestic wells.

Shortages in both public and non-public systems were more widespread geographically in the state than has been represented in media reports.

1-5. Systematically Collect Data on Private Supply Shortages

We know from voluntary reporting compiled by the state[8] that there have been thousands of private domestic well shortages and surface diversions during the ongoing drought. However, the data set on private supply shortages is incomplete and inconsistent because reporting is voluntary and handled differently across counties. We recommend that the state develop a mandatory, standardized system for reporting private supply shortages to the counties that can be compiled into a statewide dataset. Likewise, the U.S. EPA and IHS should collect data on shortages in private well and surface diversions on tribal lands.

1-6. Identify Geographic Areas at Risk of Groundwater Supply Shortages

High-quality data on household outages would enable an analysis of the causes of wells shortages or failures. Factors to consider are the rate of groundwater decline, the type of aquifer, the proximity, depth and demand of nearby wells, and nearby land uses. A more complete understanding of the causes of well outages and failures could enable predictions of where future outages are

8 See the State of California Household Water Supply Shortage Reporting System at https://mydrywatersupply.water.ca.gov/report/publicpage.

likely to occur, and allow proactive planning to find reliable water sources before shortages occur.

1-7. Identify Public Water Systems at Risk of Future Supply Problems

Can we identify characteristics of public water systems that made them more likely to experience supply impacts during the ongoing drought? In various reports and media outlets, observers have pointed to myriad factors such as system size, region, groundwater versus surface water, diversity of supplies, and ability to transfer water from other systems as indicators of drought resilience. We recommend a rigorous assessment of the common factors in systems that experienced supply impacts during the ongoing drought. This can inform further discussion about systems likely to experience problems in the future, and how to prevent shortfalls.

1-8. Identify Areas with High Potential for Consolidation or Extension of Service

The SWRCB has supported voluntary system-level consolidations, and as of 2015 has the authority in certain circumstances to mandate consolidations. High-quality data on public water systems that experienced supply problems and private supply shortages would enable the state to identify areas that could benefit the most from consolidation, either by connecting many households reliant on private wells or surface diversions into a new public water system, or by connecting them to an existing public water system that has the capacity to serve them.

SECTION 2.
DROUGHT CHARGES AND WATER AFFORDABILITY

OVERVIEW

Affordability is a central element for ensuring basic access to water—a human right recognized by the state of California—yet many Californians struggle to pay their water bills. Studies in select regions of the state have found that the cost of water for 20 to 50 percent of households with average water use exceed the U.S. Environmental Protection Agency's affordability thresholds for water and wastewater (Christian-Smith et al. 2013; United States Conference of Mayors 2014). Rising water costs are exacerbating water affordability concerns. Hanak et al. (2014) found that water bills in California's urban areas increased two to three times faster than inflation between 2000 and 2010 to cover infrastructure and other system costs. To make matters worse, Proposition 218, a ballot measure approved by California voters in 1996, prevents publicly-owned water utilities from using water-rate revenue to subsidize low-income customers (Box 2-1).

Water rates tend to rise during a drought, worsening affordability concerns. Costs may increase, for example, if a water utility must purchase more expensive drinking water supplies, install or upgrade treatment technologies for lower quality water, or pump groundwater from greater depths. For example, the East Bay Municipal Utility District drew from a more expensive emergency supply in both 2014 and 2015 (Figueroa 2014; Figueroa 2015). Administering conservation programs can also increase costs for utilities. As water use declines during the drought, water sales may become insufficient to cover the utility's operational costs, most of which are fixed. In response, water utilities may implement temporary drought surcharges, fees, and/or penalties to help cover their costs.

Raising rates or charging additional fees during a drought has important benefits, as it maintains the financial viability of water utilities, and can be an effective means of incentivizing conservation and efficiency. On April 1, 2015, following the lowest Sierra snowpack ever recorded, Governor Jerry Brown issued Executive Order B-29-15, which established a mandatory statewide water conservation target of 25 percent. It also stated:

> *"The Water Board shall direct urban water suppliers to develop rate structures and other pricing mechanisms, including but not limited to surcharges, fees, and penalties, to maximize water conservation consistent with statewide water restrictions."*

While raising per-unit costs is a key component of drought response plans for water utilities, it is nonetheless important to consider the potential equity impacts of raising water prices. Fixed

increases in water costs represent a greater proportion of the annual income for low-income households. High water bills may interfere with a family's ability to pay for other necessities, or cause them to fall behind on their water bills. Late charges can accumulate, or worse, utilities can shut off service for lack of payment. Service disconnections are three times more likely to impact the lowest income households than the average household (Cromwell 2010). Lack of water can lead to health problems, loss of custody of one's children, eviction and foreclosure, and even criminal charges (Jones and Moulton, 2016).

Low-income households tend to use less water, so designing rates, and drought charges, to keep costs low for low-volume users will benefit most low-income households (Mayer et al. 1999; Mini 2013; Rubin 2005). However, there are some complicating factors at play. First, low-income households tend to have more members, and thus larger water bills despite having relatively low per-person use (Saunders 1998). Second, other researchers have argued that low-income customers face financial challenges in upgrading their homes to be efficient, and therefore may be unable to keep their water use low (Cromwell 2010). Repairing leaks and upgrading fixtures and appliances is costly. Furthermore, many low-income customers are renters without the authority to alter their homes.

In this section, we examined available data on drought charges imposed in 2015, including information on the structure of those charges. We evaluated the impact of the structure of drought charges on meeting basic water needs. We then undertook case studies on three water utilities, estimating the monthly bill, with and without drought charges, for an average-size household using 55 gallons per capita per day (GPCD). We also examined the percentage of income that the water bill would represent for households in each of nine income brackets to understand the additional cost burden imposed by drought charges on households, some of which were already paying unaffordable rates.

While increasing costs is a key component of drought management, it is important to consider the equity impacts of raising prices.

METHODS

There are varying definitions of what constitutes affordable water. A common approach adopted by regulatory agencies has been to compare the average residential water bill to the median household income (MHI) for a given region. The California State Water Resources Control Board (SWRCB) uses average residential drinking water costs in excess of 1.5 percent of median community household income as a threshold for affordability, while the U.S. EPA uses a threshold of 2.5 percent (U.S. EPA 1998; SWRCB 2016b). This approach is referred to as "macro-affordability" because it gives a sense of average affordability for an entire region without assessing the burden of water bills for sub-groups within that region. Some have criticized the macro-affordability approach because it masks the cost of water for those that deviate from average income or water use. By contrast, micro-scale indicators of affordability disaggregate households by income group, family type (e.g., household size), or geographic sub-region (Herrington 2003). Past work in California has assessed affordability across the range of income levels within a region (United States Conference of Mayors 2014; Christian-Smith et al. 2013). Others have called for researchers to look at actual, rather than average, water bills by

income, because income is negatively correlated with water use (Osann 2016). To our knowledge there has not yet been an analysis in California that parses out affordability for different water use levels by income or household size.

For this report, we sought to keep our analysis of affordability consistent with earlier work by the SWRCB while addressing some of the criticisms of traditional affordability metrics. Given that this report focuses on California, we used the SWRCB's definition of affordable water as 1.5 percent of household income. However, rather than looking at affordability for median-income households, we divided single-family households into nine income brackets. Additionally, rather than basing water bills on average water use, we estimated water bills, with and without drought charges, for meeting basic water needs (defined below). This approach is a useful starting point to observe how additional charges imposed during drought altered costs for low-income households, and how those charges can be structured to incentivize conservation while minimizing impacts on low-income customers for basic water needs.

As with affordability, there is no single definition for the volume of water necessary to meet basic water needs. The California Human Right to Water declares that all humans have a right to water adequate for human consumption, cooking, and sanitary purposes (CA Water Code § 106.3). In their resolution adopting the Human Right to Water as a core value, the SWRCB pointed to two numbers in California laws and regulations: "The Water Efficiency Act of 2009 identifies 55 gallons per capita per day as a provisional conservation standard for 'indoor residential water use' by 2020" (Wat. Code, § 10608.20, subd. (b)(2)(A)). Similarly, a prior SWRCB emergency regulation established an exemption from a prohibition on diverting water, under specified circumstances, up to a maximum of 50 gallons per capita daily in order to meet 'minimum health and safety needs' (Cal. Code Regs., tit. 23, § 878.1, subds. (a)-(b) [operative March 30, 2015 and repealed Dec. 29, 2015]). By comparison, DeOreo et al. (2011) found that mean indoor household use in California was 63 GPCD in 2007-2009. Other studies suggest that homes equipped with high-efficiency appliances and fixtures would use between 32 GPCD (Heberger, Cooley, and Gleick 2014) and 36 GPCD (DeOreo et al. 2011). Table 2-1 reviews select standards and studies on indoor water needs.

For this report, we defined 55 GPCD as a reasonable volume for meeting basic water needs, based on the indoor water standard established by

Table 2-1.

Indoor Water Benchmarks—How Much Water Do People Need for Indoor Uses?

Gallons Per Capita Per Day (GPCD)	Description	Source
63	Mean water use in a sample of 700 homes in 10 service areas in CA from 2007-2009	DeOreo et al. (2011)
55	Provisional conservation standard for 'indoor residential water use' by 2020	CA Wat. Code, § 10608.20, subd. (b)(2)(A)
36	Mean water use in homes built with best available technologies as of 2010 for toilets, clothes washers, showers, and faucets	DeOreo et al. (2011
32	Theoretical water budget for home built using efficient appliances and fixtures and no household leaks	Heberger et al. (2014)

the California Water Efficiency Act of 2009. This is lower than the average per capita residential water use reported in DeOreo et al. (2011), but more generous than the efficient benchmarks identified by DeOreo (2011) and Heberger et al. (2014).

Structure of Drought Charges

Incomplete data are available on the number of water utilities that have instituted drought charges. We obtained state-collected data on surcharges, fees, and penalties from the SWRCB's 2015 Large Water System Electronic Annual Reports (LWS EAR) (SWRCB 2015a). The LWS EAR are annual reports from public water systems with at least 999 service connections. The 2015 database had records for 731 public water utilities (out of the 8,302 total public water systems in the state listed in the State Drinking Water Information System). All but 10 were community water systems.

In 2015, the report questionnaire asked water utilities two questions that provide some insight on drought charges: "Do you have other surcharges?" and if so, "What are the other surcharges?" The 2015 LWS EAR contained 725 answers to the question. Of these, one-third stated that they had other surcharges and used terms such as surcharges, fees, and penalties to describe them. We did a keyword search for the term "drought" in the surcharge description and found 28 water utilities that reported imposing a drought charge. We believe this is only a sample of water utilities that imposed drought charges and not a complete count. For the 28 utilities reporting drought charges, we used the water utilities' websites or contacted them via phone to determine the structure of the charges. We made up to four phone calls to a supplier and were able to obtain the relevant information for 27 of the 28 utilities.

Given that the structure of drought charges varied widely by utility and customer type, we focused on drought charges imposed on single-family households and categorized each system according to how the utility determined the minimum volume of water at which to add an additional drought charge. Our goal was to determine whether households using less than 55 GPCD would pay drought charges in each service area. The classifications we used were:

a. Threshold type (fixed or customized): Whether the threshold volume for paying a drought charge was fixed or customized according to estimated household needs. In addition, there were two types of customized thresholds:
   i. Customized by household size: The threshold was calculated based on the number of residents in the household;
   ii. Customized by prior use: The threshold was calculated as a percentage of prior use (e.g. every household was asked to reduce their pre-drought water use by a given percentage).

b. Threshold volume: The monthly threshold volume of water at which a customer paid a drought charge.

In cases where billing was bimonthly, we divided the threshold for imposing a drought surcharge by two to make it comparable with those utilities billing on a monthly basis. The results of our survey were then used as the basis for an assessment of the impact of drought charges on affordability.

Impact of Drought Charges to Affordability

Of the 27 water utilities for which data are available, we provide detailed case studies for three. We chose the two utilities with the greatest proportion of their service area in a Disadvantaged Community (DAC): Elsinore Valley Municipal Water District and the City of Glendale Water and

Power.[1] For comparative purposes, we selected at random one of the two utilities that had none of its service area in a DAC, the City of Benicia.

For each supplier, we estimated the water bill for a single-family household using 55 GPCD with and without drought charges for the main city that they serve. We used the data from the United States Census Bureau (United States Census Bureau 2010; United States Census Bureau 2014) to find mean household size and household income for the Cities of Lake Elsinore, Glendale, and Benicia, and calculated monthly indoor water needs for that household. Table 2-2 summarizes this information.

Using the University of North Carolina, Chapel Hill Water & Wastewater Residential Rates Affordability Assessment Tool (UNC—Chapel Hill Environmental Finance Center 2016), we estimated the proportion of income a mean-size single family household would pay to meet monthly indoor water needs, and compared the water bill to household income in nine income categories, ranging from below $10,000 to more than $150,000 annually. We then calculated how drought surcharges affected the percentage of income spent on water for the three lowest income brackets ($24,999 annual income and below). We reported the mean change in the cost of paying for monthly indoor water needs along with the standard deviation.

RESULTS AND DISCUSSION

Structure of Drought Charges

The 27 utilities for which we obtained data were all community water systems and were distributed across 11 counties. They were broadly dispersed geographically, but none were north of Sacramento County. One-third offered lifeline rates or low-income subsidies. Detailed information on drought charges for the utilities surveyed is provided in Appendix 2A.

1 DACs are areas with a median household income less than 80 percent of statewide median household income.

Table 2-2.

Characteristics of Cities Profiled in Affordability Case Studies

	Lake Elsinore	Glendale	Benicia
Population[1]	51,821	191,719	27,450
Number of Households[2]	14,788	72,269	10,686
Median Household Income ($)[3]	63,303	52,451	89,094
Mean Household Size[2]	3.48	2.63	2.52
Basic Household Monthly Water Use (in gallons)[4]	5,800	4,400	4,200
Water Supplier	Elsinore Valley	Glendale City	City of Benicia
Public Water System ID	CA3310012	CA1910043	CA4810001

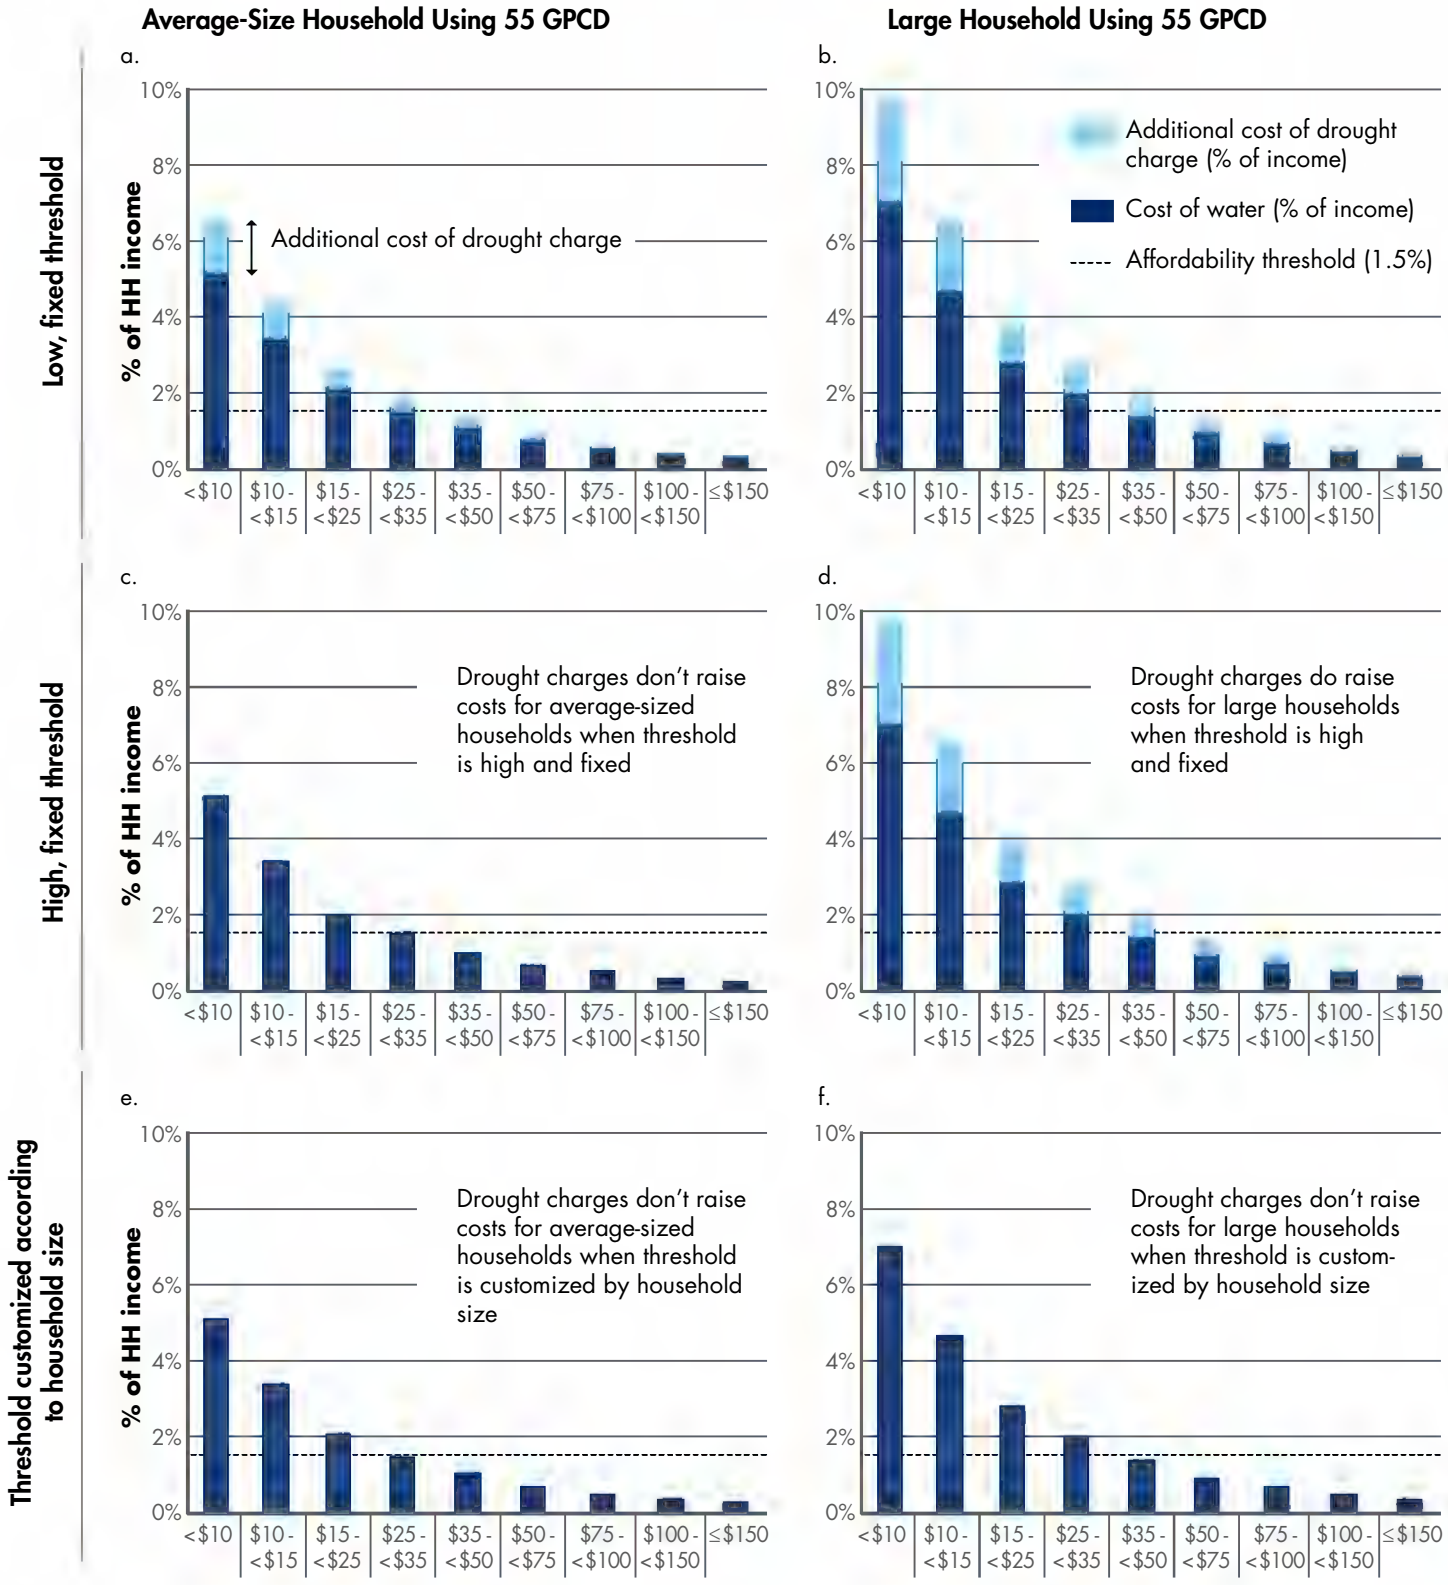
2. Data from 2010 Census: Households and Families.
3. Data from 2014 ACS.
4. Calculated as 55 GPCD × mean household size.

Among the 27 utilities surveyed, we identified four categories of drought charge structures. Table 2-3 summarizes the types of drought charges found in our sample. Those with low, fixed thresholds raised costs for everyone, regardless of the volume of water use. The exact threshold was set at either 0 gallons per month or 750 gallons a month (1 CCF), presumably because 750 gallons is the minimum sensitivity of the water meter. In this case, all customers paid an additional drought charge. Those with high, fixed thresholds raised costs for those households using more than a given volume of water. The minimum volume ranged from about 6,000 to 9,000 gallons (8-12 CCF) per month, depending on the utility. In this case, households with large total water use—such as households with many members—experienced a rate increase. The third category of drought charges had customized thresholds based on prior use—that is, water prices went up unless the household reduced their water use by a given percentage. In this case, households that cut water use sufficiently avoided drought charges. The fourth category has a customized threshold based on household size, raising costs for water use only if per-person household use was high. This is also referred to as a budget-based approach for drought charges.

Understanding how the various drought charge structures will affect water bills for low-income customers is complex because it depends on multiple factors. Figure 2-1 demonstrates the interaction between drought charges, household size, and household income across three types of drought charge structures. We held per-capita water use constant to show how the various drought charge structures would raise costs by different amounts for households using the same amount of water per person. The first scenario shows the cost of water with an additional drought charge of $2.02 on every 750 gallons (1 CCF) (Figures 2-1a&b). The second scenario (Figures 2-1c&d) shows the cost of water if drought charges were levied only on households using at least 7,500 gallons (10 CCF) a month. Figures 2-1e&f show the cost of water if drought charges were levied only on households using more than 55 gallons per household member.

Fixed-threshold drought charges aggravated affordability concerns for low-income customers, and the effect is more pronounced for large households. Only utilities that customized the minimum threshold for levying a drought charge by household size avoid raising rates for large, efficient households with high total usage.

Table 2-3.



Four Types of Drought Charge Structures

Threshold Type	Volume Threshold	Change to cost of basic water needs	Num. of Utilities (%)
Low fixed threshold	750 gal (1 CCF) or less per month	Increased	15 (56%)
High fixed threshold	5,980-8,980 gal (8-12 CCF) per month	Increased for large households	5 (19%)
Customized threshold based on prior use	70% of household's Summer 2012 or Winter 2013 monthly use	Increased if the household already had relatively low baseline of use	1 (4%)
Customized threshold based on household size	Threshold increased by at least 1,680 gal (2.24 CCF) per month for each additional person	No change	6 (22%)

Notes: Abbreviations: gal = gallons, CCF = centum cubic feet. "Basic water needs" estimated as 55 GPCD.

Figure 2-1.

Cost of Basic Water Use Under Three Drought Charges Structures Across Income Levels and Household Sizes

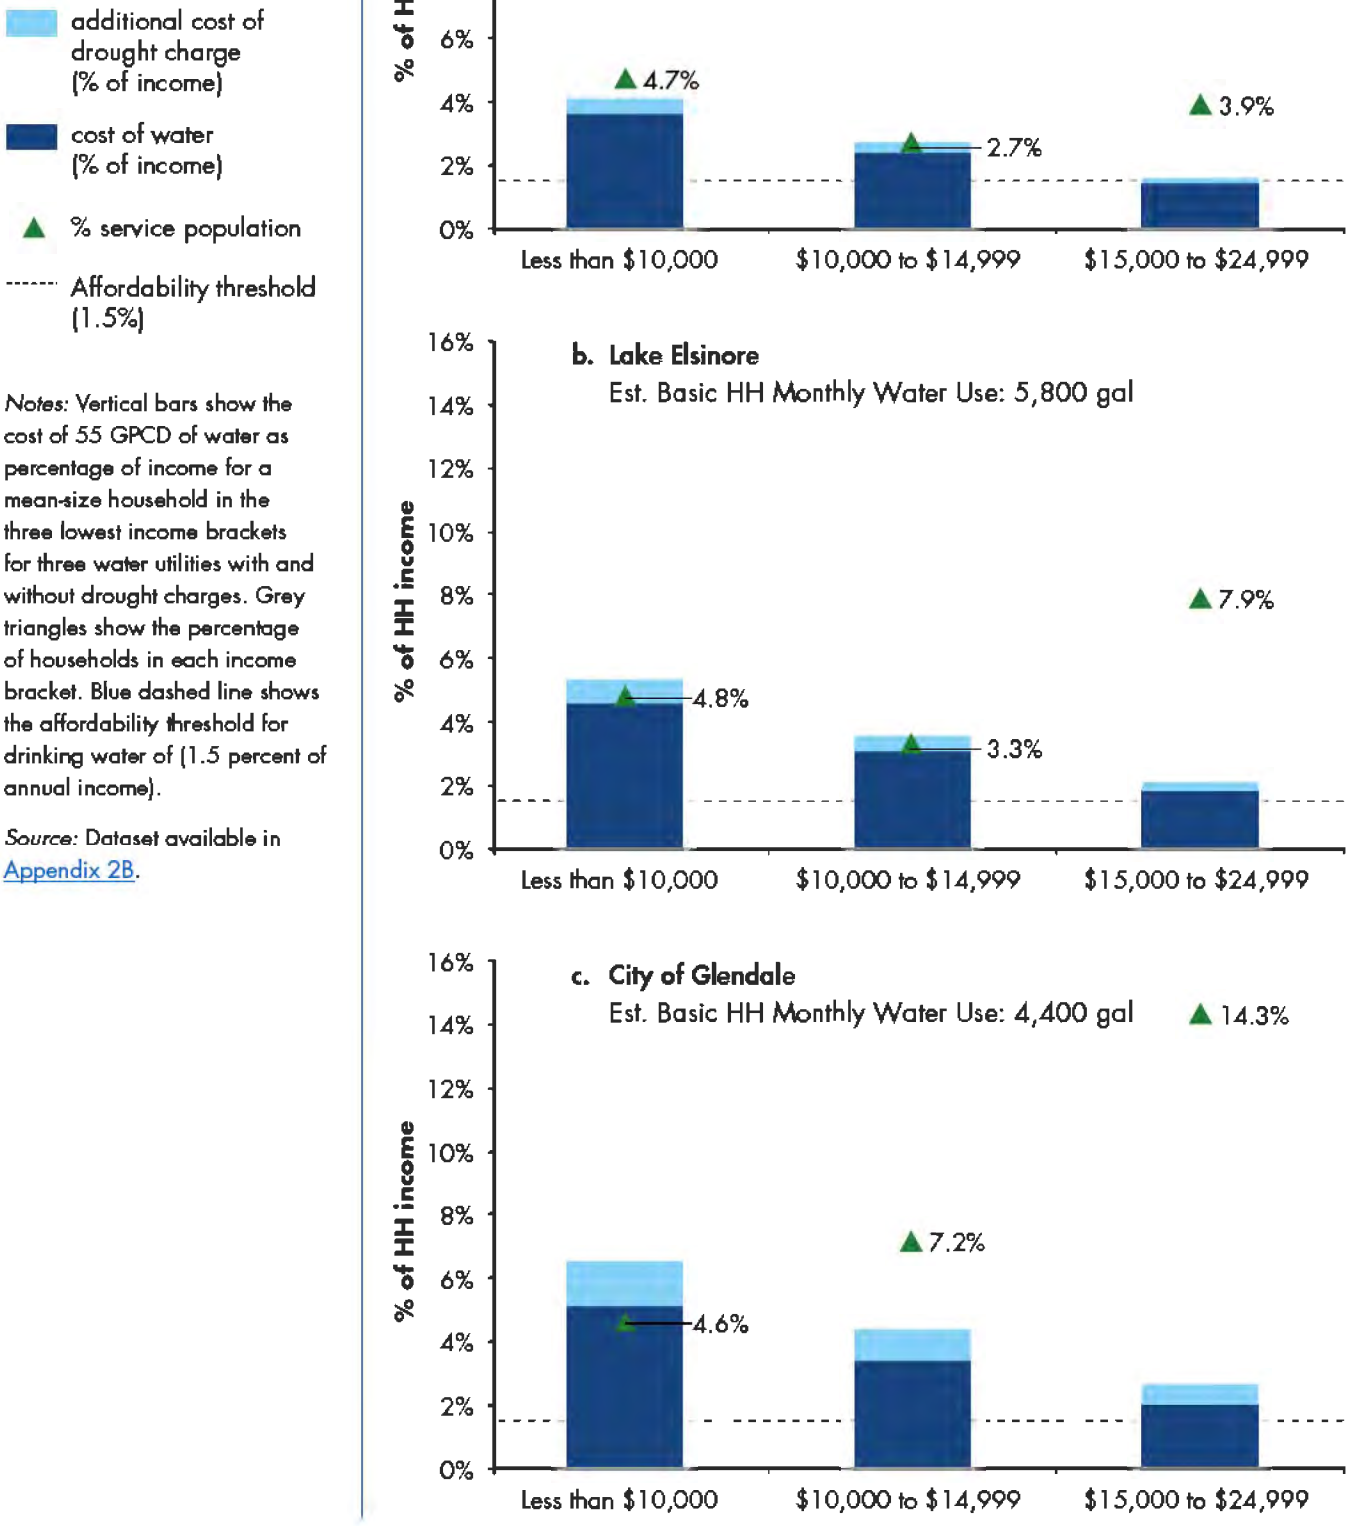
Notes: All households assumed to use 55 GPCD. Household income in $1,000s. Left column depicts costs for average-size households, with 2.63 members. Right column depicts costs for large (top 10 percent) of households, with 5 members. Low, fixed threshold = 750 gal/household/month. High, fixed threshold = 7,500 gal/household/month. Data parameters were based on City of Glendale water rates and population census data.

Impact of Drought Charges on Affordability

We conducted three in-depth case studies on drought charge in Elsinore Valley Mutual Water District in Riverside Count, the City of Glendale Water and Power in Los Angeles County, and the City of Benicia in Solano County. All three utilities imposed fixed-threshold drought charges on households using 0 to 1 CCF per month, increasing costs for homes using even relatively small amounts of water. The effect of drought charges on water affordability, however, depended on the price increase and household income level.

For all three utilities, average-sized households earning the median income paid less than 1.5 percent of their annual income for their basic water needs, with or without drought charges. With drought charges, they paid $85 more annually for their basic water needs, or 0.15 percent (less than 1/600th) of their annual income.

If, rather than focus on the median income, we use finer-resolution data on income, the story is more complex. Here, the proportion of income spent on water, and the impact of drought charges on water affordability, was much higher for low-income households (Figure 2-2). Without drought charges, single-family households earning less than $25,000 annually, which represented 11-26 percent of households in the three service areas, paid an average of 1.8 percent (±0.31) of their income for basic water needs. With drought charges, however, households pay 2.1 percent (±0.49) of their income on basic water needs. Drought charges had an even greater impact on the lowest-income households. For example, in the City of Glendale, an average-sized household earning $10,000 a year and using 55 GPCD would pay an additional 1.4 percent of their annual income on drought charges alone, increasing the cost of basic water needs from 5.1 to 6.5 percent of their income.



Of the three utilities, only the City of Benicia - the utility with the fewest low-income customers—offered financial assistance to low-income seniors in 2015; that program was expanded to provide a discount for all low-income customers in November 2016 (City of Benicia 2016).

Overall, drought charges raised the proportion of income that customers spent on water by a small amount compared to the baseline cost of water. However, the surcharges have a much larger impact on the lowest-income households, underscoring equity concerns. To better understand affordability, water utilities should evaluate how the rate structure affects the cost of meeting basic water needs for low-income households and the potential for drought charges to exacerbate affordability concerns.

An unfortunate limitation of the dataset is that it only represented large water utilities. Work by the California Urban Water Association (CUWA) confirms that affordability is a serious problem in urban areas, even those that appear relatively affluent based on median household income levels. In an assessment of water affordability in 2014-2015 for 10 urban water utilities in California, CUWA found that nearly 21 percent of households earned less than $25,000 annually and spent an average of 4.5 percent of their income on water (CUWA 2016). Information about affordability in rural areas of California is limited. However, Christian-Smith et al. (2013) compared affordability in the urban Sacramento metropolitan area and rural Tulare Lake Basin and found that, while water was unaffordable for a large number of low-income customers in both regions, the problem was more widespread in the rural region. Additionally, some rural customers must also purchase bottled water due to water contamination concerns, further increasing water costs.

Figure 2-2.

Cost of Basic Water Use for Low-Income Households, With and Without Drought Charges, in Three Cities.

Notes: Vertical bars show the cost of 55 GPCD of water as percentage of income for a mean-size household in the three lowest income brackets for three water utilities with and without drought charges. Grey triangles show the percentage of households in each income bracket. Blue dashed line shows the affordability threshold for drinking water of (1.5 percent of annual income).

Box 2-1.

Proposition 218, Tiered Water Rates, and Customer Assistance Programs

Proposition 218, adopted as a California constitutional amendment in 1996, prohibits public water utilities from charging their customers more than the cost of providing water service. In order to implement tiers, water utilities must demonstrate that the price of water at each tier is justified by the cost of providing water service to that tier. This requirement prevents water utilities from using water-rate revenue to subsidize low income customers by offering them lower rates or providing financial assistance programs. Despite this limitation, a survey of customer assistance programs nationwide found 55 such programs in California (U.S. EPA 2016). Some were investor-owned utilities regulated by the California Public Utilities Commission, and as such are not subject to Proposition 218. Others have used alternative sources of funding such as state or federal grants, private charities, and property leases (Cooley et al. 2016).

An assumption of this analysis is that customers can meet their basic water needs for consumption, cooking, and sanitation with the 55 GPCD identified as a provisional conservation standard in California statute. While several studies indicate that reducing leaks and using modern fixtures and appliances can reduce water use well below 55 GPCD, low-income customers may not be able to afford these upgrades, may lack the ready cash to take advantage of rebate programs, and, if they rent, may not have the authority to make alterations to their home. As a result, imposing drought charges on inefficient water users should go hand-in-hand with programs to assist low-income customers to reduce their water use.

CONCLUSIONS AND RECOMMENDATIONS

Drought fees, penalties, and surcharges are considered an important strategy for coping with drought—both by encouraging customers to save water, and ensuring financial stability for water utilities. They can, however, raise water affordability concerns for low-income households that must be addressed. Prior studies have demonstrated that low-income customers tend to be relatively low water users. As a result, rate structures and drought charges that keep costs lower for basic water use tend to keep costs low for the majority of low-income households. There are three promising strategies for minimizing the impacts of drought charges on water affordability: (1) impose drought surcharges on water usage above some threshold, e.g., 55 GPCD, and adjust for household size; (2) target efficiency programs to low-income households; and (3) offer financial assistance programs to offset costs for low-income households. These strategies, however, can be challenging for utilities to administer, particularly small systems that have limited technical, managerial, and financial capacity. With awareness about the equity impacts of drought charges, and technical assistance for those that need it, utilities should be able to develop drought charges that do not make basic water needs unaffordable for their low-income customers.

RECOMMENDATIONS TO IMPROVE DROUGHT COST EQUITY

Mitigating Impacts of Drought Charges on Water Affordability for Low-Income Customers

2-1. Keep per-unit water costs low for low water users during droughts

An unintended consequence of drought charges can be to increase the cost of meeting basic indoor water needs for low-income customers. To minimize the cost burden of drought charges on efficient, low-income households, water utilities should adopt drought charges that keep per-unit costs down for low water users. Specifically, we recommend that public water systems:

- Waive drought charges on water consumed at or below the amount necessary to meet basic water needs.
- Calculate each household's threshold for incurring additional drought charges based on household size to avoid unfairly penalizing large households (commonly referred to as variances).

2-2. Target conservation and efficiency programs to low-income customers

Water utilities should offer conservation and efficiency programs that enable low-income customers to keep their water use low enough to take advantage of cost structures that charge less per unit for low water users. These programs should include renters and residents of multi-unit homes who do not directly pay a water bill, as the cost of water is generally passed on to them through their rent or other fees. We recommend that utilities:

- Use strategies to reduce up-front costs for home efficiency upgrades to encourage participation by low-income households. Low-income customers are less likely to participate in rebate programs. They are more likely to take advantage of point-of-sale coupons on efficient fixtures and appliances, and programs to distribute or directly install efficient fixtures free-of-charge.
- Make informational materials available in multiple languages, do in-person outreach as well as send written materials, and reach out to customers who do not receive bills (predominantly renters and residents of multi-unit homes).
- Target conservation and efficiency programs to tenants by distributing free fixtures that are simple to install, such as low-flow showerheads and faucet aerators.
- Target incentive-based conservation and efficiency programs to landlords by offering incentives for building audits, rebates, or tax deductions for efficiency upgrades and leak repairs.

2-3 Develop low-income rate assistance programs within current legal constraints, and reform Proposition 218 to allow greater latitude in funding such programs

The best option for minimizing cost increases during droughts for efficient, low-income households is to design drought charges in a fashion that minimizes cost increases for low water users. If that is not possible, then a rate assistance program targeted at low-income customers can counteract price increases for households in need. Low-income rate assistance programs generally do not enroll all the qualified customers, so ideally they should be used in addition to, not instead of, equitably designed rate and drought charge structures. Under Proposition 218, public utilities cannot use ratepayer fees to fund low-income rate assistance programs. Water systems can use other sources of revenue such as leasing land or donations.

2-4. Address structural problems that prevent water systems from enacting equitable drought charge structures

Underlying issues prevent water utilities from addressing the greater cost burden placed on low-income customers by their water bills, both with and without drought charges. Our first recommendation, to keep per-unit costs low for low water users during droughts, requires that water systems have adequate technical, managerial and financial capacity. Stakeholders in government, water utilities and non-governmental organizations should collaborate to develop this capacity by:

- Installing and maintaining water meters and sub-meters for all customers of public water systems. Most low-income customers are low water users, but their bills do not reflect their actual water use if they live in areas without meters for single-family homes or sub-meters for units in multifamily buildings.
- Supporting water systems in developing equitable drought charge structures, and adding information about equitable approaches to drought charges to existing state programs that provide technical education for small water systems. Small water utilities need greater technical capacity to develop more complex, equitable drought charges such as tiers, variances for large households, and bill discounts for low-income customers.

Further Study and Data Collection on Drought and Affordability

2-5. Collect and analyze data on how to target hard-to-reach customers such as renters and residents of multi-unit buildings.

Designing financial assistance and efficiency programs to effectively serve renters and residents of multi-unit buildings is challenging. Better understanding how existing programs have managed to target these hard-to-reach customers could inform best practices going forward.

2-6. Determine if low-income households have less efficient fixtures and appliances, or more leaks, and therefore use more water to meet their basic needs.

The energy sector has provided ample evidence that low-income customers are more cost-burdened, mainly because they use more inefficient household appliances. This research has galvanized efforts to improve energy efficiency in low-income homes because it benefits the customer and the environment. Similar research is needed in the water sector.

2-7. The state should collect complete information on drought surcharges, fees, and penalties.

Present data collection is limited in the type of water utilities reporting data, and, given the improbably small number that reported drought charges in 2015, it seems nearly certain that even among utilities that submit an LWS EAR, most are not reporting their drought charges.

2-8. Publicly release a complete, accurate map of all public water systems in the state

A complete map of water system boundaries would enable non-government entities to assess the cost of water in relation to local income levels.

SECTION 3.
DROUGHT IMPACTS ON SALMON FISHERIES

OVERVIEW

Reports of drought impacts on California's fishing communities have been relatively limited. Many still frame water problems in California as "fish versus farms" or "humans versus ecosystems" (for example, Pollak 2016; Abcarian 2016). However, fish are essential to the well-being of communities that rely on them for food and income. We highlight salmon in this analysis due to its economic and cultural importance in many California riparian and coastal communities. A particular focus is given to the fall-run and Klamath spring-run Chinook salmon, which are the only remaining taxa that can be managed as a fishery. To examine the equity issues tied to drought impacts on salmon, we analyzed trends in the performance of commercial and tribal fisheries over the past several decades.

Ultimately, the current drought is not the only cause of the decline of California's salmon fishery; after all, salmon have coped with periodic droughts throughout their evolutionary history. However, salmon populations likely face greater difficulty surviving and rebounding from droughts given the barriers to migration to colder stretches of the river, loss of habitat, competition from non-native species, and water quality degradation (for example, Zeug et al. 2011; Jones and Nguyen 2010). In 2008, the United States District Court for the Eastern District of California issued a ruling that California water systems place wild salmon "unquestionably in jeopardy" (Jones and Nguyen 2010). Improving conditions for California's salmon, and the well-being of the communities dependent on them, will require improving management responses during short-term drought emergencies while addressing the underlying problems of habitat alteration and degradation, water allocation for the environment, and inequitable fishery access.

Salmon Natural History and Status in California

Many California rivers are breeding grounds for salmon. Chinook salmon (commonly known as King salmon) is the most abundant species in California and off its coast, but Coho, Pink, and Chum salmon are also found within the state. Chinook salmon are further divided into populations referred to as runs that migrate and breed during different seasons—namely fall, late-fall, winter, and spring, reflecting the long history of adaptation to California's seasonal flows (Hanak et al. 2011).

Salmon are an anadromous fish that spend part of their life in freshwater and the other part in the ocean. When salmon grow into small fish, they

undergo a physical change, or "smolting," to survive in saltier water as they move downstream to estuaries, where ocean water blends with freshwater and food is abundant. Those born in California rivers typically migrate to the ocean in their first few months of life, while some linger behind until they are over a year old (Fry 1979). In the ocean, salmon may stay relatively close to the mouth of the river in which they were born or swim long distances to find another feeding ground. After two to five years at sea, mature salmon return to their native river to spawn and die, with most returning at age three.

Interacting environmental and human-related factors influence annual fluctuations in salmon abundance. For example, the survival and growth of salmon can be greatly affected by changes in freshwater flows, which in many cases are regulated by upstream dams (e.g., Shasta Dam on the Sacramento River). These flows, in turn, affect water temperature, availability of floodplain habitat, water turbidity, interactions with predators and competitors, and the ability of mature fish to migrate to spawning grounds. Sufficient flows of water during migration periods are crucial for both outmigration of juvenile salmon downstream and migration of mature salmon to spawn upstream. Temperature is a key factor affecting survival of salmon at every life stage. The optimal temperature for eggs and fry is about 48 to 55 degrees F. Smolts can thrive in warmer waters, optimally about 50 to 66 degrees F (McCullough 1999, cited in Moyle, Israel, and Purdy 2008, 127-128). Other water quality parameters, including dissolved oxygen, pH (Carter 2008), and turbidity (Bash, Berman, and Bolton 2001), are also important determinants of salmon growth and survival.

Historically, salmon are remarkably abundant and widely distributed in California, from the Central Valley up to the northern region and as far inland as the Sierra Nevada and Eastern Cascades (Myers et al. 1998). The Sacramento and San Joaquin river systems are California's largest salmon-producing rivers on the West Coast, followed by the Klamath River (Fry 1979; Rankel 1982, cited in Hardy, Addley, and Saraeva 2006). As recently as the 1930s, California's residents observed spawning salmon so thick that they looked like a sheet of silver glass as far as the eye could see (Levene et al. 1976, cited in NMFS 2012).

Dams now block Central Valley Chinook salmon and steelhead from over 90% of their spawning habitat.

However, the salmon population has declined drastically over the past century, and many salmon taxa are heading toward extinction (Katz et al. 2013). Dams now block Central Valley Chinook salmon and steelhead from over 90% of their spawning habitat (NOAA 2014). For example, Coho salmon in certain reaches of the river and winter-run Chinook salmon are currently listed as endangered by the state and federal government (CDFW 2016).[1] Currently, the only salmon runs that can be harvested for subsistence, sale, or recreational purposes are the fall-run and Klamath-Trinity River spring-run Chinook salmon.[2]

A complex set of factors contributed to the widespread decline in California's salmon population. These include overfishing in the late 1800s and early 1900s (Clark 1929); extensive

1 Threatened and endangered species status may be specific to certain areas. For example, Coho salmon is listed as threatened from Punta Gorda to the northern border of California, but it is listed as endangered from south of Punta Gorda to the U.S./Mexico border. Similarly, spring run Chinook salmon is only listed as threatened for the Sacramento River drainage.

2 Commercial harvest of Coho salmon has been prohibited since 1992.

hydroelectric and irrigation development in the mid-20th century (Lichatowich 1999; Hanak et al. 2011); habitat alteration and degradation (Figure 3-1); competition for freshwater; and invasive fish species that prey on young salmon and eggs or compete with salmon for food (Moyle, Katz, and Quiñones 2011). Additionally, while salmon hatcheries—facilities that artificially breed and rear salmon—play an important role in salmon recovery and help support sustainable fisheries, there remain concerns about the hatchery's long-term impacts on wild salmon stocks from interbreeding and reductions in the genetic diversity of wild salmon (Buhle et al. 2009;

Figure 3-1.

Habitat Loss and Current Extent of Salmon-Accessible Waterways

Source: Hanak et al. (2011).

Source: ImagineGolf

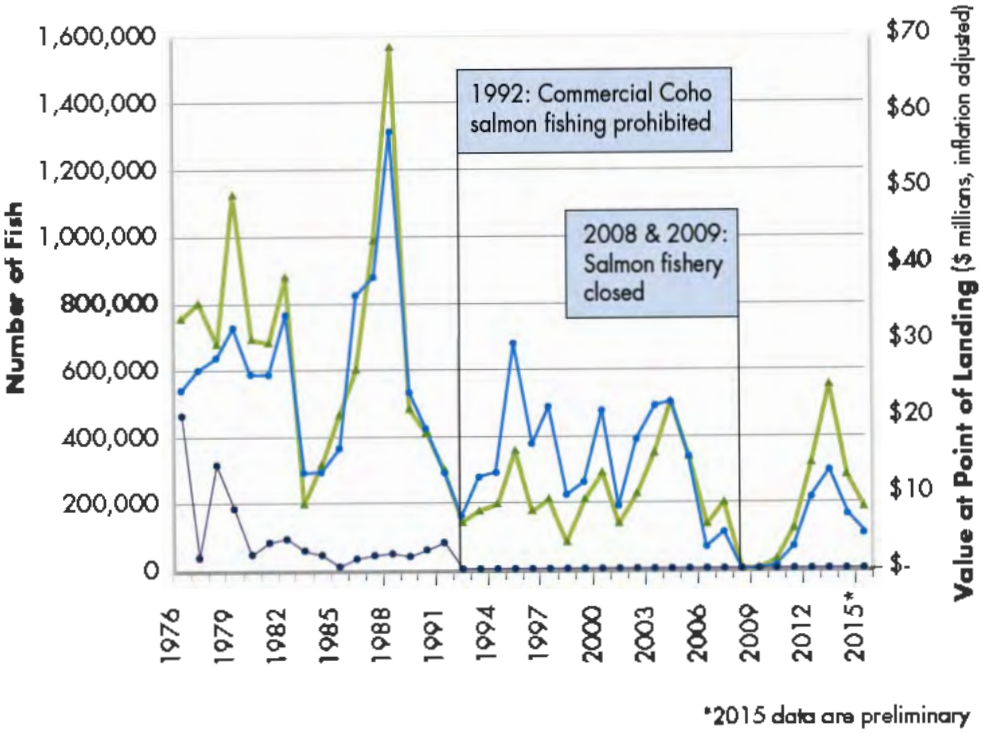
Chilcote, Goodson, and Falcy 2011; Araki, Cooper, and Blouin 2009). More recently, a dramatic decline in the Sacramento River fall Chinook salmon population in 2008 and 2009 was likely due to ocean conditions (e.g., temperature and nutrients affecting food availability), an inaccurate forecast of salmon escapement, ongoing degradation of freshwater and estuarine habitats, and heavy reliance on hatchery production (Lindley et al. 2009).

RESULTS AND DISCUSSION

Commercial Salmon Fishery Trends Over Time

DECLINE OF COMMERCIAL SALMON FISHERY

California's commercial salmon fishing communities were initially established around the mid-1800s. During the gold rush, settlers recognized the rich resources of the area and salmon fishing took off (Pomeroy, Thompson, and Stevens 2010; Smith and Kato 1977). San Francisco Bay and the Sacramento-San Joaquin Delta region were the first major fishery conducted by Euro-American immigrants in the state (Yoshiyama, Fisher, and Moyle 1998). Annual catches of the early Sacramento-San Joaquin in-river fishery were 4 -10 million pounds. An early estimate of the Central Valley Chinook salmon stock was 1-2 million spawning fish annually. The depletion of runs, however, led to legislation to restrict access to the fishery in 1980 (CDFG 2001). Presently, commercial salmon fishing in California is undertaken by small troll boats, usually with one or two people. As income from salmon is typically not enough for an entire year for most fishermen, they also harvest Dungeness crab.



Data from the PFMC show that the number of salmon caught and landed in California has declined over the last 40 years. Between 1976 and 1980, fishermen caught an average of 830,000 fish annually. The harvest declined by 80 percent to 170,000 per year between 2011 and 2015 (Figure 3-2), a result of the fall in salmon abundance as well as regulations that limited salmon fishing to more sustainable levels.

Figure 3-2 also illustrates how the value of salmon catch to fishermen, referred to as exvessel value, has trended gradually downward over the past 30 years. For 2011 to 2015, the exvessel value averaged $13 million per year—a 64 percent decrease from the 1976 to 1980 average of $36 million per year. It should be noted that the rise in salmon prices in recent years to an average of $6.15 per pound has helped mitigate the impacts of decreased salmon catch.[3]

3 We derived the average price from the PFMC's Review of Ocean Salmon Fisheries data. All values are in 2015 dollars.

Figure 3-2.

Number and Dollar Value of Commercially Harvested Chinook and Coho Salmon.

Notes: Coho salmon is now listed as an endangered species. Commercial fishing of Coho salmon has been prohibited since 1992. The value of salmon at the point to landing is termed exvessel value. It is expressed in 2015 dollars (inflation adjusted).

Source: PFMC (2016b).

Some of the decline in harvest was related to the number of commercial fishing days and areas opened to salmon fishing. Historically, California's (unregulated) commercial salmon season ran from April through October, but the fall in salmon abundance prompted the California Department of Fish and Wildlife (CDFW) to limit the number of commercial salmon fishing days. The CDFW also limits the extent of fishing grounds and shortens the commercial fishing season in certain years to avoid unintended by-catch of listed threatened and endangered species. In 2016, the Pacific Fishery Management Council noted that "long running drought conditions, coupled with suboptimal ocean conditions, have raised serious concerns for Sacramento River winter Chinook salmon." As a result, fishing seasons south of Point Arena, California, were shortened to minimize interactions with winter Chinook. Figure 3-3 highlights the curtailment of fishing seasons during recent drought years (2014-2016), with the greatest cut of 23% in 2016 compared to the 2001-2005 average.

OTHER SIGNS OF THE FISHERY DECLINE

Due to the pressures of a declining harvest and the rising cost of entry into the fishery and fishing-related inputs (e.g., ice and fuel), many fishermen have retired their permits.[4] As a result, the size of commercial salmon fleet has decreased dramatically over time (Dave Bitts, salmon fisherman, personal communication, Oct. 19, 2016).[5] Only one-sixth of the boats with salmon permits remained in 2014 compared to 1982, two years after the permitting program started (Figure 3-4). Despite a clear downward trend in total harvest, annual gross income per boat has fluctuated dramatically with no clear trend, perhaps a result of various counterbalancing

4 The entry cost is higher than before because an aspiring salmon fisherman must find a retiring fisherman to purchase the permit from.

5 The restricted access program, which came into effect in 1980, limits the number of fishing permits available. Permits may be transferable between fishermen or vessels. Under certain conditions, permits may be transferred from retired to new vessels (CDFG 2001).

Figure 3-3.

Length of Salmon Fishing Season.

Sources: 2001 – 2005, 2014, and 2015 data from PFMC (2014) and PFMC (2016b). Table C-1. 2016 data from https://www.wildlife.ca.gov/Fishing/Ocean/Regulations/Salmon.

effects: declining salmon stock, price changes, and less competition as the salmon fleet became smaller (Figure 3-5). Gross income from salmon bottomed out in 2008 and 2009 when the fishery was closed for two seasons, but it reached a record high of $35,000 per boat in 2013.[6] High income variability affects job security and reflects the fact that it is becoming more difficult to make a living as a salmon fisherman. In Morro Bay, for example, the salmon fishing community has gotten much smaller, and the average age of fishermen has been increasing as less young people enter the fishery (Lori French, salmon fisherman, personal communication, Oct. 18, 2016). We interviewed fishermen about their personal experiences to get their perspective on the challenges facing them (Box 3-1).

The salmon fishery not only provides income for those directly participating in the industry, but also supports the local economy by driving demand for goods and services in the community. During the current drought year (2012-2015), California's total (both direct and indirect) inflation-adjusted personal income from commercial salmon fishing was $27 million (PFMC 2016b).[7] The indirect economic impacts from the salmon fishery depend on the importance of the fishery to the community's economic base and whether other economic opportunities exist during a poor salmon harvest eason. Due to data limitation, we are not able to show any local or statewide trends.[8] However, it is expected that impacts from the decline in the salmon fishery could be quite dramatic for communities that heavily rely on salmon harvest.

6 The average gross income between 2006 and 2015 was $17,000 per boat per year, not including years 2008 and 2009. The fishery closure was a result of a drastic salmon population decline due to unfavorable ocean temperature and food availability conditions, not the drought (Jones and Nguyen 2010).

7 Actual impacts will vary by community and its economic base. Direct impacts consist of personal income earned by those participating directly in the fishery, including vessel owners, crew members, and processing workers. Indirect impacts are related to services provided for the fishery, processing and recreational operations, wholesale, retail and restaurant sales of locally caught fish, fishing, harbor tourism, and income re-spent in the community (e.g., income of grocery store owners and health professionals).

8 The change in PFMC's methodology limits comparable data to the last six years. However, we cannot compare data from 2012-2015 (drought years) and 2010 or 2011 as the fishery was recovering from the closure during those years.

Figure 3-4.

Boats with Salmon Permits and Salmon Boats Landed 1960-2015.

Notes: The Restricted Access Program, which requires all salmon fishermen to have a salmon fishing permit, started in 1980.

Box 3-1. The Salmon Fishery Through the Lens of Fishing Communities

We interviewed tribal members and four fishermen to gain better insights into broader impacts of the decline in salmon harvests. Summaries of their responses are provided below.

Brittani Orona (Hoopa Valley Tribe, Northern California)

Our whole culture revolves around fish and the watershed. My grandfather likes to say that we are 'River People.' Salmon feed us physically and spiritually. We rely on them for our World Renewal Ceremony by asking spiritual beings to help keep the world in balance and maintain healthy river and fish populations. There has definitely been a change in the rivers since I was young (about 20 years ago). Water quality has gotten worse and flows have reduced. The decline of salmon comes with economic depression, but more importantly it affects our spiritual health and how we live as Hupa people.

Box 3-1 *(Continued).*

The Salmon Fishery Through the Lens of Fishing Communities

Chook-Chook Hillman (Karuk Tribe, Northern California)
Unlike the Yurok and Hoopa Valley tribes, Karuk people do not have recognized tribal salmon fishing rights, and the only authorized fishing location is at Ishi Pishi Falls. Sport fishing licenses are available for sale, but it is a burden for tribal people because they cost money and fishing, to us, is not for sports. We have malnutrition and physical and mental health issues because we cannot be tribal people—being able to continue our traditional way of life.

Dave Bitts (Fisherman from Eureka)
I started fishing about 40 years ago and half of my income on average is from salmon and the other half is from Dungeness crab. I had an epiphany a few years back about the real value of the salmon fishery. We have been consulted when a natural gas industry was going to come in and it could impact the fishery. Having fishermen around gives Humboldt people a sense of place since they can buy fish locally and interact directly with us. It's our identity and we'd be culturally impoverished without the salmon fishery.

Larry Collins (Fisherman from San Francisco)
My wife and I first started fishing in 1983/84 and we were able to raise kids and pay off our house from salmon fishing. We consider fish, crabs, and other seafood as public trust resources and more attention should be given to protecting the fish's habitats. The fishery needs three things to succeed: (1) abundance of fish; (2) market; and (3) infrastructure to move fish to land, such as port, services for fuel and ice. In a bad harvest year, fishermen must live off their savings, and some people might decide to retire altogether.

Mike Ricketts (Fisherman from Monterey)
I have been fishing commercially for 40 years. Fishermen typically have one or two fisheries that they depend on, for example salmon and Dungeness crab. When we have a good salmon season, we fish less crab, and vice versa. Fishermen with a salmon fishing permit might not choose to fish salmon in a bad year because the overhead can be about $10,000 per year to start a boat up and cover the fuel, insurance, and other costs.

Lori French (Fisherman from Morro Bay)
The fishing community has gotten much smaller in Morro Bay and it's also graying out. Fishermen are getting older and the fishery is not attractive enough for younger people to enter. Salmon fishing is so uncertain that younger people don't want to risk it. For us, we are fishermen and we do not really have a backup plan in terms of what to do besides fishing. Typically, our main source of income is 80 percent Dungeness crab and 20 percent salmon, but it was probably 60-70 percent crab and 30-40 percent salmon some 30 years ago.

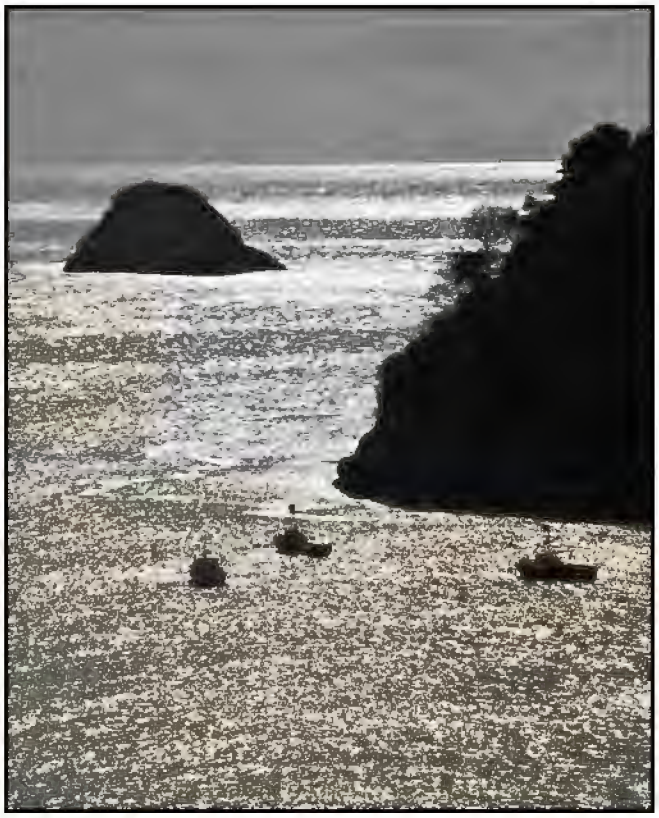
Impacts of the Drought on Salmon Fishery

Drought is a natural occurrence, and salmon populations in California have survived periods of water scarcity throughout their evolutionary history. The full effects of the current drought are yet to be determined; as of this writing, salmon that hatched and migrated to the ocean during the early part of the drought are just starting to return to spawning grounds. It is likely that alterations to their habitats, migration barriers, and competing uses of water, as mentioned in the previous section, have reduced their resilience to survive extended dry periods.[9] Lower streamflows and higher water temperatures associated with the drought have reduced the amount of cold water available for salmon during key life stages, such as for hatching, migration to the sea, and spawning (Shukla et al. 2015; Seager et al. 2014). Indeed, far fewer Sacramento Chinook salmon reached the ocean during the 2007-2009 drought years than the much wetter 2011 (Michel et al. 2015). Drought conditions, coupled with suboptimal ocean conditions, have also led to very low survival of the juvenile endangered winter-run Chinook salmon in 2014 and 2015 (PFMC 2016a; USBR 2015). These negative impacts likely hold true for the commercially fished salmon runs as well.

Biological stressors further contributed to salmon mortality during droughts. A review of the effects of temperature on salmonids shows that the parasites Ceratomyxa shasta and Ichthyophthirius multifiliis (commonly known as "Ich") are more virulent in warmer water (Carter 2005). The Klamath River system had an Ich outbreak in 2014 (Orcutt 2015), and up to 91 percent of Coho salmon juveniles were infected in 2014 and 2015 (Houston 2016a). Additionally, drought affects the overall health of the ecosystem and the food web that salmon rely on. Food is typically less abundant during drought, and salmon face more competition from invasive fish species that thrive in warm, altered habitats such as reservoirs and ponds (Moyle et al. 2013). The threats to salmon also increase as their predators, such as striped bass, can tolerate warmer water (CDFW 2010). Reduced flows also lead to higher risk of predation for juvenile salmon; less water lowers the turbidity and limits their camouflage ability. There is also less physical space for predator and prey to occupy as deep pools of cool water become shallower and warmer, and riffle stretches of river—important for the construction of salmon spawning nest and incubation—dry up (Tim Sloane, Executive Director, Pacific Coast Federation of Fishermen's Associations, personal communication, Oct. 12, 2016).

Water management decisions during the drought are critical for ensuring sufficient flows and temperature requirements for salmon; however, they have been the subject of debate and litigation following the low survival rate of juvenile winter-run Chinook salmon and mass die-offs of juvenile Coho salmon in 2014 and 2015.[10] For example, in 2015 the National Resources Defense Council and other environmental organizations took legal action against the United States Bureau of Reclamation (USBR), other federal agencies, and Central Valley water districts for not devoting enough water to the endangered winter-run Chinook salmon (Kasler 2015). In 2016, the Hoopa Valley Tribe and a group led by the Yurok Tribe also filed a separate lawsuit against the USBR and

9 See Bisson, Dunham, and Reeves (2009) for more details about freshwater ecosystems and resilience of Pacific salmon.



10 Documents regarding Sacramento River Temperature Management can be found on the SWRCB's website. NMFS biological opinions and actions, as well as the USBR's long-term plan for protecting salmon in the Lower Klamath River (and associated comment letters), can be found here and here, respectively.

the National Marine Fisheries Service (NMFS) for contributing to Ich infections and mortality of the endangered Coho salmon (The Eureka Times-Standard 2016; Houston 2016b).

Finally, climate change will likely compound existing problems and accelerate the decline in salmon population. Seasonal duration of lethally-warm stream temperatures at watershed outlets is expected to lengthen and the average annual stream temperature is projected to exceed 75 degrees F earlier in the spring (Null et al. 2013). Moyle et al. (2013) concluded that climate change will increase the vulnerability of spring-run Chinook salmon and Coho salmon in California, and ultimately lead to their total extinction by 2100 if conservation measures are not pursued.

FISHERMEN'S VIEWS OF DROUGHT IMPACTS

Responses from our interviews with salmon fishermen, conducted in October 2016, further revealed some devastating effects of the current drought. Dave Bitts, a fisherman of 40 years from Eureka, recounted that for eight of the 10 years between 1995 and 2004, fishermen could easily catch 50 fish per day. It is now very challenging to catch 10 fish a day and many people have to live off their savings or take on a different job. Lori French, who fishes with her husband in Morro Bay, revealed that during this drought, for the first time in her husband's life, he could not catch any fish in two consecutive days. Mike Ricketts, a fisherman from Monterey, similarly mentioned that conditions have been particularly devastating in the last couple of years. While many salmon fishermen also engage in the Dungeness crab fishery, the postponement and shortening of the crabbing season in late 2015 created a significant economic burden. According to Mike Ricketts, the decline in salmon harvest has also affected infrastructure that supports the fishery, such as fuel docks, ice stores, and markets, making each

Source: CampPhoto

drought recovery more difficult than the one before. To address these impacts, Larry Collins, a fisherman from San Francisco, highlighted that it is important for the public to think of fish, crabs, and other seafood as public trust resources and give more attention to protecting fish's habitats.

Tribal Salmon Harvest

TRENDS OF DECLINE EXPERIENCED BY TRIBES

Salmon are an integral part of life for Native Americans in California and the Pacific Northwest (Shilling et al. 2014; Lichatowich 1999; Yoshiyama 1999; Gunther 1926). For centuries, Native Americans have relied on salmon not only as a source of sustenance, but also for its spiritual and cultural significance, as can be seen in the First Salmon Ceremony honoring the relationship between salmon and people (Gunther 1926). Presently, the Yurok and Hoopa Valley Tribes share a federally-reserved right to 50 percent of the

Klamath River Chinook salmon harvest surplus (Pierce 1998).[11]

Subsistence fishing has always been a major part of the tribes' livelihoods, but the current salmon consumption level appears to be much lower than it was historically. Shilling et al. (2014) conducted a survey of 12 tribes throughout California to examine traditional and contemporary fish usage, fishing areas, and barriers to fish use. Results showed that salmon was the most relied-upon fish in the North Coast and was traditionally used by all tribes interviewed, except for the Timbisha Shoshone in the Death Valley area.[12] However, the interviews suggested that use of fish has declined compared to historical rates, and especially more so in recent years.

Other evidence also points to a significant decline in tribal salmon harvest and consumption. The PFMC provides a systematic collection of tribal Chinook salmon harvest data dating back to 1987, although they are quite limited in temporal and geographic scope. From the PFMC's database, we found that the average number of salmon caught by the Yurok and Hoopa tribes combined from 1995-2015 was 21,000 for subsistence and 17,000 for commercial sale (more information on the subsistence and commercial tribal harvests is provided in Appendix 3A). As of 2010, the most recent year for which we have tribal population data, the number of salmon harvested for subsistence would correspond to 10 fish per year for a family of four, or about 20 to 38 pounds of salmon per person per year.[13] This estimate greatly contrasts with pre-contact consumption estimates by Hewes (1973), which indicated that the Yurok and Hoopa Valley tribes were consuming about 365 pounds of salmon per person per year. Fish consumption by the Karuk tribe has also dropped sharply (Table 3-1). A study by Norgaard (2005) showed that the lack of fishing rights, coupled with salmon population declines, impacted the health of members of the Karuk Tribe upstream on the Klamath River. Norgaard found that the Karuk Tribe experienced a loss of livelihood, diet-related illnesses, and poverty when their fish resources become degraded or destroyed. This experience is

11 Indigenous fishing rights allow tribal members to fish for salmon at traditional fishing sites and with traditional equipment, such as gill nets. The Yurok Tribe's allocation is 80 percent and Hoopa Valley Tribe's allocation is 20 percent of the tribal allocation (Pierce 1998).

12 Tribes that have been interviewed by Shilling et al. (2014) include Habematolel Band Pomo, Paiute, Big Valley Band Pomo, Scotts Valley Band Pomo, Kahia Band Pomo, Me-Wuk, Wiyot, Yurok, Yuki, Pit, Pomo, Nomlacki, Concow, Wailaki, Mattole, Northern Paiute, Timbisha Shoshone, Maidu, Mono, Monache, Wintun-Wailaki, Chumash, Chemehuevi, Mohave, Achomawi, and Atsugewi.

13 Authors' calculations based on Yurok and Hoopa Valley Tribal population from the US Census Bureau (2013). Table 19. American Indian and Alaska Native Population by Tribe for California: 2010. Estimated consumption per capita assumes that the dressed weight of salmon (i.e., weight after inedible or undesirable parts have been removed) ranges from 8 to 15 pounds per fish.

Table 3-1.

Estimated Present and Historical Karuk Tribe Fish Consumption

	Tribal Population	Est. Total Fish for Tribe (pounds)	Per Capita (pounds/person/year)
Pre-contact	1,500	675,000	450
Year 2003-04	3,300	<1,000	< 5
Year 2004-05	3,300	< 100	< 0.5

Sources: Adapted from Norgaard (2005). Pre-contact data from Hewes (1973).

likely shared by many Native American tribes in California.

CHALLENGES UNIQUE TO PRESERVING TRADITIONAL PRACTICES

Regulated environmental conditions are responsible for current limits on traditional fish consumption and harvest practices (Shilling et al. 2014). Dam construction, water diversions, and diseases, for example, contribute to the diminishing salmon population, but tribes also face fishing restrictions and many do not have indigenous rights to fish in traditional fishing sites (Chook-Chook Hillman, member of Karuk Tribe, personal communication, Sept. 27, 2016). Illegal, water-intensive marijuana cultivation in Northern California is another driver of reduced flows and environmental degradation. Marijuana's high economic value has attracted some tribal members to work in plantations (Crane-Murdoch 2015; Anderson 2015). These activities increase pesticide pollution in waterways, change the character of the creek, and further compromise water availability for salmon.

Multiple drought years have exacerbated existing problems relating to the overall decline in salmon abundance and the loss of livelihood. According to Chook-Chook Hillman, a Karuk Tribal member, the Klamath salmon runs narrowly escaped a complete collapse when the USBR approved emergency reservoir releases to protect juvenile and spawning salmon (personal communication, Sept. 27, 2016). Tribal activists fight almost annually for "emergency flows," which is especially critical during droughts (Brittani Orona, member of Hoopa Valley Tribe, personal communication, Nov. 23, 2016). As a result, tribes are currently asking for "preventive flows" to ensure the survival of the salmon population, which ultimately links to the survival of traditional cultures. The cultural wealth of tribes depends on the availability of salmon, which members use for ceremonies. When a tribal person cannot catch enough salmon to subsist, he or she must buy, trade, be given fish, or go without. It is highly probable that a continuation of the drought will result in more severe social, economic, and cultural impacts on tribal communities.

CONCLUSIONS AND RECOMMENDATIONS

A complex set of factors have contributed to the widespread decline in California's salmon population. Alterations to habitats, migration barriers, invasive species, and competing uses of water have likely decreased salmon's resilience in the face of extended dry periods. Droughts can impact salmon in many ways, principally via reduced flows and higher water temperatures. They also increase biological stress, lead to disease outbreaks, increase competition from invasive fish species, and augment predation risk. The diminished water supply during droughts intensifies competition for water between user groups, many of which are on unequal playing fields.

The commercial salmon fishery has been experiencing an overall decline, and the salmon fishing community has been shrinking as a result of (1) a downward trend in salmon harvest over the past 40 years; (2) a lack of income security among salmon fishermen; (3) rising costs of fishing (e.g., fishing regulations and cost of inputs); and (4) the decline of infrastructure that supports the fishing fleet (e.g., fuel docks and ice stores). Native American tribes are also significantly impacted by salmon decline, as observed in their harvest and consumption patterns. Tribal salmon consumption was historically much higher than the present level, according to interviews with tribal members

and our review of the literature. Tribes face unique challenges to preserve their traditional practices, including dam construction and operations, water diversions, fishing restrictions, the absence of fishing rights, and illegal marijuana cultivation. The ongoing California drought is seen by interviewed tribal members and fishermen as an additional stressor to an already stressed system, causing further decreases in fish harvest and income. For commercial fishermen, impacts contribute to the decline of the fishery and its capacity to remain financially viable. For tribes, the impacts threaten traditional livelihoods and cultural wealth.

RECOMMENDATIONS TO IMPROVE DROUGHT RESILIENCE OF THE SALMON FISHERY

Mitigating Impacts of Drought on Commercially Fished Salmon Runs

3-1. Enhance emergency drought response to protect anadromous populations that are important to fishing communities.

A small number of drought response activities directly address impacts on anadromous fish populations depended upon by tribes and commercial fishing communities. Efforts to ensure the protection of fish listed under the federal and California Endangered Species Act (ESA), such as improving flow conditions for winter-run Sacramento Chinook, may have positive spillover effects on non-threatened species. However, they leave out drought-affected rivers and tributaries that can no longer support threatened and endangered species. Strategies to enhance these responses include an improved management of reservoirs (e.g., on the Sacramento River) to prevent warm water releases that may harm salmon eggs and juveniles; emergency salmon rescue and transportation past compromised stretches of the river to coastal net pens during critical periods; and expanded Voluntary Drought Initiatives that have been carried out by NMFS and CDFW.

3-2. Reduce pressures on critical aquatic ecosystems.

The enforcement of the Reasonable and Beneficial Use Doctrine in California's water rights law is especially important during periods of water scarcity. More monitoring and enforcement activities are needed to prevent illegal water diversions (e.g., for marijuana cultivation). Additionally, statewide water conservation and efficiency measures, as well as expansion of alternative water supplies (e.g., stormwater capture and water recycling), can reduce pressures on critical aquatic ecosystems and, in some instances, improve river flows. Minimum environmental flows should be established and maintained in key waterways, especially during salmon migrating seasons.

3-3. Provide income and/or food assistance and insurance protection for fishing communities during drought emergencies.

Native American tribes and commercial fishermen greatly depend on the salmon fishery. According to interviews with tribal members and salmon fishermen, a poor salmon harvest year can create high economic and cultural burdens on fishing communities. State and federal agencies should recognize the inequitable impacts of the drought on these communities and provide income and/or food assistance during a drought emergency as appropriate. A federally supported fishermen's insurance program, similar to a crop insurance program, might be created as a risk management tool to protect fishermen against loss of income during times of extremely low harvest.

3-4. Build resilience and limit vulnerabilities of the salmon fishery.

Integrated management of water and fishery resources is key to improving the resilience of the salmon population. A statewide strategy for

aquatic conservation is needed to coordinate efforts and track results. These efforts include:

- Engaging in physical habitat restoration projects to better approximate natural conditions, such as the San Joaquin River salmon restoration efforts and those outlined in the Golden Gate Salmon Association's Salmon Rebuilding Plan (Golden Gate Salmon Association (GGSA) 2016);
- Creating salmon sanctuaries or stretches of rivers and streams dedicated to salmon conservation;
- Adjusting dam operation and state and federal water projects to ensure minimum environmental flows, maintain water quality, and balance water uses;
- Improving federal and California ESA protections for listed salmonids during times of low water supply to avoid a repeat of the winter-run Chinook salmon's mass die-offs in 2014 and 2015. Such protections are likely to provide indirect benefits for the salmon fishery as well;
- Re-operating fish hatcheries to protect wild salmon population;
- Restoring access to cold-water habitat to improve resilience against droughts, such as creating more fish-friendly waterways and fish passage facilities; and
- Removing dams that no longer provide enough hydropower to justify operational, maintenance, and environmental costs. These dam removals can increase cold water spawning and rearing habitats for migrating fish. The new Klamath Basin Agreements are a recent example. Signed April 2016, the agreements have created a roadmap for four dam removals on the Klamath River by 2020, while helping irrigators to avoid potentially adverse financial and regulatory impacts from the dam removal.

3-5. Create mechanisms for meaningful and timely tribal engagement with local, regional, state, and federal agencies.

Indigenous communities are known as stewards of the land and the water. They have practiced sustainable management of natural resources for millennia and their perspectives and input should be considered in policy decisions that will ultimately impact their communities, such as dam operations and fishery management. Many government agencies have developed and/or adopted tribal consultation principles and practices with varying degrees of inclusivity and timeliness, but these engagements should be fully institutionalized into relevant agency operations. An example of improving this consultation process is the creation of a tribal policy advisory committee or office within all levels of government that deal with issues impacting Native Americans.

Further Study and Data Collection on the Salmon Fishery and Drought

3-6. Formalize integrated biological and environmental data systems for salmon populations throughout California.

Better and more integrated data is needed to strategize and optimize responses to protect important salmon runs. Current monitoring efforts, especially on non-threatened salmon runs, are limited; these data gaps hinder timely response to changes in flows, temperatures, and other factors that may harm spawning adult and juvenile salmon. Some efforts are already underway to support collaborative and coordinated monitoring activities to improve fish population and watershed health, such as the Klamath Basin Monitoring Program and the California Cooperative Anadromous Fish and Habitat Data Program. However, these programs still leave gaps in temporal and spatial coverage.

Formalizing these efforts would help to maintain consistency and availability of timely data and identify gaps that should be addressed.

3-7. Comprehensively examine drought impacts on the fishery from economic, environmental, and cultural perspectives.

A better understanding of drought impacts on the fishery from economic, environmental, and cultural perspectives can help identify and address inequity issues around fishery and water resource management in California. The declining salmon population is a complex legacy problem through which many factors intersect, including the loss of habitat and environmental degradation. The drought provides an opportunity to draw attention to salmon's diminished resilience to extended dry periods and its implications for fishing communities.

3-8. Evaluate ways to re-operate hatcheries in California to achieve both goals of sustaining commercial fisheries and assisting in the recovery of naturally spawned salmon runs.

Sustainable fishery management depends on genetically-diverse wild fish stock that is resilient and adaptive to the changing environment. However, hatchery fish, which are bred to thrive in hatchery conditions, are known to weaken the genetic makeup of the wild (naturally spawned) fish population as a result of interbreeding (Buhle et al. 2009; Chilcote, Goodson, and Falcy 2011; Araki, Cooper, and Blouin 2009). How can the hatchery be managed and re-operated to limit negative impacts on the wild population while continuing to support the fishery? What are the most effective and cost-efficient approaches? These questions have been explored to some extent and continued research is needed to improve the health of the fisheries.

3-9. Assess the use and effectiveness of instream flow regulations to protect the salmon population.

At present, much of the research on the impact of instream flows on salmon populations focuses on endangered and threatened species. Management decisions can be made more effective through a better understanding of the relationship between flows and fish populations that are harvested for subsistence, sale, or recreation. For example, pulse flows may be used as a measure to assist in salmon migration during a drought period. Further research is needed to understand flow-migration relationships on a per-tributary basis and to assess the effectiveness of flow regulation measures.

3-10. Examine potential impacts on stock sustainability and socioeconomic implications of expanding reserved indigenous fishing rights.

Native American tribes have relied on salmon for food and cultural uses for millennia, but only two out of over a hundred tribes have reserved rights to fish in traditional sites with traditional equipment. The issue of equity and fairness of fishery access should be explored with considerations to potential impacts on fish stocks as well as tribes and other groups with recognized fishing rights.

APPENDIX INTRODUCTION A

DROUGHT AND EQUITY ADVISORY COMMITTEE MEMBERS AND ORGANIZATION PROFILES

Sara Aminzadeh, *Executive Director, California Coastkeeper Alliance*

Colin Bailey, *Executive Director, Environmental Justice Coalition for Water*

Carolina Balazs, *Visiting Scholar, University of California, Berkeley*

Wendy Broley, *Staff Engineer, California Urban Water Agencies*

Amanda Fencl, *PhD Student, University of California, Davis Center for Environmental Policy and Behavior*

Kelsey Hinton, *Program Associate, Community Water Center*

Gita Kapahi, Director, *Office of Public Participation, State Water Resources Control Board*

Brittani Orona, *Environmental Justice and Tribal Affairs Specialist and Native American Studies Doctoral Student, University of California, Davis*

Brian Pompeii, *Lecturer, California Polytechnic State University, San Luis Obispo*

Tim Sloane, *Executive Director, Institute for Fisheries Resources*

SARA AMINZADEH

As the Executive Director of California Coastkeeper Alliance (CCKA), Sara Aminzadeh develops and executes campaigns to ensure swimmable, fishable, drinkable waters for California's communities and watersheds, in concert with locally-based California Waterkeepers. In addition to her policy work as an attorney and advocate, Sara creates and mobilizes new coalitions for clean water. Sara founded and directs CCKA's Blue Business Council, the California business network for clean water, and the California Water Partnership, a coalition of environmental and environmental justice organizations dedicated to securing a sustainable and equitable water future for California. Sara frequently writes about human rights and climate change issues, most recently authoring a chapter Rising to the Challenge: California Climate Change Adaptation in the 2014 Oxford University textbook, Climate Change Impacts on Ocean and Coastal Law. Sara holds a Bachelor of Arts (BA) in environmental studies and political science from the University of California, Santa Barbara, and a Juris Doctor (JD) from the University of California, Hastings College of the Law.

California Coastkeeper Alliance

California Coastkeeper Alliance was founded in 1999 with the belief that a healthy ocean and coast and clean water is vital to California's economy, public health, and way of life. California Coastkeeper Alliance and California Waterkeeper organizations are members of the international Waterkeeper Alliance, a network of water advocates with more than 200 programs in 21 countries on 6 continents led by Robert F. Kennedy Jr. Using law, policy, science, and creative media, CCKA is an experienced advocate that advances statewide policies and programs for healthy and clean waters. CCKA and local Waterkeeper groups develop, implement and defend policies that meet the needs of California's distinct communities and ecosystems. Together, CCKA and its network of Waterkeepers provide the public with the tools and information needed to hold decision-makers accountable and to be effective local water stewards.

COLIN BAILEY

Colin Bailey is the Executive Director of the Environmental Justice Coalition for Water and is based in Sacramento, California. He is fluent in English and conversant in Spanish. He has his Juris Doctorate from UCLA with a certificate from the Program in Public Interest Law and Policy and a concentration in Critical Race Studies. An accomplished social justice attorney, Colin leads EJCW's effort to implement the human right to water and supports EJCW's statewide policy agenda, programs, outreach and education, and grassroots member organizations.In addition, he leads EJCW's work with the Environmental Water Caucus, Community Engineering Corps, Ecological Society of America, Sacramento Valley Water Justice Network, US Human Rights Network, and more.

The Environmental Justice Coalition for Water

The Environmental Justice Coalition for Water (EJCW) works within a Community-to-Capital framework, connecting the most pressing needs of our disadvantaged community partners to our network of partners and agencies statewide. Since 1999, EJCW's work has been rooted in the communities most affected by environmental injustice. Issues and solutions are identified through regional chapters and statewide work groups. EJCW is positioned in the state capital, in order to connect communities with state agencies to bring about change multilaterally through advocacy, education, training, litigation, community organizing, and capacity-building, and by providing technical assistance. EJCW aims to effectively influence the intersections of water justice and environmental justice, community health, and human rights issues from community to global levels.

CAROLINA BALAZS

Carolina has been a UC President's Post-Doctoral Fellow at the University of California, Davis (UC Davis), bridging the academic-community water justice research community. She is also a consulting Research Scientist with California Environmental Protection Agency's Office of Environmental Health Hazards Assessment (OEHHA). At OEHHA, she is leading the development of a "Human Right to Water" tracking tool for the state of California. Her doctoral research examined drinking water quality problems in California's Central Valley and the environmental justice implications. Following graduate school, Carolina worked as a Research Scientist at the Community Water Center, promoting community-based participatory research and developing community-led water justice solutions. She holds a Bachelor of Science (BS) in Environmental Science from Brown University and both a Master of Science (MS) and Doctor of Philosophy (PhD) from the Energy and Resources Group at the University of California, Berkeley (UC Berkeley).

WENDY BROLEY

Wendy Broley is staff engineer at California Urban Water Agencies (CUWA) and Water Reuse Leader at Brown and Caldwell. Wendy is a licensed professional engineer with over 14 years of experience in water and wastewater engineering and operations, membrane technology and biosolids solutions, as well as business development for both municipal and industrial markets. She is committed to the development of a diverse and resilient water portfolio for her clients using an integrated "One Water" approach to water management. With a specific focus on transforming the perception of wastewater treatment plants into "resource recovery facilities," Wendy has stepped into the role as Water Reuse Leader at Brown and Caldwell. Wendy started her career as a consulting engineer supporting the membrane operations of multiple advanced water treatment facilities for indirect potable reuse applications totaling over 100 MGD of production capacity. Mrs. Broley holds a BS in Chemical Engineering from University of California, San Diego (UCSD).

California Urban Water Agencies

CUWA's mission is to provide a forum for combining the expertise and resources of its member agencies to advance reliable, high-quality water supplies for the State's current and future urban water needs in a cost-effective manner for the public, the environment and the economy. CUWA's efforts are guided by its 11 member agencies and supported by an Executive Director. Member agencies' resources are pooled to study water management issues, develop consensus solutions among the urban water community, and engage with California water leaders.

AMANDA FENCL

Amanda Fencl has been a member of the Center for Environmental Policy and Behavior (CEPB) for four years as a PhD student in the University of California, Davis Geography Graduate Group. Her dissertation explores the ways that drought can exacerbate California's drinking water disparities. As a PhD student she interned with the Governor's Office of Planning and Research (OPR) on drought policy, and assists OPR's Local Drought Liaison with a project on household water shortages and drought vulnerability. Since summer 2015, she has worked with Dr. Julia Ekstrom at the University of California, Davis Policy Institute's Climate Adaptation Initiative to look at extreme event impacts on California's drinking water quality. She and Dr. Ekstrom have a state grant to understand drought impacts on and responses of small, self-sufficient drinking water systems. Her dissertation is supported through a National Science Foundation (NSF) Graduate Research Fellowship (2015-2018), a NSF Climate Change, Water and Society IGERT (2013-2015) traineeship, and University of California, Davis research grants. She was a Staff Scientist at the U.S. Center of the Stockholm Environment Institute (SEI) for 6 years and has a BA in International Relations and Environmental Studies from Tufts University.

Center for Environmental Policy and Behavior

The mission of the CEPB is scientific analysis of the interactions among policy institutions, human behavior, and political decisions in the context of environmental and natural resource conflicts. Through developing and testing theoretical models from social science, CEPB seeks to derive practical lessons that can be used to improve environmental policy. We focus on a wide variety of environmental problems and issues, including watershed management, climate change, forest management, marine/coastal systems, biodiversity, and agriculture. The CEPB team includes an actively engaged group of faculty and graduate students who come from diverse backgrounds. CEPB is co-directed by Dr. Mark Lubell and Dr. Gwen Arnold, housed in the Department of Environmental Science and Policy at University of California, Davis, and affiliated with researchers from other academic universities, government agencies, and other University of California, Davis programs and departments.

KELSEY HINTON

AKelsey Hinton joined the Community Water Center (CWC) in 2015. As the former AmeriCorps Fellow, now Program Associate, Kelsey works to build the capacity of CWC through communications, fund development and policy work in order to improve and expand programs to provide disadvantaged communities with access to safe and affordable drinking water. An Indiana native, Kelsey recently graduated from Indiana University's School of Public and Environmental Affairs (SPEA) with a degree in Environmental Management. Her senior thesis focused on the feasibility of direct potable water reuse in Las Vegas. She is currently pursuing her Master's of Public Affairs (MPA) with a concentration in Policy Analysis at SPEA and will graduate in May 2017.

Community Water Center

The CWC is a non-profit environmental justice organization based in California's San Joaquin Valley, whose mission is to act as a catalyst for community-driven water solutions through organizing, education, and advocacy. CWC's fundamental goal is to ensure that all communities have access to safe, clean, and affordable water. CWC helps build strategic grassroots capacity to address water challenges in small, rural, low-income communities and communities of color. For more information, visit CWC's website at www.communitywatercenter.org and follow us on Twitter at @CWaterC.

GITA KAPAHI

Gita Kapahi is the Director of the Office of Public Participation (OPP) for the State Water Resources Control Board (SWRCB), and has been since the office was created in late 2007. In this office she serves in many capacities, including ombudsman, tribal liaison, environmental justice coordinator, small business liaison, agricultural liaison, education and outreach coordinator, facilitator, and public participation consultant. She has been with the SWRCB for 24 years, first as an Environmental Scientist in the Division of Water Quality, then in the Division of Water Rights, serving as Chief of the Bay Delta Unit. Prior to that, she was a fisheries consultant to the Canadian Department of Fisheries and Oceans.

Office of Public Participation, California State Resources Water Board

The OPP responds to public inquiries about SWRCB programs. The SWRCB created this program to strengthen our efforts at involving the public in our decision-making process. The office intends to reach out to environmental justice and other communities and have better communication and interaction with tribal governments and others. Additionally the office will assist staff with designing and implementing effective stakeholder involvement processes, including translation and other services, to ensure all interested parties can participate in SWRCB activities.

BRITTANI ORONA

Brittani is an enrolled member of the Hoopa Valley Tribe. She graduated with a BA in History from Humboldt State University, has an MA in Public History from California State University Sacramento, and is currently a doctoral student at University of California, Davis in Native American Studies with a Designated Emphasis on Human Rights. Her research focuses on indigenous memory and meaning in land use and environmental justice initiatives in California. Brittani helped to coordinate an exhibit and oral history project about the removal of four PacifiCorp dams on the Klamath River. She has also acted as an exhibit consultant for the Autry Museum of the American West, the Maidu Museum and Historic Site, and the Goudi'ni Native American Arts Gallery at Humboldt State University on exhibits related to environmental justice and water rights. Brittani has worked at the California Government Operations Agency, California State Indian Museum, the California State Office of Historic Preservation, California State Archives, and the Maidu Museum and Historic Site.

BRIAN POMPEII

Brian Pompeii is a human-environmental geographer at California Polytechnic State University, San Luis Obispo (Cal Poly) with research interests in water resources, sustainability, vulnerability, hazards, and climate adaptation. His current research project explores how drought-strained surface water access has led to an increase in groundwater usage for industrial agriculture, and subsequently a disaster-level increase in domestic well failure in disadvantaged unincorporated communities in the San Joaquin Valley of California. He received his PhD in Geography from Arizona State University.

California Polytechnic State University, San Luis Obispo

Cal Poly is a nationally ranked, four-year, comprehensive public university located in San Luis Obispo, halfway between San Francisco and Los Angeles on California's Central Coast. It is a distinctive learning community offering academically focused students a hands-on educational experience that prepares them for today's scientific and technical world.

TIM SLOANE

Tim is Executive Director for the Institute for Fisheries Resources (IFR), having begun his career with IFR and its sister organization, the Pacific Coast Federation of Fishermen's Associations (PCFFA), under the direction of William F. "Zeke" Grader, Jr. He advocates for clean, sustainable, and productive fisheries, protection of aquatic habitat, and workable fisheries management legislation. He is a member of the Marine Fish Conservation Network's National Policy Committee, and holds a seat on the Golden Gate Salmon Association Board of Directors. He received his BA in history from University of California, Berkeley, and a JD from Golden Gate University with a certificate in environmental law. He is a member of the State Bar of California.

Institute of Fisheries Resources

Established in 1993 by the PCFFA, IFR is responsible for carrying out the fishery research and conservation needs of working fishing men and women. Initially, IFR helped fishermen in California and the Pacific Northwest address salmon protection and restoration issues, with particular focus on dam, water diversion, and forestry concerns. Since 1998, IFR's range of programs has greatly expanded to encompass conservation projects and policy debates at the regional, national, and international levels. The IFR is dedicated to the protection and restoration of fish resources and the human economies that depend on them. By establishing alliances among fishing men and women, government agencies, and concerned citizens, IFR unites resource stakeholders, protects fish populations, and restores aquatic habitats.

EXHIBIT C

Social Disparities in Nitrate-Contaminated Drinking Water in California's San Joaquin Valley

Carolina Balazs,[1] Rachel Morello-Frosch,[2,3] Alan Hubbard,[2] and Isha Ray[1]

[1]Energy and Resources Group, [2]School of Public Health, and [3]Environmental Science Policy and Management, University of California, Berkeley, California, USA

BACKGROUND: Research on drinking water in the United States has rarely examined disproportionate exposures to contaminants faced by low-income and minority communities. This study analyzes the relationship between nitrate concentrations in community water systems (CWSs) and the racial/ethnic and socioeconomic characteristics of customers.

OBJECTIVES: We hypothesized that CWSs in California's San Joaquin Valley that serve a higher proportion of minority or residents of lower socioeconomic status have higher nitrate levels and that these disparities are greater among smaller drinking water systems.

METHODS: We used water quality monitoring data sets (1999–2001) to estimate nitrate levels in CWSs, and source location and census block group data to estimate customer demographics. Our linear regression model included 327 CWSs and reported robust standard errors clustered at the CWS level. Our adjusted model controlled for demographics and water system characteristics and stratified by CWS size.

RESULTS: Percent Latino was associated with a 0.04-mg nitrate-ion (NO_3)/L increase in a CWS's estimated NO_3 concentration [95% confidence interval (CI), –0.08 to 0.16], and rate of home ownership was associated with a 0.16-mg NO_3/L decrease (95% CI, –0.32 to 0.002). Among smaller systems, the percentage of Latinos and of homeownership was associated with an estimated increase of 0.44 mg NO_3/L (95% CI, 0.03–0.84) and a decrease of 0.15 mg NO_3/L (95% CI, –0.64 to 0.33), respectively.

CONCLUSIONS: Our findings suggest that in smaller water systems, CWSs serving larger percentages of Latinos and renters receive drinking water with higher nitrate levels. This suggests an environmental inequity in drinking water quality.

KEY WORDS: California, drinking water, environmental justice, nitrate, public health, Safe Drinking Water Act, social disparities, water systems. *Environ Health Perspect* 119:1272–1278 (2011). http://dx.doi.org/10.1289/ehp.1002878 [Online 3 June 2011]

An array of drinking water–related problems still exists in the United States, despite a history of investment in sophisticated water infrastructure and the existence of federal laws such as the Clean Water Act of 1972 and Safe Drinking Water Act of 1974 (SDWA) that regulate source contamination and protect the public's health. These problems include increasing source contamination (Dubrovsky et al. 2010), exposure to chemical and microbial contaminants, poor implementation of water laws (Burke 2009; Duhigg 2009), and degrading infrastructure (Levin et al. 2002). Rural areas often face the largest burden, as aquifers are contaminated by intensive agriculture and livestock production (Dubrovsky et al. 1998). Some rural unincorporated areas, such as some communities along the U.S.–Mexico border, lack access to adequate infrastructure, service provision, and clean water (Olmstead 2004; Pilley et al. 2009).

Despite these problems, there is a paucity of studies that examine social disparities in exposure to unsafe water. A literature review in the 1990s (Calderon et al. 1993) recommended that more quantitative analyses examine whether vulnerable populations, including people of color and the poor, are disproportionately affected by drinking water contamination. Since then, a handful of studies have addressed different aspects of this issue. In San Joaquin County, California, one study found a weak but significant relationship between areas with higher poverty and greater proportions of minorities and poor drinking water quality (Byrne 2003). Research in the Navajo Nation found bacteriological and chemical contamination in unregulated drinking water sources (Murphy et al. 2009). In Arizona, researchers examined whether public water systems serving higher fractions of minority or low-socioeconomic-status (SES) residents were more likely to exceed the arsenic maximum contaminant level (MCL) than were those serving higher fractions of whites or high-SES residents. They found a positive association between the percentage of Latino residents and the likelihood of exceeding the MCL of arsenic. However, they concluded that environmental justice concerns were unwarranted for Latinos, because there was no difference between the percentages of Latinos who were served by water systems with and without violations. (Cory and Rahman 2009). In New Mexico, preliminary research documented high arsenic levels in drinking water sources that provided water to predominantly Latino border communities known as "colonias" (Pilley et al. 2009).

Our research addresses several methodological limitations of previous studies, particularly regarding appropriate unit of analysis, characterization of exposure, and scale. For example, Byrne (2003) estimated average trichloroethylene levels and MCL exceedances in drinking water systems and characterized exposure as a continuous measure across San Joaquin County; the community level, however, is more appropriate when considering community-level exposure. Cory and Rahman (2009) characterized the association between percent minority and a binary outcome of arsenic, rather than a continuous measure of arsenic levels, and they did not explore this association among smaller systems where they noted that most arsenic violations occurred.

Our study used the community as the unit of analysis to examine the relationship between nitrate concentration in community water systems (CWSs) and social factors. CWSs are public water systems that serve water year-round to at least 25 people or have > 15 service connections [U.S. Environmental Protection Agency (EPA) 2010b]. We characterized potential exposure to nitrate because it is one of the most common contaminants found in groundwater (Harter 2009; Spalding and Exner 1993) yet has received little attention regarding social disparities in exposure.

Nitrate in drinking water is associated with methemoglobinemia (i.e., "blue baby syndrome") in infants (Fan and Steinberg 1996; U.S. EPA 2010a), although other risk factors include enteric infections (Charamandari et al. 2001; Hanukoglu and Danon 1996) and foods

high in nitrates (Sanchez-Echaniz et al. 2001). Epidemiologic data also suggest an association between nitrate levels in drinking water and reproductive toxicity, developmental effects, and various cancers (Fan and Steinberg 1996; Ward et al. 2005, 2010), although the consistency of these associations varies. To protect against methemoglobinemia, the SDWA has established an MCL of 45 mg/L as nitrate ion (NO_3) or 10 mg/L as nitrate-nitrogen in drinking water (U.S. EPA 2010a).

California's San Joaquin Valley is an important site for examining potential disparities in exposure to nitrate. With its intensive irrigated agriculture, the valley has two of the most contaminated aquifers in the nation and some of the highest nitrate levels in the country (Dubrovsky et al. 1998, 2010). Because nearly 95% of the valley's population relies on groundwater for drinking [Permits, Inspections, Compliance, Monitoring and Evaluation (PICME) [California Department of Public Health (CDPH) 2008a], groundwater contamination is a particular health risk. This risk is compounded by the fact that with high costs of mitigation, few systems actually treat for nitrate. The San Joaquin Valley also has some of the highest rates of poverty and minority populations—particularly Latinos—in the state (U.S. Census Bureau 2007). These communities are economically and socially disadvantaged, making it harder for them to afford mitigation or to address related health consequences of nitrate contamination. The continued use of nitrogen-based fertilizers (Dubrovsky et al. 2010; Ruddy et al. 2006) and the increasing demand for groundwater (Glover 2010) further highlight the importance of this contaminant, because exposure may become increasingly widespread.

Given this context, we used water quality monitoring data from the CDPH to analyze the association between racial/ethnic and SES characteristics of people served by CWSs and nitrate levels of these systems in the San Joaquin Valley. With few exceptions (Byrne 2003), there has been limited use of CDPH monitoring data to examine whether certain groups are disproportionately affected by exposure to drinking water contaminants. Similarly, despite an acknowledgment of the burden faced by small systems (Committee on Small Water Systems 1997), few studies have explored associated social disparities.

We hypothesized that CWSs serving a higher percentage of minority or lower-SES residents have higher nitrate levels and that these disparities are likely to be greater among smaller drinking water systems. Disparities in nitrate exposures, if they exist, could signal a potential environmental injustice. This analysis expands the emerging literature on drinking water quality and social disparities in the United States and informs national- and state-level policy on the needs of underresourced water systems.

Materials and Methods

Our units of observation were CWSs in California's San Joaquin Valley. We used three measures to test our study's hypotheses: *a*) estimated average nitrate concentrations for each CWS to describe average water quality served to customers; *b*) population potentially exposed (PEP) to three nitrate levels to estimate the population affected by nitrate contamination; and *c*) nitrate concentrations at points of entry into each CWS's distribution system to assess the relationship between demographic characteristics of customers and CWS nitrate levels. The first two measures were used in a series of descriptive statistical analyses. The third measure was used as the outcome variable in linear regression models that estimated the relationships between race/ethnicity and SES and a system's nitrate concentration.

Sample selection and time period. We included CWSs that were active in the San Joaquin Valley between 1999 and 2001, had at least one point-of-entry source with a nitrate sample reported for this period, and had any source (i.e., point of entry or not) with geographic coordinate data available to estimate CWS demographics. Point-of-entry sources can be defined as sources of supply (e.g., well with no treatment or effluent from a well/surface water plant) that directly enter into the distribution system (Figure 1). We used nitrate-sampling data from 1999 to 2001 and demographic data from the 2000 Census. The sampling period represents one full compliance period under the SDWA [California Code of Regulations (CCR) 2008, §64400.25]. Of the 873 CWSs that were active during 1999–2001, 711 had sources with geographic coordinates. Of these, 327 (37%) had nitrate water quality sampling data and were included in our final sample.

Average nitrate concentration for CWSs. To estimate nitrate concentration for each CWS, we selected two types of point-of-entry sources for inclusion (Figure 1): *a*) sources, such as well fields or surface water plants, that were in active use and had no treatment or that were treated for contaminants other than nitrate, and *b*) treatment plants in active use that potentially treated for nitrate. In both cases, we included only sources that were last in line to enter the distribution system (i.e., did not flow to another source before entering), to avoid double counting of nitrate levels. We used the CDPH's Permits, Inspections, Compliance, Monitoring and Enforcement database (CDPH 2008a) to identify source types, their location in relation to the distribution system, and their possible treatment techniques. If a plant had a treatment technique commonly used for nitrate (e.g., reverse osmosis), we assumed that it treated for nitrate.

We then used nitrate-sampling data for these sources from the CDPH (2008b) Water Quality Monitoring database to determine nitrate concentration at points of entry. This served as a proxy for water quality in each CWS's distribution system and for tap water quality. Nitrate levels are unlikely to change from these entry points to the tap (unless systems chloraminate, which those in the valley do not) (Haberman R, personal communication). CWSs using groundwater are required to sample each source for nitrate annually (unless a single sample or average of two samples exceeds the MCL, in which case the system must sample quarterly); CWSs using surface water must sample quarterly (CCR 2008, §64432.1). In practice, however, systems often fail to sample regularly (Haberman R, personal communication). If a nitrate sample was below the detection limit

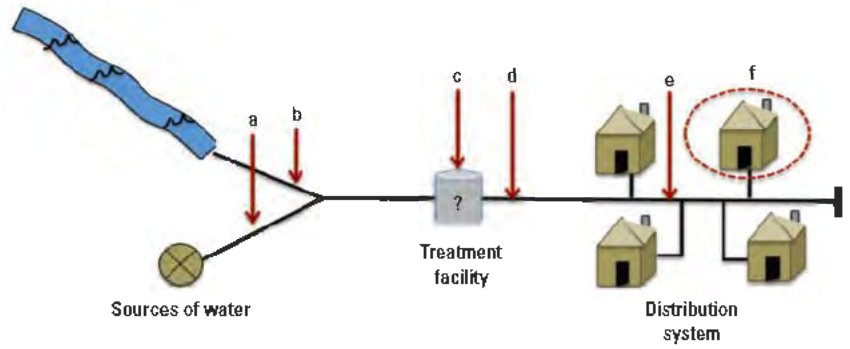

Figure 1. Schematic of a community water system (CWS) indicating the location of point-of-entry sources and the use of average nitrate concentration in the distribution system as a proxy for tap water quality. Water entering the distribution system may flow from a groundwater well (point a) or from a surface water source (i.e., stream; point b). Water may then be treated (point c; different treatment techniques may be used, depending on the contaminant of interest and original source). Water then enters the distribution system at points of entry (point d). In this example, nitrate samples would be used from point d, because points a and b flow into the same point of entry. Average nitrate level at point d is used to represent average water quality in the distribution system (point e). Nitrate levels in the distribution system are a proxy for tap water quality (point f). If points a and b are separate points of entry (i.e., do not flow into a shared point d), nitrate sample points would be used from each source separately. Constant and equal flows are assumed.

of 2 mg NO_3/L (CCR 2008, §64432), we took the square root of the value as a proxy for that sample's nitrate level (Lubin et al. 2004). We did not have flow measurements for the individual sources that contributed water to each CWS's distribution system. Therefore, we could not determine a flow-weighted measure of distribution water quality for each CWS based on the nitrate level measured in samples from each contributing source. Instead, we assumed that each point-of-entry source contributed independently and equally to a CWS's distribution system, and that each source contributed a constant amount to the system, regardless of season.

Finally, we determined the average nitrate level for each point-of-entry source and averaged the resulting values across all sources to estimate an average systemwide nitrate level. The systemwide average was then used to categorize each CWS's average nitrate concentration as *a*) low, defined as < MCL/2 (< 22.5 mg NO_3/L); *b*) medium (22.5–44.9 mg NO_3/L); and *c*) high (≥ 45 mg NO_3/L, the MCL for nitrate). These categories correspond to those used to assess source-level nitrate concentrations for regulatory purposes (CCR 2008, §64432.1). Besides the high category, the medium category is important to consider because research suggests that exposure to nitrate in drinking water at half the MCL can cause adverse health effects among susceptible subpopulations (DeRoos et al. 2003). In addition to calculating average nitrate levels, we used nitrate MCL violation data from PICME to verify whether CWSs with high nitrates did in fact receive violations, and to run a sensitivity analysis on PEP data.

Potentially exposed population. Using a method by Storm (1994), we computed the potentially exposed population (PEP) by apportioning the total population served by each CWS into three exposure categories based on the proportion of sources for that CWS with average nitrate levels that were low, medium, or high, as defined above. The population in each category was then summed across all CWS to estimate the total population potentially exposed to the three nitrate levels. The approach to calculate the PEP for the high-nitrate category is summarized by the following equation:

$$PEP = \sum_{i=1}^{327} [(X_i \times s_{il}/S_{it}) + (X_i \times s_{im}/S_{it}) + (X_i \times s_{ih}/S_{it})], \quad [1]$$

where X_i is the total population served in CWS i; s_{ih} is the number of sources for CWS i with average nitrate concentrations classified as high (h); and S_{it} is the total number of point-of-entry sources for CWS i. To calculate the PEP for the low (l) or medium (m) nitrate categories, we replaced s_{ih} with s_{il} or s_{im}, respectively. We used PICME 2008 data on the number of people served by each CWS to calculate the population size in each exposure category during 1999 to 2001. If the number of customers served by a CWS was not available from the PICME data, we used information from the CDPH Water Quality Monitoring database. To estimate population counts of potentially exposed individuals according to demographic characteristics (e.g., race/ethnicity) we multiplied the potentially exposed population in each nitrate category for each CWS by the estimated proportion of customers in each demographic subgroup for the CWS, and then summed these values across all CWS for each nitrate category. Because home ownership is based on housing units rather than population count, we did not derive a count of housing units.

Statistical analysis of nitrate levels and CWS characteristics. We used a linear regression model to analyze the relationship between CWS demographics and nitrate levels. We fitted a model selected *a priori* that controlled for known or hypothesized system-level confounders. We originally used a mixed model approach to account for clustering (Laird and Ware 1982). However, diagnostics of the mixed model indicated a very non-normal distribution of residuals. Therefore, we used an approach that provided inference that was robust under laxer modeling assumptions. To derive the inference (i.e., standard errors), we clustered outcomes at the water system level (i.e., point-of-entry nitrate concentrations measured on a given day for a given source). Thus, our final model reported sandwich-type robust standard errors (Huber 1967) that allow for arbitrary correlation, including correlation within or across sources in a CWS.

Our outcome variable, Y_{ijk}, is nitrate concentration for the ith water system, the jth source in system i, on day k (since 1 January 1999). Although nitrate samples from individual sources are our outcome measurements, the CWS is the primary unit of analysis, consistent with average nitrate level calculations discussed above. Our final model did not reweight CWSs with more samples (as the mixed model might have, depending on the implied estimated correlation structure), because we wanted CWS to contribute measurements based on a proxy of the number of people served. Thus, systems with more measurements contributed more to the estimates. We addressed this assumption by stratifying by system size, to see if smaller CWSs (with fewer samples) had a different effect than did larger CWSs. Because differences between the estimates of the mixed model and the linear model were small, this comparison provided evidence that the nonweighted approach of our final model was reasonable.

Key independent variables were the percentage of Latino and non-Latino people of color served by CWSs (referent category was non-Latino whites) and percent home ownership in the area served by a CWS. Latinos were analyzed separately because they are the largest ethnic group in the valley (40%; U.S. Census Bureau 2007). SES was represented by home ownership rate, which is a proxy for wealth and political representation (Krieger et al. 1997; Morello-Frosch et al. 2001; Oliver and Shapiro 1997). Because of our focus on CWS-level exposures, these variables were measured at the CWS level. We assumed these remained constant for all 3 years.

Race/ethnicity and home ownership data were derived from the 2000 U.S. Census (U.S. Census Bureau 2000). Because CWS service areas do not follow census boundaries, we used two spatial approaches in geographic information systems to estimate demographic variables for each CWS. We first compared an aerially weighted approach using digitized CWS boundaries in two pilot counties (Tulare and Fresno) with a second approach joining spatial coordinates from CDPH data for all sources (well fields, surface water intakes, and treatment plants) to census block groups. Based on spatial and goodness-of-fit comparisons, we concluded that it was reasonable to use the latter approach [for details on the aerially weighted approach and the comparison between the two methods, see Supplemental Material (http://dx.doi.org/10.1289/ehp.1002878)]. In brief, for each CWS, we estimated a population-based average of each variable across all block groups that included sources for the CWS. For example, if a CWS had two sources in two census block groups, we determined the population-weighted average of the variable across both census block groups and used that value to derive a percent estimate of demographic groups (e.g., 50% Latino) served by each CWS.

We controlled for other water system characteristics that could be potential confounders: source of water (groundwater or groundwater plus surface water vs. surface water alone), whether the system served a city (i.e., incorporated) or an unincorporated area, ownership structure of the system [publicly vs. privately owned and not regulated by the Public Utility Commission (PUC), with privately owned PUC-regulated systems as the referent category], system location (agricultural valley floor or not), season (summer/fall or winter/spring), year of sampling (2000 or 2001, with 1999 as referent category), and number of service connections (< 200 or ≥ 200 connections). CWSs with < 200 connections are generally considered "small" (CCR 2008, §64432.1). We determined ownership structure by combining data in PICME with data from the PUC's list

of regulated systems. We obtained all other characteristics from PICME. With the exception of year and season, which were measured at the source level, all covariates were measured at the water system level.

In addition to models including all CWSs, we stratified by system size to assess whether demographic effects on water quality might be stronger among smaller systems and to test the hypothesis that scale alone explains water quality. We also used our final model to estimate the amount of nitrate contamination attributable to the proportion of the population that is Latino. We did so by using the final model to predict expected values for each observation if percent Latino equaled zero, as described in Greenland and Drescher (1993). All statistical analyses were conducted using Stata (version 10; StataCorp LP, College Station, TX). We used Stata's cluster command (clustering at the CWS level) to derive robust SEs.

Results

Descriptive statistics. The 327 systems in our sample served approximately 2.95 million people, or 96% of the San Joaquin Valley population served by CWSs (Table 1). The distribution of average system-level nitrate concentrations is right-skewed and ranges from 0 to 150 mg NO_3/L. This distribution and range are similar for average source-level nitrate concentrations and for individual sampling points (data not shown). The mean proportion of Latinos served across these CWSs was 32%, with an interquartile range (IQR) of 10–50%. The mean proportion of homeownership was 70%, with an IQR of 60–82%. Compared with all the CWSs in the valley active from 1999 to 2001, our study sample underrepresented small CWSs that have < 200 connections (49% vs. 73%; Table 1). The number of samples per source in systems with < 200 connections ranged from 1 to 110 (mean, 3.2), compared with a range of 1–133 (mean, 4.5) for systems with ≥ 200 connections. Six percent of samples had concentrations below the detection limit.

Overall, 3% (n = 10) of all CWSs in our sample had high average nitrate concentrations (above the MCL of 45 mg NO_3/L) for at least some part of the study period, 10% (n = 33) had medium average concentrations (MCL/2 to MCL), and 87% (n = 284) had low average concentrations (< MCL/2; Figure 2). Of the 10 CWSs with an average nitrate concentration > MCL, 9 had < 200 connections and 8 had only one or two sources. All but 1 of these 10 CWSs received at least one MCL violation during the study period, and 14 CWSs in our sample (serving ~ 92,268 people) received at least one MCL violation [PICME (CDPH 2008a); see also Supplemental Material, Table 1 (http://dx.doi.org/ 10.1289/ehp.1002878)].

CWSs that served higher fractions of Latinos and lower fractions of homeowners (i.e., more renters) had higher average nitrate levels. Figure 3 shows that in the two highest Latino quartiles, proportionately more systems had average nitrate concentrations > MCL (i.e., 5% and 7% in the two higher quartiles compared with 0% in both of the lower quartiles). These two quartiles also had the largest fractions of CWSs in the medium nitrate category. The two quartiles with the lowest rates of home ownership had the

Table 1. CWSs included in study sample compared with all active CWSs, San Joaquin Valley, California, 1999–2001.

Variable of interest	Active CWSs with source location (n = 327)	CWSs in study (n = 327)	CWSs with < 200 connections (n = 160)	CWSs with ≥ 200 connections (n = 167)
Total population	3,047,822[a]	2,948,346	27,165	2,921,181
Latino population (%)	34	39	29	40
White population (%)	58	47	64	47
Population above poverty level[b] (%)	57	57	59	57

[a]Approximately 71,418 people were served by CWSs whose sources did not have geographic coordinates, and 80 CWSs had no population estimates available; including these sources, the estimate of "true" population served by active CWSs was at least 3,119,240. [b]Above 200% of the poverty level. [c]A CWS that serves a city that is a legally recognized municipal corporation with a charter from the state and governing officials that is incorporated, as opposed to a water system that serves an unincorporated area. [d]Reference group, surface water only.

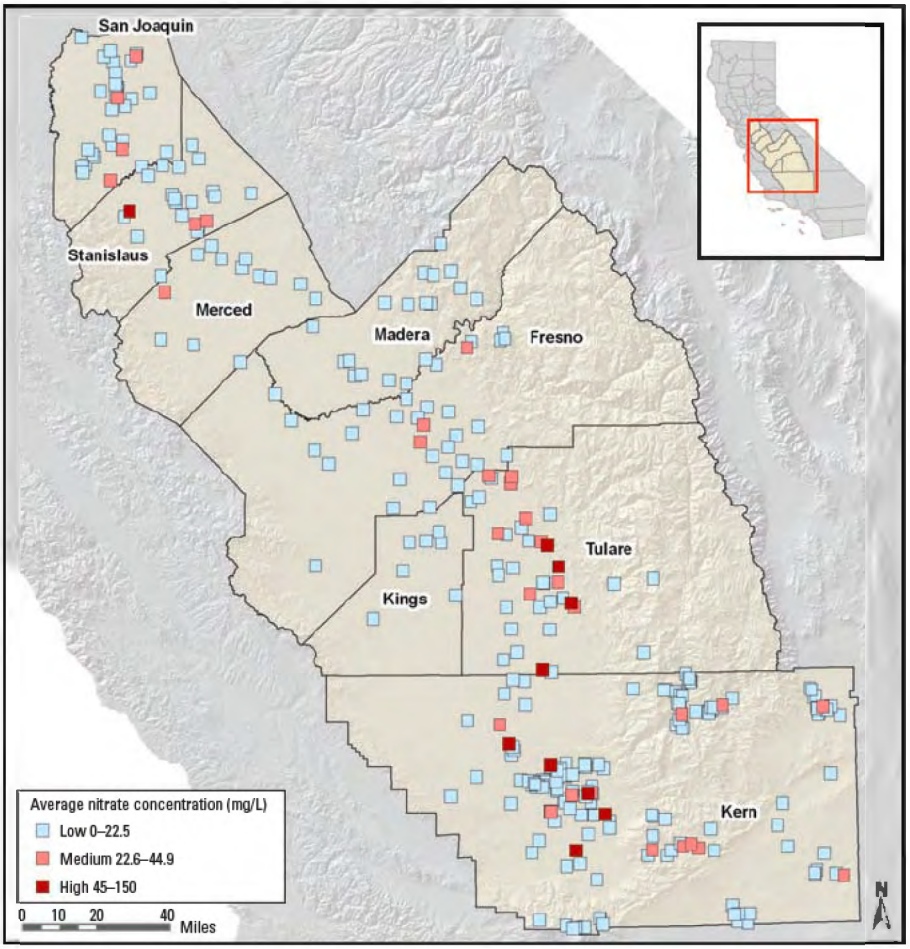

Figure 2. Average nitrate concentration of CWSs in California's San Joaquin Valley, 1999–2001 (n = 327). Estimates are based on an average of each point-of-entry source's average concentration. Data are from CDPH (2008) Water Quality Monitoring and PICME databases (CDPH 2008a, 2008b). Approximate locations of CWSs are depicted, but not true boundaries. Because of close proximity of some CWSs, some CWSs not fully visible.

largest proportions of systems in the medium and high nitrate categories (15% and 22%, respectively), compared with the two quartiles with the highest rates of home ownership (which had 7% and 8%, respectively).

Of the population served in our sample, approximately 84.6% (~ 2,494,442 people) were potentially exposed to low nitrate levels, 15.2% (~ 448,729 people) to medium nitrate levels, and 0.2% (~ 5,176 people) to high nitrate levels (Table 2). Of the 5,176 people served water with nitrates above the MCL, 56% were people of color (50% Latinos and 6% non-Latino), compared with 52% in the low and medium nitrate categories (Table 2).The percentage of Latinos served by high-nitrate CWSs was higher than the percentage of Latinos served by CWSs in the other two nitrate categories (39% and 40% for low and medium nitrate, respectively). This percentage was also greater than the percentage of Latinos in our entire study sample (39%; Table 1). This percentage was also higher than the percentage of Latinos served by CWSs in the other two nitrate categories (39% and 40% for low and medium nitrate, respectively).

Model results. Table 3 shows the multivariate modeling results. Unadjusted models indicate that percent Latino was positively and significantly [β = 0.14; 95% confidence interval (CI), 0.04–0.24] correlated with the average nitrate concentration in the distribution system. Conversely, home ownership was negatively correlated with average nitrate concentration but only marginally significant (β = –0.15; 95% CI, –0.30 to 0.003).

Our adjusted model suggests that, on average, a 1% increase in Latinos served by a CWS was associated with an increase of 0.04 mg NO_3/L (95% CI, –0.08 to 0.16). For home ownership, each percent increase was associated with a decrease of 0.16 mg NO_3/L (95% CI, –0.33 to 0.002). For systems with < 200 connections, the associations between percent Latino and home ownership and nitrate concentration were consistent with both the unadjusted model and adjusted model for all CWSs, but the strength of the association for percent Latino increased. Specifically, on average, each percent increase in Latino was associated with a 0.44 mg NO_3/L increase (95% CI, 0.03–0.84) in the smaller systems. A 1% increase in home ownership was associated with a 0.15 mg NO_3/L decrease (95% CI, –0.64 to 0.33), although the association was not statistically significant. In systems with ≥ 200 connections, neither race/ethnicity nor home ownership was associated with nitrate concentrations. Using the final model to predict expected values, we estimated that among small systems, nitrate levels for CWSs with 0% Latinos would be, on average, 6 mg NO_3/L lower compared with CWSs at the mean.

Discussion

To our knowledge, this is the first study to examine the relationship between nitrate levels in CWSs and social disparities in the United States. After stratifying by system size, we found that among systems with < 200 connections, those serving higher percentages of Latinos had higher nitrate levels. We found an inverse but not statistically significant association between home ownership and nitrate levels for smaller systems. For large systems, we did not find significant associations between race/ethnicity or home ownership and nitrate levels. Our findings corroborate previous drinking water studies (e.g., Byrne 2003) that showed a positive relationship between percent minority and poor water quality but are specific to nitrate contamination at the community level. That water quality varied by percent Latino or home ownership matters not only because of environmental equity but also because elevated nitrate levels could pose a greater hazard to subpopulations that may have less access to health care.

The association of race/ethnicity and SES with nitrate levels could be due to several factors. Race/ethnicity could have been related to proximity to agriculture, as well as the ability of residents to participate in the governance of their CWSs. For example, in systems with higher fractions of Latinos, language abilities, citizenship status, or lack of political clout could inhibit residents from speaking out and demanding improvements in water quality (for a discussion in relation to electoral politics, see Michelson 2000). Home ownership could have been negatively associated with nitrate levels because renter-based communities may have had a lower capacity to pay for improvements in water infrastructure or to hold a CWS accountable, assuming they received notices of violation as required (CCR 2008, §64463). Or, it might indicate that a lack of economic resources may influence whether CWSs can hire capable water managers or comply with regulations.

That > 5,000 people in our study sample were potentially exposed to drinking water with nitrate concentrations above the MCL raises health concerns. As noted, acute and chronic health effects have been found for vulnerable populations (e.g., infants and pregnant women) exposed to nitrate exceeding the MCL (Ward et al. 2005). Furthermore, that many of the water systems in this category had only one or two sources can lead to increased chances of high exposure for residents if these are high-nitrate sources, because there is no immediate alternative water source to draw from or blend with. These small systems often go years with high nitrate levels, until a new water source can be developed (Spath D, personal communication). PICME (CDPH 2008a) data corroborates this observation: of the 10 systems whose average nitrate concentration exceeded the MCL, 6 had recurring MCL violations over an 8-year time frame. In these systems, customers may be continually exposed (although exposure would be lower if people frequently use alternative sources). Additionally, because customers in the

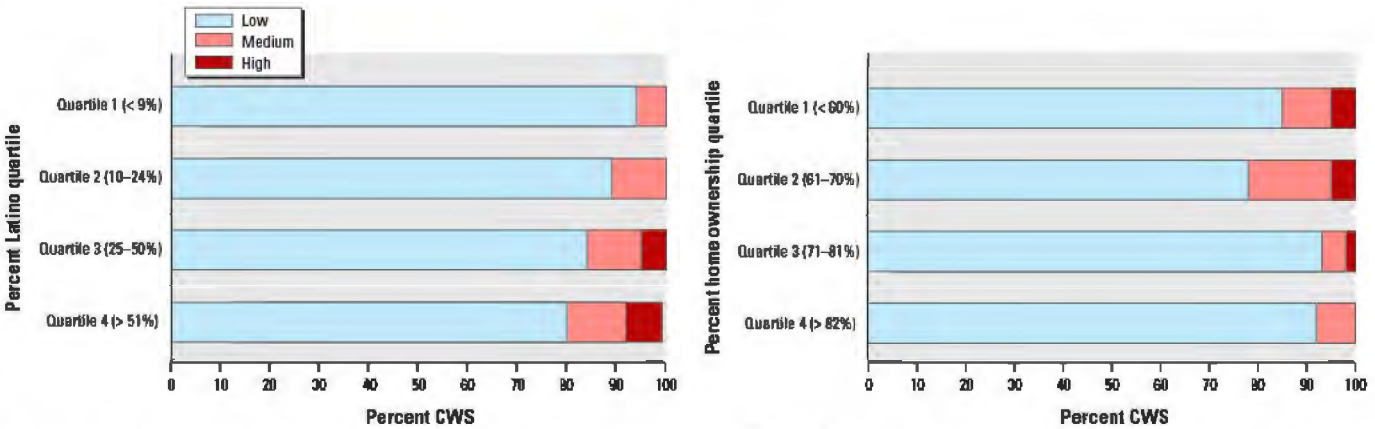

Figure 3. Percentage of CWSs with low, medium, and high average nitrate concentrations, by quartiles of percent Latino and home ownership. Average system-level nitrate concentration is derived from the average of each source's average nitrate concentration at point of entry. Low is < one half the MCL of 45 mg NO_3/L. Medium is one half the MCL up to the MCL (22.5 mg/L to 44.9 mg/L NO_3). High is ≥ to the MCL.

San Joaquin Valley often cope by purchasing bottled water, they pay two water bills—one for tap water and the other for bottled water (Moore et al. 2011).

Our results also highlight a less frequently discussed issue—approximately 448,700 residents, served by 33 CWSs, in our sample received water with medium nitrate levels (< MCL but > MCL/2). Nitrate levels in these systems could be approaching the MCL in some cases. In our study, one-third of CWSs in this category had average concentrations > 30 mg NO_3/L. Residents in these systems could be at risk of adverse health outcomes and/or could experience additional economic costs. For example, in one study, the risk of colon cancer increased for certain susceptible subgroups (e.g., those with low vitamin C intake or high meat intake) whose water had nitrate levels > MCL/2 for at least 10 years (DeRoos et al. 2003). More generally, although several authors have suggested that the current nitrate MCL could be increased to a less stringent level of regulation (L'hirondel and L'hirondel 2002), others have argued that the standard should not be changed (Ward et al. 2005) because of uncertainties in the exposure assessment data and health effect estimates of the epidemiologic study upon which the current MCL is based (Walton 1951). Some authors also argue that the MCL includes no safety factor, and documented cases of infant methemoglobinemia have occurred at levels below the MCL (Fan and Steinberg 1996). Thus, exposure to nitrates in the middle category is important to consider.

Monitoring of water quality by these CWSs is also an important consideration. CWSs with any source whose nitrate levels exceed MCL/2 (> 22.5 mg NO_3/L) are required to increase their monitoring frequency from annual to quarterly sampling (CCR 2008, §64432.1). At best, the cost of increased monitoring must be passed along to consumers. At worst, the funding and staffing constraints can limit the capacity of small CWSs to monitor; these CWSs may have nitrate levels approaching the MCL but neither the system operators nor customer base would know (Haberman R, personal communication). Such a scenario would undermine the aim of the SDWA, which is supposed to protect the public from harmful exposures and requires systems to notify their customers so that precautionary measures can be taken to reduce exposures (CCR 2008, §64480; Fan and Steinberg 1996).

This study used an appropriate unit of analysis (i.e., CWS) for estimating system-level nitrate exposure. The methods we used could be applied to other contaminants and to other regions of the United States. However, sources of error exist in our demographic estimate because *a*) surface intakes/well fields could fall in census block groups not served by the CWS, *b*) not all census block groups served by a CWS have an intake/field located within them, and *c*) Latinos in census data could be undercounted because of legal status. Despite these potential errors, for most CWSs, sources fell within the same census block groups that overlapped with service area boundaries of CWSs. And, for 9 of the 10 systems in the high-nitrate category, all sources were in the same census block groups as those included in each CWS service area [see Supplemental Material (http://dx.doi.org/10.1289/ehp.1002878)]. Additional sources of error include possible misclassification of points of entry to the distribution system because of errors in PICME. Furthermore, because the relative flow of different sources contributing to each CWS was not known, our method may have over- or underestimated average nitrate levels. However, at least among CWSs with average concentrations over the MCL, the estimated concentrations were similar to the measured concentrations for which that CWS received one or more MCL violations. Our measure of exposure was limited by data availability, so for systems with fewer samples tested for nitrates, our estimate may be less accurate. Although the number of persons potentially exposed to nitrate over the MCL is small, it is likely to be an underestimate of the actual population affected in the San Joaquin Valley. This is partly because our study underrepresented smaller CWSs, and partly because we used average rather than maximum nitrate levels or other measures of nitrate (e.g., MCL violations). Thus, our estimate is likely to be a conservative measure of potential exposure. The estimate of the PEP may also contain some error, because there may be some differences among utilities in how population estimates are calculated. Finally, although our results are based on data that are 10 years old, we believe that, at a minimum, they capture current trends in the San Joaquin Valley because nitrate concentrations generally

Table 2. Demographic profile of total PEP[a] in study sample by average level of nitrate concentration.

Variable of interest	Nitrate level		
	Low	Medium	High
Percent total population (n = 2,948,346)	84.6	15.2	0.2
Percent Latino (n = 1,164,714)	39	40	50
Percent non-Latino people of color (n = 389,336)	13	12	6
Percent white (n = 1,394,296)	47	48	44

Low is less than one-half the MCL of 45 mg NO_3/L; medium is one-half the MCL up to the MCL (22.5 mg/L to 44.9 mg/L NO_3); high is equal to or greater than the MCL.
[a]Per water system, PEP is the population count of the demographic variable of interest x (number of point-of-entry sources in one of three nitrate levels ÷ by the total number of point-of-entry sources). PEP displayed in table is equal to the sum across all water systems. This value can also be interpreted as the estimated number of people served water at this level.

change slowly in deeper public supply wells and have been increasing in most locations because of increasing fertilizer use (Dubrovsky et al. 2010).

Conclusion

Our study is one of the first to analyze the relationships between drinking water contamination, race/ethnicity, and SES in the United States and the first that focuses on social disparities in nitrate contamination. Our results indicate that Latinos in the San Joaquin Valley may be disproportionately exposed to higher levels of nitrates and that this exposure is particularly prevalent in smaller water systems. With the increasing use of nitrogen-based fertilizers and growing demand for groundwater, these trends are likely to worsen in future years. Regulatory and policy strategies to address scale-related vulnerabilities in drinking water quality have generally ignored the environmental justice implications for CWSs. Given the U.S. EPA's renewed focus on environmental justice (U.S. EPA 2009) and the paucity of environmental justice studies on drinking water, this study highlights the importance of targeting funding for mitigation and source water protection efforts for underserved communities and those with nitrate levels over the MCL. Furthermore, there is a need for resources to better monitor water quality and develop precautionary mitigation for communities with nitrate levels > MCL/2.

Environmental justice implications of arsenic contamination in California's San Joaquin Valley: a cross-sectional, cluster-design examining exposure and compliance in community drinking water systems

Carolina L Balazs[1*], Rachel Morello Frosch[2,3], Alan E Hubbard[2] and Isha Ray[1]

Abstract

Background: Few studies of environmental justice examine inequities in drinking water contamination. Those studies that have done so usually analyze either disparities in exposure/harm *or* inequitable implementation of environmental policies. The US EPA's 2001 Revised Arsenic Rule, which tightened the drinking water standard for arsenic from 50 μg/L to 10 μg/L, offers an opportunity to analyze both aspects of environmental justice.

Methods: We hypothesized that Community Water Systems (CWSs) serving a higher proportion of minority residents or residents of lower socioeconomic status (SES) have higher drinking water arsenic levels and higher odds of non compliance with the revised standard. Using water quality sampling data for arsenic and maximum contaminant level (MCL) violation data for 464 CWSs actively operating from 2005–2007 in California's San Joaquin Valley we ran bivariate tests and linear regression models.

Results: Higher home ownership rate was associated with lower arsenic levels (ß coefficient= −0.27 μg As/L, 95% (CI), 0.5, 0.05). This relationship was stronger in smaller systems (ß coefficient= −0.43, CI, 0.84, 0.03). CWSs with higher rates of homeownership had lower odds of receiving an MCL violation (OR, 0.33; 95% CI, 0.16, 0.67); those serving higher percentages of minorities had higher odds (OR, 2.6; 95% CI, 1.2, 5.4) of an MCL violation.

Conclusions: We found that higher arsenic levels and higher odds of receiving an MCL violation were most common in CWSs serving predominantly socio economically disadvantaged communities. Our findings suggest that communities with greater proportions of low SES residents not only face disproportionate arsenic exposures, but unequal MCL compliance challenges.

Background

Arsenic in drinking water is linked to skin, lung, bladder and kidney cancers [1-3]. The most common exposure pathway is consumption of groundwater containing arsenic [4]. Many epidemiological studies examining health effects of arsenic in drinking water have been conducted in areas with extremely high levels (i.e., > 100 μg As/L)—such as Argentina, Bangladesh and Taiwan. But high concentrations (i.e., 50–100 μg As/L) also occur in the U.S, especially in western regions such as Utah, Nevada, Arizona and California [5-8]. Here, arsenic in groundwater is generally naturally occurring, but can also derive from agricultural activities including pesticide application and industrial uses (e.g. wood treatment) [4,9]. In California's San Joaquin Valley, arsenic can reach elevated concentrations due to mobilization caused by agricultural activities. In particular, irrigation and drainage enhance arsenic releases, while high evapotranspiration rates can concentrate arsenic in surface water and shallow groundwater [4,10,11].

In 2001, on the basis of epidemiologic evidence and cost-benefit considerations [12] the U.S. Environmental Protection Agency (EPA) issued the Revised Arsenic Rule, reducing allowable arsenic concentrations in drinking water from 50 μg/L to 10 μg/L. The revision of this drinking water standard came with much debate. Critics of the standard argued that there was uncertainty in the risk assessment, and that the cost-benefit analyses overestimated benefits in relation to costs of compliance. Ultimately, however, the EPA's Science Advisory Board and the National Research Council (NRC) concluded that the science was sufficient to warrant a more health-protective standard [12-14].

The revised rule elicited considerable discussion regarding equity considerations for small water systems [15,16]. Of the estimated 5.5% of community water systems that were expected to be affected by the Revised Arsenic Rule, nearly 97% were small systems serving fewer than 10,000 customers [17]. Benefit-cost analyses concluded that although there would be a net benefit for households, the average annual compliance costs for residents served by smaller systems would be much greater. Recognizing this discrepancy, the US EPA extended the compliance date by two years for systems serving fewer than 10,000 customers, assessed alternative affordable technologies for small systems and focused on analyzing additional impacts that would be felt by these systems [14]. Effective in 2002, the Revised Arsenic Rule required all public water systems to comply with the new standard by January 23, 2006 [14].

Besides these scale-related considerations, however, little attention was given to other potential social disparities that could arise in, for example, exposure to arsenic, or the types of small systems that would be able to comply with the revised standard. In response, several environmental justice-oriented studies explored potential inequities in exposure to arsenic [18,19] and in enforcement of the arsenic standard [5]. Generally, these studies focused on two types of distributional issues: (1) disparities in environmental harms, such as exposure to contaminants, or disparities in health outcomes, and (2) disparities in the inequitable implementation of policies and programs, including access to federal funds or capacity to comply.

Attention to both components of environmental justice is certainly warranted. We argue, however, that a joint focus – on compliance challenges as well as exposure to contaminants – is most helpful for understanding the health and social implications of drinking water policies, including the Revised Arsenic Rule. Quantifying a water system's compliance with the arsenic MCL is important to know which systems are in violation, and to consider whether they are equipped to comply. This "compliance burden" allows for an exploration of whether certain groups or communities have unequal abilities in the capacity to meet the standard. Quantifying exposure levels and their distribution is important, given known health risks at levels even below the new standard. Thus this study employs what we term a "joint burden analysis," to analyze the environmental justice implications of compliance capacity and exposure related to arsenic contamination. Together, these analyses provide a picture of the joint burdens that water systems and residents may face.

We applied a cross-sectional analysis of social disparities related to the Revised Arsenic Rule. We conducted our study in California's San Joaquin Valley, one of the poorest regions in the country with some of the most contaminated drinking water sources in California [20], including high nitrate and high arsenic levels [21]. We focused on community water systems (CWSs), which are public water systems that serve at least twenty five customers or fifteen service connections year-round [22]. We hypothesized that CWSs serving a higher proportion of minority or lower socioeconomic status (SES) residents have a higher odds of non-compliance with the revised arsenic standard and that these CWSs serve drinking water with higher levels of arsenic.

Our analysis provides two contributions to the arsenic and drinking water literature. By assessing exposure disparities and compliance burdens at the time of the enactment of the Revised Arsenic Rule, we assess the potential exposure and compliance disparities that existed but were not fully incorporated into policy assessments. Secondly, we consider the compliance challenges that CWSs could face moving forward, broadening the discussion of policy implementation issues that must be considered by drinking water regulators and the US EPA.

Given the U.S. EPA's renewed discussion of the impact of the Revised Rule on small systems, and on how to help small systems achieve compliance, the results of this study are timely for policy circles as well. For example, the U.S. EPA recently convened a working group on arsenic in small water systems to provide input on barriers to the use of point-of-use and point-of-entry treatment units, as well as alternative affordability criteria that pay particular attention to small, rural, and lower income communities [23]. Our study's quantitative analysis of the distribution of exposure and compliance burdens therefore adds to the environmental justice literature and informs these policy discussions.

Methods

Sample selection and selection of point-of-entry sources

We selected CWSs located in California's San Joaquin Valley that were actively operating between 2005 and 2007, had at least one source with a geographic coordinate that could be used to estimate customer demographics, and had at least one active point-of-entry source with an arsenic sample reported during this period. These selection criteria resulted in a slight under-representation of smaller systems (i.e., < 200 connections) in our final sample (see Additional file 1: Table A1). Our time period represents one full compliance period under the SDWA, in which each CWS should have taken at least one arsenic sample [24].

Point-of-entry sources are those that directly enter the distribution system. We selected two types of point-of-entry sources: (1) sources in active use that had no arsenic treatment, or that treated for contaminants other than arsenic, and (2) treatment plants in active use that potentially treated for arsenic (Additional fle 2: Figure A1). We used the California Department of Public Health's (CDPH) Permits, Inspections, Compliance, Monitoring and Enforcement (PICME) database [25] to identify source types, their location in relation to the distribution system, and their possible treatment techniques. We confirmed the existence of arsenic treatment technologies with state and county regulators.

For the six CWSs with confirmed arsenic treatment plants that were in use during the study period, we used all point-of-entry sampling points prior to installation of treatment, and only sampling points from treatment plants after the installation date. For CWSs with no confirmed arsenic treatment, we selected systems where either all point-of-entry sources were labeled as untreated, or all point-of-entry sources were labeled as having treatment. In practice a CWS may have both treated and untreated sources. But because the CDPH databases did not allow us to accurately ascertain whether untreated sources entered the distribution system if treated sources were also available, we conservatively selected CWSs in this manner. We tested the sensitivity of this decision by comparing regression results using our final sample to results using all CWSs. Our final sample included 464 of the 671 CWS active in the Valley from 2005 to 2007.

Outcome measures and independent variables

In order to assess compliance with the Revised Arsenic Rule (i.e., MCL violations) and exposure burdens, we conducted two main sets of analyses: one focused on MCL violations, the other on exposure. Specifically, for each CWS, we derived four main outcome measures: (1) officially recorded arsenic MCL violations, (2) average system and source-level arsenic concentrations, (3) population potentially exposed to arsenic, and (4) water quality samples of arsenic concentrations at point-of-entry to the distribution system. We used the first measure to analyze compliance. We used the second two measures to derive descriptive exposure statistics and run sensitivity analyses. We used the fourth measure as the outcome variable in a linear regression model. We calculated average arsenic measures because (1) the MCL for arsenic is assessed using running annual average of arsenic concentrations for water systems; and (2) this MCL is based on a consideration of long-term chronic exposure making the average concentration of arsenic a suitable metric.

Arsenic MCL violations

The key outcome for our compliance analysis was officially recorded arsenic MCL violations derived from the PICME database. We created a binary variable indicating whether a system had received at least one MCL violation during the study period. This measure helped control for bias that could occur because CWSs with higher arsenic levels are required to sample more frequently [26], thereby increasing the probability that they would receive more MCL violations.

Average system and source-level arsenic concentrations

To estimate arsenic concentrations in the distribution system we used arsenic water quality sampling data for the selected point-of-entry sources from CDPH's Water Quality Monitoring database [27] (Additional file 2: Figure A1). Previous studies have noted the benefit of using such publicly available water quality monitoring records as an alternative to costly tap water samples [28]. Using these data points, we derived the average arsenic concentration served by each CWS for the entire compliance period. We calculated this by averaging the average source concentrations for each system during our time period. As in previous studies [5,19], we assumed average system-level concentrations represent the average arsenic concentration in water served to residents. We also calculated each CWS's yearly average arsenic concentration to conduct sensitivity analyses. Because we did not have flow

measurements for individual sources, we assumed that each point-of-entry source contributed independently, constantly and equally, to a CWS's distribution system, regardless of season. For sampling points below the detection limit, we took the square root of the detection limit as a proxy for the arsenic concentration [29].

We categorized source-level and system-level averages into three concentration categories defined in relation to the revised arsenic rule (> 10 μg As/L) and the old rule (> 50 μg As/L): (1) < 10 μg As/L ("low"), (2) 10–49.9 μg As/L ("medium"), and (3) ≥ 50 μg As/L ("high"). In addition, we used average source and system-level concentrations to create binary variables that we used in bivariate analyses. Here, average levels were coded as 1 (≥ 10 μg As/L), or 0 (< 10 μg As/L).

Potentially exposed population

Using a previously developed method [30] described in Balazs et al. [31], we computed the population potentially exposed to the three aforementioned exposure categories. The approach to calculate the potentially exposed population (PEP) for the high-arsenic category is summarized by the following equation:

$$PEP_h = \sum_{i=1}^{464} (X_i \times s_{ih}/S_{it}) \quad (1)$$

where X_i is the total population served in CWS i; s_{ih} is the number of sources for CWS i with average arsenic concentrations classified as high (h); and S_{it} is the total number of point-of-entry sources for CWS i. To calculate the PEP for the low (l) or medium (m) categories, we replaced s_{ih} with s_{il} or s_{im}, respectively. We used PICME data on the number of people served by each CWS to calculate the population size. If the number of customers served by a CWS was not available from the PICME database, we used information from the Water Quality Monitoring database. To estimate counts of potentially exposed individuals according to demographic characteristics (e.g. race/ethnicity) we multiplied the PEP in each arsenic category for each CWS by the estimated proportion of customers in each demographic subgroup for the CWS (e.g. 50% people of color), and then summed these counts across all CWSs for each arsenic category.

Concentration of arsenic at point-of-entry

Arsenic sampling data for each point-of-entry source were used as the outcome variable in our regression model, as described under "Regression Model" below.

Analyses

Compliance analyses

We used our binary arsenic MCL violation variable to analyze whether CWSs with higher fractions of people of color or lower SES faced greater compliance violations. Because only 34 CWSs had at least one MCL violation we did not have enough outcomes to use multivariate regression techniques. Instead we ran Fisher's Exact tests for contingency tables, comparing the presence of at least one MCL violation to CWSs with high or low levels of our variables of interest (i.e. race/ethnicity or homeownership). To determine the threshold for high and low levels of race/ethnicity (i.e., percent people of color) or homeownership rate we used the median value of these variables.

To consider the impact of under- or mis-reported violations, we ran sensitivity analyses in which we replaced official MCL violations with the number of CWSs with any source whose average yearly arsenic concentrations exceeded the MCL during the study period, and the number of CWSs with any source whose compliance period average exceeded the MCL. This allowed for an approximation of whether a system may have exceeded the MCL (and so should have been issued an MCL violation) since arsenic MCL violations are based on a running annual average [26]. Thus these sensitivity analyses should capture differences due to MCL exceedances that went under-reported.

Exposure analyses

To assess the relationship between demographics of customers served by CWSs and potential exposure, we first examined the demographic characteristics of the population potentially exposed to three different arsenic levels, and additional characteristics of the systems at those levels. To further analyze the relationship, we used our binary variables for average system-level arsenic concentrations to conduct Fisher's Exact tests.

Finally, we examined the relationship between system-level demographics and arsenic levels using our continuous measure of arsenic concentrations. We used a linear cross-sectional regression model with robust standard errors to account for clustering. To derive the inference, we clustered outcomes at the CWS-level (i.e. point-of-entry arsenic concentrations measured on a given day for a given source). Our final model reported sandwich-type robust standard errors [32] that allowed for arbitrary correlation, including correlation within CWS units. The a priori selected model controlled for known or hypothesized potential system-level confounders.

The model's outcome variable, $Y_{ijk,}$ was arsenic concentration for the i^{th} water system, the j^{th} source in system i, on day k (since January 1st, 2005). While arsenic samples from individual sources were our outcome measurements, the CWS was the primary unit of analysis, consistent with other calculations above. Our final model did not re-weight CWSs with more samples; thus systems with more

measurements contributed more to the estimates. We addressed this issue by stratifying by system size to see if smaller CWSs (with fewer samples) had a different effect on water quality than larger CWSs.

Key independent variables were the percentage of people of color served by CWSs (referent category non-Latino whites) and percent home ownership in each CWS. Home ownership rate is a proxy metric for wealth and political representation [33]. We used this SES measure as an indicator of the economic resources available to a water system to mitigate contamination [34]. Race/ethnicity and home ownership data were derived from the 2000 U.S. Census, measured at the CWS-level, and assumed to be constant for all three years [35]. Since CWS service areas do not follow Census boundaries we used a spatial approach in Geographic Information Systems (GIS) to estimate demographic variables for each CWS. In brief, for each CWS, we estimated a population-weighted average of each variable across all block groups that contained sources for the CWS. This value was used to derive a percent estimate of demographic characteristics (e.g. 50% homeownership) served by that CWS [31].

We controlled for other potentially confounding water system characteristics including: source of water (ground water or groundwater and surface water versus surface water alone); system ownership (public, privately owned and not regulated by the Public Utility Commission (PUC), with private PUC-regulated as referent category); geographic location (Valley floor and foothills, with mountains as referent category); season (summer/fall or winter/spring); year of sampling (2006 and 2007, with 2005 as referent category); and number of service connections (< 200 or ≥ 200 connections). We determined ownership structure by combining data in PICME with data from the PUC's list of regulated systems. We obtained all other characteristics from PICME. With the exception of year and season, all covariates were measured at the water system level.

We stratified by system size to assess if demographic effects on water quality might be stronger among smaller systems, and to test the hypothesis that scale alone explains water quality. We used number of connections as a threshold for small versus large CWSs, where those with fewer than 200 connections are considered "small" [26]. We used our final model to estimate the amount of arsenic contamination attributable to the proportion of the population that are homeowners by predicting expected values for each observation if percent homeownership equaled 100%, as described by Greenland and Drescher [36]. All statistical analyses were conducted using Stata v10 (College Station, Texas). We used Stata's cluster command to derive robust standard errors.

Results

Descriptive statistics

The 464 CWSs in our study sample served 1.134 million people, representing 37% of the total population served by CWSs between 2005 and 2007, and 69% of all CWSs active through 2007 (Table 1). The mean percentage of people of color served by each CWSs was 39% [inter-quartile range (IQR), 16-57%]. The mean percent of homeownership was 70% (IQR, 60-81%). The yearly average arsenic concentration in 2005, 2006 and 2007 was 7.0 μg/L (median = 3 μg/L) 7.9 μg/L (median = 2.5 μg/L), respectively and 6.8 μg/L (median = 3 μg/L), respectively. Approximately 12% of samples were below the detection limit.

Nearly 15% of all CWSs in the sample had average arsenic concentrations between 10 and 50 μg As/L, and were therefore affected by the revised standard (Table 2). Among these, 66% had fewer than 200 connections, and 86% had three active wells or less. For each CWS with average arsenic in this range, the average percentage of a CWS's sources that exceeded the revised MCL was 87% (Table 2). Less than 1% of CWSs had average levels greater than 50 μg As/L. Among these, all had fewer than 200 connections. CWSs west of Highway 99 and in the central portion of the Valley had higher arsenic levels, as did some areas in the foothills and in southeastern Kern County (Figure 1).

Of the population served in our sample, approximately 14% was potentially exposed to arsenic levels over 10 μg/L MCL (Table 3). Of the population potentially exposed to 10–50 μg As/L, 61% were people of color (i.e. Latinos and non-Latino people of color). This is higher than the corresponding percentage in the entire study sample (i.e., 55%, Table 1).

Statistical analyses

Compliance analyses: MCL violations

Thirty-four CWSs, serving 151,391 people, received at least one arsenic MCL violation during the study period. Of these, 31 had average system-level arsenic concentrations over 10 μg As/L and 3 had average concentrations of 8, 8.8 and 9.9 μg As/L. CWSs serving higher percentages of homeowners had a 67% lower chance of having at least one MCL violation (Table 4). CWSs serving higher percentages of people of color had a 260% higher chance of having at least one MCL violation. Sensitivity analyses in which we used average source-level concentrations were consistent, yielding results of similar strength and direction (see Additional file 3: Table A2).

Binary measure of exposure

CWSs serving higher percentages of homeowners had a 57% lower chance of having average arsenic levels above the revised MCL (Table 5). CWSs serving higher

percentages of people of color had a 130% higher chance of having average arsenic levels above the revised MCL.

Absolute measure of arsenic exposure

Results from the multivariate regression model examining the relationship between CWS demographics and absolute arsenic concentrations generally parallel descriptive findings. Unadjusted models had beta coefficients of –0.14 (95% Confidence Interval (CI), -0.34, 0.06) for homeownership, and –0.01 for percentage of people of color (95% CI, -.11, 0.08). Our adjusted model had a beta-coefficient of –0.27 (95% CI, -0.50, -0.05) for

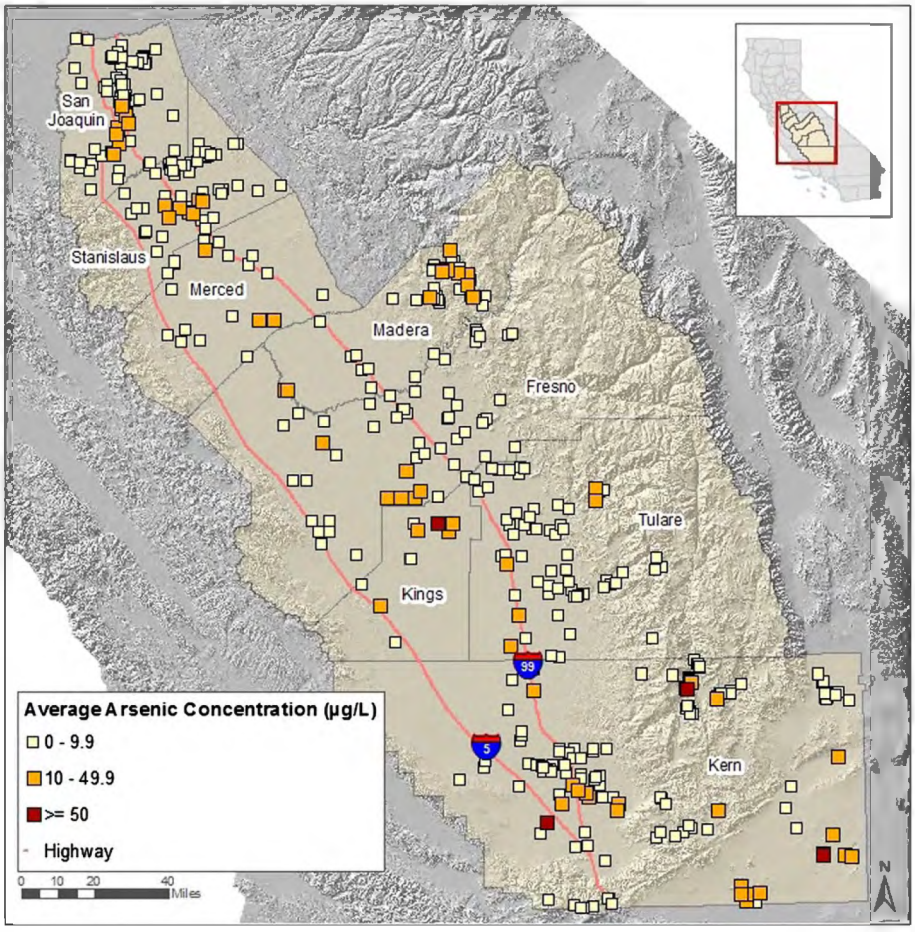

Figure 1 Average arsenic concentration[a] of community water systems (CWS [b,c]) in study sample, (n = 464), 2005 2007. [a] Estimate based on average of each point of entry source's average concentration; [b] Sources of data: CDPH Water Quality Monitoring and PICME databases (CDPH 2008a,b); [c] Approximate location of CWSs are depicted, but not true boundaries. Due to close proximity of some CWSs, map partially covers some CWSs.

homeownership. This suggests that, on average, a 10% decrease in homeownership was associated with a 2.7 μg As/L increase, or roughly one third the mean arsenic concentration across all CWSs (6.0 μg As/L, see Table 1). The beta coefficient for percentage people of color was −0.02 (95% CI, -0.13, 0.09). This suggests that a 10% increase in the percentage of people of color served by a CWS was associated with an increase of .2 μg As/L, though this association was not statistically significant.

Results from our stratified model (Table 6) suggest similar, but stronger, trends among smaller systems. Among systems with less than 200 connections, the beta coefficient for homeownership was −0.43 (95% CI, -0.84, -0.03). This suggests that, on average, a 10% decrease in homeownership is associated with a 4.3 μg As/L increase, or nearly 70% of the mean arsenic concentration across all CWSs. The beta coefficient for percentage people of color was −0.17 μg As/L (95% CI, -0.36, 0.02), although this result was not statistically significant. In systems with at least 200 connections, the coefficients on percent homeownership and people of color were −0.19 (95% CI, -0.40, 0.02) and 0.03 (95% CI, -0.09, 0.15), respectively; neither of these results was statistically significant. Using this final stratified model to predict expected values, we estimated that arsenic levels in

Table 3 Demographic profile of potentially exposed population (PEP [a]) by average arsenic levels, 2005–2007, San Joaquin Valley, CA

Population characteristics	Average arsenic concentration		
	< 10 μg/L	10 49.9 μg/L	≥ 50 μg/L
% Total Population (1,134,017)	86.1	13.7	0.2
% People of Color[b]	54	61	24
% Non Latino White	46	39	76

[a] Per water system, PEP = population count of demographic of interest x (# of sources in one of three arsenic level/total # of sources sampled). PEP displayed in table is equal to sum across all water systems. This value can also be interpreted as the estimated number of people served water at this level.
[b] People of color refer to both Latino and non Latino people of color.

Table 4 Fisher's exact tests and related odds ratio (OR) for maximum contaminant level (MCL) violations, 2005–2007, San Joaquin Valley, CA

Variable of interest	≥ 1 MCL violation	No MCL violation	OR (95% CI)	P value
High % Homeownership	12	269	.33 (.16, .67)	.003
Low % Homeownership	22	161		
High % People of Color	24	207	2.6 (1.2, 5.4)	.01
Low % People of Color	10	223		

Fisher's Exact test compares high and low category for variable of interest, where threshold is determined by median value across all CWS, and includes related odds ratio. Test compares demographics in community water systems that received at least one MCL violation to those with zero violations.

CWSs with 100% home ownership would be, on average, 3.1 μg As/L lower, compared to CWSs at the mean.

Discussion

This study analyzed demographic differences in exposure and compliance burdens associated with the Revised Arsenic Rule in the San Joaquin Valley. We found that communities with lower rates of home ownership and greater proportions of people of color had higher odds of having an MCL violation. We also found a negative association between homeownership rates and arsenic concentrations in drinking water, with a stronger effect among smaller CWSs. These results indicate that communities with fewer economic resources faced a dual burden—they were not only exposed to higher arsenic levels, but were also served by systems more likely to receive an MCL violation.

Nearly 14% of the population in the study sample was potentially exposed to average arsenic levels above the revised standard, highlighting the health risks faced by Valley residents. At the revised level, cancer risks are estimated to be 12 in 10,000 and 23 in 10,000 for bladder cancer among women and men, respectively, and 18 in 10,000 and 14 in 10,000 for lung cancer, among women and men [12]. While we did not find a significant association between race/ethnicity and arsenic levels, a disproportionate number of the population potentially exposed to levels of 10 μg As/L or more were people of color. This indicates that as a whole, this group may still face disproportionate exposure.

Our results are consistent with previous findings that CWSs with higher arsenic levels serve customers with lower income levels [19]. Our results differ somewhat from a previous study [5] that found that while percent Latino was positively associated with the likelihood of exceeding the arsenic MCL, so was high SES. This difference could be due to differences in trends across states (i.e. Arizona vs. California), our additional measurements of exposure and compliance, or our focus on CWSs rather than all public water systems.

Study limitations

Some limitations in our study are worth noting. As noted, the selection criteria we used (source location and arsenic samples) led to a slight under-representation of smaller systems in our final sample. Because the smallest systems had slightly higher arsenic levels and serve higher percentages of people of color and homeowners, this selection bias could also lead to an underestimate of our observed associations.

There are also several potential sources of measurement error in our dependent and independent variables. Under-reporting or under-issuing of violations could impact the count of MCL violations. However, sensitivity analyses comparing MCL violations in our final sample to results including all CWSs yielded consistent results. Similarly, sensitivity analyses comparing results using the binary MCL variable to binary measures that used average source-level concentrations were similar. Because of this consistent negative relationship between SES and each of these measures, we expect minimal impact on our results due to this potential under-reporting. This does not, however, explain why 41 CWSs (out of 72) had average system-level concentrations above the MCL but had no violation recorded; this may be related to selective enforcement and is worth further investigation.

Table 5 Fisher's exact tests and related odds ratio (OR) for average arsenic level, 2005-2007, San Joaquin Valley, CA

Variable of interest	≥ 10 μg As/L	< 10 μg As/L	OR (95% CI)	p value
High % Homeownership	28	233	.45 (.25, .72)	.002
Low % Homeownership	44	159		
High % People of Color	35	162	1.3 (.81, 2.2)	.3
Low % People of Color	37	230		

Fisher's Exact test compares high and low categories of the variable of interest to CWSs whose average arsenic was above or below the revised MCL. The threshold for the variable of interest is determined by median value across all CWS, and includes related odds ratio. Test compares demographics for community water systems whose average arsenic was above or below the revised MCL.

†Regression with robust standard errors, clustered by CWS. Coefficients represent the estimated difference in mean concentration at the system level associated with a unit change in the covariate (95% CI); na=not applicable, as no CWSs in this model run contains this factor, or all CWSs have this factor.
[a]Unadjusted models, all CWSs included; [b]Adjusted model, all CWSs included; [c] Surface water is referent category; combined refers to combination of groundwater and surface water sources; [d]Privately owned PUC regulated CWS as referent category; [e] 2005 is referent year; [f] Mountains is referent category.
* p < .10, ** p < .05, *** p < .01; R^2 in Model B = .08; R^2 in Model C = .09.

There may also be some misclassification of points-of-entry into the distribution system. However, sensitivity analyses, including and excluding CWSs with treated and untreated point-of-entry sources yielded consistent regression coefficients for home ownership. While results for estimated exposure and compliance burdens are nearly five years old, we believe that, at a minimum, they capture current trends because unless CWSs have installed treatment plants or are using water from new wells (which is unlikely for small systems), temporal variability of arsenic levels is likely to be small [37]. Since our study focused only on CWSs, which excludes private well owners and communities with fewer than 15 service connections, the estimated number of potentially exposed people and impacted systems is likely to be an underestimate.

There may be errors in our demographic estimates, as we had to use data from the U.S. Census 2000 to approximate demographics between 2005 and 2007. There could also be error in our demographic estimates from: (1) surface intakes/well fields falling in Census block groups not served by the CWS, (2) not all Census block groups served by a CWS having an intake/field located within them, and (3) Latinos in Census data being undercounted due to legal status. For the majority of CWSs, sources fell within the same Census block groups that overlapped with the service area boundaries of CWSs [31]. But, because not all source/intake locations fell within block groups that intersect with service area boundaries of CWSs [31], this could lead to misclassification error of our demographic variables. This could result in a bias of the estimated association, but given the relatively small proportion of these systems, and the independence of SES status and inclusion in a linked census block group/water service boundary, this bias will be relatively trivial.

Study implications

In California's San Joaquin Valley, elevated arsenic levels are primarily derived from sedimentary deposits that can be mobilized by groundwater withdrawals and irrigation practices [10,11]. This means that our observed association could be partly explained by the location of low SES communities in relation to these agricultural activities. However, one would not necessarily expect a Valley-wide relationship between low SES and high arsenic levels, since arsenic is largely naturally occurring, and there are other areas in the Valley where low SES systems rely on shallower water.

Instead, our results can be understood as a reflection of the mediating role of system-level capacity. Smaller water systems often lack the economies of scale and resource-base to ensure the technical, managerial and financial (TMF) capacity to reduce contaminant levels [34,38]. They may be less able to install treatment, apply for funding, or drill new wells. The socioeconomic status of residents directly influences TMF capacity, because it affects the ability of a water system to leverage internal (e.g., rate increases) or external (e.g., loans) resources [34]. Thus, CWSs with lower SES customers may have been less able to support adequate TMF or to ensure compliance with the revised arsenic standard by 2007. That four of the six CWSs with treatment had more than 200 connections suggests that larger CWSs (with more resources and greater economies of scale) were

able to comply more quickly with the revised standard, a result supported by previous research and acknowledged by the U.S. EPA [14,38]. Furthermore, that the majority of CWSs with average arsenic concentrations over the revised standard were small and had a high fraction of their wells with high arsenic levels indicates that these systems had few alternative sources of clean drinking water to begin with, making short-term solutions unattainable.

Our joint burden analysis highlights the need to consider not only exposure and current states of compliance, but also the *future* mitigation potential of impacted water systems and the households they serve. We have shown that CWSs with lower SES residents faced the greatest exposure and compliance burdens. Looking forward in time, these same systems may be the least equipped to comply with EPA drinking water standards for three reasons. First, these CWSs are often less able to develop long-term plans to reduce contamination. For example, some low SES communities in the Valley have secured funding to upgrade their infrastructure, but their plans failed to include steps to enter into compliance with the new arsenic standard [39]. Second, low-SES CWSs may be less able to apply for funding. By 2010, 13 of the 72 CWSs in our study with medium and high arsenic levels were not listed as having applied to the State Revolving Fund to help pay for mitigation options [40]. These CWSs were mainly small (< 200 connections) and had lower rates of home ownership (60% vs. 65%, $p < .10$) compared to CWSs that were listed. Funding sources, such as the State Revolving Fund, may further disadvantage small CWSs' efforts to mitigate arsenic exposures and comply with the standard, because they require that systems have adequate TMF capacity to be eligible for funding. Finally, even with funding secured, low-SES water systems with low TMF capacity may be unable to maintain compliance. For example, some CWSs have installed arsenic treatment technologies, only to be forced to shut the plants down because they could not pay for ongoing treatment costs [41].

The combination of the low-SES of residents and low-TMF and compliance ability of CWSs not only impacts mitigation potential and exposure levels, it can also result in significant economic burdens for poorer households. In general, CWSs that are able to mitigate arsenic contamination will incur costs that are passed along to customers. Low-income residents find it hard to pay these higher rates, and may oppose mitigation efforts because of the impact on household budgets [42]. If a CWS cannot mitigate exposure, households may be forced to cope by buying bottled water, creating an additional economic burden. However, low-income residents may forgo such exposure-reduction measures, or only partially implement them [43]. In these cases, if a CWS remains in continuous non-compliance, chronic arsenic exposure risks will be prolonged.

Current debates regarding implementation of the Revised Arsenic Rule have discussed the option of using variances for small water systems, since the Safe Drinking Water Act allows for exemptions to meet compliance rules [23]. However, a short-term variance may only serve to create and perpetuate a two-tiered and inequitable system of regulation, in which low SES residents endure higher arsenic levels in their drinking water or are forced to rely on costly bottled water as an exposure reduction measure. Rather than variances, the regulatory system should provide targeted planning and technical support for small, disadvantaged communities to enter into compliance, so that provision of safe drinking water becomes logistically feasible. This support could include funding mechanisms to support regional system consolidation efforts that help small systems achieve economies of scale or draw on alternative water supplies.

Conclusions

Using a "joint burden" approach, we examined the extent of exposure and compliance burdens in the San Joaquin Valley from 2005 to 2007. Our findings suggest that environmental justice concerns related to arsenic contamination in drinking water must consider both exposure and compliance burdens. Our work also highlights the need to better address how water systems serving low-SES residents can apply for and secure resources to enter into compliance, particularly if current funding criteria are tied to the technical, managerial and financial capacity of CWSs. That small, disadvantaged communities face greater compliance challenges highlights the need for appropriate regulatory measures and technical support. Ultimately, regional solutions that consolidate smaller CWSs serving economically disadvantaged communities within larger CWSs may be the best approach to addressing these disparities. In the interim, however, small water systems serving low SES residents will need enhanced funding and technical support to reduce community-level arsenic exposures.

Ariana Zeno

Thank you to the following who contributed content and research expertise:

Carolina Balazs
Rebecca Baran-Rees
John Capitman
Dhanya Elizabeth Elias
Ann Moss Joyner
Jonathan London
Nathaniel Roth
Stephan Schmidt
Michelle Wilde Anderson

Thanks to the PolicyLink editorial and production teams.

Finally, this work would not have been possible without the generous support of:

The James Irvine Foundation
The California Endowment
The Open Society Foundations
The Women's Foundation of California
The Kresge Foundation

Preface

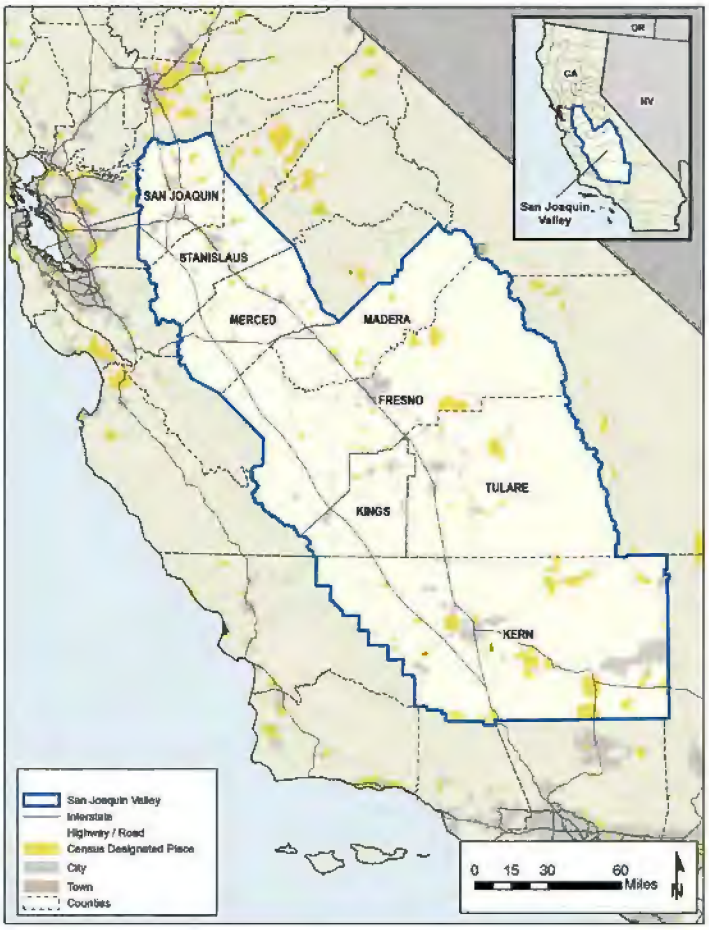
The Community Equity Initiative (CEI), a partnership of California Rural Legal Assistance Foundation, California Rural Legal Assistance, Inc. (CRLA, Inc.), and PolicyLink, is dedicated to advancing innovative solutions to address poor infrastructure quality and service delivery in communities with a particular focus on the unincorporated communities in California's San Joaquin Valley and the Coachella Valley. The initiative aims to improve the conditions in some of California's most underinvested communities, and provide models for forging new leadership and capacity within communities and developing effective policies to dismantle and overcome historical patterns of exclusion and neglect.

Early in the development of the Community Equity Initiative, the three partner organizations engaged a diverse set of stakeholders and advisors from within communities, universities, foundations, government, and the nonprofit sector to discuss how planning and infrastructure investment can build healthy, sustainable community change. As a result, the initiative pursues a four-pronged strategy that includes: increasing community capacity for political participation and advocacy, improving local and state policy, legal representation, and research.

As part of the research agenda, the initiative has developed a new methodology to shed light on and describe communities that have gone overlooked, ignored, and underinvested for decades. Using and analyzing 2000 census data and other publicly available data, the research has uncovered thousands of Californians who are living in these invisible communities, what the CEI calls "Disadvantaged Unincorporated Communities" or DUCs. Disadvantaged Unincorporated Communities are disproportionately low-income places that are densely settled and not within city limits. For the legal definition, please visit SB 244 Section 65302.10.

This document describes the new methods for identifying, measuring, and mapping disadvantaged unincorporated communities and a first account of the findings from applying these new methods to the San Joaquin Valley. For readers seeking the complete technical details of the data sources and methods, please see the Technical Guide on the Community Equity Initiative website.

All charts, tables, and maps within this report are derived from an analysis of 2000 census data, and county parcel and boundary data. This methodology will also be applied to 2010 census data with research findings to come. Ultimately, it is hoped that this new mapping methodology will help improve policies and decision-making practices not only within California's unincorporated communities but also in America's unincorporated communities at large.



For more on the Community Equity Initiative, please click **here**.

Introduction

California's San Joaquin Valley is one of the most agriculturally rich regions in our nation, contributing over half of the state's total value in agricultural production.[1] It is also home to some of the nation's poorest communities. A 2010 study found the San Joaquin Valley's 20th congressional district ranked the lowest in the nation on resident well-being, based on an assessment of health, education, and income.[2] Among the poorest and most isolated of these communities are places outside of city limits that lack the most basic features of a safe, healthy, sustainable neighborhood—potable drinking water, sewer systems, safe housing, public transportation, parks, sidewalks, and streetlights. People of color make up 54 percent of those living in the San Joaquin Valley, and make up a disproportionate number of those living in underinvested neighborhoods. Historically, these communities have been home to mostly African American and Latinos, and a growing Southeast Asian population. Governed by counties, which were not set up to provide services to dense urban areas, and lacking the representation of a city council, they are systematically underserved in the overall allocation of public resources and are frequently left out of local decision-making processes. Concentrated poverty, institutional and individual racism, and California's systems of public finance and land use regulation exacerbate the plight of disadvantaged unincorporated communities.

To make matters worse, many decision makers and county officials do not know that these communities exist. A map delineates boundaries, records a name, facilitates (though does not guarantee) data collection by the United States Census Bureau and other data collection entities, and provides a basis for demographic and special analysis used to direct programs and services from the federal or state to local level. For residents and organizations living and working in these communities the lack of official recognition and the data that flow from it presents a huge barrier. It becomes very challenging to capture political attention, aggregate and provide a sense of scale to the challenges faced across communities, and readily access critical public resources that are distributed based on community-level data. Identifying the places and their particular challenges (drinking water, waste water systems, safe roads, etc.) is the first step in a longer process to develop strategies and priorities, and to organize, and mobilize to address these challenges.

Eight Counties of San Joaquin Valley

Source: 2000 U.S. census.

2 Based on the Human Development Index of the Social Science Research Council: http://www.measureofamerica.org/maps/.

Purpose of This Research

The Community Equity Initiative developed this report, and the methodology discussed within it, as part of a larger effort to make visible the hundreds of communities that have gone neglected and ignored and are suffering critical challenges of livability as a result. Through this work, the initiative seeks to provide local and state officials, policymakers, advocates, and community organizations with a better sense of where underserved, unincorporated communities are located, and seeks to bring the problems they face into the public view. The research presented here is the first step in quantifying and locating the number of places and people that have been left off the map in the eight-county San Joaquin Valley region. It brings attention to some of California's most forgotten and underinvested places, and starts to make the case for more coordinated long-range planning, targeted resources, and community capacity building for improved quality of life.

This research aims to:

- **equip residents, community-based organizations, and policymakers** with more tools for organizing, case-making, and advocacy;
- **increase public awareness** of the breadth and scale of disadvantaged unincorporated communities and the challenges they face; and
- **support better research and data collection** of disadvantaged unincorporated communities through a new tool that can be used as a basis for future research about quality of services and infrastructure.

Key Findings

The following are key takeaways from the analysis of 2000 U.S. census data and other publicly available data for California.

3.6 million

Californians found by the Census Bureau living in Census Designated Places in 2000

2.8 million

Additional number of Californians living in unincorporated neighborhoods not recognized by the 2000 census because their communities were not characterized as Census Designated Places

310,000

People living in low-income unincorporated communities in the San Joaquin Valley

This is 70,000 more than what the Census Bureau included in its low-income Census Designated Places in the San Joaquin Valley

People of color were disproportionately represented in Disadvantaged Unincorporated Communities in comparison to cities, counties, and Census Designated Places.

65%

Percentage of the population living in disadvantaged unincorporated communities that were of color

57%

Percentage of the population living in cities that were of color

64%

Percentage of households in the San Joaquin Valley's disadvantaged unincorporated communities that were low income

This was a significantly higher percentage than in cities and counties in California where 48% of households were low income, and in Census Designated Places where 51% of the households were low income.

Emerging Areas of Impact

This research is helping to make the case for advocacy, build public awareness, and contribute to new knowledge around inequities that exist.

Supporting Organizing, Case-Making, and Advocacy

There is power in being made visible. Once a community is visible, a shared collective identity can develop, which in turn serves as the foundation for residents' capacity to organize themselves and mobilize for change. Mapping equips residents with information about their communities and others', provides them with a tool in their advocacy, and facilitates recognition within the policymaking process. This work provides an important foundation for advocates, researchers, and policymakers to layer additional information and stories about the conditions and history of these communities.

Tulare Lake Basin Study – In 2008, SB1xx and AB2356 appropriated millions of dollars to address drinking water quality and waste water services in the Tulare Lake Basin region. With the tremendous support of community advocates, these bills provide targeted funding for planning and construction of projects in disadvantaged areas. The CEI mapping of low-income unincorporated areas was one of the many data points considered when identifying disadvantaged communities for targeted inclusion in the planning process and in the outreach phase of the project. The CEI mapping helped identify some of the smaller communities that may not have shown up in an initial scan of disadvantaged communities through the census.

Increasing Public Awareness

A community's needs cannot be properly addressed—or assets leveraged—if the community itself is not known to the larger world. Early work of the initiative indicated that many policymakers at the county and state level did not know of the existence of disadvantaged unincorporated communities generally, nor were they aware of the existence of such communities within their electoral districts. Many more continue to be unaware of the basic infrastructure deficits so many of these communities face. Once these communities are officially mapped, have a name to identify them, and are tracked and recorded by the U.S. Census Bureau or city or county agencies they stand a better chance of being well represented and well served.

Local Government Support – Several local and state-level policymakers have looked to this mapping to understand the scale, location, and character of the issues in previously invisible unincorporated areas. Specifically, the mapping has supported the implementation of SB 244 that requires local government agencies—specifically LAFCOs, cities, and counties—to plan for disadvantaged unincorporated areas. The Local Agency Formation Commissions (LAFCOs) of Fresno and Tulare Counties have requested the CEI mapping to help identify and prioritize underserved areas in their planning process.

Contributing to Research

The U.S. Census Bureau is the most accessible source of periodic demographic data for unincorporated communities, yet it does not capture all unincorporated communities. Many unincorporated communities, including many low-income unincorporated communities, are too small, lack clear boundaries, or are simply not sufficiently known or recognized to be included in the census as a place. With the exception of surveying individual households, communities

are left without a reliable source of data to describe their neighborhood. As a result, their needs are often unaccounted for, they are not acknowledged in planning processes, and they cannot compete for infrastructure investments on a level playing field. This is particularly true when eligibility for these programs is tied to being able to demonstrate that community-level demographics meet specified criteria. This research begins to fill this gap. It creates a set of maps that will continue to evolve, and that identify hundreds of communities not previously mapped. These new maps can serve as the basis for layering additional information about demographics, infrastructure, and quality of life.

Sharing with the U.S. Census Bureau – Most recently, the data have served to inform the Census Bureau about additional places to consider including as 2010 Census Designated Places (CDPs) which are unincorporated places that are surveyed and tracked much like cities and towns. Typically, counties submit the names of communities that they recommend become Census Designated Places.[3] Having CDP status means that residents and local governments have more and better access to information about their communities and how they have changed over time. This is particularly important when applying for grants and loans for infrastructure and services. As a result of this new mapping, CEI staff recommended that the Census staff include 39 additional communities in their 2010 Census Designated Places survey. Nearly half of these recommended communities became CDPs in 2010. CEI staff is currently analyzing 2010 data and will continue to share findings with the Census Bureau staff.

3 Counties use a process called Census Participant Statistical Area Program to recommend Census Designated Places. Census Designated Places are defined by the U.S. Census Bureau as places that are closely settled, named, unincorporated communities that generally contain a mixture of residential, commercial, and retail areas similar to those found in incorporated places of similar sizes.

U.S. Census Bureau: Current Definitions

The most accessible source of data about unincorporated communities comes from the U.S. Census Bureau, which calls these neighborhoods Census Designated Places (CDPs). In the year 2000, the U.S. Census Bureau identified 600 Census Designated Places across California that were home to 3.6 million people. Of the 600 CDPs in California in 2000, 250 (42 percent) of them were low income. For purposes of this research, low-income communities are defined as places where half of all households have a median household income of less than 80 percent of the state's median household income. Simply put, half of all households in these communities had annual incomes of $38,000 or less. One million people lived in these low-income Census Designated Places.

Census Designated Places are areas that are closely settled, named, unincorporated communities that generally contain a mixture of residential, commercial, and retail areas similar to those found in incorporated places of similar sizes.

COMPARING LOW-INCOME CENSUS DESIGNATED PLACES

	Number of Communities Total	2000 Population (% of state population)
Total California Population	N/A	33,871,648
Total CDPs in California*	600	3,669,329 (10.8%)
Total Low-Income CDPs in California	250	1,069,778 (3.2%)
Total Low-Income CDPs in San Joaquin Valley	80	241,968 (0.7%)

*CDPs with population greater than zero.
Source: 2000 U.S. census.

While low-income CDPs are found throughout California, they are most heavily concentrated in the San Joaquin Valley. This eight-county region is home to nearly one-third of all low-income CDPs in California. Eighty of the state's 256 low-income CDPs are located in the region. There are nearly a quarter million people living in these communities, approximately 25 percent of all Californians living in low-income CDPs.

While the 2000 census tracked 3.6 million people in CDPs, in that same year nearly 2.8 million additional people lived in unincorporated areas that were not defined as CDPs. Upon launching the Community

Equity Initiative, staff at the partner organizations saw that many, if not the majority, of communities the initiative is concerned with are not captured by the Census Bureau's CDPs. CRLA, Inc. staff working in the communities found that these places were usually either not on maps, or were mapped incorrectly. PolicyLink staff working to develop a clear picture of the communities struggled with the same absent or inaccurate data. Subsequent mapping and resident interviews confirmed how widespread this phenomenon of exclusion was.

As a result of not being a CDP, these communities are not only usually left off of maps; they are rarely tracked in any systematic way, and are largely invisible to the larger public and policymakers. The mapping methodology, discussed in the next section, has established a way to identify these places using publicly available data, making it possible to begin to address their challenges and needs.

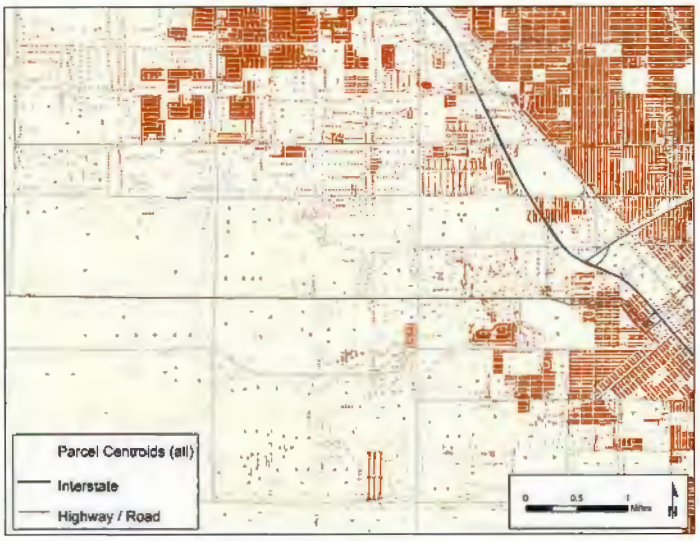


Mapping Disadvantaged Unincorporated Communities: The Methodology

This project used Geographic Information Systems (GIS) technology[4] to identify unincorporated communities in the eight-county San Joaquin Valley region. The following abbreviated methodology describes the steps and results for this initial phase of identifying what the Community Equity Initiative has termed as disadvantaged unincorporated communities or DUCs—places that are densely settled, outside of city limits, and low income.[5] For a more detailed explanation of the data and methods used, please refer to the **Community Equity Initiative** website for technical appendixes. The technical appendixes provide step-by-step guidance on data sources and methods to replicating this mapping research.

CEI used four basic types of data to identify these places:

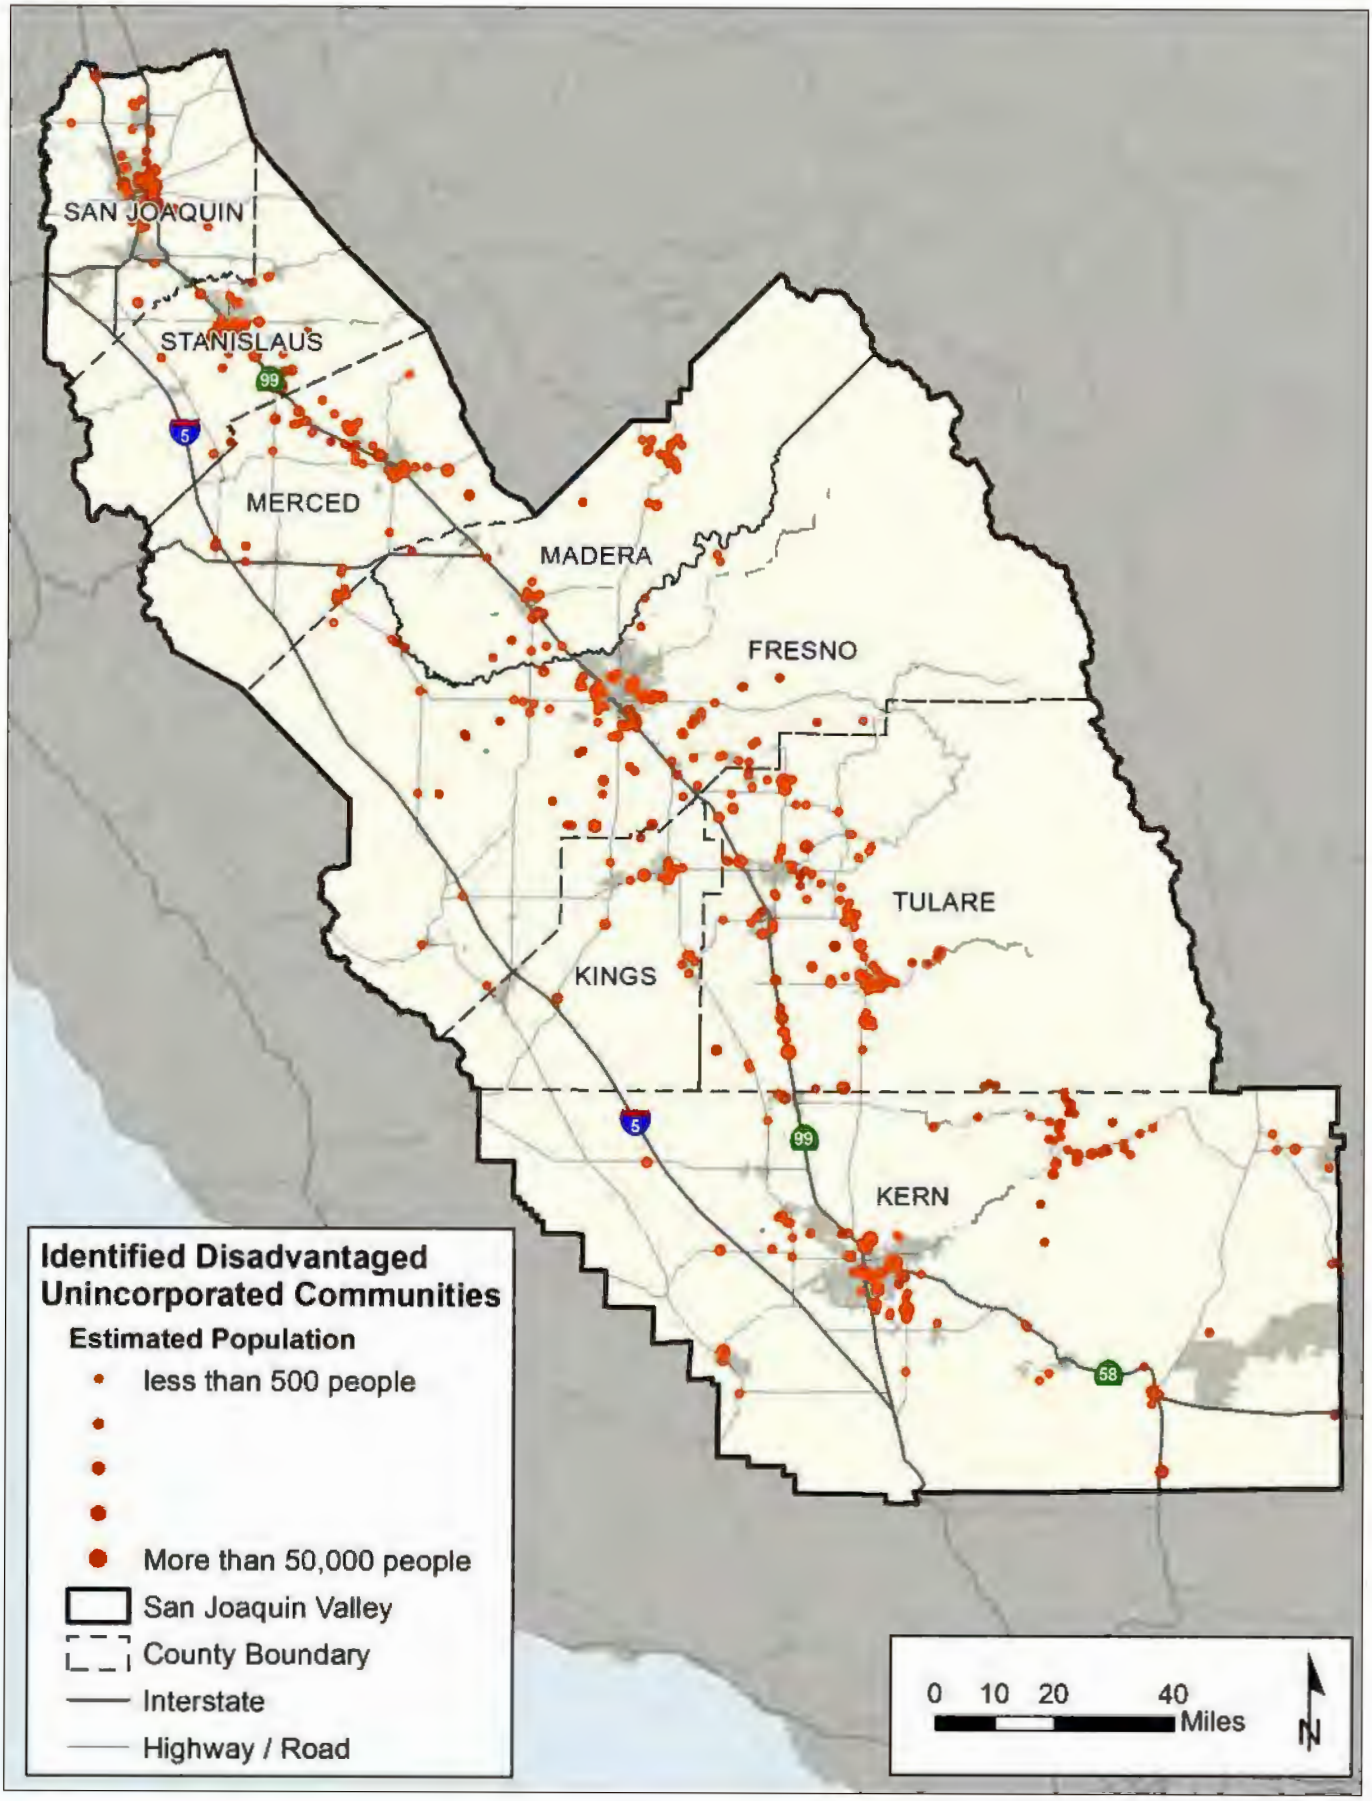
Unincorporated Status: The project used boundary shape files from cities, counties, or from the U.S. Census Bureau to determine unincorporated status (all areas that are not within city limits).

Parcel Density: The project focused on identifying places that are closely settled with a large number of homes, rather than very spread out rural communities. From publicly available sources, the outlines of parcels (land that is subdivided into lots) were gathered. The areas with a density of at least 250 parcels per square mile were identified. This benchmark was chosen because it is comparable to the density of Census Designated Places (unincorporated communities tracked by the Census Bureau).

Sample map of parcels to determine density.

Sample map of visual inspection for each DUC.

4 ESRI ArcView for ArcMap 9.3.1 with the Spatial Analyst 9.3 extension, Windows machine with an Intel Core 2 Quad CPU.



5 This term was developed by CEI to describe low-income, densely settled, unincorporated communities.

Low-Income Neighborhoods: In the work of the CEI, we have found that many low-income unincorporated communities also face infrastructure challenges. Because there is no single indicator, or discrete set of indicators, which allows us to assess infrastructure conditions, the initiative's work began by identifying low-income unincorporated communities. It used 2000 census[6] block group data to identify places of interest. Since the income status of households relative to those across the state is a frequently used criteria for state-funded programs, the initiative selected those block groups where the median household income was less than 80 percent of the median household income of the state. This is a benchmark used in several state-level infrastructure funding programs that target low-income communities, including the **Safe Drinking Water State Revolving Fund** and the **Storm Water Management program**. In 2000, the median household income of the state of California was $47,493, so any census block group with a median income of less than $37,994 was included in our analysis.

This threshold is not a perfect metric for identifying disadvantaged unincorporated communities because there are many places, like resort communities, that may have low recorded incomes, but are not actually home to significant populations of low-income people.

Visual Inspection & Additional Filters: The project mapped land use to help filter out agricultural land, and used information from aerial photography and Google street view to verify that the places highlighted by our analysis were indeed underserved communities. Through this review it was found that some communities at the edge of cities had been "low-income" agricultural fields during the 1990 census but have since been developed. Communities that had been identified as less than three-quarters of an acre in size were also removed as they often contained only one or two houses, if any.

6 While dated, the 2000 census provided a more accurate depiction of income levels at the block group level than more recent American Community Survey data.

Source: PolicyLink analysis of 2000 U.S. census and county parcel and boundary data.

525 Communities: Findings and Analysis

Once the four types of data were overlaid on one another, 525 distinct, low-income, densely settled, unincorporated areas emerged that are home to over 300,000 people in the San Joaquin Valley. In 2000, the U.S. Census Bureau recorded only 80 unincorporated communities that were low income. This research identified many communities that are smaller communities than Census Designated Places. One hundred forty-nine of these disadvantaged unincorporated communities were located within existing Census Designated Places and 23 of these 149 DUCs were small communities that fell within larger, wealthier Census Designated Places that would not have been identified by solely relying on an analysis of low-income CDPs. For those low-income communities that depend on Census Bureau data to inform their grants, advocacy, and communications work, being located and lumped in with a wealthier CDP could very well mask the challenges of the communities.

Many of the communities (188 to be exact) were named places either because they were existing CDPs or were recognized by community members. As part of the process of verifying the methodology, CEI staff hosted several workshop sessions with community members to solicit their input on maps. Participants were asked if they recognized the identified places as neighborhoods with names and did some "ground-truthing" to verify that the places highlighted were indeed places with infrastructure challenges. A listing of named places is included in Appendix 2: County Map Gallery. Those places without names were assigned a number.

Comparing Counties

The eight counties of the San Joaquin Valley vary significantly in terms of size and population distribution within incorporated and unincorporated areas. The research found that while Fresno is the most populated county, accounting for 24 percent of the valley's population, only 9 percent of the population living in the region's disadvantaged unincorporated communities are in Fresno County. On the other hand, Kern and Tulare Counties have disproportionately high percentages of their populations living in disadvantaged unincorporated communities. Kern is home to 20 percent of the region's population, but 42 percent of the population living in disadvantaged unincorporated communities, and Tulare has 11 percent of the

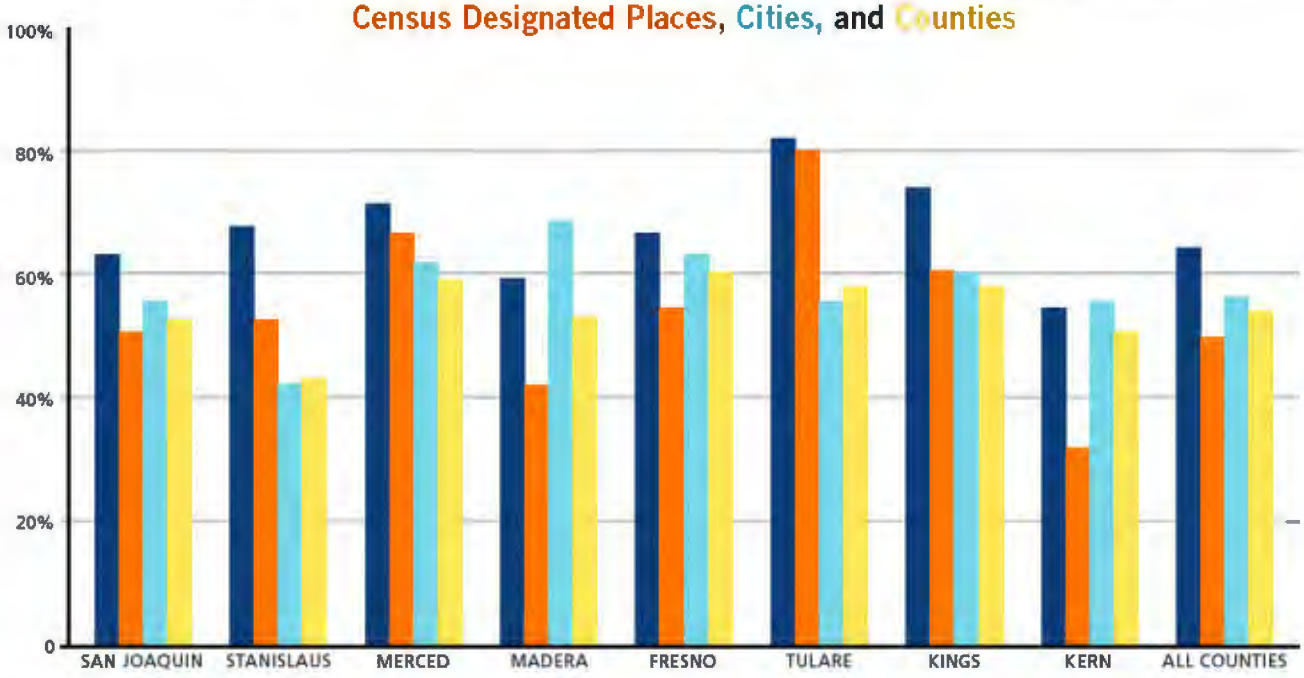
Comparing Disadvantaged Unincorporated Communities in the San Joaquin Valley

	Number of Communities	Population (% of San Joaquin Valley population)
Disadvantaged Unincorporated Communities in the Valley	525	310,231 (9.3%)
Disadvantaged Unincorporated Areas in CDPs in the Valley	149	187,180 (5.7%)
Low-income CDPs in the Valley	80	242,216 (7.3%)

Source: PolicyLink analysis of 2000 U.S. census and county parcel and boundary data.

total valley population but 18 percent of the valley's DUCs. This can largely be explained by the fact that a significant portion of the total population in Kern (46 percent) and Tulare (36 percent) Counties live in unincorporated areas. Tulare and Kern also have the highest percentages of their unincorporated populations living in low-income, densely settled communities, with 49 percent and 38 percent respectively.

Maps of each county are available in Appendix 2: County Map Gallery. The Appendix includes a breakdown of each type of community (Island, Fringe, and Legacy discussed later) listed, as well as population summaries.



Demographic Analysis

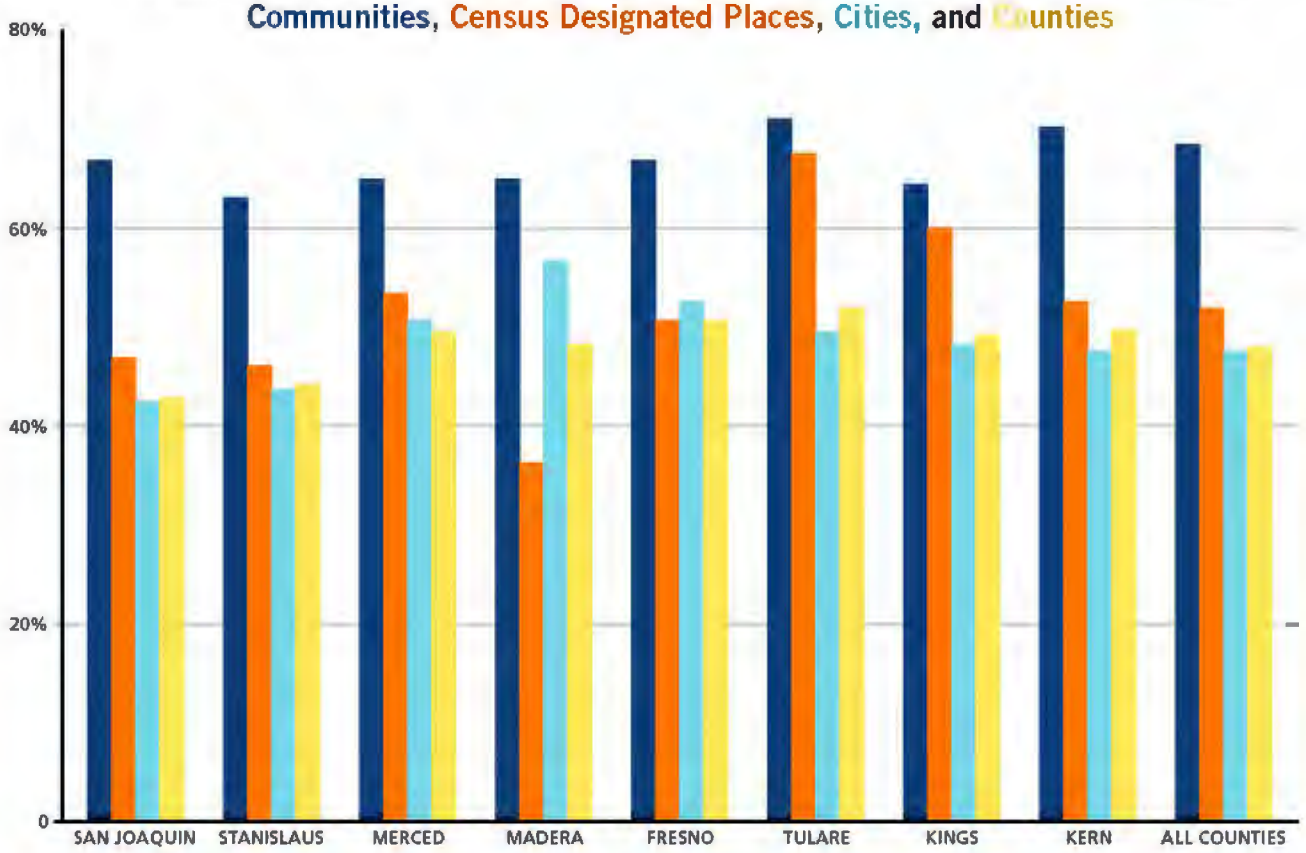
Examining the racial makeup and economic status of DUCs and comparing those to cities, other parts of unincorporated counties, and to counties, helps demonstrate whether or not underinvestment in infrastructure is correlated to race and class. The work of the CEI in large part stemmed from litigation against discriminatory practices in Stanislaus County and the city of Modesto. This case revealed that the city of Modesto was excluding low-income neighborhoods and communities of color from its growth, development, and most basic infrastructure and services.

This current research looks to build from the evidence prepared for Modesto and other cases to better understand and describe the relationship between race, income, and infrastructure quality. The new mapping and analysis shows that disadvantaged unincorporated communities are largely home to people of color,[7] making up 65 percent of the population living in San Joaquin Valley's DUCs. This number is especially high compared to the fact that throughout all of the counties, people of color make up only 54 percent of the population.

The CEI compared the racial and ethnic makeup and number of low-income households in DUCs to Census Designated Places, cities, and counties. Since Census Designated Places are the only unincorporated communities that are tracked by the U.S. Census Bureau, this is an important scale of comparison. Comparing DUCs to cities is important for understanding how much incorporated status can influence and drive

Percent People of Color in Disadvantaged Unincorporated Communities, Census Designated Places, Cities, and Counties

Source: PolicyLink analysis of 2000 U.S. census and county parcel and boundary data.



7 "People of color" describes the sum of all racial/ethnic groups that are not white (or non-Hispanic white).

disparities. A comparison to counties provides the context in which DUCs reside. Ideally, the research should find that low-income households and people of color are equally represented in all three scales.

As the graph on the previous page illustrates, in every county people of color in DUCs are overrepresented in comparison to the percentage of people of color living in CDPs, cities, and the county population as a whole.

Although the people who live in DUCs are partly defined by the fact that they meet specified income criteria, the study also wanted to understand how their income characteristics compared to other incorporated and unincorporated population groups in the region. The research found that low-income households are overrepresented in disadvantaged unincorporated communities in comparison to CDPs, cities, and counties. The results are conservative estimates due to the limitations of the census.[8] The graph below illustrates that the percentage of low-income households in DUCs across the San Joaquin Valley ranges between 11 and 20 percentage points higher than their respective counties. When compared to CDPs, DUCs generally have a much greater percentage of low-income households; the exception being in Tulare and Kings Counties where low-income households are proportionate in CDPs and DUCs. Across the entire San Joaquin Valley, it was estimated that 64 percent of households living in DUCs are low income compared to much lower rates in CDPs (51 percent), cities (48 percent), and counties (48 percent).

Percentage of Households that are Low-Income in Disadvantaged Unicorporated Communities, Census Designated Places, Cities, and Counties

Source: PolicyLink analysis of 2000 U.S. census and county parcel and boundary data.

8 For purposes of this research, low income is defined as household income below 80 percent of state household median, which is $37,994. The 2000 census only provides household income in ranges. These results include all households with income below $34,999.

Please refer to **Appendix 1** (Demographic Analysis) for a detailed table comparing the demographics of DUCs to counties, cities, and Census Designated Places.

Types of Communities

While documenting the number of communities is an important step in telling the story of the San Joaquin Valley's unincorporated communities, proximity to a neighboring community or city plays an important role in determining the opportunities that these places have to improve their infrastructure. A community that is, for example, 20 miles away from a city will have different concerns and opportunities for infrastructure investment than one that sits close or adjacent to a city, and different again from a neighborhood nearly or completely surrounded by the same city. Because of this, our work looked to further describe these communities based on their spatial relationship to incorporated areas.

Island and Fringe Communities

During the agricultural and industrial boom of the early and mid-twentieth century, communities developed on the edges of cities where industry was concentrated and housing was more affordable. As the cities grew, they annexed land around the unincorporated communities—avoiding and excluding communities of color and low-income communities. Decades of neglect and exclusion by cities and counties have been reinforced by the state's counterproductive system of taxation and land use policies. These communities find themselves stuck between the county and their neighboring city. The city does not want to invest in county territory, nor does the county wish to invest in a community that, once improved, will be more attractive for incorporation by a neighboring city.

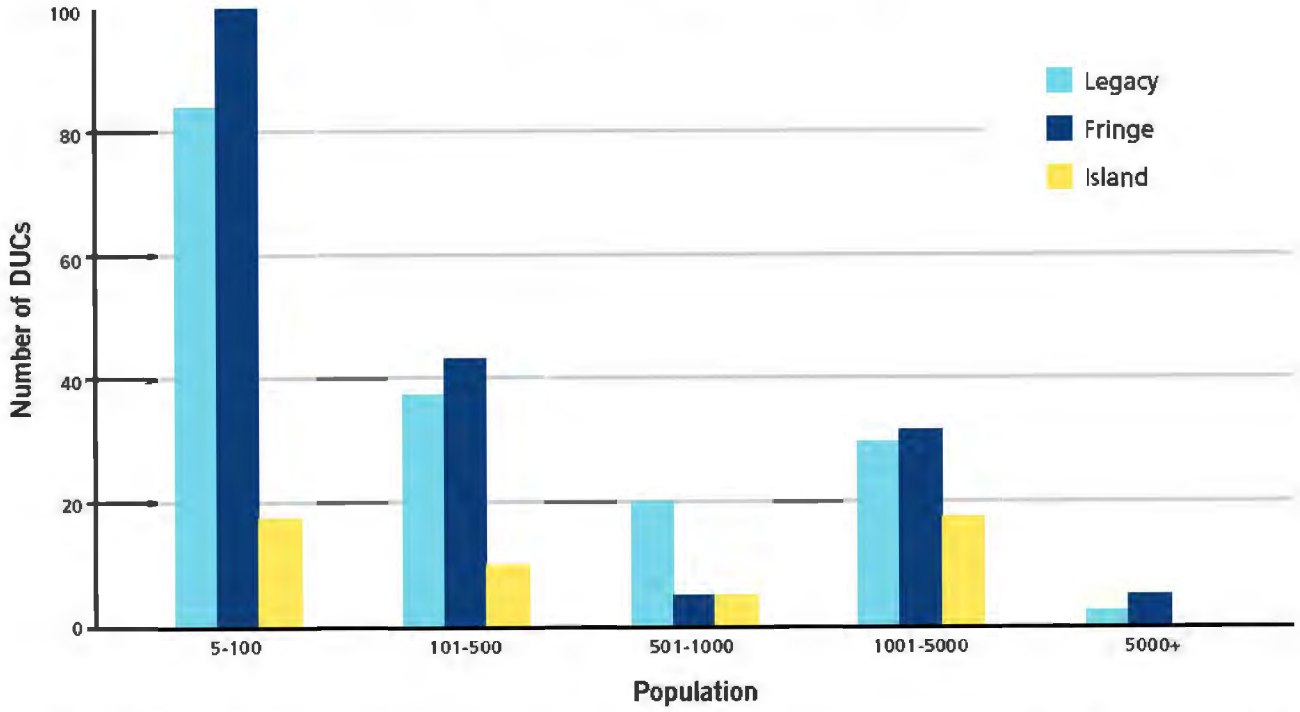
Today there are unincorporated communities that are like an island, completely surrounded by incorporated city territory but are on county land and therefore do not receive city services. Fringe communities are neighborhoods that are adjacent to incorporated areas or within a city's sphere of influence[9] but are located on county land. The isolation faced by fringe and island communities is stark: their neighbors within city limits—across the street even—receive services that they do not. Some communities may literally have city infrastructure running under or through their community but are not linked into that infrastructure to receive its benefits. Seventy percent of the population of the disadvantaged unincorporated communities identified live in island or fringe communities. As the table below shows, this is over 200,000 people in 274 island and fringe communities. Distinguishing these communities in this way is important because

Comparing Types of Disadvantaged Unincorporated Communities

	Number	Estimated Population (% of DUCs)
Total Disadvantaged Unincorporated Communities	**525**	**310,231**
Island communities	**44**	**45,501 (14.7%)**
Fringe communities	**230**	**172,237 (55.5%)**
Legacy communities	**231**	**92,358 (29.8%)**

Source: PolicyLink analysis of 2000 U.S. census and county parcel and boundary data.

9 According to the California Association of Local Agency Formation Commissions, a sphere of influence is a planning boundary typically beyond a city or special district that ensures the provision of efficient services while discouraging urban sprawl and the premature conversion of agricultural or open space lands.



the potential strategies for addressing infrastructure deficits vary depending on the proximity to cities and other communities. For example, several fringe communities have worked out agreements with neighboring cities or townships for sharing service provision or infrastructure investments like water resources.

Legacy Communities

A third type—legacy communities—are more remote. These communities lie beyond the growth boundaries of incorporated cities, and have been in existence at least 50 years.[10] Legacy communities started growing in the early to mid 20th century, principally due to the advent of industrialized agriculture. As demand for low-wage agricultural labor increased, these communities became home to workers from the American South, the Depression-era Dustbowl, and Mexico seeking work as farm laborers. Legacy communities grew close to the farms where workers labored, and over time, these communities have become stable, year-round residential areas, but without the investment to make them healthy and sustainable. Nearly 100,000 people live in legacy communities. The geographic isolation of these places means that they cannot as readily rely on shared service provisions and the typically small population size means that privately funded infrastructure investment is cost prohibitive because of a lack of economies of scale. Leveraging targeted public funding is a necessity in legacy communities.

The graph below illustrates the distribution of disadvantaged unincorporated communities by population range, number of communities in each population range, and their spatial relationship to incorporated areas (Island / Fringe / Legacy). A majority (81 percent) of these communities are small—fewer than 500 residents. While only 12 communities have populations greater than 5,000, these 12 communities make up 45 percent of the total DUC population across the valley.

Number of Disadvantaged Unincorporated Communities by Type and Population

The methods tended to underestimate population size in very small rural communities. One hundred and thirty-five of the 525 communities have an estimated population of less than five people and are not displayed here.

10 Definition in part from the Senate Bill No. 244.

Next Steps

Cities and counties cannot plan for, and serve, communities that they do not even know exist. Administrators and elected officials must understand the scale and scope of issues within their jurisdiction. This research will help build their understanding of the scope of the issues impacting unincorporated communities and will support local and regional efforts to plan for infrastructure improvements and more coherent, sustainable land uses. The Community Equity Initiative will continue hosting sessions where community members and organizations can help verify and name places on maps identified by this methodology.

The data used for this first run of the model are limited because the census has historically undercounted minority and rural populations. Also, the income data are from 2000, which are dated and do not reflect changes brought by the most recent recession. The CEI will be updating its research with more recent American Community Survey data and 2010 U.S. census data. It is also adding demographic data such as median age, length and type of housing tenure, education, and more. We are in the process of undertaking additional investigation to better understand the breadth and depth of challenges that these communities face.

The next phase of mapping will include additional "ground-truthing" with residents, further exploration of the demographics of these communities, and gathering and analysis of information about the quality of infrastructure, amenities, and services. This foundational mapping will allow us to better describe potential infrastructure challenges, disparities in investments, and trends in population over time beyond the race and income data included here. The next phase of this work, for example, may draw closer parallels between race and income and infrastructure investment per capita.

The initiative will continue to share this information with community organizations and groups who find it useful. For example, it is currently sharing its findings with community organizations and researchers who are studying how nitrate contamination in groundwater is affecting communities in the San Joaquin Valley and across California. The pairing of these data sets will add dimension to both the water quality data and the mapping of disadvantaged communities. A clearer picture should emerge of the types of communities that do not have healthy drinking water, along with increased understanding about the water quality in underserved communities. This dual approach will inform the decision-making process around setting priorities for allocating resources to areas in need.

This mapping has also sparked interest in collecting and sharing data about unincorporated areas more broadly, including access to parks, air quality data, and environmental hazards. Ultimately, the Community Equity Initiative is committed to using the information that is gathered to empower residents in California and elsewhere as advocates for better, healthier communities.

Appendix 1: Detailed Table of Demographic Analysis

The following tables compare demographics for counties, cities, Census Designated Places, and disadvantaged unincorporated communities by county. The data have been summarized in preceding charts but are presented here more comprehensively and include:

- **Total population and number** of households
- **Population and percentage** of people of color (people of color defined as the sum of all racial and ethnic groups that are not white or non-Hispanic white)
- **Total and percentage** of low-income households (households with income less than $34,999 annually)

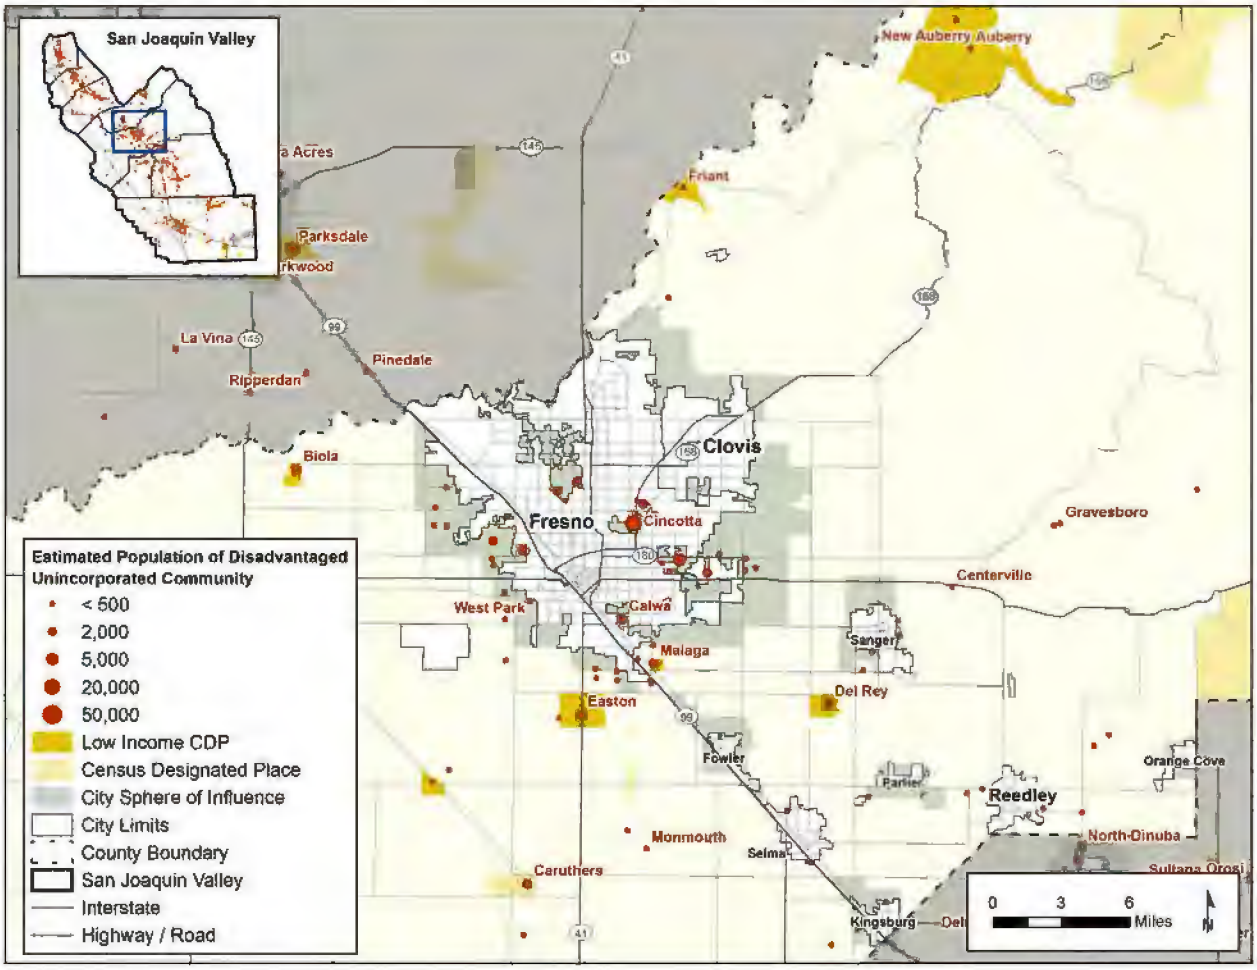
Appendix 2: County Map Gallery

The following maps illustrate the location and approximate population of disadvantaged unincorporated communities (DUCs) in each of the eight counties of the San Joaquin Valley. Tables associated with the maps show the estimated population by type of community (island, legacy, or fringe). Each county is accompanied by a list of the names of some DUCs.



Fresno County (West)

Authors' Biographies

Chione Flegal is an associate director with PolicyLink. She works to ensure that infrastructure and land use policy promote economic, social, and environmental equity. She leads the organization's policy work in California, as well as efforts to address disparities faced by low-income unincorporated communities.

Solana Rice is a senior associate with PolicyLink. As a researcher and policy advocate, she works to advance opportunity for low-income communities and communities of color by promoting equitable solutions to community development through wealth building, small business development, and other economically focused strategies.

Jake Mann is a temporary research assistant with PolicyLink supporting the mapping and analysis for the Community Equity Initiative.

Jennifer Tran is a program associate with PolicyLink. Her work focuses on equitable economic growth, conducting research, data analysis, and GIS mapping.

EXHIBIT F

Chapter 7
Analysis of Underserved Disadvantaged Unincorporated Communities

A. Introduction

Senate Bill (SB) 244 (Wolk) was approved by the state in October 2011 and requires cities and counties to address the infrastructure needs of disadvantaged unincorporated communities (DUC) in city and county general plans, Local Agency Formation Commission (LAFCo) Municipal Service Reviews (MSR), and annexation decisions.

Government Code Section 65302.10(a) requires that before the due date for adoption of the next housing element after January 1, 2012, the general plan land use element must be updated to identify and describe each DUC (fringe community, legacy community, and/or island community) that exists within unincorporated areas of the county or in spheres of influence of each city; analyze for each identified community the water, wastewater, stormwater drainage, and structural fire protection needs; and identify financial funding alternatives for the extension of services to any identified communities. SB 244 defines a DUC as a place that meets the following criteria:

- Contains 10 or more dwelling units in close proximity to one another where 12 or more registered voters reside. For the purpose of this analysis, "close proximity" in the Kern County analysis was based on the threshold of more than one dwelling unit per acre. Information on the exact number of dwelling units was sometimes not available; in these cases, the number of residential units was used, and an assumption was made that one unit was equivalent to approximately one dwelling unit.

- Is either within a city sphere of influence (also known as a fringe community), is an island within a city boundary (also known as an island community), or is geographically isolated and has existed for at least 50 years (also known as a legacy community). **Figure 7a** graphically depicts these types of communities. Only legacy communities potentially occur in the unincorporated area of Kern County. The other two types of unincorporated communities occur in city spheres of influence or in unincorporated areas surrounded by incorporated cities.

- Has a median household income that is 80 percent or less of the statewide median household income. (According to the US Census Bureau, American Community Survey (ACS), the median household income for California between 2009 and 2013 was $61,094; therefore, communities with an area median income of $48,875 or lower qualify.)

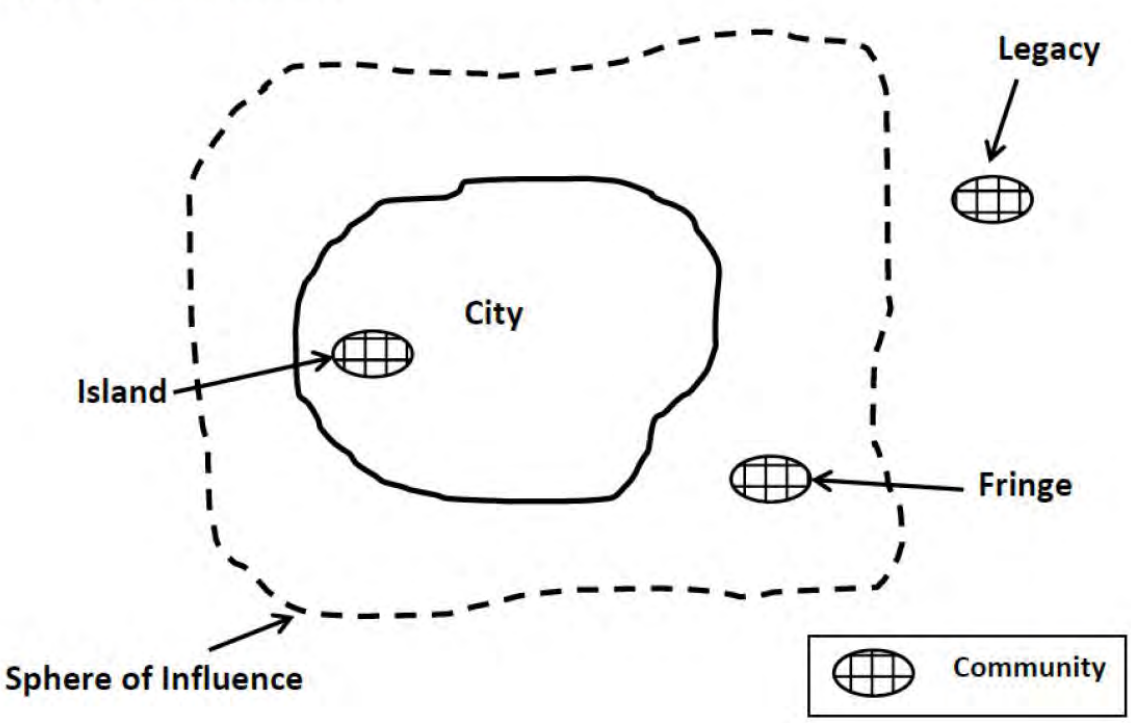

Table 70 lists the DUCs assessed in unincorporated Kern County.

B. Analysis of Kern County Disadvantaged Unincorporated Communities

An analysis to identify DUCs in unincorporated Kern County was conducted in order to address the requirements of SB 244. In conducting the analysis, resources utilized included the SB 244 Technical Advisory (OPR 2013); the Municipal Service Reviews (MSR) of Kern County, independent agencies, and special districts in the county; and the city limit boundary maps of the cities in Kern County using geographic information systems (GIS).

Disadvantaged Unincorporated Communities

Twenty-two unincorporated communities were identified using Census Designated Place (CDP) information as possible DUCs and were considered for inclusion as communities for analysis. Several additional unincorporated agricultural labor communities were also identified for analysis as DUCs. Some CDPs and agricultural labor communities were eliminated because they did not meet the qualifications, based on census income data, mapping information, County staff knowledge, and plat records. Twenty-two communities met all of the criteria for analysis of services. Services to these communities were then assessed. **Figure 7b** shows the relative location of the disadvantaged unincorporated communities in the county. **Figures 7c** through **7g** show the more specific DUCs by region. In these figures, some of the DUCs are divided into several clusters of housing and are labeled A, B, C, D, etc.

DUC 1 (Bodfish)

DUC 1 is the Census Designated Place known as Bodfish, approximately 40 miles northeast of Bakersfield. The community is located off State Route (SR) 178, south of Lake Isabella, as shown on **Figure 7e**. Bodfish has two concentrations of residential development; together containing 838 units over 334 acres. This results in an approximate density of 2.51 units per acre. The CDP has a median household income of $21,461 according to the 2009–2013 ACS, according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 2 (Boron)

DUC 2 is the Census Designated Place of Boron, located on the southeast corner of Kern County, approximately 20 miles south of California City. The community is directly west of the intersection of SR 58 and US Route 395, as shown on **Figure 7g**. Boron has six clusters of residential units, covering 212 acres of land. This results in an approximate density of 3.53 units per acre. The median income in Boron, $36,308, is below the qualifying income threshold for DUCs.

DUC 3 (Buttonwillow)

DUC 3 is the Census Designated Place of Buttonwillow, approximately 25 miles west of Bakersfield. The community is a concentration of 336 units at the intersection of SR 58 with Interstate 5 (I-5), as shown on **Figure 7c**. The community is approximately 66 acres, with an overall density of approximately 5 units per acre. Buttonwillow has a median household income of $34,732, according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 4 (Cherokee Strip)

DUC 4 is the Census Designated Place known as Cherokee Strip, located approximately 17 miles northwest of Bakersfield, as shown on **Figure 7c**. The community is a small concentration of residences surrounded by agricultural fields west of SR 43. Cherokee Strip has 60 residential units making up 17 acres, which results in an overall density of approximately 3.5 units per acre. The CDP has a median household income of $43,125, according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 5 (Edmundson Acres)

DUC 5 is the Census Designated Place known as Edmundson Acres. This community is adjacent to the northern boundary of Arvin, as shown on **Figure 7d**. The community has a single concentration of residences on approximately 62 units making up 17 acres. The community has an overall density of approximately 3.6 units per acre. The 2009–2013 ACS reports that Edmundson Acres has a median household income of $35,833, which is less than the qualifying income threshold of $48,856.

DUC 6 (Fuller Acres)

DUC 6 is a Census Designated Place known as Fuller Acres, approximately 7 miles southeast of Bakersfield. The community is south of SR 58 and centered around SR 184, as shown on **Figure 7d.** Residences are concentrated in one area containing 213 units over 67 acres. The community has an overall density of approximately 3.2 units per acre. The 2009–2013 ACS reports that Fuller Acres has a median household income of $35,833, which is less than the qualifying income threshold of $48,856.

DUC 7 (Johannesburg)

DUC 7 is the Census Designated Place known as Johannesburg, approximately 15 miles northeast of California City. The community is located off US Route 395, as shown on **Figure 7f**. Johannesburg has a single concentration of residential development, containing 106 units over 29 acres, which results in an approximate density of 3.56 units per acre. The CDP has a median household income of $32,360according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 8 (Lake Isabella)

DUC 8 is the Census Designated Place of Lake Isabella, approximately 40 miles northeast of Bakersfield. The community is located off SR 178, adjacent to the south side of Lake Isabella, as shown on **Figure 7e**. The Lake Isabella CDP has five clusters of residences in close proximity, totaling 1,323 units on 278 acres. This results in an approximate density of 4.2 units per acre. The CDP has a median household income of $20,678 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 9 (Lake of the Woods)

DUC 9 is the Census Designated Place known as Lake of the Woods, approximately 40 miles northeast of Bakersfield. The community is located off SR 178, adjacent to the south side of Lake Isabella, as shown on **Figure 7d**. Lake of the Woods is a cluster of residences on 384 units in close proximity, making up 49.6 acres, which results in an approximate density of 7.74 units per acre. The CDP has a median household income of $48,750 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 10 (Lamont)

DUC 10 is the Census Designated Place of Lamont, approximately 10 miles southeast of Bakersfield. The community is south of SR 58 and centered around SR 184. Residences are concentrated in one area containing 2,361 units over 452 acres as shown on **Figure 7d**. This DUC contains the USDA Lamont H.R. Olson farmworker housing community. The community has an overall density of approximately 3.2 units per acre. The 2009–2013 ACS reports that Lamont has a median household income of $35,833, which is less than the qualifying income threshold of $48,856.

DUC 11 (Lost Hills)

DUC 11 is the Census Designated Place of Lost Hills, approximately 25 miles west of Wasco. The community is centered at the intersection of I-5 and CA-46. Residences are concentrated in one area containing 296 units over 56.8 acres, as shown on **Figure 7c**. The community has an overall density of approximately 5.2 units per acre. The 2009–2013 ACS reports that the Lost Hills CDP has a median household income of $30,795, which is less than the qualifying income threshold of $48,856.

DUC 12 (Mettler)

DUC 12 is the Census Designated Place known as Mettler, in the southeast portion of Kern County. The community is located along SR 99 just north of the intersection with I-5, as shown on **Figure 7d**. Mettler has roughly 26 residential units in close proximity across 5.3 acres, which results in an approximate density of 4.9 units per acre. The CDP has a median household income of $38,750 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 13 (Mexican Colony)

DUC 13 is the Census Designated Place known as Mexican Colony, in the northwest portion of Kern County. The community is located west of SR 43 just south of the City of Shafter, as shown on **Figure 7c**. Mexican Colony has roughly 78 residential units in close proximity across 20.48 acres, which results in an approximate density of 3.8 units per acre. The CDP has a median household income of $21,250 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 14 (Mojave)

DUC 14 is the Census Designated Place of Mojave, approximately 14 miles southwest of California City. The community is located along SR 14, as shown on **Figure 7g**. Mojave includes seven small clusters of residences, containing 894 units in close proximity on a total of 182 acres, which results in an approximate density of 4.9 units per acre. The CDP has a median household income of $48,750 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 15 (Mountain Mesa)

DUC 15 is the Census Designated Place known as Mountain Mesa, in the northeast portion of Kern County, located below the Sequoia National Forest. The community is 48 miles from downtown Bakersfield, as shown on **Figure 7e**. Mountain Mesa has roughly 349 residential units in close proximity across 73 acres, which results in an approximate density of 4.8 units per acre. The CDP has a median household income of $29,712 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 16 (Oildale)

DUC 16, Oildale, is a Census Designated Place located along Bakersfield's northern border, as shown on **Figure 7d**. Oildale contains 8,739 residential units across 1,832 acres, which results in an approximate density of 2.0 units per acre. The CDP has a median household income of $33,305 according to the 2009-2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 17 (Onyx)

DUC 17 is the Census Designated Place of Onyx in northeast Kern County. The community is located along SR 178 about 20 miles east of Lake Isabella, as shown on **Figure 7e**. Residences are concentrated in one area containing 259 units over 104 acres. The community has an overall density of approximately 2.5 units per acre. The 2009–2013 ACS reports that the Onyx CDP has a median household income of $32,679, which is less than the qualifying income threshold of $48,856.

DUC 18 (Randsburg)

DUC 18, Randsburg, is a Census Designated Place located along Kern County's eastern border, as shown on **Figure 7f**. The community is adjacent to US Route 395. Randsburg contains 77 residential units across 17 acres, which results in an approximate density of 4.5 units per acre. The CDP has a median household income of $26,280 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 19 (USDA Ruben J. Blunt Village)

DUC 19 is the Census Designated Place located along Bakersfield's northern border, as shown on **Figure 7d**. The CDP contains 8,739 residential units across 1,832 acres, which results in an approximate density of 2.0 units per acre. The community has a median household income of $33,305 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 20 (Weedpatch)

DUC 20, Weedpatch, is a Census Designated Place located in central Kern County 15 miles south of Bakersfield's northern border, as shown on **Figure 7d.** Weedpatch has two clusters of residential units in close proximity that together contain 363 residential units across 80 acres. This results in an approximate density of 4.5 units per acre. The CDP has a median household income of $28,508 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 21 (Weldon)

DUC 21, Weldon, is the Census Designated Place located along Lake Isabella in the northeastern part of Kern County, as shown on **Figure 7e.** The community has five clusters of residential units in close proximity that together contain 925

residential units across 332 acres, which results in an approximate density of 1.6 units per acre. The Weldon CDP has a median household income of $24,972 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

DUC 22 (Wofford Heights)

DUC 22 is a Census Designated Place known as Wofford Heights located along the northwestern side of Lake Isabella, as shown on **Figure 7e.** Wofford Heights contains three clusters of residential units that together contain 1,087 residential units across 327 acres. This results in an approximate density of 3.3 units per acre. The CDP has a median household income of $28,917 according to the 2009–2013 ACS, which is less than the qualifying income threshold of $48,856.

C. Municipal Infrastructure and Services Review

1. Water

DUC 1 (Bodfish)

The community of Bodfish has two water providers. The California Water Service (Cal Water) Kern River Valley District serves lower Bodfish, and the Canyon Meadows Water Company serves upper Bodfish. According to the Cal Water 2010 Urban Water Management Plan, it has adequate water supply to meet service connection needs throughout the district. The Canyon Meadows Water Company is a small co-op with 150 connections on several groundwater wells. The co-op president (Cannell 2015) indicates that water levels in the wells remain high and that the current wells have enough capacity to meet current need. The wells meet water quality standards.

DUC 2 (Boron)

Water service to Boron is provided by the Boron Community Services District. The district has 600 connections and is supplied by groundwater or through the Antelope Valley-Eastern Kern Water Agency (Dewar 2015). Supply from these sources is blended and then distributed. The current groundwater well owned by the district is contaminated with arsenic but it concentrations are below the US Environmental Protection Agency's (EPA) maximum contaminant level for arsenic. The district is drilling an additional well, due to be completed by 2016.

DUC 3 (Buttonwillow)

Buttonwillow is provided water by the Buttonwillow County Water District. The district has 150 connections and 434 residential and business units. The district solely uses groundwater, which is adequate to meet current water needs (Houchin 2015a). The groundwater wells owned by the district provide water that meets standards and is of good quality.

DUC 4 (Cherokee Strip)

This area receives water from the City of Shafter. According to Shafter's Public Works Director (James, 2016), this area does not have drinking water quality issues and they have sufficient capacity for their current needs. However, they do not have capacity for expansion or new development.

DUC 5 (Edmundson Acres)

Water to Edmundson Acres is provided by the Edmundson Acres Water System. The system provides all supply through groundwater. Future projects involve replacing old wells with new wells that will not require treatment for arsenic or other constituents. Arsenic is a contaminant that is above the maximum concentration limit of 10 ug/l in all of the system's older wells. Edmundson Acres Water System is upgrading its distribution system and being consolidated with neighboring Arvin Community Services District (ACSD) to correct high arsenic problems. The ACSD is currently under a compliance order from the EPA to solve the problem. Because of arsenic concerns, the Edmundson Acres Water System applied for a Safe Drinking Water, Water Quality and Supply, Flood Control, River and Coastal Protection Bond Act of 2006 (Proposition 84) grant to help it achieve compliance with the order. The system is implementing a plan to drill new replacement wells in areas with unacceptable water quality, including arsenic contamination. If wells do not have acceptable levels of arsenic, centralized arsenic treatment will be installed.

DUC 6 (Fuller Acres)

According to County staff (Rojas 2016) most of the properties in the Fuller Acres DUC are served by a private water wells or water is provided by the Fuller Acres Water Company. For homes on private water wells, no information was available regarding capacity to serve current or future residents or water quality. Regarding Fuller Acres Water Company, according to Company Staff (Alcorn 2016), the Company has capacity to serve all of their current customers. However, they do not have sufficient capacity for expansion. There are no water quality issues.

DUC 7 (Johannesburg)

Water service in Johannesburg is provided by the Rand Communities Water District. The district provides water to Johannesburg, as well as to Randsburg and Red Mountain in San Bernardino County, serving a total population of 920. The district has roughly 220 connections in Kern County and another 40 connections in San Bernardino County. Based on communications with the district's general manager (Powell 2015), water levels in the district's three wells have remained constant, even during recent drought conditions, and the district has ample supply to meet existing and projected water demand. One of the wells does not meet the EPA's maximum contaminant level for arsenic. The district is currently able to meet demand with only one of the two remaining wells. In addition, the district's distribution system is failing due to age, and breaking or leaking occurs with relative frequency. The district has applied for funds through Proposition 84 grant

funding to make infrastructure improvements. This funding may result in an additional well but will not address all of the district's infrastructure needs.

DUC 8 (Lake Isabella)

Water service in Lake Isabella is primarily provided by the Lake Isabella Community Services District. Additionally, small numbers of residences are served by Cal Water and the Kern River Valley Community Services District. The Lake Isabella Community Services District has 184 total service connections, of which 145 are active. Based on communications with the district's office manager (Loseph 2015), the district purchases water from the Urston Creek Water District and operates three groundwater wells. The district reports that it has ample supply to meet existing and projected water demand. All water sources meet quality standards.

DUC 9 (Lake of the Woods)

Water service here is provided by the Lake of the Woods Water District. Currently the district is able to provide water to residents from their wells; however in the recent past they had to supplement this with water brought from the Lebec County Water District. This is because some of the wells are not as productive as they once were. The State is mandating that the Lake of the Woods Water District go to metering. They are looking into potentially annexing into the Frazier Park Public Utilities District (Jarecki, 2016).

DUC 10 (Lamont)

Water service in Lamont is provided by the Lamont Public Utility District, which currently serves a population of 19,152. Currently, the entire district is on groundwater wells. The district's 2014 Urban Water Management Plan reports that the district is currently in overdraft during the drought period and is working with neighboring water jurisdictions to secure additional supply. The district has adequate financing to develop projects to continue to meet current and projected demand. The district's water sources meet quality standards.

DUC 11 (Lost Hills)

County staff (Downs 2016) indicates that residents in this area receive water and sewer service from a local Public Utilities District.

DUC 12 (Mettler)

Water service in Mettler is provided by the Mettler County Water District. The district supplies water for 45 connections, supplied through two groundwater wells. District staff (Houchin 2015b) indicates that water supply is adequate to meet needs and that no water quality problems exist.

DUC 13 (Mexican Colony)

This area receives water from the City of Shafter. According to Shafter's Public Works Director (James, 2016), this area does not have drinking water quality issues and they have sufficient capacity for their current needs. However, they do not have capacity for expansion or new development.

DUC 14 (Mojave)

Water service in Mojave is provided by the Mojave Public Utility District, which currently has 112 water connections. The district has two sources of water, including local groundwater wells and contract supply through the Antelope Valley-East Kern Water Agency. Combined, the sources provide 1,600 acre-feet of water per year, which is greater than the current and projected needs of the community. The district's water sources meet water quality standards.

DUC 15 (Mountain Mesa)

Water service in Mountain Mesa is provided by the Mountain Mesa Water Company, which is operated by Cal Water by contract. The water supply has ongoing quality issues with nitrate and arsenic, but detected levels do not exceed standards. The district is currently making improvements to the treatment plant in order to reduce nitrate and arsenic concentrations in the groundwater supply.

DUC 16 (Oildale)

Water service in Oildale is provided by the Oildale Mutual Water Company, which has 10,200 connections supplied through groundwater wells. The company manager indicates that groundwater levels are sufficient and that the company has adequate supply to meet current and projected needs (Nunneley, 2015). All water sources meet water quality standards.

DUC 17 (Onyx)

Onyx is geographically isolated and topographically constrained. Residents there receive their water from private wells according to an employee (Aguirre, 2016) at the Lake Isabella Kern River KOA Campground. (This KOA is one of the "Possible Partnering Agencies" on the Integrated Regional Water Management Plan for the Weldon Regional Water Project.) No information on capacity or water quality was available.

DUC 18 (Randsburg)

Water service in Randsburg is provided by the Rand Communities Water District. The district also provides water to Johannesburg and Red Mountain in San Bernardino County, serving a total population of 920. The district has roughly 220 connections in Kern County and another 40 connections in San Bernardino County. Based on communications with the district's general manager (Powell 2015), water levels in the district's three wells has remained constant, even during

recent drought conditions, and the district has ample supply to meet existing and projected water demand. One of the wells does not meet the EPA's maximum contaminant level for arsenic. The district is currently able to meet demand with only one of the two remaining wells. In addition, the district's distribution system is failing due to age, and breaking or leaking occurs with relative frequency. The district has applied for funds through Proposition 84 grant funding to make infrastructure improvements. This funding may result in an additional well but will not address all of the district's infrastructure needs.

DUC 19 (USDA Ruben J. Blunt Village)

According to the Facilities Area Supervisor of the Kern County Housing Authority (Greenoe, 2016), water here is provided by the Lamont Public Utility District, which currently serves a population of 19,152. Currently, the entire district is on groundwater wells. The district's 2014 Urban Water Management Plan reports that the district is currently in overdraft during the drought period and is working with neighboring water jurisdictions to secure additional supply. The district has adequate financing to develop projects to continue to meet current and projected demand. The district's water sources meet water quality standards.

DUC 20 (Weedpatch)

Water service in Weedpatch is provided by the Lamont Public Utility District, which currently serves a population of 19,152. Currently, the entire district is on groundwater wells. The district's 2014 Urban Water Management Plan reports that the district is currently in overdraft during the drought period and is working with neighboring water jurisdictions to secure additional supply. The district has adequate financing to develop projects to continue to meet current and projected demand. The district's water sources meet water quality standards.

DUC 21 (Weldon)

According to County staff, Weldon gets its water supply from several small water co-ops and private entities, including the Long Canyon Water Company, Rainbird Valley Mutual Water Company, Tradewinds Water Association, Inc., Bella Vista Mutual Water Company, South Fork Women's Club, and Lake Isabella Kern River KOA Campground. Several of these private entities have arsenic and nitrate quality concerns.

DUC 22 (Wofford Heights)

County staff (Downs 2016) indicates that water here is provided by the California Water Service Company.

Wastewater

DUC 1 (Bodfish)

All of Bodfish depends on small private septic systems. County staff (Popiemlarp 2015) indicates that many of these systems are old and in need of replacement, but they are located on very small lot sizes and in some cases are in poor soils. Both lot size and soils can present challenges for replacement with modern and effective septic systems. Other infrastructure improvements may therefore be necessary.

DUC 2 (Boron)

All of Boron depends on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 3 (Buttonwillow)

The Buttonwillow County Water District provides wastewater collection, treatment, and disposal in limited areas of the community. The district has adequate infrastructure to meet current demand. The rest of the community is on private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 4 (Cherokee Strip)

County staff (Downs 2016) indicates that residences are on small private septic systems. The area has experienced numerous septic failures and resultant water quality impacts. State funding is currently being sought to remedy this situation.

DUC 5 (Edmundson Acres)

County staff (Downs 2016) indicates that residents in this area are on small private septic systems and that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 6 (Fuller Acres)

All of Fuller Acres depends on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 7 (Johannesburg)

All of Johannesburg depends on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 8 (Lake Isabella)

As seen in **Figure 7e**, there are four portions (labeled A-D) which comprise the Lake Isabella DUC. County staff (Downs 2016) indicates that residents in Lake Isabella A are served by sewer. The sewer system in this area is 27 years old. A portion of residents in Lake Isabella D are on a private sewer that serves some commercial and a mobile home park. Lake Isabella areas B and C depend on small private septic systems. County staff (Popiemlarp 2015) indicates that many of these systems are old and in need of replacement, but they are located on very small lots and in some cases are in poor soils. Both lot size and soils can present challenges for replacement with modern and effective septic systems. Other infrastructure improvements may therefore be necessary.

DUC 9 (Lake of the Woods)

County staff (Downs 2016) indicates that residents in this area are on small private septic systems and that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 10 (Lamont)

Wastewater service in Lamont is provided by the Lamont Public Utility District. The district's service area comprises approximately 2,000 acres, and it operates 35 miles of sewer collection pipes and one secondary-level wastewater treatment plant. The district does not indicate that there are currently any wastewater infrastructure needs.

DUC 11 (Lost Hills)

All of Lost Hills depends on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 12 (Mettler)

County staff (Downs 2016) indicates that residents in this area are on small private septic systems and that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 13 (Mexican Colony)

County staff (Downs 2016) indicates that the area is on sewer. The sewer system has no known capacity or water quality issues.

DUC 14 (Mojave)

Portions of Mojave depend on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time. The remaining portions

of the community are served by the Mojave Public Utility District wastewater system, which has adequate infrastructure and wastewater treatment capacity to meet current needs.

DUC 15 (Mountain Mesa)

All of Mountain Mesa depends on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 16 (Oildale)

Wastewater service in Oildale is provided by the North of River Sanitary District. The district operates four treated effluent storage ponds and one wastewater treatment plant. The district has the infrastructure to meet sanitary needs. However, the existing sewers will eventually need to be paralleled and/or replaced with larger diameter sewers as flow from Oildale increases. The district's 2013 Master Sewer Plan establishes a timeline and financing options for making capacity improvements as demand increases.

DUC 17 (Onyx)

All of Onyx depends on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 18 (Randsburg)

All of Randsburg depends on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 19 (USDA Ruben J. Blunt Village)

County staff (Downs 2016) indicates that residents in this area are on small private septic systems and that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 20 (Weedpatch)

Portions of Weedpatch depend on small private septic systems. County staff (Popiemlarp 2015) indicates that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time. The remaining portions of the community are served by the Lamont Public Utility Wastewater system, which has adequate infrastructure and wastewater treatment capacity to meet current needs.

DUC 21 (Weldon)

County staff (Downs 2016) indicates that residents in this area are on small private septic systems and that there are currently no issues of concern with the existing infrastructure and septic is adequate at this time.

DUC 22 (Wofford Heights)

All of Wofford Heights depends on small private septic systems. County staff (Popiemlarp 2015) indicates that many of these systems are old and in need of replacement. High groundwater levels, sloping geography, and erosion have led to water leaching issues in the area. Infrastructure improvements may therefore be necessary.

Stormwater

DUC 1 (Bodfish)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place, there is a history of flooding and it is in a 100-year floodplain.

DUC 2 (Boron)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place, there is a history of flooding and it is in a 100-year floodplain.

DUC 3 (Buttonwillow)

County staff (Hamilton, 2016) indicates the following about this area:

- Stormwater infrastructure is in place, in the form of curb/gutter, storm drain, and pump station;
- Flood protection infrastructure capacity issues are known to exist; and
- The County has Drainage Improvement Plans for this area.

Stormwater and flood protection infrastructure is insufficient in this area.

DUC 4 (Cherokee Strip)

County staff (Hamilton, 2016) indicates that there is no stormwater infrastructure in place and it is not in a 100-year floodplain. Flooding is not a known issue here, according to County staff (Evans, 2016).

DUC 5 (Edmundson Acres)

County staff (Hamilton, 2016) indicates the following about this area:

- Stormwater infrastructure is in place, in the form of curb/gutter, storm drain, and drainage basins;
- Capacity issues are not known to exist; and
- The County has Drainage Improvement Plans for this area.

Stormwater and flood protection infrastructure is sufficient in this area.

DUC 6 (Fuller Acres)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place, there is a history of flooding and it is in a 100-year floodplain. County Staff (Evans, 2016) indicates that Caliente Creek has caused repeated historical flooding in Fuller Acres.

DUC 7 (Johannesburg)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place and that it is not in a 100-year floodplain. There is not a known history of flooding, as indicated by County staff (Evans, 2016).

DUC 8 (Lake Isabella)

County staff (Hamilton, 2016) indicates the following about this area:

- Stormwater infrastructure is in place, in the form of curb/gutter, storm drain, and drainage basins;
- Flood protection infrastructure capacity issues are known to exist;
- The County has Drainage Improvement Plans and Tract Improvement Plans for this area; and
- This area is in a 100-year floodplain.

According to the Kern County Roads Department *2015 Flood Map* for the Kern River Valley and correspondence with County staff (Evans, 2016), within this DUC, adjacent to Erskine Creek, Lake Isabella Boulevard at Lake Isabella Park (Tank Park) experiences frequent flooding and road closures. Major flooding occurs here approximately every ten years. This is a rural area and generally this road is the only access to towns in the Kern River Valley. Closures can impact a few hundred residents at a time.

Stormwater and flood protection infrastructure is insufficient in this area.

DUC 9 (Lake of the Woods)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place, there is a history of flooding and it is in a 100-year floodplain. County Staff (Evans, 2016) indicates that Cuddy Creek has caused historical flooding in this area.

DUC 10 (Lamont)

County staff (Hamilton, 2016) indicates the following about this area:

- Stormwater infrastructure is in place, in the form of curb/gutter, storm drain, and drainage basins;
- Flood protection infrastructure capacity issues are not known to exist;
- The County has Drainage Improvement Plans and Tract Improvement Plans for this area; and
- This area is within the NPDES Permit Boundary. Stormwater samples are collected by the Public Works Department biannually for analysis. No water quality issues are known to exist.

County staff (Downs 2016) indicates that there are known flooding issues in the USDA Lamont H.R. Olson farmworker community portion of this area. Stormwater and flood protection infrastructure is insufficient in this area.

DUC 11 (Lost Hills)

County staff (Hamilton, 2016) indicates the following about this area:

- Stormwater infrastructure is in place, in the form of curb/gutter, storm drain, and drainage basins;
- Capacity issues are not known to exist; and
- The County has Drainage Improvement Plans for this area.

Stormwater and flood protection infrastructure is sufficient in this area.

DUC 12 (Mettler)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place and it is in a 100-year floodplain. Furthermore, this area is known to flood routinely, as indicated by County staff (Evans, 2016).

DUC 13 (Mexican Colony)

County staff (Hamilton, 2016) indicates that stormwater infrastructure, in the form of a drainage basin, is in place. County staff (Hamilton, 2016) indicates that the County has a Drainage Improvement Plan for this area. County staff (Evans, 2016) indicates that there are flood protection infrastructure capacity issues.

DUC 14 (Mojave)

County staff (Hamilton, 2016) indicates that the area is in a 100-year floodplain. As seen on **Figure 7g**, Mojave includes seven small clusters of residences. Theses clusters are identified as A-G. County staff (Hamilton, 2016) indicates the following:

Area A. No stormwater infrastructure is in place.

Area B. No stormwater infrastructure is in place.

Area C. No stormwater infrastructure is in place in this area, except in the mobile home park, which has private streets and a private drainage basin. The County is in possession of a grading plan from the mobile home park.

Area D. No stormwater infrastructure is in place in this area, except in the apartment complex, which has a private drainage basin. The County is in possession of a grading plan from the apartment complex in this area.

Area E. Stormwater infrastructure is in place here, in the form of the Victor Avenue Basin. The County has a Drainage Improvement Plan.

Area F. No stormwater infrastructure is in place in this area, except in the apartment complex, which has a private drainage basin. The County is in possession of a grading plan from the apartment complex.

Area G. Stormwater infrastructure is in place, under the purview of the private community with private streets. The County is in possession of a grading plan and Tract 4522 improvement plans.

County staff (Evans, 2016) indicates that there are no known flood protection infrastructure capacity or flooding issues here.

DUC 15 (Mountain Mesa)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place, there is a history of flooding and it is in a 100-year floodplain.

DUC 16 (Oildale)

County staff (Hamilton, 2016) indicates the following about this area:

- Stormwater infrastructure is in place, in the form of curb/gutter, storm drain, and drainage basins;
- Flood protection infrastructure capacity issues are known to exist;
- The County has Drainage Improvement Plans Tract Improvement Plans and Parcel Map Improvement Plans; and
- No water quality issues are known to exist.

According to the Kern County Roads Department *2015 Flood Map* for Metro Bakersfield and correspondence with County staff (Evans, 2016), within this DUC, generally all of the Airport Drive underpasses are frequently flooded. This is because the pumps are not big enough to remove the water fast enough. It happens frequently- every normal rain year. It will happen numerous times in an El Nino Winter. While these events are not severe enough to shut down traffic and there are alternate routes available, the flooding poses an inconvenience to motorists. Stormwater and flood protection infrastructure is insufficient in this area.

DUC 17 (Onyx)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place, there is a history of flooding and it is in a 100-year floodplain.

DUC 18 (Randsburg)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place and that it is not in a 100-year floodplain. There is not a known history of flooding, as indicated by County staff (Evans, 2016).

DUC 19 (USDA Ruben J. Blunt Village)

According to staff from the Kern County Public Works Department (Hamilton, 2016), stormwater infrastructure in the form of curb/gutter, drainage areas and drainage basins are in place here. According to the Facilities Area Supervisor of the Kern County Housing Authority (Greenoe, 2016), this site had repairs to their drainage system last summer. No drainage issues currently exist. This site is located in a 100 year flood zone, however, the drainage basin located behind the property is of adequate size.

DUC 20 (Weedpatch)

This area straddles Highway 184, which runs north-south. County staff (Hamilton, 2016) indicates that the area is not in a 100-year floodplain.

West of highway 184: County staff (Hamilton, 2016) indicates that the portion of the area to the west of Highway 184 has stormwater infrastructure, in the form of a drainage basin. County staff (Hamilton, 2016) indicates that the County has a Drainage Improvement Plan for the area served by the drainage basin. County staff (Evans, 2016) indicates that there are flood protection infrastructure capacity issues.

East of highway 184: County staff (Hamilton, 2016) indicates that the portion of the area to the east of Highway 184 does not have stormwater infrastructure. County staff (Evans, 2016) indicates that there are considerable flooding issues in this area, especially northeast of Weedpatch (east Lamont).

DUC 21 (Weldon)

County staff (Hamilton, 2016) indicates that, in this area, no stormwater infrastructure is in place, there is a history of flooding and it is in a 100-year floodplain.

DUC 22 (Wofford Heights)

County staff (Hamilton, 2016) indicates that there is no stormwater infrastructure in place and that the area is in a 100-year floodplain. Despite this, flooding is not a known issue here, according to County staff (Evans, 2016).

Fire Protection

DUC 1 (Bodfish)

Kern County contracts with the California Department of Forestry and Fire Protection (Cal Fire) to provide fire services for certain unincorporated areas, including Bodfish. Station 72 is the nearest responding fire station.

DUC 2 (Boron)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Boron. Station 17 is the nearest responding fire station.

DUC 3 (Buttonwillow)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Buttonwillow. Station 25 is the nearest responding fire station.

DUC 4 (Cherokee Strip)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Cherokee Strip. Station 32 is the nearest responding fire station.

DUC 5 (Edmundson Acres)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Edmundson Acres. Station 54 is the nearest responding fire station.

DUC 6 (Fuller Acres)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Fuller Acres. Station 51 is the nearest responding fire station.

DUC 7 (Johannesburg)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Johannesburg. Station 75 is the nearest responding fire station.

DUC 8 (Lake Isabella)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Lake Isabella. Station 72 is the nearest responding fire station.

DUC 9 (Lake of the Woods)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Lake of the Woods. Station 57 is the nearest responding fire station.

DUC 10 (Lamont)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Lamont. Station 51 is the nearest responding fire station.

DUC 11 (Lost Hills)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Lost Hills. Station 26 is the nearest responding fire station.

DUC 12 (Mettler)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Mettler. Station 72 is the nearest responding fire station.

DUC 13 (Mexican Colony)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Mexican Colony. Station 32 is the nearest responding fire station.

DUC 14 (Mojave)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Mojave. Station 14 is the nearest responding fire station.

DUC 15 (Mountain Mesa)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Mountain Mesa. Station 71 is the nearest responding fire station.

DUC 16 (Oildale)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Oildale. Station 63 is the nearest responding fire station.

DUC 17 (Onyx)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Onyx. Station 71 is the nearest responding fire station.

DUC 18 (Randsburg)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Randsburg. Station 75 is the nearest responding fire station.

DUC 19 (USDA Ruben J. Blunt Village)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including USDA Ruben J. Blunt Village. Station 51 is the nearest responding fire station.

DUC 20 (Weedpatch)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Weedpatch. Station 51 is the nearest responding fire station.

DUC 21 (Weldon)

Kern County contracts Cal Fire to provide fire services for certain unincorporated areas, including Weldon. Station 71 is the nearest responding fire station.

DUC 22 (Wofford Heights)

Kern County contracts with Cal Fire to provide fire services for certain unincorporated areas, including Wofford Heights. Station 76 is the nearest responding fire station.

Table 71. Summary of Service to DUCs in Kern County

DUC	Water Sufficient	Wastewater Treatment Sufficient	Stormwater Infrastructure Sufficient	Fire Protection Sufficient	Underserved DUC
DUC 1: Bodfish	Yes	No	No	Yes	Yes
DUC 2: Boron	Yes	Yes	No	Yes	Yes
DUC 3: Buttonwillow	Yes	Yes	No	Yes	Yes
DUC 4: Cherokee Strip	Yes	No	Yes	Yes	Yes

DUC 21: Weldon	No	Yes	No	Yes	Yes
DUC 22: Wofford Heights	Yes	No	Yes	Yes	Yes

D. Future Annexations Considered

Kern County Planning staff was consulted to determine whether any annexations from the County into any Kern County cities are anticipated. Annexations are considered on a case-by-case basis and at this time none of these DUCs have contacted the County or are under consideration for annexation into cities.

E. Conclusion

While Bakersfield average housing costs ($170,000) are shown to be consistent with the average housing costs in the United States, California's home prices and rents have risen faster than the U.S. average since the 1940's and resistance to density and the California Environmental Quality Act continue to delay or stop new housing development. Appendices B and C of this Housing Element contain two recent reports on housing development in California. Both reports were prepared by the California Legislative Analyst Office: Perspectives on Helping Low Income Californians Afford Housing, dated February 9, 2016, and California's High Housing Costs: Causes and Consequences, dated March 17, 2015. The reports indicate that "living in decent, affordable, and reasonably located housing is one of the most important determinates of well-being for every Californian. More than just basic shelter, housing affects our lives in other important ways, determining our access to work, education, recreation, and shopping. The cost and availability of housing also matters for the State's economy, affecting the ability of business and other employers to hire and retain qualified workers and influencing their decisions about whether to locate, expend, or remain in California." The report released in March 2015, and confirmed again in the report from February 2016, notes barriers to providing more housing for low income and special needs populations. The reports further identify and discuss the following challenges and concerns to expanding existing programs at the State level.

- Expanding Assistance Programs would be very expensive.
- Affordable housing construction requires large public subsidies.
- Expanding housing vouchers would be expensive and a scarcity of housing undermines the voucher program causing rents to rise.
- Environmental protection policies constrain housing development.
- Home builders are often forced to compete for limited development opportunities.

The reports conclude that while vouchers, inclusionary housing requirements and rent control have provided limited solutions, increasing the housing supply is the only factor that will ensure availability.

While there is a need to develop and identify new affordable housing developments, there is also a need to provide adequate infrastructure to those areas currently being underserved. Based on information contained in this analysis,

expansion of services will be required for 20 of the disadvantaged unincorporated communities (DUC) described above. Water quality or supply issues exist in Bodfish, Edmundson Acres, Johannesburg, Lake of the Woods, Lamont, Randsburg, U.S.D.A. Ruben J. Blunt Village, Weedpatch, and Weldon. Wastewater issues relating to private septic systems exist in Bodfish, Cherokee Strip, Lake Isabella, and Wofford Heights. Lack of stormwater and flood protection infrastructure is an issue in Bodfish, Boron, Buttonwillow, Fuller Acres, Lake Isabella, Lake of the Woods, Mettler, Mexican Colony, Mountain Mesa, Oildale, Onyx, Weedpatch, and Weldon. All of these DUCs are considered underserved. The County will continue to identify additional financing alternatives and mechanisms for improving water quality and providing better septic or installing sewer systems in these existing DUC's. **Table 72** provides an outline of potential infrastructure funding opportunities that the County can pursue to facilitate additional infrastructure projects within these identified DUC areas.

Table 72. Potential Funding Sources for Extension and Improvement of Services

Agency	Program (Year Passed or Created)	Funding Provided (in million $)	Funding Remaining/Available (in million $)	Limitations/Barriers on Use of Funds for Drinking Water Treatment (capital or O&M)
California Department of Public Health (CDPH)	Safe Drinking Water State Revolving Fund (SDWSRF) (1996) (grants and loans)	Generally $100-$150: Low-interest loans and some grants to support water systems with technical, managerial, and financial development and infrastructure improvements.	$130-$150 (revolving funds) (annually)	▪ 20 to 30% of annual federal contribution can be used for grants. The remainder must be committed to loans. ▪ Funds can be used only for capital costs. Cannot be used for O&M ▪ Only loans (not grants) for privately owned water systems. ▪ Some funds available for feasibility and planning studies for eligible projects/systems. ▪ Can only be used for Public Water Systems (not domestic wells or State Small Systems)
	Proposition 84 (2006) (grants)	$180: Small Community Improvements. --- $60: Protection and reduction of contamination of groundwater sources. $50 Matching funds for federal DWSRF --- $10: Emergency and urgent projects.	$0 (Over subscribed) --- $0 (Fully allocated) Will be fully committed with the current year grant but not yet liquidated --- ~$7	▪ Funds can be used only for capital costs. Cannot be used for O&M. ▪ Some funding available for feasibility and planning studies for eligible projects/systems. ▪ Can only be used for Public Water Systems not domestic wells or State Small Systems --- ▪ Used to address sudden unanticipated emergency situation such as fires, earthquakes and mud slides that damage critical water infrastructure. May fund short term mitigations such as hauled water.
	Proposition 50 (2002) (grants) (fully allocated)	$50: Water security for drinking water systems. --- $69: Community treatment facilities and monitoring programs. --- $105: Matching funds for federal grants for public water system infrastructure improvements.	$0 (fully allocated) --- $0 (fully allocated) --- $0 fully allocated, mostly liquidated	▪ Can only be used for capital costs. Cannot be used for O&M. ▪ Can only be used for Public Water Systems not domestic wells or State Small Systems

Agency	Program (Year Passed or Created)	Funding Provided (in million $)	Funding Remaining/Available (in million $)	Limitations/Barriers on Use of Funds for Drinking Water Treatment (capital or O&M)
State Water Resources Control Board (State Water Board)	Clean Water State Revolving Fund (Expanded Use Program) (CWSRF) (1987) (loans)	$200-$300 per year: Water quality protection projects, wastewater treatment, nonpoint source contamination control, and watershed management.	$50 per agency per year; can be waived	Eligible Uses: Stormwater treatment and diversion, sediment and erosion control, stream restoration, land acquisition. Drinking water treatment generally not eligible except under certain Expanded Use scenarios. Capital cost only. O&M not eligible.
	Small Community Groundwater Grants (Prop 40) (2004, amended 2007) (grants)	$9.5. Assist small disadvantage communities (<20,000pp) with projects where the existing groundwater supply exceeds maximum contaminant levels, particularly for arsenic or nitrate	$1.4 remaining- $0.3 available to encumber; $1.1 available to appropriate	Eligible Uses: Funds can go to local government or NGO. Must demonstrate financial hardship. Can only provide alternate water supply. No O&M costs. Program not currently active due to staff resource limitations
	State Water Quality Control Fund: Cleanup and Abatement Account (2009)	$10 in 2012 (varies annually): Projects to (a) clean up waste or abate its effects on waters of the state, when there is no viable responsible party, or (b) address a significant unforeseen water pollution problem (regional water boards only). Funds can be allocated to: Public Agencies, specified tribal governments, and not-for profit organizations that serve disadvantaged communities	$10, but varies.	Eligible Uses: Emergency cleanup projects; projects to clean up waste or abate its effects on waters of the state; regional water board projects to address a significant unforeseen water pollution problem. Recipient must have authority to clean up waste. Under certain circumstances this fund has been used to provide drinking water O&M for limited durations.
	Integrated Regional Water Management (IRWM) (2002) (grants) (fully allocated)	$380 (Prop 50): Planning ($15) and implementation ($365) projects related to protecting and improving water quality.	$0, fully committed	
California Department of Water Resources (DWR)	Integrated Regional Water Management (IRWM) (2002) (grants)	$600 remaining (Prop 84): Regional water planning and implementation.	~$28 (central coast projects) ~$33 (Tulare/Kern projects)	Must be consistent with an adopted IRWM Plan and other program requirements. For capital investment only

Agency	Program (Year Passed or Created)	Funding Provided (in million $)	Funding Remaining/Available (in million $)	Limitations/Barriers on Use of Funds for Drinking Water Treatment (capital or O&M)
(California Department of Water Resources (DWR))	Contaminant treatment or removal technology pilot and demonstration studies (2002) (grants)	Up to $5 per grant	$15 million available	Eligible applicants are public water systems under the regulatory jurisdiction of CDPH and other public entities For capital investment only
	Safe Drinking Water Bond Law (Prop 81) (1988)	Up to $74 to be awarded to current priority list. $0.025 max per project	Remaining balance to be determined	Provides funding for projects that investigate and identify alternatives for drinking water system improvements
	Drinking water disinfecting projects using UV technology and ozone treatment (2002) (grants)	$0.05 minimum, up to $5 m per grant	$19 m remaining	Eligible applicants are public water systems under the regulatory jurisdiction of CDPH For capital investment only
iBank (CA Infrastructure and Development Bank)	Infrastructure State Revolving Fund (ISRF) Program (2000) (loans)	$0.25 to $10 per project to finance water infrastructure that promotes job opportunities. Eligible projects include - construction or repair of publicly owned water supply, treatment, and distribution systems.	$52.6 million approved to date for Water Supply, Water Treatment and Distribution Applications continually accepted	Finances system capital improvements only. Must show job creation. Special loan tier for DACs was discontinued.
State Water Resources Control Board (State Water Board) & California Department of Water Resources (DWR)	Proposition 1 Water Quality, Supply and Infrastructure Improvement Act of 2014	Prop 1 was approved by voters on November 4, 2014 and authorizes $7.545 billion in general obligation bonds for water projects including surface and groundwater storage, ecosystem and watershed protection and restoration, and drinking water protection. DWR and the State Water Board will administer various Prop 1 funds.	Various. Applications ongoing.	See Appendix D for a detailed breakdown of various funding programs authorized under the passage of Proposition 1.

Regional Changes in Extreme Climatic Events: A Future Climate Scenario

JASON L. BELL, LISA C. SLOAN, AND MARK A. SNYDER

Department of Earth Sciences, University of California, Santa Cruz, Santa Cruz, California

(Manuscript received 10 July 2002, in final form 11 February 2003)

ABSTRACT

In this study a regional climate model is employed to expand on modeling experiments of future climate change to address issues of 1) the timing and length of the growing season and 2) the frequency and intensity of extreme temperatures and precipitation. The study focuses on California as a climatically complex region that is vulnerable to changes in water supply and delivery. Statistically significant increases in daily minimum and maximum temperatures occur with a doubling of atmospheric carbon dioxide concentration. Increases in daily temperatures lead to increases in prolonged heat waves and length of the growing season. Changes in total and extreme precipitation vary depending upon geographic location.

1. Introduction

Analysis of long-term temperature and precipitation records has revealed changes in the mean climatic state as atmospheric carbon dioxide (CO_2) levels have increased since the industrial revolution (Easterling et al. 1997; Gaffen and Ross 1998; Plummer et al. 1999; Salinger and Griffiths 2001). Research employing global climate models (GCMs) indicates potentially greater changes for future climate states (Cao et al. 1992; Zwiers and Kharin 1998; McGuffie et al. 1999; Yonetani and Gordon 2001). Changes in the mean climate state have been found to affect the frequency and intensity of extreme climatic events as well (Mearns et al. 1984; Katz and Brown 1992; Groisman et al. 1999; Meehl et al. 2000). Extremes in temperature and precipitation have important impacts on vital aspects of society, including crop yield, power consumption and production, and human health (Easterling et al. 2000; Meehl et al. 2000; Walther et al. 2002). Responses to climate change and mitigation of negative impacts must be resolved at regional and local levels in order for effective action to be taken; therefore, it is important to assess the potential for climate change on a regional level.

Regional changes in climate are highly variable and cannot be adequately represented by GCMs at this time. This inability necessitates the use of regional climate models (RCMs) to address potential climate change on the regional scale. Snyder et al. (2002) used an RCM to demonstrate the potential for significant changes in the mean climate of the California region due to a doubling of atmospheric CO_2 levels. The present study addresses potential changes in the frequency and intensity of extreme daily temperatures and precipitation events for the same region and CO_2 scenarios.

2. Model description and experiment design

The model description and experiment design is similar to that of Snyder et al. (2002) with a few key differences. Snyder et al. (2002) performed a sensitivity study of California climate with doubled CO_2 using a limited ensemble approach. The limited ensemble approach utilized identical GCM boundary conditions with multiple RCM simulations. Two CO_2 scenarios were compared and each scenario was comprised of three ensemble members of 5 years in length. While this approach was successful at limiting computational expense the results indicate that the GCM is responsible for the majority of the variability. Snyder et al. (2002) discovered that the year-to-year variability within a given simulation was much greater than the variability between ensemble members. Based on these conclusions we use a single 15-yr simulation for each of the CO_2 scenarios and present results based on twice-daily model output.

We used the National Center for Atmospheric Research (NCAR) Community Climate Model version 3.6.6 (CCM3) (Kiehl et al. 1998) as the global driver for our regional model. We first used a version of CCM3 with a slab ocean–thermodynamic sea ice model to perform two 15-yr simulations. The two simulations differed only in the atmospheric CO_2 concentrations, which were 280 ppm (preindustrial level) and 560 ppm (hereafter referred to as $1 \times CO_2$ and $2 \times CO_2$ scenarios, respectively). Due to the model output only being saved at monthly intervals the calculated sea surface temper-

© 2004 American Meteorological Society

atures (SSTs) were used to drive a second set of CCM3 simulations. These simulations, using the prescribed SSTs for the corresponding CO_2 concentrations, were run for 22 years and results were saved at 12-h intervals. The first 4 years of each simulation were removed as equilibration time and the remaining 18 yr of results were used to drive the RCM.

This study employs a modified version of the second-generation NCAR Regional Climate Model (RegCM2) (Giorgi and Shields 1999) (hereafter referred to as RegCM2.5) as described by Snyder et al. (2002). RegCM2.5 was run with a horizontal resolution of 40 km and a domain centered over California. We performed two 18-yr simulations with the first three years removed for equilibration. These simulations varied only in the specified atmospheric CO_2 concentrations (280 and 560 ppm).

3. Validation

It is important when discussing the need for more regional and local scale studies of climate change and impacts to be able to demonstrate the capability for such studies. Here we demonstrate 1) the ability of the regional model to adequately capture both the general (seasonal temperature and precipitation) and specific [diurnal temperature range (DTR), growing season length, frequency and intensity of extreme events] characteristics of regional climate observed for the modern day and 2) that regional models are currently better suited for this type of analysis than global models. Mearns et al. (1999) have performed a similar validation for RegCM2 with a domain centered on Nebraska while Snyder et al. (2002) performed a more general validation over California.

a. Modern climate

Here we compare the results of a modern-day regional climate simulation to observations. The model simulation of present-day conditions is similar in design to our $1 \times CO_2$ and $2 \times CO_2$ scenarios. CCM3 was run for 22 years forced with a single climatological year of SSTs (calculated from observations for the period from 1950 to 1979). The first 4 yr were removed for equilibration and the last 18 yr were used to drive RegCM2.5. The first 3 yr of the RegCM2.5 simulation were removed for equilibration and the last 15 yr are used for the analysis presented here. The atmospheric CO_2 concentration in both models was 360 ppm.

The observational data used are historical weather station data collected by the Western Regional Climate Center (2003). The types and scope of data available vary depending on the climate characteristics of interest. For each comparison with the model results we treat all data in as similar a manner as possible. For the analyses of seasonal temperature and precipitation we used climatological data calculated with a minimum of 22 yr of data from the period 1971–2001. For the more specific analyses (DTR, growing season, and extremes) the available data ranges from 27 to 100 yr in length (on average 49.4 yr) for the period from 1901 to 2001. We began our analysis with ~55 stations and, due to the shear volume of available data, narrowed it to stations where the actual and model-derived elevations differed by no more than 100 m. What remained were 16 stations representing a wide range of latitude, longitude, and elevations across California.

TABLE 1. Summary of comparison between observations (obs) and RegCM2.5 (rcm) modern-day simulation.

	obs	rcm	obs−rcm
	Temperature		
Annual mean (°C)	32.7	32.0	0.7
DJF (°C)	25.3	23.9	1.4
MAM (°C)	31.4	29.0	2.4
JJA (°C)	40.4	40.8	−0.4
SON (°C)	33.6	34.1	−0.5
$T \geq 32.2$°C (days)	71.4	43.8	27.6
$T \geq 0$°C (days)	68.5	38.2	30.3
1-day max (°C)	44.1	40.1	4.0
1-day min (°C)	−15.2	−12.9	−2.3
	DTR		
Annual mean (°C)	15.4	9.7	5.7
DJF (°C)	12.2	6.0	6.2
MAM (°C)	15.0	9.2	5.8
JJA (°C)	18.3	13.4	4.9
SON (°C)	15.9	10.2	5.7
	Precipitation*		
Annual mean (cm)	52.9	56.7	−3.8
DJF (cm)	26.6	31.6	−5.0
MAM (cm)	13.9	16.6	−2.7
JJA (cm)	2.2	0.5	1.7
SON (cm)	8.6	8.1	0.5
Light (days)	88.9	97.1	−8.2
Moderate (days)	12.3	13.3	−1.0
Heavy (days)	5.5	5.7	−0.2
1-day max (cm)	12.1	10.8	1.3

* Precipitation intensities are defined as: light days < 1.27 cm, moderate days < 2.54 cm, and heavy days ≥ 2.54 cm.

Overall the comparison between modern-day regional model results and weather station data is very good. This is especially the case considering the data record is much longer than the model simulation and therefore provides a larger sample population. Furthermore the weather stations provide point data, while the model results are derived from single grid cells with 40-km horizontal resolution. Still there are some issues with the model results, especially for the DTR and the seasonality of precipitation.

The regional model adequately captures the seasonal changes in temperature as well as the annual mean temperature. On average the RCM is only 0.7°C cooler for the annual mean and no more than 2.4°C different seasonally than the observations (Table 1). The RCM more accurately captures the summer [Jun–Aug (JJA)] and fall [Sep–Nov (SON)] temperatures than the winter [Dec–Feb (DJF)] and spring [Mar–May (MAM)] tem-

peratures. The DTR is too small by ~5° to 6°C annually and seasonally (Table 1). The growing season starts on average 16.5 days too soon and ends 13.8 days too late. For extremes the model simulates ~28 too few hot (32.2°C) days per year and ~30 too few cold (0°C) days per year (Table 1). While the model simulates too few extreme events it does not overestimate the intensity of simulated extreme events. The historic 1-day events simulated by the model fall within the range of historic events in the longer observational record (Table 1).

The regional model outputs temperature twice a day at noon and midnight. These temperatures are used as proxies for the daily maximum and minimum and are not the actual maximum and minimum temperatures. As a result, the proxy maximum temperatures are too cool and the proxy minimum temperatures are too warm, producing a dampened DTR. The use of the proxy minimum also affects the calculated beginning and end of the growing season. The growing season appears to start earlier and end later due to the use of the proxy minimum temperature. Finally the use of these proxy temperatures results in extreme events that do not appear as extreme as those in the observational record.

Annually the regional model slightly overestimates total precipitation (+3.8 cm yr^{-1}) and poorly captures the seasonality of precipitation. The model overestimates winter and spring precipitation and underestimates summer and fall precipitation (Table 1). The model also simulates ~8 too many light rainfall days per year (<1.27 cm day^{-1}). For moderate (1.27–2.54 cm day^{-1}) and heavier (>2.54 cm day^{-1}) rainfall days the model is much more accurate (Table 1). The model simulates one day too many per year of moderate precipitation and only 0.2 too many days per year of heavier rainfall. The model does a good job simulating historic 1-day events considering the differences in sample sizes. The average 1-day high is 1.3 cm less in the model than in the observations (Table 1).

b. GCM versus RCM

A RCM offers higher spatial resolution than a GCM, allowing for greater topographic complexity and smaller-scale atmospheric dynamics to be simulated and investigated. Theoretically, higher resolution should lead to more realistic simulations of regional-scale climate. The biggest weakness with RCMs is the dependence on lateral boundary input either via GCM, reanalysis, or observational data. If an RCM receives poor quality input it is not likely to output much higher quality results. So, if quality GCM input is needed, then is the use of an RCM necessary? The answer to that question depends on the inquiry to be addressed. Obviously a RCM would be inadequate to address issues of global, or even hemispheric, changes in atmospheric circulation. Likewise a GCM may not be appropriately suited for questions that are subcontinental in scale, especially for complex regions. California is a climatically and topographically complex region and therefore a study of the regional climate there warrants the use of a RCM.

Having already demonstrated that RegCM2.5 does a good job of simulating the modern observed climate of California we must answer another question: Does the RCM do a better job of simulating California climate than the GCM? The modern-day CCM3 simulation was analyzed in the same manner as the RCM output. We compared the CCM3 results for temperature and precipitation to the 16 weather stations discussed earlier. For over 540 individual comparisons of GCM and RCM versus observational data the GCM compared more favorably than the RCM only 25% of the time. Furthermore there was no one specific climatic feature or characteristic that the GCM consistently simulated better than the RCM. Clearly there is utility in using the RCM, and not just the GCM, to address issues of changes in climate for a complex region.

Overall RegCM2.5 does a good job simulating the main features of the modern-day climate, though it is not perfect. RegCM2.5 also does a much better job simulating the California climate than CCM3. Any inherent biases in RegCM2.5 will be present in both of our CO_2 scenarios. Therefore, since this is a sensitivity study, these model biases will be mitigated when calculating changes in the climate due to the doubling of CO_2.

4. Analysis methods

California spans a wide latitudinal range and contains a variety of microclimates. Due to this diversity of microclimates, we perform our analysis on the hydrologic basin scale, as defined by the California Department of Water Resources (1998) (Fig. 1). The methods for analysis of changes in extreme events are similar to those of Salinger and Griffiths (2001). Annual extreme events are defined based on the 5th and 95th percentiles of the $1 \times CO_2$ results.

a. Temperature

We define three types of extreme temperature events and examine changes between the $1 \times CO_2$ and $2 \times CO_2$ scenarios. The first type of extreme event is based on the 95th and 5th percentiles of daily maximum and minimum temperatures, respectively. These percentiles correspond to the 18th hottest maximum and coldest minimum temperatures in a year (based on the number of events per year multiplied by the percentile). For all 15 years of the $1 \times CO_2$ simulation the annual 5th-percentile events were averaged together to create a long-term extreme cold index value, likewise for the annual 95th-percentile events. These long-term indices are used for the evaluation of changes in extreme events. The second type of extreme event examined is based on specific temperature thresholds. We examine the frequency of events below 0°C and above 32.2°C. The third type of extreme event is a prolonged extreme event.

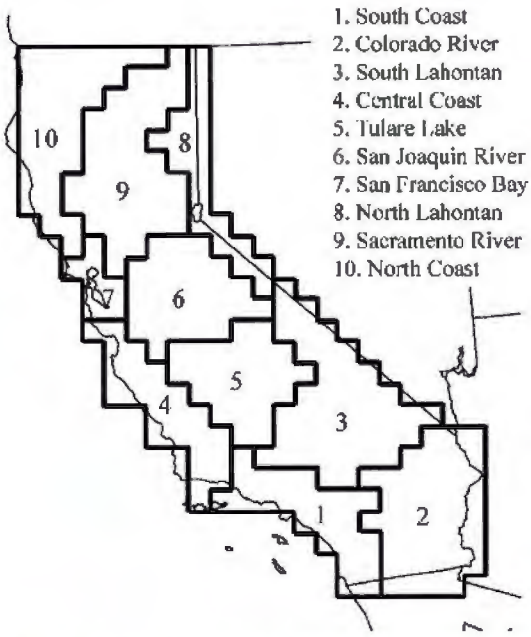

FIG. 1. The hydrologic basins of California shown here are adapted from the California Department of Water Resources (1998) to the 40-km RCM grid. Note the area shown here is a subset of the total regional model domain used in this study.

These are events where the maximum (or minimum) temperature exceeds the long-term 95th (or 5th) percentile for seven or more consecutive days.

Indices of temperature examined are the following:

- Changes in mean daily temperature maximum, minimum, and range: T_{max}, T_{min}, T_{range}, respectively.
- The frequency of days with maximum (minimum) temperatures above (below) the 95th (5th) percentile: T_{95} (T_{05}). (Extreme event of type 1 described above.)
- The frequency of days with temperatures above (below) 32.2°C (0°C): T_{32} (T_0). (Extreme event of type 2 described above.)
- Changes in prolonged extreme events, including frequency, mean length, and mean temperature of prolonged hot and cold extreme events. (Extreme event of type 3 described above.)
- Changes in the beginning and length of the annual growing season (based on the frost-free period).

b. Precipitation

Precipitation in California is highly variable on all temporal and spatial scales. For each basin we examine changes in daily and annual rainfall and the frequency of extremely heavy rainfall events. Heavy rainfall events are defined using the 95th percentile as explained above for extremely high temperatures.

Indices of precipitation examined are the following:

- Changes in mean annual rain.
- Changes in mean rain per rain day[1] and number of rain days per year.
- The frequency of extreme events exceeding the 95th percentile (as above): P_{95}.

5. Results

a. Temperature

In general the 2 × CO_2 scenario is hotter than the 1 × CO_2 scenario. For every basin the mean daily maximum and minimum temperatures are greater in the 2 × CO_2 scenario than in the 1 × CO_2 scenario (Table 2), with differences statistically significant at the 95% confidence level (5% significance level). While the increases in both maximum and minimum are similar, the increase in daily maximum is greater, for 9 of 10 basins, than the increase in daily minimum. This leads to an increased mean DTR in these regions. Although the change in DTR is relatively small, it is still significant in 7 of 10 basins (Table 2). Our results indicate an increase in extremely hot days (T_{95}), days exceeding 32.2°C, and in prolonged hot spells (Table 3). Not only are there more prolonged hot events in the 2 × CO_2 scenario, but these events are longer and hotter on average than the prolonged events in the 1 × CO_2 scenario (Table 3). While the maximum temperatures are rising in the 2 × CO_2 scenario, so are the minimum temperatures, resulting in a decrease in days below the 5th percentile (T_{05}) and in days below 0°C (Table 2). Due to the decrease in days with temperatures less than 0°C the frost-free period begins, on average, 25 days earlier in the 2 × CO_2 scenario and is on average 38 days longer. In our 2 × CO_2 scenario we also find that prolonged cold events occur less often and are shorter and warmer on average than in the 1 × CO_2 scenario.

b. Precipitation

We find decreases in mean annual rainfall across the state (Table 4). Only the North Coast and North Lahontan basins have increased rain, 1% and 3%, respectively. On average there is very little change in mean rainfall per rain day, although there are generally fewer rain days per year in each basin (~5 days). With the exceptions of the North Coast and North Lahontan basins there is also a decrease in extremely heavy rainfall (P_{95}) events as well (Table 4). On average, 2.4 fewer heavy events occur per year per basin, while the North Coast and North Lahontan basins average 2.5 *additional* heavy rainfall events per year compared to the 1 × CO_2 scenario.

[1] We define a rain day as any day with basin average of 0.1 mm or more of precipitation.

Overpumping leads to California groundwater arsenic threat

Ryan Smith [1], Rosemary Knight[1] & Scott Fendorf [2]

Water resources are being challenged to meet domestic, agricultural, and industrial needs. To complement finite surface water supplies that are being stressed by changes in precipitation and increased demand, groundwater is increasingly being used. Sustaining groundwater use requires considering both water quantity and quality. A unique challenge for groundwater use, as compared with surface water, is the presence of naturally occurring contaminants within aquifer sediments, which can enter the water supply. Here we find that recent groundwater pumping, observed through land subsidence, results in an increase in aquifer arsenic concentrations in the San Joaquin Valley of California. By comparison, historic groundwater pumping shows no link to current groundwater arsenic concentrations. Our results support the premise that arsenic can reside within pore water of clay strata within aquifers and is released due to overpumping. We provide a quantitative model for using subsidence as an indicator of arsenic concentrations correlated with groundwater pumping.

Globally, groundwater provides almost half of all drinking water[1], making it one of the world's most important resources. Within the United States, the Central Valley of California accounts for roughly 20% of groundwater withdrawals[2]. The Central Valley is an arid region that supports a $17 billion agricultural industry. In the southern, highly productive region of the valley (known as the San Joaquin Valley), aquifers are particularly stressed due to the high water demands. Further, groundwater is the main source of drinking water for roughly one million people in the San Joaquin Valley. Herein, we focus on threats to groundwater quality induced by naturally occurring arsenic, which may have devastating impacts on both human health and food production.

Arsenic is a ubiquitous, naturally occurring contaminant that is a common problem in many aquifers that are pumped for drinking water[3]; most notably, it is presently having a devasting impact on groundwater quality throughout Asia[4]. When present in significant amounts, it increases the risk of cancer, heart disease, and diabetes[5]. Hazardous levels of arsenic typically result from anaerobic conditions, as noted for the shallow, Holocene aquifers of Asia[4], or from high pH (pH > 8.5) often observed in high arsenic regions of the Andes[6]. In addition, overpumping an aquifer system has been noted to increase the arsenic levels in Southeast Asia by drawing arsenic from less permeable anaerobic clay strata into the aquifer[7].

Arsenic within pumped groundwater of the San Joaquin Valley has been noted for decades. Approximately 10% of the wells tested within the last 10 years have shown arsenic (As) concentrations above 10 µg/L (p.p.b.), the level recommended as the maximum acceptable by the World Health Organization (WHO). As groundwater is increasingly being pumped to meet agricultural and domestic needs, preserving groundwater resources (i.e., maintaining water quality) is imperative. Here we seek to determine the source of arsenic contamination within groundwater of the Central Valley, CA, and to develop quantitative means for predicting degradation of groundwater quality. We focus our study on the Tulare basin (Fig. 1), a highly productive agricultural region of the San Joaquin Valley where groundwater is essential for meeting water demands.

Groundwater pumping in the San Joaquin Valley has caused declines of ~ 60 m in groundwater levels over the past century, leading to subsidence as high as ~ 9 m from 1925 to 1970, a rate of 20 cm/year[8]. Rates of subsidence as high as 25 cm/year have been observed in more recent droughts spanning from 2007 to 2010 and from 2012 to 2016[9, 10]. Subsidence due to groundwater pumping is caused by a pore pressure drop in aquifer materials, which increases the effecive stress, σ_e, defined as $\sigma_e = \sigma_T - P_p$, where σ_T is the total stress and P_p is the pore pressure[11]. Increasing the effective stress results in aquifer compaction. The majority of compaction and linked subsidence of the overlying ground surface is caused by drainage of clays due to their weaker geomechanical properties, as indicated by their higher skeletal specific storage. Thus, the high subsidence levels provide a measure of overpumping in aquifers having substantial clay content, such as the aquifers of the San Joaquin Valley. In this region, the upper 500 m, which is the greatest depth typically drilled for groundwater pumping, consists of alternating layers of sand, gravel, and clay. In general, the aquifer system is divided into an upper aquifer, a thick clay confining unit known as the Corcoran clay, and a lower aquifer. The upper and lower aquifers contain sands and gravels, as well as numerous thin clay layers[12]. As a measure of overpumping, we use subsidence, derived from Interferometric Synthetic Aperture Radar (InSAR) data, to predict arsenic levels quantitatively.

We find that subsidence data have a strong correlation with concurrent arsenic concentrations. This demonstrates a quantitative link between overpumping of groundwater systems and arsenic contamination, a mechanism that has been proposed previously[7] but never statistically demonstrated.

Results and Discussion

Modeling arsenic concentration. We integrated estimates of subsidence with additional variables known from previous studies[13] to affect arsenic levels into a random forest model that accounts for nonlinear relationships, as well as interdependencies of different variables. Two models were developed, one that predicts recent (2007 to 2015) arsenic concentrations and a second that predicts historic (1986 to 1993) arsenic concentrations. These dates were chosen because they both span long droughts in the San Joaquin Valley, during which time appreciable groundwater decline and subsidence occurred (Supplementary Fig. 5). We did not include the mild drought conditions from 1999 to 2005, because we had limited subsidence data over that period, and because we considered more intense droughts to produce a stronger signal for our analysis. We used the output of the random forest models to assess the effect of overpumping as indicated by subsidence on arsenic levels. We found that in both models, concurrent subsidence markedly increases the risk of arsenic contamination. As both models establish similar relationships (capturing the time periods of recent and past periods of drought), we focus our discussion on the recent arsenic concentration model, pointing out where key differences exist. The full results of both models are shown in the Supplementary Information (Supplementary Figs. 1–4)

Mechanism for arsenic contamination from overpumping. The relationship between subsidence and arsenic concentration is linked to clay strata (Fig. 1). It has been noted that clay particles become enriched in arsenic due to their reactivity and high surface area to volume ratio relative to sand sized particles[4]. Arsenic has been transported to the San Joaquin Valley from the Sierra Nevada and coastal mountain ranges by rivers, which cut through arsenic bearing formations, for millions of years[14]. Clays at or near the surface at the time of deposition are the primary host of transported arsenic, which has been shown to adsorb on clay surfaces in significant amounts in the San Joaquin Valley[15], in a process similar to what occurs in other sedimentary basins, including those throughout Asia[4]. As the clays are buried over geologic time, their restricted oxygen supply results in reduction of the arsenic at depths > 60 m[14], resulting in dissolution of the arsenic within the clay pore water[7]. This mechanism for arsenic concentration in clays is supported by other studies in the area[13], who have found a positive relationship between aquifer clay content and arsenic concentration in the San Joaquin Valley.

When unperturbed, groundwater within the aquifer primarily flows horizontally through the sediments with highest permeability, typically sands and gravels. Thus, pumped groundwater comes mostly from sands and gravels, which have lower arsenic concentrations. When the aquifer system is stressed from overpumping, high vertical hydraulic gradients cause a larger volume of water to be drawn from less permeable clays, inducing the release of water with high arsenic concentrations. As a consequence, overpumping increases arsenic concentrations, as noted for the lower Mekong Delta, Vietnam[7]. Concomitant with decreased pore pressures is compaction of the aquifer and resulting land subsidence. Thus, the dual consequence of overpumping is land subsidence and increased extraction of pore water from clay layers, giving rise to a link between land subsidence and groundwater arsenic concentrations.

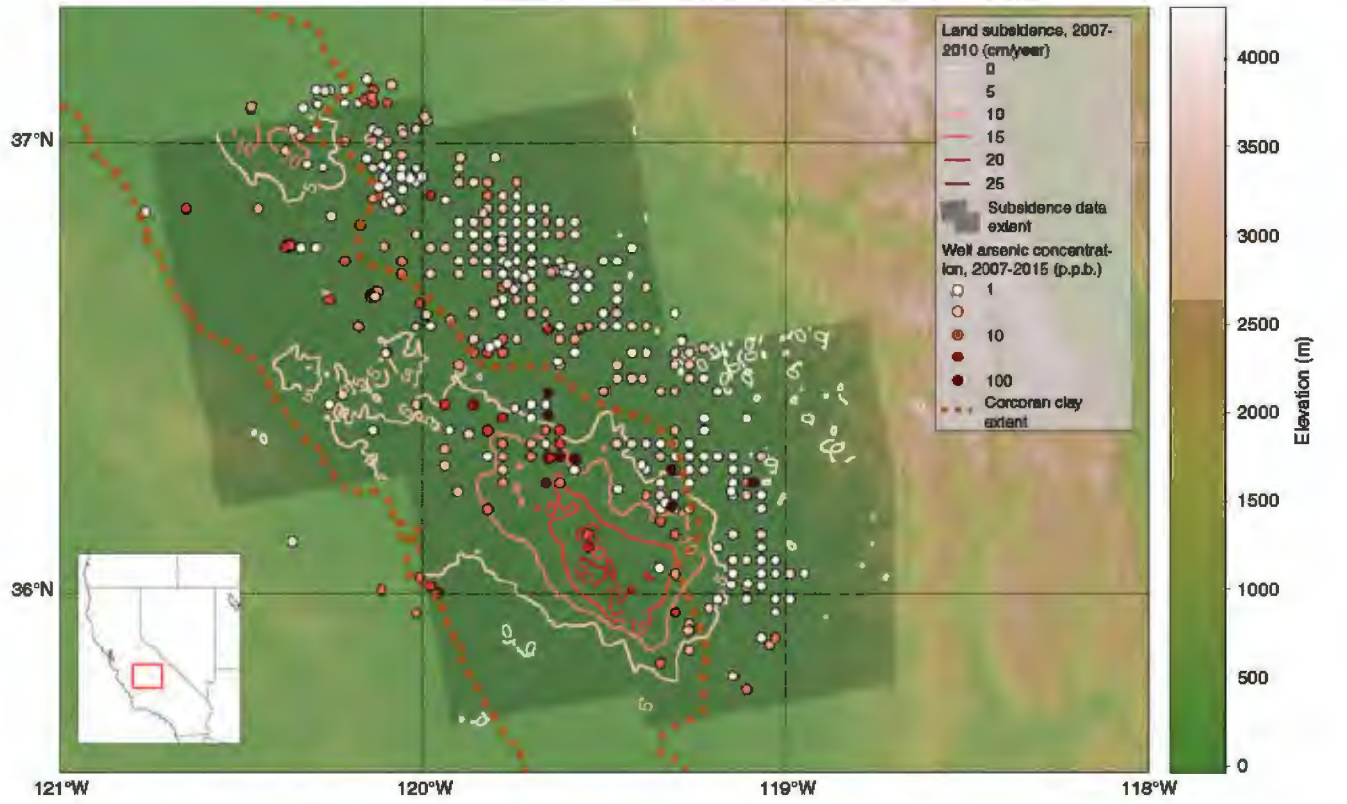

Fig. 1 Comparison of subsidence, arsenic concentration, and clay extent within the San Joaquin Valley, CA. Arsenic concentrations increase toward the center of the valley where subsidence is more extensive and a confining clay layer (known as the Corcoran clay) is present[12]. The grayed-out region is the area where recent subsidence data (obtained from InSAR) were processed. Arsenic concentrations vary by orders of magnitude and are thus shown with a logarithmic color bar (see Supplementary Fig. 8 for arsenic concentration histograms). The arsenic concentration data points were sourced from[17]. The basemap was created using elevation data from the Shuttle Radar Topography Mission[18]

Quantifying the impact of overpumping on groundwater arsenic concentrations. We highlighted four of the most important variables describing arsenic concentration within the Tulare Basin in the recent model, shown in Fig. 2a d. Of these, the thickness of the Corcoran Clay (a confining unit that overlies a lower aquifer) shows a positive correlation with arsenic con centrations due to increased clay content. Elevation has a negative correlation, as lower areas are more likely to have been water saturated and thus anaerobic. A positive correlation was found between $\log_{10}$(Mn) and arsenic concentrations, as the presence of manganese indicates an anoxic environment, in which arsenic tends to be more soluble. Significantly, recent subsidence from InSAR showed a positive correlation, as overpumping leads to increased pore water drainage from clays. The first three variables are well known from the literature and not related to human activity. The quantitative link between pumping induced sub sidence and arsenic concentrations has not been shown before, and is directly related to human activity.

By comparing the historic and recent arsenic concentration models, we see the transient nature of the relationship between pumping induced subsidence and arsenic concentrations (Fig. 2e). Although historic subsidence has a high impact on historic arsenic concentrations, it has virtually no impact on recent arsenic concentrations. A lack of correlation between present arsenic concentrations and historic subsidence (related to over pumping) suggests that arsenic levels due to overpumping slowly return to their original levels after the groundwater pumping is decreased, implying that arsenic is flushed from the auqifer. Thus, our findings indicated that avoiding overpumping of aquifers, easily seen in InSAR data, should improve water quality, at least for the San Joaquin Valley.

The historic arsenic concentration model shows a weaker, but still positive, correlation between Corcoran clay thickness and arsenic concentration, as well as manganese concentration and arsenic concentration. Due to the dynamic nature of groundwater chemistry, the relative importance of different mechanisms for arsenic contamination change over time, highlighting the need for regular calibration with up to date datasets.

To further quantify the impact of overpumping on arsenic concentrations, we simulated three different hypothetical scenar ios with our predictive random forest model: oxic, suboxic, and anoxic subsurface conditions. We used a variation of the partial dependence plot that averages all variables except subsidence, which is varied from 0 to 10 cm/year, and $\log_{10}$(Mn), which is set at 0, 1, and 2 for oxic, suboxic, and anoxic scenarios, respectively, to estimate the probability that the predicted arsenic levels exceeded the WHO's standard of 10 μg/L arsenic (Fig. 3). At ca. 8 cm/year subsidence, the probability that arsenic exceeds the WHO standard dramatically accelerates. This inflection point is also present at roughly the same location in the historic arsenic model (Fig. 2e). As inelastic deformation of clay beds begins, the rate of subsidence increases significantly[10]. As inelastic deforma tion occurs when pore pressure drops below the lowest level previously experienced, it releases pore water that has not been mixed with the main aquifer previously, which in the present case results in arsenic rich pore water being captured within the pumped groundwater.

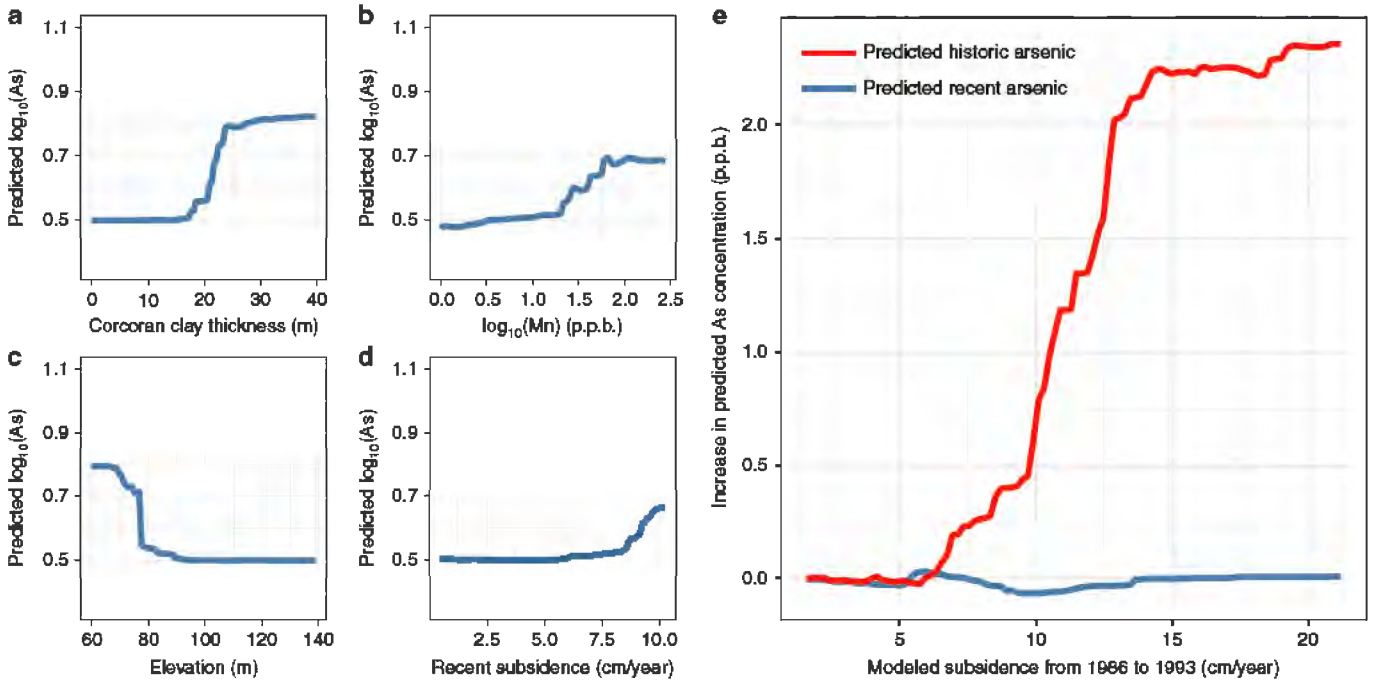

Fig. 2 Partial dependence plots of primary descriptors of groundwater arsenic concentrations. These include **a** confining clay thickness, **b** dissolved Mn concentrations, **c** elevation, and **d** recent subsidence. **e** Comparison of partial dependence plots of historic and recent subsidence. Note that historic subsidence has a great effect on historic arsenic levels but little effect on recent arsenic levels (**e**), whereas recent subsidence has a great effect on recent arsenic levels (**d**). All blue lines are derived from models predicting recent (2007–2015) arsenic concentrations, whereas the red line is derived from models predicting historic (1986–1993) arsenic concentrations

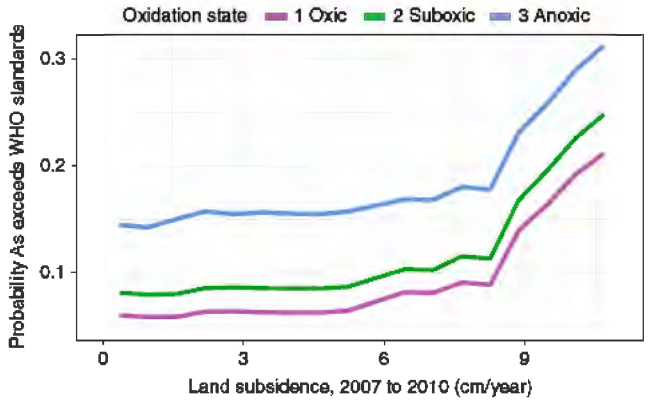

Fig. 3 Probability that arsenic levels exceeded the WHO standard. This was calculated based on recent subsidence for each arsenic risk category

Land subsidence due to overpumping increases the probability that groundwater is contaminated beyond the WHO drinking water standard by a factor of 2 to 3 for the San Joaquin Valley. Importantly, decreasing pumping below the threshold of inestastic aquifer compression will decrease arsenic concentra tions and the aquifers can recover to normal levels if over pumping is halted. Thus, subsidence maps produced by InSAR provide a means of measuring the increased risk of arsenic contamination due to overpumping of aquifers, a critically important factor as groundwater is the main source of drinking water for roughly one million people in our study area alone[16]. Moreover, with a global trend toward increase use of ground water, effectively managing water quality with quantity is essential to preserve the use of this critical resource.

Methods

Data acquisition and processing. There are many factors that control natural variation in arsenic concentration. We developed a statistical model using numerous datasets to asses the role each plays as a predictor of arsenic concentrations. We obtained arsenic level data, as well as proxy information on redox potential from manganese and sulfate concentrations, from 838 wells over the 2007 to 2015 time frame, and 424 wells over the 1986 to 1993 time frame, from the GAMA database[17], which monitors groundwater quality in California (http://geotracker.waterboards.ca.gov/gama/datadownload). We used a previously developed groundwater model[2] which provided us with several useful predictors of arsenic concentrations: percent of total water use from groundwater, which is directly related to pumping; total aquifer clay content, which sets an upper limit on available arsenic from clays; top and bottom of perforated well interval, both of which indicate the depth from which pumping occurred, a soft indicator of the oxidation state; subsidence from 1962 to 1976 and subsidence from 1986 to 1993, which provide historic measures of pumping-induced clay drainage. Elevation was also used as a predictor, obtained from the Shuttle Radar Topography Mission[18]; this is an indicator of closed-basin conditions, where contaminants such as arsenic tend to be concentrated. Slope was also derived from this dataset. As slope closely tracks predevelopment head[19], we used this with the clay content to estimate historic groundwater flow, which was also included as a predictor; our assumption being that enhanced groundwater flow would flush the system over time and reduce arsenic concentrations. We used average temperature data from PRISM; temperature variations have been related to changes in arsenic in previous work[13]. We also used evapotranspiration (ET) estimates (both from 2002 to 2007 and from 2007 to 2015)[20]; this can be used as a proxy of groundwater pumping that is independent of our InSAR measurements.

We chose not to include pesticide application as a predictor of groundwater arsenic contamination. Arsenic-bearing pesticides are largely restricted to lead arsenicals that were used predominantly on cotton and specific tree fruits (largely apples) but have been banned since the 1970's within the United States. Within the aerated surface soils, arsenic exists as arsenate[15], and would have limited mobility[4]. Thus, downward migration of surface applied arsenic is unlikely to contribute to groundwater contamination. Further, our analysis shows a correlation of groundwater arsenic with recent (last 10 years) subsidence and no correlation with older periods of subsidence. Our time series therefore further removes the possibility of arsenic pesticides impacting groundwater.

The arsenic levels, manganese levels and sulfate levels were obtained from GAMA. These levels were assumed to have a lowest detectable value of 2 p.p.b. from histogram analysis, so all values less than this were set to 2 p.p.b. As measurements of arsenic, sulfate, and manganese vary greatly with high outliers,

Table 1 Summary of scenes used for InSAR processing

Frame (region)	Path	No. of scenes	No. of interferograms
Tulare	218	15	82
Fresno	218	17	71
Mendota	219	19	82
Porterville	217	17	84

the logarithm of each was used in the statistical model to dampen the effect of outliers.

The historic groundwater flow was calculated using hydraulic conductivity (K) estimates across the Central Valley from the aforementioned groundwater model[2]. We assumed that the historic groundwater gradient ($\frac{\partial h}{\partial l}$) was equal to the land surface gradient[18]. We then used Darcy's equation to estimate flow:

$$q = K\left(\frac{\partial h}{\partial l}\right) \quad (1)$$

where q is the flux per unit area.

The distance to the nearest river was computed by determining the distance from each well to all major rivers in the study area, and taking the minimum distance as the distance to the nearest river.

InSAR processing. InSAR provides high-quality estimates of subsidence over large regions. InSAR measures subsidence over time with centimeter- to millimeter-scale accuracy over large regions with high (10 s to 100 s of meters) spatial resolution.

We acquired 68 SAR scenes from the ALOS PALSAR sensor, covering the time period from 2007 to 2010, over four frames (see Table 1) for InSAR processing from the Alaska Satellite Facility (https://www.asf.alaska.edu/). We then processed 319 interferograms using these scenes. We used 30 looks in azimuth and 10 looks in range to reduce noise in the pixels, resulting in a pixel size of roughly ~ 250 m by 250 m. We unwrapped the interferograms using the snaphu code[21]. Next, we used the small baseline subset method[22] to estimate the long-term deformation signal. This produced maps of the mean subsidence velocity for each of the four frames, which we merged to create one map of mean subsidence velocity. Overlapping areas were averaged. We then applied a moving average filter to further smooth the results, with a window size of 15 by 15 pixels. As the long-term signal dominated the total signal, seasonal fluctuations are muted over a multi-year time period. Thus, because of the temporal resolution of our arsenic measurements, we only considered the long-term signal. The resulting subsidence map is shown in Fig. 1 of the paper.

Random forest model. Groundwater overpumping, as indicated by subsidence, is one of many complex mechanisms that influence groundwater arsenic contamiantion. In order to account for additional mechanisms, as well as the interplay between various mechanisms, we employed the random forest model[23]. Random forest models can account for nonlinear relationships between multiple variables and handle outliers well . The random forest model creates ntree number of decision trees. Each decision tree makes an independent prediction of the variable of interest, in our case arsenic concentration. The best estimate is the average of the estimates from all decision trees.

Each decision tree is built using a subset of the total data. The subset is selected using random sampling without replacement, or bagging. At each split (node), the variables to be considered for that node are also randomly sampled from the list of total variables. The values of the split are chosen to maximize the variance reduction, defined as the difference between the variance before the split and the sum of the variance of the points for which the split is true, and the variance of the points for which the split is false[24].

The number of variables to be considered at each node is described by the variable *mtry*. The variables ntree and mtry are known as tuning parameters. The overall fit of the model is dependent on these tuning parameters.

In practice, increasing ntree both improves the accuracy of the results and increases the computational cost of the algorithm. Typically, increasing ntree does not significantly improve the results after roughly 100. To be conservative we chose a value of 500 for ntree. We determined the optimal value for mtry using a validation dataset. We randomly selected 75% of the dataset to calibrate the random forest model, and used the remaining 25% of the dataset as the validation to test the accuracy of the model. We chose the value for mtry that minimized the mean squared error (MSE) in the validation dataset.

We created two random forest models, one that predicted arsenic concentrations from 2007 to 2015 (recent) and one that predicted arsenic concentrations from 1986 to 1993 (historic). The response variable was $\log_{10}$(As). The variables used in calibrating both models were identical except that the recent subsidence from InSAR was not included in the historic arsenic concentrations model. In addition, the concentrations of arsenic, manganese and sulfate used to calibrate the models were taken from each respective time window (Supplementary Table 1). The resulting values for mtry were both 5, with an MSE of 0.05 and 0.10, for the recent and historic random forest models, respectively. We used these calibrated, tuned random forest models to predict arsenic concentrations and establish relationships between the variables used in the model and arsenic concentrations.

Random forests are one of many machine learning regression algorithms. In this study, we also developed models using neural networks, support vector machines, and boosted gradient trees. Our analysis showed that random forests provided the best fit to the observed data. However, similar relationships between subsidence and arsenic were observed with these additional machine learning methods.

Variable importance. With random forests, the impact of each variable in the outcome can be assessed in multiple ways. One way is to randomly shuffle (permute) each variable, and observe the increase in MSE between predicted and observed arsenic concentrations. The higher the MSE, the more important that variable is to the outcome. Another way to assess variable importance is to use partial dependence plots.

Partial dependence plots. Partial dependence plots are a common way to visualize random forest models[25]. The goal of a partial dependence plot is to show how varying one variable impacts the outcome of the prediction, while accounting for all possible values from the other variables. The partial dependence plot is calculated as shown below:

$$\tilde{f}(x) = \frac{1}{n}\sum_{i}^{n} f(x, x_{ic}) \quad (2)$$

where $\tilde{f}(x)$ is the partial dependence, n is the number of rows of the dataset, x is the predictor variable of interest, x_{ic} are the values of all other variables, and f is a function representing the random forest model The output can either be the best estimate of $\log_{10}$(As), or the probability that arsenic concentration exceeded 10 p.p.b. For the latter, we used all trees from the random forest model. Our random forest model produced 'best guess' estimates of arsenic levels, which are the mean of the estimates from all trees. It also produced an estimate for each of the 500 trees, for each observation. This provided us with a distribution which we used to determine the probability that the predicted arsenic levels exceeded the WHO standard.

Random forest models are limited in their predictions to observed data. For this reason, in the partial dependence plots of the main article (Figs. 2 and 3), we restricted the independent variable at the 5th and 95th percentile of each predictor variable. With those limits, 90% of the available data are displayed in the partial dependence plots. This reduces the likelihood of presenting results which are unconstrained by data. In the Supplementary Information section, we presented all of the data, but displayed dashed lines indicating the 5th and 95th percentiles (Supplementary Figs. 1-4).

Data availability. The geological, elevation, precipitation, temperature, ET, and water quality data have been cited throughout the paper, are listed in Supplementary Table 1, and are publicly available. The SAR data used for processing interferograms are available from the Alaska Satellite Facility following registration. The datasets developed by the authors, i.e., the processed deformation maps, estimated historic groundwater flow, and distance from each point to the nearest river, as well as the code used to produce the results, are available upon request from the corresponding author.

1. Introduction

Protecting groundwater quality is an essential component of sustainable water management. However, active groundwater management often focuses on maintaining groundwater quantity – a target that does not always ensure groundwater quality goals are met. In fact, there are many ways in which both supply- and demand-side management actions can inadvertently impact groundwater quality. These impacts range from improving groundwater quality to unintentionally creating new groundwater quality problems. For example, the implementation of a managed aquifer recharge (MAR) project aimed to increase groundwater supplies can mobilize soil contaminants (e.g., nitrate) into the underlying groundwater. Similarly, water trading programs can alter the timing, magnitude, and spatial distribution of pumping, potentially resulting in changes to irrigation return flows and contaminant loading. Potential water quality impacts of management actions are particularly important to consider in the context of the Sustainable Groundwater Management Act (SGMA) (see Box 1). However, if management actions are planned in a holistic way that incorporates both water quantity and quality considerations, unintended contamination can be avoided, and in some cases, groundwater quality can even be improved.

The purpose of this document is to provide guidance to groundwater managers, consultants, and stakeholders on groundwater quality considerations associated with management actions and methods for preventing unintended groundwater contamination. Specifically, this document focuses on naturally occurring (or geogenic) contaminants (e.g., iron, manganese, arsenic, chromium, uranium, vanadium, and selenium) and other contaminants for which limited guidance currently exists (e.g., 1,2,3-trichloropropane (TCP) and per- and polyfluoroalkyl substances (PFASs)). We focus on these specific contaminants due to their prevalence in California, their impacts to human and ecosystem health, and the lack of existing guidance for addressing these types of contaminants. This document does not address groundwater contamination by nitrate and salts; nitrate and salts are only discussed in the context of their interactions with geogenic and emerging contaminants. While nitrate and salts threaten groundwater quality in many regions throughout California, there are already a number of helpful resources and regulatory programs available that are specifically aimed at addressing these contaminants.[1,2,3,4]

Water Quality and the Sustainable Groundwater Management Act

The 2014 Sustainable Groundwater Management Act (SGMA) requires local agencies to achieve sustainable groundwater conditions within 20 years. SGMA defines sustainability as the avoidance of six "undesirable results" including: (1) declining groundwater levels, (2) reduction of groundwater storage, (3) seawater intrusion, (4) degraded water quality, (5) land subsidence, and (6) depletions of interconnected surface water.

Degraded water quality is unique from other undesirable results in that it can be caused or exacerbated by water management actions aimed to help achieve sustainability goals. For example, a managed aquifer recharge project can improve groundwater levels and groundwater storage, mitigate seawater intrusion and land subsidence, and provide benefits to interconnected surface waters (avoiding all other undesirable results). However, the same managed aquifer recharge project can also adversely impact groundwater quality by transporting or releasing contaminants into groundwater.

Briefly, geogenic contaminants are naturally abundant in Earth's soils and sediments and can be released to groundwater under certain geochemical and hydrological conditions. Emerging contaminants are contaminants that have not previously been identified as water quality concerns and pose a risk to human and ecosystem health. They are typically unregulated, but often expected to become regulated as research and awareness of their health impacts grows.

In this paper, we first present a set of key considerations for protecting water quality to set the context for why it is important to consider groundwater quality outcomes at the onset of initiating any new management action. We then describe geogenic and emerging contaminants and their importance to water management (Section 2), and then outline the main processes controlling groundwater quality as it relates to these contaminants (Section 3). Section 4 highlights management considerations and guidance for protecting groundwater quality during the planning and implementation of new management actions. Finally, Section 5 provides expanded summaries of key contaminants and the processes controlling their fate and transport.

Summary of key groundwater quality considerations

A summary of the key groundwater quality considerations discussed in Section 4 are briefly described here. If management actions are planned in a holistic way that incorporates both water quantity and quality considerations, unintended contamination can be avoided, and in some cases, groundwater quality can even be improved. Some key considerations include:

1. Careful site selection for both groundwater quantity and quality

Management actions can cause improvements or unintended impairments to water quality depending on the type of action and site conditions that existed prior to the action. For instance, if a management action is planned in an area with pristine drinking water wells and no current groundwater quality problems, a shift in geochemical and hydrological conditions can cause the release of geogenic contaminants and/or the introduction and/or migration of other contaminants. However, if a project is being considered in an aquifer with previous contamination, it is possible that the proposed management action can provide groundwater quality improvements. Careful consideration should be given to both the site suitability for the management action and its proximity to drinking water supplies.

2. Characterization of current and anticipated geochemical and hydrological conditions

Understanding the current geochemical and hydrological conditions of a site is critical for both (1) identifying any existing water quality issues and (2) defining the existing conditions in order to avoid perturbations. If possible, avoiding any significant shifts in geochemical and hydrological conditions can help minimize the likelihood of causing or exacerbating contamination.

3. Development of a monitoring program

Anticipating potential changes in geochemical and hydrological conditions can help to inform a water quality monitoring program. For example, certain contaminants are more likely to appear in groundwater when dissolved oxygen is introduced into an aquifer without previous exposure to oxygen. Based on the anticipated geochemical and hydrological shifts and site characterization, a list of the most likely contaminants can be determined. Monitoring programs should focus on these contaminants and on capturing critical geochemical and hydrological perturbations. Additionally, where possible, monitoring programs should be designed to allow sufficient response time between identification of water quality problems and arrival of contaminated water to users so that the problem can be addressed prior to reaching users.

4. Implementation of managed aquifer recharge projects

Managed aquifer recharge projects are the most likely management action to cause significant shifts in geochemical and/or hydrological conditions. Accordingly, such projects deserve special attention when evaluating potential water quality impacts. Recharging water, even clean water, into a previously uncontaminated aquifer can potentially alter the existing geochemistry and hydrology and subsequently cause the release of geogenic contaminants from soils and sediments. Specific considerations should be made for MAR projects including characterizing baseline aquifer geochemistry, the source recharge water chemistry and historical land use of the area selected for recharge. These considerations vary slightly depending on the type of MAR. A thorough understanding of the site-specific geochemical and hydrological conditions can inform the design of MAR projects that not only avoid new water quality problems, but also potentially offer water quality improvements.

5. Development of contingency plans

While precautions should be taken to avoid groundwater quality problems, a plan should be in place to address potential groundwater contamination events. This is particularly relevant if groundwater supplies are used for drinking water.

2. Geogenic and emerging contaminants

What are geogenic contaminants?

Geogenic contaminants are elements that naturally occur in Earth's soils and sediments. Some common geogenic contaminants include: iron, manganese, arsenic, chromium, uranium, vanadium, and selenium. These contaminants occur naturally in groundwater. Shifts in geochemical and hydrological conditions within an aquifer can cause new mobilization of these contaminants from primary minerals or release from soils and sediments into groundwater, where they pose a much larger risk to human and ecosystem health. Additionally, if groundwater is used for irrigation, these contaminants can threaten agricultural productivity.

Iron and manganese are only toxic at very high concentrations compared to the other geogenic contaminants discussed in this document; they are more commonly associated with taste and odor issues in water. However, iron and manganese are highly reactive in groundwater and can control the occurrence of other contaminants in an aquifer through their interactions with other contaminants. Arsenic, some forms of chromium, and uranium are toxic at very low (or trace) concentrations (on the order of micrograms per liter (µg/L)) and have both anthropogenic (man-made) and naturally occurring sources.

Naturally occurring contaminants have been increasingly associated with groundwater quality issues throughout California, particularly in the Central Valley. Vanadium is also increasingly being recognized as a groundwater contaminant, and health effects of vanadium exposure are actively being researched. While vanadium is currently not subject to enforceable regulation, it does have state drinking water Notification and Response Levels[5], and it is anticipated to be considered for more formal regulation in the future.

Selenium toxicity is a greater threat to fish and waterfowl than human health, and notable issues of geogenic selenium exposure in waterfowl have occurred in the San Joaquin Valley as a result of irrigated agriculture drainage to wetlands.

Since the source of these contaminants is natural soils and sediments, which exist in spatially extensive layers and formations, contamination can occur over large areas. This potentially large scale and diffuse source poses a significant and costly challenge for remediation once a contaminant has been released, emphasizing the importance of preventing their mobilization to groundwater.

Protection of groundwater quality requires managing aquifers so that geochemical and hydrological conditions are unlikely to cause contaminants to be released from soils and sediments into groundwater. These conditions are specific to each contaminant, can sometimes be contradictory (i.e., what is good for one is bad for another), and are further complicated by the complex interactions between contaminants and other water quality parameters.

Importantly, geogenic contaminants of concern occur in most groundwater at very low concentrations due to the ubiquity of many of these natural elements in the earth's crust – the materials and sediments derived from those rocks through which groundwater flows. Some of these elements are essential nutrients (e.g., some forms of chromium, selenium, iron, and manganese) and are important to human health. However, at contaminant-specific, higher concentration thresholds these geogenic elements become contaminants in drinking water or other beneficial uses of water and begin to pose a risk to human and ecosystem health.

What are emerging contaminants?

Emerging contaminants are contaminants that have not previously been identified or have only recently been identified as a water quality concern. Emerging contaminants often do not have established regulatory standards. Emerging contaminants may pose a risk to human and ecosystem health, though these risks may not be well understood.

Notably, vanadium is an emerging contaminant as it has no current regulation. Since it is also a geogenic contaminant, we include it in the discussion of other geogenic contaminants that behave similarly in the environment. We also discuss considerations related to 1,2,3-trichloropropane (TCP) and per- and polyfluoroalkyl substances (PFASs) which are both anthropogenic contaminants. PFASs have anthropogenic (man-made) sources and are currently unregulated. Similarly, TCP remained unregulated until 2017. We consider TCP an emerging contaminant despite its recent regulation because there remains a need for research and guidance to address TCP contamination in groundwater.

Anthropogenic contaminants can be *point source contaminants*, meaning they have specific, identifiable sources, or *nonpoint contaminants*, which originate from diffuse sources (e.g., runoff from large agricultural areas containing elevated concentrations of pesticides). TCP has both agricultural and industrial sources and can fall under either category. TCP is highly persistent in groundwater and is toxic at extremely low concentrations (on the order of nanograms per liter (ng/L)). It is important to prevent inadvertently placing new wells in areas with TCP contamination. Additionally, a disturbance to a groundwater aquifer can transport TCP into previously uncontaminated wells within the aquifer.

3. Factors controlling groundwater quality

Groundwater quality is controlled by the geology of an area, historic land use, and the resulting geochemical and hydrological conditions within the aquifer. While the geology and historic land use cannot be changed, management can significantly impact geochemical and hydrological conditions. Knowing the historic land use of a given region can help determine possible anthropogenic sources of contaminants. For example, the use of certain soil fumigants introduced TCP into groundwater at specific sites (see Section 5.8). Here, we provide an overview of relevant geological information related to the occurrence of geogenic contaminants. We also describe key geochemical and hydrological processes as they relate to overall groundwater quality.

3.1 Geology

The geology of an area determines which types of earth materials (minerals and organic material that make up soils and sediments) are present in an aquifer. Different sediment types have distinct chemical properties and concentrations of geogenic contaminants. While groundwater quality will ultimately be determined by how these particles respond to the geochemical and hydrological conditions in the aquifer, an understanding of the underlying and regional geology will provide some insight into which geogenic contaminants may be more problematic than others in a given region. During rock weathering, geogenic contaminants are deposited within the soils and sediments that compose groundwater aquifers.

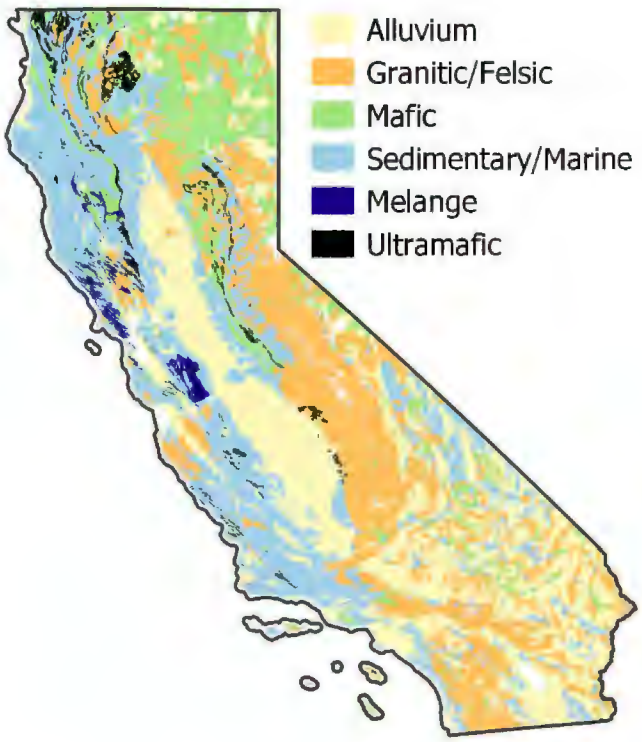

Figure 1: Map of relevant geologic features associated with various geogenic contaminants in California. Shales are included in the Sedimentary/ Marine category. Map is adapted from the California Department of Conservation and California Geological Survey's geologic map of California (Jennings et al., 2010).

Figure 1 highlights key geologic features within California that are relevant to the geogenic contaminants discussed within this document. Following aluminum, iron and manganese are the second and third most abundant metal elements in Earth's crust, respectively. Therefore, they are found in high concentrations in soils and sediments and are ubiquitous within most geologic features especially in *mafic rocks*. Arsenic and uranium are found in higher abundance in granitic materials like those comprising the Sierra Nevada. The Sierra Nevada has weathered over time, leading to the deposition of sediments containing these elements within the Central Valley. Chromium is elevated in mafic and *ultramafic rocks*. Vanadium is also enriched in mafic rocks although generally not in ultramafic rocks. Both vanadium and selenium are also associated with the marine *shales* of the California Coast Range, with selenium particularly concentrated in the Southern Coast Range and in areas affected by hydrothermal fluids (naturally heated water found in the environment).

Continued rock and mineral weathering followed by alluvial (water) transport and deposition leads to the formation of soils and sediments that compose groundwater aquifers. While not all the aquifers in California are alluvial aquifers, they are the most relevant to the water management actions described here and we use them to introduce and describe concepts related to groundwater quality.

Most groundwater aquifers, including those comprised of alluvial sediments, are heterogeneous, meaning they have multiple discontinuous layers of different types of earth materials and sediments (Figure 2). These layers vary in both their chemical and physical properties. In general, shallow portions of an aquifer have higher amounts of dissolved oxygen (DO) in groundwater as they are closer to the surface and have likely been recharged more recently, while deeper portions of an aquifer typically have older groundwater with limited DO concentrations.

The presence of oxygen and other substances affects the types of minerals and associated elements present in the aquifer. Portions of an aquifer with abundant dissolved oxygen (DO) tend to be rich in minerals like iron oxides (or rust particles/surfaces). Iron oxides are a critical mineral affecting the overall chemistry of groundwater and are discussed in Section 5.1. Deeper portions of an aquifer that typically have less abundant oxygen do not support the formation of iron oxides. Both the geochemical and physical heterogeneity of aquifers means that contaminant fate and transport can vary greatly throughout various zones of an aquifer, both vertically and laterally.

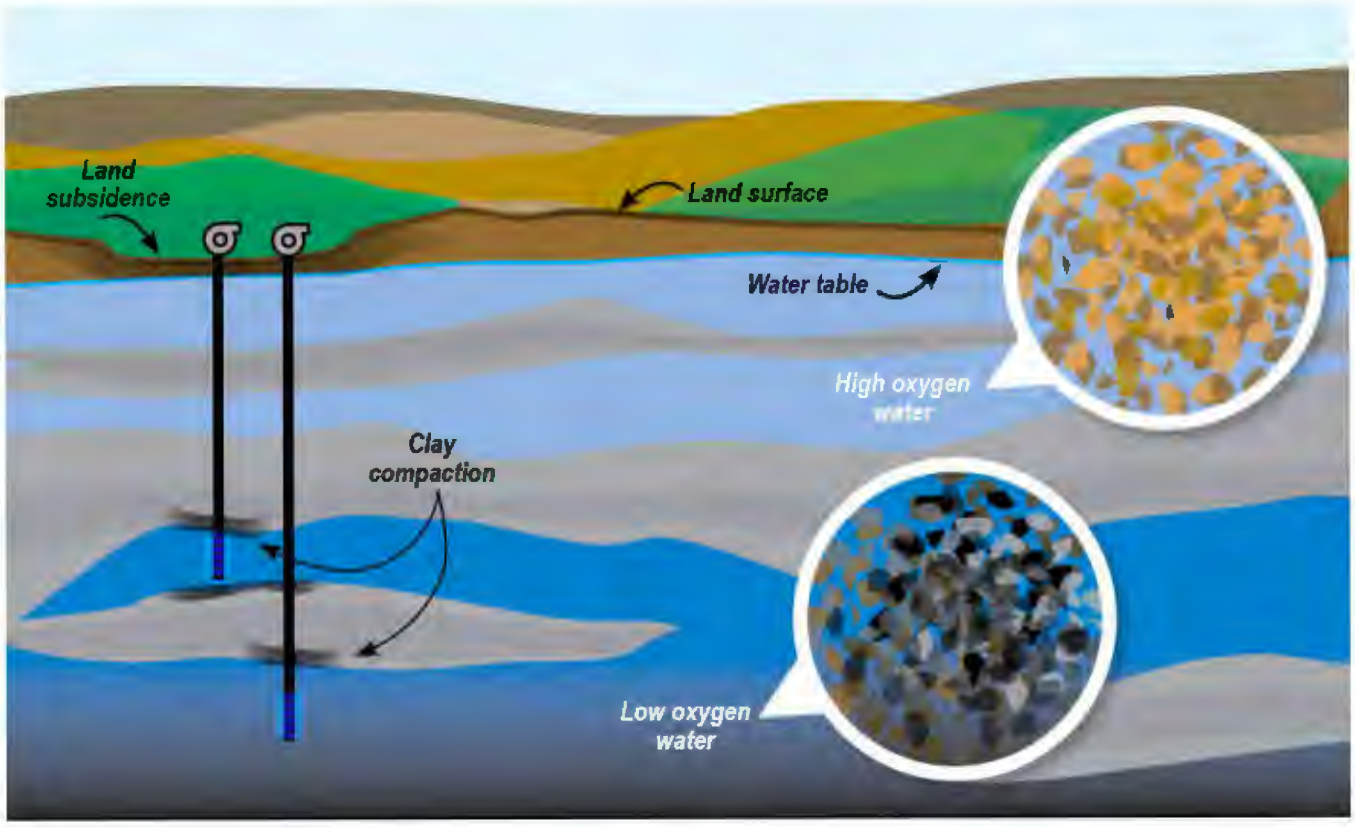

Figure 2: Generalized cross-section showing the physical and chemical heterogeneity of an alluvial groundwater aquifer system with interbedded clay layers. Shallower regions with higher oxygen abundance in groundwater tend to be enriched in minerals including orange-colored iron oxides while deeper regions with low oxygen content in groundwater tend to be enriched in darker-colored sulfide-bearing minerals. Additionally, activities like heavy pumping can compact clay layers affecting the physical (hydraulic) and chemical properties of the aquifer system.

3.2 Geochemistry

The fate and transport of contaminants depends on the geochemical reactions occurring within the aquifer system. The reactions of primary concern are those that occur at the interface between sediment materials and the surrounding groundwater. In general, contaminants are either incorporated into minerals, adsorbed to mineral surfaces, or dissolved in groundwater where they are transported by groundwater flow (Figure 3).

A contaminant that is dissolved in groundwater is considered mobile and is readily transported with the flow of groundwater. When contaminants are adsorbed to aquifer materials, they are no longer dissolved in groundwater. They can be transported when small particles (called colloids) move with the water; however, these particles are relatively easy to filter or settle out of water. In general, adsorption processes make groundwater contaminants relatively immobile unless a geochemical or hydrological trigger causes them to desorb from their host surface. Under some conditions, groundwater contaminants precipitate (form solids) and are removed from groundwater where they become immobile and remain on the aquifer solids.

Different contaminants have different levels of partitioning between the water and mineral surfaces (i.e., varying tendencies to adsorb to solids versus dissolve in groundwater) and are controlled by various chemical reactions. To avoid degrading water quality, management actions should promote geochemical conditions that favor maintaining contaminants on aquifer solids rather than geochemical conditions that release them into groundwater, or those that ensure that any such mobilization is spatially limited such that it does not materially affect extracted groundwater quality. This is a technically challenging task as multiple contaminants co-occur within aquifer solids and have varying, sometimes opposite, geochemical conditions leading to release.

Examples of the types of geochemical conditions that can control contaminant retention and release include **red**uction-**ox**idation (*redox*), *pH* (a measure of acidity), and *solubility* (ability to dissolve in water). Redox and pH refer to the state of the groundwater while solubility refers to properties of different substances found in both an aquifers' materials and groundwater. Below is a brief overview of redox, pH, and solubility as they relate to contaminant release. While the ionic strength and hardness of water can also influence its reactivity, these tend to be less concerning than shifts in redox and pH.

3.2.1 Redox reactions

Redox reactions are reactions that involve the transfer of electrons (particles with negative charge) from one substance to another. The *oxidation state* of a substance is a measure of how many electrons it has gained or lost relative to its elemental state (its pure, uncharged, and unreacted state). *Reduction* is a gain of electrons resulting in a decrease in oxidation state. Conversely, *oxidation* is a loss of electrons resulting in an increase in oxidation state. Substances gain or lose electrons by reacting with other substances. Dissolved oxygen (DO) is involved in many redox reactions and is a strong *oxidant* (it causes the oxidation of another substance, meaning it strips them of electrons).

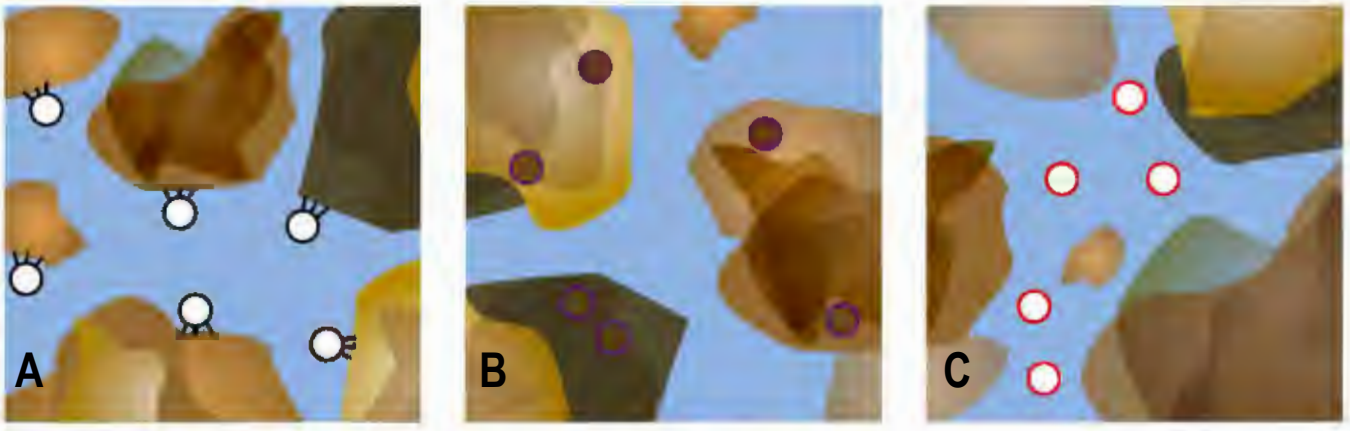

Figure 3: Contaminants in groundwater aquifers can either be (A) adsorbed to aquifer particles, (B) incorporated into aquifer particles, or (C) released to the surrounding groundwater.

Most geogenic contaminants are redox active, meaning that they are commonly found in more than one oxidation state, and each of these states may have different mobility and toxicity. For example, chromium in the environment can be found in both a trivalent (+3) oxidation state and in a hexavalent (+6) oxidation state. Trivalent chromium, Cr(III), is considered a micronutrient in human nutrition and is relatively immobile due to its low solubility and propensity to adsorb on aquifer minerals.

Generally, when oxygen is abundant, substances are more likely to be present in their more oxidized form.

By contrast, hexavalent chromium, Cr(VI), binds poorly to aqu1ifer solids and is thus mobile in groundwater. It is also toxic to humans (at concentrations greater than 0.02 µg/L according to the Public Health Goal (PHG), see Section 5). Changes in redox conditions in an aquifer can cause trivalent chromium, Cr(III), to turn into the toxic, mobile hexavalent chromium, Cr(VI), and vice versa. Therefore, it is critical to understand the redox conditions in an aquifer and how management actions can cause redox conditions to shift. Even a small change in redox condition can have a large impact on contaminant behavior in groundwater.

There are methods for determining the redox conditions within an aquifer. Groundwater monitoring wells can be measured for oxidation reduction potential (ORP), which is a commonly used metric for redox condition. Interpreting ORP as a standalone measurement can be challenging because the measurement depends on a reference measurement that can vary depending on the ORP method used. However, ORP is useful as a relative indicator of changes in redox condition. Sharp changes in ORP can signal that redox conditions within an aquifer are changing, and therefore shifts in groundwater quality could also be occurring.

Dissolved oxygen (DO) is also often used as a proxy for redox conditions within an aquifer. Generally, when oxygen is abundant, substances are more likely to be present in their more oxidized form. When oxygen is absent or very low, contaminants are more likely to be present in their more reduced form. For simplicity, we will use the terms *oxygen-abundant* (DO > 2 mg/L) and *oxygen-limited* (DO < 2 mg/L) to describe the redox conditions of an aquifer.

For example, the impacts of DO on redox condition can be visually observed with iron. In groundwater with no exposure to oxygen, iron is well-dissolved and mobile in groundwater. With exposure to DO, iron oxidizes and forms rusty solid particles (or iron oxide minerals) that separate out of water and/or coat other mineral surfaces (Figure 4). These rust particles range in color from yellow to red, with orange predominating, and can be seen in soils and sediment which have been exposed to oxygen.

Knowing the DO concentration of water is a strong indicator of whether iron will be dissolved in water or present as an iron oxide solid. More generally, knowledge of oxygen concentrations can serve as a useful proxy for redox condition and understanding of which geogenic contaminants may exist in groundwater. Measurement of DO is typically easier and more cost-effective than analyzing trace metal concentrations. Therefore, it can be measured more frequently than other *analytes* (the substances being measured) in a monitoring program. Based on which redox-sensitive analytes are measured, the redox processes occurring can be more thoroughly characterized using existing United States Geological Survey (USGS) resources for characterizing redox chemistry.[6]

Figure 4: Oxygen-limited (anoxic) groundwater rich in dissolved iron seeping into a stream, oxidizing due to exposure to the atmosphere where oxygen is abundant. This causes oxidization of the dissolved iron to occur, converting it into solid iron oxides (rust particles). (Photo credit J. Walton http://windowoutdoors.com/WindowOutdoors/Iron%20in%20Springs%20and%20Seeps.html)

3.2.3 pH

pH is one of the most important groundwater quality parameters and often strongly correlates with the presence of different contaminants. Low pH values are acidic and higher pH values are basic. Typical groundwater pH values fluctuate near neutral (pH of 7). Groundwater pH depends on the composition of the groundwater (i.e., which substances are present) and the chemical reactions occurring within the aquifer. For example, aquifers with high carbonate concentrations tend to have a higher pH and a high buffering capacity (meaning pH does not easily change). pH affects the substances dissolved in groundwater because certain chemical reactions are more likely to occur at higher or lower pH values.

Similarly, a solid mineral surface can be positively or negatively charged depending on the pH, and this in turn affects the ability of contaminants to adsorb to those surfaces and be removed from the groundwater (Figure 5). pH can also make certain minerals in sediment particles or within the rock structure more or less likely to dissolve in groundwater. In general, negatively charged ions (such as arsenic) are more mobile at high pH (> 8.5), while positively charged ions (such as iron and manganese) are mobilized at low pH.

3.2.4 Solubility and groundwater age

Solubility in the context of groundwater geochemistry refers to the maximum concentration at which a substance can be found dissolved within groundwater. Solubility can refer to solids (e.g., minerals), liquids (e.g., solvents, pesticides), and gases (e.g., oxygen, carbon dioxide) and their ability to dissolve in water. Some of these substances are more likely to dissolve (i.e., more soluble) compared to others. For example, table salt (sodium chloride) is highly soluble and dissolves when mixed with water, releasing both sodium and chloride ions into the surrounding water.

The materials that adsorb or contain contaminants have varying degrees of solubility. In the presence of water, highly soluble materials will not retain their solid form in water and will dissolve, releasing contaminants embedded within the sediment particle/rock matrix to groundwater. Insoluble contaminants will stay in the sediment particle/rock matrix and will not contaminate groundwater unless conditions promoting their dissolution evolve. For example, under certain geochemical conditions arsenic will reside in a sulfidic (sulfide-containing) mineral called arsenian pyrite. This mineral has limited solubility but can dissolve under certain low pH and/or oxygen-abundant conditions, causing arsenic to be released into groundwater.

The rate (how quickly) a substance dissolves also determines how likely it is to be found in groundwater. Near natural recharge sources, such as streams, groundwater may contain relatively small amounts of total dissolved solids (TDS) which is a measure of the amount of dissolved *species*. This is because the water is not in equilibrium with the soils and sediments (i.e.,

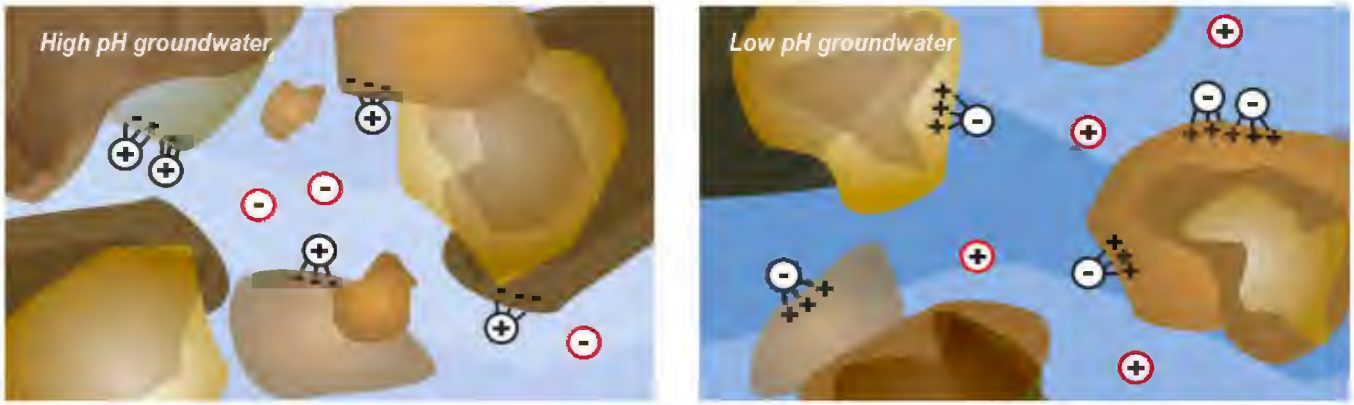

Figure 5: Schematic showing pH effects on charged particles. Mineral surface charge changes with the pH of the surrounding groundwater, causing changes in the type of contaminant likely to occur in groundwater.

the minerals in soils and sediments have not had time to dissolve because freshwater is recharging faster than the minerals are dissolving). The mineral surfaces of the sediment particles gradually dissolve over time.

These rates are an important concept relating groundwater chemistry to groundwater age. Older groundwater is typically more enriched in TDS (including naturally occurring contaminants) compared to younger groundwater. However, younger groundwater will often respond quicker to management actions owing to shorter recharge times. More information relating groundwater age to groundwater vulnerability is available through the USGS.[7]

3.3 Hydrological impacts on geochemistry

The hydrology and geochemistry of a groundwater system are closely intertwined. As water flows in the subsurface, it carries contaminants as well as other dissolved (or aqueous) substances which can react with each other. Additionally, many of the chemical reactions occurring in groundwater occur at different timescales; some are very fast while others are extremely slow. Generally, groundwater moves slowly, allowing enough time for reactions to occur between aquifer solids and groundwater. However, in heavily pumped or managed systems, groundwater movement can be accelerated and the aqueous substances in the groundwater may have less time to react with aquifer solids.

A significant rise or fall in the depth of the water table in response to pumping or recharge will also change the interaction between groundwater and the overlying unsaturated (vadose) zone, potentially affecting contaminant partitioning between the solid and mobile, dissolved phase. Depending on which chemical reactions are possible in a given aquifer, this can either have a positive, negative, or minimal impact on groundwater quality. In summary, the physical movement of groundwater can induce different types of geochemical responses.

4. Protecting groundwater quality

4.1 Managing for both groundwater quantity and quality

To the extent possible, management actions should be planned in a holistic way that incorporates both water quantity and quality considerations. Special caution should be taken if a new management action is planned in an area containing drinking water wells with no current groundwater quality problems. In these locations, there is a risk of causing groundwater contamination by changing the geochemical and hydrological conditions within the aquifer that may lead to the release of geogenic contaminants.

By the same token, if a project is being considered in an aquifer with existing contamination, it is important that the problem not be worsened by management actions. It is possible to design a proposed management action in ways that may provide groundwater quality improvements. For example, if a proposed managed aquifer recharge project does not create adverse shifts in water quality (i.e., no shifts in redox or pH which release contaminants), it has the potential to reduce existing contaminant concentrations.

Understanding the geochemical and hydrological conditions in these cases will be critical to anticipating whether contaminated water can potentially be diluted or will spread contamination to previously uncontaminated areas of the aquifer. Table 1 lists common water management actions and how they might impact groundwater quality. As mentioned previously, these projects can also offer water quality improvements. However, here we focus on the protection of groundwater supplies and prevention of unintentional, new contamination resulting from management actions. Additionally, while we provide general guidance, much of the considerations will depend on site-specific characteristics and local contaminants of concern.

TABLE 1

Common water management actions and potential impacts

Management action	Common examples	Potential water quality impacts
Managed aquifer recharge (MAR)	**Infiltration ponds**	If the infiltrating water is of a different chemistry than the native groundwater, geochemical changes can occur during infiltration (e.g., change in pH, redox chemistry). Infiltration processes gradually introduce recharge water which can allow enough time for the aquifer sediments to buffer changes in water chemistry. Infiltration can alter the shallow groundwater levels and/or cause a fluctuating water table. Resulting changes in the water table and the wetting and dewatering of shallow sediments can induce changes in redox chemistry.
	Injection wells	Potential impacts are similar to those of infiltration ponds (i.e., differences in recharge water chemistry and native groundwater chemistry can cause adverse interactions). However, during direct injection, these changes are likely to be more abrupt compared to infiltration processes as injection wells can also alter the flow regime and can cause faster transport between different zones of the aquifer.
	Agricultural managed aquifer recharge (Ag-MAR)	Ag-MAR involves the use of irrigation water for recharge on agricultural lands during fall, winter, and/or spring. Because the water has continuously been introduced to the aquifer through previous irrigation, it is unlikely to create new, abrupt changes to geochemical conditions. Since volumes of recharge water are similar to past recharge volumes, hydrological conditions would not be expected to deviate strongly from historic conditions. These areas can still mobilize contaminants, but new and significant water quality problems are less likely to occur compared to other types of recharge.
	Flood-managed aquifer recharge (Flood-MAR)	Flood-MAR involves the use of flood water from rainfall or snow melt for recharge on agricultural and working lands (e.g., refuges, floodplains). Here, the recharge water may be of differing chemistry than the native groundwater or previously applied irrigation water which may cause geochemical changes releasing geogenic or other existing contaminants. Additionally, hydrological changes may also occur and contribute to the transport of contaminants and/or changes in the underlying water table. The Department of Water Resources is working to identify research needs, including water quality, for Flood-MAR projects (see Section 4.4).
Changing timing, magnitude, and/or spatial distribution of pumping	**Water trading**	Trading programs can change the volume and use of groundwater supplies in ways that may affect return flows, magnitude and timing of pumping, and contaminant loading. Some examples include (1) increasing pumping in an area with deteriorated water quality and subsequently causing the migration of contaminants or (2) increased water use by a user with higher contaminant loading, resulting in higher contaminant concentration in return flows.
	New pumping	New pumping can increase vertical and lateral movement of water, resulting in transport of contaminants or reactants that may induce contaminant mobilization. Pumping in new regions of an aquifer can also cause fluctuating water tables which can alter geochemical conditions.
	Retiring wells	While inactive wells are no longer causing movement of groundwater via pumping, they can still serve as conduits for groundwater. Shallow groundwater, often of poorer quality, can migrate downward and degrade deeper water supplies (Gailey, 2017).

When planning and selecting locations for a new management action, careful consideration should be given to the proximity of the management action to production wells and the ultimate end use of water produced from those wells. As a first principle, it is best to exercise caution to avoid actions that are likely to cause significant geochemical and/or hydrological changes in the vicinity of clean drinking water supplies.

If a management action in the vicinity of clean drinking water supplies is required, appropriate stakeholder engagement is necessary to ensure that the whole suite of community and stakeholder considerations is acknowledged in shaping the proposed project. To aid in this process, Community Water Center (CWC) has developed guidance focused on protecting drinking water under SGMA.[8,9] Projects in these areas can take the three steps outlined below to help protect groundwater quality.

Step 1. Characterize existing groundwater quality issues where new management actions are planned.

Any existing groundwater quality issues should be identified when first planning management actions in order to avoid exacerbating or spreading existing contamination. Precautions should also be taken to avoid causing new contamination. Any available groundwater quality data should be analyzed to understand which contaminants are currently present and what trends exist for those contaminants, both spatially and temporally (i.e., Do concentrations vary seasonally? Is it a constant problem? Are concentrations increasing over time or is it getting worse?).

A summary of publicly available datasets is included in a report by Stanford University's Program on Water in the West, titled "A Guide to Water Quality Requirements under the Sustainable Groundwater Management Act" (Moran and Belin, 2019). All water quality data collected by water agencies is also publicly available via formal public records request if it is not otherwise accessible via a state or local database.

Additionally, if groundwater age data is available, it can help estimate how quickly groundwater quality will respond to new management actions. Younger groundwater tends to be more responsive to new management actions than older groundwater supplies.

Step 2. Anticipate how aquifer geochemistry and hydrology might change as a result of the planned management action.

Anticipating changes to aquifer geochemistry and hydrology requires a knowledge and understanding of the existing geochemical and hydrological conditions. Of key concern are indicators of redox condition (both DO and ORP), pH, and water composition (concentrations of substances including salts, carbonates, sulfates, phosphate). A change in redox condition is the most likely to trigger the release of geogenic contaminants, followed by a change in pH and then ionic composition (the type and concentration of different ions in the water). If the management action involves introducing a new water source into the aquifer (e.g., MAR with surface water in a region where previous recharge has been primarily from irrigation reliant on groundwater), characterizing the chemistry of this new water source will help determine if any adverse shifts may occur.

The principal means by which a shift in redox can occur is either the influx of water with differing oxygen levels or influx of an organic carbon compound that stimulates biological (e.g., bacterial) activity and the subsequent consumption of oxygen. For example, if a MAR project introduces high concentrations of organic carbon (e.g., recycled wastewater) into an oxygen-abundant aquifer, oxygen may be consumed and reducing conditions may evolve within the now oxygen-limited aquifer. Similarly, if a recharge project introduces water with high DO concentrations into a previously oxygen-limited aquifer, a shift in redox will occur.

pH-related release of certain contaminants can occur when infiltrating or injecting recharge water with a differing pH than the native groundwater. A shift in pumping regime can also cause the mixing of groundwaters with various chemistry if water from various regions within the aquifer is being transported to new locations. Therefore, it is important to obtain information on baseline geochemical conditions (including pH, DO, ORP) and, if available, any previously collected soil and/or sediment analyses or samples (e.g., soil cores and drill cuttings). These samples can be used for laboratory analysis to determine their composition and likelihood of contaminant release.

Step 3. Potential management strategies can be identified to minimize adverse changes in geochemical conditions.

Limiting changes in geochemical and hydrological baseline conditions will help limit potential adverse impacts. For instance, if recharging water, is it possible for the recharge water to have a more similar geochemical composition to the native groundwater? This could be achieved by pretreating recharge water or using an alternate source of water for recharge. If matching source water chemistry is not possible, see Table 2 to determine which contaminants to prioritize in a robust monitoring program.

Soil and aquifer sediment samples (e.g., soil cores and drill cuttings) also provide valuable information about the aquifer solids and the chemical state of contaminants residing within those solids, but are more expensive than water sampling. If there is potential for significant geochemical shifts, sediment samples should be obtained to measure the abundance of various natural contaminants in the region where the management action is taking place and what chemical form these contaminants are in.

In some areas, it may be possible to retrieve old samples from previous well drilling or core activity as a more cost-effective way of obtaining samples. While older samples may not retain the same chemical properties as those found *in situ*, they can provide valuable information about the total contaminant concentrations. It is possible that soils or sediments can contain high concentrations of certain contaminants either naturally or as a result of historic anthropogenic inputs that accumulate. Soil and sediment heterogeneity pose a complex challenge to sampling as concentrations can vary greatly within small spatial areas. Priority sampling locations should be in the region closest to the proposed management actions where the most significant shifts in geochemical and/or hydrological conditions are likely to occur. For a MAR project that includes use of recycled water, the construction of required monitoring wells presents an opportunity to collect aquifer solids samples.

For the installation of new water supply wells and associated well screening, it should be taken into account that wells can affect the transport and mixing of water from different zones within an aquifer (Gailey, 2018). For example, if contamination exists in a shallow portion of the aquifer, high rates of deep pumping can draw shallow groundwater down over time. Additionally, production wells with large screened intervals can serve as a preferential pathway connecting and transporting groundwater from different depths and potentially of varying quality. Generally, clay layers are likely to have more elevated concentrations of geogenic contaminants. While wells are typically not screened in clay layers because of their poor hydraulic conductivity, caution should be taken to avoid these layers for groundwater quality considerations as well.

4.2 Managing for co-occurring contaminants

It is likely that there will be multiple contaminants to consider and monitor, including geogenic and emerging contaminants as well as nitrates and salts. As an oxidant, nitrates create problems for geogenic contaminants that are released under oxidizing conditions, which include uranium and selenium. The co-occurrence of contaminants can be exacerbated in projects that mobilize nitrate into systems with limited prior exposure to oxygen or other oxidants.

The migration of dissolved salts into groundwater supplies can also have adverse impacts for other contaminants. One concerning example of this is the migration of high calcium and carbonate waters into groundwater prone to uranium release. Calcium and carbonate can react with uranium to form a complex that prevents uranium from adsorbing to solids and releases it into groundwater (see Section 5.5).

Table 2 describes the geochemical conditions that can cause the release of each contaminant. Rather than considering each contaminant as an individual management concern, contaminants can be conceptually grouped by the geochemical conditions that cause their release. Then, management actions can be taken to avoid specific geochemical conditions and the group of contaminants associated with those conditions. In general, trying to maintain native aquifer geochemical conditions will minimize the likelihood of releasing new contaminants.

TCP and PFASs are not included in Table 2 as they are not geochemically released like geogenic contaminants. Sections 5.8 and 5.9 provide specific information related to the management of TCP and PFAS contaminated aquifers, respectively.

TABLE 2

Groundwater conditions that can result in an increase or decrease in the mobility of each contaminant

	Contaminant Mobility Due to Aquifer Conditions				
Contaminant	Oxygen-abundant	Oxygen-limited	High pH	Low pH	Aquifer conditions to avoid
Iron (Fe)	↓	↑	↓	↑	Oxygen-limited, low pH
Manganese (Mn)	↓	↑	↓	↑	Oxygen-limited, low pH
Arsenic (As)	↓	↑	↑	↓	Oxygen-limited, high pH, high phosphate, compaction of clay layers from overpumping
Chromium (Cr)	↑	↓	↑	↓	Oxygen-abundant, high pH, fluctuating water table
Uranium (U)	↑	↓	↑	↓	Oxygen-abundant, high pH, high bicarbonate, high nitrate
Vanadium (V)	↑	↓	↑	↓	Oxygen-abundant, high pH
Selenium (Se)	↑	↓	↑	↓	Oxygen-abundant, high pH

4.3 Developing a monitoring program

A monitoring program will be critical for new management projects where an initial assessment determined that existing geochemical and hydrological conditions may be perturbed. A survey of existing wells appropriate for monitoring and resources available for drilling additional monitoring wells will help determine how best to deploy new monitoring efforts.

Detailed design of a water quality monitoring program is beyond the scope of this report, but the following are some suggestions to inform early thinking and conceptualization of a rigorous monitoring program. Design of an appropriate water quality monitoring program should be conducted by a qualified professional in an adaptive process with thorough stakeholder engagement. More detailed resources and guidance on monitoring networks and programs are available through the California Department of Water Resources (DWR).[10, 11]

Monitoring wells should provide adequate spatial and temporal coverage to identify groundwater quality problems in a timely manner. Spatial requirements will depend on the scale of the project and regulatory requirements. Understanding the flow and transport conditions in the aquifer will be critical for determining the spatial extent of monitoring. Accordingly, groundwater flow (level) monitoring should be used to help design appropriate groundwater quality monitoring programs, since groundwater gradients determine the direction and speed of groundwater flow.

Coupled with and informed by the groundwater level monitoring, groundwater flow models with particle tracking and/or mass transport capabilities or planned empirical tracer tests can help determine how fast and in which directions groundwater is movingfurther informing the appropriate design of water quality monitoring programs. This is important because there are often delayed effects; problems can arise as water moves downgradient. Monitoring wells should be placed in locations between the new project and production wells/users in such a way that provides sufficient response time should a migrating groundwater problem be observed. If groundwater quality issues are first observed in drinking water wells or in monitoring wells placed too close to the supply well to provide an adequate response time, it will be too late to address the issue before contaminated water reaches users.

Additionally, monitoring wells should span the impacted depths of the aquifer. Multi-screened wells and/or nested wells provide depth resolved data and should be used where appropriate.

Temporal coverage should allow enough frequency of monitoring to capture seasonal and short-term trends in groundwater quality. Seasonal variation in geochemical and hydrological conditions occurs naturally, and similarly, management projects often have seasonal variation (e.g., recharging in specific seasons). Looking at historical seasonal trends of groundwater quality data can provide some insights into the timescales of seasonal trends in a given location. It should be noted that seasonal timescales may vary year to year and with future variations in dry and wet conditions.

Lastly, measuring contaminants at trace concentrations is often expensive and requires laboratory instrumentation. If it is not feasible to directly measure trace contaminants on a regular basis, then close attention should be paid to the measurement of other common water quality parameters that control contaminant concentrations. Most critically, monitoring programs should include regular measurement of pH, dissolved oxygen, and ORP as proxies for the geochemical conditions in the aquifer. These parameters can be measured *in situ* at relatively low cost. Should shifts in pH, DO, and/or ORP be observed in monitoring data, there is a higher likelihood that contaminant mobilization is occurring, and samples should be taken immediately to assess whether contaminants are present. Table 2 summarizes which contaminants are most likely to occur under various geochemical conditions.

4.4 Careful implementation of managed aquifer recharge

Managed aquifer recharge is an increasingly applied method of artificially recharging groundwater aquifers. Of the possible management actions discussed in this document, MAR projects are the most likely to alter the native or preexisting geochemical and hydrological conditions within an aquifer. Accordingly, in addition to the above general guidelines, we highlight some specific recommendations for MAR. There are various types of MAR projects and each can have differing impacts on the geochemistry and hydrology of a site as summarized in Table 1.

First, the extent to which MAR will cause new changes to geochemical and hydrological conditions depends on historic recharge and land use in the area. For example, in the case of Ag-MAR, the volume and chemistry of the recharge water is the same (or very similar) to historic irrigation. Therefore, geochemical and hydrological conditions are not likely to deviate substantially from preexisting conditions, which may be less concerning for the release of geogenic contaminants as compared to other types of recharge. For Ag-MAR, knowing the historical nutrient and pesticide application is important for determining the likelihood of anthropogenic contaminants like TCP and nutrient release to groundwater. By contrast, MAR via injection wells can cause a direct, abrupt change in water chemistry. For example, if an injection well is drilled in a deep, confined aquifer with limited prior exposure to oxygen and oxic water is used for recharge, a sudden shift in redox chemistry can occur and cause the release of geogenic contaminants.

In general, sandy soils are less likely to contain, and subsequently release, geogenic contaminants. Agricultural areas will have additional water quality considerations related to legacy pesticides, nitrate, and salts. Recharge projects can be designed to help dilute pesticides, nitrate, and salt. However, in addition to mobilizing these substances, introducing nitrate and salts into the underlying groundwater can impact geogenic contaminants in the area. For example, nitrate can transform uranium into a more mobile form (see Section 5.5).

Calcium and carbonate can be introduced into underlying groundwater supplies and can also react with uranium to increase its mobility in groundwater. In general, prioritizing areas with sandy soils that have high infiltration rates and low calcium and carbonate contents is beneficial to avoiding issues related to uranium release. Additionally, continued use of the same infiltration site will deplete calcium and carbonate concentrations, decreasing the threat of contaminant mobilization over time compared to developing new recharge sites.

Water quality impacts of MAR remain a subject of ongoing research. Information and expertise specific to managed aquifer recharge on agricultural lands using flood water from rainfall or snowmelt (Flood-MAR) is currently being developed by DWR.[12] Current research at the University of California Santa Cruz includes the use of permeable reactive barriers made of woodchips for changing redox chemistry to remove nitrates during MAR via infiltration at a site in Pajaro Valley, CA (Beganskas et al., 2018).

4.5 Developing a contingency plan for groundwater contamination

After all necessary precautions have been taken to avoid creating new contamination or exacerbating existing issues, a plan should be developed if a groundwater contamination event occurs. This is particularly important if groundwater supplies are used for drinking water. The plan should account for how to (1) increase or augment monitoring, (2) assess the potential for end user well contamination, (3) notify users of water supplies, and if necessary, (4) provide alternate, safe water supplies, (5) discontinue use of affected water supplies as needed, (6) address the contamination by remediation or permanently discontinuing use, and (7) develop targeted future monitoring once the problem has been addressed to ensure it does not occur again. Having a plan for how to address these points will lead to improved response times and protection of water users.

5. Contaminant summary overview

Each contaminant behaves uniquely in the environment and is affected differently by various management actions. In this section, we provide a brief summary of each contaminant and its mobility in the environment. We include the public health considerations and regulatory limits. Some contaminants are regulated using a primary maximum contaminant level (MCL) while others have a secondary MCL. In California, the State's primary and secondary MCLs are enforceable. MCLs are determined based on the technical and economic feasibility of water treatment for each contaminant in addition to their toxicity to human health.

Notification Levels exist for certain contaminants that do not have MCLs and represent the concentration at which certain public notification requirements and recommendations apply depending on the contaminant. Notification Levels may turn into MCLs as toxicological and public health knowledge of a contaminant increases.

Finally, California's Office of Environmental Health Hazard Assessment (OEHHA) has public health goals (PHGs) for certain contaminants that are non-enforceable goals based only on toxicity and health hazards. These are summarized for each contaminant in Table 3. Detailed information on regulatory requirements surrounding groundwater quality is provided in a report recently published by Stanford University's Program on Water in the West titled "A Guide to Water Quality Requirements under the Sustainable Groundwater Management Act" (Moran and Belin, 2019).

TABLE 3

Regulatory limits and public health goals for California

Contaminant	Level of regulation	Limit	Public Health Goal (OEHHA)
Arsenic	Primary MCL	10 µg/L	0.004 µg/L
Chromium	Primary MCL	50 µg/L (total)	0.02 µg/L (hexavalent)
Uranium	Primary MCL	20 pCi/L	0.43 pCi/L
Vanadium	Notification level	50 µg/L	-
Manganese	Secondary MCL	50 µg/L	-
Iron	Secondary MCL	300 µg/L	-
Selenium	Primary MCL	50 µg/L	30 µg/L
1,2,3 TCP	Primary MCL	0.005 µg/L	0.0007 µg/L
PFASs	Notification level	0.013 µg/L for PFOA	-
		0.014 µg/L for PFOS	-

Each contaminant summary in this section shows maps of groundwater concentrations over the last year (January 2018 – January 2019) of available data from the Groundwater Ambient Monitoring and Assessment (GAMA) Program (SWRCB, 2018a). Groundwater concentrations are listed as mass of contaminant in micrograms per liter of water. These data are obtained from multiple sources including the GAMA Domestic Well Project, the USGS, Lawrence Livermore National Lab (LLNL), and public water system well data collected by the State Water Resources Control Board's (SWRCB's) Division of Drinking Water (DDW). For PFASs which are more data-limited, we include all available measurement for public supply wells on the GAMA website, which spans a measurement period from August 2016 – May 2019.

It should be noted that these data are collected at various times of year and different aquifer depths. Variation in temporal trends and depth often occurs and cannot be inferred from these maps. Additionally, these data include contamination from both anthropogenic and natural sources. We present these data to provide an overview of the magnitude of concentrations generally observed in California as well as the spatial extent of each contaminant's impact on groundwater quality.

Similarly, we show soil concentrations for each map from the USGS mineralogical database (Smith et al., 2014). Soil concentrations are listed as mass of contaminant in milligrams per kilogram of bulk soil, with the exception of iron which is listed at percent iron by weight of the bulk soil owing to iron's high abundance in soils. The soil concentrations are shown for the C horizon, which is approximately 2.6-3.3 feet deep within the soils examined, and consists primarily of unconsolidated, weathered parent material (i.e., rock or deposited sediments).

Soil C horizons are much shallower than groundwater aquifers and wells. These soil concentration maps do not provide depth information about geogenic contaminants. Ultimately, contaminant concentrations within the aquifer waters will depend on several factors including the chemical conditions of the aquifer and historic anthropogenic inputs. We show the soil C horizon maps to offer a general summary of the abundance of these contaminants as well as their relationship with underlying geologic formations.

5.1 Contaminant Summaries

Within this section, we begin with summaries of iron and manganese. Iron has limited toxicity and is of concern only at very high concentrations. Furthermore, iron and manganese solids are highly reactive in groundwater systems and are presented first because they (1) have major impacts on the overall chemistry of an aquifer, often regulating the concentration of contaminants through adsorption processes, and (2) are excellent indicators of the redox condition of an aquifer. Next, we provide summaries for arsenic, chromium, uranium, vanadium, and selenium. Finally, we discuss TCP as an emerging contaminant of critical concern.

5.2 Iron

5.2.1 Background

Iron is an essential nutrient for human health at low concentrations and has a secondary MCL of 300 µg/L. Compared to other contaminants discussed in this document, it is much less toxic and is generally associated with taste and odor issues in drinking water. Iron is highly reactive and is involved in many important chemical reactions that affect the concentrations of other toxic contaminants including arsenic, chromium, and uranium. It is important to understand iron geochemistry, as it plays a critical role in controlling overall groundwater quality.

5.2.2 Iron in the environment

In most natural systems, iron exists as either "ferrous iron" or "ferric iron." In oxygen-limited environments, ferrous iron exists and is dissolved in groundwater. By contrast, under oxygen-abundant conditions, ferric iron exists and readily forms iron oxide solids of limited solubility. There are various types of iron oxides, which collectively are commonly known as "rust." Iron oxides have colors ranging from yellow to red, with orange solids predominating, and they are a critical component of aquifer solids that control the overall groundwater quality by interacting with numerous contaminants as discussed below. From an operational standpoint, iron oxide solids can also cause clogging and biofouling issues in wells. Biofouling occurs when bacteria that consume iron are active near the well and create a slimy film of

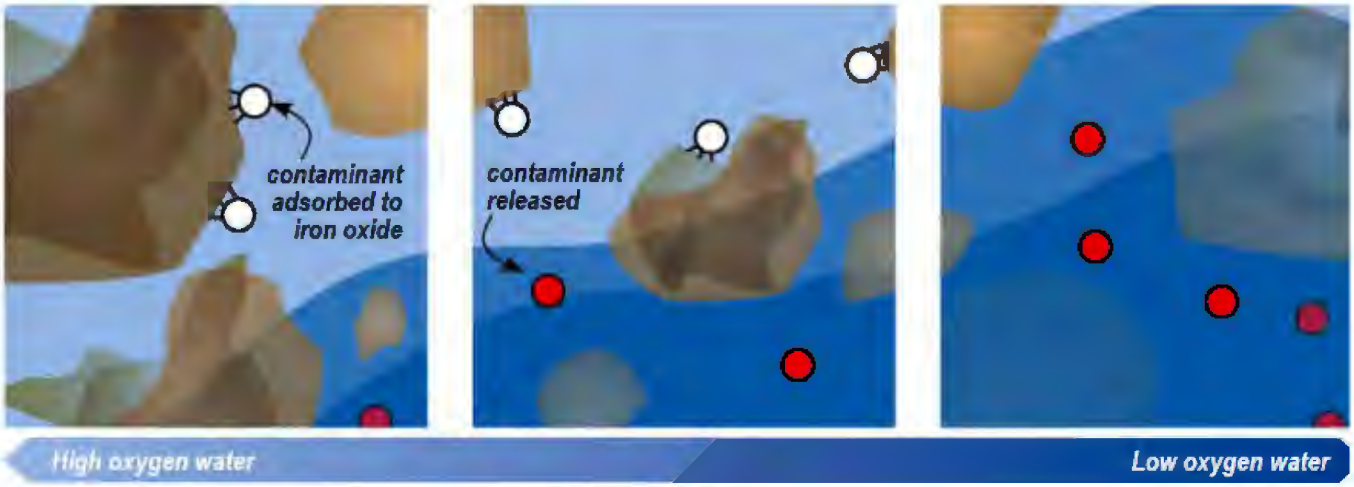

Figure 6: Iron oxides dissolving as DO concentrations become limited and subsequent release of contaminants adsorbed to the iron oxides.

bacterial residue. Both clogging and biofouling reduce water flow in a well and can cause staining.

5.2.3 Iron oxides as contaminant sinks

Dissolved contaminants including arsenic, chromium, and uranium have a strong ability to adsorb or "stick to" iron oxide solids. This adsorption process removes contaminants from groundwater and immobilizes them on iron oxide solids. Subsequently, the concentration of groundwater contaminants often depends on the stability of these iron oxide solids. For example, if oxygen becomes limited within an aquifer, the redox conditions will shift and iron oxides will no longer be stable. Once the iron oxides dissolve, they will release any adsorbed contaminants, causing an increase in iron and previously adsorbed contaminant concentrations into groundwater (Figure 6). Each contaminant has a varying ability to adsorb on iron oxides and some contaminants adsorb more strongly than others. Additionally, the extent of contaminant adsorption on iron oxides is usually pH dependent -- and may also change with the composition of the surrounding water.

5.2.4 Iron in California

Iron is widely distributed across rock types and associated soils and sediments. It is the second most

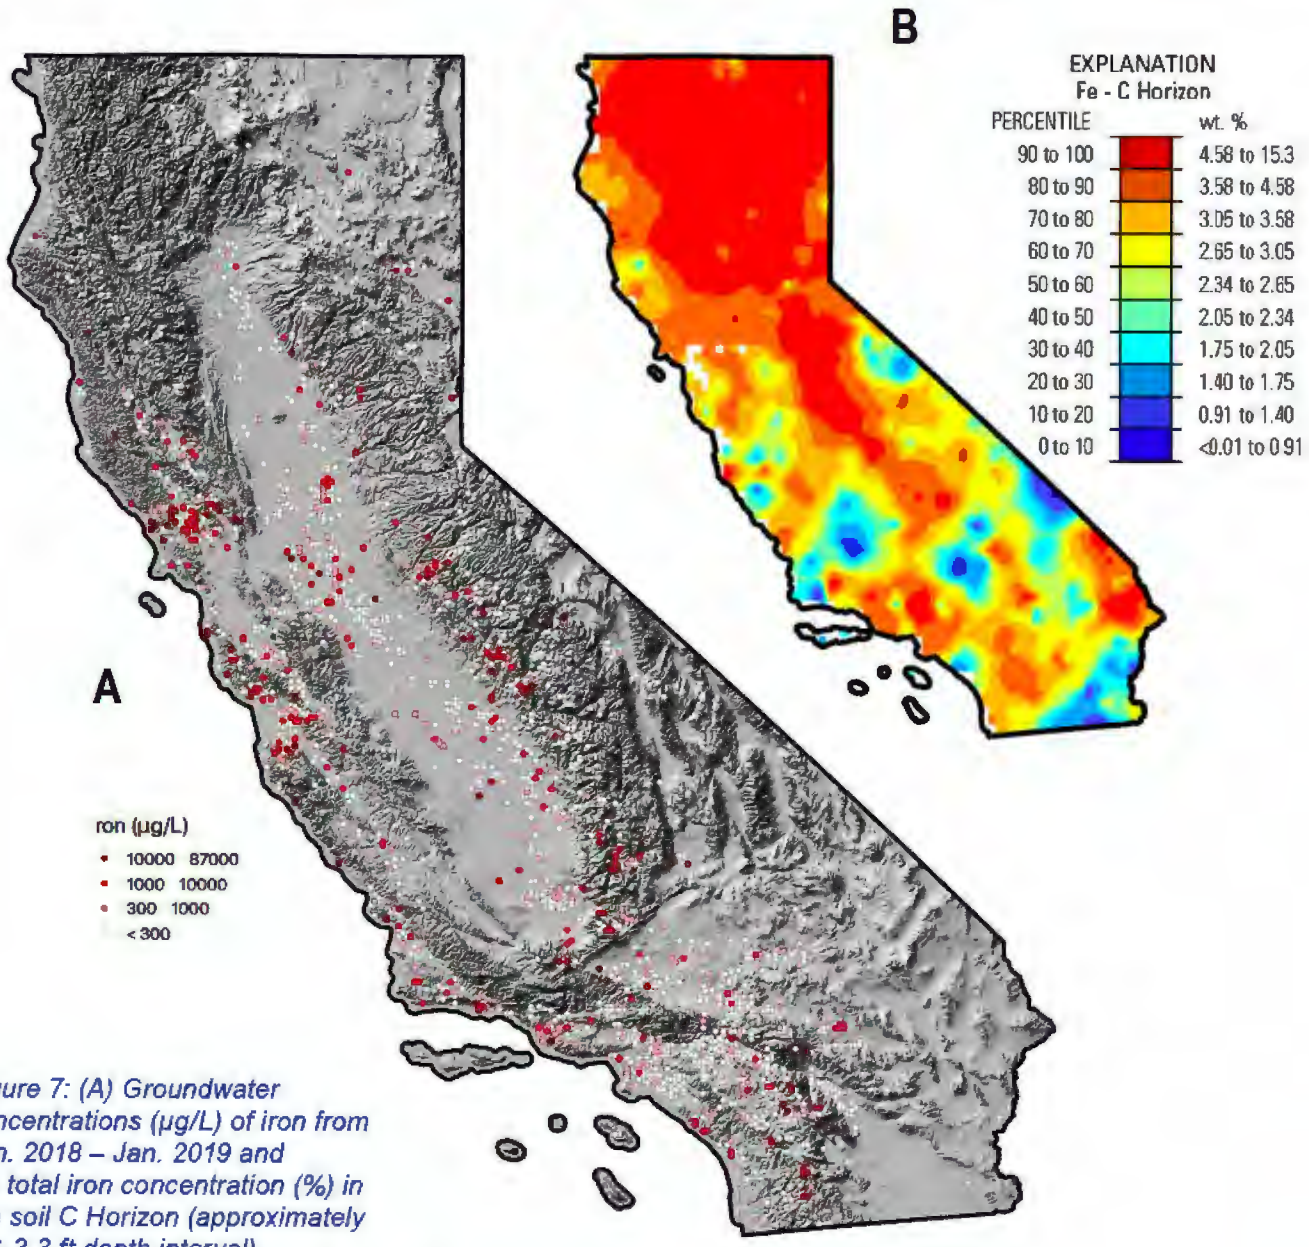

Figure 7: (A) Groundwater concentrations (µg/L) of iron from Jan. 2018 – Jan. 2019 and (B) total iron concentration (%) in the soil C Horizon (approximately 2.6-3.3 ft depth interval). The secondary MCL for iron is 300 µg/L.

abundant metal element in the Earth's crust and can be found at much higher concentrations than other geogenic metals throughout soils (Figure 7). Subsequently, iron in groundwater can occur at any location with geochemical conditions conducive to iron release. Generally, oxygen-limited groundwaters have higher iron concentrations in groundwater.

5.2.5 Management considerations for iron

If an aquifer has abundant oxygen, iron will generally reside as an iron oxide solid, and thus dissolved concentrations of iron are low. The largest threat to the stability of iron oxides is a shift in the oxygen content of an aquifer; if oxygen becomes limiting, iron oxides will dissolve. Should iron oxides dissolve, iron concentrations will increase in the groundwater, which can cause operational problems including clogging and biofouling in production wells. Conversely, if water with high concentrations of DO is introduced into an aquifer with perennially low DO, significant quantities of iron oxides could be produced through the oxidation of existing iron. This could decrease the concentration of other contaminants in the water by providing mineral surfaces with iron oxides to adsorb them.

5.3 Manganese

5.3.1 Background

Manganese is geochemically similar to iron in many ways. At low concentrations, manganese is an essential nutrient for human health. However, at high concentrations manganese causes neurological disorders, particularly in children, who are more susceptible to manganese exposure. Manganese has a secondary MCL of 50 µg/L, and a notification level of 500 µg/L. Like iron, manganese causes operational problems in wells, including clogging and staining. In drinking water, it is often associated with odor and a metallic taste. Manganese also forms oxide minerals which can adsorb and subsequently immobilize groundwater contaminants on aquifer solids, much like iron oxides.

5.3.2 Manganese in the environment

Manganese is the third most abundant metal element in Earth's crust. Under oxygen-limited conditions, manganese can dissolve in groundwater. At pH values greater than 7, manganese increasingly adsorbs to mineral surfaces within aquifer solids and groundwater concentrations will decrease. It forms solid manganese carbonates above pH 7.5, further removing it from groundwater. Under oxygen-abundant conditions, manganese forms manganese oxide solids which limit its groundwater concentrations.

5.3.3 Manganese interactions with other contaminants

Similar to iron oxides, manganese oxides play a critical role in determining the overall groundwater quality of an aquifer. Several toxic contaminants including arsenic, uranium, and selenium adsorb strongly to manganese oxides, limiting their concentrations in groundwater. However, in most oxygen-abundant groundwater systems, iron oxides will be more prevalent than manganese oxides owing to the higher abundance of iron. Therefore, iron oxides generally exert a greater control than manganese oxides on contaminant retention. Additionally, manganese oxides can have a large impact on groundwater quality through their ability to oxidize contaminants. After DO, manganese oxides are among the most reactive oxidants found in the environment and are capable of reacting with other contaminants. Manganese oxides have the most notable effect on chromium; they have the ability to transform chromium from its benign form (trivalent chromium) into a highly toxic and mobile form (hexavalent chromium), as discussed in Section 5.4.

5.3.4 Manganese in California

Similar to iron, manganese is widely distributed and abundant in rocks and associated soils and sediments (Figure 8). Manganese concentrations can be observed in groundwater in any aquifer under oxygen-limiting conditions. Historically, approximately 30 percent of drinking water supplies which monitor for manganese have observed manganese above the detection limit (SWRCB, 2019).

5.3.5 Management considerations for manganese

To promote the stability of manganese oxides and avoid manganese concentrations in groundwater, oxygen-limited conditions should be avoided. In oxygenated groundwater, manganese (like iron) will usually persist as manganese oxides. Similar to management considerations for iron, a depletion of oxygen will dissolve manganese oxides, increasing dissolved manganese concentrations and releasing adsorbed contaminants.

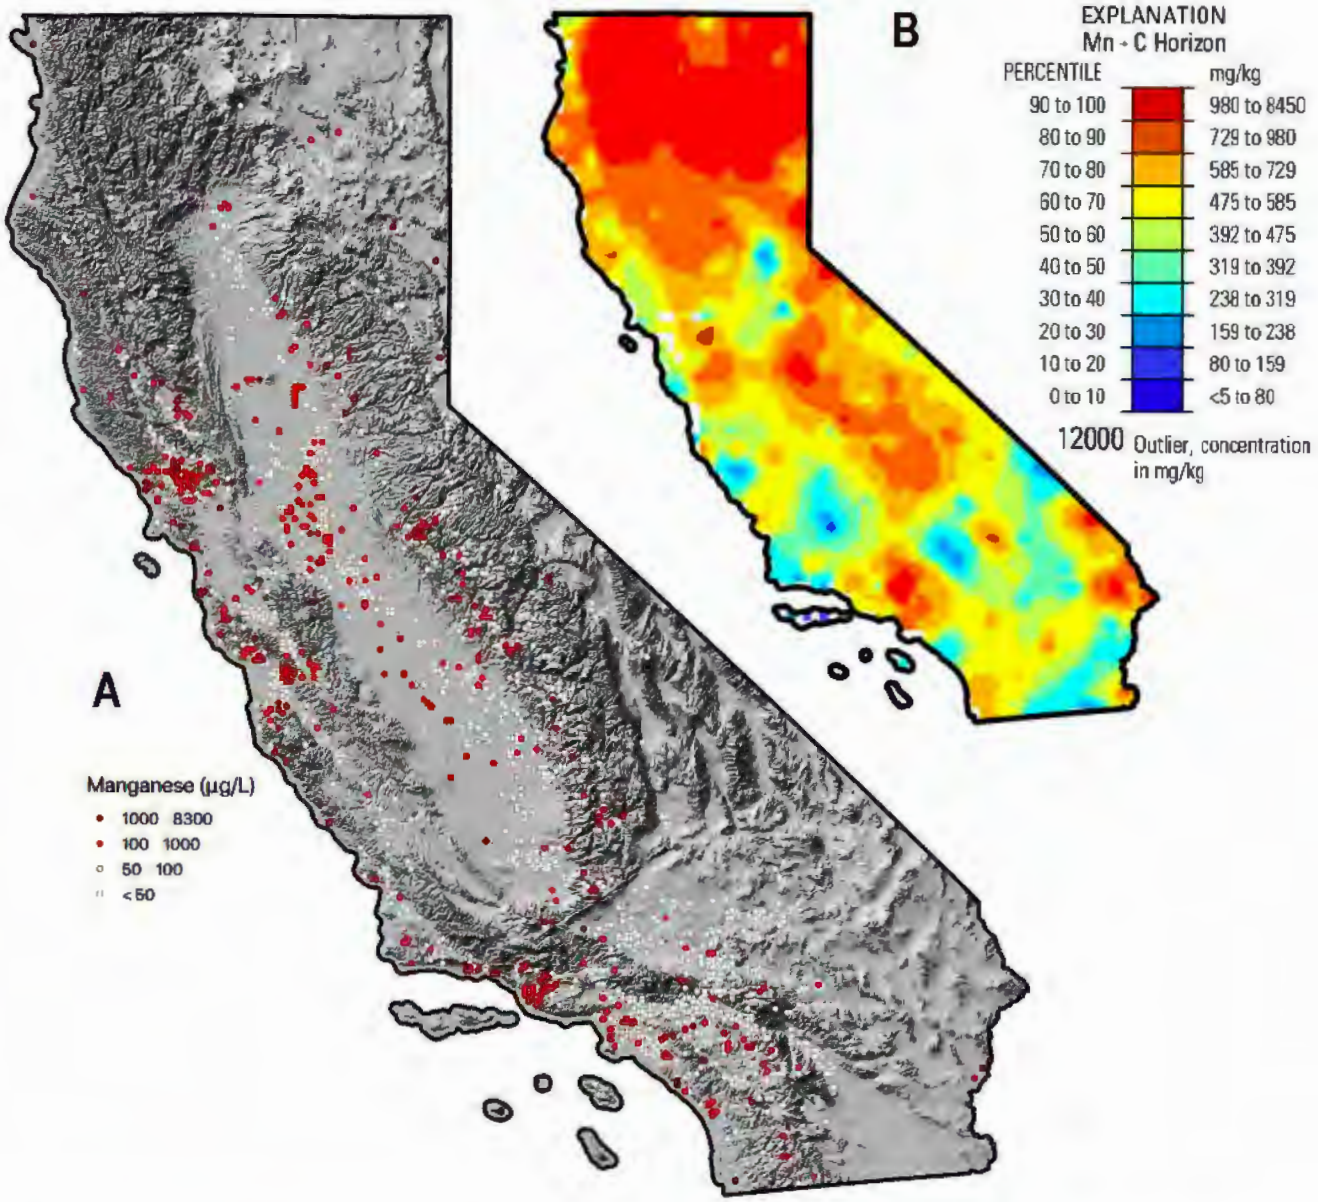

Figure 8: (A) Groundwater concentrations (µg/L) of manganese from Jan. 2018 – Jan. 2019 and (B) total manganese concentration (mg/kg) in the soil C Horizon (approximately 2.6-3.3 ft depth interval). The secondary MCL for manganese is 50 µg/L.

5.4 Arsenic

5.4.1 Background

Arsenic is one of the most toxic and ubiquitous geogenic contaminants. While arsenic can be incorporated into food supplies (e.g., rice crops) through contaminated soil and irrigation water, it poses the greatest threat to public health in drinking water supplies. Chronic exposure to arsenic-contaminated drinking water is known to cause cancers of the lungs, skin, bladder, and kidneys. The primary MCL for arsenic in drinking water is 10 µg/L and the PHG is set at 0.004 µg/L. While anthropogenic sources of arsenic, including mining and pesticide application, have historically led to point source contamination of groundwater, both natural and anthropogenic mobilization of arsenic has led to wide-scale contamination of groundwater aquifers.

5.4.2 Arsenic in the environment

Under most environmental conditions, arsenic can be found in one of two forms. Under oxygen-limited conditions, arsenic exists as arsenite in the +3 oxidation state (AsIII). Arsenite is generally considered more soluble in groundwater and more toxic than the oxidized form, arsenate, which occurs in the +5 oxidation state (AsV). This is because arsenate binds strongly to minerals found in soils and sediments under oxygen-abundant conditions including iron oxides. Under oxygen-limited conditions, these oxidized host minerals are not stable, and arsenic is more likely to exist as arsenite.

There are three primary biogeochemical triggers that mobilize arsenic from soils and sediments into groundwater. First, the most common trigger is a change in redox condition from an oxygen-abundant environment to oxygen-limited conditions. This can transform arsenate to the more soluble arsenite and/or dissolve the iron oxides hosting the adsorbed arsenate which releases it to groundwater. Shifts in redox condition can result in concentrated releases of arsenic. A second trigger of arsenic release is an increase in pH to values greater than 8.5. At these elevated pH values, iron oxides are less effective sorbents for arsenic due to changes in surface charge characteristics and lead to the release of arsenic to groundwater. Third, competitive ions can cause the mobilization of arsenic. Competitive ions are ions that closely resemble arsenic in structure and chemistry and will therefore compete for the same surface sites to bind onto minerals (Figure 9). Competitive ions like phosphate can replace arsenate on the surface of an iron oxide mineral and cause its release into groundwater.

5.4.3 Arsenic in California

In addition to the geochemical triggers of arsenic release described above, arsenic is increasingly being linked to historic pumping. Several regions within California have existing problems with geogenic arsenic, particularly the Central Valley, where arsenic release has been exacerbated by historic pumping. In the Central Valley, arsenic is deposited by granitic materials from the Sierra Nevada. Additionally, recent work has attributed arsenic release to land subsidence due to overpumping in the Tulare Basin in the San Joaquin Valley (Smith et al., 2018). Arsenic can reside in the porewater of clay layers (where oxygen-limited conditions persist). As aquifer pressures decrease and these layers compact during subsidence (Figure 2), arsenic is released and mobilized

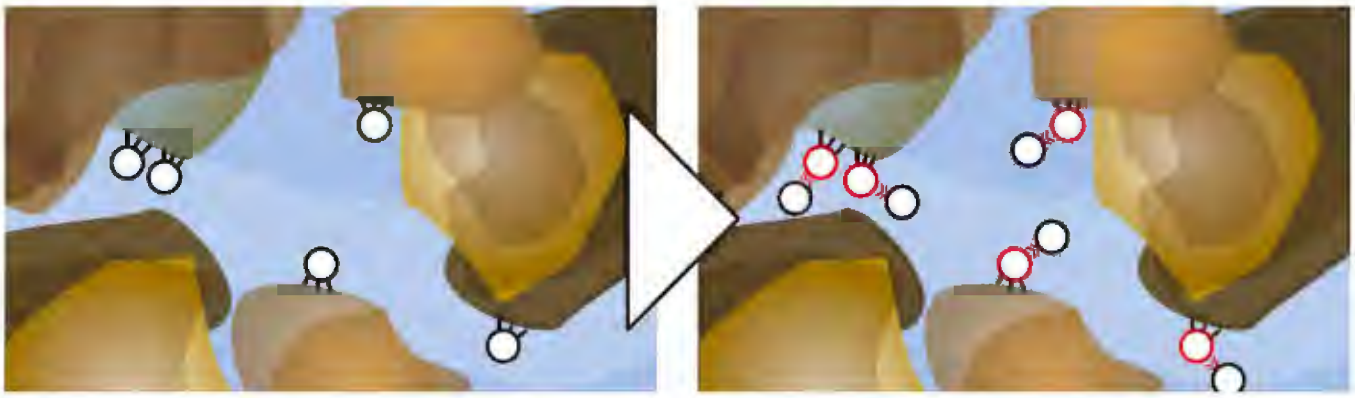

Figure 9: Competitive ion displacement. Ions with similar properties displace each other and limit adsorption to aquifer particles.

into productive aquifer units where it can reach pumping wells. This has been analogized to the release of dirty water when a sponge is squeezed. Once overpumping stops, arsenic concentrations can gradually decrease, declining to background levels as the aquifer is flushed.

5.4.4 Management considerations for arsenic

Conditions to avoid due to arsenic concerns are primarily oxygen-limited conditions and high pH (> 8.5). Inputs of competitive ions including phosphate, sulfate, and carbonate are a secondary concern. In other words, arsenic is generally not expected to be a problem in well-aerated, oxygen-abundant environments with pH values below 8.5. With respect to arsenic release from overpumping, managing for land subsidence will concurrently limit the arsenic release associated with compaction of clay layers and allow impacted aquifers to recover to background concentrations.

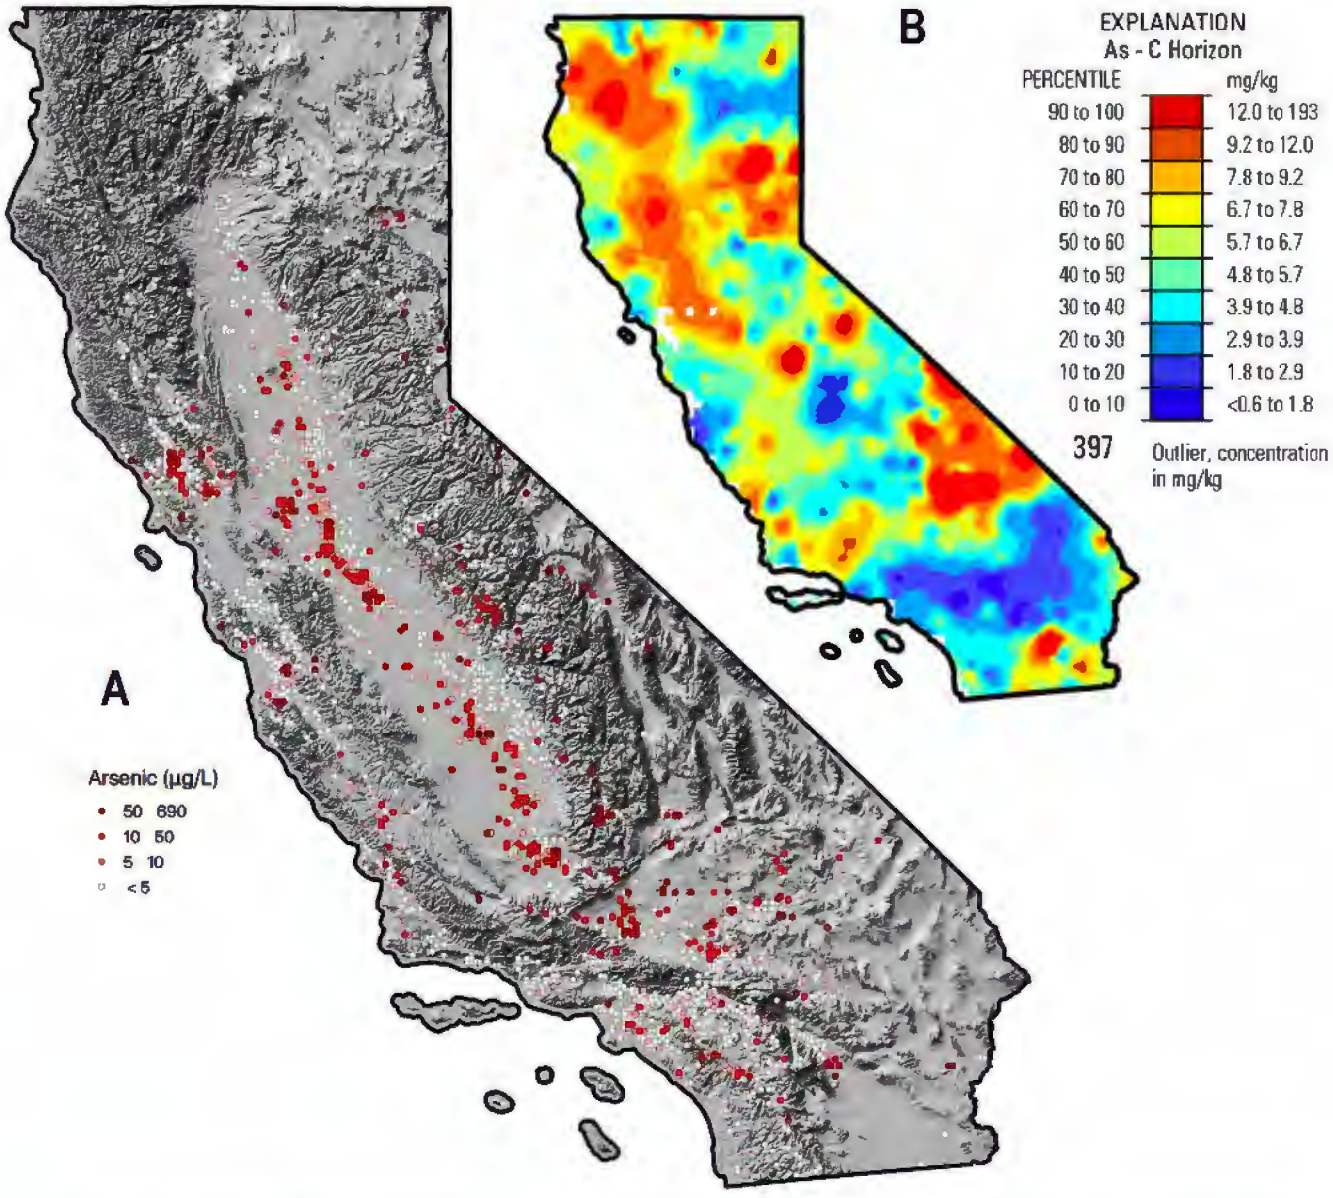

Figure 10: (A) Groundwater concentrations (µg/L) of arsenic from Jan. 2018 – Jan. 2019 and (B) total arsenic concentration (mg/kg) in the soil C Horizon (approximately 2.6-3.3 ft depth interval). The primary MCL for arsenic is 10 µg/L.

5.5 Chromium

5.5.1 Background

Chromium is a naturally occurring metal that is widely used in industrial processes (e.g., electroplating, automobile and steel manufacturing, leather tanning, pigmentation, wood treatment). It persists in two forms within natural environments: trivalent chromium (Cr3+) and hexavalent chromium (Cr6+). Hexavalent chromium is toxic, mutagenic, and carcinogenic, while trivalent chromium is non-hazardous and considered an essential micronutrient in human nutrition. Hexavalent chromium is known to damage the lungs, GI tract, liver, and kidneys and is a known carcinogen that causes cancer by inhalation and possibly by ingestion. The federal MCL for total chromium in drinking water is 100 µg/L. California currently enforces a limit of 50 µg/L. In 2014, California's Department of Public Health set a separate MCL for hexavalent chromium (not total chromium) at 10 µg/L, but this MCL was repealed in 2017 due to the analytical limitations of many water districts (SWRCB, 2018b). The PHG for hexavalent chromium is 0.02 µg/L, stressing the severe toxicity of the chemical to human health. The conversion of hexavalent chromium to trivalent chromium by human stomach acid has been documented, but this was not incorporated in the development of the PHG.

5.5.2 Chromium in the environment

Hexavalent chromium is much more mobile in groundwater than trivalent chromium because it does not bind extensively to minerals within soils and sediments. By contrast, trivalent chromium binds strongly to organic matter and mineral surfaces and may exist as solid minerals (e.g., chromite, aluminosilicate clays, hydroxides). Trivalent chromium is generally stable in oxygen-limited environments. The primary natural pathway for trivalent chromium transformation to hexavalent chromium occurs by reaction with manganese oxides. Although both trivalent chromium and manganese oxides reside in solids of limited solubility, they can react when in close proximity, leading to the generation of toxic hexavalent chromium. Oxygen can also generate hexavalent chromium, but this reaction is only significant at pH values greater than 9. For example, within high-pH, oxygen-abundant aquifers with very slow recharge rates or long residence times — such as in parts of the Mojave Desert, California — indigenous hexavalent chromium generation is appreciable (Izbicki et al., 2008). Once oxidized, hexavalent chromium does not adsorb to aquifer solids extensively and is easily replaced on surfaces by competitive ions such as sulfate and phosphate. Hexavalent chromium is more likely to remain in groundwater and pose a water quality threat.

5.5.3 Hexavalent chromium in California

Industrial activities that use chromium are important point sources of hexavalent chromium contamination in California, particularly in the San Francisco Bay and Los Angeles areas. In addition, geogenic chromium can be unintentionally oxidized by oxidants (e.g., permanganate, persulfate, hydrogen peroxide) injected during *in situ* chemical oxidation, a clean-up process for organic solvent pollution. Hexavalent chromium contamination in groundwater has historically been linked to industrial practices; however, widespread natural occurrences of hexavalent chromium concentrations approaching or exceeding the MCL also occur in groundwater wells unaffected by upstream industrial sources (Hausladen et al., 2018). These high hexavalent chromium levels in oxygen-abundant, alkaline groundwater are associated with the natural oxidation of geogenic chromium and typically affect larger geographic areas and more people than industrial sources.

In California, mafic and ultramafic rocks extend throughout the Coast Range, Klamath Mountains, northern Sierra Foothills, and San Gabriel Mountains. Soils derived from mafic/ultramafic parent material contain high amounts of geogenic chromium-bearing minerals. This leads to soil chromium concentrations exceeding the global average. Recent work proposed that distance from ultramafic outcrops is a primary control on hexavalent chromium concentrations in groundwater in some areas of California, like the western Sacramento Valley (Hausladen et al., 2018, Manning et al., 2015). The western Sacramento Valley receives extensive chromium-rich sediment deposition from the Coast Range Mountains. Here, hexavalent chromium concentrations reach up to 46 µg/L, and 11% of the measured public supply wells have hexavalent chromium levels that exceed 10 µg/L (Izbicki et al., 2015). Groundwater with mafic/ultramafic contributions also tends to be alkaline, which supports hexavalent chromium mobility. It is important to highlight that the high correlation with mafic/ultramafic outcrop proximity does not hold across all of California due in part to sediment transport processes. In these locations, hexavalent chromium contamination in groundwater may also be strongly influenced by human activities, such as agriculture.

5.5.4 Management considerations for hexavalent chromium

Multiple studies have examined geochemical signatures of groundwater in California and posited links between high hexavalent chromium concentrations and human activities, including agriculture (Izbicki et al., 2015, 2008, Hausladen et al., 2018, Manning et al., 2015, Mills et al., 2011). For example, hexavalent chromium is commonly correlated with nitrate concentrations in public-supply wells across the Central Valley. It is presumed that water management practices, like irrigation regimes, influence the geochemical processes driving hexavalent chromium contamination; however, we currently lack direct scientific evidence to confirm and explain how agricultural practices contribute to hexavalent chromium concentrations. Below is a summary of considerations about hexavalent chromium for water management based on laboratory experiments and spatial analyses of groundwater chemistry.

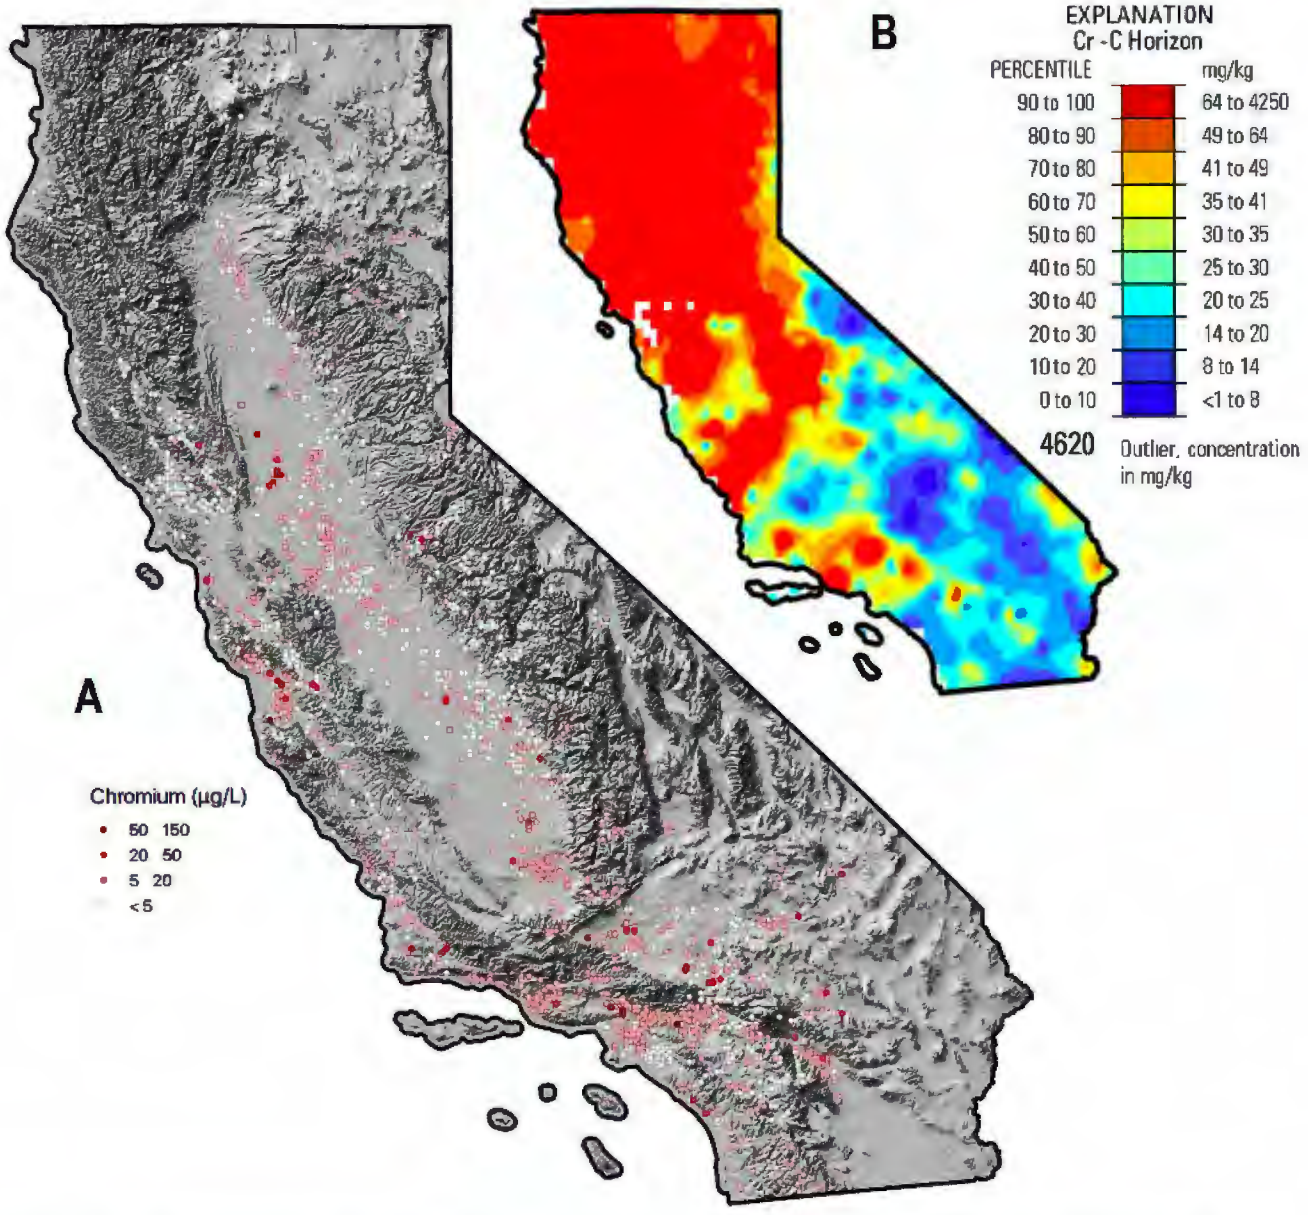

Figure 11: (A) Groundwater concentrations (µg/L) of chromium from Jan. 2018 – Jan. 2019 and (B) total Cr concentration (mg/kg) in the soil C Horizon (approximately 2.6-3.3 ft depth interval). The primary MCL for chromium is 50 µg/L.

In environments containing mafic/ultramafic-derived sediments, biogeochemical conditions to avoid for hexavalent chromium in groundwater are oxygen-abundant, alkaline (pH > 7.5) conditions. Hexavalent chromium is not considered a concern in oxygen-limited aquifers where dissolved iron is present. The use of ammonium fertilizers can introduce acidity to soil and multiple studies suggest that nitrification enhances trivalent chromium release, which leads to greater oxidation by manganese oxides (Mills et al., 2011, 2012). The downward migration of hexavalent chromium generated in the unsaturated zone to shallow aquifers can be accelerated by irrigation recharge.

Although the process remains poorly understood, hexavalent chromium concentrations have been shown to correlate with heavily pumped agricultural areas. One hypothesis is that irrigation schemes which cause the regular wetting and drying of soils leads to manganese oxides dissolving and reforming in new locations at the water table, which in turn leads to the formation of hexavalent chromium. This suggests that irrigation schemes can be modified to decrease or inhibit hexavalent chromium contamination in aquifers. When the water table fluctuates frequently, such as on a weekly basis from turning pumps on and off, soil redox conditions oscillate and activate manganese cycling. Dissolved manganese migrates in the soil during oxygen-limited, saturated conditions, and reforms manganese oxides near chromium-bearing minerals during unsaturated conditions, inducing greater hexavalent chromium production. It is suspected that by changing the pumping schedule to allow for gradual declines in the water table and more stable redox conditions in the subsurface soil and sediments, manganese cycling can be disrupted or stopped, which minimizes hexavalent chromium generation. If an irrigated area does not currently have problems with hexavalent chromium in groundwater and a management action may lead to new irrigation practices which cause intermittent wetting and drying, it should be noted that this can potentially cause the release of hexavalent chromium particularly in areas near ultramafic outcrops.

5.6 Uranium

5.6.2 Background

Uranium is a metal that naturally occurs in rocks. Igneous rocks, like the Sierra Nevada granites, typically contain more uranium than other types of rocks. The MCL for uranium in California is 20 picocuries per liter (pCi/L), which is roughly equivalent to the federal drinking water limit of 30 µg/L. While uranium is radioactive, radioactivity is not a health concern near the MCL. However, the chemical toxicity of uranium in drinking water above the MCL can lead to kidney damage.

5.6.2 Uranium in the environment

Uranium exists in the environment in two different forms: the more reduced form, uranium(IV) and the more oxidized form, uranium(VI). Uranium in groundwater is almost always uranium(VI). Uranium(IV) typically occurs in oxygen-limited environments and forms a solid that precipitate out of water and are sparingly soluble. Dissolved uranium also adsorbs to aquifer solids and organic matter. Uranium(IV) can be transformed to uranium(VI) by reacting with oxygen and nitrate within groundwater. Shallow groundwater tends to contain

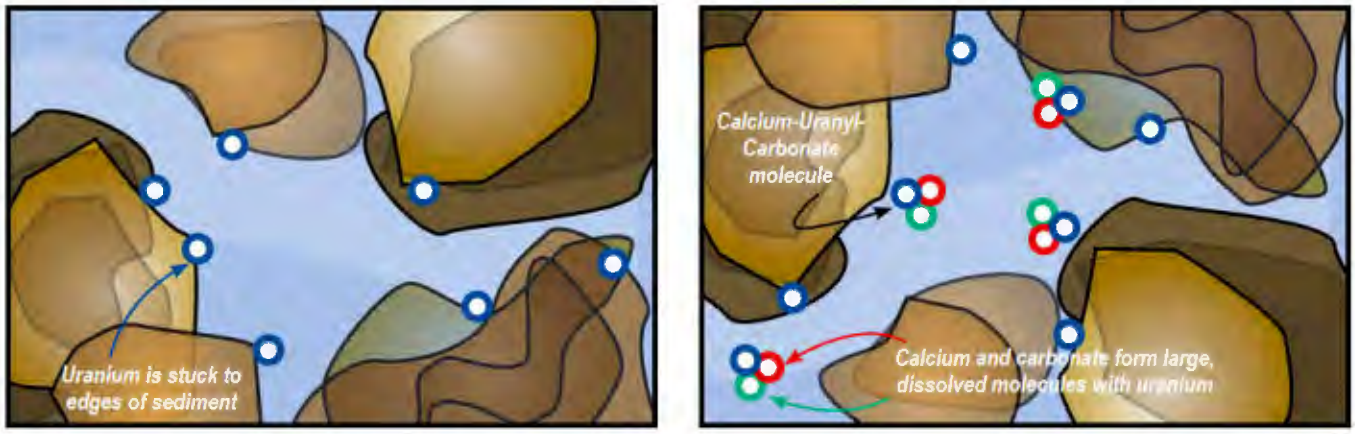

Figure 12: Schematic of calcium-uranyl-carbonate molecule keeping uranium concentrations in groundwater and preventing adsorption.

more DO, leading to uranium(VI). Deeper aquifers often have lower DO, and resulting oxygen-limited conditions promote uranium(IV) solids and subsequently lower uranium concentrations in groundwater. This is one reason why shallower wells tend to pump water with higher uranium concentrations whereas deeper wells have lower concentrations. Additionally, nitrate, when present, also tends to be higher in shallower aquifers, making uranium(VI) a concern in agricultural areas with legacy nitrate contamination.

Although uranium(VI) does not form solids regularly, it does adsorb on aquifer solids, which can limit its dissolved concentrations and mobility. However, uranium(VI) also forms molecules with calcium and carbonate that limit its ability to stick to aquifer solids, thus leading to higher groundwater concentrations of uranium. Groundwater with high levels of calcium and carbonate lead to calcium-uranyl-carbonato complexes (Figure 12) that do not easily adsorb to sediments. Studies have identified a link between increasing uranium concentrations in the Central Valley and increasing bicarbonate concentrations in groundwater due to the effects of increased plant productivity and irrigation return flow (Jurgens et al, 2009). Increased pCO2 in the root zone results in increased bicarbonate in shallow groundwater; high bicarbonate concentrations lead to higher uranium concentrations.

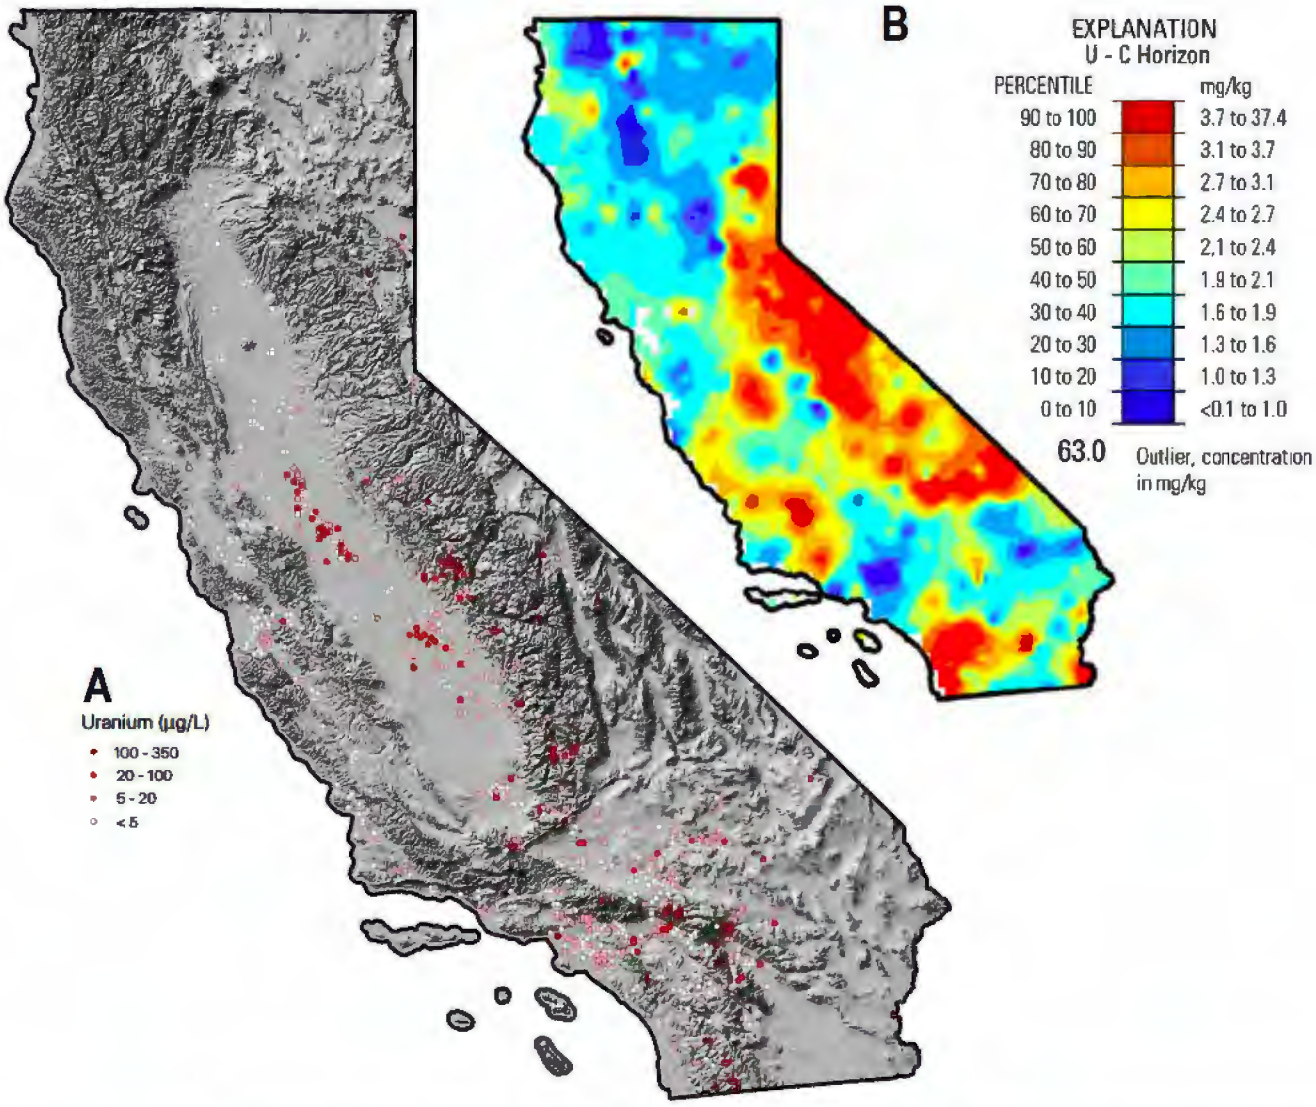

Figure 13: (A) Groundwater concentrations (pCi/L) of uranium from Jan. 2018 – Jan. 2019 and (B) total uranium concentration (mg/kg) in the soil C Horizon (approximately 2.6-3.3 ft depth interval). The primary MCL for uranium is 20 pCi/L.

5.6.3 Uranium in California

In California, wells with high uranium concentrations often occur near the Sierra Nevada (Figure 13). This is because the groundwater picks up uranium from the granitic rocks in the Sierra Nevada or from sediments in valleys that are derived from granitic materials in the Sierra Nevada (like the Eastern San Joaquin Valley). Uranium concentrations in these regions are higher in shallow wells as opposed to deeper wells. Increased pumping can transport uranium from shallow to deeper parts of the aquifer. In parts of the Eastern San Joaquin Valley, uranium levels in some wells have increased significantly over the past 30 years.

5.6.4 Management considerations for uranium

Conditions to avoid to prevent uranium contamination include increasing concentrations of DO or nitrate in an aquifer with limited prior concentrations. The transport of calcium and carbonate to the groundwater below is an additional concern. For example, during managed aquifer recharge via infiltration, when recharge water flows through shallow, calcareous (calcium carbonate containing)-alkaline soils, it can dissolve calcium and carbonate. This also can occur by when waters have elevated carbon dioxide concentrations, which leads to increased carbonates in the water. The calcium- and carbonate-rich water can then react with uranium adsorbed to sediment, promoting release (desorption) of uranium from the sediments into the groundwater. By infiltrating through sandy areas or by removing shallow, calcareous layer of soil in an infiltration basin, calcium and carbonate can be prevented from entering the groundwater. This is particularly relevant for field flooding in the Eastern San Joaquin Valley with legacy agricultural contamination.

5.7 Vanadium

5.7.1 Background

Vanadium is becoming more recognized as a geogenic groundwater contaminant. There is no formal MCL for vanadium, but a Notification Level of 50 µg/L exists. Daily exposure through food is assumed not to have negative impacts, but experiments on rats and mice have shown elevated developmental problems correlated with increasing exposure to vanadium. Concern over potential health effects has led the US Environmental Protection Agency (EPA) to list vanadium on its Contaminant Candidate List 4, which lists contaminants that are not currently regulated at the federal level but may become so in the future.

5.7.2 Vanadium in the environment

Vanadium has three forms most commonly found in the environment: vanadium(III), vanadium(IV), and vanadium(V). Vanadium is considered immobile under oxygen-limited conditions because the reduced form, vanadium(III), forms a solid of limited solubility and will thus be separate from groundwater. The geochemistry of vanadium(IV) and vanadium(V) is more complex owing to their ability to adsorb on various mineral surfaces. Vanadium(IV) is only appreciably present and mobile in groundwater at very low pH, which is generally not relevant to most natural systems. Vanadium(V) tends to partition into groundwater and is thus mobile; it is found under oxygenated conditions. If vanadium is observed in groundwater, it most likely exists as vanadium(V). While vanadium(V) can adsorb to aquifer solids including iron oxides, adsorption is limited at pH values greater than 9.

5.7.3 Vanadium in California

Vanadium is generally more abundant in mafic rocks, and shales have been shown to have extremely high concentrations reaching 16,000 mg/kg in some parts of the world (Nriagu, 1998). In California, vanadium concentrations above 25 µg/L are associated with oxygen-abundant and alkaline (pH > 8) groundwater that interacts with vanadium-bearing source rock. This interaction can take place two ways. First, the water can be located with the source rock. Second, the water can be on the borders of areas with vanadium-bearing source rock. This is evident in the eastern San Joaquin Valley near the western Mojave,Temecula Valley, and in the Tule River Basin of the Sierra Nevada. However, the presence of source rock does not necessarily mean that there will be groundwater vanadium concentrations above 25 µg/L. For instance, the Cascades, Modoc Plateau, and Sonoma Volcanics of the Northern Coast Ranges have vanadium-bearing source rocks but low vanadium concentrations in the groundwater. This is attributed to their oxygen-limited and low pH conditions. However, areas such as the Owens Valley have been shown to have volcanic source rock and oxygen-abundant, alkaline groundwater, but also have low vanadium concentrations. Other areas, such as parts of the North Coast Range and the Owens Valley, also have vanadium-bearing source rocks but do not have groundwater vanadium concentrations above 25 µg/L. This indicates the need to establish and pay close attention to the hydrologic flow paths of the

regions, as well as establishing the redox conditions of the groundwater in areas of concern (Wright and Belitz, 2010).

5.7.4 Management considerations for vanadium

General conditions which cause vanadium release to groundwater are oxygen-rich and alkaline (pH > 8) waters. This is also true for uranium and chromium, and vanadium has similar management considerations to both uranium and chromium. If an aquifer has previously limited exposure to oxygen, any management practice that introduces oxygen can cause vanadium mobilization to groundwater. Additionally, uranium and vanadium concentrations are often correlated in groundwater. If an aquifer is experiencing issues with uranium, it is recommended to also monitor for vanadium as there is a possibility these contaminants will co-occur.

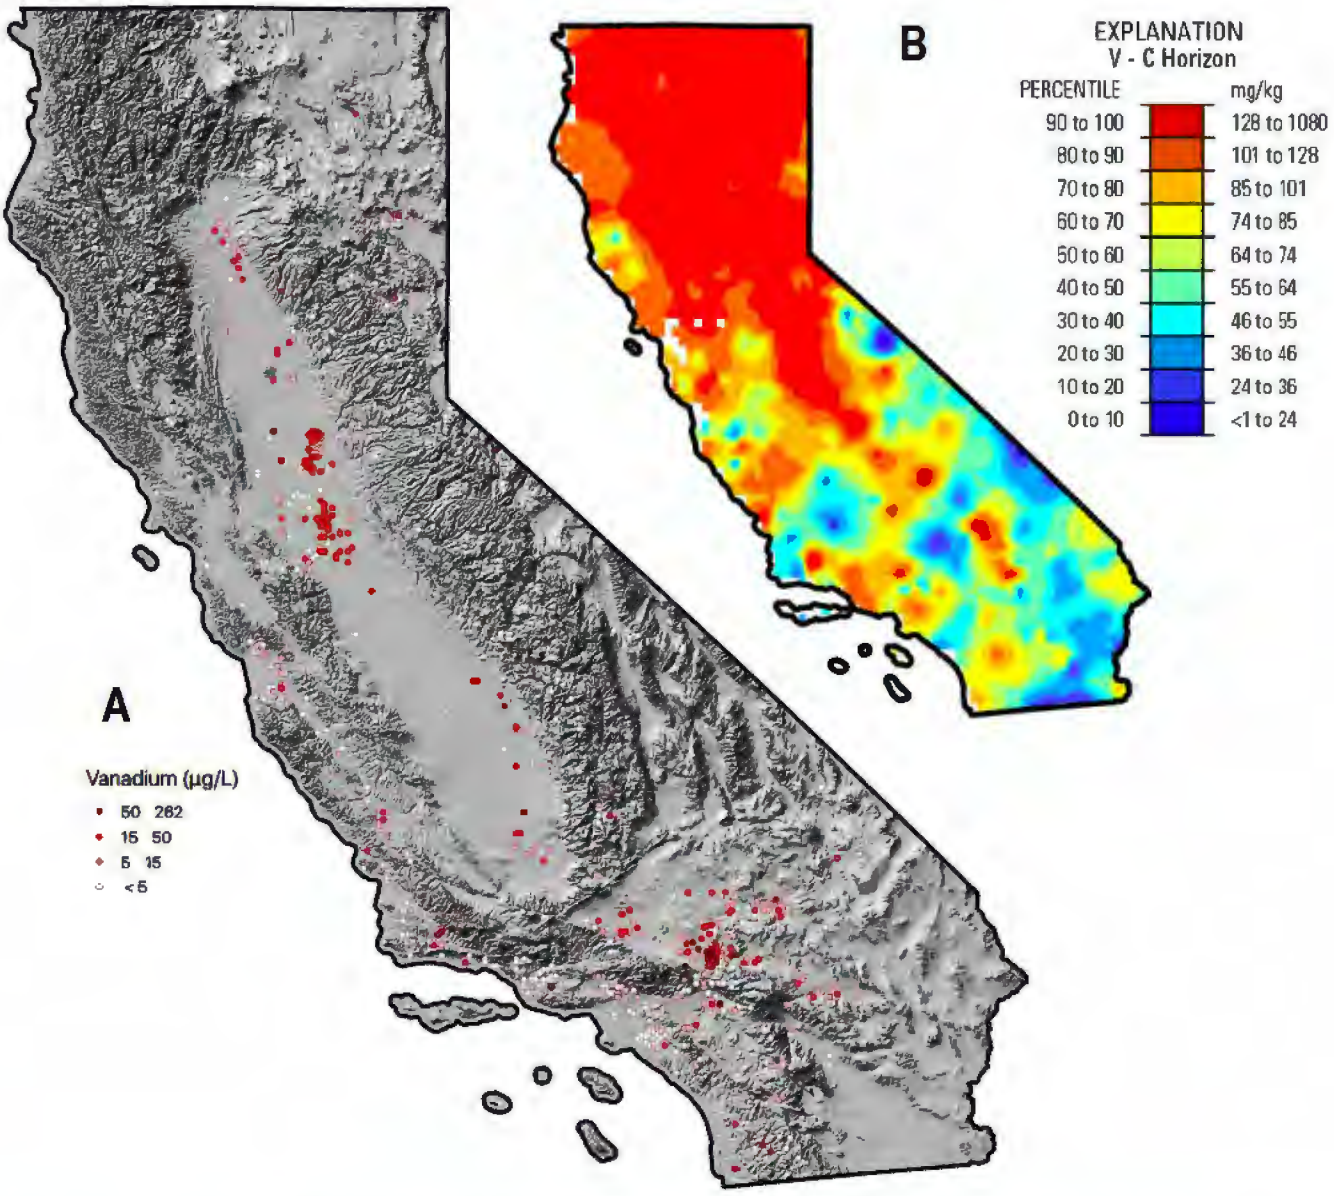

Figure 14: (A) Groundwater concentrations (µg/L) of vanadium from Jan. 2018 – Jan. 2019 and (B) total vanadium concentration (mg/kg) in the soil C Horizon (approximately 2.6-3.3 ft depth interval). The notification level for vanadium is 50 µg/L.

5.8 Selenium

5.8.1 Background

Selenium is an essential nutrient at low, trace concentrations. However, excessive selenium concentrations are toxic to human and ecosystem health. The current MCL is 50 µg/L and long-term exposure of selenium at concentrations above the MCL has been shown to cause damage to kidneys, livers, and nervous and circulatory systems in humans. Historically, selenium has been more dangerous for fish and waterfowl, for whom it is known to cause congenital disorders and death through ingestion of high doses which bioaccumulate in food sources. Anthropogenic sources of selenium include mining metal ores and coal burning.

5.8.2 Selenium in the environment

Under most environmental conditions, selenium can be found as either the oxidized selenate or the reduced selenite. Under oxygen-abundant conditions, selenium exists as selenate and is more likely to be found in groundwater owing to selenate's limited ability to adsorb to aquifer solids. Selenate is also the more toxic form of selenium. By contrast, under oxygen-limited

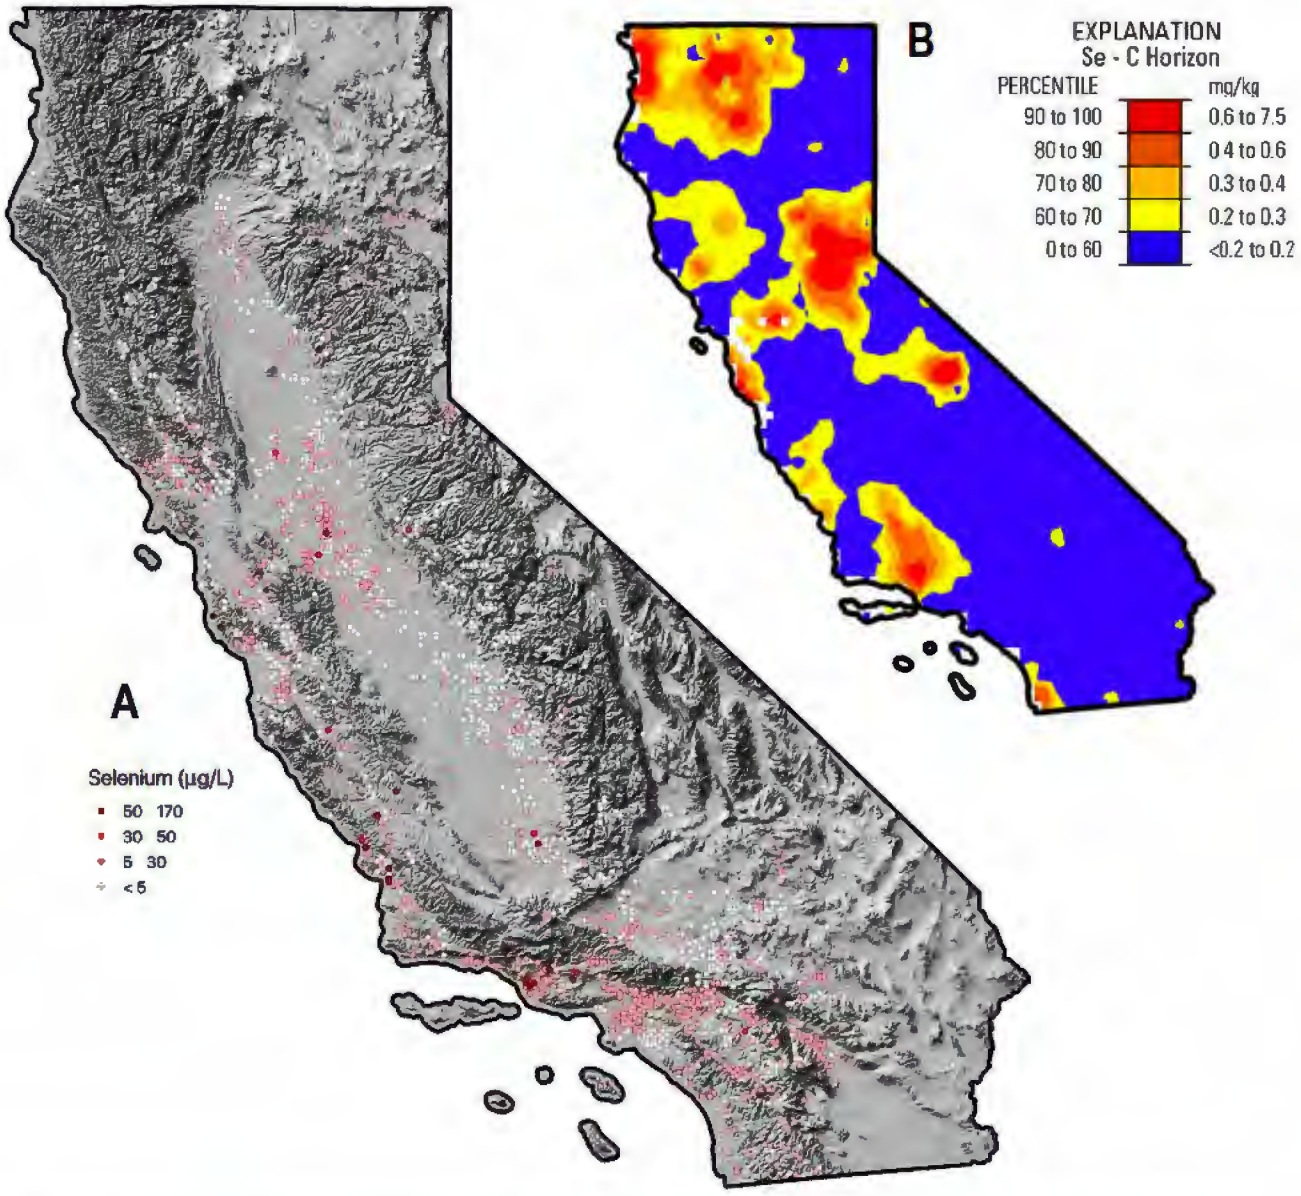

Figure 15: (A) Groundwater concentrations (µg/L) of selenium from Jan. 2018 – Jan. 2019 and (B) total selenium concentration (mg/kg) in the soil C Horizon (approximately 2.6-3.3 ft depth interval). The primary MCL for selenium is 50 µg/L.

conditions, selenium exists as selenite and will adsorb strongly to aquifer particles, limiting its concentration in groundwater. High selenium concentrations are typically found under oxygen-abundant conditions. Additionally, at high pH values, both selenate and selenite do not adsorb strongly to aquifer solids and concentrations will increase in groundwater. Similar to arsenic, selenium can be mobilized through the presence of competitive ions (e.g., phosphate). While groundwater selenium concentrations are typically low (Plant et al. 2003) and not problematic for human health, contaminated groundwater that may reach surface water bodies, particularly surface water bodies subject to high evaporation, can have adverse impacts on fish and waterfowl.

5.8.3 Selenium in California

Generally, groundwater selenium concentrations are low and soil concentrations tend to correlate with the source bedrock of the California Coast Ranges (Figure 15). Selenium is concentrated in shallow groundwaters in semi-arid regions under irrigation (Deverel et al., 1994). Irrigation water can mobilize geogenic selenium and high evaporation rates can subsequently concentrate salt and selenium concentrations on the surface. Historically, this phenomenon has been observed in the San Joaquin Valley. In the 1980's in the San Joaquin Valley, this led to one of the most documented cases of selenium toxicity in animals. Near the Kesterson reservoir, agricultural drainage tiles were installed to mitigate soil salinization problems. The agricultural drainage water that flowed into the reservoir had high selenium concentrations (250 – 650 µg/L) which were further concentrated due to evaporation losses in the reservoir. This caused significant health effects on fish and wildlife, leading to the death of at least 1,000 birds (Plant et al., 2003).

5.8.4 Management considerations for selenium

Conditions to avoid for selenium release to groundwater include oxygen-abundant and high pH environments. Of secondary concern is a high influx of phosphate concentrations. Introducing nitrate (e.g., infiltration from nitrate-contaminated areas) can also transform selenium to its more mobile form and cause an increase in groundwater concentrations. Additionally, the pumping of groundwater for irrigation can concentrate selenium in addition to concentrating salts. Selenium mobilization could be an issue during changes to irrigation methods, agricultural drainage, or on-farm recharge.

5.9 TCP

5.9.1 Background

1,2,3-Trichloropropane (TCP) has recently been identified as a widespread, emerging contaminant in California. Unlike the geogenic contaminants described above, TCP does not have natural sources. This clear, colorless liquid was present in certain agricultural products applied in California throughout the 20th century, leading to widespread nonpoint contamination. In addition, TCP was historically used as an industrial solvent and cleaning agent, and therefore has many urban point sources. Because TCP does not easily break down, groundwater contamination from these historic practices remains an issue today.

TCP is of concern for human health because of its cancer-causing properties. Research by the National Toxicology Program (NTP) found that TCP causes tumors in multiple sites in both rats and mice at low doses (Irwin, Haseman, & Eustis, 1995). Based on these and other findings, TCP is considered a known human carcinogen by the State of California. California established an MCL for TCP in drinking water (0.005 µg/L) in December 2017, recognizing TCP's health risks and widespread distribution (Figure 16).

5.9.2 TCP in the environment

TCP is not known to have the same geochemical controls as redox-sensitive and ionic contaminants. Nonetheless, TCP is detected at much higher frequencies within oxic groundwater, suggesting it could be impacted by redox conditions; however, this mechanism is currently not well documented (Burow, 2019). Transport of TCP in groundwater is therefore controlled primarily by the physical properties of TCP, the mode of source application, and the characteristics of the affected aquifer, rather than geochemical or redox conditions.

TCP is a short hydrocarbon molecule with a chlorine atom bonded to each carbon. TCP is dense, slightly water soluble, and moderately volatile (prone to evaporation). While less volatile than industrial counterparts like trichloroethylene (TCE), TCP tends to evaporate from surface water. However, TCP does not adsorb easily to soil, and TCP that does not volatilize will migrate into groundwater.

Because it is denser (heavier) than water, TCP is classified as a dense non-aqueous phase liquid (DNAPL). Like all DNAPLs, TCP that enters an aquifer will sink downward, and eventually dissolve into groundwater.

TCP that originates from a diffuse, nonpoint source will tend to dissolve relatively quickly into groundwater. However, when a large amount of TCP enters the aquifer at a single location (generally from a point source), the pure, "free product" TCP can remain in the application source zone for decades – or centuries. This free product may be trapped in large pore spaces as "residual" free product or "pooled" above low-permeability sediments, often with highly irregular distribution within the source zone. Because TCP free product dissolves very slowly over time, groundwater passing through source zones may become enriched in TCP even after application has ceased.

Once dissolved into groundwater, TCP will be transported with groundwater flow. TCP is chemically stable and resistant to degradation. A typical molecule of TCP has a half-life of 44-74 years (i.e., it takes 44-74 years to degrade to half the initial concentration in water) (Ellington, 1986). Therefore, TCP plumes persist until they are diluted by diffusion or mixing.

5.9.3 TCP in California

TCP was detected above the MCL in 8% of domestic wells and 5% of public-supply wells recently sampled in California (Burow 2019). These detections are concentrated in the San Joaquin Valley, with some affected wells in the Los Angeles basin and Salinas Valley (Figure 16). In the San Joaquin Valley, 16-18% of domestic and public supply wells have TCP concentrations above the MCL.

Unlike geogenic contaminants, the distribution of TCP is largely determined by the location of historic source applications. In agricultural regions, TCP in groundwater likely originates from the use of TCP-containing soil fumigants marketed as D-D and, later, Telone, Telone II, and Vidden D. These fumigants were composed primarily of 1,3-dichloropropene (1,3,-DCP) and 1,2-dichloropropene (1,2-DCP) but contained up to 7% TCP by weight (Cheremisinoff & Rosenfeld, 2011). TCP-containing fumigants were widely applied beginning in the 1940s to many of California's croplands, including citrus fruits, pineapples, soy beans, cotton, tomatoes, sugar beets, grapes, potatoes, and various row crops, until they were discontinued in 1984 (CH2M Hill, 2005).

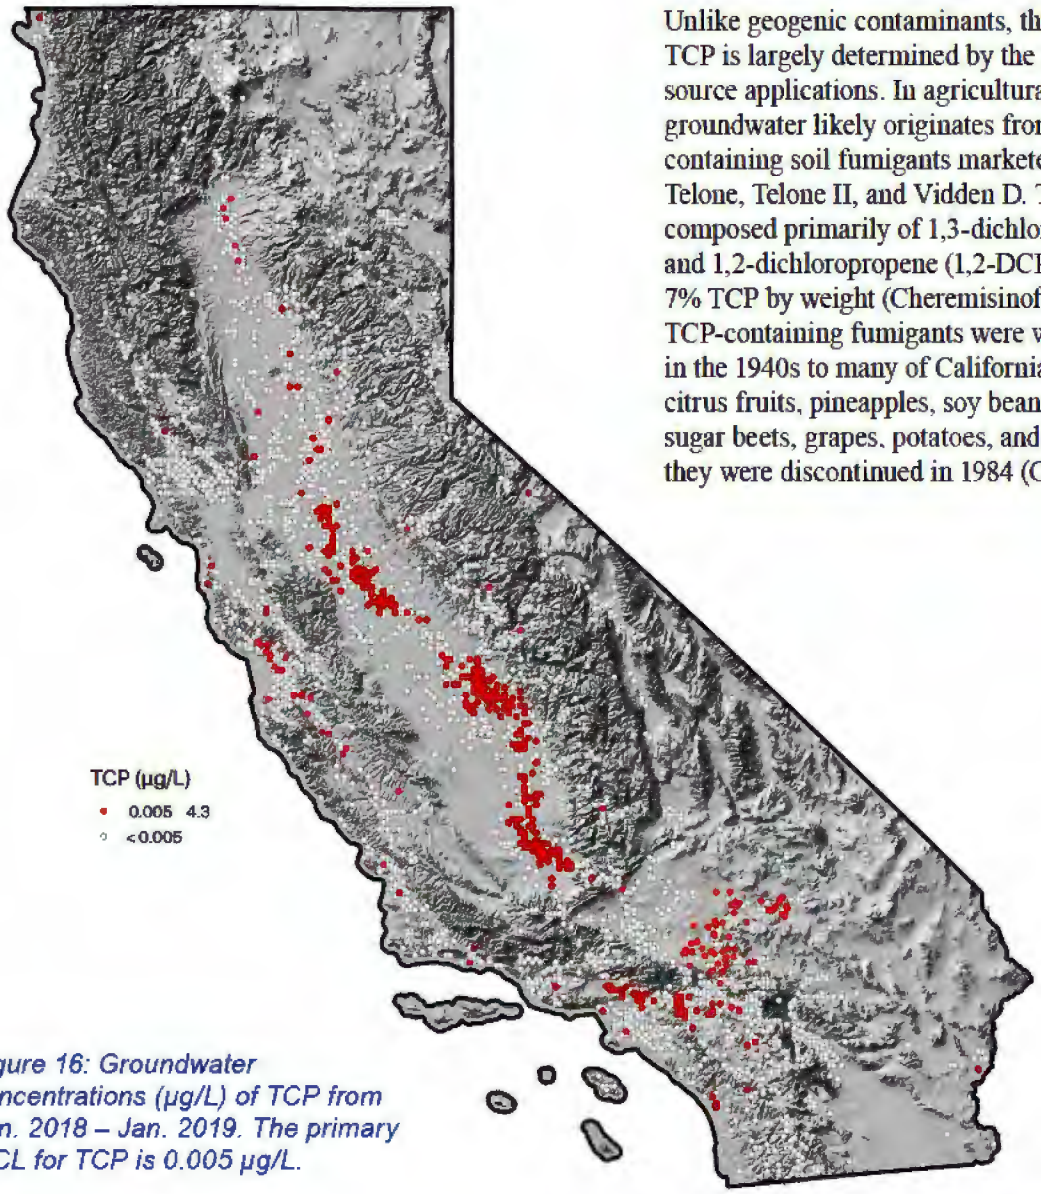

Figure 16: Groundwater concentrations (µg/L) of TCP from Jan. 2018 – Jan. 2019. The primary MCL for TCP is 0.005 µg/L.

TCP also has many point sources. These include facilities where TCP-containing fumigants were stored or where TCP was used as a solvent or cleaning agent. Suspected point sources of TCP in California include agricultural chemical supply sites, aviation facilities, chemical processing and manufacturing plants, and waste disposal sites (CH2MHill 2005, Burow 2019).

A recent evaluation of TCP in California groundwater identified several factors that are associated with TCP occurrence and concentrations: oxygen-abundant conditions; young, shallow groundwater; orchard/vineyard land use in the early 1990s; and high recharge rates (Burow 2019). Overall, TCP was found to be most prevalent and at highest concentrations near alluvial fans in the central and southern San Joaquin Valley, where orchards and vineyards are common and coarse-grained sediments and irrigation lead to high recharge. TCP was prevalent at similar rates in wells of all depths, though TCP concentrations were slightly higher in shallower wells. The authors also found that TCP co-occurs with 1,2-dibromo-3-chloropropane (DBCP, another soil fumigant) and 1,2-DCP (a TCP breakdown product and primary component of TCP-containing fumigants).

5.9.4 Management considerations for TCP

Active groundwater remediation is not a focus of this document. Best practices for TCP *in situ* remediation are still under study and will depend on the specific conditions of each plume. In general, *in situ* remediation of TCP can be achieved by injection of a strong oxidant and catalyst or by reductive dechlorination with zero-valent iron. However, California considers pump-and-treat with Granular Activated Carbon (GAC) as the Best Available Technology for affected water systems (SWRCB, 2018c).

Without active treatment, TCP plumes are likely to persist for many years. However, an awareness of aquifer characteristics, hydrology, and current/former land use can help water managers to avoid increasing TCP concentrations. Managers can avoid siting new wells in areas known to be associated with higher TCP concentrations, particularly shallow groundwater near orchards and vineyards in the central and southern San Joaquin Valley. Wells with elevated concentrations of DBCP and 1,2-DCP are also more likely to have elevated TCP.

Water managers should also be aware of historic point sources of TCP. As described above, residual or pooled TCP may be found near application zones in the pore spaces of coarse sediments or in lenses above low-permeability sediments. If water pumped from these strata becomes enriched in TCP relative to up-gradient wells, free product may be present. Subsurface soil samples can also reveal whether free product remains in source zones.

Depending on hydrological conditions of the site, managed aquifer recharge can help to reduce TCP concentrations through dilution of existing contamination. However, recharge zones should also avoid historic point source TCP contamination, as free product in the subsurface may dissolve into percolating groundwater and reach previously unaffected water supplies. Monitoring groundwater conditions down-gradient of the recharge will also allow water managers to track changes in TCP concentrations following recharge.

5.10 PFASs

5.10.1 Background

Per- and polyfluoroalkyl substances (PFASs) are a large and diverse class of fluorinated organic compounds. Like TCP, PFASs are synthetic chemicals that have no natural sources. PFASs are used to make consumer products stain-, soil-, and water-repellent, and in aqueous film-forming foam (AFFF) to extinguish flammable liquid fires. The carbon-fluorine chemical bonds that give PFASs their useful properties also make many of these chemicals extremely persistent. Interest in PFASs has increased due to recent discoveries of their widespread environmental occurrence and potential impacts on human health and biota.

Perfluoroalkyl acids (PFAAs) are a subclass of PFASs that are the focus of much scientific and regulatory attention. Exposure to PFAAs such as perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) is associated with human health harm including immune suppression, liver damage, high cholesterol, cancer, thyroid disease, reduced fertility, low birth weight, and effects on children's cognitive and neurobehavioral development. In 2016, U.S. EPA issued a Lifetime Health Advisory Level of 70 ng/L for PFOA, PFOS, or the sum of both. Researchers know less about the prevalence and toxicity of other PFASs, but the science is evolving rapidly.

PFOA, PFOS, and other long-chain PFASs have been phased out in the U.S. due to concerns over their

persistent, bioaccumulative, and toxic properties. Over the past 15 years, industry has replaced long-chain PFASs with short-chain PFASs and perfluoroether carboxylic and sulfonic acids. One notable perfluoroether carboxylic acid called GenX is used as a PFOA replacement in fluoropolymer manufacturing. GenX contamination has recently been detected in several watersheds in the eastern U.S.

5.10.2 PFASs in the environment

PFOA, PFOS, and other PFAAs are highly persistent. They are not expected to degrade at appreciable rates under environmental conditions. PFAAs are strong acids that usually carry a negative charge, which contributes to their relatively high water solubility and low volatility. PFAA releases are often associated with dissolved phase plumes. However, considerable PFAA mass can also be retained in source zones, especially in unsaturated soils. Partitioning to sediment and bioaccumulation are more pronounced for longer-chain PFAAs.

In contrast to PFAAs, polyfluorinated compounds contain a fluorinated carbon chain and at least one nonfluorinated carbon. The nonfluorinated carbons make polyfluorinated compounds more reactive than PFAAs, and some are susceptible to oxidation reactions. Polyfluorinated compounds that produce PFAAs are known as PFAA-precursors. Little is known about the fate, transport, or toxicity of many PFAA-precursors. Most are not included in standard analytical methods. PFAA-precursors are likely to serve as an ongoing source of PFAAs (e.g., PFOA) in the environment. Analytical techniques for measuring PFAA-precursors, such as the total oxidizable precursor (TOP) Assay, are increasingly available.

Important point sources of PFAS contamination include manufacturing facilities that make or use PFASs, locations where AFFF firefighting foam was used, landfills, and wastewater treatment plants.

5.10.3 PFASs in California

PFASs are not regulated under the Safe Drinking Water Act and public water systems are not required to perform routine monitoring of these chemicals. PFASs were detected in 133 drinking water samples from California through EPA's Third Unregulated Contaminant Monitoring Rule (UCMR3). The same study identified nine public water systems in the state with detections of PFOA and/or PFOS above EPA's 70 ng/L health advisory.

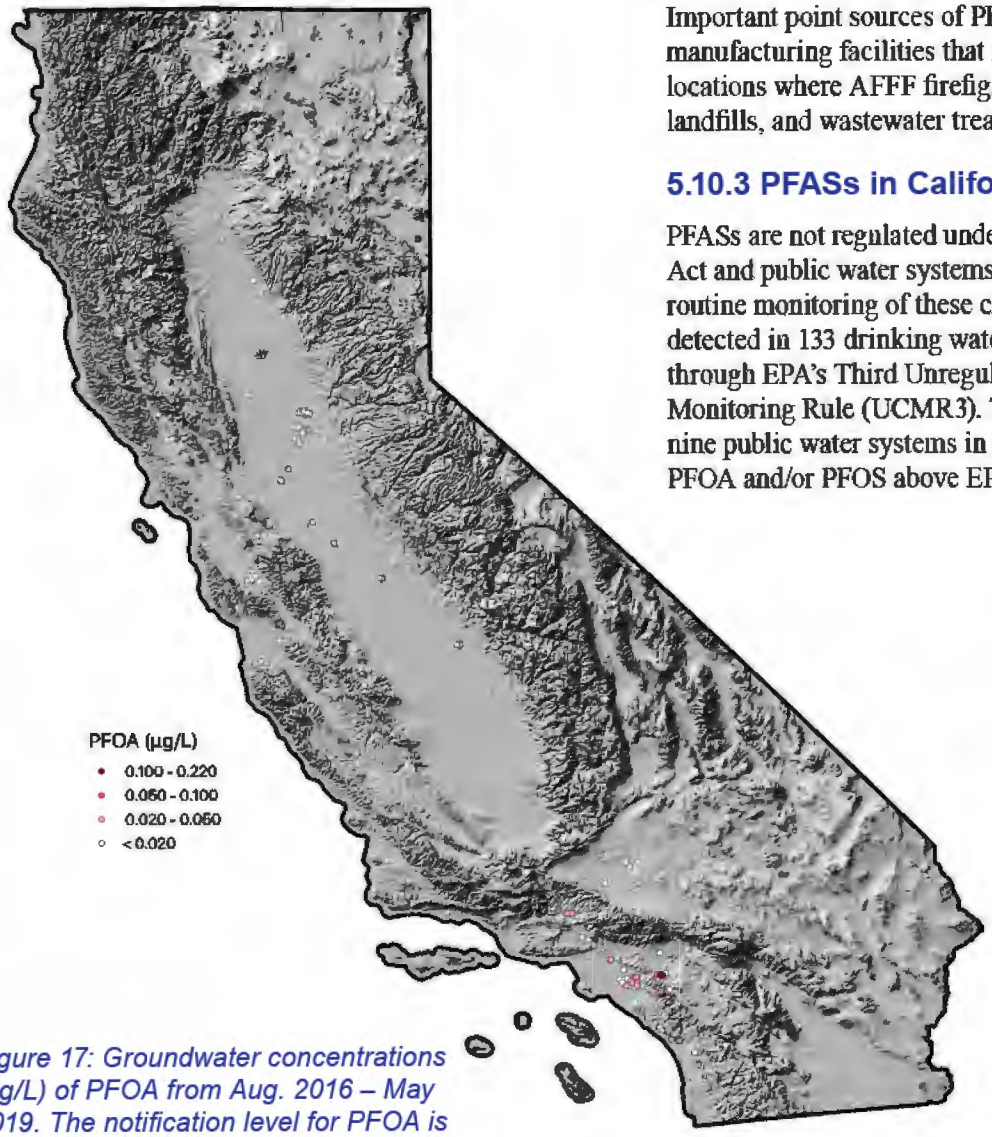

Figure 17: Groundwater concentrations (µg/L) of PFOA from Aug. 2016 – May 2019. The notification level for PFOA is 0.013 µg/L.

Aside from the UCMR3 study, there is a lack of drinking water monitoring data for PFASs in California. The Department of Defense has identified high PFAS concentrations in groundwater at military sites where AFFF was used, but none of these sites are known to have impacted drinking water off-base in California. In 2019, the State Water Resources Control Board announced a plan to require PFAS monitoring at hundreds of suspected release sites around the state, including manufacturing facilities, airports, landfills, refineries, wastewater treatment plants, and urban wildfire areas. The results of this monitoring should increase our understanding of the extent and sources of PFASs in California groundwater. When the state of Michigan carried out a similar testing program in 2018, it identified dozens of previously unknown PFAS contamination sites.

California's Division of Drinking Water has established notification levels of 13 ng/L and 14 ng/L, respectively, for PFOS and PFOA, and a response level of 70 ng/L for each individual compound of the sum of both.

5.10.4 Management considerations for PFASs

Under aerobic conditions, PFAA-precursors can undergo biotic transformation reactions to form PFAAs. Thus, if PFAA-precursors are present, management actions that introduce oxygen to an aquifer may have the unintended effect of increasing PFAA concentrations. Examples of such actions include remedial activities designed to treat contaminants other than PFASs, such as biosparging or in-situ chemical oxidation.

Recycled water is a potential source of PFASs in receiving aquifers. Given the decreasing trend in PFAS regulatory values, water managers should consider monitoring for PFASs before implementing aquifer recharge with recycled water.

Glossary

Analytes: substances being measured

Anoxic: Condition with low concentrations of dissolved oxygen

Anthropogenic: Man-made

Aqueous: Dissolved in water

Calcareous: rich in calcium carbonate

Cation: positively charged substance

Competitive ion: an ion (or charged substance) that behaves similar to another ion. Because they behave similarly, they

Desorption: The process of a substance adsorbed to a particle surface being released into the surrounding water

Felsic: describes type of volcanic rock that is rich in minerals like feldspar and quartz

Geogenic: naturally occurring in rocks

Mafic: describes a type of volcanic rock that is rich in magnesium and iron

Mobility: ability of a substance to move or be transported with water

Nonpoint source: contamination resulting from a diffuse source

Oxidant: a substance which causes the oxidation of another substance

Oxidation: the process of losing electrons or increasing oxidation state

Oxidation reduction potential: a measure of redox conditions

Oxidation state: a measure of the number of electrons a substance has gained or lost relative to its native state

Oxyanion: negatively charged substance

pH: a measure of the acidity of water

Point source: contamination resulting from a single, specific source (e.g., a leaking waste container)

Redox: chemistry related to the gain or loss of electrons also called the reduction or oxidation of substances

Reductant: a substance which causes the reduction of another substance

Reduction: the process of gaining electrons or decreasing oxidation state

Sediment: sediments are materials consisting of rocks and minerals, and remains of plants and animals; they are moved to new locations and deposited by water, ice, or wind

Sedimentary: describes rocks formed by deposition of other rocks

Shale: a fine-grained, sedimentary rock that forms when silt and clay-size mineral particles compact

Soil: unlike sediments, soil weathers in place and requires time and a stable ground surface to develop. It is a mixture of organic material, rock and mineral particles

Solubility: ability to dissolve in water

Sorption: the process of a substance adsorbing to a particle surface

Specie: a chemical substance or entity such as an atom, ion, or molecule

Ultramafic: describes a type of volcanic rock with very low silica content

Unsaturated zone: zone of an aquifer above the water table

Case Study/

Effects of Groundwater Development on Uranium: Central Valley, California, USA

by Bryant C. Jurgens[1,2], Miranda S. Fram[2], Kenneth Belitz[3], Karen R. Burow[2], and Matthew K. Landon[3]

Abstract

Uranium (U) concentrations in groundwater in several parts of the eastern San Joaquin Valley, California, have exceeded federal and state drinking water standards during the last 20 years. The San Joaquin Valley is located within the Central Valley of California and is one of the most productive agricultural areas in the world. Increased irrigation and pumping associated with agricultural and urban development during the last 100 years have changed the chemistry and magnitude of groundwater recharge, and increased the rate of downward groundwater movement. Strong correlations between U and bicarbonate suggest that U is leached from shallow sediments by high bicarbonate water, consistent with findings of previous work in Modesto, California. Summer irrigation of crops in agricultural areas and, to lesser extent, of landscape plants and grasses in urban areas, has increased Pco_2 concentrations in the soil zone and caused higher temperature and salinity of groundwater recharge. Coupled with groundwater pumping, this process, as evidenced by increasing bicarbonate concentrations in groundwater over the last 100 years, has caused shallow, young groundwater with high U concentrations to migrate to deeper parts of the groundwater system that are tapped by public-supply wells. Continued downward migration of U-affected groundwater and expansion of urban centers into agricultural areas will likely be associated with increased U concentrations in public-supply wells. The results from this study illustrate the potential long-term effects of groundwater development and irrigation-supported agriculture on water quality in arid and semiarid regions around the world.

Introduction

The Central Valley is one of the most productive agricultural regions in the world, with a cash value of more than $20 billion in 2007 (U.S. Department of Agriculture 2007). Seven counties within the Central Valley are among the top 10 counties in the United States for agricultural products sold (U.S. Department of Agriculture 2007). Nearly two-thirds of all groundwater withdrawals in California occur in the Central Valley, primarily for agricultural irrigation (Hutson et al. 2004; Maupin and Barber 2005). The San Joaquin Valley makes up the southern two-thirds of the Central Valley, and most of the population and associated municipal or public groundwater use is in the eastern San Joaquin Valley (ESJV). Reliance on groundwater as a source of drinking water in the ESJV is expected to increase with rapid population growth and diminishing availability of surface water supplies.

Uranium (U) concentrations above the California Maximum Contaminant Level (CA-MCL) of 20 picocuries per liter (pCi/L)—approximately equivalent to the U.S. Environmental Protection Agency Maximum Contaminant Level (U.S. EPA MCL) of 30 micrograms per liter (µg/L)—has led to the removal of at least 23 public-supply wells (PSWs) from service within the last 20 years in the ESJV (based on data from the California

Department of Public Health [CDPH] Database, accessed September 2008). Groundwater from several other wells affected by high U is either blended with water containing low U or removed by ion exchange to meet regulatory requirements (Ashton 2006).

Previous studies have shown that anthropogenically introduced contaminants, such as pesticides and nitrate, have degraded the quality of groundwater within the ESJV (Nightingale 1972; Schmidt and Sherman 1987; Domagalski 1997; Burow et al. 2008; Wright et al. 2004). The spatial distribution of these contaminants in groundwater is linked to patterns of fertilizer and pesticide use and their rate of application at the surface. In contrast to these agricultural contaminants, U is naturally abundant in soils and aquifer sediments in the ESJV and is not linked to the application of fertilizers or pesticides (Jurgens et al. 2008).

Uranium is mobile in oxygenated groundwater and generally only forms stable minerals in sulfate-reducing environments; formation of stable U minerals in oxic environments requires very high concentrations of U (greater than 1000 µg/L). Uranium in oxic groundwater has a valence of +6 [U(VI)] and will form the oxycation uranyl (UO_2^{+2}) in the absence of complexing ions, such as dissolved inorganic carbon (DIC) (Langmuir 1978). The aqueous concentration of U(VI) is normally limited by uranyl adsorption to iron oxyhydroxide coatings on sediment grains, clay mineral edges, or to organic matter (Hsi and Langmuir 1985; Waite et al. 1994; Davis and Curtis 2004; Catalano and Brown 2005). However, the presence of complexing ions, particularly DIC species, can increase the solubility and mobility of U(VI) (Langmuir 1978; Hsi and Langmuir 1985; Waite et al. 1994; Davis and Curtis 2004). Recent work has also shown that calcium can enhance desorption of uranyl-carbonate ternary complexes (Fox et al. 2006) and that the calcium-uranyl-carbonate complex, $Ca_2UO_2(CO_3)_3^0$, may be the dominate species of dissolved U(VI) in calcium-rich groundwater systems (Bernhard et al. 2001).

Plant root respiration and microbial oxidation of organic matter in soils produce carbon dioxide (CO_2), resulting in CO_2 partial pressures (Pco_2) in the soil zone that are greater than atmospheric pressure (Russell 1973). Water percolating through the soil equilibrates with the soil atmosphere by dissolving $CO_2(g)$ to form carbonic acid. The carbonic acid participates in mineral weathering reactions that increase DIC concentrations in water, primarily in the form of bicarbonate. Soil calcite will also dissolve under high Pco_2 pressures and therefore can be an added source of DIC to water (Appelo and Postma 1996). Water that is not taken up by plants or evaporated from the soil eventually percolates to the groundwater system as recharge. ESJV climate is characterized by cool, wet winters and hot, dry summers; thus, under natural conditions, biological productivity is limited by the lack of soil moisture during the summer season. During the last 100 years, the ESJV has been extensively developed for agricultural use, and increasingly for urban use. Warm-season irrigation (March through September) of agricultural crops and urban landscapes has greatly increased biological productivity. It is our hypothesis that increased soil zone Pco_2 beneath irrigated lands has resulted in increased bicarbonate concentrations in groundwater, and that this bicarbonate has enhanced the mobility of U.

In addition, the application of surface water and groundwater for agricultural irrigation and pumping from deep parts of the aquifer for irrigation and public supply has increased the rate of downward groundwater flow (Williamson et al. 1989; Phillips et al. 2007). The vertical movement of water from the water table to deeper parts of the groundwater flow system has increased by more than sixfold in many parts of the valley since development and caused head gradients to be in a downward direction almost everywhere (Williamson et al. 1989). It is also our hypothesis that these changes in groundwater flow patterns have caused U concentrations to increase in many PSWs throughout the ESJV.

Because the developed portion of the ESJV aquifer system is largely oxic, uranium is expected to remain mobile in groundwater and therefore poses a significant threat to the long-term sustainability of groundwater as a potable source.

This paper describes the likely linkage between the development of groundwater resources in the ESJV since the 1850s and temporal increases in U concentrations in groundwater. Data collected by the U.S. Geological Survey (USGS) for the California Ground Water Ambient Monitoring and Assessment program Priority Basin Project (USGS-GAMA), data previously collected by the USGS National Water Quality Assessment (NAWQA) program and other USGS studies (USGS historical), and data compiled by the CDPH are used to demonstrate that high U concentrations are associated with shallow, modern-age groundwater that has high concentrations of bicarbonate. We show that bicarbonate concentrations in ESJV groundwater have increased with time and that bicarbonate is likely associated with warm-season irrigation return water. Finally, we show that U concentrations in the deeper portions of the aquifer system tapped by PSWs are increasingly affected by shallow U-laden groundwater that is driven downward in response to pumping. The paper also shows that irrigation and development of lands for agricultural and urban uses can mobilize inorganic contaminants that may otherwise be sequestered under natural conditions. The results of this paper therefore illustrate the potential long-term effects of groundwater development and irrigation-supported agriculture on water quality in arid and semiarid regions around the world.

Description of Study Area

The study area is the eastern half of the San Joaquin Valley, which occupies the southern two-thirds of the Central Valley of California (Figure 1). The Central Valley is a large, northwest-trending, asymmetric structural trough

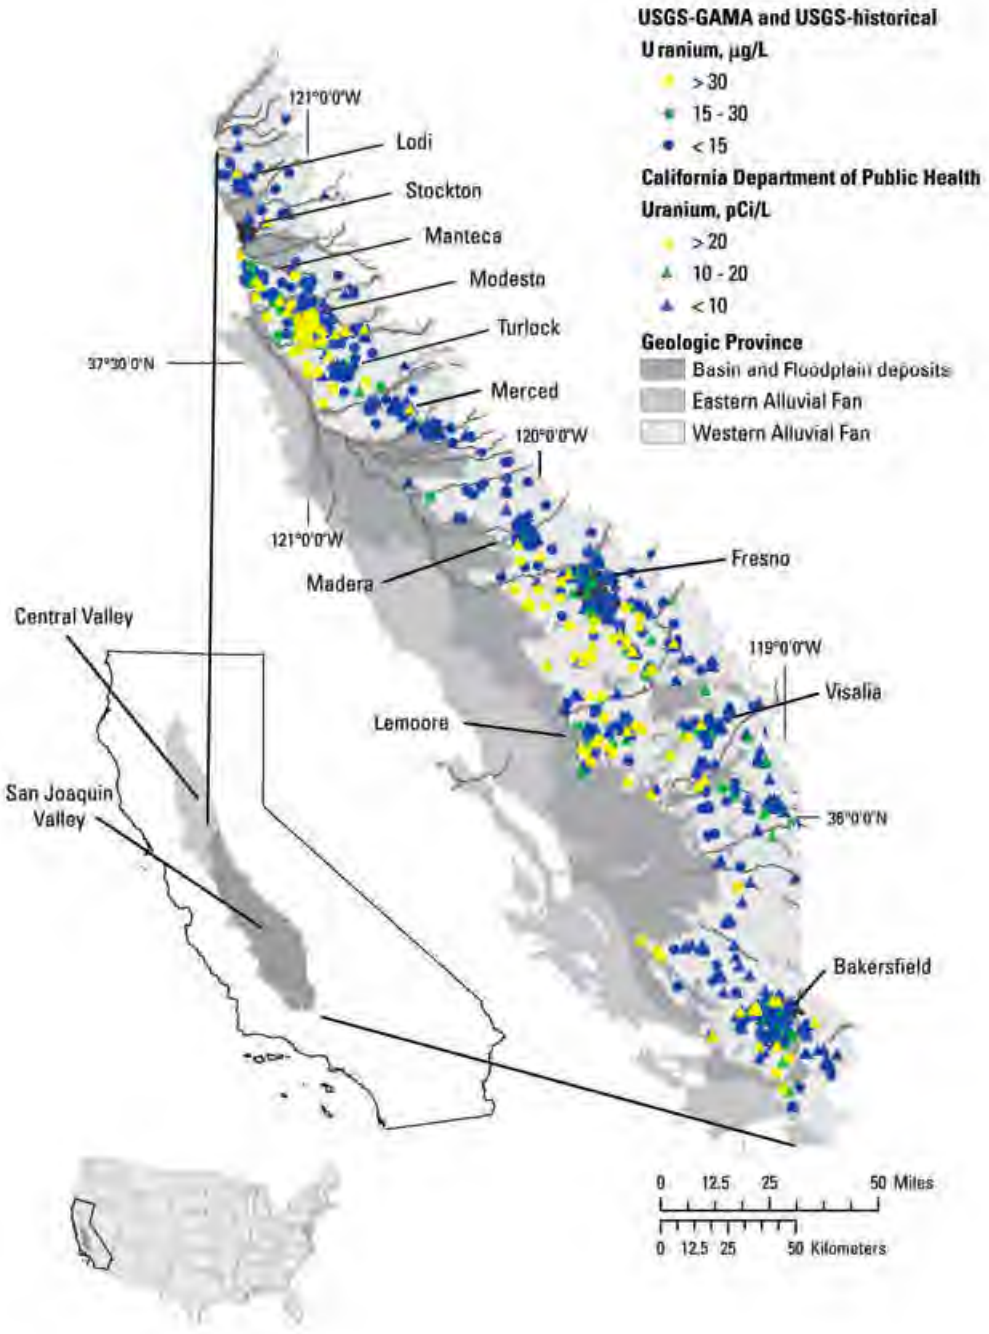

Figure 1. Location, physiographic features, and concentration of uranium in groundwater in the eastern San Joaquin Valley, California.

filled with marine and continental sediments up to 6 miles (mi) thick (Page 1986). The San Joaquin Valley is more than 248 mi long and 19 to 56 mi wide. East of the valley, the Sierra Nevada rise to an altitude of more than 8000 feet; west of the valley, the Coast Ranges form a series of parallel ridges up to 5000 feet high (Gronberg et al. 1998). Streams in the northern part of the San Joaquin Valley drain northward through the San Joaquin River to the San Francisco Bay; the southern part of the valley is a hydrologically closed basin.

Land-surface elevation rises from near sea level along the axial trough in the center of the valley to more than 300 feet at the top of dissected older alluvium near the valley margins. The climate is arid-to-semiarid, characterized by cool, wet winters and hot, dry summers. Mean annual precipitation ranges from less than 5 inches in the south to about 16 inches in the north (Gronberg et al. 1998).

Hydrogeology

Most groundwater withdrawals in the ESJV are from the upper 1000 feet of the basin-fill deposits. This part of the aquifer system mainly comprises a series of overlapping, stacked alluvial fan sequences deposited by streams draining the Sierra Nevada during the Holocene, Pleistocene, and Pliocene (Page 1986; Bartow 1991;

Weissmann et al. 2005). These unconsolidated to semiconsolidated deposits are primarily derived from granitic rocks of the Sierra Nevada, with minor contributions from metavolcanic and metasedimentary rocks of the foothills (Page 1986; Bartow 1991). Beneath these sediments, Miocene and Pliocene deposits of andesitic volcanic detritus occur in areas draining the central and northern parts of the Sierra Nevada (Burow et al. 2004).

The aquifer system can be generally described as an unconfined to semiconfined aquifer underlain by a confined aquifer, particularly where separated by a regional lacustrine clay unit commonly referred to as the Corcoran Clay (Williamson et al. 1989; Bertoldi et al. 1991). Aquifer materials are dominated by eastern and western alluvial fan deposits interspersed with fine-grained basin and floodplain deposits, and coarser-grained fluvial deposits (Figure 1).

Predevelopment Groundwater Flow

A numerical model of the predevelopment (prior to about 1850) groundwater flow system in the Central Valley suggests that recharge and discharge averaged about 2 million acre-feet/year (Williamson et al. 1989). The groundwater system was recharged primarily by streams entering the valley near the mountain fronts, and to a lesser extent by precipitation. Groundwater generally moved from areas of recharge along the valley margins toward the central low-lying areas in the basin, where artesian conditions were common. Groundwater in the northern half of the ESJV discharged to the San Joaquin River and surrounding marshlands, whereas groundwater in the southern half discharged to perennial lakes in closed basins.

Postdevelopment Groundwater Flow

Since 1850, diversion of surface water from streams and intensive groundwater pumping associated with agricultural irrigation and urban growth have significantly altered the natural flow system (Davis et al. 1959; Page and Balding 1973; Londquist 1981; Williamson et al. 1989). Development of the groundwater resource accelerated after about 1930 due to improvements to the turbine pump, which allowed farmers to pump groundwater from greater depths at greater rates (Williamson et al. 1989). Currently, percolating irrigation water is the primary form of groundwater recharge, and pumping is the primary form of groundwater discharge (Faunt 2009). Recharge and discharge are now approximately 12 million acre-feet/year (Faunt 2009).

The application of irrigation water and pumping from deep parts of the groundwater system have caused increased downward movement of groundwater. Williamson et al. (1989) simulated the predevelopment and postdevelopment groundwater flow system and found that vertical flow had increased by more than six times in many parts of the valley. In addition, repeated irrigation and pumping cycles can cause water moving laterally along the regional groundwater flow direction to be pumped and reapplied at the surface multiple times (Burow et al. 2004).

The widespread use of groundwater has caused water level declines in many parts of the valley and has greatly reduced the extent of artesian conditions. The depth-to-water table varies east-to-west and north-to-south. In the northern half of the valley, depth-to-water can be more than 60 feet near the valley margins in the east and less than 10 feet near the axial trough in the center of the basin. In the southern half of the valley, depth-to-water can be greater than 150 feet near the valley margins and less than 60 feet near the center of the basin (Faunt 2009). In urban areas, focused groundwater pumping and relatively low recharge rates have caused water level depressions within many cities in the valley (Bertoldi et al. 1991).

Methods

Description of Well Networks and Datasets

Between December 2004 and June 2008, 120 wells were sampled for U in the ESJV as part of the Priority Basin Project of the California Ground Water Ambient Monitoring and Assessment (GAMA) program (Bennett et al. 2006; Landon and Belitz 2008; Shelton et al. 2008, 2009; Burton et al. 2008). GAMA's Priority Basin Project is a statewide assessment of water quality in groundwater resources used for public supply in California (Belitz et al. 2003). The project is administered by the California State Water Resources Control Board and the USGS is the project's technical lead. Groundwater samples, primarily from PSWs, were collected for the GAMA program to assess groundwater quality in the ESJV. Samples for major ions, nitrate, and trace elements, including U, were collected from 120 wells. Additional wells were sampled by the GAMA program but were not analyzed for U. Tritium (^{3}H) and dissolved noble gas samples were analyzed from 83 of the 120 wells and carbon-14 (^{14}C) was collected from 88 wells. This dataset is referred to as USGS-GAMA.

Additional chemistry data were compiled from previous and ongoing USGS investigations in the ESJV, including the San Joaquin-Tulare Basin NAWQA program (Dubrovsky et al. 1998; Burow et al. 1998, 2008), the NAWQA Transport of Anthropogenic and Natural Contaminants project (Jurgens et al. 2008), and the San Joaquin Valley Drainage program (Fujii and Swain 1995). Combined, these sources provided data from 230 wells analyzed for major ions and trace elements since 1989 in the study area; these data are publically available in the USGS National Water Information System (NWIS) database (http://waterdata.usgs.gov/ca/nwis/). The median U concentration was used for wells that had more than one analysis. A subset of the wells also had tritium data. This dataset is referred to as USGS historical.

The CDPH maintains a database of water quality data collected from public-supply sources for regulatory purposes. The database contains U data for 941 wells sampled between 1986 and 2006. The maximum U

concentration from each well was used to describe the occurrence and distribution of high U in PSWs in the ESJV. Most of these wells were sampled for U more than once. Because U was not widely collected from wells between 1986 and 1990 (less than 10% of the total number of wells), recent U trends were examined with U data beginning on January 1, 1990, and ending on December 31, 2005 (16 years).

Sample Collection and Analysis

USGS-GAMA data were collected in accordance with the protocols established by the USGS NAWQA program (Koterba et al. 1995) and the USGS National Field Manual (USGS, variously dated). These sampling protocols ensure that a representative sample of the raw groundwater resource is collected from each well and that samples are collected and handled in a way that minimizes the potential for contamination. All public-supply well samples were collected at discharge points upstream of any chlorination or well-head treatment systems. Detailed descriptions of sample collection procedures, analytical methods, and quality-assurance results, and compilations of data can be found in Bennett et al. (2006); Burton et al. (2008); Landon and Belitz (2008); and Shelton et al. (2008, 2009). Historical chemistry data from other USGS investigations in the ESJV were collected and analyzed using the same or similar methods.

Samples for major ions, nitrate, uranium, and other trace elements were analyzed at the USGS National Water Quality Laboratory (NWQL) in Denver, Colorado. Carbon-14 was analyzed at the University of Waterloo and IsoTrace Laboratory (Ontario, Canada) by accelerated mass spectrometry. The activity of ^{14}C—expressed as percent modern carbon (pmc)—is reported with a one-sigma estimate of precision relative to the 1950 National Bureau of Standards oxalic acid standard. Samples for the noble gases, neon (Ne), argon (Ar), krypton (Kr), and xenon (Xe), were collected in copper tubes (25-cm-long, 3/8-inch [0.95] diameter) using reinforced nylon tubing connected to a hose bib at the wellhead. Copper tubes were flushed with groundwater and clamped at both ends to seal the sample. Tritium was collected in a 1-L glass bottle with each noble gas sample. Tritium, Ne, Ar, Kr, and Xe were measured at Lawrence Livermore National Laboratory (LLNL). Tritium was determined by the helium in-growth method (Bayer et al. 1989). Helium was analyzed using a VG-5400 noble gas mass spectrometer; dissolved Ne, Kr, and Xe were analyzed using a quadrupole mass spectrometer and argon was measured using a high-sensitivity capacitive manometer (Beyerle et al. 2000; Moore et al. 2006; Cey et al. 2008).

Uranium data reported in the CDPH database were collected for regulatory compliance, and California regulates U activity, rather than U mass concentration. Uranium results from the CDPH database were analyzed using standard radiochemical methods and reported in pCi/L (U.S. Environmental Protection Agency 1980). These data were assumed to be adequate for describing the occurrence, distribution, and trends in U concentrations in those PSWs having U analyses. The mass to activity conversion factor in groundwater depends on the activity of each U isotope, particularly the ratio of ^{234}U to ^{238}U. Because the U activity ratio (UAR) of ^{234}U to ^{238}U is not constant in groundwater, the mass to activity conversion factor varies. Therefore, U reported in activity units by the CDPH was not compared directly with U results reported in mass units by the USGS.

Nonparametric, rank-based methods were used for statistical analysis because the data were not normally distributed. The significance level (α) used for hypothesis testing was 5% ($\alpha = 0.05$). Correlations were investigated using Spearman's method to calculate the rank-order correlation coefficient (ρ, rho) between continuous variables. The Kruskal-Wallis rank sum test was used to test differences among groups (Conover 1980). If the Kruskal-Wallis rank sum test indicated a significant difference in more than two groups, the multiple stage Kruskal-Wallis test was used to determine whether a significant difference exists between successive groups (Helsel and Hirsch 2002). The significance level used for the multiple stage Kruskal-Wallis test was $\alpha_p = 0.025$. The signed-rank test was used to evaluate the differences in matched pairs of data.

Reduction/oxidation (redox) conditions were evaluated on the basis of dissolved oxygen (DO), nitrate (NO_3^-), manganese (Mn^{2+}), iron (Fe^{2+}), and sulfate (SO_4^{2-}) concentrations using the classification scheme of McMahon and Chapelle (2008). Because redox processes in groundwater tend to segregate into zones dominated by a single electron-accepting process, the redox framework uses the concentration of the redox sensitive species above to assign the predominant redox process to groundwater samples. An automated workbook program was used to assign the redox classification to each sample (Jurgens et al. 2009).

Recharge temperatures for 83 samples were determined from dissolved Ne, Ar, Kr, and Xe using methods described in Aeschbach-Hertig et al. (1999). Only modeled recharge temperatures having a probability greater than 1% were accepted ($P < 0.01$; Aeschbach-Hertig et al. 2000).

Speciation of dissolved U, calculated partial pressure of carbon dioxide (Pco_2), and saturation indices of U minerals and calcite in groundwater were calculated using PHREEQC, version 2.15 (Parkhurst and Appelo 1999). Data for the following species were included in the calculations: calcium, magnesium, sodium, potassium, chloride, alkalinity, sulfate, fluoride, nitrate, phosphate, barium, and strontium. Not all samples had nitrate, phosphate, barium, or strontium data, although more than 90% of the samples had data for each of these constituents. The LLNL thermodynamic database, included with PHREEQC, was modified for speciation calculations. Formation constants for U complexes were updated using thermodynamic data reported by Grenthe et al. (1992), and ternary complexes of uranyl and carbonate with the alkaline earth metals reported by Dong and Brooks (2006)

were added to the database. A two-site surface complexation model (SCM) was developed with the diffuse double layer model (Dzombak and Morel 1990) using PHREEQC. The surface species and formation constants for surface reactions were taken from Waite et al. (1994). The bidentate surface reaction expressions of Waite et al. (1994) were formatted for use with PHREEQC by Payne (1999) so that the mass action equation uses one mole of hydrous ferric oxide while the mole balance equation uses two. Model solutions contained 10^{-5} M U(VI) and aqueous U(VI) concentrations were calculated for pH values ranging from 6.25 to 9.5, the predominant pH range of ESJV groundwater. Moles of iron were estimated from ten 0.5 M HCl-hydroxylamine extractions (Jurgens unpublished data 2008). The average iron concentration was 80 mmol/L and was used to calculate site densities. The site densities were those of Waite et al. (1994): 0.8732 moles of weak sites per mole of iron and 0.0018 moles of strong sites per mole of iron. Three models were created for varying concentrations of total DIC: $10^{-3.0}$, $10^{-2.5}$, and $10^{-2.0}$ M. Each of these models had two forms: one without calcium and one with calcium at 1.2475 mmol/L (50 mg/L), a typical concentration in ESJV groundwater.

Land use was classified using an "enhanced" version of the satellite-derived (30-m pixel resolution), nationwide USGS National Land Cover Dataset (Vogelmann et al. 2001; Price et al. 2003). This dataset has been used in previous national and regional studies relating land use to water quality (Gilliom et al. 2006; Zogorski et al. 2006). The data represent land use during approximately the early 1990s. The imagery is classified into 25 land-cover classifications (Nakagaki and Wolock 2005). These 25 land-cover classifications were further classified into three principal land-use categories: urban, agricultural, and natural. Land-use statistics for circles with a radius of 500 m around each well were calculated for classified datasets using ArcGIS (version 9.2) (Johnson and Belitz 2009). Wells were then categorized by dominant land use. Mixed use was assigned where neither agricultural, urban, or natural land uses comprised more than 50% of the land surrounding the well.

Results and Discussion

Spatial Distribution of Uranium in Groundwater

Groundwater with high U content has been found throughout the ESJV (Figure 1). U concentrations for the 350 wells from the USGS-GAMA and USGS-historical datasets range from less than the detection limit (0.04) to 2,500 µg/L (Table 1). Approximately 19% of the wells (65 of 350) had a concentration greater than the US-MCL of 30 µg/L, and an additional 12% of the wells had U concentrations greater than one-half of the US-MCL.

PSWs from the CDPH database are not uniformly distributed across the ESJV and tend to be clustered in urban areas and along major transportation corridors (Figure 1). Approximately 11% (103 of 941) of the PSWs had at least one U analysis greater than the CA-MCL of 20 pCi/L, and an additional 5% of the wells had at least one U analysis greater than one-half of the CA-MCL. U concentrations ranged from less than the detection limit (1) to 102 pCi/L. Of the 941 CDPH wells, 848 wells remained active as of 2006. Twenty-three of the 93 inactive wells were abandoned because of high U concentrations.

Most of the U values greater than the CA-MCL in the CDPH dataset were in PSWs near Modesto, Fresno, and Bakersfield, major population centers in the ESJV. However, because the density of PSWs was also greatest in these areas, the clustering of high U values may reflect increased sample density. The USGS-GAMA and USGS-historical datasets show a wider distribution of wells with U concentrations above the US-MCL. USGS-GAMA wells were selected using a spatially distributed, randomized method (Scott 1990) to provide a statistically robust representation of the areal extent of the portion of the ESJV aquifer system used for public supply. The USGS-historical dataset was dominated by domestic and monitoring wells, which generally have perforation intervals in shallower portions of the aquifer than do PSWs. For example, the cluster of wells near Lemoore primarily includes monitoring and domestic wells. The USGS-GAMA and USGS-historical datasets therefore represent a larger portion of the aquifer system than the CDPH dataset, and show that groundwater with high U concentrations is indeed widespread in the ESJV.

The occurrence of groundwater with high U concentrations appears to be significantly greater in the ESJV than in other areas of the United States. In a recent survey of domestic wells in the United States (Focazio et al. 2006), U concentrations above 30 µg/L (US-MCL) were found in less than 4% of the wells (note that domestic wells are not subject to regulation). In contrast, 25% of the domestic wells in USGS-historical and USGS-GAMA datasets in the ESJV had U concentrations above the US-MCL.

High concentrations of U may not be as widespread as nitrate is in ESJV groundwater, which is above the US-MCL (10 mg/L as N) in 32% of domestic wells and 24% of all the wells in the USGS datasets. However, the percentage of wells affected by high U approaches that of nitrate and indicates that U does pose a significant threat to the continued operation of many PSWs in the ESJV.

Relation of Uranium Concentrations to Depth below Water Table and Age Tracers

The USGS-GAMA and USGS-historical datasets include well construction information and can therefore be used to estimate the vertical distribution of U within the aquifer system. Monitoring wells had the highest U concentrations, highest percentage of wells above the US-MCL, and the shallowest depths below the water table (Figure 2; Table 1). These wells are typically screened over short intervals (less than 5 feet) and provide water quality at discrete points in the aquifer system. Domestic wells, which tend to be located in rural areas, also had a high percentage of wells with U greater than 30 µg/L, but a lower median U concentration and greater depth

Table 1
Summary of Uranium Concentrations in Groundwater from Different Well Types in Eastern San Joaquin Valley, California; U.S. Geological Survey National Water Information System (NWIS)

Well Type	Number of Wells with U Analysis	Uranium (µg/L)			Number of Wells with U > 30 µg/L	Range in Depth below Water Table to Top of Uppermost Perforated Interval (feet)	Median Screen Length
		Minimum	Median	Maximum			
Observation	98	0.09	18.0	2500	31 (32%)	0.66–307 [55]	5
Domestic	122	0.04	8.7	503	30 (25%)	9.6–454 [82]	20.5
Public supply	121	0.04	1.8	41.3	3 (2.5%)	7.0–917 [140]	211
Irrigation	9	0.20	7.8	91.9	1 (11%)	42–557 [160]	175
All USGS data[1]	350	0.04	6.7	2500	65 (19%)	0.66–917 [98]	50

Notes: Percent of wells in parentheses. Median in brackets. [1]Uranium was not detected in six wells.

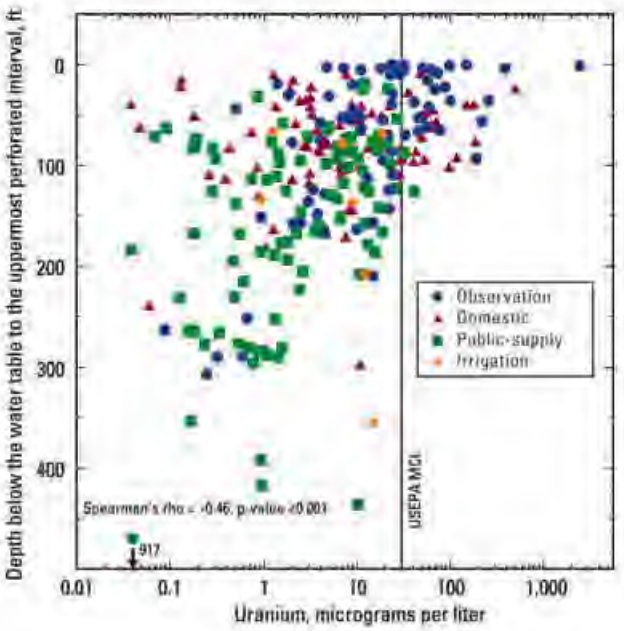

Figure 2. Relation between uranium in groundwater and depth below the water table to the uppermost perforated interval among well types in the eastern San Joaquin Valley, California.

below the water table than monitoring wells. PSWs had the lowest median U concentration. These wells tend to be located within urban areas, are perforated at deeper depths than monitoring and domestic wells, and generally have long screens (greater than 50 feet). PSWs in the ESJV typically withdraw water at rates between 200 and 2,500 gpm, much greater than those for domestic wells. Irrigation wells had the greatest depth below the water table of all the wells, but had higher U concentrations than PSWs. However, only nine irrigation wells were sampled for U in this study, and therefore may not accurately represent U concentrations in irrigation wells throughout the ESJV.

Uranium concentrations were significantly correlated to depth below the water table with the highest concentrations near the water table and decreasing with depth (Figure 2; Spearman's rho $= -0.46$, P-value < 0.001). Groundwater having U above 30 µg/L occurred in wells having perforated intervals beginning less than 150 feet below the water table, and most groundwater above 10 µg/L occurred in wells with perforated intervals starting less than 200 feet below the water table. Groundwater from less than 200 feet below the water table had a median U concentration of 8.4 µg/L; that from greater than 200 feet had a median U concentration of 0.73 µg/L.

Uranium concentrations also were significantly higher in wells with ^{3}H concentrations greater than 1 tritium unit (TU) and ^{14}C greater than 90 pmc (Kruskal-Wallis test; P-value < 0.001; Figure 3). ^{3}H activities greater than 1 TU indicate the presence of groundwater recharged after 1950 and ^{14}C activities greater than 90 pmc indicate the likely absence of groundwater with residence times greater than about 1,000 years. Together, these two age-dating criteria identify "modern" groundwater, that is, groundwater that was recharged since large-scale agricultural and urban development began in the ESJV. The median U concentration in groundwater samples with ^{3}H greater than 1 TU was 9.0 µg/L, compared with 0.60 µg/L for samples with less than 1 TU. Likewise, the median U concentration in groundwater samples with ^{14}C greater than 90 pmc was 7.2 and 0.93 µg/L for samples with less than 90 pmc. These results indicate that high U concentrations in the ESJV are preferentially associated with modern, shallow groundwater.

Uranium Mobilization

Source of Uranium

Uranium is naturally abundant in sediments in the ESJV, which are derived from granitic rocks of the Sierra Nevada. Aerial gamma-ray surveys of U in the ESJV show that U concentrations in surficial sediments range from 1.22 to 4.20 ppm and average about 3 ppm (Phillips et al. 1993). In contrast, surficial sediments of the conterminous United States have an average U concentration of 1.83 ppm. The average abundance of U in the ESJV is above the 90th percentile of U for surficial sediments of the United States. Because most of the geologic formations used for domestic and public

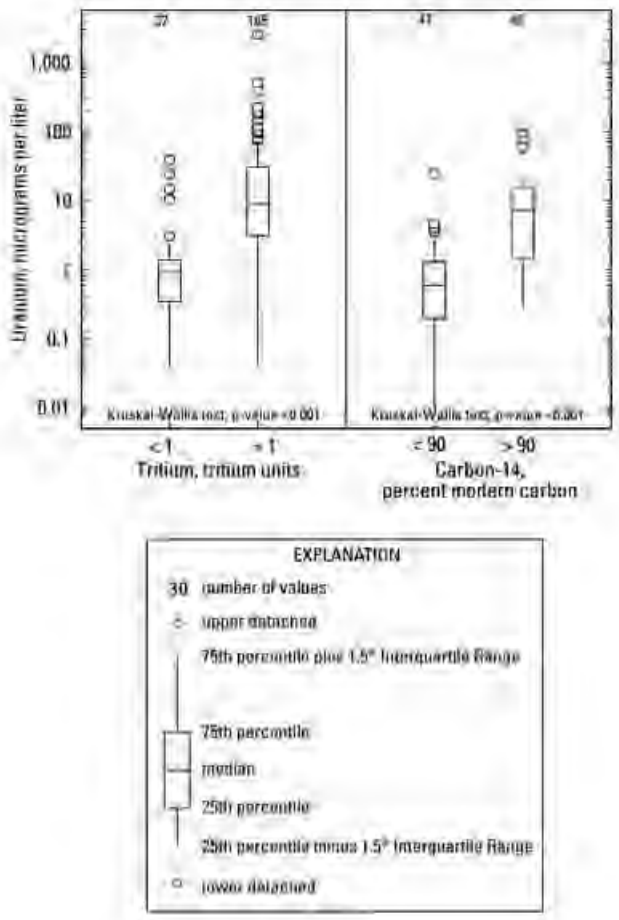

Figure 3. Uranium concentration in samples having tritium less than (<) 1 tritium unit (TU), tritium greater than (>) 1 TU, carbon-14 < 90 percent modern carbon (pmc), and carbon-14 > 90 pmc.

supply are also derived from the granitic rocks of the Sierra Nevada, it is probable that the concentration of U in aquifer sediments is similar to the concentrations in surficial sediments. However, the amount of U that may be easily mobilized is typically only a small fraction of the total U content of the sediment. This fraction is normally adsorbed to mineral surfaces on sediment grains, primarily iron oxide and oxyhydroxide coatings, and the edges of clay minerals (Hsi and Langmuir 1985; Waite et al. 1994; Davis and Curtis 2004; Catalano and Brown 2005).

Jurgens et al. (2008) measured the labile portion of U in sediments from core collected in Modesto (Figure 1). U was extracted from aquifer sediment samples using a 0.1-M sodium bicarbonate solution at a pH of 9.45 (Kohler et al. 2004). The labile portion of U in aquifer sediments ranged from less than 0.02 to 0.11 ppm (mg/kg), although the bulk U composition of the sediments was nearly constant. Leachates from the shallowest sediments (less than 60 feet below land surface [bls]) contained the least U, suggesting that some of the labile U had already been leached out. Leachates from the deepest sediments (greater than 200 feet bls) contained the most U, suggesting that deeper parts of the aquifer had not yet experienced leaching.

More strongly bound U was also extracted from sediments using 10% HNO_3 and ranged from 0.23 to 1.2 mg/kg and increased with depth below land surface (Spearman's rho = 0.75, P-value < 0.03; Jurgens et al. 2008). These results indicate that both the labile and more strongly bound fractions of U of shallow sediments have experienced leaching. Inorganic carbon was undetectable (less than 0.01%) in all sediment samples collected from the aquifer (Jurgens et al. 2008). Although calcite has been shown to host U in its structure (Kelly et al. 2006), the amount of U that could potentially be associated with undetectable levels of calcite in the aquifer would be minor in comparison to fractions associated with the labile and more strongly bound fractions.

Jurgens et al. (2008) also evaluated the potential for adsorption of U to aquifer sediments under similar pH values and bicarbonate concentrations found at the depths from which the sediment samples were collected. Adsorption experiments for the shallower sediments (less than 180 feet bls) showed no adsorption of U. In contrast, the deeper sediments (greater than 200 feet bls) showed linear type adsorption of U. The difference in adsorption behavior was not likely because of a difference in abundance of adsorption sites for U. Iron oxyhydroxide coatings on mineral grains (the primary location of absorption sites) were dissolved from sediment samples using 0.5 M HCl-hydroxylamine solutions, and the iron concentrations of resulting leachates did not vary systematically with sediment depth or U-adsorption behavior (Jurgens unpublished data 2008). These results suggest that higher U concentrations in shallower groundwater compared with deeper groundwater are because of differences in groundwater geochemistry with depth, not to reduction in the abundance of adsorption sites in the shallow sediments.

Mechanism of Mobilization—the Role of Bicarbonate

Three-hundred and ten of the 350 wells in the USGS-GAMA and USGS-historical datasets had data for DO concentrations; DO data are not compiled by CDPH. Approximately 86% (268 out of 310) of the groundwater samples had DO concentrations above 0.5 mg/L and were classified as oxic in the McMahon and Chapelle (2008) classification system. Median concentrations of DO, NO_3^-, Mn^{2+}, Fe^{2+}, and SO_4^{2-} in ESJV groundwater were 4.5, 4.8, < 0.02, < 0.1, and 22.7 mg/L respectively. Uranium in oxic groundwater had a median concentration of 6.5 µg/L. Uranium was significantly lower in anoxic groundwater (median = 0.93 µg/L; multiple stage Kruskal-Wallis rank sum test, P-value = 0.003). The reduced mobility of U under reducing conditions is likely because of reduction to U(IV) and the low solubility of U(IV) phases. Anoxic conditions occurred in less than 6% of wells and were mostly found in wells located near the basin and floodplain deposits (Figure 1). It is possible that some of the extremely high occurrences of U near the center of the basin was caused by the oxidation of U(IV) minerals as a result of irrigation and groundwater pumping; although past studies have attributed some of the high U occurrences in shallow wells in and near the center of

the basing to evaporative concentration (Fujii and Swain 1995). However, remobilization of U from redox fronts in the system does not appear to cause the vast majority of high U concentrations in groundwater. About 8% of wells had mixed redox conditions, where DO > 0.5 mg/L and manganese or iron was above 50 µg/L. Wells with mixed redox conditions had a wide range of U concentrations (0.04 to 503 µg/L; median = 16.0 µg/L). However, wells in the eastern alluvial fans that represent the bulk of the used groundwater resource in the ESJV were generally oxic.

Dissolved U species in oxic groundwater samples (262 oxic wells had measurable U) were calculated using PHREEQC. More than 85% of the dissolved U in almost all groundwater samples was in the form of ternary complexes of uranyl carbonate with calcium ($Ca_2UO_2(CO_3)_3^0$, $CaUO_2(CO_3)_3^{-2}$) and was primarily in the form of the neutral calcium-uranyl-carbonate complex. Calcium-uranyl-carbonate species comprised less than 50% of the dissolved U in just 2% of the oxic groundwater samples. Phosphate complexes comprised less than 1% in all groundwater samples. Speciation calculations indicate that magnesium-uranyl complexes are present ($MgUO_2(CO_3)_3^{-2}$), but generally comprise about 1% and at most 5% of dissolved U.

Strong correlations between U and bicarbonate (Figure 4; Spearman's rho = 0.74, P-value < 0.001) and U and calcium (Spearman's rho = 0.77, P-value < 0.001) concentrations are consistent with speciation calculations. Although the species is a complex between uranyl and the carbonate anion, the formation of the species is likely between uranyl and any one of the three inorganic carbon ions ($H_2CO_3^{0*}$, HCO_3^-, CO_3^{-2}). The predominant form of DIC species in water is pH dependent. Groundwater from this study had pH values that ranged from 6.7 to 9.7 (median pH = 7.6), and bicarbonate is the principal form of DIC in that pH range (Appelo and Postma 1996).

$$UO_2^{+2} + 2Ca^{+2} + 3HCO_3^- \leftrightarrow Ca_2UO_2(CO_3)_3^0 + 3H^+$$
$$\log K = -0.29 \text{ (modified from Dong and Brooks [2006])}$$

Calcium in groundwater is mostly a result of the dissolution of minerals in the soil zone and partly from the application of soil amendments and fertilizers at the land surface. Calcium is present in all sediments, primarily as plagioclase feldspar, and most soils contain some calcite. In many agricultural parts of the valley, gypsum is often added to irrigated soils to promote infiltration and nitrate fertilizers often contain calcium (Jurgens et al. 2008).

Strong correlations between U and bicarbonate and the results of the U extractions indicate that high concentrations of U in shallow groundwater were at least partially mobilized from adsorption sites from shallow sediments. Adsorption of U to sediments is mainly dependent on pH and the concentration of DIC (Hsi and Langmuir 1985; Waite et al. 1994; Davis et al. 2004). Calculations from

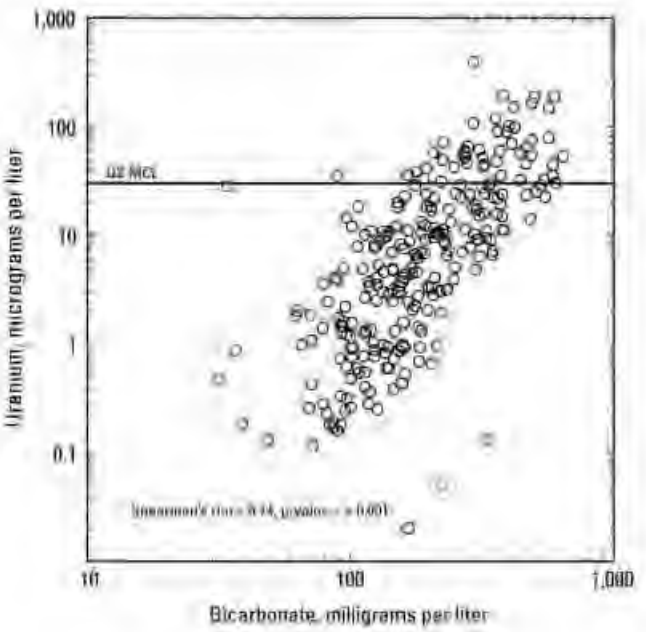

Figure 4. Relation between uranium and bicarbonate in oxic groundwater in the eastern San Joaquin Valley, California.

PHREEQC predict that U(VI) minerals are highly undersaturated in the 262 groundwater samples, suggesting that U concentrations are most likely controlled by adsorption processes. Adsorption of U(VI) is strongest at near circumneutral pH values while high pH values tend to weaken adsorption of U(VI). However, high concentrations of DIC can limit the adsorption of U. In the ESJV, U decreases with increasing pH (Spearman's rho = −0.23, P-value < 0.001; Figure 5). Consequently, U is highest in groundwater with more neutral pH values and higher concentrations of DIC, whereas groundwater with low U tends to have higher pH values and lower concentrations of DIC.

To demonstrate the effect that DIC has on U(VI) adsorption, the SCM of Waite et al. (1994) was used to calculate the dissolved U(VI) concentrations at different total DIC concentrations and pH values observed in groundwater (Figure 5; dashed lines). Dissolved U(VI) was at least an order of magnitude greater in the presence of high concentrations of DIC (0.01 M) than at lower concentrations of DIC (0.001 M). However, the SCM tended to underpredict U(VI) concentrations in groundwater at high concentrations of DIC. Fox et al. (2006) showed that the presence of calcium in solution can also reduce the adsorption of U(VI) to iron oxyhydroxides under conditions that favor the formation of the neutral calcium-uranyl-carbonate complex, $Ca_2UO_2(CO_3)_3^0$. By including a typical calcium concentration (50 mg/L) in each model, the predicted behavior of U(VI) in equilibrium with iron oxyhydroxides is remarkably similar to U and DIC concentrations observed in ESJV groundwater, especially for higher concentrations of U(VI) and DIC (Figure 5;

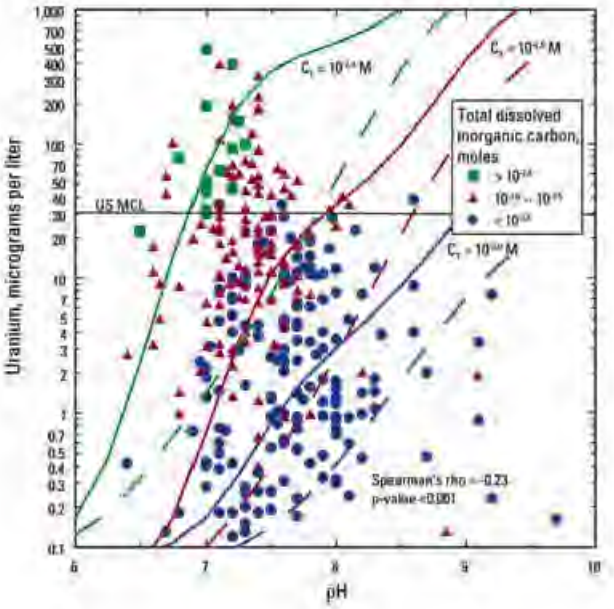

Figure 5. Relation between pH and uranium [U(VI)] in groundwater in the eastern San Joaquin Valley, California. Symbols are colored according to the concentration of total dissolved inorganic carbon (DIC). Dashed lines are equilibrium concentrations of dissolved U(VI) from a surface complexation model (SCM) based on the work of Waite et al. (1994). Solid lines are equilibrium concentrations of U(VI) from the same SCM with a calcium concentration of 1.2475 mmol/L. Each line color represents the equilibrium concentration of U(VI) for different concentrations of total DIC. $T = 25°C$; $I = 0.1$ M; U(VI) total = 0.01 mmol/L; Fe = 80 mmol/L (average concentration of 10 aquifer core samples using 0.5 M HCl-hydroxylamine extraction). Site densities were from Waite et al. (1994): total sites 0.875 moles/mole of Fe; strong sites = 0.0018 moles/mole of Fe; and weak sites = 0.8732 moles/mole of Fe.

solid lines). These results are also consistent with speciation calculations that predict the calcium-uranyl-carbonate species to predominate in ESJV groundwater.

Long-Term Bicarbonate Trends and Relation to Land Use

Comparison between data from Mendenhall et al. (1916) and data from the USGS-GAMA and USGS-historical datasets showed that concentrations of bicarbonate in ESJV groundwater have increased over the last 100 years (Figure 6). In 1910, the median bicarbonate concentration of groundwater in the ESJV was 119 mg/L. The median bicarbonate concentration from this study was 178 mg/L and is statistically greater than concentrations in 1910 (Kruskal-Wallis rank sum test, P-value < 0.001).

Wells from 100 years ago were typically shallower. The median well depth in Mendenhall's dataset was 95 feet compared to 205 feet in this study. Of course, the water table was not as deep 100 years ago as it is in many parts of the valley today. Most wells 100 years ago were probably perforated in shallower parts of the groundwater system than modern wells because of construction limitations and because the yield and quality of groundwater at those depths were sufficient for most purposes (Mendenhall et al. 1916).

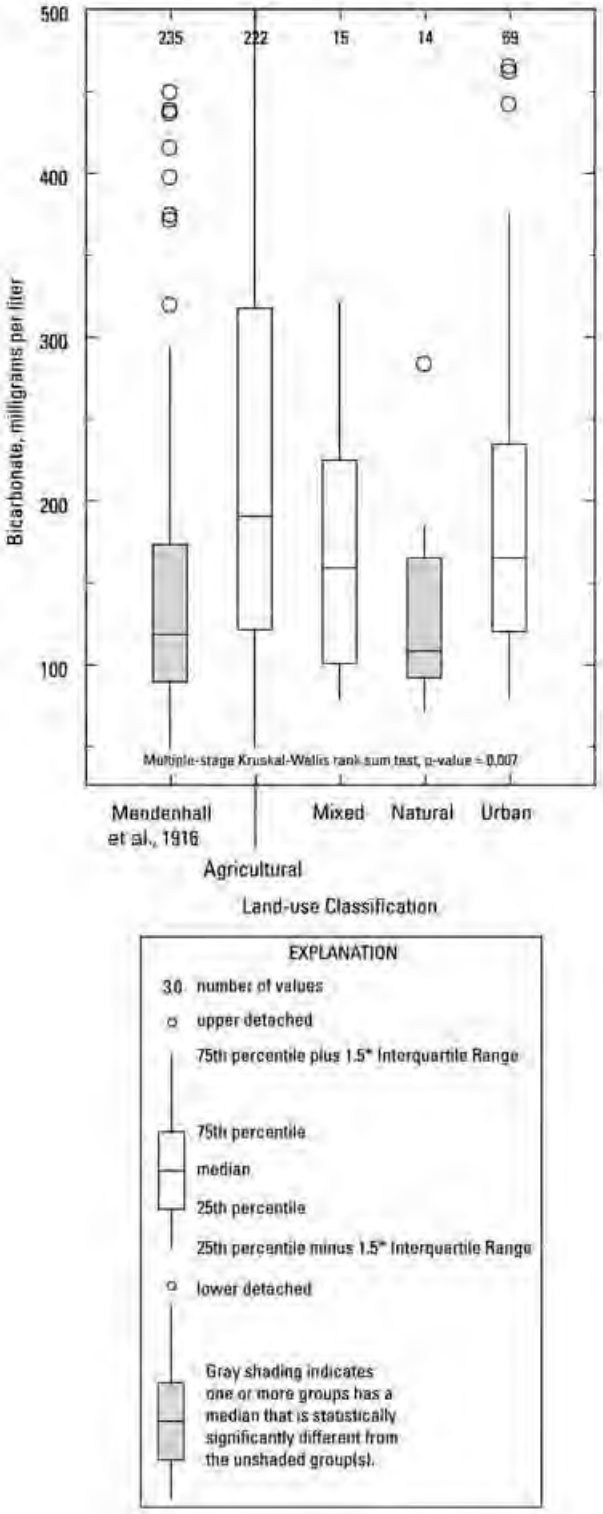

Figure 6. Bicarbonate concentrations in groundwater in 1910 (Mendenhall et al. 1916) and from this study (GAMA + USGS historical [since 1989]) among different land uses surrounding the wells in the eastern San Joaquin Valley, California. The mixed use category was assigned to wells where neither agricultural, urban, or natural land uses were more than 50% of the land surrounding the well.

The increase in bicarbonate concentration over the last 100 years is related to land-use patterns. Bicarbonate concentrations in wells surrounded predominantly

by natural land use (median = 108 mg/L) and in wells sampled in 1910 (median = 119 mg/L) were significantly lower than bicarbonate concentrations in wells surrounded predominantly by agricultural (median = 191 mg/L), urban (median = 166 mg/L), and mixed (median = 160 mg/L) land uses (Figure 6) (multiple stage Kruskal-Wallis rank sum test, P-value < 0.001). Although many of the wells sampled in 1910 were in agricultural areas, large-scale irrigation had not yet been developed, and thus water use on the landscape more closely resembled natural conditions.

Urban areas in the ESJV are typically surrounded by agricultural land, and urban groundwater pumping is areally concentrated. Consequently, bicarbonate concentrations beneath urban areas are likely affected by adjacent agricultural land use, which tends to be associated with higher bicarbonate concentrations.

Connection between Increased Bicarbonate Concentrations and Irrigation

The relations between bicarbonate concentrations, Pco_2, recharge temperature, and depth in groundwater in the ESJV suggest that high bicarbonate concentrations in shallow groundwater are the result of groundwater recharge by water that has percolated through irrigated soils. Pco_2 in the soil zone can range from equal to atmospheric Pco_2 (0.035%) to greater than 100 times atmospheric Pco_2, and is generally positively correlated with soil moisture, soil temperature, and plant growth (e.g., Russell 1973). In arid to semiarid climates, plant growth and microbial decomposition of soil organic matter are generally limited by low soil moisture. Addition of water via precipitation or irrigation results in a rise in biological activity and thus a rise in soil zone Pco_2.

Equilibrium Pco_2 values were calculated from groundwater major ion chemistry and pH data using PHREEQC. Groundwater Pco_2 ranged from 0.1 to 430 times atmospheric Pco_2 and decreased with depth below the water table (Spearman's rho = −0.51, P-value < 0.001; Figure 7). Most groundwater within 50 feet of the water table had Pco_2 pressures greater than 40 times atmospheric Pco_2, indicating that the biological activity within the soil zone has influenced the chemistry of recent recharge.

In addition, Pco_2 pressures were higher in groundwater beneath agricultural land than in groundwater beneath other land uses (multiple stage Kruskal-Wallis rank sum test, P-value < 0.001; Figure 7). The median Pco_2 pressure for groundwater beneath agricultural land was $10^{-2.1}$ atmospheres (atm) or approximately 22 times atmospheric concentrations. The median Pco_2 pressure for groundwater beneath other land uses was $10^{-2.5}$ atm or approximately nine times atmospheric concentrations. pH was not collected in data from Mendenhall et al. (1916), and therefore, Pco_2 pressures could not be directly compared. However, groundwater beneath natural land had similar bicarbonate concentrations to groundwater from 100 years ago and Pco_2 pressures beneath natural land were lowest among all land uses (median = $10^{-3.0}$ or approximately three times atmospheric concentrations). Therefore, the increase in bicarbonate concentrations in shallow groundwater over the last 100 years likely resulted from recharge water having higher Pco_2 pressures as a result of irrigation.

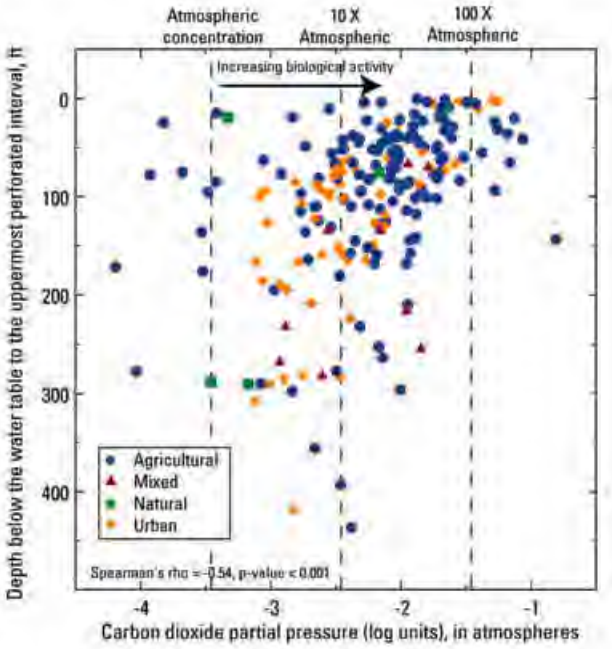

Figure 7. Relation between calculated equilibrium carbon dioxide partial pressures in groundwater and depth below the water table to the uppermost perforated interval in the eastern San Joaquin Valley, California.

Higher Pco_2 pressures can also cause the dissolution of carbonate minerals, namely calcite, within the soil zone (Appelo and Postma 1996). Calcite is present in most soils in the ESJV, but is generally much less than 5% (Schoups et al. 2005) and calcite was below detectable levels (0.01%) in core from Modesto, California (Jurgens et al. 2008). Bicarbonate and calcium (and uranium) were correlated with increasing calcite saturation (log ratio of the ion activity product to the equilibrium solubility constant). Most groundwater with elevated and high concentrations of U (U > 15 µg/L) was saturated with calcite (median = 0.13), whereas groundwater with lower U concentrations (U < 15µg/L) was mostly undersaturated (median = −0.16). The dissolution of calcite under high Pco_2 pressures could give rise to increases in bicarbonate and calcium concentrations with concomitant high calcite saturation in recharge water. Recent research also shows that calcite can accommodate uranyl in its structure and that the occurrence of uranyl in calcite formed in near-surface environments may be more common than previously thought (Kelly et al. 2006). Although the amount of U from soil calcite that would potentially contribute to groundwater is unknown, extraction results and extremely low abundance of calcite in the aquifer sediments suggest that calcite dissolution may not be an important source of

U to groundwater. Furthermore, the results of the extraction experiments indicated that the amount of U mobilized from adsorption sites would likely be sufficient to account for the increase in dissolved U concentrations in groundwater.

Higher recharge temperatures, calculated from dissolved noble gas concentrations, are associated with higher Pco_2pressures (and bicarbonate) in groundwater (Spearman's rho = 0.49, P-value $\leq$ 0.001; Figure 8). Calculated median recharge temperatures were one degree higher (18.8°C) for wells surrounded by agricultural land than for those surrounded by urban, natural, and mixed land (multiple stage Kruskal-Wallis rank sum test, P-value $<$ 0.02). High recharge temperatures and high Pco_2 pressures are consistent with recharge derived from summer irrigation, as would be found in agricultural areas in the ESJV. Under natural conditions, recharge occurred almost entirely during winter months (November through May) and therefore recharge temperatures were likely more influenced by winter air temperatures. Most of the recharge now occurs from the application of irrigation water during the summer months when air temperatures are highest.

Recharge temperatures and Pco_2 pressures were positively correlated to total dissolved solids (TDS) and $\delta^{18}O$. As stated earlier, the acidity derived by the rise in Pco_2 pressures in the soil zone is buffered by the dissolution of minerals (mainly plagioclase), such that the primary products are an increase in pH, formation of bicarbonate, and addition of cations to the residual water. Consequently, higher Pco_2 pressures will tend to lead to increases in these weathering products and in the overall TDS of the water. Calculated Pco_2 pressures (and U) were correlated with all of the major cations in ESJV groundwater. TDS has also increased in the last 100 years. The median TDS in wells from 1910 was 210 mg/L and was 311 mg/L in the USGS-GAMA and USGS-historical dataset (Kruskal-Wallis rank sum test, P-value $<$ 0.001). Correlations with $\delta^{18}O$ also suggest that the increase in bicarbonate concentrations may be partly because of evaporation of irrigation water during the summer growing season; although strong evaporation trends were not evident from stable isotope values.

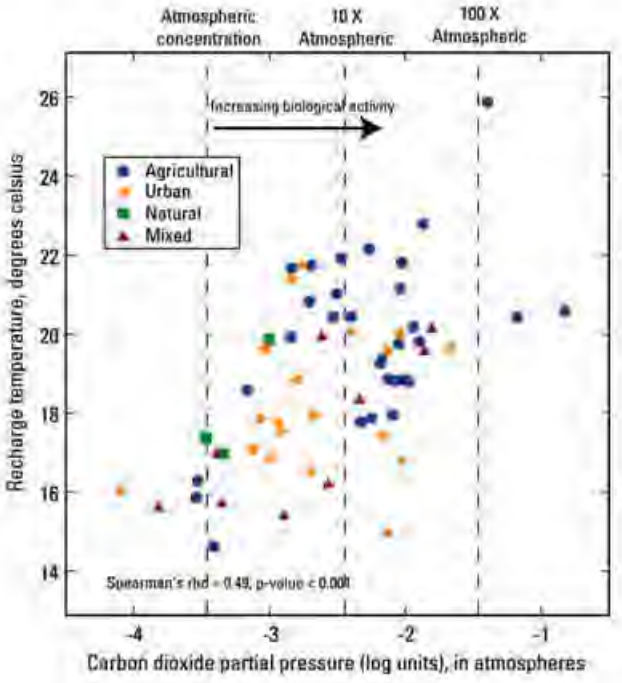

Figure 8. Relation between recharge temperature and the partial pressure of carbon dioxide in groundwater beneath different land-use settings in the eastern San Joaquin Valley, California.

Recent Uranium Trends

Recent U trends in wells from the CDPH database were evaluated using data for wells that were sampled from January 1, 1990, to December 31, 2005. This time period provided an even split in years (8), and similar number of wells analyzed during the two time periods (Table 2). For wells with more than one U analysis, the median activity from each well was used to calculate population statistics. The number of wells having at least one U sample above the CA-MCL of 20 pCi/L increased from 38 for samples collected from 1990 to 1998 to 56 from 1998 to 2006 (Table 2).

U data were available in both time periods for 317 wells. The median activity of U in these wells increased from 4.3 pCi/L between 1990 and 1998 to 5.0 pCi/L between 1998 and 2006 (signed-rank test, P-value $<$ 0.001). The average change in concentration was 1.2

Table 2
Summary of Uranium Concentrations in Groundwater from Public-Supply Wells Sampled between 1990 and 2006 in Eastern San Joaquin Valley, California; California Department of Public Health

		Uranium (pCi/L)			
Uranium Date Range	Number of Wells	Minimum	Median	Maximum	Number of Wells with U > 20 pCi/L
1990–2006	848	<1	3.7	63.9	81 (9.6%)
1990–1998	556	<1	3.6	49.4	38 (6.8%)
1998–2006	610	<1	4.2	102	56 (9.2%)

Note: Percentage of wells in parentheses.

pCi/L. U activity increased by more than 0.2 pCi/L in 53% of the wells, decreased by more than 0.2 pCi/L in 35% of the wells, and changed by less than 0.2 pCi/L in the remaining 12% of wells. These results indicate that U has increased in the majority of PSWs in the ESJV. Bicarbonate concentrations in paired samples also increased for the same time period by about 2.7 mg/L. Wells that had increased U concentrations had a median increase in bicarbonate of 6.3 mg/L, whereas wells that had decreased U concentrations had a median decrease in bicarbonate of 1.6 mg/L. These results indicate that increased U concentrations are accompanied with increased bicarbonate concentrations.

The median U concentration for unpaired samples also increased over the 16-year period (Table 2). The median for these samples increased by 0.6 pCi/L for the time period evaluated.

Conclusions

Development of the groundwater resource since the 1850s has caused two major changes that have resulted in uranium concentrations above drinking water standards in domestic and PSWs in the ESJV: (1) changes in the chemistry of recharge water and (2) increases in the rate of downward groundwater flow.

ESJV sediments have comparatively high concentrations of uranium and a fraction of this uranium is readily leachable by bicarbonate solutions. Uranium is strongly correlated with calcium and bicarbonate, the principal form of DIC in groundwater. Speciation calculations indicate that the primary form of U in oxic groundwater is a calcium-uranyl-carbonate complex. The results of the U extractions and co-occurrence of elevated concentrations of U, bicarbonate, and calcium are consistent with results from the SCM, suggesting that U likely has been leached from adsorption sites on mineral surfaces in sediment. Because bicarbonate concentrations have increased over the last 100 years, it is reasonable to assume that dissolved U has also increased during this period.

The increase in bicarbonate in groundwater over the last 100 years is primarily related to the agricultural development of the ESJV. Bicarbonate concentrations in groundwater have increased in response to an increase in recharge and the growth of crops in agricultural areas and, to lesser extent, the growth of landscape plants and grasses in urban areas. Both recharge and the growth of crops occur mostly during the summer growing season when temperatures are warmest. Consequently, groundwater beneath agricultural land tends to have higher recharge temperatures and higher P_{CO_2} pressures. Ultimately, the increase in bicarbonate concentrations in recharge water has led to the widespread occurrence of high U in shallow groundwater.

Groundwater pumping, primarily from deeper parts of the aquifer system, and increased recharge from the application of irrigation water have increased the downward movement of groundwater. Consequently, constituents that enter the groundwater system at shallow depths are moved downward at a faster rate than would be expected under natural conditions. Shallow high U groundwater has thus moved downward, resulting in increasing U in PSWs. The overall increase in the median U concentration for all wells is small (0.6 pCi/L), but the percentage of wells with at least one U analysis greater than 20 pCi/L (CA-MCL) has increased from 7% to 9% in just 16 years. Continued irrigation and pumping in the ESJV will likely be followed by additional U increases in PSWs.

This paper also shows that irrigation and development of lands for agricultural and urban uses can mobilize inorganic contaminants that may otherwise be sequestered under natural conditions. The results of this paper therefore could have broader implications for other agriculturally based arid and semiarid regions around the world.

Acknowledgments

This work was supported by the California State Water Resources Control Board with help from landowners and water purveyors throughout the San Joaquin Valley. We thank the three anonymous reviewers for their constructive comments and helpful suggestions. Major improvements also resulted from reviews by Robert A. Zielinski and Steven P. Phillips. We also thank David L. Parkhurst for his helpful guidance with the surface complexation model used in this paper.

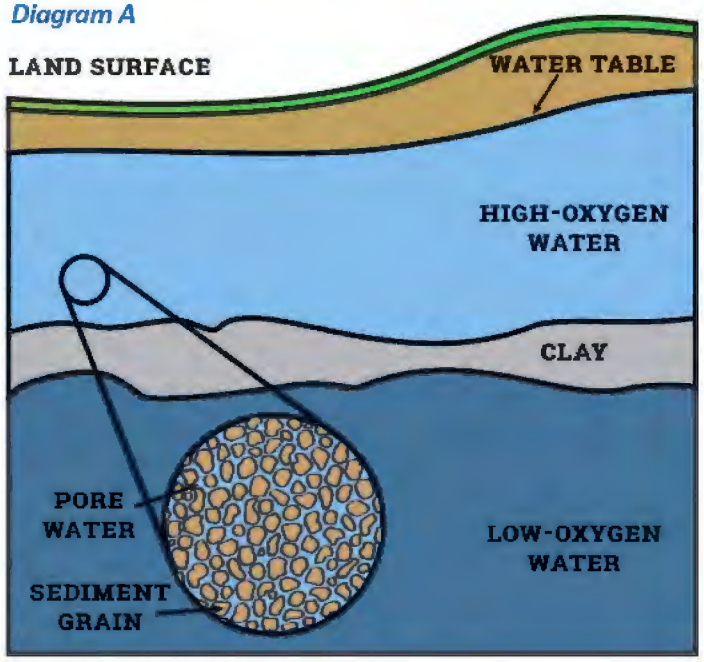
Groundwater Quality in the Sustainable Groundwater Management Act (SGMA):

Scientific Factsheet on Arsenic, Uranium, and Chromium

Groundwater is an important resource that we depend on to drink, bathe, grow food, and more. Through the implementation of the Sustainable Groundwater Management Act (SGMA) local groups called Groundwater Sustainability Agencies (GSAs) are developing Groundwater Sustainability Plans (GSPs) that indicate how they will manage groundwater in their area. One requirement of the Groundwater Sustainability Plans is to *"avoid significant and unreasonable degradation of groundwater quality"* (Water Code Section 10721(x)(4)).



Groundwater can become contaminated through the use of human-made chemicals, fertilizers, or improperly managed waste facilities. Groundwater contamination can also occur naturally from elements in soils and sediments (See Box 1). Some elements naturally present in rocks are toxic and harmful to health when they are dissolved in water, sometimes even at low concentrations. The most widespread of these metals are **arsenic** and **uranium. Chromium** is also of concern, primarily in a specific form (hexavalent chromium).

This factsheet explains how three elements — arsenic, uranium, and chromium — enter groundwater from soils and sediments, and how to address these already present impacts and work to prevent, limit, or reverse issues related to these contaminants. If you know these contaminants are present in your groundwater basin, we recommend you encourage your Groundwater Sustainability Agency to invest in additional monitoring and management practices to keep from worsening the problem. This factsheet provides illustrations based on recent scientific research to inform the design of those monitoring and management programs. For more information about best management practices for addressing drinking water in Groundwater Sustainability Plans, review Community Water Center's ***Protecting Drinking Water Under SGMA Guide.***

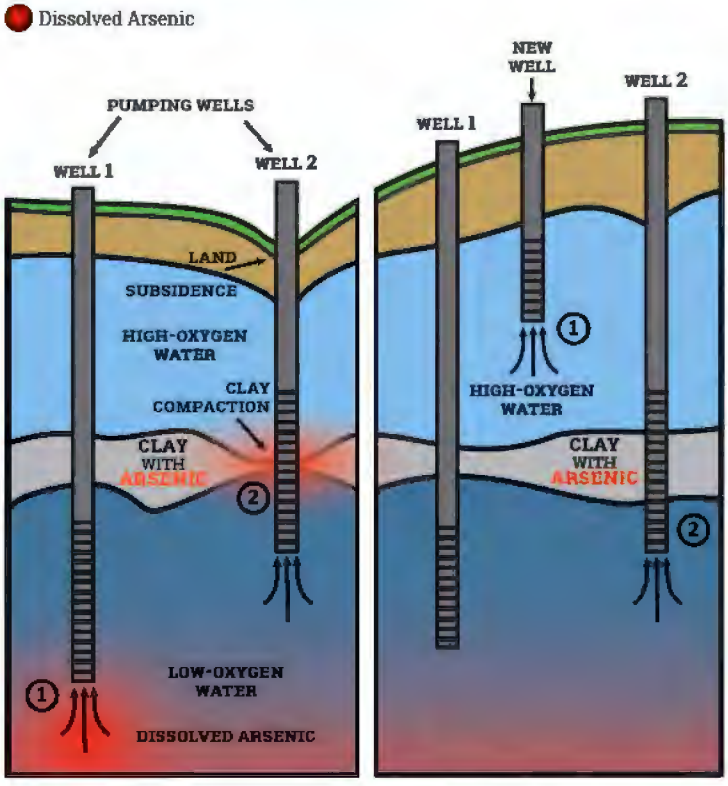
What Is Groundwater? How Can Naturally Occurring Metals Like Arsenic and Uranium Enter Groundwater?

Groundwater is water that exists below the earth's surface, either in the space between grains of sand, gravel, and clay, or in the fractures of solid rocks. The layers of rock and sand that contain groundwater are called aquifers *(Diagram A)*. Underground sediments and rocks contain many different minerals and metals, either attached to the surface of the grain, or as part of the sediment/rock itself. Under certain conditions, these minerals and metals can move into the groundwater, or become dissolved.

Diagram A

There are many conditions that affect and accelerate the movement of metals from rocks into groundwater including the pH (level of acidity) and the amount of dissolved oxygen in the water. Changes in pH and oxygen can lead to higher concentrations of dissolved metals in groundwater but each metal responds differently to these conditions.

Importance of Monitoring and Using Groundwater Information to Manage Groundwater Quality:



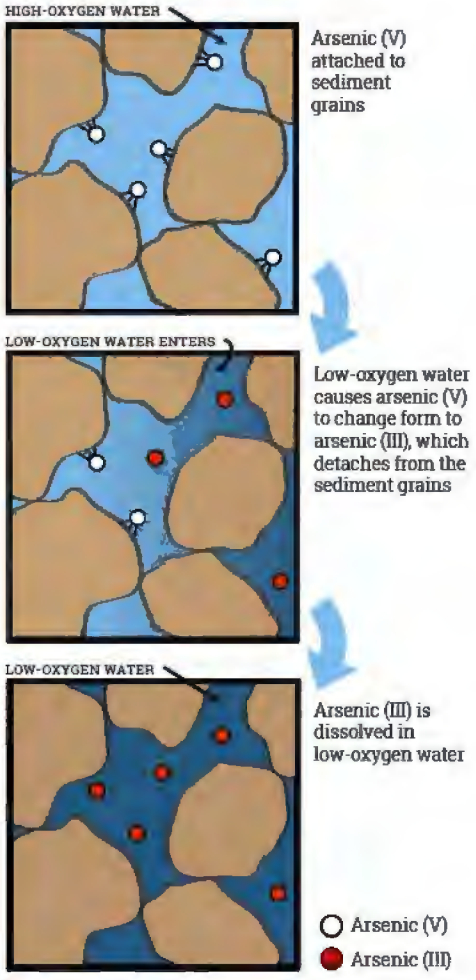
Many of the factors that cause naturally occurring contaminants to enter groundwater can be prevented or mitigated using a robust groundwater monitoring and information gathering strategy. Determining the best management technique often requires some trial-and-error. Recommendations include:

- Regularly measure levels of naturally occurring contaminants (arsenic, uranium, and chromium) in well as the conditions that can cause contamination (changes in pH, dissolved oxygen, nitrate, and electrical conductivity)
- Evaluate groundwater flow paths (for example, through the use of groundwater tracer tests) to know where contaminated water may travel over time, and use this information to strategically install monitoring wells that are upgradient of supply wells.
- Use well logs during well installation to ensure screen intervals are a maximum distance from clay layers.

ARSENIC *(Diagram B)*

PROBLEMS	SOLUTIONS
Low-oxygen conditions *(Diagram C)* When an aquifer becomes low in oxygen (~1% or lower dissolved oxygen), bacteria will dissolve the iron minerals that contain arsenic, and the arsenic itself will also change forms (from the molecule arsenate to arsenite). The outcome is an increase in dissolved arsenic in the groundwater. This is the most common cause of arsenic contamination of groundwater.	For a new well design or a well modification, avoid drawing groundwater from low oxygen zones if there is a concern about arsenic in that area.
Over-pumping Most wells draw groundwater from aquifers made of sand and gravel sediments, where water can be pumped out of the spaces between sediment grains. Aquifers can also have clay layers that may contain low-oxygen conditions and dissolved arsenic. When an aquifer is over-pumped, the clay layers can be compressed, squeezing the water with arsenic out from the clay and into the main aquifer.	Avoid over-pumping from confined aquifers to the point of clay compression (subsidence). Avoid drilling wells in aquifers with high clay content, or where pumped water may draw from clays containing arsenic.
An increase in pH When the pH of groundwater goes above 8.5, arsenic is displaced from mineral surfaces and dissolves into the groundwater.	Limit drawing from groundwater with pH greater than 8.5.

Diagram B: Problems and Solutions



PROBLEMS

1. Low-oxygen conditions cause arsenic to dissolve into water pumped by Well 1.
2. Well 2 pumps at a high flow rate, causing the clay with arsenic to compact and high-arsenic pore water is "squished" out.

MANAGEMENT SOLUTIONS

1. New well drilled in an area with high-oxygen water and low dissolved arsenic.
2. Well 2 uses a lower flow rate, which stops high-arsenic water from coming out of the clay.

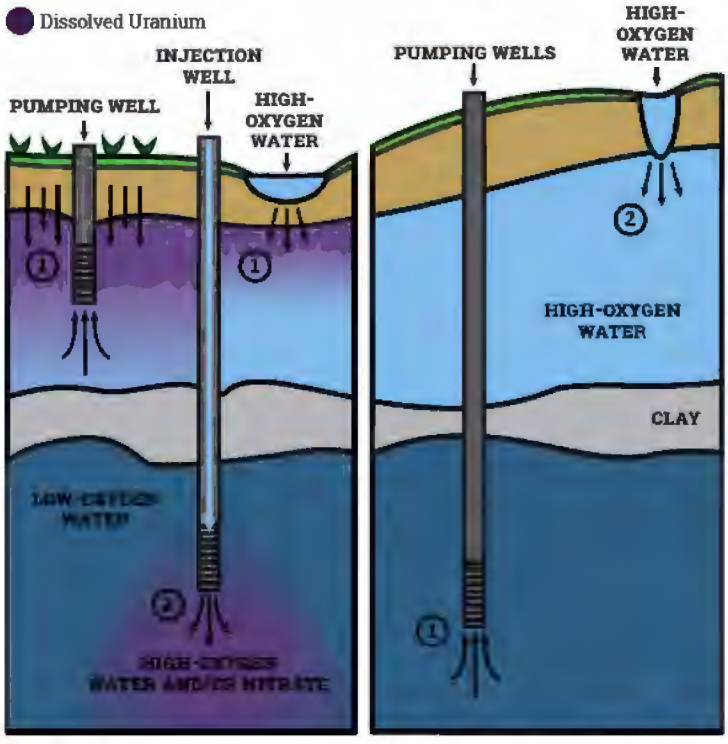


Diagram C: Arsenic dissolves in low-oxygen water (desorption)

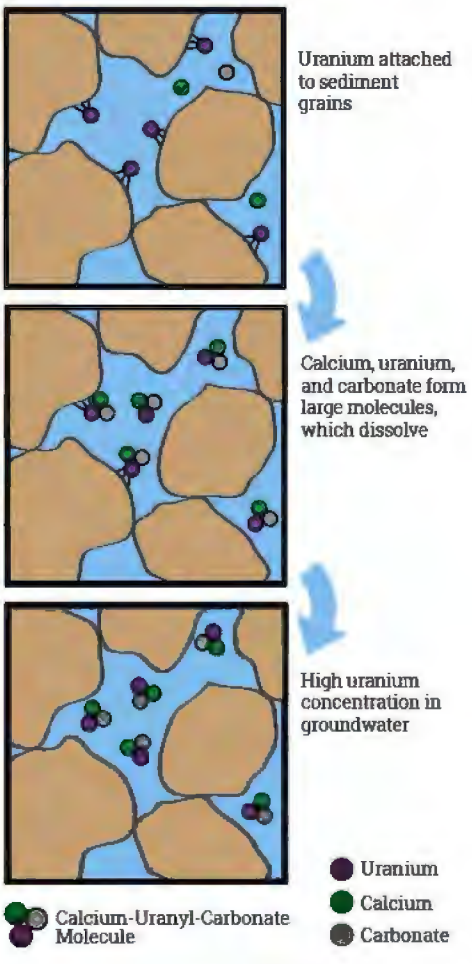
URANIUM *(Diagram D)*

PROBLEMS *(Diagram E)*	SOLUTIONS
An increase in dissolved bicarbonate and calcium Uranium is often "stuck" (adsorbed) to the edges of sediments. When uranium comes into contact with dissolved bicarbonate and calcium, it can form large molecules that are easily dissolved, increasing uranium concentrations in groundwater. Bicarbonate and calcium are naturally present in soils and are usually more concentrated at the surface because of higher biological activity (plants and microorganisms) and evaporation. As a result, water percolating through the soils, will increase in calcium and bicarbonate, which increases dissolved uranium concentrations as well.	Natural infiltration through soil from rain or drip irrigation cannot be avoided. However, if uranium is present in the proposed recharge area, managed aquifer recharge (MAR) should limit percolation through soil with high bicarbonate and/or calcium content. If there are high levels of bicarbonate or calcium in the upper layers of the soil, using recharge ponds or ditches/canals excavated through the soil (~6 to 8 ft deep) may prevent uranium contamination.
An increase in nitrate or high-oxygen conditions When uranium is present in low-oxygen conditions, it does not dissolve into groundwater. However, when nitrate or high-oxygen water enter the aquifer, they can react with uranium and change it into a form that readily dissolves, increasing uranium concentrations in groundwater.	Avoid over-pumping from confined aquifers to the point of clay compression (subsidence). Avoid drilling wells in aquifers with high clay content, or where pumped water may draw from clays containing arsenic.
Drawdown of shallow groundwater Dissolved uranium concentrations are often higher in shallow groundwater, where there are high-oxygen conditions and more dissolved bicarbonate and calcium. High rates of pumping in deep wells may draw down this shallow water, increasing the amount of dissolved uranium in extracted water.	Monitor uranium content and prevent drawdown of shallow, uranium-rich groundwater by reducing pump rates or promoting injection wells as necessary.

Diagram D: Problems and Solutions



PROBLEMS

1. Recharge through vegetated area and infiltration pond leads to an increase in bicarbonate and calcium, which causes uranium to dissolve.
2. Injection well introduces high-oxygen water or nitrate, releasing uranium.

MANAGEMENT SOLUTIONS

1. Well pumps water from deeper aquifer without bicarbonate and calcium.
2. Managed aquifer recharge through excavated ditch prevents uranium contamination.

Diagram E: Uranium dissolves as part of molecule

Arsenic and Uranium, Combined Management

When dissolved arsenic and uranium are both present in groundwater, certain management practices can help to reduce concentrations of both elements:

- Maintain pH below 8.5 to limit dissolved arsenic. If pH exceeds 8.5, more investigation is necessary.
- If uranium is present in oxygen-rich zones, keep calcium and bicarbonate concentrations low to help to keep it out of the water.
- Prevent high rates of pumping that draw uranium from shallow groundwater or arsenic from low-oxygen zones.
- Monitor levels of arsenic, uranium, dissolved oxygen and oxidation-reduction potential (ORP) in groundwater. If arsenic concentrations increase, the aquifer may be low in oxygen. If uranium concentrations increase, the aquifer may be too oxygenated.
- For recharge project recommendations, please consult CWC's Protecting Drinking Water Under SGMA Guide.

What about CHROMIUM?

When dissolved arsenic and uranium are both present in groundwater, certain management practices can help to reduce concentrations of both elements:

- Increased groundwater pumping and fluctuations in groundwater levels;
- High-oxygen conditions at the surface generate hexavalent chromium, which is pulled down into the aquifer through recharge or pumping;
- Naturally occurring manganese converts trivalent to hexavalent chromium.

More research is needed to determine the best way to minimize hexavalent chromium production and concentrations in groundwater. Where active recharge is being conducted, following strategies for uranium mitigation is likely the best practice.

GLOSSARY:

- **Adsorbed:** "Stuck" to the edges of sediments.
- **Dissolved:** In liquid form; part of the groundwater.
- **High-oxygen and low-oxygen:** Conditions that reflect how much oxygen is dissolved into groundwater. High-oxygen conditions are sometimes called "aerated", while low-oxygen (~1% or lower dissolved oxygen) is called "reduced".
- **pH:** A measure of the acidity of the water. Groundwater pH is generally between 6.5 and 8.5. Water with lower pH is more acidic, while higher pH indicates alkaline (basic) conditions.
- **Naturally occurring:** Present within the rocks that make up the aquifer; not due to human activity.

"These bills take the much needed steps to preserve and restore a limited and indispensable resource—groundwater."

—Senator Fran Pavley on the passage of the Sustainable Groundwater Management Act, September 2014

"Nothing in the budget makes me more proud than this. I'm dead serious about that. Some people wonder why the hell you get into politics. This is why."

—Governor Gavin Newsom on signing SB 200, the Safe and Affordable Drinking Water Fund, July 2019

Summary

Successful implementation of the Sustainable Groundwater Management Act (SGMA) is critical to California's prosperity, collaboration that achieves shared benefits for people and nature, and the Newsom administration's commitment to the human right to water for all residents. In 2014, California passed SGMA, a set of three laws that are intended to help the state sustainably manage its groundwater resources. Between 30% and 60% of the state's water supply comes from groundwater in any given year, and is used for drinking water, growing food, supporting industry, and maintaining a healthy environment. Groundwater over-pumping affects drinking water wells and surface water rights, pollutes water due to seawater intrusion or migrating contaminant plumes, harms ecosystems, and causes land subsidence, among other problems.

In January 2020, newly formed Groundwater Sustainability Agencies (GSAs) submitted their first Groundwater Sustainability Plans (GSPs or plans) to the state for the "critically over-drafted" sub basins, or those in the direst circumstances. Most of these sub basins are located in the San Joaquin Valley.

Since then, the COVID-19 pandemic has exposed how deeply public health, economic security, and clean water are intertwined. Put simply, a livable future in California depends on clean, reliable water, which is one of the main reasons why SGMA was passed. California's groundwater depletion challenges preceded the global pandemic and continue to persist in ways that impact drinking water, farming, economic development, public health, and environmental quality.

To support the state's implementation of SGMA and its continued progress on the human right to water, the Water Foundation commissioned an analysis of 26 GSPs in the San Joaquin Valley to understand how private domestic drinking water wells in the region will be affected on the path to sustainability. This analysis does not look at any of the other associated impacts or costs of declining groundwater levels, such as land subsidence, surface water rights, or groundwater dependent ecosystems.

California's state regulatory agencies have never had this level of detailed information about the effects of severe groundwater overdraft on the lives and livelihoods of residents, farmworkers, and rural households. Conducted in spring 2020 and using conservative estimates based on publicly available data, this analysis estimates that the goals in these San Joaquin Valley GSPs, if not proactively addressed, will result in:

- **Between roughly 4,000 and 12,000 partially or completely dry drinking water wells by 2040**
- **Between roughly 46,000 and 127,000 people who lose some or all of their primary water supply by 2040**
- **Between $88 million to $359 million in costs to restore access to drinking water**

These concerning results point to a simple fact: In spite of actions aimed at managing groundwater more sustainably, recently submitted GSPs still forecast that thousands, or tens of thousands, of Californians will lose their drinking water supply, which is inconsistent with the intent of SGMA and threatens to undermine the governor's commitment to safe and affordable drinking water for all residents. This analysis of drinking water and continued declines in groundwater also suggest that the goals of SGMA to avoid other undesirable results of groundwater mining also may not be fully addressed by GSPs.

Further analysis beyond the scope of this report is required to explore the effect of GSPs on other areas of concern, such as impacts on the environment and on important infrastructure due to land subsidence. As state decision-makers conduct their GSP review process, we hope that this brief will help bring greater attention to vulnerable Californians and their most basic need: safe, clean, and affordable water.

Key Terms

Human right to water: As defined by AB 685, "every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."

Groundwater sustainability: As defined by SGMA, "management and use of groundwater in a manner that can be maintained…without causing undesirable results."

Undesirable results: Negative results that GSAs and GSPs are required to avoid under SGMA. There are six undesirable results: groundwater level lowering, reduction of groundwater storage, seawater intrusion, land subsidence, water quality degradation, and depletions of interconnected surface water.

Measurable objective: A basin's self-determined groundwater level goal to achieve sustainability under SGMA.

Minimum threshold: A basin's self-determined minimally acceptable level of groundwater decline. Beyond this threshold, a GSA anticipates it will face undesirable results.

Partially dry drinking water well: A drinking water well that has lost or will lose most of its usable water due to unsustainable groundwater practices. These wells are also called partially dewatered wells.

Completely dry drinking water well: A drinking water well that has lost or will lose all useable water due to unsustainable groundwater practices. These wells are also called dewatered wells.

Right to Water Depends on Sustainable Groundwater

Safe drinking water for Californians and groundwater management are inextricably connected. California has enshrined the concept of the human right to water – that all Californians have a basic right to safe and affordable drinking water and sanitation – into state code. However, unsafe drinking water has been an ongoing environmental justice challenge for decades. More than 1 million Californians go without safe and affordable drinking water each year, and low-income communities of color are disproportionately affected by this water crisis. These same communities are also on the frontlines of climate change and are hit the hardest by drought conditions.

Leonicio Ramirez and Guillermina Avila in East Porterville. Florence Low / California Department of Water Resources

Yet, too often, water policy deliberations and decision-making proceed as if the water in our rivers, the water underground, and the water flowing out of our taps are distinct from one another. That is not true.

The COVID-19 pandemic has shown California how we are all better off when everyone has the basic resources to protect themselves and their neighbors. By that same token of interdependence, the health of groundwater in California is the health of families, economies, and nature. In the San Joaquin Valley, 95% of communities rely on groundwater as their main drinking water source. Valley groundwater also fuels the operations of large and small farms and sustains a hub of world-class biodiversity.

For over 100 years, California has drained San Joaquin Valley rivers and groundwater faster than nature and humans can replenish them. A changing climate is exacerbating the effects of this behavior as it delivers more devastating and longer droughts. Between 2012 and 2016, California experienced the most intense drought on record since the 1400s. Over-pumping during the drought sank roads and homes, polluted wells, lowered river flows, and put farms and communities at severe risk.

Still, in the middle of that economic, social, environmental, and public health crisis, recognizing that it was a question of when, not if, another major drought will start, California residents living in the hardest hit parts of the state spurred their elected representatives to act to save groundwater for themselves and for future generations.

In 2014, for the first time in the state's history, legislators passed, and the governor signed, a series of laws to put California on a path that reaches groundwater sustainability by 2040 or 2042, depending on the basin. These laws are known as the Sustainable Groundwater Management Act (SGMA).

Californians' ability to work together and look out for one another will shape SGMA's success in turning groundwater into a drought-proof water resource. State leaders must ensure effective governance and that local plans dependably lead to groundwater sustainability, including protecting communities that rely on private drinking water wells. Local agencies charged with implementing SGMA must use science as a foundation for their plans and meaningfully engage and represent the communities directly affected by their decisions.

Inside a groundwater monitoring well. Kelly M. Grow / California Department of Water Resources

Under the Newsom administration—the first administration to review SGMA GSPs—new initiatives are poised to support full, fair, and effective execution of the law. The Newsom administration has also underscored its commitment to fulfilling the promise of the human right to water in California.

To advance these goals, the California Department of Water Resources (DWR) has started to collect and publish data on the depth of groundwater below the surface and groundwater elevation, which can help proactively identify threats to sustainability, including at-risk drinking water wells. These domestic wells tend to be very shallow, which means they dry up sooner than agricultural or municipal wells. When groundwater levels plummet and leave private wells dry, few San Joaquin communities and residents who are dependent on them as sources of drinking water have the capital to continuously drill and maintain deeper wells.

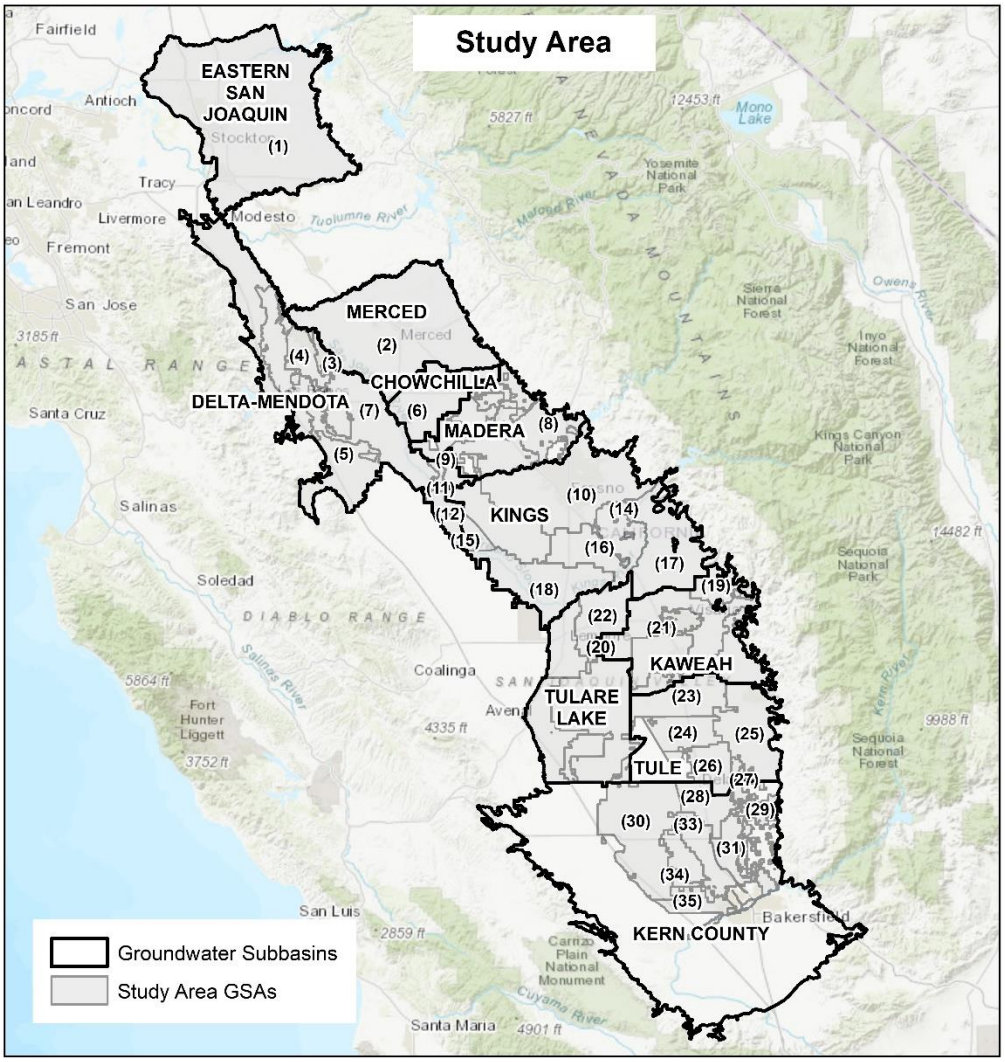
Farm workers in Pajaro Valley. Lance Cheung / US Department of Agriculture

To conduct this analysis for the Water Foundation, consultants at EKI Environment & Water, Inc. used DWR's latest Groundwater Center Interactive Map Application dataset and other publicly available information to understand how implementation of some of the first GSPs in critically over-drafted sub basins in the San Joaquin Valley would affect local drinking water wells. Because DWR's dataset does not include every part of the San Joaquin Valley, this analysis is limited to 26 GSPs in ten critically over-drafted sub basins. Further, one-quarter of the records in the dataset lack basic information about well depths and screening levels, and therefore could not be included in this evaluation.

Considering these data limitations, this analysis provides a conservative baseline assessment of how the estimated water decline predicted in these recently submitted GSPs will impact people who rely on groundwater for their primary water source. Because this analysis only addresses the ongoing impacts of GSP implementation on drinking water, additional research may be necessary to understand the impacts and costs on other undesirable results, such as land subsidence, impacts to ecosystems, and surface water flows.

Key Findings

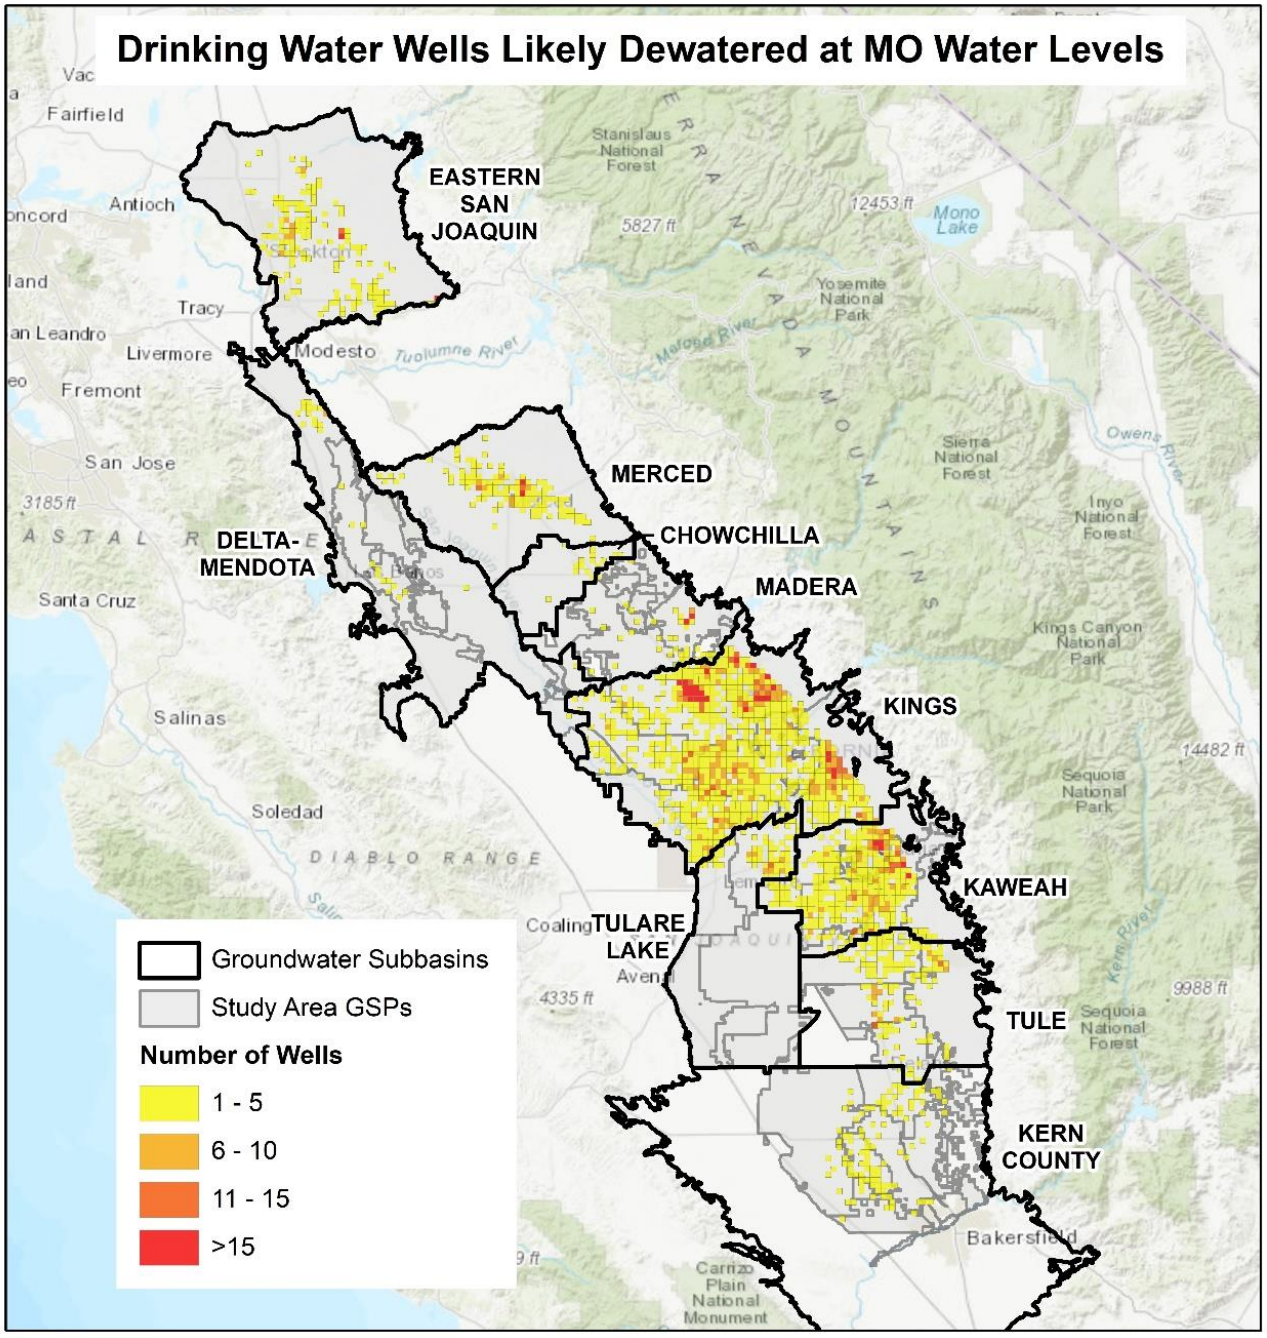
- **Between roughly 4,000 and 12,000 drinking water wells will go partially or completely dry by 2040**
- **Between roughly 46,000 and 127,000 people will lose some or all of their current water supply by 2040**
- **It will cost between $88 million to $359 million to restore access to drinking water**



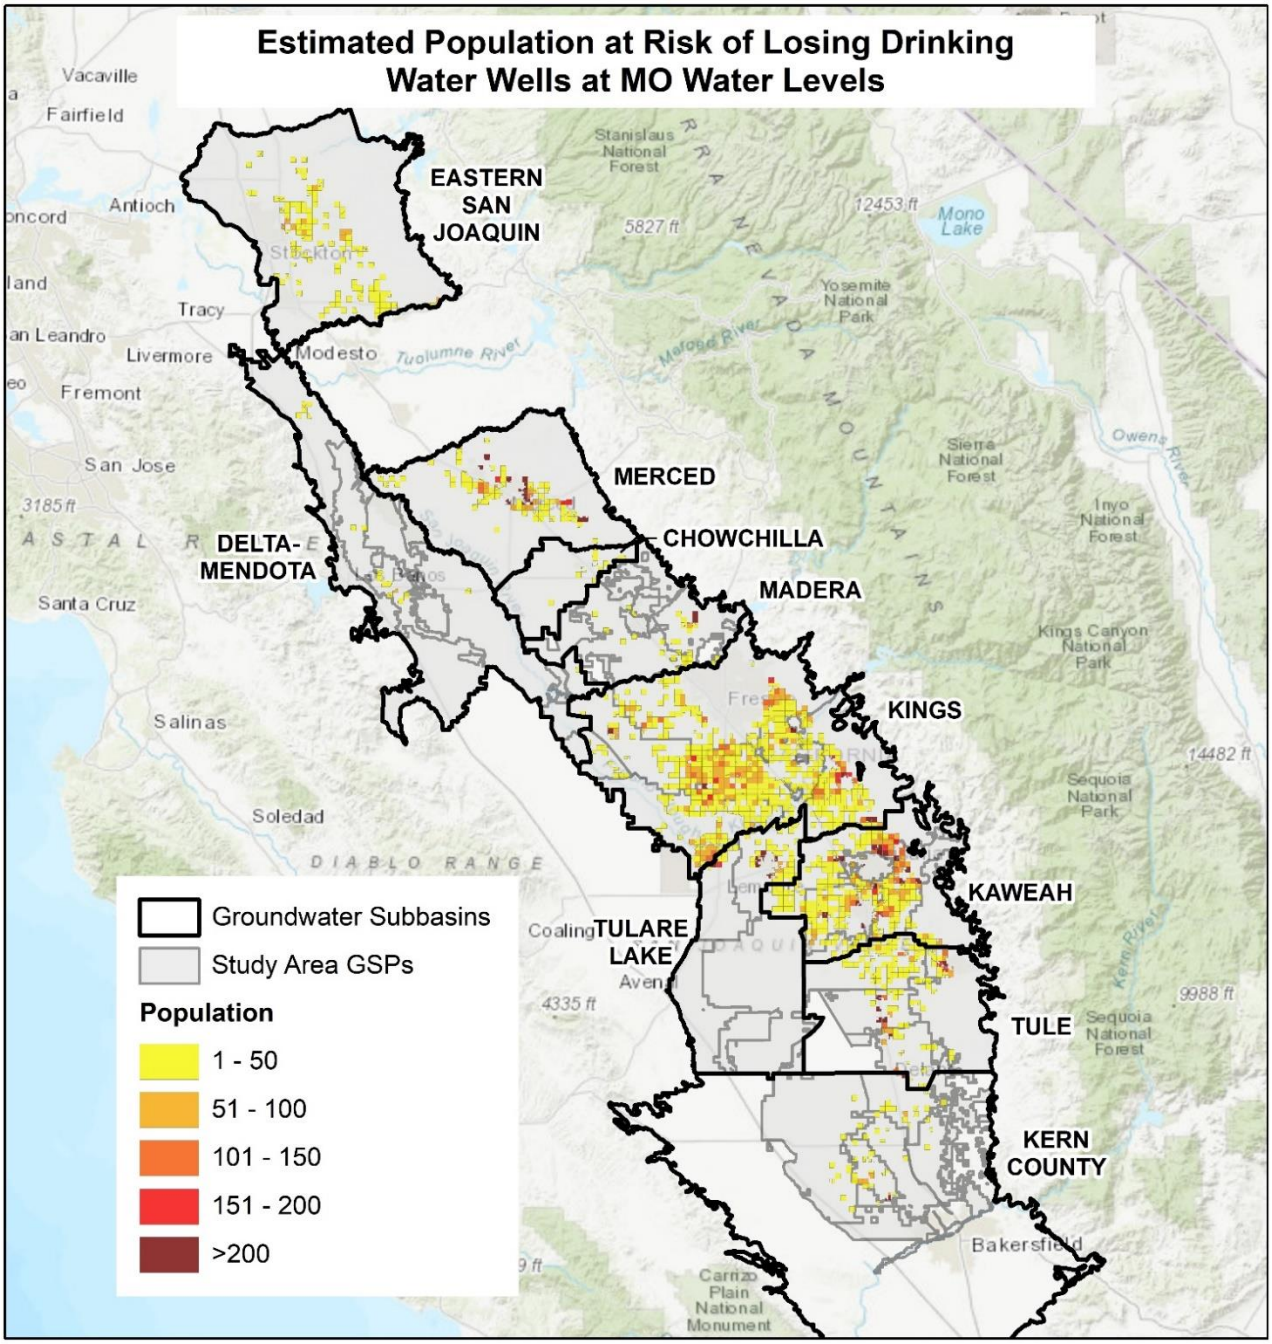
While these findings are deeply disturbing, they are not carved in stone. State regulatory agencies can work with these GSAs over the next two years to implement SGMA in a manner that avoids or mitigates these impacts, achieves groundwater sustainability by 2040, and strengthens the right to water for all California residents.

Analysis Results

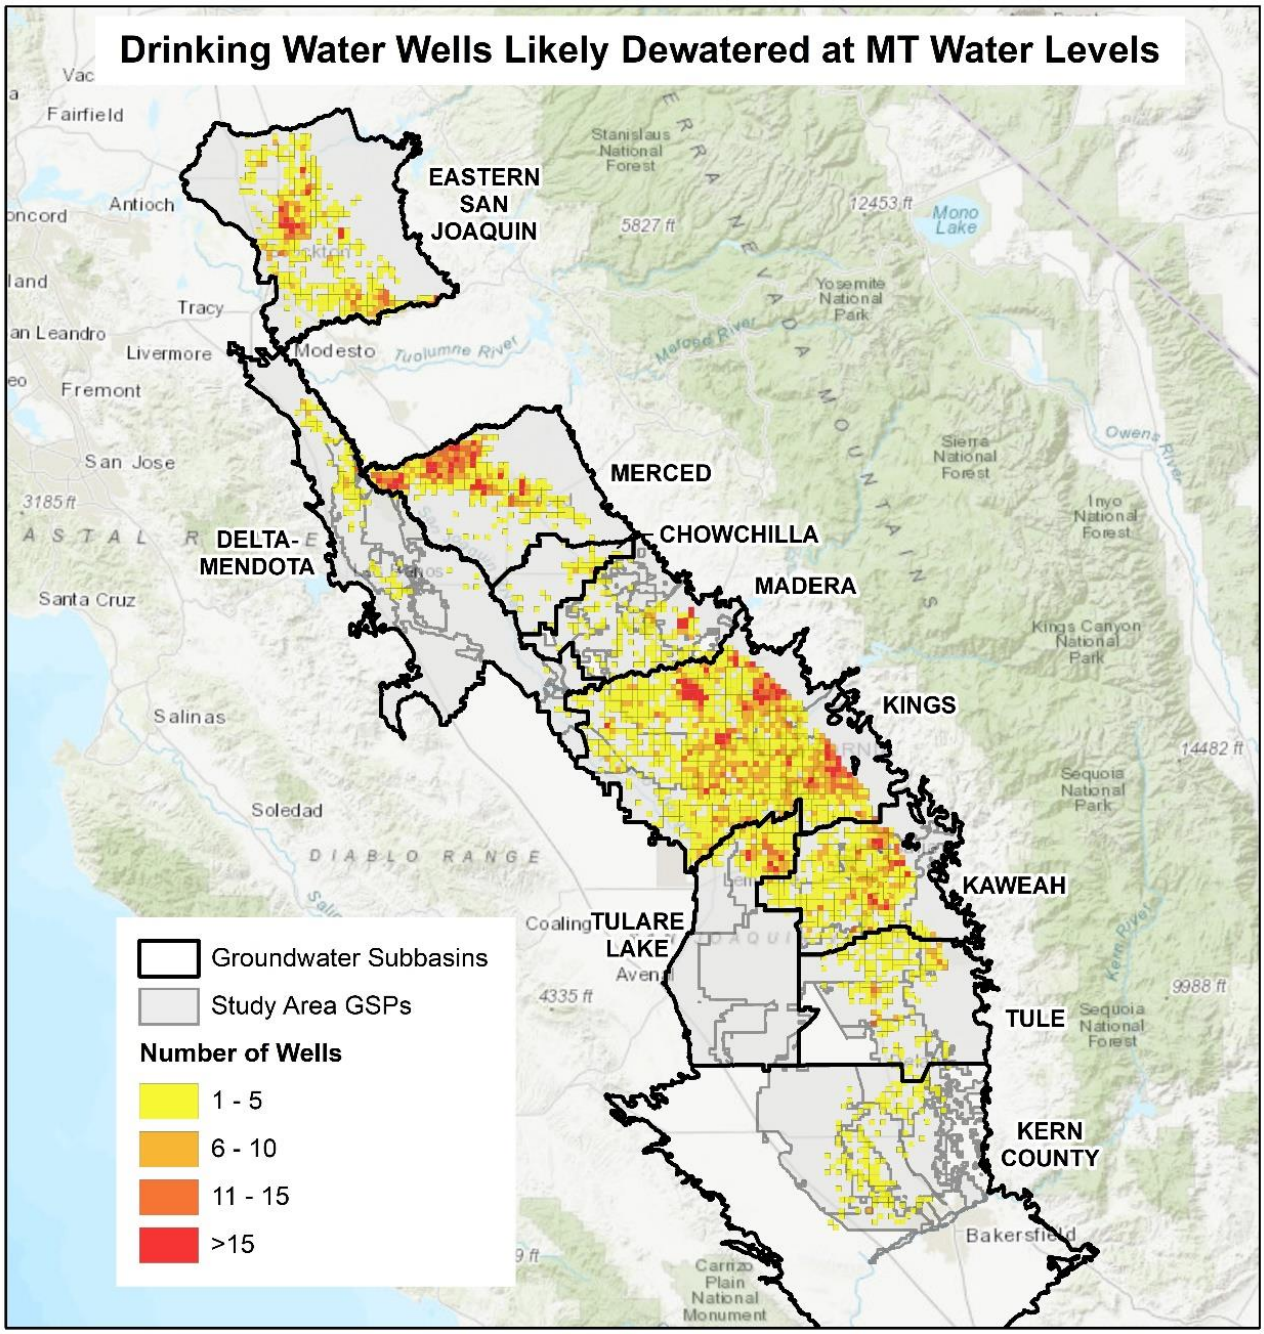
Study Area: San Joaquin Valley



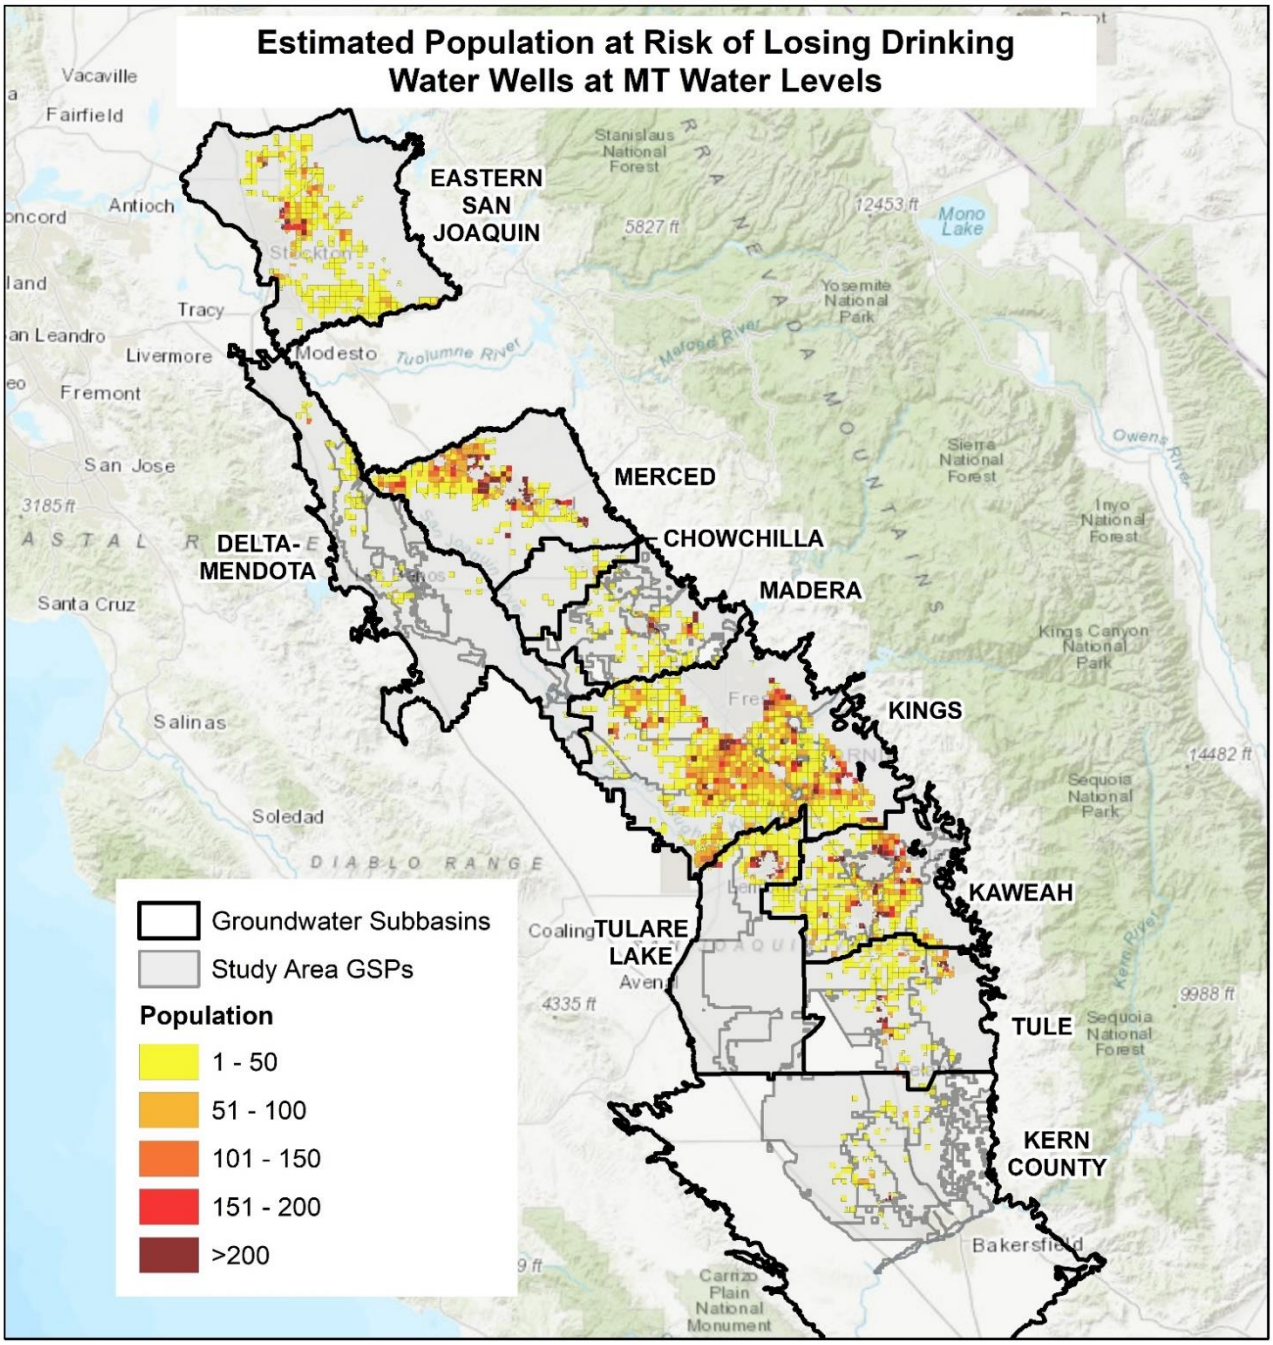
In the areas analyzed in this report, there are approximately 400,000 California residents who rely on private drinking water wells for their water supply and nearly 45,000 known drinking water wells.



Of these wells, approximately 7,000 have already been dewatered due to declining groundwater levels and another 13,000+ could not be analyzed due to insufficient data. After accounting for these factors, this analysis assessed how approximately 24,500 drinking water wells will be affected at the levels identified in their respective GSPs.



GSPs' Projected Water Levels Will Drain up to 12,000 Drinking Water Wells, Affecting up to 127,000 Residents



The GSPs have been developed with a goal of reaching sustainability by 2040. Based on the target water levels, or measurable objectives, defined in the GSPs, up to 5,600 drinking water wells in the region will go partially or completely dry. Under these circumstances, between 45,700 and 62,500 people will lose their primary drinking water source.

This analysis concludes that even if GSPs achieve their measurable objectives, groundwater levels will likely fall below those levels to minimum acceptable levels. Under this scenario, between now and 2040, up to roughly 12,000 drinking water wells in the region, or 49% of wells, could go partially or completely dry. Under these circumstances, between roughly 106,000 and 127,000 people will lose their primary drinking water source. This is a conservative estimate because it assumes that all of the actions in the GSPs will be taken and will be successful.

Restoring Water Access Could Cost between $88 and $359 Million

The stark findings detailed above demand action by GSAs to implement policies and programs to ensure that community members maintain access to reliable and safe drinking water. The first priority for GSAs must be to do more to stop groundwater declines to the extent possible. This is all the more important given that the impact of continually declining groundwater also includes worsening subsidence, dry rivers, and degradation of water quality below safe drinking water levels. Those impacts are worthy of further analysis.

DWR and the State Water Board (Board) have two years from January 31, 2020 to review critically over-drafted sub basin GSPs and make an initial determination to either 1) approve as is, 2) reject, or 3) conditionally approve with modifications. As DWR and the Board review and evaluate GSPs, they must ensure that GSAs take proactive action today to achieve sustainability and avoid devastating impacts to communities, economies, and the environment.

If this does not happen, community members will face high costs to mitigate those impacts. To ensure that community members maintain access to drinking water under circumstances where it is not possible to avoid declines in groundwater levels, drinking water well owners and users can conduct repeated well screen cleanings, drill deeper wells, develop new replacement wells, and/or spend more on operations and energy costs to lift the water from deeper underground. Based on this analysis, we expect that it will cost community members between $88 million and $359 million to pay for these mitigation measures to maintain and restore use of existing drinking water wells.

While these capital, operations, and maintenance costs are not insignificant, it is vital that GSAs and state agencies acknowledge this issue and take proactive steps to prevent these impacts. These costs are a fraction of what it will likely cost to address these issues on an emergency basis as vast and remote communities lose their drinking water wells.

For example, during the 2012-2016 drought, California taxpayers paid about $650,000 per month to provide temporary replacement bottled water to the East Porterville residents. The number of residents who will lose their primary drinking water source over the implementation of these GSPs is equivalent to up to 17 East Portervilles. Unlike the 2012-2016 drought, however, GSAs and state agencies have the benefit of the comprehensive scientific data compiled in these GSPs to plan for and address these issues before they become another more severe crisis.

The stakes are high. Failure by GSAs and state agencies charged with implementing SGMA to prevent these negative impacts will increase the current number of Californians without safe drinking water.

In 2019, the Safe and Affordable Drinking Water Fund was established to end the toxic taps crisis facing 1 million Californians today. However, the Fund was not designed or intended to address costs that could be avoided by knowledgeable and informed planning by GSAs that have failed to consider communities in their planning processes. The impacts summarized here are foreseeable, and if not proactively addressed, would add additional unnecessary demands on state and local budgets.

Jan 31, 2022: GSPs Due from Remaining High- and Medium-Priority Basins

Considerations for California's Water Future

Californians have a shared commitment to the human right to water. Residents and their elected representatives have said clearly that they want clean, affordable, and reliable tap water for all families. They want California farming to prosper, and they want to protect the breathtaking beauty of the state's land and wildlife.

This year marks the start of a new era in California water policy, where state laws and funding recognize and reflect how closely the trajectory of groundwater sustainability and safe drinking water are intertwined. As policymakers and GSAs work diligently to implement SGMA in a manner that supports the state's economy, its communities, and nature, this analysis can conservatively fill existing data gaps on how unsustainable groundwater practices directly affect drinking water wells.

GSAs must make policy decisions in GSPs that protect drinking water. As part of the state's review of GSPs, DWR and the Board should ask key questions to help achieve sustainability and avoid undesirable results. These questions, which are detailed in the Human Right to Water Scorecard shared below, include:

- If minimum thresholds are reached in the GSP, how many Californians might lose access to water?
- How might the measurable objectives and minimum thresholds set by the GSP affect water quality for vulnerable communities?
- How can GSPs go further to avoid declining groundwater levels and the associated impacts on drinking water and other undesirable results?
- What is the GSP's plan to mitigate impacts to water quantity and quality for vulnerable communities?
- How does DWR and the Board intend to assess and analyze the GSP's impacts to drinking water quality and quantity for vulnerable communities?

Thorough evaluations and smart policy decisions today will ensure SGMA implementation protects drinking water for rural communities and residents, advances the legislature's and governor's commitments to the human right to water, and turns groundwater into a drought-proof resource for generations to come.

Re: Recommendations for DWR and SWRCB Action Regarding the Kern Groundwater Authority Groundwater Sustainability Plan

Dear Department of Water Resources and State Water Resources Control Board,

Leadership Counsel for Justice and Accountability works with low-income communities of color in the San Joaquin Valley and the Eastern Coachella Valley. We have been engaged in the Sustainable Groundwater Management Act (SGMA) implementation process because most of the communities we work with are wholly dependent on groundwater for their drinking water supplies, and many have already experienced groundwater supply and quality issues. The communities where we work have not been adequately included in decision-making about their precious water resources, and their needs are not prioritized in such decisions.

Disadvantaged communities in the Kern Groundwater Authority GSA have the most to gain and the most to lose from SGMA implementation in the region. Communities like Arvin are majority

Latino and depend on small community water systems and/or domestic wells for their drinking water supply. Because residents in disadvantaged communities do not typically have the financial means to dig deeper wells or to install, operate and maintain drinking water treatment infrastructure, they are more likely to be severely impacted by lowering groundwater levels and groundwater contamination.

As a particularly vulnerable group, the critical drinking water needs of disadvantaged communities and low-income households must be considered and protected by the Groundwater Sustainability Plan (GSP). The Kern Groundwater Authority GSA has not adequately done so in this GSP. As described below, the GSP will likely allow drinking water to be contaminated by existing contaminant plumes, is likely to allow wells to go dry, and has no clear plan to help prevent and mitigate drinking water impacts.

The Department of Water Resources (DWR) and the State Water Resources Control Board (SWRCB) must evalue GSPs according to the Human Right to Water, and ensure that the GSPs comply with SGMA, the GSP regulations, and state and federal civil rights law, among other laws and regulations. In 2012, California recognized the Human Right to Water, codifying "the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."[1] Under the Human Right to Water law, DWR and the State Water Resources Control Board must consider the Human Right to Water on review of GSPs.[2] In order to comply with this obligation, the Department and Board must ensure that GSPs do not cause or allow further drinking water crises that interfere with residents' access to an adequate supply of safe drinking water. In coordination with the Community Water Center and Self-Help Enterprises, we have developed a Human Right to Water Scorecard that contains elements necessary for state review of GSPs to comply with the Human Right to Water.[3] We urge DWR and the SWRCB to use this scorecard in evaluating this GSP.

Additionally, SGMA requires GSAs to include disadvantaged communities in decision-making, and create GSPs in a transparent and inclusive way. DWR and the SWRCB must ensure that GSPs do not cause "significant and unreasonable impacts" to the beneficial uses and users of groundwater in the subbasin, that they encourage the participation of a diverse variety of stakeholders,[4] and that they "consider the interests of" an enumerated list of all types of beneficial users, including disadvantaged communities on domestic wells and community water

systems.[5] Furthermore, state law provides that no person shall, on the basis of race, national origin, ethnic group identification, and other protected classes, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state.[6] The state's Fair Employment and Housing Act guarantees all Californians the right to hold and enjoy housing without discrimination based on race, color, or national origin.[7] DWR and the SWRCB must evaluate GSPs in accordance with all of these and other relevant legal obligations.

Unfortunately, the Kern Groundwater Authority GSA did not protect the drinking water resources relied upon by disadvantaged communities or low-income households, or avoid disparate impacts, and the GSP is incomplete and does not comply with SGMA and other applicable state laws. As noted above, we reviewed the Kern Groundwater Authority GSP according to our Human Right to Water Scorecard. Our review shows that the GSP does not contain all of the information required under SGMA, does not adequately evaluate "significant" and "unreasonable" impacts to beneficial uses including the drinking water needs of disadvantaged communities, will create a disparate impact on protected classes unless significantly modified, and does not comply with the Human Right to Water statute.

For the reasons discussed in these comments, and in prior written and oral comments provided to the GSA, DWR must not approve the GSP.[8]

~ ~ ~ ~ ~ ~

A. The GSP Does Not Comply with SGMA Because It Lacks Required Information

The GSP must contain all of the elements set forth in the GSP regulations. However, this GSP omits critical data and information to comply with the GSP regulations. As discussed below, the GSP lacks required information and analyses, including among other things critical data regarding the consideration of drinking water impacts on disadvantaged communities and protected groups, sustainable management criteria that consider impacts on all beneficial users, and projects and management actions that address significant and unreasonable impacts to beneficial users. The GSP also fails to demonstrate how its proposed policies and activities will achieve its sustainability goal, which SGMA requires.[9] Therefore, the GSP fails to "include[] the information required by [SGMA] and [its accompanying regulations]," and is thus inadequate.[10] These inadequacies prevent DWR from being able to determine that the GSP will likely achieve its sustainability goal.[11] Given these deficiencies, we ask DWR not to approve the plan.

B. DWR Cannot Approve The GSP Because It Will Cause Disproportionate And Disparate Negative Impacts On Protected Classes.

The Kern Groundwater Authority GSA and DWR must ensure that the GSP does not cause disparate impacts on protected groups, and must prioritize drinking water as an essential pillar of their groundwater sustainability plan. The GSP does not comply with these requirements.

State law provides that no person shall, on the basis of race, national origin, ethnic group identification, and other protected classes, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by any state agency.[12] In addition, the state's Fair Employment and Housing Act guarantees all Californians the right to hold and enjoy housing without discrimination based on race, color, or national origin.[13]

---

[9] Water Code sec. 10727.2(b)(2)
[10] 23 CCR § 355.4(a)(2).
[11] Water Code § 10733(a); 23 CCR § 355.4(b).
[12] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].
[13] Gov. Code § 12900 et seq.

The GSP will have disparate impacts on protected classes, including negative and discriminatory impacts on the basis of race, color, ancestry, national origin, and ethnic group identification. "Low-income communities and communities of color in the Central Valley rely disproportionately on private wells because adequate public services were not developed in those communities."[14]As a result, "low-income households, people of color, and communities already burdened with environmental pollution suffered the most severe impacts [from drought]" and dry wells.[15] Similarly, communities of color in the Central Valley are disproportionately impacted by groundwater contamination.[16]

Consistent with these studies, this GSP will cause disproportionate negative impacts on communities of color reliant on small water systems and domestic wells. There are at least 105 disadvantaged unincorporated communities (DUCs) within Kern County, many of which will be impacted by this GSP.[17] Approximately 55% of the population of Kern County DUCs are people of color, slightly higher than the approximately 51% of the population of the County overall who are people of color. Many of the communities we work with and that are most susceptible to falling groundwater levels and groundwater pollution, however, are nearly 100% Latino. For example, according to the most recent American Communities Survey data, Lamont is 95% Hispanic or Latino.[18]

As discussed below, the GSP's determinations and policy decisions will result in many more dry wells, and will not prevent increased drinking water contamination from groundwater activities, particularly for disadvantaged communities reliant on small water systems and domestic wells. This will cause severe harm to residents' health and daily lives, as well as permanent impacts on residents' finances and living situations. Additionally, the GSP contains no measures to mitigate these impacts. Therefore, because the GSP is likely to have significant negative impacts on households reliant on small water systems and domestic wells, and because the people reliant on small water systems and domestic wells are disproportionately people of color, the GSP is likely

to cause disparate impacts on protected classes.

C. The GSP Does Not Adequately Evaluate Whether Adverse Impacts Are "Significant And Unreasonable" Or Consider Beneficial Uses And Users.

Under SGMA, DWR must find that a GSP is likely to achieve its sustainability goal before DWR may approve the plan.[19] "'Sustainability goal' means the existence and implementation of one or more groundwater sustainability plans that achieve sustainable groundwater management by identifying and causing the implementation of measures targeted to ensure that the applicable basin is operated within its sustainable yield."[20] "'Sustainable groundwater management' means the management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results."[21] An "undesirable result" occurs when a GSP allows a "significant and unreasonable" adverse impact to one of six sustainability indicators, including groundwater levels, groundwater storage, groundwater quality, and land subsidence.[22]

If a GSP is unlikely to achieve its sustainability goal, DWR cannot approve the plan.[23] DWR must also independently determine whether or not the GSP is likely to avoid "significant and unreasonable" adverse impacts with regard to each sustainability indicator, and if not then DWR cannot approve the plan. If a GSP will allow an undesirable result even if implemented effectively, then the GSP cannot achieve sustainable groundwater management.[24] Likewise, a plan that cannot achieve sustainable groundwater management has failed to set a valid sustainability goal, in violation of SGMA.[25] If a GSP does not contain a valid sustainability goal, DWR cannot determine that the GSP is "likely to achieve the sustainability goal for the basin," and DWR cannot approve it.[26]

In addition to defining undesirable results, GSPs must quantify benchmarks for groundwater conditions, or "minimum thresholds," that may cause undesirable results if exceeded.[27] GSPs must include "an explanation of how the Agency has determined that basin conditions at each minimum threshold will avoid undesirable results for each of the sustainability indicators."[28] A GSP's determination of when an undesirable result will occur must be based on analysis of when

[19] Water Code § 10733(a).
[20] Water Code § 10721(u).
[21] Water Code § 10721(v).
[22] Water Code § 10721(x).
[23] Water Code § 10733(a).
[24] Water Code § 10721(v).
[25] Water Code § 10721(u).
[26] Water Code § 10733(a); *see also* 23 CCR 354.24 ("Each Agency shall establish in its Plan a sustainability goal for the basin that culminates in the absence of undesirable results within 20 years of the applicable statutory deadline.").
[27] 23 CCR 354.28(a).
[28] 23 CCR 354.28(b)(2).

adverse impacts become "significant" and "unreasonable."[29]

In all of its actions, a GSA must "consider the interests of" all categories of beneficial users, including express requirements to consider disadvantaged communities on domestic wells and community water systems.[30] Failure to consider the interests of a category or categories of beneficial users is itself grounds for DWR to decline to approve a plan.[31] DWR regulations also establish that a failure to consider all beneficial uses and users of groundwater undermines the likelihood that a basin will reach its sustainability goal.[32]

We note that an impact on drinking water that persists for even a relatively short period of time (e.g., months or years rather than decades) may have permanent and irreversible impacts on households and communities. A household is not habitable without access to an adequate supply of safe drinking water, and failed wells thus may have irreparable impacts on community cohesion. These impacts are inconsistent with the very concept of sustainable groundwater management.

As explained below, the GSA has not based their policy determinations on an analysis of what impacts are "significant" and "unreasonable," and have not considered the interests of disadvantaged communities or low-income households reliant on small water systems or domestic wells.

D. DWR Cannot Approve The GSP Because It Was Developed With Inadequate Transparency, Accessibility, Consideration Of Public Input And Representation.

As public agencies, GSAs are subject to the requirements of the Brown Act, which requires transparency of public agencies through notice of meetings and prior posting of agendas, posting of meeting minutes after meetings, and public access to meeting materials upon request by a member of the public.[33] GSAs are also subject to the requirements of the Bilingual Services Act, which requires a public agency to provide interpretation and translate materials into all languages for which there is a "substantial" number of people who it serves who speak that language.[34]

---

[29] Water Code § 10721(x); 23 CCR 354.28(b); *see also* Cal. Dep't Water Res., *Draft Best Management Practices for the Sustainable Management of Groundwater* 6 (Nov. 2017) ["GSAs must consider and document the conditions at which each of the six sustainability indicators become significant and unreasonable in their basin, including the reasons for justifying each particular threshold selected."]; *id.* 8 ["The GSP must include an analysis and written interpretation of the information, data, and rationale used to set the minimum threshold."].

[32] 23 CCR 355.4(b)(4).

[33] California Gov. Code § 54954.1

[34] Bilingual Services Act, Gov. Code, §§ 7293, 7295.

In addition, GSAs must also adhere to the specific public participation and inclusivity requirements laid out in SGMA. As discussed above, SGMA requires that a GSA "shall consider the interests of all beneficial uses and users of groundwater," which expressly includes "[h]olders of overlying rights" and "[d]isadvantaged communities, including, but not limited to, those served by private domestic wells or small community water systems."[35] The emergency regulations similarly require that a GSP summarize and identify "opportunities for public engagement and a discussion of how public input and response will be used."[36] GSAs thus must engage "diverse social, cultural, and economic elements of the population within the basin."[37] The regulations recognize that failure to engage adequately with a diverse cross-section of the public undermines the likelihood that a GSP will avoid undesirable results and meet its sustainability goal.[38]

The GSA did not adequately consider the input of disadvantaged communities, either at the GSA level or the member agency level. First, the GSA itself did not adequately engage residents of disadvantaged communities in the GSP creation process. The KGA GSA held regular GSA meetings at times that were not accessible to residents working during the day, so many beneficial user groups could not be adequately represented.

The GSA held several public workshops, but the feedback from these workshops, from meetings and from written comments was not incorporated into the GSP. We submitted a comment letter to the KGA GSA in June 2019 and presented this same letter verbally to the KGA board on June 26, 2019. At this meeting we expressed our initial concerns about GSP development and shared recommendations to ensure the protection of vulnerable water users. Among other things, we asked for the GSP to set protective sustainable management criteria to protect drinking water access in disadvantaged communities, ensure the GSP development process be reflective of all beneficial users by monitoring all primary drinking water contaminants, and to engage with DAC residents. These comments were not incorporated into the GSP or the GSP development process. We repeated these same concerns and recommendations in our comment letter on the final public draft of the GSP.

The GSA had a communications plan and an online Stakeholder Survey that was available most of the GSP development period, but the survey was only in English and was only available online, thereby limiting the opportunity for diverse input from non-English speakers and those without regular access to the internet. The survey was also not promoted outside the KGA agencies' existing networks in an authentic and intentional way to reach all beneficial users including disadvantaged communities. While the GSA worked with Self-Help Enterprises to

[35] Water Code § 10723.2.
[36] 23 CCR 354.10(d).
[37] Guidance Document for Groundwater Sustainability Plan; Stakeholder Communication and Engagement, p. 1.
[38] 23 CCR 355.4(b)(4).

provide interpretation at workshops, it did not provide interpretation at its board meetings. It also did not provide translated materials at its meetings.

Additionally, the decision-making structure of the GSA created barriers to public engagement. Instead of being able to learn about GSP development and provide feedback at GSA meetings, stakeholders also had to engage with a myriad of local member agencies, which all had separate meetings, to fully understand GSP development. The KGA GSP states that, "[t]o capture the intent of SGMA as legislation better served under local control, KGA member agencies played a vital role in the development of this GSP. This process included communication and outreach at the local level, with each KGA member agency engaging with its beneficial users to gather vital input, data, and feedback to ensure the success of this GSP and individual management area plans."[39] However, this decision-making structure meant attending member agency meetings and GSA meetings to understand GSP development, which is overly burdensome to most stakeholders who do not have adequate time in their schedules to attend so many regular meetings.

This burdensome process is compounded by the fact that GSA meetings were held during work hours, and member agencies' websites did not provide adequate notice or agendas for GSP-related meetings. The GSP states that "each KGA member agency engag[ed] with its beneficial users to gather vital input, data, and feedback to ensure the success of this GSP and individual management area plans."[40] However, our organization and residents we work with in Arvin had serious barriers to actively participating in GSP development through their local member agency.

The member agency that has jurisdiction over residents we work with in the GSA area, the Arvin-Edison Water Storage District ("Arvin-Edison WSD"), states in its Management Plan, a chapter of the GSP, that it considered disadvantaged communities by engaging representatives of the Arvin CSD, which contains disadvantaged community residents; by creating a Stakeholder Communication and Engagement Plan; and by "welcom[ing] public participation" at stakeholder workshops, Arvin-Edison WSD board meetings, Arvin CSD board meetings, KGA GSA events and meetings, a stakeholder survey, letters to landowners, and small or one-on-one meetings with individual stakeholders.[41] However, as a community-based organization working directly with residents in the GSA area, we were not included in these conversations until August 15, 2019 when we attended the Arvin- Edison WSD Board meeting where they presented their GSP chapter to its board for approval. Residents we work with did not have any knowledge of the GSP development process in the Arvin-Edison Management Area. We have collaborated with many GSAs to develop more effective outreach materials and procedures for ensuring

[39] Kern Groundwater Authority GSP, p. 37, dated January 2020.
[40] Kern Groundwater Authority GSP, p. 37, dated January 2020.
[41] Arvin-Edison Water Storage District Management Area GSP, p. 3-4, dated December 2019.

disadvantaged community involvement, but it was very difficult to follow the structure of KGA. This made it difficult to relay accurate and complete information to community residents and properly engage them with the topic.

Additionally, during GSP implementation the Arvin WSD's website contained no information on SGMA or GSP meetings. We understand from conversations with staff that the agency sent notices to its list serv, but there was no way to sign up for the list serv on the website, and without knowing when and where meetings are occuring the public could not go to a meeting to sign up and be added to the interested parties list serv. A representative from Arvin CSD brought regular updates to a community meeting, but no meeting notices or agendas about GSP development meetings were published in any publicly available format. This public process did not comply with the Brown Act, the Bilingual Services Act, or the requirements under SGMA.

After we submitted our comments on the draft GSP, including the Arvin-Edison Management Area chapter of the GSP, representatives from Arvin CSD reached out to us to discuss our concerns about their public process and the substance of their portion of the GSP. The representatives from Arvin CSD expressed their commitment to public participation and drinking water needs of the residents of Arvin, and agreed to consider our feedback on improved public participation practices. Since then, Arvin WSD huas updated its website and included a link to sign up for its interested parties listserv. But these efforts, taking place after GSP development was largely complete, did not inform the GSP.

The GSA's public participation process and its choice to delegate GSP development to member agencies did not ensure a transparent and inclusive process for developing the GSP. The public engagement process for this GSP was therefore inadequate. At a minimum, an adequate process must include the following elements, which were not present here:

1. **Notice:**[42] Ensure that the GSA provided clear notice to the public about GSA meetings to develop the GSP, posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.[43]

[42] Government Code § 54954(a).

[43] Government Code sec. 7296.2: Dymally-Alatorre Bilingual Services Act, stating that local agencies providing services to the public must provide translated materials and interpretation when it serves a substantial number of non-English-speaking people. The law defines a "substantial number of non-English-speaking people" as "members of a group who either do not speak English, or who are unable to effectively communicate in English because it is not their native language, and who comprise 5 percent or more of the people served by the statewide or any local office or facility of a state agency." This is because "effective maintenance and development of a free and democratic society depends on the right and ability of its citizens and residents to communicate with their government and the right and ability of the government to communicate with them."

2. **Translation of materials:**[44] Ensure that the GSA translated materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.
3. **Interpretation:**[45] Ensure that the GSA provided interpretation services at board meetings, committee meetings and workshops for all languages spoken by at least 5 percent of the public served by the agency, to allow those who do not speak English or are unable to effectively communicate in English to effectively participate.
4. **Meaningful DAC representation on advisory committee:** Ensure that the GSA developed the GSP with an advisory committee that contained representatives from DACs, such that DAC representatives' voices were not drowned out by the overwhelming majority of another interest group.
5. **DAC representation on GSA boards and Coordination Committee:** Ensure that the GSA developed the GSP with GSA boards and a Coordination Committee that contained representatives from DACs.
6. **Incorporation of stakeholder input:** Ensure that the GSP explicitly describes how stakeholder input was incorporated into the GSP process and decisions, including sustainable management criteria and all projects and management actions.

E. The GSP's Sustainable Management Criteria for Groundwater Levels Are Not Adequate

The sustainable management criteria for groundwater levels must be made after considering the interests of all beneficial user groups, including disadvantaged communities reliant on domestic wells and community water systems,[46] and must be based on an analysis of what are "significant" and "unreasonable" impacts.[47] These policy decisions must also avoid disparate impacts on protected groups pursuant to state and federal law.[48] As discussed below, the GSP does not meet these requirements.

a. The Undesirable Result for Groundwater Levels are Inadequate

Undesirable results are the point at which groundwater conditions cause "significant and unreasonable" impacts on beneficial users. The SGMA regulations require GSAs to justify their undesirable results by including the "[p]otential effects on the beneficial uses and users of

[44] Government Code sec. 7296.2.
[45] Government Code sec. 7296.2.
[46] Water Code § 10723.2.
[47] Water Code § 10721(x); 23 CCR 354.28(b); *see also* Cal. Dep't Water Res., *Draft Best Management Practices for the Sustainable Management of Groundwater* 6 (Nov. 2017) ["GSAs must consider and document the conditions at which each of the six sustainability indicators become significant and unreasonable in their basin, including the reasons for justifying each particular threshold selected."]; *id.* 8 ["The GSP must include an analysis and written interpretation of the information, data, and rationale used to set the minimum threshold."].
[48] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).

groundwater."[49] GSAs must also describe the "processes and criteria relied upon to define undesirable results."[50] These determinations must be made based on an analysis of when decreasing groundwater levels will cause results that are either "significant" or "unreasonable" in light of the context of the basin and the real-world circumstances on the ground. The undesirable results determination does not comply with these requirements because it is unsupported by analysis, it is too vague, and it does not show how the GSA considered the interests of beneficial users in shaping its conclusions.

The KGA GSP defines undesirable results for groundwater levels as "when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each management area)."[51] Neither the KGA GSP nor the Kern Subbasin Coordination Agreement contain an analysis of how what the concrete impacts would be on beneficial users from reaching these undesirable results, including how many wells could go dry, or a process by which beneficial users were consulted in order to determine whether these potential impacts were "significant and unreasonable."

The undesirable result could allow for more than 30% of the territory in the subbasin to exceed its minimum thresholds for groundwater levels before this undesirable result is triggered. This standard allows localized impacts across the subbasin area, which would cause significant and unreasonable impacts to beneficial users of groundwater for drinking and other domestic purposes. There is no justification for dividing the GSA area up into arbitrary management areas and then defining undesirable results as occurring only where three ***adjacent*** management areas exceed minimum thresholds. In short, the GSP allows domestic and small community wells to be dewatered.

Because the undesirable result for groundwater levels allows significant and unreasonable impacts, the GSP is inadequate.

b. The Measurable Objectives for Groundwater Levels are Inadequate

The SGMA regulations require the GSA to set measurable objectives that "achieve the sustainability goal for the basin within 20 years of Plan implementation and...continue to sustainably manage the groundwater basin over the planning and implementation horizon."[52]

The GSA has not demonstrated that it evaluated how the proposed measurable objectives would contribute to the overall sustainable yield of the Kern Subbasin, which is approximately 324,326

[49] 23 CCR § 354.26.
[50] 23 CCR § 354.26.
[51] Kern Groundwater Authority GSP, p. 170, adopted January 2020.
[52] 23 CCR § 354.30(a)

acre-feet per year, according to the GSP,[53] or maintain sustainability over the implementation and planning horizon.

c. The Minimum Thresholds for Groundwater Levels are Inadequate

The groundwater levels sustainable management criteria set by a GSA must be the point that, "if exceeded, may cause undesirable results."[54] SGMA requires GSAs to analyze both the significance and reasonableness of proposed minimum thresholds,[55] and minimum thresholds must have the purpose of avoiding "significant and unreasonable" impacts on beneficial users.[56] The GSA's determination of what is "significant and unreasonable" must consider the impacts on all types of beneficial users, including disadvantaged communities.[57] For groundwater levels specifically, GSAs must place minimum thresholds for each monitoring site at the level "that may lead to undesirable results."[58] Under DWR regulations, the GSA must provide a description of "the information and criteria relied upon to establish minimum thresholds," an explanation of how the proposed minimum thresholds will "avoid undesirable results," and "how minimum thresholds may affect the interests of beneficial uses and users of groundwater."[59]

The GSP's minimum thresholds were not established in a way that considered the interests of beneficial users including domestic well owners and disadvantaged communities, and the resulting minimum thresholds cause significant and unreasonable impacts on the most vulnerable beneficial users. The GSA delegated the task of creating the sustainable management criteria to member agencies, and in the process, did not ensure that the resulting policies complied with the law. The resulting impact from the proposed sustainable management criteria will likely lead to disparate impacts on protected groups pursuant to state and federal law.

The KGA GSA did not ensure that minimum thresholds created by member agencies considered the interests of all beneficial user groups, or prioritize the security of drinking water in the subbasin, in developing minimum thresholds. For example, the Arvin-Edison Management Area GSP did not consider the impact on drinking water users in setting its minimum thresholds. The AEWSD Management Area Draft GSP details how it calculated historical water lows and divided the Management Area into four "Sustainability Criteria Zones" based on historical low groundwater levels and agency jurisdiction, and how it adjusted the minimum thresholds to protect the canal that brings surface water to farmers.[60] However, it did not evaluate or consider

[53] Kern Groundwater Authority GSP, p. 151, dated January 2020.
[54] 23 CCR § 354.28.
[55] Water Code § 10721(x); 23 CCR 354.26(a). (b), 354.28(b); see also Cal. Dep't Water Res., Draft Best Management Practices for the Sustainable Management of Groundwater 6, 8 (Nov. 2017).
[56] 23 CCR § 354.26.
[57] Water Code § 10723.2.
[58] 23 CCR § 354.28.
[59] 23 CCR § 354.28.
[60] Arvin-Edison Water Storage District Management Area GSP, p. 124, dated December 2019.

how many wells could go dry from its proposed minimum thresholds, or adjust for effects on drinking water. Figures 2-5, 2-6 and 2-7 show all of the domestic wells, public supply wells, and communities dependent on groundwater in the GSA area.[61] The GSA therefore knows the number and location of all drinking water wells, but has chosen not to evaluate what the impacts will be to these wells at the minimum thresholds, and whether those impacts are significant and unreasonable. Therefore the GSA did not consider impacts on drinking water beneficial users, or ensure the protection of drinking water as the highest beneficial use of water, despite having all the information it needed to conduct such a drinking water impact analysis.

The GSP does not show that the impact to beneficial users was evaluated. It lays out the process by which the minimum thresholds and measurable objectives were approved, states that the GSA had workshops about the sustainable management criteria and that these items "appeared as discussion items" at the GSA board meetings, but does not show that the GSA considered the impacts on beneficial users.[62] The GSP contains no evaluation of impacts on beneficial users from reaching these sustainable management criteria, and the GSA's decisions regarding sustainable management criteria were not based on an evaluation of the impacts to beneficial users' access to groundwater resources.

The groundwater levels sustainable management criteria for this GSP are therefore inadequate. At a minimum, adequate groundwater levels sustainable management criteria must include the following elements, which are not present here:

1. **Evaluate the drinking water impact:** Ensure that the GSP includes an analysis of how many drinking water wells (municipal wells, community water system wells, and domestic wells) might go fully or partially dry if groundwater levels reach the undesirable results,[63] measurable objectives and minimum thresholds,[64] including a map of wells that will go fully and partially dry at the measurable objectives and minimum thresholds. Ensure that the GSP includes estimates of the increased pumping costs from additional lift needed to pump water from lower elevations if the undesirable results, measurable objectives and minimum thresholds were to be reached.
2. **Avoid significant and unreasonable impacts to drinking water users in creating sustainable management criteria:**[65] The GSA must analyze "when significant and unreasonable effects ... are caused by groundwater conditions occurring throughout the basin," taking into account the beneficial users of groundwater and the basin's specific circumstances.[66] Therefore the GSP must explicitly state how the GSA considered

[61] Kern Groundwater Authority GSP, pg. 26-28, dated January 2020.
[62] Kern Groundwater Authority GSP, p. 177, dated January 2020.
[63] 23 CCR § 354.26(c)
[64] 23 CCR § 354.28(b)(4)
[65] Water Code § 10723.2
[66] 23 CCR § 354.26.

drinking water impacts in shaping undesirable results, measurable objectives and minimum thresholds for groundwater levels; for example, the GSP could state how its well impact analysis supported setting stricter measurable objectives and minimum thresholds near at-risk communities.

3. **Incorporate new drinking water data into sustainable management criteria:**[67] Ensure that the GSP includes a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data.
4. **Implement DAC and drinking water user input into sustainable management criteria:**[68] Ensure that the GSP discusses how stakeholder input from DAC community members was considered in the development of undesirable results, measurable objectives and minimum thresholds. For example, the GSP could state how they took the results of the well impact assessment to the public through meetings, workshops, or Advisory Committees, and together with stakeholders decided how to change sustainable management criteria to protect drinking water, or other programs to implement to mitigate these impacts.
5. **Avoid disparate impact:**[69] Ensure that the measurable objectives and minimum thresholds for groundwater levels are established in such a way that prevents a disparate impact from occurring on protected classes in the GSP area. For example, the GSP should ensure that the same minimum threshold methodology across the GSP area will not lead to disproportionately more wells going dry for residents of color than for white residents.

F. The GSP Fails To Adequately Address Groundwater Quality Through Its Sustainable Management Criteria for Groundwater Quality

GSA activities and policies could cause increased contamination in many ways. For example, the proposed timeline for implementation of demand reduction may allow for continued pumping which may create an increase in naturally occurring contaminants and/or migration of contaminant plumes.[70] Recharge projects could also have severe impacts on groundwater quality by facilitating water percolation on land contaminated with years of pesticide, herbicide, fungicide, and fertilizer application and/or by releasing natural contaminants like uranium into groundwater.[71] A groundwater market is also likely to cause geographic concentrations of

[67] 23 CCR § 354.38(e)(3)
[68] 23 CCR § 354.10(d); DWR Guidance Document for Groundwater Sustainability Plans: Stakeholder Communication and Engagement, p.1.
[69] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[70] *See* Smith et al., Overpumping Leads to California Groundwater Arsenic Threat, 9 Nature Communications 2089 (2018), available at https://www.nature.com/articles/s41467-018-04475-3.
[71] See Fakhreddine et al., Protecting Groundwater Quality In California, Management Considerations For Avoiding Naturally Occurring And Emerging Contaminants (2019), available at https://www.edf.org/sites/default/files/documents/groundwater-contaminants-report.pdf ["Recharging water, even clean water, into a previously uncontaminated aquifer can potentially alter the existing geochemistry and hydrology

pumping that increases the likelihood of contaminant plume migration, putting drinking water resources at risk. Oil and gas impacts on groundwater should also be analyzed, since Kern County is one of the largest producers of oil and gas, and reports show oil and gas activities can severely impact groundwater quality.[72]

SGMA charged GSAs with the responsibility to protect water quality from further degradation due to groundwater management practices, and requires GSAs to establish sustainable management criteria to prevent degraded groundwater quality,[73] based on a determination of what is a "significant and unreasonable" impact on all beneficial users, including domestic well users and disadvantaged communities.[74] This GSP only monitors and regulates one contaminant of concern despite its express knowledge that many other more harmful drinking water contaminants exist in its GSP area, which could be impacted by groundwater usage and activities. The GSA's sustainable management criteria for groundwater quality are inadequate.

b. The Undesirable Results Determination for Groundwater Quality Is Inadequate

Undesirable results are the point at which "significant and unreasonable" impacts on beneficial users caused by degraded groundwater quality. The SGMA regulations require GSAs to justify their undesirable results by including the "[p]otential effects on the beneficial uses and users of groundwater."[75] GSAs must also describe the "processes and criteria relied upon to define undesirable results."[76] The undesirable result cannot have a disparate impact on protected groups pursuant to state civil rights law.

Like the undesirable result for groundwater levels, the proposed definition of undesirable results for degraded water quality are "when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the

---

and subsequently cause the release of geogenic contaminants from soils and sediments."]; Jurgens, Bryant C., et al. [73] Water Code § 10721(w)(4); 23 CCR § 354.28(c)(4).

[74] Water Code §§ 10727.2(d)(2); 10721(x)(4)

[75] 23 CCR § 354.26.

[76] 23 CCR § 354.26.

Subbasin or greater than 30% of the Subbasin (as measured by each management area)."[77] As with the groundwater levels undesirable results, it is not clear what the impacts from reaching this undesirable result will be on beneficial users, and neither the KGA GSP nor the Kern Subbasin Coordination Agreement contain an analysis of how what the concrete impacts would be on beneficial users from reaching these undesirable results, including how many wells could go dry. Instead of being formed through a process in which beneficial users were consulted in order to determine whether these potential impacts were "significant and unreasonable," the process of defining undesirable results in the Kern subbasin seems to be an arbitrary determination of what is "significant and unreasonable."

The water quality undesirable results will allow significant and unreasonable impacts in localized areas and/or for short to medium periods of time. Given that more than 30% of the territory in the subbasin will be allowed to exceed its minimum thresholds for groundwater quality before this undesirable result is triggered, the GSP allows drinking water users to be impacted by drinking water contamination caused by GSA policies and activities. The definition of undesirable results therefore sets a very low inadequate bar for plan failure, and must be modified to ensure that drinking water is protected within the basin.

Because the undesirable results for groundwater quality allow significant and unreasonable impacts on sources of drinking water, DWR cannot approve the GSP.

b. The Minimum Thresholds and Measurable Objectives for Groundwater Quality Are Inadequate

GSAs must place groundwater quality minimum thresholds for each monitoring site at the level "that may lead to undesirable results."[78] Under the SGMA regulations, the GSP must provide a description of "the information and criteria relied upon to establish minimum thresholds," an explanation of how the proposed minimum thresholds will "avoid undesirable results," and "how minimum thresholds may affect the interests of beneficial uses and users of groundwater."[79] Measurable objectives must lead to compliance with the GSA's sustainable yield by 2040.

The GSP briefly states that each member agency established the minimum thresholds and measurable objectives for their management area, mentions that in many cases groundwater levels serve as a proxy for groundwater quality, lists the minimum thresholds and measurable objectives established by each member agency in Table 3-1, and states that more information can be found in the management area GSPs.[80] For several management areas, Table 3-1 does not list which contaminants are being monitored for compliance with the proposed minimum thresholds

[77] Kern Groundwater Authority GSP, p. 172, dated January 2020.
[78] 23 CCR § 354.28.
[79] 23 CCR § 354.28.
[80] Kern Groundwater Authority GSP, p. 179, dated January 2020.

and measurable objectives. Many management areas have used groundwater levels as a proxy for groundwater quality.

Groundwater levels are not a proxy for groundwater quality, and failure to set adequate minimum thresholds or measurable objectives to protect against discharge of all primary and secondary drinking water contaminants during recharge activities and/or activities that cause shifting contaminant plumes renders the GSP inadequate.

As in the case of groundwater levels, it is clear that the GSA has not considered the potential impact on drinking water users, in particular disadvantaged communities that are less able to afford solutions to treat contaminated drinking water. This has resulted in minimum thresholds and measurable objectives like those in the Arvin GSP, which will only be monitoring for compliance with sustainable management criteria in one well location, and has set the minimum threshold at the drinking water MCL for the contaminant, and the measurable objective at 75% of the MCL. The member agency is only monitoring for compliance with arsenic standards, despite the agency's knowledge of the existence of "nitrate...total dissolved solids (TDS), boron, iron and manganese...within or near the Arvin-Edison Management Area above drinking water standards and/or agricultural water quality goals."[81]

The lack of sufficient groundwater quality sustainable management criteria in areas like Arvin means that the GSP allows drinking water pollution that will be disproportionately felt by disadvantaged communities that are less able to afford treatment solutions. This significant and unreasonable impact is not adequate under SGMA or state and federal law prohibiting policy from resulting in disparate impact. The GSA has not conducted an analysis of how the minimum thresholds and measurable impacts could impact critical drinking water resources, and therefore has not considered the interests of all beneficial user groups, particularly drinking water users.

The GSA has also not specified what actions will be taken if water contamination approaches minimum thresholds, or how minimum thresholds will be triggered. Member agencies such as the Arvin-Edison WSD have not specified this in their plans. The GSA should ensure that minimum thresholds will be triggered after one test shows a violation of an MCL or a trend toward an MCL. The GSA must require that member agencies specify what actions they will take if groundwater quality approaches minimum thresholds, what point or measurement will trigger this action, and how impacted residents will be informed. The GSA must also ensure GSA-wide consistency on when minimum thresholds are triggered and what actions are taken in response, in order to protect drinking water across the GSA area.

[81] Arvin-Edison Water Storage District Management Area Plan, p. 80, dated December 2019.

Because the minimum thresholds and measurable objective fail to consider all beneficial users and cause significant and unreasonable impacts, the GSP is inadequate and DWR cannot approve it.

The groundwater quality sustainable management criteria for this GSP are therefore inadequate. At a minimum, adequate groundwater quality sustainable management criteria must include the following elements, which are not present here:

1. **Ensure that the GSP sets measurable objectives and minimum thresholds at all representative monitoring wells for all of the following contaminants:**[82]
    a. Contaminants with primary drinking water standards,
    b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health, AND
    c. Contaminants like uranium, arsenic and nitrate which are known to increase due to groundwater management practices.
2. **Ensure that the GSP triggers a violation of a minimum threshold after *one* test shows that there has been an increase in contamination since January 1st, 2015**. Once the minimum threshold is reached, the GSA must start the evaluation of whether groundwater management activities or groundwater pumping have caused the increase, or whether the increase was caused by other factors such as natural fluctuation, testing inaccuracy, or activities outside the purview of the GSA. If the increase was caused by groundwater management activities or groundwater pumping, the GSA must immediately stop increasing the contamination and remediate.
3. **Immediately remediate any contamination caused by groundwater conditions since 2015:** The GSA must immediately remediate any increased contamination caused by groundwater management policies or activities (including lack of adequate regulation of pumping) since 2015. The GSA must begin remediation immediately upon establishing causation. The GSA must remediate contamination within two years, or as soon as technologically and hydrologically possible, whichever is faster. Design and implementation of remediation measures must be done in partnership with all groundwater users, primarily disadvantaged communities. The GSA must also clearly identify funding sources for remediation, and identify a timeline for procuring those funds.
4. **Strive to remediate existing drinking water contamination:** Ensure that the GSA will strive to remediate drinking water contaminants that exceeded the MCL before 2015 wherever feasible, through projects, management actions and policies.
5. **Evaluate the drinking water impact:** Ensure that the GSP includes an analysis of how drinking water wells (municipal wells, community water system wells, and domestic

[82] 23 CCR § 354.34(b)(2) and (f)(3)

wells) are likely to be be affected by the undesirable results,[83] measurable objectives and minimum thresholds.[84]

6. **Implement DAC and drinking water user input into sustainable management criteria:**[85] Ensure that the GSP discusses how stakeholder input from DAC community members was considered in the development of undesirable results, measurable objectives and measurable objectives.
7. **Incorporate new drinking water data into sustainable management criteria:**[86] Ensure that the GSP includes a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data.
8. **Avoid disparate impact:**[87] Ensure that the minimum thresholds for groundwater quality are established in such a way that prevents a disproportionately negative impact on communities of color in the GSP area. For example, the GSP should ensure that the same minimum threshold methodology across the GSP area will not lead to disproportionately more wells going dry for residents of color than for white residents.

G. The Monitoring Network is Inadequate With Respect to Groundwater Levels and Groundwater Quality

GSAs must monitor impacts to groundwater for drinking water beneficial users,[88] including disadvantaged communities on domestic wells,[89] and must avoid disparate impacts on protected groups pursuant to state law.[90]

As discussed below, The GSA's monitoring network does not comply with SGMA regulations, and fails to capture drinking water impacts to disadvantaged communities and domestic wells. Specifically, the GSP lacks representative monitoring wells in areas of the subbasin where drinking water users may be particularly vulnerable to groundwater supply and quality issues, leaving the GSA with no ability to measure and avoid significant and unreasonable impacts to those users. The monitoring wells are also monitored two infrequently to timely detect and prevent falling groundwater levels and/or contamination.

[83] 23 CCR § 354.26(c)
[84] 23 CCR § 354.28(b)(4)
[85] 23 CCR § 354.10(d); DWR Guidance Document for Groundwater Sustainability Plans: Stakeholder Communication and Engagement, p.1.
[86] 23 CCR § 354.38(e)(3)
[87] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[88] 23 CCR § 354.34
[89] Water Code § 10723.2.
[90] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).

The lack of adequate monitoring will make it impossible for the GSA to monitor drinking water to detect and prevent undesirable results, undermining the likelihood that the basin will achieve sustainable groundwater management.

The insufficiency of the representative monitoring network renders the GSP inadequate.

a. Groundwater Level Monitoring

The SGMA regulations state that monitoring networks must include a "sufficient density of monitoring wells to collect representative measurements through depth-discrete perforated intervals to characterize the groundwater table or potentiometric surface for each principal aquifer."[91] The GSA must also make decisions about the monitoring network in a way that considers the interests of all beneficial users.[92]

The GSP here presents a map of its groundwater levels monitoring wells,[93] but does not show what aquifers the wells are monitoring, and where monitoring wells are in relation to disadvantaged communities on domestic wells and small community water systems. As such, it is not possible for the public or DWR to determine whether there is a sufficient density of wells to collect representative measurements and detect and prevent significant and unreasonable impacts on beneficial users.

The monitoring network for groundwater levels is therefore inadequate and will not detect significant and unreasonable impacts to disadvantaged communities. At a minimum, an adequate groundwater levels monitoring network must include the following elements, which are not present here:

1. **Ensure accurate detection of impacts on drinking water users and DACs:**[94] Ensure that the groundwater level monitoring network includes *representative* monitoring wells *in or near DACs*, and placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area. If new monitoring wells are required, ensure that the GSP contains a concrete plan to fund and construct new representative monitoring wells within the first year of GSP implementation to ensure that vulnerable communities' drinking water resources are monitored. The plan to improve the monitoring network should include testing of domestic wells in the interim as wells are constructed.
2. **Clearly show representative monitoring well locations in relation to DACs:**[95] Ensure that the representative monitoring wells (RMWs) for groundwater levels are presented on maps and in tables that identify which set of minimum thresholds and measurable

[91] 23 CCR § 354.34(c)(1)(A)
[92] 23 CCR § 354.34(b)(2)
[93] Kern Groundwater Authority GSP, Figure 3-3, p. 186-189, dated January 2020.
[94] 23 CCR § 354.34(b)(2) and (f)(3)
[95] 23 CCR § 354.34(b)(2) and (f)(3)

objectives will be applied to which RMWs, and that these maps clearly identify the locations of DACs, small water systems and other sensitive users.

3. **Identify and address other drinking water data gaps:**[96] Ensure that the GSP clearly identifies any other gaps in data regarding impacts to drinking water users, and that the GSP contains a clear plan to fill data gaps regarding impacts to drinking water users. The GSP explains how it will fill some monitoring data gaps, but does not ensure that these gaps will capture impacts on all drinking water users, particularly disadvantaged communities.

b. Groundwater Quality Monitoring

SGMA regulations require that GSPs create a groundwater quality monitoring network that will "collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues."[97]

The groundwater quality monitoring network does not adequately capture impacts on drinking water users. For example, in the case of the Arvin GSP, the member agency will only monitor for compliance with its minimum threshold and measurable objective for arsenic once a year in one well, ACSD Well #14, which is one of the wells that provide drinking water to the community of Arvin.[98]

First, measuring for Arsenic only once a year does not provide the member agency or the GSA with frequent enough information to detect and respond to severe drinking water contamination in a reasonable amount of time. If the member agency's management actions, projects, or decisions to let groundwater decline increase drinking water contamination for families in the management area, the member agency could go a whole year without detecting these impacts. Meanwhile, it will not be responsive to the drinking water impacts from other contaminants which it may have moved or increased from its activities. Instead, the member agency must measure for all contaminants of concern every month.

Second, only measuring for compliance with arsenic measurable objectives and minimum thresholds does not protect against increases in other contaminants that exist in other parts of the management area (boron, nitrates, TDS, 123-TCP, iron and manganese). These contaminants could extend, move or increase due to groundwater management activities and pumping patterns. The Arvin GSP does plan to monitor for these contaminants in seven other wells outside of Arvin,[99] but has not set minimum thresholds and measurable objectives for these wells, and does

[96] 23 CCR § 354.38(e)(3)
[97] 23 CCR § 354.34(c)(4)
[98] Arvin-Edison Water Storage District Management Area Plan, p. 144, dated December 2019.
[99] Arvin-Edison Water Storage District Management Area Plan, p. 144-145, dated December 2019.

not have plans to do so. Without standards against which to compare detected levels of contaminants, and concrete commitments to preventing increased contamination, inclusion of these monitoring networks are meaningless.

Furthermore, Arvin is currently experiencing 123-TCP contamination that threatens the health of Arvin residents, so the GSP must monitor for compliance with 123-TCP standards in particular. In order to ensure that member agencies are detecting new contaminant plumes that could impact drinking water quality, the GSA must ensure that these representative monitoring wells monitor for all contaminants with primary drinking water standards, as well as contaminants known to increase with groundwater management activities such as uranium.[100] The GSA must also ensure that all representative monitoring wells are held to minimum thresholds and measurable objectives, measure the extent and spread of known contaminant plumes, and are able to measure the groundwater levels at the depth at which the drinking water wells are screened.

Third, the well that was chosen, ACSD Well #14, was chosen because it does not have contaminants that are known to exist in wells in the northern part of the management area, which are not currently in use by Arvin CSD, according to our conversation with Arvin-Edison WSD staff at the Kern Subbasin Open House on September 26th, 2019. Avoiding monitoring contaminated areas is inappropriate and fails to ensure that groundwater management activities and pumping do not aggravate existing contamination. The GSA should ensure that the member agency instead monitors for all existing contaminants at minimum throughout the area and especially in areas where contamination is known to exist, and sets minimum thresholds and measurable objectives that apply to all monitoring wells.

The groundwater quality monitoring network for this GSP is therefore inadequate. At a minimum, an adequate groundwater quality monitoring network must include the following elements, which are not present here:

1. **Ensure that the GSP plans to measure the following contaminants at all representative monitoring wells:[101]**
    a. Contaminants of concern with primary drinking water standards
    b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health
    c. Contaminants like uranium, arsenic and nitrate which are known to increase due to groundwater management practices

[100] Smith et al., "Overpumping Leads to California Arsenic Threat," Nature Communications (June 2018) [arsenic discharge from clay correlated with overpumping]; Jurgens et al., "Effects of Groundwater Development on Uranium" (November 2010) [strong correlation between high bicarbonate irrigation and recharge water and leaching of uranium from shallow sediments to groundwater].
[101] 23 CCR § 354.34(b)(2) and (f)(3)

2. **Clearly describe how the GSA will monitor for drinking water impacts:** Ensure that the GSP includes a description of how the GSA(s) will monitor groundwater contamination that could affect drinking water in the GSA area. Ensure that the representative monitoring wells (RMWs) for groundwater quality are presented on maps and in tables, and that the maps of RMWs clearly identify the locations of DACs, small water systems and other sensitive users.
3. **Ensure that the GSP plans to measure the following contaminants at all representative monitoring wells:**[102]
    a. Contaminants of concern with primary drinking water standards
    b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health
    c. Contaminants like uranium, arsenic and nitrate which are known to increase due to groundwater management practices
4. **Clearly describe how the GSA will monitor for drinking water impacts:** Ensure that the GSP includes a description of how the GSA will monitor groundwater contamination that could affect drinking water in the GSA area. Ensure that the representative monitoring wells (RMWs) for groundwater quality are presented on maps and in tables, and that the maps of RMWs clearly identify the locations of DACs, small water systems and other sensitive users.
5. **Ensure accurate detection of impacts on drinking water users and DACs:**[103] Ensure that the groundwater level monitoring network includes *representative* monitoring wells *in or near DACs*, and placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area. If new monitoring wells are required, ensure that the GSP contains a concrete plan to fund and construct new representative monitoring wells within the first year of GSP implementation to ensure that vulnerable communities' drinking water resources are monitored. The plan to improve the monitoring network should include testing of domestic wells at least as an interim measure as wells are constructed.
6. **Identify baseline contaminant levels:** Ensure that the GSP identifies the current contaminant levels, minimum thresholds and measurable objectives at each RMW, so that it is clear to the public how the contamination could change at each RMW site.
7. **Frequent testing:** Ensure that the groundwater quality monitoring network tests for contaminants of concern frequently, in a way that avoids persistent drinking water contamination. Testing should be done monthly.
8. **Collaboration with other agencies:**[104] Ensure that the GSP explains how the GSA will share data with and collaborate with other groundwater quality regulatory programs, such as ILRP, IRWM, and CV SALTS, and nonregulatory programs such as SB 200, the

[102] 23 CCR § 354.34(b)(2) and (f)(3)
[103] 23 CCR § 354.34(b)(2) and (f)(3)
[104] 23 CCR § 354.34(e)

SWRCB's needs assessment and the GAMA program, in order to build better regional understanding of groundwater quality issues, commit to clear roles, and better respond to groundwater quality impacts caused by groundwater management.

H. Projects and Management Actions Are Inadequate

The GSA must consider the interests of all beneficial users including domestic well owners and disadvantaged communities[105] and avoid disparate impacts on protected groups.[106] The GSP must also concretely outline how each objective and the overall sustainability goal will be achieved.[107] The projects and management actions set forth in the GSP do not demonstrate a plan for achieving sustainability goals, and do not adequately account for the needs of disadvantaged communities pertaining to protected groups under state law. This undermines the likelihood that the basin will reach its sustainability goal by 2040, as required by SGMA.[108]

a. The Projects and Management Actions are Inadequate, Do Not Protect Drinking Water for Disadvantaged Communities, and Will Likely Cause Disparate Impacts.

The projects and management actions set forth in the GSP does not demonstrate a path towards achieving sustainability goals in the plan. The GSA has not demonstrated how they have considered the interests of beneficial users including domestic well owners and disadvantaged communities.[109] The resulting impact from the proposed sustainable management criteria will likely lead to disparate impacts on protected groups pursuant to state and federal law.[110]

The GSA has allowed member agencies like the Arvin-Edison WSD to rely heavily on increasing use of surface water.[111] This places the majority of the plan's success on surface water resources, which are variable and may not be able to be procured. The GSA must ensure that member agencies implement demand reduction strategies from the beginning to ensure that the

---

[105] Water Code § 10723.2.
[106] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[107] Water Code § 10727.2(b)(2).
[108] Water Code § 10727.2(b)(1).
[109] Water Code sec. 10723.2.
[110] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].
[111] Arvin-Edison Water Storage District Management Area Plan, p. 153-154, dated December 2019.

GSP is on a path to sustainability within the statutory time period. The GSA will not achieve its sustainability goals if water use is not limited through fully-implemented demand reduction requirements immediately. The chosen management actions undermine the likelihood that the basin will reach its sustainability goal by 2040, as required by SGMA.[112]

Despite the fact that drinking water wells may go dry at the GSP's groundwater levels minimum thresholds, and the fact that drinking water contamination is likely to occur because of changing pumping patterns and recharge activities, the GSA does not have a plan for preventing or mitigating these impacts. Furthermore, the GSA's description of projects does not include a description of any potential negative impacts on beneficial uses of water, such as groundwater contamination, and how such impacts will be mitigated and monitored.

A critical problem with the structure of the GSA is that member agencies are not required to share the cost or responsibility for critical GSA-wide projects. Many more financially powerful agricultural and water banking member agencies could and should be part of a strategy to protect drinking water resources in the GSA area as a whole, especially given that they use much larger quantities of groundwater and their continued pumping will likely lead to dry wells and groundwater contamination issues for the most vulnerable homes in the GSA area. Given that California has recognized drinking water as a human right, and the importance of drinking water that we all experience in our own lives, the GSA member agencies should collectively come together to ensure that no family has to go days, months or years without safe tap water in their home. The Arvin GSP contains two projects for treating water quality in Arvin, but these projects were already under way and fully funded so should not be included in the GSP. The GSP has no overall drinking water protection program to protect residents against dry wells and contaminated drinking water from its policies and groundwater management activities.

b. Minimum Requirements for Projects and Management Actions

The projects and management actions for this GSP are inadequate. At a minimum, adequate projects and management actions must include the following elements, which are not present here:

1. **Include a Drinking Water Well Impact Mitigation Program:** Ensure that the GSP contains a drinking water protection program to prevent impacts to drinking water users and mitigate the drinking water impacts that occur. Please reference the Framework for a Drinking Water Well Impact Mitigation Program that our organization developed with the Community Water Center and Self-Help Enterprises for more details, a draft of which is attached as part of the Human Right to Water Scorecard in Exhibit B.

[112] Water Code § 10727.2(b)(1).

2. **Establish a clear and proactive plan for demand reduction.** Demand reduction should be implemented immediately.
3. **Describe the potential drinking water impacts of each project or management action.**
4. **Include management actions to measure groundwater extraction using the most scientifically accurate method.** From our conversations with scholars, it is clear that metering is the most accurate way of measuring groundwater extraction. Metering should be required for all users, particularly large agricultural pumpers.
5. **Ensure that the GSP's projects and management actions will not cause a disparate impact:**[113] Ensure that the GSP's projects and management actions, taken as a whole, prevent a disproportionately negative impact on communities of color in the GSP area. Projects and management actions may not cause, or fail to prevent, disproportionately more dry wells and contaminated water for residents of color than for white residents in the GSP area.

I. Plan Implementation Section is Inadequate

GSPs must include a planning and implementation horizon[114] and must show how the sustainability goal will be achieved by 2040.[115] GSP implementation must continue to consider the interests of all beneficial user groups and engage a diversity of stakeholders. The GSP's plan implementation section is insufficient in regards to public engagement/outreach and does not contain adequate information regarding annual reporting or the potential to make amendments to the GSP. Absent this information, DWR cannot evaluate when and whether the plan is likely to achieve sustainable groundwater management, so DWR cannot approve the plan.[116]

The GSA's Communications and Engagement plan states that "[d]uring the implementation phase, communication and engagement efforts will be shifted to educational and informational awareness of the requirements and processes for reaching groundwater sustainability. Active involvement of all stakeholders is encouraged during this phase, and public notices are required for any public meetings and prior to imposing, and later increasing, any fees."[117] It is concerning that this statement communicates that the public will not be engaged in decisions about projects and management actions, annual reports, five year updates, or potential modifications to the sustainable management criteria and monitoring network. The public must be engaged in in all decisions about GSA policies and activities, to ensure that impacts to all beneficial users are considered.

[113] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[114] Water Code § 10727.2.(c)
[115] Water Code § 10727.2(b)(1).
[116] Water Code § 10733(a); 23 CCR 355.4(b).
[117] Kern Groundwater Authority GSP, Appendix E, pg. I-6, dated January 2020.

The GSA does not include commitments to provide translated, accessible notice about agency meetings and decisions. The GSA does not commit to providing interpretation and translated materials at workshops and board meetings, or creating an Advisory Committee with representation from disadvantaged communities. The GSP also lacks a commitment to working with local community-based organizations to ensure effective outreach and engagement of disadvantaged communities.

The plan implementation section for this GSP is therefore inadequate. At a minimum, an adequate plan implementation section must include the following elements, which are not present here:

1. **Description of DAC engagement:** Ensure that the GSP describes how ongoing engagement will be conducted during GSP implementation, including but not limited to engagement regarding: decisions about projects, management actions, modifying sustainable management criteria, changes to monitoring networks, and conducting GSP updates.
2. **Notice:**[118] Ensure that the GSP states that ongoing engagement will include clear notices about GSA meetings and workshops that are posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.[119]
3. **Translation of materials:**[120] Ensure that the GSP states that ongoing engagement will include translation of materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.
4. **Interpretation:**[121] Ensure that the GSP states that ongoing engagement will include. interpretation services provided at board meetings, committee meetings and workshops into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English.
5. **Accessible workshops:** Ensure that the GSP states that ongoing engagement will include workshops held at accessible times and locations for disadvantaged community residents.
6. **DAC representation on advisory committee and board:** Ensure that the GSP states that ongoing engagement will include an advisory committee and a GSA Board containing representatives from DACs. The GSA must include representatives on the the GSA board, and should include representatives from DACs on all advisory committees such that their voices can be as strong as other beneficial user groups.

[118] Government Code § 54954(a).
[119] Government Code sec. 7296.2.
[120] Government Code sec. 7296.2.
[121] Government Code sec. 7296.2.

7. **Partnership with local community based organizations:** Ensure that the GSP states that ongoing engagement will include partnership between the GSA and community based organizations and nonprofits.
8. **Engagement on key decisions:** Ensure that the GSP states that ongoing engagement will include strategies to keep the public informed and engaged during and prior to critical decisions about the GSP, including but not limited to the five year GSP review, modification of sustainable management criteria, design and adoption of any projects and management actions, and development and adoption of the programs to assist with impaired wells.
9. **Engagement on financial issues:** Ensure that the GSP states that it will conduct meaningful outreach to DACs and incorporate feedback before approving operating budgets and enacting groundwater fees.

J. The GSP Does Not Comply With California Water Law.

a. The GSP Conflicts With Water Code § 106.3.

As noted above, California codified access to an adequate supply of safe and affordable drinking water as a human right in 2012. Water Code § 106.3(a) provides as follows:

> It is hereby declared to be the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes.

It is often incorrectly stated that this section is not binding. This is a misnomer for several reasons. First, § 106.3(b) expressly states in that "[a]ll relevant state agencies, including the department, the state board, and the State Department of Public Health, ***shall*** consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria when those policies, regulations, and criteria are pertinent to the uses of water described in this section." (emphasis added.) The use of the mandatory "shall" rather than a permissive "may" indicates that the requirement of subsection (b) to consider the Human Right to Water is a mandatory duty of DWR and the SWRCB.

Moreover, there is nothing in § 106.3 that indicates that either a GSA or a state agency may take an action that conflicts with the human right of all Californians to access safe and affordable drinking water. Rather, the section and its requirements are subject to only three narrow exceptions. First, subsection (c) states that "[t]his section does not expand any obligation of the state to provide water or to require the expenditure of additional resources to develop water infrastructure beyond the obligations that may exist pursuant to subdivision (b)." This exception

applies only to the "state," and does not apply to GSAs. Further, it speaks only to the obligation to provide water or to require development of water infrastructure, not to any obligation to manage groundwater resources in a way that protects existing access to drinking water.

Second, subsection (d) states that "[t]his section shall not apply to water supplies for new development." It is silent regarding water supplies for existing households.

Third, subsection (e) states that "[T]he implementation of this section shall not infringe on the rights or responsibilities of any public water system." As a GSA is not a public water system, this exception is not relevant here.

Given that none of the three exceptions contained in § 106.3 apply to the development and implementation of the GSP, it must be consistent with the Human Right to Water, and separately, DWR must consider the human right on review of GSP. Because the GSP conflicts with § 106.3 by interfering with access to safe and affordable drinking water, DWR cannot approve it.

b. The GSP Threatens to Infringe Upon Water Rights

In enacting SGMA, the legislature found and declared that "[f]ailure to manage groundwater to prevent long-term overdraft infringes on groundwater rights."[122] The text of SGMA further notes that "[n]othing in this part, or in any groundwater management plan adopted pursuant to this part, determines or alters surface water rights or groundwater rights under common law or any provision of law that determines or grants surface water rights."[123] As discussed in detail above, the GSP allows continued overdraft above the safe yield of the basin, such that drinking water wells (especially domestic wells) will continue to go dry, infringing upon the rights of overlying users of groundwater. DWR cannot approve the GSP until it is revised to protect the rights of residents of disadvantaged communities and/or low-income households who hold overlying rights.[124]

c. The GSP Conflicts with the Reasonable And Beneficial Use Doctrine

The "reasonable and beneficial use" doctrine is codified in the California Constitution. It requires that "the water resources of the State be put to beneficial use to the fullest extent of which they are capable, and that the waste or unreasonable use or unreasonable method of use of water be prevented, and that the conservation of such waters is to be exercised with a view to the

[122] AB 1739 (2014).
[123] Water Code § 10720.5(b).
[124] *See also* Water Code § 10723.2 [The groundwater sustainability agency shall consider the interests of all beneficial uses and users of groundwater… [including] Domestic well owners."].

reasonable and beneficial use thereof in the interest of the people and for the public welfare."[125] The doctrine applies to all water users, regardless of basis of water right, and all water rights and methods of diversion.[126] A determination of reasonableness of a use "cannot be resolved in vacuo isolated from statewide considerations of transcendent importance."[127]

DWR and the Water Board must ensure that GSP's water allocations are consistent with the reasonable and beneficial use doctrine.[128] In doing so, DWR and the Board must follow the Legislature's directive to prioritize domestic use of water resources over irrigated agriculture[129] and ensure that SGMA implementation furthers the human right to safe and affordable drinking water[130] — both statewide considerations of transcendent importance. In other words, a GSP that allows use of water for irrigation at the expense of use of water for domestic purposes is not consistent with the reasonable and beneficial use doctrine.

The reasonable and beneficial use doctrine applies here given the negative impacts of the GSP on groundwater supply and quality, which are likely to unreasonably interfere with the use of groundwater for drinking water and other domestic uses. As the GSP authorizes waste and unreasonable use, and indeed does not even analyze the reasonable and beneficial use doctrine at all, it conflicts with the reasonable and beneficial use doctrine and the California Constitution. As a result, DWR cannot approve the GSP as presently drafted.

d. The GSP Conflicts with the Public Trust Doctrine

The public trust doctrine applies to the waters of the State, and establishes that "the state, as trustee, has a duty to preserve this trust property from harmful diversions by water rights holders" and that thus "no one has a vested right to use water in a manner harmful to the state's waters."[131]

---

[125] Cal Const, Art. X § 2; see also Water Code § 100; United States v. State Water Resources Control Bd. (1986) 182 Cal.App.3d 82, 105 ["…superimposed on those basic principles defining water rights is the overriding constitutional limitation that the water be used as reasonably required for the beneficial use to be served."].

[127] Joslin v. Marin Municipal Water Dist. (1967) 67 Cal.2d 132, 140.

[128] Water Code § 275 ["The department and board shall take all appropriate proceedings or actions before executive, legislative, or judicial agencies to prevent waste, unreasonable use, unreasonable method of use, or unreasonable method of diversion of water in this state"]; *Light*, 226 Cal.App.4th at 1482-83 [same].

[129] Water Code § 106 ["It is hereby declared to be the established policy of this State that the use of water for domestic purposes is the highest use of water and that the next highest use is for irrigation"]; *United States v. State Water Resources Control Board* (1986) 182 Cal.App.3d 82, 103 .

[130] Water Code § 106.3.

[131] *United States v. State Water Resources Control Bd.* (1986) 182 Cal.App.3d 82, 106; *see also Nat'l Audubon Soc'y v. Superior Court* (1983) 33 Cal.3d 419, 426 ["before state courts and agencies approve water diversions they should consider the effect of such diversions upon interests protected by the public trust, and attempt, so far as feasible, to avoid or minimize any harm to those interests."].

The public trust doctrine has recently been applied to groundwater where there is a hydrological connection between the groundwater and a navigable surface water body.[132] In *Environmental Law Foundation v. State Water Resources Control Board* ("*ELF*"), the court held that the public trust doctrine applies to "the extraction of groundwater that adversely impacts a navigable waterway" and that the government has an affirmative duty to take the public trust into account in the planning and allocation of water resources.[133] Under *ELF*, the Public Trust doctrine imposes an affirmative and independent obligation to consider the public trust that applies to DWR's decisions regarding submitted GSPs, imposing a legal duty on DWR to not only consider the potential adverse impacts of groundwater extractions on navigable waterways but also "to protect public trust uses whenever feasible."[134] The court also specifically held that SGMA does not supplant the requirements of the common law public trust doctrine.[135]

Notably, the public trust doctrine applies to both currently navigable surface water bodies and surface water bodies that were historically navigable at the time of statehood.[136]

In contrast to these requirements, the GSP does not consider impacts on public trust resources, or attempt to avoid insofar as feasible harm to the public's interest in those resources. DWR cannot approve the GSP without evaluating impacts to public trust resources and protecting public trust uses whenever feasible. Specifically, DWR must (1) identify any public trust resources within the basin; (2) identify any public trust uses within the basin; (3) identify and analyzing potential adverse impacts of groundwater extractions on public trust resources and uses; and (4) determine the feasibility of protecting public trust uses and protect such uses whenever feasible.

~ ~ ~ ~ ~ ~ ~ ~ ~

DWR cannot approve the GSP because it fails to protect beneficial users and access to drinking water. We welcome the opportunity to further discuss our concerns with the Department of Water Resources and the State Water Resources Control Board. Furthermore, we urge DWR to review this and all other GSPs according to the Human Right to Water Scorecard, as we have done in this letter.[137] We hope to successfully work with the GSA, communities, DWR and the SWRCB to ensure that groundwater management is equitable and sufficiently protective of vital drinking water resources. Going forward, we ask DWR to ensure that the GSP adhere to the

Re: Reviewing Groundwater Sustainability Plans In Accordance With State Agency Obligations to Consider the Human Right to Drinking Water

Our collective organizations write to express our concern regarding implementation thus far of the Sustainable Groundwater Management Act (SGMA), specifically with respect to its treatment of (or lack of consideration for) safe drinking water in many of the most vulnerable California communities -- and to urge the Department and Board to review Groundwater Sustainability Plans in accordance with state agency obligations to consider California's Human Right to Water law.

We have engaged in the SGMA implementation processes throughout the state because many of the communities with whom we work are dependent on groundwater for their drinking water supplies, and have already experienced groundwater quality and supply issues. We have participated in meetings, commented on dozens of groundwater plans, and supported engagement of residents from several communities in the development of Groundwater Sustainability Plans (GSPs). But despite our engagement and the engagement of disadvantaged community residents, most GSPs do not adequately address threats to drinking water quality or reliability for disadvantaged communities.

Historically, many of the communities most impacted by depleted and tainted groundwater sources have been excluded from the decision-making tables that determined where water would flow and what infrastructure would be laid. But California took historic steps forward with the recognition of the Human Right to Water as a state-wide goal in 2012 and with the passage of SGMA in 2014 which included requirements for a transparent and inclusive process and consideration of vulnerable communities. Specifically, decision-making processes related to groundwater management must include disadvantaged communities, and groundwater management plans must respond to the unique vulnerabilities of disadvantaged communities,[1] consider their drinking water needs,[2] and avoid causing disproportionately negative impacts on low income communities of color.[3]

Unfortunately, many of the draft GSPs released to date pose a significant threat to safe drinking water access in low-income communities. Few account for drinking water impacts on local communities dependent on groundwater— the vast majority of small communities in the San Joaquin Valley. When

[1] Water Code § 10723.2
[2] Water Code § 106.3
[3] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].

implemented, these GSPs have the potential to threaten severe and irreparable harm to drinking water supplies and the communities dependent on those supplies. As such, many of the recently approved draft GSPs undermine Governor Newsom's vision of a California where everyone has safe drinking water and run counter to California's Human Right to Drinking Water (AB 685).

With these grave concerns in mind, we urge the state to abide by the mandate the Human Right to Water demands.

The Human Right to Drinking Water in GSP Evaluation and Approval

The human right to safe and affordable water for drinking and sanitation was codified by AB 685 in 2012, which modified Water Code section 106.3 to include: "it is...the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."[4] The law obligates "all relevant state agencies" to "consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria...pertinent to" drinking water purposes.[5] The law specifically names the Department of Water Resources (DWR) and the State Water Resources Control Board (SWRCB).

The Human Right to Water has catalyzed and facilitated several new state initiatives. The State Water Resources Control Board has created a Human Right to Water Portal on its website which shows drinking water quality in all public water systems in the state and passed a resolution aligning State Board priorities and values with the Human Right to Water. The human right to water has also been used as underpinning for two successful legislative campaigns: AB 401 (2015) and the Safe and Affordable Drinking Water Fund, or SB 200 (2019). The former mandated a state-wide study of the best mechanism for delivering affordable drinking water in all publicly regulated water systems; the latter created a state-wide fund for installing, operating and maintaining drinking water infrastructure for disadvantaged communities and schools suffering from water quality and water supply issues. Governor Newsom played a strong role in the passage of the Safe and Affordable Drinking Water Fund as part of his personal commitment to securing safe water for all Californians.

These initiatives represent clear steps forward towards achieving safe and affordable drinking water for all Californians, but the state remains far from achieving the law's goal of guaranteeing "safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes" to "every human being" in the state of California.[6] In the San Joaquin Valley alone, tens of thousands of vulnerable families, including those with whom we work, suffer from contaminated drinking water, unaffordable drinking water costs, and the impacts of inadequate water supply such as dry wells and water pressure problems. As many as 350,000 people lack access to potable water in the San Joaquin Valley alone, and Hispanic communities are disproportionately impacted: while Hispanics make up just under half, or 49 percent, of the total population of the San Joaquin Valley, they represent more than two-thirds of residents in these unincorporated communities and 57 percent of all residents served by out-of-compliance water systems.[7] This number does not account for those unincorporated communities

[4] Water Code sec. 106.3(a)
[5] Water Code sec. 106.3(b)
[6] Water Code sec. 106.3(a)
[7] The Struggle for Water Justice in California's San Joaquin Valley: A Focus on Disadvantaged Unincorporated Communities, London & Fencl et al., University of California Davis, February 2018.

on private domestic wells, many of which also have contaminated water which goes unmonitored and unregulated.

Groundwater management practices have historically aggravated drinking water issues in the San Joaquin Valley by allowing agribusiness and other actors to pump unrestricted amounts of groundwater, leaving local communities with dry wells, and unreliable drinking water supplies. Moreover, there has been limited regulation on agricultural impacts to groundwater quality, leading to contamination of drinking water for communities in the San Joaquin Valley. Low-income families living in disadvantaged communities do not have the financial means to replace or deepen wells, install costly treatment mechanisms, or transition to alternative water supplies such as surface water.

SGMA created both an unprecedented and quite possibly a last opportunity to avoid further encroachment on the basic human right to water, yet our review of GSPs in the San Joaquín, Salinas and Coachella Valleys indicates that GSAs have not leveraged this opportunity. Rather, the GSPs we have reviewed rarely account for impacts on local communities dependent on groundwater, and prioritize the continued economic viability of agriculture at the expense of drinking water for low income communities. For example, some Central Valley GSPs have established minimum thresholds—or failure points—that, if reached, would allow up to 85% of domestic wells to go fully or partially dry within the GSP area. Overall, a technical review that the Community Water Center and Self-Help Enterprises commissioned of drinking water impacts of 13 GSPs in the San Joaquin Valley shows more than 8,000 wells will be dewatered in the area covered by the GSPs. Draft GSPs allow continued groundwater quality degradation in excess of water quality objectives, violating the Porter-Cologne Water Quality Control Act (Water Code sec. 13000 et seq.), the antidegradation policy, and the non-point-source policy. Even worse, some GSPs ignore water quality impacts entirely.

DWR and the SWRCB are now tasked with evaluating and deciding whether to approve GSPs. The agencies must determine whether to approve policies in these documents that set out the level to which GSAs will allow groundwater levels to decline, the extent to which GSAs will protect local drinking water users from contamination resulting from groundwater management activities, and which projects and management actions the GSA will implement to impact local groundwater resources. All of these decisions have vast drinking water implications for communities within each GSP area. As such, evaluation and approval of GSPs falls squarely within the category of "revising, adopting, or establishing policies, regulations, and grant criteria...pertinent to" drinking water purposes.[8] DWR and the State Water Resources Control Board must therefore "consider this state policy"[9] "that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes"[10] in their review of each GSP. In order to comply with this obligation, the Department and Board must ensure that GSPs do not cause or allow further drinking water crises.

Implementing the Human Right to Drinking Water in GSP Evaluation and Approval

We have compiled and attached a "Human Right to Drinking Water GSP Scorecard" which identifies the elements that must exist in GSPs in order for GSPs to adequately protect the Human Right to Drinking Water. We urge the Department of Water Resources and the State Water Resources Control Board to integrate this analysis into their review of GSPs, and to require that each GSP contain these elements

[8] Water Code § 106.3(b)
[9] Water Code § 106.3(b)
[10] Water Code § 106.3(a)

before it grants approval of the GSP. This scorecard could also be adapted to create a general evaluation rubric that is used by the two agencies as part of a drinking water review protocol for all drinking water-related activities. Additionally, we encourage DWR to use this letter and scorecard to develop a "Human Right to Water"/"Protecting Drinking Water" Best Management Practices guidance document for GSAs to consider when developing, updating and implementing GSPs. Additionally, the Scorecard references a framework that we have developed to show what an effective drinking water protection program would look like, which we have also attached.

We look forward to discussing this Human Right to Water Scorecard with you, and supporting implementation of such a scoring methodology in GSP evaluation and approval. Please do not hesitate to contact Amanda Monaco (amonaco@leadershipcounsel.org), Deborah Ores (deborah.ores@communitywatercenter.org), or Liesbet Olaerts (olaerts@selfhelpenterprises.org) with any follow-up questions or for more information.

Human Right To Water Scorecard for the Review of Groundwater Sustainability Plans……..p. 6-14

Framework and Guidance for Developing a Drinking Water Well Impact Mitigation Program (Working Draft)..……..…..p. 15-24

Human Right To Water Scorecard for the Review of Groundwater Sustainability Plans

Review Criteria *(All Indicators Must be Present in Order to Protect the Human Right to Water)*		Yes/No
A	**Plan Area**	
1	**Does the GSP identify, describe, and provide maps of all of the following beneficial users in the GSA area?**[11] a. Disadvantaged Communities (DACs). b. Tribes. c. Community water systems d. Private well communities.	
2	**Land use policies and practices:**[12] Does the GSP review all relevant policies and practices of land use agencies which could impact groundwater resources? These include but are not limited to the following: a. Water use policies General Plans and local land use and water planning documents b. Plans for development and rezoning c. Processes for permitting activities which will increase water consumption	
B	**Basin Setting (Groundwater Conditions and Water Budget)**	
1	Does the **groundwater level conditions** section include past and current drinking water supply issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities?	

[11] 23 CCR § 354.8(a) and (b)
[12] 23 CCR § 354.8(f)

2	Does the **groundwater quality conditions** section include past and current drinking water quality issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities, including public water wells that had or have MCLs exceedances?[13]	
3	Does the **groundwater quality conditions** section include a review of all contaminants with primary drinking water standards known to exist in the GSP area, as well as hexavalent chromium, and PFOs/PFOAs?[14]	
4	**Incorporating drinking water needs into the water budget:**[15] Does the Future/Projected Water Budget section explicitly include both the current and projected future drinking water needs of communities on domestic wells and community water systems (including but not limited to infill development and communities' plans for infill development, installation of additional services, and housing growth in disadvantaged communities), taking into account increased climate variability due to climate change ?	
C	**Sustainability Goal**	
1	Does the **sustainability goal** explicitly include considerations about the needs of drinking water users?[16]	
D	**Sustainable Management Criteria (SMC) for Groundwater Levels**	
1	**Evaluation of drinking water impact:** Does the GSP include an analysis of how many drinking water wells (municipal wells, community water system wells, and domestic wells) might go fully or partially dry if groundwater levels reach the Undesirable Results (URs),[17] Measurable Objectives (MOs) and Measurable Objectives (MTs),[18] including a map of wells that will go fully and partially dry at the MOs and MTs? Does this include Does the GSP include estimates of the increased pumping costs from additional lift needed to pump water from lower elevations if the URs,[19] MOs and MTs[20] were to be reached?	
2	**Considering drinking water impacts in creating SMC:**[21] Does the GSP explicitly state how it considered drinking water impacts in shaping URs, MOs, and MTs for groundwater levels? For example, the GSP could state how its well impact analysis supported on setting stricter MTs and MOs near at risk communities.	

[13] 23 CCR § 354.16(d)
[14] 23 CCR § 354.16(d)
[15] 23 CCR § 354.18(c)(2)(b)
[16] 23 CCR § 354.24: Sustainability goal must "culminate in the absence of undesirable results within 20 years."
[17] 23 CCR § 354.26(c)
[18] 23 CCR § 354.28(b)(4)
[19] 23 CCR § 354.26(c)
[20] 23 CCR § 354.28(b)(4)
[21] Water Code § 10723.2

3	**Incorporating new drinking water data into SMC:**[22] Does the GSP include a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data?	
4	**Implementing DAC and drinking water user input into SMC:**[23] Does the GSP discuss how stakeholder input from DAC community members was considered in the development of URs, MOs, and MTs? For example, the GSP could state how they took the results of the well impact assessment to the public through meetings, workshops, or Advisory Committees, and together with stakeholders decided how to change SMC to protect drinking water, or other programs to implement to mitigate these impacts.	
5	**Avoiding a disparate impact:**[24] Are the MOs and MTs for groundwater levels established in such a way that prevents a disproportionately negative ("disparate") impact from occurring on communities of color in the GSP area? For example, the GSP should ensure that the same MT methodology across the GSP area will not lead to disproportionately more wells going dry for residents of color than for white residents.	
E	**Sustainable Management Criteria for Groundwater Quality**	
1	**Evaluation of drinking water impact:** Does the GSP include an analysis of how drinking water wells (municipal wells, community water system wells, and domestic wells) might be affected by the Undesirable Results (URs),[25] Measurable Objectives (MOs) and Measurable Objectives (MTs)?[26]	
2	**Does the GSP set MOs and MTs at all representative monitoring wells for the following contaminants?**[27] a. Contaminants with primary drinking water standards, b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health, AND c. Contaminants like Uranium which are known to increase due to groundwater management practices.	

[22] 23 CCR § 354.38(e)(3)

[23] 23 CCR § 354.10(d); DWR Guidance Document for Groundwater Sustainability Plans: Stakeholder Communication and Engagement, p.1.

[24] Gov. Code § 11135 ["No person in the State of California shall, on the basis of sex, race, color, religion, ancestry, national origin, ethnic group identification, age, mental disability, physical disability, medical condition, genetic information, marital status, or sexual orientation, be unlawfully denied full and equal access to the benefits of, or be unlawfully subjected to discrimination under, any program or activity that is conducted, operated, or administered by the state or by any state agency, is funded directly by the state, or receives any financial assistance from the state."]; Gov. Code § 65008 [Any discriminatory action taken "pursuant to this title by any city, county, city and county, or other local governmental agency in this state is null and void if it denies to any individual or group of individuals the enjoyment of residence, land ownership, tenancy, or any other land use in this state…"]; Government Code §§ 12955, subd. (l) [unlawful to discriminate through public or private land use practices, decisions or authorizations].

[25] 23 CCR § 354.26(c)

[26] 23 CCR § 354.28(b)(4)

[27] 23 CCR § 354.34(b)(2) and (f)(3)

3	**Strive to remediate:** Does the GSP state that the GSA will strive to remediate groundwater quality wherever feasible, through projects, management actions and policies?	
4	**Description of when minimum threshold is triggered:** Does the GSP trigger a violation of a minimum threshold after *one* test shows that there has been an increase in contamination since January 1st, 2015?	
5	**Implementing DAC and drinking water user input into SMC:**[28] Does the GSP discuss how stakeholder input from DAC community members was considered in the development of URs, MOs, and MTs?	
6	**Incorporating new drinking water data into SMC:**[29] Does the GSP include a description of how data gaps and uncertainties of its drinking water well impact assessment will be addressed and serve to reassess the sustainable management criteria, projects and management actions in accordance with new data?	
7	**Avoiding a disparate impact:**[30] Are the minimum thresholds for groundwater quality established in such a way that prevents a disproportionately negative ("disparate") impact from occurring on communities of color in the GSP area? For example, the GSP should ensure that the same MT methodology across the GSP area will lead to disproportionately more wells go dry for residents of color than for white residents.	
F	**Monitoring Network for Groundwater Levels**	
1	**Accurately detecting impacts on drinking water users and DACs:**[31] Does the groundwater level monitoring network include *representative* monitoring wells *in or near DACs*, and placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area? If not, does the GSP contain a concrete plan to fund and implement new representative monitoring wells to ensure that vulnerable communities' drinking water resources are monitored? Such a plan could include testing of domestic wells in the interim.	
2	**Clearly showing representative monitoring well locations in relation to DACs:**[32] Are the representative monitoring wells (RMWs) for groundwater levels presented on maps and in tables that identify which set of MTs/MOs will be applied to which RMWs? Do these maps clearly identify the locations of DACs, small water systems and other sensitive users?	

[28] 23 CCR § 354.10(d); DWR Guidance Document for Groundwater Sustainability Plans: Stakeholder Communication and Engagement, p.1.
[29] 23 CCR § 354.38(e)(3)
[30] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).
[31] 23 CCR § 354.34(b)(2) and (f)(3)
[32] 23 CCR § 354.34(b)(2) and (f)(3)

3	**Identifying and addressing other drinking water data gaps:**[33] Does the GSP clearly identify any other gaps in data regarding impacts to drinking water users? Does the GSP contain a clear plan to fill data gaps regarding impacts to drinking water users?	
G	**Monitoring Network for Groundwater Quality**	
1	**Does the GSP plan to measure the following contaminants at all representative monitoring wells?**[34] a. Contaminants of concern with primary drinking water standards b. PFOs/PFOAs and chrome-6, which are contaminants known to be very harmful to human health c. Contaminants like Uranium which are known to increase due to groundwater management practices	
2	**Clear description of effective monitoring for drinking water impacts:** Does the GSP include a description of how the GSA(s) will monitor groundwater contamination that could affect drinking water in the GSA area? Are the representative monitoring wells (RMWs) for groundwater quality presented on maps and in tables, and do the maps of RMWs clearly identify the locations of DACs, small water systems and other sensitive users?	
3	**Accurately detecting impacts on drinking water users and DACs:**[35] Does the groundwater quality monitoring network include *representative* monitoring wells (RMWs) *in or near all DACs* AND placed in a way that detects impacts to the *vast majority* of drinking water users in the GSP area, including domestic well users? If not, does the GSP contain a concrete plan to fund and implement new representative monitoring wells to ensure that vulnerable communities' drinking water resources are monitored? This plan could include testing of domestic wells in the interim.	
4	**Baseline contaminant levels:** Does the GSP identify the current contaminant levels, MTs and MOs at each RMW, so that it is clear to the public how the contamination will change at each RMW site?	
5	**Frequent monitoring:** Does the groundwater quality monitoring network test for contaminants of concern frequently, in a way that avoids persistent drinking water contamination?	
6	**Collaboration with other agencies:**[36] Does the GSP explain how the GSA(s) will share data with and collaborate with other groundwater quality regulatory programs, such as ILRP, IRWM, and CV SALTS, in order to build better regional understanding of groundwater quality issues and better respond to groundwater quality impacts caused by groundwater management?	
H	**Projects and Management Actions**	

[33] 23 CCR § 354.38(e)(3)
[34] 23 CCR § 354.34(b)(2) and (f)(3)
[35] 23 CCR § 354.34(b)(2) and (f)(3)
[36] 23 CCR § 354.34(e)

1	**Does the GSP describe the potential drinking water impacts of each project or management action?** Example of impacts are provided below: a. **Recharge and on-farm recharge projects:** Carefully designed and implemented recharge projects can simultaneously increase groundwater storage and levels, as well as dilute contaminant plumes and improve groundwater quality. However, if not properly designed, recharge projects, in particular on-farm recharge, may mobilize nitrates, pesticides, fertilizers, and naturally occurring contaminants, which can lead to the further degradation of groundwater quality, negatively impacting drinking water wells. Even relatively unpolluted water used for recharge, such as most purchased water or streamflow, may contain constituents of concern and/-or mobilize contaminants. Therefore GSAs must consider potential impacts to water quality when planning groundwater recharge projects.[37] b. **Groundwater market management action:** Groundwater markets are very likely to put drinking water resources at risk for communities and residents who do not have the financial, political and technical power to participate equally in a market. Groundwater markets have the potential to seriously aggravate existing lack of equity in access to critical groundwater resources. We therefore recommend that GSAs do not include groundwater markets as a potential management action. In particular, local groundwater markets are not a viable option where the potential impacts of trading are not well understood, where trading rules cannot sufficiently address negative externalities, or where the expected benefits of a market do not outweigh the burdens and uncertainties associated with designing and implementing it. If GSAs wish to consider groundwater markets, a well-designed trading program requires a fair and adequate allocation of groundwater for drinking water uses, an additional margin for future growth prior to allocating water for trading purposes, and trading rules that avoid undesirable results as well as avoid or mitigate potential impacts to communities and ecosystems dependent on groundwater. If these components are missing, the market can have significant negative impacts upon a community's drinking water supply and the environment. Some impacts include, but are not limited to: localized drying of community and domestic wells, increased contamination levels, or unaffordable water rates.[38] c. **Funding mechanisms/Delinquent fees management action:** Any fee and/or extraction penalties structure should take into consideration that small communities have fewer economic opportunities, have a small role in overall groundwater pumping percentage, and are burdened with lower technical, managerial, and financial capacity for operations and maintenance. Overall, small drinking water systems should be exempted from GSA's fees or financial penalties for over-use to support their efforts on providing affordable safe water according to AB 685. If exemption is not viable, the GSA should create special considerations such as discounts, reduced costs, rebates, or other to ensure	

[37] State Water Boards, Water Quality Frequently Asked Questions document: https://www.waterboards.ca.gov/water_issues/programs/gmp/docs/sgma/sgma_water_quality_faq.pdf

[38] Community Water Center et al., *Groundwater Markets: Recommendations to Ensure Drinking Water Protection for Communities* (guidance document to be published soon)

	drinking water affordability. Alternatively, small drinking water systems should receive warnings prior to financial penalties tied to an appeal process. Doing so may allow these communities to explain why the overuse occurred, providing mechanisms for transparency and support on addressing the problems. d. **Groundwater allocation management action:** Any groundwater allocation scheme must protect all current and future drinking water needs for disadvantaged communities.	
2	**Drinking water protection and mitigation program:** Does the GSP contain a drinking water protection program to prevent impacts to drinking water users and mitigate the drinking water impacts that occur? Such a program should also identify the following: a. How it will be funded. b. An estimate of how much it will cost. c. How program beneficiaries will be eligible to participate. d. How it will be designed in collaboration with impacted stakeholders. e. What type of mitigation measurements it will provide. f. Timeline for program implementation. **Please refer to the attached **Framework and Guidance for Developing a Drinking Water Well Impact Mitigation Program** for a more in-depth description of what an effective drinking water mitigation program should look like.*	
3	**Demand reduction:** Does the GSP contain robust demand reduction management actions? Plans that depend mainly on imported surface water (supply augmentation through recharge projects) do not clearly demonstrate a path towards sustainability, since climate variability puts these resources at risk.	
4	**Accurate measurement of groundwater extraction:** Does the GSP include management actions to measure groundwater extraction using the most scientifically accurate method?	
5	**Avoiding a disparate impact:**[39] Do the GSP's projects and management actions, taken as a whole, prevent a disproportionately negative ("disparate") impact from occurring on communities of color in the GSP area? Projects and management actions may not cause disproportionately more dry wells and contaminated water for residents of color than for white residents in the GSA area.	
I	**Public Participation and Transparency**	
1	Is a **Stakeholder Communication and Engagement Plan** included in the GSP?	
DAC and drinking water user engagement during GSP development[40]		

[39] Gov. Code § 11135; Gov. Code § 65008; Government Code §§ 12955, subd. (l).

[40] Water Code § 10723.2; Water Code § 10727.8(a) The groundwater sustainability agency shall encourage the active involvement of diverse social, cultural, and economic elements of the population within the groundwater basin prior to and during the development and implementation of the groundwater sustainability plan.

2	**Description of DAC engagement:** Does the GSP specifically identify how DAC beneficial users were engaged in the planning process?	
3	**Notice:**[41] Did the GSA provide clear notice to the public about GSA meetings to develop the GSP, posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English? [42]	
4	**Translation of materials:**[43] Did the GSA translate materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
5	**Interpretation:**[44] Did the GSA(s) provide interpretation services at board meetings, committee meetings and workshops into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
6	**Accessible workshops:** Did the GSA(s) host workshops held at accessible times and locations for disadvantaged community residents?	
7	**DAC representation on advisory committee:** Did the GSA(s) develop the GSP with an advisory committee that contained representatives from DACs?	
8	**DAC representation on GSA board:** Did the GSA(s) develop the GSP with a Board that contained representatives from DACs?	
9	**Partnership with local community based organizations:** Did the GSA partner with community based organizations and nonprofits on outreach and engagement?	
10	**Public Comment Period:** Did the GSA provide a robust public comment period of at least 60 days, with opportunity for the public to discuss comments and proposed agency responses with staff and the GSA before GSP approval?	
11	**Incorporation of stakeholder input:** Does the GSP explicitly describe how stakeholder input was incorporated into the GSP process and decisions?	
DAC and drinking water user engagement during GSP implementation		

[41] Government Code § 54954(a).

[42] Government Code sec. 7296.2: Dymally-Alatorre Bilingual Services Act, stating that local agencies providing services to the public must provide translated materials and interpretation when it serves a substantial number of non-English-speaking people. The law defines a "substantial number of non-English-speaking people" as "members of a group who either do not speak English, or who are unable to effectively communicate in English because it is not their native language, and who comprise 5 percent or more of the people served by the statewide or any local office or facility of a state agency." This is because "effective maintenance and development of a free and democratic society depends on the right and ability of its citizens and residents to communicate with their government and the right and ability of the government to communicate with them."

[43] Government Code sec. 7296.2.

[44] Government Code sec. 7296.2.

12	**Description of DAC engagement:** Does the GSP describe how ongoing engagement will be conducted during GSP implementation, including but not limited to engagement regarding: decisions about projects, management actions, modifying sustainable management criteria, changes to monitoring networks, and conducting GSP updates?	
13	**Notice:**[45] Does the GSP state that ongoing engagement will include clear notices about GSA meetings and workshops that are posted in ways that all stakeholders were made aware of the meetings, and translated into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?[46]	
14	**Translation of materials:**[47] Does the GSP state that ongoing engagement will include translation of materials into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
15	**Interpretation:**[48] Does the GSP state that ongoing engagement will include interpretation services provided at board meetings, committee meetings and workshops into all languages spoken by at least 5 percent of the public served by the agency, who do not speak English or are unable to effectively communicate in English?	
16	**Accessible workshops:** Does the GSP state that ongoing engagement will include workshops held at accessible times and locations for disadvantaged community residents?	
17	**DAC representation on advisory committee and board:** Does the GSP state that ongoing engagement will include advisory committees and Boards containing representatives from DACs?	
18	**Partnership with local community based organizations:** Does the GSP state that ongoing engagement will include partnership between GSA and community based organizations and nonprofits?	
19	**Engagement on key decisions:** Does the GSP state that ongoing engagement will include strategies to keep the public informed and engaged during and prior to critical decisions about the GSP, including but not limited to the five year GSP review, modification of sustainable management criteria, design and adoption of any projects and management actions, and development and adoption of the programs to assist with impaired wells?	
20	**Engagement on financial issues:** Does the GSP state that it will conduct outreach to DACs before approving operating budgets and enacting groundwater fees?	

[45] Government Code § 54954(a).
[46] Government Code sec. 7296.2.
[47] Government Code sec. 7296.2.
[48] Government Code sec. 7296.2.

Appendix B: Framework and Guidance for Developing a Drinking Water Well Impact Mitigation Program [Working Draft]

Management Action Name:
Drinking Water Well Impact Mitigation Program

Potential Implementing Organization(s):
Groundwater Sustainability Agencies (GSAs) in partnership with project participants.

Purpose Statement:
The purpose of this document is to be utilized by GSAs to mitigate, prevent, and address any adverse effects on drinking water wells caused by pumping volume or location, conjunctive management, or any other forms of active management as part of Groundwater Sustainability Plan (GSP) implementation. By doing so, GSAs can better achieve the goals of the Sustainable Groundwater Management Act (SGMA), avoid jeopardizing access to safe water in vulnerable communities, and also avoid violating California laws that establish a state-wide Human Right to Water and that protect access to safe water. Adverse effects can include both issues with access to safe drinking water due to increased contamination, as well as issues with sustained access to water due to changes in groundwater levels.

This document provides a framework of elements to consider when GSAs are developing a drinking water well impact mitigation plan. Every community and every GSA will have to evaluate their own needs and particular considerations in order to develop a mitigation program that works best for all users. This document is broken down into the following sections:

1) Importance of drinking water well mitigation programs;
2) Framework for developing program / key elements to consider;
3) Cost considerations for short term and long term solutions and potential funding sources; and
4) Four local case studies of existing drinking water well mitigation programs.

Section 1. Importance of a Drinking Water Well Impact Mitigation Program:

How can GSP implementation impact domestic wells and small community wells?

Across the state, critically overdrafted basins have developed Groundwater Sustainability Plans (GSPs) to manage groundwater resources sustainably under the Sustainable Groundwater Management Act

(SGMA). Many GSPs have developed sustainable management criteria, including minimum thresholds (MTs) and measurable objectives (MOs), that if reached, would cause significant impacts to access to safe and affordable drinking water for vulnerable communities. GSP implementation, including management actions and projects, can cause changes in groundwater levels and groundwater quality that could lead to:

- Completely dewatered wells;
- Partially dewatered wells:
    - needing to lower the well pump,
    - needing to clean the well screen,
    - needing to drill deeper;
- An increased movement of contaminant plumes;
- An increase in the concentration or release of contaminants;
- An increase in salinity due to sea water intrusion in coastal wells;
- Higher energy costs from having to drill or pump from a deeper depth; and
- Emotional, psychological, and health impacts related to not having access to safe water.

If GSP sustainable management criteria are developed in a way that could potentially cause significant impact on drinking water users, the GSP must also include a robust drinking water well impact program to prevent and mitigate the drinking water impacts that occur. In some GSAs, up to 85% of domestic wells are at risk of being dewatered or partially dewatered. In these same GSAs, rural domestic and small water system demand does not contribute substantially to the overdraft conditions, yet the risks imposed on these drinking water users are overlooked and neglected, creating a disproportionate impact on already vulnerable communities.

What are the drinking water challenges of disadvantaged communities?

Without an adequate groundwater sustainability plan that is protective of groundwater sources near or within communities, more drinking water wells will run dry or be unable to provide safe, potable water to residents. This will further jeopardize the livelihood of California's most vulnerable communities. Vulnerable communities, including severely disadvantaged communities (SDACs), disadvantaged communities (DACs), small water systems, and domestic well owners, have limited technical, managerial, and financial capacity to respond to drinking water challenges.

Climate change further exacerbates drinking water challenges with more frequent, longer and more severe droughts and flood periods expected. Small water systems and rural communities reliant on domestic wells are, and will continue to be, the most adversely impacted and most at risk of experiencing water shortages and/ or having to rely on contaminated drinking water supplies. In order to increase water system resiliency, the golden rule is to protect current water sources— especially if the quality of the water is meeting safe drinking water standards. Other ways to increase resiliency are to secure more than one water source, assist communities with maintenance and operation costs, and ensure water affordability. A drinking water well mitigation program is key to increasing water resilience through minimizing risks of both short-term and long-term impacts. Having adequate plans and policies to support drinking water resilience in the face of climate change is essential to reducing the amount of emergency funding needed to respond to a water shortage emergency and to prevent human health crises. A carefully designed and implemented well impact mitigation program can support efforts to ensure all communities have long-term and sustainable access to clean, safe, and affordable drinking water.

How does California law prioritize drinking water?

A GSP which lacks a mitigation program to curtail the effects of projects and management actions on the safety, quality, affordability, or availability of domestic water, violates both SGMA itself and the Human

Right to Water law. The Human Right to Water (AB 685) (HR2W) was signed in 2012 and added § 106.3 to the California Water Code, declaring, "the established policy of the state that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes."[49] The HR2W applies to all state agencies, requiring that they "...shall consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria when those policies, regulations, and criteria are pertinent to the uses of water…".[50] With this passage of AB 685, relevant state agencies, including the State Water Resources Control Board (SWRCB) and the Department of Water Resources (DWR), are now required to consider this state policy when revising, adopting, or establishing policies, regulations, and grant criteria that may impact the uses of water for domestic purposes. These agencies must consider how state actions may impact the Human Right to Water. To ensure compliance with the legislature's long established position and accordance with 23 CCR §350.4, the HR2W requires that DWR must consider the effects on domestic water users when reviewing and approving GSPs.[51] The SWB should be consulted as part of GSP review as part of the Board's expertise on water quality matters.

Further, the California legislature has recognized that water used for domestic purposes has priority over all other uses since 1913.[52] Reserving top priority for domestic water use was later codified in 1943, in Water Code § 106, which declares it the, "established policy of this State that the use of water for domestic purposes is the highest use of water and that the next highest use is for irrigation."[53] Further, the passage of the Safe and Affordable Drinking Water Act by Governor Newsom[54] indicates a clear state-level commitment to providing safe and affordable drinking water to California's most vulnerable residents. Poor implementation of SGMA would threaten the success of the Safe and Affordable Drinking Water Fund and would run counter to Governor Newsom's vision of providing safe water to all.

A carefully designed and implemented Drinking Water Well Impact Mitigation Program can support a statewide goal of ensuring DACs' access to clean, safe, reliable, and affordable drinking water. Including this type of program in a GSP also helps to create a groundwater management plan that understands DACs' unique social and economic vulnerabilities, is sensitive to their drinking water needs, and avoids causing a further disparate impact on low-income communities.

Section 2. Key elements and a framework for developing a Drinking Water Well Mitigation Program:

This section provides a framework of elements to consider when GSAs are developing a drinking water well impact mitigation plan. This section is broken down into the following categories:

i. Drinking water well monitoring network;
ii. Adaptive management and trigger system;
iii. Drinking water well impact tool/model;
iv. Public outreach and education;
v. Mitigation measures;
vi. Program eligibility.

---

[49] WAT § 106.3 (a).
[50] WAT § 106.3(b).
[51] *See generally,* WAT § 106.3 (b).
[52] California Water Commission Act of 1913 § 20.
[53] WAT§ 106; This policy is also noted in the Legislative Counsel's Digest for AB 685.
[54] SB 200, Monning (2019).

i. Drinking water well monitoring network: As required by GSP Regulation, Section 354.34, GSAs must describe how potential impacts to groundwater users and uses will be monitored. It must be recognized that most public water systems have wells deeper than domestic wells, thus monitoring networks must be able to capture impacts to deeper public water system wells as well as shallow domestic wells. The following approach will allow GSAs to comply with GSP regulations and take a proactive approach to protect DACs' and domestic well owners' access to safe and affordable drinking water:

- Map and assess drinking water well vulnerabilities to better understand:
  (1) Locations and depth of drinking water wells (both domestic and public supply wells);
  (2) Whether changes in groundwater levels and quality may be exacerbated in specific areas by pumping volume or location, conjunctive management (i.e. groundwater recharge projects) or other forms of active management as part of GSP implementation;
  (3) The proximity of potentially impacted wells to nearby existing public water systems; and
  (4) If there are areas with a high density of likely impacted wells.
  Assessment should acknowledge that not all existing and utilized wells may be documented in available resources from DWR or Counties.

- Designate key monitoring wells to assess impacts to drinking water wells: Based on the drinking water well vulnerability assessment, identify which wells from the GSP proposed monitoring network are critical to assess impacts to drinking water wells caused by changes to groundwater levels and quality. Expand and improve the monitoring network to assess potential impacts in particular for groundwater conditions near DACs, areas with high density of private domestic wells, and water systems serving schools. The monitoring network needs to be representative of conditions in all aquifers in general, including the shallow aquifer upon which domestic wells rely. The water quality monitoring network needs to routinely monitor for all contaminants that could impact public health (not only nitrate, but also chromium-6, arsenic, 123-TCP, uranium, and DBCP). This will allow the GSA to better comply with GSP regulations Section 354.34, which requires GSAs to describe how potential impacts to groundwater users and uses will be monitored, and to take a proactive approach to protect DACs and domestic well owners' access to safe and affordable drinking water.

ii. Develop an adaptive management/trigger system: Develop a protective warning system, also referred to as an adaptive management approach. Such an approach can alert groundwater managers when groundwater levels and groundwater quality are dropping to a level that could potentially negatively affect drinking water users. These "triggers" are essential for groundwater management and can be adjusted to fit the needs of different management actions as well as the basin as a whole. The table below provides an example of what a warning system might look like, using green, yellow, and red light indicators or triggers, and some potential corrective actions groundwater managers can take to remedy the problem. Ultimately, this approach allows for the evaluation of current conditions in order to respond accordingly to prevent or mitigate negative impacts.

Triggers	Groundwater Status	Potential Corrective Actions
Green-light	Groundwater levels and quality are stable.	No action required
Yellow-light	Groundwater levels and quality are approaching concerning levels and impacts may occur or are occurring at a	- Undertake an analysis to pinpoint the cause; - Undertake water quality testing for selected domestic and public supply wells; - Provide immediate support to groundwater users experiencing impacts;

	low rate. Some corrective actions are needed.	- Reassess pumping allocation and pumping patterns. Consider restricting or limiting groundwater extraction near the impacted area.
Red-light	Time to stop groundwater pumping and management actions and mitigate as significant impacts are imminent or are occurring.	- Reassess pumping allocation and pumping patterns. Consider further restricting or limiting groundwater extraction near the triggered area or reevaluating minimum thresholds or measurable objectives; - Provide interim emergency solution while working with impacted groundwater users to pursue a permanent, long-term solution.

iii. Drinking water well impact tool/model: Develop a tool or model tied to the monitoring network and the adaptive management framework (trigger system) to evaluate groundwater levels and predict potential groundwater impacts to drinking water wells. Update model regularly and develop a prediction of the potential groundwater impacts to drinking water wells. Results of this assessment should be incorporated into an annual GSP progress report to domestic well owners and DACs water systems. The tool or model could be used to:

- Monitor and forecast changes in groundwater levels and quality;
- Monitor and forecast any localized areas for special attention and/or monitoring;
- Attempt to identify domestic wells or small public supply wells at risk of impacts, and;
- Determine if triggers have been met based on the adaptive management framework.

iv. Public outreach and education: Develop public outreach and educational materials to increase awareness of groundwater management activities within the GSA. This outreach could inform groundwater pumpers of the rules, restrictions, and impacts of groundwater over-pumping. This outreach could also inform residents about the potential well impacts that could occur based on groundwater management actions, describe potential options available for well mitigation, and include information for who to contact in the event their wells experience negative impacts. This outreach could take place in the form of pamphlets, mailers, additions to the public website, or radio announcements. This information can also be included in regular GSA updates. To ensure that this program can benefit S/DAC residents, information about the program must be disseminated widely, and such materials must be translated into all threshold languages. The GSA should work with local agencies, organizations and associations to spread materials about the program. The GSA should work with local agencies and organizations to ensure that residents with impacted wells are referred quickly to the GSA for assistance. GSAs should conduct regular, door-to-door outreach (in partnership with other outreach experts as needed) to ensure that communities — particularly for communities location in areas the trigger system identifies within the yellow and red-light ranges— are aware of the well mitigation program and know who to contact in times of emergency.

v. Mitigation measures: Mitigation measures should be implemented as soon as the trigger system reaches its yellow light indicator. Groundwater should be managed in a way that prevents or avoids reaching the red light indicator and before wells become unusable. This will allow communities working with the GSA to access funding and develop a long-term plan that protects community member access to drinking water. The mitigation program should be designed to be proactive, rather than reactive to public health harms. When mechanical failures or other operational problems have occurred, or are likely to occur, due to declining water levels or deteriorating groundwater quality, mitigation should be provided as described below:

- **Third Party Determination of Causality:** Work with an objective third party to establish whether their policies and actions caused the drinking water impact. Based on a field inspection and discussion with the residents impacted, define the level of mitigation that is necessary. Verify well construction information and pump setting information, if possible;
- **Interim Drinking Water Supply Solution:** Provide short-term drinking water supply while a permanent solution is pursued. Short-term interim solutions serve to address the immediate impacts and ensure access to both water suitable for consumptive and other domestic needs, such as sanitation. Short-term emergency supplies shall be provided as soon as reasonably possible and can include bottled water, bottled water paired with tanked water, or another combination. For groundwater quality issues, bottled water may be an acceptable interim solution but if the issue is lack of access to water, providing bottled water is not an adequate interim solution and would require a combination of solutions as well as a long-term sustainable plan.
- Since short-term solutions are expensive over a prolonged period of time, it would be important to quickly identify potential long-term solutions. As an example, GEI's feasibility study for East Porterville at the height of the drought in 2016 estimated tank and bottled water programs cost $633,500 per month just for East Porterville, which has an estimated population of 7,331 residents.
- Long-term water supply can include (where appropriate):
    - Providing funding to lower a well pump and/or deepen the well;
    - Financial and technical support to complete a connection to a nearby municipal and/or industrial water provider;
    - Providing an equivalent water supply from an alternate source;
    - Providing funding to replace the affected well with a deeper well;
    - Providing funding to treat contaminated water;
    - Reducing or adjusting pumping near the impacted drinking water well as necessary to avoid the impact; and/or
    - Providing other acceptable mitigation through a collaboration with the affected drinking water well users.

  Note that lowering the pump and/or deepening the well will increase operational costs of the well and may require additional monitoring to ensure the well is not dewatered again. Further, these solutions may not address water quality concerns, depending upon aquifer conditions and screen depths.
- For a long-term water supply option, connecting current domestic well users to a nearby public water system should be pursued whenever possible. In areas with a high density of domestic wells, the establishment of a new small public water system may also be feasible. Public water systems have an obligation to test water quality for water served, and although some public water systems have limited resources, they do have a greater ability to install treatment systems to address water quality impacts, recoup funds for litigated contamination such as 1,2,3-TCP, and apply for and receive grant funding for beneficial projects. Because of this, public water systems, including small community water systems, often provide a more reliable drinking water source than privately-owned domestic wells. It should be noted that once a resident is connected to a public water system, they are then subject to water bills that will likely be higher than the operation costs of the well. As these long-term solutions are being developed, the community should be engaged in the process to learn about the benefits of a public water supply in terms of water reliability and water quality, and should also be informed of why water bills may be more costly. It is possible that some residents may request some sort of stipend to assist with the monthly water bills associated with their new water connection.

xi. Eligibility: Eligible beneficiaries should include communities that quality as DAC or SDAC, and households who qualify as low income. S/DAC residents should not be required to undertake burdensome actions or overcome other barriers to entry in order to benefit from the program. For example, residents should not be required to register before impacts occur in order to benefit from the program, and beneficiaries should not be required to prove that the GSA's activities or lack of action caused impacts. Instead, the GSA should proactively identify all well locations and information. When the GSA is notified of an impacted well, it should use the well information collected to rapidly evaluate the cause of the impact and provide adequate mitigation measures. Some questions GSAs could consider when determining eligibility are:

- What is the process for determining eligibility?
- Who determines if the well is eligible?
- What documentation does the well owner need to demonstrate eligibility? Is there an unreasonable onus on the owner to demonstrate past use that would constitute a barrier to access?
- When a well is found to have been constructed in a way that is not consistent with current regulations, is it still eligible?
- If a well is poorly constructed, does the program address replacing or repairing the well rather than just deepening it?

Section 3. Costs and Potential Funding Sources:

Costs: Costs are dependent on many factors including: how protective the GSA defines its sustainability goal and related sustainability criteria, the number of vulnerable wells, the condition of the vulnerable wells, proximity to existing public water systems, the depth of the aquifer, local contractor costs, fluctuations in material costs, etc. For comparison purposes, the San Antonio well mitigation project materials include the following average costs:

- Perform well diagnostics ($2,700);
- Lower pump ($4,000);
- Drill/outfit/connect replacement well ($58,000);
- Water purveyor connection ($5,000), and close existing well ($4,500).

The table below provides examples of interim and long-term solution costs based on Self-Help Enterprises' experience in providing solutions to disadvantaged communities in the San Joaquin Valley during the 2012-2014 drought. Costs are provided for illustrative purposes only and should be considered as rough estimates.

Solution	Problem	Options	General Overview of Pros and Cons	Estimate of Costs[1]
Interim solution	Water quality	Point-of-Use (POU)	Treats water for one tap within the household. While this option does provide safe drinking water in the home, if everything is perfect, maintenance is less likely to be carried out and assistance must be provided until a long-term solution is implemented. Costs estimates include initial capital costs (installation, treatment system, monitoring system) and also ongoing operation, maintenance, routine	$1000 to $1500 / unit per home.

			monitoring, and waste disposal costs.	
		Bottled water	Bottled water provides an effective and reliable source of safe drinking water and may be the only option available depending upon contaminant concentrations. However, bottled water can be expensive over a long period of time and can come with distribution challenges.	$30 to $50 per month per house, includes delivery.
	Access to water	Water tank program with bottled water	Tank water can meet basic sanitation needs but should not be used to meet drinking water needs, as tank water is susceptible to bacteriological or other issues making it unsafe for consumptive purposes. Instead, the program must be paired with delivery of bottled water to meet drinking water needs.	- 2,600 gallon water tank and materials roughly $2100.00. - Labor and tank installation $1500.00, does not include mileage. - Electrical permit $80.00, depending on the county. - Tank water between $300 to $500 depending on delivery charge by water hauler, per load or per hour. - $30 to $50 per month per house, includes delivery.
Permanent solution	Water quality	Water treatment system	Technical, managerial, and financial capacity of the community should be considered when assessing water treatment options.	Costs vary depending on the technology, water contaminant, and number of households.
		Alternate supply source	Options include surface water, construction of a new well, and consolidation with a nearby water system.	Costs vary depending on the desired solution, technology, and number of households.
	Access to water	Lowering of well pump	Less expensive long-term solution, if conditions allow. The following factors should be taken into account: lowering of a pump in the well is limited by the depth of the well, proximity of pump to the base of the well increases energy consumption, may require more frequent screen cleaning, and water quality may be degraded due to sediments that are drawn in.	Less than $10K, maybe around 5K.
		Drill a new deeper well	A well test is necessary to assess yield capacity and water quality on deeper levels.	Build a new private well: $20k to $45k.
				Build a new well for a water systems: up to $1.5 million.

		Alternative water supply source	Options include surface water or consolidation with a nearby water system. Recommend considering consolidation when households understand and agree with the advantages and disadvantages of connecting to a local water system.	Costs vary depending on the desired solution, technology, and number of households.

Potential Funding Sources: A secure and reliable funding source and mechanism for the implementation of this type of mitigation program needs to be identified in the GSP. While grant or emergency funding could potentially be available to support a mitigation program, the availability of these funds is not certain. Therefore, the GSA should plan to establish a more secure, on-going funding mechanism that accrues funds that would be available as water levels decline in the future. Funding for these types of programs should be considered as an operational cost of the GSA and funded with other ongoing costs such as administration and monitoring and should be included in the annual budget for the GSA. The following are potential other sources of funding to consider:

- Service or land-based fee assessments using Proposition 26 or Proposition 218;
- State Water Resource Control Board programs such as Proposition 1 Groundwater Grant Program and Prop 68 Groundwater Treatment and Remediation Grant Program;
- Department of Water Resources funding programs for groundwater projects and technical assistance programs to aid SGMA implementation;
- Central Valley Basin Plan Amendment (BPA) project funding: The BPA for the regulation of salts and nitrates has been approved by the SWRCB and implementation may result in additional funding sources for nitrate contaminated aquifers. If appropriate, GSAs should consider coordinating with nitrate dischargers forming Management Zones in order to comply with the BPA in order to streamline administrative costs and leverage resources;
- United States Department of Agriculture (USDA) Rural Development Utilities funding (if available).

Note that any well mitigation projects should be coordinated with the SWRCB's Safe and Affordable Drinking Water Fund Program (which will be seeking to implement short and long-term drinking water solutions within vulnerable communities) via the SWRCB's Division of Drinking Water. Funding from the SWRCB's Safe and Affordable Drinking Water Fund Program should not be utilized to ameliorate negative impacts to safe drinking water access in vulnerable communities that are a result of implementation of the GSPs.

Mitigation measures should not put a financial burden on S/DAC residents and communities. Where feasible, coordinate with relevant agencies to procure funding for cost-effective and affordable solutions. Solicit stipends and grants from agencies where there will be an added cost on residents.
Wherever consolidation is possible, the GSA should assist in pursuit of feasibility studies and assist in negotiations with public water systems. GSAs should also assist in pursuit of grants/funds to ensure that this water is affordable. This work must be initiated with community involvement, oversight, and leadership during "yellow light" phase. GSAs play a unique role in regional groundwater management and the ability to convene multiple agencies to leverage multiple funding sources can support both long-term access to safe and affordable drinking water while also supporting sustainable groundwater management.

ABOUT THE PACIFIC INSTITUTE

The Pacific Institute envisions a world in which society, the economy, and the environment have the water they need to thrive now and in the future. In pursuit of this vision, the Institute creates and advances solutions to the world's most pressing water challenges, such as unsustainable water management and use; climate change; environmental degradation; food, fiber, and energy production; and basic lack of access to fresh water and sanitation. Since 1987, the Pacific Institute has cut across traditional areas of study and actively collaborated with a diverse set of stakeholders, including leading policymakers, scientists, corporate leaders, international organizations such as the United Nations, advocacy groups, and local communities. This interdisciplinary and independent approach helps bring diverse groups together to forge effective real-world solutions. More information about the Pacific Institute and its staff, board of directors, and programs can be found at www.pacinst.org.

ABOUT THE ENVIRONMENTAL JUSTICE COALITION FOR WATER

The Environmental Justice Coalition for Water (EJCW) works within a Community-to-Capital framework, connecting the most pressing needs of our disadvantaged community partners to our network of partners and agencies statewide. Since 1999, EJCW's work has been rooted in the communities most affected by environmental injustice. Issues and solutions are identified through regional chapters and statewide work groups. EJCW is positioned in the state capital, in order to connect communities with state agencies to bring about change multilaterally through advocacy, education, training, litigation, community organizing, and capacity-building, and by providing technical assistance. EJCW aims to effectively influence the intersections of water justice and environmental justice, community health, and human rights issues from community to global levels.

ABOUT THE AUTHORS

LAURA FEINSTEIN, *Senior Research Associate, Pacific Institute*

Laura Feinstein joined the Water Program at the Pacific Institute in 2016. Laura conducts research on aquatic ecosystems; the impacts of climate change on water resources, water, and energy; and environmental health and justice. Prior to joining the Pacific Institute, she was a research scientist and project manager with the California Council on Science and Technology. She also served as a Science and Technology Policy Fellow with the California Senate Committee on Environmental Quality and was a California SeaGrant Delta Science Fellow. Laura holds a BA in Anthropology from the University of California, Berkeley and a PhD in Ecology from the University of California, Davis.

RAPICHAN PHURISAMBAN, *Research Associate, Pacific Institute*

Rapichan Phurisamban has worked in the Pacific Institute's Water Program since 2014, focusing on economic and policy analysis relating to domestic and international water resources. Prior to joining the Pacific Institute, she was a research consultant and project coordinator at a nonprofit organization in Thailand, where she promoted sustainable food and agricultural systems. Rapichan holds a BA in Economics from the University of British Columbia and an MPP from the University of California, Berkeley.

AMANDA FORD, *Coalition Coordinator, Environmental Justice Coalition for Water*

Rev. Ford is based in Sacramento, California. In addition to being an ordained interfaith minister, she has an MA in Sustainable International Development from Brandeis University with an emphasis in Environmental Peacebuilding and Project Management. Amanda leads the development, coordination, and implementation of EJCW's environmental justice coalition efforts, programs and advocacy campaigns at a statewide level, including Human Right to Water (AB 685) implementation, pollution prevention, democratic water governance, and tribal outreach. She has worked on environmental peacebuilding and environmental justice projects in 20+ countries and still actively advises projects around the world.

CHRISTINE TYLER, *Water Policy Leadership Intern, Pacific Institute*

Christine Tyler was a Congressman George Miller Water Policy Leadership Intern with Pacific Institute in 2016. Christine holds a BA in Political Science from the University of California, Berkeley. Her research interests revolve around international development, water and resource rights, colonialism, and climate change's effect on marginalized communities. She has previously worked on wastewater management and land rights issues in Oakland and abroad.

AYANA CRAWFORD, *Water Policy Leadership Intern, Pacific Institute*

Ayana Crawford was a Congressman George Miller Water Policy Leadership Intern with Pacific Institute in 2016. Ayana holds a BA in Environmental Studies from the University of California, Santa Cruz, where she completed a number of research and conservation internships and focused her coursework on social and environmental justice. Ayana pursued these passions after graduation through her work with the Pacific Institute, which revolved around water equity and water access, and as a research intern at Food First, a food justice think tank. She is presently studying Spanish at the University of Granada in Spain.

ACKNOWLEDGMENTS

This work was supported by a grant from the TomKat Foundation. We thank them for their generosity. The Drought and Equity Advisory Committee and report authors wish to thank the many people who gave their time to assist us in writing this report. Staff of the Community Water Center (CWC) organized two meetings with impacted communities. Marina Perez and Esther Tracy from the California State Water Resources Control Board (SWRCB) joined our Advisory Committee meetings. Many people participated in interviews or shared useful data with us, including Bruce Barton, Dave Bitts, Chris Brady, Donald Brafford, Larry Collins, Lori French, Kathy Frevert, Max Gomberg, Chook-Chook Hillman, Steve Lindley, Michael O'Farrell, Mike Ricketts, and Kurt Souza. East Porterville for Water Justice (EPWJ) and la Asociación de Gente Unida por el Agua (AGUA) Coalition met with us to discuss report recommendations. Heather Cooley gave many helpful review comments, and Matthew Heberger provided input and technical support. Brendan McLaughlin copyedited our dubious prose. Finally, our communications team, Rebecca Olson and Deb Janes, helped guide this report through its final stages. The opinions expressed in this report are those of the authors and do not necessarily reflect the views of the Drought and Equity Advisory Committee or the project funder. All conclusions and errors are our own.

Acronyms and Abbreviations

ACS – American Community Survey

AGUA – Association of People United for Water (or la Asociación de Gente Unida por el Agua)

CA HSC – California Health and Safety Code

CalEPA – California Environmental Protection Agency

CBC – Cumulatively Burdened Communities

CCF – Centum Cubic Feet (100 cubic feet)

CDPH – California Department of Public Health

CUWA – California Urban Water Association

CWS – Community Water System

DAC – Disadvantaged Community

DWR – Department of Water Resources

ESA – Endangered Species Act

GAMA – Groundwater Ambient Monitoring and Assessment Program

GPCD – Gallons Per Capita Per Day

IHS – Indian Health Service
