Lead ug/L	15								
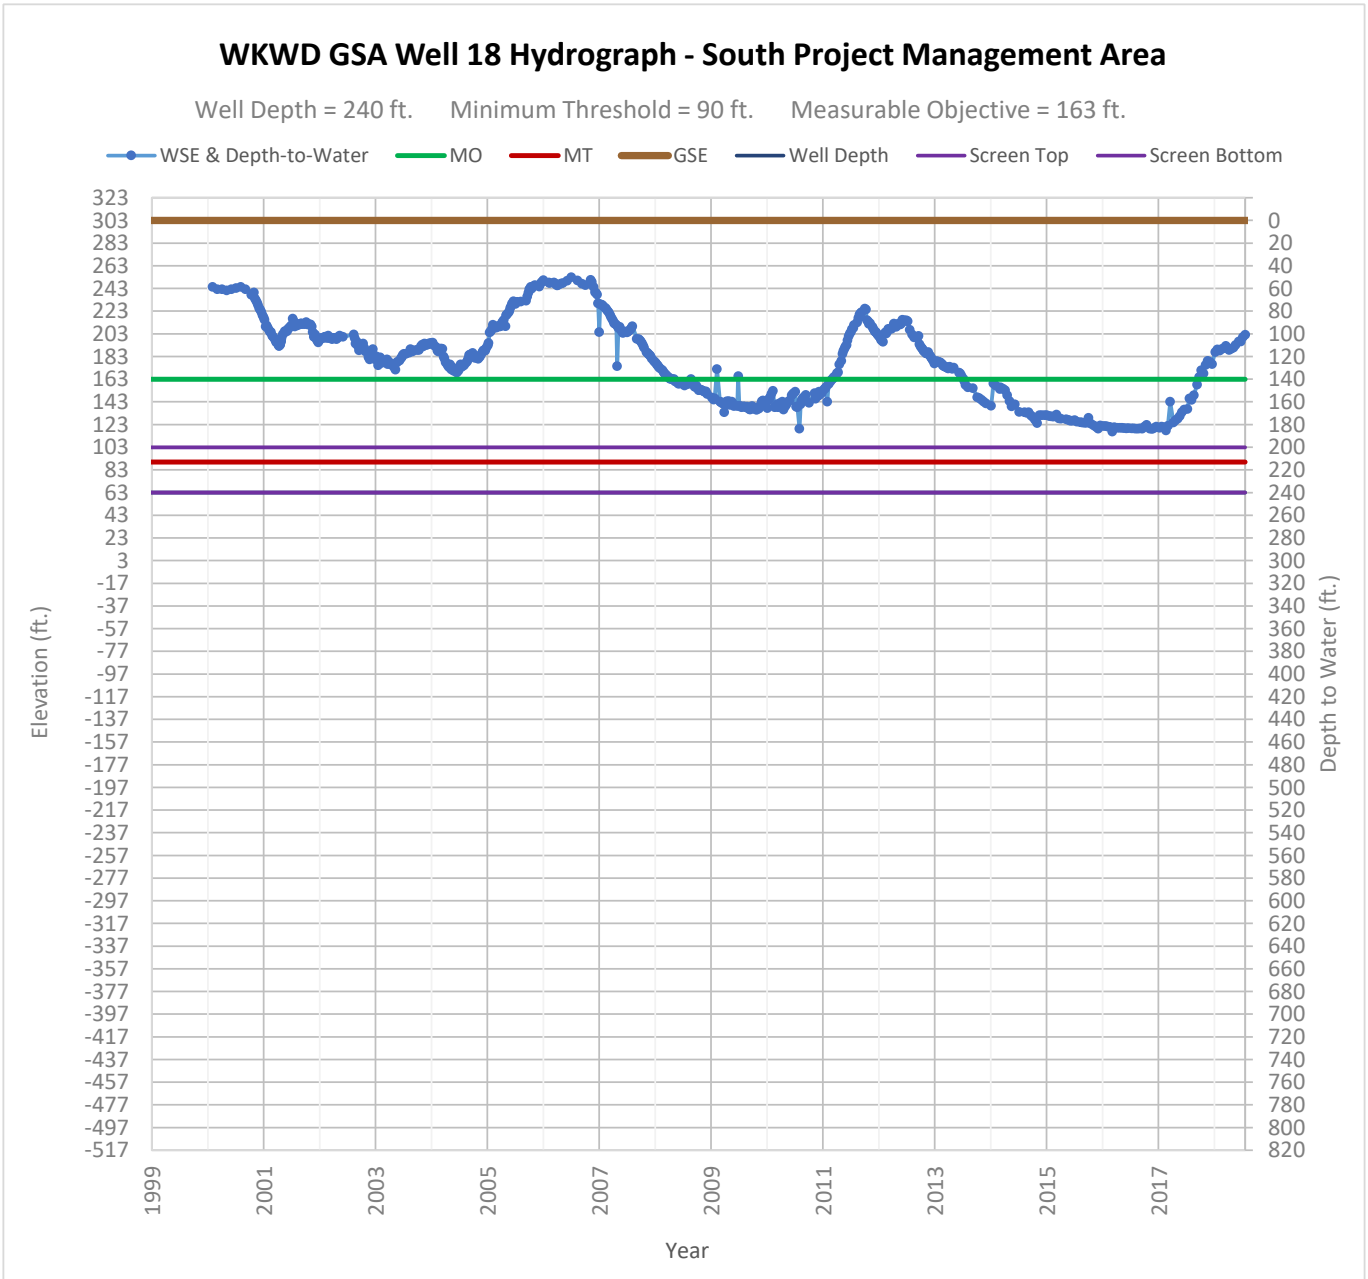
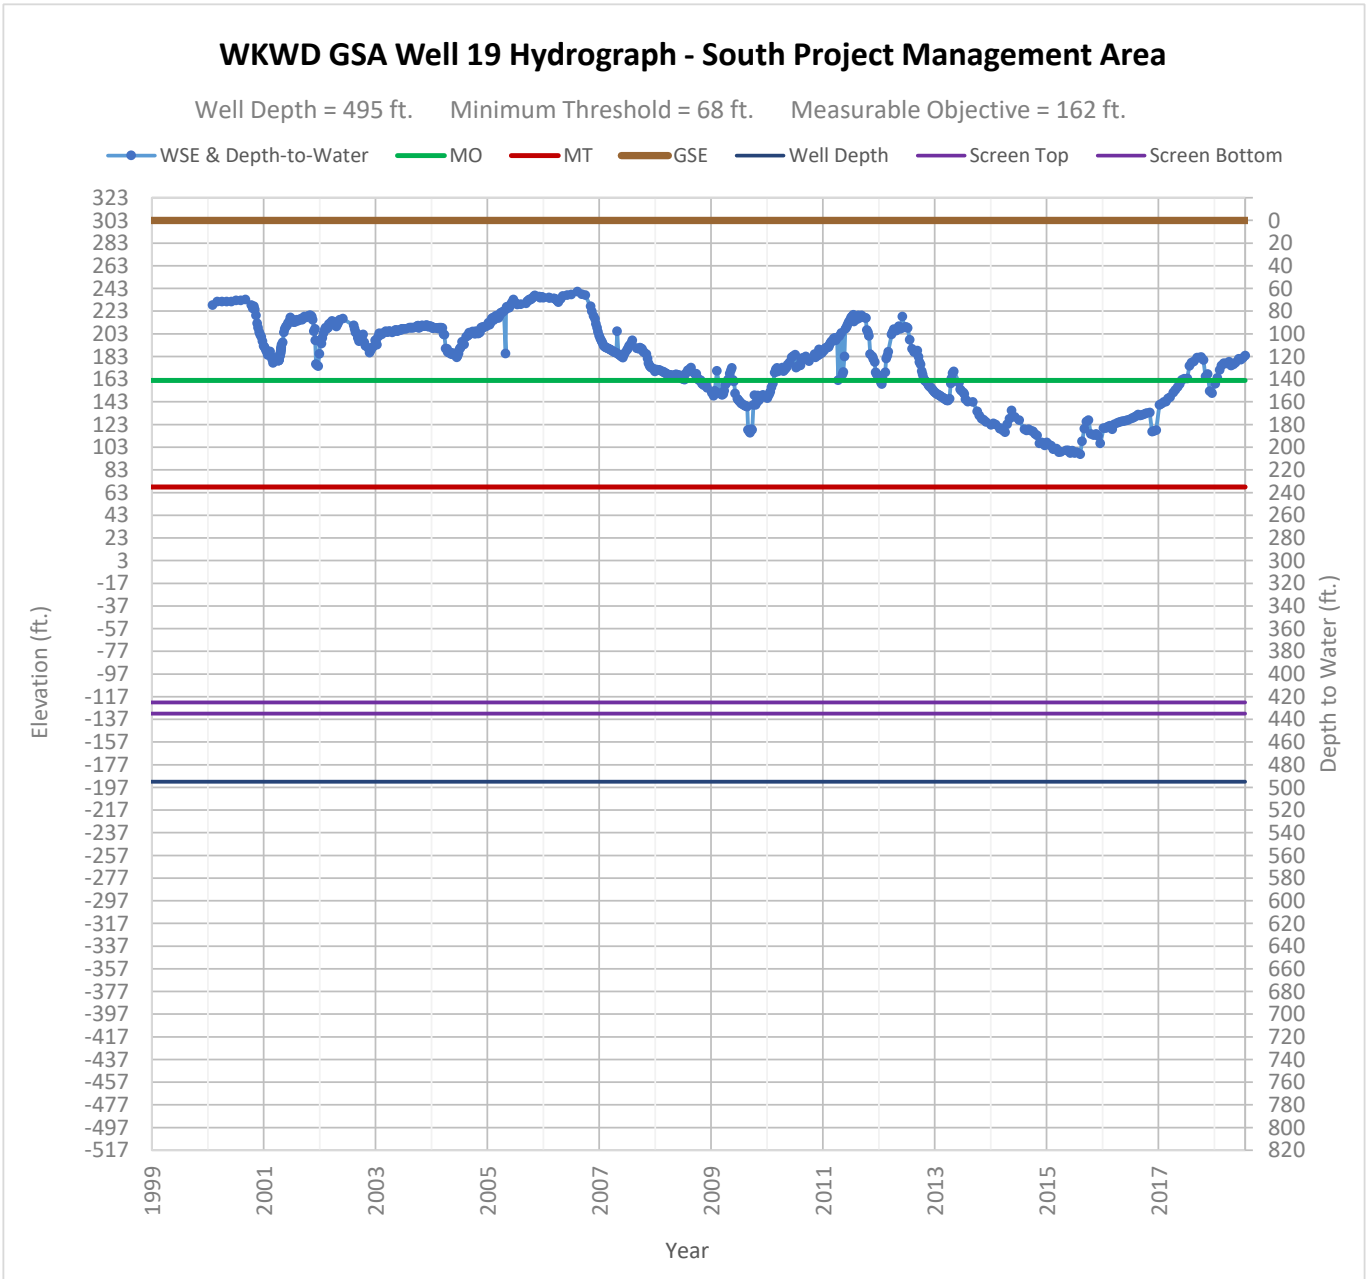
LSI	None		0.04			-0.064			
Manganese ug/L	50		0						
MBAS ug/L	None								
Magnesium mg/L	None		0.66			0.52			0.58
Mercury ug/L	2								
MTBE ug/L	None								
Nitrate mg/L	10						4.82	28.9	58.3
Nitrate (as N) mg/L	10		6.09			6.15	21.4	6.54	6.39
Nitrogen (as N)	10		6.09						
ODOR Units	3								

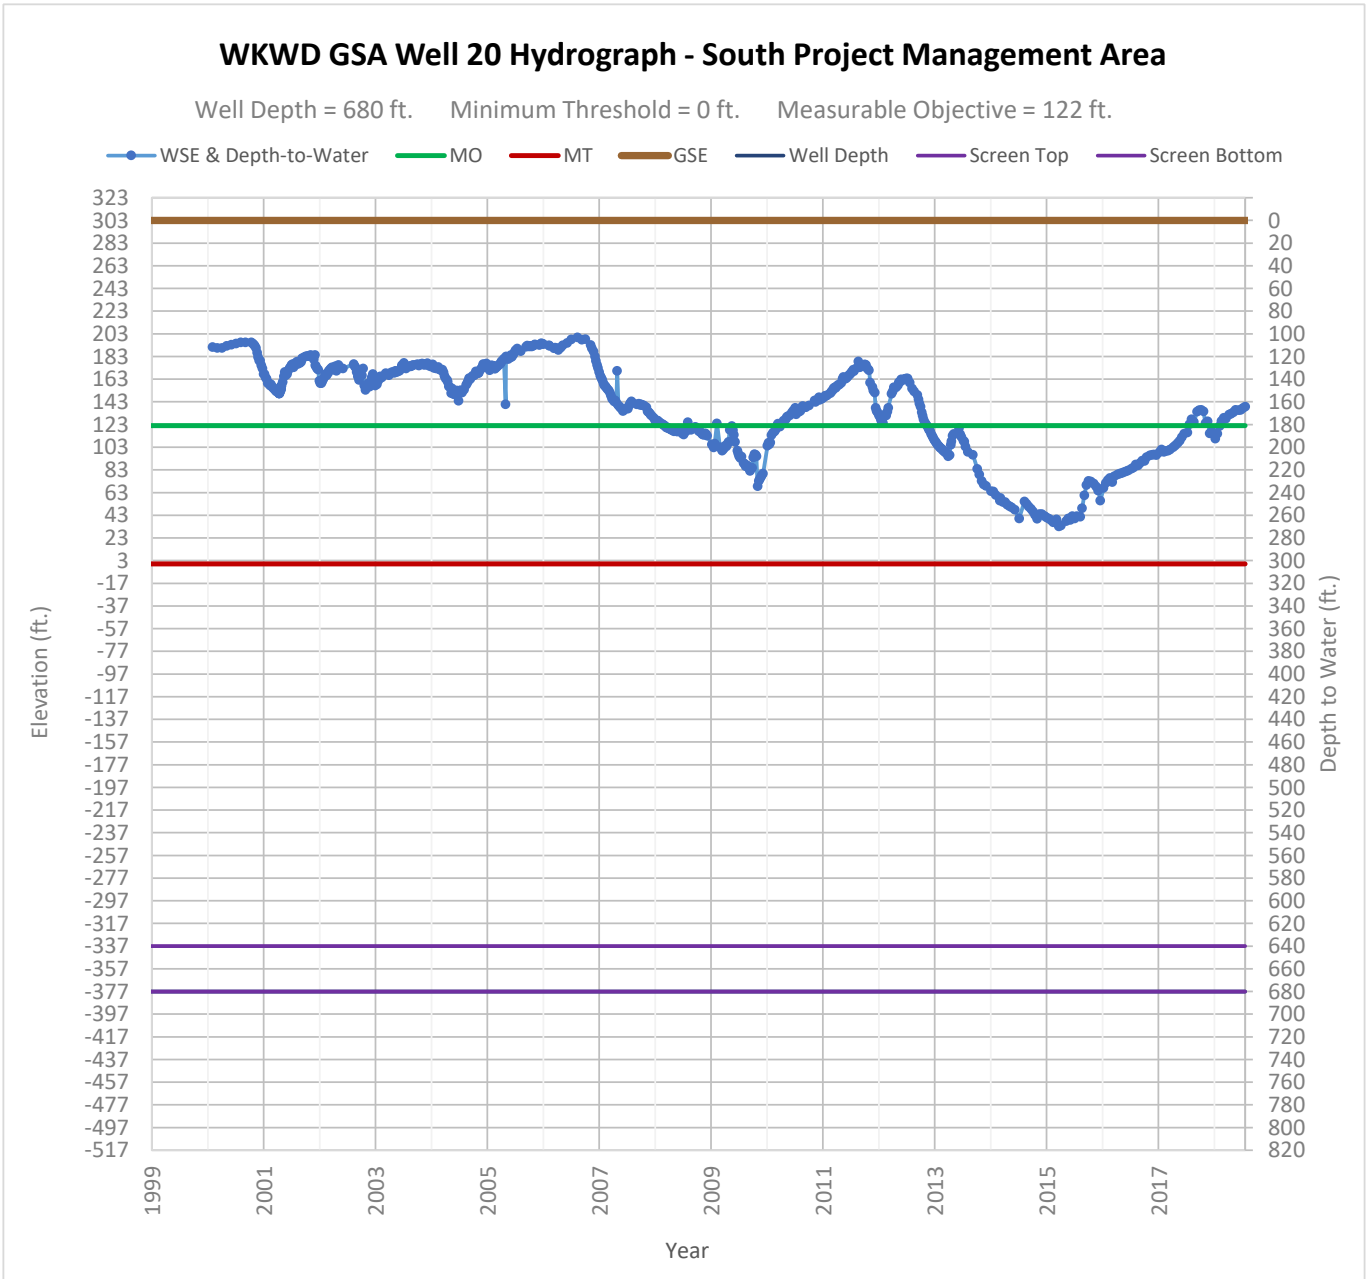
Groundwater Quality Monitoirng



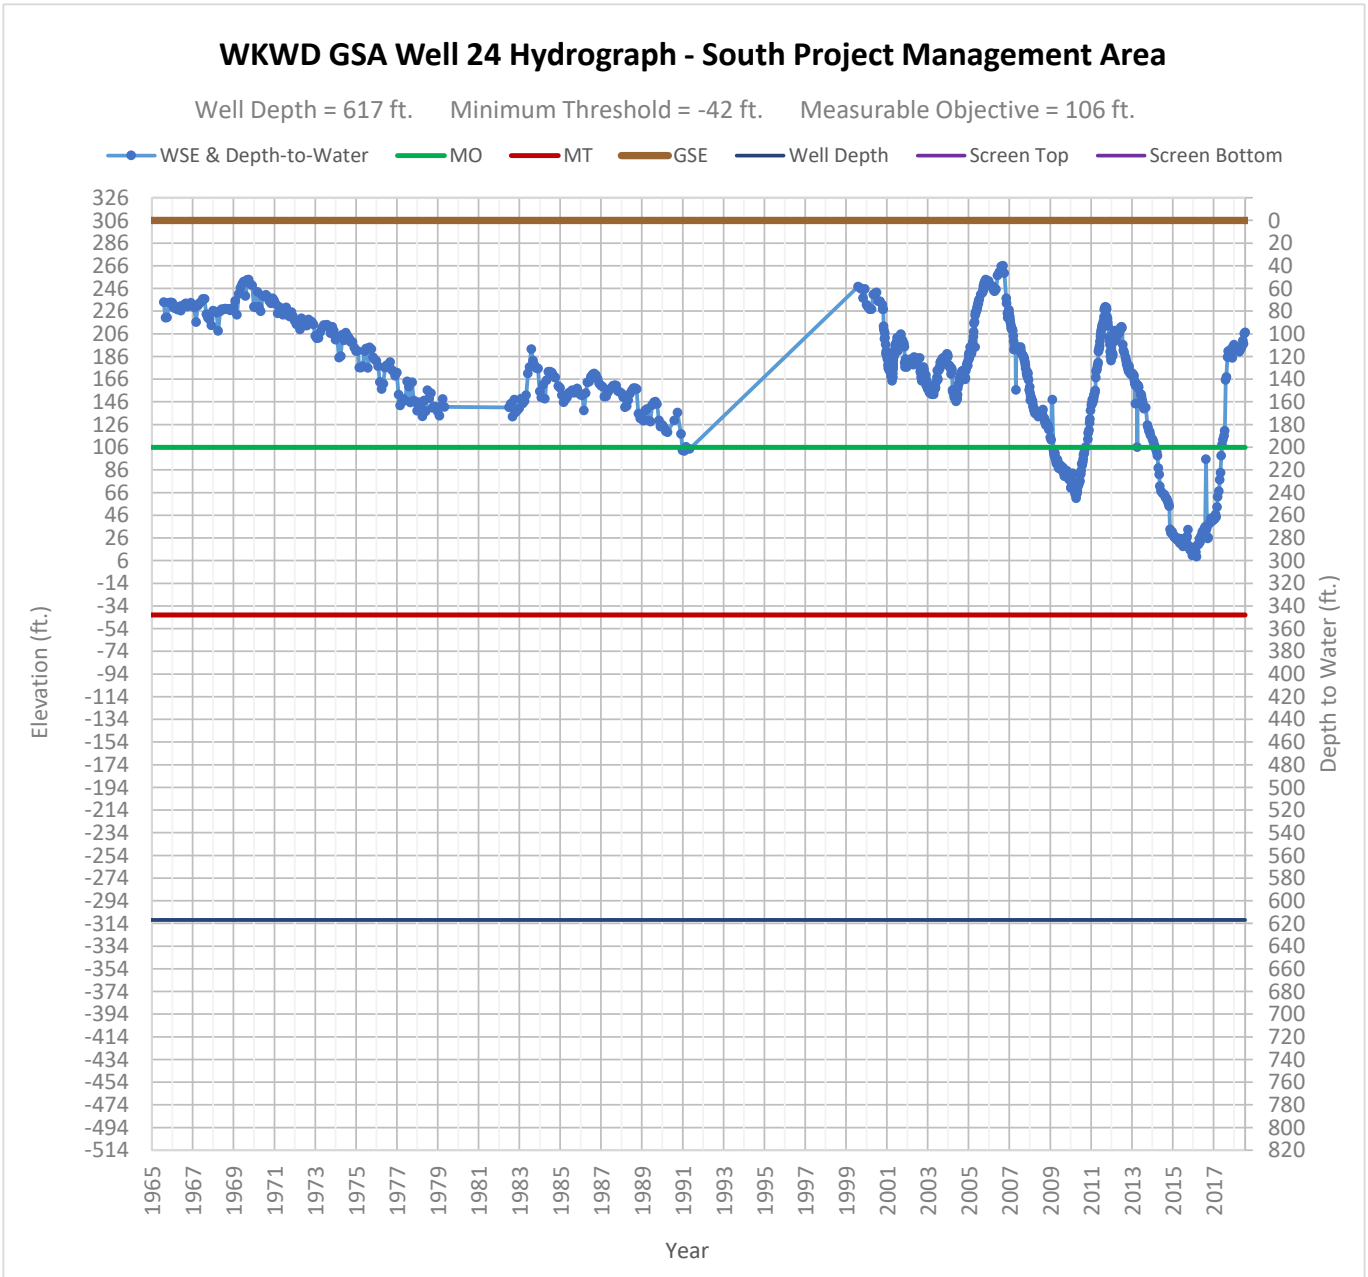
WKWD Well NW-5
GSP Well 106



Percholrate	None								
PH units	6.5-8.5		7.78			7.9			7.95
Potassium mg/L	None		0.802						
Radium 228	None								
Radium 226	None								
Radium 226	None								
Radium 228	None								
Selenium ug/L	50		0.003						2.2
Silver ug/L	100		0						
Sodium mg/L	None		129			110			110
Sulfate mg/L	250		271			260			240
TDS mg/L	1000		693			560			560
Temp	None		68			23.9			
Tert-ButylEthyl Ether	None								
Thallium ug/L	2		0						
Turbity NT Units	None		0.15			0.15			1.2
Uranium pCi/L	None					9.3			6.5
Uranium	None								
1,2,3 Trochloropropane	None								
Tert - Butyl Alcohol	None								
Tert - Amyl Methyl Ether	None								
Vanadium	None								
Zinc ug/L	5		0						



Appendix G



Well Hydrographs with Minimum Thresholds and Measurable Objectives

Section 1.0 Agency Information, Plan Area, and Communication

This appendix describes Sustainable Groundwater Management Act (SGMA) components required by regulation for the Little Santa Maria Valley (LSMV) Management Area (MA). The LSMV MA is in the West Kern Water District (WKWD) Groundwater Sustainability Agency (GSA)'s jurisdiction for their *Chapter Groundwater Sustainability Plan* (Chapter GSP). As part of the larger study, the LSMV MA needs to be distinguished from the WKWD GSA's Western MA.

This appendix also provides additional information about the LSMV MA, and refers to WKWD GSA's Chapter GSP for SGMA content required and covered in the Chapter GSP.

This appendix is organized in a similar way to the WKWD GSA's Chapter GSP. Some portions of this appendix directly refer to the Chapter GSP to address pertinent content, and some portions of this appendix add to or replace Chapter GSP content.

The following GSP content for the LSMV MA is fully covered in the WKWD GSA's Chapter GSP:

- Introduction and agency information
- Relationship to the Kern Groundwater Authority's Umbrella GSP and other subbasin GSAs
- WKWD background
- WKWD GSA contact information
- Management structure
- Legal authority

1.1 Plan Area

This section describes the LSMV MA's plan area components. The following GSP content for the LSMV MA is fully covered in the WKWD GSA's Chapter GSP:

- Existing water management programs
- Permitting new or replacement wells
- Conjunctive use programs in the subbasin
- Plan elements from California Water Code Section 10727.4
- Outreach and engagement
- Decision-making process
- Public engagement, stakeholder involvement, and GSP implementation progress

1.1.1 Introduction and Agency Information

The LSMV MA is covered as part of the WKWD GSA's Chapter GSP through an agreement among local landowners and WKWD. Per this agreement dated November 22, 2019, the Owner/Operator as Landowner has agreed to be responsible for actual costs incurred as a result of adding certain Owner/Operators' LSMV properties to WKWD's GSA area. These costs include directly attributable general and administrative costs and pro rata shares of consultant and service provider costs. According to the agreement, the Owner/Operator may reimburse WKWD for attributable expenditures or make direct payment to consultants or other service providers.

1.1.2 Plan Area Definition

The LSMV MA's plan area consists of a portion of the LSMV that is bounded according to criteria presented in Appendix G of the California Department of Water Resources' (DWR's) *Bulletin 118–Update 2003, California's Groundwater* (DWR, 2003). As described above, Landowners, in agreement with WKWD, added the LSMV MA to the WKWD GSA area. The LSMV MA also includes a portion of the hills surrounding the LSMV (Figure 1-1).

1.1.3 Existing Surface Water Monitoring Program

There is no natural surface water supply in the LSMV MA; additionally, there is no imported water supply available to the LSMV MA.

1.1.4 Existing Groundwater Monitoring Programs

From spring of 2018 to the present, landowners in the LSMV have monitored groundwater levels biannually in 20 wells. Water produced from all active wells is comingled and delivered through a single meter at a delivery point in the McKittrick Oil Field. This water is blended with treated oil field-produced water for use generating steam. As a result, the LSMV MA has well production metering data for all 20 wells combined but has no data about individual wells.

1.1.5 LSMV MA Description

The LSMV MA is a perched alluvial valley located 2 miles southwest of the town of McKittrick, in Kern County, California. The LSMV MA is in the Temblor Range on the west side of the southern San Joaquin Valley and is isolated from the Central Valley proper. The U.S. Geological Survey classifies the geomorphic province for the LSMV MA as dissected uplands (Faunt, 2009). Natural vegetation consists primarily of native grasses; land use in the valley and surrounding hills, other than producing oil and gasoline, is limited to ranching and surface mining of diatomaceous earth.

The LSMV MA is distinct and separate from the adjacent Western MA due to its higher elevation, local groundwater source, concentration of active and idle groundwater wells, water chemistry, and apparent isolation from the lands immediately east in the San Joaquin Valley portion of the WKWD GSA area.[1]

[1] The Western MA is described in WKWD Chapter GSP Section 4.6.4.

1.1.6 Wells in the LSMV MA

Figure 1-2 shows the general location of wells in the LSMV MA by type (i.e., agricultural, domestic, and industrial). The only known uses for water wells in the LSMV MA are industrial for oil field steam, and agricultural for cattle water.

Section 2.0 Basin Settings: Hydrogeologic Conceptual Model

This section describes the LSMV MA's hydrogeologic conceptual model (HCM). The HCM provides a framework for understanding how water moves through the LSMV MA. The following GSP content for the LSMV MA is fully covered in the WKWD GSA's Chapter GSP:

- HCM definition
- Useful terms

2.1 Regional Geologic Features

As shown on Figure 2-1, the LSMV consists of alluvium deposited above an unconformity on the Tulare Formation or Miocene shales, and is roughly co-located with the Belgian Anticline oil field and is close to other major oil fields such as McKittrick and Midway-Sunset.

The LSMV is nearly surrounded by the Monterey Shale, which is water bearing only in fractures.

2.1.1 Regional Geologic and Structural Setting

The LSMV is a perched alluvial valley located 2 miles southwest of the town of McKittrick, in Kern County, California. The LSMV is in the Temblor Range and within the west side foldbelt that contains several oil fields, including the Belgian Anticline, McKittrick, and Midway-Sunset fields (Figure 2-1). Specifically, the LSMV MA water wells are located over portions of the Belgian Anticline oil field. The San Andreas Fault is approximately 4.5 miles to the southwest from the west end of the valley, and the McKittrick Thrust Fault is approximately 1 mile to the northeast from the east end of the valley.

The LSVM is approximately 7 miles long and 1.3 miles wide at its widest, and valley floor elevations range from 2,600 feet on the west end to 1,700 feet on the east. The surrounding hills have elevations ranging from over 4,000 feet in the west to approximately 1,800 feet in the east. The valley alluvium is bounded on the north and west by Miocene shales, to the south by Miocene shales and a series of landslides made up primarily of Miocene shale. To the east, where the valley narrows to approximately 1,700 feet, alluvium is bounded by the Plio-Pleistocene age Tulare Formation. Active oil wells are common in and around the valley, and in some cases are in close proximity to LSMV MA water wells.

2.1.2 Geologic History

The LSMV formed as the Temblor Range was uplifted and older rocks eroded. The foldbelt has been and continues to be tectonically active, and the result has been a variable stratigraphy (Bartow, 1991). In the LSMV area, a younger member of the Tulare Formation appears to be in contact with the underlying Miocene shales. The Pliocene marine formations present immediately to the east are missing, and Miocene shales are partially eroded. All of this suggests the valley was formed late, perhaps from the late Pleistocene to recent (Figure 2-2).

2.1.3 Geologic Formations/Stratigraphy

This section describes geologic formations and stratigraphy in the LSMV MA.

Stratigraphy

Formations in outcrop are Miocene and Plio-Pleistocene and younger in age. At the east end of the LSMV, the non-marine Tulare Formation sits unconformably on the marine Miocene Monterey Formation. Missing either by erosion or non-deposition are the intervening marine and marginal marine Pliocene strata commonly observed in the surface and subsurface immediately to the east, and the Etchegoin and San Joaquin formations. Figure 2-1 shows a stratigraphic column in the map legend. Figure 2-2 shows a cross section through the length of the LSMV. The figure also shows that alluvium in the LSMV is separated from the rest of the Kern County Subbasin by the Tulare Formation, and indicates alluvium and Tulare Formation depths.

Alluvial and Colluvial Deposits

The hills surrounding the LSMV are formed by landslides of Miocene shale material. Recent soil boring samples obtained from valley fill (Attachment 1) contain material that appears to be derived from the same Miocene sources, though further petrographic work is needed to confirm provenance.

Tulare Formation (East End of LSMV)

The east end of the LSMV is bounded by the Tulare Formation. In McKittrick Field (Township 30 south, Range 22 east, Section 20) approximately 4 miles to the east, two separate members (i.e., Main or Upper Tulare and Amnicola) have been identified and are oil producing. In the broader area, the Main or Upper Tulare consists primarily of debris-flow deposits, and the Amnicola is a fine-grained, clay-rich lacustrine deposit with a characteristic fossil assemblage (Miller, 1999). The facies of the Tulare Formation in the immediate vicinity of the LSMV need to be determined, but it appears perhaps some of the Upper and all of the Amnicola are missing (Nielsen and Campbell, 1996).

Miocene Marine Shales

The Miocene Monterey Formation is present both at the surface and in the subsurface in the LSMV. In the subsurface, four members have been identified, but a siliceous member is present at the surface around the LSMV and exhibits extensive natural fractures.

2.1.4 Faults and Structural Features

The LSMV MA contains a number of tectonic features already described in the WKWD Chapter GSP, and locally significant features are discussed below.

Synclines and Anticlines

The LSMV is located in the Temblor Range and within the foldbelt that contains several multiple anticlines, many of which define oil fields. Specifically, the LSMV water wells are located over portions of the Belgian Anticline Oil Field (Figure 2-1).

Major Faults

Faulting in LSMV alluvium itself is not observed, though faulting exists in the deeper formations (Division of Oil, Gas, and Geothermal Resources, 1998). Several major faults can be seen in the region on Figure 2-1, including the San Andreas and Temblor faults (strike-slip), the McKittrick Thrust, and the Recruit Pass Faults (Thrusts), as well as numerous unnamed folds. The LSMV is positioned in a structurally complex area.

Outcrops of Bedrock Inside the GSA Area

Bedrock and relatively impermeable or very poorly permeable formations that are excluded from the groundwater basin (i.e., Miocene shales and in some cases Tulare Formation) are included in the Kern Subbasin, which is at the eastern limit of the LSMV. Figure 2-2 shows that, within the GSA area of the LSMV, bedrock does not outcrop at the surface.

2.2 Basin Boundaries

2.2.1 Lateral Boundaries

As defined in Appendix G of *Bulletin 118–Update 2003, California's Groundwater* (DWR, 2003), the Kern Subbasin boundary wraps around the LSMV, roughly approximating the contact between the valley alluvium and the Miocene shales and landslides of the surrounding hills of the Temblor Range. These formations form the LSMV boundary.

2.2.2 Boundaries with Neighboring Subbasins

There are no neighboring basin boundaries in immediate contact with the LSMV. The LSMV is adjacent to uplands that are not part of the groundwater basin. Despite its elevation, isolation, and likely water source, the LSMV is presently a part of the Kern Subbasin.

2.2.3 Bottom of the Subbasin in the GSA Area

The bottom of the subbasin is formed by the same formation that forms the primary lateral boundary, the Miocene Monterey Formation. The depth to bottom was estimated by review of local well construction depths and oil well logs, which indicate that depth to Miocene shales is likely less than 500 feet bgs at its deepest. The bottom of the basin is shown in the cross section prepared from the northwest to the south east in Figure 2-2.

2.2.4 Additional Basin Boundary Information

WKWD intends to reapply for a basin boundary modification (BBM) to separate the LSMV from the Kern Subbasin. Prior to application, WKWD will further investigate the LSMV's unique characteristics to determine whether criteria for separation can be met.

2.3 Principal Aquifers and Aquitards

The only principal aquifer in the LSMV is the Quaternary alluvium in the center and lower portions of the valley. Its properties have not been determined. Within the alluvium, aquitards have not been defined or mapped.

2.3.1 Aquifers

Geologic maps of the surrounding hills indicate most of the southern boundary is formed by landslides of Miocene shale material. Recent soil boring samples obtained from valley fill (Attachment 1) contain material that appears to be derived from the same Miocene sources, though further petrographic work is needed to confirm provenance. The LSMV is bounded by marine shales, and it's proximity to the shales, along with the large amount of recent uplift suggest that most of the valley sediments are also locally derived. The soil boring descriptions note the prevalence of diatomite, diatomaceous clasts, and siliceous shale clasts in the gravels, sands and silts (Attachment 1). Groundwater was also encountered when advancing these soil borings.

2.3.2 Aquitards

Clay layers were noted in the soil boring descriptions, and their areal extent is unknown at this time. Water level monitoring indicates that there is no separate confined aquifer, as all monitored wells respond similarly in the LSMV in the monitoring record.

2.3.3 Aquifer Properties

Aquifer properties are not known at this time.

2.3.4 Natural Water Quality Characterization

Figure 2-3 shows general inorganic water chemistry analysis results from a single sample of the comingled water production described in Section 1.1.4. The sample was taken at the point of delivery. Analysis results indicate total dissolved solids (TDS) are 1,800 milligrams per liter (mg/L) with elevated sulfates at 560 mg/L. These results are typical of the fresh water produced on the west side of Kern County, and are distinct from water quality in the Kern Subbasin proper (Gillespie, 2017). These high TDS and sulphates are also typical of naturally occurring conditions in groundwaters that originate from marine units such as the Monterey Shale.

2.3.5 Topography, Surface Water, and Recharge Information

This section discusses the LSMV MA's topography, the absence of surface water, and recharge information.

Topography

The LSMV sits in a shallow basin surrounded by low-relief rolling hills. In general, the topography slopes east-southeast toward the San Joaquin Valley. The LSVM is approximately 7 miles long and 1.3 miles wide at its widest, and valley floor elevations range from 2,600 feet on the west end to 1,700 feet on the east. The surrounding hills have elevations from over 4,000 feet to the west to approximately 1,800 feet to the east.

Surface Water Bodies

The only streams that cross the LSMV are ephemeral (Figure 2-4).

Groundwater Discharge, and Areas of Recharge and Potential Recharge

It is not known to what degree discharge, if any, occurs to the east within the alluvium. The Tulare Formation, which is present on the eastern limit of the valley, may form a barrier to flow, effectively preventing discharge. Surface discharge occurs in an ephemeral stream located along Reward Road as indicated on aerial images where green vegetation follows the stream course. Green vegetation does not occur beyond the immediate vicinity of the stream bed (Figure 2-5).

Ephemeral streams exist in and around the perimeter of the LSMV, and during rare heavy rain events, limited surface groundwater replenishment may occur. The most likely source of recharge is through the naturally fractured shales that underlie and are in contact with the LSMV aquifer. In California south of the Diablo Range, precipitation on the west side of the San Joaquin Valley does not make significant contributions to usable groundwater (Davis and Coplen, 1989). Studies completed for other agencies also demonstrate the improbability of rain contributing to groundwater due to high potential evapotranspiration versus precipitation in the (Provost & Pritchard, 2015; Provost & Pritchard, 2018).

Based on this information, water is most likely recharged to the alluvium in the LSMV from mountain front recharge through fractured flow from marine shale surrounding the valley.

Soils

A soils map is in the WKWD Chapter GSP as Figure 2-6.

2.4 Hydrogeologic Conceptual Model Data Gaps

HCM data gaps are related to the nature of the LSMV's isolation from the Kern Subbasin. Further study should include investigating the following:

- Presence of concealed faults
- Transmissivity or lack of transmissivity in the Tulare Formation on the east end of the LSMV
- Physical relationship between alluvium and fractured Miocene shales
- More thorough characterization of water quality and source

Section 3.0 Basin Settings: Groundwater Conditions

This section describes the LSMV MA's groundwater conditions. Groundwater conditions information describe the trends, gradients, and movement of groundwater in the LSMV MA.

3.1 Groundwater Trends

This section discusses groundwater condition trends in the LSMV MA.

General Groundwater Elevation Hydrographs

Routine water level measurements have been made since spring of 2018 in LSMV MA water wells owned by local landowners. Hydrographs based on the last two years of data show water elevations averaging approximately 1,744 feet in the westerly upper portion of the LSMV MA and 1,627 feet in the easterly lower portion. Figure 3-1 shows the locations of monitoring wells. Figure 3-2 is a combined hydrograph showing all 20 wells monitored. In general, the hydrographs show limited change in elevation over the monitoring period of spring 2018 through fall 2019, as the groundwater elevation in some wells increased by up to 2 feet, and some decreased by as much as 3 feet.

Vertical Gradients

Vertical gradients are not known in the LSMV MA and are a data gap.

Groundwater Elevation Contour Maps

Figure 3-3 (spring 2019) and Figure 3-4 (fall 2019) show water level contours. Figure 3-3 shows that in the spring groundwater levels typically match topography in the LSMV MA, are higher in the west and lower in the east, and generally flatten out toward the eastern end of the monitored area. Figure 3-4 shows that in the fall groundwater elevations are similar in pattern to spring conditions, indicating that pumping in the LSMV MA did not have a seasonal effect on groundwater movement in 2019.

3.2 Historical Change in Storage

Figure 3-5 shows the 2019 change in water levels. Since monitoring began in spring of 2018, no earlier data are available. Figure 3-5 shows that groundwater levels changed slightly from spring to fall, with the majority of the monitored area increasing to over 2 feet in the central/north portion. The western portion of the monitored area also saw increases in elevation to over 1 foot. A small area in the northern portion of the LSMV saw slightly over 1 foot of decline during this period. Increased groundwater elevations in the vicinity of the Monterey Shale (orange on Figure 3-5) indicate that mountain front recharge may be occurring in the north/central portion of the area.

3.3 Groundwater Quality

The only known groundwater quality information available for the LSMV MA is discussed in Section 2.1.9, and is shown in Figure 2-3.

3.4 Land Subsidence

Land subsidence has not been monitored in the LSMV MA, and no data available.

3.5 Interconnected Surface Water Systems

Figure 2-4 shows that the only surface water in the LSMV MA is ephemeral streams, which dry up within days of rainfall; therefore, there is no connectivity between groundwater and surface water in the area.

3.6 Groundwater Dependent Ecosystems

There are no known groundwater dependent ecosystems in the LSMV MA. The Natural Communities Commonly Associated with Groundwater (NCCAG) dataset provided by DWR shows that there are two areas identified as potential wetlands in the LSMV MA. Aerial imagery reveals that the two locations indicated by NCCAG are not wetlands, and are similar to nearby areas. Therefore, there are no groundwater dependent ecosystems in the LSMV MA (Figure 3-6).

3.6.1 Data Gaps

Because no well monitoring was conducted prior to 2018, conditions in the LSMV MA prior to 2018 are unknown, and the LSMV MA's response to drought conditions is not known. Wells with vertically varying monitoring depths in close proximity are not available; as a result, the vertical gradient is not known. Additionally, land subsidence has not been monitored in the LSMV MA.

Because the LSMV MA is small in relation to the WKWD GSA's other MAs, the WKWD GSA does not plan to fill these data gaps. Measured conditions do not indicate overdraft in the LSMV MA, and groundwater production is limited in quantity. If additional monitoring becomes necessary due to changes in groundwater elevation in the future, WKWD GSA will evaluate an approach to fill these data gaps.

Section 4.0 Water Budget

This section describes the LSMV MA's water budget. The water budget provides an understanding of water supply and use in the LSMV MA.

4.1.1 LSMV MA Historical Water Budget Estimates

The LSMV MA is hydrologically separate from the majority of the Kern County Subbasin. Because of this separation, the water budget for the LSMV MA cannot be extracted from the Kern Delta GSA's groundwater modeling efforts, which are used across the majority of the basin. A single water budget estimate for 2019 has been prepared for the LSMV MA due to the limited data collected, the small amount of water produced, limited recharge from precipitation, and unmeasurable mountain front recharge.

The 2019 water budget estimate for the LSMV MA is based on the following two measurements and calculations:

- Metered pumping from LSMV MA in 2019
- Estimated change of storage from spring to fall 2019

Figure 4-1 shows the locations of metered pumping from the 20 wells in use by local landowners. Figure 4-1 also shows that pumping averaged 20 acre-feet per month in 2016, and 10 acre-feet per month from 2017 to 2019. This indicates that current groundwater extraction in the LSMV MA is 120 acre-feet per year.

To complete the water budget, an estimate change of storage from spring to fall of 2019 was prepared. A volumetric calculation was performed based on the change in groundwater elevation shown in Figure 3-5. The volume of 140 acre-feet in aquifer space was multiplied by a specific yield of 0.08 to estimate that an approximately 10 acre-foot increase in water in storage was added to the LSMV MA from spring to fall of 2019.

Metered pumping averaged 120 acre-feet in 2019, and the estimated change in groundwater storage was 10 acre-feet from spring to fall 2019, indicating that pumping by landowners in the LSMV MA is sustainable. Continued monitoring and an expanded water budget will be needed for the 2025 GSP update to fill data gaps around projected water budgets.

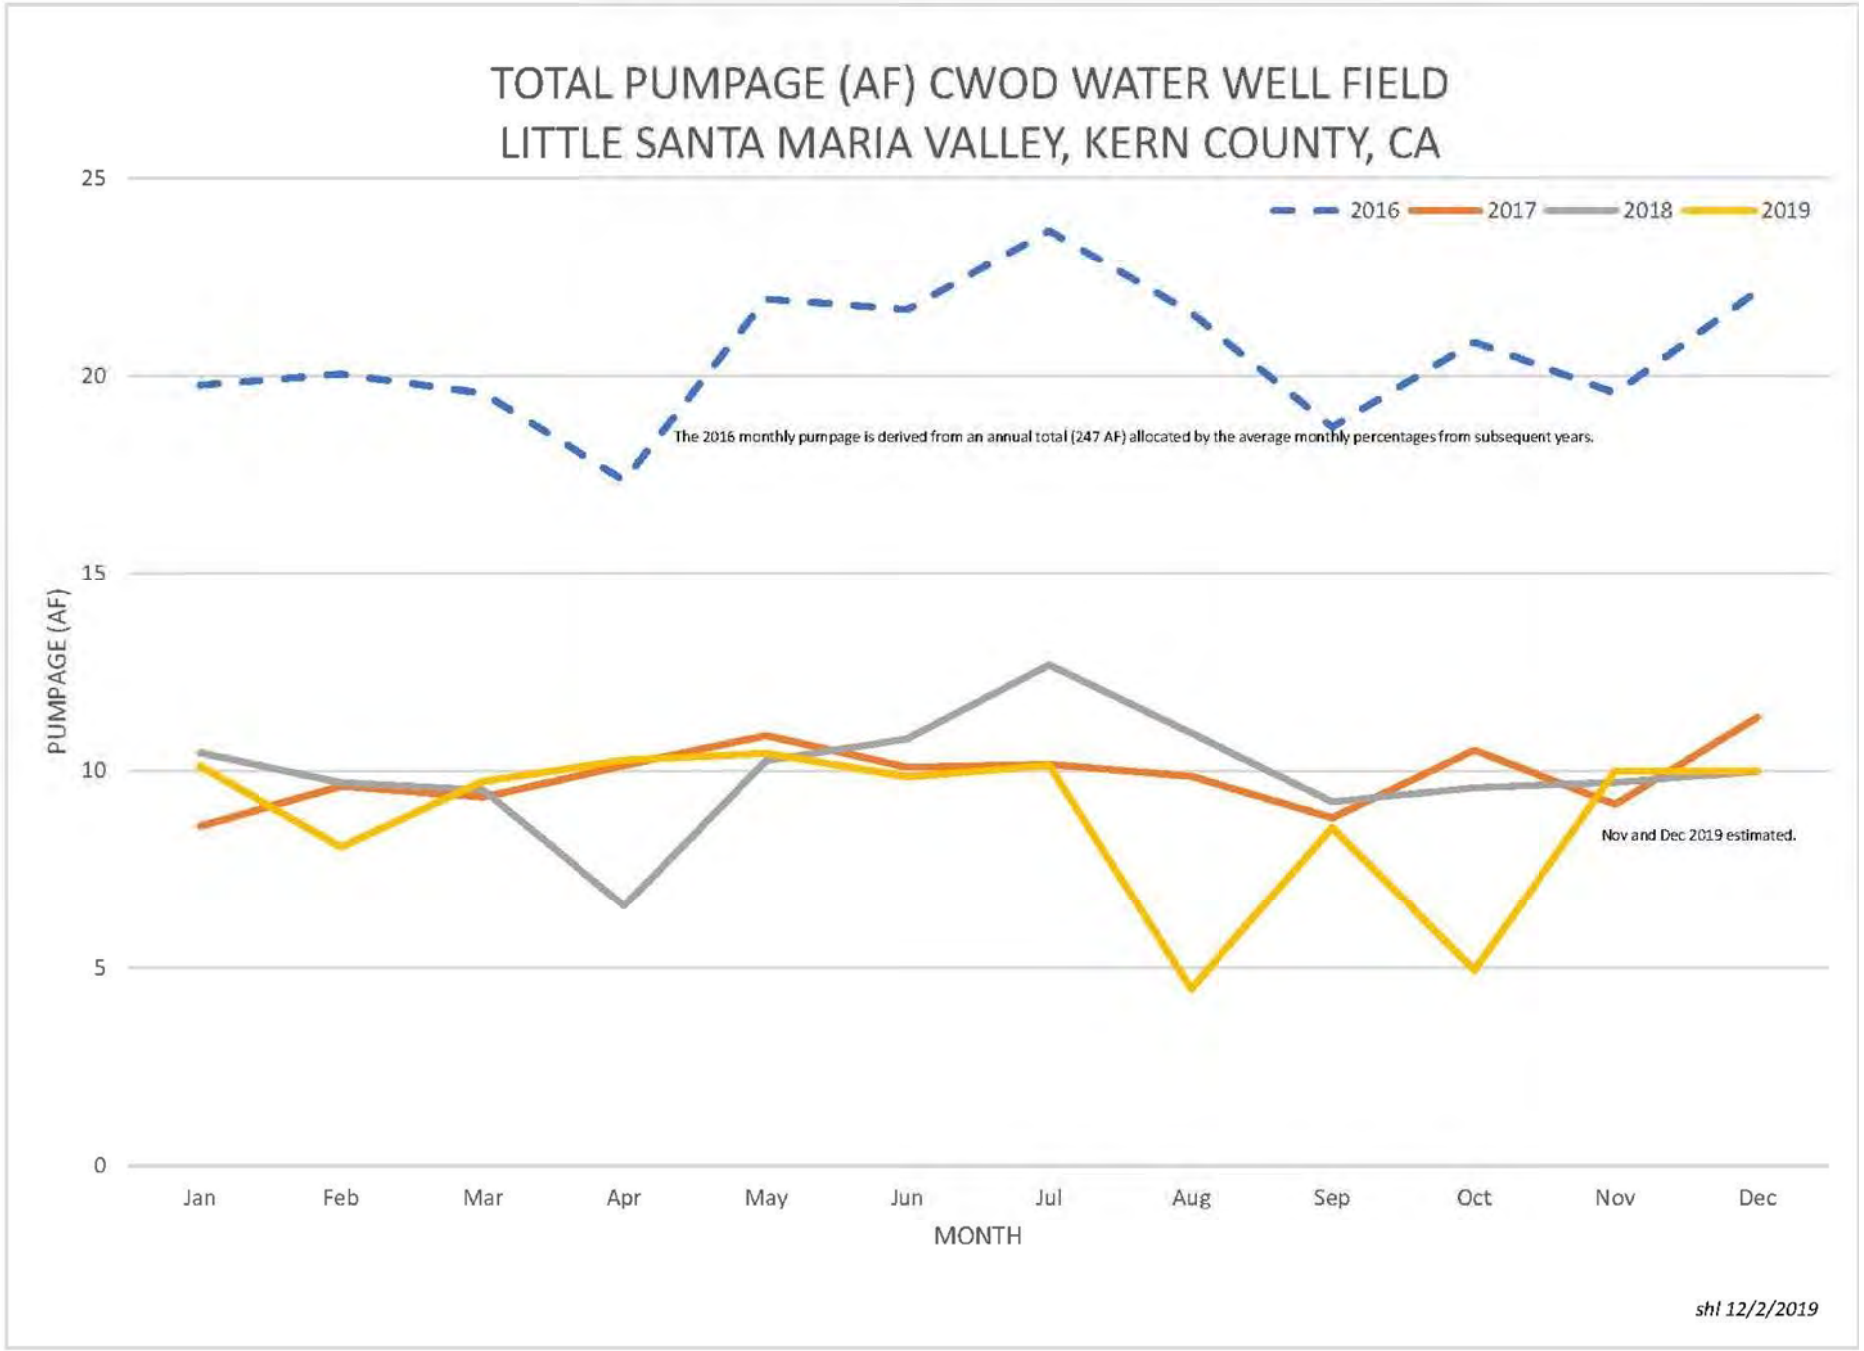

Figure 4-1. LSMV MA Well Field Pumping

Section 5.0 Undesirable Results Statements

Undesirable results were agreed to at the Kern County Subbasin level, and are included in both the Kern Groundwater Authority's Umbrella GSP, and WKWD GSA's Chapter GSP.

This page intentionally left blank.

Section 6.0 Monitoring Networks

This section describes the monitoring networks used in the LSMV MA. This section includes information about the objectives, rationales, and protocols used in the monitoring networks. This section also addresses how the GSP will monitor for the six sustainability indicators. The following GSP content for the LSMV MA is fully covered in the WKWD GSA's Chapter GSP:

- Monitoring network objectives
- Monitoring rationales
- Monitoring protocols

6.1 Groundwater Level Monitoring Network

Groundwater level monitoring is conducted through a groundwater well monitoring network. This section describes the following:

- How the level monitoring network was developed
- Criteria for selecting representative wells
- Monitoring frequency
- Spatial density
- Monitoring protocols
- Data gap identification and strategies to fill data gaps

6.1.1 Monitoring Wells Selected for Monitoring Network

The LSMV MA monitoring network includes almost all of the existing wells in LSMV MA. There are 25 known wells in LSMV, 20 of which are monitored by oil and gas industries and 5 of which are used for animal stock watering. Given the low number of wells in the area, there is limited spatial distribution and observation history; however, since 80 percent of the wells in the LSMV MA are monitored for level, data density is sufficient in the LSMV MA. All 20 monitored wells were selected for the monitoring network. Figure 6-1 shows the wells' locations.

6.1.2 Monitoring Frequency

Section 6.6.3 in the WKWD Chapter GSP describes the DWR best management practices for monitoring frequency. The Kern Groundwater Authority's Umbrella GSP requires Chapter GSPs to report monitoring twice per year: one round taken at a time from January 15 through March 30, and one round taken at a time from September 15 to November 15. More information about monitoring frequency is provided in the Umbrella GSP. To comply with GSP requirements, and to provide additional data for GSA planning and monitoring purposes, local landowners on behalf of the WKWD are committed to collecting groundwater level data biannually. This monitoring frequency will capture seasonal and long-term trends in groundwater levels.

6.1.3 Spatial Density

Section 6.6.4 in the WKWD Chapter GSP describes the DWR best management practices for spatial density of groundwater level monitoring networks. Of the recommended monitoring well densities in Table 6-3 of the WKWD Chapter GSP, the maximum density is 10 wells per 100 square miles. The LSMV MA itself is 3.05 square miles in size and has 20 monitoring wells, doubling the number of required wells for only one-twentieth of the area. Spatial density of the LSMV MA monitoring network exceeds minimum recommendations.

6.1.4 Representative Groundwater Level Monitoring Network

The LSMV MA groundwater level monitoring network consists of 20 wells, all of which are considered representative wells (Figure 6-1). Table 6-1 lists the wells in the groundwater level monitoring network and summarizes their construction information, their first and last measurement date, and other associated metadata.

The combination of monitoring well density and measurement frequency will provide useful information for determining flow directions, hydraulic gradients, and change in storage calculations. This information will be used in future water budgeting efforts for the LSMV MA.

6.1.5 Representative Monitoring

As described in WKWD Chapter GSP Section 6.6.6, SGMA specifies two categories of wells: representative wells and monitoring wells. Given that the 20 selected wells represent long-term, regional changes in the LSMV MA and are suitable to monitor sustainability, all monitoring network wells are considered representative wells.

6.1.6 Monitoring Protocols

Monitoring protocols for the groundwater level monitoring network are included in the Kern Groundwater Authority's Umbrella GSP. The WKWD GSA will continue its program of ongoing monitoring using current protocols until coordination of monitoring protocols described in the Umbrella GSP are completed.

6.1.7 Data Gaps

Spatial distribution of existing production wells does not expand to the boundaries of the LSMV MA. Given the number of wells and limited groundwater extraction in the region, the current number and density of monitoring wells is adequate.

6.2 Groundwater Storage Monitoring Network

Groundwater levels are used in the LSMV MA to monitor by proxy for change in groundwater storage. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in storage.

6.3 Seawater Intrusion Monitoring Network

The WKWD GSA area is geographically and geologically isolated from the Pacific Ocean, and any other large source of saline water. As a result, the Subbasin is not at risk for seawater intrusion.

6.4 Degraded Groundwater Quality Monitoring Network

Groundwater levels are used in the LSMV MA to monitor by proxy for change in groundwater quality. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in groundwater quality.

6.5 Land Subsidence Monitoring Network

Groundwater levels are used in the LSMV MA to monitor by proxy for change in subsidence. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in subsidence.

6.6 Depletions of Interconnected Surface Water Monitoring Network

Groundwater levels are used in the LSMV MA to monitor by proxy for change in depletions of interconnected surface water. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in interconnected surface water.

Section 7.0 Minimum Thresholds, Measurable Objectives, and Interim Milestones

This section defines the sustainability criteria that LSMV MA will use to avoid undesirable results during GSP implementation. SGMA requires the application of minimum thresholds, measurable objectives, and interim milestones to all representative monitoring sites identified in a GSP. These values will guide the LSMV MA and groundwater users within LSMV MA as they identify sustainable values for sustainability indicators and progress indicators over the GSP's 20-year plan implementation period.

7.1 Management Areas

The LSMV MA is its own MA within the WKWD GSA area, and has distinct minimum thresholds, measurable objectives, and interim milestones. Additional information about the sustainability indicators for other MAs (i.e., the Lake MA, North Project MA, South Project MA, and Western MA) are described in Section 7.1.1 of the WKWD Chapter GSP.

7.2 Chronic Lowering of Groundwater Levels

The undesirable result for chronic lowering of water levels is the point at which significant and unreasonable impacts occur over the planning and implementation horizon, as determined by depth/elevation of water, and affect the reasonable and beneficial use of, and access to, groundwater by overlying users. The LSMV MA has only two years of groundwater level data. The limited temporal extent of these groundwater level data do not provide a period of record that can be used to identify how the principal aquifer will respond during a drought. Because of the limited monitoring period, the LSMV MA will need to update its sustainable management criteria during the 2025 GSP update.

7.2.1 Minimum Thresholds, Measurable Objectives, and Interim Milestones

Minimum thresholds and measurable objectives were established in the LSMV MA to allow for an appropriate margin of operational flexibility that would allow for recovery of water as regularly conducted during normal operations.

Measurable objectives for the LSMV MA were calculated from the average groundwater levels observed between 2018 and 2019. Over the two-year observation period, groundwater levels do not fluctuate more than 10 feet even in wells that were pumping during measurement.

To provide an operational flexibility range, the minimum threshold was calculated to be lower than the measurable objective based on a fraction of the wetted portion of the well. Figure 7-1 illustrates the wetted portion of the well, 20 percent of which was subtracted from the fall 2019 groundwater levels to determine the minimum threshold. Calculated as the distance between the fall 2019 water surface elevation and the total well depth, 20 percent of the wetted portion of the well was subtracted from the fall 2019 water levels. Based on this methodology, the minimum threshold ranges between 15 and 122 feet below fall 2019 groundwater levels.

Total well depth was unavailable for eight wells. In these cases, the average fraction of wetted well portion was used (i.e., 71 feet) below fall 2019 levels. Since all representative wells are currently at or above the measurable objective, interim milestones were not established for the LSMV MA.

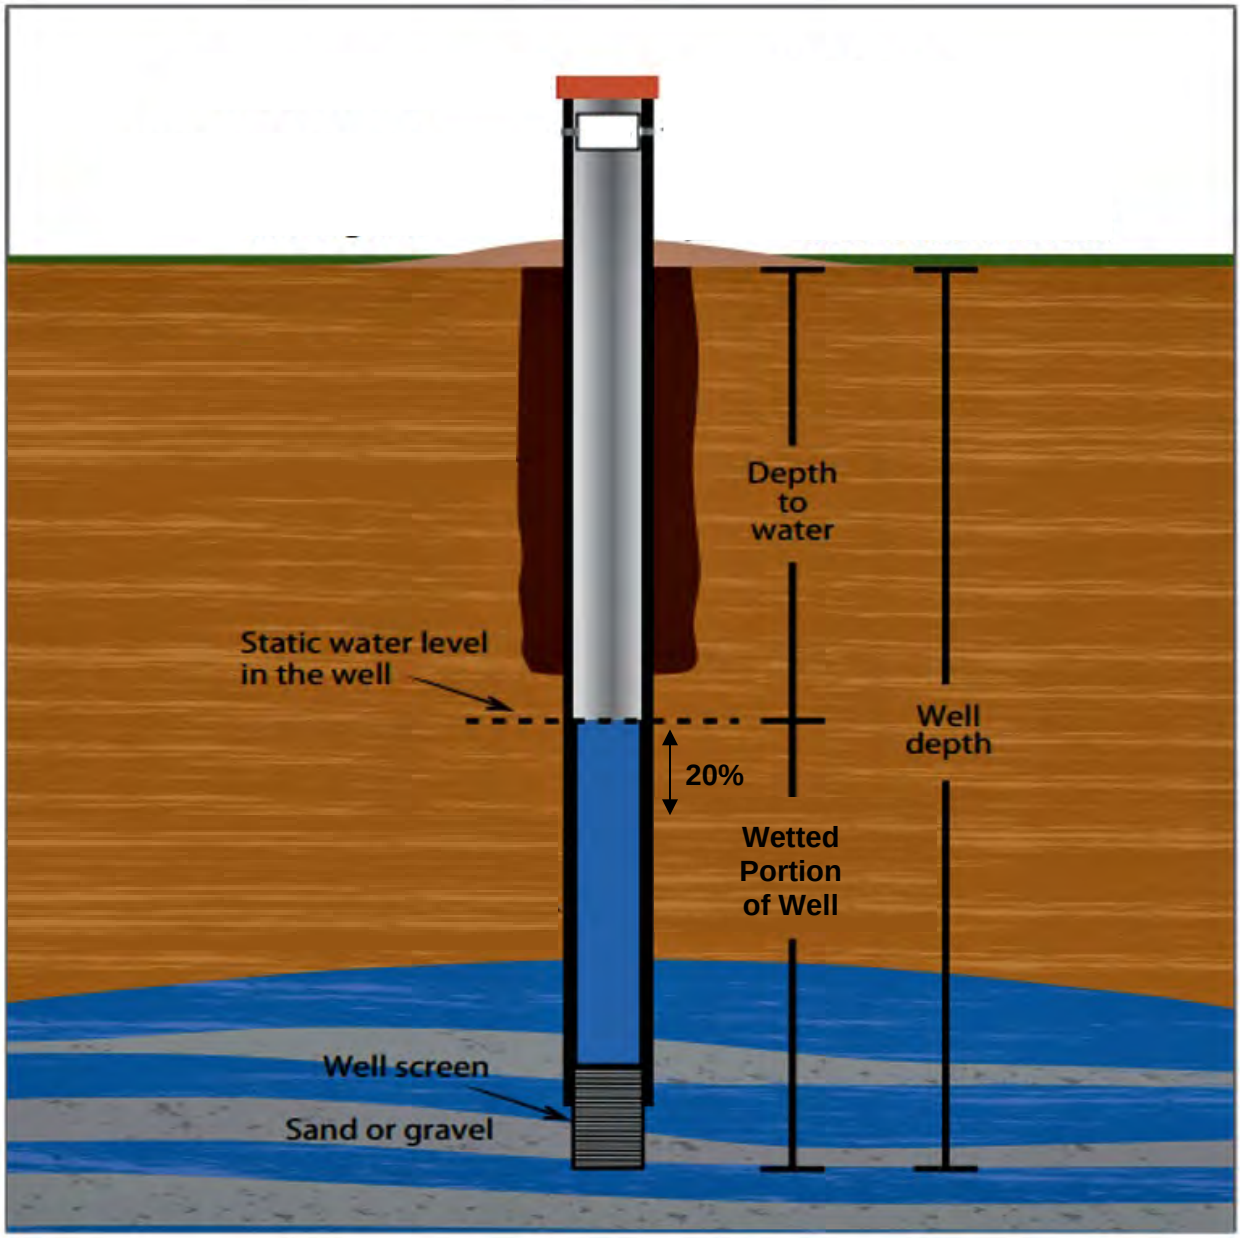

Figure 7-1. Wetted Portion of Well to Calculate Minimum Thresholds

7.2.2 Selected Minimum Thresholds and Measurable Objectives, Figures, and Tables

This section summarizes information about the data used to determine minimum thresholds and measurable objectives for each representative well. Figure 7-2 is an example hydrograph with the applied minimum threshold and measurable objective, and Table 7-1 summarizes data for each well.

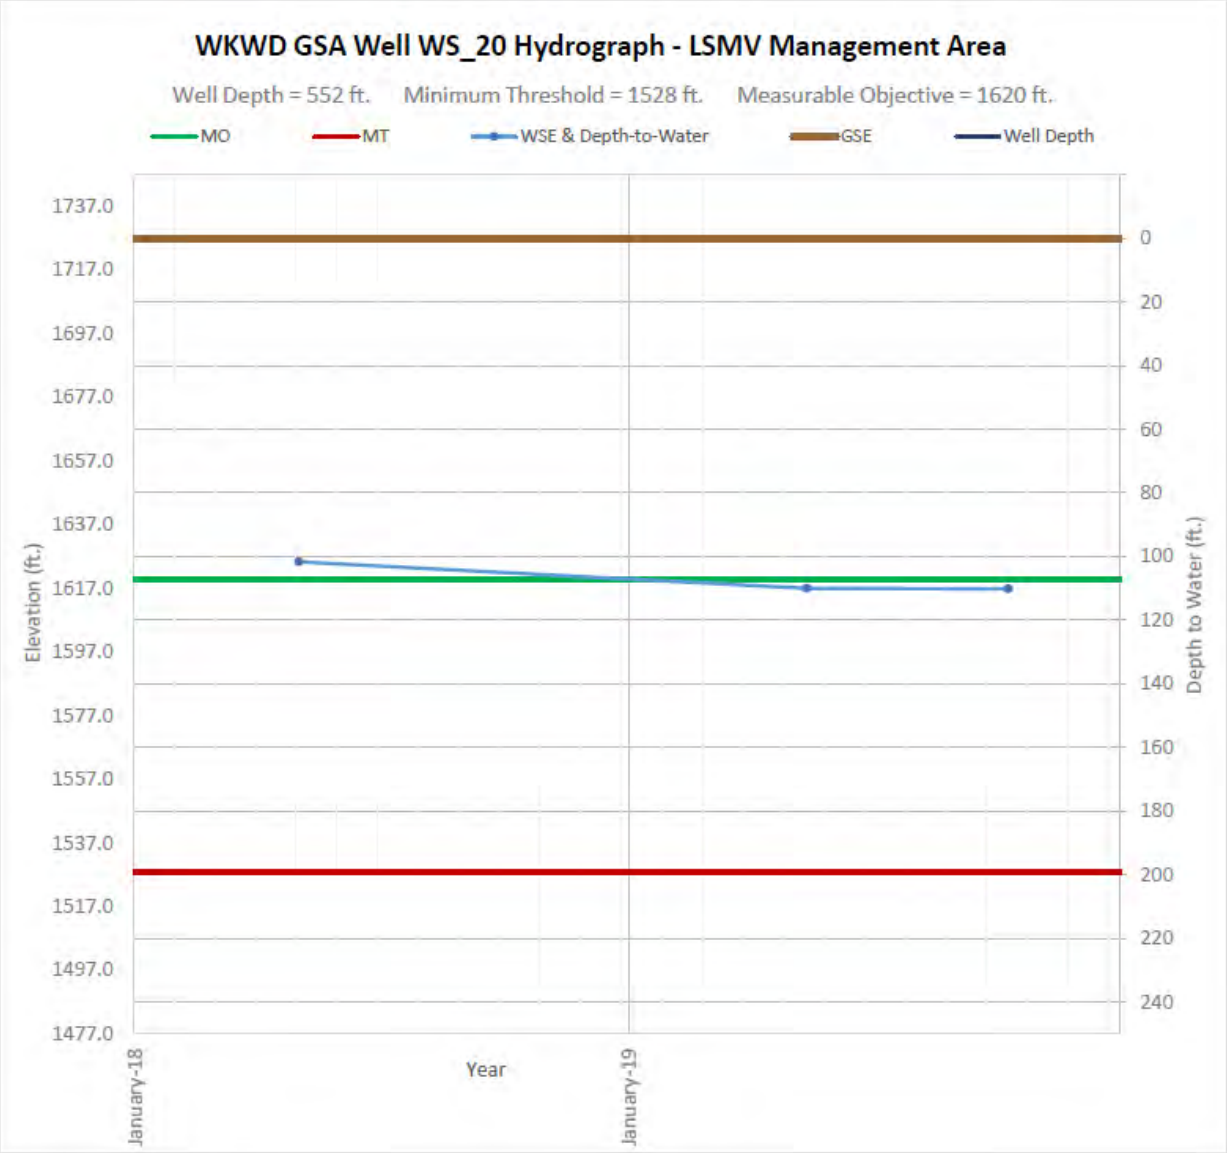

Figure 7-2. LSMV MA Example Hydrograph with Thresholds

Table 7-1. LSMV MA Minimum Thresholds, Measurable Objectives, and Interim Milestones

Representative Well	Minimum Threshold (feet above mean sea level)	Measurable Objective (feet above mean sea level)
WS_01	1,631	1,722
WS_02	1,593	1,715
WS_03	1,641	1,737
WS_04	1,662	1,735

WS_19	1,536	1,633

7.3 Reduction of Groundwater Storage

Groundwater levels are used in the LSMV MA to monitor by proxy for change in groundwater storage. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in storage.

7.4 Seawater Intrusion

The WKWD GSA area is geographically and geologically isolated from the Pacific Ocean, and any other large source of saline water. As a result, the Subbasin is not at risk for seawater intrusion.

7.5 Degraded Water Quality

Groundwater levels are used in the LSMV MA to monitor by proxy for change in groundwater quality. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in groundwater quality.

7.6 Subsidence

Groundwater levels are used in the LSMV MA to monitor by proxy for change in subsidence. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in subsidence.

7.7 Depletions of Interconnected Surface Water

Groundwater levels are used in the LSMV MA to monitor by proxy for change in depletions of interconnected surface water. The WKWD GSA will use information collected from its groundwater level monitoring network to monitor for changes in interconnected surface water.

This page intentionally left blank.

Section 8.0 Projects, Management Actions, and Adaptive Management Strategies

This section describes projects and management actions planned for implementation in the WKWD Chapter GSP that apply to the LSMV MA.

8.1 Management Actions

There are two planned management actions for the LSMV MA in addition to continuing monitoring activities: filing for a BBM with DWR, and simultaneous continued monitoring and sustainable management as part of the WKWD's Chapter GSP.

8.1.1 File for Basin Boundary Modification

This management action will expand understanding of the LSMV MA by exploring the scientific rationale for filing for a BBM. If criteria for modification are met, the WKWD GSA will request removal of the LSMV MA from the Kern County Subbasin. In the WKWD GSA's 2018 BBM application, the emphasis was regional in nature and covered most of the west side from Wheeler Ridge to the Kern-Kings county line. The BBM application was based on precedent and broad geologic characteristics. At the time, not enough was understood about the LSMV MA, particularly the nature of its isolation from the rest of the subbasin. Consequently, DWR denied that component of the 2018 BBM application.

While more is now known as a result of work begun during the 2018 BBM application process and during preparation of this addendum, additional research and data gathering is under way to improve the upcoming BBM application for the LSMV MA.

8.1.2 Continued Monitoring and Sustainable Management as Part of the WKWD GSA

If criteria for modification are not met, and a BBM application is not submitted, or if the upcoming BBM application is denied, WKWD and the operator of the LSMV well field will continue existing water management programs and develop additional programs if required. Routine reporting of pumping to the WKWD GSA, continuing the current groundwater level monitoring program, coordination, and developing water management tools and strategies are among the anticipated activities.

WKWD GSA will work with the KGA to add the monitoring identified in this appendix to the KGA's Umbrella monitoring list as a part of implementation in 2020.

8.2 Adaptive Management Strategies

If monitoring indicates that sustainability is at risk in the LSMV MA, the WKWD GSA will work with local stakeholders to develop a plan (likely as part of a five-year update to the Chapter GSP) to address reductions in levels and potential effects on other sustainability indicators.

This page intentionally left blank.

Section 9.0 GSP Implementation

Implementation of monitoring and management actions will occur on a similar timeline to the WKWD Chapter GSP. Sections of WKWD Chapter GSP that cover the LSMV MA include the following:

- Annual reports
- Five-year Chapter GSP update
- Implementation schedule

9.1 GSA and GSP Implementation Costs and Funding Source

This section describes implementation costs and how implementation will be funded in the LSMV MA.

9.1.1 GSP Implementation Costs

Below is a rough cost estimate for implementing monitoring and reporting/collaboration with WKWD.

- Water level monitoring: approximately $2,400 per year, including staff time to perform monitoring in the field, and to update hydrographs
- Water metering monitoring: approximately $4,000 per year, including staff time to physically read meters
- Prepare BBM: approximately $35,000 in 2021
- Participate in annual reports: approximately $5,000, including an estimated 40 hours of staff time to prepare figures and analysis for use in the WKWD GSA's annual report
- Participate in five-year update: approximately $25,000 in 2024

9.1.2 GSP Implementation Funding

Per the agreement dated November 22, 2019, the Owner/Operator as Landowner has agreed to be responsible for actual costs incurred as a result of adding certain Owner/Operators' LSMV properties to WKWD's GSA area. These costs include directly attributable general and administrative costs and pro rata shares of consultant and service provider costs. According to the agreement, the Owner/Operator may reimburse WKWD for attributable expenditures or make direct payment to consultants or other service providers.

Kern Groundwater Authority Subsidence Monitoring Recommendations

This page intentionally left blank.

T E C H N I C A L M E M O R A N D U M

TO: Kern County Subbasin

FROM: GEI Consultants, Inc.

DATE: October 25, 2019

RE: IMPROVEMENTS TO REGIONAL SUBSIDENCE MONITORING IN THE KERN COUNTY SUBBASIN

This memorandum was prepared, in coordination with subbasin stakeholders, to discuss improvements to fill data gaps in the Kern County Subbasin subsidence monitoring network. It prioritizes areas of interest, at a subbasin-level, that require additional subsidence monitoring. It also includes the design approach and parameters to be monitored, and references DWR guidelines regarding subsidence monitoring design.

Background and Purpose

The development of a network to monitor sustainability indicators, including subsidence, is one of the requirements of the Groundwater Sustainability Plans (GSPs) to be submitted to the Department of Water Resources (DWR) for compliance with the Sustainable Groundwater Management Act (SGMA).

In the public draft of the Kern Groundwater Authority GSP (KGA GSP) (KGA, 2019), existing land surface elevation and land subsidence monitoring is identified, along with data gaps within the existing network. The KGA GSP describes the process and rationale for identifying subsidence areas of interest (AOIs) to address data gaps, the current monitoring network, and the location of future monitoring points. The GSP includes the following objectives for monitoring, which are applicable to land subsidence:

1. Demonstrate progress toward achieving measurable objectives described in the management area and throughout the Subbasin;
2. Monitor impacts to the beneficial uses and users of groundwater, surface land uses, and critical infrastructure; and
3. Monitor changes in groundwater conditions (or land subsidence) relative to measurable objectives and minimum thresholds.

The monitoring network is designed to monitor impacts to surface land uses or critical infrastructure as stated in the Subbasin-wide definition of undesirable results for land subsidence (KGA, 2019 emphasis added):

> *The point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.*
>
> *This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan.*

One of the purposes for improving the subsidence monitoring network is to collect additional data at each AOI to fill data gaps so that sustainable management criteria (SMCs) can be set. As more data are gathered for the AOIs, Kern County Subbasin GSAs and stakeholders can establish SMCs to avoid undesirable results stemming from subsidence.

AOI Screening and Monitoring Approach

The first step in the subsidence monitoring approach is to identify AOIs based on the presence of critical infrastructure or other surface land uses. These AOIs can then be evaluated based on the decision-making criteria listed below to determine if monitoring is required. This process is illustrated in Figure 1.

An AOI requires monitoring if the following three criteria apply:

1. Infrastructure or surface land uses are susceptible to land subsidence.
2. Significant land subsidence has been observed in screening from Interferometric Synthetic-Aperture Radar (InSAR) or other remote sensing techniques.
3. The subsidence is caused by groundwater extraction.

Where data gaps exist in evaluating the criteria, additional investigation may be necessary. For example, further investigation at AOI-2 is necessary to evaluate if groundwater extraction is causing subsidence.

Monitoring Parameters

If the area is identified as an AOI that requires monitoring, then the following actions should be taken:

A. Groundwater level monitoring near the AOI,

B. Ground-truthing of subsidence detected by InSAR (CGPS, extensometer, or level surveying), and

C. Monitoring of the critical infrastructure.

As depicted in Figure 1, the process for establishing monitoring points includes locations with susceptible critical infrastructure where InSAR and/or other historical and recent monitoring has detected recent subsidence that is likely caused by groundwater extraction.

Regional Coordination

Regional coordination of monitoring is key to the design of the network in the subbasin because regional groundwater extraction is a main driver of subsidence. In addition, many of the critical infrastructure are regional and may require coordination for access within the vicinity and data sharing.

Subsidence associated with oil and gas activities may also occur in the subbasin. However, any subsidence potentially associated with oil and gas activities is regulated by the California Division of Oil, Gas, and Geothermal Resources (DOGGR) under the California Public Resources Code and is therefore separate from SGMA requirements. Coordination between groundwater and oil and gas stakeholders may be needed where there is potential for both activities to cause subsidence that impacts critical infrastructure.

Figure 1 on next page

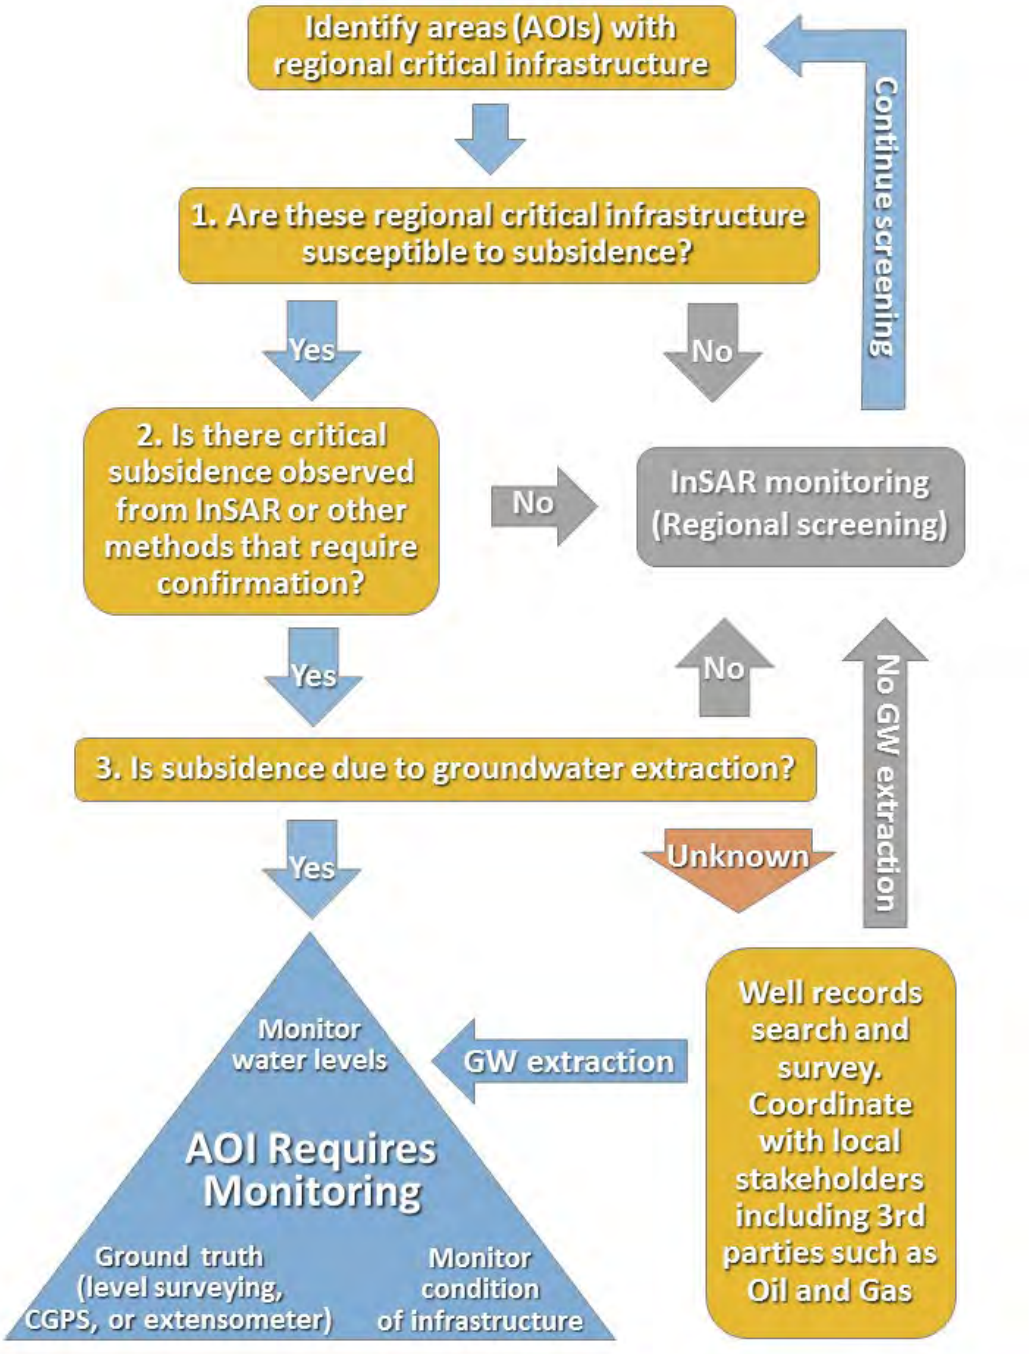

Figure 1. Subsidence Monitoring Decision Making Process and Criteria.

Improvements to Monitoring Network

Timeline and Approach

Five AOIs were identified, in order of priority, to improve the subbasin monitoring network (AOI-1 to AOI-5). Two of these areas are located along the Friant-Kern Canal (FKC), two are along the California Aqueduct, and one area is for monitoring changes in land surface elevation along the northern boundary of the subbasin where a significant amount of subsidence has been reported in the InSAR data.

It is anticipated that these sites will be evaluated in order of priority and may take up to several years to design and implement monitoring points.

Each monitoring site design will consider the following:

1. Confirm groundwater extraction is the cause of subsidence (if necessary),
2. Land siting and ownership,
3. Site access,
4. Monitoring design (CGPS or extensometer),
5. Confirmation that data for all three monitoring parameters can be collected (a. groundwater elevations, b. subsidence, and c. condition of infrastructure), and
6. Connection to the monitoring network and data sharing.

The subsidence monitoring network AOIs are presented on Figure 2. AOI-1 was selected to monitor along the FKC where subsidence has been detected near the northern boundary of the subbasin. AOI-2 was selected where the California Aqueduct has had historical impacts partially attributed to subsidence. AOI-3 along the FKC south of Poso Creek has had subsidence detected and reported by the North Kern WSD. AOI-4 along the California Aqueduct has had subsidence reported by DWR Division of Engineering (DOE) and InSAR, and AOI-5 along the northern boundary of the subbasin is not associated with critical infrastructure but is the location of high cumulative subsidence at the boundary of the subbasin and may be indicative of conditions in the neighboring subbasins which have the potential to impact the conditions of the Kern County Subbasin.

Groundwater Elevations

A key parameter in evaluating subsidence as a sustainability indicator for groundwater management is understanding groundwater level changes with respect to subsidence, particularly regional changes in water level. Figure 3 presents the regional water level monitoring points (RMWs) from the draft GSP with respect to the five AOIs for subsidence monitoring. The following are observations of RMWs within AOI vicinity:

- AOI-1 has a few surrounding RMWs; however, none are within 1 mile of the FKC.
- AOI-2 has one RMW within a mile of the Aqueduct and the AOI.
- AOI-3 has one RMW in the central portion about 1 mile from FKC.
- AOI-4 has two RMWs within the vicinity of the Aqueduct.
- AOI-5 has no RMWs within 1 mile.

Recommendation

Where possible, subsidence monitoring stations should be installed within 1 mile of a reliable RMW. If necessary, a new RMW may be installed to provide a point at which groundwater level may be collected in proximity to the land surface elevation monitoring point.

AOIs listed on subsequent pages

AOI-1. FKC Milepost 120 to 130

This high priority area is located along the FKC between Mileposts 120 to 130 (Figure 2), east-northeast of the City of McFarland. The purpose of this AOI is to monitor subsidence along the FKC and its related infrastructure. At times, InSAR monitoring has reported up to 5 inches per year of subsidence in areas surrounding this segment of the FKC. At present, no significant impacts to the FKC have been reported along this portion of the canal's alignment. According to leveling survey data from Friant Water Authority (FWA, 2019), the FKC invert may have subsided from 2 ft to 3 ft below original as-built elevations between Mileposts 120 to 135. Continued lowering of the canal invert can decrease freeboard from the original as-built conditions, which may contribute to reduction in emergency storage capabilities and delivery options of the Canal.

In contrast, beyond the subbasin's northern boundary, subsidence has caused significant impacts to the FKC conveyance capabilities between Mileposts 101 to 108.

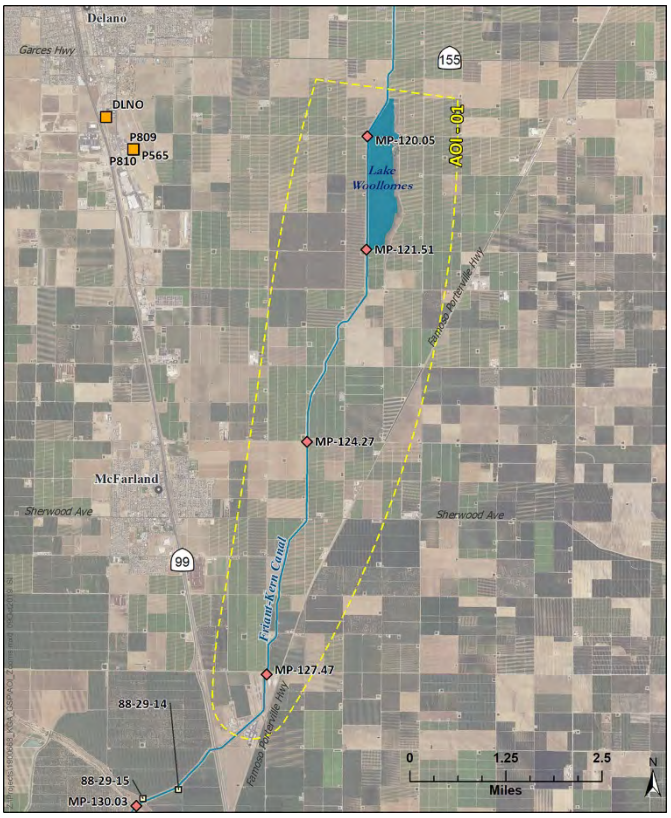

Figure 4. AOI-1. FKC Milepost 120 to 130
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR, and previous level surveying was performed by FWA at the mileposts labeled on Figures 2 and 4. There are no other active monitoring points except for InSAR along this stretch.

New Monitoring Approach

A new CGPS station that monitors at the ground surface any subsurface subsidence, regardless of the depth interval, is recommended because the only known cause of subsidence in this area is attributed to groundwater extraction. This CGPS data will complement any manual level surveys that may incorporate the FWA reported measuring points. CGPS data may also provide on-demand data as needed.

Coordination of Monitoring

Subsidence monitoring along the FKC benefits local stakeholders, CVP contractors, and the FWA. It is anticipated that this monitoring can be coordinated with FWA to share data as well as potentially share resources and cost.

Any level surveying along the canal from the United States Bureau of Reclamation (USBR) Friant-Kern benchmarks (Figure 2) will require coordination with the FWA.

AOI-2. California Aqueduct Milepost 196 to 215

This high priority area is the segment of the California Aqueduct where an embankment failure occurred at Milepost 208 in June 2011 (DWR, 2017). This failure is partially attributed to subsidence. The cause of this subsidence is unknown and is therefore a subject of monitoring at this location. This area is along the Aqueduct between Mileposts 196 to 215 in the western central subbasin (Figure 2). In addition to embankment failure, other consequences of subsidence include loss in freeboard in the Aqueduct. This area has experienced at least 2 feet of subsidence since the Aqueduct was constructed.

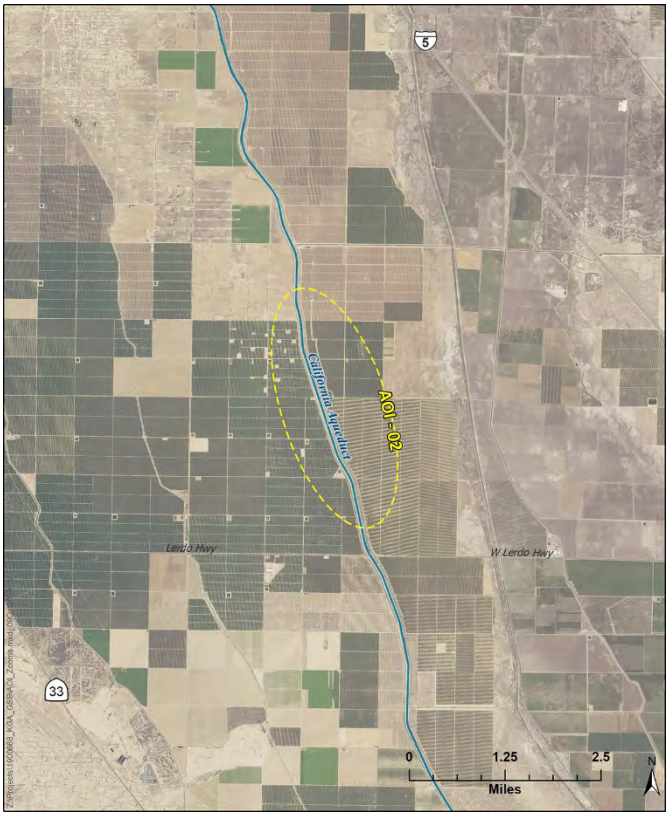

Figure 5. AOI-2. CA Aqueduct Milepost 196 to 215
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR and is monitored with level surveys every three to seven years by the DWR's DOE. There are no other active monitoring points along this stretch.

New Monitoring Approach

The source of subsidence, either by groundwater extraction activities or other activities, will be investigated by performing well records searches from DWR well completion records, the Kern County Public Health Department well permit records, and the DOGGR's databases. If necessary, a field well survey may be performed. Coordination may be needed with local stakeholders to confirm the magnitude of groundwater extracted within 1 mile of this portion of the Aqueduct's alignment and the volume of fluids extracted and injected by oil and gas activities within 1 mile of this alignment. A third potential source for subsidence in this area could be hydrocompaction, which was identified during the initial design and construction of the Aqueduct. Pre-consolidation of soil was performed during initial construction so hydrocompaction is likely not significant, however, it cannot be ruled out at this time.

If it is determined that groundwater extraction is playing a role in subsidence for this area, a monitoring point should be installed away from the footprint of the Aqueduct to avoid potential signatures of hydrocompaction if any exist. If there is question of whether some of the subsidence is related to nearby oil and gas activities, then an extensometer should be installed in the interval where groundwater production occurs. An extensometer will provide data of subsidence pertaining to intervals with groundwater production, whereas a CGPS would capture any subsidence regardless of the depth interval.

Coordination of Monitoring

Subsidence monitoring along the Aqueduct benefits local stakeholders, State Water Project (SWP) contractors, and the DWR's DOE. It is anticipated that this monitoring can be coordinated with DWR to share data as well as potentially share resources and cost.

AOI-3. FKC Milepost 130 to 137

This medium priority area is located along the FKC between Mileposts 130 to 137 (Figure 2), southwest of Famoso and Poso Creek. The purpose of this AOI is to monitor subsidence along the FKC infrastructure where InSAR and local stakeholders have reported subsidence in the surrounding area. As with AOI-1, no significant impacts to the FKC have been reported along this stretch. According to leveling survey data from the FWA (2019), the FKC invert may have subsided from 2 ft to 3 ft below original as-built elevation between Mileposts 120 to 135. Continued lowering of the canal invert can decrease freeboard from the original as-built conditions, which may contribute to reduction in emergency storage capabilities and delivery options of the Canal.

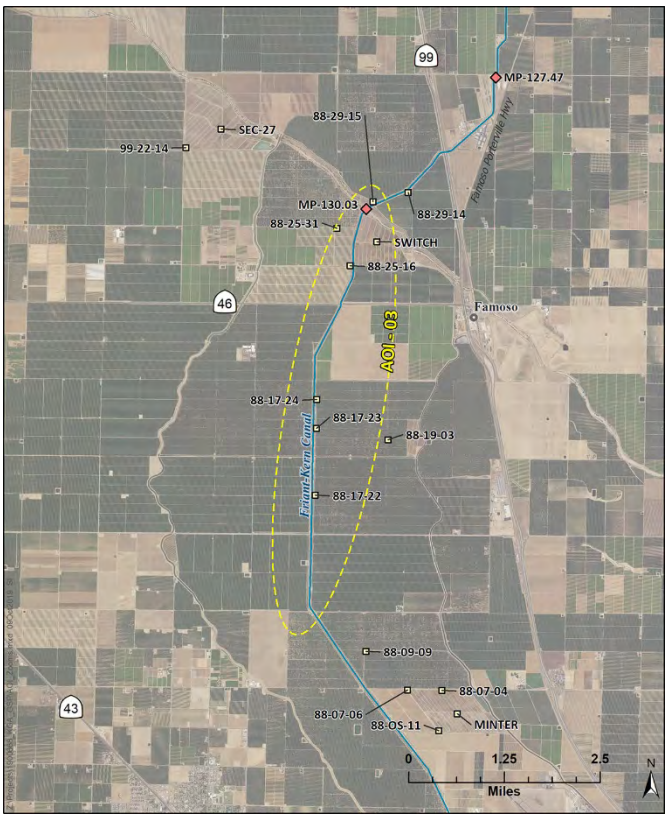

Figure 6. AOI-3. FKC Milepost 130 to 137
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR, and previous level surveying was performed by the FWA at Mileposts labeled on Figure 2. Local districts monitor this stretch regularly as labeled on Figures 2 and 6. Currently there are no continuous monitoring points along this stretch.

New Monitoring Approach

A CGPS station that monitors from the ground surface, any subsurface subsidence regardless of the depth interval, is recommended because the only known cause of subsidence in this area is attributed to groundwater extraction. This CGPS data will complement manual level surveys from local district surveys. CGPS data will also provide nearly on-demand data as needed.

Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the FKC benefits local stakeholders, CVP contractors, and the FWA. It is anticipated that this monitoring can be coordinated with FWA to share data as well as potentially share resources and cost.

Any level surveying along the canal from USBR Friant-Kern benchmarks (Figures 2 and 6) will require coordination with the FWA.

AOI-4. California Aqueduct Milepost 267 to 271

This medium priority area is located along the Aqueduct between Milepost 267 to 271 near Old River Road. InSAR data report subsidence southwest and along I-5 and southwest toward the Aqueduct along Old River Road. A former CGPS station (BKR1/2) located about 5 miles north of the Aqueduct along Old River Road also reported significant subsidence; however, this station has since been decommissioned (2016).

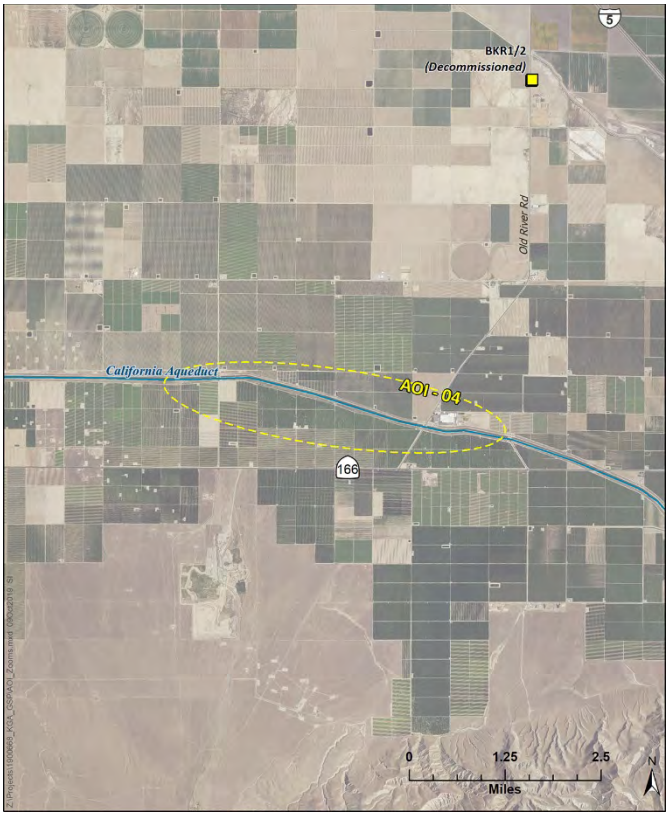

Figure 7. AOI-4. CA Aqueduct Milepost 267 to 271
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR, and is monitored by level surveying every three to seven years by the DWR's DOE. There are no other active monitoring points along this stretch.

New Monitoring Approach

Groundwater extraction is potentially the source of subsidence, so a continuous monitoring station such as a CGPS or extensometer will be installed. Other potential sources could be oil and gas extraction and hydrocompaction. A DOGGR records search may provide sufficient information to understand the extent of oil and gas extraction in this area. Although hydrocompaction may not be significant because of pre-consolidation practices during Aqueduct construction, nonetheless, in order to avoid potential signatures of hydrocompaction, a monitoring point should be installed away from the footprint of the Aqueduct. If feasible during the siting study, the site location may be selected to the north between the Aqueduct and former BKR1/2.

Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the Aqueduct benefits local stakeholders, SWP contractors, and the DWR's DOE. It is anticipated that this monitoring can be coordinated with DWR to share data as well as potentially share resources and cost.

AOI-5. Central-Northern Boundary of Subbasin

This medium priority area is in the northern quarter of T25S-R24E and T25S-R25E. Currently, this AOI does not have recognized susceptible critical infrastructure. It has significant subsidence reported both historically (USGS level surveys) and recently (InSAR). A CGPS station in this area will provide a needed ground truthing point to confirm InSAR readings and will act as a useful monitoring point to gauge progress of groundwater management along the border of the subbasin in relation to neighboring subbasins to the north.

Figure 8. AOI-5 Central-Northern Boundary of Subbasin
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR. There are no other active monitoring points along this stretch.

New Monitoring Approach

Groundwater extraction is potentially the source of subsidence, so a CGPS or extensometer monitoring station should be installed. Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the subbasin boundary benefits local stakeholders in Kern County subbasin and adjacent subbasins. In the future, data may be shared with neighboring GSAs for coordination.

Monitoring and Design Guidelines

According to the BMP (DWR, 2016), Leveling surveys and CGPS surveys must follow, at a minimum, guidelines in the *CalTrans Survey Manual*: https://dot.ca.gov/programs/right-of-way/surveys-manual-and-interim-guidelines. Extensometer resources from USGS are also listed in the BMP (DWR, 2016).

In addition to CalTrans guidance, UNAVCO has provided many CGPS design specifications on their website. UNAVCO offers a robust CGPS monument design (deep drill based monument [DDBM] that minimizes interference in data recording from soil expansion and temperature effects. Attachments 1 and 2 include example specifications for CGPS stations from CalTrans and UNAVCO, respectively. Attachment 3 includes sample extensometer designs for reference.

Rough Costs to Consider

For subbasin-wide monitoring to be implemented with the recommended AOIs in this memorandum, Kern Subbasin stakeholders will coordinate how the work will be implemented. Below is a brief summary of rough costs expected for the installation of each monitoring solution. Costs do not include ongoing management and maintenance of the stations. Actual costing will be confirmed during procurement and the planning process.

Level Surveying and Benchmarks (not proposed in this memo, but is an alternative approach).

- Install benchmarks where none available along linear features every 1/8 to 1/4 mile in area of interest.
- Each ~$500 to $2500 installation
- Initial Survey (5 to 8 monuments per day). ~$1500-$2500 per day (includes reporting).
- Subsequent Surveys (8 to 10 monuments per day). ~$1500-$2500 per day (includes reporting).

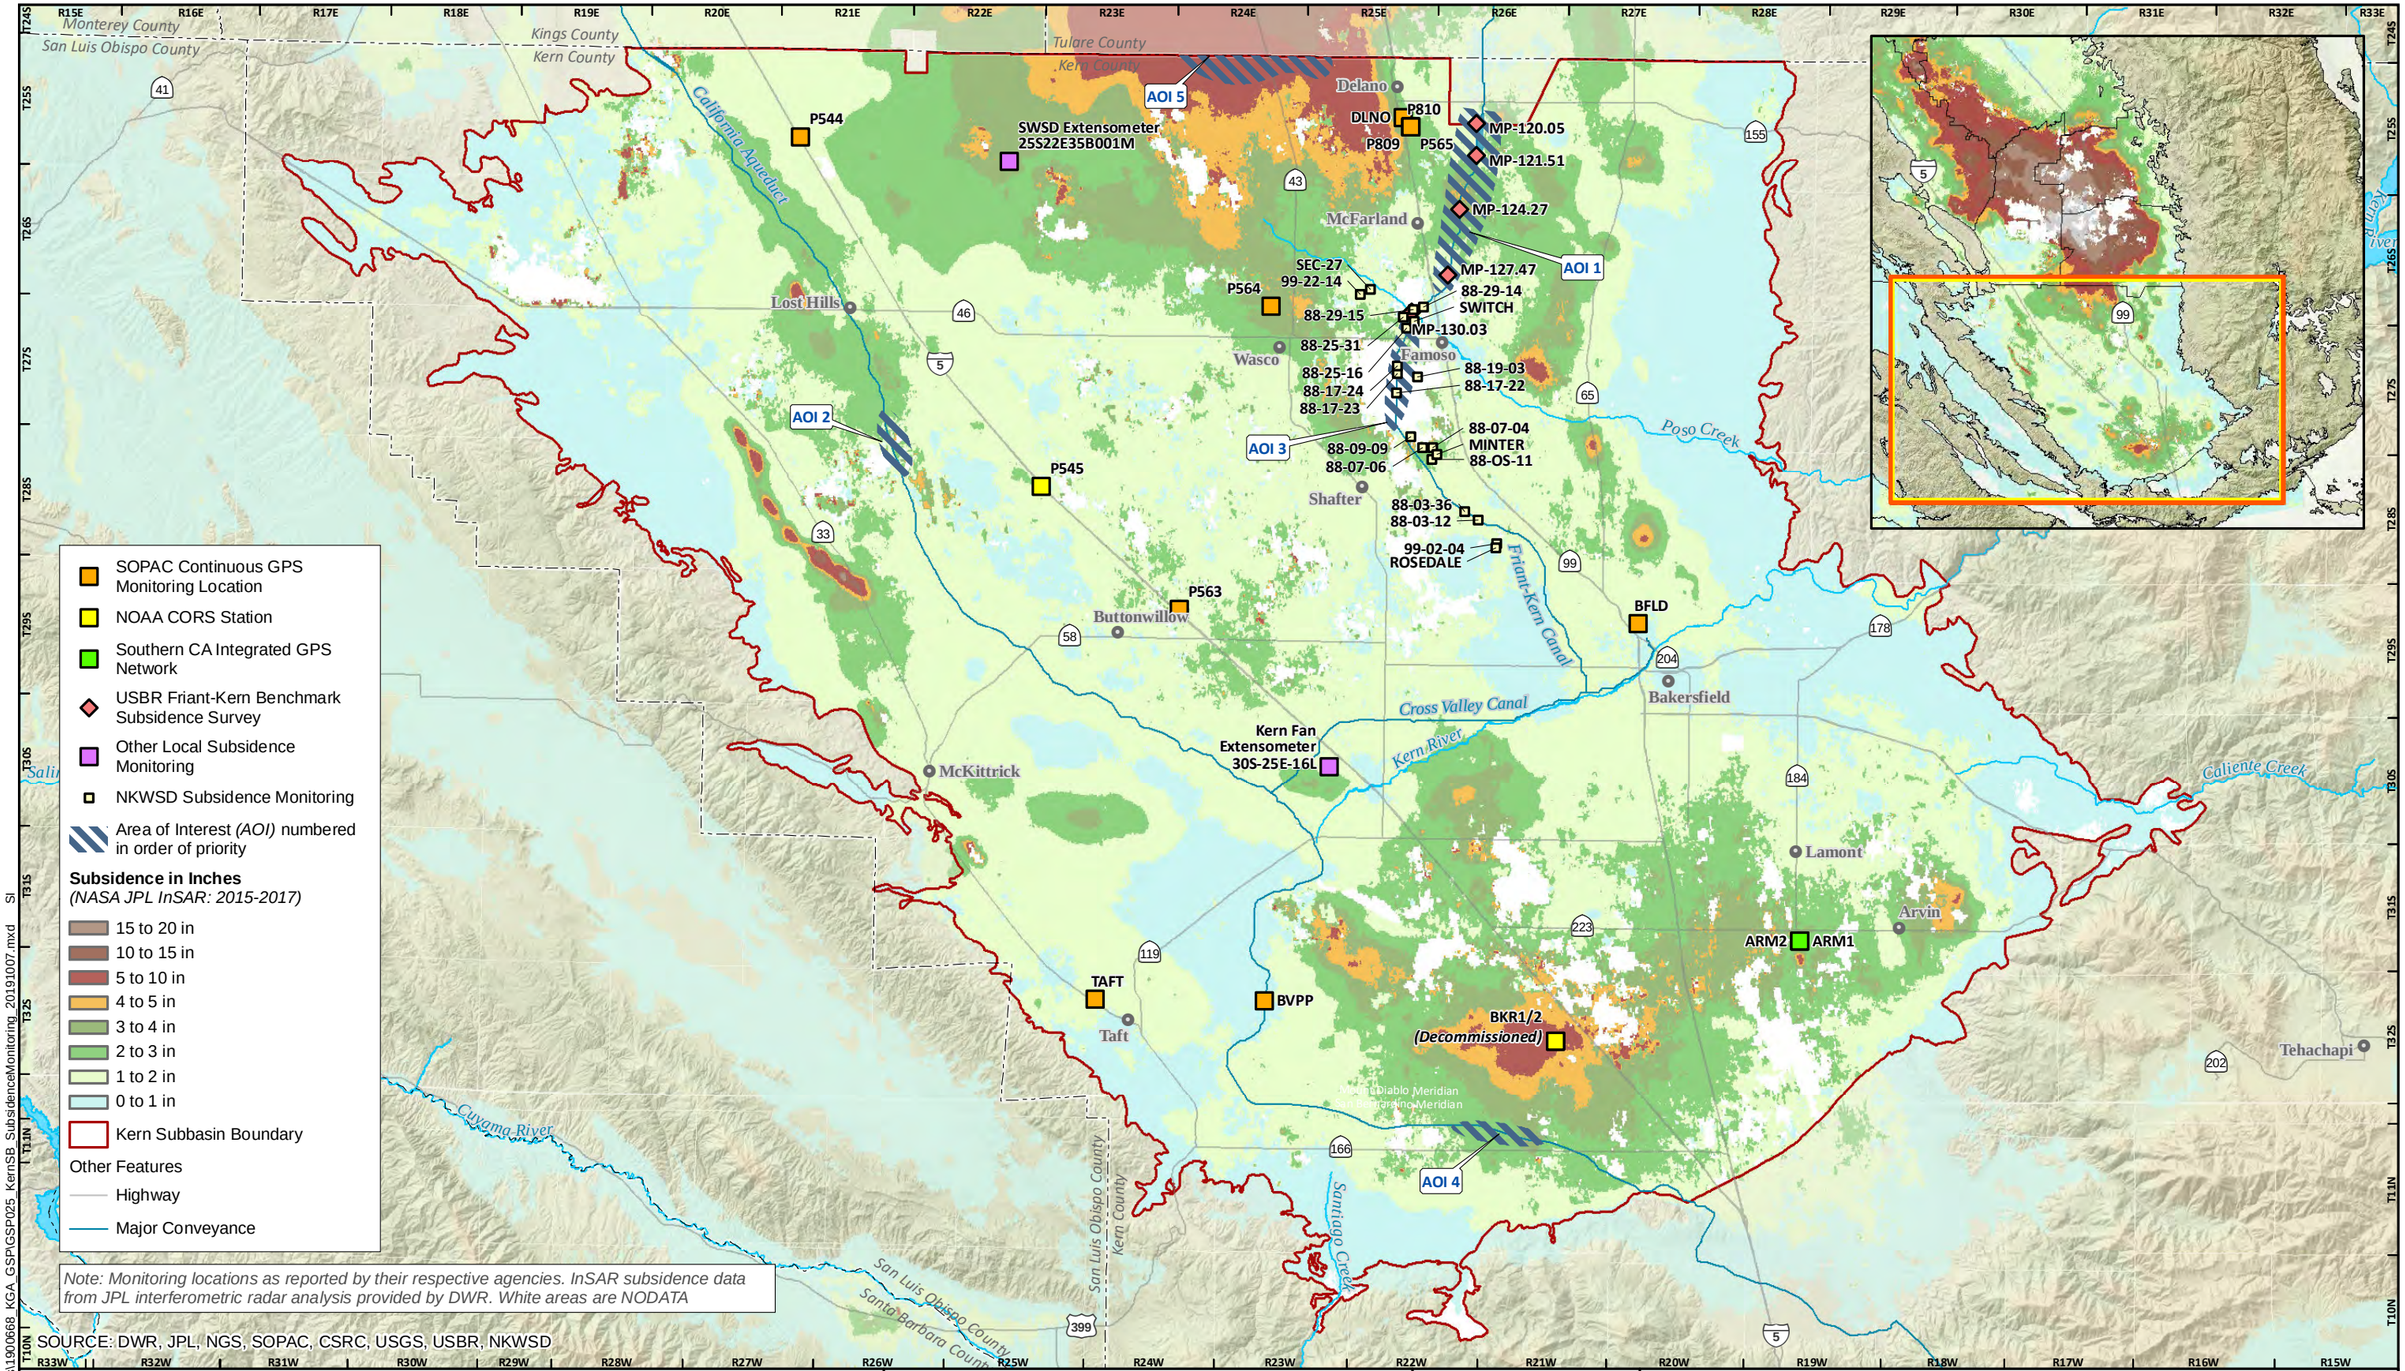
CORS CGPS Station

- ~$30k to $100k depending on equipment (purchase and installation). This may not include programming and digital network setup.
- DWR may be able to provide technical assistance, and at a minimum, review design specifications if DWR concurrence is wanted. DWR has not at this time offered any current specifications or assistance in developing designs.
- Optional outside consulting may be recommended for design and programming.

Extensometer

Drilling and installation costs ~$200k to $300k (design and operation not included).

Conclusions



This memorandum was prepared, in coordination with subbasin stakeholders, to improve the Kern County Subbasin subsidence monitoring network. It prioritizes areas of interest, at a subbasin-level, that require additional subsidence monitoring. Figures 2 and 3 present the AOIs for future monitoring points and associated water level monitoring wells (RMWs). AOIs are listed in order of highest priority for investigation and monitoring installation. Figures 4 to 8 present aerial images of these areas. In AOIs where groundwater extractions and oil and gas activities may be contributing to subsidence, extensometers will be installed in lieu of CGPS points in order to monitor the depth interval of groundwater extractions. Where subsidence monitoring is required, monitoring water levels and the condition of infrastructure is necessary. Where groundwater extraction is not causing subsidence, the AOI can be screened by the region-wide InSAR subsidence monitoring network.

Deep Drilled Braced Monument Overview

Article ID: 300 | Rating: Unrated | Last Updated: Wed, Oct 26, 2011 at 6:49 PM

Deep Drilled Braced Monument

Back to comparison table	Mount Commonly Used	Stability	Cost	Install Time	Labor	Substrate	Site Impact
	 SCIGN mount	high	$7,500-15,000	2-4 d	3-4	BR, U	high

The deep drilled braced monument (UNAVCO DDBM*) provides for a high degree of stability and longevity and can be anchored in bedrock or unconsolidated material. It is in the form of a tripod, each leg extending into the ground up to about 40 feet and welded at the top with gusset reinforcements. If site access is an issue and bedrock is available, the short drilled braced monument is the next best alternative to this type. The UNAVCO DDBM is used throughout the PBO network. It is based on the SCIGN design used at older installations in the SCIGN, BARGEN, PBO and PANGA networks.

* Modified from the original SCIGN DDBM design of Duncan Agnew and Frank Wyatt.

Site ASHM of the BARGEN network, Nevada, Utah, and California.

Pros

- high stability
- longevity
- can be installed in either bedrock or unconsolidated materials

Cons

- labor and tool intensive (requires a drilling rig and crew)
- expensive (can be $7,500 to $15,000, depending on drilling)
- time intensive (requires 2-4 days)
- may not be able to install in some remote locations... depends upon ease of site access
- large construction disturbance footprint

Design and Construction

A drilling contractor is required to install this monument. The cost of installation can typically range between $6,000 and $10,000 depending upon factors such as the type of drilling rig used, distance the drill rig and crew need to travel to site (mobilization/de-mobilization), foundation material (ground) being drilled, etc.

Installation Photos

- Construction Photos

Approximate Cost

$7,500-15,000 depending principally on drilling (substrate, distance drill rig needs to travel to and from the site)

This cost is for the monumentation only; the antenna mount (e.g. SCIGN mount) is not included.

Materials

- 21-foot 1.25" diameter schedule 40 stainless steel pipe, threaded (5 per site)

- 10-foot 1.25" diameter schedule 40 stainless steel pipe, threaded (5 per site)
- 1.25" schedule 40 stainless steel threaded adapters (5 per site)
- 3 weld gussets
- threaded adapter (if using the SCIGN antenna mount; see below)
- 2.5" diameter schedule 40 PVC (for each leg and for center post)
- foam wrapper (for each leg and for center post)
- rebar (for each leg and for center post)
- duct tape (for foam)
- concrete (provided by drillers)
- water (provided by drillers)
- welding rod
- gas for the generator (if there is no AC hookup)
- string, paint, nails, and wood stakes (for marking legs)

Tools

- generator (if there is no AC hookup)
- compass
- reel measuring tape (30m/100ft)
- leg alignment tool
- mallet
- large vice grips (2 or more)
- grinder
- vertical and angle level(s)
- welder
- file, pick, brush, gloves, helmet, long-sleeved shirt, hat (for welding)

Mount Commonly Used

The SCIGN mountis the antenna mount most commonly used with the deep drilled braced monument, although it is only required when using the SCIGN radome. Otherwise, any other leveling mount, such as the SECO 2072-series antenna mount, is acceptable.

GPS Deep Drilled Braced Monument Installation
Driller Instructions

Overview

The deep drilled braced GPS monument (DDBM) is designed to create a highly rigid and immobile structure isolated from surface soil movement and cemented in place at depth. The monument consists of 5 legs (stainless steel pipes) placed into drilled holes, and welded together above the surface to create a "tripod" frame. Of the 5 legs, the center leg is vertical and the 4 other legs are installed at angles to brace the vertical leg.

The Plate Boundary Observatory (PBO) project will require the installation of at least 600 of these DDBM monuments throughout the Western US and Alaska. We hope to locate a small number of highly skilled contractors throughout the Western US and Alaska to install these monuments during the next five years. This scope of work is for a one-time installation project consisting of a small number (1-5) of these installations. This will allow us to evaluate the contractor for possible future work within PBO. Please provide a quote for services based upon the scope of work outlined below.

Material

Contractor to supply to the following material:

1) A sufficient amount of grout to fill 5-35 foot deep holes (4.5"-6" diameter) will be used. Contractor will assure the following:

   a) Type I, II Portland cement and Class F Flyash shall be used for grout materials.
   b) Flyash shall replace 10-15% of the volume of Portland cement.
   c) Grout shall be proportioned to have a water to cementitious material ratio of 0.50.
   d) If using pre-packaged grout, grout shall be 1118 Grout supplied by Surecrete, Seattle, WA, or an approved equal meeting these specifications. Grout 1119 should be used for applications when water is present in the hole.

2) Water sufficient to mix grout. Final mix should be consistency of a milk shake.

All other material will be supplied by UNAVCO.

Construction Procedure

<u>Drilling/Casing/Pipe Placement</u>

1) Drill rig type and size selection shall be determined by contractor such that equipment used is most suited to site geology and hole precision requirements.

2) UNAVCO shall provide to the contractor a summary of expected site conditions such as surface topography and subsurface material.

3) Contractor shall drill 5 holes of 4.5" diameter to minimum depths of 35 ft.
   a) Center hole shall be drilled at vertical orientation plus/minus 2 degrees.
   b) Four angled holes shall be drilled at 35 degrees from vertical plus/minus 2.5 degrees.

4) Holes drilled at precise locations specified by UNAVCO engineering staff. Frequent measurement of hole inclination during drilling shall be made to ensure holes are drilled to exact specifications. The centerlines of all 5 holes shall intersect at a single point plus/minus 3". This point of intersection shall be located 62" above the surface, at the center leg. On level ground, each of the 4 angled legs will enter the ground at 43.5" from the center leg.

5) All holes shall be drilled straight enough so that PVC casing can be installed in the top 15.5 ft of each hole, and that the steel pipe can be freely lowered, not forced, for its entire 35 ft length.

6) Hole depth is to be determined by actual measurement after drilling. If necessary, loose material may need to be removed from the bottom of the holes to achieve required depth.

7) 2.5" PVC casing (wrapped with insulation) shall be installed in upper 15.5 ft of each hole immediately after drilling. It may be necessary to use drill rig to push casing into hole.

8) Contractor shall assist UNAVCO staff in placement of steel piping immediately after drilling and casing installation. 1.25" schedule 40 steel pipe shall be installed inside casing in each hole to a depth of 32-38 ft.

9) A single 5 foot vertical hole shall be drilled for the equipment enclosure.

10) UNAVCO is responsible for siting and alignment.

11) Contractor shall assist in the clearing of cuttings from the hole, during the drilling operation.

Grout Installation

1) Contractor shall provide grouting material and water for mixing.

2) All five legs are to be cemented in place with expansive grout.

3) Contractor shall prepare the pumpable grout to a "milkshake" consistency. Jobsite conditions may affect actual quantities of water needed.

4) Following steel pipe installation, contractor shall pump grout down steel pipes until grout fills pipe and pipe-casing annulus, and is seen emerging from top of annulus. Due to small clearances within pipe and at pipe-casing annulus, high pressures may be encountered during grout placement.

5) Contractor shall place grout such that no air bubbles are introduced. Ensuring a continuous flow of grout through pipe and back up through annulus requires proper grout handling, mixing, and pumping equipment and procedures.

6) Contractor shall neatly finish grout at surface of casing such that water will not puddle around monument legs.

Site Documentation and Cleanup

Contractor shall assist UNAVCO personnel in compiling site documentation including:

1) Depths of holes. All drilling documentation including drilled, measured, tamped, and shimmed pipe depths shall be recorded by contractor.

2) Grout information. Time of day, grout sack ID#, grout amount sifted, mixed, pumped, and lost shall all be monitored by contractor and reported to UNAVCO engineer for recording.

3) Contractor shall be responsible for removal of hazardous materials (i.e. hydraulic fluid, diesel fuel and/or contaminated soil) and debris. Site shall be left in suitable condition.

4) Contractor shall be responsible for containing and disposing of excess grouting material and debris such as cement bags, trash, and cigarette butts.

5) Contractor shall be responsible for leveling and raking of areas that were disturbed by drill rig and support vehicles at the site.

Miscellaneous

1) Contractor is responsible for hotel and per diem for the drilling crew.

2) Contractor shall assist UNAVCO personnel in any tasks related to GPS site installation such as pipe/coupling preparation, installation of pipe and insulation piping.

3) UNAVCO will mark for Underground Services Alert.

4) UNAVCO will provide maps, directions and relevant access information for drilling access.

5) Contractor's equipment and tools are the sole responsibility of the contractor. UNAVCO will not reimburse the contractor for any lost or damaged equipment.

All work shall be done to highest professional standards.

Available as special buy: Special pricing is available to UNAVCO members and associate members on select equipment. For more information see the GNSS Equipment Purchase Information page.
Available on loan: UNAVCO maintains a large pool of GPS and related equipment, available on loan to member and associate member institutions and NSF-funded programs. To submit a request, fill out the Online Support Request Form .
Serviceable at UNAVCO: UNAVCO is licensed to repair select GNSS receivers and antennas. For more information see the Equipment Repairs page.
File size (24 hr, 15 s): File size for a 24 hour-long file collected at a 15 second sample rate. File size is approximate and varies based on # of satellites tracked and frequencies recorded. File sizes shown here were taken from site data in the UNAVCO data archive.
Memory: Memory for receivers from the dealer may vary; values are given for UNAVCO-owned receivers.
Time last recording at 15 s: Estimated length of time the receiver can record at its given internal memory at a sample rate of 15 seconds.
Power draw: Estimated power draw in Watts. The power draw varies depending on the other equipment e.g. antenna(s) connected to the receiver.
Time lasts on 18 amphr battery: Estimated length of time the receiver can operate on the 12 volt, 18 amphr battery standard for UNAVCO campaign systems, without a solar panel. Time will vary based on temperature and battery health.

UNAVCO Resources: GNSS Antennas

Dual frequency (L1/L2) Choke Ring Antennas provide geodetic-quality GNSS measurements for surveying, map
Typical dual-frequency choke ring antennas maintain a stable phase center that has less than 1 mm of drift. T
on the geodetic research standard and features aluminum choke rings and a Dorne Margolin antenna elemen
have a low power consumption, and have excellent multipath rejection characteristics. Less-expensive but alsc
available as well. The UNAVCO Facility currently supports the following GNSS antennas.

GPS/GNSS Antennas Used by UNAVCO

	Trimble Choke Ring	MENU • NGS antenna calibration (Trimble GNSS Choke Ring, TRM59800.00 SCIT) (http://www.ngs.noaa.gov/ANTCAL/LoadFile?file=TRM59800.00_SCIT.atx) • NGS antenna calibration (TRM29659.00 SCIT) (http://www.ngs.noaa.gov/ANTCAL/LoadFile?file=TRM29659.00_SCIT.atx) • Note: Trimble GNSS Choke Ring TRM59800.80 is a TRM29659.00 reworked with a wide-band low noise amplifier (LNA) for GNSS. The TRM59800.00 and TRM59800.80 elements are identical in construction, the two antenna types are assumed to show similar phase center corrections. The TRM59800.80 calibrations are copies of the TRM59800.00 calibrations.
	Ashtech Choke Ring	• NGS antenna calibration (ASH701945G_M SCIT) (http://www.ngs.noaa.gov/ANTCAL/LoadFile?file=ASH701945G_M_SCIT.atx) • NGS antenna calibration (ASH701945E_M SCIT) (http://www.ngs.noaa.gov/ANTCAL/LoadFile?file=ASH701945E_M_SCIT.atx) • NGS antenna calibration (ASH701945C_M SCIT) (http://www.ngs.noaa.gov/ANTCAL/LoadFile?file=ASH701945C_M_SCIT.atx) • NGS antenna calibration (ASH701945B_M SCIT) (http://www.ngs.noaa.gov/ANTCAL/LoadFile?file=ASH701945B_M_SCIT.atx) • NGS antenna calibration (ASH700936D_M NONE) (http://www.ngs.noaa.gov/ANTCAL/LoadFile?file=ASH700936D_M_NONE.atx) • Preliminary Report on Data Quality with a Trimble 5700 GPS Receiver and an Ashtech Choke Ring Antenna (2002) (http://kb.unavco.org/kb/article.php?id=237)

UNAVCO Resources: Permanent GNSS Station Enclosures

Article ID: 381 | Rating: 1/5 from 2 votes | Last Updated: Wed, Aug 24, 2016 at 8:36 PM

UNAVCO Resources: Permanent GNSS Station Enclosures

UNAVCO has installed and supports a large variety of equipment enclosures for both AC and DC GNSS sites, from enclosures specifically designed for solar systems (the SunWize battery enclosure) to simple storage containers modified to accommodate cable pass-throughs. We can work to find the most suitable enclosure given the budget and the location of each permanent or semi-permanent GNSS installation. Below is a list of enclosures used within the last several years in UNAVCO-supported projects; click on the photographs to see sample content lists and more photos of actual installations. For standard UNAVCO campaign enclosures, check out UNAVCO Campaign GNSS Systems .

	SunWize Premium F-Series Battery Enclosure	The SunWize F-Series 4-battery enclosure is used throughout the Plate Boundary Observatory network, as well as in several other permanent GPS station networks in the US. Benefits include reasonable strength (the enclosure is made of aluminum), security (two key locks secure the enclosure), both internal and external knockouts for passing wires and cables, weatherproof seals, and a generous amount of space. Drawbacks include cost ($700-$1000 as of February 2009), size (if on-site space is limited or if equipment must be shipped), and mounting requirements (enclosure is designed to be mounted on a post, which must be cemented into the ground and strong enough to support batteries).
	Hardigg Case	Hardigg (now owned by Pelican Products) makes rugged, well-sealed plastic enclosures which are stackable, easy to handle, and UV resistant. Connectors are recessed within the ribs of the case to reduce the risk of damage during shipping.

	JOBOX	JOBOX chests, made by Delta Consolidated Industries, Inc. , are durable, weatherproof metal enclosures that UNAVCO has used in several long-term installations, including the EarthScope-sponsored Rio Grande Rift network. Chests are secured with key locks. The major drawback of the JOBOX is weight; boxes are heavy and cumbersome, thus not ideal for shipping and for transporting by foot over long distances. Cost of the box shown here is approximately $300-400 (as of February 2009).
	Pelican Case (large)	The Pelican case is easily portable, can be used to transport equipment, and is weatherproof. The case shown here, as deployed in the EarthScope-sponsored Rio Grande network, contains 2 100 amphr batteries in addition to the GPS receiver. The case is difficult to destroy and can be locked with padlocks. Cost is approximately $250-$300 (February 2009). Smaller cases are available (see below), and have been used in networks with year-round, reliable sunlight where large battery banks are not required.
	Pelican Case (small)	Like the larger Pelican cases (above), the smaller Pelican case is weatherproof and can be used to transport equipment. A smaller case is ideal if space is not an issue--specifically, if the requirement for amount of power stored is small (e.g. in a year-round sunny environment, as is common near the equator). The case is difficult to destroy and can be locked with padlocks. Networks utilizing small Pelican cases include Afar, Ethiopia, and Sierra Negra, Galapagos. Cost for the case shown here is approximately $125 (February 2009).
	Commercial Electrical Enclosure	Electrical boxes can be often purchased 'locally,' in major cities, rather than being shipped. Boxes may include knock-outs for passing cables through and locking options, like the box shown here. Electrical boxes are often sturdy, made of either strong plastic or of metal, and may or may not be weatherproof. Networks utilizing local electrical enclosures include Calabria, Italy and Bangladesh. Typical price range is about $100-$300.

	Storage Container	A heavy-duty storage container, such as the Contico Tuff Box, designed for the back of a truck or other outdoor use may work well for an equipment enclosure. They are generally low cost (about $70 for the container shown here, as of February 2009), available in most US cities, rugged, and lockable with padlocks. The case shown here fits four sealed 100 Amphr batteries along with the GPS and communications equipment. Used as enclosures in the Peatland Bog, Minnesota network.

Cellular Modem Summary

Article ID: 357 | Rating: Unrated | Last Updated: Wed, Oct 28, 2009 at 3:12 PM

Cellular Modem Summary

Cellular modems need to be very robust as the inherent disadvantages of the analog cellular phone system become especially evident with high speed data transfers. Cellular coverage could be of a quality not compatible with high speed data transfers and handshaking protocols. Often more than one cellular provider offers coverage in an area and it is worthwhile to investigate several options. A good voice communication does not translate into an acceptable data communication. Your choice of cellular modem and cellular phone should be able to run off 12VDC, even if AC power is available, to facilitate DC (battery) backup.

Suggested Minimum Requirements

- 12 VDC power
- V.32, V.32bis communication protocols
- V.42, MNP error correction/data compression
- RTS/CTS hardware flow control
- High speed baud rates (2.4-19.2 kbps)
- Compatible with CCITT and Bell standards
- Support industry-standard AT command set
- Compatible with RS-232 Control Signals

CHAPTER GROUNDWATER SUSTAINABILITY PLAN
WESTSIDE DISTRICT WATER AUTHORITY
Kern County, California

Prepared for:
Kern County Groundwater Authority
1800 30th Street, Suite 280
Bakersfield, California 93301

Project No.: 043-04

January 2020

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
§ 354.			**Introduction to Plan Contents**					
			This Article describes the required contents of Plans submitted to the Department for evaluation, including administrative information, a description of the basin setting, sustainable management criteria, description of the monitoring network, and projects and management actions.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
SubArticle 1.			**Administrative Information**					
§ 354.2.			**Introduction to Administrative Information**					
			This Subarticle describes information in the Plan relating to administrative and other general information about the Agency that has adopted the Plan and the area covered by the Plan.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.4.			**General Information**					
			Each Plan shall include the following general information:					
(a)			An executive summary written in plain language that provides an overview of the Plan and description of groundwater conditions in the basin.	30:55	ES			
(b)			A list of references and technical studies relied upon by the Agency in developing the Plan. Each Agency shall provide to the Department electronic copies of reports and other documents and materials cited as references that are not generally available to the public.	155:158	7.0			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10733.2 and 10733.4, Water Code.					
§ 354.6.			**Agency Information**					
			When submitting an adopted Plan to the Department, the Agency shall include a copy of the information provided pursuant to Water Code Section 10723.8, with any updates, if necessary, along with the following information:					
(a)			The name and mailing address of the Agency.	30:55,69	ES,1.5.4			
(b)			The organization and management structure of the Agency, identifying persons with management authority for implementation of the Plan.	30:55 58:63	ES,1.3			
(c)			The name and contact information, including the phone number, mailing address and electronic mail address, of the plan manager.	30:55,69	ES,1.5.4			
(d)			The legal authority of the Agency, with specific reference to citations setting forth the duties, powers, and responsibilities of the Agency, demonstrating that the Agency has the legal authority to implement the Plan.	30:56	ES,1.2			
(e)			An estimate of the cost of implementing the Plan and a general description of how the Agency plans to meet those costs.	63	1.3.6			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.8, 10727.2, and 10733.2, Water Code.					
§ 354.8.			**Description of Plan Area**					

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
			Each Plan shall include a description of the geographic areas covered, including the following information:					
(a)			One or more maps of the basin that depict the following, as applicable:					
	(1)		The area covered by the Plan, delineating areas managed by the Agency as an exclusive Agency and any areas for which the Agency is not an exclusive Agency, and the name and location of any adjacent basins.	30:55 64:65	ES,1.4.2	1a:3b		
	(2)		Adjudicated areas, other Agencies within the basin, and areas covered by an Alternative.	64:65	1.4.2	1a:3b		
	(3)		Jurisdictional boundaries of federal or state land (including the identity of the agency with jurisdiction over that land), tribal land, cities, counties, agencies with water management responsibilities, and areas covered by relevant general plans.	64:65, 75	1.4.2,2.3	2b, 10a:10c		
	(4)		Existing land use designations and the identification of water use sector and water source type.	76:77		10b:10c, 11a:11d		
	(5)		The density of wells per square mile, by dasymetric or similar mapping techniques, showing the general distribution of agricultural, industrial, and domestic water supply wells in the basin, including de minimis extractors, and the location and extent of communities dependent upon groundwater, utilizing data provided by the Department, as specified in Section 353.2, or the best available information.	88		18		1.2 wells/sq.mile, no municipal use
(b)			A written description of the Plan area, including a summary of the jurisdictional areas and other features depicted on the map.	64:65	1.4.2	1a:1b,2a:2b,3a:3b		
(c)			Identification of existing water resource monitoring and management programs, and description of any such programs the Agency plans to incorporate in its monitoring network or in development of its Plan. The Agency may coordinate with existing water resource monitoring and management programs to incorporate and adopt that program as part of the Plan.	122:125 135:140	2.8.2,3.0			
(d)			A description of how existing water resource monitoring or management programs may limit operational flexibility in the basin, and how the Plan has been developed to adapt to those limits.	124:125	2.8.2			Not applicable, will not limit.
(e)			A description of conjunctive use programs in the basin.	149:153	5.3			
(f)			A plain language description of the land use elements or topic categories of applicable general plans that includes the following:					
	(1)		A summary of general plans and other land use plans governing the basin.	65	1.4.3			
	(2)		A general description of how implementation of existing land use plans may change water demands within the basin or affect the ability of the Agency to achieve sustainable groundwater management over the planning and implementation horizon, and how the Plan addresses those potential effects	76:77	2.4			
	(3)		A general description of how implementation of the Plan may affect the water supply assumptions of relevant land use plans over the planning and implementation horizon.	65:67 75:77	2.3,2.4	10a;10c, 11a:11d		

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(4)		A summary of the process for permitting new or replacement wells in the basin, including adopted standards in local well ordinances, zoning codes, and policies contained in adopted land use plans.	66:67	1.4.5			
	(5)		To the extent known, the Agency may include information regarding the implementation of land use plans outside the basin that could affect the ability of the Agency to achieve sustainable groundwater management.	66:67	1.4.3			
(g)			A description of any of the additional Plan elements included in Water Code Section 10727.4 that the Agency determines to be appropriate.	66:67	1.4.3			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10720.3, 10727.2, 10727.4, 10733, and 10733.2, Water Code.					
§ 354.10.			**Notice and Communication**					
			Each Plan shall include a summary of information relating to notification and communication by the Agency with other agencies and interested parties including the following:					
(a)			A description of the beneficial uses and users of groundwater in the basin, including the land uses and property interests potentially affected by the use of groundwater in the basin, the types of parties representing those interests, and the nature of consultation with those parties.	31:32 67:69 93:95 130:132	ES,1.5.2, 2.6.4	20b		Groundwater naturally degraded. Basin Plan Amendement Pending.
(b)			A list of public meetings at which the Plan was discussed or considered by the Agency.	67:69	1.5.2			
(c)			Comments regarding the Plan received by the Agency and a summary of any responses by the Agency.	67:69	1.5			Appendix A
(d)			A communication section of the Plan that includes the following:					
	(1)		An explanation of the Agency's decision-making process.	67:69	1.5			
	(2)		Identification of opportunities for public engagement and a discussion of how public input and response will be used.	67:69	1.5			
	(3)		A description of how the Agency encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin.	67:69	1.5			
	(4)		The method the Agency shall follow to inform the public about progress implementing the Plan, including the status of projects and actions.	67:69	1.5			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.8, 10728.4, and 10733.2, Water Code					
SubArticle 2.			**Basin Setting**					
§ 354.12.			**Introduction to Basin Setting**					

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
			This Subarticle describes the information about the physical setting and characteristics of the basin and current conditions of the basin that shall be part of each Plan, including the identification of data gaps and levels of uncertainty, which comprise the basin setting that serves as the basis for defining and assessing reasonable sustainable management criteria and projects and management actions. Information provided pursuant to this Subarticle shall be prepared by or under the direction of a professional geologist or professional engineer.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.14.			**Hydrogeologic Conceptual Model**					
(a)			Each Plan shall include a descriptive hydrogeologic conceptual model of the basin based on technical studies and qualified maps that characterizes the physical components and interaction of the surface water and groundwater systems in the basin.	31:32 77:87	2.5	3a:3c, 12a:12e,13, 17a:17c		
(b)			The hydrogeologic conceptual model shall be summarized in a written description that includes the following:					
	(1)		The regional geologic and structural setting of the basin including the immediate surrounding area, as necessary for geologic consistency.	30:55 77:87	ES,2.5	12b		
	(2)		Lateral basin boundaries, including major geologic features that significantly affect groundwater flow.	77:87	2.5			
	(3)		The definable bottom of the basin.	77:87	2.5	16		
	(4)		Principal aquifers and aquitards, including the following information:					
		(A)	Formation names, if defined.	77:87	2.5	13,15b		
		(B)	Physical properties of aquifers and aquitards, including the vertical and lateral extent, hydraulic conductivity, and storativity, which may be based on existing technical studies or other best available information.	77:87	2.5	13		
		(C)	Structural properties of the basin that restrict groundwater flow within the principal aquifers, including information regarding stratigraphic changes, truncation of units, or other features.	77:87	2.5			
		(D)	General water quality of the principal aquifers, which may be based on information derived from existing technical studies or regulatory programs.	31:32 77:87	ES,2.5	15a,20b, 21:22		Groundwater naturally degrded. Basin Plan Amendment pending
		(E)	Identification of the primary use or uses of each aquifer, such as domestic, irrigation, or municipal water supply.	77:87	2.5			
	(5)		Identification of data gaps and uncertainty within the hydrogeologic conceptual model	77:87	2.5			
(c)			The hydrogeologic conceptual model shall be represented graphically by at least two scaled cross-sections that display the information required by this section and are sufficient to depict major stratigraphic and structural features in the basin.	77:87	2.5	12a:12c, 17a:17c		
(d)			Physical characteristics of the basin shall be represented on one or more maps that depict the following:					

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(1)		Topographic information derived from the U.S. Geological Survey or another reliable source.	77:87	2.5	4		
	(2)		Surficial geology derived from a qualified map including the locations of cross-sections required by this Section.	77:87	2.5	12b:12c, 17a:17c		
	(3)		Soil characteristics as described by the appropriate Natural Resources Conservation Service soil survey or other applicable studies.	77:87	2.5	14a:14c		
	(4)		Delineation of existing recharge areas that substantially contribute to the replenishment of the basin, potential recharge areas, and discharge areas, including significant active springs, seeps, and wetlands within or adjacent to the basin.	77:87	2.5	3c, 12a		
	(5)		Surface water bodies that are significant to the management of the basin.	77:87	2.5	10a		
	(6)		The source and point of delivery for imported water supplies.	118	2.7	27a:27c		
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10727.2, 10733, and 10733.2, Water Code.					
§ 354.16.			**Groundwater Conditions**					
			Each Plan shall provide a description of current and historical groundwater conditions in the basin, including data from January 1, 2015, to current conditions, based on the best available information that includes the following:					
(a)			Groundwater elevation data demonstrating flow directions, lateral and vertical gradients, and regional pumping patterns, including:					
	(1)		Groundwater elevation contour maps depicting the groundwater table or potentiometric surface associated with the current seasonal high and seasonal low for each principal aquifer within the basin.	88:91	2.6.2	19a:19b		Identified gap to be addressed
	(2)		Hydrographs depicting long-term groundwater elevations, historical highs and lows, and hydraulic gradients between principal aquifers.	121:122		20a		
(b)			A graph depicting estimates of the change in groundwater in storage, based on data, demonstrating the annual and cumulative change in the volume of groundwater in storage between seasonal high groundwater conditions, including the annual groundwater use and water year type.	121:122	2.7.2			
(c)			Seawater intrusion conditions in the basin, including maps and cross-sections of the seawater intrusion front for each principal aquifer.	128				Not applicable, 40 miles inland
(d)			Groundwater quality issues that may affect the supply and beneficial uses of groundwater, including a description and map of the location of known groundwater contamination sites and plumes.	31:32 107:122 130:132	ES,2.7, 2.15.5			Groundwater naturally degraded due to geology
(e)			The extent, cumulative total, and annual rate of land subsidence, including maps depicting total subsidence, utilizing data available from the Department, as specified in Section 353.2, or the best available information.	132:133		28a:28b		
(f)			Identification of interconnected surface water systems within the basin and an estimate of the quantity and timing of depletions of those systems, utilizing data available from the Department, as specified in Section 353.2, or the best available information.	128	2.12.2			

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(g)			Identification of groundwater dependent ecosystems within the basin, utilizing data available from the Department, as specified in Section 353.2, or the best available information.	129:130	2.12.3.1			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.2, 10727.4, and 10733.2, Water Code.					
§ 354.18.			**Water Budget**					
(a)			Each Plan shall include a water budget for the basin that provides an accounting and assessment of the total annual volume of groundwater and surface water entering and leaving the basin, including historical, current and projected water budget conditions, and the change in the volume of water stored. Water budget information shall be reported in tabular and graphical form.	110:122	2.7	24b:24d		KGA "Checkbook" Method
(b)			The water budget shall quantify the following, either through direct measurements or estimates based on data:					
	(1)		Total surface water entering and leaving a basin by water source type.	110:122	2.7			
	(2)		Inflow to the groundwater system by water source type, including subsurface groundwater inflow and infiltration of precipitation, applied water, and surface water systems, such as lakes, streams, rivers, canals, springs and conveyance systems.	110:122	2.7			KGA "Checkbook" method, CV2SIM-Kern pending
	(3)		Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow.	110:122	2.7			KGA "Checkbook" method, CV2SIM-Kern pending
	(4)		The change in the annual volume of groundwater in storage between seasonal high conditions.	110:122	2.7			
	(5)		If overdraft conditions occur, as defined in Bulletin 118, the water budget shall include a quantification of overdraft over a period of years during which water year and water supply conditions approximate average conditions.	107:122	2.7			
	(6)		The water year type associated with the annual supply, demand, and change in groundwater stored.	110:122	2.7			
	(7)		An estimate of sustainable yield for the basin.	120:121	2.7.6	24b:24d		
(c)			Each Plan shall quantify the current, historical, and projected water budget for the basin as follows:					
	(1)		Current water budget information shall quantify current inflows and outflows for the basin using the most recent hydrology, water supply, water demand, and land use information.	107:122	2.7	24b:24d,25		KGA Umbrella GSP
	(2)		Historical water budget information shall be used to evaluate availability or reliability of past surface water supply deliveries and aquifer response to water supply and demand trends relative to water year type. The historical water budget shall include the following:					
		(A)	A quantitative evaluation of the availability or reliability of historical surface water supply deliveries as a function of the historical planned versus actual annual surface water deliveries, by surface water source and water year type, and based on the most recent ten years of surface water supply information.	75:76 110:122	2.3,2.7	24b:24d,25		

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
		(B)	A quantitative assessment of the historical water budget, starting with the most recently available information and extending back a minimum of 10 years, or as is sufficient to calibrate and reduce the uncertainty of the tools and methods used to estimate and project future water budget information and future aquifer response to proposed sustainable groundwater management practices over the planning and implementation horizon.	110:122	2.7	24b:24d		
		(C)	A description of how historical conditions concerning hydrology, water demand, and surface water supply availability or reliability have impacted the ability of the Agency to operate the basin within sustainable yield. Basin hydrology may be characterized and evaluated using water year type.	30:55 110:122	ES,2.7	24a:24d		
	(3)		Projected water budgets shall be used to estimate future baseline conditions of supply, demand, and aquifer response to Plan implementation, and to identify the uncertainties of these projected water budget components. The projected water budget shall utilize the following methodologies and assumptions to estimate future baseline conditions concerning hydrology, water demand and surface water supply availability or reliability over the planning and implementation horizon:					
		(A)	Projected hydrology shall utilize 50 years of historical precipitation, evapotranspiration, and streamflow information as the baseline condition for estimating future hydrology. The projected hydrology information shall also be applied as the baseline condition used to evaluate future scenarios of hydrologic uncertainty associated with projections of climate change and sea level rise.	80:81 107:122	2.5.4,2.7			KGA Umbrella GSP pending CV2SIM-Kern
		(B)	Projected water demand shall utilize the most recent land use, evapotranspiration, and crop coefficient information as the baseline condition for estimating future water demand. The projected water demand information shall also be applied as the baseline condition used to evaluate future scenarios of water demand uncertainty associated with projected changes in local land use planning, population growth, and climate.	107:122	2.7	24b:24d		KGA"Checkbook" method pending CV2SIM-Kern
		(C)	Projected surface water supply shall utilize the most recent water supply information as the baseline condition for estimating future surface water supply. The projected surface water supply shall also be applied as the baseline condition used to evaluate future scenarios of surface water supply availability and reliability as a function of the historical surface water supply identified in Section 354.18(c)(2)(A), and the projected changes in local land use planning, population growth, and climate.	80:81 107:122	2.5.4,2.7	24b:24d,25		KGA "Checkbook" pending CV2SIM-Kern
(d)			The Agency shall utilize the following information provided, as available, by the Department pursuant to Section 353.2, or other data of comparable quality, to develop the water budget:					
	(1)		Historical water budget information for mean annual temperature, mean annual precipitation, water year type, and land use.	107:122	2.7			
	(2)		Current water budget information for temperature, water year type, evapotranspiration, and land use.	107:122	2.7			

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(3)		Projected water budget information for population, population growth, climate change, and sea level rise.	107:122	2.7			
(e)			Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, climate change, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow. If a numerical groundwater and surface water model is not used to quantify and evaluate the projected water budget conditions and the potential impacts to beneficial uses and users of groundwater, the Plan shall identify and describe an equally effective method, tool, or analytical model to evaluate projected water budget conditions.	30:55 110:122	ES,2.7	24b,24d		KGA "Checkbook" method pending CV2SIM-Kern
(f)			The Department shall provide the California Central Valley Groundwater-Surface Water Simulation Model (C2VSIM) and the Integrated Water Flow Model (IWFM) for use by Agencies in developing the water budget. Each Agency may choose to use a different groundwater and surface water model, pursuant to Section 352.4.	110:122	2.7			KGA "Checkbook" method pending CV2SIM-Kern
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10721, 10723.2, 10727.2, 10727.6, 10729, and 10733.2, Water Code.					
§ 354.20.			**Management Areas**					
(a)			Each Agency may define one or more management areas within a basin if the Agency has determined that creation of management areas will facilitate implementation of the Plan. Management areas may define different minimum thresholds and be operated to different measurable objectives than the basin at large, provided that undesirable results are defined consistently throughout the basin.	126	2.10	1a:1b,2a		KGA Umbrella GSP
(b)			A basin that includes one or more management areas shall describe the following in the Plan:					
	(1)		The reason for the creation of each management area.	126	2.10			
	(2)		The minimum thresholds and measurable objectives established for each management area, and an explanation of the rationale for selecting those values, if different from the basin at large.	141:145	4.0	29a:30f		
	(3)		The level of monitoring and analysis appropriate for each management area.	141:145	4.0			
	(4)		An explanation of how the management area can operate under different minimum thresholds and measurable objectives without causing undesirable results outside the management area, if applicable.	127:134 141:145	2.12:2.13, 4.0			Will coordinate with adjacent GMAs
(c)			If a Plan includes one or more management areas, the Plan shall include descriptions, maps, and other information required by this Subarticle sufficient to describe conditions in those areas.	58:63 141:145	1.3,4.0	1a:1b, 2a:2b		
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10733.2 and 10733.4, Water Code.					
SubArticle 3.			**Sustainable Management Criteria**					
§ 354.22.			**Introduction to Sustainable Management Criteria**					

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
			This Subarticle describes criteria by which an Agency defines conditions in its Plan that constitute sustainable groundwater management for the basin, including the process by which the Agency shall characterize undesirable results, and establish minimum thresholds and measurable objectives for each applicable sustainability indicator.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.24.			**Sustainability Goal**					
			Each Agency shall establish in its Plan a sustainability goal for the basin that culminates in the absence of undesirable results within 20 years of the applicable statutory deadline. The Plan shall include a description of the sustainability goal, including information from the basin setting used to establish the sustainability goal, a discussion of the measures that will be implemented to ensure that the basin will be operated within its sustainable yield, and an explanation of how the sustainability goal is likely to be achieved within 20 years of Plan implementation and is likely to be maintained through the planning and implementation horizon.	126:140	2.11:3.0			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10721, 10727, 10727.2, 10733.2, and 10733.8, Water Code.					
§ 354.26.			**Undesirable Results**					
(a)			Each Agency shall describe in its Plan the processes and criteria relied upon to define undesirable results applicable to the basin. Undesirable results occur when significant and unreasonable effects for any of the sustainability indicators are caused by groundwater conditions occurring throughout the basin.	127:133	2.12:2.13			
(b)			The description of undesirable results shall include the following:					
	(1)		The cause of groundwater conditions occurring throughout the basin that would lead to or has led to undesirable results based on information described in the basin setting, and other data or models as appropriate.	30:55 127:133	ES, 2.12:2.13			Groundwater natrually degraded. Simulated under flow toward axis of the basin beoynd the control of the WDWA.
	(2)		The criteria used to define when and where the effects of the groundwater conditions cause undesirable results for each applicable sustainability indicator. The criteria shall be based on a quantitative description of the combination of minimum threshold exceedances that cause significant and unreasonable effects in the basin.	127:133	2.12:2.13			
	(3)		Potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results.	127:133	2.12:2.13			
(c)			The Agency may need to evaluate multiple minimum thresholds to determine whether an undesirable result is occurring in the basin. The determination that undesirable results are occurring may depend upon measurements from multiple monitoring sites, rather than a single monitoring site.	141:145	4.0	29a:30f		

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(d)			An Agency that is able to demonstrate that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin shall not be required to establish criteria for undesirable results related to those sustainability indicators.	141:145	4.0			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10721, 10723.2, 10727.2, 10733.2, and 10733.8, Water Code.					
§ 354.28.			**Minimum Thresholds**					
(a)			Each Agency in its Plan shall establish minimum thresholds that quantify groundwater conditions for each applicable sustainability indicator at each monitoring site or representative monitoring site established pursuant to Section 354.36. The numeric value used to define minimum thresholds shall represent a point in the basin that, if exceeded, may cause undesirable results as described in Section 354.26.	141:145	4.0	29a:30f		GW naturally gegraded,GW elev.data identified as a data gap to be addressed
(b)			The description of minimum thresholds shall include the following:					
	(1)		The information and criteria relied upon to establish and justify the minimum thresholds for each sustainability indicator. The justification for the minimum threshold shall be supported by information provided in the basin setting, and other data or models as appropriate, and qualified by uncertainty in the understanding of the basin setting.	141:145	4.0	29a:30f		
	(2)		The relationship between the minimum thresholds for each sustainability indicator, including an explanation of how the Agency has determined that basin conditions at each minimum threshold will avoid undesirable results for each of the sustainability indicators.	141:145	4.0	29a:30f		
	(3)		How minimum thresholds have been selected to avoid causing undesirable results in adjacent basins or affecting the ability of adjacent basins to achieve sustainability goals.	141:145	4.0	29a:30f		
	(4)		How minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests.	141:145	4.0	29a:30f		
	(5)		How state, federal, or local standards relate to the relevant sustainability indicator. If the minimum threshold differs from other regulatory standards, the Agency shall explain the nature of and basis for the difference.	141:145	4.0	29a:30f		
	(6)		How each minimum threshold will be quantitatively measured, consistent with the monitoring network requirements described in Subarticle 4.	141:145	4.0	29a:30f		Will coordinate with adjacent GMA's.
(c)			Minimum thresholds for each sustainability indicator shall be defined as follows:					
	(1)		Chronic Lowering of Groundwater Levels. The minimum threshold for chronic lowering of groundwater levels shall be the groundwater elevation indicating a depletion of supply at a given location that may lead to undesirable results. Minimum thresholds for chronic lowering of groundwater levels shall be supported by the following:					
		(A)	The rate of groundwater elevation decline based on historical trends, water year type, and projected water use in the basin.	141:145	4.0	29a:30f		Minimal pumping due to naturally degraded GW.

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
		(B)	Potential effects on other sustainability indicators.	141:145	4.0	29a:30f		
	(2)		Reduction of Groundwater Storage. The minimum threshold for reduction of groundwater storage shall be a total volume of groundwater that can be withdrawn from the basin without causing conditions that may lead to undesirable results. Minimum thresholds for reduction of groundwater storage shall be supported by the sustainable yield of the basin, calculated based on historical trends, water year type, and projected water use in the basin.	141:145	4.0	29a:30f		
	(3)		Seawater Intrusion. The minimum threshold for seawater intrusion shall be defined by a chloride concentration isocontour for each principal aquifer where seawater intrusion may lead to undesirable results. Minimum thresholds for seawater intrusion shall be supported by the following:					
		(A)	Maps and cross-sections of the chloride concentration isocontour that defines the minimum threshold and measurable objective for each principal aquifer.					Not applicable, 40 miles inland
		(B)	A description of how the seawater intrusion minimum threshold considers the effects of current and projected sea levels.					Not applicable, 40 miles inland
	(4)		Degraded Water Quality. The minimum threshold for degraded water quality shall be the degradation of water quality, including the migration of contaminant plumes that impair water supplies or other indicator of water quality as determined by the Agency that may lead to undesirable results. The minimum threshold shall be based on the number of supply wells, a volume of water, or a location of an isocontour that exceeds concentrations of constituents determined by the Agency to be of concern for the basin. In setting minimum thresholds for degraded water quality, the Agency shall consider local, state, and federal water quality standards applicable to the basin.	31:32 95:114 130:132 141:145	ES, 2.6, 2.12.5, 4.0	15a,16,20b		Groundwater naturally degraded due to geology.Basin Plan Amendment pending.
	(5)		Land Subsidence. The minimum threshold for land subsidence shall be the rate and extent of subsidence that substantially interferes with surface land uses and may lead to undesirable results. Minimum thresholds for land subsidence shall be supported by the following:					
		(A)	Identification of land uses and property interests that have been affected or are likely to be affected by land subsidence in the basin, including an explanation of how the Agency has determined and considered those uses and interests, and the Agency's rationale for establishing minimum thresholds in light of those effects.	132:133 141:145	2.12.6,4.0	28a:28b		
		(B)	Maps and graphs showing the extent and rate of land subsidence in the basin that defines the minimum threshold and measurable objectives.	132:133 141:145	2.12.6,4.0	28a:28b		
	(6)		Depletions of Interconnected Surface Water. The minimum threshold for depletions of interconnected surface water shall be the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results. The minimum threshold established for depletions of interconnected surface water shall be supported by the following:					
		(A)	The location, quantity, and timing of depletions of interconnected surface water.	120:134	2.12	27d:27f		

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
		(B)	A description of the groundwater and surface water model used to quantify surface water depletion. If a numerical groundwater and surface water model is not used to quantify surface water depletion, the Plan shall identify and describe an equally effective method, tool, or analytical model to accomplish the requirements of this Paragraph.	127:134	2.12			
(d)			An Agency may establish a representative minimum threshold for groundwater elevation to serve as the value for multiple sustainability indicators, where the Agency can demonstrate that the representative value is a reasonable proxy for multiple individual minimum thresholds as supported by adequate evidence.	127:134 141:145	1.12.4, 4.0	29a:30f		GW elev. will serve as proxy for GW storage.
(e)			An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in Section 354.26, shall not be required to establish minimum thresholds related to those sustainability indicators.	127:134 141:145	1.12.4, 4.0			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.2, 10733, 10733.2, and 10733.8, Water Code.					
§ 354.30.			**Measurable Objectives**					
(a)			Each Agency shall establish measurable objectives, including interim milestones in increments of five years, to achieve the sustainability goal for the basin within 20 years of Plan implementation and to continue to sustainably manage the groundwater basin over the planning and implementation horizon.	141:145	4.0	29a:30f		
(b)			Measurable objectives shall be established for each sustainability indicator, based on quantitative values using the same metrics and monitoring sites as are used to define the minimum thresholds.	141:145	4.0	29a:30f		
(c)			Measurable objectives shall provide a reasonable margin of operational flexibility under adverse conditions which shall take into consideration components such as historical water budgets, seasonal and long-term trends, and periods of drought, and be commensurate with levels of uncertainty.	141:145	4.0	29a:30f		
(d)			An Agency may establish a representative measurable objective for groundwater elevation to serve as the value for multiple sustainability indicators where the Agency can demonstrate that the representative value is a reasonable proxy for multiple individual measurable objectives as supported by adequate evidence.	121:122 141:145	2.7.7,4.0	29a:30f		GW elevation will be used as proxy for GW storage
(e)			Each Plan shall describe a reasonable path to achieve the sustainability goal for the basin within 20 years of Plan implementation, including a description of interim milestones for each relevant sustainability indicator, using the same metric as the measurable objective, in increments of five years. The description shall explain how the Plan is likely to maintain sustainable groundwater management over the planning and implementation horizon.	121:122 141:145	2.11,4.0	29a:30f		
(f)			Each Plan may include measurable objectives and interim milestones for additional Plan elements described in Water Code Section 10727.4 where the Agency determines such measures are appropriate for sustainable groundwater management in the basin.	141:145	4.0	29a:30f		

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(g)			An Agency may establish measurable objectives that exceed the reasonable margin of operational flexibility for the purpose of improving overall conditions in the basin, but failure to achieve those objectives shall not be grounds for a finding of inadequacy of the Plan.	141:145	4.0	29a:30f		Not applicable, no MOs that exceed regional margin of operational flexibility
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10727.2, 10727.4, and 10733.2, Water Code.					
SubArticle 4.			**Monitoring Networks**					
§ 354.32.			**Introduction to Monitoring Networks**					
			This Subarticle describes the monitoring network that shall be developed for each basin, including monitoring objectives, monitoring protocols, and data reporting requirements. The monitoring network shall promote the collection of data of sufficient quality, frequency, and distribution to characterize groundwater and related surface water conditions in the basin and evaluate changing conditions that occur through implementation of the Plan.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.34.			**Monitoring Network**					
(a)			Each Agency shall develop a monitoring network capable of collecting sufficient data to demonstrate short-term, seasonal, and long-term trends in groundwater and related surface conditions, and yield representative information about groundwater conditions as necessary to evaluate Plan implementation.	132:133 135:140 141:145	2.12,3.0, 4.0	29a:30f		Appendix G
(b)			Each Plan shall include a description of the monitoring network objectives for the basin, including an explanation of how the network will be developed and implemented to monitor groundwater and related surface conditions, and the interconnection of surface water and groundwater, with sufficient temporal frequency and spatial density to evaluate the affects and effectiveness of Plan implementation. The monitoring network objectives shall be implemented to accomplish the following:					
	(1)		Demonstrate progress toward achieving measurable objectives described in the Plan.	135:145	3.0,4.0			Will cordinate with adjacent GMA's
	(2)		Monitor impacts to the beneficial uses or users of groundwater.	135:145	3.0,4.0			
	(3)		Monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds.	135:145	3.0,4.0			
	(4)		Quantify annual changes in water budget components.	135:145	3.0,4.0			
(c)			Each monitoring network shall be designed to accomplish the following for each sustainability indicator:					
	(1)		Chronic Lowering of Groundwater Levels. Demonstrate groundwater occurrence, flow directions, and hydraulic gradients between principal aquifers and surface water features by the following methods:					
		(A)	A sufficient density of monitoring wells to collect representative measurements through depth-discrete perforated intervals to characterize the groundwater table or potentiometric surface for each principal aquifer.	135:140	3.0,4.0			One well every ~19 square miles

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
		(B)	Static groundwater elevation measurements shall be collected at least two times per year, to represent seasonal low and seasonal high groundwater conditions.	135:145	3.0,4.0			
	(2)		Reduction of Groundwater Storage. Provide an estimate of the change in annual groundwater in storage.	135:145	3.0,4.0			
	(3)		Seawater Intrusion. Monitor seawater intrusion using chloride concentrations, or other measurements convertible to chloride concentrations, so that the current and projected rate and extent of seawater intrusion for each applicable principal aquifer may be calculated.					Not applicable, 40 miles inland
	(4)		Degraded Water Quality. Collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues.	31:32 95:114 130:132 141:145	ES, 2.12.5, 4.0	15a,16,2ob		GW naturally degraded due to geology. Basin Plan Amendment pending.
	(5)		Land Subsidence. Identify the rate and extent of land subsidence, which may be measured by extensometers, surveying, remote sensing technology, or other appropriate method.	132:134 139:140	2.12.6, 3.1:3.2	28a:28b		
	(6)		Depletions of Interconnected Surface Water. Monitor surface water and groundwater, where interconnected surface water conditions exist, to characterize the spatial and temporal exchanges between surface water and groundwater, and to calibrate and apply the tools and methods necessary to calculate depletions of surface water caused by groundwater extractions. The monitoring network shall be able to characterize the following:					
		(A)	Flow conditions including surface water discharge, surface water head, and baseflow contribution.	127:128	2.12			Depletion of interconnected GW not identified
		(B)	Identifying the approximate date and location where ephemeral or intermittent flowing streams and rivers cease to flow, if applicable.	72:75	2.1			
		(C)	Temporal change in conditions due to variations in stream discharge and regional groundwater extraction.	72:75	2.1			
		(D)	Other factors that may be necessary to identify adverse impacts on beneficial uses of the surface water.	72:75	2.1			Not applicable, use Aqueduct water
(d)			The monitoring network shall be designed to ensure adequate coverage of sustainability indicators. If management areas are established, the quantity and density of monitoring sites in those areas shall be sufficient to evaluate conditions of the basin setting and sustainable management criteria specific to that area.	135:140	3.0,4.0		2	Appendix G
(e)			A Plan may utilize site information and monitoring data from existing sources as part of the monitoring network.	135:140	3.0,4.0		2	Appendix G
(f)			The Agency shall determine the density of monitoring sites and frequency of measurements required to demonstrate short-term, seasonal, and long-term trends based upon the following factors:					
	(1)		Amount of current and projected groundwater use.	88:92 110:122	2.6.2, 2.7	24b:24d		~3,000AFY, currently

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(2)		Aquifer characteristics, including confined or unconfined aquifer conditions, or other physical characteristics that affect groundwater flow.	77:84	2.5.5	15b:15c		
	(3)		Impacts to beneficial uses and users of groundwater and land uses and property interests affected by groundwater production, and adjacent basins that could affect the ability of that basin to meet the sustainability goal.	127:134	2.12.3:2.13			Minimal pumping due to naturally degraded GW
	(4)		Whether the Agency has adequate long-term existing monitoring results or other technical information to demonstrate an understanding of aquifer response.	124:125	2.8.2			Identified data gap
(g)			Each Plan shall describe the following information about the monitoring network:					
	(1)		Scientific rationale for the monitoring site selection process.	135:145	3.0,4.0			
	(2)		Consistency with data and reporting standards described in Section 352.4. If a site is not consistent with those standards, the Plan shall explain the necessity of the site to the monitoring network, and how any variation from the standards will not affect the usefulness of the results obtained.	135:145	3.0,4.0			AppendixG
	(3)		For each sustainability indicator, the quantitative values for the minimum threshold, measurable objective, and interim milestones that will be measured at each monitoring site or representative monitoring sites established pursuant to Section 354.36.	135:145	3.0,4.0	29a:30f		
(h)			The location and type of each monitoring site within the basin displayed on a map, and reported in tabular format, including information regarding the monitoring site type, frequency of measurement, and the purposes for which the monitoring site is being used.	135:145	3.0,4.0	29a:30f		
(i)			The monitoring protocols developed by each Agency shall include a description of technical standards, data collection methods, and other procedures or protocols pursuant to Water Code Section 10727.2(f) for monitoring sites or other data collection facilities to ensure that the monitoring network utilizes comparable data and methodologies.	135:145	3.0,4.0			Appendix G
(j)			An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in Section 354.26, shall not be required to establish a monitoring network related to those sustainability indicators.	135:145	3.0,4.0			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.2, 10727.4, 10728, 10733, 10733.2, and 10733.8, Water Code					
§ 354.36.			**Representative Monitoring**					
			Each Agency may designate a subset of monitoring sites as representative of conditions in the basin or an area of the basin, as follows:					
(a)			Representative monitoring sites may be designated by the Agency as the point at which sustainability indicators are monitored, and for which quantitative values for minimum thresholds, measurable objectives, and interim milestones are defined.	135:145	3.0,4.0			Appendix G
(b)			(b) Groundwater elevations may be used as a proxy for monitoring other sustainability indicators if the Agency demonstrates the following:					

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(1)		Significant correlation exists between groundwater elevations and the sustainability indicators for which groundwater elevation measurements serve as a proxy.	121:122 135:145	2.7.2, 3.0,4.0			
	(2)		Measurable objectives established for groundwater elevation shall include a reasonable margin of operational flexibility taking into consideration the basin setting to avoid undesirable results for the sustainability indicators for which groundwater elevation measurements serve as a proxy.	135:145	3.0,4.0			
(c)			The designation of a representative monitoring site shall be supported by adequate evidence demonstrating that the site reflects general conditions in the area.	135:145	3.0,4.0			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10727.2 and 10733.2, Water Code					
§ 354.38.			**Assessment and Improvement of Monitoring Network**					
(a)			Each Agency shall review the monitoring network and include an evaluation in the Plan and each five-year assessment, including a determination of uncertainty and whether there are data gaps that could affect the ability of the Plan to achieve the sustainability goal for the basin.	124:125 154:155	2.8.2,6.0			Appendix G, one well every ~19sq. miles
(b)			Each Agency shall identify data gaps wherever the basin does not contain a sufficient number of monitoring sites, does not monitor sites at a sufficient frequency, or utilizes monitoring sites that are unreliable, including those that do not satisfy minimum standards of the monitoring network adopted by the Agency.	124:125 154:155	2.8.2,6.0			
(c)			If the monitoring network contains data gaps, the Plan shall include a description of the following:					
	(1)		The location and reason for data gaps in the monitoring network.	135:145	3.0,4.0			
	(2)		Local issues and circumstances that limit or prevent monitoring.	135:145	3.0,4.0			
(d)			Each Agency shall describe steps that will be taken to fill data gaps before the next five-year assessment, including the location and purpose of newly added or installed monitoring sites.	135:145	3.0,4.0			
(e)			Each Agency shall adjust the monitoring frequency and density of monitoring sites to provide an adequate level of detail about site-specific surface water and groundwater conditions and to assess the effectiveness of management actions under circumstances that include the following:					
	(1)		Minimum threshold exceedances.	135:145	3.0,4.0			
	(2)		Highly variable spatial or temporal conditions.	135:145	3.0,4.0			
	(3)		Adverse impacts to beneficial uses and users of groundwater.	135:145	3.0,4.0			
	(4)		The potential to adversely affect the ability of an adjacent basin to implement its Plan or impede achievement of sustainability goals in an adjacent basin.	135:145	3.0,4.0			Minimum pumping due to naturally degraded GW
			Note: Authority cited: Section 10733.2, Water Code.

SubArticle 5.			**Projects and Management Actions**					
§ 354.42.			**Introduction to Projects and Management Actions**					
			This Subarticle describes the criteria for projects and management actions to be included in a Plan to meet the sustainability goal for the basin in a manner that can be maintained over the planning and implementation horizon.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.44.			**Projects and Management Actions**					
(a)			Each Plan shall include a description of the projects and management actions the Agency has determined will achieve the sustainability goal for the basin, including projects and management actions to respond to changing conditions in the basin.	146:153	5.0			
(b)			Each Plan shall include a description of the projects and management actions that include the following:					
	(1)		A list of projects and management actions proposed in the Plan with a description of the measurable objective that is expected to benefit from the project or management action. The list shall include projects and management actions that may be utilized to meet interim milestones, the exceedance of minimum thresholds, or where undesirable results have occurred or are imminent. The Plan shall include the following:					
		(A)	A description of the circumstances under which projects or management actions shall be implemented, the criteria that would trigger implementation and termination of projects or management actions, and the process by which the Agency shall determine that conditions requiring the implementation of particular projects or management actions have occurred.	141:153	4.0,5.0			
		(B)	The process by which the Agency shall provide notice to the public and other agencies that the implementation of projects or management actions is being considered or has been implemented, including a description of the actions to be taken.	67:69	1.5			
	(2)		If overdraft conditions are identified through the analysis required by Section 354.18, the Plan shall describe projects or management actions, including a quantification of demand reduction or other methods, for the mitigation of overdraft.	141:153	4.0,5.0			
	(3)		A summary of the permitting and regulatory process required for each project and management action.	141:153	4.0,5.0			

Article 5.			Plan Contents for Westside Districts Water Authority (WDWA) Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(4)		The status of each project and management action, including a time-table for expected initiation and completion, and the accrual of expected benefits.	141:153	4.0,5.0			
	(5)		An explanation of the benefits that are expected to be realized from the project or management action, and how those benefits will be evaluated.	141:153	4.0,5.0			
	(6)		An explanation of how the project or management action will be accomplished. If the projects or management actions rely on water from outside the jurisdiction of the Agency, an explanation of the source and reliability of that water shall be included.	141:153	4.0,5.0			
	(7)		A description of the legal authority required for each project and management action, and the basis for that authority within the Agency.	141:153	4.0,5.0			
	(8)		A description of the estimated cost for each project and management action and a description of how the Agency plans to meet those costs.	141:153	4.0,5.0			
	(9)		A description of the management of groundwater extractions and recharge to ensure that chronic lowering of groundwater levels or depletion of supply during periods of drought is offset by increases in groundwater levels or storage during other periods.	141:153	4.0,5.0			
(c)			Projects and management actions shall be supported by best available information and best available science.	141:153	4.0,5.0			
(d)			An Agency shall take into account the level of uncertainty associated with the basin setting when developing projects or management actions.	141:153	4.0,5.0			
			Note: Authority cited: Section 10733.2, Water Code.

EXECUTIVE SUMMARY

On September 16, 2014, the State of California enacted into law three legislative bills (Senate Bill [SB] 1168 [Pavely], SB 1319 [Pavely], and Assembly Bill [AB] 1739 [Dickinson]). These bills are collectively known as the Sustainable Groundwater Management Act (SGMA). In simple terms the goal of SGMA is the sustainable management and use of the State of California's (State's) groundwater resources in a way that does not cause undesirable results.

To achieve the sustainable management of groundwater, SGMA requires that all groundwater basins identified by the State as high or medium priority, and subject to conditions of critical overdraft, be managed under a Groundwater Sustainability Plan (GSP) by January 31, 2020. The Kern County Subbasin (KCS, subbasin, or Subbasin) has been identified as a critically over drafted High Priority Basin subject to SGMA. As such, a special entity called the Kern Groundwater Authority (KGA) was formed on April 26, 2017. An amended and restated Joint Powers Agreement between Kern County and the general members of the KGA provided the necessary legal authority for the KGA to prepare, submit, and implement the required GSP.

Because of the many independent Water Districts within the KCS, which serve a variety of differing water users, it was decided to prepare a general GSP for the KGA, referred to in this Chapter GSP as the "KGA Umbrella GSP" or "Plan". Within this framework individual Water Districts or groups of Water Districts in the KGA are to prepare more detailed individual "Chapter GSPs", which discuss local groundwater conditions that, although are often related to adjoining Water Districts, have hydrogeology or other factors which may be distinct to their respective management area(s). Additionally, the Chapter GSPs provide the ability for the KGA to identify which of the undesirable results identified in SGMA may apply to a specific area of the KCS, and how these results would best be monitored and mitigated over both the short- and long-term, in order to meet KGA and SGMA sustainability goals.

This Chapter GSP focuses on a select subset of Water Districts within the KGA. Those participating Districts, referred to as the Westside Districts Water Authority (WDWA), are:

1. Lost Hills Water District (LHWD);
2. Belridge Water Storage District (BWSD); and
3. Berrenda Mesa Water District (BMWD).

Commensurate with SGMA, and based on the current level of understanding of the WDWA within the KCS basin setting, the purpose of this Chapter GSP is to describe in plain language the groundwater conditions that currently exist within the WDWA. This Chapter GSP also identifies hydrologic data gaps and focused remedies, and presents a proposed groundwater management plan that, if determined to be technically and economically feasible, has the potential to achieve and maintain the sustainability goals of the WDWA and, by extension, those

of the KGA over the required SGMA implementation horizon. Due the complex and interrelated nature of the hydrology and consumptive use of the water resources within the KGA, details and data from the KGA GSP, and some data from individual adjacent GSPs and/or Groundwater Sustainability Agencies (GSAs), may be included in this Chapter GSP. Issues related to preliminary coordination with adjacent Districts, if any, will be addressed during the first five-year reassessment period after acceptance of the KGA Plan.

The WDWA currently covers approximately 227,193 acres, or roughly 355 square miles of western Kern County, California. Of this total, approximately 88,989 acres (~140 square miles) is irrigated. Preliminary numerical modeling by the KGA indicates that the WDWA has a historic annual water demand of approximately 285,000 acre-feet per year (AFY), which is projected to escalate to approximately 316,000 AFY by 2040 due to climate change. Historically, significantly more than 95% of the water used for irrigation in the WDWA has been surface water, with most of the supply coming from the State Water Project (SWP) and other supplemental sources delivered via the California Aqueduct (Aqueduct). This volume of water consists of a combination of SWP "Table A" and "Article 21" water along with purchased supplemental import water, although not all supplemental water is SWP water. When available, a combined 100 percent (%) WDWA allocation from the SWP is around 332,218 AFY. Current surface water deliveries (all WDWA sources) are approximately 266,290 AFY. The WDWA preliminary minimum estimated volume of groundwater available that would not cause an undesirable result (i.e. "Native Yield"), is approximately 34,079 AFY. This volume is based on basic water supply inputs. When additional water budget inputs, such as those proposed in Project Management Action #3, are considered this volume may be higher (~68,158 AFY). Groundwater is primarily utilized for blending when California Aqueduct (Aqueduct) water supply is low. Current groundwater pumping in the WDWA is on the order of 3,000 AFY. It is emphasized that groundwater in the WDWA is of poor quality and unsuitable for practical use without blending or treatment. As such, brackish groundwater is considered to be "outside" the water budget unless blended or treated.

Unique hydrogeologic characteristics of the WDWA that set it apart from the other Water Districts in the KCS are:

1. The WDWA is isolated from other groundwater basins and adjoining water districts along its entire western boundary by the Temblor Mountain Range, its primary source of subsurface groundwater inflow. On the north and east, groundwater underflow towards the axis of the basin is impeded or slowed by a series of roughly north-south oriented geologic anticlines and synclines (up folds and down folds). To the south groundwater flow is impeded by geologic structural ridges that include spurs of the Temblor Range and the Elk Hills Anticline. This geologic setting has contributed to the poor groundwater quality in the WDWA and

limits necessary groundwater coordination to just a few downgradient management areas to the north and east.

2. Groundwater is naturally degraded and of poor quality throughout most of the WDWA due to the presence of geologic sediments derived from marine environments, some of which contain saline connate water. These conditions make groundwater in the WDWA unsuitable for practical beneficial use, without treatment or blending with better quality water.
3. Irrigation demand is met almost entirely by water delivered via the Aqueduct. Groundwater is estimated to make up less than 2% of the water used for irrigation by private well owners due to its poor quality. Current pumping for the purpose of blending with the Aqueduct-delivered water supply is estimated to be approximately 3,000 AFY.
4. The most significant amount of brackish groundwater discharge from the WDWA modeled by the KGA is in the form of natural subsurface groundwater underflow to the north, towards the former Tulare Lake bed, a beneficial use exemption area, and eastward towards the axis of the Valley. The total combined volume of modeled underflow discharge to these areas is estimated to be approximately 111,000 AFY. Given the limited amount of pumping in the WDWA, underflow out of the WDWA is the most significant contributor to estimated groundwater deficits (change in groundwater storage) in the WDWA. This natural phenomenon is beyond the control of the WDWA.
5. Pumping for consumptive use in downgradient adjacent water districts has resulted in noticeable differences in groundwater elevations between the WDWA and these areas. The adjacent pumping has likely increased the velocity and volume of underflow out of the WDWA along shared administrative boundaries to the east and southeast. While the WDWA plans to coordinate with adjacent water districts during the implementation of the GSP, activities in adjacent districts which may affect WDWA groundwater elevations are beyond the direct control of the WDWA.
6. In 2016, due to the near ubiquitous poor quality of groundwater in the KCS west side, the Westside Water Quality Coalition (WWQC) prepared a Basin Plan Amendment Workplan (BPAW), which is inclusive of a significant percentage of the irrigated lands within the WDWA. The BPAW recommends delisting municipal and unlimited agriculture as a designated beneficial use for perched groundwater and deeper unconfined/semi-confined groundwater above the sub-regional Corcoran Clay (or its equivalent) due to naturally poor groundwater quality. The draft BPAW has been provided to the CV-SALTS Technical Committee and the Regional Water Quality Control Board (RWQCB) for preliminary review and input. The final determination by the RWQCB on the BPAW application will be reported in the relevant GSP annual update report.

A brief description of the member districts of the WDWA follows.

Lost Hills Water District

The LHWD was formed in 1963 to provide irrigation water from the SWP to the District. The LHWD boundaries begin just south of the town of Lost Hills and extend north and west to the Kings-Kern County line. Key landmarks include the California Aqueduct and Interstate 5 (I-5), the latter of which bisects the District diagonally from northwest to southeast. Adjacent Water Districts include Dudley Ridge Water District (DRWD) to the north (Kings County, Tulare Lake Subbasin), the BWSD to the south, the Semitropic Water Storage District (SWSD) and a portion of the Buena Vista Water Storage District (BVWSD) to the east, and the BWSD to the west.

The LHWD is comprised of approximately 74,357 acres, of which 70,453 acres are considered farmable. Not all of this acreage is currently being utilized for agricultural purposes. As of 2015, the net area under irrigated cultivation is approximately 27,900 acres. Agricultural activities rely primarily on surface water from the Aqueduct. In addition to agriculture, oil and gas production is an important non-irrigated land use within the LHWD. Groundwater use in the LHWD is mostly limited to periods of contracted surface water shortfalls and is generally relied upon for the purpose of blending. During periods of drought the LHWD also relies on groundwater coordination with adjacent Water Districts or growers as well as for surface water transfers, supplemental water purchases and nearby water banking programs (i.e., Berrenda Mesa and Pioneer Projects). These two banking projects are located outside of the District, just southwest of the City of Bakersfield. Individual landowners within the WDWA may also participate in surface-water banking projects, which can provide a significant amount of banked water for, and on, their own behalf. Groundwater quality is documented to be naturally degraded due to elevated concentrations of total dissolved solids (TDS). Groundwater is considered unsuitable for most uses and is non-beneficial for a majority of crops, and in some cases livestock. The LHWD supplies no municipal water from surface water or groundwater.

Berrenda Mesa Water District

Like the LHWD, the BMWD was formed in 1963 by landowners for the purpose of providing a reliable supply of irrigation water to the BMWD from the SWP. To the north of the BMWD lies the adjacent Devil's Den Water District (DDWD) (Kern County, outside of the KCS), to the south is the BWSD, to east are Undistricted Lands and the LHWD, and to the west is the Temblor Mountain Range.

Of the approximate 55,440 acres within the BMWD, all but 6,400 acres are considered farmable. The estimated net acreage currently being farmed is around 35,240 acres, of which 24,204 acres is irrigated by surface water from the SWP. Remaining lands are used for dry land farming or livestock grazing. At 100% delivery, the volume of contract water available to the BMWD is approximately 92,600 acre-feet (AF). Current water demand is approximately 88,000 AFY.

During times of drought, when contract water deliveries are reduced, in addition to groundwater blending, the BMWD can recover previously stored (i.e. banked) surface water from the Pioneer and Berrenda Mesa Projects. These two banking projects are located outside of the District, just southwest of the City of Bakersfield. Individual landowners within the WDWA may also participate in surface-water banking projects, which can provide a significant amount of banked water for, and on, their own behalf.

Groundwater use is limited in the BMWD due to elevated concentrations of TDS. The BMWD supplies no municipal water either from groundwater or surface water supply.

Belridge Water Storage District

The BWSD was formed by landowners in 1962 to provide surface water from the SWP for irrigation. The BWSD is bounded on the north by the LHWD and BMWD along with some currently Undistricted Lands, to the south by additional currently Undistricted Lands and the West Kern Water District (WKWD), to the east by the BVWSD, and to the west by the Temblor Mountain Range.

The principal source of water supply for the BSWD is surface and other imported water delivered by the Aqueduct, with agriculture as the main consumer. Of the 91,397 acres within the BWSD, approximately 88,223 acres are considered farmable, although not all of this land is currently being used for agriculture. As of 2015, there were approximately 36,885 acres being irrigated in the BWSD. In addition to agriculture, a percentage of the BWSD annual import allocation, when available, is delivered for industrial use in oil recovery operations in the North and South Belridge oil fields.

During periods of drought the BWSD relies chiefly on groundwater blending and coordination with adjacent Water Districts or growers for water transfers, supplemental water purchases and transfers from nearby water banking programs (i.e., Berrenda Mesa and Pioneer Projects). These two banking projects are located outside of the District, just southwest of the City of Bakersfield. Individual landowners within the WDWA may also participate in surface-water banking projects, which can provide a significant amount of banked water for, and on, their own behalf. The BWSD supplies no municipal water either from groundwater or surface water supply.

Public Meetings and Stakeholder Engagement

The KGA maintains a website (www.kerngwa.com) where it routinely posts information related to the GSP preparation process and proactively solicits stakeholder engagement and input. KGA

Coordination Meetings with stakeholders are typically held on the first Monday of every month. A partial list of items that are made available on the KGA website includes:

- Agendas and dates for upcoming and past public meetings;
- Stakeholder surveys;
- Relevant documents and reports for public review and input;
- Presentations, research, and white papers; and
- KGA contact information.

Additionally, the WDWA members have their own individual websites that provide information that is focused on the status of WDWA operations and GSP development within their respective district areas. The WDWA-member websites are:

- LHWD: www.lhwd.org
- BWSD: www.belridgewsd.com
- BMWD: www.bmwd.org

WDWA public outreach activities to date include:

- The WDWA participated in a KGA sponsored public workshop at the Kern County Agricultural Center in Bakersfield, California on May 14, 2019. The evening workshop was open to all community members and stakeholders. The workshop afforded interested parties the opportunity to interact one-on-one with WDWA staff and consultants who were there to answer and discuss questions or concerns related to the WDWA Chapter GSP, potential undesirable results and groundwater sustainability. The forum afforded the public an opportunity to also learn more about other KGA Chapter GSPs and the SGMA process.
- A second public KGA workshop was held on the evening of September 26, 2019 at the Kern County Agricultural Center in Bakersfield, California. This workshop took place during the KGA Umbrella GSP 90-day public review period and provided another opportunity for interested parties to communicate with WDWA staff and consultants regarding SGMA, the WDWA Chapter GSP, potential undesirable results and groundwater sustainability in the WDWA.
- A public meeting (WDWA regularly scheduled Board meeting) was held on June 5, 2019 at the BWSD offices. The purpose of this meeting was to discuss WDWA-specific issues related to this Draft Chapter GSP, such as current and projected water budgets, potential undesirable results, groundwater quality and Measurable Thresholds (MTs) and Measurable Objectives (MOs). The meeting updated Board members, the public and stakeholders on the status of the WDWA GSP Chapter findings, costs and the SGMA process. Initial comments received from the public or other stakeholders were incorporated into the Chapter GSP prior to the next scheduled update on August 21, 2019.

- A second update meeting with the WDWA Board and members of the public to discuss the Draft Chapter GSP was held on August 21, 2019 at the BWSD offices. In addition to presenting the latest information on the draft WDWA Chapter GSP, the WDWA Board approved submittal of the draft Chapter GSP for inclusion in the KGA Umbrella GSP prior to a 90-day public review period for the KGA Umbrella GSP. Initial comments received from stakeholders were incorporated in the update Chapter GSP presented at this meeting.
- The Draft Chapter GSP components and status were presented at three other regularly scheduled WDWA Board meetings open to the public, and at two public KGA Board Meetings held in Bakersfield on August 28, 2019 and December 18, 2019.
- The WDWA Manager received one direct comment letter during the 90-day public comment period for the KGA Draft Umbrella GSP. Relevant and applicable comments pertaining to the WDWA were incorporated in this version of the Chapter GSP. A copy of the letter is provided in the appendices of this report. Five other, more global, comment letters related to the Draft KGA Umbrella GSP and addressed to the KGA GSP Manager were also reviewed for relevant or applicable comments for incorporation that might pertain to the WDWA. It should be noted that the WDWA does not supply groundwater for municipal supply. Copies of those letters are on file with the KGA. Based on Fish & Wildlife comments the Lokern Ecological Reserve was identified and discussed in the Chapter GSP.

Basin Setting

The Central Valley of California (Valley) covers about 20,000 square miles and is bounded by the Cascade Mountain Range to the north, the Sierra Nevada Mountain Range (Sierra Nevada) to the east, the Tehachapi Mountains to the south, and the Coast Ranges (e.g., Temblor Range) and San Francisco Bay area to the west. The Valley is divided into three groundwater hydrologic regions according to the California Department of Water Resources (DWR's) Bulletin 118: (1) the northern one-third of the Valley is within the Sacramento River Basin; (2) the central one-third is within the San Joaquin River Basin; and (3) the southern one-third is within the Tulare Lake Basin, which in turn contains the KCS and the WDWA (DWR, 2016; GEI Consultants [GEI] 2019).

The WDWA, which is the focus of this Chapter GSP, covers approximately 227,193 acres (i.e. 355 square miles) along the extreme western side of the KCS. Of this total, approximately 89,989 acres, or about 140 square miles, is currently irrigated. The WDWA is bounded on the north by the Kings-Kern County line and the DRWD, on the south by the WKWD, on the east by various Undistricted Lands, the SWSD, and BVWSD, and on the west by the Temblor Mountain Range.

Topography

Topography in the WDWA is mostly gentle and flat, with steeper foothills of the Temblor Range lying at the western edge. Elevations range from approximately 250 feet above mean sea level (MSL) in the east-southeast to 1,200 feet above MSL in the southwest. Typical slopes within the WDWA range from 25 to 50 feet per mile. The California Aqueduct, which runs along the eastern edge and through other parts of the WDWA, is at an approximate elevation of 310 feet above MSL. The western portion of the WDWA, known as the Antelope Plain, is enclosed by the Coastal (Temblor) Range on the west and north and by various geologic structural arches (anticlinal folds) on the east and south.

Climate

The climate in the WDWA is generally hot and dry and is characterized as inland Mediterranean. The main growing season for the KCS runs from May through October, although various crops are grown year-round. Historic wet season precipitation averages around 5.2 inches per year (inches/year). The length of the frost-free season is currently about nine months, or approximately 270 days per year. Surface water delivered by the SWP is the chief source of supply for irrigation in the WDWA (GEI, 2019; Amec Foster Wheeler [Amec], 2015).

Basin Setting and Geology

The KCS is located in the southern most extent of the Tulare Lake Basin Hydrologic Region. The KCS encompasses a surface area of around 1,792,000 acres (2,800 square miles) and is underlain by approximately 32,000 feet (6 miles) of marine and continental sediments (Page, 1986; DWR, 2006; Amec, 2015; GEI, 2019). Near the end of the Late Cretaceous, tectonic movements elevated the Coast Ranges to the west of the Valley and created a marine embayment. During the Tertiary, seas episodically advanced and retreated within the embayment, resulting in deposits comprised of both continental and marine sediments. Structural deformation along the early and present-day San Andreas fault zone resulted in the formation of a series of anticlinal folds that form many of the prolific oil fields along the west side of the KCS (Farrar and Bertoldi, 1988; GEI, 2019).

During Pleistocene and Holocene times, the seas retreated, and continental deposits from alluvial and fluvial systems were deposited over Tertiary-age marine deposits. Some of these marine deposits contained naturally occurring connate (saline) water which have subsequently migrated into adjacent and overlying continental deposits (Page, 1986). Within the WDWA in general, eroded marine deposits are common and contribute to the overall poor, and mostly unusable, groundwater quality in the western KCS (GEI, 2019).

Surface Water

Ephemeral streams that originate on the east-facing slopes of the Temblor Range drain eastward toward the Antelope Plain and from there towards the Valley floor. The stormwater runoff in these channels is not controlled and typically percolates within the Antelope Plain and does not reach the bed of the former Tulare Lake to the northeast or the axis of the Valley as surface flow. The 10-year, 24-hour, storm event for the area ranges from 3.0 to 3.5 inches of precipitation (National Oceanic and Atmospheric Administration [NOAA], 2013; Amec, 2015; GEI, 2019).

Lined irrigation canals and drainage facilities are the principal surface and imported water conveyance features in the WDWA. Chief among these are the California Aqueduct, and its Coastal Aqueduct inter-tie.

Partially overlapping with a small area in the LHWD, and adjacent to the WDWA on the east, is the Kern National Wildlife Refuge (KNWR). The KNWR is another important natural surface water feature in the KCS that variably depends primarily on precipitation and seasonal irrigation to maintain several different wildlife habitats at the KNWR. The portion of the KNWR that overlaps with the WDWA is designated as dry "Uplands Habitat", which relies on precipitation for its sole water source.

To the south, in the Belridge WSD, are portions of the 3,100 acre Lokern Ecological Reserve (LER). Within the WDWA the LER consists of small, scattered and generally non-contiguous parcels. A review of Google Earth imagery shows those portions of the LER in the WDWA are likely Valley sink scrub, and/or Valley saltbrush scrub habitat (aka Alkali Scrub). The scattered parcels are more or less centered on either side of the Aqueduct and along the dry Kern River Flood Channel between the 7th Standard Road to the north and Lokern Road (Highway 58) to the south. Typical native plant species in Valley sink scrub, as described by the California Department of Fish and Wildlife, are iodine bush and seepweed, with the understory dominated by non-native species. Those portions of the LER in the WDWA appear to consist entirely of dry, non-irrigated scrub lands that, with no operational wells, rely on annual precipitation as its source of water.

Larger, more contiguous blocks of the LER are present further south of the WDWA roughly between the towns of Lokern and Tubman. The California Department of Fish and Wildlife website describes the LER at large as consisting of marsh, valley sink scrub, and valley saltbush scrub habitat. Although not likely present in the WDWA, vegetation in the marsh habitat includes tule, cattail and other common marsh species.

Current uses for surface and imported water in the WDWA include:

- Agriculture;
- Industrial and Process Water; and
- Groundwater Recharge (banking).

Agriculture on the west side of Kern County has become a mainstay of the State and local economy. In response to a myriad of factors including climate change, imported surface water availability, emerging farm technologies, and product market forces; the land use and crop selection on the west side of the KCS has evolved. A majority of the irrigated acreage in the WDWA is currently supplied by Aqueduct water and is utilized for growing permanent crops such as almonds, pistachios, citrus, and pomegranates.

Principal Aquifers and Aquitards

The thickness of the aquifer systems beneath the WDWA vary greatly from a few hundreds of feet to around 2,500 feet in thickness (DWR, 2003). From oldest to youngest, the principal water bearing zones in western Kern County include the Etchegoin Formation, the Tulare Formation, older alluvium and terrace deposits, and younger alluvium and floodplain deposits. Groundwater occurs in three loosely constrained aquifer packages within the WDWA. These are:

- Shallow perched groundwater;
- Unconfined/semi-confined groundwater; and
- Confined groundwater.

The occurrence of perched groundwater in the WDWA is sporadic, limited in quantity, and is recognized as having poor quality due to elevated TDS. It therefore has no beneficial use, nor does it contribute to or support groundwater dependent ecosystems.

Unconfined/semi-confined aquifers represent the principal aquifer packages for groundwater in the WDWA. These zones exist below occasional shallow perched groundwater in the upper and lower Tulare. The Tulare Formation was deposited as a series of coalescing alluvial fans and debris flows shed from the Temblor Mountain Range. As such it contains interbedded and interlensing sequences of fine-grained silt and clay mixed with gravels and sands. The unconfined/semi-confined aquifer zone extends from approximately 50 feet below ground surface (bgs), downward to the top of the so called modified “E-Clay” that is considered to be equivalent to the Corcoran Clay. This sub-regional aquitard, where present, is typically found at approximately 500 feet bgs or deeper.

Confined groundwater conditions exist below the Corcoran Clay and its generally accepted equivalent on the Westside, the modified E-Clay. Studies by the United States Geological Survey (USGS) (2009) indicate that the Corcoran Clay extends from the Valley floor westward to approximately the east-facing flank of the Lost Hills Anticline. The modified E-Clay is poorly constrained and is not known to extend significantly into the Antelope Plain, which constitutes a majority of the interior surface area of the WDWA. Depths to confined groundwater are variable but are usually deeper than 500 feet bgs. Concentrations of TDS in the confined groundwater zones (typically Etchegoin Formation and deeper) can initially range between 250 to 434 milligrams per liter (mg/L), but often degrade over time, suggesting the volume of better-quality water is limited. Sediments in this stratigraphic package consist of unconsolidated to consolidated, interbedded medium to coarse sand, silt, and clay (Amec, 2015; GEI, 2019). The presence or lack thereof of a well-defined and contiguous confining layer beneath the Antelope Plain separating shallow and deeper groundwater zones, and Westside complex structural geology could explain the general poor quality of groundwater throughout the WDWA, as well as the occurrence of better-quality groundwater in certain areas. Together with the documented low volumes of groundwater pumping in the WDWA it may also explain why, with the possible exception of oilfield areas, there does not appear to be any significant inelastic land subsidence in the WDWA.

Groundwater Quality

In the WDWA management area, marine-derived geologic sediments have contributed to the documented naturally poor and unsuitable quality of groundwater. Along the western side of the KCS, including the WDWA, unconfined/semi-confined groundwater is characterized geochemically as sodium/calcium-sulfate (Na/Ca-SO_4) water with TDS concentrations often exceeding 2,000 mg/L. Other deeper groundwater aquifers beneath the WDWA, and elsewhere in the KCS, are referred to as sodium-chloride (Na-Cl) water, which exhibits high to very high levels of TDS and is likely saline connate water (Amec, 2015; GEI, 2019).

In 2016, the WWQC prepared a Basin Plan Amendment Workplan (BPAW) which is inclusive of a significant portion of the irrigated lands within the WDWA. The BPAW recommends delisting municipal and unlimited agriculture as a designated beneficial use for perched and deeper unconfined/semiconfined groundwater due to natural poor groundwater quality. Confined groundwater sources immediately east of the Lost Hill Anticline would remain unchanged with regards to current designated use, pending further monitoring. The draft BPAW has been provided to the CV-SALTS Technical Committee and the Regional Water Quality Control Board (RWQCB) for review and input. Final determination by the RWQCB on the request for a change in designated beneficial uses will be included in the relevant annual update to the KGA Umbrella GSP.

The occurrence of high TDS groundwater in the west side of the KCS has recently been further documented in a preliminary groundwater salinity mapping study conducted by the USGS (Metzger and Landon, 2018). In the study, the distribution of groundwater salinity for 31 oil fields and adjacent aquifers across major oil-producing areas of central and southern California were mapped. The objective of the study was to describe the distribution of groundwater near oil fields having TDS less than 10,000 mg/L by using existing TDS data from petroleum and groundwater wells to map concentrations and document data gaps. Within the KCS, the study reported much higher TDS in groundwater from Westside oil field wells and groundwater wells, when compared with east side groundwater wells and oil wells. Metzger and Landon (2018), among others, suggest that higher TDS in the Westside could be related to a combination of natural conditions (Westside sediments derived from marine deposits containing saline connate water) and anthropogenic factors such as infiltration from former oil field produced water evaporation ponds and/or agricultural drainage ponds. This higher TDS water is consistent with historical reports completed prior to widespread agricultural development and is documented for more than 60 miles from north to south in the west side of the KCS (KCDEH, 1980; KCDEH and KCWA, 1982; GEI, 2019).

Lateral Boundaries and Bottom of the Basin

To the west of the WDWA the consolidated rocks that form the Temblor Range mountain front is both a boundary of the KCS, and a barrier to westward groundwater flow. Structural impediments to downgradient eastward groundwater flow from the Antelope Plain are poorly constrained but may include post-depositional folding of then-soft sediments and faulting. These fold belt structures include, among others, the Belridge, Lost Hills, and Kettleman Anticlines, and the Buttonwillow and Semitropic ridges and associated north-south oriented synclines. Page (1986) and the DWR (2006) also identified the anticlinal folds, and specifically Lost Hills Anticline, as restrictions that slow or impede groundwater flow towards the Valley axis. To the south, groundwater flow is impeded by geologic structures that include spurs of the Temblor Range and the Elk Hills Anticline. This condition likely applies to other geologic structures within the WDWA.

In simplest form, the geologic bottom of the sedimentary Subbasin can be identified as the depth at which crystalline basement rock is encountered. Alternatively, and more applicable with regards to the conditions within the WDWA and the objectives of SGMA, the bottom of the groundwater Subbasin is more aptly defined by applying criteria of Title 40 of the Code of Federal Regulations (40 CFR) §146.4. The bottom of the Subbasin varies vertically and laterally with:

- Depth to commercially producible minerals or hydrocarbons;
- Depth to exempted aquifers;

- The depth that makes recovery of water for drinking water purposes no longer economically or technologically feasible; and
- The depth at which groundwater cannot now, or in the future, serve as a source of drinking water (GEI, 2019).

Recognizing that the hydrogeology of the Subbasin is highly variable, and that it is not possible at this time to predict the future maximum depth at which groundwater might be economically recoverable, or at which groundwater TDS concentrations below 10,000 mg/L may be economically treatable for drinking water, the KGA umbrella GSP has proposed the following combination of criteria for determining the hydrologic bottom of the Subbasin. The criteria take into account existing relevant and applicable rules and regulations. Utilizing this approach, the bottom of the Subbasin may be described as the combination of the itemized list below (i.e., item A, and either item B or C) (GEI, 2019).

A. Depth to commercially producible minerals or hydrocarbons (40 CFR §146.4) (where it applies to discrete areas of the Subbasin), or the depth to an exempted aquifer which has been approved by the United States Environmental Protection Agency (US EPA) and California Division of Oil, Gas, and Geothermal Resources (DOGGR) according to the criteria of 40 CFR §146.4; and either:
B. Depth to water at a TDS that is no longer economically or technologically feasible for groundwater beneficial use; or
C. Depth to waters of TDS greater than 10,000 mg/L (40 CFR §144.3), these being referred to here as not suitable as an Underground Source of Drinking Water (USDW).

In the WDWA, oil is produced from geologic structures that are comprised of some of the same formations that produce brackish groundwater elsewhere in the WDWA. The Tulare and Etchegoin Formations are two examples of this condition. In addition to containing hydrocarbons, many of these oil-bearing zones also contain naturally degraded formation water (i.e. produced water). Based on the presence of hydrocarbons in these structures, many of the associated formations are also designated as exempt aquifers by the DOGGR and the US EPA, within the administrative limits of the individual oil field. Examples of oil fields with aquifer exemptions include, among many others, the Lost Hills Oil Field and the Belridge Oil Field complex. Both oil field produced water and WDWA groundwater are naturally degraded by elevated concentrations of TDS and other constituents. With few exceptions, these conditions are found throughout the WDWA.

There have been numerous groundwater studies conducted in the west side of the KCS over the past 90 years. Several of these were conducted in the 1930s and 1950s prior to wide-spread development of agriculture. With rare exception all such studies have documented the poor quality of groundwater due to the presence of marine derived geologic sediments. Because

groundwater in the WDWA is degraded to a level where it is unsuitable for most practical beneficial use without blending or treatment, it is proposed the base of groundwater suitable for general beneficial use in the WDWA is where TDS concentrations exceed 2,000 mg/L. Groundwater quality is discussed further in **Section 2.6.5** of this Chapter GSP.

Groundwater Trends

Groundwater elevation data in the WDWA is scarce due to the minimal amount of annual groundwater pumping. Groundwater elevation data has been identified as a data gap that will be addressed during the first five-year reassessment period. However, based on the limited data available, groundwater trends in the WDWA appear to be generally downward, albeit likely not at rates currently simulated in the KGA C2VSim-Kern groundwater model. Groundwater trends in the WDWA are governed principally by drought and downgradient subsurface outflows that may be accelerated by irrigation withdrawals in adjacent water districts. Groundwater flow direction in the WDWA is believed to be primarily eastward from the Temblor Range toward the floor of the Valley, and northeastward along the northern boundary of the WDWA towards the former bed of Lake Tulare. Subsurface flow is thought to be both impeded, and sometimes sourced by, runoff from the aforementioned structural ridges and anticlines that separate the Antelope Plain from the axis of the Valley floor. In the north, geologic gaps between the Lost Hills Anticline and the South Dome of the Kettleman Hills Anticline may provide pathways for restricted groundwater migration. In the south, geologic gaps around the Belridge Anticline complex and the more easterly Buttonwillow and Semitropic ridges may be pathways for groundwater to move towards the Valley. Further study of WDWA geology and groundwater trends will be conducted during the first five-year reassessment period (i.e. 2020-2025).

Climate Change

Current climate modeling indicates that by 2050 there may be a significant reduction in the amount of winter snowpack in the Sierra Nevada. The gradual late-spring to mid-summer snowpack melt has historically allowed for organized management of this important resource, which currently provides around 65% of California's water supply. If current predictions are realized, it is possible that runoff from the Sierra Nevada Range will occur earlier in the year, and a majority of precipitation may come in the form of rain instead of snow. The ability to harvest and store the runoff for use later in the growing season may become a critical issue for Valley agriculture and by extension, the State's economy, in the next decade. Assuming no change to cropping patterns, and no new water storage or reuse projects, predicted climate change will likely result in increased competition for all water resources. In the KCS at large, it is expected that reliance on groundwater will increase in order to augment potential further reductions to deliveries from the SWP and the CVP. Adaptive planning and management actions that may mitigate these conditions include demand reduction measures, continued conservation,

improvements in groundwater and surface water storage, and the innovative treatment and conjunctive reuse of all water resources. This Chapter GSP has included many of these concepts in its sustainability planning (**Section 6.0**).

Beneficial Use and Users

As noted previously, a BPAW which proposes delisting unlimited agricultural and municipal use of perched and unconfined/semiconfined groundwater over a significant portion of the WDWA is under regulatory review. Current beneficial uses of groundwater for the WDWA are established in the Tulare Lake Basin Plan. The WDWA is within Detailed Analysis Unit (DAU) 259. Existing designated beneficial uses of groundwater in the WDWA include:

- Municipal (MUN);
- Agriculture (AGR); and
- Industrial (IND).

There currently is no MUN pumping of groundwater in the WDWA. Because of the ubiquitous presence of elevated concentrations of TDS, the use for AGR is primarily limited to blending with higher-quality Aqueduct water when those deliveries are reduced. Industrial use is mainly limited to oil field operations, such as water for well drilling or enhanced oil recovery (EOR) via steam generation and reinjection, etc.

Water Budget

All GSAs in the Kern County subbasin (Subbasin) coordinated and collaborated on the development of a groundwater model (Model) to evaluate historical, baseline and projected groundwater conditions. The GSAs entered into a Cost Share Agreement with the Kern River GSA who took the lead and contracted with Todd Groundwater to develop the Model on behalf of the Subbasin. The contract required that Todd Groundwater use the C2VSim model provided by DWR. Considerable effort and resources were expended to update the C2VSim model with local data to better represent Subbasin conditions. The process Todd Groundwater used to update C2VSim is more fully described in the Historical and Projected Future Water Budget Development (see Attachment H in Umbrella GSP). Basin-wide water budget results from the Model are provided in Attachment H and show the Subbasin, as a whole, has a total storage deficit of approximately 324,326 AFY over the baseline period.

The Subbasin's dynamic conjunctive use programs, water banking operations, and water transfers/exchanges made it necessary to coordinate a GSA-level water accounting system (Checkbook) using Subbasin specific values for supply, demand and net results. The Model results reflect Subbasin-wide conditions and do not allocate water shortages/surpluses, nor do

the results allocate the "ownership" of water. As a result, the GSAs, through a coordinated effort, developed the Checkbook that estimates current conditions for each GSA that are generally consistent with the Model results under baseline condition. The Checkbook and Model budgets are based upon best available information, recognizing however, each estimate includes data gaps and has varying degrees of accuracy and/or reliability in the interest of developing a Subbasin coordinated approach.

To ensure the individual water budgets reflected actual conditions, the KGA members developed the Checkbook budget and coordinated water accounting methodology. The result of that effort indicates a current baseline shortage/deficit for KGA members of approximately-256,281 AFY. This reflects the difference between a total demand for KGA members of 1,939,409 AFY, and a total supply of 1,683,128 AFY. Of the shortage/deficit of the KGA, the WDWA's portion of the KGA shortage/deficit is a surplus of +33,167 AFY. Or a difference in demand of 285,000 AFY and a water supply of 318,167 AFY.

As is mentioned above, each estimate includes data gaps and has varying degrees of accuracy and/or reliability. The Checkbook is complimentary to the Model and reflects the allocation of water supply benefits and obligations independent of geographic constraints within the Subbasin. This was important to recognize and ensure the coordination of the various groundwater banking projects and water management programs amongst the various GSAs within the groundwater basin.

It should be noted that the six unique WDWA hydrogeologic conditions (e.g. naturally degraded groundwater quality etc.), relative to the rest of the Subbasin, rend WDWA groundwater unusable unless it is blended or treated.

With regard to the WDWA, agricultural activities are the largest source of water demand. These activities rely almost exclusively on imported water delivered by the Aqueduct; groundwater pumping is minimal. Sources of surface water include SWP Table A and Article 21 water and purchased supplemental imported water, although not all supplemental water is SWP water. Because of a lack of representative groundwater data, the water budget for the WDWA is currently based on two independent and contrasting surrogate approaches that bookend the range of potential water supply: (1) the Checkbook Approach and (2) C2VSim-Kern. The Checkbook Approach is a typical approach based on a simple accounting of preliminary supply and demand and, as noted previously, is also used by other GMAs in the KGA. The KGA Checkbook approach combines SWP water, imported water, a preliminary value of groundwater Native Yield, and a current value of precipitation to estimate the available water supply. Groundwater pumping is not explicitly accounted for in the Checkbook but is rather considered a portion of the Native Yield. The Checkbook value of Native Yield is intended to encompass all groundwater recharges and discharges that apply to the WDWA but does not explicitly include

groundwater underflow, which is a critical component of the WDWA water budget. It is also important to understand that the term, "Native Yield", implies *suitable groundwater quality*, a condition that does not generally apply to the WDWA.

The WDWA Native Yield for the purpose of the preliminary Brackish Water Checkbook is conservatively estimated to be 0.15 acre-feet per acre (af/ac) multiplied by all WDWA acreage (i.e. 227,193 acres). This results in a volume of approximately 34,079 AFY. The currently estimated Checkbook precipitation factor is based on KGA and CIMIS data for the WDWA. It utilizes a factor of 0.2 af/ac. multiplied by the number of irrigated acres (88,989 acres) in the WDWA. This results in a volume of approximately 17,798 AFY that can potentially meet a portion of crop demand. Unique to the WDWA is the fact that all sources of groundwater (i.e. underflow, natural recharge etc.) are eventually degraded due to the geology and are rendered unsuitable for most direct use. Therefore, brackish groundwater in the WDWA is considered as "outside" the water balance unless blended or treated. If the poor water quality, minimal levels of pumping in the WDWA, the volume of KGA-modeled underflow (~111,000 AFY) leaving the WDWA, and potential reuse of oil field produced water (considered outside the water budget) are accounted for, a Native Yield range of 0.15 af/ac. to 0.30 af/ac. is supportable. If applied, it would result in a potential Native Yield of 34,079 AFY to 68,158 AFY, depending on the volume of oil field produced water, which together with brackish groundwater could be utilized for blending or treatment for conjunctive reuse. This volume represents approximately 30%-60% of the current total KGA-modeled brackish groundwater underflow leaving the WDWA. Project Management Action (PMA) #3, discussed in **Section 5.3.1,** proposes to treat brackish groundwater and potentially, oil field produced water for irrigation and other beneficial reuses.

The WDWA Brackish Water Checkbook is at best an illustration of potential groundwater resources and is only capable of providing an estimate of the current operational water budget, as well as preliminary 2030 and 2040 water supply operational budgets. The projected future estimates encompass phased pumping of naturally degraded groundwater for the twin purposes of landowner blending, including anticipated increased pumping for this purpose in response to climate change, and for pumping and treatment as part of a proposed conjunctive reuse management action discussed in **Section 5.0** of this Chapter GSP (i.e. PMA #3). It is stressed that the Checkbook approach groundwater volumes (i.e. Native Yield) should not be construed as a current or future groundwater allocation.

The second approach to estimating the WDWA water budget is based on groundwater numerical modeling conducted by the KGA with C2VSim-Kern. The C2VSim-Kern is considered a preliminary, albeit more detailed water budget than the Checkbook approach. It is emphasized that the subject KGA model is intended to be a KCS-wide assessment of groundwater conditions and is not specifically calibrated to the WDWA service area. Additional reconciliation of basin

water budgeting efforts is a high priority for all of the GSAs within the KCS as part of GSP implementation.

C2VSim-Kern is based on a Beta version of the DWR California Central Valley Groundwater-Surface Water Simulation Model, C2VSimFG-BETA (2018). KGA updated the managed supply and demand components of the model for the purpose of calculating preliminary volumetric flow rates for water budget components for the individual GMAs within the KCS. Like the Checkbook approach, the KGA model does not take into account that groundwater in the WDWA is naturally degraded and is unsuitable for most uses without blending or treatment. Currently, C2VSim-Kern modeling results for the WDWA are available only for historical conditions (1995-2014), which were used to develop the current-conditions water budget. It should be noted, that the C2VSim-Kern model simulations of historical conditions overstate the amount of groundwater pumping that has and is occurring in the WDWA. It is expected that the C2VSim-Kern modeling results for WDWA "future scenarios", which will include groundwater pumping volumes more aligned WDWA projections, will be available as part of future data assessment efforts. Details of the preliminary WDWA groundwater budget are provided in **Section 2.7** of this report.

Neither of these two approaches (Brackish Water Checkbook or KGA Model) currently provides a definitive illustration of the WDWA water budget and neither considers that the WDWA groundwater is naturally degraded and therefore outside the water budget However, in the absence of any alternative methodology they do provide a framework for revising the KGA water budget components based on additional data collected in the coming years. Given this, the Brackish Water Checkbook approach presented in this Chapter GSP is currently the more representative estimate of a "water balance" for the WDWA. Additional reconciliation of basin water budgeting efforts is a high priority for all of the GSAs within the basin as part of KGA Umbrella GSP implementation.

Sustainable Yield

Sustainable yield, as defined by SGMA, means the maximum quantity of water, calculated over a base period representative of long-term conditions in a basin, and including any temporary surplus; which can be withdrawn annually from a groundwater supply without causing an undesirable result. This definition implies that the groundwater supply is of *suitable quality* for beneficial use without significant treatment (i.e., the groundwater supply is not brackish or otherwise naturally degraded). Data to support an assessment of detailed Sustainable Yield is not currently available for the WDWA. This data gap will be addressed by implementing a Network Monitoring Plan (MNP) during the first 5-year reassessment period. Based on the

basin-wide estimates promulgated by the KGA, the normalized (native) sustainable yield for the KCS at large is estimated to be 0.15 af/ac. This factor was applied to all acreage (developed and undeveloped) in the WDWA (KGA, 2019; Todd Groundwater Consultants [Todd], 2019), resulting in a WDWA Native Yield of approximately 34,079 AFY that could be potentially harvested in a phased fashion through 2040 for blending and potential treatment and conjunctive reuse by the WDWA. The KGA Native Yield is considered to be a preliminary minimum estimate pending (1) continued refinement and calibration of theC2VSim-Kern model, (2) WDWA-specific sampling, and (3) modeling updates conducted by the KGA during the first five-year reassessment period. Data collected during the first five-year reassessment period will be utilized to model and refine the estimated sustainable yield for the WDWA. This information will be reported in relevant future update reports.

Water Budget Baseline and Projected Conditions

Due to the previously mentioned lack of reliable groundwater data, the water budget presented herein is considered preliminary. The water budget will be refined by incorporation of updated KGA C2VSim-Kern modeling results and new data acquired by the implementation of the MNP discussed in **Section 3.0** of this Chapter GSP. For the purpose of this submittal, the WDWA is assessing the two approaches noted above, namely, the Checkbook approach and the draft KGA C2VSim-Kern hydrologic model, to represent the key water budget components described below, with adjustments to account for known inaccuracies of the current model.

WDWA Estimated Groundwater Inflows

Based on current KGA modeling with C2VSim-Kern for the period WY 1995-2014, total groundwater recharge is ~92,300 AFY:

- Underflow from the Coastal Ranges: ~55,300 AFY
- Underflow from adjacent Districts: ~800 AFY
- Water loss from imported water canals: ~8,800 AFY
- Areal recharge (deep percolation): ~24,200 AFY
- Water loss from ephemeral stream flow: ~3,200 AFY

WDWA Estimated Groundwater Discharges

Because the primary source of water for agriculture in the WDWA is the SWP and various supplemental purchases of imported water, the volume of discharge due to extraction by pumping wells has historically averaged less than 2% of annual demand (pumping is currently estimated to be 3,000 AFY). However, the current C2VSim-Kern historical simulation overstates groundwater pumping by nearly a factor of ten. The total estimated discharge for the current

C2VSim-Kern historical model simulation, which includes the overstated pumping, is 138,540 AFY. The KGA-modeled discharge volumes for the Westside are approximately:

- ~111,000 AFY for underflow out of the WDWA; and
- ~28,000 AFY by pumping extraction.

Overdraft, under the current C2VSim-Kern model simulation, is estimated to be ~46,200 AFY (rounded up to 47,000 AFY to account for model uncertainty). However, because groundwater pumping is overstated in the model, the estimated overdraft is likely significantly less (~22,000 AFY). KGA-calculated climate change estimates adjust the areal recharge (deep percolation) downwards from 24,200 AFY to 18,900 AFY, while the WDWA simultaneously estimates an increase in pumping extractions for the purpose of blending from the current 3,000 AFY to 5,400 AFY by 2030. The deficit under this scenario would be approximately 29,400 AFY (conservatively rounded to 30,000 AFY). This conservative estimate is still lower than the current modeled overdraft of ~46,200 AFY. It should be reiterated and noted that:

1. WDWA groundwater is naturally degraded, is generally unsuitable for most use, and is therefore considered outside of the water budget unless used for blending or treated.
2. The WDWA meets almost all of its demand through the use of surface water delivered by the Aqueduct.
3. Even if the WDWA were to theoretically cease all pumping extractions, a deficit would still be realized under the C2VSim-Kern model simulations due entirely to the projected downgradient groundwater underflow of approximately 111,000 AFY leaving the WDWA, a phenomenon outside the control of the WDWA.

Sustainability Goals

Sustainable management in the KCS will result from continuation of current water management practices and the implementation of projects and management actions at the member-agency level to maintain their respective use of groundwater within the sustainable yield of the Subbasin, operate at or above established measurable objectives, and operate above established minimum thresholds. The sustainable yield, measurable objectives, and minimum thresholds have been developed based on available technical information and will be reviewed, updated, and reported as additional data are collected, as required by SGMA. The overarching goal of the KGA is to bring the subbasin into sustainability and maintain sustainability over the implementation and planning horizon.

Sustainability goals for the WDWA are designed to support those proposed in the KGA Umbrella GSP while simultaneously acknowledging and addressing: 1.) the previously listed unique hydrogeologic characteristics of the WDWA. 2.) identified data gaps and, 3.) the potential for

undesirable results within the WDWA. The goals will be achieved through the implementation of coordinated measurable objectives (MOs), such as specific administrative policies, projects and plans designed to enhance the sustainability of groundwater resources within the WDWA and the KCS at large. The sustainability goals for the WDWA are:

- Collect representative hydrologic information to more fully characterize and model the occurrence, condition, and elevation of groundwater beneath the WDWA through the implementation of a comprehensive Monitoring Network Plan (MNP);
- Leverage, to the extent feasible, the harvesting and treatment of naturally degraded groundwater underflow leaving the WDWA for the twin benefits of conjunctive reuse and mitigation of potential adverse effects to better quality water in adjacent downgradient districts; and
- Mitigate the potential for the chronic lowering of groundwater levels and significant reduction of groundwater in storage through the coordinated implementation of minimum thresholds (MTs) and MOs within WDWA areas that are adjacent to other downgradient GMAs.

Monitoring Network Objectives

Data related to representative aquifer characteristics and groundwater monitoring within the WDWA has, until most recently, been limited and non-contemporaneous. This is likely due to the limited amount of annual groundwater pumping in the WDWA. The lack of groundwater elevation data has been identified as an important data gap that must be filled for effective implementation of this Chapter GSP over the short-term, and for the assessment and planning of future adaptive management strategies over the long-term and SGMA implementation horizon. Associated groundwater components that rely on representative groundwater level monitoring include, among others, groundwater in storage and changes in storage, water budgets, and land subsidence. Objectives and elements of the MNP will address the need for representative data and will help reduce uncertainty for the purpose of sustainability planning. The MNP, once fully implemented, will help achieve the following objectives:

- Acquisition of representative groundwater data sufficient to assess and document short-term, seasonal, and long-term groundwater trends related to WDWA water budgets, groundwater pumping volumes, groundwater in storage, groundwater elevation, and potential future land subsidence;
- Ability to assess changes in groundwater conditions relative to identified MOs and MTs; and
- Coordination with adjacent GMAs by way of scheduled sampling events, updating MTs and MOs that mutually lead to groundwater sustainability, and regularly scheduled status meetings to ensure sustainability outcomes.

The MNP will include a minimum of 21 primary wells for monitoring, and will be based, to the extent feasible, on existing locations currently being monitored by the Westside Water Quality Coalition (WWQC). The preliminary monitoring locations were selected to cover all three aquifer zones (perched, unconfined/semi-confined, and confined). To the extent feasible selected wells will be used for both groundwater elevation and water quality monitoring. The initial distribution of wells across the WDWA is as follows:

- LHWD: 8 wells
- BMWD: 4 wells
- BWSD: 6 wells

The area of the WDWA is approximately 355 square miles. The well density of the proposed MNP is around one well per every 19.72 miles. While there is currently no established number for monitoring well density in a basin or management area, for comparison the monitoring well density for a basin recommended by the California Statewide Groundwater Elevation Monitoring (CASGEM) Groundwater Elevation Monitoring Guidelines ranges between one to 10 wells per 100 square miles. The current proposed groundwater monitoring network is capable of providing representative data to define short-term, seasonal, and long-term data trends in groundwater and associated surface conditions. Based on the density of the monitoring well network there will be sufficient data to utilize groundwater elevation changes as a surrogate for evaluating potential changes in groundwater in storage. To ensure reliable groundwater-level data, monitoring events will be scheduled in the late fall and early spring when many irrigation wells are typically idled. Monitoring activities will follow KGA guidance protocols.

Minimum Thresholds and Measurable Objectives

Pursuant to SGMA, MTs/ MOs shall be established for each sustainability indicator, based on quantitative analysis using the same metrics and monitoring sites as those utilized to define MTs. In accordance with the KGA Plan, the following general definitions apply to this Chapter GSP (California Code of Regulation [CCR] Title 23):

- MTs: Numeric values for each sustainability indicator used to define an undesirable result.
- MOs: Interim milestones in increments of five years, to achieve the sustainability goals for the WDWA, and by extension, the KGA, within 20 years of the Plan implementation.

Minimum Thresholds and Measurable Objectives for the WDWA Groundwater Management Area

Based on an assessment of the six potential undesirable results identified in SGMA, there are three co-related elements (lowering of groundwater elevation, change in groundwater storage,

and inelastic land subsidence) that require monitoring and/or focused MTs and MOs in order to sustainably manage the groundwater resources of the WDWA. The WDWA will conduct sentry monitoring to track groundwater elevations and quality along its northern and eastern boundary where groundwater leaves the WDWA as underflow. This underflow has been identified as the most significant contributor to the modeled groundwater deficit in the WDWA. Preliminary MTs and MOs have been proposed for these areas and are discussed further in **Section 4.0.**

Land Subsidence

Irrigation pumping, an activity sometimes correlated to land subsidence, has been limited in the WDWA due to its naturally degraded water quality. The potential for land subsidence will be monitored by the WDWA in coordination with a KCS-wide subsidence monitoring plan administered by the KGA. Special emphasis will be placed on monitoring between Aqueduct Mileposts 195 and 215. In 2011, an Aqueduct embankment failure of unknown cause at the time was documented at Milepost 208. Changes in topographic surface elevations will be reported at a minimum every five years in the relevant GSP update report. The MT for inelastic land subsidence in the KGA will be established and reviewed in consultation with adjacent GMA's and will be based on future KGA InSAR and other geodetic land survey data that may be collected by the WDWA in coordination with adjacent districts to the east. Data will be utilized to assess for potential inelastic subsidence and the potential for undesirable results to critical infrastructure. Subsidence associated with local oil field activities is under the oversight of DOGGR. Subsidence in the WDWA caused by oil field activities and by pumping in adjacent GMAs is outside the control of the WDWA. To the extent feasible the WDWA will coordinate the sharing of land-subsidence data with DOGGR and local oil producers that are party to the KGA Umbrella GSP.

Reduction of Groundwater Elevation/Groundwater Storage

Because changes in groundwater storage cannot be measured directly, the WDWA will utilize changes in groundwater elevations as a proxy to assess potential changes in groundwater storage. According to the draft C2VSim-Kern model, a principal cause of the groundwater deficit in the WDWA is the discharge of poor-quality groundwater (~111,000 AFY) from the WDWA as underflow toward the axis of the basin. By comparison, current groundwater pumping extractions in the WDWA are approximately 3,000 AFY. Said another way, even if all pumping extractions were to cease in the WDWA, it would still be in deficit and would experience reductions in groundwater elevation and changes in groundwater storage due to the preliminary modeled volume of underflow leaving the WDWA. The rate of underflow leaving the WDWA may be further influenced by groundwater extraction being conducted in some of the adjacent down-gradient GMAs. These conditions are beyond the control of the WDWA. Therefore, the WDWA has proposed two coordination sentry zones along shared boundaries with adjacent GMAs to monitor groundwater level elevations at the north and east boundaries of the WDWA.

Based on hydrologic conditions and preliminary simulated hydrographs, these zones each have separate preliminary MOs and MTs.

The preliminary MTs are:

- Sentry Zone #1 (well 25S21E-01): ~-115 feet below MSL
- Sentry Zone #2 (well 27S22E-30H- aka well #7106-63): ~59 feet above MSL
- Sentry Zone #2 (well 28S21E16 (sim centroid): ~56 feet above MSL
- Sentry Zone #2(well 28S21E13H): ~59 feet above MSL

The preliminary MOs are:

- Sentry Zone #1 (well 25S21E-01): ~-62 feet below MSL
- Sentry Zone #2 (well 27S22E-30H- aka well # 7106-63): ~101 feet above MSL
- Sentry Zone #2 (well 28S22E16 (sim centroid): ~112 feet above MSL
- Sentry Zone #2 (well 28S21E13H): ~127 feet above MSL

These MTs and MOs are preliminary and subject to review and change at a minimum every five years based on newly acquired data, and subsequent coordination discussions with adjacent GMAs. Proposed changes will be reported in the relevant GSP update report. There are currently no MTs or MOs proposed at this time for interior WDWA areas outside of the specified sentry coordination zones. The rationale for this approach is the aforementioned minimal historic pumping, and natural groundwater underflow over which the WDWA has no control. Data collected as part of the MNP for this Chapter GSP will be utilized to coordinate with adjacent downgradient GMAs and to assess whether the proposed MTs need updating. Planned coordination with adjacent management areas and data collected as part of the MNP for this Chapter GSP will be utilized to assess whether and how this approach may need to be revised.

Projects, Management Actions, and Adaptive Management

To meet WDWA sustainability goals, and ensure the ability to reduce current uncertainty related to the characterization of MTs, MOs, groundwater elevation monitoring, and other sustainability indicators, the WDWA will address the data gaps identified in this Chapter GSP through:

- The preparation and implementation of a comprehensive MNP during the first five-year reassessment period to collect data and document short-term, seasonal, and long-term groundwater trends related to the WDWA. The MNP will be designed to collect the necessary data to establish or update MTs and MOs, as needed in order to refine WDWA

water budgets, and sustainably manage and assess the potential for the chronic lowering of groundwater levels and significant reduction of groundwater in storage over the implementation horizon of the GSP;
- Coordination of water resources and data with adjacent GMAs; and
- The identification and assessment of potential projects and WDWA-specific management actions designed to support the sustainability goals of the WDWA, and by extension, the KGA.

To further enhance its sustainable and adaptive management strategies the WDWA is evaluating the feasibility of an innovative project that will integrate the treatment and conjunctive reuse of naturally degraded brackish groundwater and oil field produced water. Based on preliminary planning the project will ultimately harvest and treat approximately 40% oil field produced water and 60% brackish groundwater underflow for multiple beneficial uses including, among other things:

- A potential new water supply for adjacent and nearby disadvantaged communities (DACs) in order to improve water reliability and drought resiliency;
- A reliable supplemental source of better-quality water that, together with imported water, can be used for irrigation;
- Provide potential environmental flows to the adjacent Kern National Wildlife Refuge; and
- Protect groundwater quality adjacent to the WDWA by reducing the volume of naturally degraded groundwater underflow migrating to the northeast and east from the WDWA toward potentially better-quality groundwater in the axis of the Valley and adjacent management areas. This objective will be accomplished via strategic and sustainable monitoring and focused pumping for treatment and conjunctive reuse.

GSP Reporting and Periodic Evaluations

SGMA reporting standards, as enumerated in Section 352.4 of CCR 23, Subchapter 2, Groundwater Sustainability Plans, shall apply to all WDWA Chapter GSP reporting. Additional reporting details are provided below. Data from the various monitoring and well installation activities, if any, will be provided to the appropriate State and County databases (e.g., well installation information and groundwater level and water quality monitoring). Data will also be coordinated with adjacent GMAs and the KGA, which will coordinate with the KCS database. All data collected by the WDWA will be provided and summarized in the various reports detailed in this section.

Pursuant to SGMA, the WDWA will prepare Annual Reports for inclusion in the KGA GSP. The Annual Reports will comport with KGA guidance and will be submitted by the KGA by April 1st of each year following adoption of the Plan. The Annual Reports shall include the following topics:

- Groundwater elevation data and contour maps;
- Key well hydrographs;
- Groundwater extractions;
- Surface water supplies;
- Total water use;
- Change in groundwater storage; and
- Implementation progress.

Periodic reevaluation reports will be prepared a minimum of every five years for inclusion in the Plan. The five-year reassessments will be submitted electronically by the KGA to the DWR via the online reporting system and format provided by the Agency per Section 10733.2, Water Code and Section 353.2 and 356.4, of CCR 23, Subchapter 2, Groundwater Sustainability Plans. The submittal of updates or amendments to this Chapter GSP will be accompanied by a transmittal letter signed by the Plan Manager, or duly authorized representative. A coordinated data management system for the KCS is necessary to improve the accuracy, usefulness and confidence in groundwater data reported by the individual GMA's and GSA's within the KGA. Data system perimeters, inputs and a coordinated data system methodology will be established and reported in the relevant KGA update report. In the meantime, the WDWA will continue to rely on established State data bases for updating and reporting new data.

1.0 INTRODUCTION AND PURPOSE OF THE CHAPTER GSP

1.1 General Information

On September 16, 2014, the State of California (State) enacted into law three legislative bills (Senate Bill [SB] 1168 [Pavely], SB 1319 [Pavely], and Assembly Bill [AB] 1739 [Dickinson]). These bills are collectively known as the Sustainable Groundwater Management Act (SGMA). In simple terms, the goal of SGMA is the sustainable management and use of the State's groundwater resources in a way that does not cause undesirable results. SGMA defines undesirable results as:

- Chronic lowering of groundwater levels;
- Significant and unreasonable reduction of groundwater stored in aquifers;
- Seawater intrusion;
- Significant and unreasonable degraded water quality;
- Significant and unreasonable land subsidence; and
- Depletions of interconnected surface water that have significant and unreasonable impacts on the beneficial use of surface water.

1.2 Legal Authority

To achieve the sustainable management of groundwater, SGMA requires that all groundwater basins identified by the State as high or medium priority, and subject to conditions of critical overdraft, be managed under a Groundwater Sustainability Plan (GSP) by January 31, 2020. The Kern County Subbasin (KCS, subbasin, or Subbasin) has been identified as a critically over drafted High Priority Basin subject to SGMA. As such, a special entity called the Kern Groundwater Authority (KGA) was formed on April 26, 2017. An amended and restated Joint Powers Agreement between Kern County and the general members of the KGA provided the necessary legal authority for the KGA to prepare, submit, and implement the required GSP. Recently, due to potential liability concerns regarding groundwater rights, Kern County supervisors decided to cede their leadership role in SGMA-related issues to the Kern County Water Agency (KCWA). Reportedly, the State Water Board, in a letter to Kern County, has stated that the withdrawal of Kern County from direct involvement in the SGMA process for the subbasin will not trigger the State's intervention nor jeopardize local control of sustainable groundwater use.

Because of the many independent Water Districts within the KCS, which serve a variety of differing water users, it was decided to prepare a general GSP for the KGA, referred to in this Chapter GSP as the "KGA Umbrella GSP" or "Plan". Within this framework individual Water Districts or groups of Water Districts (groundwater management areas [GMAs]) in the KGA are

to prepare more detailed individual "Chapter GSPs", which discuss local groundwater conditions that, although are often related to adjoining Water Districts, have hydrogeology or other factors that may be distinct to their respective management area(s). Additionally, the Chapter GSPs provide the ability for the KGA to identify which of the undesirable results identified in SGMA may apply to a specific area of the KCS, and how these results would best be monitored and mitigated over both the short- and long-term, in order to meet KGA and SGMA sustainability goals. The individual GMAs have also entered into a Coordination Agreement, the components of which are:

1. Groundwater Elevation Data
2. Groundwater Extraction Data
3. Surface Water Supply
4. Total Water use
5. Change in Groundwater Storage
6. Water Budget
7. Sustainable Yield

This Chapter GSP focuses on a select subset of Water Districts within the KGA. Those participating Districts, referred to as the Westside District Water Authority (WDWA), are:

1. Lost Hills Water District (LHWD)
2. Belridge Water Storage District (BWSD)
3. Berrenda Mesa Water District (BMWD)

Figure 1a presents the current extent of the KGA administrative area, member agencies, and adjacent groundwater sustainability agencies (GSAs) in the KCS. **Figure 1b** presents the KGA member agencies. **Figure 2a** shows details of the WDWA. A list of the other agencies and groups in alphabetical order that are participating in the KCS are:

- Arvin-Edison Water Storage District;
- Buena Vista Water Storage District (BVWSD);
- Cawelo Water District;
- City of Bakersfield;
- Delano Cutout;
- Henry Miller Water District;
- Kern-Tulare Water District;
- Kern Water Bank Authority;
- North Kern Water Storage District;
- Olcese Water District;
- Pioneer Project;

- Rosedale-Rio Bravo Water Storage District;
- Semitropic Water Storage District (SWSD);
- Shafter-Wasco Irrigation District;
- Southern San Joaquin Municipal Utility District;
- Undistricted Lands of Kern County (or "unmanaged" on certain figures);
- West Kern Water District (WKWD); and
- Wheeler Ridge-Maricopa Water Storage District.

Commensurate with SGMA, and based on the current level of understanding of the WDWA within the KCS basin setting, the purpose of this Chapter GSP is to describe in plain language the groundwater conditions that currently exist within the WDWA. This Chapter GSP also identifies hydrologic data gaps and focused remedies, and presents a proposed groundwater management plan that, if determined to be technically and economically feasible, has the potential to achieve and maintain the sustainability goals of the WDWA and, by extension, those of the KGA, over the SGMA implementation horizon. Due the complex and interrelated nature of the hydrology and consumptive use of the water resources within the KGA, details and data from the KGA GSP, and some data from individual adjacent GSPs and/or GSAs, may be included in this Chapter GSP. Issues related to coordination with adjacent Districts, if any, will be addressed during the first five-year reassessment period after acceptance of the KGA Plan.

1.3 WDWA Agency Information and Contacts

The WDWA currently covers approximately 227,193 acres, or roughly 355 square miles of western Kern County, California. Of this total, approximately 89,989 acres (140 square miles) is irrigated. Preliminary numerical modeling by the KGA indicates that the WDWA has a historic annual water demand of approximately 297,000 acre-feet per year (AFY). However, the KGA modeled water demand appears to be overestimated. WDWA data shows that current demand is approximately 285,000 AFY, which is projected to escalate to approximately 316,000 AFY by 2040 due to climate change. Significantly more than 95% of the water used for irrigation in the WDWA has historically been delivered via the Aqueduct from SWP Table A and Article 21 water and supplemental import water purchases, although not all supplemental water is from the SWP. When available, a combined 100 percent (%) contract allocation from the SWP is around 332,218 AFY. Current surface water deliveries (all WDWA sources) are estimated by the WDWA to be approximately 266,290 AFY. This volume does not include supplemental water purchases and transfers by individual growers. Current estimated recharge by precipitation is 17,798 AFY, and minimum "Native Yield is approximately 34,079 AFY. This results in an estimated total water supply of 318,167 AFY. The WDWA water budget is described in more detail in **Section 2.7**. Groundwater is estimated to have made up less than 2% of the water used for irrigation by private well owners due to the general poor quality of groundwater in the WDWA. Groundwater pumping in the WDWA is approximately 3,000 AFY. The main use of groundwater in the WDWA

has been for blending to augment supply when Aqueduct deliveries have been reduced by drought or other factors.

A brief description of the WDWA participating members follows. More detailed information regarding each member is provided on their respective District websites, and in their specific 2015 Agricultural Water Management Plan (AWMP) reports. The AWMP reports are prepared to comply with the requirements of California SB X7-7 (Water Conservation Act of 2007), and are available online at the relevant District's website.

1.3.1 Lost Hills Water District

The LHWD was formed in 1963 to provide irrigation water from the SWP to the District. The LHWD boundaries begin just south of the town of Lost Hills and extend north and west to the Kings-Kern County line. Key landmarks include the California Aqueduct and Interstate 5 (I-5), which bisect the District diagonally from northwest to southeast. Adjacent Water Districts include Dudley Ridge Water District (DRWD) to the north (Kings County, Tulare Lake Subbasin), the BWSD to the south, the SWSD to the east, and the BMWD to the west.

The LHWD is governed by a five-member Board of Directors, all of which must be landowners or be designated as a representative of a landowner. Day-to-day administration of the District is the responsibility of the General Manager, who reports directly to the Board of Directors. The LHWD has two offices. The main administration office is located at 1405 Commercial Way, Bakersfield, California. The operations office is located in the town of Lost Hills. The website address is: www.lhwd.org.

The LHWD is comprised of approximately 74,357 acres, of which 70,453 acres are considered farmable. Not all of this acreage is currently being utilized for agricultural purposes. As of 2015, the net area under irrigated cultivation is approximately 27,900 acres. Agricultural activities rely primarily on surface water from the SWP. In addition to agriculture, oil and gas production is an important non-irrigated land use within the LHWD. A small portion of the LHWD surface water supply is sometimes delivered as industrial water to agricultural processors and oil field production customers. Other non-farmable service areas within the LHWD include Service Area 6E, which has been excluded from the water service area, and Service Area 8 which includes lands that were annexed by the District, for which a water delivery system is not yet available. During times of reduced allocations, the District relies on coordination with adjacent water districts and landowners for water transfers, supplemental water purchases and water banking (e.g., Berrenda and Pioneer Projects). The District owns and operates over 23 miles of concrete- or geomembrane-lined canals, 42 miles of pipelines, and an additional 27 miles of unlined canals, most of which are out of use.

Groundwater use in the LHWD is mostly limited to periods of SWP and other supplemental source delivery shortfalls, and is principally relied upon for the purpose of blending. During periods of drought or other shortages the LHWD relies on coordination with adjacent Water Districts or growers for water transfers, supplemental import water purchases, and nearby water banking programs (i.e., Berrenda Mesa and Pioneer Projects). These two banking projects are located outside of the WDWA, just southwest of the City of Bakersfield. Individual landowners within the WDWA may also participate in surface water banking projects, which can provide a significant amount of banked water for, and on, their own behalf. Groundwater quality is naturally degraded in many areas due to elevated concentrations of total dissolved solids (TDS) and other minerals. Groundwater is considered unsuitable for most uses and is non-beneficial for a majority of crops, and in some cases livestock. There are three groundwater monitoring wells in the LHWD with extended historic groundwater-level monitoring data. These wells are monitored for groundwater elevation and a focused suite of water quality analytes on a now-regular schedule (last few years) by the KGA and are also part of the California Statewide Groundwater Elevation Monitoring (CASGEM) Program. The subject wells are discussed further in **Section 2.6**.

The LHWD supplies no municipal water from surface water or groundwater. The town of Lost Hills is served by two groundwater supply wells owned and operated by the Lost Hills Utility District (LHUD). These wells are located 12 miles east of the town and are outside of the WDWA (Provost & Prichard, 2015).

1.3.2 Berrenda Mesa Water District

Like the LHWD, the BMWD was formed in 1963 by landowners for the purpose of providing a reliable supply of irrigation water to the BMWD from the SWP. To the north of the BMWD lies the adjacent Devil's Den Water District (DDWD) (Kern County, outside of the KCS), to the south is the BWSD, to east are Undistricted Lands and the LHWD, and to the west is the Temblor Range (**Figure 2**).

The BMWD is also governed by a five-member Board of Directors, all of which must be landowners or be designated as a representative of a landowner. Day-to-day administration of the District is the responsibility of the General Manager, who reports directly to the Board of Directors. The administration office for the BMWD is located at 14823 Highway 33, Lost Hills, California. A field office for the District is located in nearby unincorporated Blackwell's Corner, California, located at the intersection of Highways 33 and 46. The website address for the BMWD is: www.bmwd.org.

Of the approximate 55,440 acres within the BMWD, all but 6,400 acres are considered farmable. The estimated net acreage currently being farmed is around 35,240 acres, of which 24,204 acres is irrigated by surface water from the SWP. Remaining lands are used for dry-land farming or

livestock grazing. At 100% delivery, the volume of contract water available to the BMWD from the SWP is approximately 92,600 acre-feet (AF). Current water demand is approximately 88,000 AFY. During periods of drought or other shortages the BMWD relies on coordination with adjacent Water Districts or growers for water transfers, supplemental import water purchases, and nearby water banking programs (i.e., Berrenda Mesa and Pioneer Projects). These two banking projects are located outside of the WDWA, just southwest of the City of Bakersfield. Individual landowners within the WDWA may also participate in surface-water banking projects, which can provide a significant amount of banked water for, and on, their own behalf. Other alternative management techniques include discretionary deficit irrigation implemented by individual growers.

Groundwater use is limited in the BMWD due to elevated levels of TDS. The BMWD supplies no municipal water either from groundwater or surface water supply (Provost & Prichard, 2015b).

1.3.3 Belridge Water Storage District

The BWSD was formed by landowners in 1962 to provide surface water from the SWP for irrigation. The BWSD is bounded on the north by the LHWD and BMWD along with some currently Undistricted Lands, to the south by additional currently Undistricted Lands and the WKWD, to the east by the Buena Vista Water Storage District (BVWSD), and to the west by the Temblor Range (**Figure 2**).

Similar to the LHWD and BMWD, the BWSD is also governed by a five-member Board of Directors, all of which must be landowners or be designated as a representative of a landowner. Day-to-day administration of the District is the responsibility of the General Manager, who reports directly to the Board of Directors. The administration office for the BWSD is located at 21908 Seventh Standard Road, McKittrick, California. The website address for the BWSD is: http://www.belridgewsd.com.

The principal source of water supply for the BWSD is surface water from the SWP, with agriculture as the main consumer. Of the 91,396 acres within the BWSD, approximately 88,223 acres are considered farmable, although not all of this land is currently being used for agriculture. As of 2015, approximately 36,885 net acres are irrigated. In addition to agriculture, a percentage of the BWSD annual allocation from the SWP is delivered for industrial use in oil recovery operations in the North and South Belridge oil fields.

Groundwater use in the BWSD has historically been limited, primarily due to the readily available source of good quality water provided by the SWP and various supplemental import sources, versus the naturally degraded groundwater found in the WDWA. The main use of groundwater by private well owners in the BWSD is for blending with SWP water. During periods of drought or other shortages the BWSD relies on coordination with adjacent Water Districts or

growers for water transfers, supplemental import water purchases, and nearby water banking programs (i.e., Berrenda Mesa and Pioneer Projects). These two banking projects are located outside of the WDWA, just southwest of the City of Bakersfield. Individual landowners within the WDWA may also participate in surface-water banking projects, which can provide a significant amount of banked water for, and on, their own behalf. Other alternative management techniques include discretionary deficit irrigation implemented by individual growers. Representative historic groundwater data are limited within the BWSD because of the aforementioned availability of other better quality water sources, and because until recently, records from privately owned wells in the WDWA at large were generally sporadic or not available. The BWSD supplies no municipal water either from groundwater or surface water supply (BWSD AWMP, 2015).

1.3.4 WDWA Undistricted Lands

There are approximately 341,048 acres of Undistricted Lands within the KCS (**Figure 2b**). Of these, approximately one third (113,682 acres) are located within the WDWA. These lands consist of a mixture of uses, including, among other things, mountain-front slopes, non-irrigated lands, grazing land, oil field production, quarry operations, and limited agriculture. Groundwater use among these different categories varies widely. Mountain-front slopes, grazing and non-irrigated lands, which comprise a large portion of the Undistricted Lands within the WDWA, use no groundwater and instead rely on precipitation. The limited agriculture and quarry uses in the WDWA are believed to use little or no groundwater based on typical operational practices. Oil field activities may utilize some groundwater from water wells for field activities (e.g. well drilling, enhanced oil recovery "make-up water" etc.). Oil fields also generate produced water as part of oil extraction activities. Produced water contains residual oil, elevated TDS derived from geologic formations, and other constituents common to crude oil production. A majority of produced water from oil field operations is either reinjected into the same zone it was extracted from for enhanced oil recovery (EOR), or is sequestered in deeper exempt aquifers pursuant to the United States Environmental Protection Agency (US EPA) Underground Injection Control (UIC) Program which, along with other oilfield activities in California, is administered by the Division of Oil, Gas, and Geothermal Resources (DOGGR).

The potential for impacts to the occurrence or quality of groundwater posed by oil field operations, and those undistricted lands that are not part of the WDWA Chapter GSP, are beyond the control of the WDWA. Recently, in response to potential water rights liability and County staff resource considerations, Kern County decided it would no longer oversee these lands with regard to SGMA compliance. Going forward, the KGA will oversee these lands within the KCS for the purpose of SGMA compliance, provided they are covered by a KCS GSP. The KGA has initiated an effort to enroll these landowners into an appropriate existing GSP group. Those Undistricted Lands that do not join the KGA or other GSP will be responsible for individually

complying with all relevant SGMA requirements (KGA, 2019). The Kern County Public Health Services Department (KCPHSD) has retained its jurisdictional authority over, among other things, groundwater well permitting and destruction in the County. The Kern County Environmental Health Services Department develops guidelines for the protection of groundwater quality and well construction standards.

1.3.5 Non-Managed Monitoring Areas

Non-Managed Monitoring Areas are lands defined within the KCS and included in an adopted GSP, in which underlying groundwater has not been significantly developed or used historically and is not actively pumped, excepting *de minimis* extractors[1], and whose consumptive use of groundwater (e.g., evapotranspiration [ETo]) is less than or equal to the consumptive use of native vegetation. As such, lands within a Non-Managed Monitoring Area are typically native/range land. All lands designated as Non-Managed Monitoring Areas will be monitored by satellite imaging or equivalent technology that provides a comparative estimate of the amount of consumptive water use relative to native vegetation (KGA, 2019).

If non *de minimis* groundwater extraction, or if water consumed increases above the baseline of native vegetation ETo, is either proposed or is documented within a Non-Managed Monitoring Area, the lands overlying these areas will be reclassified as "Actively Managed Lands" and will become subject to the groundwater monitoring, sustainability criteria, water budget requirements of the governing GSP, and any applicable water management actions (e.g., water use restrictions) under the governing GSP. Upon reclassification as Actively Managed Lands, failure to comply with the requirements for Actively Managed Lands under the governing GSP may result in the subject lands being removed from coverage under the GSP (KGA, 2019). Any such lands would be subject to SWRCB regulations.

1.3.6 Chapter GSP Development Costs

Development and implementation costs for the KGA Umbrella GSP incurred to date are currently being shared by the individual member water districts. Costs are being allocated under a Special Activity Agreement. The agreement is basically a two-tiered system that allows for cost-sharing either by a direct pro rata approach (i.e., split 16 ways by the member water districts) for such items as KGA administration costs, or by allocating costs based on a water district's (or Management Area's) percentage of total acreage overlying the area of fresh groundwater in the KCS. This method is applied to various required scientific studies, such as the KCS numerical groundwater flow model. Costs for the development of the WDWA Chapter GSP are being allocated on a direct pro rata basis between the three member agencies of the WDWA (LHWD, BWSD, and BMWD) (WDWA, 2019).

[1] *De minimis* extractors are defined under SGMA; California Water Code (CWC) §1072 (e).

1.3.7 Chapter GSP Implementation Funding

Estimates for the implementation and administration of the Chapter GSP are currently being assessed as part of the GSP development activities. The sources of implementation funding, while not specially identified at this time, may likely include a combination of State and Federal low-interest financing and grants for specific projects, as well as base and incremental water tolls paid by member landowners of the various respective Water Districts that comprise the WDWA (WDWA, 2019).

1.4 Description of Plan Area

1.4.1 Geographic Areas Covered

As noted previously, the WDWA encompasses approximately 227,193 acres, or roughly 355 square miles along northwestern edge of Kern County, California. The WDWA is bounded on the north by the Kings-Kern County line (an administrative boundary); on the south by areas of Undistricted Lands and the WKWD; on the east by some scattered Undistricted Lands, the SWSD, and BVWSD; and on the west by some Undistricted Lands and the Temblor Range.

As discussed in **Section 1.3.4**, Undistricted Lands are those lands within the WDWA that are not currently a part of a recognized GSA, but may be assimilated through separate agreements by the KGA. These areas are primarily associated with grazing lands and oil and gas operations such as the Belridge and Lost Hills Oil Fields. The KGA is currently working with these interested stakeholders to execute the necessary agreements to include them in the KGA GSP framework. Oil and gas operators within the WDWA include among others, California Resource Corporation (CRC), Chevron U.S.A, Inc., and Aera Energy, LLC.

1.4.2 Plan Area Setting

Geography and geology of the western KCS are discussed in further detail in **Section 2.0**. Within the WDWA; there are currently no adjudicated areas. A small dryland portion of the LHWD overlaps on the Kern National Wildlife Refuge (KNWR). The KNWR parcels within the LHWD are designated “Upland Habitat” areas, which rely on annual precipitation as its sole source of water (i.e. no operational wells). To the south, in the Belridge WSD, are portions of the 3,100 acre Lokern Ecological Reserve (LER). Within the WDWA the LER consists of small, scattered and generally non-contiguous parcels. A review of Google Earth imagery shows those portions of the LER in the WDWA are likely Valley sink scrub, and/or Valley saltbrush scrub habitat (aka Alkali Scrub). The scattered parcels are more or less centered on either side of the Aqueduct and along the dry Kern River Flood Channel between the 7th Standard Road to the north and Lokern Road (Highway 58) to the south. Typical native plant species in Valley sink scrub, as described by the California Department of Fish and Wildlife, are iodine bush and seepweed, with the understory dominated by non-native species. Those portions of the LER in the WDWA appear to consist

entirely of dry, non-irrigated scrub lands that, with no operational wells, rely on annual precipitation as its source of water. Other discrete State, Federal and County parcels in the WDWA are primarily associated with rangeland and mineral extraction activities (e.g. oil, gas, and gypsum).

As stated previously, the majority of water within the WDWA that is utilized for agricultural purposes is delivered as surface water via the Aqueduct. The WDWA distributes this water through a network of infrastructure facilities including, but not limited to, lined main canals, pipelines, pump stations, and control structures. Some of this surface water, when available, is provided to oil field operators and others for industrial use. As noted previously, the use of groundwater by landowners in the WDWA is generally limited and is mostly used for blending. The town of Lost Hills obtains its municipal water supply from two wells located approximately 12 miles to the east of the LHWD, an area outside of the WDWA. Existing land use is predominately agricultural, followed by currently undistricted oil field operations, some natural range and grazing uses, and fallow lands.

1.4.3 Existing General Plans

The Kern County Planning and Natural Resources Department (KCPNRD) provides consolidated land use planning and development guidance and programs for the County's industry, businesses, and residents through the Kern County General Plan (General Plan). The General Plan is a policy document designed to provide long-range guidance to County officials and stakeholders regarding the priorities, growth, and resources of the unincorporated jurisdictional portions of the County, of which the WDWA is a part. Metropolitan areas, such as the City of Bakersfield, are part of separate planning areas. The stated objectives of the subject General Plan are:

- Encourage economic development;
- Adopt policies and goals that reflect the County's commitment to consult and cooperate with State, Federal, and local agencies to plan for the long-term future of Kern County;
- Ensure protection of environmental resources, the development of adequate infrastructure with specific emphasis on conserving agricultural areas, adequate water supplies, and addressing air quality issues;
- Periodically revise the General Plan to reflect ongoing activities, changes to rules and regulations, and demographic changes in the County in order to ensure that the interests of the County in the health, safety, and welfare of residents and visitors are reflected in current policies and goals; and
- Maintain compliance with the provisions of State Planning and Zoning Laws as they pertain to General Plan requirements (KCPNRD, 2009).

Implementation of the WDWA Chapter GSP will provide additional drought resiliency and flexibility for agriculture and sustainability to water planning in Kern County. As such, it will not adversely affect water supply assumptions in the current General Plan and, by coordinating with adjacent GMAs and the KGA at large; will satisfy the requirements of SGMA.

1.4.4 Existing Groundwater Ordinances

Well drillers have been required by State law (CWC 13751) to submit well logs to the State since 1949. Public entity and other groundwater well owners within the WDWA are subject to all relevant and applicable rules and regulations regarding groundwater well drilling, development, monitoring, well abandonment, water use, and recycling, unless otherwise exempted by the State. An existing Kern County Ordinance, enacted in 1998, which requires a conditional use permit for groundwater exports both external and internal to the County, applies only to the southeastern drainage of the Sierra Nevada and the Tehachapi Mountains; and, thus, is not applicable to groundwater management in the WDWA. It should be noted that, based on a review of State records, it appears not all private well owners in Kern County have fully complied with well data reporting requirements.

1.4.5 Well Drilling, Replacement, and Abandonment

Kern County and the State Division of Water Resources (DWR) have respective water well permitting, wellhead protection and well construction and abandonment requirements that are germane to protection of groundwater quality and this Chapter GSP. Well drilling and monitoring requirements specific to the WDWA will be documented in the WDWA Monitoring Network Plan (MNP), which will be developed and implemented in coordination with adjacent management areas during the first 5-yeat reassessment period. Both sets of requirements (Kern County and State) for well permitting, construction and abandonment will apply in relation to applicable site-specific conditions and permitted drilling activities conducted in support of this Chapter GSP. Kern County well requirements can be found at: https://kernpublichealth.com/water-wells. State of California well drilling requirements can be found in DWR Bulletin 74, located, along with other details, at: https://water.ca.gov/Programs/Groundwater-Management/Wells.

A general summary of the process for permitting new or replacement wells in the WDWA is:

- Compliance with the most current version of the WDWA MNP and KGA protocols with regards to sediment logging, well and water quality testing and reporting;
- Compliance with Kern County Public Health requirements for well permitting, wellhead protection and well inspection; and
- Compliance with all applicable requirements as detailed in California Well Standards (Bulletin 74) for water wells, monitoring wells and cathodic protection wells.

Oil and gas wells in the WDWA are drilled under the purview of the DOGGR and US EPA rules and regulations.

1.5 Notice of Intent and Stakeholder Outreach and Communication

Stakeholder outreach and communication is central to the successful outcome of the KGA GSP. As such, the KGA has implemented a wide-ranging outreach program designed to maximize stakeholder involvement in order to ensure a transparent and inclusive GSP process. The subsections below provide further information on this important topic.

1.5.1 GSP Participating Agencies

A list of KGA-participating Water Districts is provided in **Section 1.2**. In addition to regulatory oversight by the California Department of Water Resources (DWR) for GSP development and implementation, participating agencies include, among others, the State Water Resources Control Board (SWRCB), Regional Water Quality Control Board (RWQCB), United States Geological Survey (USGS), and the KCWA. The KGA and the WDWA recognize that maintaining a close collegial relationship with the various State and Federal regulatory agencies with oversight on water management and SGMA in the KCS are essential to achieving proposed sustainability objectives. Private landowners are also supporting the GSP effort by providing, among other things, historic and current groundwater well and hydrogeologic data, as well as relevant planning and land-use information.

1.5.2 Public Meetings and Stakeholder Engagement

The KGA maintains a website (www.kerngwa.com) where it routinely posts information related to the GSP preparation and development process and actively solicits stakeholder engagement and input. KGA Coordination Meetings with stakeholders are typically held on the first Monday of every month. A partial list of items that are made available on the KGA website includes:

- Agendas and dates for upcoming and past public meetings;
- Stakeholder surveys;
- Relevant documents and reports for public review and input;
- Presentations, research, and white papers; and
- KGA contact information.

Additionally, the WDWA maintains a website for growers and the community at: www.westsidedwa.org. Member Water Districts within the WDWA have their own individual websites that provide information that is focused on Water District operations and GSP development within their respective management areas. As previously noted, the WDWA-member websites are:

- LHWD: www.lhwd.org
- BWSD: www.belridgewsd.com
- BMWD: www.bmwd.org

WDWA public outreach activities to date include:

- The WDWA participated in a KGA sponsored public workshop in Bakersfield, California at the Kern County Agricultural Center on May 14, 2019. The evening workshop was open to all community members and stakeholders. The workshop afforded interested parties the opportunity to interact one-on-one with WDWA staff and consultants who were there to answer and discuss questions or concerns related to the WDWA Chapter GSP, and afford the public an opportunity to learn more about other KGA Chapter GSPs, WDWA undesirable results, and the SGMA process.
- A second public KGA workshop was held the evening of September 26, 2019 at the Kern County Agricultural Center in Bakersfield, California. This workshop took place during the KGA Umbrella GSP 90-day public review period and provided another opportunity for interested parties to communicate with WDWA staff and consultants regarding SGMA, the WDWA Chapter GSP, undesirable results and groundwater sustainability in the WDWA.
- A public meeting (WDWA regularly scheduled Board meeting) to discuss WDWA-specific issues related to this Draft Chapter GSP, such as current and projected water budgets, groundwater quality and Measurable Thresholds (MTs) and Measurable Objectives (MOs) was held on June 5, 2019 at the BWSD offices. The meeting updated the Board members, the public and stakeholders on the status of the WDWA GSP Chapter findings, undesirable results, GSP costs and the SGMA process.
- The Draft Chapter GSP components and key findings and conclusions were presented a second time to the public at a regularly scheduled WDWA Board meeting on August 21, 2019 at the offices of the BWSD. At the meeting the WDWA Board approved submittal of the WDWA Chapter GSP to the KGA for inclusion in the formal 90-day KGA Umbrella GSP public review process. Prior comments were addressed in the draft Chapter GSP prior to this update presentation.
- The Draft Chapter GSP components and status were presented at three other regularly scheduled WDWA Board meetings open to the public, and at two public KGA Board meetings held in Bakersfield on August 21, 2019 and December 18, 2019.
- The WDWA Manager received one direct comment letter (Wonderful Orchards) during the 90-day public comment period for the KGA Draft Umbrella GSP. Relevant and applicable comments pertaining to the WDWA were incorporated in this version of the Chapter GSP. A copy of the letter is provided in Appendix A. Five other more global comment letters related to the Draft KGA Umbrella GSP (The Nature Conservancy, California Fish & Wildlife, Hancock Farmland Services, Westchester Group, and Leadership Council for Justice and

Accountability) addressed to the KGA GSP Manager were also reviewed for relevant or applicable comments for incorporation that might pertain to the WDWA. It should be noted that the WDWA does not provide groundwater for municipal supply. Copies of those letters are on file with the KGA. Based on Fish & Wildlife comments the Lokern Ecological Reserve was identified and discussed in the Chapter GSP.

The WDWA will continue stakeholder outreach during the implementation and planning horizon with periodic updates at its Board meetings, which are open to the general public, and by making SGMA annual reports and other relevant information available on its website.

1.5.3 SGMA Checklist and Notice of Intent to Develop a GSP

The SGMA check list for preparation of this Chapter GSP is provide in the front portion of this report. A copy of the KGA Notice of Intent (NOI) to prepare a GSP is provided in **Appendix B**. The NOI outlines the organization of the KGA and the general approach for developing the Plan. The NOI was submitted to the DWR on December 20, 2017. A complete list of undistricted lands to date that have opted into the WDWA Chapter GSP is included as **Appendix C.**

1.5.4 Kern Groundwater Authority GSP Managers

The KGA GSP Managers are:

Mr. Terry Erlewine, Basin Coordinator
Kern Groundwater Authority
1800 30th Street, Suite 280
Bakersfield, California 93301
Email: terlewine@ppeng.com
Telephone: 530.220.0752

Ms. Patricia Poire, Planning Manager
Kern Groundwater Authority
1800 30th Street, Suite 280
Bakersfield, California 93301
Email: ppoire@kerngwa.com
Telephone: 661.479.7171

1.5.5 WDWA Chapter GSP Manager

The WDWA Chapter GSP Manager is:

Mr. Phil Nixon, General Manager, WDWA
1405 Commercial Way, Suite 125
Bakersfield, California 93309
Email: pnixon@lhwd.org
Telephone: 661.633.9022

The KGA is responsible for making decisions on issues related to the GSP and KCS at large. Individual Water Districts and GMAs are responsible for taking the day to day decisions necessary to simultaneously meet the needs of their individual members and those actions related to meeting the sustainability objectives detailed in their respective Chapter GSPs.

Decisions related to the funding and implementation of items specific to the WDWA Chapter GSP are considered for adoption by the Boards of the respective WDWA member districts and the WDWA at large.

1.6 Chapter GSP Organization

This Chapter GSP for the WDWA is organized into the following sections.

- *Section 1.0 Introduction and Purpose of the Chapter GSP*
  This section discusses the regulatory requirements of the SGMA, participating Water Districts that comprise the KGA, and the subset of those agencies that make up the WDWA, which is the subject of this Chapter GSP.
- *Section 2.0 Basin Setting*
  This section includes a description, based on the current understanding of the subbasin, of the physical characteristics of the subbasin and the dynamic groundwater and local water budget conditions. A Hydrogeologic Conceptual Model (HCM) for the area covered by this Chapter GSP discusses hydrogeologic conditions, current and projected water budgets, identified data gaps, how these gaps will be addressed, the qualitative and quantitative understanding of the subbasin, and how the local aquifers might react to stress over time. The HCM takes into account how conditions in the WDWA may affect, or be affected by, adjacent Water Districts.
- *Section 3.0 Sustainability Goals and Undesirable Results*
  This section discusses and describes the suite of sustainability goals that, once fully implemented, will result in the absence of undesirable results identified in the WDWA within the statutory deadlines described in the SGMA.
- *Section 4.0 WDWA Monitoring Network*
  This section describes existing monitoring wells in the WDWA and the improved monitoring network that will be developed during the implementation of the Monitoring Network Plan (MNP) and reassessment periods after GSP approval. Development of the improved monitoring network will result in representative data sufficient to document attainment of identified WDWA sustainability goals, the monitoring for undesirable results, and the ability to provide for adaptive management of groundwater, both within the WDWA and as coordinated with adjacent GMAs.
- *Section 5.0 Minimum Thresholds and Measurable Objectives*
  This section describes relevant sustainability indicators and the numerical value(s) for each sustainability indicator used to define undesirable results, and the specific, quantifiable objectives for the maintenance or improvement of specified groundwater conditions.
- *Section 6.0 Projects, Management Actions, and Adaptive Management*
  This section describes the necessary sustainability projects and management actions that are currently being planned for implementation beginning in the first five-year reassessment

period to address identified data gaps within the WDWA. The objective is to coordinate with other adjacent GMAs in order help achieve the stated sustainability goals for the WDWA and KCS.

- *Section 7.0 GSP Reporting and Periodic Evaluations*
  This section discusses the coordinated data management system that will be used to store GSP data and required reports pursuant to the SGMA, as wells as report submittal schedules.
- *Section 8.0 References*
  This section contains relevant technical references relied upon to prepare this Chapter GSP.
- *Tables, Figures, and Appendices*
  These appendices s contain figures, tables, guidance protocols and other documents relevant to this Chapter GSP.

2.0 BASIN SETTING

2.1 WDWA Plan Setting within the Kern Groundwater Authority

The Central Valley of California (Valley) covers about 20,000 square miles and is bounded by the Cascade Mountain Range to the north, the Sierra Nevada Mountain Range (Sierra Nevada) to the east, the Tehachapi Mountains to the south, and the Coast Ranges (e.g., Temblor Range) and San Francisco Bay area to the west. The Valley is an expansive agricultural region drained by the Sacramento and San Joaquin rivers. The Valley averages about 50 miles in width and extends around 400 miles from the Tehachapi Mountains in the south, to near the town of Redding, California in the north. The Valley is divided into three groundwater hydrologic regions according to DWR's Bulletin 118: (1) the northern one-third of the Valley is within the Sacramento River Basin; (2) the central one-third is within the San Joaquin River Basin; and (3) the southern one-third is within the Tulare Lake Basin, which in turn contains the KCS and the WDWA (DWR, 2016; GEI Consultants [GEI], 2019) (**Figure 3a and 3b**). Conceptual inflow of groundwater into the WDWA is presented on **Figure 3c**. The groundwater conditions in the KCS at large are described in the KGA umbrella GSP.

Unique hydrogeologic characteristics of the WDWA that set it apart from the other water districts in the KCS are:

1. The WDWA is isolated from other groundwater basins and adjoining water districts along its entire western boundary by the Temblor Mountain Range, its primary source of subsurface groundwater inflow. On the north and east, groundwater underflow towards the axis of the basin is impeded or slowed by a series of roughly north-south oriented geologic anticlines and synclines (up folds and down folds). To the south groundwater flow is impeded by geologic structural ridges that include spurs of the Temblor Range and the Elk Hills Anticline. This geologic setting has contributed to the poor groundwater quality in the WDWA and limits necessary groundwater coordination to just a few downgradient management areas to the north and east.
2. Groundwater is naturally degraded and of poor quality throughout most of the WDWA due to the presence of geologic sediments derived from marine environments, some of which contain saline connate water. These conditions make groundwater in the WDWA unsuitable for practical beneficial use, except for blending with better quality water.
3. Irrigation demand is met almost entirely by surface and imported water delivered via the California Aqueduct (Aqueduct). Groundwater is estimated to make up less than 2% of the water used for irrigation by private well owners due to its poor quality. Current pumping for the purpose of blending with Aqueduct water is estimated to be approximately 3,000 AFY.
4. The most significant amount of discharge from the WDWA simulated by the KGA model is in the form of subsurface groundwater flow to the north towards the former Tulare Lake bed,

a beneficial use exemption area, and eastward towards the axis of the Valley. The total combined volume of underflow discharge to these areas is estimated to be approximately 111,000 AFY. Given the limited amount of pumping in the WDWA, underflow out of the WDWA is the most significant contributor to estimated groundwater deficits (change in groundwater storage) in the WDWA. This phenomenon is beyond the control of the WDWA.

5. Pumping for consumptive use in adjacent water districts has resulted in noticeable differences in groundwater elevations between the WDWA and these areas, and has likely increased the velocity and volume of underflow out of the WDWA along shared administrative boundaries to the east and southeast. Pumping activities in adjacent downgradient water districts are beyond the control of the WDWA.
6. In 2016, due to the near ubiquitous poor quality of groundwater in the KCS West Side, the Westside Water Quality Coalition (WWQC) prepared a Basin Plan Amendment Workplan (BPAW), which is inclusive of a significant percentage of the irrigated lands within the WDWA. The BPAW recommends delisting municipal and unlimited agriculture as a designated beneficial use for perched groundwater and deeper unconfined/semi-confined groundwater above the sub-regional Corcoran Clay (or its equivalent) due to natural poor groundwater quality. The draft BPAW has been provided to the CV-SALTS Technical Committee and the Regional Water Quality Control Board (RWQCB) for preliminary review and input. The final determination by the RWQCB on the BPAW application will be reported in the relevant GSP annual update report.

The WDWA, which is the focus of this Chapter GSP, covers approximately 227,193 acres (355 square miles) along the western side of the KCS. Of this total, approximately 89,989 acres, or about 140 square miles, is currently irrigated. The WDWA is bounded on the north by the Kings-Kern County line (administrative boundary) and the DRWD, on the south by the WKWD, on the east by various Undistricted Lands, the SWSD, and BVWSD, and on the west by the Temblor Mountain Range.

Topography in the WDWA is mostly gentle and flat, with steeper foothills of the Temblor Range lying at the western edge (**Figure 4**). Elevations range from approximately 250 feet above mean sea level (MSL) in the east-southeast to 1,200 feet above MSL in the southwest. Typical slopes within the WDWA range from 25 to 50 feet per mile. The California Aqueduct, which runs along the eastern edge and through other parts of the WDWA, is at an approximate elevation of 310 feet above MSL. The elevation of I-5, which transects portions of the WDWA, varies from approximately 225 to 240 feet above MSL. East of I-5, the ground surface is nearly flat. The western portion of the WDWA is known as the Antelope Plain and is enclosed by the Temblor Range on west and north, and by various geologic structural arches (folds) on the east and south.

2.2 Climate

The climate in the WDWA is generally hot and dry and is characterized as inland Mediterranean. The main growing season for the KCS runs from May through October, although various crops are grown year-round. The length of the frost-free season is currently about nine months, or approximately 270 days per year. Surface water delivered by the SWP and supplemental purchases of supplemental import water, not all of which are SWP water, are the chief sources of supply for irrigation (Amec, 2015; GEI, 2019).

The WDWA is characteristic of the southern Valley climate with temperatures in the summer often exceeding 100 degrees Fahrenheit (°F), and winter low temperatures occasionally falling below freezing. Summers are generally hot and dry, and winters are semi-arid with ground fog a common occurrence. The rainy season usually occurs from November through April, when nine-tenths of the annual precipitation falls (Provost & Prichard, 2015a). The average annual KCS precipitation for the period extending from 1998 through 2012 was approximately 5.2 inches per year (inches/year). KCS reference ETo rates range from 52.4 to 65.8 inches/year, with an average of 58.3 inches/year. Rainfall is considered sufficient for grazing purposes, but not for large-scale agricultural purposes. The SWP was specifically designed to offset the lack of regional precipitation (Amec, 2015; GEI, 2019).

Monthly reference ETo and precipitation data for the WDWA for the most recent 10-year period, water year (WY) 2009-2018, were obtained from the California Irrigation Management Information System (CIMIS) website for the Blackwells Corner (Station 54) and Belridge (Station 146) stations (**Figure 5**). These stations were chosen for the continuity of their respective data sets and because their locations, near the northern and southern extent of the WDWA, provided representative data for extrapolation across the WDWA.

For the Blackwells Corner station during the 10-year period, the average annual ETo rate ranged from 59.4 inches/year in 2011 to 70.2 inches/year in 2014 (**Figure 6**). The average monthly ETo ranged from 1.6 inches in December to 10.0 inches in July. The average annual precipitation rate ranged from 2.5 inches/year in 2013 to 8.4 inches/year in 2011. The average monthly precipitation ranged from 0.01 inches in June to 0.98 inches in January (**Figure 7**). During the 10-year period, the maximum monthly precipitation of 3.4 inches occurred in May 2014.

For the Belridge station during the same 10-year period, the average annual ETo rate ranged from 51.4 inches/year in 2011 to 61.9 inches/year in 2014 (**Figure 8**). The average monthly ETo ranged from 1.5 inches in December to 8.2 inches in July. The average annual precipitation rate ranged from 1.1 inches/year in 2014 to 9.3 inches/year in 2011. The average monthly precipitation ranged from 0.02 inches in August/September to 1.0 inches in December (**Figure**

9). During the 10-year period, the maximum monthly precipitation of 5.3 inches occurred in December 2010.

2.3 Surface Water

The major surface water feature in the WDWA, is the California Aqueduct (**Figure 10a**). Ephemeral streams that originate on the east-facing slopes of the Temblor Range drain eastward toward the Valley floor. The stormwater runoff in these channels is not controlled and typically percolates within the Antelope Plain and does not reach the bed of the former Tulare Lake or the axis of the Valley as surface flow. The 10-year, 24-hour storm event for the area ranges from 3.0 to 3.5 inches of precipitation (National Oceanic and Atmospheric Administration [NOAA], 2013; Amec, 2015).

A small northeastern portion of the LHWD overlaps with a dry Upland Habitat Area of the KNWR (**Figure 10b**). The KNWR at large covers approximately 11,250 acres, most of which lie within the adjacent SWSD. Established in 1960, habitats within the KNWR consist of:

- Seasonal Wetlands of which a significant portion are irrigated via deliveries from the Central Valley Project (CVP);
- Moist Soil Units are wetland habitats that are divided into irrigated and seasonal units;
- Seasonal Marsh are areas within the KNWR that maintain water depths of between 4 feet and a few inches and do not typically receive summer irrigation;
- Riparian Areas are located along former or seasonal stream courses within the KNWR; and
- Upland Areas are drier and are not irrigated during the summer and rely solely on precipitation as their source of water. Upland areas within the KNWR are generally closed to the public and are located in the northeast and northwest portions (LHWD portion) of the refuge.

To the south, in the Belridge WSD, are portions of the 3,100 acre Lokern Ecological Reserve (LER). Within the WDWA the LER consists of small, scattered and generally non-contiguous parcels (**Figure 10c**). A review of Google Earth imagery shows those portions of the LER in the WDWA are likely Valley sink scrub, and/or Valley saltbrush scrub habitat (aka Alkali Scrub). Those portions of the LER in the WDWA appear to consist entirely of dry, non-irrigated scrub lands that, with no operational wells, rely on annual precipitation as its source of water.

Larger, more contiguous blocks of the LER are present further south of the WDWA roughly between the towns of Lokern and Tubman. The California Department of Fish and Wildlife website describes the LER at large as consisting of marsh, valley sink scrub, and valley saltbush scrub habitat. Although not likely present in the WDWA, vegetation in the marsh habitat includes tule, cattail and other common marsh species.

Irrigation canals and drainage facilities are the principal surface water conveyance features in the WDWA. Chief among these are the California Aqueduct, and its Coastal Aqueduct inter-tie.

Current designated uses for surface water provided by the SWP in the WDWA include:

- Agriculture;
- Industrial and process water; and
- Groundwater recharge (i.e. banking).

Other uses of California Aqueduct and CVP water adjacent to the WDWA include irrigation, non-contact recreation, wildlife habitat, and warm freshwater habitat.

The topographic highlands that source naturally occurring surface water runoff in the WDWA consist of several small watersheds that range from less than 10 square miles to around 100 square miles in area. Surface water runoff flow in the WDWA is considered unreliable and of poor (brackish) quality. As a result, it is unsuitable for beneficial use, does not support most agricultural uses, and requires blending with better quality water for irrigation. A USGS 1959 survey of water quality in highland streams and springs, which predates much of the later agricultural development of the Westside, found the following (Amec, 2105):

Surface Water	EC (umhos/cm)	TDS (mg/L)
USGS Streams	590 – 3,100	540 – 3,200
USGS Springs	542 – 16,100	362 – 10,900

Notes:
EC: electrical conductivity
umhos/cm: micromhos per centimeter
mg/L: milligrams per liter

By contrast, the average concentration of TDS in surface water imported via the Aqueduct indicates that this water is of markedly better quality. Sample data from Kettleman Check 21 between 2008 and spring 2013 found EC averaging around 449 umhos/cm, and an average TDS concentration of 252 mg/L (Amec, 2015). A general definition of freshwater is TDS concentrations of less than 500 mg/L.

2.4 Land Use

Prior to the development of the Kern County Westside for agriculture, much of the land in the area was dry, native rangeland. A USGS (1959) report on groundwater conditions in the vicinity of Avenal and McKittrick described the area as: "*…uninhabited desert*" (GEI, 2019). Since that time, along with oil and gas, Westside agriculture has become a mainstay of the State and local

economy. In response to a myriad of factors including climate change, imported water availability, emerging farm technologies, and product market forces, Westside land use, crop selection and agricultural practices have evolved. A majority of the 89,989 acres presently under cultivation in the WDWA are utilized for growing permanent crops such as almonds, pistachios, citrus, and pomegranates. Scattered State, Federal, and County parcels are adjacent or present in the WDWA. A preponderance of such parcels, aside from the aforementioned portions of the KNWR and the LER, are related to rangeland or mineral extraction activities like those in the Shale Hills, Pyramid Hills, and Lost Hills Anticline areas. **Figures 11a through 11d** provide WDWA land use for the years 1992 and 2014.

2.5 Hydrogeologic Conceptual Model

The HCM is the framework for the iterative development of water budgets, numerical and analytical models, and assessment of groundwater monitoring networks. Details from a subset of previous reports and investigations relating to the regional geologic and structural setting of the KCS, as well as the occurrence, quantity, and quality of groundwater in the WDWA are described below. This information, along with data provided in the KGA Umbrella GSP and KGA groundwater modeling, is the foundation for the HCM. An HCM differs from a numerical or analytical model in that it does not quantify or compute actual specific quantities of water flowing through or moving into or out of the basin via the surface or subsurface. Its purpose is to provide a general understanding of the physical setting and processes related to groundwater sources, occurrence and movement in the WDWA (**Figure 12a**). Therefore, it does not provide specific data on the water balance for the WDWA. In general, recharge to the WDWA occurs via mountain-front underflow, water loss as a result of leakage from imported water canals, areal deep percolation, and water loss from ephemeral streams. Based on the preliminary KGA C2V Sim-Kern groundwater model, by far the largest component of discharge in the WDWA is groundwater underflow (~111,000 AFY) migrating toward down-gradient GMAs. Pumping for the purpose of blending in the WDWA is presently estimated at around 3,000 AFY. A more detailed discussion of KCS geology is provided in the KGA umbrella GSP. A summary of the physical setting follows.

2.5.1 Kern County Subbasin Geology

The KCS is located in the southern most extent of the Tulare Lake Basin Hydrologic Region. The KCS encompasses a surface area of around 1,792,000 acres (2,800 square miles) and is underlain by approximately 32,000 feet (6 miles) of marine and continental sediments (Page, 1986; DWR, 2006; Amec, 2015; GEI, 2019). **Figure 12b** provides a geologic map of the KCS. **Figures 12c-12e** provides conceptual KGA geologic cross sections for the vicinity of the WDWA.

Near the end of the Late Cretaceous, tectonic movements elevated the Coast Ranges to the west of the Valley and created a marine embayment. During the Tertiary, seas episodically advanced and retreated within the embayment, resulting in deposits comprised of both continental and marine sediments. Structural deformation along the early and present-day San Andreas fault zone resulted in the formation of a series of geologic faults and anticlinal folds that form many of the prolific oil fields along the west side of the KCS (Farrar and Bertoldi, 1988; GEI, 2019). During and since marine deposition, sediments derived from erosion of igneous and metamorphic rocks and consolidated marine sediments in the surrounding mountains to the east and west were transported into the Valley by streams. The continental sediments at the southern end of the Valley have an average thickness of about 2,400 feet (Planert and Williams, 1995). The continental sediments consist mostly of basin-fill or lake and marsh deposits of interlensing sand and gravel interbedded with clay and silt. Within the WDWA, sediments deposited by coalescing alluvial fans and debris flows are common. Depending on location, deposits of fine-grained materials (mostly clay and silt) comprise as much as 50% of the thickness of the basin-fill sediments (Planert and Williams, 1995; GEI, 2019).

During Pleistocene and Holocene times, the seas retreated, and continental deposits from alluvial and fluvial systems were deposited over Tertiary-age marine deposits (Page, 1986). Some of these marine deposits contained naturally occurring connate (saline) water which have subsequently migrated into adjacent and overlying continental deposits (Page, 1986). Overall, the continental deposits make up a significant portion of the regional aquifer system within the eastern and central parts of the Valley. Within the WDWA, and Westside in general, eroded marine deposits are common and contribute to the overall poor groundwater quality that has been documented throughout the western KCS (GEI, 2019). According to several reports, the Pleistocene Epoch saw the development of brackish and freshwater lakes within the basin, resulting in thick deposits of silts and clay and associated minerals, as found throughout the upper Tulare Formation. In particular, the Corcoran Clay has been mapped over much of the central and eastern San Joaquin Valley. The Corcoran Clay has been correlated to equivalent clays beneath the Kern and Buena Vista dry lake beds in the southern part of the KCS; as well as the Tulare Lake sediments on the northern boundary of Kern County (Wood and Dale, 1964; Croft, 1972; GEI, 2019). This clay, when present, acts as an aquitard that isolates accessible shallow poor-quality water from slightly higher quality water of the deeper regional aquifer system. On the Westside, including beneath the WDWA, and those other areas west of the Lost Hills Anticline, this clay appears to be either poorly constrained or absent (**Figure 13**).

Since the Pleistocene, stream channels, lakes, and rivers have dominated the deposition of sediments in the Valley. Alluvial fans have continued to form on both sides of the Valley, especially on the eastern side. Over time, shifting stream channels have created overlapping and coalescing sediment fans, forming broad sheets of inter-fingering, wedge-shaped lenses of

gravel, sand, and finer sediments which make up the shallow continental water-bearing deposits of the regional aquifer system (Page, 1986). During this time, fine-grained floodplain, lake, and marsh conditions were predominate on the western side of the Valley resulting in aquifers with less reliable hydraulic properties (Amec, 2015; GEI, 2019).

2.5.2 Surficial Geology

The surficial geology of the KCS has been documented in a variety of previous investigations (Bartow, 1991; Page, 1986; California Geological Survey [CGS], 2010; GEI, 2019). Based on published studies, the center of the basin consists mainly of Pleistocene to recent unconsolidated and semi-consolidated alluvial lake, playa (alkali/salt flat), and terrace deposits. Older Pleistocene alluvium is present in the eastern portion of the basin on top of Pliocene-Pleistocene deposits of sandstone, shale, and gravel deposits, including the Kern River Formation. The Pliocene-Pleistocene sediments also include the Tulare Formation. The Tulare and Etchegoin Formations are known to be variably a source of both brackish groundwater (unconfined/semi-confined) and oil within the WDWA. Small remnants of older continental sediments along the southeastern flank of the KCS, consist of undivided Tertiary-age sandstone, shale, conglomerate, breccia (clastic rock with a matrix of sand and/or mud), and lake deposits. Miocene-age sandstone, shale, conglomerate, and fanglomerate, plus smaller remnants of older marine sediments are also present. These remnant units include the Santa Margarita Formation, Round Mountain Silt, and Olcese Sand (Amec, 2015; GEI, 2019).

The geologic structure of the western KCS is distinguished by numerous northwest-trending folds that are subparallel to the nearby right-lateral San Andreas Fault. Most of the mapped folds are anticlines that occur in the older sediments and appear as anticlinal ridges that crop out approximately 30 to 50 feet or more above the surrounding topography. Some of these features include the Buttonwillow Ridge, Semitropic Ridge, and the Lost Hills and Elk Hills Anticlines (Bartow, 1991; GEI, 2019). Many anticlines and associated synclines in the Westside are known to be concealed beneath younger Quaternary age sediments. Similarly, several northwest-trending faults are concealed by the younger sediments and some have also been mapped within outcrop islands of older sediments (GEI, 2019).

2.5.3 Surface Soils

Surface soils for western Kern County have been described in various studies and reports (United States Department of Agriculture [USDA], 1986; USDA, 1988; USDA, 2018; Amec 2015). In the WDWA, surface soils are somewhat poorly drained basin clays and silty loams derived predominately from the erosion of sediments deposited in former continental environments. These soil types are considered to be a contributing factor to the overall natural poor quality of groundwater in the WDWA. Near surface soils in western Kern County generally include the following soil type series (USDA, 1988, Amec, 2015):

Series	pH (s.u.)	Salinity (mmhos/cm)
Buttonwillow	7.9 – 8.4	< 4
Kimberlina	6.6 – 8.4	<2 – 8
Lethent	>7.8 – 9.0	4 – 16
Lokern	6.6 – 9.0	<2 – 16
Milham	7.4 – 8.4	<2 – <8
Nahrub	>7.4 – >7.8	4 – 16
Panoche	7.4 – 8.4	<2 – 16
Twisselman	7.9 – 9.0	<2 – >16
Yribarren	7.9 – 8.4	<2 – <8

Notes:
mmhos/cm: millimhos per centimeter
s.u.: standard unit
pH: potential of hydrogen

Soil maps for the three individual Water Districts that comprise the WDWA, are presented in **Figures 14a through 14c**. The USDA's list of landscape soil types is provided in **Appendix D**.

2.5.4 WDWA Management Area Hydrogeology

WDWA hydrogeology is unique from other areas of the KGA. A key distinction is, with the exception of small, localized areas of higher-quality groundwater, the groundwater beneath the WDWA is almost exclusively naturally brackish, with TDS levels generally exceeding the drinking water maximum contaminant level (MCL) of 500 mg/L (**Figure 15a**). Overall, TDS concentrations routinely exceed 2,000 mg/L in many areas. The sediments that comprise the subsurface in the WDWA have accumulated since the Cretaceous. A large portion of the sediments were either eroded into, or deposited by, an inland sea bounded by an ancient fore-arc ridge to the west and the Sierra Nevada Range to the east. Naturally occurring saline connate water still exists in some of these sediments today. These saline waters, along with naturally occurring salts and other minerals in surface soil and shallow sediments, are the primary sources of the elevated TDS concentrations detected in WDWA groundwater (Amec, 2015; GEI, 2019). **Figure 15b** provides a general stratigraphic column, which depicts the transitional nature of the environments of sediment deposition in the KCS. Elevated concentrations of other constituents, such as arsenic, boron, and nitrates (most naturally occurring), have also been detected in parts of the WDWA. Data indicate that these minerals are likely the result of depositional concentration as the former marine embayments and lakes that previously covered much of the WDWA retreated and evaporated. Isolated pockets of fresh groundwater exist within relatively thin layers of continental sediments deposited on top of the marine sediment layers. Due the predominance of surrounding brackish groundwater conditions, these pockets of higher-quality water have been known to degrade after only a few months or years of pumping. Available data

appear to indicate that poor-quality water is migrating from the WDWA down-gradient to the north and east, towards areas of higher-quality water found in adjacent GMAs, such as SWSD and BVWSD. Impediments to this underflow are likely presented by various geologic structures including folding and faulting. One such example is the Buttonwillow Syncline.

The Pliocene-Pleistocene Tulare Formation represents a west-to-east change in depositional environments across the Subbasin. The Tulare Formation in the western part of the Subbasin contains up to 2,200 feet of interbedded, oxidized to reduced sands, gypsiferous clays, and gravels derived predominantly from erosion of Coast Range sources. Up to 250 feet of Pleistocene-age older alluvium/stream and terrace deposits occur as lenticular deposits of clay, silt, sand, and gravel that are loosely consolidated to cemented, and are exposed mainly at the margins of the Subbasin and along the crests of some Valley anticlines. Collectively, these sediments are typically moderately to highly permeable and can initially yield large quantities of water to wells (DWR, 2003; Amec, 2015; GEI, 2019). These deposits are reportedly often indistinguishable from the underlying Tulare Formation, and together, form the principal (unconfined/semi-confined) aquifer system in the WDWA.

The younger Holocene-age lacustrine, alluvium and flood plain deposits vary in character and thickness across the WDWA and consist of silt, silty clay, sandy clay, and clay interbedded with poorly permeable sand layers. The flood plain deposits are reported to be difficult to distinguish from underlying fine-grained alluvium and the total thickness of both units may be as much as 1,000 feet (DWR, 2003; GEI, 2019).

2.5.5 Principal Aquifers, Physical Properties and Aquitards

The thickness of the aquifer systems beneath the WDWA and Westside are thought to vary greatly from a few hundreds of feet to around 2,500 feet in thickness (DWR, 2003; GEI, 2019). From oldest to youngest, the principal water-bearing zones in western Kern County include the Etchegoin, and Tulare Formations, Older Alluvium and Terrace Deposits, and Younger Alluvium and Floodplain Deposits. Groundwater occurs in three loosely constrained aquifer packages within the WDWA. These are:

- Shallow perched groundwater;
- Unconfined/semi-confined groundwater; and
- Confined groundwater.

Perched groundwater was reported historically in the WDWA, especially along the eastern side of the WDWA management area. Its presence is attributed to a shallow clay layer known as the “A-Clay”. Depth to perched water was historically measured at 3 feet to 24 feet below ground surface (bgs). Perched water samples analyzed from six tile drains between 1986 and 2012

found average TDS concentrations of 13,250 mg/L, in addition to elevated concentrations of boron and other elements (Amec, 2015).

In late 2018, the Westside Water Quality Coalition (WWQC) reportedly attempted to record water-level data from several previously monitored perched zone piezometers; a majority of which were found to be dry (WDWA, 2019). The change in perched groundwater levels from 1989 to present indicates its occurrence is greatly reduced and sporadic. This condition is believed to be due to a change in crop types, recent drought conditions, and the increased efficacy of irrigation methods. For example, approximately 97% of crop irrigation in the WDWA now utilizes drip or micro-irrigation technology. The evolution in crop types away from the cotton and row crops being grown in the mid-1990s to predominately nut and other permanent crops today, coupled with more modern irrigation methods, may have reduced the volume of direct recharge via irrigation return flows. These return flows are believed to have been a likely contributor to perched groundwater in those areas where geologic conditions favored the accumulation of perched groundwater. Given the unreliability of the occurrence, the de minimis available volume of perched water, and its documented high salinity and mineral content, it is considered to be non-beneficial for Municipal (MUN), Agriculture (AGR), and most, if not all, Industrial (IND) use in the WDWA. Consequently, perched water wells will not be used to establish sustainability minimum thresholds (MTs) or measurable objectives (MOs) in the WDWA. It will however continue to be monitored along the eastern boundary of the WDWA. If future planned monitoring identifies a change in status of perched groundwater, these findings will be presented in future reassessment reports.

Unconfined/semi-confined aquifers represent the principal aquifer packages for groundwater in the WDWA. These zones generally exist well below the afore-described potential shallow perched groundwater zones in the upper and lower Tulare Formation or deeper. Groundwater quality in these sediments is regarded as poor to very poor due to significant concentrations of naturally occurring TDS, which often exceed 2,000 mg/L. The unconfined/semi-confined aquifer zone extends variably from approximately 50 feet bgs, downward to the top of the so called modified “E-Clay” that may be equivalent to the Corcoran Clay. This aquitard, where present, is typically found at approximately 500 feet bgs or deeper. Most groundwater in the unconfined/semi-confined zone in the WDWA is found at depths greater than 75 ft. bgs.

Where the modified E-Clay is present, confined groundwater conditions can exist below this horizon. Studies by the USGS in 2009 indicate that this confining layer extends from the Valley floor westward to approximately the east-facing flank of the Lost Hills Anticline. The modified E-Clay is poorly constrained and not known to extend with any significance into the Antelope Plain. This area constitutes a majority of the surface area of the WDWA, and occupies the structural trough between the Temblor Range and the west facing flank of the Lost Hills Anticline. Depths to confined groundwater, where present, are variable, but are usually deeper

than 500 feet bgs. Concentrations of TDS from confined groundwater reportedly range between 250 to 434 mg/L, but are known to sometimes degrade over time. Sediments in this stratigraphic package consist of unconsolidated, interbedded medium to coarse sand, silt, and clay (Amec, 2015; GEI, 2019). The presence, or lack thereof of a well-defined and contiguous confining layer beneath the Antelope Plain separating shallow and deeper groundwater zones, and complex structural geology, could explain the general poor quality of groundwater throughout the WDWA, as well as the occurrence of better quality groundwater in certain areas. Together with the documented low volumes of groundwater pumping in the WDWA it may also explain why, with the possible exception of oilfield areas, there does not appear to be any significant inelastic land subsidence in the WDWA.

Physical properties of aquifers within the KCS are derived from both well pumping tests and calibrated groundwater flow models. These data are summarized in the KGA Umbrella GSP. Physical properties include hydraulic conductivity (i.e. transmissivity), which is a function of the ability of an aquifer to transmit water through a given saturated thickness of aquifer, and specific yield (unconfined aquifers) and storage coefficient (confined aquifers). Specific yield and the storage coefficient are functions of the ability of an aquifer to store and release water. **Figure 15c** provides the range of horizontal conductivity for the principal aquifer types in the KCS (i.e. Unconfined/Semi-confined, and Confined). These ranges are typical of the silty sands and clean medium to coarse sands found in KCS aquifers, and are collaborated by various calibrated groundwater flow models predicated on field test data.

The Corcoran Clay varies from fine grained silts and clays to coarse sands in parts. The USGS estimated horizontal conductivities for the silts to medium sands within the range of 0.0024 to 33 feet per day. The vertical conductivity for these sediments was estimated at between 6.6 x 10^{-6} and 1.5 x 10^{-3} feet per day.

2.5.6 Lateral Boundaries and Structural Impediments to Groundwater Flow

The following federal regulations are foundational to the subsections pertaining to the lateral and basal extents of the effective groundwater Subbasin:

- Title 40 of the Code of Federal Regulations (40 CFR) §144.3
- 40 CFR §146.4

Title 40 of the Code of Federal Regulations defines an underground source of drinking water (USDW) in §144.3, as an aquifer or its portion which (GEI, 2019):

a. 1. supplies any public water system; or
2. contains a sufficient quantity of ground water to supply a public water system; and
i. currently supplies drinking water for human consumption; or

ii. contains fewer than 10,000 mg/L total dissolved solids; and

b. is not an exempted aquifer.

It should also be noted that the area of the effective groundwater Subbasin can be separated from the jurisdictional boundaries of the Subbasin by the criteria for exempted aquifers per 40 CFR §146.4; which includes, but is not limited to, areas in which the presence of commercially producible minerals or hydrocarbons are present in the aquifer, such as those found within the WDWA at the Belridge, South Belridge, Monument Junction, Lost Hills, and many other oil and gas fields in the WDWA (GEI, 2019).

To the west of the WDWA, the consolidated rocks that form the Coastal (Temblor) Range mountain front is both a boundary of the KCS and a barrier to westward groundwater flow. Structural impediments to downgradient eastward groundwater flow from the Antelope Plain are poorly constrained, but may include post-depositional folding of then-soft sediments. These fold belt structures include among others, the Belridge, Lost Hills, and Kettleman Anticlines, and the Buttonwillow and Semitropic Ridges (Bartow, 1991) and associated synclines. To the south, groundwater flow is impeded by geologic ridges that include spurs of the Temblor Range and the Elk Hills Anticline. Page (1986) and the DWR (2006) also identified the anticlinal folds and specifically Lost Hills, as restrictions that slow or impede groundwater flow downgradient and eastward towards the Valley axis. This condition likely applies to other folds and anticlines in the Subbasin beneath the WDWA. It is believed that several of these anticlines are associated with faults that trend subparallel to the San Andreas Fault and, if confirmed by future studies, they may also affect groundwater flow. Based on current draft C2VSim-Kern hydrologic modeling by the KGA, there appears to be some underflow towards the immediate north and the former bed of Lake Tulare. In that direction, Subbasin boundaries include the separate Kettleman Plain, the former Tulare Lake bed, which is a beneficial use exemption area, and the Tule subbasin (GEI, 2019).

2.5.7 Bottom of the Basin

In simplest form, the geologic bottom of the sedimentary Subbasin can be identified as the depth at which crystalline basement rock is encountered. Alternatively, and more applicable with regards to the objectives of SGMA, the bottom of the groundwater Subbasin is more aptly defined by applying criteria of 40 CFR §146.4. The bottom of the Subbasin varies vertically and laterally with the following criteria:

- Depth to commercially producible minerals or hydrocarbons, or primacy productive limits;
- Depth to exempted aquifers;
- The depth that makes recovery of water for drinking water purposes no longer economically or technologically feasible; or

- The depth at which groundwater cannot now, or in the future, serve as a source of drinking water.

Recognizing that the hydrogeology of the WDWA is highly variable, and that it is not possible at this time to predict the future maximum depth at which groundwater might be economically recoverable, or at which groundwater TDS concentrations below 10,000 mg/L may be economically treatable for drinking water. The following combinations of criteria are proposed for determining the hydrologic bottom of the Subbasin. The criteria take into account existing relevant and applicable rules and regulations. Utilizing this approach, the bottom of the Subbasin (i.e., base of "fresh water") may be described as the combination of the itemized list below (i.e., item A, and either item B or C) (GEI, 2019):

A. Depth to commercially producible minerals or hydrocarbons (40 CFR §146.4) (where it applies to discrete areas of the Subbasin), or the depth to an exempted aquifer which has been approved by the US EPA and DOGGR according to the criteria of 40 CFR §146.4; and either:
B. Depth to water with a TDS concentration that is no longer economically or technologically feasible for groundwater beneficial use; or
C. Depth to waters of TDS greater than 10,000 mg/L (40 CFR §144.3), these being referred to here as not suitable as an USDW.

In the WDWA, concentrations of TDS routinely exceed 2,000 mg/L, making the groundwater unsuitable for practical beneficial use in the WDWA. The base of fresh groundwater in the KCS (**Figure 16**) has historically been defined by Page (1973), as the depth at which specific conductance (SpC) is 3,000 umhos/cm or microsiemens per centimeter (uS/cm). This value is considered to be generally equivalent to a TDS concentration of 2,000 mg/L. These values are reported in this Chapter GSP because they are considered a limiting factor for irrigation and other practical beneficial uses in the WDWA. The conversion factor from SpC to TDS used for this determination was 0.67, which is midway between the typical range of 0.55 to 0.75 (Hem, 1985), and is dependent on the composition of groundwater. Available groundwater data indicates that, with few exceptions, most of the accessible groundwater of sufficient quantity to be economically viable within the WDWA meets or exceeds this threshold (Amec, 2015; GEI, 2019). Further, in support of this concept, the WWQC is in the process of submitting a BPAW for regulatory review that proposes delisting agriculture and municipal beneficial uses for perched and unconfined/semiconfined aquifers over a significant portion of the WDWA.

In reference to item "A" above, in the WDWA oil and gas is produced from geologic structures that are comprised of some of the same formations that produce brackish groundwater elsewhere in the WDWA. The Tulare and Etchegoin Formations are two examples of this

condition. The uppermost hydrocarbon producing zones are variable, but can be a shallow as 400 feet below ground surface. In addition to containing hydrocarbons, many of these oil-bearing zones also contain naturally degraded formation water (i.e. produced water). Based on the presence of hydrocarbons in these structures many of the associated formations are also designated as exempt aquifers by the DOGGR and the US EPA, within the administrative limits of the individual oil field. Examples of oil fields with aquifer exemptions include, among many others, the Lost Hills Oil Field and the Belridge Oil Field complex. Both oil field produced water and WDWA groundwater are naturally degraded by elevated concentrations of TDS and other minerals and compounds. Brackish groundwater conditions are found throughout a majority of the WDWA.

The depth to groundwater with a TDS of 10,000 mg/L, also known as the base of the USDW, is predicated on recent research in the KCS (Gillespie et. al., 2017; Kong, 2016). As described by Gillespie et al. (2017), the base of USDW is identified by geochemical analysis of discrete water samples and geophysical log (E-log) analysis. Gillespie found that salinity in the western KCS are much higher, and the depth to the base of USDW is more variable, than elsewhere in the KCS. These findings may be due to the geological complexity of the western KCS. Gillespie and others cite numerous wells with TDS between 3,000 mg/L and 10,000 mg/L in the non-marine Tulare Formation and overlying alluvium in the western KCS. Although lacking an extensive data set, Page (1973) reported very little data with specific conductance of less than 3,000 umhos/cm (i.e., ~2,000 mg/L) in the western KCS. TDS concentrations in the WDWA are often found to be much higher than 2,000 mg/L, supporting the conclusion there is very little “fresh water” on the western side of the KCS as corroborated further by other sources (Metzger and Landon, 2018; Amec, 2015 etc.). Therefore, the base and lateral extent of groundwater suitable for general beneficial use in the WDWA is proposed as where TDS concentrations exceed 2,000 mg/L.

2.5.8 Geologic Cross-Sections

The two geologic cross-sections provided in this Chapter GSP are based on driller descriptive logs and well completion forms filed with Kern County. The datum for both cross-sections is ground surface. Cross-sections presenting the structure and hydrogeology of the KCS at large are provided in the KGA umbrella GSP. The WDWA cross-section location map is provided on **Figure 17a**.

WDWA cross-section A-A’ (**Figure 17b**) extends from near the northeastern edge of the LHWD, southwards to near the southern boundary of the BWSD. Stratigraphy depicted on this cross-section matches that described in **Section 2.0** and is generally comprised of interbedded and interlensing series of silts, sands, and clays. Of note are the apparent fine-grained (silt and clay) layers that are evident in several of the wells (e.g., Well No.7108-69). Based on the similar geochemistry of groundwater found across the WDWA it is not clear if any of these fine-grained

or clayey sediments are fully competent confining layers. This condition will be assessed further as part of the Chapter MNP data collection.

Cross-section B-B' (**Figure 17c**) extends from west to east, from well 026S020E07E001M to a location near the boundary between LHWD and the adjacent SWSD (well 026S021E14EH002M). This cross-section exhibits the same sediment types as those in the Section A-A', and transects the Lost Hills anticline.

2.5.9 Data Gaps

The limited use of groundwater in the WDWA has resulted in data gaps related to the availability of DWR data, well construction information, and continuous and representative groundwater level and pumping data over historic and contemporaneous intervals. Historic studies by the USGS and others have provided sufficient hydrogeologic data and background to construct a preliminary HCM. The current HCM and WDWA water budget presented in this report are based on the preliminary KGA CV2Sim-Kern hydrologic model and the "Brackish Water Checkbook" approach from which an estimate of available water supply was derived. Once additional representative hydrogeologic data has been collected, the existing preliminary groundwater modeling will be further refined by the KGA to include the incorporation of local groundwater elevation, groundwater in storage, cropping, and groundwater pumping and water quality data. The WDWA will also refine and report its HCM and water budget information as new data become available. Until then, the WDWA will rely upon the Brackish Water Checkbook approach for estimating available water and Native Yield. Data gaps will be addressed through the implementation of the focused network monitoring plan described further in **Section 3.0** of this Chapter GSP.

2.6 Groundwater Conditions

Groundwater within the WDWA has been documented by numerous studies to be of poor quality and unsuitable for most practical beneficial use without blending or treatment. Because of the dynamic nature of the occurrence and movement of groundwater in the subsurface, it is recognized that groundwater conditions are transient through time and are subject to change. Factors that can affect groundwater conditions and quality include, but are not limited to, volume of precipitation, quality and quantity of direct recharge, topography, climate (ETo), soil geochemistry, aquifer thickness and physical properties, and subsurface geologic impediments or restrictions to groundwater flow. Land use, and anthropogenic activities (e.g., evaporation ponds) are other factors that might further degrade existing brackish groundwater quality. Data to more fully quantify groundwater elevation and occurrence within the WDWA will be addressed as a priority during the first five-year reassessment period. However, current KGA C2VSim-Kern modeling indicates that the principal source of discharge, and thus the most significant change in storage in the WDWA, is not pumping extractions. Instead it is natural

subsurface groundwater underflow towards the axis of the Valley. This condition may be accelerated by pumping in adjacent downgradient water districts. Both conditions are beyond WDWA control.

2.6.1 Description of Historic and Current Groundwater Conditions

Historic and current groundwater data that is representative of local conditions is a recognized data gap in the WDWA. Although there are many well installations recorded in various agency databases, for the most part a majority of these are lacking the continuous information necessary to fully characterize groundwater conditions. **Figure 18** presents the universe of known well installations as derived from various regulatory agency databases, and a 2015 groundwater assessment conducted by Amec on behalf of the WWQC. In total there are approximately 409 known well sites in the WDWA. This number represents a well density of approximately 1.2 wells per square mile.

Available water quality data in the WDWA confirms that a significant portion of groundwater is brackish and of poor, unsuitable quality. The trend for groundwater elevation levels are downward although, based on the limited data available, appear generally to be at a rate that is less pronounced than as modeled by the KGA and documented elsewhere in the KCS. This is likely due to the limited pumping in the WDWA which is currently estimated at 3,000 AFY, and the fact that natural downgradient groundwater underflow is believed to be the most significant discharge factor in the current C2VSim-Kern model simulation.

Information regarding historic and recent groundwater elevations in the WDWA is limited because many wells are often completed in more than one aquifer, and it is rare that pumping volume or water-level data is collected in a systematic and coordinated way using a common set of sampling protocols and data recording standards that are implemented on a set schedule. In addition, public availability of gauged pumping volumes has been, and still is, difficult to obtain, as most wells are privately owned. Another contributing factor to this data gap is the fact that, historically in the WDWA, groundwater was generally considered a secondary source when compared to the ready availability of good-quality surface water from the SWP for the purpose of irrigation. This factor may have further militated against consistent detailed record keeping. Currently, based on the best available information, the aforementioned data gaps related to the need for additional representative data persist. Steps to decisively remedy this data gap pursuant to SGMA will be addressed in the WDWA MNP, described in **Section 3.0**.

2.6.2 Groundwater Trends

Groundwater elevation data in the WDWA are scarce due to the minimal amount of annual groundwater pumping. Groundwater elevation data has been identified as a data gap that will be addressed during the first five-year reassessment period. However, based on the data

available, including historic maps generated prior to widespread development of the WDWA, groundwater trends in the WDWA appear to be generally downward, albeit not at the rates currently simulated in the KGA groundwater model. Groundwater trends in the WDWA are governed principally by drought and downgradient subsurface outflows that may be accelerated by irrigation withdrawals in adjacent water districts. Groundwater flow direction in the WDWA is believed to be primarily eastward toward the floor of the Valley, with some northeastward flow along the northern boundary of the WDWA towards the former bed of Lake Tulare. Subsurface flow is reportedly impeded by geologic synclinal troughs, and sometimes sourced by runoff from the aforementioned anticlinal ridges that separate the Antelope Plain from the axis of the Valley floor. Seismic profiles and other geologic data made publicly available in applications for oil field aquifer exemptions in the WDWA show that gaps do exist in and around anticlinal ridges and synclinal down-folds that could present pathways for groundwater underflow. For example, in the north, geologic gaps between the Lost Hills Anticline and the South Dome of the Kettleman Hills Anticline could provide pathways for subsurface groundwater migration. In the southeast, geologic gaps around the Belridge Anticline complex, and the more easterly Buttonwillow and Semitropic Ridges, may also be pathways for restricted groundwater movement towards the Valley (**Figures 19a and 19b**). A possible obstruction to groundwater flow further eastward may be the Buttonwillow Syncline. Further study of groundwater trends and flow will be conducted during the first five-year reassessment period (i.e. 2020-2025).

An alternative interpretation for the occurrence and condition of groundwater in the WDWA is based on the presence of buried complex geologic structures that are known to exist beneath the Antelope Plain. Many of these features are visible only by viewing geophysical seismic data. It is possible that these structures may have some added influence over the distribution and quality of groundwater in the WDWA beyond what is currently known. The WDWA plans to assess these conditions by reviewing new data, including publicly available seismic data, during the first five-year reassessment period. Findings of this evaluation will be included in the HCM as appropriate and reported in the relevant SGMA update report

Preliminary C2VSim-Kern modeling conducted by the KGA indicates that the WDWA management area is variably recharged by underflow from the east-facing slopes of Coastal Mountain Ranges, seepage losses from the mostly ephemeral streams after significant storm events, deep percolation of precipitation above calculated ETo, by direct recharge returns of imported water from crop (surface water) application, and incidental losses from irrigation canals and ditches.

Pumping extractions under current conditions in the WDWA are minimal (estimated at ~3,000 AFY), primarily due to the poor groundwater quality and the availability of better quality Aqueduct import water. The simulated estimate of WDWA groundwater recharge is sufficient

to cover pumping extraction volumes. However, as noted previously, based on the preliminary KGA C2VSim-Kern model, the largest component of discharge in the WDWA is natural underflow (111,000 AFY) downgradient towards the axis of the Valley. Recharge via agricultural applications of surface water (i.e., deep percolation of agricultural return flow), although still an important source of recharge in the WDWA, is believed to be somewhat less than in the past because of the now-widespread use of modern drip and micro-irrigation technology by growers.

The general lack topographic of definition of stream drainage channels in the WDWA management area indicates that these are likely seasonal losing streams, and that most stream flow never leaves the Antelope Plain as surface water flow; with the possible exception of during extreme precipitation events (GEI 2019). Deep percolation of rainfall may be a source of recharge, but only during periods that significantly exceed the current 5.2 inches of average annual rainfall. The average ETo of approximately 58.3 inches/year, and long-term precipitation data for the KCS, suggest that direct percolation of precipitation in the Antelope Plain is not a significant source of recharge in the WDWA (Amec, 2015; GEI, 2019). There is no evidence for widespread, continuous saturated conditions extending from the surface to first regional groundwater aquifer in the WDWA.

As noted previously, representative groundwater elevation data within the WDWA is limited. The KCWA now (last few years) monitors three groundwater monitoring wells within the LHWD area as part of the CASGEM Program. In addition to these three wells, the WDWA has proposed to monitor another 18 (total of 21) well locations throughout the WDWA. In coordination with the WWQC, the WDWA MNP will implement monitoring on a biannual (Spring and Fall) basis going forward.

A hydrograph for one of the three aforementioned KCWA CASGEM wells (25S/21E-01R001M), located in the extreme northeast of the LHWD, was selected to assess for current and projected groundwater trends due to its continuous record of groundwater elevations for the period 1976 through 2017. **Figure 20a** shows the hydrograph for the period 1975-2018 for well 25S/21E-01R001M. This well is located basin-ward on the boundary between the WDWA and the SWSD. The general groundwater elevation trend in this well has been downward since approximately 1992. Monitoring data are more or less continuous, with some minor gaps starting in 1976 and extending periodically to other short intervals where data was not collected. Groundwater elevations range from a low of 6.2 feet above MSL in 2017, to a high of 84 feet above MSL in 1987. For the period 2007 through 2017, the average downward trend was approximately 5.3 feet per year (feet/year). The reported top of the well screen intervals is approximately 409 feet below MSL (624 feet bgs), which suggest that groundwater in 2017 was standing at approximately 400 feet above the top of the first well screen. Projecting a linear decline rate of 5.3 feet/year outwards to 2040 indicates that groundwater levels would be approximately -62 feet below MSL in 2030 and at 2040 approximately -115 feet below MSL.

Three other well hydrographs and linear decline graphs were generated for the period 1995 through 2004 by CV2SimFG-BETA to help assess groundwater elevation trends along the shared boundary of the WDWA with the BVWSD. One hydrograph is located in the center of Section 16, Township 28S, Range 21E (**Section 4.1.1)**. Based on the simulation data, the projected rate of decline for a well at this location for the specified period would be approximately 5.6 feet/year. The projected water level in 2030 would be approximately 112 feet above MSL, and in 2040 it would be approximately 56 feet above MSL. A second hydrograph is a relatively new well located at Township 27S, Range 22E, Section 30 (**Section 4.1.1**). The projected decline rate for this well based on reported groundwater elevations was determined to be approximately 4.2 feet/year. The projected water level in 2030 is estimated to be approximately 101 feet above MSL. The 2040 level is approximately 59 feet above MSL. The third hydrograph is for a well located 28S21E30H. The projected decline rate is approximately 6.8 ft. year. Estimated water level in 2030 is 127 feet above MSL. The projected 2040 water level is approximately 59 feet above MSL. These projected water levels inform the selection of the preliminary MOs and MTs, which are discussed further in **Section 4.0**.

2.6.3 Projected 2016-2065 Climate Change

Current climate modeling indicates that by 2050 there may be a significant reduction in the amount of winter snowpack in the Sierra Nevada Mountain Range. The gradual late-spring to mid-summer snowpack melt has historically allowed for an organized management of this important resource, which currently provides around 65% of California's water supply. If the current predictions are realized, it is possible that runoff from the Sierra Nevada will occur earlier in the year, and a majority of precipitation may come in the form of rain instead of snow. The ability to harvest and store the runoff for use later in the growing season may become a critical issue for Valley agriculture, and by extension, the State's economy in the coming decades. Assuming no change to cropping patterns, and no new water storage or reuse projects, predicted climate change will likely result in increased competition for all water resources.

In the KCS at large, it is expected that demand reduction measures and reliance on groundwater will increase in order to augment any potential further reductions to deliveries from imported surface water. In the Sacramento River Delta, which is a source of SWP water, less summer Sierra Nevada runoff equates to calculated reductions in Valley surface water deliveries. A corresponding rise in sea level caused by glacier and ice sheet melt off and a rise in ocean temperatures, could also affect water quality for irrigation by increasing the salinity in the Sacramento Delta. In the WDWA, where SWP water is the primary contractual supply of irrigation water and groundwater is used primarily for blending, it is anticipated that SWP deliveries may be further reduced and could become less reliable, while ETo will increase with rising temperatures.

Total (100%) designated SWP allocations to the WDWA, when available, are on the order of 332,218 AFY. However, current KGA preliminary modeling with C2VSim-Kern for the baseline period 1995 to 2014 indicates SWP deliveries averaged around (~272,000 AFY). A preliminary KGA-modeled climate-change scenario for the WDWA covering the period 2016 to 2065 assumes SWP deliveries would be reduced to approximately 61% of the current total Table A allocation (i.e., ~204,698 AFY). Preliminary KGA C2VSim-Kern modeled projections of climate change influences may result in the following groundwater budget components:

Inflows

- Underflow from Coastal Ranges: 55,600 AFY
- Water loss from imported water canals: 8,800 AFY
- Areal recharge (deep percolation): 18,900 AFY
- Water loss from ephemeral stream flow: 3,200 AFY
- Total inflow: 86,500 AFY

Outflows

- Underflow out of the WDWA: 111,000 AFY
- Pumping Extraction: 5,400 AFY
- Total outflow: ~116,400 AFY

Modeled groundwater underflow out of the WDWA and not pumping is by far the most significant factor contributing to change in groundwater storage. This natural phenomenon is outside the control of the WDWA. Due to the poor quality of groundwater, irrigation demand in the WDWA is and will continue to be met almost entirely by Aqueduct water. To help ameliorate the modeled groundwater outflows over the GSP implementation horizon, the WDWA will continue to utilize conservation and demand reduction measures, intra-area water trading, advanced irrigation technology, deficit irrigation methods, and the potential innovative conjunctive reuse of degraded groundwater and oilfield produced water. Data derived from the MNP will be used to update the KGA water budget model for the WDWA in order to coordinate forward looking and sustainable water management strategies and projects with adjacent GMAs.

As a first step towards future sustainability and climate change resiliency, the WDWA is considering an innovative approach to treat and reuse oil field produced water and naturally degraded groundwater to increase flexibility and diversity in its water portfolio. This project is discussed further in **Section 6.0**.

2.6.4 Beneficial Uses and Users

Current designated beneficial uses of groundwater for the WDWA are established in the Tulare Lake Basin Plan. The WDWA is within Detailed Analysis Unit (DAU) 259. Existing designated beneficial uses of groundwater in DAU 259 include:

- MUN
- AGR
- IND

It should be clarified that although MUN is a designated beneficial use for groundwater within the WDWA, there is no MUN use in the WDWA at this time. For these designated beneficial uses, the Tulare Lake Basin Plan specifies numeric water quality criteria for certain water quality parameters and provided narrative water quality for other parameters. In the Tulare Lake Basin Plan, the designated water quality criteria for MUN are described as (Amec, 2015):

> *"At a minimum, waters designated MUN shall not contain concentrations of chemical constituents in excess of maximum contaminant levels (MCLs)…or secondary Maximum Contaminant Levels (SMCLs)…"*

The Tulare Lake Basin Plan also identified the following narrative water quality criteria for groundwater (Amec, 2015):

> *"Ground waters shall not contain chemical constituents in concentrations that adversely affect beneficial uses."*

> *"Ground waters shall not contain taste or odor-producing substances in concentrations that cause nuisance or adversely affect beneficial uses."*

The US EPA drinking water SMCL for TDS is 500 mg/L. The California Department of Public Health (DPH) has established a range of TDS and EC in drinking water (Section 64449, Title 22, CFR). The DPH SMCLs are:

Constituent	Recommended	Upper Level	Short-Term
TDS	500 mg/L	1,000 mg/L	1,500 mg/L
EC	900 umhos/cm	1,600 umhos/cm	2,200 umhos/cm

Aside from potential hazards to irrigated crops, adverse effects from the consumption of water with elevated TDS include nuisance aesthetic concerns such as bad taste or unpleasant odor, and cosmetic effects, such as skin or tooth discoloration. Physical effects to infrastructure, such as staining, corrosion, pitting, and scaling of pipes, valves, and other water equipment is also common. Consumption of highly brackish to saline waters can result in severe health effects.

Based on available data, a majority of the groundwater in the WDWA contains elevated levels of TDS that make it unsuitable for MUN use without additional treatment (Amec, 2015).

The SWP, along with other supplemental sources of surface water, delivers the vast majority of the water used for AGR activities, such as crop irrigation in the WDWA. Groundwater in the WDWA is of sufficiently poor mineral quality to severely impair AGR beneficial uses, and often exceeds published water quality criteria for MUN and AGR-Irrigation (severe restrictions; Food and Agriculture Organization of the United Nations [FAO], 1994). The Tulare Lake Basin Plan has designated beneficial uses of AGR that, for the most part, do not currently exist and cannot be sustained in the WDWA due to poor groundwater quality. Groundwater in the WDWA requires significant blending to be usable for AGR-Irrigation. As noted in **Section 2.1** and elsewhere in this Chapter GSP, the WWQC has transmitted a Draft Basin Plan Amendment Workplan (BPAW) to the Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS) Technical Committee and the Regional Water Quality Control Board (RWQCB) for their preliminary review and input, prior to final submittal to the RWQCB (**Figure 20b**) for a regulatory determination. The BPAW currently recommends the following:

- Delist the beneficial use of MUN and domestic supply in perched and unconfined/semi-confined groundwater in a portion of the WWQC, which also includes a significant portion of the WDWA; and
- Delist the beneficial use of AGR water supply in perched and unconfined/semiconfined groundwater in those same areas.

Principal land use within the WDWA, aside from open undeveloped rangeland, consists of two general categories:

- AGR: farming, livestock, etc.
- IND: primarily oil and gas production

Users that could be potentially affected by use of groundwater in the WDWA include:

- AGR users;
- IND users (i.e., principally oil and gas); and
- MUN and individual domestic users.

There is no public water supply use of groundwater in the WDWA, nor is there likely to be over the duration of Plan implementation because of the ubiquitous extent of naturally degraded groundwater, and the remoteness of the WDWA where the predominate land uses are agriculture, oil and gas production and grazing. The ready supply of other water sources of better quality, such as Aqueduct water, and groundwater from adjacent management areas also make it unlikely that WDWA groundwater would be used for local public water system supply.

According to the DWR well completion reporting and the CASGEM Program, historically there have been a few well completions recorded as "domestic" within the WDWA. However, it is unknown if this well designation is accurate or, if so, whether any of these wells are still in use. The majority of active groundwater wells in the WDWA were completed for the following purposes:

- Irrigation/stock, etc.;
- Industrial; and
- Monitoring/observation.

2.6.5 Groundwater Quality

A literature review was conducted to ascertain and document water quality. Among the various technical reports reviewed were USGS studies as well as data culled from the State GeoTracker and EnviroStor databases, which identify contaminant releases to soil and groundwater. The SWRCB's Human Right to Water Quality Portal was accessed to identify common contaminants that are typically found to be in concentrations that are out of compliance with drinking water standards. The evaluation also included data from local Water Districts and the State Drinking Water Information System (SDWIS).

This characterization of groundwater quality was conducted to comply with California Code of regulations (CCR) Title 23-Waters: Sub-article 2§ 354.16(d)-Groundwater Conditions. Of the regulated *drinking water* constituents considered, the most common water quality constituents encountered in the WDWA are; Arsenic, Nitrate, Boron, Hexavalent Chrome, Pesticides (Synthetic Organics), and TDS. To the extent applicable, the constituents evaluated and the methodology utilized are consistent with guidance provided in:

- Assembly Bill 1249 (AB 1249), which states *"…if the Integrated Regional Water Management (IRWM) region has areas of nitrate, arsenic, or hexavalent chromium contamination, the (IRWM) Plan must include a description of location, extent, and impacts of the contamination; actions undertaken to address the contamination, and a description of any additional actions needed to address the contamination*" (Water Code §10541.(e)(14).
- Division of Drinking Water (DDW) Human Right to Water (HR2W) portal, which identifies the contaminants for which public water systems have received MCL violations.
- Water Quality Control Plan for the Tulare Lake Basin (Basin Plan), dated May 2018, which is the SWRCB's implementation plan for Water Code §106.3. The amended basin Plan requires permitees to *"…address the immediate needs of those drinking groundwater that exceeds the drinking water standard for nitrate*".

Much of this information, including maps of public water systems within the KCS, is contained in the KGA Umbrella GSP. Because of the naturally degraded quality of groundwater in the WDWA, district groundwater is not utilized as a source for public supply.

The quality of groundwater varies greatly across the KCS. Most of this difference is due to natural conditions related to the mineral content of the sediments and lithology and geologic structure of the Subbasin. In the WDWA management area, marine-derived formations have contributed to the documented poor and unsuitable quality of groundwater. Along the western side of the KCS, including the WDWA, unconfined/semi-confined groundwater is characterized geochemically as Na/Ca-SO_4 water with TDS concentrations most often above 2,000 mg/L. Other deeper groundwater aquifers beneath the WDWA, and elsewhere in the KCS, are referred to as sodium-chloride (Na-Cl) water, which exhibits high to very high levels of TDS and is likely saline connate water (Amec, 2015; GEI, 2019).

Groundwater beneath the WDWA exhibiting TDS concentrations above 2,000 mg/L are naturally degraded and are considered unsuitable for all practical beneficial use. This includes waters found in, or produced from, oil field hydrocarbon-bearing zones, and US EPA designated exempt aquifers regardless of depth. In addition to TDS, other minerals and compounds that can affect groundwater quality present in WDWA groundwater are described in the subsections below.

It should be noted that generally accepted concentrations of TDS for defining water quality are:

- Fresh Water: up to 500 mg/L
- Brackish Water: 500 mg/L to 30,000 mg/L
- Saline: 30,000 mg/L to 40,000 mg/L
- Hypersaline: greater than 40,000 mg/L

In its 2003 update to California Water Bulletin 118, the DWR provided the following information with regard to the range of TDS values and related suitability for agricultural use (DWR, 2003):

- TDS: <500 mg/L, no restrictions
- TDS: 500 mg/L to 1,250 mg/L, slight restrictions on use
- TDS: 1,250 mg/L 2,500 mg/L, moderate restrictions on use
- TDS: >2,500 mg/L, severe restrictions on use

2.6.5.1 Arsenic

Arsenic has a primary drinking water MCL of 10 micrograms per liter (ug/L) (parts per billion [ppb]), and an agricultural goal of 100 ppb. Reports published by the Department of Pesticide Regulation and USGS studies indicate that the major source of arsenic in the KCS is naturally occurring. A significant source of arsenic in KCS groundwater is derived from erosion and mobilization of arsenic found in geologic sediments. Throughout the southern San Joaquin

Valley arsenic rich minerals, such as arsenopyrite, a common constituent of shales, the mineral apatite, and phosphorites are the most frequent sources of arsenic leaching to groundwater. **Figure 21** presents the KCS regional distribution of arsenic in wells for the years 2001 to 2007 (GEI, 2019). The distribution of elevated arsenic concentrations in the KCS is localized and appear to be associated with natural clay deposition in and around the former Tulare Lake, Kern Lake, and Buena Vista Lake areas, where the process of evaporative concentration likely acted to further increase naturally occurring concentrations in associated clays and silts (DWR, 2003; Amec, 2015). A study by the USGS reported that arsenic is the trace element most often present at elevated concentrations in the KCS, with concentrations ranging from 10ppb to 30 ppb.

2.6.5.2 Nitrate

Nitrate (NO_3) has an acute drinking water MCL of 10 mg/L (ppm) nitrate-nitrogen. There is no agricultural goal. Nitrate is a form of nitrogen that can be produced naturally by the atmosphere or by decomposing organic matter. Naturally occurring nitrate concentrations are generally less than 10 milligrams per liter as nitrogen (mg/L-N), and generally do not exceed 20 mg/L-N in groundwater (Hounslow, 1995; Todd, D.K. [Todd], 2008; Amec, 2015). Elevated nitrate concentrations are also attributable to the application of nitrogen fertilizers, runoff from feedlots or dairies, percolation of wastewater and food processing waste, and leachate from septic systems (Harter et al., 2012). Groundwater recharge from septic systems is not thoroughly measured or estimated in the KCS, but this potential source is believed to be a minor contributor in the WDWA due to the sparse population and remoteness of towns and individual dwellings. Recharge from wastewater generated by food processing, confined animal facilities, and other industries can also be significant but, like some other wastes, are generally regulated under individual waste discharge requirements (WDRs) (Amec, 2015). Treated wastewater is regulated by the various RWQCBs under site/facility-specific WDRs. Point source discharges from facilities, including stormwater discharges to surface water are regulated by the National Pollutant Discharge Elimination System (NPDES) under the Federal Clean Water Act (Amec, 2015).

Wells in the San Joaquin Valley, including those on the western side of the KCS, have higher nitrate concentrations in shallower zones, likely the result of return-flow percolation due to past agricultural activities and irrigation practices. Recent improvements to irrigation technology and the evolution to permanent crops like nut trees in the WDWA have significantly reduced the amount of agricultural return flows and fertilizer application. Public water supplies are required to treat raw water to meet all established drinking water MCLs. Within the WDWA, there are no public water systems sourced by district groundwater. The water supply for the town of Lost Hills is from outside the WDWA and is managed by LHUD (Amec, 2015). **Figure 22** presents

nitrate as nitrogen detected in KGA wells and proximity of septic tanks for the years 2009 to 20019 (GEI, 2019).

2.6.5.3 Boron

Currently, there is no Federal or State drinking water MCL for boron. However, the State does have a notification level of 1,000 ug/L, and there is an agricultural goal of 700 ug/L. Since the WDWA is largely dedicated to agriculture, the agricultural goal is used as a reference point in this Chapter GSP. The agricultural goal is intended to protect various agricultural uses of water including various crop types and stock watering. The agricultural level is a baseline to compare against and should not be used to represent an acceptable maximum level for the KCS. According to USGS Scientific Investigations Report 2011-5218, boron is commonly found in the southern part of the KCS. It generally occurs in association with basin-fill sediments of marine origin like those in the southern and western sides of the Subbasin. Brackish and saline connate waters, common to the WDWA, are also known to contain elevated concentrations of naturally occurring boron. Other sources of boron include leaching from wastewater, and fertilizer/pesticides (Amec, 2015; GEI 2019).

2.6.5.4 Hexavalent Chromium

Currently, there is no Federal drinking water MCL for hexavalent chromium. A court-challenged State drinking water MCL of 10ug/L is in the legislative process to be re-adopted. In the meantime, the Federal MCL of 50 ppb for total chromium applies. Anthropogenic sources of hexavalent chromium include commercial and industrial activities such as discharges of chrome-plating liquid wastes, various pigments, wood preservatives, and leaching from landfills and hazardous waste sites. Chromium is also prevalent in soils and plants. The process of leaching chromium into groundwater is believed to be similar to that for arsenic described in a previous section above. The occurrence and concentrations of hexavalent chromium detected to date in the KCS (i.e., in the range of ~5 ug/L to 13 ug/L [or ppb]) indicate that many of the existing detections are likely result of natural conditions (Amec, 2015). There is no Agricultural Water Quality Goal for hexavalent chromium. A review of the GeoTracker and EnviroStor databases found no open contamination hexavalent chromium cleanup sites or point source releases in the WDWA.

2.6.5.5 Pesticides (Synthetic Organic Chemicals)

In a Groundwater Assessment Report prepared for the WDWA and the Western Supplemental Area in 2015 (Undistricted Lands), it was reported that a review of available relevant databases for pesticide detections in the study area determined pesticides were infrequently detected in groundwater samples, and these were generally below established corresponding MCLs. The following table summarizes the review of the GeoTracker and Groundwater Ambient Monitoring and Assessment (GAMA) databases for the pesticides atrazine, simazine, 1,2-dichloropropane

(1,2-DCP), Diuron, 1,2,3-trichloropropane (TCP), and 1,2-dibromo-3-chloropane (DBCP) (Amec,2015).

Pesticide	Wells with Data	Wells with Detections	MCL (mg/L)
Atrazine	24	1(E)	0.001
Simazine	30	1(E)	0.004
TCP	21	0	0.000005
Diuron	15	0	NA
DBCP	31	0	0.0002
1,2-DCP	25	1	0.005

Note:
(E): estimated value at or below established reporting limit

The US EPA cancelled registrations for DBCP use, with the exception of Hawaii, in 1977. Its use was subsequently banned in the continental United States in 1979. In 1985, the registration for use in Hawaii was also cancelled. The State MCL for DBCP is 0.2 ug/L (ppb). There is no Agricultural Water Quality Goal for this chemical.

To date, there have been no reported detections of TCP in the WDWA. The drinking water MCL for TCP is 5 parts per trillion (ppt.), which became effective in January 2018. In Kern County, 18 water systems have a combined total of 124 wells impacted with TCP. This number represents approximately 52% of all wells for these specific water systems. Typically released to the environment through industrial processes and leaching of soil fumigants, residual concentrations of these chemicals are still reportedly being detected in soil and groundwater in the KCS. These detections are expected to attenuate over time (Amec, 2015; SWRCB, 2019). As stated previously, there is no municipal supply use of groundwater in the WDWA.

2.6.5.6 Total Dissolved Solids, Sodium and Chloride

Based on current drinking water standards, the recommended SMCL for TDS is 500 ppm, with an upper limit of 1,000 ppm. The SMCL for chloride is 250 ppm, with an upper limit of 500 ppm. There are no drinking water standards for sodium. Agricultural Water Quality Goals set by the United Nations Food and Agriculture Organization (FAO) for TDS, sodium and chloride are 450 ppm, 69 ppm and 106 ppm, respectively. Chloride concentrations in the WDWA often exceed FAO limits. This is likely due to leaching from geologic sediments, the presence of saline connate water in the WDWA and anthropogenic impacts from oil industry evaporation ponds. The naturally occurring concentration of TDS in groundwater in the WDWA typically exceeds 2,000 Mg/L (ppm), the level at which it is considered unsuitable for practical beneficial use in the WDWA.

2.6.5.7 United States Geological Survey

A USGS study designed to assess the groundwater quality of the western KCS, prior to widespread agricultural development, sampled 45 supply wells between 1930 and 1955. Water uses of the 45 study wells were described as follows:

Number of Wells	Well Use
2	Industrial
3	Domestic
6	Idle/Unused
13	Stock
21	Irrigation

In a subsequent report that discussed the study data, USGS (1959) provided the following results for EC, TDS, boron and sulfate. Based on these data, most of the groundwater tested beneath the USGS study area exceeded current water quality criteria for MUN, AGR-Irrigation, AGR-Livestock, and AGR-Poultry (Amec, 2015).

EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)
890 – 8,370	537 – 7,040	0.4 – 18	48 – 3,930

In 1963, a multi-depth monitoring well cluster was installed near the Kern County National Wildlife Refuge (25S/21E-01N). The well cluster was part of a wider USGS study to characterize vertical groundwater quality in the KCS. The various individual well screens that made up the subject well cluster were as follows (Amec, 2015):

- Well 1N15: 10 feet to 20 feet bgs
- Well 1N57: 56 feet to 62 feet bgs
- Well 1N95: 90 feet to 100 feet bgs
- Well 1N194: 189 feet to 199 feet bgs

Each well in the cluster was sampled in August 1990. The data are summarized in the table below.

Well	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Arsenic (ug/L)
1N15	1,750	1,270	0.87	220	6
1N57	12,000	9,280	9.4	4,600	16
1N95	6,250	4,260	2.1	1,500	10
1N194	4,540	2,620	1.3	420	8

These data, together with data from other studies identified in this Chapter GSP, reinforce the finding that the groundwater in the WDWA is, with few exceptions, brackish and of poor quality and is unsuitable for current designated uses including MUN and AGR-related uses. The relatively better water quality found in the shallow zone well (1N15) may be attributable to imported fresh surface water used to artificially maintain surface water levels and quality at the Kern County National Wildlife Refuge (Amec, 2015). Deeper groundwater zones appear to be representative of sub-regional conditions, as evidenced by comparison other study data.

A USGS (1995) report provided data on 15 perched groundwater wells in eastern LHWD and BWSD. Concentration of TDS ranged from 1,130 mg/L to 37,300 mg/L. Boron detections ranged from 0.8 mg/L to 70 mg/L. Sulfate and arsenic concentrations ranged from 160 mg/L to 34,000 mg/L and 1.0 ug/L to 20 ug/L, respectively (Amec, 2015). The data show that perched water, where present, in eastern LHWD and BWSD, generally exceed current water quality criteria for MUN, AGR-Irrigation, ARG-Livestock, and ARG Poultry (Amec, 2015).

As part of a separate USGS KCS study, groundwater data below the Westside (hydrographic unit 18030012) were obtained from the National Water Information System (NWIS) (USGS/NWIS) (Amec, 2015). This data set was comprised of 59 wells for which some general mineral data had been collected between 1930 and 1992. The data is summarized as follows (Amec, 2015):

EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Chloride (mg/L)
1,080 – 102,000	544 – 91,900	58 – 70	100 – 27,000	59 – 44,000

These data reiterate the conclusion that, with few exceptions, a majority of the groundwater, including oil field produced water beneath the WDWA on a sub-regional basis is brackish, and of little, if any, beneficial use without blending or treatment.

2.6.5.8 California Department of Water Resources

As a technical basis for the adoption of WDRs for oil field operations, the SWRCB contracted with the DWR for a hydrologic assessment of selected oil fields within the Westside, including several located in the WDWA. The following subsections provide a summary of those and other assessments with in the WDWA (Amec, 2015).

Vicinity of Lost Hills Water District

In the 1956 Geologic and Waste Disposal Investigation, Lost Hills Oil Field, the DWR identified 12 supply wells: 10 stock wells and 2 domestic wells. The ranges of general mineral concentrations were reported as follows (Amec, 2015):

Wells	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Chloride (mg/L)
Stock	2,750 – 8,410	1,860 – 6,780	2.9 – 10	470 – 3,630	230 – 1,460
Domestic	3,600 – 6,100	2,700	5.2	920 – 2,700	500 – 542

These data indicate that groundwater in the vicinity of the Lost Hills Oil Field is of poor quality and generally not suitable for use without expensive treatment. Chloride and boron concentrations from all but one well (26S/21E-12F), are sufficient to be classified as injurious for irrigation use (Amec, 2015).

A RWQCB (1990) report of groundwater quality samples collected from Tulare Lake Basin tile drains, including four in the LHWD, found TDS concentrations in these drains ranging from 11,000 mg/L to 14,000 mg/L. Concentrations of boron ranged from 29 mg/L to 63 mg/L (Amec, 2015). Based on the reported data, the LHWD tile drain water samples do not meet the criteria for beneficial use for MUN or AGR.

In 2012, as part of DWR's Agricultural Drainage Monitoring Program, the DWR collected samples from two tile drains in the LHWD. The concentration of TDS from the subject drains (DWR 5467 and DWR 6467) ranged between 12,520 mg/L and 23,300 mg/L. Boron was detected at concentrations between 26.6 mg/L to 43.5 mg/L (DWR, 2013; Amec, 2015). The results are comparable to those from the 1990 study described immediately above. Neither data set meets the beneficial use criteria for MUN or ARG use.

Vicinity of Berrenda Mesa Water District

In the 1957 Geologic and Waste Disposal Investigation, Blackwells Corner Oil Field, and Geologic and Waste Disposal Investigation, Welcome Valley Oil Field, the DWR identified nine irrigation wells and one stock well for study. The ranges of general mineral concentrations were reported as follows (Amec, 2015):

Wells	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Chloride (mg/L)
Stock	8,370 – 15,700	5,450 – 10,400	11 – 18	1,180 – 4,870	2,200 – 4,870
Irrigation	2,030 – 3,450	1,370 – 2,660	1.0 – 2.7	600 – 1,450	166 – 288

In their report the DWR concluded that, *"These concentrations are excessive for drinking water"* (Amec, 2015). In addition, these concentrations would also be excessive for most if not all AGR use without treatment or blending with better quality water.

Vicinity of Belridge Water Storage District

In the 1957, Geologic and Waste Disposal Investigation, North and South Belridge Oil Fields the DWR was able to sample two water wells in the vicinity of the Belridge Oil Fields; an industrial supply well in the oil field and a nearby stock well. The ranges of general mineral concentrations were reported as follows (Amec, 2015):

Wells	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Chloride (mg/L)
Stock	5,450	3,863	3.3	1,775	766
Industrial	4,730	2,848 – 2,950	0.4 – 7.6	462 – 464	830 – 870

2.6.5.9 Regional Water Quality Control Board

The RWQCB has oversight on several facilities and sites within the WDWA and Westside at large. A selection of these facilities and sites are described below.

Vicinity of Lost Hills Water District

As of 2015, the RWQCB regulated two facilities in the vicinity of the LHWD. These are the former Chevron USA oil field ponds, and the irrigation drainage evaporation ponds operated by the LHWD. The former Chevron ponds are located along the eastern flank of the Lost Hills Oil Field, north of the town of Lost Hills and Highway 46. Down-gradient monitoring in 2012 detected the following concentrations in groundwater (Amec, 2015):

Wells	EC (umhos/cm)	TDS (mg/L)	Sulfate (mg/L)	Chloride (mg/L)
Chevron	4,600 – 30,000	4,100 – 30,000	1,500 – 23,000	880 – 7,900

These data exceed the criteria for MUN and AGR use, and the poor water quality is consistent with other studies and locations discussed in this Chapter GSP.

The LHWD evaporation ponds consist of six cells covering about 534 acres. In the LHWD 2018 Biannual Wildlife Monitoring Report, it was stated that the ponds were dry for that year due to a lack of discharge by the LHWD. Shallow and deep groundwater monitoring samples collected in 2009/2010 reported the following concentrations (Amec, 2015):

Wells	EC (umhos/cm)	Sulfate (mg/L)	Chloride (mg/L)
LHWD Shallow	13,000 – 171,000	NA	NA
LHWD Deep	2,500 – 50,600	500 – 20,000	980 – 23,000

Note: NA: not available

These data show that groundwater at this location is very brackish and has been impacted, likely both by the nearby ponds and the naturally poor quality of groundwater found throughout the WDWA. As such, this groundwater would be unsuitable for any beneficial use without expensive advanced water treatment technology capable of desalination such as reverse osmosis (RO) or other membrane technology. Because of the location of the ponds on the eastern boundary of the LHWD there is also the likelihood that brackish, poor quality groundwater, has migrated down-gradient towards the adjacent SWSD. If confirmed, coordinated monitoring and management of the brackish water will be required during the implementation of the KGA GSP to mitigate the potential for further undesirable results to better quality water to the east of the WDWA.

Vicinity of Berrenda Mesa Water District

The RWQCB oversees the Lost Hills Sanitary Landfill (LHSL), operated by Kern County, and the cleanup of the Antelope Pump Station, managed by Chevron. The LHSL is located along the southwestern flank of the Lost Hills Anticline, while the Antelope Pump Station is located in the west-central part of the BMWD. Monitoring of shallow groundwater at the LHSL was reported by Kern County Waste Management District (KCWMD) in 2012. This report found TDS in the range of 3,400 mg/L to 4,300 mg/L, chloride concentrations in the range of 620 mg/L to 1,200 mg/L, and sulfate concentrations in the range of 1,400 mg/L to 1,500mg/L.

Monitoring of shallow groundwater at the Antelope Pump Station and reported by Chevron in 2012, found EC values in the range of 1,175 umhos/cm to 2,416 umhos/cm. For comparison, a value of 3,000 umhos/cm equates to approximately 2,000 mg/L of TDS.

Vicinity of Belridge Water Storage District

In the vicinity of the BWSD, the RWQCB regulates several sites. Among these are:

- Aera Energy's former South Belridge Oil Field Ponds;
- Clean Harbors Disposal Facility;
- Exxon/Mobil Hill Lease; and
- Valley Water Management Ponds.

Aera's former oil field ponds are located on the southern edge of the BWSD on State Highway 33. Adjacent areas to the north include the other member Districts of the WDWA, while to the east are the BVWSD and Undistricted Lands. To the west lies the Temblor Range, and to the south is the WKWD. Monitoring wells in shallow groundwater are maintained to assess groundwater quality both beneath, and down-gradient of the former ponds.

Data from a 2012 sampling event included the following (Amec, 2015):

Wells	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)
Aera	3,000 – 70,000	2,400 – 45,000	2.4 - 110	520 – 3,000

At the Clean Harbors Buttonwillow facility groundwater is monitored in three zones identified by the company. The zones are described as the Upper Perched Zone (80 to 140 feet bgs), Intermediate Perched Zone (185 to 201 feet bgs), and Lower Water Table (260 to 290 feet bgs). Adjacent down-gradient areas to this facility include the town of McKittrick, California, and the WKWD. A 2012 groundwater monitoring event provided the following results (Cameron-Cole, 2013; Amec, 2015):

Wells	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Chloride (mg/L)
Upper	1,390 – 3,980	4.7 – 11.8	559 – 2,100	185 – 2,400
Intermediate	2,230 – 2,670	4.8 – 6.9	980 – 1,560	162 – 555
Lower	2,100 -3,200	6.2 – 9.4	806 – 1,280	385 – 527

The Exxon/Mobil Hill Lease is located in the western part of the BWSD along State Highway 33. Shallow groundwater is monitored both beneath and down-gradient of the Hill Lease. A 2012 monitoring event reported the following (Cardno ERI, 2013; Amec, 2015):

Wells	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)
Hill Lease	4,000 – 25,000	4,160 – 19,300	2.5 – 48.7	830 – 2,000

The Valley Water Management (VWM) Ponds located near the Belridge oil field complex were recently found to be in non-compliance with several regulations by the RWQCB. Members of the VWM cooperative are reportedly working with the RWQB to come into compliance in order to avoid further enforcement, including the recent imposition of a Cease and Desist Order from the RWQCB.

As with the totality of other data sets discussed elsewhere in this subsection, these data support the conclusion that the groundwater quality beneath the BWSD is largely naturally degraded and is sometimes impacted by localized anthropogenic activity (e.g., evaporation ponds). That said; the groundwater beneath the WDWA is almost exclusively unsuitable for MUN and most, if not all, AGR or other beneficial use without blending and/or desalination. There is also the potential for these primarily naturally degraded groundwaters to migrate outside the WDWA where it would produce or perpetuate an undesirable result in adjacent GMAs. To mitigate any undesirable result related to poor water quality originating from the WDWA, the WDWA will work in close cooperation with oil producers and down-gradient, adjacent GMAs during the

implementation of the KGA GSP to conduct sentry monitoring as part of the WDWA MNP in order to assess for changes in groundwater quality on its boundaries.

2.6.5.10 Kern County Water Agency

As part of a recent study, Amec (2015) requested the KCWA groundwater data from across the Westside. A review of data for 66 wells found that EC values ranged from 370 umhos/cm to 55,600 umhos/cm. Boron ranged from 0.48 mg/L to 14 mg/L, and sulfate ranged from 130 mg/L to 1,300 mg/L (Amec, 2015). The breadth and scope of this review again documents and confirms that, with few exceptions, the water quality beneath the WDWA is predominately brackish to saline and of poor quality.

2.6.5.11 Adjacent Areas and Other Studies

The Dudley Ridge Water District (DRWD), located outside and generally down-gradient to parts of the WDWA, is immediately north of the LHWD in Kings County. Like the WDWA, the groundwater beneath the DRWD is similarly degraded by naturally occurring TDS and salts. A DWR (1964) Feasibility Study (FS) to evaluate the viability of providing SWP surface water to the DRWD found that, *"There are some producing water wells in the extreme northern portion of the District which provide a small portion of the present water supply. Most wells that have been drilled, however, have been abandoned due to poor yield and poor quality of groundwater..."* (Amec, 2015). A subsequent siting study and monitoring program conducted by Amec on behalf of the Los Angeles County Sanitation District for its bio-solids composting facility on the eastern side of the DRWD, found TDS and sulfate concentrations in groundwater ranging from of 5,920 mg/L to 26,800 mg/L and 2,930 mg/L to 11,600 mg/L, respectively.

Starrh & Starrh Growers provided Amec with 2010 data from a then newly installed well in the southern part of the WDWA. The summarized results are provided below (Sanden, 2012; Amec, 2015).

Wells	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Arsenic (mg/L)
Starrh & Starrh	3,000	2,300	7.1	1,000	16

The Starrh & Starrh well data is consistent with a majority of the other groundwater data in the WDWA and indicates this water is unsuitable for MUN without membrane desalination, and is also unsuitable for many sustained AG uses without blending.

Adjacent, and generally down-gradient to the east of the WDWA; the SWSD is susceptible to undesirable results from naturally degraded brackish groundwater migrating out of the WDWA and towards the SWSD. In a recent SWSD AWMP, the SWSD stated that, *"In general, groundwater in the west has higher TDS content relative to the eastern part of the District.*

Groundwater of poor quality, typically a sodium chloride or sodium chloride-sulfate type with high concentrations of dissolved solids and chlorides, can be found extensively along the western side of the San Joaquin Valley" (Provost & Prichard, GEI 2013; Amec, 2015).

As described elsewhere in this section, the BVWSD, located to the east and south east of the WDWA, and portions of the WKWD located to the south of the WDWA, are also potentially susceptible to groundwater quality undesirable results by migration of brackish groundwater originating from the WDWA.

In 2013, Amec, on behalf of the WWQC, sampled a total of 21 wells. Twenty samples were collected from the WDWA, and one sample from the adjacent down-gradient DRWD. The wells were of various depths and screen intervals and were distributed across the WDWA as follows (Amec, 2015):

- LHWD (4 wells)
- BMWD (6 wells)
- BWSD (10 wells)
- DRWD (1 well

The results for this sampling event are summarized below (Amec, 2015):

Wells	EC (umhos/cm)	TDS (mg/L)	Boron (mg/L)	Sulfate (mg/L)	Arsenic (mg/L)
LHWD	2,700 – 5,800	2,000 – 4,000	0.8 – 3.3	470 – 1,300	<2 – 10
BMWD	1,800 – 3,200	1,300 -2,600	1.6 – 6.7	450 – 1,200	<2 – 22
BWSD	2,900 – 21,000	1,800 – 18,000	3.3 – 47	510 – 2,200	2 – 33
DRWD	4,500	3,000	1.2	1,200	14

In addition, water hardness was also evaluated. The results for the hardness analysis are provided below (Amec, 2015):

Wells	Hardness (mg/L)
LHWD	790 – 1,200
BMWD	470 – 890
BWSD	510 – 5,600
DRWD	960

It was concluded that all 21 samples exceeded the State MCLs for drinking water for EC and TDS. The results for hardness in this study would classify all of the samples as being very hard water. Hardness values above 120 mg/L typically require softening in order to prevent scaling deposits in pipes and water heaters (Amec, 2015).

The occurrence of high TDS groundwater in the Westside has recently been further documented in a preliminary groundwater salinity mapping study conducted by the USGS (Metzger and Landon, 2018). In the study, the distribution of groundwater salinity for 31 oil fields and adjacent aquifers across major oil-producing areas of central and southern California were mapped. The objective of the study was to describe the distribution of groundwater near oil fields having TDS less than 10,000 mg/L by using existing TDS data from petroleum and groundwater wells to map concentrations and document data gaps. Within the KCS, the study reported much higher TDS in groundwater from Westside oil field wells and groundwater wells, when compared with east side groundwater wells and oil wells. Metzger and Landon (2018), among others, suggest that higher TDS in the Westside of the KCS could be related to a combination of natural conditions (Westside sediments derived from marine deposits with some saline connate water) and anthropogenic factors such as, among other things, infiltration of TDS from former oil field disposal ponds and/or agricultural drainage ponds. Naturally occurring higher TDS water is consistent with historical reports (several reports from before wide-spread agricultural development) and is documented for more than 60 miles from north to south in the KCS (KCDEH, 1980; KCDEH and KCWA, 1982; GEI, 2019).

2.6.5.12 Contamination Plumes

An evaluation of contamination plumes was conducted via the GAMA Groundwater Information System. The GAMA contains information from other State data bases such as the Department of Toxic Substances Control (DTSC) EnviroStor, and the SWRCB GeoTracker. This section presents the potentially impacted sites as were listed in the regulatory databases it should be noted that it is not the intent of this Chapter GSP to evaluate or confirm whether any of these sites are impacting beneficial use. It is important to recall that information provided in this Chapter GSP has documented that groundwater in the WDWA is primarily naturally degraded and is not suitable for most uses, including drinking water, nor is there any public water system use. The following programs from GAMA were reviewed:

- WDR;
- Underground Storage Tank (UST);
- Leaking Underground Storage Tank (LUST);
- Cleanup Program Sites;
- DTSC Hazardous Waste Sites;
- Department of Pesticide Regulation;
- Oil and Gas Sites; and
- Integrated Lands Regulatory Program.

Although the GeoTracker database did not show any sites with WDRs, in the WDWA, there are many sites in the KCS and WDWA that operate on WDRs issued by the Central Valley Regional

Water Quality Control Board (CVRWQCB or RWQCB). Facilities with WDR's typically include water treatment facilities, wastewater treatment facilities, oil and gas produced water treatment facilities, confined animal facilities and sites that are under active groundwater remediation. The GeoTracker also does not identify any confined animal facilities in the KCS, even though CIWQS shows there are approximately 264 such sites in Kern County. A non-profit Central Valley Dairy Monitoring program was formed in 2010 to develop a monitoring and research program to study the ecological effects of dairies in the Valley. This group recently submitted a report summarizing the findings of their monitoring. One of the recommendations was to develop and administer a web-based portal and data management system. Sites that were or are currently being studied under the oversight of the RWQCB were discussed in **Section 2.6.5.9**

Oil field wells permitted under the DOGGR and the US EPA UIC Program were not included on the figures or the related site table described below because the UIC requires that oil operators confine injected produced water to the approved zone to ensure that injected fluid does not impact off site underground sources of drinking water. Produced oil field water is discussed further in **Section 2.7.4.**

Figure 23a shows the location of sites extracted from the EnviroStor and GeoTracker data bases. **Figure 23b** presents Permitted Discharge Locations, of which there are approximately 44 in the WDWA, a majority of which appear to be related to oil field produced water treatment facilities. **Appendix E** lists the data acquired from the aforementioned regulatory sources in this section. Data was included on the subject table only if they applied to the following criteria (GEI, 2019):

1. Potential media was described as "groundwater", "other groundwater", or "unknown"
2. Contaminate of concern was described or classified as "unknown"
3. Site was classified as "not closed", and had one of the following modifiers:
    - Active cleanup
    - Active land use restrictions
    - Open remediation
    - Open site assessment
    - Open-eligible for closure
    - Inactive-action required
    - Under review
    - Open-inactive
    - Inactive permitted
    - Inactive unpermitted

2.7 Water Budget

2.7.1 KCS and KGA Water Budget Development

All GSAs in the Kern County subbasin (Subbasin) coordinated and collaborated on the development of a groundwater model (Model) to evaluate historical, baseline and projected groundwater conditions. The GSAs entered into a Cost Share Agreement with the Kern River GSA who took the lead and contracted with Todd Groundwater to develop the Model on behalf of the Subbasin. The contract required that Todd Groundwater use the C2VSim model provided by DWR. Considerable effort and resources were expended to update the C2VSim model with local data to better represent Subbasin conditions. The process Todd Groundwater used to update C2VSim is more fully described in the Historical and Projected Future Water Budget Development (see Attachment H in Umbrella GSP). Basin-wide water budget results from the Model are provided in Attachment H and show the Subbasin, as a whole, has a total storage deficit of approximately 324,326 AFY over the baseline period.

The Subbasin's dynamic conjunctive use programs, water banking operations, and water transfers/exchanges made it necessary to coordinate a GSA-level water accounting system (Checkbook) using Subbasin specific values for supply, demand and net results. The Model results reflect Subbasin-wide conditions and do not allocate water shortages/surpluses, nor do the results allocate the "ownership" of water. As a result, the GSAs, through a coordinated effort, developed the Checkbook that estimates current conditions for each GSA that are generally consistent with the Model results under baseline condition. The Checkbook and Model budgets are based upon best available information, recognizing however, each estimate includes data gaps and has varying degrees of accuracy and/or reliability in the interest of developing a Subbasin coordinated approach.

To ensure the individual water budgets reflected actual conditions, the KGA members developed the Checkbook budget and coordinated water accounting methodology. The result of that effort indicates a current baseline shortage/deficit for KGA members of approximately-256,281 AFY. This reflects the difference between a total demand for KGA members of 1,939,409 AFY, and a total supply of 1,683,128 AFY. Of the shortage/deficit of the KGA, the WDWA's portion of the KGA shortage/deficit is a surplus of +33,167 AFY. Or a difference in demand of 285,000 AFY and a water supply of 318,167 AFY.

As is mentioned above, each estimate includes data gaps and has varying degrees of accuracy and/or reliability. The Checkbook is complimentary to the Model and reflects the allocation of water supply benefits and obligations independent of geographic constraints within the Subbasin. This was important to recognize and ensure the coordination of the various groundwater banking projects and water management programs amongst the various GSAs within the groundwater basin.

As with other GSA-level budgets, the preliminary WDWA estimates also include data gaps and have varying degrees of accuracy and/or reliability that will be addressed by the collection, analysis, and reporting of additional representative data. However, it should be noted that the six unique WDWA hydrogeologic conditions (e.g. naturally degraded groundwater quality etc.), relative to the rest of the KCS, rend WDWA groundwater unusable unless it is blended or treated.

2.7.2 WDWA-Specific Water Budget Development and Issues

With regard to the WDWA, agricultural activities are the largest source of water demand, and such activities rely almost exclusively on surface and other imported water from the Aqueduct. There is currently a lack of representative groundwater elevation data in the WDWA. This data gap is due to the limited amount of annual groundwater pumping, which is directly attributable to naturally poor water quality. As discussed in **Section 2.7.1**, the water budget for the WDWA is currently based on the two independent and contrasting surrogate approaches described below that bookend the range of potential water supply: (1) The Checkbook Approach and (2) The Modeling Approach.

The Checkbook Approach is a typical approach based on an accounting of preliminary supply and demand and, as previously noted, is used by other GMAs in the KGA. The KGA Checkbook approach combines SWP water, alternative imported water (i.e. total Aqueduct water), a preliminary value of groundwater "Native Yield", and a currently estimated value of precipitation in areas of irrigated acreage, to estimate the available water supply. The Checkbook value of "Native Yield" is intended to encompass all groundwater recharges and discharges that apply to the WDWA but does not explicitly include groundwater underflow, which as discussed below is a critical element of the WDWA water budget. Furthermore, it is important to understand that the term, "Native Yield*",* implies *suitable groundwater quality,* a condition that does not generally apply to the WDWA. Due to the six aforementioned unique hydrogeologic characteristics of the WDWA discussed in the **Executive Summary** and **Section 2.1**, with geologic sediments of marine origin contributing directly to naturally degraded groundwater, and degraded brackish groundwater underflow chief among them, groundwater quality in the WDWA is poor and unsuitable for most uses. For example, virtually all groundwater pumping is and has been minimal and is used for the sole purpose of blending with better quality imported surface water when the supply of Aqueduct water is low.

All of the groundwater in the Native Yield in the modified WDWA Checkbook is comprised of naturally degraded brackish groundwater that is considered unsuitable for most use without blending or treatment and is therefore *"outside"* of the water budget. The Checkbook approach is a simplified illustration of potential groundwater resources and is only capable of providing an estimate of the current operational water budget, as well as preliminary 2030 and 2040 water

supply operational budgets. The projected estimates are sufficient to encompass phased groundwater pumping for the twin purposes of landowner blending, including anticipated increased pumping in response to climate change, as well as pumping and treatment for a proposed conjunctive reuse management action discussed in **Section 5.0** of this Chapter GSP.

The second Water Budget approach used in this Chapter GSP is based on available modeling conducted by the KGA. As noted above, it should be emphasized that the subject numerical groundwater model, C2VSim-Kern, is intended as a Subbasin-wide assessment of groundwater conditions and is not specifically calibrated to the WDWA service area. The C2VSim-Kern model is based on an uncalibrated Beta version of the DWR California Central Valley Groundwater-Surface Water Simulation Model, known as the C2VSimFG-BETA. The C2VSim-Kern modeling results are available for historical conditions for the WDWA, which were used to develop the current conditions water budget. C2VSim-Kern modeling results are also available for future baseline conditions and future conditions that include water projects proposed by all KCS GSAs, but these results are only available for the KCS at large; WDWA-specific results are not currently available (see **Section 2.7.2.2**). These scenarios will continue to be updated and adjusted for the KCS as a whole during the first GSP reassessment period. Additional pumping to support the planned treatment conjunctive reuse of brackish groundwater is described in **Section 2.7.2.1 and Section 5.3**.

Neither of these two approaches (Brackish Water Checkbook or C2VSim-Kern) explicitly considers the poor water quality in the WDWA or provides a definitive illustration of the WDWA-specific water budget but, in the current absence of sufficient groundwater elevation data in the WDWA, they do provide a framework for revising the water budget components based on data collected in the coming years. **Figure 24a** presents the C2VSim-Kern model zone map for the water budget area. **Figures 24b, 24c, and 24d** show graphic presentations of both approaches to estimating a preliminary WDWA groundwater budget, and current and projected groundwater pumping.

It should be noted that the C2VSim-Kern historical model overstates the amount of groundwater pumping that has and is occurring in the WDWA. For the purpose of comparison, the relatively low actual groundwater pumping (i.e. currently 3,000 AFY) is used in the following and ongoing discussions, and the overstated pumping volume from the C2VSim-Kern historical model is retained for the time being in those respective current-condition water budget estimates, as described below in **Sections 2.7.2.1 and 2.7.2.2**. Given this, the Brackish Water Checkbook approach is presently the more representative estimate of a water balance for the WDWA. Additional reconciliation of basin water budgeting efforts is a high priority for all of the GSAs as part of GSP implementation.

2.7.2.1 Brackish Water Checkbook Approach

The WDWA Checkbook approach combines SWP surface water, various supplemental surface water supplies (i.e. other Aqueduct water), a preliminary value of operational Native Yield, and a current value of precipitation to estimate the available water supply. Groundwater pumping is not explicitly accounted for in the Checkbook but is rather considered a portion of the Native Yield. As noted above, the Checkbook value of Native Yield is intended to encompass all groundwater recharges and discharges that apply to the WDWA but does not include groundwater underflow. The WDWA Native Yield for the purpose of the preliminary Checkbook is conservatively estimated to be 0.15 af/ac., multiplied by all WDWA acreage (i.e. 227,193 acres). This results in a volume of approximately 34,079 AFY. Unique to the WDWA is the fact that all sources of groundwater (e.g. underflow, recharge etc.) are eventually degraded due to the geology and are unsuitable for most use. Therefore, the brackish groundwater is necessarily considered as "*outside*" the water balance unless blended or treated. If the poor water quality, minimal levels of pumping in the WDWA, and volume of modeled degraded underflow (~111,000 AFY; see **Section 2.7.2.2**) leaving the WDWA are accounted for, a Native Yield of up to 0.30 af/ac may be supportable. If applied, it would result in a potential Native Yield range of 34,079 AFY to 68,158 AFY that could be utilized for blending or treatment for conjunctive reuse. This volume represents approximately 30%-60% of the current total C2VSim-Kern estimate of brackish groundwater underflow leaving the WDWA (**Figures 24b, 24c and 24d**).

The currently estimated Brackish Water Checkbook precipitation factor was based on KGA and CIMIS data for the WDWA. It utilizes a factor of 0.2 af/ac. multiplied by the number of irrigated acres (88,989 acres) in the WDWA. This results in a volume of approximately 17,798 AFY that can potentially meet a portion of crop demand.

The volume of available surface water includes SWP Table "A" water (204,698 AFY), Article 21 water (23,878 AFY), as well as purchased alternative imported water (37,714 AFY), which includes just WDWA purchases from outside the basin, but excludes WDWA intra-basin purchases/transfers and intra-basin purchases/transfers by individual landowners. All of this water is delivered to WDWA via the California Aqueduct. Together, this results in a currently available surface water supply of approximately 266,290 AFY. The surface water supply for current conditions was not adjusted for the preliminary 2030 and 2040 water budgets. Rather, if delivered volumes of surface water decrease over this time horizon it was assumed that management actions would be taken by the WDWA and is growers to reduce demand or increase supply.

As noted above, groundwater pumping is not explicitly accounted for in the Checkbook, but illustrations of current and projected pumping are shown on **Figures 24b, 24c, and 24d**. Pumping in the WDWA is not expected to approach the preliminary range of brackish Native

Yield until 2040. Current conditions (**Figure 24b)** indicate only 3,000 AFY of brackish groundwater is utilized to meet demand, and this water is used primarily for blending with Aqueduct water. In 2030 (**Figure 24c),** a projected pumping increase to 5,400 AFY is anticipated for the purpose of blending in order to account for climate change, in addition to another 20,000 AFY of brackish groundwater underflow being pumped for treatment and conjunctive reuse as described in Proposed Management Action (PMA) No. 3. In 2040 (**Figure 24d),** the full potential range of brackish Native Yield of 34, 079 to 68,158 AFY is utilized: 5,400 AFY for blending, and the remainder for proposed PMA No. 3 feedstock water for treatment and conjunctive reuse. This amount of feedstock pumping is considered a maximum value, because it is anticipated that some percentage of oilfield-produced water will be available for treatment and reuse in conjunction with brackish groundwater underflow. In the WDWA, total water demand is essentially equivalent to crop demand. For current conditions, demand is estimated to be 285,000 AFY (**Figure 24b**). To account for climate change, estimated demand is conservatively increased to 300,000 AFY in 2030 (**Figure 24c**) and 316,000 AFY in 2040 (**Figure 24d**).

The Brackish Water Checkbook method provides a preliminary estimate of available water supply. It should be emphasized that the values stated above provide a framework for data-based updates in the coming years and are not intended to be used for allocation purposes. Future allocations, if any, will be addressed through a stakeholder process.

2.7.2.2 Modeling Approach

Groundwater modeling conducted for the KGA utilizing the C2VSim-Kern model provided estimated volumetric flow rates for key water budget components. It should be noted again that the subject model is intended to be a Subbasin-wide assessment of groundwater conditions and is not specifically calibrated to the WDWA service area at this time. Additional reconciliation of water budgeting efforts for the Subbasin and the WDWA is a priority as part of GSP implementation. The managed supply and demand components of the model were updated with data provided by KGA-member water management agencies and other KCS GSAs to develop C2VSim-Kern. The details of the model updates, as well as the KCS-level modeling results, are described in a Technical Memorandum prepared by Todd Groundwater, *Historical and Projected Future Water Budget Development* (Attachment H in the KGA Umbrella GSP).

Water demand in the WDWA is dominated by irrigated agriculture. The C2VSim-Kern model calculates crop demand based on crop type and distribution, climate, and soil type. In the WDWA, water supply is predominately (approximately 95-98%) delivered via the California Aqueduct, which includes SWP water and other supplemental import (i.e. Aqueduct) water. Based on available data, less than 2% of the WDWA water demand is met by groundwater pumping, which is utilized primarily for the purpose of blending.

According to the C2VSim-Kern model, there is currently an imbalance in the WDWA between agricultural water supply and demand, resulting in an average agricultural shortage (deficit) of 80,000 AFY for the WY 1995-2014 period. This equates to an estimated shortage of 8.4 inches/year per irrigated acre. By way of contrast, available data indicate that actual demand more or less tracks with average Aqueduct deliveries for this same period. Locally, this imbalance indicates that either: (1) a substantial amount of deficit irrigation or other water management techniques are being implemented by the growers in the WDWA and/or (2) the crop demand is overestimated by the C2VSim-Kern model. A preliminary review of the model data indicates that an overestimation of crop types and associated demand (i.e. pumping) likely account for a majority of this disparity in the model. This phenomenon, and other refinements to the numerical model, will be assessed further during the first five-year reassessment period and reported in a future reassessment report. As noted previously, current WDWA Aqueduct surface water deliveries, less intra-basin WDWA purchases and individual land-owner intra-basin purchase and transfers are approximately 266,290 AFY. Total current demand WDWA is estimated at 285,000 AFY.

Current Conditions

Based on KCS-level C2VSim-Kern modeling for the period WY 1995-2014 (i.e. current conditions), total groundwater recharge is approximately 92,341 AFY:

- Underflow from the Coastal Ranges: ~ 55,264 AFY
- Underflow into the WDWA from adjacent Districts: ~837 AFY
- Water loss from imported water canals: ~8,844 AFY
- Areal recharge (deep percolation): ~24,227 AFY
- Water loss from ephemeral stream flow: ~3,169 AFY

Areal recharge (i.e., deep percolation in C2VSim-Kern) is the distributed recharge to groundwater from the unsaturated zone. It is equal to percolation out of the root zone plus or minus flow out of or into unsaturated zone storage. Percolation out of the root zone is a combination of applied water and precipitation in excess of ET.

As noted previously in this report, C2VSim-Kern is overestimating the volume of WDWA pumping extractions under current conditions. Because the primary source of water for agriculture in the WDWA is via the Aqueduct, the volume of discharge due to extraction by pumping wells has historically averaged less than 2% of annual demand. Pumping is currently estimated at approximately 3,000 AFY. The overestimated pumping volumes in the model will be addressed in future model simulations. The total estimated groundwater discharge for the current-conditions model simulation is approximately 138,540 AFY. The individual C2VSim-Kern discharge volumes, which will be refined as new data become available, are:

- 98,581 AFY for underflow out of the WDWA towards the down-gradient axis of the Valley;
- 12,403 AFY for underflow to non-districted areas to the north, south, and west; and
- 27,556 AFY by pumping extraction (significantly overstated in the current model).

The current C2VSim-Kern overdraft for the WDWA, which uses the overstated higher value of pumping, is estimated to be -46,200 AFY (rounded up here to 47,000 AFY to account for uncertainty in the model). This deficit in the water budget is met in the C2VSim-Kern model by approximately 46,000 AFY that enters the groundwater flow system from groundwater storage. Because groundwater pumping is overstated in C2VSim-Kern, the current simulated change in groundwater storage is also overstated and is likely significantly lower (i.e.~22,000 AFY). Taking into account future conditions due to climate change (i.e. reduced precipitation and recharge) and an associated increase in pumping extraction from the current 3,000 AFY to 5,400 AFY, the change in storage could conservatively increase to approximately 30,000 AFY. This adjusted estimate of change in groundwater storage is still significantly less than that derived from the current C2VSim-Kern model. Because actual discharge by pumping extraction is approximately 3,000 AFY, the majority of the modeled change in groundwater storage for the WDWA is due to downgradient groundwater underflow out of the WDWA towards adjacent management areas generally to the north and east. Said another way; even if all pumping were to cease in the WDWA, a deficit (and resultant decrease in groundwater storage) would still exist due solely to groundwater underflow leaving the WDWA toward the axis of the basin. This natural phenomenon, which is possibly being accelerated by pumping in adjacent downgradient GMAs, is beyond the control of the WDWA.

C2VSim-Kern Future Conditions

A total of six C2VSim-Kern future-conditions model scenarios were developed by Todd Groundwater for the KGA for the KCS as a whole (KGA Umbrella GSP Attachment H). Future-conditions scenarios are not available for the WDWA at this time. Three of these KCS scenarios are for “baseline” conditions, i.e. scenarios that do not consider water management actions:

- Future Baseline Conditions: Repeat historical hydrology with expected future water supply;
- 2030 Climate Conditions: Adjust historical hydrology for 2030 climatic conditions and expected water supply; and
- 2070 Climate Conditions: Adjust historical hydrology for 2070 climatic conditions and expected water supply.

The other three future-conditions scenarios are the same as above but include proposed water management actions (i.e. SGMA and other projects). Future-conditions results for the KCS as a whole are:

- Future Baseline Conditions;

- No Projects: shortage/deficit of -324,326 AFY
- With Projects: surplus of +85,578 AFY

- 2030 Climate Conditions;
  - No Projects: shortage/deficit of -372,120 AFY
  - With Projects: surplus of +46,829
- 2070 Climate Conditions;
  - No Projects: shortage/deficit of -472,336 AFY
  - With Projects: shortage/deficit of -45,969 AFY

It should be noted that C2VSim-Kern is uncalibrated, particularly with regard to the groundwater flow system (i.e. geologic complexity, aquifer storage parameters, and hydraulic conductivity). The lack of calibration may significantly affect the modeled change in groundwater storage and groundwater underflow. For purposes of this Chapter GSP, it is assumed that this issue will be addressed in the coming years and any changes will be reported in the relevant update report.

2.7.3 Surface Water

All significant surface and imported water delivered by the Aqueduct to the WDWA is utilized for agricultural irrigation, except for minor amounts diverted for industrial use, when available. The supplies sourced from the Aqueduct are primarily SWP water, along with some supplemental import water purchases, although not all supplemental water is from the SWP. Current annual surface water deliveries (i.e. all Aqueduct sources) are estimated at approximately 266,290 AFY. The C2VSim-Kern average annual Aqueduct deliveries to the WDWA for the WY 1995-2014 period are approximately 272,000 AFY. The C2VSim-Kern evapotranspiration of applied water (ETAW) for this period is 241,000 AFY, for a balance of 31,000 AFY potentially available for groundwater recharge. For comparison purposes, the C2VSim-Kern ETAW in 1989 was 287,000 AFY and in 2015 it was 257,000 AFY. **Figure 25** presents annual surface water deliveries to the combined WDWA.

2.7.4 Source and Point of Delivery of Imported Water Supply

The sources of imported surface water used for irrigation in the WDWA are the SWP and other supplemental surface water delivered via the Aqueduct to the member water districts of the WDWA. Member water-district infrastructure for delivery of Aqueduct water is detailed in their individual AWMPs, which are available on their respective websites.

2.7.4.1 State Water Project (SWP)

Two types of contract water are available from the SWP, including a contract supply of “Table A Water”, and surplus “Article 21 Water”. Table A Water takes its name from an exhibit to the contract between the DWR and the SWP contracting agencies that serves as the basis for

allocating surface water among the agencies. Due to a variety of factors, including hydrologic conditions, reservoir storage capacity, and projected runoff, the SWP cannot deliver full Table A Water allocations in most years. Accordingly, a percent allocation is set each year and is applied to each contractor's Table A Water amount. Deliveries to the WDWA from the SWP are via the California Aqueduct (GEI, 2019).

While the reliability of SWP water is less than was anticipated when the contracts were executed, a contract amendment, introduced in the Monterey Agreement of 1994, put agricultural and urban contractors on equal footing with respect to the allocation of water supply during shortages. Prior to the amendment, agricultural contractors were burdened with a larger share of any shortages (Amec, 2015; GEI, 2019).

Article 21 Water cannot be scheduled and must be taken when declared to be available. The following conditions govern the availability of Article 21 Water:

- Available only when deliveries do not interfere with Table A allocations and SWP operations;
- Available only when excess water is determined to be available by DWR;
- Available only when conveyance capacity is not being used for SWP purposes or scheduled SWP deliveries; and
- Cannot be stored within the SWP system. In other words, contractors must be able to use the Article 21 water directly or store it in their own system.

Article 21 Water is typically only available during the December through March wet months of the year (GEI, 2019). **Figures 27a** through **27c** present the infrastructure utilized for the delivery of import water to the three members of the WDWA. Average Article 21 deliveries to the combined WDWA member water districts over the period between 1995 and 2017 were approximately 23,878 AFY (KGA, 2019).

2.7.4.2 Central Valley Project (CVP)

In 1973, DWR completed the initial facilities of the SWP, including the main line of the California Aqueduct. Portions of the SWP were constructed for use in conjunction with the facilities of the CVP. As the State and Federal projects developed, a group of water users planned the Cross Valley Canal as a means of taking delivery of CVP water conveyed through the California Aqueduct. The KCWA was formed in the 1960s to contract with the DWR for the importation of SWP water to Kern County. The California Aqueduct, the SWP's principal conveyance feature, transports water from the Delta along the western side of the San Joaquin Valley to the KCS. Individual water districts holding contracts with KCWA have turnouts directly from the Aqueduct into their service areas or receive water via the Cross Valley Canal. The Cross Valley Canal was completed in 1975 and, in 1976, the water users entered into three-party contracts with DWR and the Department of Reclamation. Under these contracts, CVP water available to Reclamation

in the Sacramento River Delta can be pumped by the SWP's Harvey O. Banks Pumping Plant into the California Aqueduct for delivery to the Tupman turnout, where this water is diverted into the Cross Valley Canal. This Federal water conveyance, which is subordinate to conveyance of SWP water, can then be delivered to water users in the KCS (GEI, 2019).

2.7.5 Oil field Produced Water

There are currently 16 oil and gas fields or portions thereof in the WDWA (**Figure 26**). Productive oil and gas reservoirs (pools) include:

- Tulare Formation (Pleistocene);
- Etchegoin Formation (Pliocene);
- Monterey Formation (Miocene);
- Temblor Formation (Oligocene); and
- Kreyenhagen Formation (Eocene).

Oil field produced water in western Kern County typically contains entrained oil, elevated TDS, and other constituents. Because of this, oil field produced water is unsuitable for any beneficial use without extensive treatment. Produced water is managed by either recycling it for enhanced oil recovery (EOR) operations, such as steam/cyclic steam flooding or water flooding, or by exempted disposal in deeper zones. Both of these activities are under the regulatory oversight of the DOGGR and the US EPA. Produced water used for steam or water flood EOR is typically reinjected under permit into the same geologic zone from which it was produced (e.g., Tulare or Etchegoin Formations) to help maintain oil reservoir pressures and sweep residual oil towards planned oil extraction wells. During this process, a portion of the water that is recycled is inevitably lost to the geologic formations within the field or to the process of steam generation, etc. In addition, so called "*make up water*", from freshwater sources like the Aqueduct, may be added to the process depending on field conditions. Reinjection of produced water back into the zone from which it was extracted potentially helps to mitigate the rate of local land subsidence. It is important to clarify that the type of EOR discussed here is not hydraulic fracturing.

Disposal of brackish and saline oil field produced water in Western Kern County has typically employed two methods: (1) evaporation ponds; or (2) reinjection into exempt aquifers identified for this purpose pursuant to regulations of the Federal UIC Program. The UIC is administered in California under the oversight of the DOGGR and the US EPA. Due to water quality concerns, many of the produced water disposal ponds in Kern County have been closed. Consequently, reinjection into exempt aquifers has become the primary method of produced water disposal. Aquifers identified for permitted disposal reinjection are by design isolated from nonexempt underground sources of drinking water. As with the EOR methods described above, disposal-well reinjection does not involve, nor is it in this case related to, hydraulic fracturing.

As part of the aquifer exemption (AE) process, oil producers are required to complete a detailed geologic study of the zones selected for reinjection. When reviewing applications for AE permits, DOGGR consults with the SWRCB and/or the relevant RWQCB. A key requirement of this multi-agency review for AE approval is to ensure that oil field reinjection activities do not impact designated underground sources of drinking water.

In summary, a significant percentage of the oil field produced water in the WDWA is either recycled into the same geologic zones it was produced from for the purpose of EOR or is sequestered in deeper zones that are isolated from underground sources of drinking water. Like groundwater in the WDWA in general, produced oil field water is naturally degraded and exhibits elevated levels of TDS. The concentrations of TDS and crude oil residual in untreated produced water make it unsuitable for any beneficial use without treatment.

Oil field activities, including land subsidence associated with the extraction of oil and gas, are under the oversight of DOGGR, and are therefore outside the control of the WDWA. This element will be assessed further as part of the WDWA MNP and the KGA land subsidence monitoring plan. Data and findings will be reported during the first five-year reassessment period. **Table 1** provides a summary of produced water statistics for the selected oil and gas fields found within the WDWA.

2.7.6 Sustainable Yield

Unique to the WDWA is the fact that all sources of groundwater (e.g. underflow, recharge etc.) are eventually degraded due to the geology and are unsuitable for most uses. Therefore, the brackish groundwater is considered as "*outside*" the water balance unless blended or treated. As defined by SGMA, Sustainable Yield means the maximum quantity of water, calculated over a base period representative of long-term conditions in a basin, and including any temporary surplus; which can be withdrawn annually from a groundwater supply without causing an undesirable result, such as a significant change in groundwater storage or impacts to water quality. The WDWA relies almost entirely on imported surface water to meet current and projected demand. Groundwater use in the WDWA is chiefly limited to blending because of the documented poor quality of WDWA groundwater. Current pumping is on the order of 3,000 AFY. A vast majority of the C2VSim-Kern-modeled change in groundwater storage for the WDWA is therefore not related to groundwater pumping. Instead it is due to brackish groundwater underflow moving downgradient out of the WDWA towards adjacent management areas generally to the north and east. This natural condition, which could potentially impact water quality in adjacent downgradient GMAs, is possibly being accelerated by pumping in adjacent downgradient GMAs and is beyond the control of the WDWA.

The WDWA normalized sustainable yield (i.e. Native Yield) for the purpose of the preliminary Brackish Water Checkbook approach discussed in **Section 2.7** is conservatively estimated to be 0.15 af/ac., multiplied by all WDWA acreage (i.e. 227,193 acres). This results in a volume of approximately 34,079 AFY. If the poor water quality, minimal levels of pumping in the WDWA, the volume of C2VSim-Kern-modeled underflow (~111,000 AFY) leaving the WDWA, and the potential treatment and potential reuse of oil field produced water are accounted for, a Native Yield range of 0.15 af/ac. to 0.30 af/ac. may be supportable. If applied, it would result in a potential Native Yield of 34,079 AFY to 68,158 AFY that could be utilized for blending or treatment for conjunctive reuse. This volume, depending on the amount of oilfield-produced water utilized, represents approximately 30%-60% of the current total C2VSim-Kern-modeled brackish groundwater underflow leaving the WDWA.

2.7.7 Groundwater Storage

The assessment of the quantity and extent of groundwater in the subsurface, and the amount of water that can be sustainably extracted for use, is dependent on the understanding and monitoring of a myriad of factors of a complex natural system; none of which can be determined with absolute certainty. This is because all of these systems are interrelated in some fashion and most are transitory through time. As a result, the WDWA will use directly observable groundwater elevation data as a proxy for determining change in groundwater storage.

Key hydraulic properties used to define changes in storage of groundwater within the saturated parts of an unconfined aquifer system are specific yield and specific retention (irreducible storage). Specific yield and specific retention are functions of sediment porosity and moisture retention characteristics (Faunt et al., 2015; Todd, 2008). Specific yield plus specific retention is equal to sediment porosity. These two properties represent and govern the reversible uptake and release of water to and from storage in unconfined aquifers. In its simplest form, specific yield is a volumetric fraction of the bulk aquifer volume, representing the amount of water that an aquifer yields when it drains under the force of gravity, the results of which are observable by changes in water table elevations. Storativity is defined as the amount of water an aquifer releases from, or takes into, storage per unit surface area of the aquifer per unit of change in head. In unconfined aquifers, storativity is equal to specific yield.

The availability of storage capacity changes with the amount of groundwater withdrawn or recharged. For unconfined aquifers, which comprise a majority of the well completions in the WDWA, a change in storage is expressed as the product of the volume of the aquifer lying between the water table (i.e., groundwater elevation) at the beginning and end of a period of time and the average specific yield of the formation (Todd, 2008). Based on the current preliminary KGA model, the average WDWA groundwater-in-storage during the WY 1995-2014

period is estimated to be 42,400,000 AF. One acre-foot is equivalent to approximately 325,851 US gallons of water.

2.7.8 Water Budget Baseline and Projected Conditions

As previously noted, there is a general lack of representative water budget data available for the WDWA, including changes in groundwater storage. This condition will be remedied by implementation of the MNP discussed in **Section 4.0**. The MNP will collect representative groundwater elevation data for the purpose of, among other things, assessing for lowering of groundwater levels, calculation of changes in groundwater storage and monitoring for land subsidence. The WDWA water budget will be assessed and revised during the first five-year reassessment period as additional representative data become available. For the purpose of this initial submittal, the WDWA is relying on the Brackish Water Checkbook approach to estimate total water supply and demand **(Section 2.7.2.1).** Additionally, the Brackish Water Checkbook and C2VSim-Kern model are being used as a framework for revising the water budget components based on data collected in the coming years. Because of the reliance on Aqueduct water as the primary source of irrigation, the historic use of groundwater has been primarily for blending due to high levels of TDS. Assuming projected climate change estimates are realized, it is likely that projected water budget components over the GSP implementation period of 2040 and beyond will change and evolve as will groundwater and land use management practices. It is expected that pumping volumes for the purpose of blending would increase to approximately 5,400 AFY by 2030 and beyond, up from the current 3,000 AFY.

2.8 Existing/Ongoing Water Resources Programs/Policies

Knowledge of existing and ongoing water resource programs and a close working relationship with the respective lead agencies are key to successful groundwater sustainability planning and management. The sections below discuss some of the key programs utilized to help coordinate data between the various KGA Chapter GSPs.

2.8.1 Existing Monitoring Programs

Various public agencies currently collect and coordinate groundwater monitoring data for wells within the KCS. Based on current conditions, these programs and proposed MNP monitoring activities will not limit the operational flexibility in the WDWA. Where applicable, several databases were utilized to prepare the Basin Setting and other sections of this Chapter GSP for the WDWA. Chief among these are the following:

2.8.1.1 Local Agency Monitoring Programs

Within the WDWA, there are two local groundwater monitoring programs. As reported elsewhere in this Chapter GSP, those agencies are the KCWA, which manages and maintains the

CASGEM Program, and the WWQC, which includes the WDWA. The WWQC began an annual groundwater monitoring program in 2018. These programs will be used as the primary basis of the WDWA MNP described in more detail in **Section 4.0** of this Chapter GSP.

2.8.1.2 Groundwater Ambient Monitoring and Assessment Program (GAMA)

GAMA was implemented in 2000 by the SWRCB to integrate existing groundwater monitoring programs in order to better assess and monitor groundwater quality. The GAMA Basin Priority Project assessed public water system wells to identify and understand risks to drinking water supply. Historically, the program has sampled over 2,900 public and domestic drinking water supply wells. Relevant data from this program will be utilized to compare with the future MNP data for this Chapter GSP in order to quantify and interpret historic and contemporary groundwater level and quality trends.

2.8.1.3 GeoTracker and EnviroStor Databases

GeoTracker is a SWRCB database which allows the agency to manage and share data related to sites that currently impact groundwater or have the ability to adversely impact groundwater resources. Data available on GeoTracker include records of Leaking Underground Storage Tank (LUST) sites, Department of Defense sites, and various permitted activities such as land disposal sites, and oil and gas production sites. GeoTracker is unique in that it collects data from multiple agencies, making it very useful.

The EnviroStor database is managed by the DTSC. EnviroStor provides records of site cleanup activities beginning in 2009 or later. EnviroStor only maintains records of sites where the DTSC is the lead agency and is typically focused on soil cleanups, many of which could have impacted groundwater as a secondary condition. Both GeoTracker and EnviroStor were utilized to assess for potential anthropogenic impacts to groundwater in the WDWA.

2.8.1.4 California Statewide Groundwater Elevation Monitoring Program (CASGEM)

The CASGEM program was created by the State legislature as part of the 2009 California Comprehensive Water Package, which established a coordinated statewide program to collect groundwater elevations and facilitate cooperation between local monitoring agencies and the DWR. The CASGEM database was utilized to search for representative groundwater level and well completion data within the WDWA.

2.8.1.5 Irrigated Lands Regulatory Program (ILRP)

The goal of the ILRP is to protect receiving waters (natural surface waters) from impairment associated with agricultural runoff, tile drain flows, and stormwater flows from irrigated crops and fields. To augment existing surface water data collected by the program, the ILRP was to have started collecting groundwater data beginning in late 2018. The focus of the groundwater

sampling will be to assess water quality related to individual domestic wells. The WWQC, of which the WDWA is a member, has been cooperating with ILRP surface water sampling efforts since its inception in 2003. While the number of individual domestic wells within the WDWA is believed to be limited, the requirements and goals of the ILRP will be considered in the **Section 4.0**.

2.8.1.6 Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS)

CV-SALTS is a stakeholder-managed program whose main objective is to facilitate salt and nitrate management and reduction strategies in the Valley. The objectives and goals of the CV-SALTS program are foundational to those of SGMA and the KCS GSP. Key CV-SALTS goals are:

- Ensure safe drinking water supply;
- Achieve balanced salt and nitrate loading of surface water and groundwater; and
- Implement the long-term restoration and management of impaired water bodies.

Sampling, when required, is conducted in association with explicit WDRs specified by the State and relevant RWQCBs. These typically include, among other things, sampling for chloride, sodium, nitrate/nitrite, and EC. As mentioned, because of the naturally occurring elevated levels of TDS found throughout the WDWA, the WWQC has engaged the CV-SALTS Technical Committee to review its recent draft BPAW prior to submittal to the State. The subject plan recommends the de-listing of MUN and AGR as beneficial uses for perched and unconfined/semi-confined groundwater found beneath a portion of the WDWA. The WDWA plans to coordinate the Chapter GSP MNP with the ongoing sampling activities being conducted by the WWQC to support the BPAW.

2.8.2 Monitoring Data Gaps and Uncertainty

A coordinated (and standardized) database and calibrated groundwater numerical flow model is necessary to ensure that all relevant data is input in a timely manner for the purpose of ongoing sustainability planning. Planning discussions within the KGA at large regarding this topic are ongoing. To achieve coordinated monitoring, data must be collected and reported by local well owners in a systematic way on contemporaneous schedules. To the extent feasible and practical, until a KCS-wide data system is identified, components of the above referenced existing programs and databases will be utilized to help address identified data gaps. It is not anticipated that these plans will significantly limit the flexibility of operations in the WDWA as they will be implemented in cooperation with well owners, adjacent groundwater management areas, existing programs such as the WWQC, and established water banking operations being utilized by the WDWA and its member landowners. Minimum sampling parameters include:

- Groundwater elevation;
- Annual extraction (pumping) volumes; and

- Groundwater quality.

These data, along with surface water supply volumes provided by the WDWA members, will be utilized to assess identified data gaps, and the potential for undesirable results in order to update WDWA water budget components, including precipitation, ETo, sustainable yield and groundwater storage. It is important to note that per SGMA requirements, water budgets must include current, historic, and future conditions. Projected water budgets will be used to estimate and refine future conditions of supply, demand in response to Umbrella GSP implementation, and to identify any new or evolving data gaps or uncertainties pertaining to these water budget components.

Within the WDWA, existing monitoring for representative groundwater occurrence and elevation levels is recognized as a key data gap. A WDWA-specific MNP will be designed to address, to the extent feasible, uncertainties that would affect the efficacy of the implementation of the KGA Plan and, therefore, the WDWA's ability to assess whether the WDWA is being managed sustainably. Identified data gaps within the WDWA management area are:

- Representative groundwater occurrence, groundwater elevations, groundwater trends, groundwater quality and flow directions, and annual extraction volumes; and
- WDWA-specific water budget components and modeling.

2.9 Plans to Address Identified Data Gaps

Preparation and implementation of a comprehensive MNP will directly address the identified data gaps by coordinating a systematic and contemporaneous collection of representative groundwater monitoring and pumping data in consultation with adjacent GMAs. The data will be utilized to update water budget and model components.

2.10 Groundwater Management Area

For the purpose of this Chapter GSP, the WDWA is considered a single combined GMA. The rationale for this approach is threefold:

1. The similar hydrogeologic conditions found across the WDWA and the occurrence of poor-quality brackish groundwater identified throughout the WDWA;
2. The ability to cost effectively leverage and better coordinate future monitoring and adaptive management actions due to the similarities of organizational structure among the WDWA member Districts, as well as similar groundwater use by stakeholders that are served by the WDWA; and

3. The ability to streamline communications, coordination, and planning of sustainability objectives and management actions between the WDWA and adjacent KGA GMAs that are implementing their individual Chapter GSPs.

As designated, the WDWA will operate under a single set of MTs and MOs which, while focused on the WDWA, are also designed to coordinate, to the extent feasible, with adjacent GMAs. As part of the SGMA-required annual update and five-year reassessment process, the status of the WDWA GMA will be re-evaluated and adjusted, as needed. In the unlikely event of internal conflicts between individual member districts of the WDWA, the WDWA Board will consider and resolve the item pursuant to its established rules.

2.11 WDWA Sustainability Goals

Sustainable management in the KCS will result from the implementation of projects and management actions at the member-agency level to maintain its respective use of groundwater within the sustainable yield of the Subbasin, operate at or above established measurable objectives, and operate above established minimum thresholds. The sustainable yield, measurable objectives, and minimum thresholds have been developed based on available technical information and will be reviewed and updated as additional data are collected, as required by SGMA.

Sustainability goals for the WDWA are designed to support the goals proposed in the KGA umbrella GSP, address identified and projected issues and hydrogeologic data gaps, and mitigate the potential for undesirable results within the WDWA. The goals will be achieved through the implementation of coordinated MTs and MOs, such as specific administrative policies, projects, and plans designed to enhance the sustainability of groundwater resources within the WDWA, and by association the KGA at large. It is not anticipated that County land use plans, as currently formulated, will affect the ability of WDWA to achieve its planned sustainability goals, nor will WDWA activities, as part of the GSP, adversely affect County land use planning. The coordination process established in development of the KGA Umbrella GSP and memorialized in the KCS Coordination Agreement will ensure that the KCS is managed as a cohesive unit, and that the individual GMAs within the KCS work collaboratively towards sustainability.

The sustainability goals for the WDWA are:

- Collect additional representative hydrogeologic information to more fully characterize and model the occurrence, condition, and elevation of groundwater beneath the WDWA through the implementation of a comprehensive MNP;
- Leverage, to the extent feasible, the harvesting and treatment of naturally degraded groundwater underflow leaving the WDWA for the twin benefits of conjunctive reuse and

mitigation of potential adverse effects to better quality water in adjacent downgradient districts; and

- Mitigate the potential for the chronic lowering of groundwater levels and significant reduction of groundwater in storage through the coordinated implementation of minimum thresholds (MTs) and MOs within WDWA areas that are adjacent to other downgradient GMAs.

2.12 WDWA Undesirable Results

Based on the current understanding of available WDWA data, an assessment of the six undesirable results identified in SGMA found that two of these do not directly apply to the WDWA. These being:

- Seawater intrusion; and
- Depletion of interconnected surface water.

Of the remaining four, further assessment is provided in the following subsections. The four potential undesirable results are:

- Chronic lowering of groundwater levels;
- Significant reduction of groundwater in storage;
- Degraded water quality;
- Land subsidence.

2.12.1 Seawater Intrusion

The WDWA is located more than 40 miles inland from the Pacific Ocean. Seawater intrusion to aquifers is not feasible, and will not affect groundwater quality within the WDWA, which is naturally brackish. Therefore, seawater intrusion is not considered further in this Chapter GSP.

2.12.2 Depletion of Interconnected Surface Water

Interconnected surface water systems are defined by the State as surface waters that are known to be hydraulically connected by a "*…continuous saturated zone*" to an underlying aquifer (DWR, 2016). As such, there are no interconnected natural surface water systems in monitored areas associated within the WDWA. Various small creeks and drainages within the WDWA are ephemeral and only carry water for brief times during the wet season, usually only immediately after intense precipitation events. The dryland portion of the KNWR that overlaps with the WDWA is not irrigated and relies on seasonal precipitation for habitat maintenance. The scant volume of annual precipitation, and high level of ETo in the WDWA, militates against the likelihood of interconnected surface water systems. Further, recent WWQC monitoring activities have found that the presence of perched groundwater in the WDWA is greatly reduced and

sporadic. As such, depletion of interconnected natural surface water and associated groundwater dependent ecosystems are not considered a recognized or feasible undesirable result. Therefore, no MTs or MOs will be established at this time. Further assessment will be conducted as part of the proposed monitoring Network Plan. Any changes in this finding will be reported in the relevant GSP update report.

2.12.3 Chronic Lowering of Groundwater Levels

The chronic lowering of groundwater levels is the point at which significant and unreasonable impacts over the GSP implementation horizon, as determined by the depth/elevation of water, affects the reasonable and beneficial use of, and access to, groundwater by overlying users. In the KGA, an exceedance is triggered when the MT for groundwater levels are exceeded by at least three adjacent management areas that collectively represent at least 15% of the subbasin or, if non-contiguous GMAs, comprising 30% or more of the subbasin, as measured by the acreage of each management area that exceed their respective MTs (GEI/KGA, 2019).

Groundwater levels in the WDWA are being reduced primarily by the volume of underflow migrating downgradient towards the axis of the basin. Within the WDWA extractions by pumping have been limited due to the demonstrated naturally degraded quality of groundwater which is of little practical beneficial use. There is presently a lack of representative data in the WDWA sufficient to assess for potential chronic lowering of groundwater elevations with a high level of certainty, especially along the downgradient eastern border of the WDWA. A review of currently available data, including, but not limited to, various recorded WDWA well pumping volumes and the individual AWMP reports for the WDWA, indicate there has been little historic reliance on groundwater for the purpose of irrigation in the WDWA due to the availability of Aqueduct and other imported surface water.

The current estimated volume of pumping for irrigation is less than 2% of total demand (i.e., ~3,000 AFY). Of further relevance is the C2VSim-Kern modeled water budget for the WDWA, has identified approximately 111,000 AFY of brackish groundwater underflow migrating from the WDWA towards adjacent downgradient GMAs. The WDWA is studying the feasibility of a project to harvest a portion of the lost underflow by focused pumping for treatment and conjunctive reuse. If determined to be viable, this project could substantially increase the quality and quantity of groundwater retained in the WDWA water budget. In the interim, while MNP data are being collected and the C2VSim-Kern model is refined and calibrated, the WDWA proposes to utilize a groundwater well hydrograph and a series of CV2SimFG-BETA simulated hydrographs to determine historic and projected groundwater trends along its eastern boundary. These data will also be used to establish provisional informational MOs and MTs for the area of the WDWA directly adjacent to the aforementioned down-gradient GMAs. Based on the limited pumping in the WDWA, there are no MTs or MOs proposed for groundwater

elevation for the remaining interior areas of the WDWA at this time. This approach allows for sentry monitoring along the WDWA's downgradient northern and eastern borders with the objective of sustainable management via the harvesting and treatment of a portion of the groundwater underflow as it leaves the WDWA. If reuse is determined to be feasible, it will significantly reduce the potential for an undesirable result related to the accelerated chronic lowering of groundwater levels and significant reduction of groundwater in storage.

2.12.3.1 Groundwater Dependent Ecosystems

The following factors weigh against the presence of groundwater dependent ecosystems in the WDWA:

- The sporadic occurrence and further diminution of the already limited amount of perched water in the WDWA due to drought, physiographic and hydrogeologic conditions and less agricultural surface runoff as a result of improved irrigation and water conservation methods;
- The overall general depth to the unconfined/semiconfined groundwater zone (~200 feet bgs);
- The lack of interconnected surface water systems in the WDWA; and
- The predominately brackish quality of groundwater.

As stated elsewhere in this Chapter GSP a small portion of the WDWA in the LHWD overlaps with the Kern National Wildlife Refuge. These lands are designated as "Uplands Habitat". As such, the area is dry rangeland and, with no operating wells, relies solely on precipitation for its only source of water. To the south, in the Belridge WSD, are portions of the 3,100 acre Lokern Ecological Reserve (LER). Within the WDWA the LER consists of small, scattered and generally non-contiguous parcels (**Figure 10c**). A review of Google Earth imagery shows those portions of the LER in the WDWA are likely Valley sink scrub, and/or Valley saltbrush scrub habitat (aka Alkali Scrub). Those portions of the LER in the WDWA appear to consist entirely of dry, non-irrigated scrub lands that, with no operational wells, rely on annual precipitation as its source of water.

Larger, more contiguous blocks of the LER are present further south of the WDWA roughly between the towns of Lokern and Tubman. The California Department of Fish and Wildlife website describes the LER at large as consisting of marsh, valley sink scrub, and valley saltbush scrub habitat. Although not likely present in the WDWA, vegetation in the marsh habitat includes tule, cattail and other common marsh species.

Further assessment of these areas will be conducted as part of the proposed monitoring Network Plan. Any change to current conditions regarding groundwater dependent ecosystems in the WDWA will be discussed in the relevant annual updates and five-year reassessment

reports as required by SGMA. In the meantime, impacts to groundwater dependent ecosystems will not be evaluated further, and no MTs or MOs are warranted at this time. **Figures 27d through 27f** provide the additional supporting information pertaining to groundwater dependent ecosystems in the KCS.

2.12.4 Significant Reduction of Groundwater in Storage

Change in groundwater in storage cannot be measured directly. In its simplest form, a change in groundwater in storage is reflected by a change in groundwater elevations. A significant reduction in groundwater storage is the point at which significant and unreasonable impacts, as determined by the estimated amount of groundwater in the subbasin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended drought period, which is proposed to be 10 years for the purpose of the KGA GSP. Within the KGA, an undesirable result is determined when groundwater elevations, which act as the proxy for groundwater storage, are depleted to elevations lower than the respective groundwater-level MTs in at least three adjacent management areas that collectively represent at least 15% of the Subbasin or, if non-contiguous GMAs, comprising 30% or more of the Subbasin, as measured by the acreage of each management area that exceed their respective MTs (GEI/KGA, 2019).

The current KGA C2VSim-Kern simulated water budget for the WDWA indicates that changes in groundwater storage in the WDWA management area are largely attributable to non-pumping activities, such as the downgradient underflow of brackish groundwater from the WDWA towards adjacent GMAs and the axis of the KCS. As such, this natural condition, which may be accelerated by pumping in adjacent downgradient GMAs, is beyond the control of the WDWA. As described in **Section 2.11.3**, additional groundwater elevation data and numerical modeling is required, especially along the WDWA's downgradient eastern and northern borders, in order to fully assess this important hydrologic parameter with a high level of certainty. Data gaps related to groundwater elevation (a proxy for change in storage) will be addressed by the collection of representative groundwater elevation data during the first five-year reassessment period. In the interim, the MTs and MOs for this component will be assessed as presented in **Section 3.3.2**.

2.12.5 Degraded Water Quality

Degraded groundwater quality is defined in SGMA as the point at which significant and unreasonable impacts occur over the GSP planning and implementation horizon, as caused by water management actions that affect the reasonable and beneficial use of, and access to, groundwater by overlying users. In the KGA, this is determined when the MT for a groundwater quality constituent of concern is exceeded in at least three adjacent management areas that collectively represent at least 15% of the subbasin or, if non-contiguous GMAs, comprising 30% or more of the subbasin, as measured by the acreage of each management area exceed their respective MTs (KGA, 2019).

Due to the overall naturally degraded quality of WDWA groundwater, as documented by the various groundwater studies presented in this Chapter GSP, no water quality MTs or MOs are proposed for the interior areas west of the California Aqueduct in the WDWA. Groundwater within the WDWA has been documented to be predominately degraded by elevated concentrations of TDS due primarily to the presence of naturally occurring basin-fill sediments derived from marine dispositional environments and associated saline connate waters. These conditions have been documented to exist before widespread development of the west side of the KCS and are outside the control of the WDWA. Because of the poor quality water, agriculture within the WDWA relies primarily on surface water and other imported water provided by the Aqueduct for irrigation. Historically, the primary use of brackish groundwater has been for blending, when deliveries from the Aqueduct are low. Groundwater with TDS concentrations in excess of 2,000 mg/L, which is common in the WDWA, is considered unsuitable for designated beneficial uses without blending or treatment. Because of the presence of naturally occurring brackish groundwater beneath a majority of the WDWA, the WWQC has prepared a BPAW for regulatory review that recommends delisting the designated agriculture and municipal beneficial use for perched and unconfined/semiconfined groundwater under a significant portion of the WDWA.

The current KGA C2VSim-Kern model water budget for the WDWA estimates there is a significant volume of combined natural downgradient groundwater underflow (~111,000 AFY) migrating from the WDWA towards adjacent down-gradient GMAs and the axis of the KCS. This underflow is predominantly brackish. This condition, which may be accelerated by groundwater pumping in adjacent downgradient GMAs, is beyond the control of the WDWA. The downgradient migration of brackish groundwater has the potential to cause an undesirable result by impacting better quality groundwater found in adjacent downgradient GMAs. Therefore, assessment of groundwater quality within the WDWA will focus on sentry monitoring of the boundary between the WDWA and affected down-gradient GMAs to the, northeast, east and southeast in the KCS. The purpose of the sentry monitoring will be to provide timely notification to adjacent GMAs in the event that existing water quality related to TDS concentrations changes significantly. Sentry monitoring will be implemented for groundwater quality along the boundary area that lies generally east of the California Aqueduct in the WDWA. The sentry monitoring activities will be detailed in the MNP and will be coordinated with the relevant adjacent GMAs.

As part of GSP implementation groundwater quality will be assessed in any new wells drilled in the interior of WDWA to help inform planning and implementation of future sustainable management practices and projects.

2.12.6 Land Subsidence

In the KGA, an undesirable result for land subsidence is defined by significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a coordinated basin wide GSP subsidence monitoring plan (KGA, 2019).

Based on recent satellite-based Interferometer Synthetic Aperture Radar (InSAR) data for the period 2007 to 2011, two localized areas of land subsidence were identified in the WDWA: one is adjacent; and just west of the portion of the Aqueduct that lies immediately north and south of the town of Lost Hills (approximately Aqueduct mile post 195-203 and milepost 205-215). Subsidence here is estimated to range between 4 inches to 15 inches. This portion of the Aqueduct coincides with an embankment failure in June 2011 at Milepost 208. This incident was confirmed by surveying, but a specific cause was not identified at the time of the breach. It is important to emphasize that agricultural groundwater pumping in this area has historically been limited due to poor groundwater quality. The other area of subsidence is located approximately midway between town of McKittrick and State Highway 46 and is likely associated with the Belridge Anticline oil field complex. InSAR subsidence there has reportedly ranged from 4 inches to over 25 inches (**Figure 28a**).

A subsequent update to the earlier KGA InSAR data for the period 2015 to 2016 found improved conditions, with the areas adjacent to the town of Lost Hills (e.g. Mileposts 195-215) mostly displaying only minimal subsidence (approximately 2 inches to 6 inches). The areas around the Belridge Anticline oil field also improved somewhat, with the exception of areas immediately proximal to the oil fields, which appear to have remained more or less unchanged from the findings of the earlier InSAR survey (**Figure 28b**). The rebound of topographic surface elevation indicated by the latter InSAR survey in several areas suggests that some of the WDWA subsidence may have a reversible (elastic) component that benefited from the increased winter precipitation during 2015 to 2016.

There currently is no definitive evidence that the subsidence adjacent to the aqueduct near Lost Hills (i.e., Mile Posts 195-215), or elsewhere in the WDWA, is attributable to a single factor. Given that groundwater pumping in the WDWA is limited, the measured subsidence may be the result of a combination of factors, including, but not limited to, oil well extraction, sub-regional geologic structural forces, such as geologic folding or compression, and/or loss of soil moisture in the shallow subsurface via accelerated ETo due to prolonged drought. Still other factors include existing deficiencies in the aqueduct structure itself that could result in shallow differential settlement. Assessment by a combination of iterative geodetic techniques over time (e.g. InSAR, established continuous geo-positioning system (CGPS) data, and depth-specific extensometer monitoring will likely be necessary to more definitively identify the cause of the

embankment failure at Mile Post 208, and to monitor for potential future subsidence in the identified area of interest between Mile Posts 195-215.

Inelastic land subsidence related to the potential dewatering of the Corcoran Clay or other clay layers by water-well pumping is recognized as a potential undesirable result in that portion of the WDWA east of the California Aqueduct, between the WDWA boundary with the SWSD and the BVWSD. To monitor for this type of land subsidence going forward, the WDWA will rely on future InSAR studies and other iterative subsidence monitoring techniques (e.g. CGPS, extensometer, etc.) to be implemented over time in coordination with adjacent management areas as part of the KCS-wide land subsidence monitoring program administered by the KGA.

The WDWA will establish a preliminary MO and MT for land subsidence for those areas closest to the Aqueduct in coordination with adjacent GMAs during the first five-year reassessment report. The subject areas are more or less along the downgradient eastern boundary between the WDWA, the Semitropic Water Storage District and the Buena Vista Water Storage District. This includes the area between Aqueduct Mileposts 195 and 215. Based on current InSAR data results, and the limited amount of groundwater pumping in WDWA, subsidence MTs or MOs for areas interior to the WDWA will not be established at this time. Instead, the WDWA will monitor InSAR data and other geodetic subsidence data adjacent to its eastern boundary in order to make any necessary adjustments to its current MT/MO network for land subsidence. It should be noted that subsidence associated with oil and gas activities is under the oversight of DOGGR pursuant to the California Public Resources Code. The WDWA will coordinate and share subsidence data with those operators that are a party to the KGA Umbrella GSP, but oil field related subsidence is outside the control of the WDWA.

2.13 Effects Beyond the WDWA Chapter Area

Assessment of identified undesirable results that could potentially extend beyond the boundaries of the WDWA will be coordinated with adjacent GMAs, as needed, to ensure the integrated and sustainable management of the WDWA and, by extension, adjacent GMAs and the KGA. For example, although these natural systems and conditions are outside the control of the WDWA, underflow of brackish groundwater found to be migrating downgradient from the WDWA, towards areas of better-quality groundwater in response to regional groundwater flow patterns and adjacent GMA pumping, will be assessed in cooperation with the Dudley Ridge (Kings County) and the Semitropic, and Buena Vista GMAs. To help ameliorate the potential for impacts to adjacent water quality, the WDWA will share groundwater level and water quality data with these adjacent management areas, and will work to coordinate relevant groundwater monitoring activities so that sentry monitoring occurs at the WDWA boundaries contemporaneously with sampling activities being conducted at the SWSD and BVWSD. These data will then become the foundation for other WDWA initiated, or joint management actions

with adjacent GMAs, such as detailed groundwater numerical flow modeling to better track and predict brackish water occurrence and migration.

3.0 WDWA MONITORING NETWORK

To reduce the current level of uncertainty pertaining to groundwater conditions and occurrence within the WDWA, a Monitoring Network Plan (MNP) will be prepared and implemented during the first five-year reassessment period after adoption of KGA GSP. The MNP, which will be reassessed and updated as needed based on data results, will be specifically designed to address data gaps and sustainability indicators identified in this Chapter GSP. The MNP will simultaneously promote coordination with adjacent GMAs and GSAs through the collection of representative data necessary to evaluate changing groundwater conditions that may occur during the planning and implementation horizon of the WDWA Chapter GSP. **Figure 29a** presents the proposed MNP wells. **Table 2** presents well construction details for the proposed MNP monitoring wells. To the extent possible, wells included in the MNP will serve as monitor points for both groundwater quality and groundwater elevation and include wells currently being monitored by the Westside Water Quality Coalition (WWQC). New monitoring wells, if any, will funded by the WDWA. Any new wells constructed expressly for the MNP will be permitted, constructed or abandoned pursuant to relevant Kern County and State requirements. To the extent feasible, costs for new wells and monitoring may be shared with the WWQC and/or other adjacent GMAs/GSAs.

3.1 Monitoring Network Objectives and Rationale

As reported in this Chapter GSP, data related to representative aquifer characteristics and groundwater elevation monitoring within the WDWA is limited and have been identified as an important data gap that must be filled for effective implementation of this Chapter GSP over the short-term, and for the assessment and planning of future adaptive management strategies over the long-term and SGMA implementation horizon. Associated groundwater components that rely on representative groundwater level monitoring include, among others, water budget components, and the identified undesirable results of chronic lowering of groundwater levels, reduction of groundwater in storage and land subsidence. Although not identified as requiring a specific MT/MO, due to previously discussed physiographic and hydrogeologic conditions (**Section 2.12.2**), monitoring of perched groundwater will also be conducted in coordination with the WWQC in order to asses for potential changes in the status of depletion of interconnected natural surface water or undesirable results to groundwater dependent ecosystems. Objectives and elements of the MNP will address the need for representative data and help reduce uncertainty for the purpose of sustainability planning. The MNP, once fully implemented, will help achieve the following objectives:

- Acquisition of representative groundwater level and water quality data sufficient to assess and document short-term, seasonal, and long-term groundwater trends related to WDWA

water budgets, groundwater pumping volumes, changes to groundwater in storage, groundwater elevation, and potential future land subsidence;

- Ability to assess for changes in groundwater conditions relative to identified MOs and MTs; and
- Coordination with adjacent management areas by way of contemporaneous scheduled sampling events, mutually sustainable MTs and MOs, and regularly scheduled status meetings to ensure sustainable outcomes.

The rationale for selecting monitoring wells for inclusion in the MNP are:

- Ability to economically meet the overall MNP objectives; and
- Ability to provide representative data based on physical location, age of well construction and aquifer screened intervals.

The MNP shall incorporate the data quality objective (DQO) process as outlined in the US EPA Guidance on Systematic Planning Using the DQO Process. The MNP shall also include a data quality assurance/quality control (QA/QC) plan to guide the collection and assessment of data. Monitoring will include the use of a standardized database and well data collection form. A summary of MNP protocols and a sample well data collection form is provided in **Appendix F**. MNP field activities will be based on the methodologies described in the USGS National Field Manual for the Collection of Water Quality Data as well as Kern County and State well permitting, construction and abandonment regulations. At a minimum, the following sampling analytical methods and monitoring frequency will be implemented as part of the MNP:

Groundwater Sampling Analysis							
Frequency			Indicator Parameter	Reporting Units	Field Measurement	Laboratory Analysis	Analysis Method
Initial Sample	5-Year	Semi-Annual	EC	umhos/cm	•		Field Instrument
			pH	s.u.	•		Field Instrument
			Dissolved Oxygen (DO)	mg/L	•		Field Instrument
			Temperature	°C	•		Field Instrument
		Annual	Nitrate as Nitrogen	mg/L		•	Method 300.0
			TDS	mg/L		•	Method 2540C
			General Minerals – Anions (carbonate, bicarbonate, chloride, sulfate)	mg/L		•	Method 2320B
			General Minerals – Cations (boron, calcium, sodium, magnesium, potassium)	mg/L		•	Method 200.7

Note: C°: degrees Celsius

3.1.1 Monitoring Protocols

Monitoring protocols are designed to detect changes in groundwater elevation levels, groundwater quality, and act as a proxy to assess for changes in groundwater storage. In addition, MNP data will be utilized to assess for potential inelastic subsidence and groundwater flow that may directly affect groundwater levels, quality, or changes caused by groundwater extraction in adjacent GMAs. The WDWA will comport with all KGA-established monitoring protocols and will coordinate its monitoring activities and well access/agreements with adjacent GMAs, GSAs and other established monitoring programs, such as the WWQC **(Appendix G and Appendix H)**. Note: some well access agreements are pending.

3.1.2 Description of Monitoring Network

The modeled overdraft in the WDWA is largely attributed to groundwater underflow leaving the WDWA to the northeast and east. The most critical sustainability criteria to be monitored by the MNP are chronic lowering of groundwater levels associated with groundwater underflow leaving the WDWA, associated groundwater quality that might affect downgradient GMAs, reduction (changes) in groundwater in storage and the potential for significant inelastic land subsidence. The direct measurement of groundwater levels along the northeast and east boundary of the WDWA that is shared with adjacent down-gradient management areas is best suited to provide representative data for this purpose. The geochemical composition of naturally degraded water that may impact better water quality in adjacent down-gradient management area will also be assessed as part of the sentry monitoring implemented as part of the MNP. The location of proposed monitoring wells (including MT/MO regional monitoring wells) in this Chapter are intended to be preliminary and are subject to change in number and/or location as data becomes available. For example, additional monitoring well location(s) in the northeast of the LHWD may be necessary to better characterize groundwater conditions in the area where groundwater underflow is believed to be migrating from the WDWA toward the former bed of Lake Tulare. Data collected as part of the GSP implementation will be utilized to assess the need for MNP modifications and to optimally site new monitoring locations for best technical and economic benefit.

3.1.2.1 Chronic Lowering of Groundwater Levels

Monitoring of representative groundwater levels are an important and obvious metric for determining changes to groundwater storage and thus WDWA and KCS sustainability. The recording of groundwater levels along the northern and eastern boundary between the WDWA and downgradient management areas will also provide insight into changes in groundwater in storage and potential land subsidence. The rationale for focusing the sentry monitoring wells in the MNP along the north and eastern boundaries of the WDWA are:

- The western and southern sides of the WDWA are isolated from other groundwater basins and districts by the Temblor Mountain Range and geologic structures such as the Elk Hills Anticline;
- There is minimal pumping in the WDWA (~3,000 AFY);
- A majority of WDWA groundwater underflow is towards the northeast and east (modeled to be ~111,000 AFY); and
- Groundwater quality in the WDWA is naturally degraded with TDS concentrations often exceeding 2,000 mg/L, making it unsuitable for practical beneficial uses in the WDWA.

The initial MNP will include a minimum of 21 primary wells for monitoring, including three locations currently monitored by the WWQC. The monitoring locations were selected to cover the aquifer zones associated with economic (agricultural) pumping activities (unconfined/semi-confined, and confined). The wells are distributed across the WDWA as follows:

- LHWD: 8 wells
- BMWD: 4 wells
- BWSD: 6 wells

The areal extent of the WDWA is approximately 355 square miles. The well density of the proposed MNP is around one well per every 19.72 square miles. While there is currently no established number for monitoring well density in a basin or management area, for comparison the monitoring well density for a basin recommended by the CASGEM Groundwater Elevation Monitoring Guidelines ranges between one to 10 wells per 100 square miles. The current proposed groundwater monitoring network is therefore capable of collecting representative data of sufficient quantity to define short-term, seasonal and long-term data trends in groundwater and associated surface conditions. To ensure reliable groundwater level data, monitoring events will be scheduled in the late fall and early spring when many irrigation wells are typically idled.

3.1.2.2 Reduction in Groundwater in Storage

Changes in groundwater in storage cannot be measured directly. For the proposed MNP groundwater elevations will be used as a proxy indicator for calculating estimated changes in groundwater in storage. The MNP monitoring well network will be used to gather groundwater elevations and generate groundwater elevation contour maps and discern groundwater flow direction. Based on the density of the proposed monitoring well network there will be sufficient data to utilize groundwater elevation changes as a surrogate for evaluating potential changes in groundwater in storage.

3.1.2.3 Land Subsidence

Land subsidence in the WDWA will be monitored utilizing various iterative geodetic techniques over time including InSAR, surveying of permanent benchmarks, CGPS monitoring, and installation of well extensometers. Special emphasis will be placed on the previously identified area of interest between Aqueduct Mileposts 195-215. CGPS continuously collects geodetic data related to land surface monitoring at established stations within the KCS. CGPS is a reliable method for assessing changes related to geologic processes such a folding or faulting. Extensometers measure a depth- discrete interval in the subsurface. Extensometer data is useful for identifying changes in land elevation that may be caused by groundwater extractions in a specific ground water bearing zone, and together with CGPS and InSAR help provide a more complete understanding of factors contributing to subsidence (GEI 2019). InSAR is a proven technology and is capable of reliably detecting variations of land surface elevations over time on the order of millimeters, particularly when the surveyed elevations of so called "persistent scatterers" of InSAR signals are utilized to ground-truth the results. Persistent scatterers include hard fixed surfaces such as buildings, roadways and intersections, InSAR reflective corners, tanks and other permanent infrastructure that provide a stable reflective surface of known elevation for InSAR signals. Subsidence monitoring and reporting activities in the WDWA will be coordinated with adjacent GMAs and the KGA Land Subsidence Monitoring Plan for the KCS. In the KGA, an undesirable result for land subsidence is defined by significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin-wide coordinated GSP subsidence monitoring plan (KGA, 2019). Oil field related activities, including subsidence, is under the oversight of DOGGR and are therefore outside the control of the WDWA. However, the WDWA will coordinate and share data with DOGGR and oil field operators that are a party to the KGA Umbrella GSP. With few exceptions InSAR data for non-oil field areas in the WDWA indicate there is little or no significant inelastic subsidence at this time. InSAR data and other geodetic data for the WDWA will be evaluated a minimum of every five years.

3.2 Assessment and Improvement of the Monitoring Network and Timelines

As envisioned, the WDWA MNP will be dual-phased. Phase I would be implemented during the initial five-year reassessment period of 2020 to 2025 and would consist of preparing the detailed MNP for review and approval, coordination with adjacent GMAs and the WWQC, and implementation of the subject monitoring activities. A key component of the Phase I MNP will be the assimilation of the initial proposed 21 monitoring wells into the MNP. These locations are spatially located throughout the WDWA boundary areas. If it is determined after further review that some of these wells are either not needed or are unacceptable adjustments will be made to the MNP to better characterize targeted groundwater conditions. All substantive changes to the

MNP will be reported in the relevant update report. The goal of Phase I is to identify and sample a sufficient number of wells to establish representative data within and along the northeast and east boundary of the WDWA where groundwater underflow is migrating from the WDWA. To ensure reliable groundwater level data, monitoring events will be scheduled in cooperation with the WWQC and adjacent GMAs in the late fall and early spring. Phase I will also include completion of the technical and economic feasibility studies for the proposed Project Management Action No.3, (PMA No.3) described in **Section 5.3** of this Chapter GSP. PMA No.3 proposes to harvest a combination of brackish groundwater and oil field produced water for treatment and conjunctive reuse.

Phase II will utilize the Phase I data during the second five-year reassessment period (2030 to 2035) to adjust the monitoring network as needed and coordinate as necessary with adjacent GMAs in order to better maximize the cost effective collection of representative data. A central objective of Phase II is to provide the data necessary to plan and implement adaptive management strategies and projects, such as PMA No.3, which are designed to achieve long term sustainable management of the groundwater resources in the WDWA. Undistricted lands within the WDWA that are subsequently incorporated into the KGA GSP framework will be assessed for potential as additional monitoring locations.

4.0 MINIMUM THRESHOLDS AND MEASURABLE OBJECTIVES

Pursuant to SGMA, MOs and MTs shall be established for each sustainability indicator, based on quantitative analysis using the same metrics and monitoring sites as those utilized to define MTs. In accordance with the KGA Plan, the following general definitions apply to this Chapter GSP (CCR Title 23). **Figures 29b and 29c** depict the KGA regional MO and MT groundwater elevations for the KGA. The lack of representative data is a recognized data gap in the WDWA. Hydrographs related to MTs/MOs are preliminary and will be updated based on data collected during the first reassessment period.

- MTs: Numeric values for each sustainability indicator used to define an undesirable result.
- MOs: Interim milestones in increments of five years, to achieve the sustainability goals for the WDWA, and by extension, the KGA, within 20 years of the Plan implementation.

4.1 Minimum Thresholds for the WDWA Groundwater Management Area

Based on an assessment of the six potential undesirable results identified in SGMA, there are three co-related elements that require monitoring or MTs to sustainably manage the groundwater resources of the WDWA. Two potential undesirable results (Seawater Intrusion and Depletion of Interconnected Surface Water) were determined to be not applicable to the WDWA. A sixth element, Degraded Water Quality, is predominately the result of naturally occurring sub-regional geologic conditions. Therefore, it is not feasible to set direct MOs or MTs for this condition as the WDWA has no control over this natural phenomenon. However, the quality of groundwater underflow leaving the WDWA as it migrates toward the axis Valley will be monitored as a surrogate to assess for potential undesirable results to neighboring (down-gradient) management areas.

The three indicators that require monitoring and/or MOs and MTs are:

- Chronic lowering of groundwater levels;
- Reduction in groundwater storage; and
- Potential for localized land subsidence.

4.1.1 Chronic Lowering of Groundwater Levels/Significant Reduction of Groundwater in Storage

Fluctuations in groundwater levels and changes to groundwater in storage are linked to the extent that if sustainable groundwater level elevations are achieved, significant reductions in groundwater storage are avoided. There has been little historic reliance on groundwater for the purpose of irrigation or other uses in the WDWA due to poor groundwater quality. Therefore,

the potential for a significant lowering of groundwater levels or reduction in storage due to WDWA pumping extractions is believed to be minimal. It is unlikely this condition will change through at least 2040. Current estimates of WDWA groundwater well extraction is less than 2% of total demand (i.e. ~3,000 AFY). According to the current and projected KGA C2VSim-Kern model results, a principal cause of the lowering of groundwater levels in the WDWA, and by extension changes to groundwater in storage and projected groundwater deficits, is groundwater underflow (~111,000 AFY) migrating downgradient northeast and east toward the axis of the Valley. This condition, if confirmed by future data, indicates that a significant portion of changes to groundwater storage in the WDWA are not caused by pumping. It is believed that rate of underflow migrating from the WDWA could also be influenced by groundwater extractions being conducted in some of the adjacent downgradient GMAs. Therefore, the subject conditions of sub-regional downgradient underflow and most specifically adjacent pumping are outside the control of the WDWA. The WDWA has proposed two sentry coordination zones with adjacent GMAs to monitor groundwater elevations along the north and east boundaries of the WDWA where underflow exits the WDWA. Based on known hydrologic conditions, and preliminary simulated hydrographs these zones each have separate preliminary MTs and MOs. These are depicted in **Figures 30a through 30f**.

The preliminary MTs are:

- Sentry Zone #1 (well 25S21E-01): ~-115 feet below MSL
- Sentry Zone #2 (well 27S22E-30H- 7106-63): ~59 feet above MSL
- Sentry Zone#2 (well 28S21E-16 sim centroid): ~ 56 feet above MSL
- Sentry Zone #2 (well 28S21E-13H): ~59 feet above MSL

Because groundwater underflow is beyond the control of the WDWA, these MTs are preliminary and will be revised as necessary as additional groundwater elevation data is acquired. The proposed MTs are subject to review and revision at a minimum of every five years based on new data and subsequent coordination discussions with adjacent GMAs. Proposed changes will be reported in the relevant GSP update report. There are currently no MTs proposed for the WDWA areas not within the specified coordination zones at this time. The rationale for this approach is the aforementioned minimal historic pumping, and natural groundwater underflow over which the WDWA has no control. Data collected as part of the MNP for this Chapter GSP will be utilized to coordinate with adjacent downgradient GMAs and to assess whether the proposed MTs need updating or supplementing with additional MT/MO monitoring locations.

4.1.2 Land Subsidence

Irrigation pumping has been limited in the WDWA due to its naturally degraded quality. Land subsidence will be monitored by the WDWA in coordination with a land subsidence monitoring plan to be administered by the KGA. Special emphasis will be placed on monitoring Aqueduct

Mileposts 195-215. In 2011, an Aqueduct embankment failure of unknown cause was documented at Milepost 208. Changes in topographic surface elevations will be reported at a minimum every five years in the relevant GSP update report. The MT for inelastic land subsidence will be established and reviewed in consultation with adjacent GMA's and will be based on future InSAR and other geodetic land survey data. This data will be utilized to assess for potential inelastic subsidence and the potential for undesirable results to critical infrastructure. Subsidence in the WDWA caused by oil field activities and by pumping in adjacent GMAs is outside the control of the WDWA. To the extent feasible, the WDWA will coordinate the sharing of land-subsidence data with DOGGR and local oil producers that are party to the KGA Umbrella GSP.

4.1.3 Degraded Groundwater Quality

Given the ubiquitous occurrence of naturally degraded groundwater quality throughout the WDWA, groundwater is considered to be unsuitable for general use without treatment or blending with better quality water. The WDWA has no control over this phenomenon, therefore, no MT's or MO's are proposed at this time for this condition. To assist adjacent downgradient GMAs in their sustainability planning, the WDWA will conduct sentry monitoring within the WDWA lands east of the California Aqueduct adjacent to the shared boundaries with the GMAs northeast and east of the WDWA. The sentry monitoring data will be utilized to assess for any significant changes in groundwater quality (e.g., TDS) that might be migrating to the north or east from the WDWA as underflow. This condition, in conjunction with the aforementioned sentry data, will be re-assessed a minimum of every five years. Any proposed changes will be reported in the relevant GSP update report.

4.2 Measurable Objectives for the WDWA Groundwater Management Area

4.2.1 Chronic Lowering of Groundwater Levels/Significant Reduction of Groundwater in Storage

As discussed in **Section 5.1.1** and elsewhere in this report, the existing KGA C2VSim-Kern model has identified natural downgradient underflow (~111,000 AFY) as a principal cause of discharge and groundwater deficits (change in storage) in the WDWA. The rate of groundwater underflow migrating out of the WDWA may be accelerated by pumping activities in adjacent downgradient GMAs. Collectively these conditions are outside the control of the WDWA. Therefore, the WDWA has proposed two sentry coordination zones near the WDWA boundary with adjacent GMAs to monitor water level elevations to the north and east. Representative data will be collected for use in modeling changes to groundwater storage, and to act as a sentry for naturally degraded water quality migrating from the WDWA. The objective is to assess the potential for undesirable results to groundwater levels, and by proxy changes in groundwater

storage, within the WDWA. In addition, the data will be used to assess groundwater quality migrating into adjacent down-gradient management areas. The coordination zones each have separate preliminary MTs and MOs that will be re-evaluated, as needed, in coordination with the subject downgradient GMAs/GSAs and the KGA.

The preliminary MOs are:

- Sentry Zone #1 (well 25S21E-01): -62 feet below MSL
- Sentry Zone #2 (well27S22E-30H- 7106-63): 101 feet above MSL
- Sentry Zone #2 (well 28S21E-16 sim centroid): ~112 feet above MSL
- Sentry Zone #2 (well 28S21E-13H): ~127 feet above MSL

As discussed, these MOs and associated hydrograph simulations are preliminary and subject to review and change at a minimum every five years based on new data and subsequent coordination discussions with adjacent GMAs. Proposed changes will be reported in the relevant GSP update report. There are currently no MOs proposed for the areas not within the specified sentry coordination zones (i.e. areas internal to the WDWA) at this time. The rationale for this approach is the aforementioned poor quality groundwater and the low volume of historic pumping, which is expected to continue for the foreseeable future (2040). As stated, additional MT/MO monitoring locations may be proposed and reported in relevant GSP update reports based on MNP monitoring data collected during the first reassessment period.

4.2.2 Land Subsidence

The MO for inelastic land subsidence is to avoid significant impacts to critical infrastructure. Land subsidence will be monitored by an iterative approach that includes satellite-based InSAR and various focused geodetic land survey methodology as part of the KGA-wide land subsidence monitoring plan. In the WDWA, special emphasis will be placed on Aqueduct Mileposts 195-215. In 2011, an Aqueduct embankment failure was documented at Milepost 208. The monitoring activities will be conducted in coordination with adjacent GMAs via the monitoring plan administered by the KGA. Changes in topographic surface elevations will be reported in the relevant GSP update report. Oil field activities, including field subsidence, are under the oversight of DOGGR. Therefore, land subsidence in the WDWA caused by oil field activities, and by groundwater pumping in adjacent GMAs is outside the control of the WDWA. To the extent feasible, the WDWA will share subsidence data with DOGGR and those oil operators party to the KGA Umbrella GSP. The MO for inelastic land subsidence will be set in consultation with adjacent GMAs and the KGA and will be based on data that will be collected and reported during the first five-year reassessment period.

4.2.3 Degraded Groundwater Quality

As explained elsewhere in this Chapter GSP, because of the widespread occurrence of naturally degraded groundwater quality in the WDWA, there are no proposed MOs for this indicator. Instead, the WDWA will conduct sentry monitoring along its down-gradient (northeastern and eastern) boundaries in order to assess for significant changes to existing concentrations of TDS in groundwater underflow leaving the WDWA. A pending Basin Plan Amendment Workplan being submitted by the WWQC requests delisting of beneficial use designations for MUN and AGR for perched and unconfined/semi-confined groundwater over a portion of the WDWA.

5.0 PROJECTS, MANAGEMENT ACTIONS, AND ADAPTIVE MANAGEMENT

Groundwater quality in the WDWA is largely naturally degraded by elevated concentrations of TDS and other minerals that make it unsuitable for beneficial use. Further, due to the degraded quality of this groundwater, pumping extractions in the WDWA are estimated to be minimal (~3,000 AFY). The most significant source of discharge from the WDWA is groundwater underflow (~111,000 AFY) towards the north and east. This condition is a natural phenomenon that is outside the control of the WDA, and which may also be influenced by groundwater extractions in some adjacent GMAs. To the extent feasible and practical, Projects and Management Actions (PMAs) have been developed to address sustainability goals, undesirable results and MTs/ MOs for the WDWA. Recognizing that the hydrogeologic characteristics of the WDWA are transitory through time and that adaptive management is an iterative process, the PMAs have been selected and developed with consideration to climate change and drought resiliency, as well as coordination with adjacent GMAs. The initial proposed PMAs are:

1. Collect Representative Hydrogeologic Data
2. Water Resource Coordination
3. Conjunctive Reuse of Naturally Degraded Brackish Groundwater

5.1 PMA No.1 - Collect Representative Hydrogeologic Data

Historically, because of the brackish and naturally degraded quality of groundwater in the WDWA, growers have relied almost exclusively on surface water from the SWP for their irrigation needs. Groundwater is used primarily for blending when annual SWP deliveries are less than expected. As a result, there is currently little representative hydrogeologic data in the WDWA. This lack of data represents a significant data gap that must be addressed in order to refine the current understanding of the WDWA HCM, including key elements such as native yield/sustainable yield, groundwater elevations, pumping, and changes to groundwater in storage as well as the overall water budget.

5.1.1 Description of PMA No.1

As reported in this Chapter GSP, representative data related to aquifer characteristics and groundwater elevation monitoring within the WDWA is limited. This important data gap will be filled by implementation of the MNP. The MNP, once fully implemented, will help achieve the following objectives:

- Acquisition of additional representative groundwater elevation data sufficient to assess and document short-term, seasonal, and long-term groundwater trends related to WDWA,

native yield/sustainable yield, proposed sentry MTs/MOs, water budgets, groundwater pumping volumes, groundwater in storage, groundwater elevation, and potential future land subsidence;
- Ability to assess for changes in groundwater storage and conditions relative to identified MOs and MTs; and
- Coordination with adjacent management areas by way of scheduled sampling events, mutually sustainable MTs and MOs, and regularly scheduled status meetings to ensure sustainable outcomes.

5.1.2 Expected Benefits of PMA No.1

The expected benefits to be realized from the coordinated collection of groundwater data within the WDWA are:

- The ability to generate representative data for use in updating native yield/sustainable yield, sentry MTs/MOs and various water budget elements;
- Improved numerical groundwater modeling results; and
- Better forecasting and planning of adaptive management projects and management actions.

The PMA No.1 will also directly support WDWA MTs/MOs by providing foundational data to monitor and manage adaptive management projects that are designed and implemented to ameliorate the potential for significant reduction of groundwater elevations and groundwater in storage.

5.1.3 Timetable and Metrics for PMA No.1

Public noticing of proposed sampling activities or other field implemented as part of the MNP will be made on the WDWA member websites in advance of any field work. Permitting, if necessary, will comply with State and local requirements.

The PMA No.1 will be implemented beginning with implementation of the GSP and subsequent acceptance of the MNP. It will directly support WDWA MT/MOs by providing foundational data to monitor and manage adaptive management projects that are designed and implemented to ameliorate the potential for significant reduction of groundwater elevations and groundwater in storage. Metrics include sufficient representative water level data, pumping data, and additional water quality data.

5.1.4 Costs of PMA No.1

The cost of implementing PMA No 1. will be apportioned between the member water districts of the WDWA. It is possible that some costs might also be shared by adjacent management areas, and/or the WWQC as part of coordination agreements that are currently being negotiated.

Detailed costs and the MNP document will be developed and implemented during the first five-year reassessment period. If cost sharing with adjacent areas is implemented it will increase efficiency and flexibility in data collection and will reduce costs to the WDWA. Preliminary annual monitoring and reporting costs are estimated at $150,000 to $175,000. A more refined estimate of monitoring costs will be available and reported once the MNP is finalized for implementation.

5.2 PMA No.2 - Water Resource Coordination

5.2.1 Description of PMA No.2

The landowners in the WDWA have historically made significant investment in efficient irrigation technologies and methods that promote water conservation and sustainable management. They have also coordinated amongst themselves as individuals or via the various water districts to implement focused reduction demand measures, and trade or purchase surplus water when deliveries from the SWP have been reduced. It is assumed that these effective approaches and arrangements will continue after GSP implementation. In addition, the WDWA will work cooperatively and in close consultation with its landowners, the KGA and adjacent GMAs/GSAs to coordinate groundwater resource monitoring, testing and reporting as part of its overall strategy for the sustainable management of all its available water resources.

5.2.2 Expected Benefits of PMA No.2

Expected benefits from PM No.2 include:

- More reliability and flexibility in water availability;
- Drought resiliency; and
- Sustainable water strategies for both short- and long-term planning horizons.

5.2.3 Timetable and Metrics for PMA No.2

The implementation of the different Water Resource Coordination Programs varies; some as described above are already in place and ongoing. Others, like a KCS-wide groundwater coordination program would likely begin with planning by the KGA during the first five-year reassessment period after KCS Plan implementation. Groundwater coordination between the WDWA and its immediately adjacent GMAs, although already in place, would likely be structured to begin with meetings shortly after the Umbrella GSP approval. Metrics for PMA No.2 include regularly scheduled coordination meetings, a common data base system, frequent sharing of relevant water resource data (surface and groundwater) and discussion and planning of coordinated groundwater management actions and projects where feasible. Public noticing for SGMA related activities will be via WDWA district websites.

5.2.4 Costs of PMA No.2

Costs related to spot purchase or trading of supplemental water between individual growers is typically transactional between the relevant parties and thus not directly part of the WDWA operations. Purchase of supplemental water by the WDWA or individual member water districts is generally conducted on an as-needed (and available basis). Therefore, these transactions are not standard and subject to future market forces and an estimate of cost cannot be made at this time. The cost of this type of purchase would be within the WDWA or individual water district budget. The costs of each such unit of water would ultimately be borne by the respective recipient (i.e. pass-through cost). All such data would be reported in the member district AWMP report. Costs related to groundwater testing and monitoring will be determined once the MNP is finalized.

5.3 PMA No.3 - Conjunctive Reuse of Naturally Degraded Brackish Groundwater

To further enhance the sustainable and adaptive management strategies for the WDWA, the WDWA is evaluating the feasibility of an innovative, phased project that will integrate the treatment and conjunctive use of brackish groundwater and oil field produced water for potential multiple beneficial uses including, among other things:

- A new water supply for adjacent and nearby disadvantaged communities (DACs) in order to improve water reliability and drought resiliency;
- A reliable supplemental source of better-quality water that, together with the Aqueduct supplies, can be used for irrigation and other uses;
- Provide for potential environmental flows to the adjacent Kern National Wildlife Refuge; and
- Protect groundwater quality adjacent to the WDWA and reduce potential changes to groundwater storage by reducing the volume of naturally degraded groundwater migrating north and east from the WDWA toward better-quality groundwater in the axis of the Valley via the focused pumping, treatment and conjunctive reuse of modeled groundwater underflow leaving the WDWA (provided adjacent GMAs address their existing pumping-related groundwater gradient issues through their individual GSP management actions).

5.3.1 Description of PMA No.3

The supporting rationale for PMA No. 3 is multifaceted and relies on the unique hydrogeologic characteristics of the WDWA previously enumerated in this Chapter GSP, proven and available water treatment technologies that allow for innovative solutions to seemingly complex water quality challenges, and the potential for a variety of beneficial reuse opportunities derived from a degraded resources of little to no current practical use. Unlike other existing and proposed

State water supply projects, PMA No.3 would also have the added benefit of being planned, constructed and operated under local control.

Sub-regionally, most of the groundwater in the WDWA is of poor to very poor quality, with TDS concentrations routinely greater than 2,000 mg/L, making it unsuitable for practical beneficial use within the WDWA without blending or treatment. The poor water quality is caused by geologic sediments of marine origin, some of which contain saline connate water. The principal source of modeled deficit in the WDWA is due to natural downgradient underflow out of the WDWA towards the northeast (former Tulare Lake bed, a designated beneficial use exemption area), and eastward towards the axis of the basin. Historically, WDWA growers have, among other water management techniques, used Aqueduct water (significantly more than 95%) to meet their water supply demand. Groundwater withdrawals have been minimal (~3,000 AFY), and have been used largely for the purpose of blending. However, climate variability has placed stress on the reliability of imported water. During the recent extended drought period (2007 to 2016), actual deliveries from the SWP to the WDWA averaged less than 50% of the stipulated allocation. The proposed drought resiliency infrastructure project (Project), when fully implemented, would provide for treatment and conjunctive reuse of a mixture of oil field produced water, and naturally degraded groundwater that is currently escaping the WDWA as underflow.

Membrane technologies and associated system control software to treat brackish and saline water are well established and the cost of treatment is declining. Many of these proven technologies are now “off the shelf” and modular, allowing for cost-effective facility upscaling as part of planned project phasing, or as operational conditions change. The Project proposes to utilize a modular treatment system in order to right-size the project and maximize and maintain the balance between project economics and desired benefits. As envisioned, the PMA No. 3 would include at least two similar construction phases over the next 10-20 years, each with an array of brackish groundwater underflow-capture wells located along the eastern or northern boundaries of the WDWA. These wells along with some oilfield produced water would eventually provide the source water for two or more distributed modular treatment systems. When fully operational, the Project, as currently planned, could produce up to 50,000 AFY of new, high-quality water for multi-beneficial reuse options.

Potential sources of feed water for the project include degraded brackish groundwater underflow from the WDWA and surplus oil field produced water. Current groundwater underflow that migrates from the WDWA, downgradient towards the axis of the basin, has been preliminarily estimated by the KGA C2VSim-Kern model at approximately 111,000 AFY. Because of the brackish quality of this water, it is considered to be non-beneficial without treatment or blending.

The oil fields of West Kern County generate approximately 10 to 12 barrels of brackish or saline produced water for every barrel of oil. A large portion of the produced water is recycled and used at the oil fields for steam flooding for EOR, and other oil field operations. However, any remaining surplus volume of produced water requires disposal. Due to water quality concerns, many of the produced water disposal ponds in Kern County have been closed. This leaves permitted reinjection into typically deeper zones under the oversight of the DOGGR and the Federal UIC program as the primary method for disposal of produced waters. The Project would, if determined to be feasible, divert a portion of this surplus produced water for additional treatment and conjunctive reuse.

5.3.2 Expected Benefits of PMA No.3

When operational, the Project will result in multiple potential beneficial uses, including many of the "One Water" concepts enumerated in the State's California Water Action Plan:

1. Increase drought resiliency, regional and local water self-reliance, and flexible integrated water management;
2. Potentially help protect, maintain and restore important ecosystems (e.g., Kern National Wildlife Refuge);
3. Provide a potential alternative water source for use by local DACs;
4. Increase WDWA operational flexibility and regulatory efficiency; and
5. Help mitigate the rate of subsidence through the treatment, potential banking and conjunctive reuse of surplus oilfield produced water.

The Project will also directly support WDWA MTs/MOs by providing a new reliable local source of better quality water for conjunctive reuse that is derived from groundwater that is currently considered unsuitable for beneficial use and is typically lost to underflow from the WDWA, or is injected deep underground as part of oilfield produced water disposal where it beyond practical reach for reuse.

5.3.3 Timetable and Metrics for PMA No.3

Preliminary planning for a Project Engineering feasibility study (FS) for the first phase of the project has already begun. It is expected there will be at a minimum two phases of distributed treatment facility construction. The FS will examine the viability of the project for regulatory acceptance, potential for undesirable results (e.g. significant subsidence), and for the economics of treating both brackish groundwater and oil field produced waters in a distributed modular facility via the use of readily available membrane technologies, such as reverse osmosis (RO).

Treatment technologies to be assessed would include pre-treatment, pH adjustment and filtration followed by either a single-pass RO configuration, a double-pass RO, or a RO modification called a closed-circuit RO. Treated water quality would, at a minimum, meet Basin Plan requirements.

Project FS components include:

- Evaluating existing hydrogeologic data pertaining to brackish groundwater and oil field produced water quality, water use, and volumes;
- Development of preliminary engineering options and costs for siting the treatment facility, source wells, water treatment, energy demand, concentrate disposal, and treated water transmission;
- Examination of the potential for undesirable results (e.g. subsidence); and
- Assessment of permitting and public notification requirements (California Environmental Quality Act [CEQA], etc.).

Sustainable objectives and metrics will be developed to comport with those identified in the KGA Umbrella GSP and the WDWA Chapter GSP. Data gaps will be filled, as needed, through water sample analysis, geophysics (e.g. airborne, surface, borehole), aquifer pumping tests, and groundwater flow and solute transport modeling.

The FS will include information on the study area, as well as water supply, source water, and RO concentrate characteristics and treatment facilities. A project alternative analysis will be performed leading to a recommended plan for implementation including a preliminary construction schedule and financing plan, a revenue program, and a net present worth analysis. Findings and status of the FS implementation would be reported in the first five-year GSP reassessment. It is a goal to have the first modular treatment system online before the end of the second five-year reassessment period (by 2030). Public noticing for this project would be implemented pursuant to relevant and applicable rules and regulations and would be distributed via the websites of the stakeholder water districts and other methods, as required. Permitting (CEQA, construction, etc.) will also comply with relevant and applicable rules and regulations.

5.3.4 PMA No.3 Issues, Outcomes and Costs

Key issues to be addressed during the FS include those related to technical feasibility, project phasing, regulatory and public acceptance, potential project-related undesirable results, the development of an engineering cost/benefit analysis, State or other funding alternatives and permitting (e.g. CEQA, etc.). The FS will seek to identify the preferred project alternative by examining the CEQA required “no project alternative”, in addition to several different construction and RO configurations, combined with varying approaches for concentrate (brine)

disposal. End-users of the new water supply will be identified, including local DACs, agricultural, oil field, and environmental users.

Ultimately, this project directly supports WDWA water resources and provides the benefit of a new water supply to the State. Specific benefits include:

- Ability to wheel water of acceptable quality to neighboring management areas that may be facing shortage;
- Increased regional and local water self-reliance, flexibility and integrated management;
- Drought resiliency;
- Ability to decrease agricultural reliance on diversions from the Delta via the Aqueduct; and
- Increase operational and regulatory efficiency for improved drought resiliency.

Only broad order-of-magnitude cost ranges are available at this time. More refined cost estimates will be generated by the proposed FS. Rough order-of-magnitude costs for the initial phase of the project range from $50 million to $60 million +/- 20% depending on site location and number of capture wells to be installed. Refined costs will be generated by the aforementioned FS. Project costs and funding are among key feasibility factors. Funding sources could include a combination of State, WDWA and other stakeholder or private funding.

6.0 GSP REPORTING AND PERIODIC EVALUATIONS

SGMA reporting standards, as enumerated in Section 352.4 of CCR 23, Subchapter 2, Groundwater Sustainability Plans, shall apply to all WDWA Chapter GSP reporting and WDWA Chapter GSP amendments. Additional reporting details are provided below. Data from the various monitoring and well installation activities will be provided to the appropriate State and County databases (e.g., well installation information and groundwater level and water quality monitoring). Data will also be coordinated with adjacent GMAs, and will be maintained in the appropriate State data bases (e.g. GeoTracker), and a WDWA data base that is coordinated with the KGA. All data collected by the WDWA will be provided and summarized in the various reports detailed in this section (**Appendix G and Appendix H**).

6.1 GSP Reporting and Data Management

Pursuant to SGMA, the WDWA will prepare Annual Reports for inclusion in the KGA GSP. The Annual Reports will be prepared consistent with KGA guidance and formats. The compiled reports from the individual Chapter GSPs/ GSAs will submitted by the KGA by April 1st of each year following adoption of the Umbrella GSP. The Annual Reports shall, at a minimum, include the following topics:

- Groundwater elevation data and contour maps;
- Key well hydrographs;
- Groundwater extractions;
- Surface water supplies;
- Total water use;
- Change in groundwater storage; and
- Implementation progress.

Periodic reevaluation reports will be prepared a minimum of every five years for inclusion in the Umbrella GSP. The five-year reassessments will be submitted electronically by the KGA to the DWR via the online reporting system and format provided by the Agency per Section 10733.2, Water Code and Section 353.2 and 356.4, of CCR 23, Subchapter 2, Groundwater Sustainability Plans. The submittal of updates or amendments to this Chapter GSP will be accompanied by a transmittal letter signed by the Plan Manager, or duly authorized representative. A coordinated data management system for the KCS is necessary to improve the accuracy, usefulness and confidence in groundwater data reported by the individual GMA's and GSA's within the KGA. Data system perimeters, inputs and a coordinated data system methodology will be established and reported in the relevant KGA update report. In the meantime, the WDWA will continue to rely on established State data bases for updating and reporting new data.

Notes:

1. All MNP wells in the table will be sampled for groundwater elevation twice yearly (fall and spring). In the spring, all the MNP wells will be sampled via field instruments for EC, pH, DOC, and temperature. In the fall, all the MNP wells, in additional to all of the spring parameters, will be sampled and analyzed in a certified lab for nitrate-nitrogen, TDS, general mineral ions and cations. All monitoring will be conducted pursuant to KGA Monitoring Protocols.

TDS Groundwater Quality Results in the Kern County Groundwater Subbasin 2011 - 2017

Date: 12/3/2019 | Project #: 043-04 | **Figure 15a**

Age	Geologic Units of Interest	General Description	
Recent	Alluvium	Discontinuous beds of sand, silt, clay and gravel, becoming finer grained toward the valley.	
Pleistocene	Older Alluvium		
	Tulare Formation	Interbedded gravel, sand, silt, and clay.	
	Corcoran Clay	Silt and clay. Lacustrine.	
	Tulare Formation	Kern River Formation Alluvial Fan Deposits. Interbedded gravel, sand, silt, and clay. Fresh water production on east side of the valley.	Interbedded gravel, sand, silt, and clay. Siltstone, clayey, diatomaceous with thin lenticular sand beds.
Pliocene	San Joaquin Formation		
Miocene	Etchegoin Formation	AE	Clay and silt to sand, gravel, and sandstone
	Santa Margarita Sandstone	Chanac Formation AE Conglomerate with lenses of coarse sand and clays Non-Marine Clastic. Limited fresh water production on east side.	Fine to coarse white sand, gravel, and sandstone.
	Round Mountain Silt	Brown siltstone, diatomaceous	
	Olcese Sand	Light gray sandstone with a few pebble and siltstone beds.	
	Freeman-Jewett Silt	Brown siltstone with interbedded ash.	
Oligocene	Pyramid Hills and Vedder Sands	Interbedded sandstone and siltstone

Hydraulic Conductivity Values

Date: 12/3/2019	Project #: 043-04	**Figure 15c**

Approximate WDWA Boundary

NOTES:

(Approximate) Elevation of base of fresh water (Specific conductance generally less than 3,000 micomhos per centimeter) or ~2,000 mg/L TDS.

Hydrocarbon elevations from primacy productive limits represent difference between average surface elevation and minimum depth of productive limit.

Elevation to hydrocarbons and the top of exempted aquifers are generalized. Refer to the report table for details. Exemptions are subject to change as applications are approved.

Per 40 CFR §144.3, exempted aquifers are not USDWs. Based on criteria of 40 CFR §146.4, primacy productive limits are not suitable USDWs.

USDW: Underground Source of Drinking Water (Source: Code of Federal Regulations).

Datum is Mean Sea Level

- Elevation Contour of Specific Conductance 3,000 micromhos per centimeter (Page-1973)
- Elev — Aquifer Exemption (max Elevation)
- Elev — Primacy Productive Limits (Hydrocarbon max Elevation)

Notes:
Vertical ground surface displacement rates are derived from Interferometric Synthetic Aperture Radar (InSAR) data that are collected by the European Space Agency (ESA) Sentinel-1A satellite and processed by the National Aeronautics and Space Administration (NASA) Jet Propulsion Laboratory (JPL), under contract with to the California Department of Water Resources (DWR). JPL presented preliminary processing results in the Progress Report: Subsidence in California, March 2015 – September 2016, and submitted a later version of the processing results that are still preliminary to the California Department of Water Resources (DWR). These files provided by JPL to DWR are multiband floating point GeoTIFFs with each band representing a date. GeoTIFF pixel values are in inches equal to the cumulative vertical displacement from the first date. JPL processed Sentinel-1A InSAR data separately for three different geographic regions; The Sacramento Valley, the San Joaquin Valley, and the South Central Coast. DWR temporarily interpolated the JPL data to end-of-month values, merged the resulting rasters from all three regions into a single raster for each month, and clipped all rasters to Bulletin 118 groundwater basins. Processing results that are still preliminary. (JPL/CIT Farr et al, 2017)

VIA EMAIL: pnixon@lhwd.org

Re: Comments on Draft Kern Groundwater Authority Umbrella Groundwater Sustainability Plan and Westside Management Area Plan

Dear Mr. Nixon and Board of Directors,

Wonderful Orchards LLC and Wonderful Citrus LLC (collectively, "Wonderful") appreciate all the hard work that has gone into preparing the draft Groundwater Sustainability Plan ("Umbrella GSP") and Management Area Plans ("MAPs") by the Kern Groundwater Authority ("KGA") and its member agencies ("Members") including Westside District Water Authority.

Wonderful, and our related entities, farm and process almonds, pistachios, various citrus varietals, pomegranates and nursery stock in Central California, including Kern County. As a major agricultural entity in the Central Valley, we understand just how important it is to formulate a GSP that meets the sustainability needs of the groundwater basin well into the future.

In order to best execute the GSP's goal to achieve sustainability by 2040, we encourage all GSAs and Members in the subbasin to initiate stakeholder-driven processes and to work together cooperatively to develop coordinated, subbasin-wide management actions and implementation strategies. To that end, we request that the following comments be considered prior to the Umbrella GSP and MAPs being finalized and implemented.

Quantification of Native Yield[1]

It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource.

For example, a district or pumper located adjacent to the foothills does not necessarily have a superior claim to native yield over someone located in the center of the basin just because they are geographically closer to the source of mountain front recharge. Similarly, a district or

[1] Native yield as defined in Section 4.2.1 of Appendix J to the GSP.

pumper located in a cone of depression does not necessarily have a superior claim to native yield just because groundwater is flowing toward them. Surface water entering the groundwater via seepage in natural channels, including the Kern River and small streams, may be attributable to the native yield depending upon the circumstances of that seepage. A thorough technical and legal analysis is necessary to determine appropriate sources contributing to the native yield and to quantify these supplies.

Allocation of Native Yield

In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. Appendix J of the GSP indicates the subbasin native yield is approximately 0.144 acre-feet per acre. It is our understanding that subsequent to the release of the draft GSP, all MAPs and other GSPs in the basin agreed to utilize the same number for their water budgets. If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights. Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross or net area.

In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and be generally consistent with groundwater rights, recognizing that GSAs do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in *Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – Environmental Defense Fund and New Current Water & Land, July 2018*.

Groundwater Markets

Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.

Pumping Restrictions

Wonderful understands that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity.

As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).

Groundwater Recharge and Banking

GSAs must develop clear policies and conditions that protect existing investment in groundwater banking and banked inventory, and without interference with existing rules and regulations. GSAs must also find a way to incentivize additional investment, such as on-farm recharge, and allow flexibility for recharged or banked water to be freely transferrable (subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results). Where possible, GSPs should also identify management areas that may benefit from additional recharge and banking. We also recommend that GSAs work to develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).

Measurement and Data Management

Finally, GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions.

Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).

***

Wonderful appreciates the opportunity to provide feedback on the GSP and MAPs. We would be happy to discuss these comments at your convenience. Thank you for your consideration.

Sincerely,

Rob C. Yraceburu

APPENDIX B KERN GROUNDWATER AUTHORITY NOTIFICATION OF INTENT TO DEVELOP A GROUNDWATER SUSTAINABILITY PLAN

KERN
GROUNDWATER AUTHORITY

December 20, 2017

Mr. Trevor Joseph
Sustainable Groundwater Management Section Chief
California Department of Water Resources
P. O. Box 94236
Sacramento, CA 94236

Re: Notification of Intent to Develop a Groundwater Sustainability Plan

Dear Mr. Joseph:

The purpose of this letter is to notify you that the Kern Groundwater Authority Groundwater Sustainability Agency (KGA) intends to develop a Groundwater Sustainability Plan (GSP) pursuant to Water Code Section 10727.8 for its service area within the Kern County Subbasin (Basin Number 5-22.14, DWR Bulletin 118). The KGA is an exclusive GSA whose formation was posted by DWR on April 21, 2016.

The KGA is engaged in several coordination and outreach efforts across the Kern County Subbasin, as well as within the more specific service area of the KGA. The KGA actively participates in technical and planning meetings and forums with other GSAs in the Kern County Subbasin, recognizing that the findings of the KGA's GSP will need to be coordinated with other GSP development efforts occurring in parallel within the Kern County Subbasin. In addition to the monthly KGA Board of Directors meetings, the KGA holds monthly public meetings to review and discuss on-going planning activities in support of the GSA and GSP development process. These meetings welcome public input and feedback to the GSA and the GSP development process.

The KGA will also be holding educational workshops specifically intended for the interested parties and general public living, working and operating farms and businesses in the KGA service area. These additional workshops will have an educational focus to inform attendees on the overall role and purpose of the GSA, describe the method and process to develop the GSP, and solicit input on the development of the GSP. An initial workshop in 2018 will focus on public involvement and seek input on approaches, such as an Advisory Committee, to regularly acquire input from a wide variety of public stakeholders, and from disadvantaged communities in particular. One of the key goals of the public workshops will be to hear comments and feedback from the public that can be used to further inform the GSP development process.

1800 30th Street, Suite 280, Bakersfield, CA 93301 • Tel: (661) 616-6500 • Fax: (661) 616-5890 • www.kerngwa.com

The KGA has established a website at: http://kerngwa.com/. This website is already actively in use and will continue to provide the public with key information regarding the GSA and GSP development process including the dates of public meetings and workshops. The KGA website also makes our resource planning and GSP documents available to the public.

If you have any questions regarding our GSP development process, please don't hesitate to contact me at the phone number or email below.

Sincerely,

Terry L. Erlewine
Kern Groundwater Authority

APPENDIX D UNITED STATES DEPARTMENT OF AGRICULTURE LANDSCAPE CHARACTERISTICS

USDA Landscape Characteristics

Topography Characteristic			% of the District				Effect on Water Operations and Drainage
Rolling Land			(20% of Irrigated land)				Land is adaptable to sprinkler and micro irrigation systems. There are no effects on water operations and drainage because of the existence of pressurized irrigation systems
Flat Land			(80% of irrigated land)				Land is adaptable to flood and other types of irrigation systems
Soil Unit	**Soil Name / Characteristic / Classification**	**Description**	**Percent of District**	**Depth (in)**	**Clay (%)**	**Permeability (in/hr)**	**Effect on Water Operations and Drainage**
115	Bitterwater sandy loam, 9 to 15 percent slopes	Deep, well drained soil is on foothills. Formed in residuum derived dominantly from sandstone.	0.00	0-23	5-10	1.98 - 5.95	No irrigation operations impact
				23-60	5-10	1.98 - 5.95	
				60-70	---	1.98 - 5.95	
124	Buttonwillow clay, partially drained	Deep, somewhat poorly drained soil is in basins. Formed in alluvium derived dominantly from granitic rock. Slope is 0-2 percent.	0.29	0-28	40-55	0.06 - 0.2	No irrigation operations impact
				28-55	8-15	1.98 - 5.95	
				55-64	35-50	0.06 - 0.2	
125	Cajon loamy sand, 0 to 2 percent slopes	Deep, somewhat excessively drained soil is on alluvial fans. Formed in alluvium derived dominantly from granitic rock.	0.05	0-9	5-18	5.95 - 19.98	No irrigation operations impact
				9-44	0-5	5.95 - 19.98	
				44-60	5-10	5.95 - 19.98	
129	Carollo-Twisselman saline alkali association, 2 to 15 percent slopes	Carollo (60% of area), clay loam, saline-alkali. Moderately deep and well drained soil is on hill tops. Formed in residuum derived dominantly from shale.	0.01	0-2	27-32	0 - 0.06	No irrigation operations impact
				2-15	40-60	0 - 0.06	
				15-30	30-40	0 - 0.06	
		Twisselman (40% of area), clay, saline-alkali. Deep and well drained soil is on side slopes and drainageways. Formed in alluvium derived dominantely from sedimentary rock.		0-9	40-60	0 - 0.06	
				9-60	35-60	0 - 0.06	
				30-60	---	0 - 0.2	
144	Delgado sandy loam, 5 to 30 percent slopes	Shallow, somewhat excessively drained soil is on hills. Formed in residuum derived dominantly from sedimentary rock.	0.06	0-2	8-20	1.98 - 5.95	No irrigation operations impact
				2-10	8-20	1.98 - 5.95	
				10-14	---	0.2 - 1.98	
150ki	Panoche loam, 0 to 2 percent slopes	Component is on alluvial fans. Parent material consists of alluvium derived from sedimentary rock. Natural drainage class is well drained.	0.16	0-7	18-27	0.57 - 1.98	No irrigation operations impact
				7-60	18-35	0.57 - 1.98	
156	Garces silt loam	Deep, well drained, saline-alkali soil is on basin rims. Formed in alluvium derived dominantly from granitic rock.	1.19	0-2	10-18	0.2 - 0.57	No irrigation operations impact
				2-9	27-35	0 - 0.06	
				9-23	20-35	0 - 0.06	
				23-37	20-27	0	
				37-60	10-27	0.2 - 0.57	
157	Garces silt loam, moderately wet	Deep, well drained, saline-alkali soil is on basin rims. Formed in alluvium derived dominantly from granitic rock.	0.40	0-2	10-18	0.2 - 0.57	No irrigation operations impact
				2-9	27-35	0 - 0.06	
				9-23	20-35	0 - 0.06	
				23-37	20-27	0	
				37-60	10-27	0.2 - 0.57	
164	Houser fine sandy loam, partially drained	Deep, somewhat poorly drained, saline-alkali soil is on basin rims. Formed in alluvium derived dominantly from granitic rock. Slope is 0-1 percent.	1.77	0-4	5-20	1.98 - 5.95	No irrigation operations impact
				4-60	40-60	0 - 0.06	
165ki	Twisselman silty clay. Slopes are 0 to 1 percent	Component is on alluvial fans. Parent material consists of alluvium derived from sedimentary rock. Natural drainage class is well drained.	0.27	0-9	40-60	0.06 - 0.2	No irrigation operations impact
				9-60	35-60	0.06 - 0.2	
166ki	Twisselman silty clay, saline-alkali	Component is on alluvial fans. Parent material consists of alluvium derived from sedimentary rock. Natural drainage class is well drained.	0.80	0-9	40-60	0.06 - 0.2	No irrigation operations impact
				9-60	35-60	0.06 - 0.2	
174	Kimberlina fine sandy loam, 0 to 2 percent slopes	Deep, well-drained soil on alluvial fans & plains. Formed in alluvium derived dominantly from granitic & sedimentary rock.	7.44	0-9	6-18	1.98 - 5.95	No irrigation operations impact
				9-45	10-18	1.98 - 5.95	
				45-71	10-25	0.57 - 1.98	
175	Kimberlina sandy loam, 2 to 5 percent slopes	Deep, well-drained soil on alluvial fans & plains. Formed in alluvium derived dominantly from granitic & sedimentary rock.	1.46	0-9	6-18	1.98 - 5.95	No irrigation operations impact
				9-45	10-18	1.98 - 5.95	
				45-71	10-25	0.57 - 1.98	
176	Kimberlina sandy loam, 5 to 9 percent slopes	Deep, well-drained soil on alluvial fans & plains. Formed in alluvium derived dominantly from granitic & sedimentary rock.	0.12	0-9	6-18	1.98 - 5.95	No irrigation operations impact
				9-45	10-18	1.98 - 5.95	
				45-71	10-25	0.57 - 1.98	
183	Lethent silt loam	Deep, moderately well drained, saline-alkali soil on basin rims. Formed in alluvium derived dominantly from granitic & sedimentary rock.	0.07	0-3	20-27	0.2 - 0.57	No irrigation operations impact
				3-53	35-55	0 - 0.06	
				53-60	10-30	0.06 - 0.2	
189	Lokern clay, saline-alkali, partially drained	Deep, somewhat poorly drained soil is on basins. Formed in alluvium derived from mixed rock sources, mainly granitic rock. Slope is 0-2 percent.	0.16	0-7	40-55	0.06 - 0.2	No irrigation operations impact
				7-21	40-60	0.06 - 0.2	
				21-48	40-60	0.57 - 1.98	
				48-66	10-26	0.57 - 1.98	
196	Milham sandy loam, 0 to 2 percent slopes	Deep, well-drained soil on alluvial fans, plains, & low terraces. Formed in alluvium derived dominantly from granitic & sedimentary rock.	7.95	0-10	5-20	1.98 - 5.95	No irrigation operations impact
				10-49	20-35	0.2 - 0.57	
				49-60	5-25	0.57 - 1.98	
197	Milham sandy loam, 2 to 5 percent slopes	Deep, well drained soil on alluvial fans, plains, & low terraces. Formed in alluvium derived dominantly from granitic & sedimentary rock.	0.01	0-10	5-20	1.98 - 5.95	No irrigation operations impact
				10-49	20-35	0.2 - 0.57	
				49-60	5-25	0.57 - 1.98	
207	Nahrub clay, drained	Deep, somewhat poorly drained soil; is in basins. Derived dominately from granitic and sedimentary rock.	3.54	0-18	40-50	0 - 0.06	No irrigation operations impact
				18-52	35-50	0 - 0.06	
				52-61	15-30	0.57 - 1.98	
208	Nahrub clay, partially drained	Deep, somewhat poorly drained soil; is in basins. Derived dominately from granitic and sedimentary rock.	9.90	0-18	40-50	0 - 0.06	No irrigation operations impact
				18-52	35-50	0 - 0.06	
				52-61	15-30	0.57 - 1.98	
209	Nahrub, drained-Lethent complex	Located in basins. 75% Nahrub clay & 25% Lethent silt loam; intermingled	1.42	0-18	40-50	0 - 0.06	No irrigation operations impact
				18-52	35-50	0 - 0.06	
				52-61	15-30	0.57 - 1.98	
210	Nahrub, partially drained-Lethent complex	Located in basins. 75% Nahrub clay & 25% Lethent silt loam; intermingled	3.21	0-18	40-50	0 - 0.06	No irrigation operations impact
				18-52	35-50	0 - 0.06	
				52-61	15-30	0.57 - 1.98	
211	Panoche clay loam, 0 to 2 percent slopes	Deep, well-drained soil on alluvial fans & plains. Formed in alluvium derived dominately from granitic or sedimentary rock.	13.64	0-16	27-35	0.57 - 1.98	No irrigation operations impact
				16-60	18-35	0.57 - 1.98	
212	Panoche clay loam, 2 to 5 percent slopes	Deep, well-drained soil on alluvial fans & plains. Formed in alluvium derived dominately from granitic or sedimentary rock.	4.51	0-16	27-35	0.57 - 1.98	No irrigation operations impact
				16-60	18-35	0.57 - 1.98	
213	Panoche clay loam, 5 to 9 percent slopes	Deep, well-drained soil on alluvial fans & plains. Formed in alluvium derived dominately from granitic or sedimentary rock.	0.10	0-16	27-35	0.57 - 1.98	No irrigation operations impact
				16-60	18-35	0.57 - 1.98	
214	Panoche clay loam, saline-alkali, 0 to 2 percent slopes	Deep, well drained soil on alluvial fans & plains. Formed in alluvium derived dominately from granitic or sedimentary rock.	0.19	0-16	27-35	0.57 - 1.98	No irrigation operations impact
				16-60	18-35	0.57 - 1.98	
215	Panoche clay loam, saline-alkali, moderately wet, 0 to 2 percent slopes	Deep, well drained soil on alluvial fans & plains. Formed in alluvium derived dominately from granitic or sedimentary rock.	0.77	0-16	27-35	0.57 - 1.98	No irrigation operations impact
				16-60	18-35	0.57 - 1.98	
233	Twisselman sandy loam, saline-alkali, 0 to 2 percent slopes	Deep, well-drained soil on alluvial fans & basin rims. Formed in alluvium derived dominately from sedimentary rock. Drainage has been altered due to extensive irrigation.	5.14	0-8	5-20	1.98 - 5.95	No irrigation operations impact
				8-60	35-60	0 - 0.06	
234	Twisselman sandy loam, saline-alkali, moderately wet, 0 to 2 percent slopes	Deep, well-drained soil on alluvial fans & basin rims. Formed in alluvium derived dominately from sedimentary rock. Drainage has been altered due to extensive irrigation.	3.42	0-8	5-20	1.98 - 5.95	No irrigation operations impact
				8-60	35-60	0 - 0.06	
235	Twisselman clay, 0 to 2 percent slopes	Deep, well-drained soil on alluvial fans. Formed in alluvium derived dom-inantly from sedimentary rock.	12.88	0-14	40-60	0.06 - 0.2	No irrigation operations impact
				14-60	35-60	0.06 - 0.2	
236	Twisselman clay, 2 to 5 percent slopes	Deep, well-drained soil on alluvial fans. Formed in alluvium derived dom-inantly from sedimentary rock.	1.06	0-14	40-60	0.06 - 0.2	No irrigation operations impact
				14-60	35-60	0.06 - 0.2	
237	Twisselman clay, saline-alkali, 0 to 2 percent slopes	Deep, well-drained soil on basin rims. Formed in alluvium derived dom-inantly from sedimentary rock. Drainage has been altered due to extensive irrigation.	1.88	0-9	40-60	0 - 0.06	No irrigation operations impact
				9-60	35-60	0 - 0.06	
238	Twisselman clay, saline-alkali, moderately wet, 0 to 2 percent slopes	Deep, well-drained soil on basin rims. Formed in alluvium derived dom-inantly from sedimentary rock. Drainage has been altered due to extensive irrigation.	9.65	0-14	40-60	0 - 0.06	No irrigation operations impact
				14-60	35-60	0 - 0.06	
239	Typic Gypsiorthids-Kimberlina association, 0 to 5 percent slopes	Deep and well drained. Formed in alluvium derived dominantly from sedimentary rock.	2.94	0-9	6-18	1.98 - 5.95	No irrigation operations impact
				9-45	10-18	1.98 - 5.95	
				45-71	10-25	0.57 - 1.98	
251	Yribarren loam, 0 to 2 percent slopes	Deep, well drained soil on alluvial fans & plains. Formed in alluvium derived dominantly by sedimentary rock.	0.65	0-7	20-27	0.57 - 1.98	No irrigation operations impact
				7-19	35-55	0 - 0.06	
				19-22	15-35	0 - 0.06	
				22-60	15-30	0.2 - 0.57	
253	Yribarren clay loam, 2 to 5 percent slopes	Deep, well-drained soil on alluvial fans & plains. Formed in alluvium derived dominantly by sedimentary rock.	2.90	0-7	20-27	0.57 - 1.98	No irrigation operations impact
				7-19	35-55	0 - 0.06	
				19-22	15-35	0 - 0.06	
				22-60	15-30	0.2 - 0.57	

APPENDIX E LIST OF REGULATORY CLEANUP SITES

Table 2-5
GeoTracker and EnviroStor Sites with Potential Groundwater Media
Kern Groundwater Authority
Kern County, California
(Updated January 2019)

New Map ID	Site / Facility Name	ENVIROSTOR/ Geotracker ID	Source	Program Type	Status	Address	City	Zip	CALEnviroscreen Score	X Coord	Y Coord	Constituents of Concern
1	CROP PRODUCTION SERVICES (CPS) DELANO	SL185724257	Geotracker	CLEANUP PROGRAM SITE	OPEN - REMEDIATION	930 WOOLOMES AVE	DELANO	93215-9553	---	-119.2422	35.7466	VOCs and Pesticides, NITRATE, OTHER CHLORINATED HYDROCARBONS, OTHER SOLVENT OR NON-PETROLEUM HYDROCARBON
2	CHEVRON USA (AKA: CHEVRON REFINERY & WAIT TANK YD)	SL205064267	Geotracker	CLEANUP PROGRAM SITE	OPEN - REMEDIATION	2525 NORTH MANOR STREET	BAKERSFIELD	93308	---	-119.0087	35.4238	BENZENE, CRUDE OIL, LEAD, OTHER PETROLEUM
3	PG&E KERN POWER PLANT (FORMER:COFFEE RD. OVERPASS)	SLT5FP024290	Geotracker	CLEANUP PROGRAM SITE	OPEN - REMEDIATION	2401 COFFEE ROAD	BAKERSFIELD	93308-5748	---	-119.094919	35.37920074	BENZENE, CRUDE OIL, OTHER PETROLEUM
4	BAKERSFIELD REFINERY	SL205314279	Geotracker	CLEANUP PROGRAM SITE	OPEN - REMEDIATION	6451 ROSEDALE HIGHWAY	BAKERSFIELD	93308	---	-119.071219	35.38198244	BTEX, TPH, MTBE / TBA / OTHER FUEL OXYGENATES, OTHER SOLVENT OR NON-PETROLEUM HYDROCARBON

APPENDIX F WDWA MONITORING NETWORK PLAN (MNP) PROTOCOLS AND SAMPLING FORM

Monitoring Network & Protocols

Monitoring Network shall be developed to be capable of collecting sufficient data to demonstrate short-term, seasonal, and long-term trends in groundwater and related surface conditions, and yield representative information about groundwater conditions as necessary to evaluate Plan implementation. The monitoring network objectives shall be implemented to accomplish the following:

1) Demonstrate progress toward achieving measurable objectives described in the Plan
2) Monitor impacts to the beneficial uses and users of groundwater
3) Monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds
4) Quantify annual changes in water budget components

Monitoring Network shall be designed to ensure adequate coverage of sustainability indicators. If management areas are established, the quantity and density of monitoring sites in those areas shall be sufficient to evaluate conditions of the basin setting and sustainable management criteria specific to that area. To the extent possible, the use of existing monitoring data and infrastructure should be utilized to meet the needs for characterization, historical record documentation and continued monitoring requirements.

Monitoring Network shall describe the scientific rationale for the monitoring site selection and for each sustainability indicator, the quantitative values for the minimum threshold, measurable objective and interim milestones shall be indicated at each monitoring site.

Monitoring Protocols developed shall include a description of technical standards, data collection methods, and other procedures or protocols for monitoring sites or other data collection facilities to ensure that the monitoring network utilizes comparable data and methodologies. There is no definitive rule for the density of groundwater monitoring points needed in a basin. The table below provides guidance for the density of monitoring wells per hundred square miles. One important item to consider is how the definitions of undesirable results will be impacted to provide the necessary information to indicate compliance.

Reference	Monitoring Well Density (wells per 100 miles2)
Heath (1976)	0.2 - 10
Sophocleous (1983)	6.3
Basins pumping more than 10,000 acrefeet/year per 100 miles	4.0
Basins pumping between 1,000 and 10,000 acre-feet/year per 100 miles	2.0
Basins pumping between 250 and 1,000 acre-feet/year per 100 miles	1.0
Basins pumping between 100 and 250 acre-feet/year per 100 miles	0.7

Measuring Groundwater Levels

Given the significant variations in groundwater elevations throughout the Kern subbasin which are due to variations in hydrologic conditions, no single groundwater elevation surface should be considered a representation of groundwater flow directions in this basin.

Requirements for well selections:

- A long-term access agreement that includes year-round site access to allow for increased monitoring frequency
- A unique identifier that includes a general written description of the site location, date established, access instructions and point of contact, type of information to be collected, latitude, longitude and elevation
- Monitoring location should also track all modifications to the site in a modification log

The following data collection protocols are to be followed within the Kern subbasin:

- Groundwater level data shall be sufficient to produce seasonal maps of potentiometric surfaces or water table surfaces throughout the basin that clearly identify changes in groundwater flow direction and gradient.
- Use the Well Data form provided (see attached)
- Groundwater level data shall be collected from each principal aquifer in the basin
- Collection of data between the approved time frames only
    - January 15th to March 30th
    - September 15th to November 15th
- A weighted water level meter or other CASGEM approved measuring device will be used to measure the depth to groundwater
- Depth to groundwater must be measured relative to an established Reference Point on the well casing. If no mark or reference point is apparent, the person performing the measurement should measure the depth to groundwater from the north side of the top of the well casing
- The elevation of the Reference Point of the well must be referenced to the North American Vertical Datum of 1988. The accuracy of the reference point should be consistent with CASGEM established guidelines.
- Each well's Reference Point will be cataloged to ensure identical procedures are followed for subsequent measurements.
- The data collector should remove the appropriate cap, lid or plug that covers the monitoring access point listening for pressure release. If a release is observed, the measurement should follow a period of time to allow the water level to equilibrate.
- Depth to groundwater must be measured to the accuracy associated with the approved monitoring method or device.
- The water level meter shall be decontaminated after measuring each well.
- The data collector shall calculate the groundwater elevation as:
    - GWE = RPE – DTW
    - GWE = Groundwater Elevation

    - RPE = Reference Point Elevation
    - DTW = Depth to Water
- The data collector must ensure that all measurements are consistent units of feet, tenths of feet or hundredths of feet. Measurements and Reference Point Elevations should not be recorded in feet and inches.

.

Groundwater Quality

Groundwater quality monitoring networks shall be designed to demonstrate that the degraded water quality sustainability indicator is being observed for the purpose of meeting the definition of the sustainability goal.

Requirements for well selections:

- A long-term access agreement that includes year-round site access to allow for increased monitoring frequency
- A unique identifier that includes a general written description of the site location, date established, access instructions and point of contact, type of information to be collected, latitude, longitude and elevation
- Monitoring location should also track all modifications to the site in a modification log
- The use of existing water quality data within the basin should be done to the greatest extent possible
- Monitoring network should consist largely as a supplemental monitoring locations where known groundwater contamination plumes are under existing regulatory management

The following data collection protocols are to be followed within the Kern subbasin:

- Monitor groundwater quality data from each principal aquifer in the basin
- Data should be sufficient for mapping movement of degraded water quality
- Data should be sufficient to assess groundwater quality impacts to beneficial uses and users
- Data should be sufficient to evaluate whether management activities are contributing to water quality degradation.
- All analyses should be performed by a laboratory certified under the State Environmental Laboratory Accreditation Program
- Samples will be collected according to the standards listed in the Standard Methods for the Examination of Water and Wastewater, USGS National Field Manual for the Collection of Water Quality Data
- Prior to sampling, the sampler must contact the laboratory to schedule laboratory time, obtain appropriate sampler containers, and clarify any sample holding times or sample preservation requirements
- Each well used for groundwater quality monitoring must have a unique identifier. This identifier must appear on the well housing or the well casing to avoid confusion
- In the case of wells with dedicated pumps, samples should be collected at or near the wellhead. Samples are not to be taken/collected from storage tanks, at the end of long pipe runs or after any water treatment infrastructure

- Samples will be taken/collected only after the appropriate volume of water has been purged from the casing and field parameters have stabilized
- Sampler will clean the sampling port and/or sampling equipment. The sampling port and/or sampling equipment must be free of any contaminants
- Groundwater elevation in the well should be measured following the protocols described in the groundwater level measuring protocols
- Field parameters of pH, electrical conductivity and temperature should be collected for each sample. Lab pH analysis are typically unachievable due to short hold times.
- All field instruments should be calibrated daily and evaluated for drift throughout the day
- Sample containers should be labeled prior to sample collection. The sample label must include:
    - Sample ID (well ID)
    - Sample date and time
    - Sample personnel
    - Sample location
    - Preservative used
    - Analytes and analytical method
- Samples shall be collected under laminar flow conditions. This may require reducing pumping rates prior to sample collection
- Samples requiring preservation must be preserved as soon as practically possible
- Samples to be analyzed for metals should be field-filtered prior to preservation. Do not collect an unfiltered sample in a preserved container
- Samples will be chilled and maintained at 4 C to prevent degradation of the sample
- Samples will be shipped under a chain of custody documentation to the appropriate laboratory promptly to avoid violating holding time restrictions
- Custody Seal will be used by the field technician if a third-party transportation service is used
- A Field Sampling Log will include:
    - Sampler's identification
    - Well identification
    - Climatic conditions
    - Depth to water prior to purging
    - Type of purging and sampling device
    - Purging rate and volume
    - Relative well yield volume
    - Field parameter measurements (pH, temperature, EC, DO)
    - Type and number of samples collected
    - Date and time collected

Change in Groundwater Storage

Since the groundwater storage is not a directly measurable condition, it does rely heavily on the collection of accurate groundwater levels. The changes in groundwater levels reflect changes in storage and can thus be estimated with assumptions of thickness of units, porosity, and connectivity. These observations will be essential for use in calculating the water budget.

A water budget is a foundational tool used to compile water flows (supplies) and outflows (demands). It is an accounting of the total groundwater and surface water entering and leaving a basin or user-defined area. The difference between flows and outflows is a change in the amount of water stored.

Coordination of Water Budget Data to comply with groundwater storage:

- Surface water supply
- Total water use
- Water budget
- Sustainable yield

The change in the annual volume of groundwater storage between seasonal high conditions shall be quantified in the water budget.

Land Subsidence

Land subsidence protocols are to be set up to identify the rate and extent of land subsidence, which maybe measured by extensometers, surveying, remote sensing technology, or other appropriate method. To the extent possible, the use of existing data should be utilized.

Prior to development of a specific subsidence monitoring network a screening level analysis should be conducted. The screening of subsidence occurrence should include:

- Review of the HCM and understanding of grain-size distributions and potential for subsidence to occur
- Review of any known regional or correlative geologic conditions where subsidence has been observed.
- Review of historic range of groundwater levels in the principal aquifers of the basin
- Review of historic records of infrastructure impacts, including but not limited to damage to pipelines, canals, roadways or bridges or well collapse potentially associated with land surface elevation changes
- Review of remote sending results such as InSAR or other land surface monitoring data
- Review of existing CGPS surveys

This basin has decided to work together on this protocol with a consultant to obtain the required data.

APPENDIX H WELL ACCESS AGREEMENTS AND WELL COMPLETION REPORTS

MONITORING WELL ACCESS AGREEMENT

This Monitoring Well Access Agreement ("Agreement") is made and entered into by and between the Westside District Water Authority (hereafter "District") and Wonderful Nut Orchards, LLC (hereafter "Landowner"), both of whom shall be referred to individually as a "Party" to this Agreement and collectively as the "Parties" to this Agreement.

RECITALS

WHEREAS, the District is a member of the Kern Groundwater Authority ("KGA") which has adopted or will adopt a Groundwater Sustainability Plan ("GSP") to comply with the Sustainable Groundwater Management Act ("SGMA"); and

WHEREAS, the District developed and is responsible for implementing a chapter of the KGA GSP; and

WHEREAS, SGMA requires the long-term monitoring of groundwater levels and water quality; and

WHEREAS, to comply with this requirement, the District may need access rights from Landowners within its service area to monitor groundwater elevations and water quality; and

WHEREAS, real property owned by Landowner as set forth on Exhibit A attached hereto ("Landowner's Land") contains one or more groundwater wells in the District GSP chapter area for which the District is required to monitor for groundwater elevation and water quality monitoring activities; and

WHEREAS, Landowner has agreed to grant the District limited access onto Landowner's Land, subject to the terms and conditions as set forth in this Agreement.

NOW, THEREFORE, the Parties have entered into this Agreement to allow the District to access to Landowner's Land under the following terms and conditions:

TERMS AND CONDITIONS

1. Incorporation of Recitals. The foregoing recitals are incorporated herein as terms and conditions of this Agreement.

2. Right of Entry. Landowner grants to the District and its employees, agents, consultants, and contractors a non-exclusive year-round license to enter onto Landowner's Land (as generally described in Exhibit A) for the sole purpose of obtaining groundwater elevation and water quality data from Landowner's well(s). Unless otherwise agreed to by the Parties in a written amendment to this Agreement, the Parties agree that the District's access to Landowner's Land shall be limited to wells described in Exhibit A's "Monitoring Well Locations" and in compliance with any conditions listed under "Access Instructions."

3. Access and Control. Except as otherwise provided in this Agreement, Landowner retains the exclusive right of access to and control over the Landowner's Land. Nothing contained in this Agreement shall be construed as affording the public a right of access to any portion of the Landowner's Land or precluding Landowner's right to grant access to third parties across the Landowner's Land, provided that such access is not inconsistent with this Agreement.

4. Duration of Right. The Parties agree that this Agreement shall remain in effect until either of the following occurs: (a) Termination of the Agreement by either Party, or (b) Change in Ownership of Landowner's Land.

a. Termination by a Party. The Parties agree that this Agreement may be terminated at any time, with or without cause, by either Party upon sixty (60) days written notice to the other Party.

b. Landowner's Land: Change in Ownership. The Parties agree that this agreement shall terminate upon any change in ownership of Landowner's Land. Thereafter, the District acknowledges that it will need to enter into a new access agreement with the new owner(s) of Landowner's Land.

5. No Easement. The Parties agree that this Agreement does not grant the District a possessory right, easement, or other land interest with respect to Landowner's Land.

6. Costs. The Parties agree that all groundwater elevation and water quality monitoring performed by the District under this Agreement shall be funded by the District.

7. No Storage. The right of entry does not include permission to store soil or any measurement apparatus on the Landowner's Land. All materials and tools shall be removed from the Landowner's Land on the date of entry.

8. Use of Collected Data. The data collected as a result of well monitoring will be used to fulfill District's SGMA-related reporting requirements. The District will exclude landowner specific information and only site the location of the well and data.

9. Maintenance of Landowner's Land. The Parties acknowledge that this Agreement grants the District a non-exclusive year-round license to access Landowner's Land for the limited purpose of obtaining groundwater elevation and water quality data from Landowner's well(s). Accordingly, except as provided in section 10 of this Agreement below ("Damage/Restoration"), the Parties agree that the District (including its employees, agents, consultants, and contractors) is under no obligation to maintain or otherwise repair the Landowner's Land.

10. Damage/Restoration. The District (including its employees, agents, consultants, and contractors) shall take all reasonable precautions to avoid damaging Landowner's Land. If any damage is caused to Landowner's Land by the District in the course of performance of this Agreement, the District shall notify the Landowner immediately. In addition, the District will at its sole cost and expense work with the Landowner to take all action reasonably necessary to repair the damage and restore the areas of Landowner's Land to the condition that existed immediately prior to the damage caused by the District.

11. Schedule or Notice of Access. The District may develop a schedule of dates/times it will access Landowner's Land for the purposes of well monitoring. If the District does not provide a schedule, it shall undertake reasonable efforts to notify the Landowner in advance of accessing Landowner's Land pursuant the access rights granted under this Agreement.

12. Indemnity. The District agrees to defend, indemnify, and hold harmless Landowner and Landowner's past, present and future parents, subsidiaries and affiliates, and their respective directors, officers, shareholders, partners, members, managers, employees, agents, trustees, attorneys, representatives, affiliates, predecessors in interest, successors and assigns (collectively, the "Landowner Parties") for any costs, claims, damages, losses or other liabilities arising out of the District's (including any employees, agents, consultants, and contractors) actions on Landowner's Land under this Agreement, with the exception that the District shall not be responsible for defending, indemnifying, or holding harmless Landowner with regard to costs, claims, damages, losses, or other liabilities arising out of the sole negligence or intentional misconduct of Landowner.

13. Insurance. Prior to entering onto Landowner's Land, District shall provide to Landowner a certificate that the District or District's consultant a certificate evidencing general liability insurance in the amount of at least $500,000 Dollars aggregate limit.

14. If District or any of its contractors, invitees or other agents shall cause any release of any hazardous substances on, in or above Landowner's Land, or otherwise violate any applicable environmental law, District, at its sole cost and expense, shall promptly remediate such release to the satisfaction of Landowner and any governmental body having jurisdiction. If District fails to do the foregoing, Landowner may do such work at the cost and expense of the District.

15. District shall not permit or allow any mechanic's lien, materialmen's lien or other similar lien to attach to or be enforced against any portion of Landowner's Land arising out of District's exercise of rights under this agreement.

16. In no event shall Landowner be liable to District for any direct, indirect or consequential damages incurred by District resulting from District's use of, or inability to use, Landowner's Land for the purpose set forth herein.

17. District shall not assign, sublease, license or apportion its rights under this Agreement, in whole or in part, to any other party without Landowner's prior written consent, which consent may be withheld in Landowner's sole and absolute discretion.

18. Written Notices. Written notices between the Parties shall be sent via U.S. mail to the addresses listed below the parties' respective signatures.

19. Entire Agreement. This Agreement contains the entire understanding of the Parties and supersedes all prior agreements and understandings among the Parties related to the subject matter of this Agreement.

20. Amendment. Amendments to this Agreement shall become effective upon execution of a written amendment signed by both Parties.

21. Severability. If any provision of this Agreement is held to be unenforceable for any reason, it shall be adjusted, rather than voided, if possible, to achieve the intent of the Parties, and the balance of the Agreement shall remain in full force and effect.

22. Governing Law. This Agreement shall be interpreted and enforced pursuant to the laws of the state of California.

23. Effective Date. This Agreement shall become effective as of the latest date of execution below.

MONITORING WELL ACCESS AGREEMENT

This Monitoring Well Access Agreement ("Agreement") is made and entered into by and between the Westside District Water Authority (hereafter "District") and Wonderful Nut Ranches III, LLC (hereafter "Landowner"), both of whom shall be referred to individually as a "Party" to this Agreement and collectively as the "Parties" to this Agreement.

RECITALS

WHEREAS, the District is a member of the Kern Groundwater Authority ("KGA") which has adopted or will adopt a Groundwater Sustainability Plan ("GSP") to comply with the Sustainable Groundwater Management Act ("SGMA"); and

WHEREAS, the District developed and is responsible for implementing a chapter of the KGA GSP; and

WHEREAS, SGMA requires the long-term monitoring of groundwater levels and water quality; and

WHEREAS, to comply with this requirement, the District may need access rights from Landowners within its service area to monitor groundwater elevations and water quality; and

WHEREAS, real property owned by Landowner as set forth on Exhibit A attached hereto ("Landowner's Land") contains one or more groundwater wells in the District GSP chapter area for which the District is required to monitor for groundwater elevation and water quality monitoring activities; and

WHEREAS, Landowner has agreed to grant the District limited access onto Landowner's Land, subject to the terms and conditions as set forth in this Agreement.

NOW, THEREFORE, the Parties have entered into this Agreement to allow the District to access to Landowner's Land under the following terms and conditions:

TERMS AND CONDITIONS

1. Incorporation of Recitals. The foregoing recitals are incorporated herein as terms and conditions of this Agreement.

2. Right of Entry. Landowner grants to the District and its employees, agents, consultants, and contractors a non-exclusive year-round license to enter onto Landowner's Land (as generally described in Exhibit A) for the sole purpose of obtaining groundwater elevation and water quality data from Landowner's well(s). Unless otherwise agreed to by the Parties in a written amendment to this Agreement, the Parties agree that the District's access to Landowner's Land shall be limited to wells described in Exhibit A's "Monitoring Well Locations" and in compliance with any conditions listed under "Access Instructions."

3. Access and Control. Except as otherwise provided in this Agreement, Landowner retains the exclusive right of access to and control over the Landowner's Land. Nothing contained in this Agreement shall be construed as affording the public a right of access to any portion of the Landowner's Land or precluding Landowner's right to grant access to third parties across the Landowner's Land, provided that such access is not inconsistent with this Agreement.

4. Duration of Right. The Parties agree that this Agreement shall remain in effect until either of the following occurs: (a) Termination of the Agreement by either Party, or (b) Change in Ownership of Landowner's Land.

a. Termination by a Party. The Parties agree that this Agreement may be terminated at any time, with or without cause, by either Party upon sixty (60) days written notice to the other Party.

b. Landowner's Land: Change in Ownership. The Parties agree that this agreement shall terminate upon any change in ownership of Landowner's Land. Thereafter, the District acknowledges that it will need to enter into a new access agreement with the new owner(s) of Landowner's Land.

5. No Easement. The Parties agree that this Agreement does not grant the District a possessory right, easement, or other land interest with respect to Landowner's Land.

6. Costs. The Parties agree that all groundwater elevation and water quality monitoring performed by the District under this Agreement shall be funded by the District.

7. No Storage. The right of entry does not include permission to store soil or any measurement apparatus on the Landowner's Land. All materials and tools shall be removed from the Landowner's Land on the date of entry.

8. Use of Collected Data. The data collected as a result of well monitoring will be used to fulfill District's SGMA-related reporting requirements. The District will exclude landowner specific information and only site the location of the well and data.

9. Maintenance of Landowner's Land. The Parties acknowledge that this Agreement grants the District a non-exclusive year-round license to access Landowner's Land for the limited purpose of obtaining groundwater elevation and water quality data from Landowner's well(s). Accordingly, except as provided in section 10 of this Agreement below ("Damage/Restoration"), the Parties agree that the District (including its employees, agents, consultants, and contractors) is under no obligation to maintain or otherwise repair the Landowner's Land.

10. Damage/Restoration. The District (including its employees, agents, consultants, and contractors) shall take all reasonable precautions to avoid damaging Landowner's Land. If any damage is caused to Landowner's Land by the District in the course of performance of this Agreement, the District shall notify the Landowner immediately. In addition, the District will at its sole cost and expense work with the Landowner to take all action reasonably necessary to repair the damage and restore the areas of Landowner's Land to the condition that existed immediately prior to the damage caused by the District.

11. Schedule or Notice of Access. The District may develop a schedule of dates/times it will access Landowner's Land for the purposes of well monitoring. If the District does not provide a schedule, it shall undertake reasonable efforts to notify the Landowner in advance of accessing Landowner's Land pursuant the access rights granted under this Agreement.

12. Indemnity. The District agrees to defend, indemnify, and hold harmless Landowner and Landowner's past, present and future parents, subsidiaries and affiliates, and their respective directors, officers, shareholders, partners, members, managers, employees, agents, trustees, attorneys, representatives, affiliates, predecessors in interest, successors and assigns (collectively, the "Landowner Parties") for any costs, claims, damages, losses or other liabilities arising out of the District's (including any employees, agents, consultants, and contractors) actions on Landowner's Land under this Agreement, with the exception that the District shall not be responsible for defending, indemnifying, or holding harmless Landowner with regard to costs, claims, damages, losses, or other liabilities arising out of the sole negligence or intentional misconduct of Landowner.

13. Insurance. Prior to entering onto Landowner's Land, District shall provide to Landowner a certificate that the District or District's consultant a certificate evidencing general liability insurance in the amount of at least $500,000 Dollars aggregate limit.

14. If District or any of its contractors, invitees or other agents shall cause any release of any hazardous substances on, in or above Landowner's Land, or otherwise violate any applicable environmental law, District, at its sole cost and expense, shall promptly remediate such release to the satisfaction of Landowner and any governmental body having jurisdiction. If District fails to do the foregoing, Landowner may do such work at the cost and expense of the District.

15. District shall not permit or allow any mechanic's lien, materialmen's lien or other similar lien to attach to or be enforced against any portion of Landowner's Land arising out of District's exercise of rights under this agreement.

16. In no event shall Landowner be liable to District for any direct, indirect or consequential damages incurred by District resulting from District's use of, or inability to use, Landowner's Land for the purpose set forth herein.

17. District shall not assign, sublease, license or apportion its rights under this Agreement, in whole or in part, to any other party without Landowner's prior written consent, which consent may be withheld in Landowner's sole and absolute discretion.

18. Written Notices. Written notices between the Parties shall be sent via U.S. mail to the addresses listed below the parties' respective signatures.

19. Entire Agreement. This Agreement contains the entire understanding of the Parties and supersedes all prior agreements and understandings among the Parties related to the subject matter of this Agreement.

20. Amendment. Amendments to this Agreement shall become effective upon execution of a written amendment signed by both Parties.

21. Severability. If any provision of this Agreement is held to be unenforceable for any reason, it shall be adjusted, rather than voided, if possible, to achieve the intent of the Parties, and the balance of the Agreement shall remain in full force and effect.

22. Governing Law. This Agreement shall be interpreted and enforced pursuant to the laws of the state of California.

23. Effective Date. This Agreement shall become effective as of the latest date of execution below.

MONITORING WELL ACCESS AGREEMENT

This Monitoring Well Access Agreement ("Agreement") is made and entered into by and between the Westside District Water Authority (hereafter "District") and Wonderful Nut Ranches I, LLC (hereafter "Landowner"), both of whom shall be referred to individually as a "Party" to this Agreement and collectively as the "Parties" to this Agreement.

RECITALS

WHEREAS, the District is a member of the Kern Groundwater Authority ("KGA") which has adopted or will adopt a Groundwater Sustainability Plan ("GSP") to comply with the Sustainable Groundwater Management Act ("SGMA"); and

WHEREAS, the District developed and is responsible for implementing a chapter of the KGA GSP; and

WHEREAS, SGMA requires the long-term monitoring of groundwater levels and water quality; and

WHEREAS, to comply with this requirement, the District may need access rights from Landowners within its service area to monitor groundwater elevations and water quality; and

WHEREAS, real property owned by Landowner as set forth on Exhibit A attached hereto ("Landowner's Land") contains one or more groundwater wells in the District GSP chapter area for which the District is required to monitor for groundwater elevation and water quality monitoring activities; and

WHEREAS, Landowner has agreed to grant the District limited access onto Landowner's Land, subject to the terms and conditions as set forth in this Agreement.

NOW, THEREFORE, the Parties have entered into this Agreement to allow the District to access to Landowner's Land under the following terms and conditions:

TERMS AND CONDITIONS

1. Incorporation of Recitals. The foregoing recitals are incorporated herein as terms and conditions of this Agreement.

2. Right of Entry. Landowner grants to the District and its employees, agents, consultants, and contractors a non-exclusive year-round license to enter onto Landowner's Land (as generally described in Exhibit A) for the sole purpose of obtaining groundwater elevation and water quality data from Landowner's well(s). Unless otherwise agreed to by the Parties in a written amendment to this Agreement, the Parties agree that the District's access to Landowner's Land shall be limited to wells described in Exhibit A's "Monitoring Well Locations" and in compliance with any conditions listed under "Access Instructions."

3. Access and Control. Except as otherwise provided in this Agreement, Landowner retains the exclusive right of access to and control over the Landowner's Land. Nothing contained in this Agreement shall be construed as affording the public a right of access to any portion of the Landowner's Land or precluding Landowner's right to grant access to third parties across the Landowner's Land, provided that such access is not inconsistent with this Agreement.

4. Duration of Right. The Parties agree that this Agreement shall remain in effect until either of the following occurs: (a) Termination of the Agreement by either Party, or (b) Change in Ownership of Landowner's Land.

a. Termination by a Party. The Parties agree that this Agreement may be terminated at any time, with or without cause, by either Party upon sixty (60) days written notice to the other Party.

b. Landowner's Land: Change in Ownership. The Parties agree that this agreement shall terminate upon any change in ownership of Landowner's Land. Thereafter, the District acknowledges that it will need to enter into a new access agreement with the new owner(s) of Landowner's Land.

5. No Easement. The Parties agree that this Agreement does not grant the District a possessory right, easement, or other land interest with respect to Landowner's Land.

6. Costs. The Parties agree that all groundwater elevation and water quality monitoring performed by the District under this Agreement shall be funded by the District.

7. No Storage. The right of entry does not include permission to store soil or any measurement apparatus on the Landowner's Land. All materials and tools shall be removed from the Landowner's Land on the date of entry.

8. Use of Collected Data. The data collected as a result of well monitoring will be used to fulfill District's SGMA-related reporting requirements. The District will exclude landowner specific information and only site the location of the well and data.

9. Maintenance of Landowner's Land. The Parties acknowledge that this Agreement grants the District a non-exclusive year-round license to access Landowner's Land for the limited purpose of obtaining groundwater elevation and water quality data from Landowner's well(s). Accordingly, except as provided in section 10 of this Agreement below ("Damage/Restoration"), the Parties agree that the District (including its employees, agents, consultants, and contractors) is under no obligation to maintain or otherwise repair the Landowner's Land.

10. Damage/Restoration. The District (including its employees, agents, consultants, and contractors) shall take all reasonable precautions to avoid damaging Landowner's Land. If any damage is caused to Landowner's Land by the District in the course of performance of this Agreement, the District shall notify the Landowner immediately. In addition, the District will at its sole cost and expense work with the Landowner to take all action reasonably necessary to repair the damage and restore the areas of Landowner's Land to the condition that existed immediately prior to the damage caused by the District.

11. Schedule or Notice of Access. The District may develop a schedule of dates/times it will access Landowner's Land for the purposes of well monitoring. If the District does not provide a schedule, it shall undertake reasonable efforts to notify the Landowner in advance of accessing Landowner's Land pursuant the access rights granted under this Agreement.

12. Indemnity. The District agrees to defend, indemnify, and hold harmless Landowner and Landowner's past, present and future parents, subsidiaries and affiliates, and their respective directors, officers, shareholders, partners, members, managers, employees, agents, trustees, attorneys, representatives, affiliates, predecessors in interest, successors and assigns (collectively, the "Landowner Parties") for any costs, claims, damages, losses or other liabilities arising out of the District's (including any employees, agents, consultants, and contractors) actions on Landowner's Land under this Agreement, with the exception that the District shall not be responsible for defending, indemnifying, or holding harmless Landowner with regard to costs, claims, damages, losses, or other liabilities arising out of the sole negligence or intentional misconduct of Landowner.

13. Insurance. Prior to entering onto Landowner's Land, District shall provide to Landowner a certificate that the District or District's consultant a certificate evidencing general liability insurance in the amount of at least $500,000 Dollars aggregate limit.

14. If District or any of its contractors, invitees or other agents shall cause any release of any hazardous substances on, in or above Landowner's Land, or otherwise violate any applicable environmental law, District, at its sole cost and expense, shall promptly remediate such release to the satisfaction of Landowner and any governmental body having jurisdiction. If District fails to do the foregoing, Landowner may do such work at the cost and expense of the District.

15. District shall not permit or allow any mechanic's lien, materialmen's lien or other similar lien to attach to or be enforced against any portion of Landowner's Land arising out of District's exercise of rights under this agreement.

16. In no event shall Landowner be liable to District for any direct, indirect or consequential damages incurred by District resulting from District's use of, or inability to use, Landowner's Land for the purpose set forth herein.

17. District shall not assign, sublease, license or apportion its rights under this Agreement, in whole or in part, to any other party without Landowner's prior written consent, which consent may be withheld in Landowner's sole and absolute discretion.

18. Written Notices. Written notices between the Parties shall be sent via U.S. mail to the addresses listed below the parties' respective signatures.

19. Entire Agreement. This Agreement contains the entire understanding of the Parties and supersedes all prior agreements and understandings among the Parties related to the subject matter of this Agreement.

20. Amendment. Amendments to this Agreement shall become effective upon execution of a written amendment signed by both Parties.

21. Severability. If any provision of this Agreement is held to be unenforceable for any reason, it shall be adjusted, rather than voided, if possible, to achieve the intent of the Parties, and the balance of the Agreement shall remain in full force and effect.

22. Governing Law. This Agreement shall be interpreted and enforced pursuant to the laws of the state of California.

23. Effective Date. This Agreement shall become effective as of the latest date of execution below.

Well Construction	
Casing	4-inch Schedule 80 PVC
Screen	4-inch Schedule 80 PVC, 0.02-inch slot size
Filter Material	No. 3 sand
Transition Seal	Hydrated bentonite pellets
Grout Seal	Cement grout with 5% bentonite by weight and bentonite grout
Surface Finish	10" locking steel stovepipe, centered in a 3x3 concrete pad

Notes:

1. Elevation in feet above mean sea level (NAD27).
2. Grout seal consists of bentonite grout and neat cement grout installed at different intervals. See Table 1 for grout seal intervals.
3. Decommissioned due to melted casing. Backfilled with neat cement and upper 15' removed.

LOCATION OF WELL: **TOTAL ACRES** _____

Attach a plot plan with the exact location of water well with respect to the following items: property lines, adjoining properties, water bodies or courses, drainage pattern, roads, existing wells, structures, sewers or private disposal systems. Include dimensions. Draw a 200' radius circle from well site location. For monitoring wells provide a description of the facility to be monitored, including: location of tanks, proposed monitoring and placement, nearest street or intersection, location of any water wells or surface water within 500' radius of facility.

Provide detailed directions to site:

Wells are located 1,335 feet south and 1,100 feet west of the intersection of Lerdo Highway and Starrh Road.

Starrh Road is located 2 miles east of the intersection of Lerdo Highway and Lost Hills Road.

See attached site plan for general well locations.

WELL DESTRUCTION INFORMATION

WELL NUMBER			
WELL DEPTH			
CASING MATERIAL			
SEALANT MATERIAL			
SEALANT PLACEMENT METHOD			

GENERAL CONDITIONS FOR DESTRUCTION:

1. A well destruction application must be filed with this Division if a well is being destroyed that is not in conjunction with a test hole permit.
2. Destruction procedures must be followed as per UT-50.
3. Placement of the seal must be witnessed by a representative of this Division. Forty-eight hour advanced notice is required for an appointment.

SPECIAL CONDITIONS:

13A1
13A2

GENERAL CONDITIONS FOR ALL PERMITS:

Permit applications may be submitted to the Planning Department by county staff for zoning, access, and flood plain clearances prior to approval of the Environmental Health Division (EHD). If you are drilling within city's limits, you will have to receive approval from their Planning Department:

1. Permit applications must be submitted to EHD at least ten (10) working days prior to the proposed starting date.
2. Well site approval is required before beginning any work related to water well construction. It is unlawful to continue work past the stage at which an inspection is required unless inspection is waived or completed.
3. Other required inspections include: setting conductor casing, E-Logs, all seals, and final construction features.
4. In areas where a water well penetrates more than one aquifer, and one or more of the aquifers may contain water which is of a quality which may degrade the other aquifer(s) penetrated if allowed to commingle, an E-Log shall be required to determine the location of the confining clay layer(s) and assist in the placement of any required annular seal(s).
5. A phone call to the Division Hotline at (661) 862-8788 is required 48 hours before the placement of any seals or plugs.
6. Approval of water quality and final construction features is required before the water well is put into use.
7. Construction under this permit is subject to any instructions by EHD representatives.
8. Any misrepresentation or noncompliance with required permit conditions, or regulations, will result in issuance of a "Stop Work Order."
9. A copy of the Department of Water Resources Driller's Report and water quality analyses must be submitted to EHD within sixty (60) days after completion of the work.
10. "Dry" holes must be properly destroyed within two (2) weeks of drilling. A water well destruction application must be filed with EHD.
11. The permit is void one (1) year after date of issuance if work has not been started and reasonable progress toward completion made. Fees are not refundable or transferable.
12. Lead appurtenances shall not be used in construction of any private or public water supply system. The use of solders containing more than 2/10 of 1% lead is prohibited in making joints and fittings in any private or public potable water system.
13. Drilling of a water well shall be performed by a C-57 contractor licensed in accordance with the provisions of the Contractors License Law (Chapter 9, Division 3, of the Business and Professions Code) unless exempted by that act, and registered to drill within the County of Kern.
14. Permittee shall assume entire responsibility for all activities and uses under this permit and shall indemnify, defend and save the County of Kern and/or Kern County Water Agency, its officers, agents, and employees, free and harmless from any and all expense, cost or liability in connection with or resulting from the exercise of this permit, including, but not limited to, property damage, personal injury, and wrongful death.

☑ I UNDERSTAND THAT FUTURE DEVELOPMENT PERMITS MAY NOT BE ISSUED (KCOC 17.04.120) UNLESS RECORDED LEGAL ACCESS TO THE PROPERTY CAN BE DEMONSTRATED.

I certify that I am the owner of the above-described property, or the authorized representative of such owner, and that all the information I have furnished is current and accurate to the best of my knowledge, and I intend to construct the water well as represented above. I understand that all work is to be done in accordance with Kern County Ordinance Code Chapter 14.08, Bulletin 74-81 and all subsequent bulletins and the conditions of the Permit Application, including any conditions which may be added or changed by EHD upon review of this Application and issuance of the Permit. I further understand that any permit issued pursuant to this application is subject to such further conditions as may be deemed necessary to ensure compliance with the permit regulations.

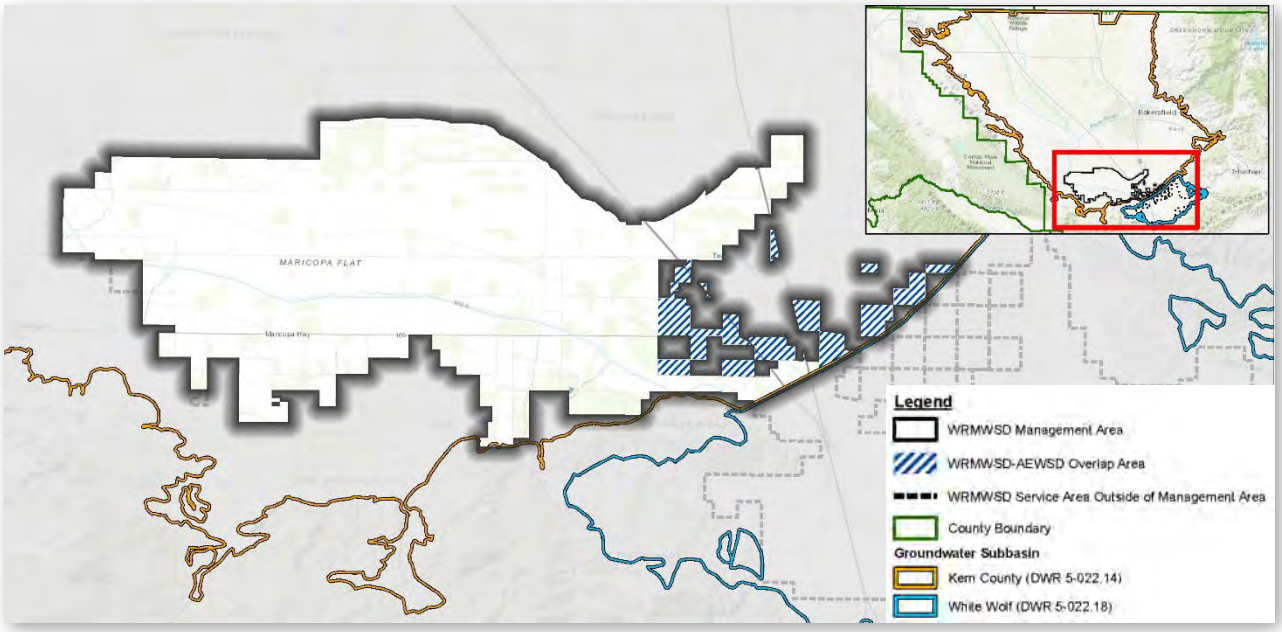
EXECUTIVE SUMMARY



☑ 23 CCR § 354.4(a)

ES.1. Introduction

On 16 September 2014, the California legislature enacted the Sustainable Groundwater Management Act (SGMA) whose primary purpose is to achieve and/or maintain sustainability within the state's high and medium priority groundwater basins. Key tenets of SGMA are the concept of local control, use of best available data and science, and active engagement and consideration of all beneficial uses and users of groundwater. As such, SGMA empowers certain local agencies to form Groundwater Sustainability Agencies (GSAs) whose purpose is to manage basins sustainably through the development and implementation of Groundwater Sustainability Plans (GSPs). Under SGMA, GSPs are required to contain certain elements, the most significant of which include: a Sustainability Goal; a description of the area covered by the GSP ("Plan Area"); a description of the Basin Setting, including hydrogeologic conceptual model, historical and current groundwater conditions, and a water budget; locally-defined sustainability criteria; monitoring networks and protocols for sustainability indicators; and a description of projects and/or management actions that will be implemented to achieve or maintain sustainability. SGMA also requires a significant element of stakeholder outreach to ensure that all beneficial uses and users of groundwater are given the opportunity to provide input into the GSP development and implementation process.

This GSP Management Area Plan ("MA Plan") has been prepared by Wheeler Ridge-Maricopa Water Storage District (WRMWSD) and covers an area called the "Wheeler Ridge-Maricopa Management Area" or "Management Area" (see figure below). The Management Area underlies the WRMWSD service area, excluding the area (approximately 2,809 acres) also overlain by the West Kern Water District, and is located in the southern portion of the Kern County Subbasin of the San Joaquin Valley Groundwater Basin (Department of Water Resources [DWR] Basin No. 5-022.14; referred to herein as the "Kern Subbasin"). The Kern Subbasin is one of 21 basins and subbasins identified by the DWR as being critically overdrafted, a designation that triggers an accelerated timetable for GSP development by 2020 and achievement of sustainability by 2040.

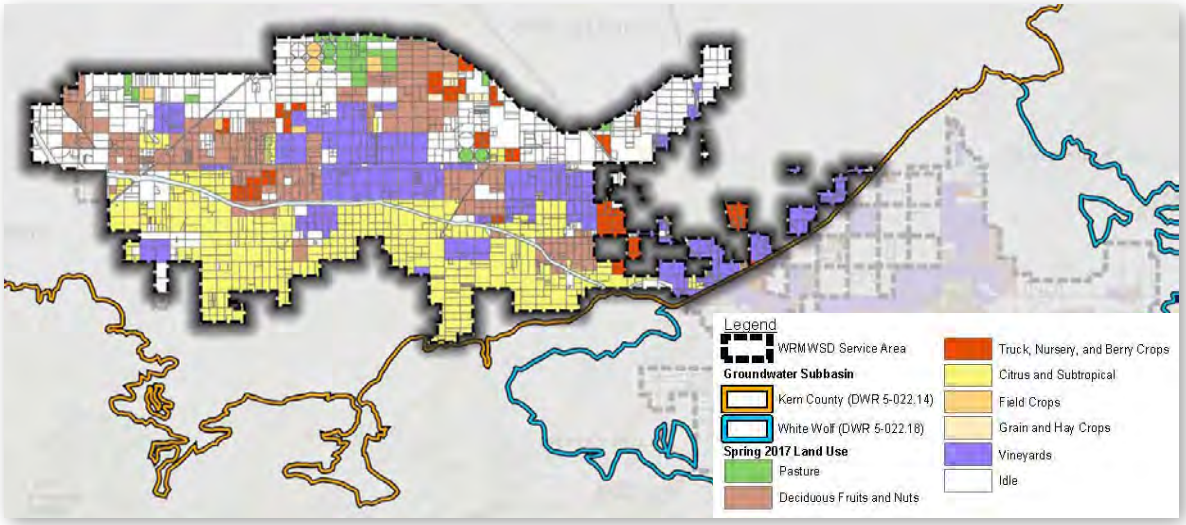
The Kern Groundwater Authority (KGA) GSA, of which WRMWSD is a member, is the largest of the 11 GSAs that have been formed within the Kern Subbasin. The KGA GSA was formed in 2017 upon adoption of a Joint Powers Agreement by all members and is governed by a 16-member Board of Directors that includes a representative of each member agency. The KGA GSA is preparing an "Umbrella GSP" that, in addition to providing content for the entire KGA GSA area, includes individual Management Area Plans that contain more detailed information for each member agency's service area. Areas of the Kern Subbasin that are outside of the KGA GSA GSP are covered under five separate, coordinated GSPs that have been developed by other GSAs.

Wheeler Ridge-Maricopa Management Area

The Arvin-Edison Water Storage District (AEWSD) jurisdictional boundary overlaps approximately 5,318 acres of the Management Area (see figure above), and WRMWSD serves surface water to approximately 3,186 acres in this area. AEWSD is a participating member of the KGA GSA and is developing a separate Management Area Plan for its jurisdictional area within the Kern Subbasin in close coordination with WRMWSD. For purposes of SGMA monitoring and management, WRMWSD and AEWSD have agreed that AEWSD will cover the overlap areas. However, WRMWSD will continue in the future to serve surface water to those lands within the overlap area that have historically received District supplies in accordance with the District's water delivery contracts with landowners.

The KGA Umbrella GSP and this MA Plan for the Wheeler Ridge-Maricopa Management Area have been developed to meet SGMA regulatory requirements[1] while reflecting local needs and preserving local control over water resources. Together, these documents provide a path to maintain the long-term sustainability of locally-managed groundwater resources now and into the future.

ES.2. Sustainability Goal



The sustainability goal for the Wheeler Ridge-Maricopa Management Area is to maintain an economically-viable groundwater resource for the beneficial use of the Management Area's landowners and water users by utilizing the area's groundwater resources within the local sustainable yield. Long-term groundwater sustainability, i.e., the absence of undesirable results within 20 years of the applicable statutory deadline, will be achieved and maintained through the implementation of projects and management actions as described herein to both increase water supplies and reduce demands within the Management Area.

[1] Regulations for GSP development are contained within Title 23 of the California Code of Regulations (CCR) Division 2 Chapter 1.5 Subchapter 2.

The local sustainability goal, above, is consistent with and in addition to the basin-wide sustainability goal being adopted by all GSAs in the Kern Subbasin.

ES.3. Plan Area

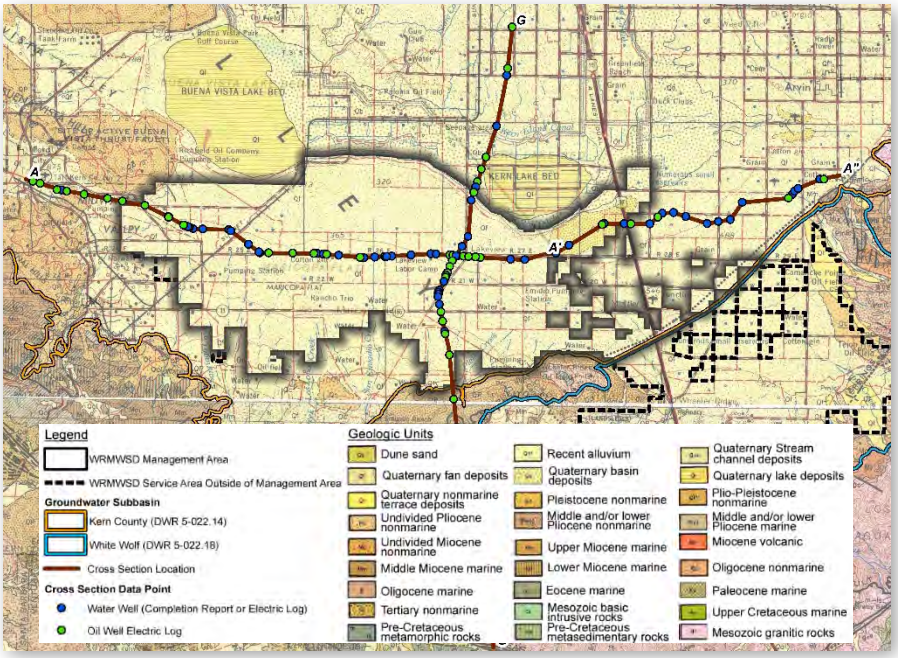
The Wheeler Ridge-Maricopa Management Area covers 91,430 acres in the southwestern portion of the Kern Subbasin. Located at the far southern end of the state's Central Valley, the Kern Subbasin is the largest groundwater basin in the state and is bounded on the north by the Tulare Lake Subbasin, the Tule Subbasin, the Kettleman Plain Subbasin and on the south by the White Wolf Subbasin. The Wheeler Ridge-Maricopa Management Area is bordered on the north by the Kern Delta Water District and Henry Miller

Spring 2017 Land Use

Water District, on the west by West Kern Water District, and on the east by (and overlapped with) the Arvin-Edison Water Storage District. To the south are "non-districted" lands, some of which have requested inclusion in this MA Plan and whose information is included in an Appendix hereto.

Most lands within the Wheeler Ridge-Maricopa Management Area are developed for irrigated agriculture, especially in the central and southern portions of the Management Area (see figure above). These agricultural lands use a combination of imported surface water provided by WRMWSD and groundwater from private wells for their water supply. WRMWSD has a water supply contract through Kern County Water Agency for State Water Project water which is obtained through turnouts off the California Aqueduct which runs through the District. WRMWSD has invested considerably over the years to import, convey, and distribute water to its customers within the Management Area (and also to customers in the portion of the District that is in the White Wolf Subbasin). Through its conjunctive management of water supplies, WRMWSD has provided a substantial net benefit to groundwater conditions within its service area.[2]

[2] WRMWSD supplies surface water to certain lands with WRMWSD water supply contracts within the eastern portion of the Wheeler Ridge-Maricopa Management Area that overlaps with the Arvin-Edison Water Storage District (AEWSD) service area and Arvin-Edison Management Area. WRMWSD will continue to serve surface water to those lands within the overlap area that have contracts with and have historically received water from WRMWSD.



Two small public water systems exist within the Management Area, serving small populations of residents or workers at various commercial/agricultural facilities. Most of the Management Area is designated by the U.S. Census Bureau as either Disadvantaged Community (DAC) or Severely Disadvantaged Community (SDAC). In the preparation of this MA Plan the interests of DACs have been considered.

ES.4. Stakeholder Outreach Efforts

WRMWSD has developed and adopted a Stakeholder Communication and Engagement Plan (SCEP) for the Wheeler Ridge-Maricopa Management Area to fulfill notice and communication requirements and enable the interests of all beneficial users of groundwater within the Management Area during the development and implementation of the MA Plan. The goal of the outreach efforts described in the SCEP is to encourage open and transparent engagement by diverse stakeholders and gain knowledge and perspectives provided by basin stakeholders. Public participation has been welcomed throughout the MA Plan development process. Venues for public stakeholder engagement and input throughout the MA Plan development process have included: Wheeler Ridge-Maricopa Management Area SGMA Landowner Workshops, WRMWSD Board meetings, KGA GSA Board meetings, and KGA GSA Stakeholder Workshops and Meetings. Other outreach to Management Area stakeholders throughout the MA Plan development process has included: distribution and collection of a Stakeholder Survey and an Agricultural Stakeholder Survey, and various letters from WRMWSD and KGA to landowners. WRMWSD has also conducted extensive coordination with other KGA members and GSAs in the Kern Subbasin.

ES.5. Hydrogeologic Conceptual Model

The Wheeler Ridge-Maricopa Management Area is located in the southwestern portion of the Kern Subbasin, south of the Kern River. The Kern Subbasin occupies a large structural trough filled with thick sedimentary deposits of continental and marine origin. The local geology underlying the Management Area reflects its location near the edge of the basin, proximal to the San Emigdio Mountains which are a source for the sediments washed down into the basin.

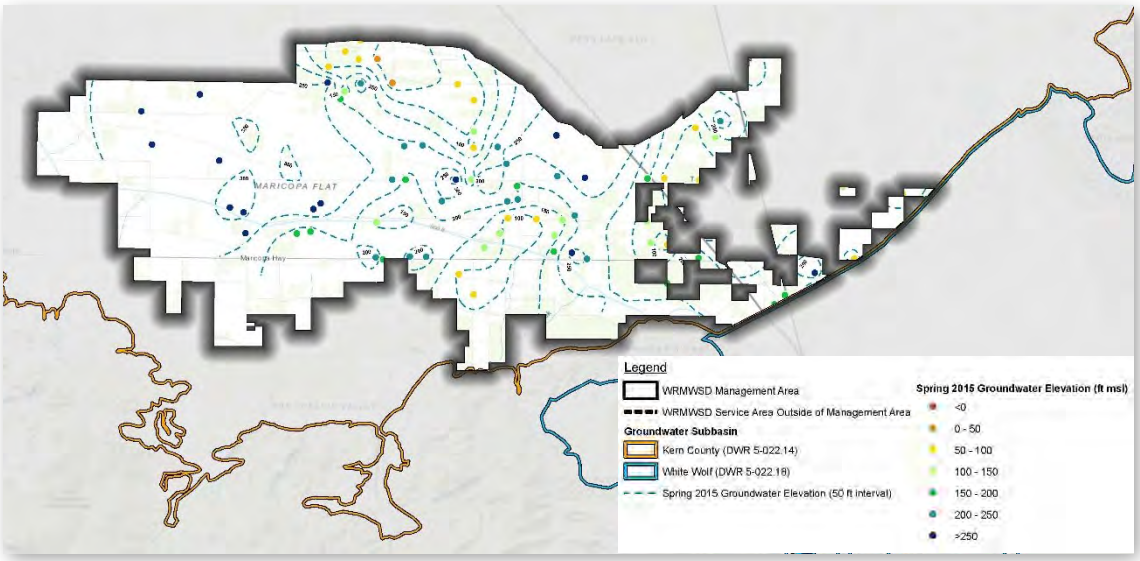
Surficial Geology and Cross-Section Locations

The "principal aquifer" is defined in the Management Area as the aquifer materials encountered within the depths of production wells in the area (i.e., the top 2,600 feet) and is comprised of fluvial and alluvial deposits of Mio/Pliocene to Recent age. In the northeastern portion of the Management Area, a regionally-extensive clay layer (the "E"-Clay) is found at intermediate depths and creates more confined

conditions in the underlying sediments. Aquifer conditions in general are more unconfined to semi-confined in the shallower zones and southern and western areas and more confined in the deeper zones and northern areas. The White Wolf Fault forms the southern boundary of the Kern Subbasin and has been demonstrated to be a significant impediment to groundwater flow as evidenced by higher groundwater levels on the upgradient (southern) side.

Due to its location near the edge of the basin, the southern half of the Management Area has fairly coarse and permeable soils that are conducive to recharge from precipitation and excess applied water[3] . The northern half of the Management Area is underlain by finer soils with lower recharge potential, and in some locations perched groundwater is present due to low permeability soils and sediments close to the surface. The Management Area also receives recharge from percolation of natural surface water flows in several creeks that flow from the uplands in the south into the Management Area.

ES.6. Existing Groundwater Conditions



Information on groundwater conditions within the Management Area is presented in this MA Plan with respect to the six "Sustainability Indicators" defined under SGMA, which include the following:

- Chronic lowering of groundwater levels
- Reduction in groundwater storage
- Seawater intrusion
- Degraded water quality
- Land subsidence
- Depletion of interconnected surface water

[3] Irrigation practices are generally highly efficient within the Wheeler Ridge-Maricopa Management area; however, recharge of applied water includes some irrigation inefficiency as well as water applied for leaching purposes and other non-consumptive operational uses.

Water Levels: Groundwater levels within the Management Area are presented using contour maps depicting recent (2015) seasonal high (spring) and seasonal low (fall) conditions, as well as hydrographs from 16 wells throughout the Management Area that have long records. The available data indicate groundwater flow directions are variable throughout the Management Area, with groundwater levels generally higher in the west and lower in the southern central and north central areas. Relative highs and lows appear to be controlled, at least in part, by the distribution of groundwater pumping versus surface water deliveries, with the exception of the south central where groundwater levels in 2015 were relatively low despite being within the District's Surface Water Service Area. Depths to groundwater in Spring 2015 range from approximately 100 to 560 feet below ground surface (ft bgs)[4]. The fact that most groundwater levels are greater than 100 ft bgs indicates that connections to surface water and the existence of groundwater dependent ecosystems (GDEs) are unlikely. Hydrographs show the long-term positive effects of WRMWSD's surface water importation in raising groundwater levels, tempered by the effects of the recent severe drought.

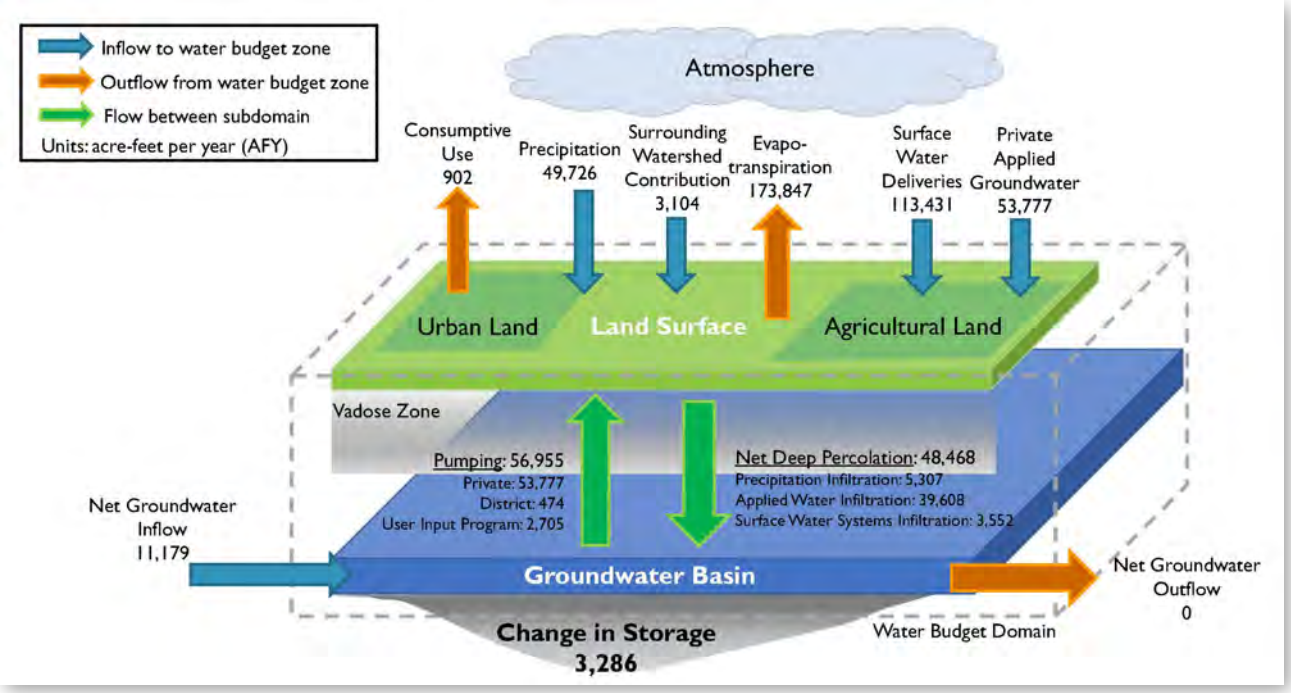
Groundwater Storage: Changes in groundwater storage over selected time periods of interest were analyzed by comparing water levels at the beginning and end of the period. The water levels show the positive impacts of water importation and the variability caused by wet and dry climate periods. Over the period from Fall 1994 through Fall 2014 (the KGA historical water budget period of interest), the average annual change in storage was +3,286 acre-feet per year (AFY), indicating sustainable conditions although annual changes in groundwater storage ranged from +83,000 AFY to -46,000 AFY. Spatially, the changes in storage (directly related to changes in water level) are more positive in the WRMWSD Surface Water Service Area compare to areas that rely solely on groundwater for supply.

Spring 2015 Groundwater Elevations

[4] A perched groundwater zone exists along the northern boundary of the Management Area, where depth to groundwater has historically been encountered as shallow as 20 ft bgs. This perched zone is hydraulically disconnected from the underlying principal aquifer system and does not yield significant or economic quantities of groundwater to wells, springs, or surface water systems (see **Section 8.2 Groundwater Elevations and Flow Direction**).

Water Quality: Agricultural use is the dominant beneficial use within the Management Area, and groundwater quality is generally suitable for agricultural uses. That being said, in some instances concentrations of nitrate, arsenic, total dissolved solids (TDS), boron, iron, manganese and sulfate have been detected in groundwater within or near the Management Area above drinking water standards and/or agricultural water quality goals. Future monitoring efforts will include routine collection of water quality data throughout the Management Area; these data will be periodically reviewed and water quality trends will be evaluated as part of future GSP implementation efforts. Further, water quality issues related to potential constituents or concern are regulated separately under the Irrigated Lands Regulatory Program (ILRP), Central Valley-Salinity Alternatives for Long-term Sustainability (CV-SALTS), and the State Water Resources Control Board (SWRCB).

Land Subsidence: Some amount of land subsidence has been documented within the Wheeler Ridge-Maricopa Management Area over both historical (1949-2005) and recent (2015-2016) timeframes. Subsidence due to aquitard depressurization following groundwater withdrawal tends to be greater in the north central area, with some localized subsidence historically in the far western area and more recently in the south-central area. Subsidence has the potential to affect critical infrastructure including gravity-driven water conveyance systems (canals) and has been monitored and observed along the California Aqueduct. However, subsidence has been historically managed by DWR through maintenance and improvements to its facilities and no reaches of the Aqueduct in this area have less than the minimum recommended freeboard.



Interconnected Surface Waters: Due to the great depth to groundwater in the principal aquifer (i.e., greater than 100 ft bgs in most places), it appears that there are no interconnection surface water systems within the Management Area. Similarly, while the DWR dataset of Natural Communities Commonly Associate with Groundwater (NCCAG) shows some areas along the northern boundary of the Management Area as NCCAG, due to the great depth to groundwater in the principal aquifer, these areas do not appear to be GDEs.

Seawater Intrusion: The Management Area is located far from coastal areas. As a result, seawater intrusion is not considered to be an issue for this area.

ES.7. Water Budget

For the Kern Subbasin as a whole, the basin GSAs coordinated on two basin-wide water budget approaches, as described in the KGA Umbrella GSP: (1) development of a numerical model based on the California Central Valley Groundwater/Surface Water Simulation Model (C2VSim) to estimate the basin-wide water budget, and (2) development of a "checkbook" water accounting approach that estimates supply, demand, and shortages using certain management assumptions. In addition, on a local Management Area basis, a spreadsheet water budget model was developed and calibrated to observed water level/storage changes to provide locally-refined water budget information. While the numerical model and checkbook water accounting approaches are described in the Coordination Agreement and Appendices thereto, the calibrated spreadsheet model is the basis for the detailed historical and current water budget information presented herein (see figure below) but is not a determination of water rights. Based on the 1995 to 2014 historical water budget time period (DWR water years [WY] 1995 through 2014; October 1994 through September 2014) The sustainable yield for the Management Area is conservatively estimated to be at a minimum approximately 60,300 AFY under current supply and demand conditions (approximately 0.65 AFY/acre over the 91,430-acre Management Area). Because it is based on

a calculation of pumping to achieve net zero decrease in groundwater storage, this sustainable yield is defined in such a way as to avoid the occurrence of Undesirable Results for relevant Sustainability Indicators (discussed further below), and is consistent with the assumptions for "native yield" and effective precipitation being used basin-wide and also reflects the contribution to groundwater from return flow of applied imported surface water.

Illustrated Historical Water Budget (WY 1995-2014)

Over this historical period, the average annual change in groundwater storage in the Management Area was +3,286 AFY.

Water budget information under projected (future) conditions was also developed using the calibrated spreadsheet water budget model, with DWR-provided inputs for climate variables (i.e., precipitation and evapotranspiration) and water supply assumptions (i.e., changes to imported water supplies). The projected water budget assesses the magnitude of the net water supply deficit under future conditions that would need to be addressed through Projects and Management Actions (P/MAs) to prevent Undesirable Results and achieve the Sustainability Goal. Consistent with the basin-wide efforts, three projected water budget scenarios were developed for this analysis: a Baseline Scenario, a 2030 Climate Change Scenario, and a 2070 Climate Change Scenario. For the projected Baseline condition, the long-term average change in groundwater storage was estimated to be -14,665 AFY for both the analytical spreadsheet model and basin-wide "checkbook" method (see table below). The projected deficit under the 2030 Climate Change Scenario (-21,429 AFY) was used as the basis to develop P/MAs for the Management Area.

Comparison of Change in Storage Estimates (AFY) from Three Water Budget Estimation Methods

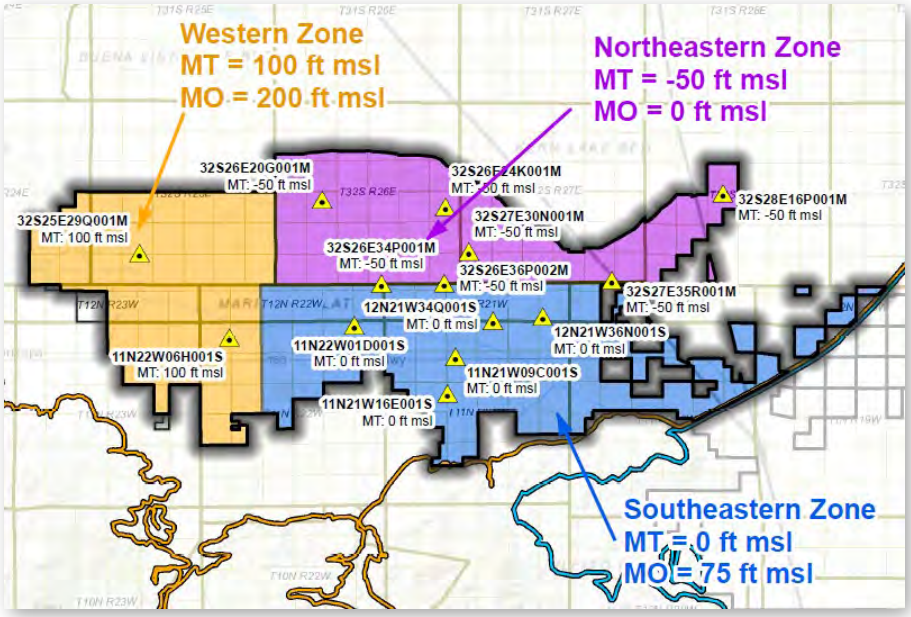
Period / Scenario	Basin-wide Numerical Model	Local Analytical Spreadsheet Model	Basin-wide "Checkbook" Water Accounting Approach
Historical Period (WY 1995 – 2014)	-8,654	3,286	Not Applicable
Current Period (WY 2015)	-45,191	-42,898	Not Applicable
Projected Period (50 years; 2021 – 2070) Baseline with no Projects	**-5,423**	**-14,665**	**-14,665**
Projected Period (50 years; 2021 – 2070) 2030 Climate Change with no Projects	-9,712	-21,429	Not Applicable
Projected Period (50 years; 2021 – 2070) 2030 Climate Change with Projects	9,780	53	Not Applicable
Projected Period (50 years; 2021 – 2070) 2070 Climate Change with no Projects	-17,952	-33,326	Not Applicable
Projected Period (50 years; 2021 – 2070) 2070 Climate Change with Projects	1,571	47	Not Applicable

Each estimate presented above includes data gaps and has varying degrees of accuracy and/or reliability. As part of MA Plan implementation, these numbers will be refined as additional information is developed.

ES.8. Sustainable Management Criteria

Sustainable Management Criteria (SMCs) are the metrics by which groundwater sustainability is judged under SGMA. Key terms related to SMCs under SGMA include the following:

Undesirable Results: Undesirable Results are the significant and unreasonable occurrence of conditions, for any of the six Sustainability Indicators defined under SGMA, that adversely affect groundwater use in the basin. Definitions of Undesirable Results for the basin have been developed through a coordinated effort of the basin GSAs and are described in the KGA GSA Umbrella GSP. The basin-wide definitions of Undesirable Results allow for local definition of Minimum Thresholds and the combination thereof that is considered significant and unreasonable. Therefore, the broad basin-wide Undesirable Results definitions were refined locally for the Wheeler Ridge-Maricopa Management Area to better reflect local groundwater conditions and beneficial uses.



Minimum Thresholds: Minimum Thresholds (MTs) are the numeric criteria for each Sustainability Indicator that, if exceeded in a locally-defined combination of monitoring sites, may constitute an Undesirable Results for that indicator. Where appropriate, the Minimum Thresholds for the Sustainability Indicators have been set using groundwater levels as a proxy.

Measurable Objectives: Measurable Objectives (MOs) are a specific set of quantifiable goals for the maintenance or improvement of groundwater conditions. Measurable Objectives use the same units and metrics as the Minimum Thresholds and are thus directly comparable.

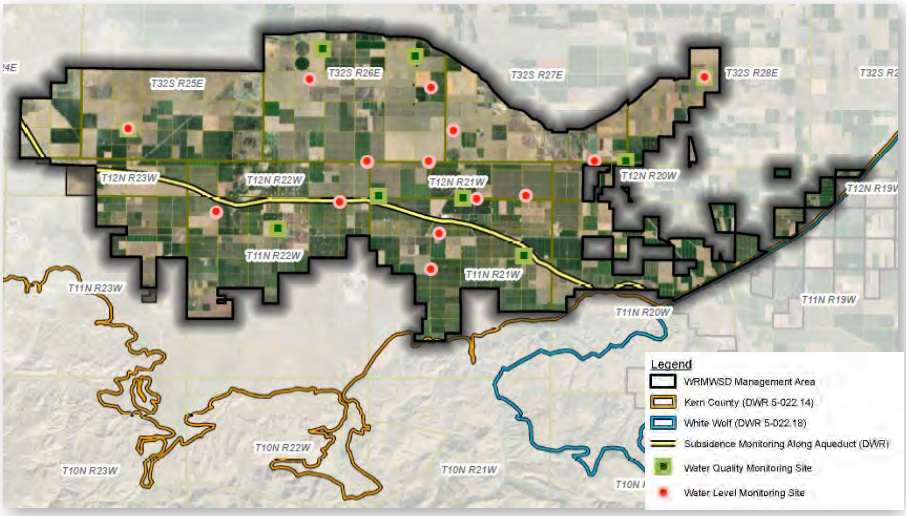
Interim Milestones: Interim Milestones are a set of target values representing measurable groundwater conditions in increments of five years over the 20-year statutory deadline for achieving sustainability.

Chronic Lowering of Groundwater Levels is arguably the most fundamental Sustainability Indicator, as it influences several other key Sustainability Indicators, including Reduction of Groundwater Storage and Land Subsidence. MTs and MOs for Chronic Lowering of Groundwater Levels were developed through temporal analysis of long-term groundwater level data. Briefly, at each of 15 locations with long-term records, an initial MT estimate was calculated considering historical lows, recent groundwater level trends, and the variability or range in groundwater levels. Initial MOs were set based on Fall 2015 levels. These initial individual estimates were then generalized into three Sustainability Zones to allow flexibility in the ultimate monitoring locations. An evaluation of these generalized MTs against known well construction information was performed to understand the potential impacts on wells (i.e., potential dewatering of shallow wells). MTs and MOs were presented on multiple occasions in public meetings to allow for stakeholder input.

Significant Groundwater Storage exists within the Wheeler Ridge-Maricopa Management Area, and it is estimated that it would take roughly 100 years of zero recharge to deplete the usable storage under current extraction rates. As such, it was determined to be sufficiently protective to define the SMCs for Reduction of Groundwater Storage based on the use of SMCs for Chronic Lowering of Groundwater Levels as a proxy.

Minimum Thresholds (MT) and Measurable Objectives (MO) for Chronic Lowering of Groundwater Levels

No SMCs for Degraded Water Quality are defined within the Wheeler Ridge-Maricopa Management Area because, based the existing beneficial uses and users of groundwater within, there are no Undesirable Results for Degraded Water Quality occurring, and the MTs for Chronic Lowering of Groundwater Levels are anticipated to be protective in terms of preventing migration of poor-quality water. Monitoring for water quality will continue to be conducted at a set of Representative Monitoring Sites, and if a nexus between these constituent concentrations and water levels and groundwater management actions is established, then the SMCs for water quality will be revisited.



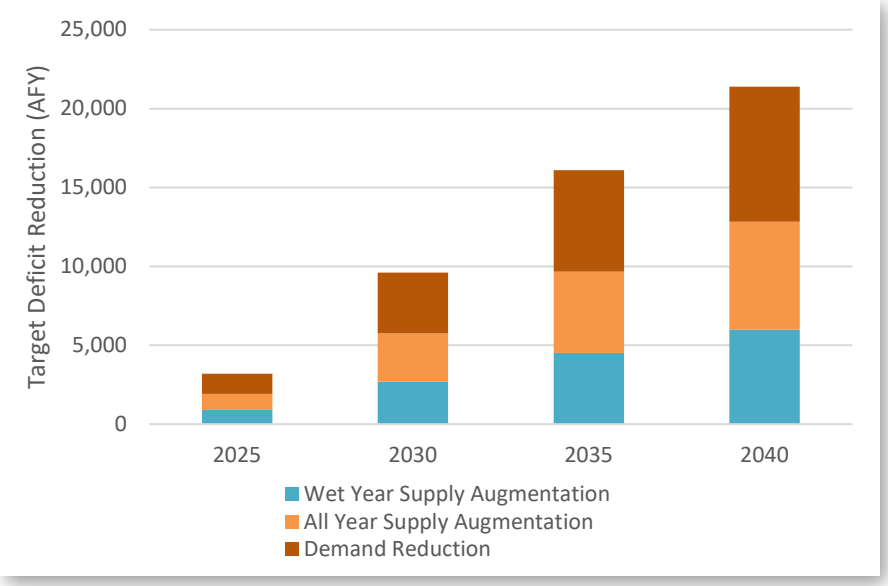
The SMCs for Land Subsidence are based on observed rates of subsidence from ground-based surveys along the California Aqueduct between 1975 and 2019. Specifically, the MT is set as the maximum rate of

subsidence that was observed during that period extended through the GSP implementation timeframe. The rationale for this MT rate of subsidence is that such subsidence has been historically managed by DWR through maintenance and improvements to its facilities and no reaches of the Aqueduct in this area have less than the minimum recommended freeboard. The MO is defined as the amount of land subsidence that would occur if the Minimum Threshold rate were to continue through 2030 and then cease.

As discussed above, Depletion of Interconnected Surface Water has not been observed within the Wheeler Ridge-Maricopa Management Area and is not applicable due to the great depths to groundwater in the principal aquifer. Likewise, Seawater Intrusion does not exist within the Kern Subbasin. Therefore, no SMCs for these Sustainable Indicators are defined in this MA Plan.

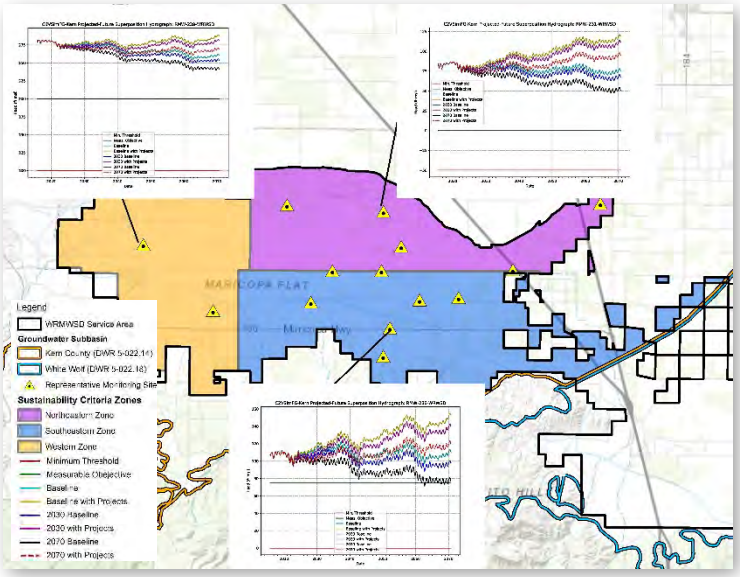
ES.9. Monitoring Network

The objective of the Wheeler Ridge-Maricopa Management Area Monitoring Network is to collect sufficient data to allow for assessment of the Sustainability Indicators relevant to the Management Area, and potential impacts to the beneficial uses and users of groundwater. The proposed Monitoring Network was developed to ensure sufficient spatial distribution and spatial density. The network consists of 14 Representative Monitoring Sites for groundwater levels and (by proxy) groundwater storage, nine sites for monitoring groundwater quality (although as discussed above, no SMCs are defined for this Sustainability Indicator), and 40 sites along the California Aqueduct for monitoring land subsidence. The SGMA-compliance network for the Management Area supplements other monitoring networks and programs in the basin such as DWR California Statewide Groundwater Elevation Monitoring (CASGEM), Central Valley-Salinity Alternatives for Long-term Sustainability (CV-SALTS), Kern County Water Agency [KCWA] semiannual groundwater monitoring program, etc. and basin-wide monitoring networks related to SGMA compliance such as the KGA's land subsidence network.



Monitoring Networks for Water Levels, Water Quality and Land Subsidence

Data collected from the SGMA-compliant Monitoring Network will be uploaded to the Data Management System maintained for the basin and reported to the DWR in accordance with the Monitoring Protocols developed for the basin as described in the KGA Umbrella GSP. In addition, local data will be stored and managed in a Wheeler Ridge-Maricopa Management Area-specific DMS. Additional data collected as part of WRMWSD's other regular monitoring programs may be used in conjunction with data collected from the SGMA-compliant Monitoring Network to meet compliance with GSP Emergency Regulations regarding Annual Reporting or as otherwise deemed necessary for the Management Area.



ES.10. Project and Management Actions

Achieving sustainability in the Wheeler Ridge-Maricopa Management Area will require implementation of P/MAs to address projected water budget deficits. As such, WRMWSD has developed a portfolio of P/MAs, each with specific expected benefits, implementation triggers, and costs. A preliminary "glide path" has been developed that results in closing of the currently identified projected "deficit"[5] of approximately -21,400 AFY by 2040. Accelerated implementation of P/MAs will be triggered if observed groundwater conditions deteriorate, as measured against defined SMCs at the representative monitoring sites.

Project & Management Action Implementation Glide Path

The Projects in WRMWSD's P/MA portfolio have supply augmentation as their primary expected benefit, and are grouped into the following categories:

Simulated Hydrographs Showing Achievement of Sustainability with Planned P/MAs

- Projects to Enhance Recharge / Banking;
- Projects to Increase Water Management Flexibility; and
- Projects to Develop New Supplies.

The Management Action in the P/MA portfolio have water demand reduction as their primary expected benefit and are grouped into the following categories:

- Management Actions to Raise Funds to Support SGMA Compliance; and
- Management Actions / Policies to Reduce Groundwater Pumping.

The supply augmentation and demand reduction P/MAs listed above comprise a diverse portfolio of options that can be

[5] The net deficit to be addressed by the 2040 GSP implementation deadline is the estimated deficit under the 2030 Climate Change scenario.

implemented as necessary by WRMWSD to achieve sustainability from a total water quantity perspective. Simulation results from the basin-wide numerical (C2VSim) model indicate that P/MA implementation along the planned glide path will successfully achieve sustainability and avoid Undesirable Results for Groundwater Levels (and by proxy for the other applicable Sustainability Indicators) (see figure above). The glide path provides a general guide to how quickly these benefits are to be realized. However, the exact schedule and order of implementation is not known, and further analysis will be conducted to prioritize the P/MAs in consideration of factors including permitting, engineering feasibility, cost effectiveness and other factors. In general, P/MAs being considered for implementation will be discussed during regular WRMWSD Board Meetings, which are open to the public. Additional stakeholder outreach efforts will be conducted prior to and during P/MA implementation, as required by law.

ES.11. GSP Implementation

Key GSP implementation activities to be undertaken over the next five years include:

- Monitoring and data collection;
- Projects & Management Action (P/MA) implementation, including policy development to support GSP implementation;
- Technical and non-technical coordination with other water management entities within the Kern County Subbasin (Kern Subbasin);
- Continued outreach and engagement with stakeholders;
- Annual reporting;
- Enforcement and response actions, as necessary; and
- Evaluation and updates, as necessary, of the Wheeler Ridge-Maricopa MA Plan as part of the required periodic evaluations (i.e., “five-year updates”).

ES.12. GSP Implementation Costs and Funding

Costs to implement this MA Plan can be divided into several groups, as follows:

- Costs of local groundwater management activities;
- WRMWSD’s proportional share of costs for basin-wide groundwater management activities; and
- Costs to implement P/MAs, including capital/one-time costs and ongoing costs.

The estimated costs to WRMWSD for local groundwater management activities is approximately $261,000 per year, the estimated proportional share of costs for basin-wide groundwater management activities is approximately $120,000 per year, and the estimated costs to implement P/MAs is approximately $3.5 million per year in the first five years, increasing to between approximately $4.5 million to $7.1 million per year in the subsequent 15 years.

Sources of funding for SGMA compliance activities will include primarily regular fees and assessments from customers and rate payers. This primary source of revenue will be supplement to the greatest extent possible through loans and grants, and possibly by additional fees imposed as an incentive to discourage

unsustainable water use practices. All efforts by WRMWSD to raise revenue through fees and charges will be conducted pursuant to applicable laws and regulations (e.g., Proposition 218 and related laws).

ES.13. Conclusion

The passage of SGMA in 2014 ushered in a new era of mandatory groundwater management in California's most intensively used groundwater basins. The law was followed by promulgation of a robust regulatory framework for GSA formation and GSP development and implementation. The law and regulations emphasize the use of best available science, local control and decision making, and active engagement of affected stakeholders. Because of the breadth and scope of the groundwater sustainability problem in California and the legislative and regulatory response to it, SGMA presents significant challenges both for local implementing agencies and groundwater users alike. Achieving and maintaining sustainability in the face of uncertain future water supply conditions while addressing and balancing the needs of all beneficial uses and users will require significant effort, creative solutions, and unprecedented collaboration. As the implementing agency within the Wheeler Ridge-Maricopa Management Area, WRMWSD is committed to facing these challenges in a manner that upholds the interests of its landowners and other beneficial uses and users of groundwater.

INTRODUCTION

1. PURPOSE OF THIS GROUNDWATER SUSTAINABILITY PLAN

The purpose of this Groundwater Sustainability Plan (GSP) Management Area Plan (MA Plan) is to, in combination with the Kern Groundwater Authority (KGA) Groundwater Sustainability Agency (GSA) and the other GSAs in the Kern County Subbasin (Kern Subbasin), meet the regulatory requirements set forth in the three-bill legislative package consisting of Assembly Bill (AB) 1739 (Dickinson), Senate Bill (SB) 1168 (Pavley), and SB 1319 (Pavley), collectively known as the Sustainable Groundwater Management Act (SGMA)[6]. SGMA defines sustainable groundwater management as the "management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results". Undesirable results are defined by SGMA as any of the following effects caused by groundwater conditions occurring throughout the basin:

- Chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply;
- Significant and unreasonable reduction of groundwater storage;
- Significant and unreasonable seawater intrusion;
- Significant and unreasonable degraded water quality;
- Significant and unreasonable land subsidence; and/or
- Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water.

The Kern Subbasin has been identified by the California Department of Water Resources (DWR) as critically overdrafted. WRMWSD's MA Plan has been developed in coordination with the KGA GSA to meet SGMA regulatory requirements by the 31 January, 2020 deadline for critically-overdrafted basins while reflecting local needs and preserving local control over water resources. WRMWSD's MA Plan, in coordination with the KGA Umbrella GSP and the other GSPs in the Kern Subbasin, provides a path to achieve and document sustainable groundwater management within 20 years following Plan adoption, and preserves the long-term sustainability of locally-managed groundwater resources now and into the future. This MA Plan was approved for inclusion in the KGA GSA Umbrella GSP by the WRMWSD Board on 11 December 2019 (**Appendix J**).

[6] Nothing in this Management Area Plan or in the related Groundwater Sustainability Plan determines or alters surface water rights or groundwater rights under common law, any provision of law that determines or grants surface water rights, or otherwise (see, California Water Code section 10720.5(b)). This Management Area Plan and the related Groundwater Sustainability Plan shall be construed consistent with Section 2 of Article X of the California Constitution and nothing provided in this Chapter modifies rights or priorities to use or store groundwater except as expressly stated in California Water Code section 10720.5(a). The District reserves and retains all rights to the use of water to the extent provided by law.

2. SUSTAINABILITY GOAL

☑ **23 CCR § 354.24**

The sustainability goal for the Wheeler Ridge-Maricopa Management Area is to maintain an economically-viable groundwater resource for the beneficial use of the Management Area's landowners and water users by utilizing the area's groundwater resources within the local sustainable yield. Long-term groundwater sustainability, i.e., the absence of undesirable results within 20 years of the applicable statutory deadline, will be achieved and maintained through the implementation of projects and management actions as described herein to both increase water supplies and reduce demands within the Management Area.

The local sustainability goal, above, is consistent with and in addition to the basin-wide sustainability goal being adopted by all GSAs in the Kern Subbasin, shown below (as of 9 August 2019).

> "The sustainability goal of the Kern County Subbasin is to:
>
> - Achieve sustainable groundwater management in the Kern County Subbasin through the implementation of projects and management actions at the member agency level of each GSA
> - Maintain its groundwater use within the sustainable yield of the basin
> - Operate within the established sustainable management criteria, which are based on the collective technical information presented in the GSPs in the Subbasin.
> - Implement projects and management actions that include a variety of water supply development and demand management actions
> - Collectively bring the Subbasin into sustainability and to maintain sustainability over the implementation and planning horizon.
>
> Further, the Subbasin sustainability goal includes a commitment to monitor and report groundwater conditions, as required by SGMA, and to continue coordination among the KGA member agencies and all other GSA's in the Subbasin to identify the potential for, or presence of, undesirable results and actions to prevent undesirable results. The coordination process established in the development of this GSP and memorialized in the Coordination Agreement will ensure that the Subbasin is managed as a shared groundwater resource and that the districts within the Subbasin work collaboratively towards achieving and maintaining sustainable groundwater use."

3. AGENCY INFORMATION

3.1. Name and Mailing Address of the Agency

☑ 23 CCR § 354.6(a)

The Wheeler Ridge-Maricopa Water Storage District Management Area (Wheeler Ridge-Maricopa Management Area)[7] is the portion of the Kern County Subbasin of the San Joaquin Valley Groundwater Basin (Department of Water Resources [DWR] Basin No. 5-022.14) that underlies the WRMWSD. WRMWSD is member of the Kern Groundwater Authority Groundwater Sustainability Agency (KGA GSA or Agency) per a Joint Power Agreement (JPA) executed on 22 March 2017. Information regarding the Agency's mailing address is provided in the KGA "Umbrella" GSP.

The mailing address for the WRMWSD is:

12109 Highway 166
Bakersfield, California 93313-9630

The mailing address for the KGA GSA is:

Kern Groundwater Authority
(c/o Provost & Pritchard Consulting Group)
1800 30th Street, Suite 280
Bakersfield, CA 93301

3.2. Organization and Management Structure of the Agency

☑ 23 CCR § 354.6(b)

Per the JPA executed on 22 March 2017, the KGA GSA Board is composed of one representative from each of the general member agencies[8], including: Arvin Community Services District (ACSD), Arvin-Edison Water Storage District (AEWSD), Cawelo Water District (CWD), Kern County Water Agency (KCWA), Kern-Tulare Water District (KTWD), Kern Water Bank Authority (KWBA), North Kern Water Storage District (NKWSD), Rosedale-Rio Bravo Water Storage District (RRBWSD), Semitropic Water Storage District (SWSD), Shafter-Wasco Irrigation District (SWID), Southern San Joaquin Municipal Utility District (SSJMUD), Tejon-Castac Water District (TCWD), West Kern Water District (WKWD), Westside District Water Authority (WDWA) and WRMWSD, and the City of Shafter.

To facilitate the implementation of the KGA GSA GSP, the Agency is divided into management areas formed by the portion of the Kern Subbasin that underlies the boundaries of each general member agency. Each general member agency will prepare a refined Management Area Plan for their management area.

[7] In this document, the term "Wheeler Ridge-Maricopa Management Area" is used in its entirety the first time the area is being referenced in each paragraph; subsequent references to this area in each paragraph use the term "Management Area".
[8] See executed JPA for a full list of member agencies to the KGA.

The WRMWSD Board of Directors also represents the Wheeler Ridge-Maricopa Management Area and it is formed by nine directors. A current list of WRMWSD Directors can be found on the District's website at https://wrmwsd.com/board-of-directors/.

The KGA GSA was formed by a resolution of the Board of Directors of the Kern Groundwater Authority on 26 April 2017. The KGA GSA is governed by a Board of Directors that includes a representative of each member agency. Information regarding current KGA GSA Board members can be found on the KGA's website at http://www.kerngwa.com/.

3.3. MA Plan Manager

☑ **23 CCR § 354.6(c)**

The Plan Manager for this MA Plan is Sheridan Nicholas, Engineer-Manager of the WRMWSD. Mr. Nicholas can be reached at:

Sheridan Nicholas
Engineer-Manager
Wheeler Ridge-Maricopa Water Storage District
12109 Highway 166
Bakersfield, California 93313-9630
661-858-2281 office phone
email: snicholas@wrmwsd.com

The KGA GSP Plan Manager is Patricia Poire. Ms. Poire can be reached at:

Patricia Poire, Planning Manager
Telephone: (661) 479-7171
Fax: (661) 479-7172
Email: ppoire@kerngwa.com

3.4. Legal Authority of the GSA

☑ **23 CCR § 354.6(d)**

The KGA GSA applied for and was granted GSA status under SGMA Section 10723(c). Please refer to the KGA Umbrella GSP for further discussion of the legal authority of the KGA GSA, demonstrating that it has the legal authority to implement the GSP.

3.5. Estimated Cost of Implementing the GSP and the GSA's Approach to Meet Costs

☑ **23 CCR § 354.6(e)**

Information on estimated costs to implement the GSP within the Wheeler Ridge-Maricopa Management Area, and the WRMWSD's plan to meet those costs is provided in **Section 19 *Plan Implementation Costs***.

4. GSP ORGANIZATION

This MA Plan is organized as follows:

- Sections 1 through 4 comprise the **Introduction**, including the following sections:
  - Section 1. Purpose of this Groundwater Sustainability Plan
  - Section 2. Sustainability Goal
  - Section 3. Agency Information
  - Section 4. GSP Organization
- Section 5 provides the **Description of the Plan Area**.
- Sections 6 through 10 present the **Basin Setting**, including the following sections:
  - Section 6. Introduction to Basin Setting
  - Section 7. Hydrogeologic Conceptual Model
  - Section 8. Current and Historical Groundwater Conditions
  - Section 9. Water Budget Information
  - Section 10. Management Areas
- Sections 11 through 15 present the **Sustainable Management Criteria**, including the following sections:
  - Section 11. Introduction to Sustainable Management Criteria
  - Section 12. Sustainability Goal
  - Section 13. Undesirable Results
  - Section 14. Minimum Thresholds
  - Section 15. Measurable Objectives and Interim Milestones
- Section 16 presents the **Monitoring Network**.
- Section 17 presents the **Projects and Management Actions**.
- Sections 18 through 20 present **Plan Implementation**, including the following sections:
  - Section 18. WRMWSD Plan Implementation
  - Section 19. Plan Implementation Costs
  - Section 20. Plan Implementation Schedule
- **References and Technical Studies** are included at the end of this document.
- Supporting information is provided in appendices as follows:
  - Appendix A. GSP Submittal Checklist
  - Appendix B. Parcels Outside of WRMWSD Covered by MA Plan
  - Appendix C. Summary of Stakeholder Communications and Engagement

- Appendix D. Detailed Responses to Selected Comments Received Regarding the MA Plan
- Appendix E. Potential Additional Water Quality Data Sources
- Appendix F. Analysis of Temporal Characteristics of Available Groundwater Quality Data
- Appendix G. Methods and Data Used in the Water Budget Spreadsheet Model Approach
- Appendix H. WRMWSD Long-term Monitoring Access Agreement
- Appendix I. DWR California Aqueduct Subsidence Study (June 2017), Plates 20 – 24; DWR California Aqueduct Benchmark Survey Data, 2016-2019
- Appendix J. Board Resolution

PLAN AREA

5. DESCRIPTION OF THE PLAN AREA

☑ 23 CCR § 354.8

This section presents a description of the Plan Area for the Wheeler Ridge-Maricopa Management Area[9], and a summary of the relevant jurisdictional boundaries and other key land use features potentially relevant to the sustainable management of groundwater in the Management Area. This section also describes the water monitoring programs, water management programs, and general plans relevant to the Management Area and their influence on the development and execution of this Groundwater Sustainability Plan (GSP) Management Area Plan (MA Plan).

5.1. Summary of Jurisdictional Areas and Other Features

5.1.1. Area Covered by the Plan

☑ 23 CCR § 354.8(a)(1)
☑ 23 CCR § 354.8(b)

As discussed previously in **Section 3.2** ***Organization and Management Structure of the Agency***, this MA Plan is a locally refined subcomponent of the "Umbrella" GSP prepared by the Kern Groundwater Authority (KGA) Groundwater Sustainability Agency (GSA). This MA Plan covers a portion of the KGA GSA area, specifically the portion underlying Wheeler Ridge-Maricopa Water Storage District (WRMWSD). The area covered by this MA Plan, referred to herein as the "Wheeler Ridge-Maricopa Management Area" and shown on **Figure PA-1**, includes all WRMWSD lands within the Kern County Subbasin (Department of Water Resources [DWR] Basin 5-022.14) (referred to herein as the Kern Subbasin or basin) excepting 2,809 acres that occur within the West Kern Water District (WKWD). Lands within the WRMWSD service area that are located in the White Wolf Subbasin are managed under a separate GSP being prepared by the White Wolf GSA. The Arvin-Edison Water Storage District (AEWSD) jurisdictional boundary also partially overlaps the Management Area, both in the Kern Subbasin and the White Wolf Subbasin; AEWSD is a participating member of the KGA GSA and is developing a separate Management Area Plan for its jurisdictional area within the Kern Subbasin in close coordination with WRMWSD. For purposes of SGMA monitoring and management, WRMWSD and AEWSD have agreed that AEWSD will cover the overlap areas.

The Wheeler Ridge-Maricopa Management Area is in the southern-southeastern portion of the Kern Subbasin. The basin is bounded on the north by the Tulare Lake Subbasin (DWR Basin 5-022.12), the Tule Subbasin (DWR Basin 5-022.13), and the Kettleman Plain Subbasin (DWR Basin 5-022.17), and on the south by the White Wolf Subbasin (DWR Basin 5-022.18).

[9] In this document, the term "Wheeler Ridge-Maricopa Management Area" is used in its entirety the first time the area is being referenced in each paragraph; subsequent references to this area in each paragraph use the term "Management Area".

The Wheeler Ridge-Maricopa Management Area encompasses 91,430 acres of the KGA GSA. There are 10 other GSAs that are located within the Kern Subbasin[10]: Buena Vista Water Storage District (BVWSD), Cawelo GSA, Greenfield County Water District, Henry Miller Water District (HMWD), Kern River GSA, McFarland GSA, Olcese GSA, Pioneer GSA, Semitropic Water Storage District, and West Kern Water District (WKWD). These GSAs were formed by several other GSA-eligible public agencies in the basin and in some cases are preparing separate GSP documents that will be coordinated with the GSP prepared by the KGA GSA. The rest of the basin is comprised of undistricted lands (i.e. "white lands"), some of which have executed management agreements with nearby water districts or other public agencies.

5.1.2. Adjudicated Areas

☑ 23 CCR § 354.8(a)(2)
☑ 23 CCR § 354.8(b)

The basin is not adjudicated, and no portion of the basin is being managed pursuant to an alternative.

5.1.3. Jurisdictional Boundaries

☑ 23 CCR § 354.8(a)(3)
☑ 23 CCR § 354.8(b)

The Wheeler Ridge-Maricopa Management Area is entirely within Kern County and the Kern County Water Agency. As shown on **Figure PA-1**, water agencies that partially overlie the Management Area are AEWSD and the WKWD[11]. Additional water agencies and public water systems in the vicinity of the Management Area include: BVWSD, HMWD, Kern Delta Water District (KDWD), Opal Fry and Son Water System, and Mettler County Water District (MCWD).

According to the information made available by DWR[12] in support of the development of GSPs, there are no tribal lands nor state lands within or in the vicinity of the Wheeler Ridge-Maricopa Management Area. Federal lands within the Management Area include approximately 500 acres of national public lands managed by the U.S. Bureau of Land Management, located in the northern portion of the District (see **Figure PA-2**). Tribal, federal and state lands within the KGA GSA are identified in the KGA Umbrella GSP.

DWR further presents information regarding U.S. Census Blocks, Tracts and Places that are defined as Disadvantaged Communities (DAC) or Severely Disadvantaged Communities (SDAC). **Figure PA-3** shows DAC/SDAC areas within the Wheeler Ridge-Maricopa Management Area. As shown on **Figure PA-3**, a majority of the Management Area is considered either a severely disadvantaged or a disadvantaged community based on the Census Block Group and Census Tract characterizations (see **Figure PA-3**).

The Wheeler Ridge-Maricopa Management Area is located entirely within the Kern County General Plan area (see **Figure PA-7**). This plan is described in further detail below in **Section *5.3 Land Use Elements or Topic Categories of Applicable General Plans*** .

[10] SGMA Portal: https://sgma.water.ca.gov/portal/gsa/all, retrieved on 11/30/2018.
[11] WKWD overlaps a portion of WRMWSD, however, the GSA formed by this district (WKWD GSA) does not include such area.
[12] SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer

5.1.4. Existing Land Use and Water Use

☑ 23 CCR § 354.8(a)(4)
☑ 23 CCR § 354.8(b)

As shown on **Figure PA-4**, agriculture is the primary land use within the Wheeler Ridge-Maricopa Management Area, followed by idle/non-irrigated lands. As of Spring 2017, approximately 63,620 acres (71%) are classified as irrigated agricultural lands within the Management Area, ~23,950 acres (27%) are classified as non-irrigated agricultural/native lands, and ~2,260 acres (3%) are classified as urban areas and artificial channels.

Agricultural water demands are met with surface water and/or groundwater depending on location within the Wheeler Ridge-Maricopa Management Area. The District has a contract for 197,088 acre-feet per year (AFY) of Table A water from the State Water Project (SWP) through the Kern County Water Agency (KCWA) (WRMWSD, 2015). **Figure PA-5** shows the parcels within the District's surface water service area (SWSA). The reminder of the Management Area relies solely on groundwater to meet demands; surface water customers are not precluded from pumping underlying groundwater for beneficial use.

Imported surface water is served only to agricultural water users for irrigation. All municipal/industrial (M&I) and domestic demands are met by groundwater pumping. The potable consumption of groundwater in the Management Area is limited to domestic well owners.

Land use designations under the Kern County General Plan are discussed in **Section 5.3.1** ***Kern County General Plan*** and shown on **Figure PA-7**.

5.1.5. Well Density per Square Mile

☑ 23 CCR § 354.8(a)(5)
☑ 23 CCR § 354.8(b)

Figure PA-6 shows the density of wells per square mile within the Wheeler Ridge-Maricopa Management Area, based on Well Completion Report records compiled by DWR[13] and refined information on active domestic wells obtained from the Community Water Center.[14] According to these records, approximately 121 production wells, 27 active domestic wells, and one public supply wells have been installed within the Public Land Survey System (PLSS) sections[15] that fall partially or entirely within the Management Area.

The WRMWSD Data Management System (DMS) identifies 559 wells within the Wheeler Ridge-Maricopa Management Area; 100 of these wells are known to be active, 49 inactive or abandoned, and the status of 410 wells is unknown. Of the active wells, 79 are production wells, 14 are domestic/Municipal & Industrial (M&I) wells, and seven are monitoring wells. As part of GSP preparation efforts, the District is attempting to reconcile the information in its DMS with the DWR records. These data reconciliation efforts are expected to continue as part of GSP implementation.

[13] DWR Well Completion Report Map Application website: https://dwr.maps.arcgis.com/apps/webappviewer/index.html?id=181078580a214c0986e2da28f8623b37, accessed 08/17/2018.
[14] Community Water Center Drinking Water Vulnerability Tool, obtained 24 May 2019.
[15] Each PLSS section represents approximately 1 square mile of area (i.e., 640 acres).

The closest urban communities to the Wheeler Ridge-Maricopa Management Area are Maricopa and Mettler but there are no communities dependent on groundwater within the Management Area. The only potable groundwater consumption comes from the domestic wells.

5.1.6. Lands Outside of District Covered by MA Plan

Under SGMA (CWC § 10724), counties are presumed to be the GSA for areas that are not otherwise covered by another GSA, unless the county specifically opts out of this GSA role. In the Kern Subbasin, the County of Kern opted out of this role in early 2019 which resulted in lands outside of the other GSA boundaries being "uncovered". To address this, the KGA sent notices to these "undistricted" land owners offering an opportunity to sign an agreement for coverage under the Management Area Plans of nearby KGA members. Three landowners with a total of four parcels outside of the District totaling approximately 1,122 acres accepted the offer to gain coverage under the WRMWSD MA Plan. Given the late time at which these offers were made and accepted following the County's withdrawal, KGA determined that it would not be possible to cover these undistricted lands in the KGA member's Management Area Plans to the same degree of detail as lands that were covered by KGA members from the start; instead, KGA determined that it would be appropriate to include the lands in an appendix to the Management Area Plans, providing basic information about each parcel including the owner, APN, area, land/water use, and well information. As such, **Appendix B** includes a table of these lands[16] with the above information as well as a figure showing their locations. It is the intention of KGA and its members to include additional information for these lands (if they still need GSP coverage) in their 2025 Management Area Plan updates.

5.2. Water Resources Monitoring and Management Programs

5.2.1. Existing Monitoring and Management Programs

☑ **23 CCR § 354.8(c)**

Existing Monitoring Programs

Existing groundwater monitoring in the Wheeler Ridge-Maricopa Management Area includes:

- The California Statewide Groundwater Elevation Monitoring (CASGEM) Program is a program that tracks long-term groundwater elevation trends in groundwater basins throughout California. The program's mission is to establish a permanent, locally-managed program of regular and systematic monitoring in all of California's alluvial groundwater basins, including within the Management Area. In 2011, the District submitted to DWR an application to be the CASGEM Monitoring Entity for the District's service area (except the overlap areas with AEWSD and WKWD), but a full CASGEM monitoring plan has not been completed. Therefore, all wells monitored within the District are designated as "voluntary wells" under the CASGEM program at this point.
- The Groundwater Ambient Monitoring and Assessment (GAMA) Program is California's comprehensive groundwater quality monitoring program that was created by the State Water Resources Control Board (SWRCB) in 2000. The GAMA Program monitors groundwater quality trends throughout California, including within the Management Area.[17]

[16] All four undistricted parcels included in **Appendix B** are unirrigated.
[17] GAMA Website: https://www.waterboards.ca.gov/water_issues/programs/gama/about.html.

- The Monitoring and Reporting Program (MRP) from the Irrigated Lands Regulatory Program (ILRP), establishes the specific surface and groundwater monitoring, reporting, and electronic data deliverable requirements for irrigated lands used for commercial purposes within the Tulare Lake Basin Area (The ILRP is further described in the section below "Existing Management Programs"). The purpose of this MRP is to determine the effects of irrigated lands waste discharges on water quality and assess the effectiveness of ILRP management actions. Data collected and reports are available in the GAMA database (Central Valley Regional Water Quality Control Board [CVRWQCB], 2013).
- Central Valley-Salinity Alternatives for Long-term Sustainability (CV-SALTS) is a collaborative stakeholder driven and managed program to develop sustainable salinity and nitrate management planning for the Central Valley. The Kern Subbasin is a Priority 2 basin for nitrate management. Consequently, the nitrate control program schedule is set to begin in 2021 as described in the KGA Umbrella GSP.
- The District conducts periodic groundwater level monitoring and groundwater quality sampling in selected wells throughout the Management Area as part of its on-going water resources management efforts, including the AEWSD-WRMWSD overlap portion of the Management Area.

CASGEM groundwater elevations (and groundwater elevations from wells in the WRMWSD and AEWSD monitoring networks) have been used to characterize groundwater level conditions (see **Section 8.2 *Groundwater Elevations and Flow Direction***)[18]. Water quality data from the above sources have been used to assess groundwater quality conditions (see **Section 8.5 *Groundwater Quality***).

Existing surface water monitoring in the Wheeler Ridge-Maricopa Management Area includes the following:

- The WRMWSD is establishing a network of five stream gauges in the San Emigdio mountains, three of which are on streams that flow into the Management Area and two of which flow into the White Wolf Subbasin.
- The California Data Exchange Center (CDEC) provides a centralized database to store, process, and exchange real-time hydrologic information gathered by various cooperators throughout the State[19]. The CDEC has three monitoring points within or in the vicinity of the Management Area.

Another surface water monitoring program in the basin is the United States Geological Survey (USGS) National Water Information System; however, there are not monitoring points within or in the vicinity of the Wheeler Ridge-Maricopa Management Area.

[18] While they collect groundwater level data on a regular basis, WRMWSD is not an official CASGEM monitoring entity for the Kern Subbasin.
[19] CDEC Website: http://cdec.water.ca.gov/cdecstation2/

Land subsidence data in the vicinity of WRMWSD is available through the following sources:

- University Navstar[20] Consortium (UNAVCO) Plate Boundary Observatory's continuous and conventional Global Positioning System (GPS) network; and
- Remote sensing studies by the National Aeronautics and Space Administration (NASA) Jet Propulsion Laboratory (JPL).
- USGS San Joaquin Valley Land Subsidence Network. A subsidence monitoring network in the San Joaquin Valley was implemented in the 1960s to help quantify the extent and magnitude of the subsidence that was first discovered in the 1950s. To identify existing and future subsidence, a new monitoring network is currently being developed[21].
- The DWR's San Luis Field Division and the San Joaquin Field Division conducted a land subsidence study along the California Aqueduct (DWR, 2017) to understand the magnitude, location and effects of past and present land subsidence. For this study, data from 940 survey benchmarks along the California Aqueduct that have been monitored at 1-year and 7-year intervals by the San Luis Field Division, and 1,009 benchmarks monitored at 3-year and 7-year intervals by the San Joaquin Field Division was used.

The WRMWSD will incorporate information from these existing regional and local programs to inform GSP development and implementation. The Wheeler Ridge-Maricopa Management Area Monitoring Network is further described in **Section 16 *Monitoring Network***.

Existing Management Programs

Existing groundwater management programs within the Wheeler Ridge-Maricopa Management Area include:

- The Wheeler Ridge-Maricopa Management Area falls within the South County Subregion of the Kern County Integrated Regional Water Management Region (Kern Region) and is therefore included in the November 2011 Kern Integrated Regional Water Management Plan (Kern IRWMP; Kennedy/Jenks Consultants, 2011). The Kern Region covers approximately 5,690 square miles of Kern County and a small portion of southern Kings County. The Kern Region is separated into nine subregions, in acknowledgement of the variation in geography, agency boundaries, and water management strategies. These subregions are: (1) Greater Bakersfield, (2) Kern Fan, (3) Mountains/Foothills, (4) Kern River Valley, (5) North County, (6) South County, (7) West Side, (8) KCWA1 and (9) the County of Kern.

  The key issues, needs, challenges, and priorities for the South County subregion, according to the Kern IRWMP (2011), include the following:

  - Decreased Imported Water Supply;
  - Water Quality/Groundwater Contamination;
  - Urban Growth Encroachment on Key Recharge Areas; and

[20] Navstar is a network of U.S. satellites that provide GPS services.
[21] From USGS California Water Science Center website: https://ca.water.usgs.gov/projects/central-valley/land-subsidence-san-joaquin-valley.html

- Water Rights.

A 2019 Kern IRWMP update that is consistent with the 2016 IRWM Guideline requirements was recently approved by DWR (9 December 2019) and is now entering a 30-day Public Comment Period that is expected to be completed in mid-January 2020. Subsequent adoption of the 2019 Plan update is anticipated to occur in February 2020.

- The WRMWSD has an existing Groundwater Management Plan (GWMP). Although this MA Plan extends and supersedes the groundwater management efforts outlined in the GWMP, a brief summary of this GWMP is included below for completeness.

- The WRMWSD GWMP was developed in 2007 and aimed to increase reliability and sustainability of water supply by conjunctively integrating groundwater with imported surface water supply. Specifically, the WRMWSD GWMP (2007) set forth the following groundwater management objectives to guide future water management actions:
  - Prevent a return to historical overdraft conditions;
  - Maintain groundwater quality;
  - Monitor water levels, water quality, and groundwater storage; and
  - Estimate groundwater use and future groundwater demands on the basin.
- The ILRP, initiated in 2003 and last modified in 2013 to include groundwater provisions, is a program whose objective is to protect both groundwater and surface water from irrigated agricultural waste dischargers throughout the Central Valley. The ILRP is implemented through CVRWQCB Orders, also called Waste Discharge Requirements (WDRs). Order R5-2013-0120 (Order) regulates discharges in the Tulare Lake Basin. Under this order, third parties are responsible for fulfilling regional requirements and conditions (e.g. surface and groundwater monitoring). WRMWSD is a member of the Kern River Watershed Coalition Authority (KRWCA) which is a third-party coalition that formed in 2014 to respond to the Order. Key elements of the ILRP are: Surface water/Groundwater Quality Monitoring Plan, Sediment and Erosion Control Plan, Nitrogen Management Plan and Mitigation Monitoring. The overall goals of the ILRP for the Tulare Lake Basin Area are:
  - To restore and/or maintain the highest reasonable quality of state waters;
  - Minimize waste discharge from irrigated agricultural lands that could degrade state waters quality;
  - Maintain the economic viability of agriculture in California's Central Valley; and
  - Ensure that irrigated agricultural discharges do not impair access by Central Valley communities and residents to safe and reliable drinking water.

  In accordance with these goals, the objectives are the following:
  - Restore and/or maintain appropriate beneficial uses established in CVWQCB plans by ensuring that all state waters meet applicable water quality objectives; and

- Encourage implementation of management practices that improve water quality in keeping with the first objective, without jeopardizing the economic viability for all sizes of irrigated agricultural operations.

- The District prepared an Agricultural Water Management Plan (AWMP) in accordance with the requirements of Senate Bill (SB) X7-7 and Governor's Executive Order B-29-15 and it was last modified in December 2015. The purpose of this AWMP is to describe and document the District's existing and proposed agricultural water management programs and activities aimed to provide reliable agricultural water supply for its landowners. The document provides a description and quantification of water supply sources for agricultural users (surface and groundwater), a water reliability assessment, and efficient water management practices (WRMWSD, 2015).

5.2.2. Operational Flexibility Limitations

☑ 23 CCR § 354.8(d)

The above water resource monitoring programs are not expected to limit operational flexibility in the basin. In fact, some of these management and monitoring programs will be integral to the on-going monitoring and reporting that will be conducted pursuant to this MA Plan (see **Section 16 *Monitoring Network***).

For example, the IRWMP and GSP development are complimentary management processes. To the extent that the issues identified for the greater IRWMP region affect the Wheeler Ridge-Maricopa Management Area, these issues will be discussed in the following sections of this MA Plan. The implementation of this MA Plan will contribute to the sustainable use of water supplies within the IRWMP region and the IRWMP is not expected to limit operational flexibility in the Management Area.

Most of the groundwater management objectives identified in the WRMWSD GWMP are consistent with the issues and objectives identified in the following sections of this MA Plan. The implementation of this MA Plan will contribute to the sustainable groundwater use within the Wheeler Ridge-Maricopa Management Area. Therefore, this GSP compliments and supersedes the GWMP.

5.2.3. Conjunctive Use in the Wheeler Ridge-Maricopa Management Area

☑ 23 CCR § 354.8(e)

Since 1971, WRMWSD has imported SWP surface water, supporting the conjunctive use of surface water and groundwater resources within the Wheeler Ridge-Maricopa Management Area, which has been the primary cause of the recovery and stability of groundwater levels observed in the area (see **Section 8 *Current and Historical Groundwater Conditions***). WRMWSD banks water in and returns it from out-of-District water banks (e.g., the Pioneer Water Bank; see **Section 9.2.1 *Surface Water Inflows and Outflows***) through its own conveyance network and the California Aqueduct. As of December 2018, the District has a combined 200,700 acre-feet (AF) stored in its banking projects. The California Aqueduct is also used for intra-District conveyance, wherein delivered water supplies are blended with groundwater, the proportion of which varies depending on the season and the water year type.

5.3. Land Use Elements or Topic Categories of Applicable General Plans

☑ 23 CCR § 354.8(f)

The following sections describe topic categories of general plans and other planning documents with specific relevance to the Wheeler Ridge-Maricopa Management Area MA Plan. Other planning documents developed for Kern County and the Wheeler Ridge-Maricopa Management Area vicinity (e.g., habitat conservation plans, hazard mitigation plans, etc.) are further described in the Umbrella GSP.

5.3.1. Kern County General Plan

☑ 23 CCR § 354.8(f)(1)

The Wheeler Ridge-Maricopa Management Area is located within the Kern County General Plan area (Kern County, 2009). The current Kern County General Plan was first adopted in 2004 and has undergone several amendments, the most recent amendment approved in 2009 (General Plan). The County is currently working to update its General Plan through 2040, with completion of the "2040 General Plan" expected in 2019. This section identifies relevant policies in the current General Plan that could: (1) affect water demands in the Management Area (e.g., due to population growth and development of the built environment), (2) influence the GSP's ability to achieve sustainable groundwater use, and (3) affect implementation of General Plan land use policies.

Figure PA-7 shows the current General Plan land use designations within the Wheeler Ridge-Maricopa Management Area. The land use designations include primarily intensive and extensive agriculture, residential, mineral and petroleum, resource management, federal land, and seven other designations that account for less than 1% of the Management Area. These designations are generally consistent with the predominantly agricultural land use within the Management Area as shown in **Figure PA-4**.

The Land Use, Open Space, and Conservation Element (Chapter 1) of the General Plan includes the following goals, policies, and implementation measures that are related to groundwater or land use management, and that could potentially influence the implementation of this GSP.

Physical and Environmental Constraints

- **Implementation Measure C.** Cooperate with the Kern County Water Agency to classify lands in the County overlying groundwater according to groundwater quantity and quality limitations.

Public Facilities and Services

- **Goal 5.** Ensure that adequate supplies of quality (appropriate for intended use) water are available to residential, industrial, and agricultural users within Kern County.
- **Goal 7.** Facilitate the provision of reliable and cost-effective utility services to residents of Kern County.
- **Policy 2.** The efficient and cost-effective delivery of public services and facilities will be promoted by designating areas for urban development which occur within or adjacent to areas with adequate public service and facility capacity.

- **Policy 2.a.** Ensure that water quality standards are met for existing users and future development.

Residential

- **Goal 6.** Promote the conservation of water quantity and quality in Kern County.
- **Goal 7.** Minimize land use conflicts between residential and resource, commercial, or industrial land uses.

Industrial

- **Goal 2.** Promote the future economic strength and well-being of Kern County and its residents without detriment to its environmental quality.

Resource

- **Policy 7.** Areas designated for agricultural use, which include Class I and II and other enhanced agricultural soils with surface delivery water systems, should be protected from incompatible residential, commercial, and industrial subdivision and development activities.
- **Policy 10.** To encourage effective groundwater resource management for the long-term economic benefit of the County the following shall be considered:
- **Policy 10.a.** Promote groundwater recharge activities in various zone districts.
- **Policy 10.c.** Support the development of groundwater management plans.
- **Policy 10.d.** Support the development of future sources of additional surface water and groundwater, including conjunctive use, recycled water, conservation, additional storage of surface water and groundwater and desalination.

General Provisions

- **Goal 1.** Ensure that the County can accommodate anticipated future growth and development while maintaining a safe and healthful environment and a prosperous economy by preserving valuable natural resources, guiding development away from hazardous areas, and assuring the provision of adequate public services.
- **Policy 40.** Encourage utilization of community water systems rather than the reliance on individual wells.
- **Policy 41.** Review development proposals to ensure adequate water is available to accommodate projected growth.
- **Policy 45.** New high consumptive water uses, such as lakes and golf courses, should require evidence of additional verified sources of water other than local groundwater. Other sources may include recycled stormwater or wastewater.
- **Implementation Measure U.** The Kern County Environmental Health Services Department will develop guidelines for the protection of groundwater quality which will include comprehensive well construction standards and the promotion of groundwater protection for identified degraded watersheds.

☑ 23 CCR § 354.8(f)(2)
☑ 23 CCR § 354.8(f)(3)

The above goals, policies and implementation measures established by the General Plan are complementary to sustainable groundwater management of the Wheeler-Ridge Management Area relative to future land use development and conservation (i.e., the General Plan encourages development of the County's groundwater supply to ensure that existing users have access to high quality water, and states that future growth should be accommodated only while ensuring that adequate high-quality water supplies are available to existing and future users). Successful implementation of this MA Plan will help to ensure that the Management Area groundwater supply is managed in a sustainable manner by avoiding undesirable results as defined under SGMA. Therefore, implementation of General Plan policies is not expected to affect the ability of the Management Area to achieve groundwater sustainability.

Likewise, implementation of this MA Plan is not anticipated to significantly affect the water supply assumptions or land use plans within the General Plan over the planning horizon. Given that the General Plan is being updated concurrently with the development of this MA Plan, and the County is engaged in the process of GSP development through its participation in the KGA GSA, it is anticipated that the 2040 General Plan would take into account this MA Plan and utilize consistent water supply assumptions over the 2040 planning horizon. As required by California Government Code § 65352.5(d), the GSA will coordinate with and provide the necessary information to land use planning agencies that are adopting or amending their general plan.

5.3.2. Well Permitting Process

☑ 23 CCR § 354.8(f)(4)

Well permits within the Wheeler Ridge-Maricopa Management Area are issued by the Kern County Public Health Services Department Water Well Program. The Water Well Program issues permits to construct, reconstruct and destroy water wells. All wells must be constructed in accordance with Kern County Ordinance Code Section 14.08, and DWR Bulletins 74-81 and 74-90, except as modified by subsequent revisions. The ordinance requires, among other things, that domestic and agricultural wells be installed a minimum distance from potential pollution and contaminant sources, water quality be tested for new and reconstructed wells, an NSF 61 approved flowmeter be installed, and the final well construction be inspected by County staff. It is expected that as part of GSP implementation, the Water Well Program may be more closely coordinated with KGA GSA activities to support long-term sustainability within the Management Area and the Basin at large. Recently, the Kern County Public Health Services Department (KCPHSD) released a supplemental well application for wells intended to be installed on overdrafted basins. This new form additionally requires water district and GSA information, granting GSAs review power. Starting in 2019, it is WRMWSD's policy to provide a written response to KCPHSD and the well applicant when supplemental well application forms are received.

5.4. Additional GSP Elements

☑ 23 CCR § 354.8(g)

Per California Water Code (CWC) Section (§) 10727.4, a GSP shall include, where appropriate and in collaboration with the appropriate agencies, all of the following:

Control of saline water intrusion

Because the Wheeler Ridge-Maricopa Management Area is located far from coastal areas, seawater intrusion is not considered to be an issue.

Wellhead protection

The Kern County Public Health Services Department Water Well Program issues permits to construct, reconstruct and destroy water wells (see **Section 5.3.2 *Well Permitting Process***).

Migration of contaminated groundwater

There are no known active contaminated groundwater sites within the Wheeler Ridge-Maricopa Management Area. The Central Valley Regional Water Quality Control Board's (CVRWQCB) GeoTracker and California Department of Toxic Substances Control (DTSC) EnviroStor databases show two closed Cleanup Program sites, one closed Leaking Underground Storage Tank (LUST) site, and four sites listed as "inactive – Needs Evaluation". These sites are discussed further in **Section 8.5 *Groundwater Quality*** below.

Well abandonment and well destruction program

The Kern County Public Health Services Department Water Well Program issues permits to construct, reconstruct and destroy water wells (see **Section 5.3.2 *Well Permitting Process***).

Replenishment of groundwater extractions

The District actively manages the groundwater basin within its boundaries through conjunctive use and other programs (see **Section 5.2.3 *Conjunctive Use in the Wheeler Ridge-Maricopa Management Area***).

Conjunctive use and underground storage

The District actively manages the groundwater basin within its boundaries through conjunctive use and other programs (see **Section 5.2.3 *Conjunctive Use in the Wheeler Ridge-Maricopa Management Area***).

Well construction policies

The Kern County Public Health Services Department Water Well Program issues permits to construct, reconstruct and destroy water wells (see **Section 5.3.2 *Well Permitting Process***).

Groundwater contamination cleanup, recharge, diversions to storage, conservation, water recycling, conveyance, and extraction projects

The District constantly pursues water conservation through its water management practices. Currently its efficient water management practices for agricultural users are described in the WRMWSD Agricultural Water Management Plan (WRMWSD, 2015). This plan is summarized in **Section 5.2.1 *Existing Monitoring and Management Programs***.

The District also operates a "User Input pump-in program" to facilitate conveyance of groundwater pumped by landowners through its distribution system to other lands within the WRMWSD service area owned by that same landowner.

Efficient water management practices

The District constantly pursues gaining efficiency through its water management practices. Currently its efficient water management practices for agricultural users are described in the WRMWSD Agricultural

Water Management Plan (WRMWSD, 2015). This plan is summarized in **Section 5.2.1** ***Existing Monitoring and Management Programs***.

Relationships with State and federal regulatory agencies

As described above, WRMWSD maintains a water supply contract with DWR for its SWP surface water supply that remains in effect until 2035. Currently, the Contractors and DWR are in the validation process of approving a contract extension to 2085.

Land use plans and efforts to coordinate with land use planning agencies to assess activities that potentially create risks to groundwater quality or quantity

Applicable land use planning documents and processes are discussed in **Section 5.3** ***Land Use Elements or Topic Categories of Applicable General Plans***.

Impacts on Groundwater Dependent Ecosystems

This topic is discussed in **Section 8.8** ***Groundwater Dependent Ecosystems***.

5.5. Notice and Communication

☑ **23 CCR § 354.10**

The Wheeler Ridge-Maricopa Management Area adopted its Stakeholder Communication and Engagement Plan (SCEP) in August 2018 to fulfill notice and communication requirements. The SCEP is included herein as **Appendix C**. Following the public process described herein, this MA Plan was approved for inclusion in the KGA GSA Umbrella GSP by the WRMWSD Board on 11 December 2019, as documented in **Appendix J**.

5.5.1. Beneficial Uses and Users of Groundwater

☑ **23 CCR § 354.10(a)**

As part of the SCEP, beneficial uses and users of groundwater in the basin were identified, including various holders of overlying groundwater rights (agricultural users, domestic users, commercial/industrial users, etc.), public water systems, local land use planning agencies, environmental users of groundwater, surface water users, the federal government, and DACs/SDACs (see SCEP Section 3). Additionally, a Stakeholder Constituency "Lay of the Land" exercise was developed which identified stakeholders in the Wheeler Ridge-Maricopa Management Area, key interests and issues, and the level of engagement expected with each stakeholder (see SCEP Table 1). This exercise will be updated during MA Plan implementation.

5.5.2. Public Meetings Summary

☑ **23 CCR § 354.10(b)**

The list below identifies public meetings, workshops, and direct outreach specific to SGMA and WRMWSD's MA Plan development and progress.

WRMWSD Board Meetings

The WRMWSD Board meets every month at its offices. Regular SGMA and MA Plan development updates are provided by Staff and/or WRMWSD's consultant, and stakeholders are provided the opportunity to provide input on the GSP development and implementation process. **Appendix C** includes a list of meeting dates where SGMA topics have been discussed at the WRMWSD Board Meeting. This information will be updated throughout MA Plan development and/or implementation.

Stakeholder Workshops

WRMWSD has hosted and/or participated in workshops intended to educate local landowners and other stakeholders within the Wheeler Ridge-Maricopa Management Area regarding SGMA, including:

- WRMWSD Sustainable Groundwater Management Act (SGMA) Landowner Workshop #1 – 05/24/2018
- Kern Subbasin Open House – 14 May 2019
- WRMWSD SGMA Landowner Workshop #2 – 12 June 2019
- Kern Subbasin GSP Public Review Open House – 26 September 2019

This list will be populated throughout MA Plan implementation. While stakeholders were very engaged during the workshops, no direct feedback was provided for input into the MA Plan.

Direct Outreach

Through the distribution of letters and surveys, WRMWSD has made numerous efforts to secure local stakeholder input during the SGMA process:

- KGA stakeholder survey distribution and respondence (May 2018 – July 2018);
- KGA agricultural stakeholder survey distribution and respondence (December 2018 – January 2019);
- Public water system data request (October 2018 – January 2019); and
- KGA Landowner Letter (June 2019).

Results from these outreach efforts have been compiled and reviewed. Data and information received from respondents has been incorporated into the WRMWSD DMS and into this MA Plan, as appropriate. The list above will be updated throughout MA Plan development and/or implementation.

5.5.3. Comments Received Regarding the MA Plan

☑ 23 CCR § 354.10(c)

As described in the above sections and in the remainder of this section, WRMWSD has conducted extensive engagement of stakeholders through the MA Plan development process. During this time, input and feedback from the public has been encouraged. **Table PA-1** below summarizes the comments and input received and how that input was incorporated into the MA Plan. In some cases, more detailed responses can be found in **Appendix D**.

Table PA-1 Comments and Input Received from Public During MA Plan Development

Source	Date	Type of Input	How Input was Incorporated
Chevron	19 November 2019	Email to WRMWSD with comments on Public Draft MA Plan	WRMWSD has taken the comments of Chevron into consideration in defining the bottom of the basin (**Section 7.1.3**). See **Appendix D** for additional information.
Farmland Reserve	27 November 2019	Letter to WRMWSD with comments on WRMWSD Public Draft MA Plan	Clarifying text added to the **Executive Summary** and **Section 9.1.3**. Detailed responses are included in **Appendix D.**
Wonderful Orchards / Wonderful Citrus	27 November 2019	Letter to WRMWSD with comments on KGA Public Draft GSP and WRMWSD Public Draft MA Plan	Clarifying text added to the **Executive Summary** and **Sections 8.1**, **9.1.3**, **18.2** and **18.4**. Detailed responses are included in **Appendix D.**

WRMWSD welcomes further comments during MA Plan implementation. **Table PA-1** will be updated as more comments are received during MA Plan implementation.

5.5.4. Communication

☑ **23 CCR § 354.10(d)**

The SCEP outlines WRMWSD's communication goals.

Decision-Making Process

☑ **23 CCR § 354.10(d)(1)**

The SCEP Section 2.2 outlines the WRMWSD decision-making process. Briefly, the process involves decision making by the WRMWSD Board of Directors during District Board meetings which are open to the public. In addition, the KGA GSA Board of Directions makes decisions of the KGA GSA at its public Board meetings. The KGA GSA Board is supported by a Coordination Committee composed of representatives of each KGA GSA board member, whose role is to provide recommendations to the KGA GSA Board on technical and other matters.

Public Engagement Opportunities

☑ **23 CCR § 354.10(d)(2)**

The SCEP Section 6 discusses public engagement opportunities and SCEP Sections 5 and 6 discuss how public input and responses will be handled. These opportunities include WRMWSD Board meetings, the planned public hearing at which the Draft MA Plan will be available for public comments, and the various stakeholder workshops and surveys, discussed below.

Stakeholder Involvement

☑ **23 CCR § 354.10(d)(3)**

The SCEP Section 5 outlines WRMWSD's goals, including open and transparent engagement with diverse stakeholders. Additionally, SCEP Section 4 outlines describes the Stakeholder Survey which the District used to gain additional knowledge on stakeholders within the Management Area. Only three entities have responded to the survey to date.

District staff have made numerous outreach efforts to landowners within the District regarding well access for monitoring. This effort has represented a constructive effort to improve local knowledge of well conditions and to engage landowners in SGMA implementation efforts.

Public Notification

☑ **23 CCR § 354.10(d)(4)**

The SCEP Section 5 and 6 details the methodology that is being followed to inform the public regarding all MA Plan updates, status, and actions.

5.5.5. Interagency Coordination

WRMWSD has actively engaged in both intrabasin and interbasin coordination efforts through multiple avenues during the GSP development process, including:

KGA Board/Coordination Committee Meetings

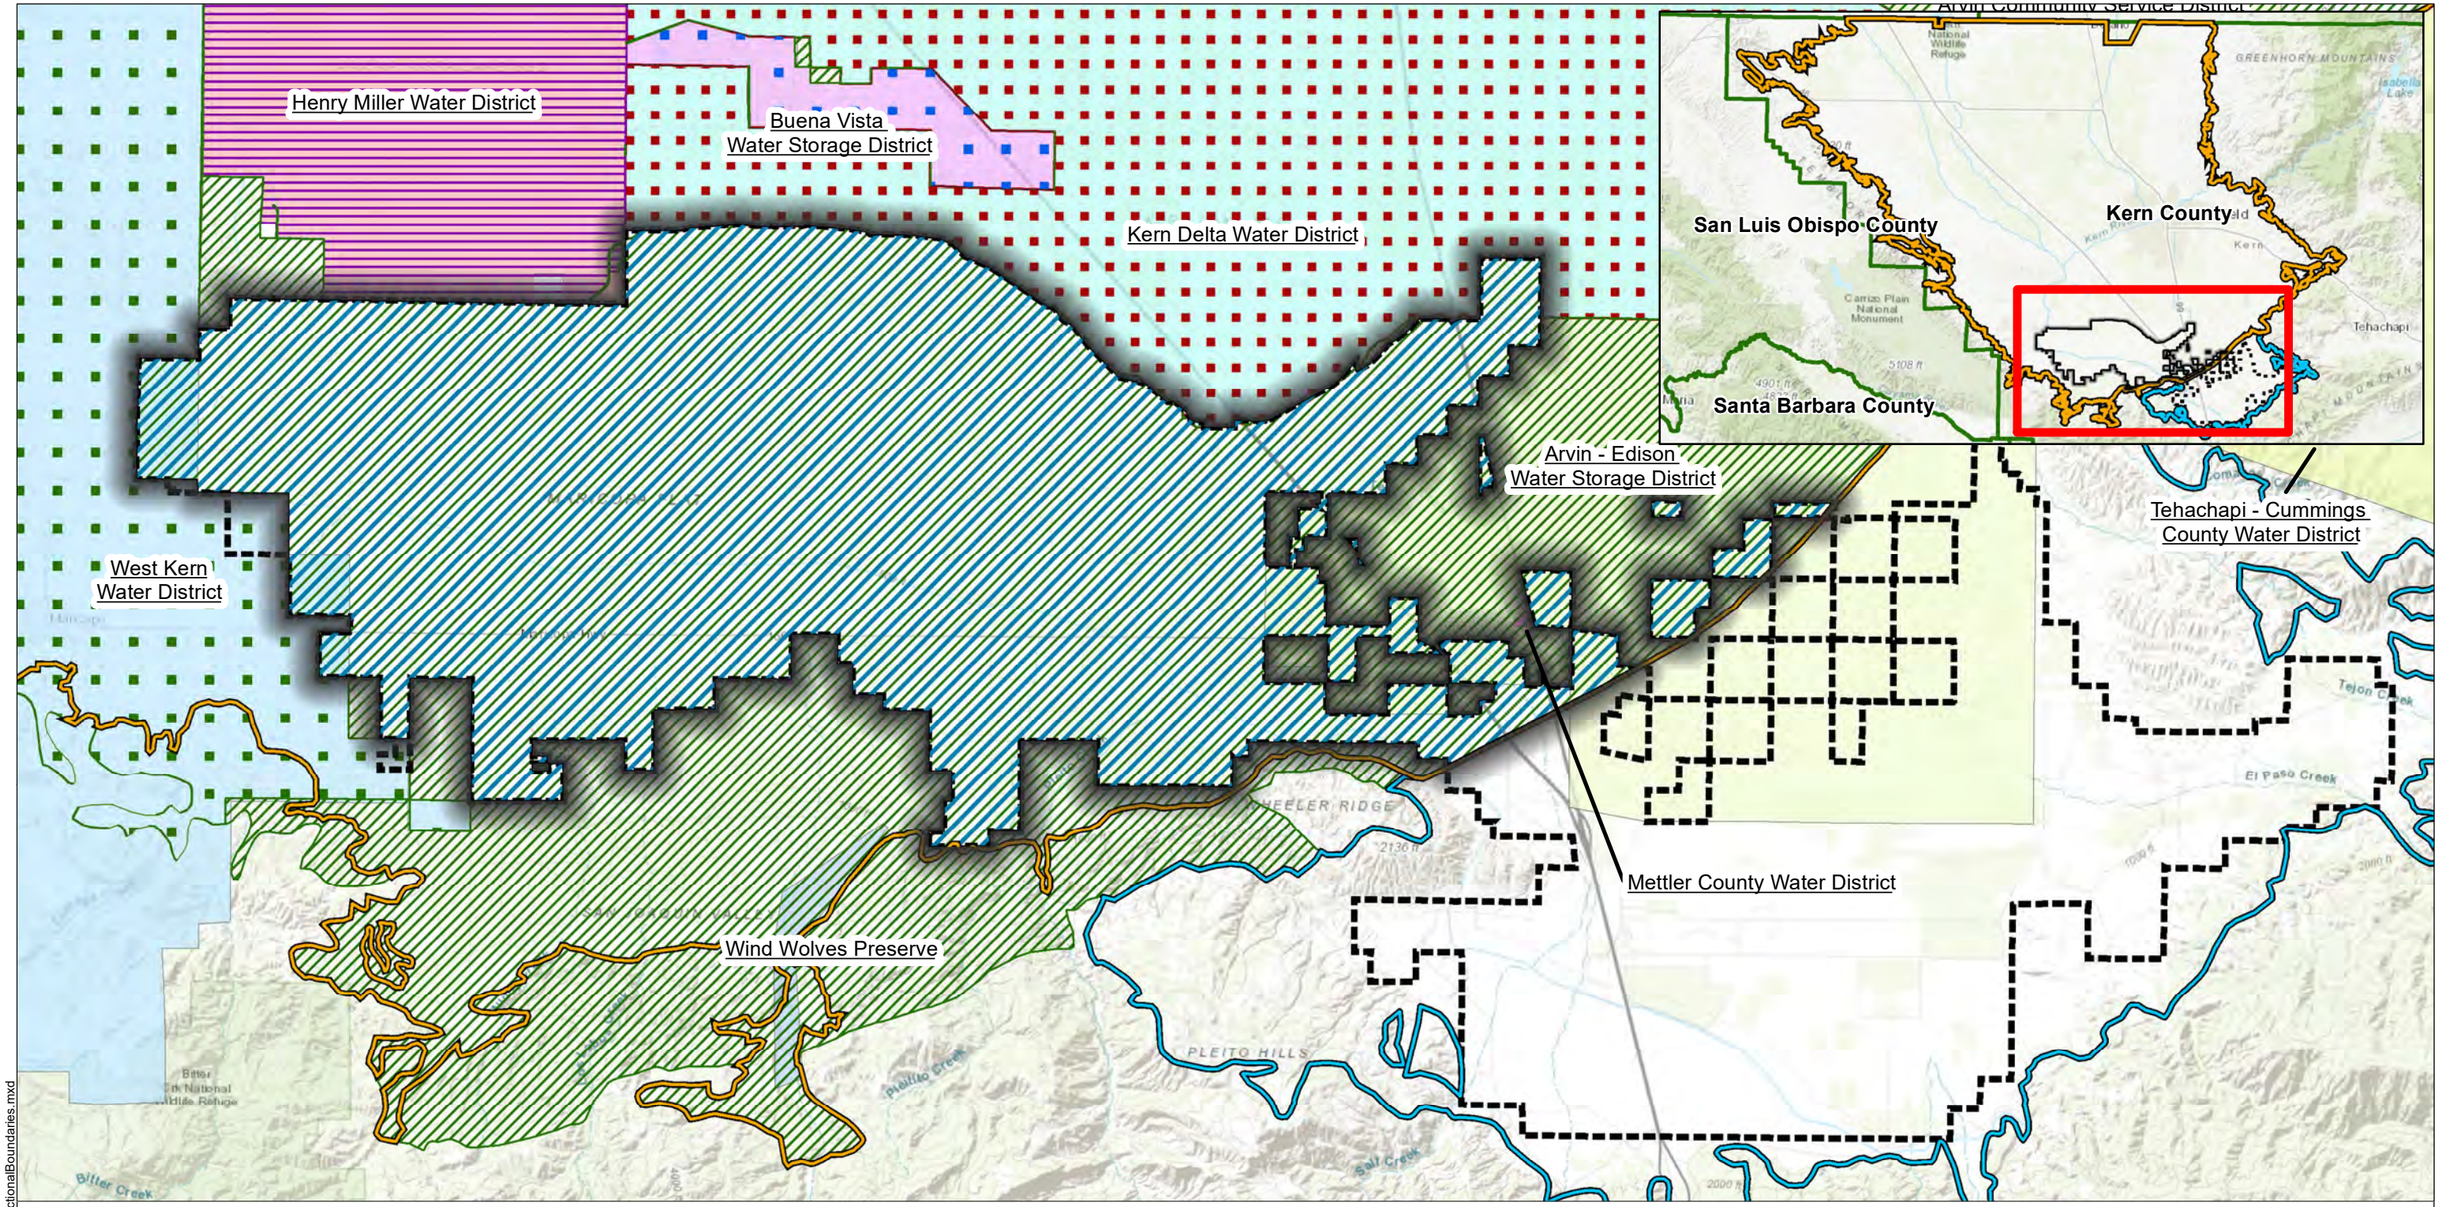
Prior to enactment of the SGMA, the KGA was established to provide a framework for the active, comprehensive management of the groundwater basin underlying the valley portion of Kern County, to preserve and maintain local control of groundwater resources and provide long term surety for all basin users. With passage of the SGMA, the KGA seeks to coordinate local groundwater management efforts and is working with its members to determine the most cost effective and efficient way of meeting the new requirements of the SGMA. During 2016-2018 the KGA Board of Directors met monthly at the Kern County office in Bakersfield. These monthly meetings have continued into 2019, now at the Great Bakersfield Chamber. Meeting agendas and other information can be found at http://www.kerngwa.com.

The KGA Coordination Committee meets monthly at the Rosedale-Rio Bravo WSD office. Meeting agendas and other information can be found at http://www.kerngwa.com/.

Kern Managers Meetings

Managers of member agencies to the KGA as well as representatives from other Kern GSAs (Kern River GSA, HMWD, etc.) meet weekly at Rosedale-Rio Bravo WSD to discuss Basin-wide SGMA topics ranging from monitoring network coordination to Basin-wide modeling efforts and sustainable management criteria development.

South of Kern River Coordination Meetings



WRMWSD and neighboring agencies in the "south of Kern River" portion of the Basin have periodically convened to coordinate on major GSP development topics, including methodologies and data sources used to develop the Basin Setting, Water Budget, and Sustainability Criteria sections of their respective GSPs/Management Area Plans and the development of projects and management actions.

White Wolf Basin GSA

The White Wolf GSA was formed in 2017 by three water districts: WRMWSD, AEWSD, Tejon-Castac Water District (TCWD), as well as Kern County (as a non-voting member). Prior to that, the GSA parties coordinated in an effort to subdivide the Kern Subbasin into two separate subbasins and remove the critical-overdraft status from the newly formed White Wolf Subbasin. By December of 2016, both goals were accomplished, and the White Wolf GSA is currently in the process of developing a GSP. The White Wolf GSA meets quarterly at WRMWSD's offices.

5.5.6. Interbasin Coordination

WRMWSD has actively participated in interbasin coordination with the neighboring White Wolf Subbasin (DWR 5-022.18), Tule Subbasin (DWR 5-022.13), and Tulare Lake Subbasin (DWR 5-022.12) throughout the GSP development process through its membership with the KGA. Coordination topics have included subsidence concerns along the California Aqueduct, delineation of the White Wolf Fault, and cross-boundary flows between subbasins.

BASIN SETTING

6. INTRODUCTION TO BASIN SETTING

☑ **23 CCR § 354.12**

This section presents Basin Setting information for the Wheeler Ridge-Maricopa Management Area[22]. As discussed previously in ***Section 5 Description of the Plan Area,*** the Management Area consists of the portion of the Wheeler Ridge-Maricopa Water Storage District (WRMWSD) service area within the Kern County Subbasin (Kern Subbasin) that is not overlapped by the West Kern Water District (WKWD) Groundwater Sustainability Agency (GSA; **Figure HCM-1**). In some cases, Basin Setting information for areas proximal to, but outside of, the Management Area is provided for context. Basin Setting information includes the Hydrogeologic Conceptual Model, Groundwater Conditions, and Water Budget.

[22] In this document, the term "Wheeler Ridge-Maricopa Management Area" is used in its entirety the first time the area is referenced in each paragraph; subsequent references to this area in each paragraph use the term "Management Area".

7. HYDROGEOLOGIC CONCEPTUAL MODEL

☑ 23 CCR § 354.14(a)

This section presents the hydrogeologic conceptual model (HCM) for the Wheeler Ridge-Maricopa Management Area. As described in the Hydrogeological Conceptual Model Best Management Practices (BMP) document (California Department of Water Resources [DWR], 2016), an HCM provides, through descriptive and graphical means, an understanding of the physical characteristics of an area that affect the occurrence and movement of groundwater, including geology, hydrology, land use, aquifers and aquitards, and water quality. This HCM serves as a foundation for subsequent Basin Setting analysis including water budgets and numerical models, monitoring network development, and the development of sustainable management criteria. The HCM information presented herein is supplemental to the HCM provided in the Kern Groundwater Authority (KGA) Umbrella Groundwater Sustainability Plan (GSP) and provides refined detail on HCM topics specific to the Management Area.

7.1. General Description

☑ 23 CCR § 354.14(b)

7.1.1. Geological and Structural Setting

☑ 23 CCR § 354.14(b)(1)

The Wheeler Ridge-Maricopa Management Area is located at the southern end of the San Joaquin Valley which is the portion of California's Central Valley that is south of the San Joaquin/Sacramento River Delta. The San Joaquin Valley is a structural trough filled with tens of thousands of feet of Cenozoic continental and shallow marine sedimentary deposits shed from the surrounding mountains which include the Sierra Nevada Mountains to the east, the Temblor Range and Coast Range Mountains to the west, and the San Emigdio and Tehachapi Mountains to the south (Davis et al., 1959). The structural trough is asymmetric, with its axis located west of the valley's centerline at land surface (Scheirer, 2013). Locally, to the north of the Management Area, the Maricopa Depocenter is a structural depression which has accumulated thicker deposits than the surrounding areas. The Buena Vista Hills are located to the northwest of the Management Area. The reader is referred to the Basin-wide geologic and structural setting discussion included in the KGA Umbrella GSP for additional information and map figures.

Due to its location near the North American and Pacific plate boundary, the southern San Joaquin Valley underwent complex patterns of tectonic evolution during the Cenozoic era, including phases of extension, uplift, subsidence, faulting, and flexure (Goodman and Malin, 1992). The White Wolf Fault cuts through the District and forms the boundary between the Kern Subbasin to the north and the White Wolf Subbasin to the south. The White Wolf Fault is a recently active southward-dipping high-angle reverse fault that has resulted in significant displacement of stratigraphic units on either side of the fault trace (California Division of Mines, 1955; Hagan, 2001).

The general geologic setting of the Wheeler Ridge-Maricopa Management Area consists of multiple alluvial fans derived from sediments washed into the basin from the surrounding highlands, coarser near their source and finer towards the basin interior. These fan deposits wash up against Quaternary lake and

basin deposits that border the Management Area to the north. The basin deposits, including those beneath the Buena Vista Lake Bed, Kern Lake Bed, and the slough that connects them, are generally fine-grained due to the low energy depositional environment in which they were formed. The "E Clay", a significant regional aquitard (Croft, 1972), underlies the western portion of the southern Central Valley including portions of the Management Area. The E Clay is several tens of feet thick in this area and becomes thinner and shallower towards the east, pinching out in the vicinity of the City of Arvin. On the northern edge of the Management Area, shallow clay layers and fine-grained soils create areas of perched groundwater that is separate from the main groundwater system. Two hydrogeologic cross-sections through the Management Area that further illustrate the subsurface structural relationships are discussed further in **Section 7.2 *Cross-Sections***.

7.1.2. Lateral Basin Boundaries

☑ 23 CCR § 354.14(b)(2)

This MA Plan covers only the Wheeler Ridge-Maricopa Management Area (see **Figure HCM-1**) which is within the larger Kern Subbasin. With the exception of its southeastern edge, the Management Area does not coincide with any part of the Kern Subbasin boundary, and therefore a complete discussion of the lateral basin boundaries is not provided herein, but rather in the KGA Umbrella GSP.

The southeastern edge of the Wheeler Ridge-Maricopa Management Area is coincident with the White Wolf Fault which is the boundary between the Kern Subbasin and the White Wolf Subbasin. As discussed above, the White Wolf Fault is a south-dipping reverse fault, with the northern block down-dropped relative to the southern block. There is also a component of left-lateral slip on the fault (California Division of Mines, 1955). The total vertical displacement is estimated to be over 10,000 feet and is greatest at the southwestern end and less to the northeast (California Division of Mines, 1955). As evidenced by surface rupture during the major earthquake of 21 July 1952, the White Wolf Fault is active, and its displacement plane extends to the ground surface, affecting the youngest sedimentary deposits.

Based on multiple lines of evidence, the fault acts as a significant barrier to groundwater flow, which is the basis for the Kern Subbasin boundary (Erler & Kalinowski, Inc., 2016). These lines of evidence include substantial groundwater elevation differences across the fault (based on analysis of available water level data and reports prepared by others), aquifer testing data from wells close to the fault that showed boundary effects, and groundwater modeling studies.

7.1.3. Bottom of the Basin

☑ 23 CCR § 354.14(b)(3)

As discussed above, the southern San Joaquin Valley is a deep structural trough filled with a thick sequence of Tertiary sediments including sandstone, siltstone, shale, and conglomerate. As described below, multiple sources of information can be relied on to define the "bottom of the basin" for purposes of the Sustainable Groundwater Management Act (SGMA), including elevation maps of the basement bedrock surface, information on the base of fresh water, the presence, location and depth of oil and gas fields, and depth of groundwater extraction. Each of these is discussed below, with depth information presented as feet below ground surface (ft bgs) or feet above mean sea level (ft msl), based on the original source information. A summary comparison, including a unit normalization, is included in **Table HCM-1**.

Depth to Basement Bedrock

The depth of pre-Tertiary basement rocks which form the impermeable floor of the San Joaquin Valley groundwater basin generally increases from east to west within the southern end of the San Juaquin Valley. Within the Wheeler Ridge-Maricopa Management Area, the elevation of the top of the basement rock surface ranges from between -21,000 to -22,000 ft msl in the western area and -16,000 to -20,000 ft msl in the eastern area (Scheirer, 2013). Given the land surface elevations, discussed further in **Section 7.3 *Physical Characteristics*** below, the depth to bedrock ranges from less than 16,500 ft bgs in the eastern area to approximately 23,000 ft bgs in the far western area.

Base of Fresh Water

Despite the substantial thickness of sedimentary strata overlying impermeable basement rock within this structural basin, in the case of the Central Valley it is more appropriate to consider geochemical properties (i.e., water quality) in determining the definable bottom of the basin (DWR, 2016). Documentation of the DWR's C2VSim model states that "although the Central Valley sedimentary basins are very thick, the fresh water aquifer in each basin is very thin" (Brush et al., 2016).

Page (1973) mapped the elevation of the base of fresh water in the Kern Subbasin using a criterion for fresh water of specific conductance (also known as electrical conductivity or EC) of less than 3,000 micromhos per centimeter (umhos/cm). This EC is equivalent to a total dissolved solids (TDS) concentration of approximately 2,000 milligrams per liter (mg/L). The Page (1973) base of fresh water map only characterizes the northernmost portion of the Wheeler Ridge-Maricopa Management Area and is therefore less informative in this case. O'Bryan (1992) used the same criteria as Page to map the base of fresh water in areas farther south in the San Joaquin Valley, including most of the Management Area. O'Bryan shows that the base of fresh water ranges from -1,000 ft msl in the western portion of the Management Area to below -5,000 ft msl near the Rio Viejo oil field in the east-central portion of the Management Area (**Figure HCM-2**). These elevations translate to a range of depths of approximately 1,300 ft bgs to 5,600 ft bgs.

Base of Fresh Water from Oil Field Information

For over a century, oil and gas exploration and development has taken place throughout the Kern Subbasin, tapping various Tertiary sedimentary deposits. Such activity continues to this day and has resulted in the accumulation of a substantial body of knowledge concerning the regional geology, including stratigraphy, structural features, hydrocarbon occurrence, and the geochemical character of groundwater. **Figure HCM-3** shows the locations of oil fields in and around the Wheeler Ridge-Maricopa Management Area, as mapped by the Division of Oil, Gas, and Geothermal Resources (DOGGR). The San Emidio Nose oil field, located in the central portion of the Management Area, contains two "pools" (subareas with distinct production characteristics and rules) – the Main Area and the Northwest Area. The base of fresh water indicated on the field data sheets for these pools ranges from 4,500 ft bgs to 5,000 ft bgs in the Main Area to 3,800 ft bgs to 5,000 ft bgs in the Northwest Area (DOGGR, 1998). The DOGGR base of fresh water determination is based primarily on salinity derived from borehole electric log (e-log) data. The Rio Viejo oil field, located just north of the San Emigdio Nose oil field, has a base of fresh water of 5,500 ft bgs. The Yowlumne oil field, located in the western portion of the Management Area, has a base of fresh water between 1,600 ft bgs and 4,000 ft bgs. The Los Lobos oil field overlies a small portion of the southwestern corner of the Management Area and has a base of fresh water between 500 and 3,000 ft bgs. The Midway-Sunset oil field overlies portions of the far western edge of the Management

Area, and is largely in an area without fresh water, except in the far southeastern tip of the oil field near Santiago Creek where fresh water is found down to approximately 500 ft bgs.

Deepest Groundwater Extractions

The HCM BMP states that "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions" (DWR, 2016). Based on well construction information from 191 wells within the Wheeler Ridge-Maricopa Management Area, all wells have depths less than 2,600 ft bgs and approximately 90% of wells have depths less than 1,800 ft bgs.

Another indication of the "bottom" of the basin in the Wheeler Ridge-Maricopa Management Area comes from the basin representation within groundwater flow models, specifically the Department of Water Resources C2VSim basin model (Brush et al., 2016).[23] The C2VSim model (C2VSim-CG, version R374) divides the Central Valley alluvial basin vertically into three layers, the top two of which are pumped (i.e., could be considered to define the vertical extent of the basin). C2VSim-CG layer thickness data for 33 model nodes within and near the Management Area show that the combined thickness of Layers 1 and 2 (i.e., the unconfined and confined pumped layers) ranges from 1,252 ft to 3,910 ft, averaging 1,834 feet (ft). The updated version of C2VSim[24] which utilizes a finer grid (C2VSim-FG, Beta version) uses the same layering scheme, but has a refined grid/mesh, adjusts the thickness of Layers 1 through 3 and adds an additional deeper Layer 4. C2VSim-FG layer thickness data for 103 model nodes within the Management Area show a combined thickness of Layers 1 and 2 ranging from 597 ft to 1,807 ft, averaging 1,446 ft (see **Figure HCM-4**). These combined Layer 1 and 2 thicknesses correspond to the total depth of the pumped zone in this model.

Given the above information, the controlling factor for the definable "bottom of the basin" is determined to be the depth of the base of fresh water. Within the Wheeler Ridge-Maricopa Management Area, the bottom of the basin ranges in elevation from -1,000 ft msl in the western portion to below -5,000 ft msl near the Rio Viejo oil field in the east-central portion, corresponding to depths of approximately 1,300 ft bgs to 5,600 ft bgs. In the certain areas where pools within the Yowlumne, San Emigdio Nose, and Rio Viejo oil fields are shallower than the previously mentioned depths, the bottom of the basin is defined as the (shallower) depth of fresh water from the DOGGR oil field data. It is recognized, however, that the maximum depth of wells is only about 2,600 feet, with 90% of wells screened to depths of 1,800 feet or less, and therefore a substantial volume of groundwater above the "bottom of the basin" has not been tapped by water wells.

[23] http://baydeltaoffice.water.ca.gov/modeling/hydrology/C2VSim/index_C2VSIM.cfm

[24] C2VSim-FG, Beta version is currently uncalibrated, and various potential concerns have been identified regarding this model's parameterization of the Kern and White Wolf Subbasins, including representation of the White Wolf Fault (location and hydraulic properties), hydraulic properties of the aquifers, etc. as discussed in detail in the letter to DWR from the White Wolf GSA, of which WRMWSD is a member, on 9 July 2018.

Table HCM-1. Information Relevant to Definition of the Bottom of the Basin

Type of Information	Source(s)	Parameter Range within Wheeler Ridge-Maricopa Management Area	
		Elevation Range (ft msl)	Depth Range (ft bgs)
Bedrock Basement Composite Surface	Scheirer, 2013	Western Area: -22,000 to -21,000 Eastern area: -20,000 to -16,000	Western Area: 21,500 to 23,000 Eastern area: 16,500 to 20,500

7.1.4. Principal Aquifers and Aquitards

☑ **23 CCR § 354.14(b)(4)**

Principal aquifers are defined in the GSP Emergency Regulations as "aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water

systems" (23 CCR § 351(aa)). In an area with significant groundwater development, such as the Wheeler Ridge-Maricopa Management Area, it is therefore reasonable to equate the principal aquifer(s) with the aquifer(s) from which wells pump water. This in turn can be deduced through examination of the depths of production wells.

As discussed previously and shown on **Figure HCM-5**, well construction information from 191 wells within the Wheeler Ridge-Maricopa Management Area indicates that all wells have depths[25] less than 2,600 ft bgs, and approximately 90% of wells have depths less than 1,800 ft bgs. Therefore, the principal aquifer is considered to be the aquifer materials encountered within the top 2,600 ft bgs. The surficial geology within the Management Area is discussed further below in **Section 7.3 *Physical Characteristics***, and the stratigraphic relations and well log information along the lines of section are presented on cross-sections A-A'-A'' and G-G', discussed further below in **Section 7.2 *Cross-Sections***.

Formation Names and Occurrence

☑ **23 CCR § 354.14(b)(4)(A)**

The stratigraphy within the depth zone of the principal aquifer includes (from shallowest to deepest; youngest to oldest): Quaternary (Recent to Pleistocene) Alluvium deposits and the late Tertiary (Pliocene/Pleistocene) Tulare Formation. Underlying the Tulare Formation (and generally well below the depth of the principal aquifer) are Miocene and Pliocene marine sedimentary rocks of the San Joaquin and Etchegoin Formations. Owing to their similar continental origin and fluvial mode of deposition, the Quaternary Alluvium and Plio/Pleistocene Tulare Formation can be difficult to distinguish from one another. The Alluvium and Tulare Formations are generally unconsolidated, although consolidation increases with age and depth.

The Alluvium unit, sometimes divided into Younger (Recent) and Older (Pleistocene) units (e.g., Wood and Dale, 1964), is composed generally of unconsolidated sands and gravels of fluvial origin, coarser towards its base, and is somewhat coarser than the underlying deposits (Croft, 1972). The Tulare Formation is correlative to and interfingers with the Kern River Formation which underlies the Quaternary Alluvium on much the eastern side of the Kern Subbasin. In the vicinity of the southwestern border of the San Joaquin Valley, the Tulare Formation is exposed in the foothills and is folded or tilted. It consists of poorly sorted lenticular beds of sand and conglomerate with interbeds of siltstone and mudstone. The fluvial origin of the Tulare Formation results in channel-like bodies of coarse-grained materials which can provide anisotropic hydraulic connections, although these channels are largely unmapped. Underlying the Tulare Formation (generally well below the depth of the principal aquifer) are the Etchegoin Formation and, towards the east, the Miocene Chanac to the east of the Wheeler Ridge-Maricopa Management Area.

A significant regional aquitard within the Tulare Formation, the Pleistocene E Clay (Croft, 1972), underlies the northern portion of the center of the Wheeler Ridge-Maricopa Management Area (**Figure HCM-6**). The E Clay, correlative with and sometimes referred to as the "Corcoran Clay", is one of several flood-basin, lacustrine and marsh deposits within the southern San Joaquin Valley. It is often described as "blue clay" in well driller logs (Croft, 1972). The E Clay dips generally southwestward, and beneath the Management Area the base of the E Clay ranges in elevation from approximately -200 ft msl in the

[25] The depth of wells is determined from well construction information using the following data, in order of preference (if data are available): bottom of screen depth, completed depth, or total depth.

northeastern portion to -400 ft msl in the north-central portion. The depth to top of the E Clay ranges is approximately 250 ft bgs in its most southwestern extent beneath the Management Area (DWR, 2008). The E Clay, where present, acts as a confining unit for the underlying groundwater; above the E Clay (and where it does not exist) groundwater occurs under unconfined conditions (Croft, 1972). As shown on **Figure HCM-6**, the E Clay is not known to extend all the way underneath the Management Area to the western or southern extents, and thus is not known to consistently confine the underlying aquifer. Another similar regional aquitard unit, the "A Clay", exists at shallower depths to the north of the Management Area but does not underlie it. The A Clay may be the cause of perched groundwater conditions observed in this area (Croft, 1972).

It should be noted that despite the variably confined conditions in this area, it is not deemed appropriate to define separate unconfined and confined principal aquifers because (1) the regional aquitards are not extensive throughout the Wheeler Ridge-Maricopa Management Area; and (2) many wells are screened over large vertical intervals including above and below the regional aquitard (where it is present), thus creating a vertical hydraulic connection.

Physical Properties of Aquifer(s) and Aquitard(s)

☑ **23 CCR § 354.14(b)(4)(B)**

Given the range of lithologies and grain sizes within the formations that comprise the principal aquifer (i.e., ranging from gravels and sands, to silts and clays, generally poorly-sorted and interbedded), the physical properties of the aquifer vary widely both laterally and with depth. In general, wells drilled into the principal aquifer tap into sufficient coarse-grained material to be productive enough to support overlying agricultural demands. Wood and Dale (1964) developed a map of "yield factors" for the Edison-Maricopa area. The yield factor is defined as the specific capacity (gallons per minute per foot of drawdown) per 100 feet of aquifer screened by a well (i.e., units of gpm/100ft^2). The Wood and Dale (1964) map (**Figure HCM-7**) shows that most of the central portion of the Wheeler Ridge-Maricopa Management Area has yield factors between 1 and 5 gpm/100ft^2, with some areas to the west having lower yield factors, and some areas to the east having higher yield factors of 6 to 10 gpm/100ft^2. Well testing data collected in 2017 from 19 wells located in the north-central portion of the Management Area indicates specific capacity ranging from 10.8 gallons per minute per foot of drawdown (gpm/ft) to 61.4 gpm/ft, averaging 28.1 gpm/ft.

While the yield factors of Wood and Dale (1964) provide insight into the relative productivity of wells, they do not directly translate into aquifer hydraulic properties. Multiple-well aquifer pumping test data, which is necessary to accurately determine hydraulic conductivity and storage parameters, is generally not available. Another potential source of information regarding hydraulic properties is extraction of parameters from calibrated numerical groundwater models, although this information must be used with caution, particularly in areas such as Wheeler Ridge-Maricopa Management Area where the model parameters are not based on local calibration.[26] As mentioned previously, the DWR's C2VSim model covers the Management Area and is therefore one such source of hydraulic property information. **Table**

[26] Numerical models that are regional (i.e., large scale) in extent should be assumed to possess a high degree of uncertainty with respect to local parameter values. Nonetheless, where local measurements are not available, such model parameters can serve as an approximation for unknown values.

HCM-2, below, shows a summary of hydraulic property information for C2VSim nodes in Layers 1 and 2 within the Management Area, based on the R374 version of the coarse grid (CG) model and the "beta" version of the fine grid (FG) model. **Figure HCM-8** shows selected hydraulic property values for the 103 C2VSim-FG nodes within the Management Area, including hydraulic conductivity for Layers 1 and 2, specific yield for Layer 1, and specific storage for Layer 2.

Table HCM-2. Hydraulic Properties Extracted from C2VSim Models

Parameter	C2VSim-CG (R374)	C2VSim-FG (Beta version)
Number of Nodes within Wheeler Ridge-Maricopa Management Area	9	103
Layer 1 Node Properties: Average (Minimum to Maximum)		
Hydraulic Conductivity (ft/day)	33.6 (30.0 to 41.4)	20.8 (8.7 to 37.3)
Specific Yield (-)	0.27 (0.11 to 0.40)	0.082 (0.075 to 0.087)
Specific Storage (-)	N/A	N/A
Layer 2 Node Properties: Average (Minimum to Maximum)		
Hydraulic Conductivity (ft/day)	20.7 (8.7 to 49.9)	15.6 (2.2 to 71.2)
Specific Yield (-)	0.122 (0.122 to 0.123)	0.080 (0.071 to 0.097)
Specific Storage (-)	1.8E-05 (9E-06 to 4.6E-05)	0.0014 (0.0002 to 0.0021)

Abbreviations:
ft/day = feet per day
NA = not applicable

As shown in the table above, the upper unconfined zone, represented by Layer 1 in both the coarse-grid and (uncalibrated) fine-grid versions of C2VSim, is somewhat more permeable than the confined zone represented by Layer 2. The specific yield of Layer 1 is much greater in the Wheeler Ridge-Maricopa Management Area in C2VSim-CG than in C2VSim-FG; however, these values may change in C2VSim-FG upon completion of model calibration.

Another numerical groundwater model that covers the entire Central Valley is the U.S. Geological Survey's (USGS's) Central Valley Hydrologic Model (CVHM) (Faunt, ed., 2009). The CVHM model is based on the USGS MODFLOW software package and simulates integrated subsurface and surface water flow processes, including agricultural water demand based on climate and land use information, for the period from October 1961 through September 2003. Hydraulic properties for each 1 square mile model grid cell were assigned based on the spatially interpolated (using kriging) distribution of coarse-grained deposits that was ascertained through review and lithologic coding of thousands of well logs. **Figure HCM-9** shows the horizontal hydraulic conductivity of active cells of CVHM model layers 3, 4, 6, and 8 which correspond, respectively and approximately, to (Layer 3) the upper unconfined, saturated portion of the principal aquifer, (Layer 4) the Corcoran Clay, and (Layers 6 and 8), the confined portion of the principal aquifer. As

shown on **Figure HCM-9**, the hydraulic conductivity of Layer 3 is high (generally in the 250 feet per day [ft/d] to 500 ft/d range), which is much higher than in C2VSim. For the confined aquifer represented in CVHM by Layers 6 and 8, hydraulic conductivity ranges from 5 ft/d to 50 ft/d.

From the information discussed above, it is clear that considerable uncertainty exists in the values for aquifer properties including hydraulic conductivity and specific yield. This is not unexpected, given the heterogeneous nature of the Tulare Formation. As a further indication of the variability in these parameters, Dale et al. (1966) provided estimates of permeability (analogous to hydraulic conductivity) of the various types of continental deposits in the Kern River alluvial fan area, and they range over several orders of magnitude. Permeability for gravel and clay is stated in Dale et al. (1966) to range between 10 and 100 gallons per day per foot squared (gpd/ft^2)[27], for fine sand and silt from 0.001 to 10 gpd/ft^2, for medium and coarse sand from 100 to 1,000 gpd/ft^2, and for the gravel (dominated) lentil from 1,000 to 10,000 gpd/ft^2. As such, an accurate spatial distribution of hydraulic properties remains a significant data gap, although one that may be filled via further local investigation and/or model calibration.

Structural Properties of the Basin that Restrict Groundwater Flow Within the Principal Aquifer(s)

☑ 23 CCR § 354.14(b)(4)(C)

The White Wolf Fault that forms the southeastern border of the Wheeler Ridge-Maricopa Management Area and the Kern Subbasin is known to act as a significant barrier to (lateral) groundwater flow from the White Wolf Subbasin northwards into the Kern Subbasin, especially at lower groundwater levels (Erler & Kalinowski, Inc., 2016). As discussed above, the E Clay acts as a regional aquitard that limits vertical flow to some extent between the unconfined and confined portions of the aquifer in the northern portion of the Management Area. It should be noted, however, that many wells are screened through this aquitard and therefore serve as a hydraulic connection between the two zones. The Plieto Fault is a southward dipping thrust fault located roughly two to six miles south of the Management Area that separates Miocene and older rocks on the south from Pliocene and Quaternary rocks on the north. The fault is active in Recent times and is roughly coincident with the southern boundary of the Kern Subbasin (as defined in 2016).

General Water Quality of the Principal Aquifer(s)

☑ 23 CCR § 354.14(b)(4)(D)

General groundwater quality within most of the Wheeler Ridge-Maricopa Management Area is categorized by Wood and Dale (1964) as "west-side waters" (see **Figure HCM-10**). Small areas on the far eastern side are categorized as "transition waters" and "axial waters". The Wood and Dale (1964) groundwater quality categories reflect differences in the chemical characteristics of streams that recharge groundwater and differences in the rock types through which groundwater moves. The "west-side waters" have sulfate as the predominant anion and with intermediate cation composition. Total ionic concentrations, indicated by the size of the pie charts on **Figure HCM-10**, are highest in the west, which reflects that the source of water is marine rocks of the Coast Range Mountains. The "transition" waters represent the transition from water emanating chiefly from the Sierra Nevada Mountains to the east and

[27] One gpd/ft^2 is equal to 0.133 ft/day.

"axial" and "west-side" waters whose chemical composition reflects geochemical processes occurring in the central and western San Joaquin Valley, respectively. The "transition" waters have bicarbonate as the predominant anion and an intermediate cation composition. Further discussion of specific constituents of particular relevance to the beneficial uses within the Management Area, including maps of the distribution of these constituents, is provided in **Section 8.5 *Groundwater Quality***.

Primary Uses of Each Aquifer

☑ **23 CCR § 354.14(b)(4)(E)**

The predominant use of groundwater from the principal aquifer in the Wheeler Ridge-Maricopa Management Area is for irrigated agriculture. This includes groundwater pumped by individual landowners for use on their crops, as well as groundwater pumped by WRMWSD and subsequently distributed to WRMWSD customers. There are also several domestic wells in the Management Area, mostly in the east-central portion. WRMWSD also supplies small quantities of water (approximately 1% of total water deliveries) to several industrial entities. **Figure HCM-11** shows the distribution of wells within the Management Area by well type (i.e., agricultural, domestic, industrial, monitoring, and unknown). As shown on **Figure HCM-11**, the density of wells is much lower in the western half of the Management Area, presumably due to the relatively lower yields and poorer water quality in that area.

7.1.5. Data Gaps and Uncertainty

☑ **23 CCR § 354.14(b)(5)**

Key data gaps and uncertainties identified during development of this HCM for the Wheeler Ridge-Maricopa Management Area include:

- Uncertainty in hydraulic properties (hydraulic conductivity, specific yield) of the principal aquifer;
- Uncertainty in the degree of hydraulic connection between the unconfined and confined zones of the principal aquifer where the E Clay is present;
- Uncertainty about well construction details, including well screen intervals, for many in-District wells (i.e., many available well logs are old and no longer legible, or the well logs cannot be accurately mapped to the correct well location); and
- Uncertainty about well status (i.e., whether or not certain wells are active).

7.2. Cross-Sections

☑ **23 CCR § 354.14(c)**

Two hydrogeologic cross-sections (A-A'-A'' and G-G') were developed for this HCM (see **Figure HCM-12** and **Figure HCM-14**, respectively). The locations of the cross-sections with respect to the surficial geology are shown on **Figure HCM-12**. The cross-sections extend laterally slightly beyond the boundaries of the Wheeler Ridge-Maricopa Management Area and extend vertically down to an elevation of -15,000 ft msl. As such the cross-sections include the entire thickness of aquifer materials that are or could reasonably be tapped for groundwater supply purposes (i.e., down through the Pliocene and younger

continental/alluvial deposits of the Tulare Formation) and include the entire zone above the Page (1973) and O'Bryan (1992) base of fresh water surfaces. The cross-sections include the following:

- Land surface elevation extracted from the USGS 10-meter digital elevation model (DEM);
- Surficial geologic units after Chapman and Saleeby (2012), Bartow and McDougall (1984), and Wood and Dale (1964), and other geologic references, discussed further below;
- The locations and State Well IDs of water wells proximal to the cross-section lines, that were used to infer lithology based on inspection of well logs. The locations of water supply wells included on the cross-sections are also shown on **Figure HCM-12**;
- The locations an American Petroleum Institute (API) ID numbers of DOGGR oil wells proximal to the cross-section lines from which the elevations of various stratigraphic markers were extracted from well records;
- Subsurface geologic units, after Chapman and Saleeby (2012), Bartow and McDougall (1984), Wood and Dale (1964), and other geologic references (i.e., lithologic information from water well and DOGGR oil well records);
- Base of fresh water, after O'Bryan (1992);
- Locations of relevant boundaries and landmarks, including the WRMWSD jurisdictional boundary, the Kern Subbasin boundary, the centerlines of various roadways, etc.; and
- The Spring and Fall 2015 groundwater elevations as measured in wells screened in the principal aquifer.

As shown on the cross-sections and discussed previously, all groundwater supply wells with known construction information within the Wheeler Ridge-Maricopa Management Area are less than 2,800 feet in total depth, whereas the Tulare Formation extends significantly deeper. The base of fresh groundwater (after O'Bryan, 1992) is generally deeper than groundwater supply wells in the Management Area. Wells are typically not drilled deeper than needed to obtain the desired quantity of water. Therefore, while usable groundwater may be present below the depths currently tapped by groundwater wells, it may not be economical to do so, especially given that water quality tends to be poorer at greater depths, even above the nominal base of fresh water.

Cross-Section A-A'-A''

Cross-sections A-A'-A'' extends for approximately 37 miles in a west-east direction through the center and extending out of the Wheeler Ridge-Maricopa Management Area. The cross-section starts between the bases of the Little Signal Hills and Buena Vista Hills to the west of the Management Area, where the ground surface is highest in elevation (approximately 1,000 ft msl). The cross-section then crosses through Maricopa Flat in the center of the Management Area, passes through the south-central portion of the Arvin-Edison Management Area, and ends near the southeastern boundary of the Kern Subbasin and the northeastern corner of the White Wolf Subbasin. After declining in elevation from the hills in the west, the ground surface along the cross-section remains approximately constant near 400 to 500 ft msl.

The surficial geologic unit traversed by the cross-section is "Qa", Undifferentiated Surficial Deposits (Pleistocene/Holocene). This deposit is approximately 500 to 700 feet in thickness within the Wheeler Ridge-Maricopa Management Area. Underlying the Qa unit is the Plio-Pleistocene Tulare Formation, which

thickens from west to east and extends down to approximately 5,000 feet in the eastern portion of the Management Area. The contact with the Kern River Formation on the east is approximated and gradational. Underlying the Tulare Formation are the Pliocene San Joaquin Formation, the Miocene/Pliocene Etchegoin Formation, and the Miocene Monterey Formation.

The groundwater elevation in Spring and Fall 2015 is shown to be several hundred feet below the land surface which is within the Pleistocene/Holocene surficial deposits. The base of fresh water is shown to increase in depth from west to east, roughly in line with the base of the Tulare Formation.

Cross-Section G-G'

Cross-section G-G' extends for approximately 26 miles in a north-south direction through the center of the Wheeler Ridge-Maricopa Management Area. The northern end of the cross-section is roughly seven miles north of the Management Area within the Kern Delta Water District (KDWD) service area at an elevation of approximately 300 ft msl. Moving southward the land surface elevation rises through the Management Area and then more steeply as it nears the Plieto Fault Zone and the southern boundary of the Kern Subbasin. Further south, the cross-section extends up into the San Emigdio Mountains, reaching an elevation at its southern end of approximately 5,000 ft msl. The portion of the cross-section within the Management Area has similar stratigraphy as in cross-section A-A', including the Undifferentiated Surficial Deposits, underlain by the Tulare, San Joaquin, Etchegoin, and the Monterey Formations. The groundwater levels in Spring and Fall 2015 are relatively flat, showing a slight decrease to the south. The base of fresh water is found at elevations between -4,000 and -5,000 ft msl. On the southern end of the cross-section, outside of the Management Area and Subbasin, the structural regime is dominated by the Plieto Fault which has raised older (Miocene and older) marine sedimentary units upwards on the south relative to the younger continental rocks on the north side. Another prominent feature in this area is the Devil's Kitchen Syncline.

7.3. Physical Characteristics

☑ 23 CCR § 354.14(d)

7.3.1. Topographic Information

☑ 23 CCR § 354.14(d)(1)

Figure HCM-15 shows the topography within the Wheeler Ridge-Maricopa Management Area. Topography generally slopes to the north in the western and central portions of the Management Area and to the northwest in the eastern portion. Elevations within the Management Area range from approximately 300 ft msl in the central low spot to 1,000 ft msl in the southern highlands of the San Emigdio Mountains.

7.3.2. Surficial Geology

☑ 23 CCR § 354.14(d)(2)

Figure HCM-12 shows the surficial geology within the Wheeler Ridge-Maricopa Management Area, based on the Geologic Map of California, Bakersfield Sheet (CDMG, 1964) and associated map explanation. The predominant surficial geologic unit of Management Area is "Qf" (i.e., Recent alluvial fan deposits in the Great Valley). These deposits were deposited by streams entering the San Joaquin Valley from the uplands

to the south and west. A small portion of Cross-Section A-A'-A'' cuts through "Qs" (Recent dune sand) in the northeastern extent of the Management Area and just south of the Kern Lake Bed.

Along the northern boundary of the Wheeler Ridge-Maricopa Management Area, "Qf" alluvial fan deposits transition to fine-grained "Qb" Quaternary basin deposits that connect two areas of "Ql" Quaternary lake deposits associated with the Buena Vista Lake Bed and Kern Lake Bed. These recent "Basin" deposits ("Qb") are relatively less permeable and were deposited under lower-energy floodplain or marsh environments. The basin and lake deposits may contribute to local perched water conditions in that area in the very shallow subsurface (i.e., approximately the top 20 feet). These perched zones are often composed of poor-quality water (Central Valley Regional Water Quality Control Board [CVRWQCB], 2009) and do not yield significant or economic quantities of water to wells, springs, or surface water systems, and therefore are not considered part of the principal aquifer.

Just south of the Wheeler Ridge-Maricopa Management Area and along the boundary of the Kern Subbasin, "Qc", Quaternary (Pleistocene) non-marine deposits, and "QP", Quaternary (Pliocene-Pleistocene) non-marine deposits are prevalent. The "Qc" deposits consist of older alluvium, including slightly consolidated and dissected fan deposits. The "QP" deposits underlie the Recent Alluvium throughout the Management Area.

7.3.3. Soil Characteristics

☑ **23 CCR § 354.14(d)(3)**

Soils within the Wheeler Ridge-Maricopa Management Area are shown on **Figure HCM-16**, based on the U.S Department of Agriculture Natural Resources Conservation Service (USDA-NRCS) Soil Survey Geographic Database (SSURGO) for western Kern County. Soils are generally of intermediate texture, with the predominant type being loam with lesser amounts of fine sandy loam, sandy loam, loamy sand, and other. As shown on **Figure HCM-16**, saturated hydraulic conductivity of soils is generally in the range of 2 to 4 inches per hour (4 to 8 ft/d) in the southern area, decreasing towards the north. As shown on **Figure HCM-17**, soils are predominantly in the B Hydrologic Soil Group in the south and the C Hydrologic Soil Group in the north. These B and C Hydrologic Soil Groups indicate moderate and slow infiltration rates, respectively, and moderately low and moderately high runoff potential, respectively. The northernmost portion of the Management Area, where the "Qf" alluvial fan deposits transition to fine-grained "Qb" Quaternary basin deposits, has soils belonging to the D Hydrologic Soil Group, with very slow infiltration rates and high runoff potential.

7.3.4. Recharge and Discharge Areas

☑ **23 CCR § 354.14(d)(4)**

Figure HCM-18 shows the existing and potential recharge and discharge areas within the Wheeler Ridge-Maricopa Management Area. The groundwater system underlying the Management Area is recharged from several sources, including deep percolation of excess irrigation water applied to agricultural lands (i.e., due to inherent irrigation inefficiency), and seepage/shallow subsurface inflow from natural surface water channels entering the Management Area from the uplands. Recharge of precipitation via deep percolation likely occurs primarily during particularly wet time periods and rarely if ever during normal and dry periods. Discharge of groundwater is predominantly through groundwater pumping from wells. Because water levels are far below the land surface, no significant springs, seeps, or

wetlands exist within the Management Area. Outside of the Management Area, recharge areas include spreading grounds associated with other water banking operations and agricultural lands, and discharge areas are primarily to groundwater supply and recovery wells.

SAGBI Soil Recharge Potential

Figure HCM-19 shows groundwater recharge suitability on agricultural lands within the Wheeler Ridge-Maricopa Management Area based on the UC Davis California Soil Resource Lab's Soil Agricultural Groundwater Banking Index (SAGBI) dataset. This dataset ranks agricultural lands for groundwater recharge suitability based on soil types and five key factors: deep percolation potential, root zone residence time, topography, chemical limitations, and soil surface conditions. The SAGBI dataset ranks a majority of lands within the southern two thirds of the Management Area as having "Good" suitability for groundwater recharge, whereas areas in the northern third are classified as "Moderately Good" or "Very Poor". As discussed in **Section 17 *Projects and Management Actions***, WRMWSD plans to study and pursue in-District banking and recharge efforts as part of its portfolio approach to supply augmentation projects. Any additional future groundwater recharge facilities proposed within the Management Area will be screened against the SAGBI dataset along with other local sources of information to determine their potential suitability for groundwater recharge operations.

7.3.5. Surface Water Bodies

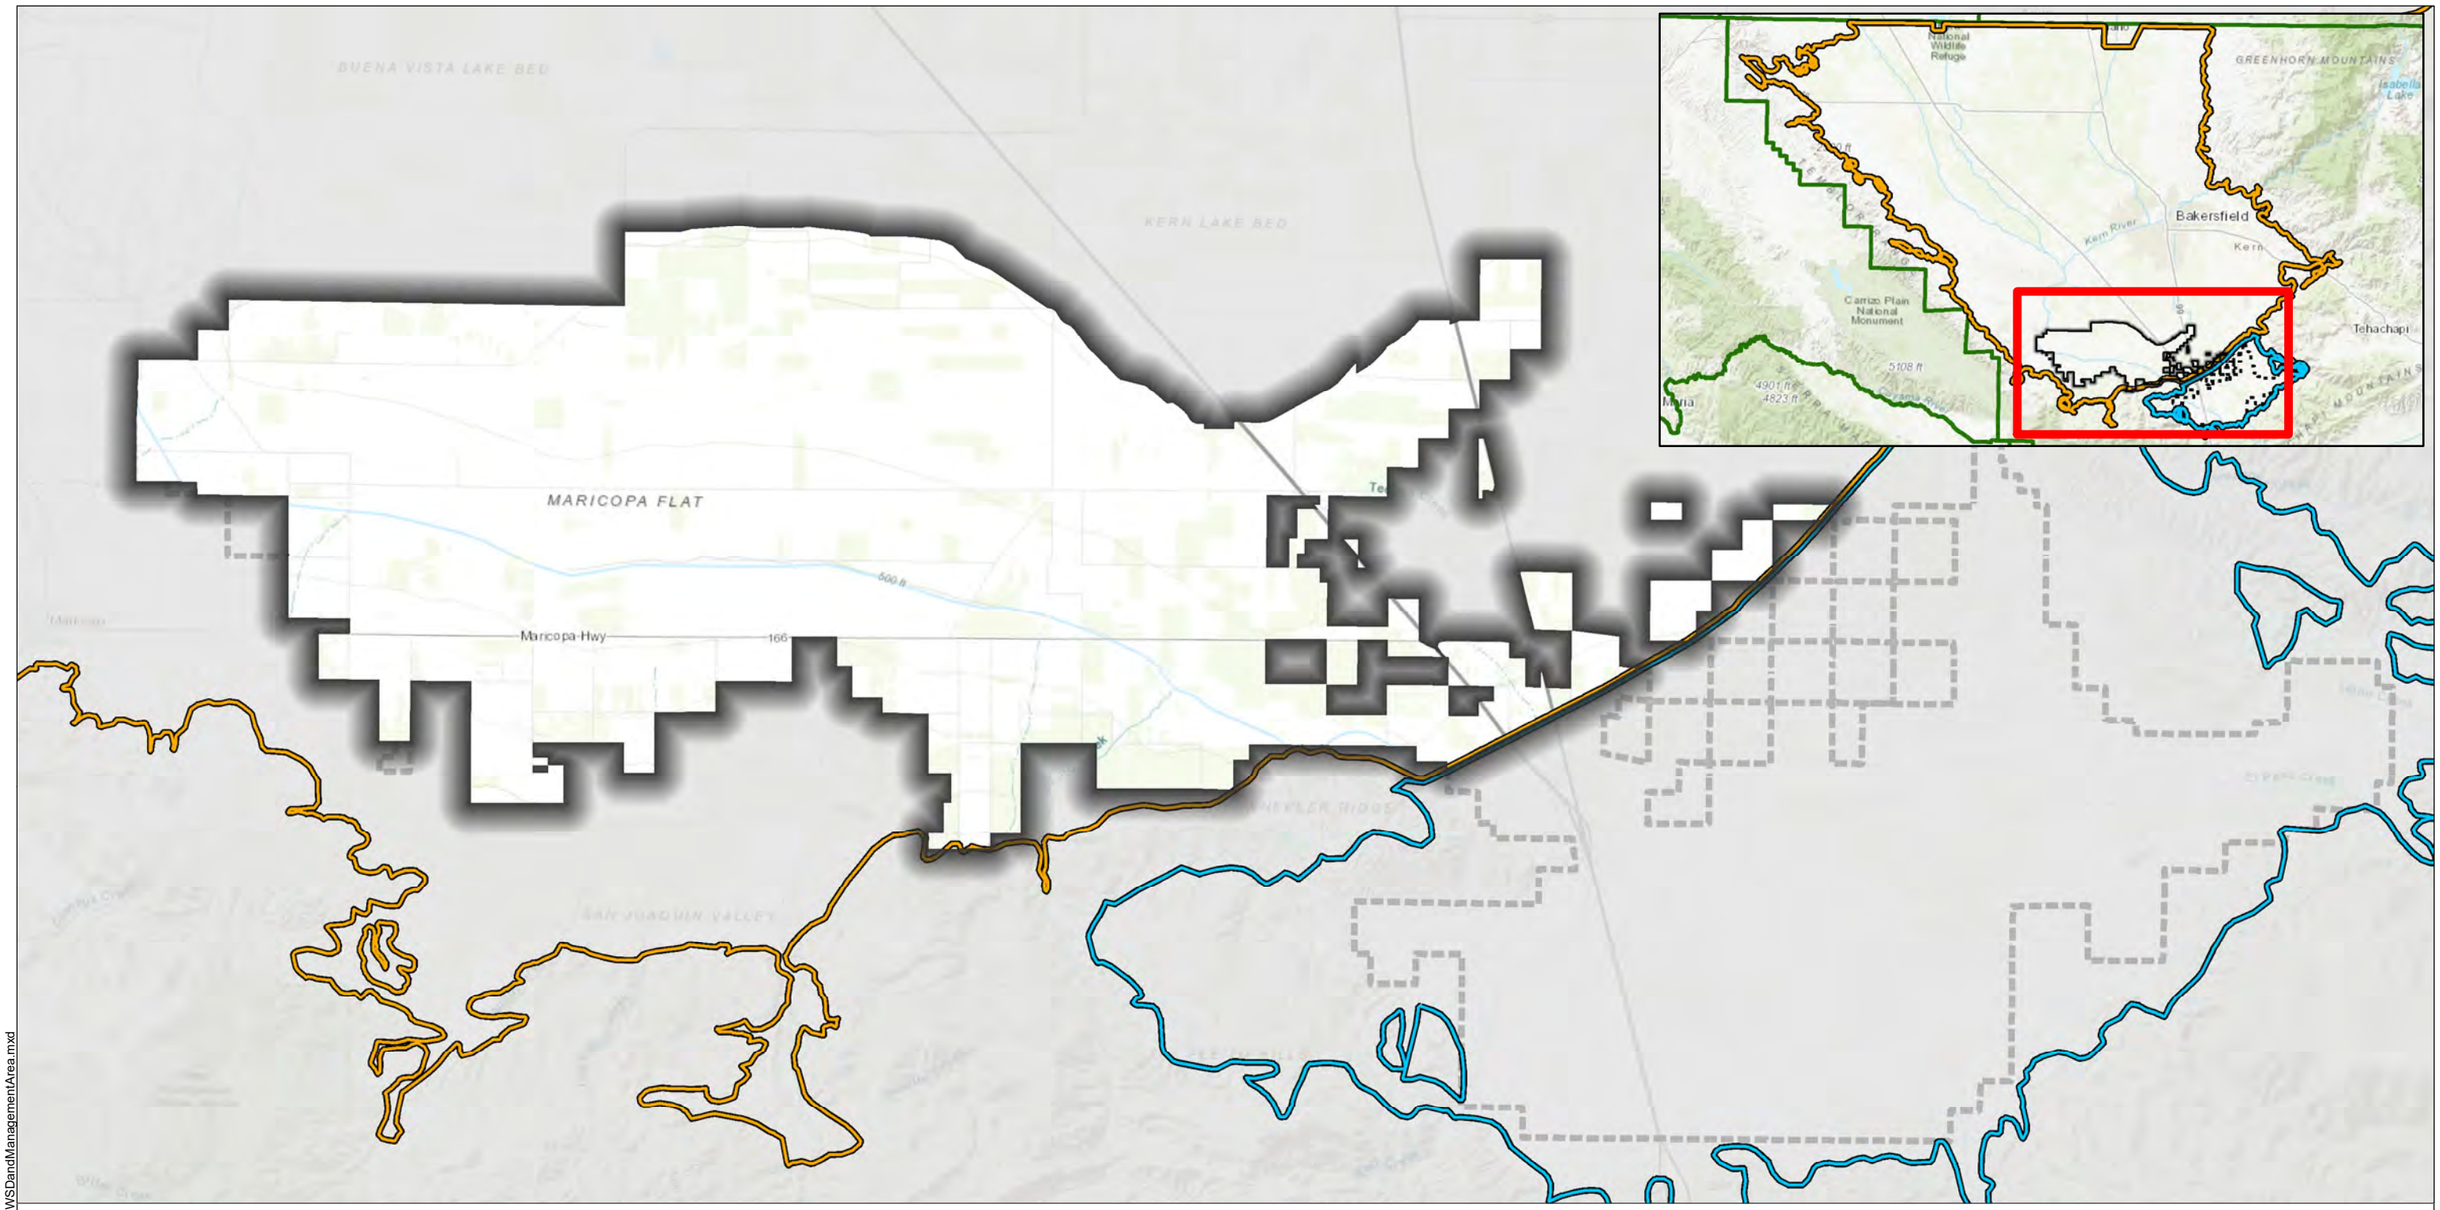
☑ **23 CCR § 354.14(d)(5)**

Surface water bodies significant to the management of the Wheeler Ridge-Maricopa Management Area include both natural surface water features as well as man-made features. **Figure HCM-20** shows the natural surface water features in the vicinity of the Management Area.

To the south of the Wheeler Ridge-Maricopa Management Area, approximately 309 square miles of upland watershed area drains into the area, providing occasional surface water inflows and likely some shallow subsurface inflow. Several creeks whose headwaters are in the Tehachapi and San Emigdio mountains drain northward into the Management Area, including (from west to east) Bitterwater Creek, Cienega Creek, Bitter Creek, Santiago Creek, Muddy Creek, Los Lobos Creek, San Emigdio, and Pleito Creeks. Several smaller unnamed watersheds along the southern valley margin also drain into the Management Area. In addition, several other watersheds and creeks, including El Paso Creek, Pastoria Creek, Grapevine Creek, and Tecuya Creek drain into the White Wolf Subbasin which ultimately drains into the Kern Subbasin. The mapped extents of these creeks mostly terminate along the southern edge of the Management Area, implying that channelized flow does not continue further into the basin, but rather seeps out into the subsurface. The mountain watersheds that drain into the Management Area receive substantially greater precipitation than the Management Area itself and therefore surface/shallow subsurface inflows from these watersheds are likely a considerable source of recharge.

The USGS historically operated a stream gauge on San Emigdio Creek[28], south of the Wheeler Ridge-Maricopa Management Area but the gauge has not been in operation since 1981. WRMWSD is establishing a network of five stream gauges in the San Emigdio mountains, three of which are on streams

[28] https://waterdata.usgs.gov/nwis/inventory/?site_no=11195500



that flow into the Management Area and two of which flow into the White Wolf Subbasin. No streamflow data are yet available from these gauges.

7.3.6. Source and Point of Delivery for Imported Water Supplies

☑ 23 CCR § 354.14(d)(6)

WRMWSD conjunctively manages its surface water and groundwater supplies. The District imports State Water Project (SWP) water through a contract with Kern County Water Agency (KCWA) for 197,088 acre-feet per year (AFY) of Table A Allocation (WRMWSD, 2015). During wet years, the District also receives "Article 21" wet period, surplus water from the SWP. Pursuant to transfer agreements with partner agencies (e.g., Buena Vista Water Storage District, Tehachapi-Cummings Community Water District, etc.), the District has also obtained additional imported water from the SWP, the Central Valley Project (CVP), and other sources. Additionally, the District banks water with the Kern Water Bank, Pioneer Project, and Berrenda Mesa Project in wet years and recovers banked water during dry years.[29] **Figure PA-5** shows the District's facilities and infrastructure used for the conveyance and distribution of imported water supplies. The California Aqueduct runs through the District from west to southeast, and the District has approximately twenty pump stations along the Aqueduct that feed SWP water into the District pipelines, distributing water to the District's Surface Water Service Area.

[29] Table 28 of the WRMWSD Agricultural Water Management Plan provides a complete listing of water transfer and exchange partners.

8. CURRENT AND HISTORICAL GROUNDWATER CONDITIONS

☑ 23 CCR § 354.16

This section presents information on historical and current groundwater conditions within the Wheeler Ridge-Maricopa Management Area based on available data. Sources of data used to inform the current conditions assessment are described within each data topic section and include data from District records, various state and federal databases, and other reports.

For the purposes of this assessment, "current conditions" refers to conditions in calendar year 2015 (i.e., the effective date of SGMA), which is consistent with how "current" is defined by the KGA in the KGA Umbrella GSP. For historical conditions, two periods are relevant. The first is DWR Water Years (WY) 1995 through 2015 (i.e., October 1994 through September 2015) which is the period being used by KGA and its member entities for historical water budget development. As discussed further below, this period is climatically close to normal/average, but includes a significantly dry (drought) period between 2012 and 2015, as well as other years that were drier or wetter than normal. The second historical period discussed herein is the period from 1971 through 2017/2018 which corresponds to the period since WRMWSD began its water importation operations. Consideration of this longer period allows assessment of the long-term effects of District operations and various sustainability indicators (i.e., groundwater levels, storage, and water quality). In some cases, certain other historical periods are also discussed in this section when either (a) the discussion is constrained by the time periods of available datasets (e.g., for land subsidence), or (b) the groundwater conditions characterization is improved by incorporation of data from other time periods.

8.1. Data Sources and Compilation

☑ 23 CCR § 352.6

Per the GSP Emergency Regulations (23 CCR § 352.6), each GSA "shall develop and maintain a data management system that is capable of storing and reporting information relevant to the development or implementation of the Plan and monitoring of the basin". In support of GSP development (i.e., HCM development, analysis of groundwater conditions, water budget development, and Plan Area information) a substantial number of data sources were compiled, organized, and processed, and stored within a District-specific DMS. The data compiled, which are described in greater detail in the sections that follow, included:

- Groundwater level measurements for in-District and nearby wells compiled by the District from its own records and state data sources such as the California Statewide Groundwater Elevation Monitoring (CASGEM) Program, 1924-2017;
- District records of in-District wells and associated Geographic Information System (GIS) shapefiles;
- Well construction information compiled by the District;
- GIS shapefiles of the District service area and surface water conveyance and distribution infrastructure;
- Annual district-wide land use survey and associated GIS shapefile, 2000-2017;
- Groundwater quality data, 1951-2016;

- District data for evapotranspiration (ET) as provided to the Kern Groundwater Authority (KGA) by the Cal-Poly Irrigation Training and Research Center (ITRC) at monthly intervals, 1993-2015 (excluding 2012).
- Surficial geology maps from the California Geological Survey (CGS; formerly known as the California Division of Mines and Geology);
- GIS shapefiles of watershed boundaries and surface water features from National Hydrography Dataset (NHD);
- Locations of known contamination sites from the State Water Resources Control Board (SWRCB) GeoTracker database;
- Aquifer parameter information from California Central Valley Groundwater-Surface Water Simulation Model (C2VSim) for model nodes within the District5;
- Percent coarse information from the Central Valley Hydrologic Model (CVHM) for model elements within the AOI;
- Division of Oil, Gas, and Geothermal Resources (DOGGR) oil field reports for the District area;
- Soils data from the National Resources Conservation Service's (NRCS) Soil Survey Geographic Database (SSURGO);
- California water agency administrative boundary shapefiles from DWR;
- Various regional geologic reports, maps and cross-sections;
- Various land subsidence studies encompassing the District; and
- Base of fresh water studies.

All geospatial data were integrated into the ArcGIS software platform as a "geodatabase", a composite file structure (.gdb) which packages attribute data with associated geospatial information in a user-defined coordinate system.

Much of the data compiled for GSP development and analyses needed at least some pre-processing before the data could be integrated into ArcGIS. These pre-processing tasks included digitization, georeferencing, filtering, and linking georeferenced datasets to associated attribute data from other sources. For example, water level information in some instances did not have any coordinate or elevation information attributed to individual wells. To bring water level information into ArcGIS and create groundwater elevation maps, unique well identifiers based on the Public Land Survey System (PLSS) township information were assigned and then used to link water level records with their associated well coordinates derived from the well survey.

The result of these processing steps is a series of compiled spreadsheets containing, to the extent the information was available: (1) Well IDs, coordinates, and elevation information; (2) well construction information; (3) seasonal water level measurements for the period of collection (1924-2017); and (4) water quality information compiled by the District (1951-2016). These data were subsequently brought into ArcGIS and stored in a geodatabase created for the District along with other geospatial data sources used for HCM development and further assessment of groundwater conditions. Last, selected data types

(i.e., water level and water quality data at wells) were brought into a Microsoft Access database. Together these spreadsheets, geodatabase files, and Microsoft Access database comprise the working DMS for the District. Efforts to develop a coordinated Kern Subbasin DMS are planned as part of Plan Implementation (see **Section 18.3** ***Intrabasin Coordination***).

8.2. Groundwater Elevations and Flow Direction

☑ 23 CCR § 354.16(a)

Groundwater elevation data have been collected and compiled from WRMWSD monitoring records, datasets from other neighboring entities (i.e., Arvin-Edison Water Storage District [AEWSD], Kern Delta Water District [KDWD], and Kern County Water Agency [KCWA]), and the DWR's California Statewide Groundwater Elevation Monitoring (CASGEM) database. The multiple datasets were reconciled and processed for quality assurance/quality control prior to analysis for groundwater conditions. These data cleaning efforts included removal of erroneous data points identified through examination of hydrographs and removal of very shallow depth-to-water data points (less than 20 ft bgs) suspected of being affected by perched conditions along the northern boundary and to the north of the Wheeler Ridge-Maricopa Management Area. The resulting dataset used to inform this discussion of groundwater elevation conditions consists of over 100,000 groundwater elevation data points from over 1,600 wells over the period from 1936 to Spring 2018 throughout the Kern Subbasin.[30] For the purposes of this analysis the periods of Spring and Fall 2015 are used to represent seasonal high and low conditions under current land and water use, which is consistent with how other Management Area Plans under the KGA Umbrella GSP and other GSPs within the Kern Subbasin (i.e., Kern River GSA's GSP) are being prepared.

Lateral Gradients

Lateral gradients are discussed below in the context of groundwater elevation contour maps.

Vertical Gradients

Vertical gradients between the different zones within the principal aquifer (i.e., the unconfined zone above the E Clay versus the confined zone below the E Clay, where it exists) may develop due to variability in proximity to recharge sources and the intensity of pumping. Vertical gradients may also vary in time as the stresses affecting water levels are also temporally variable. Evaluation of vertical gradients can be accomplished by examination of water levels in well pairs where one well is representative of the upper, unconfined zone and the other well is representative of the lower, confined zone. This approach requires water level information from wells that: (a) have known well construction information, (b) are screened in different depth zones, (c) have contemporaneous measurements (i.e., water levels measured at least in the same year and season), and (d) are in close spatial proximity to each other (i.e., to minimize the influence of lateral gradients in water level). At this time, data that meets all of the above criteria are limited. Available data indicate that vertical gradients within the District are generally downwards but vary and between years and seasons. Compiling additional well screen interval information for associated groundwater elevation data would help fill to better define vertical gradients between different zones of the principal aquifer.

[30] Within the Wheeler Ridge-Maricopa Management Area, the dataset consists of roughly 11,000 groundwater elevation data points from 381 wells over the period from 1943 to 2018.

Groundwater Elevation Contour Maps

☑ 23 CCR § 354.16(a)(1)

Groundwater elevation contour maps for "current conditions" – Spring 2015 and Fall 2015 – are presented on **Figure GWC-1** and **Figure GWC-2**, respectively. The following generalities can be made based on groundwater elevation data compiled for wells within the Wheeler Ridge-Maricopa Management Area.

- Groundwater levels are consistently lowest in the southern central portion of the Management Area near the California Aqueduct, in the northernmost portion between the Buena Vista Lake Bed and Kern Lake Bed, and in the far eastern portion just north of the White Wolf Fault.
- Groundwater levels are highest in the western portion of the Management Area and just south of the Kern Lake Bed.
- The barrier effects of White Wolf Fault tend to cause higher groundwater levels on the upgradient (South) side just outside of the Management Area, due to "backing up" of water.
- Assuming groundwater flow is perpendicular to groundwater elevation contours, flow directions are highly variable throughout the Management Area. Generally, groundwater flows into the Management Area across the White Wolf Fault at a relatively low rate due to low transmissivity. Flow across the northern boundary is variable and may result in net inflow or outflow from season to season.
- Average lateral groundwater gradients across the northern boundary of the Management Area under current conditions were extracted from the Spring and Fall 2015 groundwater elevation contour maps (**Figure GWC-1** and **Figure GWC-2**) using GIS analysis. This boundary was divided into three sections – northwest (where data are very limited and gradients therefore uncertain), north-central, and northeast. The estimated lateral gradients across these three northern boundary sections in Spring 2015 were 0.005 feet per foot (ft/ft) 0.0016 ft/ft, and 0.0022 ft/ft, all in a northerly (outflow) direction. In Fall 2015, the gradients for these sections were 0.0049 ft/ft, 0.0033 ft/ft, and 0.0039 ft/ft, respectively, also all in an outflow direction. Average lateral gradients across the White Wolf Fault in Spring and Fall 2015 were approximately 0.01 ft/ft.
- An area of relatively high groundwater levels exists to the northeast of the Management Area, which may potentially be due to the impact of finer-grained "basin" deposits.

The relative highs and lows within the Wheeler Ridge-Maricopa Management Area appear to be controlled, at least in part, by the distribution of groundwater pumping versus surface water deliveries; with the notable exception of the south-central area with low groundwater elevations mentioned in the first bullet above, areas within the District's Surface Water Service Area (SWSA) (see **Figure GWC-3**) tend to exhibit higher groundwater elevations than areas outside of the SWSA that rely exclusively on groundwater.

Depth to Groundwater

As shown on **Figure GWC-4**, depth to groundwater for "current conditions" in Spring 2015 within the Wheeler Ridge-Maricopa Management Area varies from about 23 ft bgs to 559 ft bgs within the principal aquifer. Most of the Management Area had depths to water of between 100 and 350 ft bgs, with shallower depths interspersed in the northern portion and deeper depths concentrated in the south-central portion.

The shallowest depths to water (i.e., less than 50 ft bgs), were measured in wells along the far northern portion of the Management Area near the Kern Lake Bed and Buena Vista Lake Bed and may be indicative of perched groundwater atop the fine-grained "basin" deposits in that area. It appears that these shallow measurements are representative of perched water that is not connected to the principal aquifer system. The fact that depth to water in the principal aquifer system is in most cases more than 100 ft bgs indicates that interconnected surface water and groundwater-dependent ecosystems are unlikely to occur with respect to the principal aquifer in the Management Area. These topics are discussed further below in **Section 8.7 *Interconnected Surface Water Systems*** and **Section 8.8 *Groundwater Dependent Ecosystems***, respectively.

Long-Term Groundwater Elevation Trends

☑ 23 CCR § 354.16(a)(2)

Long-term trends in groundwater levels were evaluated based on examination of hydrographs for 16 wells throughout the Wheeler Ridge-Maricopa Management Area. Wells were selected for hydrograph analysis based on the length of record, their distribution throughout the Management Area, and their representativeness of conditions in their area. Hydrographs were developed for two periods: a long-term period from 1955 through February 2018 which captures the entire operational history of the District through the most recent available data (**Figure GWC-5**), and the more recent period from October 1994 through September 2015 which is consistent with the KGA period of interest (**Figure GWC-6**). As shown on **Figure GWC-5**, a majority of the wells with long-term records in the Management Area have shown increased groundwater levels over the long-term, reflecting the increased storage resulting from the WRMWSD's importation of surface water starting in 1971. Prior to 1971, groundwater levels in many wells were experiencing steep declines. Wells in the far eastern and northwestern portions of the Management Area show more moderate long-term increases or slight declines in groundwater level. The effects of drought cycles (e.g., late 1980s/early 1990s) are apparent in some but not all wells, with greater declines during dry periods and recovery during wet periods. As shown on **Figure GWC-6**, over the more recent period from October 1994 to September 2015, the same general behavior and spatial patterns are apparent, except that the long-term increase in water levels due to surface water importation is tempered by recent declines due to drought, especially in the central portion of the Management Area.

To evaluate long-term water level trends, linear regression of the water level data was used (recognizing that this method can be slightly biased by the data's temporal frequency and distribution). Over the period from 1971 (i.e., the start of surface water imports) through February 2018, trends ranged from -1.38 feet per year to +4.06 feet per year, with 12 out of 16 wells showing positive trends greater than 0.5 feet per year, and only two wells with negative trends. Over the period from Fall 1994 through Fall 2015 (i.e., the KGA period of interest), trends ranged from -2.06 feet per year to +3.86 feet per year, with 9 out of 16 wells showing positive trends greater than 0.5 feet per year, and six wells with negative trends.

Table GWC-1 below shows the DWR Water Year Hydrologic Classification Index for the San Joaquin Valley (i.e., water year type)[31,32]. Based on the DWR San Joaquin Valley Water Year Index for the 21 Water Years from 1995 through 2015, the period included five "critical" (dry) years, four dry years, two below normal

[31] http://cdec.water.ca.gov/reportapp/javareports?name=WSIHIST
[32] DWR defines a Water Year as extending from October 1 of the previous year to September 30 of the year in question. For example, Water Year 2005 extends from 1 October 2004 through 30 September 2005.

years, three above normal year, and seven wet years. The first third of this period was relatively wet, the middle third was a mix of wet and dry years, and the last third of the period was extremely dry. This climatic factor is reflected in the hydrographs which tend to exhibit water level increases in the 1990s, relative stability in the early 2000s, and then greater decreases starting in the late 2000s.

Table GWC-1. Summary of DWR Water Year Types, 1995 - 2015

Water Year	WY Index	Water Year	WY Index	Water Year	WY Index
1995	Wet	2002	Dry	2009	Below Normal
1996	Wet	2003	Below Normal	2010	Above Normal
1997	Wet	2004	Dry	2011	Wet
1998	Wet	2005	Wet	2012	Dry
1999	Above Normal	2006	Wet	2013	Critical
2000	Above Normal	2007	Critical	2014	Critical
2001	Dry	2008	Critical	2015	Critical

Groundwater Levels Relative to Well Screens

One factor to consider when setting minimum thresholds for chronic lowering of groundwater levels is the potential for dewatering of wells or well screens[33]. Based on available well construction information, the elevation of the top of well screen (TOS) varies substantially across the Wheeler Ridge-Maricopa Management Area, with differences of several hundred feet between neighboring wells (**Figure GWC-7**). In order to understand how wells may have been historically or currently impacted, groundwater levels were compared to known TOS elevation information.

Under the assumption that historical low water levels occurred in Fall 1971, just prior to the start of surface water imports by WRMWSD (which is generally supported by the long-term hydrographs shown on **Figure GWC-5**), historic groundwater elevation lows from Fall 1971 were compared to TOS data (**Figure GWC-8** (a))[34]. Wells in the western and northern portions of the Wheeler Ridge-Maricopa Management Area tended to be less impacted (i.e., not dewatered) than wells in the central portion of the Management Area.

To assess potential vulnerability due to drought under the current water supply regime (i.e., since surface water imports have been in effect), groundwater levels from Fall 2016[35] were compared to the TOS data

[33] DWR, 2017, Draft Best Management Practices for the Sustainable Management of Groundwater: Sustainable Management Criteria

[34] Groundwater elevation data used are interpolated values in order to include all wells for which the District has well screen data in the analysis, as opposed to only those with both well screen and Fall 1971 groundwater elevation records.

[35] Data from Fall 2016, near the end of the recent historic drought, were used to understand the extent of drought impacts.

(**Figure GWC-8**(b)). As this analysis was focused on assessing recent and future potential impact, only wells known to be active are shown.

Of the four active domestic wells for which the District has well screen data, one showed groundwater elevations more than 100 ft below the TOS elevation, two showed groundwater elevations between 50 and 100 feet below the TOS, and one showed groundwater elevations between 100 and 200 feet above the TOS. Of the 30 active agricultural production wells (including 28 private wells and two District-owned wells) for which the District has well screen data, groundwater levels were below the TOS for 10 wells and were within 50 ft of the TOS for four other wells.

Lack of complete well screen data[36] currently prevents a comprehensive analysis of impacts of lowering groundwater levels on wells in the Wheeler Ridge-Maricopa Management Area. To better understand the potential impacts of groundwater level changes on active wells in the Management Area, it would be necessary to acquire and compile data on well screen interval information for additional domestic, agricultural, and industrial wells. Additionally, it would be necessary to update data on well status (i.e., whether or not the well is active) to determine potential impacts to existing wells, as District data show that the status of some wells was most recently assessed in January 1991.

8.3. Change in Groundwater Storage

☑ **23 CCR § 354.16(b)**

Change in groundwater storage was estimated based on data for selected periods of interest. The method used to estimate storage change for these periods used water level data collected at the start and end of each period, spatially-variable specific yield information, and the following relationship, applied in a distributed manner:

$$\textit{Change in Storage} = [\textit{Ending Water Level} - \textit{Starting Water Level}] * \textit{Specific Yield} * \textit{Area}$$

Specifically, this approach was implemented by: (1) interpolating groundwater elevations for both years onto a 100-ft grid of pixels using the geostatistical spatial interpolation method known as kriging, (2) similarly interpolating the specific yield values from C2VSim-FG node data[37], (3) calculating the water level difference at each pixel, (4) multiplying the water level difference from (3) by the specific yield at each pixel, (5) multiplying the result from (4) by the area of each pixel (i.e., 100 ft x 100 ft = 10,000 ft^2), and (5) summing all calculated values over the area of the Wheeler Ridge-Maricopa Management Area. To avoid errors caused by comparison of interpolated data that is based on different well points, a paired-well approach was used, wherein wells were selected for inclusion only if they were present in both datasets or if they were in close proximity (less than 1 mile) to a well in the other dataset.

[36] District records indicate that there are thirteen active domestic wells in the Wheeler Ridge-Maricopa Management Area; the District has well screen data compiled for four of these wells. There are 74 active agricultural production wells within the Management Area, not including the District's own production wells, and the District has well screen data for 28 of these and is lacking well screen data for 46. There are three active District production wells in the Management Area (the District has thirteen additional active production wells in its area within the White Wolf Basin), and the District has well screen information for two of these wells. The District also lacks well screen information for the one active industrial well in the Management Area.

[37] As discussed previously, specific yield values in the C2VSim-FG model used in this calculation may change upon completion of the model calibration.

Table GWC-2, below, presents the results of this storage change estimation for selected time periods of interest. As shown in **Table GWC-2**, the total change in storage from 1971 through 2016 (i.e., since the start of District water imports through the latest available data) was 77,180 AF or approximately 1,715 AFY. The total change in storage from Fall 1994 through Fall 2015 (i.e., the recent KGA period of interest) was 27,180 AF or approximately 1,294 AFY. To put this annual change in storage value into context, it represents approximately 2.3% of the average annual rate of groundwater pumping within the Wheeler Ridge-Maricopa Management Area over that same period (approximately 57,000 AFY; discussed further below in **Section 9.3.2** ***Historical Water Budget***). This indicates that groundwater storage over the Management Area has shown long-term stability over the WY 1994 – 2015 period.[38]

Table GWC-2. Change in Storage for Selected Time Periods

Period	Relevance of Time Period	Total Change in Storage (AF)	Annual Rate of Change in Storage (AFY)
Spring 1971 – Spring 2016	Entire period of District Operations	77,180	1,715
Fall 1971 – Fall 1990	Entire Bookman-Edmonston Water Budget Period	358,993	18,894
Fall 1994 – Fall 2015	KGA water budget period of interest	27,180	1,294
Spring 2003 – Spring 2015	Longer normal/dry period	-80,939	-6,745
Spring 2003 – Spring 2012	Longer normal/wet period	81,839	9,093
Fall 2014 – Fall 2015	Short dry period	-76,197	-76,197

Figure GWC-9 shows the distribution of groundwater elevation change throughout the Wheeler Ridge-Maricopa Management Area for the periods from Spring 1971 through Spring 2016, Fall 1994 through Fall 2015, and Fall 2014 through Fall 2015 (groundwater elevation change is directly related to storage change). As shown on **Figure GWC-9**, from Spring 1971 through Spring 2016 groundwater levels increased throughout most of the Management Area, with the exception of the south- central portion and a small area along the west/central portion of the northern border. The area in the south-central portion

[38] Results from the basin-wide numerical modeling indicated a negative average annual storage change of approximately 7,900 AFY between Fall 1994 and Fall 2014.However, that estimate is considered less accurate than the locally-derived storage change estimates presented here because the basin-wide model has not undergone calibration of subsurface parameters on a local scale against actual local water level data.

appears to have been influenced by several low water level measurements that may be indicate short-term pumping-related levels rather than static levels, but because they were observed in several wells they were not considered outliers. Over the recent period from Fall 1994 through Fall 2015, changes in groundwater elevation were variable, with slight increases in the west, north-central, and east portions of the Management Area, and slight decreases along the southern central and northeastern areas. Over the period from Fall 2014 to Fall 2015, groundwater elevation changes were slightly positive in most areas, but negative in the south-central area.

Determination of the change in storage on a yearly basis using the method described above is more difficult due to a lack of consistent water level monitoring data. To address this issue, annual change in storage estimates were extracted from the output of the water budget model, described further in **Section 9 *Water Budget Information*** below. A graph of estimated annual change in storage between seasonal water level highs (i.e., from March of each year to March of the following year), is presented on **Figure GWC-10**. Also shown on **Figure GWC-10** is the Water Year type based on DWR's San Joaquin Valley Water Year Index[39]. As shown on **Figure GWC-10**, annual change in storage within the Wheeler Ridge-Maricopa Management Area ranged from an increase of 83,000 AF for the period from March 1998 – February 1999 to a decrease of 46,000 AF for the period between March 2013 and February 2014. Change in storage tends to be more negative during dry Water Years and more positive during wet Water Years. Change in groundwater storage is discussed further below in **Section 9.3.2 *Historical Water Budget***.

8.4. Seawater Intrusion

☑ **23 CCR § 354.16(c)**

Because the Wheeler Ridge-Maricopa Management Area is located far from coastal areas, seawater intrusion is not considered to be an issue.

8.5. Groundwater Quality

☑ **23 CCR § 354.16(d)**

8.5.1. Groundwater Quality Constituents of Concern

Groundwater quality constituents that may affect the supply and beneficial uses of groundwater in the Wheeler Ridge-Maricopa Management Area were identified by comparing the highest measured concentrations detected at an individual well for each constituent between 2012 and 2016 to applicable screening levels for the various beneficial uses (i.e., Maximum Contaminant Levels [MCLs] for domestic/Municipal & Industrial (M&I) use and various thresholds for irrigated agricultural use). Constituents for which at least 15% of samples exceeded the applicable screening level include TDS, nitrate, arsenic, boron, iron, manganese, and sulfate, as discussed below. Of the seven constituents

[39] The seasonal high groundwater condition occurs typically in late winter or spring and for the purposes of **Figure GWC-10** is assumed to occur in March. March groundwater levels are affected by both the amount of pumping during the prior summer (i.e., previous DWR Water Year) as well as the amount of precipitation during the winter months of the current DWR Water Year. In **Figure GWC-10**, the color of each bar is based on the Water Year type for the year the begins in the October between the March and February represented by the bar.

mentioned above, only nitrate and arsenic are regulated with a primary (i.e., health risk-based) MCL[40], while TDS, iron, manganese, and sulfate have secondary (i.e., aesthetically-based) MCLs[41]. Boron does not have a primary nor secondary MCL, but levels exceeding 0.50 mg/L can be harmful to sensitive crops (including oranges and grapes) and thus may cause a slight to moderate restriction of use to prevalent crops in the Management Area (United Nations Food and Agriculture Organization, 1985).

- Nitrate was detected above the primary MCL of 10 mg/L (as N) or 45 mg/L (as NO_3) in zero of 37 wells sampled between 2012 and 2016. Higher concentrations were measured in locations along the southeastern edge of the Management Area, near the White Wolf Fault, and several wells just southeast of the Management Area across the White Wolf Fault show nitrate exceedances (**Figure GWC-11**).
- Arsenic was detected above the primary MCL of 10 micrograms per liter (ug/L) in six (38%) of 16 wells sampled between 2012 and 2016, with most MCL exceedances in the northern and central portions of the Management Area (**Figure GWC-11**). Arsenic concentration varies over short distances, with relatively high values in close proximity to "non-detect" values. Arsenic is naturally-occurring in this area, derived from the granitic source rocks whose eroded sediments are present within the alluvial Tulare Formation (Thiros, 2010).
- Boron was detected at levels that may restrict a water's use for irrigation for common crops (i.e., above 0.5 mg/L; Ayers and Westcot, 1985) in 13 (87%) of 15 wells sampled between 2012 and 2016. Boron is commonly detected throughout the central portion of the Management Area (**Figure GWC-12**). Boron was also cited as the cause of a base of fresh water determination for nearby oil field pools (Jeppi, Main Area of the Edison oil field) (DOGGR, 1988).
- Sulfate is detected above the recommended secondary MCL of 250 mg/L throughout the Management Area; 34 (92%) of 37 wells sampled between 2012 and 2016 show sulfate concentrations above 250 mg/L. In many cases (41%, or 15 of 37 wells), the sulfate concentration exceeds the upper secondary MCL of 500 mg/L.
- TDS was detected above the recommended secondary MCL of 500 mg/L in 35 (95%) of 37 wells sampled between 2012 and 2016 and was present throughout the Management Area (**Figure GWC-13**). TDS exceeded the upper secondary MCL of 1,000 mg/L in 10 (27%) of 37 wells sampled between 2012 and 2016, primarily in the northern central portion of the Management Area. As shown on **Figure GWC-13**, recent water quality sampling has not occurred in the western portion of the Management Area, as groundwater use and monitoring have mostly ceased in this area due to a combination of poor water quality and relatively low yield. Historical water quality sampling from the 1960s shows high concentrations of TDS in the western portion of the Management Area, with TDS detected in most wells above the upper secondary MCL.

[40] Primary MCLs are drinking water standards set by the USEPA and California Environmental Protection and Agency (CalEPA) based on human health considerations.

[41] Secondary MCLs are non-health related standards set by the State Water Resources Control Board based on aesthetic characteristics of drinking water such as taste, odor, and color. For four common constituents – TDS, specific conductance, chloride and sulfate – the SWRCB sets three levels of secondary MCLs for consumer acceptance, referred to as (lowest to highest concentration): "recommended", "upper", and "short term".

- Both iron and manganese exceeded their respective secondary MCLs (300 ug/L and 50 ug/L, respectively) in some locations. Iron exceeded its secondary MCL in eight (33%) of 24 wells sampled between 2012 and 2016, and manganese exceeded its secondary MCL in six (25%) of 24 wells sampled between 2012 and 2016. Though these naturally-occurring constituents can impair the aesthetic quality of drinking water and at high enough concentrations can result in staining of fixtures or clothes washed therein, they are not likely to significantly affect beneficial uses of groundwater in the Management Area.
- The District has indicated that chloride and Uranium may be of concern; groundwater sample data collected between 2012 to 2016 showed no exceedances of MCLs (primary for Uranium and secondary for chloride) for either constituent. Because chloride can negatively affect crop health, recent (2012-2016) groundwater quality sample data were screened against a lower concentration threshold associated with sensitive rootstocks and cultivars for major tree and berry crops (Ayers and Westcot, 1985). Only one of 43 samples exceeded the lowest (most conservative) threshold concentration of 117 mg/L (3.3 milliequivalents per liter of chloride).

Recent District sampling has included primarily inorganic constituents such as major ions and metals, as well as volatile organic compounds (VOCs) and semi-volatile organic compounds (SVOCs). VOCs and SVOCs constituents are typically not a concern for agricultural beneficial uses, but some are harmful to humans if consumed at high enough concentrations (often at parts per million or parts per billion concentrations) and are thus regulated by the U.S. Environmental Protection Agency (EPA) and California EPA (specifically the State Water Resources Control Board [SWRCB]) in drinking water sources. Some of these compounds are, or have been historically, used in agriculture as pesticides, herbicides, fungicides, and can be transported to groundwater by deep percolation of excess applied water, although this is more of a concern for the older "legacy" chemicals and less so for the current generation of chemicals that are designed to avoid deep percolation. One compound in particular, 1,2,3-trichloropropane (1,2,3-TCP), which is an industrial solvent that was also historically a component in a soil fumigant, was recognized in 2006 as a "constituent of special interest" in Kern County (Shelton et al., 2006), and was recently assigned a (primary) MCL of 0.005 ug/L (five parts per trillion) by the California EPA[42], effective 14 December 2017. Limited data from the District's water quality sampling (43 samples since 2000) indicate that 1,2,3-TCP has not been detected in the Wheeler Ridge-Maricopa Management Area. Additionally, limited data from the USGS Groundwater Ambient Monitoring and Assessment (GAMA) program (Shelton et al., 2006) showed that 1,2,3-TCP was not detected in wells within the Management Area but was detected in 2006 in one location in the adjacent Arvin-Edison Management Area at a concentration of 0.40 ug/L, 80 times the MCL.

More generally, additional efforts to compile and characterize water quality data from additional data sources will continue as part of Plan Implementation. **Appendix E** includes a list and description of potential water quality datasets that may be analyzed to further assess groundwater quality conditions in the Arvin-Edison Management Area, including, for example, the CalEPA's Regulated Site Portal, Cortese List, GeoTracker, Drinking Water Watch, GAMA-PBP, California Pesticide Information Portal, USEPA's National Priorities List, and DOGGR's CalStim'D and WellFinder datatsets.

[42] https://www.waterboards.ca.gov/drinking_water/certlic/drinkingwater/documents/123-tcp/2017_1115_01S_app.pdf

8.5.2. Temporal Characteristics of Groundwater Quality

Historical water quality sampling data are limited both in spatial extent and temporal frequency within the Wheeler Ridge-Maricopa Management Area, thus making analysis of water quality trends and their potential nexus to groundwater elevations difficult. The most regularly monitored constituents of concern within the District include TDS, Arsenic, and Nitrate. For these constituents, time-series water quality data were plotted relative to groundwater level measurements for all wells with at least five historical water quality and groundwater level records (see **Appendix F**). For each constituent, there was no discernable relationship between groundwater levels and groundwater quality trends that could be consistently identified. Thus, additional data collection and analysis will be needed to further evaluate this potential relationship.

8.5.3. Point-Source Contamination Sites

In addition to the relatively widespread non-point source groundwater quality constituents of concern, there are a small number of point-source contamination sites that historically or currently affect shallow (possibly perched) groundwater within the Wheeler Ridge-Maricopa Management Area. These sites, shown on **Figure GWC-14**, are typically associated with certain industrial or commercial land uses (e.g., gas stations).

As shown on **Figure GWC-14**, there are a total of two closed Cleanup Program sites and one closed Leaking Underground Storage Tank (LUST) Cleanup site. The LUST Cleanup site was managed by Kern County and the two of the Cleanup Program sites were managed under the oversight of the CVRWQCB. There are no active cleanup sites within the Wheeler Ridge-Maricopa Management Area. The LUST Cleanup site has gasoline listed as a potential contaminant of concern and one of the Cleanup Program sites has crude oil listed as a contaminant of concern. **Table GWC-3** below summarizes these three closed sites within the Management Area.

As shown on **Figure GWC-14**, there are five inactive sites that need evaluation listed in the Department of Toxic Substances Control EnviroStor database within the Wheeler Ridge-Maricopa Management Area. Four of these are military sites, and one is a firing range that has been identified for State Response.

In addition to the closed and inactive sites discussed above, there are several open and closed Cleanup Program Sites, several closed LUST Cleanup sites, a few active Corrective Action and State Response Sites, and Certified Voluntary Cleanup Sites just outside of the Wheeler Ridge-Maricopa Management Area. Given the lack of open sites and the fact that groundwater is generally hundreds of feet below the surface and separated from near-surface contamination by numerous thin low permeability layers, the threat to groundwater from the closed sites is likely minor.

Table GWC-3. Summary of Active Point-Source Contamination Sites

Site ID (see **Figure GWC-14**)	Site Name	Site Type	Regulatory Oversight Agency	Potential Contaminants of Concern	Status
1	Tenneco - Rancho Loma Farm	Cleanup Program Site	CVRWQCB	None Listed	Completed - Case Closed
2	Robert Andrews Farms	LUST Cleanup Site	Kern County	Gasoline	Completed - Case Closed
3	Four Corners Pipeline Company	Cleanup Program Site	CVRWQCB	Crude Oil	Completed - Case Closed

8.5.4. Oil Field Injection Wells and Produced Water Ponds

As described in **Section 7.1.3 *Bottom of the Basin***, there are five oil fields that overlap the Wheeler Ridge-Maricopa Management Area – the San Emidio Nose, Yowlumne, Rio Viejo, Los Lobos, and Midway-Sunset oil fields. **Figure GWC-15** shows the locations of active underground injection wells (based on DOGGR data) and produced water ponds (based on data from the SWRCB's GeoTracker website) used for oil field operations in these areas. Within the Management Area there are 12 active injection wells, all but one of which are in the Yowlumne oil field (the other being in the Rio Viejo oil field). There are also a large number of injection wells in the Midway-Sunset oil field to the west of the Management Area. There are no produced water ponds within the Management Area, but there are many in the Midway-Sunset oil field.

Underground injection wells used to dispose of wastewater from oil and gas development are regulated in California by the USEPA, DOGGR, and SWRCB (see California Health and Safety Code § 25159.10 et seq). Produced water discharges to ponds are under the purview of SWRCB and CVRWQCB regulatory oversight and are subject to regulation under individual and general Waste Discharge Requirements (WDRs) amongst other requirements to ensure adequate protection against impacts to underlying groundwater resources. Pursuant to SB 4 (2013), the SWRCB established a Regional Groundwater Monitoring Program[43] to assess the potential effects on groundwater resources of well stimulation activities in oil and gas producing areas. The Regional Monitoring Program has been implemented through cooperative efforts between the SWRCB and the USGS, including collection of groundwater quality samples in selected wells in proximity to oil fields within the Kern Subbasin (Dillon et al., 2017).

[43] https://www.waterboards.ca.gov/water_issues/programs/groundwater/sb4/regional_monitoring/

8.6. Land Subsidence

☑ 23 CCR § 354.16(e)

The Kern Subbasin has a documented history of land subsidence, including historical and recent subsidence in the southern portion of the Kern Subbasin, south of the Kern River, which includes the Wheeler Ridge-Maricopa Management Area (Lofgren, 1975; DWR, 2014). Subsidence in this area has been caused primarily by withdrawal of groundwater, with some areas also affected by hydrocompaction (Lofgren, 1975). Subsidence due to oil and gas production has also occurred in some areas but is minor in importance. **Figure GWC-16** depicts maps of areas of hydrocompaction and historical (1949-2005) and recent (2015-2016) subsidence, which are discussed below. The KGA Umbrella GSP provides additional information on subsidence throughout the Kern Subbasin and over time, and with particular reference to critical delivery system infrastructure such as the California Aqueduct and the Friant-Kern Canal.

Historical Subsidence

During the mid-20th century, when groundwater levels were declining rapidly before the importation of surface water supplies by WRMWSD and others began, subsidence was widespread throughout the area, with the greatest amounts – over nine feet between 1926 and 1970 – occurring just south of Kern Lake Bed northwest of Mettler (Lofgren, 1975). Subsidence amounts tended to decrease in all directions from this central "hot spot". This area of historical subsidence generally coincides with the presence of the regional E Clay aquitard and other shallower regional aquitards, which is also presumably an area that includes a greater proportion of other unnamed fine-grained compactible materials.

Between 1957 and 1965, the estimated rate of subsidence as a function of groundwater level decline varied widely from approximately 0.01 to 0.4 feet of subsidence per foot of head decline in the Wheeler Ridge-Maricopa Management Area (Lofgren, 1975).

Extending the historical record further into recent times, DWR has mapped subsidence in this portion of the Kern Subbasin between 1949 and 2005. The southern and northwestern areas of the Wheeler Ridge-Maricopa Management Area are shown in this dataset as having subsidence over that period of between zero and five feet and the northern central areas having subsidence between five and 15 feet (see **Figure GWC-16**). DWR has noted that between 7.5 and 9 feet of land subsidence was observed within the Management Area between 1965 and 1968 as a result of hydrocompaction upon the development of pre-construction ponds along the proposed alignment of the California Aqueduct Mileposts 255.7 – 274.3 (DWR, 2017).

Recent Subsidence

Subsidence due to water level decline has continued in recent times of groundwater level decline associated with dry climatic conditions; between May 2015 and September 2016 most areas within the Wheeler Ridge-Maricopa Management Area experienced between one and eight inches of subsidence, with some small areas between eight and twelve inches (see **Figure GWC-16**; based on Farr et al., 2016).[44] The continued recent subsidence, occurring at a time when groundwater levels are not necessarily below

[44] It should be noted that subsidence estimates based on interferometric synthetic aperture radar (InSAR) methods can be subject to errors when the period of time between measurements is short and when the land is subject to surface disturbance, as is typical in agricultural areas (personal communication, Michelle Sneed, USGS, 27 June 2018).

their historic minima, demonstrates that subsidence can continue to occur even after water levels are partially recovered. This continued subsidence could be elastic or could be inelastic subsidence resulting from the temporally-lagged, continued slow depressurization of compactible fine-grained materials (Lofgren, 1975).

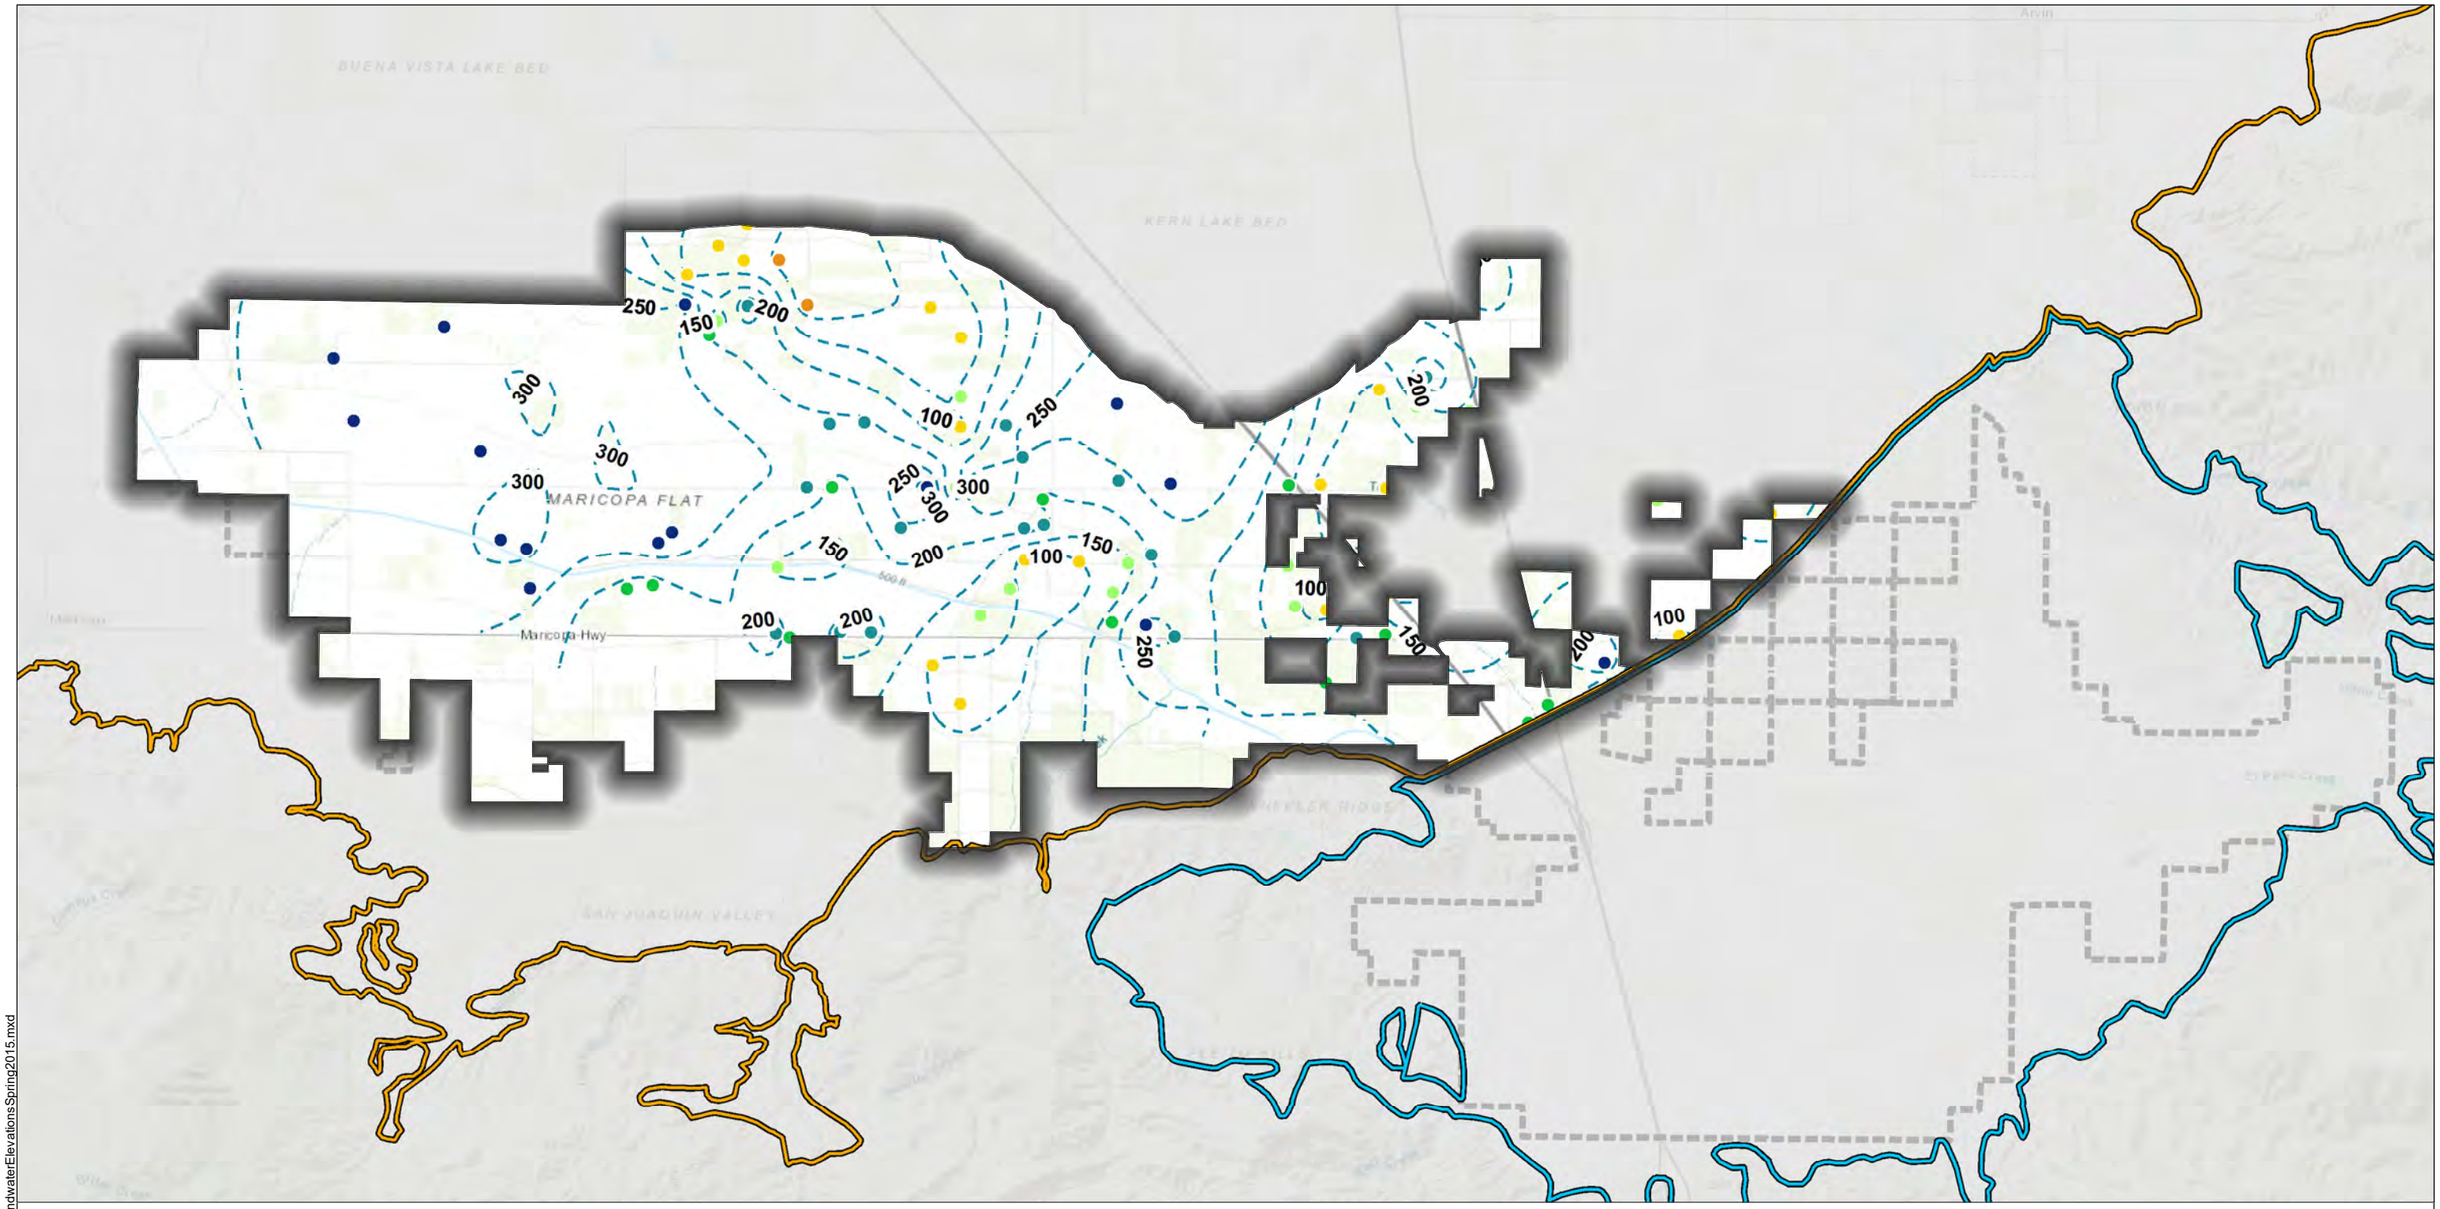
As discussed further in **Section 13 *Undesirable Results*** the localized areas of increased subsidence in the near-vicinity of the alignment of the California Aqueduct within the Wheeler Ridge-Maricopa Management Area highlights the potential impacts of subsidence on critical infrastructure. Approximately 22 miles of the California Aqueduct runs through the Management Area, from approximately Milepost 256.14 (Check No. 31) to Milepost 278.13 (Teerink Pumping Plant). This portion of the California Aqueduct includes pools 32-35. DWR has documented subsidence by milepost of the California Aqueduct with a baseline of 1967 or 1969 ground surface elevation and estimated hydraulic impacts of differential settling (DWR, 2017). Within this section of the Aqueduct, measured values for survey benchmark locations within the Management Area show up to approximately 1.7 feet of settlement from the 1967/1969 baseline through 2013 (DWR, 2017), and up to approximately 9 inches of additional settlement between 2013 and 2017 (Walker, 2017). Subsidence measurements based on InSAR data between April 2014 and June 2016 indicate a localized area of subsidence in the south-central portion of the Management Area in close proximity to the California Aqueduct (**Figure GWC-17**).

8.7. Interconnected Surface Water Systems

☑ 23 CCR § 354.16(f)

As discussed above, groundwater levels in the principal aquifer are far below the ground surface within the Wheeler Ridge-Maricopa Management Area. Depths to groundwater are generally 100 or more feet below ground surface, and even deeper (greater than 350 ft bgs) in the southern areas where surface water streams enter the Management Area from the south. (see **Figure GWC-4**). The few water level data that show shallower groundwater in the northern portion of the Management Area are from wells that are not screened in the principal aquifer, but rather shallow monitoring wells monitoring perched conditions. Therefore, with respect to the principal aquifer, it is assumed there is no interconnected surface water. As such, depletion of interconnected surface water is not considered to be an issue in this area.

8.8. Groundwater Dependent Ecosystems



☑ 23 CCR § 354.16(g)

Groundwater dependent ecosystems (GDEs) are those natural communities that depend on near-surface groundwater as a source of water. Guidance for identification of GDEs developed by The Nature Conservancy (TNC) states that groundwater depths less than 30 feet below ground surface are "generally accepted as being a proxy" for confirming that potential GDEs are actually supported by groundwater (TNC, 2019)[45]. As discussed above, depths to groundwater in the principal aquifer are several hundred

[45] https://groundwaterresourcehub.org/public/uploads/pdfs/TNC_NCdataset_BestPracticesGuide_2019.pdf

feet below ground surface, and it is therefore highly unlikely that any ecosystems depend on groundwater from this aquifer system.

DWR has developed a map of "Natural Communities Commonly Associated with Groundwater" (NCCAG) for use by GSAs in identifying potential GDEs. **Figure GWC-18** shows the distribution of NCCAG within the Wheeler Ridge-Maricopa Management Area. As shown on **Figure GWC-18**, the primary area where NCCAG were identified is along the northern boundary of the Management Area near the Kern Lake Bed. These wetlands and vegetation may be connected to perched groundwater atop the fine-grained "basin" deposits in that area, where depth to groundwater is generally encountered at less than 20 ft bgs. This perched zone is not used for groundwater production within the Management Area. Water level data collected from monitoring wells screening the principal aquifer in the area indicate depth to water of approximately 120-200 ft bgs in the area as of Spring 2015, suggesting that the perched zone is fully disconnected from the underlying principal aquifer. Due to the great depth to the principal aquifer, these vegetation communities (i.e., mostly areas of iodine bush, quailbush, and tamarisk) are likely not dependent on groundwater from the principal aquifer system. Other potential GDE features identified by the NCCAG within the north-central portions of the Wheeler Ridge-Maricopa Management Area are vegetation communities that generally line artificial reservoirs, ditches, or other small open water bodies within the District. Based on groundwater level data collected from surrounding monitoring wells, depth to water is generally encountered at 140-300 ft bgs in these areas, indicating that these vegetation communities are not connected to the principal aquifer system and are therefore not considered to be GDEs. This judgement is consistent with the guidance developed by The Nature Conservancy (TNC, 2019).

9. WATER BUDGET INFORMATION

☑ 23 CCR § 354.18(a)
☑ 23 CCR § 354.18(f)

All GSAs in the Kern County subbasin (Subbasin) coordinated and collaborated on the development of a groundwater model (Model[46]) to evaluate historical, baseline and projected groundwater conditions. The GSAs entered into a Cost Share Agreement with the Kern River GSA who took the lead and contracted with Todd Groundwater to develop the Model on behalf of the Subbasin. The contract required that Todd Groundwater use the C2VSim model provided by DWR. Considerable effort and resources were expended to update the C2VSim model with local data to better represent Subbasin conditions. The process Todd Groundwater used to update C2VSim is more fully described in the Historical and Projected Future Water Budget Development (see Attachment H in Umbrella GSP). Basin-wide water budget results from the Model are provided in Attachment H and show the Subbasin, as a whole, has a total storage deficit of approximately 324,326 acre-feet per year (AFY) over the baseline period.

The Subbasin's dynamic conjunctive use programs, water banking operations, and water transfers/exchanges made it necessary to coordinate a GSA level water accounting system (Checkbook) using Subbasin specific values for supply, demand and net results. The Model results reflect Subbasin-wide conditions and do not allocate water shortages/surpluses, nor do the results allocate the "ownership" of water. As a result, the GSAs, through a coordinated effort, developed the Checkbook that estimates current conditions for each GSA that are generally consistent with the Model results under baseline condition. The Checkbook and Model budgets are based upon best available information, recognizing however, each estimate includes data gaps and has varying degrees of accuracy and/or reliability in the interest of developing a Subbasin coordinated approach.

To ensure the individual water budgets reflected actual conditions, the KGA members developed the Checkbook budget and coordinated water accounting methodology. The result of that effort indicates a current baseline shortage/deficit for KGA members of approximately -256,281 AFY.[47] This reflects the difference between a total demand for KGA members of 1,939,409 AFY, and a total supply of 1,683,128 AFY. Of the shortage/deficit of the KGA, the Wheeler Ridge-Maricopa Management Area's portion of the KGA shortage/deficit is -14,655 AFY. Or a difference in demand of 202,402 AFY and a water supply of 192,237 AFY.

As is mentioned above, each estimate includes data gaps and has varying degrees of accuracy and/or reliability. The Checkbook is complimentary to the Model and reflects the allocation of water supply benefits and obligations independent of geographic constraints within the Subbasin. This was important to recognize and ensure the coordination of the various groundwater banking projects and water management programs amongst the various GSA's within the groundwater basin.

[46] The "Model" is referred to elsewhere in this water budget discussion as the "numerical model".
[47] The water supplies available to each KGA member from the Pioneer and Kern Water Bank banking programs are incorporated into the listed total available supplies. Note that both programs only store surface supplies, and do not have consumptive demands that contribute to the listed shortages. For more detail on the banking projects, please see the respective management area plans.

These two Basin-level water budgeting efforts (i.e., the numerical model and the "checkbook" water accounting approach) are described in the Coordination Agreement and Appendices thereto. These Basin-level efforts are supplemented by the local water budget information presented in this section for the Wheeler Ridge-Maricopa Management Area. Consistent with DWR's GSP Emergency Regulations and DWR's Water Budget BMP (DWR, 2016b), this local water budget information provides an accounting of the total annual volume of water entering and leaving the Management Area, for historical, current, and projected future conditions.

The two Basin-level water budgeting efforts and the local water budget assessment discussed in detail in this section provide a range of results. **Table WB-1** below shows a comparison of results for change in groundwater storage from the three water budget approaches for several time periods. Change in groundwater storage is considered an appropriate term for comparison, as it amounts to an integration of all of the other inflow and outflow terms and represents the overall quantitative balance of the system.

The range of change in groundwater storage results shown in **Table WB-1** is due to several reasons. These include:

- Slight differences in the spatial area considered by the numerical model and the other two approaches (i.e., due to the fact that the model's grid cells/elements do not exactly align with the boundaries of the Wheeler Ridge-Maricopa Management Area);
- Slight differences in the way that project and management actions are implement over time;
- Inherently different levels of spatial resolution between methods, affecting the parameterization and subsequent calculation of subsurface flow across boundaries;
- Slight differences in the way in which land surface processes are treated (i.e., evapotranspiration demand, precipitation);
- Differences in the apportionment of native/natural water supplies stemming from the different perspectives and objectives of the multiple methods (i.e., the numerical model and local [analytical spreadsheet] model consider water supplies from a purely physical perspective whereas the Checkbook utilized a water accounting approach that assumes for management purposes a uniform Basin distribution).[48]

Despite these differences, each approach provides valuable information that can support effective groundwater management within the Basin and the Wheeler Ridge-Maricopa Management Area. As part of Plan Implementation, WRMWSD will continue to refine the water budget parameters based on additional data and modeling (see **Section 18 *WRMWSD Plan Implementation***).

[48] Nothing in this water budget information presented herein results in or is intended to be a determination of water rights.

Table WB-1. Comparison of Change in Groundwater Storage Estimates from Three Water Budget Estimation Methods

Period / Scenario	Basin-wide Numerical Model	Local Analytical Spreadsheet Model	Basin-wide "Checkbook" Water Accounting Approach
Historical Period (WY 1995 – 2014)	-8,654 (a)	3,286 (b)	NA
Current Period (WY 2015)	-45,191 (a)	-42,898 (b)	NA
Projected Period (50 years; 2021 – 2070) Baseline with no Projects	-5,423 (c)	-14,665 (d)	-14,665 (e)
Projected Period (50 years; 2021 – 2070) 2030 Climate Change with no Projects	-9,712 (f)	-21,429 (d)	NA
Projected Period (50 years; 2021 – 2070) 2030 Climate Change with Projects (2)	9,780 (g)	53 (h)	NA
Projected Period (50 years; 2021 – 2070) 2070 Climate Change with no Projects	-17,952 (i)	-33,326 (d)	NA
Projected Period (50 years; 2021 – 2070) 2070 Climate Change with Projects (2)	1,571 (j)	47 (h)	NA

Abbreviations
NA = not applicable

Notes:
(1) All values are in AFY.
(2) The Projected Period is 50 years in length. For the 2030 Climate Change scenarios, the Basin-wide numerical model approach includes a 20-year (2021-2040) "implementation period" and a 30-year (2041-2070) "sustainability period". The Analytical Spreadsheet Model results assumes projects and management actions are fully implemented for the entire 50-year projected period.

9.1. Water Budget Methods and Data Sources

☑ 23 CCR § 354.18(d)
☑ 23 CCR § 354.18(e)

This District-level water budget uses a **spreadsheet model approach** that quantifies each flow component and enforces mass balance principles for each "subdomain" that collectively comprise the water budget domain (i.e., the Wheeler Ridge-Maricopa Management Area). Details of this approach and the corresponding data sources employed within the water budget model are described further below.

9.1.1. Spreadsheet Model Approach

The spreadsheet model approach was developed for WRMWSD to serve as an independent estimate of the local historical, current, and projected water budget conditions within the Wheeler Ridge-Maricopa Management Area. The spreadsheet model approach uses a variety of data and analytical methods to quantify each water budget flow component. Processes and groups of processes are grouped into "subdomains" and "flow components". These water budget flow components are quantified on a monthly timestep for the period from January 1994 through December 2015.

Water Budget Subdomains

The water budget is divided into five internal subdomains, each influenced by a number of flow components and within which mass-balance is enforced (i.e., the sum of inflow components is balanced by the sum of outflow components and/or a change in storage component). **Figure WB-1** shows the water budget domain, and the following internal subdomains:

1. Artificial Channels and Pipelines;
2. Agricultural Lands;
3. Urban Lands;
4. Natural Channels; and
5. Groundwater System

In addition to the five internal subdomains, several external subdomains are incorporated into the spreadsheet model. These include the watersheds that contribute streamflow to streams entering the Wheeler Ridge-Maricopa Management Area, the atmosphere which is a source of precipitation and sink for evapotranspiration, the adjacent and connected portions of the groundwater basin, and the external surface water sources including out-of-basin and in-basin (but outside of the District) storage "accounts". The spreadsheet model does not explicitly account for the vadose (unsaturated) zone between the land surface and the (saturated) groundwater system, but instead incorporates temporal lag factors to account for the movement of water through this zone. An implicit assumption in this approach, therefore, is that the vadose zone does not experience any change in storage over time.

Water Budget Flow Components

Within and between each subdomain are 31 water budget flow components that route water through the Wheeler Ridge-Maricopa Management Area. **Figure WB-2** shows a conceptual diagram of the individual water budget flow components between subdomains as well as flow components that are external to the

overall water budget domain (i.e., serve only as an inflow or outflow to the entire system, rather than a flow between subdomains).

Certain components are based on "raw" data which are directly measured and based on historical records. These "raw" components are considered to have a relatively high degree of certainty. Other components are estimated using a variety of analytical methods (e.g., Darcy's Law to calculated subsurface flows across the domain's external boundaries) and are thus subject to uncertainty based on the parameters used in their estimation. Some components (i.e., groundwater pumping for agricultural use) constitute major proportions of the overall water budget and have thus been given significant attention. Others are relatively minor in magnitude (e.g., seepage from artificial channels) and are, to some degree, less significant to the overall water budget and less well defined. Details of the methods and data used in the spreadsheet model approach are provided in **Appendix G**.

Wheeler Ridge-Maricopa / Arvin-Edison Overlap Lands

The District also supplies surface water to certain lands within the portion of its service area that overlaps with the AEWSD service area. The total acreage of overlap lands within the Kern Subbasin is approximately 5,318 acres, and WRMWSD serves surface water to approximately 3,186 acres in this area. Although the overlap lands are being covered by AEWSD for SGMA monitoring and management purposes, WRMWSD will continue in the future to serve surface water to those lands within the overlap area that have historically received District supplies in accordance with the District's water delivery contracts with landowners. The water budget presented herein is quantified for the entire Wheeler Ridge-Maricopa Management Area, but also specifically identifies inflow and outflow quantities associated with these overlap lands. For the projected water budget "checkbook" accounting exercise conducted by all entities within the Kern Subbasin, the demands for the overlap lands are only included in the Arvin-Edison Management Area "checkbook" and the supplies for those lands include WRMWSD-provided surface water (included as an import to the Arvin-Edison "checkbook") and groundwater.

9.1.2. Data Sources

☑ **23 CCR § 354.18(d)**
☑ **23 CCR § 354.18(e)**

Per 23 CCR § 354.18(e), the best-available data were used to evaluate the water budget for the Wheeler Ridge-Maricopa Management Area and include the following:

- Precipitation Records from the various local climate stations including:
    - WRMWSD's own climate stations (WRM-2 Pumping Plant, SP-P2 Pumping Plant, Greenlee's Pasture, District Headquarters, PA-2 Pumping Plant, and Spillway Basin), *Monthly, January 1971 – December 2017*
    - Two additional climate stations (Lebec and Tejon Rancho) maintained by the National Oceanic and Atmospheric Administration (NOAA)[49]; *Monthly resolution, January 1971 – December 2015 (data availability varies by station)*

[49] See **Appendix G** for a detailed description of how climate stations are used to estimate precipitation on District lands and surrounding watersheds.

- Satellite Evapotranspiration (ET) Data from the California Polytechnic Institute's Irrigation Training and Research Center's "Mapping Evapotranspiration at High Resolution with Internalized Calibration" (ITRC-METRIC) Study, funded by the KGA[50]; *Monthly, January 1993 -December 2015* [51]

- WRMWSD Land Use Surveys from the District's internal land use records; *Seasonal*, *Spring 2001 – Spring 2017 (data availability varies by season)*

- WRMWSD Surface Water Delivery Records from the District's internal operations records; *Monthly resolution, January 1999 – December 2016*

- Historical Groundwater Level Records from selected wells within the District; *Seasonal resolution, Spring 1936 – Fall 2017 (data availability varies by well)*

- Streamflow Records for San Emigdio Creek (USGS stream gauge 11195500), *Monthly, April 1959 – September 1981*

9.1.3. Intended Purpose of Water Budget

The water budget spreadsheet model described herein (as well as the basin-wide numerical modelling approach to water budget estimation described in the Coordination Agreement and Appendices thereto) aims to assess the water budget from a purely quantitative, physical perspective, which is consistent with SGMA and the GSP Emergency Regulations (i.e., CWC § 10720.5 and 23 § CCR 354.18(a)). The spreadsheet model does not aim to evaluate the water budget from the perspective of water rights. As discussed above, the Checkbook "water accounting" approach described in the Coordination Agreement and Appendices thereto attempts to evaluate the water budget using certain management assumptions (e.g., a uniform "native yield" component to all lands within the Basin). However, nothing in this water budget information results in or is intended to be a determination of water rights within the Wheeler Ridge-Maricopa Management Area.

9.2. Water Budget Results

Results are presented below in terms of both annual values during the historical water budget period (DWR Water Years [WY] 1995 – 2014)[52], as well as long-term averages over that period. As such, some information presented here aligns with the requirements of the historical water budget described under **Section 9.3 *Current and Historical Water Budget***. below, and is not repeated there.

[50] Howes, D. 2017. 1993-2015 ITRC-METRIC ETc for Kern County. prepared for the Kern Groundwater Authority on behalf of the Cal Poly Irrigation Training and Research Center.
[51] There is no ITRC satellite ET data for calendar year 2012, as the LANDSAT satellite system employed in the ITRC-METRIC analysis was non-operational during this period. See **Appendix G** for further details.
[52] DWR Water Years run from October of the previous year to September of the current year (e.g. DWR Water Year 2015 is October 2014 – September 2015.

9.2.1. Surface Water Inflows and Outflows

☑ 23 CCR § 354.18(b)(1)

Table WB-2 presents an annual summary of the total surface water inflows to and outflows from the Wheeler Ridge-Maricopa Management Area between WY 1995 – 2015. These inflows include imported surface water, natural streamflow into the area, and precipitation. **Figure WB-3** shows the total surface water inflows by type. Total surface water inflows to the Management Area average approximately 166,000 AFY over WY 1995 – 2014 but have varied widely from year to year. On average, 68% of surface water inflows are from imported water supplies, and 30% are from direct precipitation, and 2% are from intermittent streamflow from surrounding watersheds.

Imported Water Supplies

WRMWSD has been importing surface water into its service area since 1971. Annual surface water imports (District-wide) from 1971 through WY 2015 have ranged from approximately 41,000 AFY to over 250,0000 AFY, and cumulatively a total of 7.49 million AF have been imported through September 2015 (see **Figure WB-4**)[53]. WRMWSD's primary source of imported water is the State Water Project (SWP), delivered via the California Aqueduct which runs through the District. WRMWSD has a contract with the Kern County Water Agency for 197,088 AFY of Table A water from the SWP. In addition to its Table A water allocation, in the District has access to Article 21 water when it is available (primarily during wet years). When surplus supplies are available, the District banks water in several out-of-District water banks[54]. Recovery of banked water during dry years is used to supplement SWP allocations. The District also actively and regularly pursues additional water supplies through banking programs, water transfers, and purchases. Imported surface water supplies have averaged approximately 113,000 AFY over WY 1995 – 2014 but vary substantially from year to year.

Natural Streamflow

As discussed in **Section 7.3.5 *Surface Water Bodies***, several creeks drain into the Wheeler Ridge-Maricopa Management Area from watersheds to the south and west (see **Figure HCM-20**). There are no stream gauges on these creeks that have data during the historical water budget period (WY 1995 – 2014). However, in 2018 the District installed gauges on five streams and will be establishing rating curves for these gauges over the next few years. Between April 1959 and September 1981, the USGS operated a stream gauge on San Emigdio Creek (USGS stream gauge 11195500)[55], located approximately four miles south of the District boundary. Data from this gauge were used as a proxy for all contributing watersheds (i.e., runoff as a function of precipitation was upscaled for the remaining watersheds by proportional area). During this gauge's period of record, average monthly discharge at this location ranged from 2.2 cubic feet per second (cfs) in October to 3.5 cfs in May. Annual average discharge ranged from 0.71 cfs in 1966 to 9.87 cfs in 1978. Annual peak flows ranged from a minimum of 16.0 cfs in 1968 to a maximum of 6,690 cfs in 1961. These data indicate a mildly seasonal pattern in streamflow at this location with substantial variability from year to year.

[53] Through 11 July 2019, WRMWSD has imported and delivered a total of 7,974,462 AF.
[54] WRMWSD has participated in the following groundwater banking and recovery projects: Kern Water Bank, 2800 Acres, Pioneer Project, and Berrenda Mesa Project (WRMWSD, 2015).
[55] https://waterdata.usgs.gov/ca/nwis/inventory/?site_no=11195500; upstream catchment area = 48.8 square miles.

Precipitation

Precipitation on lands within the Wheeler Ridge-Maricopa Management Area contributes some water to the overall water budget and is grouped herein with "surface water inflows". WRMWSD operates six rainfall measurement stations, four of them are within the Management Area. Data from the District's rain gauges are similar in magnitude and temporal pattern. Annual rainfall over the period of WY 1995 – 2014 ranged from approximately 1.5 inches in WY 2014 to over 16 inches in WY 1998, with an average of 6.5 inches per year. Overall, an average of approximately 49,700 AFY of precipitation fell on lands within the Management Area during this period. This water serves to wet the near surface soil and then either evaporates, contributes to crop water demand, or (when a rainfall event is intense enough or long enough) percolates through the root zone to eventually recharge groundwater. "Effective precipitation", i.e. the volume of precipitation that ultimately contributes to meeting evapotranspiration demands within the root zone, is estimated to be approximately 24,100 AFY (or 49% of total precipitation) within the Management Area.[56]

Surface Water Outflows

As shown in **Table WB-2**, natural surface water outflows from the Wheeler Ridge-Maricopa Management Area are essentially zero. This is because there are no natural stream channels that flow through the District to the north; any natural stream inflows percolate into the ground before reaching the northern District boundary.

The District uses its network of canals and pipelines to convey and deliver not only imported surface water, but also groundwater pumped by the District, and by District customers participating in its "User Input" groundwater pump-in program. These deliveries are made to customers throughout the WRMWSD service area, including some customers in the White Wolf Subbasin. At times, the District also uses the California Aqueduct for intra-District conveyance. Some of these conveyance facilities, including the California Aqueduct, cross the basin boundary between the Kern Subbasin and the White Wolf Subbasin. Therefore, outflows leaving the Wheeler Ridge-Maricopa Management Area through these conveyance facilities have been blended upstream and may include a variable percentage of groundwater depending on the given season and Water Year type.

Out-of-District Groundwater Storage

As described in **Section 5.2.3 *Conjunctive Use in the Wheeler Ridge-Maricopa Management Area***, WRMWSD also participates in several out-of-District groundwater storage and recovery programs both within and outside the Kern Subbasin. As of December 2018, the District has a combined 200,774 acre-feet (AF) stored and available to withdraw in its various banking projects outside the Management Area, including:

- 160,564 AF in the Kern Water Bank;
- 29,288 AF in the Pioneer Project; and
- 10,922 AF in the Berrenda Mesa water bank.

[56] Based on application of the U.S. Department of Agriculture-Soil Conservation Service method (USDA-SCS, 1970); see **Appendix G**.

These banked imported water supplies are not included in the quantification of total surface water inflows into the Wheeler Ridge-Maricopa Management Area or in the subsequent determination of change in groundwater storage, as they are currently being physically stored outside the Management Area boundaries. However, these banked supplies contribute to the overall storage within the Kern Subbasin. WRMWSD maintains rights to recover these banked supplies in the future per the contract terms specified in the individual agreements with the entities mentioned above.

9.2.2. Groundwater Inflows and Outflows

☑ 23 CCR § 354.18(b)(2)
☑ 23 CCR § 354.18(b)(3)

Table WB-3 and **Figure WB-5** provide an annual summary of inflows to and outflows from the groundwater system by water source type for WY 1995 – 2014. As evident from these two exhibits (as well as the groundwater hydrographs shown in **Figure GWC-5** and **Figure GWC-6**), the groundwater system is highly sensitive to climatic conditions and WRMWSD operations. As such, annual inflows and outflows vary widely depending on availability of surface water supplies to meet irrigation demands. Sources of inflow to the groundwater system include:

- Subsurface inflows across the District's northern boundary (from north to south), across its southern boundary (from southern foothills to north), and across the White Wolf Fault (from southeast to northwest);
- Infiltration of a portion of applied irrigation water;
- Infiltration of precipitation; and
- Infiltration from surface water systems (e.g., seepage from streams and channels).

Figure WB-6 provides a summary of long-term (WY 1995 – 2014) annual average inflows to and outflows from the groundwater system. Total inflows to the groundwater system averaged approximately 60,300 AFY. Approximately 20% of total inflows to the groundwater system came from subsurface groundwater inflows, 66% from infiltration of applied water, 6% from infiltration from surface water systems, and 9% from infiltration of precipitation.

Due to the District's position at the southern edge of the Kern Subbasin (near pre-development discharge areas) and the resulting low hydraulic heads which are further drawn down by pumping, there are virtually no subsurface outflows, losses to surface water systems, or evapotranspiration losses occurring from the groundwater system (see **Figure GWC-1**). As shown on **Figure WB-6**, total outflows from the groundwater system averaged approximately 57,000 AFY over WY 1995 – 2014 and were entirely related to groundwater extraction. Of this value, approximately 94% of groundwater extraction can be attributed to private agricultural pumpage, 5% to pumpage from private wells related to its "User Input" pump-in program, and the remaining 1% to pumpage from District wells.

9.2.3. Change in Groundwater Storage

☑ 23 CCR § 354.18(b)(4)

Figure WB-7, **Figure WB-8**, and **Table WB-4** present the annual and cumulative change in groundwater storage between seasonal high conditions, which are defined in this chapter to be March through February

of the following year. Note that this time window is distinct from DWR's definition of the Water Year, which runs from October of the previous year to September of the current year (e.g. DWR WY 2014 is October 2013 – September 2014); thus the values presented in **Table WB-4** are slightly different than the annual and cumulative change in storage estimates provided for DWR WY 1995 – 2014 in **Table WB-3**, **Table WB-5**, and **Table WB-6**.

Annual change in groundwater storage under the Wheeler Ridge-Maricopa Management Area averaged approximately +2,300 AFY between seasonal high conditions for the period of March 1994 – February 2015, with a cumulative change in storage of +47,700 AF over the same period. However, as seen in **Figure WB-7** and **Figure WB-8**, change in storage varied widely between years, from a -29,400 AF decrease in storage to a +51,000 AF increase in storage.

Figure WB-9, **Figure WB-10**, and **Table WB-5** compare the annual and cumulative change in storage in the Wheeler Ridge-Maricopa Management Area associated with each DWR Water Year from WY 1995 – 2014 to the water year type based on DWR's San Joaquin Valley Water Year Index. Annual change in groundwater storage under the Management Area averaged approximately +3,300 AFY from DWR WY 1995 – 2014, with a cumulative change in storage amounting to +65,700 AF over this period. These exhibits depict a clear relationship between change in groundwater storage to WY type, whereby change in storage becomes more positive with an increasing "wet" condition and more negative with an increasing "dry" condition. The net benefit of a "wet" period on groundwater conditions is especially evident in WYs 1995 – 2000, whereas the impact of a severe multi-year drought becomes increasingly evident in WYs 2012 – 2015.

9.2.4. Overdraft Conditions

☑ **23 CCR § 354.18(b)(5)**

The Kern Subbasin is designated by DWR in its latest version of *Bulletin 118 – California's Groundwater* as being in a condition of critical overdraft (DWR, 2016c). With respect to overdraft conditions and basins subject to those conditions, DWR has made the following statements:

- "A basin is subject to critical conditions of overdraft when continuation of present water management practices would probably result in significant adverse overdraft-related environmental, social, or economic impacts." (DWR, 1980)
- Groundwater overdraft is "... the condition of a groundwater basin or subbasin in which the amount of water withdrawn by pumping exceeds the amount of water that recharges the basin over a period of years, during which the water supply conditions approximate average conditions. Overdraft can be characterized by groundwater levels that decline over a period of years and never fully recover, even in wet years. If overdraft continues for a number of years, significant adverse impacts may occur, including increased extraction costs, costs of well deepening or replacement, land subsidence, water quality degradation, and environmental impacts." (DWR, 2003)
- "Overdraft occurs where the average annual amount of groundwater extraction exceeds the long-term average annual supply of water to the basin. Effects of overdraft result can include seawater

> intrusion, land subsidence, groundwater depletion, and/or chronic lowering of groundwater levels".[57]

In evaluating basins for critical overdraft conditions in its most recent Bulletin 118 update, DWR considered the time period from WY 1989 – 2009. This period excludes the recent drought which began in 2012, includes both wet and dry periods, is at least 10 years in length, and includes precipitation close to the long-term average; these were all criteria used in selecting the time period.

The historical water budget information discussed herein covers the period from WY 1995 through 2014[58] (i.e., it does not cover the entire period used in DWR's evaluation). However, within the period covered by this water budget, the timeframe between WYs 1997 and 2009 (October 1996 through September 2009) meets all of the same criteria. During this 13-year period, the cumulative departure in statewide average precipitation increased by approximately 9% (DWR, 2016c Figure 1), indicating that, on average, each year was less than 1% wetter than the long-term average. Over this time period, the cumulative change in storage within the Wheeler Ridge-Maricopa Management Area increased by approximately 48,100 AF, averaging 3,700 AFY. Therefore, based on local historical water budget information, the Management Area as a whole does not show a deficit. According to the results of the "checkbook" water accounting approach for the projected baseline condition, the Management Area has a projected annual deficit of -14,665 AFY. The District has developed a suite of Projects and Management Actions (see **Section 17 Projects and Management Actions**) whose intended benefit is to prevent or eliminate any future net water budget deficit condition by the statutory deadline. As discussed in **Section 9** above, however, significant uncertainty exists regarding the actual magnitude of projected water budgets, and the water budget will be refined over time as additional data is collected. In the meantime, the planned P/MAs will be implemented according to the implementation plan outlined **Section 18 WRMWSD Plan Implementation**.

9.2.5. Water Year Types

☑ **23 CCR § 354.18(b)(6)**

Table WB-5 presents the annual total supplies, total demands, and change in groundwater storage in the Wheeler Ridge-Maricopa Management Area along with the DWR Water Year type (October – September) for the period from WY 1995 through 2015. Also shown on **Table WB-5** are the averages for total supplies, total demands and change in groundwater storage for each of the five Water Year types. **Figure WB-9** and **Figure WB-10** present the change in groundwater storage versus Water Year type on an annual and cumulative basis, respectively. The Water Year type is based on DWR's San Joaquin Valley Water Year Index. These exhibits depict a clear relationship between Water Year type and change in groundwater storage, whereby change in storage is more positive during wet and above normal Water Years and more negative during below normal, dry and critical Water Years. This variability can be traced largely to differences in supplies during different Water Year types, as the total demands are relatively constant.

[57] https://water.ca.gov/Programs/Groundwater-Management/Bulletin-118/Critically-Overdrafted-Basins, accessed 1 July 2018.
[58] This timeframe is consistent with the water budgeting timeframes incorporated into basin-level modeling efforts for the Kern Subbasin.

The net benefit of a "wet" period on groundwater conditions is especially evident in Water Years 1995 – 2000, whereas the impact of a severe multi-year drought becomes increasingly evident in WYs 2012 – 2015.

Section 8.3 *Change in Groundwater Storage*, of the Groundwater Conditions section of this MA Plan, reported values for change in storage based on interpolated groundwater levels and specific yield values (see **Table GWC-2**). Some of those water level-based change in storage values were used in the calibration of the water budget spreadsheet model[59]. **Figure WB-11** shows a comparison of the spreadsheet model-based transient change in storage against the water level-based change in storage values for the entire District service area as well as for the Wheeler Ridge-Maricopa Management Area. As shown on **Figure WB-11**, the spreadsheet model matches the water level-based estimates well; the root-mean squared error (RMSE) for the annual rate of change for the three long-term periods (Fall 1994 – Fall 2015, Spring 2003 – Spring 2012, and Spring 2003 – Spring 2015) over the Management Area is approximately 4,300 AFY, which is a relatively small fraction (<4%) of the overall groundwater subdomain water budget magnitude (e.g., average annual groundwater inflows and outflows of approximately 60,300 AFY and 57,000 AFY, respectively).

9.2.6. Sustainable Yield

☑ **23 CCR § 354.18(b)(7)**

SGMA defines sustainable yield as "the maximum quantity of water, calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result" (CWC § 10721(w)). DWR's Water Budget BMP (DWR, 2016b), further states that "Water budget accounting information should directly support the estimate of sustainable yield for the basin and include an explanation of how the estimate of sustainable yield will allow the basin to be operated to avoid locally defined undesirable results. The explanation should include a discussion of the relationship or linkage between the estimated sustainable yield for the basin and local determination of the sustainable management criteria (sustainability goal, undesirable results, minimum thresholds, and measurable objectives)."

A key part of the codified definition and the BMP statement is the avoidance of Undesirable Results, defined as "significant and unreasonable" effects for any of the six SGMA sustainability indicators. For example, in regard to groundwater levels, declining levels during a drought do not constitute and Undesirable Result for Chronic Lowering of Groundwater Levels if extractions and groundwater recharge are managed as necessary to ensure that reduction in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods (CWC § 10721(x)(1)). Therefore, while the water budget should provide support for sustainable yield, determination of the sustainable yield for the Wheeler Ridge-Maricopa Management Area ultimately depends upon whether Undesirable Results are avoided within the time-frames required by SGMA.

A conservative estimate of the sustainable yield of the groundwater system underlying the Wheeler Ridge-Maricopa Management Area can be made by adding the average annual change in storage to the average annual groundwater extraction. This simplified approach provides a sustainable yield number

[59] The water budget spreadsheet model calibration was completed for the entire WRMWSD service area, inclusive of the area within the White Wolf Subbasin.

corresponding to the volume of groundwater that, if pumped over the water budget period of interest, would have resulted in zero change in storage – a reasonable metric for sustainability. Based on the average annual change in groundwater storage over the water budget period from WY 1995 – 2014 (i.e., +3,300 AFY) and the average annual groundwater extraction (i.e., 57,000 AFY), using this simple method the sustainable yield is conservatively estimated to be at a minimum approximately 60,300 AFY under current supply and demand conditions. This equates to an acreage-normalized sustainable yield of approximately 0.65 AFY/acre over the (92,343 acre) Wheeler Ridge-Maricopa Management Area.[60]

This number is conservative because SGMA itself does not require that the basin or any particular management area to be balanced at any particular point in time, as discussed above. As mentioned above, the sustainable yield estimate does not factor in the additional ~200,700 AF of imported District supplies currently stored within other groundwater banking facilities outside the District but within the Kern Basin (see **Section 9.2.1**).

This sustainable yield number is also inherently conservative in that it is based on a pumping rate that, under similar hydrologic conditions as the historical period, would result in no decrease in storage. As discussed in **Section 13.1** ***Undesirable Results for Chronic Lowering of Groundwater Levels*** and **Section 13.2** ***Undesirable Results for Reduction of Groundwater Storage***, the locally defined criteria for what constitutes an Undesirable Result for groundwater levels and change in storage is not strictly limited to a zero net decrease; rather, those criteria allow for some operation of the basin at groundwater levels and storage levels below current conditions. For the other relevant sustainability indicators (i.e., water quality degradation and land subsidence), a sustainable yield value that amounts to a zero change in storage would also be expected to avoid Undesirable Results. Therefore, this sustainable yield estimate takes into account Undesirable Results, as required by CWC § 10721(w).

Moreover, as described earlier in this section, WRMWSD has also participated in a Basin-wide numerical modeling effort in addition to developing a more refined local water budget for their Management Area. Results from the C2VSim-FG historical water budget model, extracted for model elements corresponding approximately to the Management Area, indicate an average annual groundwater extraction rate of approximately 107,200 AFY for the historical period of WY 1995 – 2014, and an average annual change in storage of -7,900 AFY during that same period. Under the same approach as described above, the C2VSim-FG historical water budget results indicate a sustainable yield estimate of 99,300 AFY within the Management Area, or 1.08 AFY/acre. It is important to note that this model is intended to be a Basin-wide assessment of groundwater conditions and, unlike the local water budget described above, is not specifically calibrated to the WRMWSD service area. Additional reconciliation of basin water budgeting efforts is a high priority for basin GSAs as part of GSP implementation.

[60] The acreage-normalized sustainable yield values presented herein should not be viewed as an "allocation" but rather is presented herein to facilitate comparisons to commonly-used agronomic quantities (e.g., crop water demands in AFY/ac).

9.3. Current and Historical Water Budget

9.3.1. Current Water Budget

☑ 23 CCR § 354.18(c)(1)

This section presents results for the "current" water budget, based on values extracted from the spreadsheet model for WY 2015. This is consistent with how "current" is being defined by the KGA in the KGA Umbrella GSP.

WY 2015 was classified as the third consecutive "Critical" (dry) Water Year and fourth consecutive "Dry" or "Critical" Water Year within the San Joaquin Valley and is thus representative of perhaps the worst drought condition in recent history within the region.

Table WB-6 and **Figure WB-12** provide a summary of total inflows and outflows to the Wheeler Ridge-Maricopa Management Area for WY 2015, while **Table WB-3** and **Figure WB-13** provide a summary of groundwater inflows and outflows.

Total inflows to the Wheeler Ridge-Maricopa Management Area amounted to approximately 150,000 AF in WY 2015, comprised of 36% precipitation, 56% surface water imports, 6% subsurface inflows, and 2% natural surface water inflows. This resulted in a total inflow to the groundwater system of approximately 57,600 AF, comprised of 15% subsurface inflow, 70% infiltration of applied water, 6% infiltration from surface water systems, and 9% infiltration of precipitation.

Total outflows from the Wheeler Ridge-Maricopa Management Area amounted to approximately 187,000 AF in WY 2015, comprised entirely (100%) of evapotranspiration (consumptive use by vegetation). This resulted in a total outflow from the groundwater system of approximately 103,000 AF, 100% of which is due to groundwater extraction.

As evident from these water budget values, the Wheeler Ridge-Maricopa Management Area (like nearly all areas in the Kern Subbasin and San Joaquin Valley as a whole) was impacted significantly by the extreme drought condition of WY 2015, resulting in a net loss of approximately -42,900 AF of groundwater storage during this timeframe. However, as evidenced by the recovery of water levels and storage following previous dry periods, the groundwater system is resilient, and the "current" (WY 2015) conditions are not indicative of a normal condition but rather represent the late stages of a major drought period from which the groundwater system has already started to recover (see **Figure GWC-6**).

9.3.2. Historical Water Budget

☑ 23 CCR § 354.18(c)(2)

Water budget results are presented for the historical water budget period in **Section 9.2 *Water Budget Results***, including associated figures and tables, and are not repeated here. Rather, this section focuses on providing: (a) a quantitative evaluation of historical surface water availability and reliability (23 CCR § 354.18(d)(2)(A)), (b) a quantitative assessment of the historical water budget (23 CCR § 354.18(d)(2)(B)), and (c) a description of how historical conditions have impacted the ability of the Wheeler Ridge-Maricopa Management Area to be operated within its sustainable yield (23 CCR § 354.18(d)(2)(C)).

Historical Surface Water Availability and Reliability

☑ 23 CCR § 354.18(c)(2)(A)

As described above, WRMWSD's only contracted source of surface water supply is its SWP supply contract with KCWA for 197,088 AFY of Table 1 water. Between WY 1995 – 2014, WRMWSD received an average allocation (entitlement) of approximately 73% of this contractual amount. **Figure WB-14** presents an annual breakdown of total imported SWP supplies relative to the District's existing SWP contract volumes.

This large inter-annual variability in supply indicates that, while SWP water remains the primary and most important source to the District, its reliability is not iron-clad, and has been impacted significantly in recent years due to natural drought, and by federal court rulings and other regulatory measures which have served to limit pumping of northern California supplies through the Delta to the southern part of the state. For this reason, the District actively and regularly pursues additional water supplies through transfers, purchases, exchanges, and banking programs.

Quantitative Assessment of Historical Water Budget

☑ 23 CCR § 354.18(c)(2)(B)

Based on the DWR San Joaquin Valley Water Year Index for the 20-year period from WY 1995 through 2014, this period included four "critical" (dry) years, four dry years, two below normal years, three above normal year, and seven wet years. The first third of this period was relatively wet, the middle third was a mix of wet and dry years, and the last third of the period was extremely dry. This climatic factor is clearly reflected in the water budget for the Wheeler Ridge-Maricopa Management Area, whereby the groundwater system shows consistent increases in storage with wetter conditions and decreases in storage under "drier" conditions (see **Figure WB-9**, **Figure WB-10**, and **Table WB-5**).

Table WB-6 and **Figure WB-15** provide a tabular and graphical breakdown of total inflows and outflows to the Wheeler Ridge-Maricopa Management Area for WY 1995 – 2014, with a summary of average annual total inflows and outflows provided in **Figure WB-16**. **Table WB-3** and **Figure WB-5** provide a tabular breakdown of inflows and outflows to the groundwater system underlying the Management Area for WY 1995–2014, with a summary of average annual groundwater inflows and outflows provided in **Figure WB-6**.

Total inflows to the Wheeler Ridge-Maricopa Management Area amounted to an average of 178,000 AFY for WY 1995 – 2014, including 64% from surface water imports, 28% from precipitation, 7% from subsurface inflows, and 2% from natural surface water inflows. This resulted in an average net inflow to the groundwater system of approximately 60,300 AFY, comprised of 66% of infiltration of applied water, 20% of subsurface inflow, 6% of infiltration from surface water systems, and 9% of infiltration of precipitation.

Total annual outflows from the Wheeler Ridge-Maricopa Management Area amounted to 175,000 AFY for WY 1995 – 2014, comprised nearly entirely (99.99%) of evapotranspiration (consumptive use by vegetation). This resulted in a net outflow from the groundwater system of approximately 57,000 AF, 100% of which comes from groundwater extraction.

Operation Within Sustainable Yield

☑ 23 CCR § 354.18(c)(2)(C)

Average annual change in groundwater storage under the Wheeler Ridge-Maricopa Management Area amounted to approximately +3,300 AFY between WY 1995 – 2014, resulting in a cumulative change in groundwater storage of 65,700 AF during this period. This cumulative storage change over a 20-year historical record, that includes the recent severe drought, indicates that the groundwater system is in a state of relative balance. Although some years in this period showed negative changes in storage as much as -34,000 AF, the calculated transient change in storage and water levels measured in wells within the Management Area (see **Figure WB-18**, **Figure GWC-5**, and **Figure GWC-6**) demonstrate that the groundwater system is sensitive to climatic variability and WRMWSD operations, with decreases in storage during drought followed by increases in storage during wet periods.

As discussed previously, through September 2015 WRMWSD has imported nearly 7.5 million AF of water into its service area since it began imports in 1971. Since that time, the groundwater system has experienced a long-term increase in storage of approximately 77,100 AF (see **Table GWC-2**) and groundwater elevations have increased in areas where imported surface water is delivered (see **Figure GWC-5**). Clearly District operations have resulted in a net benefit to the groundwater supply beneath the Wheeler Ridge-Maricopa Management Area, demonstrating successful groundwater management.

9.4. Projected Water Budget

☑ 23 CCR § 354.18(c)(3)

Projected water budgets are required as a way to estimate future conditions of water supply and demand within a basin, as well as the aquifer response to implementation of the Plan over the planning and implementation horizon. To develop the projected water budget, the same tools and methodologies that were used for the historical and current water budget were used, with updated inputs for climate variables (i.e., precipitation and ET) and water supply assumptions (i.e., imported water supplies). The chief purpose of this projected water budget analysis is to assess the magnitude of the net water supply deficit that would need to be addressed through Projects and Management Actions to prevent Undesirable Results (discussed further in **Section 13 *Undesirable Results*** and **Section 17 *Projects and* Management Actions**) and achieve the Sustainability Goal. This section describes the development and results of the projected water budget for the Wheeler Ridge-Maricopa Management Area.

9.4.1. Development of 50-Year Analog Period

☑ 23 CCR § 354.18(c)(3)(A)
☑ 23 CCR § 354.18(c)(3)(B)
☑ 23 CCR § 354.18(c)(3)(C)

Per 23 CCR § 354.18(c)(3)(A), the projected water budgets must use 50 years of historical precipitation, evapotranspiration, and streamflow information as the basis for evaluating future conditions under baseline and climate-modified scenarios. The process by which a 50-year period of precipitation, evapotranspiration and streamflow information was developed is based on the process adopted by all

GSAs within the Basin, as described in the KGA Umbrella GSP and the Coordination Agreement and Appendices thereto. That process is briefly summarized here.

To develop the required 50 years-worth of hydrologic input information, first an "analog period" was created from the 20 years-worth of historical information (WY 1995-2014) by combining the years in a specific way that, on average, maintained the long-term average hydrologic conditions. This approach, which was used for both the spreadsheet water budget model approach and the basin-wide C2VSim-FG modeling approach, allowed for the creation of a complete 50-year period to inform the projected water budget analysis, even when certain component datasets were not available for that length of time. The sequence of actual years that were combined to create the 50-year analog period is as follows:

- Analog Years 1-12: Based on actual years 2003-2014
- Analog Years 13-32: Based on actual years 1995-2014
- Analog Years: 33-50: Based on actual years 1995-2012

The above mapping of actual years to analog years within the required 50-year projected water budget period applies to precipitation and ET datasets. It also applies to imported surface water datasets with some additional modifications as described in the following section.

9.4.2. Development of Projected Water Budget Scenarios

☑ **23 CCR § 354.18(c)(3)(A)**
☑ **23 CCR § 354.18(c)(3)(B)**
☑ **23 CCR § 354.18(c)(3)(C)**

Using the 50-year analog period, three projected water budget scenarios were developed for this analysis: a baseline scenario, and 2030 climate change scenario, and a 2070 climate change scenario. Development of the three scenarios was done consistent with the agreed-upon process being used basin-wide. Details of the scenario development are contained within in the KGA Umbrella GSP and the Coordination Agreement and Appendices thereto and are briefly summarized here.

Baseline Scenario

Per 23 CCR § 354.18(c)(3)(C), the projected water budgets must use "the most recent water supply information as the baseline condition for estimating future surface water supply". Consistent with the process applied basin-wide, the information used to inform the baseline conditions for SWP supplies is based on information published by and/or obtained from DWR, including data from DWR's CalSim water resources planning model, historical SWP operations data, and impacts from new operations regulations pursuant to the 2008/2009 Long-Term Operations Criteria and Plan (OCAP) Biological Opinion (BO).[61,62]

[61] CalSim deliveries data from: https://data.cnra.ca.gov/dataset/sgma-climate-change-resources; SWP operational data from: https://water.ca.gov/Programs/State-Water-Project/Operations-and-Maintenance/Monthly-and-Annual-Operations-Reports; new operations regulations pursuant to the 2008-2009 OCAP BOs used as basis for calculation of SWP impacts by KGA's consultant.

[62] The District has a long history of actively striving to achieve sustainable groundwater use within the District. In fact, the District was specifically formed to contract for a substantial surface water supply because of declining groundwater levels. Since that time, groundwater levels within the District have stabilized, and in many areas have risen. In the 1990s, with regulatory shifts in the State Water Project, the District invested in groundwater storage facilities in order to capture and recharge wet

As part of the basin-wide approach to Baseline Scenario development, certain substitutions and/or adjustments to years were made to the 50-year analog period for certain water supplies because the available datasets did not cover the entire historical water budget time period (WY 1995-2014). These substitutions included the following:

- Adjusting years 2004-2007 for SWP supplies to account for the recent regulatory changes to SWP operations made effective in 2008 and 2009 (i.e., the OCAP BO[63]); and
- Replacing years 1995-2003 for SWP supplies with values from DWR's 2030-level CalSim study[64], increased by 3.03%, again to account for the OCAP BO.

The above substitutions and adjustments were made by KGA GSA consultants based upon their analysis of the DWR studies and were provided to all Districts as a basis for development of projected water budgets. As such, the information used for this analysis is consistent with the basin-wide approach.

2030 Climate Change Scenario

☑ 23 CCR § 354.18(d)(3)

In order to estimate the potential effects on the projected water budget of climate change during the GSP implementation period (i.e., between 2020 and 2040), a water budget scenario based on 2030 climate change factors published by DWR was developed. For this scenario, precipitation and ET were both adjusted based on the change factors published by DWR. SWP supply projections were taken from the DWR 2030-Level CalSim studies, except for years 2004-2007 which were taken as the actual SWP data, adjusted for the OCAP BO and reduced by 3.03%, and years 2008-2014 which were taken as the actual SWP data, reduced by 3.03%. Again, the assumptions upon which this scenario was based are from the KGA consultant's analysis of DWR information and are therefore consistent with the basin-wide approach.

2070 Climate Change Scenario

☑ 23 CCR § 354.18(d)(3)

In order to estimate the potential effects on the projected water budget of climate change towards the end of the planning and implementation horizon (i.e., 50 years out into the future), a water budget scenario based on 2070 "central tendency" climate change factors for the published by DWR was developed. It should be noted that estimates of climate change impacts on water supplies this far into the future have significant uncertainty. For this scenario, precipitation and ET were both adjusted based on the 2070 "central tendency" change factors published by DWR. SWP supply projections were taken from the DWR 2070-Level CalSim studies, except for years 2004-2007 which were taken as the actual SWP data, adjusted for the OCAP BO and reduced by 8.09%, and years 2008-2014 which were taken as the actual

year supplies to augment the District's contractual supplies. The Wenger decision in 2008, and the subsequent Biological Opinions, had a dramatic negative impact on the availability of the District's contractual supplies. Although the District does not agree with the decision nor the subsequent Biological Opinions, it has been forced to adapt to those negative impacts.

[63] https://www.fws.gov/sfbaydelta/Documents/SWP-CVP_OPs_BO_12-15_final_OCR.pdf https://www.westcoast.fisheries.noaa.gov/publications/Central_Valley/Water%20Operations/Operations,%20Criteria%20and%20Plan/nmfs_biological_and_conference_opinion_on_the_long-term_operations_of_the_cvp_and_swp.pdf

[64] Consistent set of CALSIM operations studies at current, 2030 and 2070 climate levels for Bay Delta Conservation Plan evaluation provided by DWR Bay Delta Office staff.

SWP data, reduced by 8.09%. Again, the assumptions upon which this scenario was based are from the KGA consultant's analysis of DWR (CalSim) information and are therefore consistent with the basin-wide approach.

9.4.3. Projected Water Budget Results

Results of the projected water budget analysis are summarized in **Table WB-7** for both the entire water budget domain and for the groundwater subdomain, as well as in **Figure WB-19**. As shown in **Table WB-7**, water budget components are presented as averages over the 20-year historical period and averages over the 50-year analog period for the Baseline, 2030 Climate Change, and 2070 Climate Change scenarios. Water budget components are grouped into inflows and outflows, relative to the domain or subdomain they pertain to (also see **Figure WB-2**). Also shown in **Table WB-7** is the average annual change in groundwater storage for the historical period and each projected scenario. Results from **Table WB-7** were subsequently used to inform the development of Projects and Management Actions (P/MAs) as further described in **Section 17** ***Projects and Management Actions***. Implementation of the P/MAs described in **Section 17** were then input into the 2030 and 2070 projected water budget model scenarios to assess their estimated impacts to the groundwater balance within the Wheeler Ridge-Maricopa Management Area. Results of this exercise are presented in **Table WB-8** and briefly mentioned below.

Baseline Scenario

In the Baseline Scenario, the water budget components that are not dependent on surface water imports differ only slightly from the historical period. The percent difference from the historical average period to the Baseline Scenario ranges from approximately -4.0% for M&I consumptive use (including evapotranspiration from urban lands) to natural surface water inflows to -1.2% for precipitation. This demonstrates that the 50-year analog period is a good representation of the historical conditions.

The water budget components that are dependent on surface water imports differ more significantly from the historical averages, due to the different assumptions about imported surface water availability under the Baseline Scenario, as discussed above. In particular, the surface water imports component is approximately 17.7% lower under the Baseline Scenario than it is under the historical period, due a projected decrease in SWP supplies due to factors including the OCAP BO.

Overall, the Baseline Scenario indicates a net "deficit" (i.e., outflows greater than inflows) of approximately -14,700 AFY.

2030 Climate Change Scenario

Under the 2030 Climate Change Scenario, changes in precipitation, natural surface water inflows, and M&I consumptive use relative to the Baseline Scenario are all relatively small (i.e., relative changes of 1.1% to 2.9% and absolute changes of approximately 0 AFY to 550 AFY). The most significant changes relative to the Baseline Scenario are a reduction in surface water imports of approximately -2,800 AFY (-3.0%) and an increase in evapotranspiration of approximately 4,700 AFY (+2.8%).

Overall, the 2030 Climate Change Scenario indicates a net deficit of approximately -21,400 AFY. Consistent with the approach being used by all KGA GSA members (and other GSAs in the basin), this estimated net deficit under the 2030 Climate Change Scenario is the amount that the Projects and Management Actions

are targeted to address by the GSP implementation deadline (i.e., January 2040).[65] As shown on **Table WB-8** and further described in **Section 17.1.4** ***Implementation Glide Path*** and in **Table PMA-2**, WRMWSD has proposed to address approximately 60% of the projected deficit of -21,400 AFY by the GSP implementation deadline (i.e. January 2040) through adoption of supply augmentation projects (i.e., ~12,900 AFY), and may address the remaining 40% of the projected deficit (i.e., ~8,600 AFY) through adoption of demand reduction management actions as necessary in order to achieve and maintain the sustainability goal within the Management Area.

It should be noted that the results from the numerical model show that, upon implementation of the planned Projects and Management Actions, the Wheeler Ridge-Maricopa Management Area achieves its sustainability goal (i.e., avoids Minimum Thresholds and Undesirable Results and achieves Measurable Objectives for Chronic Lowering of Groundwater Levels) (see **Section 17.8.2** ***Evaluation Relative to Water Level Sustainability Criteria***).

2070 Climate Change Scenario

Under the 2070 Climate Change Scenario, changes in precipitation, natural surface water inflows, and M&I consumptive use relative to the Baseline Scenario are somewhat greater than in the 2030 Climate Change Scenario, but still not significant (i.e., relative changes of -1.3% to 6.8% and absolute changes of approximately 0 AFY to -700 AFY). Surface water imports are lower by approximately -7,200 AFY (-7.7%) and evapotranspiration is greater by approximately +10,700 AFY (+6.2%).

Overall, the 2070 Climate Change Scenario indicates a net deficit of approximately -33,300 AFY. As shown on **Table WB-8** and further described in **Section 17.1.4** ***Implementation Glide Path*** and in **Table PMA-2**, WRMWSD has proposed to address approximately 56% of the projected deficit of -33,300 AFY by the end of the 50-year GSP planning and implementation horizon (i.e. January 2070) through adoption of supply augmentation projects (i.e., ~18,800 AFY), and may address the remaining 44% of the projected deficit (i.e., ~14,600 AFY) through adoption of demand reduction management actions as necessary in order to achieve and maintain the sustainability goal within the Management Area..

It should be noted that the results from the numerical model show that, upon implementation of the planned Projects and Management Actions, the Wheeler Ridge-Maricopa Management Area achieves its sustainability goal (i.e., avoids Minimum Thresholds and Undesirable Results and achieves Measurable Objectives for Chronic Lowering of Groundwater Levels) (see **Section 17.8.2** ***Evaluation Relative to Water Level Sustainability Criteria***).

[65] The District, as required by law, is planning on implementing Projects and Management Actions to address the potential impacts due to climate change. The District does note that making planning decisions based on models has real and substantial economic impacts on District landowners and residents and does not agree with this exercise.

TABLE WB-2

Annual Surface Water Inflows and Outflows by Source Type

Wheeler Ridge-Maricopa Water Storage District

Kern Subbasin Management Area

Abbreviations

AFY = acre-feet per year
DWR = California Department of Water Resources
Precip. = precipitation
WRMWSD = Wheeler Ridge-Maricopa Water Storage District
WY = Water Year

Notes

(a) All values reported in acre-feet per year (AFY).
(b) Surface water import sources include State Water Project water, as well as recovered groundwater from out-of-district banking operations, including (1) Kern Water Bank, (2) Pioneer Project, (3) Berrenda Mesa Project, and (4) 2800 Acres. These sources are blended into the California Aqueduct prior to delivery to WRMWSD customers and thus cannot be independently quantified.

Abbreviations

AF = acre-feet
AFY = acre-feet per year
DWR = California Department of Water Resources
ITRC = Cal Poly Irrigation Training & Research Center
WY = Water Year

Notes

(a) All values reported in acre-feet per year (AFY), except cumulative change in storage (reported in acre-feet).

(b) This value includes all groundwater extractions from WRMWSD wells for its long-term groundwater banking and recovery program. On certain years, this value also includes minor groundwater inputs to the District delivery system from private wells that have elected to participate in the District's groundwater "pump-in" program to augment delivery supplies in times of drought.

(c) There are years for which ITRC-measured evapotranspiration from non-irrigated lands exceeds the total measured rainfall to these lands. In these cases, residual water demands on non-irrigated lands are accounted for as a reduction in total infiltration ("inflows") rather than an explicit groundwater "outflow" due to evapotranspiration. This is based on the understanding that the groundwater table is fully disconnected from the root zone under the District. ITRC-measured residual water demands on non-irrigated lands are likely caused in part by evaporation from local surface water bodies (e.g., storage ponds) and/or are met by a reduction of root zone soil moisture, which is not explicitly accounted for in the water budget spreadsheet model.

Water Year Type (a)	Number of Years During WY 1995 - 2015 Period	Average Total Supplies [AFY] (b)	Average Total Demands [AFY] (c)	Average Annual Change in Groundwater Storage [AFY]
C	5	147,516	170,608	-23,011
D	4	150,837	168,204	-12,204
BN	2	160,360	164,490	-4,181
AN	3	183,796	175,992	9,760
W	7	213,894	185,642	23,681

Abbreviations

AFY = acre-feet per year
DWR = California Department of Water Resources
WY = Water Year

Notes:

(a) DWR Water Year Types are as follows: W = wet, AN = above normal, BN = below normal, D = dry, C = critical
(b) Total supplies equal the sum of inflow terms (see Table WB-6 for individual inflow components).
(c) Total demands equal the sum of outflow terms (see Table WB-6 for individual outflow components).
(d) The apparent residual of water-budget calculated change in groundwater storage to [Total Inflows - Total Outflows] can be attributed to the deep percolation lag effect in the water budget spreadsheet model, which serves to delay infiltration from reaching the groundwater system. See "Appendix E - Methods & Data Used in the Water Budget Spreadsheet Model Approach" for further details on how monthly storage change is calculated within the water budget spreadsheet model.

Sources:

(1) DWR Water Year Type is from DWR's Water Year Hydrologic Classification Indices for the San Joaquin Valley <http://cdec.water.ca.gov/reportapp/javareports?name=WSIHIST>.

Notes

(a) All values reported in acre-feet per year (AFY), except cumulative change in storage (reported in acre-feet).
(b) "Evapotranspiration" includes all estimated crop and vegetative evapotranspirative demands as well as evaporation of excess rainfall and from open water bodies within the District.
(c) Apparent residual of water-budget calculated change in groundwater storage to [Total Inflows - Total Outflows] can be attributed to the deep percolation lag effect in the water budget spreadsheet model, which serves to delay infiltration from reaching the groundwater system. See "Appendix A - Methods & Data Used in the Water Budget Spreadsheet Model Approach" for further details on how monthly storage change is calculated within the water budget spreadsheet model.

TABLE WB-7

Summary of Projected Water Budget Results without Project & Management Action Implementation

Wheeler Ridge-Maricopa Water Storage District

Kern Subbasin Management Area

Total Water Budget Domain

Water Budget Category	Water Budget Component	Historical Period (WY 1995-2014)	Projected		
			Baseline (50-year Synthetic Hydrologic Period)	2030 Climate (scaled from Baseline Period)	2070 Climate (scaled from Baseline Period)
Inflows	(Net) Subsurface Inflow [(b)]	11,779	11,551	11,704	11,485
	Precipitation	49,726	49,144	49,707	48,485
	Surface Water Imports	113,431	93,328	90,541	86,119
	Natural Surface Water Inflows	3,104	3,044	3,095	3,022
	TOTAL INFLOWS	**178,041**	**157,067**	**155,046**	**149,111**
Outflows	Evapotranspiration [(c)]	173,847	171,023	175,767	181,702
	M&I Consumptive Use [(d)]	902	866	891	925
	Surface Water Exports	0	0	0	0
	Natural Surface Water Outflows	0	0	0	0
	Subsurface Groundwater Outflow	0	0	0	0
	TOTAL OUTFLOWS	**174,749**	**171,888**	**176,658**	**182,627**
Change in Groundwater Storage	**Equivalent to "Deficit"**	**3,286**	**-14,665**	**-21,429**	**-33,326**

Groundwater Subdomain

Water Budget Category	Water Budget Component	Historical Period (WY 1995-2014)	Projected		
			Baseline (50-year Synthetic Hydrologic Period)	2030 Climate (scaled from Baseline Period)	2070 Climate (scaled from Baseline Period)
Inflows	(Net) Subsurface Inflow[(b)]	11,779	11,551	11,704	11,485
	Infiltration of Precipitation	5,307	4,997	4,974	4,678
	Infiltration from Surface Water Systems	3,552	3,443	3,450	3,308
	Infiltration of Applied Water	39,608	33,132	32,618	30,935
	TOTAL GW INFLOWS	**60,247**	**53,123**	**52,745**	**50,406**
Outflows	Pumpage from District Wells	474	463	463	463

10. MANAGEMENT AREAS

☑ 23 CCR § 354.20(a)

The information presented in the Basin Setting sections of this GSP (i.e., **Section 7** ***Hydrogeologic Conceptual Model,*** **Section 8** ***Current and Historical Groundwater Conditions*** and **Section 9** ***Water Budget Information***) is specific to and describes conditions within the Wheeler Ridge-Maricopa Management Area. As discussed in **Section 5.1.6** ***Lands Outside of District Covered by MA Plan***, information regarding the undistricted lands (i.e., "White Lands") covered by this MA Plan is presented in **Appendix B**.

10.1. Description and Justification

☑ 23 CCR § 354.20(b)(1)
☑ 23 CCR § 354.20(c)

As discussed previously in **Section 5.1.1** ***Area Covered by the Plan***, the Kern Subbasin is overlain by a large number of entities with water or land use management authority. A subset of these entities formed the Kern Groundwater Authority GSA. WRMWSD is a member of the KGA GSA but is locally responsible for SGMA compliance within a specific portion of the KGA GSA -- the Wheeler Ridge-Maricopa Management Area. This Management Area includes all of WRMWSD's service area within the Kern Subbasin except for small portions on the far western side (see **Figure HCM-1**).

The reason for creation of the Wheeler Ridge-Maricopa Management Area is to ensure that WRMWSD maintains maximum flexibility and control over sustainable groundwater management within the portion of its service area where land and water use is predominantly agricultural, and where there is a strong nexus between WRMWSD management decisions and groundwater conditions.

10.2. Minimum Thresholds and Measurable Objectives

☑ 23 CCR § 354.20(b)(2)
☑ 23 CCR § 354.20(b)(4)

The Sustainable Management Criteria developed for the Wheeler Ridge-Maricopa Management Area, including the rationale for their selection, are described in detail in **Section 14** ***Minimum Thresholds*** and **Section 15** ***Measurable Objectives and Interim Milestones***.

10.3. Monitoring

☑ 23 CCR § 354.20(b)(3)

Monitoring networks for each applicable Sustainability Indicator, including a discussion of the level of monitoring an analysis appropriate for the Wheeler Ridge-Maricopa Management Area, are described in detail in **Section 16** ***Monitoring Network***.

SUSTAINABLE MANAGEMENT CRITERIA

11. INTRODUCTION TO SUSTAINABLE MANAGEMENT CRITERIA

☑ **23 CCR § 354.22**

The Sustainable Groundwater Management Act (SGMA) legislation defines "Sustainability Goal" as "the existence and implementation of one or more groundwater sustainability plans that achieve sustainable groundwater management by identifying and causing the implementation of measures targeted to ensure that the applicable basin is operated within its sustainable yield" (California Water Code [CWC] § 10721(u)). SGMA requires Groundwater Sustainability Plans (GSPs) to develop and implement plans to meet the Sustainability Goal (CWC § 10727(a)) and defines terms related to achievement of the Sustainability Goal, including:

- Interim Milestone - a target value representing measurable groundwater conditions, in increments of five years, set by an Agency as part of a plan (23 CCR § 351(q));
- Measurable Objective - specific, quantifiable goals for the maintenance or improvement of specified groundwater conditions that have been included in an adopted plan to achieve the sustainability goal for the basin (23 CCR § 351(s)); and
- Minimum Threshold - a numeric value for each sustainability indicator used to define undesirable results (23 CCR § 351(t)).

Collectively, the Sustainability Goal, Interim Milestones, Measurable Objectives, and Minimum Thresholds are referred to herein as Sustainable Management Criteria (SMCs).

The GSP Emergency Regulations specify how Groundwater Sustainability Agencies (GSAs) must establish SMCs for each applicable Sustainability Indicator. **Sections 12**, **13**, **14**, and **15** of this GSP describe the **Sustainability Goal**, **Undesirable Results**, **Minimum Thresholds**, and **Measurable Objectives and Interim Milestones**, respectively, developed as part of this MA Plan.

12. SUSTAINABILITY GOAL

☑ 23 CCR § 354.24

SGMA requires that a Sustainability Goal be defined for the basin (CWC § 10727(a)). The sustainability goal for the Wheeler Ridge-Maricopa Management Area is to maintain an economically-viable groundwater resource for the beneficial use of the Management Area's landowners and water users by utilizing the area's groundwater resources within the local sustainable yield. Long-term groundwater sustainability, i.e., the absence of undesirable results within 20 years of the applicable statutory deadline, will be achieved and maintained through the implementation of projects and management actions as described herein to both increase water supplies and reduce demands within the Management Area.

The local sustainability goal, above, is consistent with and in addition to the basin-wide sustainability goal being adopted by all GSAs in the Kern Subbasin, shown below.

"The sustainability goal of the Kern County Subbasin is to:

- Achieve sustainable groundwater management in the Kern County Subbasin through the implementation of projects and management actions at the member agency level of each GSA.
- Maintain its groundwater use within the sustainable yield of the basin.
- Operate within the established sustainable management criteria, which are based on the collective technical information presented in the GSPs in the Subbasin.
- Implement projects and management actions that include a variety of water supply development and demand management actions.
- Collectively bring the Subbasin into sustainability and to maintain sustainability over the implementation and planning horizon.

Further, the Subbasin sustainability goal includes a commitment to monitor and report groundwater conditions, as required by SGMA, and to continue coordination among the KGA member agencies and all other GSA's in the Subbasin to identify the potential for, or presence of, undesirable results and actions to prevent undesirable results. The coordination process established in the development of this GSP and memorialized in the Coordination Agreement and Appendices thereto will ensure that the Subbasin is managed as a shared groundwater resource and that the districts within the Subbasin work collaboratively towards achieving and maintaining sustainable groundwater use."

13. UNDESIRABLE RESULTS

☑ 23 CCR § 354.26(a)

This section describes the Undesirable Results defined for the Wheeler Ridge-Maricopa Management Area[66]. Pursuant to the GSP Emergency Regulations, which state that Undesirable Results are to be defined consistently throughout the basin (23 CCR § 354.20), definitions of Undesirable Results have been developed through a coordinated effort of the Kern Subbasin GSAs and are described in the KGA Umbrella GSP.

As discussed below for each Sustainability Indicator, the Undesirable Results definitions for the Basin refer to and rely on Minimum Thresholds established at the local management area level. Specifically, Undesirable Results for the Basin occur when Minimum Thresholds for a certain percentage (by acreage) of management areas are exceeded. Each management area determines what the local Minimum Thresholds values are and what combination of local exceedances constitutes a local Undesirable Result. If a local Undesirable Result manifests in a management area, that area counts towards the basin-wide Undesirable Results definition.

In the following sections, the Undesirable Results statements adopted by the Kern Groundwater Authority (KGA) GSA and other Basin GSAs for each Sustainability Indicator are presented, along with a description of the local Wheeler Ridge-Maricopa Management Area definition of Undesirable Results (i.e., what combination of Minimum Threshold exceedances, if any, constitutes a local Undesirable Result).

13.1. Undesirable Results for Chronic Lowering of Groundwater Levels

The basin-wide definition of Undesirable Results for Chronic Lowering of Groundwater Levels is as follows:

> "The point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users.
>
> This is determined when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas which represent at least 15% of the sub-basin or greater than 30% of the subbasin (as measured by each Management Area). Minimum thresholds shall be set by each of the management areas through their respective Groundwater Sustainability Plans."

The above basin-wide definition requires local definition within each management area of the Minimum Thresholds and combination of exceedances that constitute a significant and unreasonable impact to the reasonable and beneficial use of, and access to, groundwater by overlying users. As such, it is necessary to consider local conditions and beneficial uses and users within each management area.

[66] In this document, the term "Wheeler Ridge-Maricopa Management Area" is used in its entirety the first time the area is being referenced in each paragraph; subsequent references to this area in each paragraph use the term "Management Area".

13.1.1. Potential Causes of Undesirable Results

☑ 23 CCR § 354.26(b)(1)

Potential causes of Undesirable Results due to Chronic Lowering of Groundwater Levels in the Wheeler Ridge-Maricopa Management Area include increased pumping and/or reduced recharge. Because the primary use of groundwater from the principal aquifer in the Management Area is for agricultural purposes, increased pumping from the principal aquifer could occur if new land is put into agricultural production or if water use per acre on existing irrigated land increases. Pumping from the principal aquifer for potable domestic use is relatively small and unlikely to substantially increase. Reduced recharge could occur due to increased agricultural irrigation efficiency, reduced surface water imports, reduced groundwater inflows, or due to climate change that results in decreased precipitation and increased evapotranspiration (ET), as discussed in **Section 9.4 *Projected Water Budget***.

13.1.2. Criteria Used to Define Undesirable Results

☑ 23 CCR § 354.26(b)(2)
☑ 23 CCR § 354.26(c)

Per Section 354.26(b)(2) of the GSP Emergency Regulations, the description of Undesirable Results must include a quantitative description of the number of Minimum Threshold exceedances that constitute an Undesirable Result. As discussed further below in **Section 14 *Minimum Thresholds*** and in **Section 16 *Monitoring Network***, within the Wheeler Ridge-Maricopa Management Area Minimum Thresholds for groundwater levels are set at 15 Representative Monitoring Sites by considering groundwater levels and trends, well depths (i.e., beneficial users), and proximity to critical infrastructure. In a similar manner to how Undesirable Results are defined at the basin level, at the local Management Area level it is considered an Undesirable Result for Chronic Lowering of Groundwater Levels if Minimum Thresholds are exceeded in 40% or more of the Representative Monitoring Sites (i.e., 6 or more out of 14 sites) over four consecutive seasonal measurements (i.e., two measurements at the seasonal high condition and two measurements at the seasonal low condition).

13.1.3. Potential Effects of Undesirable Results

☑ 23 CCR § 354.26(b)(3)

The primary potential effects of Undesirable Results caused by Chronic Lowering of Groundwater Levels on beneficial uses and users of groundwater in the Wheeler Ridge-Maricopa Management Area include groundwater well dewatering, increased pumping lift, and potential land subsidence. Well dewatering is detrimental to wells as it can lead to increased maintenance costs (i.e., well rehabilitation/redevelopment, pump lowering) and reduced well lifespan due to corrosion of well casing and screen. Increased pumping lift results in more energy use per unit volume of groundwater pumped and greater pumping costs and can cause increased wear and tear on well pumps/motors. Land subsidence can affect critical infrastructure as discussed further below in **Section 13.5 *Undesirable Results for Land Subsidence***.

13.2. Undesirable Results for Reduction of Groundwater Storage

The basin-wide definition of Undesirable Results for Reduction of Groundwater Storage is as follows*:*

> "The point at which significant and unreasonable impacts, as determined by the amount of groundwater in the basin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended drought period. (10-years?)
>
> This is determined when the volume of storage (above the groundwater level minimum thresholds) is depleted to an elevation lower than the groundwater level minimum threshold in at least three (3) adjacent management areas that represent at least 15% of the subbasin or greater than 30% of the subbasin (as measured by the acreage of each Management Area).
>
> Minimum thresholds shall be set by each of the management areas through their respective Groundwater Sustainability Plans."

The above basin-wide definition ties the Undesirable Result for Reduction of Groundwater Storage directly to the Minimum Thresholds for Chronic Lowering of Groundwater Levels which, as stated above, are defined locally within each management area of the Kern Subbasin.

13.2.1. Potential Causes of Undesirable Results

☑ **23 CCR § 354.26(b)(1)**

Reduction of Groundwater Storage is generally correlated to Chronic Lowering of Groundwater Levels. Therefore, the potential causes of Undesirable Results due to Reduction in Groundwater Storage are generally the same as the potential causes listed above for Undesirable Results due to Chronic Lowering of Groundwater Levels (i.e., increased groundwater pumping and reduced recharge).

13.2.2. Criteria Used to Define Undesirable Results

☑ **23 CCR § 354.26(b)(2)**
☑ **23 CCR § 354.26(c)**

The criteria used to define Undesirable Results for Reduction of Groundwater Storage in the basin-wide definition above are the Minimum Thresholds established at a local management area level for Chronic Lowering of Groundwater Levels. Furthermore, Minimum Thresholds set related to Subsidence protect against excessive loss of aquifer storage (and resulting reduction of Groundwater Storage). Extending this definition to the local Wheeler Ridge-Maricopa Management Area level, it would be considered an Undesirable Result if groundwater storage were to be reduced by an amount that would cause the groundwater levels in 40% or more of Representative Monitoring Sites to exceed their Minimum Thresholds for Chronic Lowering of Groundwater Levels over four consecutive seasonal measurements. As discussed below in **Section 14 *Minimum Thresholds***, due to the great depth of fresh water and wells able to access it, there is significant usable groundwater storage within the Management Area even below the elevation of the Minimum Thresholds. As such, on a local level it is not necessary to define unique SMCs for Reduction of Groundwater Storage; the criteria set for Chronic Lowering of Groundwater Levels are "protective" and a reasonable proxy.

13.2.3. Potential Effects of Undesirable Results

☑ 23 CCR § 354.26(b)(3)

The primary potential effect of Undesirable Results caused by Reduction of Groundwater Storage on beneficial uses and users of groundwater in the Wheeler Ridge-Maricopa Management Area is reduced groundwater supply reliability. The effect of reduced groundwater supply reliability would be most significant during periods of reduced surface water supply availability due to, for example, natural drought conditions, regulatory restrictions, natural disasters, or other causes. However, as discussed below in **Section 14 *Minimum Thresholds***, there is significant groundwater storage within the Management Area, and so these effects are unlikely to occur.

13.3. Undesirable Results for Seawater Intrusion

☑ 23 CCR § 354.26(d)

The GSP Emergency Regulations state that "An Agency that is able to demonstrate that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin shall not be required to establish criteria for undesirable results related to those sustainability indicators" (23 CCR § 354.26(d)). Because the Kern Subbasin is not located near any saline water bodies, seawater intrusion is not present and not likely to occur. Therefore, the Seawater Intrusion Sustainability Indicator is not applicable to the Kern Subbasin and no Undesirable Results for this Sustainability Indicator are defined.

13.4. Undesirable Results for Degraded Water Quality

The basin-wide definition of Undesirable Results for Degraded Water Quality is as follows:

> "The point at which significant and unreasonable impacts over the planning and implementation horizon, as caused by water management actions, that affect the reasonable and beneficial use of, and access to, groundwater by overlying users.
>
> This is determined when the minimum threshold for a groundwater quality constituent of concern is exceeded in at least three (3) adjacent management areas which represent at least 15% of the subbasin or greater than 30% of the designated monitoring points within the basin. Minimum thresholds shall be set by each of the management areas through their respective Groundwater Sustainability Plans."

As with Chronic Lowering of Groundwater Levels, the above basin-wide definition allows for local definition, within each Management Area of the Kern Subbasin, of the Minimum Thresholds that constitute a significant and unreasonable impact to the reasonable and beneficial use of, and access to, groundwater by overlying users. Key to the basin-wide definition is the phrase "as caused by water management actions". This phrase rightfully distinguishes between water quality impacts that are due to human actions and those that are the result of natural conditions. Because impacts due to natural conditions are not caused by (and in some cases, cannot be remedied by) human action, those impacts are not considered to be Undesirable Results subject to SGMA compliance.

13.4.1. Potential Causes of Undesirable Results

☑ 23 CCR § 354.26(b)(1)

Potential causes of Undesirable Results due to Degraded Water Quality within the Wheeler Ridge-Maricopa Management Area include the addition of constituents of concern (COCs) to groundwater in the principal aquifer through processes that are causatively related to water management or land use activities. These potential processes include:

- Deep percolation of precipitation, seepage from various natural and man-made channels, and recharge from reservoirs and spreading basins;
- Irrigation system backflow into wells and flow through well gravel pack and screens from one formation to another[67];
- Deep percolation of excess applied irrigation water and other water applied for cultural practices (e.g., for soil leaching). Potential COCs include salinity (i.e., Total Dissolved Solids [TDS]), nitrate, and agricultural chemicals;
- Lateral migration from adjacent areas with poorer quality groundwater (e.g., the area to the west of the Management Area). Potential COCs include salinity and other natural constituents (e.g., chloride and sulfate);
- Leaching from internal sources such as fine-grained, clay-rich interbeds. Potential COCs include arsenic and other constituents associated with fine-grained depositional environments (Smith et al., 2018);
- Upwards vertical flow from deeper zones below the bottom of the basin. Potential COCs include salinity, petroleum hydrocarbons, and other naturally-occurring constituents.

In the case of deep percolation of excess applied irrigation and leaching water, such activities are regulated separately under the Central Valley Regional Water Quality Control Board's (CVRWQCB's) Irrigated Lands Regulatory Program (ILRP) and CV-SALTS. For the last three items listed above, the underlying cause has to do with hydraulic gradients and heads (groundwater levels), and thus the causes are the same as those associated with the Undesirable Effects of Chronic Lowering of Groundwater Levels, discussed above. As discussed in **Section 8.5 *Groundwater Quality*** and shown by the groundwater level and quality graphs included in **Appendix F**, there is no discernable and consistent relationship between groundwater levels and groundwater quality that is consistent across the Wheeler Ridge-Maricopa Management Area. Additional data collection and analysis will be needed to evaluate this potential relationship further.

13.4.2. Criteria Used to Define Undesirable Results

☑ 23 CCR § 354.26(b)(2)

The basin-wide definition of Undesirable Results provides for local definition of the combination of Minimum Threshold exceedances that constitute and Undesirable Result in a Management Area. As described in **Section 8.5 *Groundwater Quality***, agricultural use is the dominant beneficial use within the

[67] Kern County's existing well destruction programs are designed to help minimize cross-connection between aquifer zones and prevent groundwater quality impairments that can result from cross-contamination of aquifer zones

Wheeler Ridge-Maricopa Management Area, and groundwater quality is generally suitable for agricultural uses, with the exception of groundwater on the western side of the District which has poorer quality (i.e., higher TDS and sulfate) due to natural geologic conditions. Water quality issues related to deep percolation of agricultural chemicals such as nitrate are regulated separately under the ILRP and CV-SALTS. Therefore, based on the existing and potential beneficial uses and users of groundwater within the Management Area, Undesirable Results for Degraded Water Quality are not defined on a local level. It should be noted, however, that monitoring for water quality will be conducted at a set of Representative Monitoring Site locations, as discussed further in **Section 16.1.4** ***Monitoring Network for Degraded Water Quality***.

13.4.3. Potential Effects of Undesirable Results

☑ **23 CCR § 354.26(b)(3)**

Per **Section** 354.26(b)(3) of the GSP Emergency Regulations, potential effects of Undesirable Results must be identified. As discussed above, because the dominant beneficial use is agricultural, and water quality is generally suitable for agricultural uses within the Wheeler Ridge-Maricopa Management Area, Undesirable Results are not defined for this Sustainability Indicator.

The above notwithstanding, more generally the potential effects of Undesirable Results caused by Degraded Water Quality on beneficial uses and users of groundwater may include: increased costs to treat groundwater to drinking water standards if it is to be used as a potable supply source; increased costs to blend relatively poor-quality groundwater with higher quality sources for agricultural and non-agricultural uses; limitations on viable crop types or crop yield depending on crop sensitivity and tolerance to COCs in groundwater used for irrigation; and potential reduction in "usable storage" volume of groundwater in the basin if large areas of aquifer are impacted to the point that they cannot be used to support beneficial uses and users.

As discussed in **Section 5.2.1** ***Existing Monitoring and Management Programs***, the District conducts groundwater quality sampling and monitoring for its own agricultural water management program, as does the State Water Resources Control Board (SWRCB) through its Groundwater Ambient Monitoring and Assessment (GAMA) program. These groundwater quality monitoring programs are expected to continue during the SMGA implementation horizon and will be incorporated into future SGMA reporting and analysis.

13.5. Undesirable Results for Land Subsidence

The basin-wide definition of Undesirable Results for Land Subsidence is as follows:

> "The point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.
>
> This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan."

Critical infrastructure is defined in the adopted Undesirable Results definition document as:

> "facilities which are utilized to provide public services such as water, utilities, and or transportation service for a region"

Unlike the Undesirable Results definitions for Chronic Lowering of Groundwater Levels, Reduction in Groundwater Storage, and Degraded Water Quality, the above basin-wide definition for Undesirable Results for Land Subsidence does not look towards a local definition of Minimum Thresholds on a management area level, but instead refers to a basin-wide coordinated GSP subsidence monitoring plan and affected water, utilities, and transportation service "for a region". Thus, the definition is focused on regional impacts, rather than local impacts.

13.5.1. Potential Causes of Undesirable Results

☑ **23 CCR § 354.26(b)(1)**

Land subsidence can be caused by several mechanisms, but the mechanism most relevant to sustainable groundwater management is the depressurization of aquifers and aquitards due to lowering of groundwater levels, which can lead to compaction of compressible strata and lowering of the ground surface. Therefore, the potential causes of Undesirable Results due to Land Subsidence are generally the same as the potential causes listed above for Undesirable Results due to Chronic Lowering of Groundwater Levels.

13.5.2. Criteria Used to Define Undesirable Results

☑ **23 CCR § 354.26(b)(2)**

The basin-wide definition of Undesirable Results refers to significant and unreasonable impacts to critical infrastructure which, as noted above, is defined with a regional emphasis. Within the Wheeler Ridge-Maricopa Management Area, the only critical infrastructure is the California Aqueduct. The California Aqueduct is the backbone of the State Water Project and is vital to the movement of water from northern California to the south. As such, the aqueduct is subject to ongoing subsidence monitoring by the DWR, which is anticipated to continue during the SGMA implementation period.

Recent monitoring has shown some land subsidence impacts to the section of the Aqueduct within the Wheeler Ridge-Maricopa Management Area. Recognizing the importance of the California Aqueduct to regional and statewide water infrastructure, it is considered an Undesirable Result for land subsidence to continue indefinitely in the vicinity of the Aqueduct. That being said, it is also recognized that due to the inherent time lag of the aquitard depressurization process, there may still be some "built-in" subsidence potential that has yet to manifest. It is therefore unrealistic to define the Undesirable Result as "any further land subsidence", as such an outcome would almost certainly be unavoidable, and therefore would prevent achievement of the Sustainability Goal. Therefore, the Undesirable Result for land subsidence is defined based on exceedance of a Minimum Threshold rate of subsidence which is based on historical observations of subsidence along the California Aqueduct.

Given the variability in subsidence throughout the Wheeler Ridge-Maricopa Management Area, it is appropriate to incorporate a fraction of monitoring sites in the definition of Undesirable Results, similar to how the Undesirable Results definition for Chronic Lowering of Groundwater Levels states that it occurs when Minimum Thresholds for that indicator are exceeded in 40% of Representative Monitoring Sites. For Land Subsidence, it is considered an Undesirable Result if the Minimum Threshold rate is exceeded in 40%

or more (i.e., 16 out of 40) of the DWR survey benchmark locations[68] between Mileposts 256.14 (Check No. 31) and 278.13 (Teerink Pumping Plant). The Minimum Threshold rate is described in **Section 14.5 *Minimum Threshold for Land Subsidence***

13.5.3. Potential Effects of Undesirable Results

☑ **23 CCR § 354.26(b)(3)**

Potential effects of Undesirable Results caused by land subsidence on beneficial uses and users of groundwater and overlying land uses within the Wheeler Ridge-Maricopa Management Area would include damage to gravity-driven water conveyance infrastructure (i.e., the California Aqueduct) which could impair its ability to move water to points further south. Land subsidence could also affect non-critical infrastructure such as local water conveyance systems (e.g., the District's pressure pipeline distribution system) and groundwater well casings, but those land uses are not considered critical infrastructure per the basin-wide definition which emphasizes regional impacts.

13.6. Undesirable Results for Depletions of Interconnected Surface Water

No basin-wide definition of Undesirable Results for Depletions of Interconnected Surface Water has been developed by the Kern Subbasin GSAs. Based on available data and information, depletion of interconnected surface water has not been observed within the Wheeler Ridge-Maricopa Management Area.

13.6.1. Potential Causes of Undesirable Results

☑ **23 CCR § 354.26(b)(1)**

Depletion of Interconnected Surface Water is generally correlated to Chronic Lowering of Groundwater Levels in an interconnected groundwater aquifer system. Therefore, the potential causes of Undesirable Results due to Depletion of Interconnected Surface Water are generally the same as the potential causes listed above for Undesirable Results due to Chronic Lowering of Groundwater Levels (i.e., increased groundwater pumping and reduced recharge). However, as discussed above, the degree of hydraulic connection between the principal aquifer and surface water within the Wheeler Ridge-Maricopa Management Area is unknown but suspected to be small based on available water level information. Therefore, there does not appear to be any active potential causes for Undesirable Results due to Depletion of Interconnected Surface Water.

13.6.2. Criteria Used to Define Undesirable Results

☑ **23 CCR § 354.26(b)(2)**

As described in **Section 8.7 *Interconnected Surface Water Systems***, there are no major surface water systems that are believed to be interconnected to the underlying groundwater table within the Wheeler Ridge-Maricopa Management Area. Because there is little to no interconnected surface water, no

[68] The DWR surveyed benchmark locations at which the Undesirable Results are defined are those within Pools 32 through 35 presented in Table 6-7 of DWR (2017).

Undesirable Result for Depletion of Interconnected Surface Water is defined within the Management Area.

13.6.3. Potential Effects of Undesirable Results

☑ 23 CCR § 354.26(b)(3)

Potential effects of Undesirable Results of Depletion of Interconnected Surface Water may include reduced surface water flows to support downstream or in-stream uses. As discussed above, there is little to no interconnected surface water within the Wheeler Ridge-Maricopa Management Area, and therefore no effects from Undesirable Results for this indicator have occurred or are expected to occur within the Management Area.

13.7. Undesirable Results Summary

Table SMC-1 below provides a summary of the local definitions of Undesirable Results for each Sustainability Indicator.

Table SMC-1. Summary of Undesirable Results Definitions within the Wheeler Ridge-Maricopa Management Area

Sustainability Indicator	Undesirable Results Definition within the Wheeler Ridge-Maricopa Management Area
Chronic Lowering of Groundwater Levels	Minimum Threshold exceedance in at least 40% (i.e., 6 or more out of 14) of Representative Monitoring Sites over four consecutive seasonal (bi-annual) measurements
Reduction of Groundwater Storage	No local Undesirable Results definition; Chronic Lowering of Groundwater Levels used as a proxy.
Seawater Intrusion	No local Undesirable Results definition; Sustainability Indicator not applicable within the Kern Subbasin
Degraded Water Quality	No local Undesirable Results definition
Land Subsidence	Subsidence at rates exceeding the Minimum Threshold rate throughout the SGMA implementation period in at least 40% (16 of 40) of subsidence monitoring locations
Depletion of Interconnected Surface Water	No local Undesirable Results definition; Sustainability Indicator not applicable within the Wheeler Ridge-Maricopa Management Area

14. MINIMUM THRESHOLDS

☑ 23 CCR § 354.28(a)

Minimum Thresholds are the numeric criteria for each Sustainability Indicator that, if exceeded, may cause Undesirable Results. This section describes the Minimum Thresholds that have been developed to avoid Undesirable Results for each applicable Sustainability Indicator in the Wheeler Ridge-Maricopa Management Area. These Minimum Thresholds have been developed in coordination with other KGA members and GSAs within the "south of Kern River" portion of the Kern Subbasin (e.g., Arvin-Edison Water Storage District and the Kern River GSA).

As shown in **Table SMC-2**, Minimum Thresholds within the Wheeler Ridge-Maricopa Management Area are defined at different spatial scales and locations, or not at all, depending on the Sustainability Indicator. Where appropriate, the Minimum Thresholds for the Sustainability Indicators have been set using groundwater levels as a proxy, based on demonstration "that there is a significant correlation between groundwater levels and the other metrics" (California Department of Water Resources [DWR] Sustainable Management Criteria Best Management Criteria [BMP] document; DWR, 2018).

Table SMC-2. Spatial Scale of Minimum Threshold Definition

Sustainability Indicator	Spatial Scale of Minimum Threshold Definition	Notes
Chronic Lowering of Groundwater Levels	Sustainability Criteria Zones	There are three Sustainability Criteria Zones defined; Groundwater levels will be measured at 14 Representative Monitoring Sites (i.e., wells)
Reduction of Groundwater Storage	No Minimum Threshold defined	Chronic Lowering of Groundwater Levels will be used as a proxy
Seawater Intrusion	No Minimum Threshold defined	Sustainability Indicator not applicable within the Kern Subbasin
Degraded Water Quality	No Minimum Thresholds defined	Monitoring for groundwater quality at selected locations will continue as part of District agricultural water management and as part of compliance with other regulatory programs
Land Subsidence	Representative Monitoring Sites	Surface elevations will be monitored at a network of benchmarks along the California Aqueduct by DWR and others

Depletion of Interconnected Surface Water	No Minimum Thresholds defined	Sustainability Indicator not applicable within the Wheeler-Ridge Maricopa Management Area

14.1. Minimum Threshold for Chronic Lowering of Groundwater Levels

☑ **23 CCR § 354.28(c)(1)**

Chronic Lowering of Groundwater Levels is arguably the most fundamental Sustainability Indicator, as it influences several other key Sustainability Indicators, including Reduction of Groundwater Storage, Land Subsidence, and in certain ways, Degraded Water Quality. Groundwater levels are also the most readily available and measurable metrics of groundwater conditions, which allows for a systematic, data-driven approach to development of Minimum Thresholds to be applied. There are no state, federal, or local standards that relate to this Sustainability Indicator.

14.1.1. Minimum Threshold Development

☑ **23 CCR § 354.28(c)(1)(A)**
☑ **23 CCR § 354.28(c)(1)(B)**

Consistent with the GSP Emergency Regulations (23 CCR § 354.28(c)), the definition of Minimum Thresholds for Chronic Lowering of Groundwater Levels in the Wheeler Ridge-Maricopa Management Area is based on consideration of trends in historical groundwater levels, water year types, projected water use in the management area, and the relationship to other Sustainability Indicators. Specifically, the information and criteria relied on to establish the Minimum Thresholds for Chronic Lowering of Groundwater Levels includes:

- Historical water level data from selected wells with long-term representative water level records[69];
- The proximity to critical infrastructure (i.e., for consideration of potential land subsidence impacts); and
- Well construction information (i.e., for consideration of impacts to beneficial users).

This information was used to develop initial Minimum Threshold estimates using a quantitative algorithm that accounted for trends, historical lows, and water level variability (discussed below) and then these initial estimates were mapped and generalized spatially to create three "Sustainability Criteria Zones" within the Wheeler Ridge-Maricopa Management Area. This approach allowed for the most complete and representative historical water level information to inform the Minimum Thresholds, while also allowing

[69] The representativeness of the wells with long-term hydrograph records is illustrated on **Figure SMC-1**, which shows the Fall 2015 groundwater level at each well compared to the average Fall 2015 groundwater elevation by Public Land Survey System (PLSS) section for all sections "associated with" (i.e., closest to) each long-term hydrograph location. The figure shows that the percent difference in water level in the local area around each well is small in most cases, indicating that the well is representative of that local area.

for potentially different wells (i.e., other than those with the best historical records) to be used as Representative Monitoring Sites.

Minimum Threshold Algorithm

☑ 23 CCR § 354.28(b)(1)

The initial Minimum Threshold estimates for Chronic Lowering of Groundwater Levels were developed for each long-term hydrograph well location through development and application of an algorithm that considers the above information, as follows:

- Historical low water levels over a relevant time period are used as a starting point for Minimum Thresholds based on the fact that significant and unreasonable impacts to beneficial uses and users of groundwater due to groundwater levels are not known to have occurred since the time when water levels were at their historical low. The relevant time period for historical low determination is defined as Water Year (WY) 1966 - 2018 for the following reasons:
    - The assumed upper-end usable lifespan of groundwater wells is approximately 50 years, and therefore most wells would likely not have experienced conditions prior to about 50 years ago;
    - The WRMWSD started surface water importation in 1971, and AEWSD (which overlaps WRMWSD in the eastern portion of the management area) began importing water in 1966. These actions represented a significant change to water management in this part of the Kern Subbasin; and
    - The relevant time period includes conditions observed up to "present" (Fall 2018).
- Variability in groundwater levels is accounted for by calculating a Variability Correction Factor as the product of the observed water level range over a relevant time period and a "Range Fraction". This Variability Correction Factor is applied to the historical low (as discussed below) and acknowledges the fact that different locations within the Wheeler Ridge-Maricopa Management Area have experienced different amounts of water level variability.
    - The time period for water level range determination is defined as WY 1995 – 2015 for the following reasons:
        - The 21-year length of this period is roughly the same as the 20-yr SGMA implementation period, and therefore the SGMA implementation period is expected to include a similar range of variability as the groundwater level range period;
        - The period includes a mix of wet and dry years and so variability in groundwater levels during this time should be reflective of variable climate;
        - The period is climatically close to the long-term average for precipitation and Kern River Flow (Todd Groundwater, 2016); and
        - This period is the same as the historical and current water budget period of interest defined by KGA and its member agencies, and therefore water budget and model results are available for this period.

- The Range Fraction is set at 25% as a conservative allowance for water level fluctuation within a well.

- Recent trends in groundwater levels and projected water use are accounted for by extending the trend for a certain amount of time (the "Trend Extension Period") to determine a Trend Continuation Factor. This factor is also applied to historical low water levels (as discussed below) in order to avoid rapid disruption to land uses and allow time for implementation of any Projects and/or Management Actions needed to eliminate declining trends.
  - The time period for water level trend calculation is defined as WY 2009 – 2018 for the following reasons:
    - This period reflects the effects of changes to SWP/CVP deliveries resulting from Delta-related federal District Court rulings; and
    - The period includes the recent significant drought, and therefore allows the Trend Continuation Factor to incorporate the possibility of another long-term drought in the future (e.g., potentially exacerbated by climate change), consistent with the basin-level Undesirable Results definition for Reduction in Groundwater Storage.
  - The Trend Extension Period was set to ten years for the following reasons:
    - This length of time is considered reasonable and necessary to implement the various Projects & Management Actions that may be required to reverse declining groundwater level trends, in consideration of the potential regulatory, environmental, logistical, engineering, socioeconomic and other challenges that the various Projects & Management Actions may entail, as well as the time that such measures would likely take to manifest in observed groundwater level conditions; and
    - This length of time is half the duration of the SGMA implementation period, suggesting that by the halfway point, the Wheeler Ridge-Maricopa Management Area should be on a trajectory towards achieving the Sustainability Goal.

- Using the above values (i.e., the Historical Low, the Variability Correction Factor, and the Trend Continuation Factor), the initial Minimum Threshold estimates for Chronic Lowering of Groundwater Levels at each long-term hydrograph location are calculations as the lower of: (a) the historic low groundwater level minus the Variability Correction Factor), and (b) the recent (Fall 2015) groundwater level minus the greater of either the Variability Correction Factor or the Trend Continuation Factor. In mathematical terms, the algorithm for defining the initial Minimum Threshold estimates for Chronic Lowering of Groundwater Levels at each long-term hydrograph location is as follows:

$$MT = min\begin{cases} HL - VCF \\ Recent - max\begin{cases} VCF \\ TCF \end{cases} \end{cases}$$

$$VCF = Range * 25\%$$

$$TCF = Trend * 10\ yrs$$

where:

MT is the initial Minimum Threshold estimate (ft msl);

HL is the historical low groundwater level over the WY 1965 – 2018 period (ft msl),

VCF is the Variability Correction Factor (ft);

TCF is the Trend Continuation Factor (ft);

Recent is the Fall 2015 groundwater level (ft msl);

Range is the water level range over the WY 1995 – 2015 period; and

Trend is the groundwater level trend over the 2009 – 2015 period (ft/yr).

Adjustment in Areas Proximal to Critical Infrastructure

☑ **23 CCR § 354.28(b)(2)**
☑ **23 CCR § 354.28(b)(4)**

In areas proximal to critical infrastructure that may be particularly sensitive to significant and unreasonable effects from land subsidence (discussed further below), an adjustment to the initial Minimum Threshold estimates was applied in the algorithm to keep the values at historical low groundwater levels. Specifically, for long-term hydrograph locations that were within one mile of critical infrastructure, the initial Minimum Threshold estimates were set to their historical low groundwater levels, as this theoretically prevents any further subsidence from occurring. Results from the initial Minimum Threshold estimation exercise described above are shown on **Figure SMC-2**. Also shown on this figure are the proposed Sustainability Criteria Zones defined within the Wheeler Ridge-Maricopa Management Area which are discussed below.

Consideration of Adjacent Basins

☑ **23 CCR § 354.28(b)(3)**

Minimum Thresholds have been developed in consideration of and in coordination with neighboring water agencies within the Kern Subbasin (see **Section 5.5.5 *Interagency Coordination***) and in neighboring basins (see **Section 5.5.6 *Interbasin Coordination*).** Through its membership in the White Wolf GSA (along with AEWSD and TCWD), WRMWSD has and will continue to consider the effects of Sustainability Criteria in the Wheeler Ridge-Maricopa Management Area on the adjacent White Wolf Basin's ability to achieve its sustainability goal.

Spatial Generalization into Sustainability Criteria Zones

Once the initial Minimum Threshold estimates for the long-term hydrograph locations were calculated using the algorithm described above, they were plotted on a map and examined for spatial patterns that could be used to generalize the values into zones. The purpose of this step was to allow flexibility in the selection of Representative Monitoring Sites for this Sustainability Indicator, recognizing that not all of the wells with long-term hydrograph data are available for use in the monitoring network. It was determined that the Wheeler Ridge-Maricopa Management Area could be divided into three zones, referred to as the Western, Northeastern, and Southeastern zones, as shown on **Figure SMC-2**. The Minimum Threshold Values for each Sustainability Criteria Zone is shown on **Figure SMC-3**.

As part of the delineation of Sustainability Criteria Zones within the Wheeler Ridge-Maricopa Management Area, an analysis was performed regarding potential well impacts associated with various Minimum Threshold values. Using available well construction information for domestic, production (agricultural), and public supply wells, an assessment was made of the number of wells that could be dewatered at different generalized Minimum Threshold levels. Through this analysis which was performed iteratively with different Minimum Threshold levels, the proposed Minimum Thresholds would potentially result in seven wells being dewatered, the impacts would not be unreasonable and would be prevented and/or mitigated through an Impacted Well Mitigation Program (see **Section 18.6.1 *Impacted Well Mitigation Program***), to be developed as part of GSP Implementation. Results from this well impact analysis of Minimum Thresholds are shown on **Figure SMC-4** and **Figure SMC-5** for the Sustainability Criteria Zones and the PLSS sections, respectively.

The final Minimum Thresholds for Chronic Lowering of Groundwater Levels in each Sustainability Criteria Zone and at each Representative Monitoring Site are shown in **Table SMC-3** and on **Figure SMC-3**.

14.2. Minimum Threshold for Reduction of Groundwater Storage

☑ **23 CCR § 354.28(c)(2)**

As discussed above, the Undesirable Results definition for Reduction of Groundwater Storage at the basin level refers to a decrease in storage that would cause water levels to decline below Minimum Thresholds established in each management area for Chronic Lowering of Groundwater Levels. It is logical to tie these two Sustainability Indicators together, as the amount of groundwater in storage is directly, if not linearly, related to groundwater levels. Because of the close relationship between these two Sustainability Indicators, and because the Minimum Thresholds for Chronic Lowering of Groundwater Levels (discussed above) are protective of the beneficial uses and users of groundwater, it is not necessary to set a unique Minimum Threshold for Reduction of Groundwater Storage. Rather, Minimum Thresholds for Chronic Lowering of Groundwater Levels will be used as a proxy for the Reduction of Groundwater Storage Sustainability Indicator. There are no state, federal, or local standards that relate to this Sustainability Indicator.

14.2.1. Use of Groundwater Levels as Proxy

☑ **23 CCR § 354.28(d)**

Pursuant to the GSP Emergency Regulations (23 CCR § 354.28(d)) and as further described in the DWR Sustainable Management Criteria BMP, Minimum Thresholds for Reduction of Groundwater Storage may be set by using groundwater levels as a proxy if it is demonstrated that a correlation exists between the two metrics. One approach to using groundwater levels as a proxy, described in the DWR Sustainable Management Criteria BMP, is to demonstrate that Minimum Thresholds for Chronic Lowering of Groundwater Levels are sufficiently protective to ensure prevention of significant and unreasonable occurrences of the Sustainability Indicator in question.

To demonstrate that the Minimum Thresholds for Chronic Lowering of Groundwater Levels are sufficiently protective, a calculation was performed to determine the volume of groundwater that would be removed from the primary aquifer if groundwater levels were to decline from current (Fall 2015) levels to their respective Minimum Thresholds for Chronic Lowering of Groundwater Level. This volume is then compared to the volume of usable storage, and it is shown that there is more usable storage is greater,

and therefore, the Minimum Thresholds for Chronic Lowering of Groundwater Levels are protective for the Reduction of Groundwater Storage Sustainability Indicator.

Usable Storage

To support the use of Minimum Thresholds for Chronic Lowering of Groundwater Levels as a proxy for Reduction of Groundwater Storage, it is informative to define an actual volume of "usable storage" above the median bottom depth of wells. This volume is calculated based on the following data and assumptions:

- Area of Wheeler Ridge-Maricopa Management Area (92,343 acres)
- Storage coefficient (0.08)[70]
- Average depth to groundwater in Fall 2015 (approximately 303 ft)
- Depth corresponding to the 50% cumulative bottom depth of wells (approximately 1,100 ft)

The volume of usable storage is approximately 5.9 million AF. This volume corresponds to the volume that would be pumped in roughly 100 years of pumping at the average rate pumped from WY 1995 through 2015 (i.e., 59,152 AFY).

Storage Reduction at Minimum Threshold Levels

The volume of groundwater that would be removed from storage if groundwater levels were to decline to Minimum Threshold levels volume is calculated for each PLSS section by subtracting the Minimum Threshold from the associated Sustainability Criteria Zone from the "current" (Fall 2015) gridded groundwater elevation data, multiplying the difference by the storage coefficient, and then summing the values for each PLSS section to arrive at a total volume for the entire Wheeler Ridge-Maricopa Management Area. This calculation is shown in the equation below:

$$MT_Stor = \sum_{k=1}^{n} (GWL_i - MT_GWL_i) * A_k * S_k$$

where:

MT_Stor is the Minimum Threshold for Reduction of Groundwater Storage (AF);

GWL is the current groundwater elevation (ft msl);

MT_GWL is the Minimum Threshold for Chronic Lowering of Groundwater Levels within the Sustainability Criteria Zone (subscript *i*) (ft msl);

A is the area (acres); and

S is the storage coefficient (dimensionless). The subscript *k* refers to each PLSS section (a total of *n* sections within the Wheeler Ridge-Maricopa Management Area).

The resulting volume is approximately 1.08 million AF which is much less than the 5.9 million AF of "usable storage". Therefore, the Minimum Thresholds for Chronic Lowering of Groundwater Levels are sufficiently protective to ensure prevention of significant and unreasonable occurrences of Reduction of Groundwater

[70] There is uncertainty in the value for the storage coefficient used in the above calculations, as discussed in Section **7.1.4** ***Principal Aquifers and Aquitards***. However, the value of 0.08 is considered conservative.

Storage. Therefore, no Minimum Threshold for Reduction of Groundwater Storage is set within the Wheeler Ridge-Maricopa Management Area.

14.3. Minimum Threshold for Seawater Intrusion

☑ 23 CCR § 354.28(c)(3)
☑ 23 CCR § 354.28(e)

The GSP Emergency Regulations state that "An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in Section 354.26, shall not be required to establish minimum thresholds related to those sustainability indicators" (23 CCR § 354.28(e)). Because the Kern Subbasin is not located near any saline water bodies, seawater intrusion is not present and not likely to occur. Therefore, the Seawater Intrusion Sustainability Indicator is not applicable to the Kern Subbasin and no SMCs for this Sustainability Indicator are defined in the Wheeler Ridge-Maricopa Management Area.

14.4. Minimum Threshold for Degraded Water Quality

☑ 23 CCR § 354.28(c)(4)

The GSP Emergency Regulations state that "An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in Section 354.26, shall not be required to establish minimum thresholds related to those sustainability indicators" (23 CCR § 354.28(e)). As discussed above, based on the existing beneficial uses and users of groundwater within the Wheeler Ridge-Maricopa Management Area, there are not Undesirable Results for Degraded Water Quality occurring and the Minimum Thresholds for Chronic Lowering of Groundwater Level are anticipated to be protective in terms of preventing migration of poor-quality water. Therefore, no unique Minimum Thresholds are set for this Sustainability Indicator. It should be noted, however, that monitoring for water quality will be conducted at a set of Representative Monitoring Site locations, as discussed further in **Section 16.1.4 *Monitoring Network for Degraded Water Quality***.

14.5. Minimum Threshold for Land Subsidence

☑ 23 CCR § 354.28(c)(5)

Minimum Thresholds for Land Subsidence are defined herein as levels of land subsidence that, if they occurred, would result in significant and unreasonable impacts to critical infrastructure and surface land uses. There are no state, federal, or local standards that relate to this Sustainability Indicator.

Within the Wheeler Ridge-Maricopa Management Area, the critical infrastructure that has the potential to be significantly and unreasonably impacted by land subsidence includes the California Aqueduct. While certain other land uses exist within the Management Area that are potentially affected by land subsidence (see **Section 13.5 *Undesirable Results for Land Subsidence***), the Aqueduct is considered the most critical to avoid Undesirable Results from land subsidence in the Management Area because it is associated with the regional water supply system as well as the central mission of WRMWSD which is the importation and delivery of surface water.

14.5.1. Minimum Threshold Development

☑ 23 CCR § 354.28(b)(1)
☑ 23 CCR § 354.28(b)(4)

Historical and recent rates of subsidence measured within the Wheeler Ridge-Maricopa Management Area in proximity to the sensitive land uses listed above are discussed in **Section 8.6 *Land Subsidence***. The Minimum Threshold rate for Land Subsidence is defined herein based on the maximum rate of subsidence observed through ground-based surveys between 1975 and 2019 at survey benchmarks along the California Aqueduct. The Minimum Threshold amount of subsidence is defined as the amount that would occur if the Minimum Threshold rate were extended forward until the end of the SGMA implementation timeline (i.e., to 2040).[71] Specifically, the Minimum Threshold for Land Subsidence is calculated as follows:

$$MT_Sub = Max_rate_Aqueduct * t_impl$$

where:

MT_Sub is the Minimum Threshold for Land Subsidence as a cumulative amount (in);

$Max_rate_Aqueduct$ is the maximum average rate of subsidence between 1975and 2019 observed at any survey benchmark along the California Aqueduct between Mileposts 256.14 (Check No. 31) and 278.13 (Teerink Pumping Plant), equal to 0.50 inches per year[72]; and

t_impl is time from 2019 until the end of the SGMA GSP implementation timeframe (2040), equal to 22 years.

The rationale for this Minimum Threshold rate of subsidence is that such subsidence has been historically managed by DWR through maintenance and improvements to its facilities. Within the Wheeler Ridge-Maricopa Management Area, as of 2013 there are no reaches of the Aqueduct that have less than the minimum recommended freeboard (2.5 ft); the minimum freeboard is approximately 3.9 ft in one location around milepost 256.56, and along most other portions of these reaches the freeboard is between 6 and 8 feet (DWR, 2017).

14.5.2. Final Minimum Thresholds

☑ 23 CCR § 354.28(b)(2)
☑ 23 CCR § 354.28(b)(6)

Per the above calculation, the resulting Minimum Threshold rate of subsidence is 0.5 in/yr, and the Minimum Threshold cumulative amount of subsidence is 10.93 inches, relative to elevations measured in 2018. The Minimum Threshold applies to the 40 DWR survey benchmark locations between Mileposts 256.56 (Check No. 31) and 278.13 (Teerink Pumping Plant) that are included on the profiles included in

[71] Satellite-based land subsidence measurements (i.e., InSAR data) indicate recent subsidence of 1 to 4 inches between May 2015 and September 2016, with localized amounts of between 4 and 8 inches (see **Figure GWC-15**). However, this data collected method, while useful for spatial understanding of subsidence patterns, is considered less accurate at any given location than ground-based survey methods, and for purposes of subsidence monitoring near critical infrastructure, ground-based survey methods will be used. Therefore, the ground-based survey data collected by DWR along the California Aqueduct are used herein to define Minimum Thresholds for Land Subsidence in the vicinity of critical infrastructure.

[72] The maximum rate of subsidence between 1975 and 2019 of 0.50 inches per year was observed at Mileposts 257.63 and 275.00.

the DWR (2017) report plates included in Appendix I. The final Minimum Thresholds for Land Subsidence are shown in **Table SMC-4**. Additional information about the Representative Monitoring Sites for this Sustainability Indicator is provided in **Section 16 *Monitoring Network***.

It should be noted that the Minimum Thresholds for Chronic Lowering of Groundwater Levels include consideration of land subsidence by limiting the Minimum Thresholds to the historical low groundwater levels in those Representative Monitoring Sites that are within one mile of critical infrastructure (see **Section 14.1**

Minimum Threshold for Chronic Lowering of Groundwater Levels). While groundwater level measurements are not being used as a proxy for land subsidence measurements in these areas (i.e., the land subsidence monitoring network will consist of survey benchmark locations maintained and measured by DWR), these Minimum Thresholds for Chronic Lowering of Groundwater Levels are set conservatively to avoid further land subsidence.

14.6. Minimum Threshold for Depletion of Interconnected Surface Water

☑ **23 CCR § 354.28(c)(6)**
☑ **23 CCR § 354.28(e)**

The GSP Emergency Regulations state that "An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in 23 CCR § 354.26, shall not be required to establish minimum thresholds related to those sustainability indicators" (23 CCR § 354.28(e)). As discussed above, based on available data and information, Depletion of Interconnected Surface Water has not been observed within the Wheeler Ridge-Maricopa Management Area, and depths to groundwater are so deep as the preclude the possibility of occurrence of interconnected surface water. Therefore, there are no Undesirable Results and no Minimum Thresholds defined for this Sustainability Indicator.

15. MEASURABLE OBJECTIVES AND INTERIM MILESTONES

☑ 23 CCR § 354.30(a)
☑ 23 CCR § 354.30(b)

This section discusses the development of Measurable Objectives and Interim Milestones for all relevant Sustainability Indicators in the Arvin-Edison Management Area.

15.1. Measurable Objective and Interim Milestones for Chronic Lowering of Groundwater Levels

15.1.1. Measurable Objective for Chronic Lowering of Groundwater Levels

☑ 23 CCR § 354.30(c)

Initial estimates for Measurable Objectives for Chronic Lowering of Groundwater Levels were developed based on the groundwater levels that were observed in the 16 long-term hydrograph locations in or around Fall 2015. As with the Minimum Thresholds, the initial Measurable Objective estimates were then adjusted and generalized into values for each Sustainability Criteria Zone. The adjustments and generalizations generally entail decreasing the Measurable Objective for the zone relative to the Fall 2015 levels. The downward adjustments were made in recognition of the fact that in most cases groundwater levels in 2015 were not near their historical low, and therefore an ample Margin of Operational Flexibility could be achieved even with levels lower than they were in 2015. Also, considering the potential for reduced surface water imports in the future and potentially increased groundwater use, it was considered appropriate to set the Measurable Objectives to allow for some decrease from 2015 levels. Measurable Objectives for Chronic Lowering of Groundwater Levels for each Sustainability Criteria Zone and at each Representative Monitoring Site are shown in are shown on **Table SMC-3** and **Figure SMC-6**.

15.1.2. Interim Milestones for Chronic Lowering of Groundwater Levels

☑ 23 CCR § 354.30(e)

Interim Milestones for Chronic Lowering of Groundwater Levels are defined herein based on a trajectory for groundwater levels informed by the current (Fall 2018) levels, the Minimum Thresholds, and the Measurable Objectives. This trajectory allows for and assumes a continuation of current groundwater level trends for the first 5-year period, a deviation from that trend over the second 5-year period, a recovery to the 5-year Interim Milestone in the third 5-year period, and recovery towards the Measurable

Objectives over the fourth (last) 5-year period. Specifically, the trajectory for groundwater levels prescribed in the Interim Milestones is as follows:

Table SMC-5. Interim Milestone Trajectory for Chronic Lowering of Groundwater Levels

Calendar Year	Interim Milestone for Chronic Lowering of Groundwater Levels	Basis for Interim Milestone
2020	Not applicable	Not applicable
2025	$IM\text{-}5_{GWL}$	$½ * (GWL_{Fall2018} + MT_GWL)$
2030	$IM\text{-}10_{GWL}$	$½ * (IM\text{-}5_{GWL} + MT_GWL)$
2035	$IM\text{-}15_{GWL}$	$½ * (IM\text{-}10_{GWL} + MO_GWL)$
2040	Not applicable (Measurable Objective)	Not applicable (Measurable Objective)

where:

$IM\text{-}5_{GWL}$, $IM\text{-}10_{GWL}$, and $IM\text{-}15_{GWL}$ are the Interim Milestones for Chronic Lowering of Groundwater Levels after 5 years, 10 years and 15 years, respectively;

$GWL_{Fall2018}$ is the groundwater elevation measured in Fall 2018;

MT_GWL is the Minimum Threshold for Chronic Lowering of Groundwater Levels (defined previously); and

MO_GWL is the Measurable Objective for Chronic Lowering of Groundwater Levels (defined previously;)

Interim Milestones and Measurable Objectives for Chronic Lowering of Groundwater Levels are presented in **Table SMC-3**, and are displayed relative to historical water levels at each Representative Monitoring Site on **Figure SMC-7**.

15.2. Measurable Objective for Reduction of Groundwater Storage

☑ 23 CCR § 354.30(c)
☑ 23 CCR § 354.30(d)

As discussed above, the Undesirable Results definition for Reduction of Groundwater Storage at the basin level refers to a decrease in storage that would cause water levels to decline below Minimum Thresholds established in each management area for Chronic Lowering of Groundwater Levels. It is logical to tie these two Sustainability Indicators together, as the amount of groundwater in storage is directly, if not linearly, related to groundwater levels. Because of the close relationship between these two Sustainability Indicators, the Measurable Objective for Chronic Lowering of Groundwater Levels serves as a proxy for Reduction of Groundwater Storage, and it is not necessary to set a unique Measurable Objective for Reduction of Groundwater Storage. As stated above, the Measurable Objectives for Chronic Lowering of Groundwater Levels provide an adequate Margin of Operational Flexibility.

15.3. Measurable Objective for Seawater Intrusion

The GSP Emergency Regulations state that "An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in 23 CCR § 354.26, shall not be required to establish minimum thresholds related to those sustainability indicators" (23 CCR § 354.28(e)). Because the Kern Subbasin is not located near any saline water bodies, and seawater intrusion is not present and not likely to occur, the Seawater Intrusion Sustainability Indicator is not applicable to the Kern Subbasin, and therefore no SMCs for this Sustainability Indicator are defined.

15.4. Measurable Objective for Degraded Water Qualtiy

☑ **23 CCR § 354.30(c)**

As discussed above, based on the existing beneficial uses and users of groundwater within the Wheeler Ridge-Maricopa Management Area, there are not Undesirable Results for Degraded Water Quality occurring and the Minimum Thresholds for Chronic Lowering of Groundwater Level are anticipated to be protective. Therefore, no unique Minimum Thresholds or Measurable Objectives are set for this Sustainability Indicator.

15.5. Measurable Objectives and Interim Milestones for Land Subsidence

☑ **23 CCR § 354.30(c)**
☑ **23 CCR § 354.30(e)**

The Measurable Objective for Land Subsidence is defined as half of the amount of land subsidence that would be observed if the Minimum Threshold subsidence rates (0.5 in/yr) were to continue from 2018 through 2030 and then cease, which amounts to approximately half of the Minimum Threshold amount. This corresponds to a total amount of subsidence by 2040 of no more than 5.96 inches in no more than 40% of the Representative Monitoring Sites. While ideally there would be no further land subsidence along the Aqueduct, as stated above, due to the inherent time lag of the aquitard depressurization process, there may still be some "built-in" subsidence potential that has yet to manifest. Therefore, it is not considered reasonable to expect an immediate and complete cessation to the historic subsidence rates. Rather, it is considered a reasonable and potentially achievable goal to reduce the historical rate by half over the SGMA implementation period (i.e., by 2040). Interim Milestones for land subsidence are specified as follows:

Table SMC-6. Interim Milestone Trajectory for Land Subsidence

Calendar Year	Interim Milestone for Land Subsidence	Basis for Interim Milestone
2020	Not applicable	Not applicable
2025	$IM\text{-}5_{Subs}$	$GS_Elev_{2018} - 7 * MT_Rate$
2030	$IM\text{-}10_{Subs}$	$GS_Elev_{2018} - 12 * MT_Rate$
2035	$IM\text{-}15_{Subs}$	$GS_Elev_{2018} - 12 * MT_Rate$
2040	Not applicable (Measurable Objective)	$GS_Elev_{2018} - 12 * MT_Rate$

where:

$IM\text{-}5_{Subs}$, $IM\text{-}10_{Subs}$, and $IM\text{-}15_{Subs}$ are the Interim Milestones for Land Subsidence after 5 years, 10 years and 15 years, respectively;

GE_Elev_{2018} is the measured ground surface elevations in 2018; and

MT_Rate is the Minimum Threshold rate for Land Subsidence (0.5 in/yr; defined previously).

Interim Milestones and Measurable Objectives for Land Subsidence are presented in **Table SMC-4**.

15.6. Measurable Objective for Depletions of Interconnected Surface Water

As discussed above, based on available data and information, Depletion of Interconnected Surface Water has not been observed within the Wheeler Ridge-Maricopa Management Area. Therefore, there are no SMCs defined for this Sustainability Indicator.

Notes

1. All locations are approximate.
2. "Normalized Difference" is defined herein as the difference between the Fall 2015 GWE at the RML and the average Fall 2015 GWE within each section, divided by the total range of Fall 2015 GWE within the WRMWSD Kern Management Area.
2. Negative normalized differences (i.e. where the GWE at RML is less than the average Fall 2015 GWE within the section), are represented in green as these sections have an RML that is considered "overprotective" of local water level conditions.

MONITORING NETWORK

16. MONITORING NETWORK

☑ 23 CCR § 354.32

This section describes the monitoring network designed for the Wheeler Ridge-Maricopa Management Area, subsequently referred to as the "SGMA Monitoring Network". Pursuant to the GSP Emergency Regulations, the SGMA Monitoring Network objective is to collect sufficient data for the correct assessment of the Sustainability Indicators relevant to the Management Area (see **Section 13** ***Undesirable Results***), and the impacts to the beneficial users of groundwater. Per 23 CCR § 354.32(e), the SGMA Monitoring Network incorporates elements from the existing monitoring programs occurring within the Management Area (see **Section 5.2.1** ***Existing Monitoring and Management Programs***) and includes additional components to comply with the GSP Emergency Regulations. All monitoring will be performed in accordance with the protocols agreed upon for the Basin, as described the KGA Umbrella GSP.

16.1. Description of Monitoring Network

☑ 23 CCR § 354.34(a)
☑ 23 CCR § 354.34(b)
☑ 23 CCR § 354.34(d)
☑ 23 CCR § 354.34(f)

The objective of the Wheeler Ridge-Maricopa Management Area SGMA Monitoring Network is to collect data with sufficient temporal frequency and spatial density necessary to evaluate Plan implementation as it relates to:

- Monitoring short-term, seasonal, and long-term trends in groundwater and related surface water conditions (see **Section 8** ***Current and Historical Groundwater Conditions***);
- Demonstrating progress toward achieving measurable objectives described in the Plan (see **Section 15** ***Measurable Objectives and Interim Milestones****);*
- Monitoring impacts to the beneficial uses and users of groundwater (see **Section 5.5.1** ***Beneficial Uses and Users of Groundwater***);
- Monitoring changes in groundwater conditions relative to Measurable Objectives (see **Section 15** ***Measurable Objectives and Interim Milestones***) and Minimum Thresholds (see **Section 14** ***Minimum Thresholds***); and
- Quantifying annual changes in water budget components (see **Section 9** ***Water Budget Information****)*.

The Representative Monitoring Network consists of a series of Representative Monitoring Sites that: (1) were selected from the existing monitoring programs that are active within the Wheeler Ridge-Maricopa Management Area (see **Section 5.2.1** ***Existing Monitoring and Management Programs***), (2) have been demonstrated to be representative of groundwater conditions within the Management Area (see **Figure**

SMC-1, for example), and (3) where Sustainability Criteria (Minimum Thresholds, Measurable Objectives, and Interim Milestones) have been defined for at least one of the relevant Sustainability Indicators to the Basin (see **Section 13 *Undesirable Results***):

- Chronic Lowering of Groundwater Levels;
- Reduction of Groundwater Storage;
- Degraded Water Quality[73]; and
- Land Subsidence[74].

Per 23 CCR § 354.32(e), the selection of Representative Monitoring Sites was informed by the existing local monitoring programs (see **Section 5.2.1 *Existing Monitoring and Management Programs***) and leverages historical data wherever possible to help assess and quantify Basin response to Plan implementation relative to historical groundwater conditions (see **Section 8 *Current and Historical Groundwater Conditions***). Pursuant to 23 CCR § 354.32(f), the spatial distribution, spatial density, and temporal frequency of measurements collected from Representative Monitoring Sites is determined for each Sustainability Indicator based on considerations of:

- Amount of current and projected groundwater use;
- Aquifer characteristics, including any vertical and/or lateral barriers to groundwater flow;
- Potential impacts to beneficial uses and users of groundwater, land uses, and property interests affected by groundwater production, and other adjacent basins (and GSAs within the Basin); and
- Availability of historical data to evaluate long-term trends in groundwater conditions associated with the above factors.

Per 23 CCR § 354.32(g), other factors considered in the selection of Representative Monitoring Sites include:

- Availability of existing technical information about the Representative Monitoring Site (e.g., well location, construction information, condition, status, etc.);
- Quality and reliability of historical data at the Representative Monitoring Site;
- "Representativeness" to local groundwater conditions and nearby well populations (per 23 CCR § 354.36); and
- Projected availability of long-term access to the Representative Monitoring Site.

Table MN-1 summarizes the site type, site count, measured constituent(s), measurement frequency, and spatial density of the Monitoring Network for each of the relevant Sustainability Indicators mentioned

[73] No Sustainability Criteria are defined for Degraded Water Quality within the Wheeler Ridge-Maricopa Management Area. Representative Monitoring Sites for Degraded Water Quality are included in the SGMA Monitoring Network for use in collecting supplemental data to allow for continued evaluation of groundwater quality trends within the Management Area (see **Section 16.1.4**).

[74] WRMWSD will leverage DWR's existing regional subsidence monitoring program along the California Aqueduct for use in evaluating land subsidence conditions within the Management Area (see **Section 16.1.5**).

above. Further details about the SGMA Monitoring Network for each Sustainability Indicator can be found in **Sections 16.1.1** through **16.1.6**.

Table MN-1. Summary of SGMA Monitoring Network

Sustainability Indicator	Site Type	Site Count	Measured Constituent(s)	Measurement Frequency	Spatial Density (# sites / 100 mi^2)
Chronic Lowering of Groundwater Levels	Well	14	Water Level	Semiannually	10.4
Reduction of Groundwater Storage	Well	15	Water Level	Semiannually	10.4
Degraded Water Quality[75]	Well	9	see list in **Section 16.1.4**	Annually	6.7
Land Subsidence (2)	Stationary GPS	40	Ground Surface Elevation	Annually, or per DWR schedule	27.7

Note:

(1) Spatial density of monitoring sites is calculated based on only the area of the Wheeler Ridge-Maricopa Management Area that is not overlapped by AEWSD (86,112 acres), as WRMWSD and AEWSD have agreed that AEWSD will cover the overlap lands for SGMA monitoring purposes.

(2) The land subsidence monitoring network described herein is supplemental to the basin-wide subsidence monitoring network being implemented, as discussed in the KGA Umbrella GSP and Appendices thereto.

Pursuant to 23 CCR § 354.32(i), in all cases the SGMA Monitoring Network will adhere to the monitoring protocols specified for the Basin as described in **Section 16.2** and in the KGA Umbrella GSP.

16.1.1. Monitoring Network for Chronic Lowering of Groundwater Levels

☑ 23 CCR § 354.34(c)(1)

The SGMA Monitoring Network for Chronic Lowering of Groundwater Levels consists of 14 wells distributed across the Wheeler Ridge-Maricopa Management Area (spatial density of 10.4 wells / 100 mi^2.) for which water level Sustainability Criteria have been defined within this MA Plan (see **Section 14.1** ***Minimum Threshold for Chronic Lowering of Groundwater*** Levels and **Section 15.1** ***Measurable Objective and Interim Milestones for Chronic Lowering of Groundwater Levels***). As described in **Section 14.1**

Minimum Threshold for Chronic Lowering of Groundwater Levels, a series of 15 wells with long-term groundwater level records were initially selected to analyze historical and current groundwater conditions

[75] *Ibid [73].*

across the Management Area and to inform the development of Sustainability Criteria for Chronic Lowering of Groundwater Levels (see **Sections 14.1** and **15.1**). These wells were included in the selection of Representative Monitoring Sites wherever possible; however, in WRMWSD's recent stakeholder outreach efforts, it became clear that there were several instances in which the "long-term hydrograph" wells would not be available for continued monitoring. In these cases, alternative Representative Monitoring Sites were identified in areas proximate to the long-term hydrograph well locations such that the SGMA Monitoring Network achieves a comparable spatial density, distribution, and "representativeness" to local groundwater conditions. Specific details regarding each of the Representative Monitoring Sites are listed in **Table MN-2.** The site locations and their spatial distribution are displayed on **Figure MN-1**. These Representative Monitoring Sites were selected based on the following considerations:

- **Current and projected groundwater use** – The Monitoring Network includes ten wells located within or immediately adjacent to WRMWSD's surface water service area and four wells located in the "groundwater only" portion of the Management Area.
- **Aquifer characteristics** – All 14 wells included in the Monitoring Network screen the Tulare Formation, which is the only principal aquifer defined within this portion of the Basin.
- **Potential impacts to beneficial uses and users of groundwater, land uses or property interests, and adjacent Basins (or GSAs) –** The Monitoring Network includes three wells situated within one mile of the California Aqueduct (11N22W06H001S, 11N22W01D001S, and 11N21W09C001S), which is defined as "critical infrastructure" to the Management Area (see **Section 13.5 *Undesirable Results for Land Subsidence***). The Monitoring Network also includes one well situated within half a mile of San Emigdio Creek (11N21W16E001S), which will be used to monitor hydraulic gradients between the creek and underlying principal aquifer[76]. Finally, the Monitoring Network includes three wells near the WRMWSD-KDWD boundary (32S26E20G001M, 32S26E24K001M, and 32S29E16P001M) and two wells near the WRMWSD-AEWSD boundary (32S28E16P001M and 32S27E35R001M), which will be used to assess hydraulic gradients between the Management Area, the KDWD portion of the Kern River GSA, and AEWSD.
- **Availability of historical data –** Eight of the 14 Representative Monitoring Sites have associated water level records spanning back through at least 1971, the year that WRMWSD began importing surface water and coincident to the general period of historical low groundwater elevations within the Wheeler Ridge-Maricopa Management Area (see **Section 8 *Current and Historical Groundwater Conditions***). Thirteen out of 14 Representative Monitoring Sites have associated water level records spanning back through at least October 1994, coincident with the start of the historical water budget period (see **Section 9.3.2 *Historical Water Budget***).
- **Availability of site-specific technical information –** As shown in **Table MN-2**, each of the 14 Representative Monitoring Sites have known geographic coordinates, ground surface elevations, and reference point elevations. Nine of the 14 sites contain known well depths, and 11 of the 14 sites contain known well screen intervals. Four of the 14 wells are presumed to still be active and

[76] There are no interconnected surface water features presumed to occur within the Management Area as the water table is encountered well below the ground surface (i.e., depth to water greater than 100 ft. bgs) throughout WRMWSD (see **Section 8.7 *Interconnected Surface Water Systems***).

in use for irrigation or production purposes, while the other 10 are inactive wells which will be used for dedicated monitoring purposes only. All 14 wells are confirmed to be in suitable condition for recording water level measurements. For the sites where well construction information is incomplete or currently unavailable, WRMWSD has developed a plan to fill these data gaps in accordance with 23 CCR § 354.38 (see **Section 16.4 *Assessment and Improvement of Monitoring Network***).

- **Quality and reliability of historical data –** Twelve of the 14 Representative Monitoring Sites contain at least 35 water level records, and 13 of 14 have at least one record in the last five years (i.e., since January 2014). Nine of the 14 sites are included in WRMWSD's voluntary CASGEM network, and most sites have been monitored biannually for at least the past 10 years as part of WRMWSD's routine water level monitoring program.
- **"Representativeness" to local groundwater conditions –** As described above, Representative Monitoring Sites were selected from the list of "long-term hydrograph" wells demonstrated to be representative of local groundwater conditions (see Figure SMC-1) wherever possible; however, there were several cases where the long-term hydrograph wells would not be available for continued monitoring going forward. In these cases, alternative Representative Monitoring Sites were identified in areas proximate to the long-term hydrograph well locations such that the SGMA Monitoring Network achieves a comparable spatial density, distribution, and "representativeness" to local groundwater conditions.
- **Long-term access –** For each of the 14 Representative Monitoring Sites, a preliminary agreement has been reached with associated landowners/well owners allowing WRMWSD long-term access to the site to conduct monitoring for SGMA compliance purposes. A copy of the long-term access agreement can be found in **Appendix H**.

All Representative Monitoring Sites will be monitored semiannually in accordance with the monitoring protocol described in **Section 16.2 *Monitoring Protocols for Data Collection and Monitoring***. All data will be reported to DWR per the requirements specified under **Section 16.5 *Reporting Monitoring Data to the Department***.

16.1.2. Monitoring Network for Reduction of Groundwater Storage

☑ **23 CCR § 354.34(c)(2)**

As described in **Section 13.2.2 *Criteria Used to Define Undesirable Results*** and in **Section 14.2.1 *Use of Groundwater Levels as Proxy***, the criteria used to define Undesirable Results for Reduction of Groundwater Storage are the Minimum Thresholds established at a local management area level for Chronic Lowering of Groundwater Levels. As such, the SGMA Monitoring Network for Reduction of Groundwater Storage will be comprised of the same Representative Monitoring Sites described in **Section 16.1.1 *Monitoring Network for Chronic Lowering of Groundwater Levels***. The information collected from this SGMA Monitoring Network will be sufficient to estimate the change in annual groundwater in storage.

16.1.3. Monitoring Network for Seawater Intrusion

☑ 23 CCR § 354.34(c)(3)
☑ 23 CCR § 354.34(j)

As described in **Section 13.3 *Undesirable Results for Seawater Intrusion***, seawater intrusion is not present and not likely to occur within the Kern Subbasin. Therefore, the Seawater Intrusion Sustainability Indicator is not applicable to the basin and no Undesirable Results for this Sustainability Indicator are defined for the basin. As such, per the stipulations defined under 23 CCR § 354.32(j), a monitoring network has not been defined for the Seawater Intrusion Sustainability Indicator as it is demonstrated to not be applicable to the Basin.

16.1.4. Monitoring Network for Degraded Water Quality

☑ 23 CCR § 354.34(c)(4)

As described in **Section 14.4 *Minimum Threshold for Degraded Water Quality***, based on the existing beneficial uses and users of groundwater within the Wheeler Ridge-Maricopa Management Area, Undesirable Results for Degraded Water Quality are not likely to occur and no unique Minimum Thresholds are currently defined for this Sustainability Indicator. However, WRMWSD has historically conducted routine monitoring of groundwater quality conditions (see **Section 5.2.1 *Existing Monitoring and Management Programs***), and has elected to develop a SGMA Monitoring Network for Degraded Water Quality to facilitate continued monitoring and evaluation of groundwater quality trends within the Wheeler Ridge-Maricopa Management Area throughout Plan implementation.

The SGMA Monitoring Network for Degraded Water Quality includes nine Representative Monitoring Sites selected from WRMWSD's existing water quality sampling program. Specific details regarding each of the Representative Monitoring Sites are listed in **Table MN-2.** The site locations are displayed on **Figure MN-2**. These Representative Monitoring Sites were selected based on the following considerations:

- **Current and projected groundwater use** – The Monitoring Network includes five wells located within WRMWSD's surface water service area and four wells located in the "groundwater only" portion of the Management Area.
- **Aquifer characteristics** – All nine wells included in the Monitoring Network screen the Tulare Formation, which is the only principal aquifer defined within this portion of the Basin.
- **Potential impacts to beneficial uses and users of groundwater, land uses or property interests, and adjacent Basins (or GSAs) –** The Monitoring Network is spread generally evenly across the Management Area and includes Representative Monitoring Sites in the areas of groundwater quality concern identified in **Section 8.5 *Groundwater Quality***.
- **Availability of historical data –** All nine Representative Monitoring Sites have been sampled for groundwater quality constituents (including the constituents of concern [COCs] identified in **Section 8.5 *Groundwater Quality***) at least three times, and six of nine at least 15 times. Eight of the nine sites have been sampled at least once since the year 2000, and seven sites have sampling records extending back through at least 1981.
- **Availability of site-specific technical information –** As shown in **Table MN-2**, each of the nine Representative Monitoring Sites have known geographic coordinates, ground surface elevations,

and reference point elevations. Three of the nine sites contain known well depths, and five of the nine sites contain known well screen intervals. Four of the nine wells are presumed to still be active and in use for irrigation purposes, while the other five will be used for dedicated for monitoring purposes only. All nine wells are confirmed to be in suitable condition for collecting water quality samples. For the sites where well construction information is incomplete or currently unavailable, WRMWSD has developed a plan to fill these data gaps in accordance with 23 CCR § 354.38 (see **Section 16.4 *Assessment and Improvement of Monitoring Network***).

- **Quality and reliability of historical data –** Each of the nine Representative Monitoring Sites contains at least three water quality sampling records, and eight of nine contain at least one record since 2000, and four of nine contain at least one record in the last five years (i.e., since January 2014). Most sites have been monitored regularly for at least the past ten years as part of WRMWSD's routine water quality sampling program.
- **"Representativeness" to local groundwater conditions –** As described above, the nine sites are spread generally evenly across the Management Area, including some wells in the areas of groundwater quality concern identified in **Section 8.5 *Groundwater Quality***.
- **Long-term access –** For each of the nine Representative Monitoring Sites, a preliminary agreement has been reached with associated landowners/well owners allowing WRMWSD long-term access to the site to conduct monitoring for SGMA compliance purposes. A copy of the long-term access agreement can be found in **Appendix H**.

All Representative Monitoring Sites will be sampled annually in accordance with the monitoring protocol described in **Section 16.2 *Monitoring Protocols for Data Collection and Monitoring***. Representative Monitoring Sites will be sampled for the COCs identified in **Section 8.5 *Groundwater Quality***, namely:

- Total Dissolved Solids
- Nitrate
- Arsenic
- Boron
- Iron
- Manganese
- Sulfate
- Chloride
- Uranium

In addition, Representative Monitoring Sites will be monitored for other relevant groundwater quality constituents[77] which may include constituents within some or all of the following categories:

- Descriptive parameters (temperature, pH, etc.)

[77] As identified in Stanford University's "A Guide to Water Quality Requirements under the Sustainable Groundwater Management Act" (Moran & Belin, 2019).

- Major ions
- Heavy metals
- Organic substances
- Pesticides
- Microbes

All data will be reported to DWR per the requirements specified under **Section 16.5 *Reporting Monitoring Data to the Department***.

16.1.5. Monitoring Network for Land Subsidence

☑ **23 CCR § 354.34(c)(5)**

As described in **Section 14.5 *Minimum Threshold for Land Subsidence,*** the California Aqueduct is considered the most critical infrastructure to avoid Undesirable Results from Land Subsidence in the Management Area. As such, WRMWSD intends to utilize DWR's existing land subsidence monitoring program along the California Aqueduct for its local SGMA Monitoring Network for Land Subsidence (see **Appendix I**).

DWR maintains 40 ground surface elevation survey benchmark locations within the Wheeler Ridge-Maricopa Management Area, between Mileposts 256.56 (Check No. 31) and 278.13 (Teerink Pumping Plant) of the California Aqueduct. These benchmarks have been surveyed intermittently since 1967, including the most recent surveys completed in 2019[78]. WRMWSD will coordinate with DWR to obtain access to future survey data collected between Pools 32 – 35 (i.e., Mileposts 256.56 – 278.13) from this regional monitoring program, and will use these publicly-available data to evaluate changes in ground surface elevation along the local reaches of the California Aqueduct within the Management Area, and to assess Plan Implementation relative to the Sustainability Criteria for Land Subsidence defined under **Section 14.5 *Minimum Threshold for Land Subsidence*** and **Section 15.5 *Measurable Objectives and Interim Milestones for Land Subsidence*** of this MA Plan.

16.1.6. Monitoring Network for Depletions of Interconnected Surface Water

☑ **23 CCR § 354.34(c)(6)**
☑ **23 CCR § 354.34(j)**

As described in **Section 13.6 *Undesirable Results for Depletions of Interconnected Surface Water***, no basin-wide definition of Undesirable Results for Depletions of Interconnected Surface Water has been developed and, based on available data and information, depletion of interconnected surface water has not been observed within the Wheeler Ridge-Maricopa Management Area. As such, per the stipulations

[78] DWR survey information along the California Aqueduct through 2013 are presented in DWR (2017), several plates of which are included as **Appendix I**. Additional benchmark survey data provided by DWR on 22 July 2019 is also included in **Appendix I**.

defined under 23 CCR § 354.32(j), a monitoring network has not been defined for the Depletion of Interconnected Surface Water Sustainability Indicator as it is demonstrated to not be applicable.

16.2. Monitoring Protocols for Data Collection and Monitoring

☑ **23 CCR § 352.2**

Pursuant to 23 CCR § 354.32(i), in all cases the Wheeler Ridge-Maricopa Management Area SGMA Monitoring Network will adhere to the monitoring protocols specified for the Basin as described in the KGA Umbrella GSP and Appendices thereto.

16.3. Representative Monitoring

☑ **23 CCR § 354.36**

As described in **Section 16.1 *Description of Monitoring Network***, WRMWSD has defined a SGMA Monitoring Network for each relevant Sustainability Indicator in the Management Area that will be used for SGMA reporting purposes to evaluate Plan implementation with respect to meeting the Sustainability Goal defined for the Basin through compliance with the Minimum Thresholds and Measurable Objectives described in the Plan. The rationale for selecting Representative Monitoring Sites are described for each Sustainability Indicator in **Sections 16.1.1** - **16.1.6** of this MA Plan.

As described in **Section 16.1.2 *Monitoring Network for Reduction of Groundwater Storage***, the Monitoring Network for Chronic Lowering of Groundwater Levels will be used as a proxy to monitor Reduction in Groundwater Storage. As described in **Section 14.2 *Minimum Threshold for Reduction of Groundwater Storage***, groundwater levels are considered sufficiently protective of Reduction in Groundwater Storage, and thus no Sustainability Criteria have been defined for this Sustainability Indicator. There are no other Sustainability Indicators for which groundwater levels will be used as a proxy for representative monitoring.

16.4. Assessment and Improvement of Monitoring Network

☑ **23 CCR § 354.38**

As described above and in the Basin-wide Monitoring Protocols (see KGA Umbrella GSP and Appendices thereto), the Wheeler Ridge-Maricopa SGMA Monitoring Network for the Kern Subbasin will be reevaluated in each five-year GSP update, including a determination of uncertainty and whether there are data gaps that could affect the ability of the Plan to achieve the Sustainability Goal for the Basin.

In all cases, the SGMA Monitoring Network developed for each Sustainability Indicator includes a sufficient density and spatial distribution of monitoring sites to meet the monitoring objectives outlined in **Section 16.1 *Description of Monitoring Network***. In most cases, the existing Representative Monitoring Sites selected for each Sustainability Indicator conform to the best management practices for monitoring networks outlined in DWR's BMP 2 – *Monitoring Networks and Identification of Data Gaps.* As identified in **Sections 16.1.1** - **16.1.6**, there are a few notable exceptions:

Regarding the Monitoring Network for Chronic Lowering of Groundwater Levels

- Five of the 14 sites are missing well depth information (wells 32S26E24K001M, 11N22W01D001S, 11N22W06H001S, 12N21W35G001S, and 32S28E16P001M));
- Three of the 14 sites are missing perforation interval information (wells 32S26E24K001M, 12N21W35G001S, and 11N22W06H001S); and
- Four of the 14 wells are presumed to still be active and in use for irrigation or production purposes (wells 11N21W16E001S, 32S27E35R001M, 32S26E34P001M, and 32S25E29Q001M).

Regarding the Monitoring Network for Degraded Water Quality

- Six of the nine sites are missing well depth information (wells 32S28E16P001M, 32S26E17H001M, 11N21W12N002S, 11N22W09A001S, 12N21W31P001S, and 32S26E14J001M);
- Four of the nine sites are missing perforation interval information (wells 11N21W12N002S, 11N22W09A001S, 12N21W31P001S, and 32S26E14J001M); and
- Four of the nine wells are presumed to still be active and in use for irrigation or municipal and industrial purposes (wells 32S25E29Q001M, 11N21W12N002S, 12N21W31P001S, and 32S26E14J001M).

For the Representative Monitoring Sites currently missing well information and well screen information, WRMWSD has developed a plan to fill these data gaps by conducting video-logging on the identified wells (see **Section 18 *WRMWSD Plan Implementation***). In the event these data gaps cannot be readily filled, WRMWSD will identify alternative sites or develop plans to construct new Representative Monitoring Sites for Chronic Lowering of Groundwater Levels and Degraded Water Quality as deemed necessary by the District.

For the Representative Monitoring Sites still under active use, WRMWSD will work to convert these sites to dedicated monitoring sites or will otherwise identify or develop alternative sites by the GSP implementation deadline (i.e., by January 2040).

16.5. Reporting Monitoring Data to the Department

☑ 23 CCR § 354.40

Data collected from the SGMA Monitoring Network will be uploaded to the Data Management System maintained for the Kern Subbasin and reported to the DWR in accordance with the Monitoring Protocols developed for the Basin as described in the KGA Umbrella GSP and Appendices thereto. Additional data collected as part of WRMWSD's other regular monitoring programs (see **Section 5.2.1 *Existing Monitoring and Management Programs***) may be used in conjunction with data collected from the SGMA Monitoring Network to meet compliance with GSP Emergency Regulations regarding Annual Reporting (23 CCR § 356.2) or as otherwise deemed necessary by the District.

TABLE MN-2
Summary of Representative Monitoring Sites
Wheeler Ridge-Maricopa Water Storage District
Kern Subbasin Management Area

Monitoring Site ID	Representative Monitoring Well (RMW) ID	Monitoring Site Type	Type of Measurement Taken	Frequency of Measurement	Sustainability Indicator(s) *(1,2)*						CASGEM Details			Monitoring Site Location

Abbreviations

amsl = above mean sea level
bgs = below ground surface
CASGEM = California Statewide Groundwater Elevation Monirtoring
DWR = California Department of Water Resources
ft = feet
gpm = gallons per minute
in = inches
KRF = Kern River Formation
N/A = not applicable
NAD = North American Datum
t/o = turnout

Notes

(1) Seawater intrusion is not considered to be a sustainability indicator of concern to the Wheeler Ridge-Maricopa Management Area and is thus not monitored for SGMA compliance
(2) Depletion of Interconnected Surface Water is not considered to be a sustainability indicator of concern to the Wheeler Ridge-Maricopa Management Area and is thus not monitored for SGMA compliance
(3) Only one Principal Aquifer is defined for the Wheeler Ridge-Maricopa Management Area - the "Kern River Formation Principal Aquifer"

PROJECTS AND MANAGEMENT ACTIONS

17. PROJECTS AND MANAGEMENT ACTIONS

☑ **23 CCR § 354.42**

Pursuant to the GSP Emergency Regulations, this section presents the Projects and Management Actions (P/MAs) proposed to support achievement of the sustainability goal within the Wheeler Ridge-Maricopa Management Area[79]. The P/MAs were developed using a portfolio approach whereby individual P/MAs were identified and grouped into categories based on their expected benefits. Implementation of P/MAs within those benefit categories is estimated to occur along a "glide path" that will result in closing of the currently identified "deficit" under the 2030 Climate Change Scenario by the January 2040 GSP implementation deadline (see **Section 9.4.3 *Projected Water Budget Results***), as well as in response to observed groundwater conditions relative to the associated Sustainability Indicators. The proposed P/MAs thus represent a path to achieve the sustainability goal for the Management Area, as further demonstrated by results from the basin-wide numerical groundwater flow model that show groundwater levels exceeding Measurable Objectives when P/MAs are implemented. This approach allows for flexible implementation of P/MAs as needed to address future conditions throughout the 50-year GSP planning and implementation horizon (i.e., out to 2070). The P/MAs presented herein were developed with consideration of costs and benefits and preliminary feasibility analysis; however, each P/MA will require significant further evaluation (i.e., engineering, economic, legal, etc.) prior to implementation. In addition to the P/MAs presented herein, WRMWSD will continue to conduct data gap filling activities as part of Plan Implementation that may include, but are limited to, validating the status of existing wells, refining the water budget parameters based on additional data and modeling, collecting additional data related to aquifer conditions and properties, and conducting additional data compilation and analysis of groundwater conditions information (see **Section 18 *WRMWSD Plan Implementation***).

This section first presents the goals and objectives of the P/MAs, including the relevant Sustainability Indicators, the spatial "focus areas" within the Wheeler Ridge-Maricopa Management Area, the categories of expected benefits and the implementation glide path. Next, a list of specific P/MAs grouped by benefit category and type is presented, information which is also provided in. Following this list is a discussion of how the P/MAs address overdraft conditions or other Undesirable Results (i.e., water quality); a description of the various potentially applicable permitting and regulatory requirements; a discussion of the P/MA status and implementation timeline; a discussion of how the expected benefits will be evaluated; a description of sources of outside water that are relied upon; a discussion of the legal authority required to implement the P/MAs; a summary of estimated costs and how the Wheeler Ridge-Maricopa Water Storage District (WRMWSD) plans to meet those costs; and a discussion of how recharge and extraction will be managed to avoid depletion of groundwater levels and storage.

[79] In this document, the term "Wheeler Ridge-Maricopa Management Area" is used in its entirety the first time the area is being referenced in each paragraph; subsequent references to this area in each paragraph use the term "Management Area".

17.1. Goals and Objectives of Projects and Management Actions

17.1.1. Relevant Sustainability Indicators

Per the GSP Emergency Regulations, GSPs must include P/MAs to address any existing or potential future Undesirable Results for the identified relevant Sustainability Indicators. As discussed in **Section 13 *Undesirable Results***, the relevant Sustainability Indicators in the Wheeler Ridge-Maricopa Management Area for which Undesirable Results and Sustainable Management Criteria (SMCs) have been defined include: (1) Chronic Lowering of Groundwater Levels, (2) Reduction of Groundwater Storage, and (3) Land Subsidence. Because groundwater levels and storage area directly correlated, P/MAs that address groundwater levels also address groundwater storage, and the two Sustainability Indicators are considered together in this discussion of P/MAs. Each of these relevant Sustainability Indicators is further associated with specific areas within the Management Area. Therefore, the goal of the P/MAs discussed herein is to address significant and unreasonable effects related to the relevant Sustainability Indicators in the relevant areas.

17.1.2. Focus Areas

As discussed in **Section 8.2 *Groundwater Elevations and Flow Direction*,** groundwater levels in 2015 were lowest in the southern central portion and the far northernmost portion of the Wheeler Ridge-Maricopa Management Area, and the patterns likely reflect, in part, the distribution of groundwater pumping (the latter of these two areas is outside of the Surface Water Service Area [SWSA] and therefore relies exclusively on groundwater) (see **Figure GWC-1**, **Figure GWC-2**, and **Figure GWC-5**). For that reason, the proposed P/MAs that address groundwater levels and storage are focused on those areas. Land Subsidence is also closely tied to groundwater levels but is only relevant where there is critical infrastructure (defined with an emphasis on regional infrastructure, as discussed in **Section 13.5 *Undesirable Results for Land Subsidence*** above). The area most relevant to the Land Subsidence Sustainability Indicator is along the California Aqueduct, which is also within the SWSA. Groundwater quality is generally suitable for agricultural uses within the Management Area, except for the far western portion of the Management Area where naturally-occurring salinity affects groundwater quality, and therefore no SMCs are defined, and no P/MAs are proposed to address effects related to this Sustainability Indicator.

17.1.3. Benefit Categories

☑ 23 CCR § 354.44(b)(5)

The primary water management "tools" (i.e., authorities) by which Groundwater Sustainability Agencies (GSAs) can address conditions that may lead to Undesirable Results associated with water quantity (i.e., Chronic Lowering of Groundwater Levels and Reduction of Groundwater Storage) pertain to management of inflows (supplies) and outflows (demands). Therefore, the primary categories of expected benefits for these water quantity-related P/MAs are:

- Water supply augmentation, including
    - Wet year supplies
    - Other (i.e. all year) new supplies; and
- Water demand reduction.

All of the P/MAs have a water quantity-related benefit relating to at least one of those two primary categories. In addition, some P/MAs also have secondary benefits, including:

- Water quality improvement; and
- Water management flexibility/efficiency.

17.1.4. Implementation Glide Path

☑ 23 CCR § 354.44(d)

As stated above, the goals and objectives of the P/MAs presented herein are to address any existing or potential Undesirable Results by the GSP implementation deadline for the Kern County Subbasin (Kern Subbasin) (i.e., by January 2040). As such, P/MAs will be implemented incrementally on an as-needed basis to achieve this goal. While the exact schedule and timetable for implementation of individual P/MAs is not known at this time, a general implementation schedule, also known as a "glide path", has been developed and is summarized in **Table PMA-2**. This preliminary "glide path" aims to address a certain percentage of the projected deficit during each five-year period through 2040, which in turn will affect conditions of the relevant Sustainability Indicators based on the assumption that those conditions are directly related to the balance of supplies and demands within the Wheeler Ridge-Maricopa Management Area. The "glide path" also includes a preliminary estimate of the supply augmentation and/or demand reduction measures necessary to address the projected deficit specified under the 2070 Climate Change Scenario by the end of the 50-year GSP planning and implementation horizon (i.e., January 2070).

Table PMA-2. General Project and Management Actions Implementation Schedule ("Glide Path")

		P/MA Implementation Schedule				
		By 2025	**By 2030**	**By 2035**	**By 2040**	**By 2070**
Projected Deficit [1] (AFY)		21,400				33,300
Target Deficit Reduction (%)		15%	45%	75%	100%	100%
Target Deficit Reduction (AFY)		3,200	9,600	16,100	21,400	33,300
P/MA Benefits, by Type (AFY)						
Water Supply Augmentation	Wet Year Supplies	896	2,688	4,508	5,992	5,992
	Other New Supplies	1,024	3,072	5,152	6,848	12,798
Demand Reduction		1,280	3,840	6,440	8,560	14,510
Total P/MA Benefits		**3,200**	**9,600**	**16,100**	**21,400**	**33,300**

Abbreviations:
AFY = acre-feet per year
P/MA = Project and Management Actions

Notes:
1. Projected Deficit to be addressed by implementation of P/MAs up to 2040 is the net water supply shortfall based on the 2030 Climate Change Scenario. Projected Deficit to be addressed by future P/MA implementation beyond 2040 (i.e., up to 2070) is the net water supply shortfall based on the 2070 Climate Change Scenario.
2. In the 2025 through 2040 periods, 60% of the target deficit reduction is met by Water Supply Augmentation P/MAs and the remaining 40% may be met by Demand Reduction P/MAs as necessary. In the period from 2040 through 2070, 50% of the additional target deficit reduction is met with Water Supply Augmentation P/MAs, and the remaining 50% with Demand Reduction P/MAs as necessary.

17.2. List of Projects and Management Actions

☑ 23 CCR § 354.44(b)(1)

This section provides a list of the P/MAs identified by WRMWSD, divided into the two primary benefit categories discussed above, both of which address the Chronic Lowering of Groundwater and Reduction of Groundwater Storage Sustainability Indicators. Within these two categories, the P/MAs are further classified into five types based on the mechanism by which the primary benefit is achieved. Details of the P/MAs are provided in **Table PMA-1**.

17.2.1. Water Supply Augmentation Projects

The Projects listed below have supply augmentation as their primary expected benefit, and include Projects to Enhance Recharge/Banking, Projects to Increase Water Management Flexibility, and Projects to Develop New Supplies.

Projects to Enhance Recharge/Banking

1. On-Farm Recharge[80]
2. In-District District Banking Facilities
3. Increase Out-of-District Banking Operations

Projects to Increase Water Management Flexibility

4. Expand District Distribution System

Projects to Develop New Supplies

5. Purchase Additional Supplies
6. Desalination Facilities
7. "Thru Delta" Facility

17.2.2. Water Demand Reduction Management Actions

The Management Actions listed below have water demand reduction as their primary expected benefit and include Management Actions / Policies to Raise Funds to Support Sustainable Groundwater Management Act (SGMA) Compliance and Management Actions / Policies to Reduce Groundwater Pumping.

Management Actions to Raise Funds to Support SGMA Compliance

8. Acreage Assessment

Management Actions / Policies to Reduce Groundwater Pumping

9. Groundwater Allocation and Market
10. Voluntary Pumping Limitations
11. Mandatory Pumping Limitations
12. Land Retirement

17.3. Circumstances for Implementation

☑ 23 CCR § 354.42(b)(1)(A)

Using the portfolio approach, P/MAs will be selected for implementation based on further consideration of the magnitude of expected benefit, the relative cost and ease of implementation, and other factors.

[80] As discussed in Section **7.3.4 Recharge and Discharge Areas**, much of the District, especially the southern portion, has surface conditions deemed suitable for recharge (see **Figure HCM-19**).

Some P/MAs will be implemented immediately upon adoption of the GSP. Others will be implemented when grant funds are obtained or upon completion of feasibility studies, economic evaluations, and/or other necessary planning studies. A key precursor to implementing some of the P/MAs will be renegotiation and modification to the contracts between the District and landowners to allow for certain funding and assessment provisions, and to allow greater flexibility in the types of water supplies that the District can purchase. Renegotiation of the contracts will be pursued by the District's Board immediately upon adoption of the GSP.

As discussed above, an overall P/MA implementation schedule, or "glide path" has been developed that serves as a framework to guide the level of benefits that are planned to be achieved over the GSP implementation period (i.e., until 2040), and further through the SGMA planning and implementation horizon (i.e., through 2070). Accelerated implementation of P/MAs (i.e., at expected benefit accrual rates faster than those shown in **Table PMA-2** above) will be triggered if Minimum Thresholds for Chronic Lowering of Groundwater Levels are exceeded in more than 20% of (i.e., at least 3 out of 14) of Representative Monitoring Sites.

17.4. Public Notice Process

☑ 23 CCR § 354.42(b)(1)(B)

Public notice requirements vary for the different P/MAs listed above. Some projects that involve infrastructure improvements only may not require specific public noticing (other than that related to construction), whereas certain other management actions that involve, for example, imposition of fees by WRMWSD, may require public noticing pursuant to Proposition 218 or Proposition 26. In general, P/MAs being considered for implementation will be discussed during regular WRMWSD Board Meetings which are open to the public. Additional stakeholder outreach efforts will be conducted prior to and during P/MA implementation, as required by law.

17.5. Addressing Overdraft Conditions

☑ 23 CCR § 354.44(b)(2)

As discussed in **Section 9.2.4 *Overdraft Conditions***, the Wheeler Ridge-Maricopa Management Area as a whole does not have a net water budget deficit over the historical period based on the Management Area-specific spreadsheet water budget model.[81] However, groundwater levels in some areas, both inside and outside of the SWSA, have shown decreasing trends in recent years, suggesting a local imbalance of supplies versus pumping over this period (which includes a significant drought period). Furthermore, the projected water budget indicates that under the 2030 Climate Change Scenario, imported water supplies to the Management Area may be reduced, resulting in a net deficit of approximately -21,400 AFY. The P/MAs presented herein are expected to result in benefits (discussed below) that will address the projected deficit so as to avoid Undesirable Results and achieve sustainability.

[81] Prior to the start of water importation into the WRMWSD area in 1971, groundwater levels were in a state of chronic decline.

17.6. Permitting and Regulatory Process

☑ 23 CCR § 354.44(b)(3)

Permitting and regulatory requirements vary for the different P/MAs depending on whether they are infrastructure projects, recharge projects, demand reduction management actions, and so forth. The various types of permitting and regulatory requirements (not all applicable to every P/MA) include the following:

- Federal
  - National Environmental Policy Act (NEPA) documentation, if federal grant funds are used;
  - National Pollution Discharge Elimination System (NPDES) stormwater program permit (administered by the California State Water Resources Control Board [SWRCB]);
- State
  - California Environmental Quality Act (CEQA) documentation, including one or more of the following: Initial Study (IS), Categorical Exemption (CE), Negative Declaration (ND), Mitigated Negative Declaration (MND), Environmental Impact Report (EIR);
  - California State Water Resources Control Board permits and regulations regarding recycled water use, waste discharge, and stormwater capture for recharge;
- Regional
  - San Joaquin Valley Air Pollution Control District (SJVAPCD) permit and regulations;
- County/Local
  - Encroachment permits – Kern County, Caltrans, and others;
  - Kern County grading permit.

Specific currently-identified permitting and regulatory requirements for each P/MA are listed in **Table PMA-1**. Upon implementation of any P/MA, the regulatory and permitting requirements of the P/MA will be re-examined.

17.7. Status and Implementation Timetable

☑ 23 CCR § 354.44(b)(4)

With a few exceptions, the current status of P/MAs listed in **Table PMA-1** is "not yet initiated". As discussed above in **Section 17.3 *Circumstances for Implementation***, P/MAs related to water quantity will be initiated in a manner and sequence that achieves the "glide path" level of expected benefits shown in **Table PMA-2**, with accelerated implementation if Minimum Thresholds for Chronic Lowering of Groundwater Levels are exceeded in more than 20% (i.e., at least 3 out of 14) of Representative Monitoring Sites. **Table PMA-1** presents preliminary estimates of the time required to complete/implement each P/MA and a timetable for accrual of expected benefits. These estimates will be refined, as necessary, upon further evaluation of the P/MAs.

17.8. Expected Benefits

☑ 23 CCR § 354.44(b)(5)

The different categories of expected benefits are presented above in **Section 17.1.3 *Benefit Categories***, and the specific expected benefits of each P/MA are presented in **Table PMA-1**. Below is a discussion of how the expected benefits will be evaluated.

17.8.1. Evaluation of Benefits

Each of the P/MAs has expected benefits related to water quantity. Once a P/MA is implemented, it is important for there to be a way to evaluate, ideally to quantify, the benefits resulting from that P/MA. The way in which P/MA benefits are evaluated/quantified depends on the P/MA type. For those P/MAs that involve direct supply augmentation, the benefit is quantified directly through measurement of those flows and corresponding response in water levels. For P/MAs that involve indirect supply augmentation through, for example, increased delivery flexibility, quantification of the benefit will require a comparison of the observed water supply condition (e.g., total imported water) For P/MAs that involve water demand reduction the benefit will be evaluated by comparison of the observed water demand condition (e.g., irrigated acreage) against a hypothetical condition where the P/MA was not in place. Because it is not possible to determine with certainty what the condition without the P/MA would be like, quantification of the benefits is inherently uncertain.

As discussed above, although the P/MAs described herein are laid out along a general timetable defined by incremental elimination of water budget deficits (i.e., the "glide path"), the goals and objectives of P/MA implementation are not necessarily to achieve a certain water budget outcome, but rather to ensure that Undesirable Results for relevant Sustainability Indicators are avoided by the end of the SGMA implementation period (i.e., by 2040). For this reason, ultimately the success of the collective implementation of P/MAs will be determined by whether the Sustainability Goal is achieved.

17.8.2. Evaluation Relative to Water Level Sustainability Criteria

As mentioned in **Section 9 *Water Budget Information***, as part of its involvement in the KGA GSA, WRMWSD is participating in the development of a numerical groundwater water flow model for the Kern Subbasin based on DWR's California Central Valley Groundwater-Surface Water Simulation beta fine-grid model (C2VSim-FG). As part of this process, all Basin GSAs were asked to input their proposed P/MAs into the Baseline and 2030 Climate Change C2VSim-FG projected model scenarios to assess water level responses to GSP implementation relative to proposed Water Level Sustainability Criteria defined for each GSA/Management Area (see **Sections 14.1** and **15.1**). As demonstrated in **Figure PMA-1**, for each of the fifteen water level Representative Monitoring Sites within the Wheeler Ridge-Maricopa Management Area, groundwater elevations are expected to meet their Minimum Thresholds under P/MA implementation in both the Baseline and 2030 Climate Change Scenarios. In all cases, water levels are also maintained at or above the Measurable Objectives upon full P/MA implementation. The results of this Basin-wide projected modeling exercise thus further support the notion that the proposed P/MA implementation strategy is expected to result in sustainable management of groundwater levels within the Wheeler Ridge-Maricopa Management Area.

17.9. Source and Reliability of Water from Outside WRMWSD

☑ 23 CCR § 354.44(b)(6)

Several of the P/MAs discussed below and shown in **Table PMA-1** rely on additional water supplies from outside of the WRMWSD area. Specifically, certain P/MAs rely on the availability of water during wet years to conduct managed recharge, banking inside and outside of the District, and offset groundwater pumping. As discussed in **Section 9.4 *Projected Water Budget***, the volume of SWP supplies is anticipated to decrease under the 2030 Climate Change Scenario relative to the historical water budget period (Water Year [WY] 1995 – 2014) and the Baseline Scenario, and that decrease is the main cause of the projected deficit. However, the District understands that additional wet year supplies may be available, if sufficient infrastructure is developed to take it in (within or outside of the District). Furthermore, the District is an active participant in the various surface water transfer, exchange and purchase markets in the Central Valley and will continue those efforts.

The District is also participating in efforts to develop several new surface water supplies that would provide a more regular (i.e., year to year) source of supply, to be conveyed through the California Aqueduct. These potential additional sources of supply include the following:

- Sites Reservoir Project; and
- Water Fix and Eco Restore (formerly known as the Bay Delta Conservation Plan, referred to in **Table PMA-1** as the "Thru Delta" Facility).

17.10. Legal Authority Required

☑ 23 CCR § 354.44(b)(7)

WRMWSD is a Participating Member of the KGA GSA, which is organized as a joint powers authority. WRMWSD, as a water storage district, possesses the legal authority to implement the supply augmentation P/MAs discussed herein. As a GSA, per California Water Code (CWC) § 10725 through 10726.8, the KGA GSA possesses the legal authority outlined in necessary to implement the demand management P/MAs described herein and will either act upon WRMWSD's behalf to enforce these P/MAs as necessary or will delegate authority to WRMWSD itself to enforce the GSP within the Wheeler Ridge-Maricopa Management Area. As mentioned above, the District will pursue renegotiation of landowner contracts as one of the initial steps of GSP implementation.

17.11. Estimated Costs and Plans to Meet Them

☑ 23 CCR § 354.44(b)(8)

Estimated costs for each P/MA are presented in **Table PMA-1**. Given the uncertainty in the scope and timing of these P/MAs, in some cases the costs are presented as ranges, and in all cases are considered approximate subject to refinement. These costs include "one-time" costs and ongoing costs. The one-time costs may include capital costs associated with construction, feasibility studies, permitting, environmental (CEQA) compliance, or any other costs required to initiate a given P/MA. The ongoing costs are associated with operations and maintenance (O&M) of facilities, costs for purchased water supplies, and/or costs to otherwise continue implementing a given P/MA. It should be noted that depending on the source and

nature of funding for the P/MAs, the one-time costs may or may not be incurred entirely at the beginning of the P/MA; in some instances, loans or other financing options may allow for spreading out of "one-time" costs over time.

Potential sources of funding for the various P/MAs are also presented in **Table PMA-1**, and include the following:

- WRMWSD funds, generally supported by fees charged to landowners within WRMWSD, including potentially the following:
    - General fund
    - SGMA compliance subaccount
- Partnering agencies for certain P/MAs
- Grant funding from sources including DWR and others
- Other

Upon implementation of any given P/MA, the available funding sources for that P/MA will be re-examined.

17.12. Management of Recharge and Groundwater Extractions

☑ 23 CCR § 354.44(b)(9)

As stated previously in **Section 9 *Water Budget Information***, under historical conditions (WY 1995 – 2014), the Wheeler-Ridge Maricopa Management Area is in a state of approximate water supply/demand balance (i.e., with a moderate net surplus of approximately 3,300 AFY, based on the Management Area-specific spreadsheet water budget model). Under the Baseline and 2030 (and 2070) Climate Change Scenarios, however, a net water supply deficit is projected to occur. That projected deficit is due, in large part, to a projected reduction in imported water supplies. However, as discussed above, one of the primary means by which the deficit will be addressed is through the implementation of P/MAs that obtain additional outside sources of water, in particular during normal to wet years. Most of the supply augmentation projects discussed herein and shown on **Table PMA-1** take advantage of additional wet year supplies that are assumed to be available once demands increase. These P/MAs include various direct recharge projects and projects that increase storage capacity and delivery flexibility.

In addition to these supply augmentation projects, the portfolio also includes policy-based management actions aimed at demand reduction. Some of these management actions aim to reduce overall water demand, and others are more specifically focused on reducing groundwater pumping. These management actions will rely initially on financial incentives (e.g., tiered pricing and/or fees) to drive voluntary demand reduction, but also include setting of mandatory groundwater pumping allocations, if necessary. A groundwater allocation program would likely include mechanisms to allow for trading or exchange of pumping allocations, subject to constraints dictated by groundwater conditions observed within the Monitoring Network and policies developed by the WRMWSD Board. Through this combination of increased recharge during wet years and as-needed demand reduction, WRMWSD's P/MA efforts will ensure that chronic lowering of groundwater levels and storage during drought will be offset by increases in groundwater levels and storage during other periods.

Table PMA-1
Details of Projects and Management Actions
Wheeler Ridge-Maricopa Water Storage District
Kern Subbasin Management Area

P/MA Number	P/MA Name	Summary Description	Relevant Sustainability Indicators Affected			Circumstances for Implementation	Public Noticing Process	Permitting and Regulatory Process Requirements	Status	Timetable / Circumstances for Initiation
			Groundwater Levels & Storage	Groundwater Quality	Land Subsidence					
Projects to Enhance Recharge / Banking										
1	**On-Farm Recharge**	Study and implement on-farm recharge where viable.	•	•		To be implemented upon adoption of WRMWSD GSP Chapter	Regular District Board meetings	CEQA	Not yet initiated	2020
2	**In-District Banking Facilities**	Program to promote private and/or District-owned banking facilities within the District.	•	•		To be implemented upon adoption of WRMWSD GSP Chapter	Regular District Board meetings	CEQA	Not yet initiated	2020
3	**Increase Out-of-District Banking Operations**	Increase size/participation in out-of-District banking facilities (i.e., Kern Water Bank and Pioneer Project). Increased banking of wet year supplies outside of the District would support deliveries of imported water into the District in normal/dry years.	•	•		To be implemented upon adoption of WRMWSD GSP Chapter	Regular District Board meetings	CEQA	Not yet initiated	2020
Projects to Increase Water Management Flexibility										
4	**Expand District Distribution System**	Project to expand District distribution system into area currently using only private groundwater.	•	•	•	upon modification of water service contracts	Regular District Board meetings	CEQA	Not yet initiated	TBD
Projects to Develop New Supplies										
5	**Purchase Additional Supplies**	Continue purchase of additional supplies, as available, for banking outside of the District or direct delivery within the District.	•	•	•	Ongoing	Regular District Board meetings	CEQA	Ongoing	Ongoing
6	**Desalination Facilities**	Desalination facilities to allow for use of additional poor quality groundwater for agricultural use, easing demand on principal aquifer.	•	•	•	Localized pumping lowering GW levels near MT	Regular District Board meetings	CEQA	Not yet initiated	TBD
7	**"Thru Delta" Facility**	Particpation of some sort of "Thru Delta" Facility to increase access to contracted (SWP) supplies.	•	•	•	State-led effort underway	Prop 218	CEQA	State-led effort underway	Underway
Management Actions to Raise Funds to Support SGMA Compliance										
8	**Acreage Assessment**	Set policy to implement an acreage assessment to fund purchase of additional supplies, purchase of land for fallowing, and other investments to support SGMA compliance.	•		•	To be implemented upon adoption of WRMWSD GSP Chapter	Prop 218	CEQA	Not yet initiated	2020

Table PMA-1
Details of Projects and Management Actions
Wheeler Ridge-Maricopa Water Storage District
Kern Subbasin Management Area

P/MA Number	P/MA Name	Timetable for Completion	Timetable for Accrual of Expected Benefits	Expected Benefits				Source(s) of Water, if applicable	Legal Authority Required	Estimated Costs		
				Primary		Secondary						
				Water Supply Augmentation	Water Demand Reduction	Water Quality Improvement	Water Management Flexibility / Efficiency			One-time Costs	Ongoing Costs (per year)	Potential Funding Source(s)
Projects to Enhance Recharge												
1	**On-Farm Recharge**	TBD; depending on grower interest	First wet year after construction	approx. 2,000 AFY (10,000 AF every five years)		•	•	Additional wet-year imported water supplies	None	CEQA Costs <$50K	Costs tied to water purchases plus pumping costs (~ $50/AF)	WRMWSD
2	**In-District Banking Facilities**	construction duration: TBD	First wet year after construction	approx. 2,000 AFY (10,000 AF every five years)	approx. 2.75 AFY per acre of land converted to basins	•	•	Additional wet-year imported water supplies	None	Approx. $40K per acre for land purchase and recharge basin construction	Costs tied to water purchases plus pumping costs (~ $50/AF)	WRMWSD
3	**Increase Out-of-District Banking Operations**	construction duration: TBD	First wet year after construction	TBD; depends on recharge basin area		•	•	Additional wet-year supplies	None	Approx. $40K per acre for land purchase and recharge basin construction	Costs tied to water purchases plus pumping costs (~ $50/AF)	WRMWSD
Projects to Increase Water Management Flexibility												
4	**Expand District Distribution System**	construction duration: TBD	First wet year after construction	approx. 2,000 AFY		•	•	Additional wet-year imported water supplies	District authority as a Water Storage District	approx. $18M for 2,000 acre SWSA expansion	Costs tied to water purchases plus pumping costs (~ $50/AF)	WRMWSD; grants
Projects to Develop New Supplies												
5	**Purchase Additional Supplies**	Ongoing	Immediately	Increase purchases by 5,000 AFY		•		Additional imported water supplies	District authority as a Water Storage District	NA	District has been an active purchaser of additional supplies for some time. Average costs are approx. $500/AF.	WRMWSD
6	**Desalination Facilities**	construction duration: 1-3 years	Immediately upon completion of construction	No net supply augmentation, but minimizes local GW pumping impacts		•		poor-quality (currently unused) groundwater	None	NA	Annual costs approximately $600/AF	WRMWSD; grants
7	**"Thru Delta" Facility**	2035	1 year after completion	up to 25,000 AFY		•		State Water Project	None	NA; as this Project would be bonded through SWP, costs would occur on annual bills	TBD; estimates of Cal WaterFix Project were >$600/AF	WRMWSD
Management Actions / Policies to Reduce Overall Water Demand												
8	**Acreage Assessment**	upon modification of water service contracts	1-3 years after completion		•			NA	District authority as a Water Storage District	approx. $50,000 to set up program	This management action would be used to fund other P/MA	WRMWSD; grants

PLAN IMPLEMENTATION

18. WRMWSD PLAN IMPLEMENTATION

☑ 23 CCR § 351(y)

Per the GSP Emergency Regulations, "plan implementation" refers to "an [Groundwater Sustainability] Agency's exercise of the powers and authorities described in the Act, which commences after an Agency adopts and submits a Plan or Alternative to the Department and begins exercising such powers and authorities" (23 CCR § 351(y)). This section describes the activities that will be performed by Wheeler Ridge-Maricopa Water Storage District (WRMWSD or District) as part of GSP implementation within the Wheeler Ridge-Maricopa Management Area, with a focus on the first five years. This section does not address any actions by other entities with potential management authority in the Management Area – i.e., the Kern Groundwater Authority (KGA) Groundwater Sustainability Agency (GSA).

Key GSP implementation activities to be undertaken by the District over the next five years include:

- Monitoring and data collection;
- Data gap filling;
- Projects & Management Action (P/MA) implementation, including policy development to support GSP implementation;
- Technical and non-technical coordination with other water management entities within the Kern County Subbasin (Kern Subbasin);
- Continued outreach and engagement with stakeholders;
- Annual reporting;
- Enforcement and response actions, as necessary; and
- Evaluation and updates, as necessary, of the District's MA Plan as part of the required periodic evaluations (i.e., "five-year updates").

Each of these activities is discussed in more detail below.

18.1. Monitoring and Data Collection

As discussed in **Section 16 *Monitoring Network***, successful sustainable groundwater management relies on a foundation of data to support decision making. As such, collection of data within the Wheeler Ridge-Maricopa Management Area will be a key part of GSP implementation. These data collection efforts include data on applicable sustainability indicators to be collected from the networks of Representative Monitoring Sites (RMS), as well as other data and information required for management and reporting under the Sustainable Groundwater Management Act (SGMA), as described below.

Monitoring of Applicable Sustainability Indicators

Section 16 *Monitoring Network* discusses the monitoring networks (i.e., Representative Monitoring Sites) and protocols that will be used for the applicable sustainability indicators within the Wheeler Ridge-Maricopa Management Area, including Chronic Lowering of Groundwater Levels, Reduction of Groundwater Storage (using groundwater levels as a proxy), and Land Subsidence. Those protocols will be followed in the defined networks as part of GSP implementation. Data collected will be incorporated into the District's own Data Management System (DMS) for subsequent inclusion in the basin-wide DMS. These data will be used to support coordination efforts within the KGA GSA and the Kern Subbasin (e.g., as part of Annual Reports; see **Section 18.5 *Annual Reporting***).

Monitoring results will be evaluated against applicable Sustainable Management Criteria (SMCs; i.e., Undesirable Results, Minimum Thresholds, and Measurable Objectives) to support local management efforts. In addition, although no SMCs are defined at this time for Degraded Water Quality, a network of water quality monitoring sites and sampling protocols have been established within the Wheeler Ridge-Maricopa Management Area. Those data collection activities will also be conducted to support improved local understanding and groundwater management decisions. If it is determined in the future that SMCs are warranted for this Sustainability Indicator, the MA Plan will be amended as such.

The District anticipates that within the first five years of GSP implementation (i.e., in the 2020 – 2025 timeframe), the following efforts related to monitoring will be performed:

- Refinement of the local DMS to comply with the basin-wide DMS;
- Refinement of the Monitoring Network, including potentially adding, replacing or drilling new wells and/or video-logging to collect missing screen/depth info of Representative Monitoring Sites with data existing data gaps (see **Section 16.4 *Assessment and Improvement of Monitoring Network***);
- Semi-annual monitoring for water levels at the RMS, with the potential for more frequent (i.e., monthly) monitoring and/or monitoring of additional well sites;
- Annual monitoring for water quality at the RMS, with the potential for monitoring of additional well sites; and
- Compilation and review of publicly available subsidence data.

Collection of Other Required Information

Besides the data on Sustainability Indicators described above, collection and reporting of other types of information is required under SGMA (see further discussion below in **Section 18.5 *Annual Reporting***). These other types of information include:

- Groundwater extraction information; and
- Surface water supply data

Groundwater extraction information will be quantified for inclusion in the Annual Reports through methods described in the Coordination Agreement and Appendices thereto.

Surface water supply data will be based on metered diversions at each of the turnouts off the California Aqueduct. All surface water delivered into the Wheeler Ridge-Maricopa Management Area will have a

source/type (e.g., State Water Project [SWP], Kern River, Central Valley Project [CVP], or other) assigned to it to facilitate basin-wide accounting of these supply sources.[82]

Data Gap Filling

The District will prioritize and begin to fill the key data gaps identified in this MA Plan related to the hydrogeologic conceptual model, groundwater conditions, and water budgets, among other things. Such efforts will include, but not be limited to, validating the status of existing wells, refining the water budget parameters based on additional data and modeling, collecting additional data related to aquifer conditions and properties, and conducting additional data compilation and analysis of groundwater conditions information using sources identified in **Appendix E** and other public datasets as they become available (e.g., California Department of Fish and Wildlife's new "Critical Species Lookbook" dataset[83]).

18.2. Project and Management Action Implementation

A main part of GSP implementation will be the implementation of P/MAs to address and prevent potential Undesirable Results. As described in **Section 17 *Projects and Management Actions***, a portfolio of P/MAs has been developed with the goal of addressing the relevant Sustainability Indicators in the specific areas of concern within the Wheeler Ridge-Maricopa Management Area, and each P/MA in the portfolio has certain expected benefits. **Table PMA-1** provides the required details about each P/MA, including the circumstances under which they will be implemented.

For many of the P/MAs shown in **Table PMA-1**, initial steps in implementation will include performing various studies or analyses to refine the concepts into actionable projects and/or policies[84]. Studies and work efforts may include, but are not limited to, the following:

- White papers exploring policy options;
- California Environmental Quality Act (CEQA) studies and documentation;
- Engineering feasibility studies and preliminary design reports;
- Financial and/or economic analysis such as Proposition 218 studies; and
- Legal analyses.

Once the necessary initial studies are completed, P/MAs will undergo, as necessary, final engineering design (in the case of infrastructure projects) and final drafting (in the case of policy-based actions). At that point, construction of projects and/or adoption of policies will occur, followed by ongoing operations and maintenance (O&M), as necessary. It is anticipated that each implemented P/MA will have its own set of monitoring or data collection components to allow for P/MA assessment and, if necessary, modification.

[82] The District's sole contractual source for imported water supplies is for SWP supplies through the Kern County Water Agency (KCWA). However, the District also obtains water through various exchanges, transfers and sales of water from other sources from time to time.
[83] https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/
[84] Studies conducted in support of P/MA implementation will be based on the best available data and science.

The District anticipates that within the first five years of GSP implementation (i.e., in the 2020 – 2025 timeframe), the following efforts related to P/MA implementation will be performed:

- Initiate study, permitting (i.e., CEQA), and implementation of on-farm recharge (P/MA #1);
- Initiate program to promote private and/or District-owned banking facilities within the District (P/MA #2);
- Explore options to increase size/participation in out-of-District banking facilities (P/MA #3);
- Initiate feasibility and engineering studies to expand the District's distribution system to areas currently using only private groundwater (P/MA #4);
- Actively participate in the local, regional and state-wide water market(s) to secure additional short- and long-term surface water supplies through exchanges, trades, and sales (P/MA #5);
- Actively participate in the efforts supporting the "Thru-Delta" facility (P/MA #7);
- Initiate re-negotiation of the District's landowner contracts to provide, among other things, greater flexibility to the District in terms of water purchase and delivery (in support of P/MA #4 and others) and revenue to support other P/MAs (P/MA #8);
- Initiate study of potential groundwater allocation and market system (P/MA #9); and/or
- Develop policies to implement voluntary pumping limitations (P/MA #10).

18.3. Intrabasin Coordination

Just as this MA Plan has been developed as part of a coordinated GSP process in the Kern Subbasin, coordination amongst all water management entities involved in SGMA in the Kern Subbasin will continue during GSP implementation. This coordination will include both technical and non-technical matters, as discussed below.

18.3.1. Technical Coordination

Continued technical coordination will be critical to ensure that all entities in the Kern Subbasin as a whole approach local groundwater management using a robust shared framework of data, information, and technical assumptions. WRMWSD will coordinate with other water management entities on technical matters including, but not limited to, the following:

- DMS development and maintenance;
- Groundwater model refinement and updates;
- Water budget refinement and collection of supporting data; and
- Basin-wide monitoring and reporting efforts.

18.3.2. Non-Technical Coordination

Non-technical coordination will involve matters related to policy, advocacy, governance, and the like. The District will continue to actively participate in coordination meetings with and amongst fellow KGA members and the other Kern Subbasin GSAs. The WRMWSD Board has also adopted a resolution to become an exclusive GSA for the Wheeler Ridge-Maricopa Management Area and plans to finalize this in early 2020. This GSA formation effort will be conducted in coordination with all other GSAs in the Kern

Subbasin to ensure continued GSA coverage of the Subbasin. Other non-technical coordination activities will be pursued, as necessary.

18.4. Stakeholder Engagement

The District's Stakeholder Communication and Engagement Plan (SCEP; **Appendix C**) is a key part of the MA Plan, and will continue to be refined, updated and executed during GSP implementation. Anticipated stakeholder engagement activities include, but are not limited to:

- Regular SGMA updates during District Board meetings;
- Hosting stakeholder workshops, as needed;
- Posting of relevant announcements and information on the District website; and
- Conducting informational discussions and meetings, as necessary, with interested stakeholders.

Any GSP implementation actions that relate to establishment of allocations of groundwater pumping or "native yield" on a landowner level will be conducted through a robust stakeholder engagement process.

18.5. Annual Reporting

☑ 23 CCR § 356.2(b)(1)(2)(3)

Per the GSP Emergency Regulations, an annual report on basin conditions and GSP implementation status is required to be submitted to the Department of Water Resources (DWR) by April 1 of each year following GSP adoption. These annual reports will be prepared on the basin-level but will require input from each local entity, including from WRMWSD. Activities required at the District level and the Basin level are described below.

18.5.1. District-Level Activities

In support of the annual reporting requirements, the District will provide to the basin-level entity preparing the reports all monitoring data from the RMS in its designated monitoring networks, as well as the other required information discussed in above. The District will also provide review and comment on the draft reports to ensure that local information is properly incorporated into the basin-level reports.

18.5.2. Basin-Level Activities

An entity will be designated at the basin level to compile and consolidate all of the local information into annual reports that meet the requirements of the GSP Emergency Regulations (23 CCR § 356.2).

18.6. Enforcement and Response Actions

Part of successful management involves the ability to adapt and respond to unforeseen or uncertain circumstances. To the extent possible, methods to address foreseeable problems should be developed before those problems arise. It is anticipated that there may need to be actions taken to enforce compliance with the GSP and any policies adopted thereunder. Such actions, if necessary, will be taken in accordance with applicable laws and authorities.

18.6.1. Impacted Well Mitigation Program

In other cases, a response action may be needed that is driven not by a non-compliance concern (e.g., an Undesirable Result), but rather by a physical, social or economic condition that falls outside of the six Sustainability Indicators defined under SGMA. One such condition that may arise is that of wells being impacted by low groundwater levels. Impacts could include dewatering of pumps or dewatering of well screens to the point of significant reduction in production. To address this potential occurrence, an Impacted Well Mitigation Program will be developed whereby a potential remedy will be provided to owners of wells that are demonstrably impacted by groundwater conditions, as defined within the policy. Funding for such a program may be sourced from the WRMWSD general fund or from a dedicated fund supported by a fee on owners of commercial (i.e., agricultural or industrial) supply wells. The program may be modeled after similar programs developed elsewhere in the basin or around the state (e.g., the Kern Water Bank's program]), and may include remedies such as lowering of pumps, deepening of wells, drilling new wells, and support for access to alternative water sources. The program will be developed in coordination with and in consideration of the interests of local stakeholders within the MA Plan area.

18.7. Periodic Evaluations of GSP

☑ **23 CCR § 356.4**

The District will conduct a periodic evaluation of its MA Plan, at least every five years, and will modify the MA Plan as necessary to ensure that the Sustainability Goal defined for the Kern Subbasin (see **Section 12 *Sustainability Goal***) is achieved within the Wheeler Ridge-Maricopa Management Area. The GSP elements that will be covered in the periodic evaluation are described below. It is anticipated that the 2025 plan will require substantial revision, especially on matters related to the water budget, P/MAs and sustainability criteria.

18.7.1. Sustainability Evaluation

This section will evaluate the current groundwater conditions for each applicable sustainability indicator within the Wheeler Ridge-Maricopa Management Area, including progress toward achieving Interim Milestones and Measurable Objectives.

18.7.2. Plan Implementation Progress

This section will evaluate the current implementation status of P/MAs, along with an updated project implementation schedules and any new projects that are not included in this MA Plan.

18.7.3. Reconsideration of GSP Elements

Per 23 CCR § 356.4 (c), elements of the MA Plan, including the Basin Setting, Management Areas, Undesirable Results, Minimum Thresholds, and Measurable Objective, will be reviewed and revised if necessary.

18.7.4. Monitoring Network Description

This section will provide a description of the Monitoring Network, including identification of data gaps, assessment of monitoring network function with an analysis of data collected to date, identification of actions that are necessary to improve the monitoring network, and development of plans or programs to fill data gaps.

18.7.5. New Information

This section will provide a description of significant new information that has been made available since the adoption or amendment of the MA Plan, or the last five-year assessment, including data obtained to fill identified data gaps. As discussed in **Section 18.7.3 *Reconsideration of GSP Elements***, if evaluation of the Basin Setting, Measurable Objective, Minimum Threshold, or Undesirable Results definition warrant changes to any aspect of the MA Plan, these new information would also be included.

18.7.6. Regulations or Ordinances

WRMWSD possesses the legal authority to implement regulations or ordinances related to the MA Plan. This section will provide a description of relevant actions taken by WRMWSD, including a summary of related regulations or ordinances.

18.7.7. Legal or Enforcement Actions

This section will summarize legal or enforcement actions taken by WRMWSD or the KGA GSA in relation to the MA Plan, along with how such actions support sustainability in the Wheeler Ridge-Maricopa Management Area.

18.7.8. Plan Amendments

This section will provide a description of proposed or complete amendments to the MA Plan.

18.7.9. Coordination

This section will describe coordination activities relevant to the Wheeler Ridge-Maricopa Management Area.

19. PLAN IMPLEMENTATION COSTS

☑ 23 CCR § 354.6(e)

Per the GSP Emergency Regulations (23 CCR § 354.6(e) and 354.44(b)(8)), this section provides estimates of the costs to WRMWSD to implement this MA Plan and potential sources of funding to meet those costs.[85]

19.1. Estimated Costs

Costs to the District to implement this MA Plan can be divided into several groups, as follows:

- Costs of local groundwater management activities;
- District's proportional share of costs for basin-wide groundwater management activities; and
- Costs to implement P/MAs, including capital/one-time costs and ongoing costs.

Table PI-1 provides an estimate of the costs for each of the above groups. Costs to implement P/MAs are shown in **Table PI-1** for each main P/MA category; estimated costs for individual P/MAs are provided in **Table PMA-1**.

19.2. Sources of Funding to Meet Costs

As shown in **Table PI-1**, costs for GSP implementation are estimated to be significant – i.e., ranging from approximately $3.8 million to $7.5 million per year on average over the next 20 years. To meet these costs, the District will need to establish new funding sources or increase existing funding sources. SGMA grants GSAs certain financial authorities (California Water Code [CWC] § 10725.4 and 10730 through 10731), including to raise revenue through use of fees, assessments, pump taxes, and other methods to pay for the costs incurred by the GSA for SGMA compliance. The District will likely meet the estimated costs through a combination of the following:

- District revenue from assessments/fees;
- Special assessments/fees for specific projects;
- Grant funding or other financing options; and/or
- Penalties levied on prohibited activities.

20. PLAN IMPLEMENTATION SCHEDULE

This section discusses a general estimated schedule for GSP implementation. The GSP Emergency Regulations do not specifically require that a schedule for GSP implementation over the 20-year implementation period (i.e., 2020 through 2040) be provided, and any such schedule would be subject to

[85] Implementation of this MA Plan is likely to result in additional costs to landowners and stakeholders within the Wheeler Ridge-Maricopa Management Area; however, this section does not attempt to quantify those potential costs, but rather focuses on the costs, and funding sources to meet those costs, for the District.

considerable uncertainty. However, the following factors and constraints inherent to the GSP process guide the schedule for GSP implementation:

- The GSP Emergency Regulations require achievement of the Sustainability Goal (i.e., avoidance of Undesirable Results) within 20 years of GSP adoption, which in the case of the Kern Subbasin means by 2040.
- The P/MA implementation glide path discussed in **Section 17.1.4 *Implementation Glide Path*** above spells out the general schedule for when expected benefits from P/MAs will accrue between 2020 and 2040.
- Annual reports are due on April 1 of the following year.
- Periodic evaluations are required at least every five years, meaning this MA Plan will be updated no later than 31 January 2025.

GSP Chapter Submittal Checklist

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
§ 354.			**Introduction to Plan Contents**					
			This Article describes the required contents of Plans submitted to the Department for evaluation, including administrative information, a description of the basin setting, sustainable management criteria, description of the monitoring network, and projects and management actions.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
SubArticle 1.			**Administrative Information**					
§ 354.2.			**Introduction to Administrative Information**					
			This Subarticle describes information in the Plan relating to administrative and other general information about the Agency that has adopted the Plan and the area covered by the Plan.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.4.			**General Information**					
			Each Plan shall include the following general information:					
(a)			An executive summary written in plain language that provides an overview of the Plan and description of groundwater conditions in the basin.	15:28	ES			
(b)			A list of references and technical studies relied upon by the Agency in developing the Plan. Each Agency shall provide to the Department electronic copies of reports and other documents and materials cited as references that are not generally available to the public.	250:252	References			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10733.2 and 10733.4, Water Code.					
§ 354.6.			**Agency Information**					
			When submitting an adopted Plan to the Department, the Agency shall include a copy of the information provided pursuant to Water Code Section 10723.8, with any updates, if necessary, along with the following information:					
(a)			The name and mailing address of the Agency.	31	3.1			
(b)			The organization and management structure of the Agency, identifying persons with management authority for implementation of the Plan.	31:32	3.2			
(c)			The name and contact information, including the phone number, mailing address and electronic mail address, of the plan manager.	32	3.3			
(d)			The legal authority of the Agency, with specific reference to citations setting forth the duties, powers, and responsibilities of the Agency, demonstrating that the Agency has the legal authority to implement the Plan.	32	3.4			
(e)			An estimate of the cost of implementing the Plan and a general description of how the Agency plans to meet those costs.	32, 248	3.5, 19			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.8, 10727.2, and 10733.2, Water Code.					
§ 354.8.			**Description of Plan Area**					
			Each Plan shall include a description of the geographic areas covered, including the following information:					
(a)			One or more maps of the basin that depict the following, as applicable:					
	(1)		The area covered by the Plan, delineating areas managed by the Agency as an exclusive Agency and any areas for which the Agency is not an exclusive Agency, and the name and location of any adjacent basins.	35:36, 52	5.1.1	PA-1		
	(2)		Adjudicated areas, other Agencies within the basin, and areas covered by an Alternative.	36, 52:54	5.1.2	PA-1:PA-3		

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(3)		Jurisdictional boundaries of federal or state land (including the identity of the agency with jurisdiction over that land), tribal land, cities, counties, agencies with water management responsibilities, and areas covered by relevant general plans.	36, 53	5.1.3	PA-2		
	(4)		Existing land use designations and the identification of water use sector and water source type.	37, 55, 58	5.1.4	PA-4, PA-7		
	(5)		The density of wells per square mile, by dasymetric or similar mapping techniques, showing the general distribution of agricultural, industrial, and domestic water supply wells in the basin, including de minimis extractors, and the location and extent of communities dependent upon groundwater, utilizing data provided by the Department, as specified in Section 353.2, or the best available information.	37:38, 57	5.1.5	PA-6		
(b)			A written description of the Plan area, including a summary of the jurisdictional areas and other features depicted on the map.	35:38, 56, 272:273	5.1, Appendix B	PA-5		
(c)			Identification of existing water resource monitoring and management programs, and description of any such programs the Agency plans to incorporate in its monitoring network or in development of its Plan. The Agency may coordinate with existing water resource monitoring and management programs to incorporate and adopt that program as part of the Plan.	38:42	5.2.1			
(d)			A description of how existing water resource monitoring or management programs may limit operational flexibility in the basin, and how the Plan has been developed to adapt to those limits.	42	5.2.2			
(e)			A description of conjunctive use programs in the basin.	42	5.2.3			
(f)			A plain language description of the land use elements or topic categories of applicable general plans that includes the following:					
	(1)		A summary of general plans and other land use plans governing the basin.	43:45	5.3			
	(2)		A general description of how implementation of existing land use plans may change water demands within the basin or affect the ability of the Agency to achieve sustainable groundwater management over the planning and implementation horizon, and how the Plan addresses those potential effects	43:45	5.3			
	(3)		A general description of how implementation of the Plan may affect the water supply assumptions of relevant land use plans over the planning and implementation horizon.	43:45	5.3			
	(4)		A summary of the process for permitting new or replacement wells in the basin, including adopted standards in local well ordinances, zoning codes, and policies contained in adopted land use plans.	45	5.3.2			
	(5)		To the extent known, the Agency may include information regarding the implementation of land use plans outside the basin that could affect the ability of the Agency to achieve sustainable groundwater management.	N/A				Not applicable - no land use plans outside the basin are anticipated to affect WRMWSD's ability to achieve sustainability
(g)			A description of any of the additional Plan elements included in Water Code Section 10727.4 that the Agency determines to be appropriate.	45:47	5.4			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10720.3, 10727.2, 10727.4, 10733, and 10733.2, Water Code.					
§ 354.10.			**Notice and Communication**					
			Each Plan shall include a summary of information relating to notification and communication by the Agency with other agencies and interested parties including the following:					

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(a)			A description of the beneficial uses and users of groundwater in the basin, including the land uses and property interests potentially affected by the use of groundwater in the basin, the types of parties representing those interests, and the nature of consultation with those parties.	47, 275:306	5.5.1, Appendix C			
(b)			A list of public meetings at which the Plan was discussed or considered by the Agency.	47:48, 275:306	5.5.2, Appendix C			
(c)			Comments regarding the Plan received by the Agency and a summary of any responses by the Agency.	48:49, 308:334	5.5.3, Appendix D		PA-1	
(d)			A communication section of the Plan that includes the following:					
	(1)		An explanation of the Agency's decision-making process.	49:50, 275:306	5.5.4, Appendix C			
	(2)		Identification of opportunities for public engagement and a discussion of how public input and response will be used.	49:50, 275:306	5.5.4, Appendix C			
	(3)		A description of how the Agency encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin.	49:50, 275:306	5.5.4, Appendix C			
	(4)		The method the Agency shall follow to inform the public about progress implementing the Plan, including the status of projects and actions.	49:50, 275:306	5.5.4, Appendix C			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.8, 10728.4, and 10733.2, Water Code					
SubArticle 2.			**Basin Setting**					
§ 354.12.			**Introduction to Basin Setting**					
			This Subarticle describes the information about the physical setting and characteristics of the basin and current conditions of the basin that shall be part of each Plan, including the identification of data gaps and levels of uncertainty, which comprise the basin setting that serves as the basis for defining and assessing reasonable sustainable management criteria and projects and management actions. Information provided pursuant to this Subarticle shall be prepared by or under the direction of a professional geologist or professional engineer.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.14.			**Hydrogeologic Conceptual Model**					
(a)			Each Plan shall include a descriptive hydrogeologic conceptual model of the basin based on technical studies and qualified maps that characterizes the physical components and interaction of the surface water and groundwater systems in the basin.	60:96	7	HCM-1:HCM-11	HCM-1:HCM-2	
(b)			The hydrogeologic conceptual model shall be summarized in a written description that includes the following:					
	(1)		The regional geologic and structural setting of the basin including the immediate surrounding area, as necessary for geologic consistency.	60:61	7.1.1			
	(2)		Lateral basin boundaries, including major geologic features that significantly affect groundwater flow.	61	7.1.2			
	(3)		The definable bottom of the basin.	61:64	7.1.3			
	(4)		Principal aquifers and aquitards, including the following information:					
		(A)	Formation names, if defined.	64:69	7.1.4			
		(B)	Physical properties of aquifers and aquitards, including the vertical and lateral extent, hydraulic conductivity, and storativity, which may be based on existing technical studies or other best available information.	64:69	7.1.4			

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
		(C)	Structural properties of the basin that restrict groundwater flow within the principal aquifers, including information regarding stratigraphic changes, truncation of units, or other features.	64:69	7.1.4			
		(D)	General water quality of the principal aquifers, which may be based on information derived from existing technical studies or regulatory programs.	64:69	7.1.4			
		(E)	Identification of the primary use or uses of each aquifer, such as domestic, irrigation, or municipal water supply.	64:69	7.1.4			
	(5)		Identification of data gaps and uncertainty within the hydrogeologic conceptual model	69	7.1.5			
(c)			The hydrogeologic conceptual model shall be represented graphically by at least two scaled cross-sections that display the information required by this section and are sufficient to depict major stratigraphic and structural features in the basin.	69:71 , 86:90	7.2	HCM-12:HCM-14		
(d)			Physical characteristics of the basin shall be represented on one or more maps that depict the following:					
	(1)		Topographic information derived from the U.S. Geological Survey or another reliable source.	71, 91	7.3.1	HCM-15		
	(2)		Surficial geology derived from a qualified map including the locations of cross-sections required by this Section.	71:72, 86	7.3.2	HCM-12		
	(3)		Soil characteristics as described by the appropriate Natural Resources Conservation Service soil survey or other applicable studies.	72, 92:93	7.3.3	HCM-16:HCM-17		
	(4)		Delineation of existing recharge areas that substantially contribute to the replenishment of the basin, potential recharge areas, and discharge areas, including significant active springs, seeps, and wetlands within or adjacent to the basin.	72:73, 94:95	7.3.4	HCM-18:HCM-19		
	(5)		Surface water bodies that are significant to the management of the basin.	73:74, 96	7.3.5	HCM-20		
	(6)		The source and point of delivery for imported water supplies.	56, 74, 115	7.3.6	PA-5, GWC-3		
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10727.2, 10733, and 10733.2, Water Code.					
§ 354.16.			**Groundwater Conditions**					
			Each Plan shall provide a description of current and historical groundwater conditions in the basin, including data from January 1, 2015, to current conditions, based on the best available information that includes the following:					
(a)			Groundwater elevation data demonstrating flow directions, lateral and vertical gradients, and regional pumping patterns, including:					
	(1)		Groundwater elevation contour maps depicting the groundwater table or potentiometric surface associated with the current seasonal high and seasonal low for each principal aquifer within the basin.	99:103, 113:114, 116	8.2	GWC-1:GWC-2, GWC-4	GWC-1	
	(2)		Hydrographs depicting long-term groundwater elevations, historical highs and lows, and hydraulic gradients between principal aquifers.	99:103, 117:120	8.2	GWC-5:GWC-8		
(b)			A graph depicting estimates of the change in groundwater in storage, based on data, demonstrating the annual and cumulative change in the volume of groundwater in storage between seasonal high groundwater conditions, including the annual groundwater use and water year type.	103:105, 121:122	8.3	GWC-9:GWC-10	GWC-2	
(c)			Seawater intrusion conditions in the basin, including maps and cross-sections of the seawater intrusion front for each principal aquifer.	105	8.4			

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(d)			Groundwater quality issues that may affect the supply and beneficial uses of groundwater, including a description and map of the location of known groundwater contamination sites and plumes.	105:109, 123:127, 336:374, 376:385	8.5, Appendix E, Appendix F	GWC-11:GWC-15	GWC-3	
(e)			The extent, cumulative total, and annual rate of land subsidence, including maps depicting total subsidence, utilizing data available from the Department, as specified in Section 353.2, or the best available information.	110:111, 128:129	8.6	GWC-16:GWC-17		
(f)			Identification of interconnected surface water systems within the basin and an estimate of the quantity and timing of depletions of those systems, utilizing data available from the Department, as specified in Section 353.2, or the best available information.	111	8.7			
(g)			Identification of groundwater dependent ecosystems within the basin, utilizing data available from the Department, as specified in Section 353.2, or the best available information.	111:112, 130	8.8	GWC-18		
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.2, 10727.4, and 10733.2, Water Code.					
§ 354.18.			**Water Budget**					
(a)			Each Plan shall include a water budget for the basin that provides an accounting and assessment of the total annual volume of groundwater and surface water entering and leaving the basin, including historical, current and projected water budget conditions, and the change in the volume of water stored. Water budget information shall be reported in tabular and graphical form.	131:176, 387:482	9, Appendix G			
(b)			The water budget shall quantify the following, either through direct measurements or estimates based on data:					
	(1)		Total surface water entering and leaving a basin by water source type.	137:139, 151, 160:161	9.2.1	WB-3:WB-4	WB-2	
	(2)		Inflow to the groundwater system by water source type, including subsurface groundwater inflow and infiltration of precipitation, applied water, and surface water systems, such as lakes, streams, rivers, canals, springs and conveyance systems.	139, 152, 162:163	9.2.2	WB-5:WB-6	WB-3	
	(3)		Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow.	139, 152, 162:163	9.2.2	WB-5:WB-6	WB-3	
	(4)		The change in the annual volume of groundwater in storage between seasonal high conditions.	139:140, 153:155, 164:165	9.2.3	WB-7:WB-8	WB-4:WB-6	
	(5)		If overdraft conditions occur, as defined in Bulletin 118, the water budget shall include a quantification of overdraft over a period of years during which water year and water supply conditions approximate average conditions.	140:141, 153:155	9.2.4		WB-4:WB-6	
	(6)		The water year type associated with the annual supply, demand, and change in groundwater stored.	141:142, 154, 166:167	9.2.5	WB-9:WB-10	WB-5	
	(7)		An estimate of sustainable yield for the basin.	142:143	9.2.6			
(c)			Each Plan shall quantify the current, historical, and projected water budget for the basin as follows:					
	(1)		Current water budget information shall quantify current inflows and outflows for the basin using the most recent hydrology, water supply, water demand, and land use information.	144, 152, 155, 169:170	9.3.1	WB-12:WB-13	WB-3, WB-6	

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(2)		Historical water budget information shall be used to evaluate availability or reliability of past surface water supply deliveries and aquifer response to water supply and demand trends relative to water year type. The historical water budget shall include the following:					
		(A)	A quantitative evaluation of the availability or reliability of historical surface water supply deliveries as a function of the historical planned versus actual annual surface water deliveries, by surface water source and water year type, and based on the most recent ten years of surface water supply information.	133, 144:146, 171, 175	9.3.2	WB-14, WB-18	WB-1	
		(B)	A quantitative assessment of the historical water budget, starting with the most recently available information and extending back a minimum of 10 years, or as is sufficient to calibrate and reduce the uncertainty of the tools and methods used to estimate and project future water budget information and future aquifer response to proposed sustainable groundwater management practices over the planning and implementation horizon.	144:146, 168, 172:175	9.3.2	WB-11, WB-15:WB-18		
		(C)	A description of how historical conditions concerning hydrology, water demand, and surface water supply availability or reliability have impacted the ability of the Agency to operate the basin within sustainable yield. Basin hydrology may be characterized and evaluated using water year type.	144:146, 154, 166:167	9.3.2	WB-9:WB-10	WB-5	
	(3)		Projected water budgets shall be used to estimate future baseline conditions of supply, demand, and aquifer response to Plan implementation, and to identify the uncertainties of these projected water budget components. The projected water budget shall utilize the following methodologies and assumptions to estimate future baseline conditions concerning hydrology, water demand and surface water supply availability or reliability over the planning and implementation horizon:					
		(A)	Projected hydrology shall utilize 50 years of historical precipitation, evapotranspiration, and streamflow information as the baseline condition for estimating future hydrology. The projected hydrology information shall also be applied as the baseline condition used to evaluate future scenarios of hydrologic uncertainty associated with projections of climate change and sea level rise.	140:150, 156:157, 176	9.4	WB-19	WB-7:WB-8	
		(B)	Projected water demand shall utilize the most recent land use, evapotranspiration, and crop coefficient information as the baseline condition for estimating future water demand. The projected water demand information shall also be applied as the baseline condition used to evaluate future scenarios of water demand uncertainty associated with projected changes in local land use planning, population growth, and climate.	140:150, 156:157, 176	9.4	WB-19	WB-7:WB-8	
		(C)	Projected surface water supply shall utilize the most recent water supply information as the baseline condition for estimating future surface water supply. The projected surface water supply shall also be applied as the baseline condition used to evaluate future scenarios of surface water supply availability and reliability as a function of the historical surface water supply identified in Section 354.18(c)(2)(A), and the projected changes in local land use planning, population growth, and climate.	140:150, 156:157, 175	9.4	WB-18	WB-7:WB-8	
(d)			The Agency shall utilize the following information provided, as available, by the Department pursuant to Section 353.2, or other data of comparable quality, to develop the water budget:					
	(1)		Historical water budget information for mean annual temperature, mean annual precipitation, water year type, and land use.	135:136	9.1.2			

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(2)		Current water budget information for temperature, water year type, evapotranspiration, and land use.	135:136	9.1.2			
	(3)		Projected water budget information for population, population growth, climate change, and sea level rise.	135:136, 147:149	9.1.2, 9.4.2			
(e)			Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, climate change, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow. If a numerical groundwater and surface water model is not used to quantify and evaluate the projected water budget conditions and the potential impacts to beneficial uses and users of groundwater, the Plan shall identify and describe an equally effective method, tool, or analytical model to evaluate projected water budget conditions.	134:136	9.1			
(f)			The Department shall provide the California Central Valley Groundwater-Surface Water Simulation Model (C2VSIM) and the Integrated Water Flow Model (IWFM) for use by Agencies in developing the water budget. Each Agency may choose to use a different groundwater and surface water model, pursuant to Section 352.4.	131	9			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10721, 10723.2, 10727.2, 10727.6, 10729, and 10733.2, Water Code.					
§ 354.20.			**Management Areas**					
(a)			Each Agency may define one or more management areas within a basin if the Agency has determined that creation of management areas will facilitate implementation of the Plan. Management areas may define different minimum thresholds and be operated to different measurable objectives than the basin at large, provided that undesirable results are defined consistently throughout the basin.	177	10			
(b)			A basin that includes one or more management areas shall describe the following in the Plan:					
	(1)		The reason for the creation of each management area.	177	10.1			
	(2)		The minimum thresholds and measurable objectives established for each management area, and an explanation of the rationale for selecting those values, if different from the basin at large.	177	10.2			
	(3)		The level of monitoring and analysis appropriate for each management area.	177	10.3			
	(4)		An explanation of how the management area can operate under different minimum thresholds and measurable objectives without causing undesirable results outside the management area, if applicable.	177	10.2			
(c)			If a Plan includes one or more management areas, the Plan shall include descriptions, maps, and other information required by this Subarticle sufficient to describe conditions in those areas.	177	10.1			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10733.2 and 10733.4, Water Code.					
SubArticle 3.			**Sustainable Management Criteria**					
§ 354.22.			**Introduction to Sustainable Management Criteria**					
			This Subarticle describes criteria by which an Agency defines conditions in its Plan that constitute sustainable groundwater management for the basin, including the process by which the Agency shall characterize undesirable results, and establish minimum thresholds and measurable objectives for each applicable sustainability indicator.					

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.24.			**Sustainability Goal**					
			Each Agency shall establish in its Plan a sustainability goal for the basin that culminates in the absence of undesirable results within 20 years of the applicable statutory deadline. The Plan shall include a description of the sustainability goal, including information from the basin setting used to establish the sustainability goal, a discussion of the measures that will be implemented to ensure that the basin will be operated within its sustainable yield, and an explanation of how the sustainability goal is likely to be achieved within 20 years of Plan implementation and is likely to be maintained through the planning and implementation horizon.	30, 179	2, 12			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10721, 10727, 10727.2, 10733.2, and 10733.8, Water Code.					
§ 354.26.			**Undesirable Results**					
(a)			Each Agency shall describe in its Plan the processes and criteria relied upon to define undesirable results applicable to the basin. Undesirable results occur when significant and unreasonable effects for any of the sustainability indicators are caused by groundwater conditions occurring throughout the basin.	180:188, 205:206, 208:209	13	SMC-1:SMC-2, SMC-4:SMC-5	SMC-1	
(b)			The description of undesirable results shall include the following:					
	(1)		The cause of groundwater conditions occurring throughout the basin that would lead to or has led to undesirable results based on information described in the basin setting, and other data or models as appropriate.	180:188	13			
	(2)		The criteria used to define when and where the effects of the groundwater conditions cause undesirable results for each applicable sustainability indicator. The criteria shall be based on a quantitative description of the combination of minimum threshold exceedances that cause significant and unreasonable effects in the basin.	180:188	13			
	(3)		Potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results.	180:188	13			
(c)			The Agency may need to evaluate multiple minimum thresholds to determine whether an undesirable result is occurring in the basin. The determination that undesirable results are occurring may depend upon measurements from multiple monitoring sites, rather than a single monitoring site.	180:188	13			
(d)			An Agency that is able to demonstrate that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin shall not be required to establish criteria for undesirable results related to those sustainability indicators.	180:188	13			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10721, 10723.2, 10727.2, 10733.2, and 10733.8, Water Code.					
§ 354.28.			**Minimum Thresholds**					
(a)			Each Agency in its Plan shall establish minimum thresholds that quantify groundwater conditions for each applicable sustainability indicator at each monitoring site or representative monitoring site established pursuant to Section 354.36. The numeric value used to define minimum thresholds shall represent a point in the basin that, if exceeded, may cause undesirable results as described in Section 354.26.	189:198, 189:190, 203:204, 207	14	SMC-3	SMC-2:SMC-4	
(b)			The description of minimum thresholds shall include the following:					

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(1)		The information and criteria relied upon to establish and justify the minimum thresholds for each sustainability indicator. The justification for the minimum threshold shall be supported by information provided in the basin setting, and other data or models as appropriate, and qualified by uncertainty in the understanding of the basin setting.	189:198	14			
	(2)		The relationship between the minimum thresholds for each sustainability indicator, including an explanation of how the Agency has determined that basin conditions at each minimum threshold will avoid undesirable results for each of the sustainability indicators.	189:198	14			
	(3)		How minimum thresholds have been selected to avoid causing undesirable results in adjacent basins or affecting the ability of adjacent basins to achieve sustainability goals.	189:198	14			
	(4)		How minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests.	189:198	14			
	(5)		How state, federal, or local standards relate to the relevant sustainability indicator. If the minimum threshold differs from other regulatory standards, the Agency shall explain the nature of and basis for the difference.	189:198	14			
	(6)		How each minimum threshold will be quantitatively measured, consistent with the monitoring network requirements described in Subarticle 4.	189:198	14			
(c)			Minimum thresholds for each sustainability indicator shall be defined as follows:					
	(1)		Chronic Lowering of Groundwater Levels. The minimum threshold for chronic lowering of groundwater levels shall be the groundwater elevation indicating a depletion of supply at a given location that may lead to undesirable results. Minimum thresholds for chronic lowering of groundwater levels shall be supported by the following:					
		(A)	The rate of groundwater elevation decline based on historical trends, water year type, and projected water use in the basin.	190:194, 206	14.1	SMC-2		
		(B)	Potential effects on other sustainability indicators.	190:194	14.1			
	(2)		Reduction of Groundwater Storage. The minimum threshold for reduction of groundwater storage shall be a total volume of groundwater that can be withdrawn from the basin without causing conditions that may lead to undesirable results. Minimum thresholds for reduction of groundwater storage shall be supported by the sustainable yield of the basin, calculated based on historical trends, water year type, and projected water use in the basin.	194:195	14.2			
	(3)		Seawater Intrusion. The minimum threshold for seawater intrusion shall be defined by a chloride concentration isocontour for each principal aquifer where seawater intrusion may lead to undesirable results. Minimum thresholds for seawater intrusion shall be supported by the following:					
		(A)	Maps and cross-sections of the chloride concentration isocontour that defines the minimum threshold and measurable objective for each principal aquifer.	196	14.3			
		(B)	A description of how the seawater intrusion minimum threshold considers the effects of current and projected sea levels.	196	14.3			

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(4)		Degraded Water Quality. The minimum threshold for degraded water quality shall be the degradation of water quality, including the migration of contaminant plumes that impair water supplies or other indicator of water quality as determined by the Agency that may lead to undesirable results. The minimum threshold shall be based on the number of supply wells, a volume of water, or a location of an isocontour that exceeds concentrations of constituents determined by the Agency to be of concern for the basin. In setting minimum thresholds for degraded water quality, the Agency shall consider local, state, and federal water quality standards applicable to the basin.	196	14.4			
	(5)		Land Subsidence. The minimum threshold for land subsidence shall be the rate and extent of subsidence that substantially interferes with surface land uses and may lead to undesirable results. Minimum thresholds for land subsidence shall be supported by the following:					
		(A)	Identification of land uses and property interests that have been affected or are likely to be affected by land subsidence in the basin, including an explanation of how the Agency has determined and considered those uses and interests, and the Agency's rationale for establishing minimum thresholds in light of those effects.	197	14.5			
		(B)	Maps and graphs showing the extent and rate of land subsidence in the basin that defines the minimum threshold and measurable objectives.	197, 208, 489:517	14.5	Appendix I	SMC-4, Appendix I	
	(6)		Depletions of Interconnected Surface Water. The minimum threshold for depletions of interconnected surface water shall be the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results. The minimum threshold established for depletions of interconnected surface water shall be supported by the following:					
		(A)	The location, quantity, and timing of depletions of interconnected surface water.	198	14.6			
		(B)	A description of the groundwater and surface water model used to quantify surface water depletion. If a numerical groundwater and surface water model is not used to quantify surface water depletion, the Plan shall identify and describe an equally effective method, tool, or analytical model to accomplish the requirements of this Paragraph.	198	14.6			
(d)			An Agency may establish a representative minimum threshold for groundwater elevation to serve as the value for multiple sustainability indicators, where the Agency can demonstrate that the representative value is a reasonable proxy for multiple individual minimum thresholds as supported by adequate evidence.	194:196	14.2.1			
(e)			An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in Section 354.26, shall not be required to establish minimum thresholds related to those sustainability indicators.	196, 198	14.3,14.6			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.2, 10733, 10733.2, and 10733.8, Water Code.					
§ 354.30.			**Measurable Objectives**					
(a)			Each Agency shall establish measurable objectives, including interim milestones in increments of five years, to achieve the sustainability goal for the basin within 20 years of Plan implementation and to continue to sustainably manage the groundwater basin over the planning and implementation horizon.	199:200, 202:204, 210:211	15	SMC-6:SMC-7	SMC-3:SMC-6	

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(b)			Measurable objectives shall be established for each sustainability indicator, based on quantitative values using the same metrics and monitoring sites as are used to define the minimum thresholds.	199	15			
(c)			Measurable objectives shall provide a reasonable margin of operational flexibility under adverse conditions which shall take into consideration components such as historical water budgets, seasonal and long-term trends, and periods of drought, and be commensurate with levels of uncertainty.	199	15			
(d)			An Agency may establish a representative measurable objective for groundwater elevation to serve as the value for multiple sustainability indicators where the Agency can demonstrate that the representative value is a reasonable proxy for multiple individual measurable objectives as supported by adequate evidence.	200	15.2			
(e)			Each Plan shall describe a reasonable path to achieve the sustainability goal for the basin within 20 years of Plan implementation, including a description of interim milestones for each relevant sustainability indicator, using the same metric as the measurable objective, in increments of five years. The description shall explain how the Plan is likely to maintain sustainable groundwater management over the planning and implementation horizon.	199	15			
(f)			Each Plan may include measurable objectives and interim milestones for additional Plan elements described in Water Code Section 10727.4 where the Agency determines such measures are appropriate for sustainable groundwater management in the basin.	N/A				Not applicable - no additional Plan elements were incorporated into Sustainability Criteria.
(g)			An Agency may establish measurable objectives that exceed the reasonable margin of operational flexibility for the purpose of improving overall conditions in the basin, but failure to achieve those objectives shall not be grounds for a finding of inadequacy of the Plan.	N/A				Not applicable - all measurable objectives tied to reasonable margin of operational flexibility.
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10727.2, 10727.4, and 10733.2, Water Code.					
SubArticle 4.			**Monitoring Networks**					
§ 354.32.			**Introduction to Monitoring Networks**					
			This Subarticle describes the monitoring network that shall be developed for each basin, including monitoring objectives, monitoring protocols, and data reporting requirements. The monitoring network shall promote the collection of data of sufficient quality, frequency, and distribution to characterize groundwater and related surface water conditions in the basin and evaluate changing conditions that occur through implementation of the Plan.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.34.			**Monitoring Network**					
(a)			Each Agency shall develop a monitoring network capable of collecting sufficient data to demonstrate short-term, seasonal, and long-term trends in groundwater and related surface conditions, and yield representative information about groundwater conditions as necessary to evaluate Plan implementation.	212:219, 222, 224:225	16.1	MN-1:MN-2	MN-1:MN-2	
(b)			Each Plan shall include a description of the monitoring network objectives for the basin, including an explanation of how the network will be developed and implemented to monitor groundwater and related surface conditions, and the interconnection of surface water and groundwater, with sufficient temporal frequency and spatial density to evaluate the affects and effectiveness of Plan implementation. The monitoring network objectives shall be implemented to accomplish the following:					

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(1)		Demonstrate progress toward achieving measurable objectives described in the Plan.	212:219	16.1			
	(2)		Monitor impacts to the beneficial uses or users of groundwater.	212:219	16.1			
	(3)		Monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds.	212:219	16.1			
	(4)		Quantify annual changes in water budget components.	212:219	16.1			
(c)			Each monitoring network shall be designed to accomplish the following for each sustainability indicator:					
	(1)		Chronic Lowering of Groundwater Levels. Demonstrate groundwater occurrence, flow directions, and hydraulic gradients between principal aquifers and surface water features by the following methods:					
		(A)	A sufficient density of monitoring wells to collect representative measurements through depth-discrete perforated intervals to characterize the groundwater table or potentiometric surface for each principal aquifer.	214, 224:225	16.1.1	MN-1	MN-1:MN-2	
		(B)	Static groundwater elevation measurements shall be collected at least two times per year, to represent seasonal low and seasonal high groundwater conditions.	214	16.1.1			
	(2)		Reduction of Groundwater Storage. Provide an estimate of the change in annual groundwater in storage.	216, 224:225	16.1.2	MN-1	MN-1:MN-2	
	(3)		Seawater Intrusion. Monitor seawater intrusion using chloride concentrations, or other measurements convertible to chloride concentrations, so that the current and projected rate and extent of seawater intrusion for each applicable principal aquifer may be calculated.	217	16.1.3			
	(4)		Degraded Water Quality. Collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues.	217, 222, 224:225	16.1.4	MN-2	MN-1:MN-2	
	(5)		Land Subsidence. Identify the rate and extent of land subsidence, which may be measured by extensometers, surveying, remote sensing technology, or other appropriate method.	214, 219, 489:517	16.1.5		MN-1, SMC-4, Appendix I	
	(6)		Depletions of Interconnected Surface Water. Monitor surface water and groundwater, where interconnected surface water conditions exist, to characterize the spatial and temporal exchanges between surface water and groundwater, and to calibrate and apply the tools and methods necessary to calculate depletions of surface water caused by groundwater extractions. The monitoring network shall be able to characterize the following:					
		(A)	Flow conditions including surface water discharge, surface water head, and baseflow contribution.	219	16.1.6			
		(B)	Identifying the approximate date and location where ephemeral or intermittent flowing streams and rivers cease to flow, if applicable.	219	16.1.6			
		(C)	Temporal change in conditions due to variations in stream discharge and regional groundwater extraction.	219	16.1.6			
		(D)	Other factors that may be necessary to identify adverse impacts on beneficial uses of the surface water.	219	16.1.6			
(d)			The monitoring network shall be designed to ensure adequate coverage of sustainability indicators. If management areas are established, the quantity and density of monitoring sites in those areas shall be sufficient to evaluate conditions of the basin setting and sustainable management criteria specific to that area.	212:219, 222, 224:225	16.1	MN-1:MN-2	MN-1:MN-2, SMC-3:SMC-4	

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(e)			A Plan may utilize site information and monitoring data from existing sources as part of the monitoring network.	212:219, 222, 224:225	16.1	MN-1:MN-2	MN-2	
(f)			The Agency shall determine the density of monitoring sites and frequency of measurements required to demonstrate short-term, seasonal, and long-term trends based upon the following factors:					
	(1)		Amount of current and projected groundwater use.	212:219	16.1			
	(2)		Aquifer characteristics, including confined or unconfined aquifer conditions, or other physical characteristics that affect groundwater flow.	212:219	16.1			
	(3)		Impacts to beneficial uses and users of groundwater and land uses and property interests affected by groundwater production, and adjacent basins that could affect the ability of that basin to meet the sustainability goal.	212:219	16.1			
	(4)		Whether the Agency has adequate long-term existing monitoring results or other technical information to demonstrate an understanding of aquifer response.	212:219	16.1			
(g)			Each Plan shall describe the following information about the monitoring network:					
	(1)		Scientific rationale for the monitoring site selection process.	212:219, 222	16.1		MN-1:MN-2	
	(2)		Consistency with data and reporting standards described in Section 352.4. If a site is not consistent with those standards, the Plan shall explain the necessity of the site to the monitoring network, and how any variation from the standards will not affect the usefulness of the results obtained.	212:219, 222	16.1		MN-2	
	(3)		For each sustainability indicator, the quantitative values for the minimum threshold, measurable objective, and interim milestones that will be measured at each monitoring site or representative monitoring sites established pursuant to Section 354.36.	200, 202:204, 207, 210:211, 222:223	16.1	SMC-3, SMC-6, SMC-7	SMC-3:SMC-6	
(h)			The location and type of each monitoring site within the basin displayed on a map, and reported in tabular format, including information regarding the monitoring site type, frequency of measurement, and the purposes for which the monitoring site is being used.	212:219, 222, 224:225	16.1	MN-1:MN-2	MN-2	
(i)			The monitoring protocols developed by each Agency shall include a description of technical standards, data collection methods, and other procedures or protocols pursuant to Water Code Section 10727.2(f) for monitoring sites or other data collection facilities to ensure that the monitoring network utilizes comparable data and methodologies.	220	16.2			
(j)			An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in Section 354.26, shall not be required to establish a monitoring network related to those sustainability indicators.	217, 219	16.1.3, 16.1.6			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.2, 10727.4, 10728, 10733, 10733.2, and 10733.8, Water Code					
§ 354.36.			**Representative Monitoring**					
			Each Agency may designate a subset of monitoring sites as representative of conditions in the basin or an area of the basin, as follows:					
(a)			Representative monitoring sites may be designated by the Agency as the point at which sustainability indicators are monitored, and for which quantitative values for minimum thresholds, measurable objectives, and interim milestones are defined.	220	16.3			

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
(b)			(b) Groundwater elevations may be used as a proxy for monitoring other sustainability indicators if the Agency demonstrates the following:					
	(1)		Significant correlation exists between groundwater elevations and the sustainability indicators for which groundwater elevation measurements serve as a proxy.	220	16.3			
	(2)		Measurable objectives established for groundwater elevation shall include a reasonable margin of operational flexibility taking into consideration the basin setting to avoid undesirable results for the sustainability indicators for which groundwater elevation measurements serve as a proxy.	220	16.3			
(c)			The designation of a representative monitoring site shall be supported by adequate evidence demonstrating that the site reflects general conditions in the area.	220	16.3			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10727.2 and 10733.2, Water Code					
§ 354.38.			**Assessment and Improvement of Monitoring Network**					
(a)			Each Agency shall review the monitoring network and include an evaluation in the Plan and each five-year assessment, including a determination of uncertainty and whether there are data gaps that could affect the ability of the Plan to achieve the sustainability goal for the basin.	220	16.4			
(b)			Each Agency shall identify data gaps wherever the basin does not contain a sufficient number of monitoring sites, does not monitor sites at a sufficient frequency, or utilizes monitoring sites that are unreliable, including those that do not satisfy minimum standards of the monitoring network adopted by the Agency.	212:219	16.1			
(c)			If the monitoring network contains data gaps, the Plan shall include a description of the following:					
	(1)		The location and reason for data gaps in the monitoring network.	212:219	16.1			
	(2)		Local issues and circumstances that limit or prevent monitoring.	212:219	16.1			
(d)			Each Agency shall describe steps that will be taken to fill data gaps before the next five-year assessment, including the location and purpose of newly added or installed monitoring sites.	212:219	16.1			
(e)			Each Agency shall adjust the monitoring frequency and density of monitoring sites to provide an adequate level of detail about site-specific surface water and groundwater conditions and to assess the effectiveness of management actions under circumstances that include the following:					
	(1)		Minimum threshold exceedances.	212:219	16.1			
	(2)		Highly variable spatial or temporal conditions.	212:219	16.1			
	(3)		Adverse impacts to beneficial uses and users of groundwater.	212:219	16.1			
	(4)		The potential to adversely affect the ability of an adjacent basin to implement its Plan or impede achievement of sustainability goals in an adjacent basin.	212:219	16.1			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10723.2, 10727.2, 10728.2, 10733, 10733.2, and 10733.8, Water Code					
§ 354.40.			**Reporting Monitoring Data to the Department**					
			Monitoring data shall be stored in the data management system developed pursuant to Section 352.6. A copy of the monitoring data shall be included in the Annual Report and submitted electronically on forms provided by the Department.					
			Note: Authority cited: Section 10733.2, Water Code.

SubArticle 5.			**Projects and Management Actions**					
§ 354.42.			**Introduction to Projects and Management Actions**					
			This Subarticle describes the criteria for projects and management actions to be included in a Plan to meet the sustainability goal for the basin in a manner that can be maintained over the planning and implementation horizon.					
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Section 10733.2, Water Code.					
§ 354.44.			**Projects and Management Actions**					
(a)			Each Plan shall include a description of the projects and management actions the Agency has determined will achieve the sustainability goal for the basin, including projects and management actions to respond to changing conditions in the basin.	226:240	17	PMA-1	PMA-1	
(b)			Each Plan shall include a description of the projects and management actions that include the following:					
	(1)		A list of projects and management actions proposed in the Plan with a description of the measurable objective that is expected to benefit from the project or management action. The list shall include projects and management actions that may be utilized to meet interim milestones, the exceedance of minimum thresholds, or where undesirable results have occurred or are imminent. The Plan shall include the following:					
		(A)	A description of the circumstances under which projects or management actions shall be implemented, the criteria that would trigger implementation and termination of projects or management actions, and the process by which the Agency shall determine that conditions requiring the implementation of particular projects or management actions have occurred.	230	17.3			
		(B)	The process by which the Agency shall provide notice to the public and other agencies that the implementation of projects or management actions is being considered or has been implemented, including a description of the actions to be taken.	231	17.4			
	(2)		If overdraft conditions are identified through the analysis required by Section 354.18, the Plan shall describe projects or management actions, including a quantification of demand reduction or other methods, for the mitigation of overdraft.	231	17.5			
	(3)		A summary of the permitting and regulatory process required for each project and management action.	232	17.6			
	(4)		The status of each project and management action, including a time-table for expected initiation and completion, and the accrual of expected benefits.	232	17.7			
	(5)		An explanation of the benefits that are expected to be realized from the project or management action, and how those benefits will be evaluated.	233	17.8			
	(6)		An explanation of how the project or management action will be accomplished. If the projects or management actions rely on water from outside the jurisdiction of the Agency, an explanation of the source and reliability of that water shall be included.	234	17.9			
	(7)		A description of the legal authority required for each project and management action, and the basis for that authority within the Agency.	234	17.10			
	(8)		A description of the estimated cost for each project and management action and a description of how the Agency plans to meet those costs.	234	17.11			

Article 5.			Plan Contents for Kern County Basin	GSP Document References				
				Page Numbers of Plan	Or Section Numbers	Or Figure Numbers	Or Table Numbers	Notes
	(9)		A description of the management of groundwater extractions and recharge to ensure that chronic lowering of groundwater levels or depletion of supply during periods of drought is offset by increases in groundwater levels or storage during other periods.	235	17.12			
(c)			Projects and management actions shall be supported by best available information and best available science.	226:240	17			
(d)			An Agency shall take into account the level of uncertainty associated with the basin setting when developing projects or management actions.	226:240	17			
			Note: Authority cited: Section 10733.2, Water Code.					
			Reference: Sections 10727.2, 10727.4, and 10733.2, Water Code.

1. INTRODUCTION

> *§ 354.10. Each Plan shall include a summary of information relating to notification and communication by the Agency with other agencies and interested parties including the following:*
> *(a) A description of the beneficial uses and users of groundwater in the basin, including the land uses and property interests potentially affected by the use of groundwater in the basin, the types of parties representing those interests, and the nature of consultation with those parties.*
> *(b) A list of public meetings at which the Plan was discussed or considered by the Agency.*
> *(c) Comments regarding the Plan received by the Agency and a summary of any responses by the Agency.*
> *(d) A communication section of the Plan that includes the following:*
> *(1) An explanation of the Agency's decision-making process.*
> *(2) Identification of opportunities for public engagement and a discussion of how public input and response will be used.*
> *(3) A description of how the Agency encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin.*
> *(4) The method the Agency shall follow to inform the public about progress implementing the Plan, including the status of projects and actions.*

The Wheeler Ridge-Maricopa Water Storage District (WRMWSD or District) has developed this Stakeholder Communication and Engagement Plan (SCEP) to describe its approach to communication and engagement throughout the Groundwater Sustainability Plan (GSP) Chapter development process. This SCEP was prepared in accordance with California Water Code (CWC), the GSP Regulations (Title 23 of the California Code of Regulations [CCR] §354.10 [see above]), and the California Department of Water Resources (DWR) *Guidance Document for Groundwater Sustainability Plan Stakeholder Communication and Engagement* (DWR, 2018), as well as additional reference documents recommended by DWR for guidance.

Communication and engagement efforts carried out as described in this SCEP will help to ensure that local beneficial uses and users of groundwater are adequately considered in the GSP Chapter development process as required by GSP Regulations (23-CCR §354.10). Specifically, in this SCEP:

- **Section 2** describes the District and Groundwater Sustainability Agency (GSA) decision-making process (23-CCR §354.10(d)(1));
- **Section 3** identifies stakeholders;
- **Section 4** describes how the District intends to build upon its current understanding of stakeholders in the Management Area (23-CCR §354.10(d)(3) and CWC §10723.4);
- **Section 5** describes the key messages for communication and engagement efforts, and anticipated questions as well as possible responses (23-CCR §354.10(d)(4));
- **Section 6** identifies opportunities for public engagement and how public input an response will be used (23-CCR §354.10(d)(2));

- **Section 7** describes the Communications and Engagement (C&E) implementation timeline, including when this SCEP will be updated to inform the public about GSP Chapter implementation progress, including the status of projects and actions (23 CCR §354.10(d)(4));
- **Section 8** describes SCEP assessment and evaluation during the GSP Chapter development process.

2. OBJECTIVES AND DECISION-MAKING

This SCEP is designed to effectively engage a variety of relevant stakeholders in the development of a GSP Chapter that will guide the District, in coordination with the Kern Groundwater Authority (KGA) GSA, to demonstrate sustainability by 31 January 2040 and maintain sustainability through the Sustainable Groundwater Management Act (SGMA)'s 50-year planning timeline.

2.1. GSA and Management Area Description and Boundary

The WRMWSD is a public agency whose jurisdiction encompasses about 147,000 acres of land in Kern County, California, at the southern end of the San Joaquin Valley. The WRMWSD is one of the member agencies of the KGA GSA. The KGA GSA overlies a portion of the Kern County Subbasin (Basin; DWR 5-022.18) of the San Joaquin Valley Basin.

The Wheeler Ridge-Maricopa Management Area (Management Area) comprises approximately 91,000 acres of the KGA GSA, as shown in Figure 1. The remainder of the WRMWSD service area is located outside of the Management Area and within the White Wolf Subbasin. The Basin is a high priority basin that has been designated as being in critical groundwater overdraft condition and has a GSP submission deadline of 31 January 2020.

2.2. WRMWSD Structure and Decision-Making Process

Key GSP Chapter development and implementation decisions are made by the WRMWSD Board of Directors (District Board). The WRMWSD staff help to guide the GSP Chapter development technical consultant team and provide feedback on draft work products.

2.2.1. WRMWSD Board Structure and Meetings

The District is governed by an elected nine-member Board of Directors. District Board meetings are held on the second Wednesday of the month (unless otherwise noticed) and are open to the public. District Board meeting agendas and packets are posted to the WRMWSD website (https://wrmwsd.com) at least 72 hours before each Board meeting.

An ad-hoc committee of the District Board has been formed that will support more detailed engagement with the GSP Chapter development process. The ad-hoc committee will meet on an as-needed basis.

2.2.2. KGA Board Structure and Meetings

Per the Joint Powers Agreement (JPA) executed on 22 March 2017, the KGA GSA Board is composed of one representative from each of the general member agencies (Arvin Community Services District [ACSD], Arvin-Edison Water Storage District [AEWSD], Cawelo Water District [CWD], Kern County Water Agency [KCWA], Kern-Tulare Water District [KTWD], Kern Water Bank Authority [KWBA], North Kern Water Storage District [NKWSD], Rosedale-Rio Bravo Water Storage District [RRBWSD], Semitropic Water Storage District [SWSD], Shafter-Wasco Irrigation District [SWID], Southern San Joaquin Municipal Utility District [SSJMUD], Tejon-Castac Water District [TCWD], West Kern Water District [WKWD], Westside District Water Authority [WDWA], and WRMWSD plus one representative from the County as well as the City of Shafter).

The KGA GSA Board meetings are held on the fourth Wednesday of every month and are open to the public. The KGA GSA Board meeting agendas and packets are posted to the KGA website (www.kerngwa.com\board-of-directors.html).

The KGA GSA Board is supported by a Coordination Committee (CC) that is composed of one to two (1-2) representatives from each voting party of the KGA GSA and encompasses residential, agricultural, environmental, rural, domestic well, and municipal interests[1]. The specific role of the KGA's CC is to make recommendations to the KGA GSA Board regarding technical and other matters (e.g., stakeholder outreach) related to GSP development.

The CC meetings are held the first Monday of each month, and they are open to the public. Meeting agendas and packets are posted to the KGA website (www.kerngwa.com/committees.html).

2.3. Desired Outcome

The WRMWSD aims to develop a GSP Chapter that sets its Management Area on a path to maintain sustainability through SGMA's 50-year planning timeline.

[1] Kern Groundwater Authority Communication & Engagement Plan (http://www.kerngwa.com/assets/kga-communication---engagement-plan---may-2018.pdf)

2.4. Communication Objectives to Support the GSP Chapter

The WRMWSD SCEP efforts aim to support development of a GSP Chapter that meets the needs of beneficial uses and users of groundwater in the Management Area and reflects and incorporates stakeholder input as appropriate. The WRMWSD aims to be knowledgeable about and anticipate stakeholder interests and concerns.

2.5. Challenges for the Plan Area

The WRMWSD is aware of and plans to address the following challenges:

- Several large landowners in the District overlie both the Basin and the White Wolf Subbasin (White Wolf Basin; DWR 5-022.18). The WRMWSD will need to coordinate with entities and landowners in the White Wolf Basin to ensure that communication and engagement efforts conducted by the District and the KGA GSA align with communication and engagement efforts in the White Wolf Basin. Should substantially different groundwater management decisions be made in each basin, WRMWSD will communicate with stakeholders near and straddling the basin boundary to help them understand how GSP implementation in each basin will impact them.

- Irrigated agriculture is the primary land use in the District. It is anticipated that there will be concerns regarding how SGMA compliance could impact that land and water use. The District will be open and transparent in decisions that will have a substantial impact on beneficial users of groundwater, and will engage stakeholders early in the decision-making process to consider their interests and concerns.

3. STAKEHOLDER IDENTIFICATION

The KGA GSA identified current beneficial uses and users of groundwater in the Basin in its formation Notice submitted on 30 May 2017 in accordance with the interests listed in CWC §10723.2. The following are the identified beneficial uses and users of groundwater within the Management Area. Representatives of specific organizations on this list form the basis of the District's list of interested parties, as required by CWC §10723.2.

3.1. Holders of overlying groundwater rights

3.1.1. Agricultural Users

The primary land use in the Management Area is irrigated agriculture. The WRMWSD provides water service to agricultural water users within its service area.

3.1.2. Domestic Well Owners

There are several known domestic wells scattered throughout the Management Area, but the full extent and distribution of active domestic wells within the Management Area is currently unknown.

3.2. Municipal Well Operators

There are currently no identified municipal well operators within the Management Area.

3.3. Public Water Systems

The WRMWSD provides untreated water for irrigation and industrial purposes. However, there are some small public water systems that provide treated groundwater for domestic uses[2], including:

1. Andrews Ag – Non-community water system that serves a residential population of two (2) and a transient population of 50.
2. Opal Fry and Son – Community water system that serves a residential population of 40.
3. Wheeler Farms Headquarters – Non-Transient Non-Community water system that serves a non-transient population of 25.

While publicly available data have been examined to identify Public Water Systems in the Management Area[3], WRMWSD acknowledges that these datasets are known to be incomplete.

3.4. Local Land Use Planning Agencies

The Management Area is comprised of unincorporated County land, for which the Kern County Planning and Community Development is responsible for land use planning. The County will be involved in the

[2] The State Water Resources Control Board Safe Drinking Water Information System (https://sdwis.waterboards.ca.gov/PDWW/JSP/WaterSystems.jsp?PointOfContactType=none&number=&name=&county=Kern).

[3] Including the California Environmental Health Tracking Program Water System Map Viewer (http://www.cehtp.org/page/water/water_system_map_viewer).

development and implementation of the KGA GSP (which includes the District's GSP Chapter) through its participation in the KGA GSA.

3.5. Environmental Users of Groundwater

There is minimal interaction between groundwater and surface water in the Management Area, except in the area of known perched groundwater along the northern boundary. While this perched groundwater appears to support localized wetlands areas, as mapped by DWR[4], this system is disconnected from and not part of the principal aquifer. In most of the Management Area, the groundwater table is encountered more than 200 feet below ground surface and thus there is no groundwater contribution to streamflow or other surface water features.

Wind Wolves Preserve is a nature preserve that is adjacent to the Management Area.

3.6. Surface Water Users

Surface water features in the Basin include ephemeral streams draining the San Emigdio Mountains, several small lakes and ponds, the California Aqueduct, and a network of irrigation canals and ditches.

The US Bureau of Land Management holds appropriative water rights, Wildlands Conservancy holds diversion water rights, and CalMat Co. holds both appropriative and diversion water rights on San Emigdio Creek[5]. There are also several entities with diversion rights from springs near the boundary of the Basin. These include inactive rights held by Dole Dried Fruit & Nut Company and active federal claims held by USDA – Los Padres National Forest.

3.7. The Federal Government

Two parcels located south of the Rim Ditch within the Management Area, Southeast ¼ of Section 20 and South ½ of Section 22 within Township 32 South, Range 26 East, are identified as federal lands owned by the US Bureau of Land Management.

3.8. California Native American Tribes

There are no identified California Native American tribal lands within the Management Area.

3.9. Disadvantaged Communities

There were no Disadvantaged Community Places identified within the Management Area (U.S. Census, 2015). A portion of US Census Tracts 33.04, 33.06, and 62.02, which overlie almost the entire Management Area, was identified as a Disadvantaged Community Census Tract based on an average household income less than 80% of the State median (U.S. Census, 2015). Census Tract 33.06 includes a Severely Disadvantaged Community Census Block Group (Block Group 1 of Census Tract 33.05) in the southern portion of the Management Area.

[4] DWR NC Dataset Viewer (https://gis.water.ca.gov/app/NCDatasetViewer/).
[5] According to the SWRCB Electronic Water Rights Information Management System (eWRIMS), accessed 26 July 2018.

As described in the KGA GSA Community & Engagement Plan to engage residents of disadvantage communities/areas, the KGA GSA is coordinating with Self-Help Enterprises (SHE) to identify convenient times and locations for public outreach meetings and to distribute meeting notices.

3.10. Groundwater Monitoring Entities

The WRMWSD submitted a notice to become a monitoring entity for its service area under the California Statewide Groundwater Elevation Monitoring (CASGEM) Program in 2011. The current status for this application process is under review and pending development of the CASGEM monitoring network. However, AEWSD is a Monitoring Entity in the Basin and overlaps with the Management Area. AEWSD is a member of the KGA GSA and will be involved in coordinating GSP Chapter development

Additionally, Kern River Fan Group (comprised of Kern Delta Water District, Henry Miller Water District, and Buena Vista Water Storage District) is a Monitoring Entity just north of the Management Area. Henry Miller Water District and Buena Vista Water Storage District have formed their own GSAs, and Kern Delta Water District is part of the Kern River GSA. Monitoring coordination will be included in a coordination agreement as required by the GSP Regulations (23-CCR §357.4).

4. STAKEHOLDER SURVEY AND MAPPING

The WRMWSD intends to update its list of stakeholders based on new information as appropriate. To learn more about its stakeholders, WRMWSD has coordinated with the KGA GSA to distribute a stakeholder survey (Appendix A) by:

- Posting the survey on WRMWSD website (https://wrmwsd.com/);
- Having copies of the survey available at WRMWSD Board meetings and stakeholder workshops;
- Sending the survey in water bill mailings or special mailings; and
- Coordinating with the community organizations (e.g., Kern County Farmers Bureau, Self-Help Enterprises, etc.) to distribute the survey to diverse members of the population that may not be otherwise be reached.

Based on current knowledge of stakeholders, WRMWSD has completed a "Lay of the Land" exercise in **Table 1**, identifying specific stakeholder organizations/individuals, stakeholder type, key interests and issues, the sections of the GSP Chapter likely to be relevant to this stakeholder, and the level of engagement (e.g., inform, consult, involve) expected with each stakeholder organization/individual.

Given that WRMWSD will gain more knowledge of the interests, issues, and challenges of stakeholders over the course of GSP Chapter development, **Table 1** will be updated as part of GSP Chapter development. Should WRMWSD need to learn more about specific stakeholders, individual meetings will be arranged to find out more about their issues, interests, and challenges.

In addition to the more detailed stakeholder survey, WRMWSD intends to maintain a simple form or an e-mail request link on its webpage for individuals to enroll in WRMWSD interested parties list and provide their contact information.

5. MESSAGES

The WRMWSD aims to convey consistent high-level messaging to stakeholders throughout GSP Chapter development and implementation. The following are the key messages that will form the foundation for communication and engagement efforts:

1. WRMWSD aims to engage with diverse stakeholders to best represent their interests in the GSP Chapter development process;
2. Key GSP Chapter development decisions will be made in an open and transparent fashion during public District Board meetings; and
3. Technical GSP Chapter development progress will be communicated in an accessible manner to support stakeholder understanding and input.

Additionally, the GSA has developed **Table 2** to document anticipated questions as well as possible responses. **Table 2** will be updated, as needed, to add additional, frequently received questions as well as to build upon responses based on GSP Chapter development progress.

Table 2 Likely Questions and Responses

Likely Questions	Responses
How can I participate in the GSP Chapter development and implementation process?	District Board meetings are open to the public and held at 8:30 AM on the second Wednesday of the month unless otherwise noticed in the District Headquarters, 12109 Highway166, Bakersfield CA 93313. Stakeholder workshops will be held throughout the GSP Chapter development process, and will be publicized on WRMWSD website (https://wrmwsd.com/).
Will I have to fallow my land?	We are currently in the initial phases of GSP Chapter development. Projects and management actions to achieve sustainability will be discussed later in the process, with opportunity for stakeholder input.
What types of management actions or projects are going to occur in my area?	We are currently in the initial phases of GSP Chapter development. Projects and management actions to achieve sustainability will be discussed later in the process, with opportunity for stakeholder input.
Are pump meters going to be required? Who will pay for meters?	We are currently in the initial phases of GSP Chapter development. Projects and management actions to achieve sustainability will be discussed later in the process, with opportunity for stakeholder input.
Who is paying for GSP Chapter development and implementation?	Agencies in the Basin have obtained state funding to support specific efforts related to GSP development (https://www.water.ca.gov/Work-With-Us/Grants-And-Loans/Sustainable-Groundwater). The WRMWSD will pay for GSP Chapter development and will contribute to the development of a GSP Umbrella by the KGA GSA. The actual cost to the landowner has yet to be determined.

6. VENUES FOR ENGAGING

The WRMWSD intends to provide a variety of opportunities for engagement with stakeholders. Stakeholder input received will inform and be incorporated into corresponding sections of the GSP Chapter as appropriate.

6.1. District Board Meetings

As described in Section 2.2.1, District Board meetings are open to the public and are a consistent venue for public engagement.

The WRMWSD understands that Basin-wide public outreach meetings will direct residents to the member agency in whose management area they reside, and welcomes residents within its Management Area, including the overlying DAC areas, to attend its public board meetings.

6.2. Stakeholder Workshops

Stakeholder workshops will be held to communicate progress on GSP technical components to stakeholders and to receive input on upcoming decisions and work efforts. At least two stakeholder workshops and one public hearing will be held during GSP Chapter development:

- **Stakeholder Workshop #1** – held 24 May 2018 – SGMA Overview, draft results of Basin Setting Information, Preliminary Undesirable Results, and Key Policy Decisions
- **Stakeholder Workshop #2** – to be held in Winter 2018/2019 – Draft Sustainable Management Criteria and Discussion of Projects and Management Actions.
- **Public Hearing** – Review of the draft GSP Chapter.

The WRMWSD will publicize all stakeholder workshops on its website (https://wrmwsd.com/) and to its list of interested parties and will coordinate with community organizations (e.g., Kern County Farmers Bureau, Self-Help Enterprises, etc.) to send out emails and mailings as appropriate.

The KGA GSA is holding a series of stakeholder workshops focused on Basin-wide GSP development. The WRMWSD will coordinate with the KGA GSA as appropriate about their respective stakeholder workshops.

Additional stakeholder workshops may be held during GSP Chapter implementation. The timing and content of these stakeholder workshops will be determined when the GSP Implementation Plan is developed shortly before GSP Chapter submission.

6.3. Website Communication

The WRMWSD will update its website with WRMWSD Board meeting materials as described in Section 2.2.1, and will additionally update the website with key GSP Chapter updates.

6.4. Stakeholder Surveys

The WRMWSD intends to learn about stakeholder interests using surveys that will be distributed as discussed in Section 4. This stakeholder survey is included as Appendix A.

7. IMPLEMENTATION TIMELINE

The GSA's C&E implementation timeline aligns with a four phase GSP Chapter development timeline, as described in **Table 3** below.

Table 3 GSP Development and C&E Efforts by Phase

Phase	Timeframe	Overall GSP Efforts (led by technical consultant team)	C&E Efforts (led by the WRMWSD staff)
GSP Foundation	May 2018 – September 2018	• Select and design a Data Management System (DMS) • Conduct data gaps assessment • Evaluate numerical groundwater model options	• Develop SCEP • Distribute Stakeholder Survey • Update Stakeholder Constituency Table
Basin Characterization and Analysis	May 2018 – October 2018	• Implement plan for filling data gaps • Develop Hydrogeologic Conceptual Model (HCM) and definition of groundwater conditions • Develop water budget • Assess existing monitoring programs	• Conduct Stakeholder Workshop #1 • Update Stakeholder Constituency Table
Sustainability Planning	August 2018 – December 2018	• Evaluate potential management areas • Develop sustainable management criteria • Identify projects and management actions • Create GSP implementation plan • Finalize monitoring network and protocols	• Conduct Stakeholder Workshop #2 • Update Stakeholder Constituency Table • Update SCEP to reflect plan for C&E efforts during GSP Implementation
GSP Preparation and Submittal	December 2018 – January 2020	• Compile complete draft GSP • Revise draft GSP (if necessary) per stakeholder feedback • Finalize GSP and submit to DWR	• Distribute draft GSP • Hold Public Hearing on draft GSP • Assess C&E progress and plan for C&E related to GSP Implementation • Update Stakeholder Constituency Table

The WRMWSD will update this SCEP while creating a GSP Chapter implementation plan. This update will focus on informing the public about GSP implementation progress, including the status of projects and actions (23-CCR §354.10(d)(4)).

8. EVALUATION AND ASSESSMENT

The WRMWSD intends to assess its SCEP during GSP Chapter development, as shown in **Table 3**. The WRMWSD staff will present brief summaries of SCEP implementation progress at District Board meetings and will lead a discussion about lessons learned and what can be improved as part of GSP implementation. The following questions will guide SCEP evaluation:

- What worked well?
    - What allowed us insight into stakeholder concerns?
    - What types of materials best communicated GSP development to stakeholders?
- What didn't work as planned?
    - Could materials (e.g., presentation slides, website pages) have been improved to better communicate GSP development progress?
    - Are certain stakeholder groups less represented in the GSP development process than they should be?
- What do we plan on doing differently during the next phase based on what we have learned?
- How much of our communication and engagement budget have we spent relative to work completed? Do we have enough remaining budget to complete our SCEP?

APPENDIX A – STAKEHOLDER SURVEY

Stakeholder Survey

KERN GROUNDWATER AUTHORITY

Date: _____

Stakeholder Type (check all that apply):

☐	Agricultural User	☐	Domestic Well Owner/User	☐	Municipal Well Operator
☐	Public Water Systems	☐	Local Land Use Planning Agency	☐	Environmental User
☐	Surface Water User	☐	Native American Tribe	☐	Disadvantaged/Rural Community Resident
☐	City Resident	☐	Food Processor	☐	Industrial User/Oil Producer
☐	Entity monitoring and reporting groundwater elevations in all or part of the groundwater basin				

Note: Please complete your name and contact information if you'd like to be added to the GSA's email and mailing list for future updates and information regarding Sustainable Groundwater Management Act (SGMA) and the Kern Groundwater Authority.

Name: _____

Address: _____

City: _____ State: _____ Zip: _____

Email: _____ Telephone: _____

1. Are you familiar with Sustainable Groundwater Management Act (SGMA) regulations? ☐ Yes ☐ No

2. Are you currently working on or discussing groundwater management in this region? ☐ Yes ☐ No

3. Do you own or manage/operate land in this region? ☐ Yes ☐ No

4. Where are you getting your water supply?
   ☐ City or Community Water System ☐ Surface ☐ Groundwater
   ☐ Both Groundwater & Surface Water ☐ Unknown

5. Agriculture & Domestic Well Users: What is your well(s) depth? _____

6. Agriculture & Domestic Well Users: Has your well(s) ever gone dry? ☐ Yes ☐ No
   If yes, when (month/year)? _____

7. If you are an Agricultural User, do you: ☐ Irrigate ☐ Dry Farm ☐ Graze Livestock
   ☐ Other: _____

8. How reliable is your current groundwater supply? _____

   _____

   _____

9. If you grow crops, do you use irrigation for frost protection? ☐ Yes ☐ No

10. Do you manage water resources? ☐ Yes ☐ No
    If yes, what is your role? _____

11. What is your primary interest in land or water resources management? _____

12. Do you have concerns about groundwater management? ☐ Yes ☐ No

If so, what are they? _____

13. Do you have requests or recommendations regarding groundwater management? ☐ Yes ☐ No

If so, what are they? _____

14. Any other information the Kern Groundwater Authority should be aware of or take into consideration while developing the Groundwater Sustainability Plan (GSP)?

Please return completed surveys to the Kern Groundwater Authority by emailing tbarton@ppeng.com, faxing to (661) 479-7172, or mail to Kern Groundwater Authority 93301.

Stakeholder Surveys may also be completed online by visiting www.kerngwa.com.

KERN GROUNDWATER AUTHORITY

Encuesta de Partes Interesadas

Fecha: _____

Tipo de Interesado (marque todas que apliquen):

☐	Usuario agrícola	☐	Propietario / usuario de pozo doméstico	☐	Operador municipal de pozos
☐	Sistema de agua público	☐	Agencia local de planificación del uso de la tierra	☐	Usuario ambiental
☐	Usuario de agua superficial	☐	Tribu native americana	☐	Residente de comunidad desventajada/ rural
☐	Residente de la ciudad	☐	Procesador de alimentos	☐	Usuario industrial/Productor de petróleo
☐	Entidad que monitorea y reporta elevaciones de aguas subterráneas en toda o parte de la cuenca de agua subterránea				

Nota: Por favor complete su nombre y la información de contacto si desea ser agregado a la lista de correo electrónico de la GSA y lista de correo para futuras actualizaciones e información sobre la Ley del Manejo Sostenible del Agua Subterránea (SGMA) y la Autoridad de Aguas Subterráneas de Kern (KGA GSA).

Nombre: _____

Dirección Postal: _____

Ciudad: _____ Estado: _____ Código postal: _____

Correo Electrónico: _____ Teléfono: _____

1. ¿Está usted familiarizado con las regulaciones de la ley de Manejo Sostenible del Agua Subterránea (SGMA)? ☐ Sí ☐ No

2. ¿Está usted actualmente involucrado en actividades o discusiones Sobre el manejo de aguas subterráneas en esta regíon? ☐ Sí ☐ No

3. ¿Usted es propietario o administra/opera tierra en esta región? ☐ Sí ☐ No

4. ¿De dónde recibe su suministro de agua?
   ☐ Sistema de agua de la ciudad o la comunidad ☐ Superficie ☐ Agua subterránea
   ☐ Agua subterránea y superficial ☐ No sé

5. Usuarios de pozos Agrícolas Y Domésticos: ¿Cuál es la profundidad de su pozo(s)? _____

6. Usuarios de poza Agrícolas Y Doméesticos: ¿Alguna vez se ha secado su pozo(s)? ☐ Sí ☐ No
   ¿Si la respuesta es sí, cuándo (mes/año)? _____

7. Si eres un usuario agrícola, qual haces: ☐ Irrigar ☐ Granja seca ☐ Pastoreo
   ☐ Otro: _____

8. ¿Qué tan seguro es su suministro de agua subterránea, corrientemente ?_____

   _____

   _____

9. Si cultiva, ¿utiliza el riego para la protección contra las heladas? ☐ Sí ☐ No

10. ¿Usted administra recursos de agua? ☐ Sí ☐ No
    Si la respuesta es sí, ¿cuál es su papel? _____

11. ¿Cuál es su interés principal en el manejo de recursos de agua o tierra? _____

12. ¿Tiene preocupaciones acerca el manejo de las aguas subterráneas? ☐ Sí ☐ No

Si la respuesta es sí, ¿cuáles son? _____

13. ¿Tiene used alguna recomendación sobre el manejo de agua subterráneas? ☐ Sí ☐ No

Si la respuesta es sí, ¿cuáles son? _____

14. ¿Tiene used alguna otra información pertinente que debería tener en cuenta el Kern Groundwater Authority GSA para desarroler el Plan de Sostenibilidad de Aguas Subterránease (GSP)?

Por favor regrese la encuesta terminada al Kern Groundwater Authority GSA enviando un corre electrónico a tbarton@ppeng.com , manduando un fax al (661) 478-7172, o por correo a Kern Groundwater Authority GSA, 1800 30th Street, Suite 280, Bakersfield, CA 93301.

Landowner

Re: Sustainable Groundwater Management Act Compliance and Coverage

Dear Landowner,

The Sustainable Groundwater Management Act (SGMA) went into effect on January 1, 2015 and requires the formation of Groundwater Sustainability Agencies (GSA) to sustainably manage all groundwater basins in California including the Kern Sub-Basin. SGMA authorizes public agencies with land use or water management authority to become a GSA and manage groundwater. If no agency or group of agencies elects to be a GSA for the entire basin, SGMA designates the county as the default GSA to manage groundwater sustainably for the unmanaged lands in the basin. If the county declines to act as the GSA, SGMA requires the unmanaged lands report groundwater pumping directly to the State Water Resources Control Board and pay applicable fees.

The Kern Groundwater Authority (KGA) was formed on April 26, 2017 by several public agencies, which included the County of Kern, through a joint power agreement (JPA). Pursuant to the JPA and SGMA requirements, each member district of the KGA is responsible for the management of the groundwater within its respective jurisdiction and the County was responsible for managing groundwater in the areas not otherwise included in the jurisdiction of a member district ("undistricted lands").

On December 11, 2018, Kern County Board of Supervisors voted to withdraw from the KGA and stated that it would no longer manage groundwater in the undistricted lands of the Kern Sub-Basin. The County sent a notice of withdrawal to the KGA dated December 12, 2018. However, the County did not provide written notice to the affected landowners regarding its withdrawal from the KGA or of its decision to not provide SGMA coverage to those landowners not within the jurisdiction of a member district.

In response to the County's withdrawal, the KGA and its members have been working diligently to provide a means for those undistricted lands to have SGMA coverage. Accordingly, the KGA and its member districts are allowing landowners in these areas the opportunity to sign up to be managed by neighboring KGA member districts. Landowners who do not sign up with KGA member districts will be removed from the KGA GSA boundary and will be designated as unmanaged by the State Water Board.

You are receiving this letter because your property, or a portion thereof, has been identified as unmanaged land due to the County's action to withdraw from the KGA and by its decision to no longer provide SGMA management. This letter provides you notice that the opportunity to obtain coverage through the KGA will be closed on July 1, 2019. If you would like to avoid being designated as unmanaged by the State Water Board (see attachment 1 [State Water Board unmanaged notice]), please contact the KGA member closest to your property (see attachment 2 [Kern Basin Map]) and execute the necessary management documents by July 1, 2019. If you have questions regarding this notice, please contact Patty Poire at 661-479-7171.

Respectfully,
Kern Groundwater Authority

1800 30th Street, Suite 280, Bakersfield, CA 93301 • Tel: (661) 616-5900 • Fax: (661) 616-5890 • www.kerngwa.com

NOTICE OF GROUNDWATER EXTRACTION REPORTING UNDER THE SUSTAINABLE GROUNDWATER MANAGEMENT ACT (SGMA).

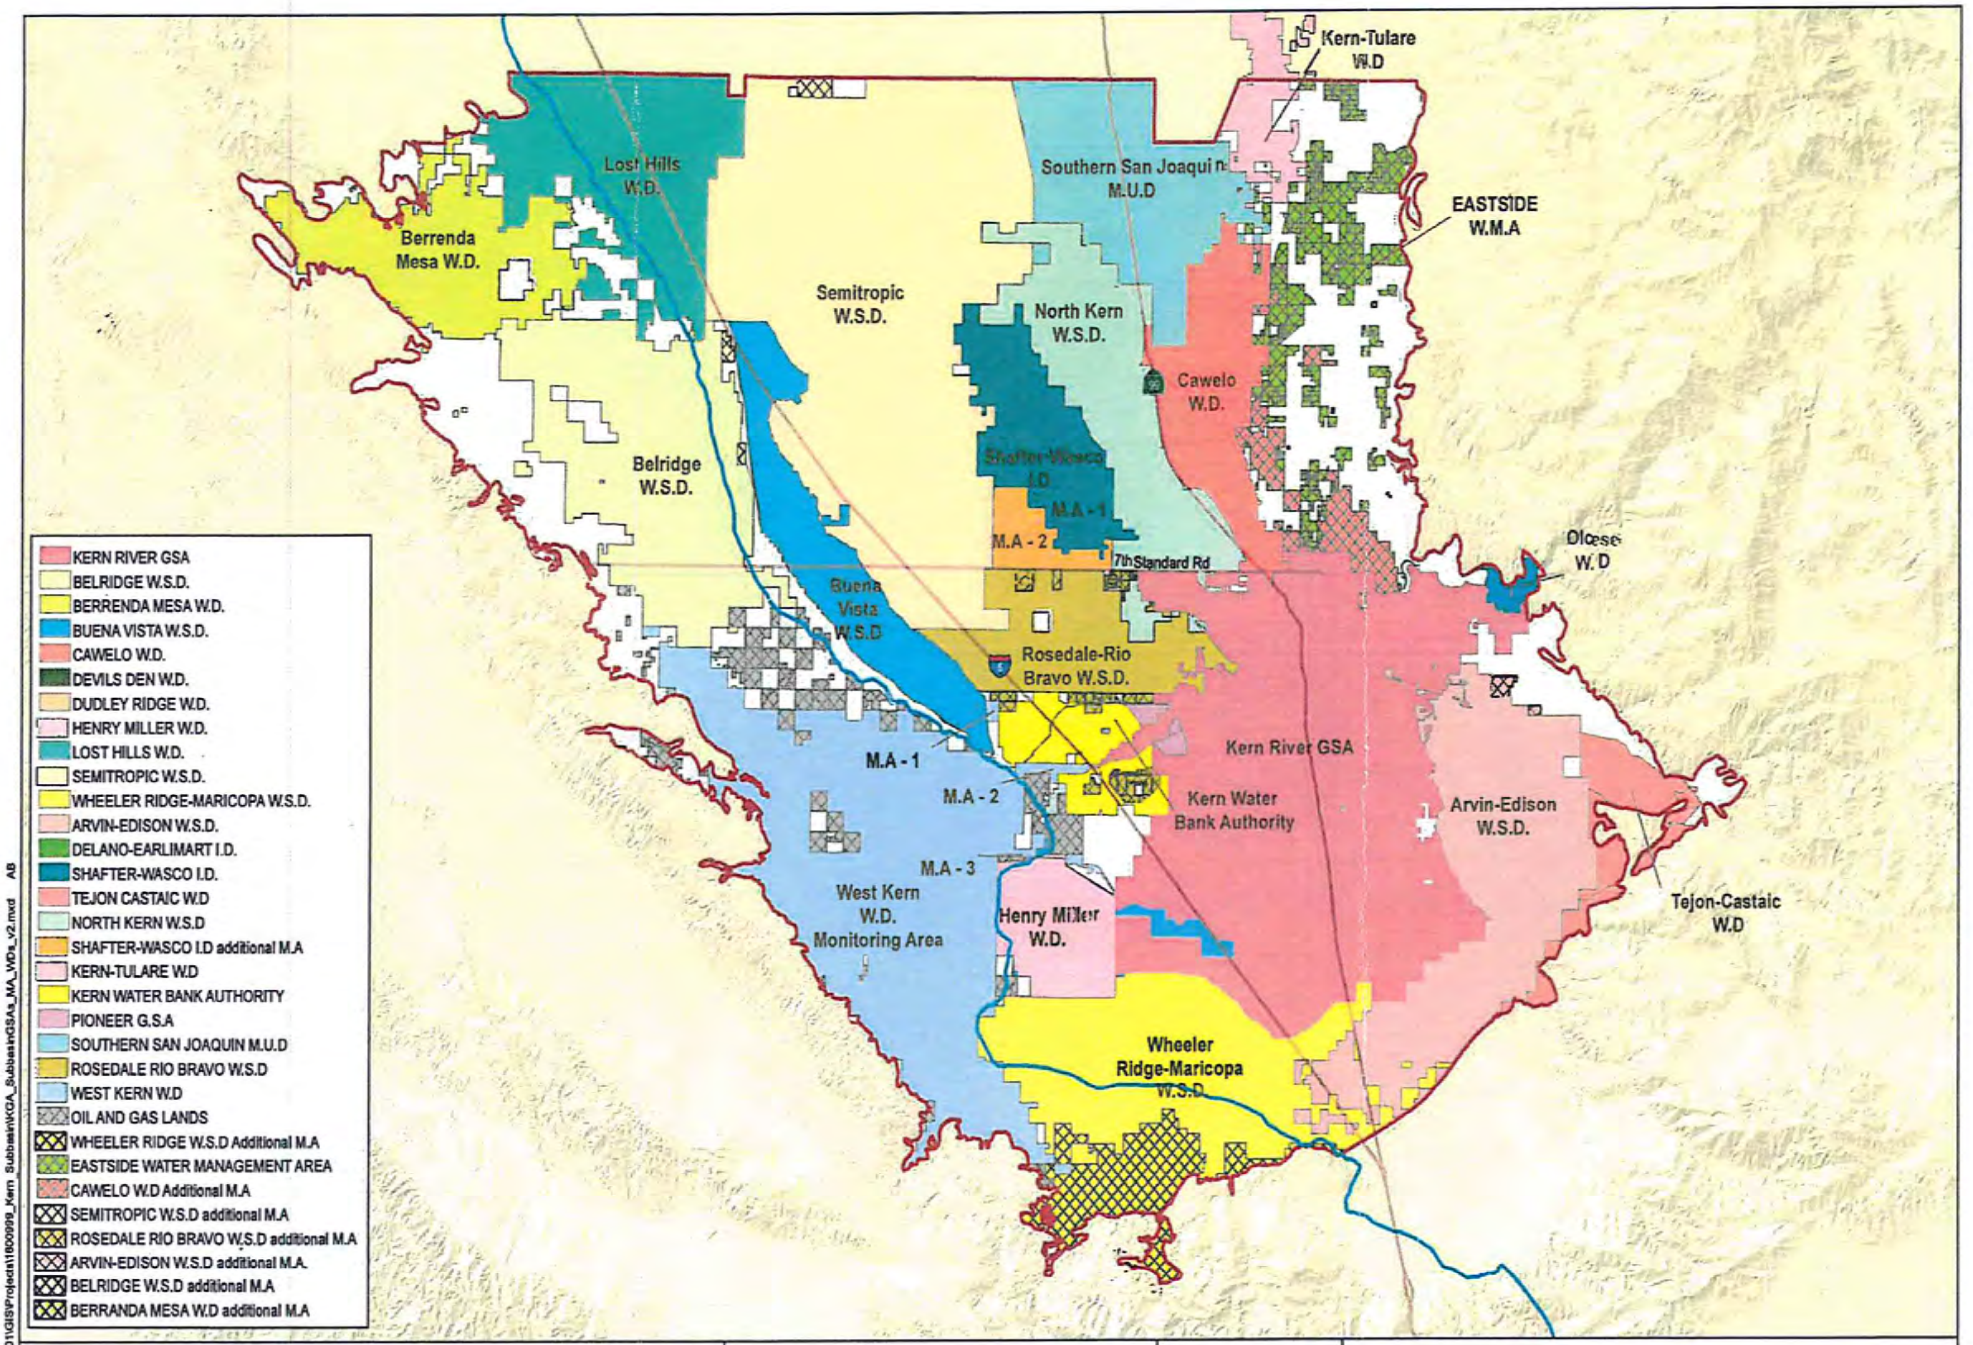
AVISO DE ENVIAR REPORTE(S) SOBRE EXTRACCIÓN DE AGUA SUBTERRÁNEA REQUERIDO POR LA LEY DE GESTIÓN SUSTENTABLE DEL AGUA SUBTERRÁNEA (SGMA)

This letter requires your immediate attention. This letter provides notice that you may be required to file one or more groundwater extraction reports with the State Water Resources Control Board (Board) pursuant to the Sustainable Groundwater Management Act (SGMA). Failure to file a required report may result in penalties of up to $500 per day.

Para obtener más información en español (formularios u otra información), nos puede llamar al (916) 322-6508 o enviar un mensaje a: groundwater_management@waterboards.ca.gov.

Why you are receiving this notice

This Notice is being sent to persons who may own property or operate a public water supply system in an unmanaged area where groundwater was extracted on or after DATE through DATE. An unmanaged area is an area within a high- or medium-priority groundwater basin that is outside the jurisdiction of any groundwater sustainability agency (GSA) and not subject to an alternative or other exemption from SGMA requirements.



Data indicate that you own or are responsible for the parcel(s) or public water supply system(s) listed at the end of this notice. The Board has identified this parcel(s) or water supply system(s) as located within an unmanaged area. If you extract groundwater from an unmanaged area and you are not a small domestic user, SGMA requires that you file an annual groundwater extraction report for extractions made during the previous water year.

If you have questions regarding this notice or need assistance completing the online groundwater extraction report, please contact Board staff by email at groundwater_management@waterboards.ca.gov or by phone at 916-322-6508.

Appendix D

Detailed Responses to Selected Comments Received Regarding the MA Plan

Appendix D

Detailed Responses to Selected Comments Received on the Public Draft Wheeler Ridge-Maricopa Management Area Plan

Summary of Comments in Chevron email (11/19/2019) to WRMWSD, and Responses from WRMWSD

Chevron Comment Number	Chevron Comment	Response from WRMWSD
1	An aquifer may not be suitable for beneficial use if: a) is not currently serving as a source of drinking water, b) it has commercially producible minerals or hydrocarbons, or c) it is not expected to supply a public water system and d) is either economically or technologically infeasible for treatment or recovery now or in the future for domestic, agricultural, or industrial use. The purpose of this plan is not to exempt aquifers, nor is it to define the maximum depth or water quality concentration at which groundwater is economically recoverable or treatable now or in the future. However, by applying the criteria of 40 CFR §144.3 and 40 CFR §146.4, active oil and gas aquifers and exempted aquifers are not a part of the groundwater basin for beneficial use. As described above, the following, whichever is shallowest, are the lateral and vertical boundaries of the groundwater Subbasin: a) depth to producible minerals or hydrocarbons or primacy productive limits, b) depth to exempted aquifers, c) depth that makes recovery of water for domestic, commercial, or industrial purposes no longer economically or technologically feasible, or	• ***Section 7.1.3 was modified to clarify that in areas where pools in oil fields in the MA Plan area are at shallower depths than the base of fresh water, the bottom of the basin is defined as the shallower depth of fresh water from the DOGGR oil field data.***

Chevron Comment Number	Chevron Comment	Response from WRMWSD
	d) the depth at which groundwater cannot now or in the future serve as a source of drinking water. For example, water bearing zones below the depth to producible hydrocarbons are not within the groundwater basin; likewise, water bearing zones below an exempted aquifer are not within the groundwater basin.	

Summary of Comments in the California Department of Fish and Wildlife (CDFW) Comment Letter (11/25/2019) to KGA and Semitropic WSD, and Responses from WRMWSD

CDFW Comment Number	CDFW Comment	Response from WRMWSD
1	The Plan Area narrative does not identify Department-owned lands.	• There are no state-owned lands within the Wheeler Ridge-Maricopa Management Area. • See KGA response to this comment for further information.
2	The GSP identifies an 'environmental' category of beneficial user but does not specify how impacts to environmental beneficial uses and users of groundwater were considered throughout the GSP.	• The process used to assess the potential occurrence of "environmental" uses/users of groundwater in the Management Area is based on depth to groundwater based on available data from wells in the principal aquifer, as described in **Section 8.2**, **8.7** and **8.8**. This process was informed by the TNC (2019) guidance for evaluation of GDEs. • See KGA response to this comment for further information.
3	The GSP identifies the potential for interconnected surface waters but dismisses further evaluation of interconnectivity and abdicates oversight of shallow groundwater-surface water communication.	• The process used to assess the potential occurrence of interconnected surface water in the Management Area is based on depth to groundwater (similar to the process used for evaluation of GDEs, which was done consistent with TNC (2019) guidance; see below) based on available data from wells in the principal aquifer, as described in **Section 8.2** and **8.7**. • See KGA response to this comment for further information.
4	The GDE identification section, pursuant to 23 CCR§ 354.16 (g), identifies ecosystems that may depend on groundwater. A report completed by the California Department of Water Resources (CDWR) (1997) shows that a large area of Kern County has 0 to 10 feet to depth to free water below the surface (see CDWR Figures 2, 3 and 5). Based	• The process used to assess the potential occurrence of GDEs in the Management Area is based on depth to groundwater based on available data from wells in the principal aquifer, as described in **Section 8.2** and **8.8**.

CDFW Comment Number	CDFW Comment	Response from WRMWSD
	on the presence of shallow groundwater, the Department supports the further investigation of GDEs and recommends including additional references for a more robust GDE evaluation. The Department recognizes that Natural Communities Commonly Associated with Groundwater (NCCAG) (Klausmeyer et al. 2018) provided by CDWR is a good starting reference for GDEs. There are additional resources available for evaluating GDE locations and habitat types, as well as information for State and Federal listed species. These recommended references include, but not limited to the following tools and other resources: the California Department of Fish and Wildlife (CDFW) Vegetation Classification and Mapping Program (VegCAMP) (CDFW 2019A); the CDFW California Natural Diversity Database (CNDDB) (2019B); the California Native Plant Society (CNPS) Manual of California Vegetation (CNPS 2019A); the CNPS California Protected Areas Database (CNPS 2019B); the United States Fish and Wildlife Service (USFWS) National Wetlands Inventory (2018); the USFWS online mapping tool for listed species critical habitat (2019); the United States Forest Service CALVEG ecological grouping classification and assessment system (2019); and other publications by Klausmeyer et al. (2019), Rohde et al. (2018), The Nature Conservancy (TNC) (2014, 2019), and Witham et al. (2014).	• ***Section 8.8 was modified to include mention the use of the TNC (2019) guidance and criteria therein.*** • The criteria used to remove NCCAG from the list of potential GDEs is a depth to water greater than 30 feet, which is based on guidance from The Nature Conservancy (2019). • See KGA response to this comment for further information.
5	The identification of undesirable results and selection of minimum thresholds are based on an extended 10-year drought period and exclude Sustainable Management Criteria for surface water depletions.	• Because interconnected surface waters are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, sustainable management criteria for Depletion of Interconnected Surface Waters are deemed not applicable/necessary. • See KGA response to this comment for further information.

Summary of Comments in the Leadership Counsel for Justice and Accountability (LCJA) Comment Letter (11/26/2019) to KGA, and Responses from WRMWSD

Page Number in LCJA Letter	LCJA Comment	Response from WRMWSD

6	The GSP was not crafted in a way that adequately considered the input of disadvantaged communities, either at the GSA level or the member agency level.	• WRMWSD conducted substantial stakeholder outreach and engagement during the Wheeler Ridge-Maricopa Management Area Plan (MA Plan) development process. This outreach is described in in **Section 5.5** of the MA Plan, as well as the Stakeholder Communication and Engagement Plan (SCEP) included as **Appendix C**. WRMWSD outreach efforts included:
		  • letters sent to all landowners and all interested parties;
		  • distribution and compilation of a Stakeholder Survey (direct mail in WRMWSD billing statements);
		  • Outreach to certain well owners to discuss domestic well status and location and regarding development of a monitoring network;
		  • Letters to "white land" owners;
		  • Multiple public stakeholder workshops,
		• The above outreach efforts are in addition to those performed by the KGA. ***A list of meetings during which GSP and SGMA were discussed is included in Appendix C of the MA Plan, which was updated to reflect additional recent meetings***.
		• See KGA response to this comment for further information.

12	The KGA GSA did not ensure that minimum thresholds created by member agencies considered the interests of all beneficial user groups,	• WRMWSD <u>did</u> evaluate potential impacts of Minimum Thresholds on dewatering of wells, including an assessment of how many wells could potentially be

Page Number in LCJA Letter	LCJA Comment	Response from WRMWSD
	or prioritize the security of drinking water in the subbasin, in developing minimum thresholds.	dewatered (see **Section 14.1.1** and **Figures SMC-4** and **SMC-5**). • ***Section 18.1.6 of the MA Plan includes discussion of development of an Impacted Well Mitigation Program (also referred to as a Well Dewatering Mitigation Program) to address potential impacts arising from low groundwater levels, and has been updated to include more information on the types of mitigation that may be included in the program.*** • See KGA response to this comment for further information.
14-15	As in the case of groundwater levels, it is clear that the GSA has not considered the potential impact on drinking water users, in particular disadvantaged communities who are less able to afford solutions to treat contaminated drinking water.	• WRMWSD did conduct an extensive analysis of water quality based on the available data (see **Section 8.5** and **Figures GWC-11 through GWC-13**, and **Appendix F**). • Constituents in groundwater within the Wheeler Ridge-Maricopa Management Area are either naturally occurring or related to land use practices which are regulated under separate programs such as the Irrigated Lands Regulatory Program [ILRP], Waste Discharge Requirements [WDRs], etc. WRMWSD is involved with those efforts as part of the Kern River Watershed Coalition Authority (see **Section 8.5.1** of the MA Plan). • All monitoring sites will be sampled for the constituents identified in the Groundwater Quality Concerns section (**Section 8.5.1**), as well as other relevant groundwater quality parameters (see **Section 16.1.4**). Collection of additional data during plan implementation will be used to refine SMC definitions, as discussed in **Section 13.4**.

Page Number in LCJA Letter	LCJA Comment	Response from WRMWSD
		• See KGA response to this comment for further information.
18	The groundwater quality monitoring network does not adequately capture impacts on drinking water users.	• As described in **Section 16.1.4**, the water quality monitoring in this MA Plan includes nine locations throughout the MA and is considered representative. • See KGA response to this comment for further information.
20	The GSA has allowed member agencies like the Arvin-Edison WSD to use a "glidepath" approach that increases surface water and groundwater recharge before demand reduction measures are implemented.[67]	• Demand reduction and supply augmentation Projects and Management Actions (P/MAs) are to be implemented concurrently and in a balanced approach under the "glide path" laid out in the Wheeler Ridge-Maricopa MA Plan (see **Section ES.10**; **Section 9.4.5**; **Section 17.1.4**; and **Table PMA-2**). • See KGA response to this comment for further information.

Summary of Comments in the Wonderful Orchards/Wonderful Citrus (WOWC) Comment Letter (11/27/2019) to KGA and Responses from WRMWSD

Page Number in WOWC Letter	WOWC Comment	Response from WRMWSD
1	**Quantification of Native Yield** It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource. For example, a district or pumper located adjacent to the foothills does not necessarily have a superior claim to native yield over someone located in the center of the basin just because they are geographically closer to the source of mountain front recharge. Similarly, a district or pumper located in a cone of depression does not necessarily have a superior claim to native yield just because groundwater is flowing toward them. Surface water entering the groundwater via seepage in natural channels, including the Kern River and small streams, may be attributable to the native yield depending upon the circumstances of that seepage. A thorough technical and legal analysis is necessary to determine appropriate sources contributing to the native yield and to quantify these supplies.	• "Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). • ***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and not a determination of actual legal ground water rights.*** • Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.2**. • See KGA response to this comment for further information.
2	**Allocation of Native Yield** In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. Appendix J of the GSP indicates the subbasin native yield is approximately 0.144 acre-feet per	• ***Section 18.4 which describes Stakeholder Engagement as part of MA Plan implementation, has been modified to include a statement that any actions to establish landowner-level allocations of native yield will be***

Page Number in WOWC Letter	WOWC Comment	Response from WRMWSD
	acre. It is our understanding that subsequent to the release of the draft GSP, all MAPs and other GSPs in the basin agreed to utilize the same number for their water budgets. If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights. Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross or net area. In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and be generally consistent with groundwater rights, recognizing that GSAs do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – Environmental Defense Fund and New Current Water & Land, July 2018.	***conducted through a robust stakeholder engagement process.*** • See KGA response to this comment for further information.
2	**Groundwater Markets** Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent	• The MA Plan includes in its portfolio of P/MAs a management action to evaluate and potentially implement a groundwater marketing and trading system (see **Section 17.2.2**). • As described in **Section 18.2**, implementation of P/MAs, including the potential establishment of a market-based

Page Number in WOWC Letter	WOWC Comment	Response from WRMWSD
	undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.	system, will include performance of any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. • See KGA response to this comment for further information.
2	**Pumping Restrictions** Wonderful understands that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).	• Demand reduction Management Actions are included in the MA Plan as one element in a portfolio of P/MAs (see **Section 17**). • The P/MA implementation timetable is based on a phased/incremental "glide path" approach (see **Section 17.1.4**). • P/MA implementation will entail, in many cases, performing studies and/or analysis to refine concepts into actionable projects or policies (see **Section 18.2**). ***Section 18.2 was modified to clarify that such studies will be based on using the best available data and science.*** • See KGA response to this comment for further information.
3	**Groundwater Recharge and Banking** GSAs must develop clear policies and conditions that protect existing investment in groundwater banking and banked inventory, and without interference with existing rules and regulations. GSAs must also find a way to incentivize additional investment, such as on-farm recharge, and allow flexibility for recharged or banked water to be freely transferable (subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results). Where possible, GSPs should also identify management areas that may	• As described in **Section 18.2**, implementation of P/MAs, including projects to enhance recharge and projects to manage and/or capture floodwater, will include performance of any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. • See KGA response to this comment for further information.

Page Number in WOWC Letter	WOWC Comment	Response from WRMWSD
	benefit from additional recharge and banking. We also recommend that GSAs work to develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	
3	**Measurement and Data Management** Finally, GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	• ***Section 8.1 has been added to the MA Plan to describe data sources used in MA Plan development and how this local DMS will be coordinated with the basin-wide DMS.*** • ***Appendix E has been added to the MA Plan to list additional water quality data sources that will be evaluated during MA Plan implementation.*** • The Plan implementation section includes an action to refine the local DMS to comply with (coordinate with) the basin-wide DMS (see **Sections 18.1** and **18.3**). • See KGA response to this comment for further information.

Summary of Comments in the Farmland Reserves (FR) Comment Letter (11/27/2019) and Responses from WRMWSD

Comment Number	FR Comment	Response from WRMWSD
1	**Allocation of Groundwater Rights.** Though not specifically addressed, we are concerned that the overlying right to extract groundwater will be allocated among all District landowners based on gross acreage. While this is a simple approach to what can be a complex issue, it ignores accepted principles of law intended to more fairly allocate this right among those who have historically used groundwater for irrigation purposes-and made substantial investments based on that use. We wish to at least see identification of this issue in the Chapter and an acknowledgment that it will not be decided now. If the District determines that the issue is broader, then we leave it to the District to address it at the Umbrella GSP level. Any implication that the District has decided to allocate the overlying groundwater rights based simply on gross acreage could invite some to pursue premature legal action to challenge the District's conclusion, which might not be necessary depending on the success of the proposed actions in the Chapter. While this issue certainly affects our interests, we are equally concerned about avoiding unnecessary legal challenges made by others and the instability that would bring to the sub-basin.	• "Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). • ***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and not a determination of actual legal ground water rights.*** • Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.2**. • See KGA response to this comment for further information.
2	**Native Yield.** The Chapter identifies a coordinated estimated native yield of 0.15-.0.30 acre feet per acre across the KGA. We understand and acknowledge that some number needed to be identified for Water Budget and planning purposes and support the use of these numbers for such purposes. However, these numbers should not be seen as establishing a precedent or used to establish some legal right. Therefore, a statement emphasizing the above points should be made - the planning purpose nature of these numbers and not establishing legal precedent. Additionally, in coordinating with other members of the KGA under the Umbrella GSP, the District should push for a consistent native yield and related methodology across the sub-basin. We understand that this can be a politically charged process, but we are confident the District	• "Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). • ***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and not a determination of actual legal ground water rights.*** • Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.2**. • See KGA response to this comment for further information.

Comment Number	FR Comment	Response from WRMWSD
	can provide support for a consistent approach, which will enable a more stable sub-basin.	
3	**Groundwater Market.** This issue might be premature at this point. However, the Chapter could address the possibility of a market for the exchange or transfer of groundwater credits. If a market system were contemplated, we would encourage such a system to be as flexible as possible (within the requirements of SGMA, the Chapter and the Umbrella GSP) to facilitate the needs of farmers with lands in different areas of the sub-basin and those with the ability to store surface water underground. Again, this might be premature at this time, but a mention of the District's position to support a flexible groundwater market could help move the discussion forward once the Umbrella GSP is submitted to the Department of Water Resources and agencies begin the implementation process.	• The MA Plan includes in its portfolio of P/MAs a management action to evaluate and potentially implement a groundwater marketing and trading system (see **Section 17.2.2**). • As described in **Section 18.2**, implementation of P/MAs, including the potential establishment of a market-based system, will include performance of any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. • See KGA response to this comment for further information.

Summary of Comments in the Hancock Financial Services (HFS) Comment Letter (11/27/2019) to KGA and Responses from WRMWSD

Page Number in HFS Letter	HFS Comment	Response from WRMWSD
1	**Allocation of Native Yield** The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water, for example xxx,xxx acre-feet and not associated with a given gross or net area. In the event that allocations of any sort are distilled to a landowner or property level, HFS encourages the GSAs in the basin to initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations that are coordinated across the basin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and attempt to be consistent with groundwater rights, recognizing that GSAs do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations, in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – EDF and NCWL, dated July, 2018	• "Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). • ***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and not a determination of actual legal ground water rights.*** • Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.2**. • ***Section 18.4 which describes Stakeholder Engagement as part of MA Plan implementation, has been modified to include a statement that any actions to establish landowner-level allocations of native yield will be conducted through a robust stakeholder engagement process.*** • See KGA response to this comment for further information.
1	**Groundwater Recharge and Banking** GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge	• As described in **Section 18.2**, implementation of P/MAs, including projects increase in-District and out-of-District banking operations, will include performance of any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate.

Page Number in HFS Letter	HFS Comment	Response from WRMWSD
	by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	• See KGA response to this comment for further information.
3	**Refinement and Validation of Consumptive Use Calculations Based on ET Measurement** HFS supports use of efficient and accurate systems to determine groundwater use. GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water.	• The comment is noted. • See KGA response to this comment for further information.

Summary of Comments in the Westchester Group Investment Management (WGIM) Comment Letter (11/27/2019) to KGA and Responses from WRMWSD

Page Number in WGIM Letter	WGIM Comment	Response from WRMWSD
1	**Allocation of Native Yield** The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water and not associated with a given gross or net area. In the event that allocations are to be made at a landowner or property level, WGIM encourages the KGA and other GSAs in the basin to initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations that are coordinated across the basin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and attempt to be consistent with groundwater rights, recognizing that GSAs and Management Areas (MAs) do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations, in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – EDF and NCWL, dated July, 2018.	• "Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). • ***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and not a determination of actual legal ground water rights.*** • Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.2**. • ***Section 18.4 which describes Stakeholder Engagement as part of MA Plan implementation, has been modified to include a statement that any actions to establish landowner-level allocations of native yield will be conducted through a robust stakeholder engagement process.*** • See KGA response to this comment for further information.
1	**Pumping Restrictions** We understand that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs and MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible without creating undesirable results, pumping should be ramped down gradually over the	• Demand reduction Management Actions are included in the MA Plan as one element in a portfolio of P/MAs (see **Section 17**). • The P/MA implementation timetable is based on a phased/incremental "glide path" approach (see **Section 17.1.4**).

Page Number in WGIM Letter	WGIM Comment	Response from WRMWSD
	implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated and consistent across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).	• P/MA implementation will entail, in many cases, performing studies and/or analysis to refine concepts into actionable projects or policies (see **Section 18.2**). ***Section 18.2 was modified to clarify that such studies will be based on using the best available data and science.*** • See KGA response to this comment for further information.
2	**Groundwater Recharge and Banking** GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked water inventory, and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	• As described in **Section 18.2**, implementation of P/MAs, including projects to increase in-District and out-of-District banking operations, will include performance of any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate.
2	**Measurement and Data Management** GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions.	• The comment is noted. • ***Section 8.1 has been added to the MA Plan to describe data sources used in MA Plan development and how this local DMS will be coordinated with the basin-wide DMS.*** • ***Appendix E has been added to the MA Plan to list additional water quality data sources that will be evaluated during MA Plan implementation.***

Page Number in WGIM Letter	WGIM Comment	Response from WRMWSD
	Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	• The Plan implementation section includes an action to refine the local DMS to comply with (coordinate with) the basin-wide DMS (see **Sections 18.1** and **18.3**). • See KGA response to this comment for further information.
3	**Refinement and Validation of Consumptive Use Calculations Based on ET Measurement** WGIM supports use of efficient and accurate systems to determine groundwater use. GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water.	• The comment is noted. • See KGA response to this comment for further information.

Summary of Comments in The Nature Conservancy (TNC) Comment Letter (11/27/2019) to KGA, and Responses from WRMWSD

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
9	**Notice and Communication** Please describe the other beneficial uses and users of groundwater in the Subbasin identified by the Water Code including: GDEs; managed wetlands; Protected Lands, including preserves, wildlife refuges, conservation areas, recreational areas and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, recreation and navigation. Please identify any environmental uses and users of groundwater in the plan area, and take particular note of the species with protected status.	• See KGA response to this comment for further information.
10	**Plan Area Setting** Please provide a description of any current and planned instream flow requirements or regulatory requirements for protection of species of concern in the Kern River, Poso Creek and Caliente Creek. If there are no requirements in place or planned, then please state that in the GSP.	• See KGA response to this comment for further information.
10	**Existing Plans in the Plan Area** We suggest adding a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. Please include a description of any land use or environmental plans relevant to wetlands, aquatic resources and other GDEs and ISWs and their relationship to the GSP. Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands around the Kern Wildlife Refuge, aquatic resources and other GDEs and ISWs.	• **Section 5.3** of the MA Plan includes information about land use plans (i.e., General Plans), including a summary of goals, policies and implementation measures related to land and water use. • See KGA response to this comment for further information.

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
	Please identify all relevant HCPs and NCCPs within the Subbasin and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.	
10	**Existing and Ongoing Water Resource Programs** Please provide a description of resource management plans, monitoring activities and responsibilities by State, Federal and local agencies and jurisdictions related to aquatic resources and GDEs that could be affected by groundwater withdrawals, and list them in Table 2-1. Please review and discuss the potential groundwater reliance of critical species in the Subbasin. Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP. Please include a discussion of any monitoring programs related to GDEs and sensitive habitats.	• See KGA response to this comment for further information.
11	**Well Permitting Process, Well Construction Policies** Please discuss that future well permitting and well construction must be coordinated with the GSP to assure achievement of the Plan's sustainability goals. Please state how the well permitting process incorporates protection of GDEs and ISWs within the Subbasin. Please include a discussion of the need for well permitting programs to comply with this requirement.	• **Sections 5.3.2** and **5.4** of the MA Plan includes discussion of the Kern County Well Permitting Process. • See KGA response to this comment for further information.
11	**Hydrogeologic Conceptual Model – Bottom of the Subbasin** Please characterize groundwater well extractions from the deepest wells in relation to defining the basin bottom.	• **Section 7.1.3** of the MA Plan describes the definition of the bottom of the basin, which includes consideration of the deepest groundwater wells.

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
	If the bottom boundary of the Subbasin has not been clearly defined in certain management areas, please identify this as a data gap and elaborate in the monitoring section how and where additional observations can be made to reconcile this data gap.	• See KGA response to this comment for further information.
12	**Hydrogeologic Conceptual Model – Principal Aquifers and Aquitards** Please provide additional description of the shallow aquifers within the Subbasin including characteristics of interconnections with surface water and GDEs, vertical groundwater gradients, connections with underlying production aquifers, and the resulting potential interaction of groundwater pumping with ISWs and GDEs. Please state whether localized perched aquifers are present in the Subbasin. Describe any data gaps. The function and significance of the Shallow Aquifers that provide groundwater to ISWs and GDEs should be summarized in Table 2-3. Please describe whether the existence of Aquifer Exemptions has any bearing or implications related to environmental beneficial uses of groundwater.	• **Section 7.1.4** of the MA Plan mentions the occurrence of the "A"-Clay which may result in localized perched groundwater in some areas. • **Section 7.3.2** of the MA Plan mentions that these perched zones are often poor quality and do not yield significant or economic amounts of water to wells, springs, or surface water systems, and are therefore not considered part of the principal aquifer. • See KGA response to this comment for further information.
12	**Hydrogeologic Conceptual Model – Data Gaps and Uncertainty** If data are not present to produce the information requested in the comment above, please clearly identify this as a data gap. Please elaborate in the monitoring section how and where additional observations are to be conducted in order to address this data gap.	• See KGA response to this comment for further information.
	Hydrogeologic Conceptual Model – Cross-Sections Please include near-surface cross sections or insets that depict the conceptual understanding of shallow groundwater and ISW interactions at different locations, including perched and regional aquifers and GDEs.	• See KGA response to this comment for further information.
13	**Hydrogeologic Conceptual Model - Elevation and Flow Directions** Please provide any available stratigraphic data, hydrograph data, pumping test data or other information to substantiate these claims. If the data are not available, please identify this as a data gap.	• See KGA response to this comment for further information.

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
14	**Interconnected Surface Water Systems** Please provide additional data or analysis to substantiate the nature of the hydrologic relationship between the shallow aquifer and production aquifers and ISWs. If data are not available to verify that such a connection does not exist, acknowledge where ISWs may exist and identify appropriate sustainable management criteria, monitoring networks and management actions for sustainable ISW management or to address data gaps. Data could include groundwater level data from shallow or nested monitoring wells, comparison of stream stages to groundwater levels, modeling information or additional gaging data. Please elaborate how and where additional observations (shallow monitoring wells, stream gauges, and nested / clustered wells) along surface water features can be used to address data gaps in the Monitoring Network section of the GSP to improve identification of ISWs rather than prematurely disregarding them in the GSP.	• The process used to assess the potential occurrence of interconnected surface water in the Management Area is based on depth to groundwater (similar to the process used for evaluation of GDEs, which was done consistent with TNC (2019) guidance; see below) based on available data from wells in the principal aquifer, as described in **Section 8.2** and **8.7**. • See KGA response to this comment for further information.
14	**Groundwater-Dependent Ecosystems** Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gaps will be addressed. Please support this statement with specific groundwater level data that indicate a gap in the saturated zone between the production aquifers and shallow groundwater, and define the extent of the NCCAG dataset polygons that are excluded from consideration as GDEs on this basis. Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gap will be resolved. Please revise the GDE analysis in the GSP by conducting more substantial, data-based evaluation focusing on GDE identification in	• The process used to assess the potential occurrence of GDEs in the Management Area is based on depth to groundwater based on available data from wells in the principal aquifer, as described in **Section 8.2** and **8.8**. Specific data regarding depths to groundwater water in the principal aquifer in Spring 2015 were provided. • ***Section 8.8 was modified to include mention of the use of TNC (2019) guidance and criteria therein.*** • The criteria used to remove NCCAG from the list of potential GDEs is a depth to water greater than 30 feet, which is based on guidance from The Nature Conservancy (2019). • See KGA response to this comment for further information.

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
	the GSP, clearly identify which NCCAG polygons are excluded, which polygons are determined to be GDEs and which polygons are uncertain at this time and will be verified as data gaps are address. Confirmation of GDEs should be performed based on depth to groundwater in the shallow zone, and additional information provided as to whether the shallow zone may be affected by groundwater withdrawal from the production aquifers. Please refer to Appendix D of this letter for best practices for using groundwater data to verify a connection to groundwater. Therefore, we recommend using depth to groundwater contour maps derived from subtracting groundwater levels from a DEM, as described above, to identify whether a potential connection to groundwater exists for the wetlands mapped in Attachment H of the GSP. Please refer to Attachments D and E of this letter for best practices for using local groundwater data to 1) verify whether polygons in the NC Dataset are supported by groundwater in an aquifer, and 2) verify whether ecosystem decline or recovery is correlated with groundwater levels. We recommend the inclusion of a discussion regarding the nature and characteristics of GDEs. Please provide information on the historical or current groundwater conditions near the GDEs or the ecological conditions present. We recommend an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes vegetation or habitat types and rank the GDEs as having a high, moderate or low value. Explain how each rank was characterized.	

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
	Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs. Some organisms rely on uplands and wetlands during different stages of their lifecycle.	
17	**Water Budget** Please provide a breakdown of ET for native and riparian vegetation (such as wetlands, riparian vegetation, phreatophytes and other communities). Please evaluate the spatial relationship of native vegetation ET to NCCAG polygons to determine the groundwater use by this beneficial user for inclusion in the water budget. Identify any data gaps and outline the actions needed to address them.	• ET information used in the water budget analysis is from the ITRC-METRIC study and includes all lands, including non-irrigated lands. • See KGA response to this comment for further information.
17	**Sustainability Goal** Please clarify the sustainability goal and expand its description to ensure that all beneficial uses and users of groundwater are identified as being protected from undesirable results, and in particular, include GDEs, ISWs and related critical habitats. Since GDEs and ISWs may be present in the Subbasin (please see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be specifically included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included. Please include ISWs in the Sustainability Goal until/unless sufficient data is available and provided to verify the status of ISWs. Given that there are potential GDEs in the Subbasin and that they may be affected by water quality, they should be included in the Sustainability Goal and addressed in the Water Quality section.	• The sustainability goal for the MA Plan area is stated in **Section 2** and **Section 12**, and does include mention of beneficial uses including environmental. • See KGA response to this comment for further information.
18	**Minimum Thresholds and Measurable Objectives** For each of these applicable sustainable management criteria, please include a discussion of GDEs (see comments under checklist items 16-	• Because GDEs are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, sustainable management

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
	20) and whether the minimum thresholds, measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment. Please modify Section 3.2.2 to specifically address impacts from degraded water quality to the plant and wildlife communities within GDEs.	criteria for Depletion of Interconnected Surface Waters are deemed not applicable/necessary. • See KGA response to this comment for further information.
19	**Undesirable Results** Please add "possible adverse impacts to potential GDEs and ISWs" to the list of potential undesirable results. Please review these spatial patterns and, where possible, correlate them with water level trends. Any indications of adverse trends and any data gaps should be identified. For each identifiable GDE unit with supporting hydrological datasets, please include the following: For identifiable GDE units without supporting hydrological datasets please describe data gaps and / or insufficiencies. Compile and synthesize biological data for each GDE unit by: Describe possible effects on potential ISWs, GDEs, land uses, and property interests, including:	• Because GDEs and ISW are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, sustainable management criteria for Depletion of Interconnected Surface Waters are deemed not applicable/necessary. • See KGA response to this comment for further information.
20	**Monitoring Network** Please modify the description of the monitoring network to provide methodologies, data and other information to address the data gaps associated with GDEs and ISWs. This modification should include 1) locating new wells that are appropriately screened to detect changes in groundwater levels in the uppermost water table and the connectivity of GDEs and ISWs with the upper unconfined or shallow zone aquifer; and 2) identifying or installing additional stream gauges in areas where there is potential for ISWs and GDEs. Please expand on	• See KGA response to this comment for further information.

Page Number in TNC Comment Letter	TNC Comment	Response from WRMWSD
	the discussion of how the new well and stream data will be used to improve ISW mapping and inform an adequate analysis, and how the data will be used to verify possible GDEs. Please address data gaps along the Kern River and tributary creeks identified earlier in the GSP in this section of the GSP to improve ISW mapping in companion or future GSPs (e.g., through shallow monitoring wells, stream gauges, and nested/clustered wells).	
21	**Projects and Management Actions** For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue. Please consider additional management actions and projects targeted for protecting ISWs and GDEs. Please describe how the projects and management actions will be evaluated to assess whether adverse impacts to GDEs may occur and/or will be mitigated or prevented.	• Because GDEs and ISW are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, P/MAs to benefit and protect GDEs and ISW are deemed not applicable/necessary. • See KGA response to this comment for further information.

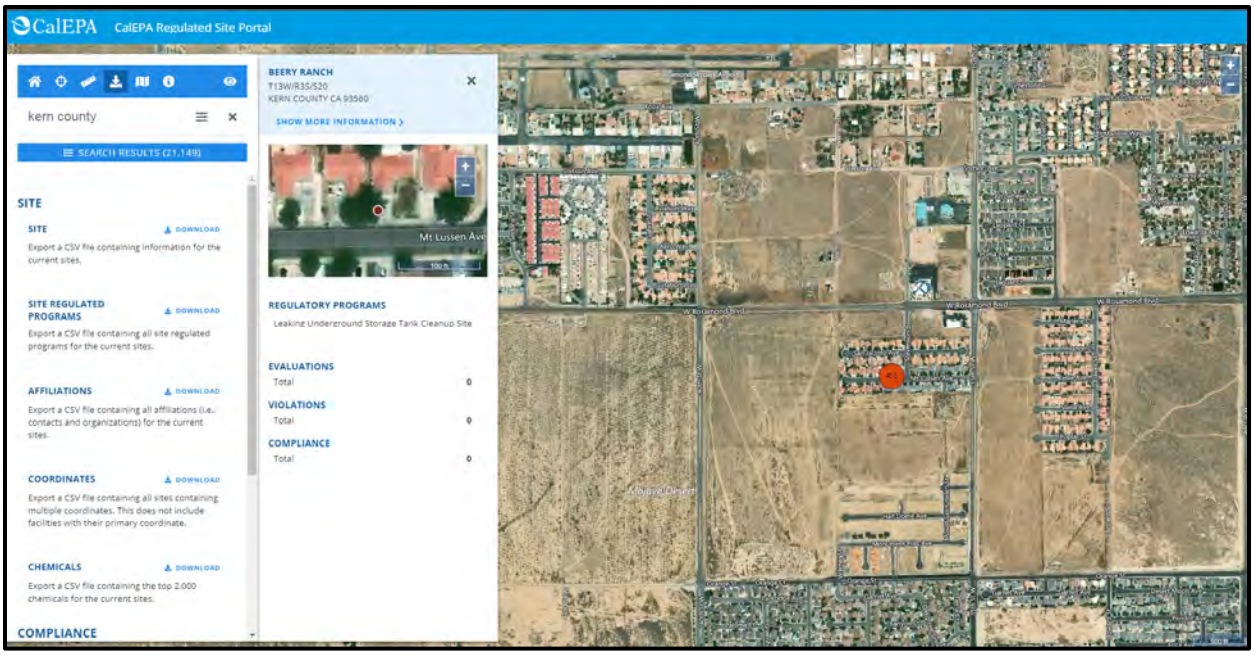
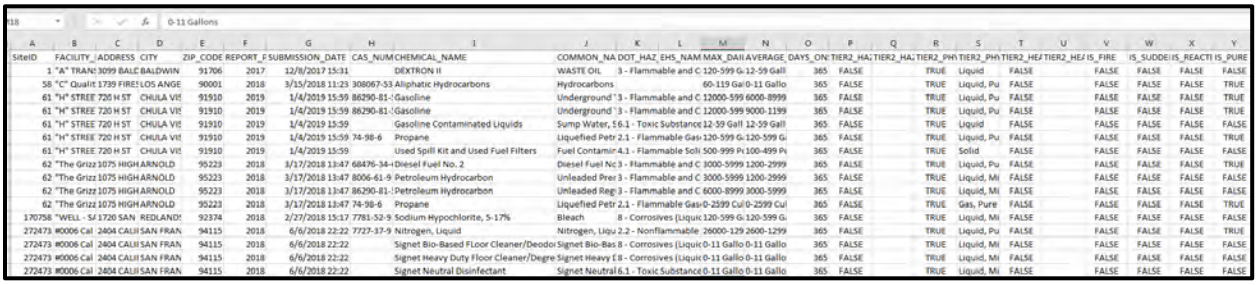
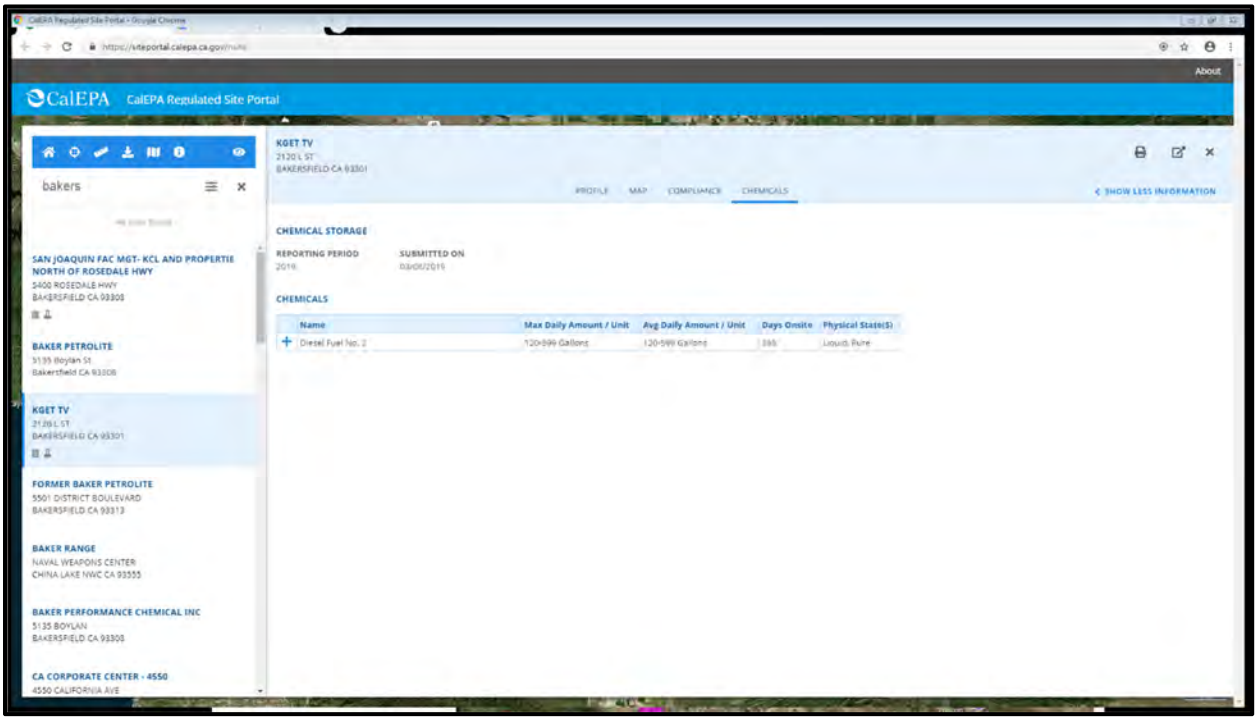
1. California EPA – Information on Hazardous Waste in Groundwater



1.1. Regulated Site Portal



https://siteportal.calepa.ca.gov/nsite



- Lists many environmentally regulated sites and facilities, including: hazardous waste and materials, hazardous waste facilities and sites, and storm water management sites.
- Data sources include California Occupational Safety and Health Administration (Cal/OSHA), California Environmental Reporting System (CERS), California Integrated Water Quality System (CIWQS), US EPA's Emission Inventory System (EIS), the California Department of Toxic Substances Control's (DTSC) EnviroStor site, the State Water Resources Control Board's (SWRCB) GeoTracker site, the SWRCB's Stormwater Multiple Application and Report Tracking System (SMARTS), the Solid Waste Information System (SWIS), and the federal Toxic Release Inventory (TRI) database.
- Contains downloadable data (e.g., quantity of chemical release), and other regulatory documents.
- No available spatial or temporal concentration data.

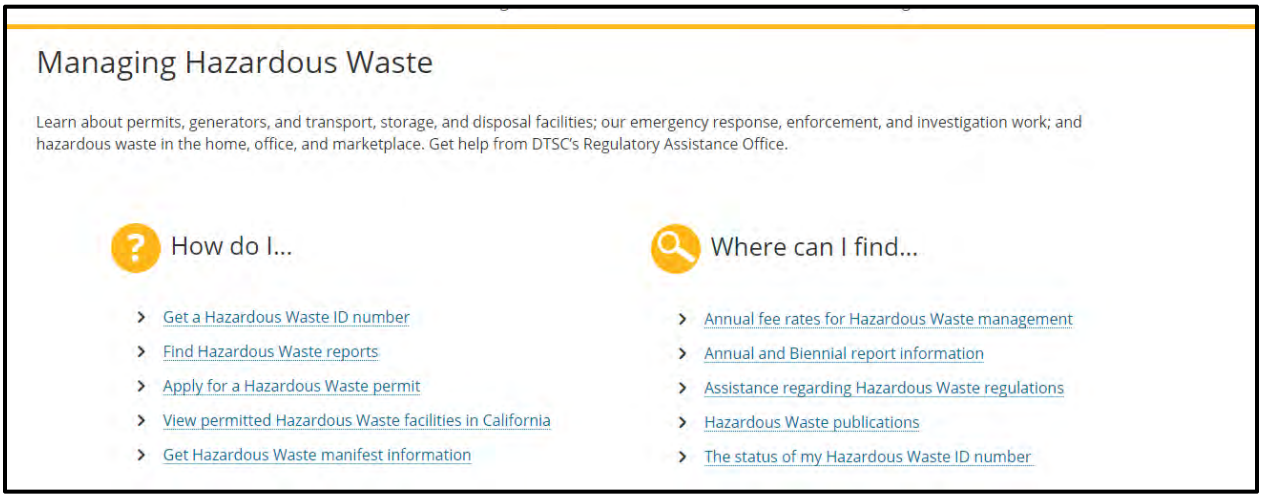
1.2. Cortese List

https://calepa.ca.gov/sitecleanup/corteselist/

- A list released by CalEPA annually, including hazardous waste and substance sites (DSTC), leaking USTs, solid waste disposal sites, "active" CDO and CAO sites.
- Data sources from DTSC, SWRCB, and local enforcement agencies.
- No available spatial or temporal concentration data.

Screenshot of website:

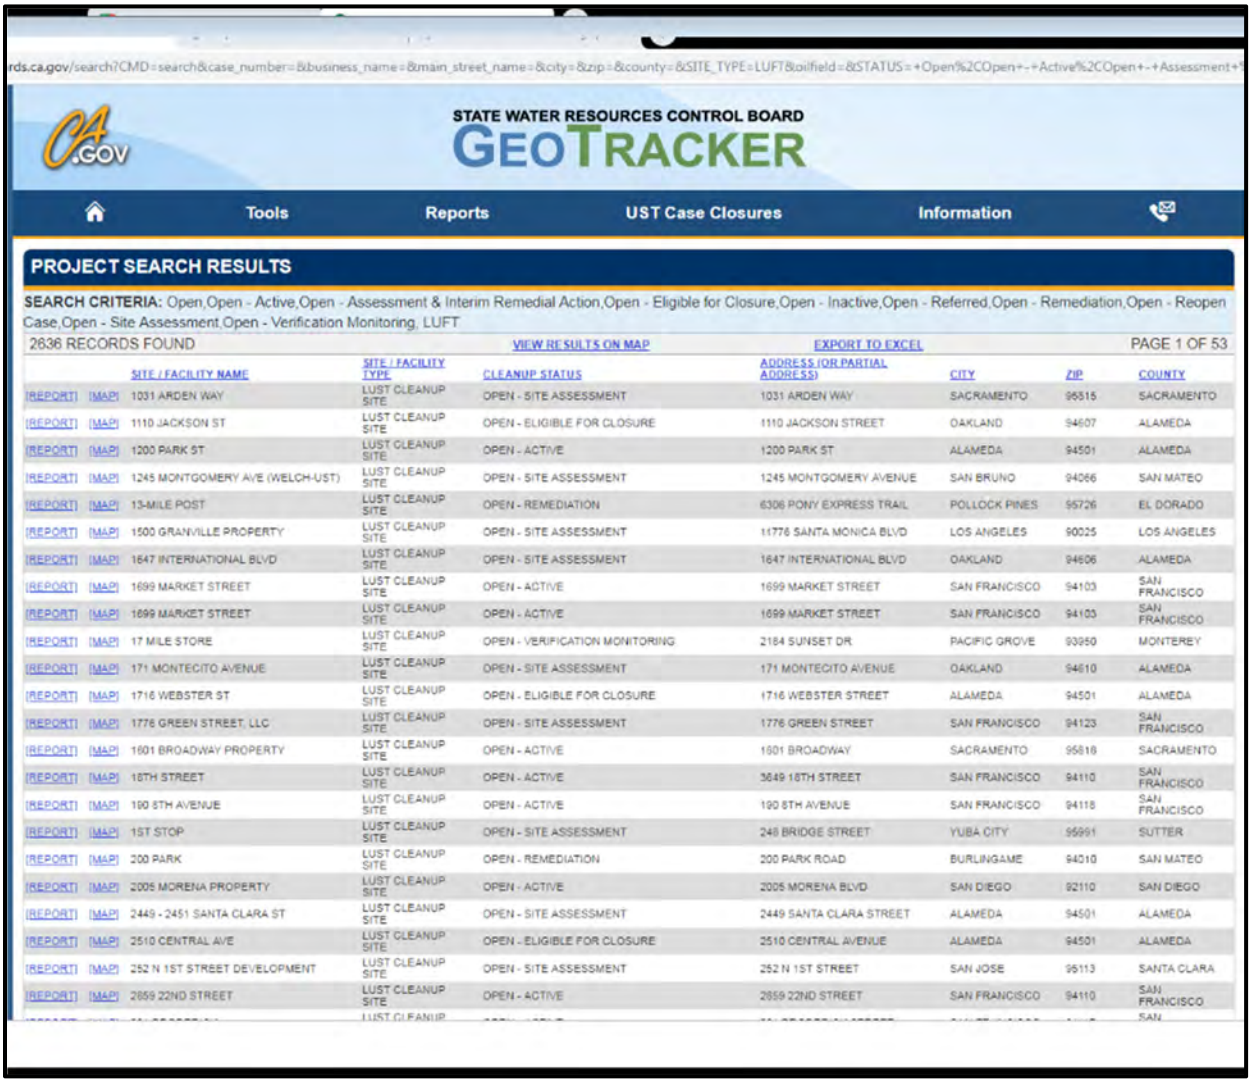


1.3. Managing Hazardous Waste website

https://dtsc.ca.gov/managing-hazardous-waste/

- Hazardous waste sites updates/status/current regulation.

Screenshot of website:



1.4. GeoTracker

https://geotracker.waterboards.ca.gov/map/?global_id=T10000006808

- Lists relevant information about the hazardous sites, including location, substance of spill, clean up timeline, monitoring reports, site investigation reports, regulatory correspondence, etc.
- Chemical data available for each county (as txt file, can be opened with Access or Excel). https://geotracker.waterboards.ca.gov/data_download_by_county
- Temporal and spatial chemical concentration data.

Screenshots of website and selected downloadable data:

Superfund: National Priorities List (NPL)

The National Priorities List (NPL) is the list of sites of national priority among the known releases or threatened releases of hazardous substances, pollutants, or contaminants throughout the United States and its territories. The NPL is intended primarily to guide the EPA in determining which sites warrant further investigation.

- New Proposed NPL Sites & New NPL Sites - Documents for the most recently proposed NPL sites and recently added NPL sites, including: Documentation Records, Site Listing Narratives, Support Documents and other supporting documentation.
- View a map of all the sites in the U.S., currently on the NPL, proposed to the NPL and deleted from the NPL.

ADVANCED MICRO DEVICES, INC. SUNNYVALE, CA

Announcements and Key Topics

EPA continues indoor air sampling for TCE vapors in homes and school buildings near the Site and is overseeing the installation of more than 20 mitigation systems in residences and classrooms affected by vapor intrusion.

Background

The former Advanced Micro Devices, Inc. 901/902 Thompson Place Superfund Site (Site) covers 6 acres in Sunnyvale, California. AMD designed and fabricated semiconductor devices at two adjoined low-rise buildings at ...

3. California EPA – Information on Drinking Water Quality

3.1. Water Quality Analysis Database Files

https://www.waterboards.ca.gov/drinking_water/certlic/drinkingwater/EDTlibrary.html

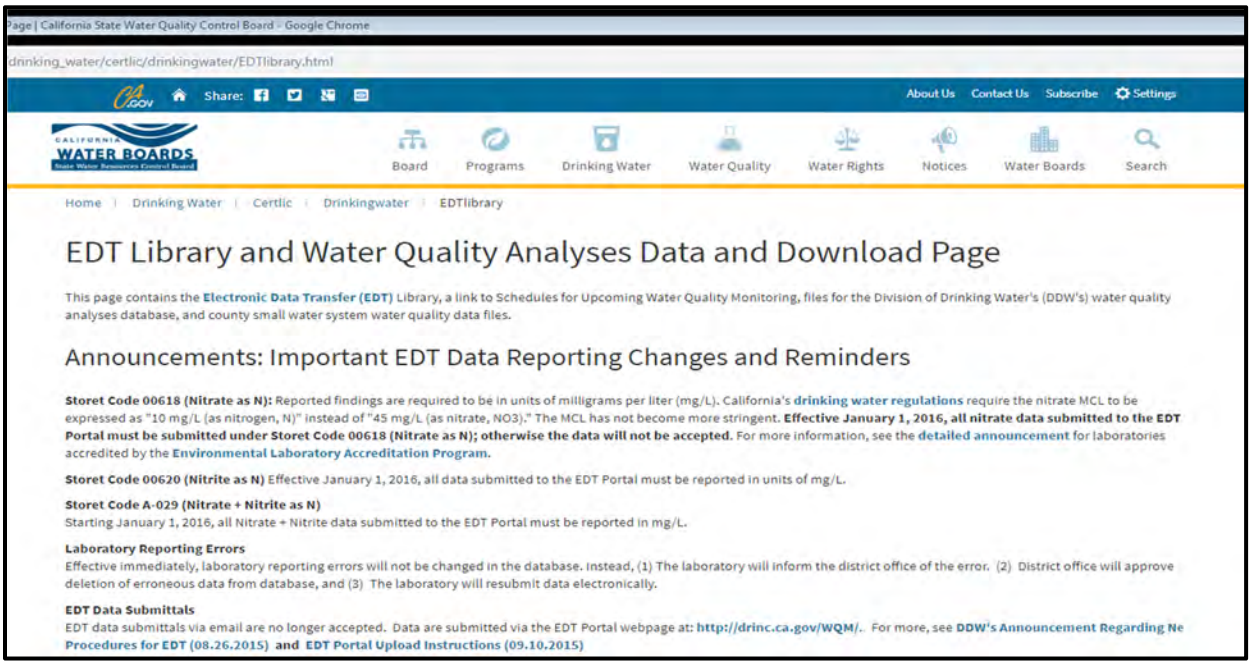
- Electronic Data Transfer (EDT) Library, a link to Schedules for Upcoming Water Quality Monitoring, files for the Division of Drinking Water's (DDW's) water quality analyses database, and county small water system water quality data files.
- Statewide current and historical chemical data from water suppliers.
- Downloadable data, including temporal data.
- Chemical data from April 1947 to current; data format: dbf, can be opened in Access; supporting database files are needed to interpret the data.

Screenshots of website and downloadable data:

Drinking water analyses reported directly from laboratories - Last Update May 1, 2019.

- **CHEMICAL.ZIP** contains chemical data from January 1, 2013 through this month
- **CHEMHIST.ZIP** contains chemical data from January 1, 2007 through December 31, 2012
- **CHEMARCH.ZIP** contains chemical data from January 1, 2000 through December 31, 2006
- **CHEMXARC.ZIP** contains chemical data from April 1974 through December 31, 1999

Supporting database files - Last Update May 1, 2019.



- Drinking Water Source identification number (PS Code), name and type **(SITELOC.DBF)**
- Water Systems identification number, name, and address **(WATSYS.DBF)**
- Laboratories reporting water quality analyses **(LAB.DBF)**
- Chemical (Storet) Reported **(STORET.DBF) (Pre 2016 STORET - .zip version)**
- Word file **WQM Documentation.doc** provides additional description and explanation of the individual files available for downloading - Last Update June 1, 2017

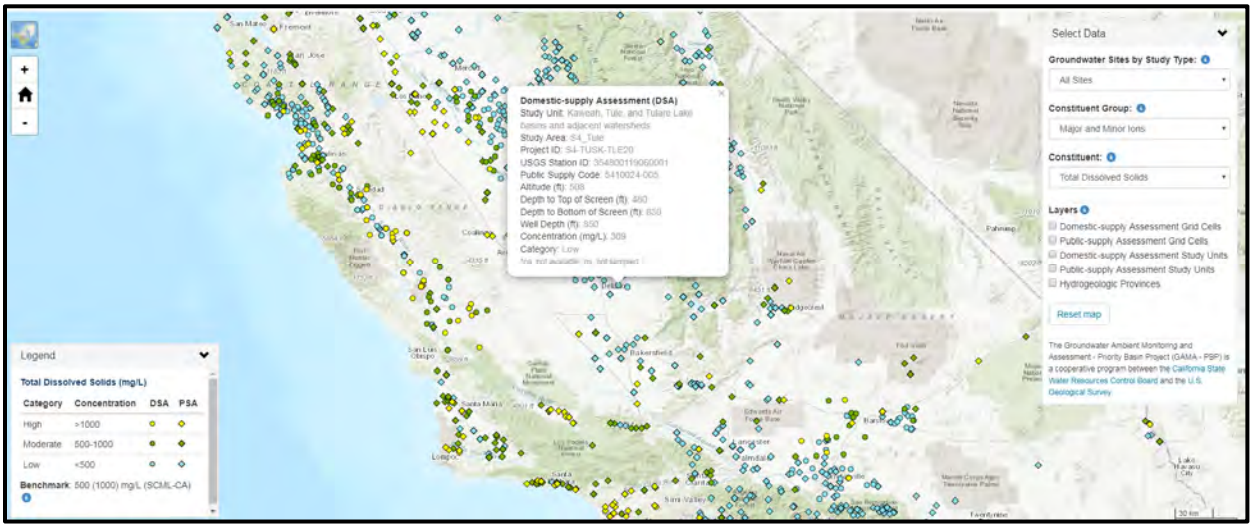
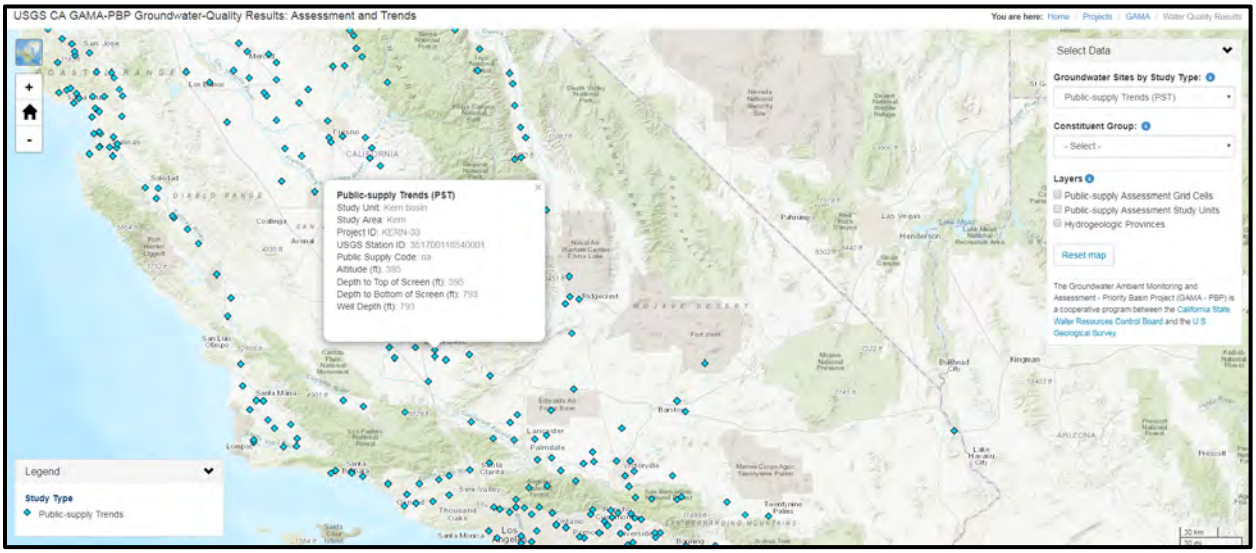
3.2. Drinking Water Watch

https://sdwis.waterboards.ca.gov/PDWW/

- This website provides a variety of chemical data (including many uncommon chemicals) for wells and distribution systems. Includes historical data (at least dated back in the 1980s).
- Data are available in the pdf form (convertible to Excel).
- With well locations and temporal changes in chemical concentrations, a trendline analysis is feasible.

Screenshots of website and downloadable data:





3.3. GAMA-PBP Groundwater-Quality Results: Assessment and Trends

https://ca.water.usgs.gov/projects/gama/water-quality-results/

- From USGS California Water Science Center, Groundwater Ambient Monitoring and Assessment (GAMA) Priority Basin Project (PBP)
- Map viewer showing concentrations and trends of many constituents, such as metal ions, nutrients, TDS, pesticides, VOCs, age-dating tracers, radioactivity, etc.
- Concentrations are provided and categorized as different ranges, with color code. No date is associated with the measurements.
- No downloadable data.

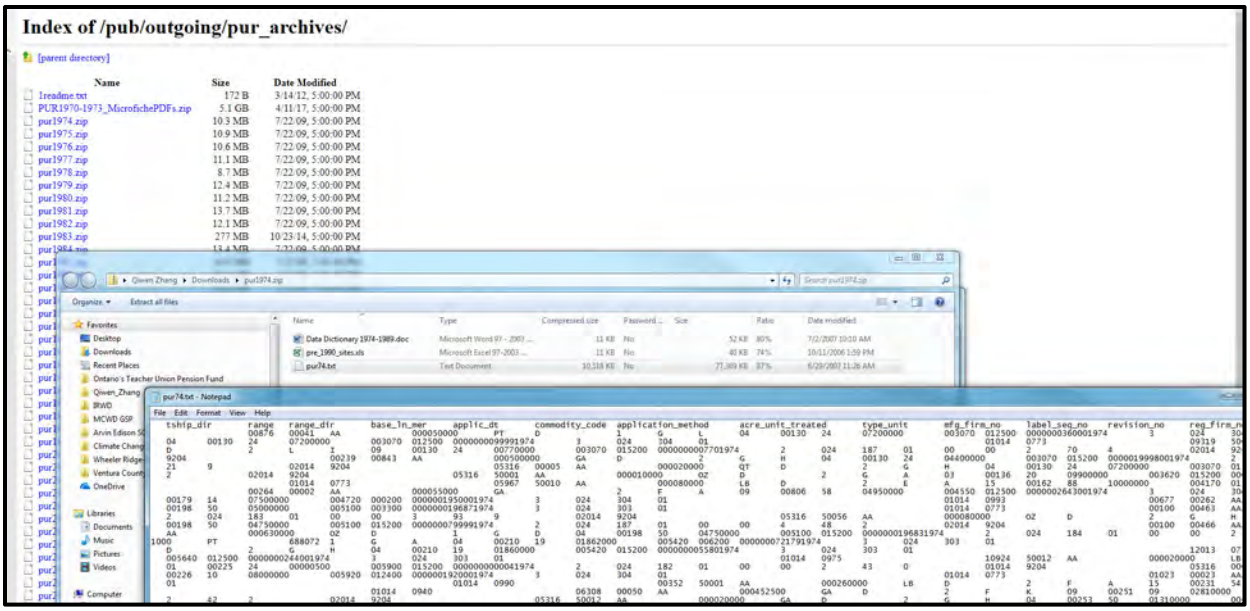
4. Information on Pesticide Use pertaining to groundwater quality



4.1. California Pesticide Information Portal (CalPIP)

https://calpip.cdpr.ca.gov/main.cfm

- From Department of Pesticide Regulation (DPR).
- Pesticide use reporting (PUR) data, and Groundwater Protection Areas (GWPAs).
- Downloadable data in text files, shapefiles, maps, and KML files.
- Data can be sorted by locations, chemicals, years, counties.
- Trendline analysis can be done on usage of pesticides, but not on groundwater elevation or chemical concentrations.
- Data archives are available for download. ftp://transfer.cdpr.ca.gov/pub/outgoing/pur_archives/
    - List the locations and quantities of pesticide uses for that year.
- Pesticide use reporting (PUR) https://www.cdpr.ca.gov/docs/pur/purmain.htm
    - Choose location of interests and generate a report.

4.1.1. Locations of Ground Water Protection Areas (GWPA)

https://www.cdpr.ca.gov/docs/emon/grndwtr/gwpa_locations.htm

- GWPA maps and county lists.
- Downloadable maps, shapefiles, KML files.
- Contains locations of regulated sites, but no data.
- Choose a township and check whether it contains GW Protection Areas. https://calpip.cdpr.ca.gov/county.cfm?ds=GWPA
- Ground Water Protection Area Lists https://www.cdpr.ca.gov/docs/emon/grndwtr/gwpa_lists.htm

Choose a Township (COMTR) or townships under the county(s) specified and click **Select**. Then choose a Section (COMTRS) or sections under the township(s) specified and click **Select**. Then go to **Submit**.

Available COMTR Township and Range under selected county(s) (257):

15 M24S18E
15 M24S34E
15 M24S36E
15 M25S17E
15 M25S18E

Select

Available COMTRS Sections within selected Township-Range (1):

15 M24S34E 31

Select

Township(s) Selected (1):

15 M24S34E

Unselect | Unselect All

Section(s) Selected (1):

15 M24S34E 31

Unselect | Unselect All

Please click on the SUBMIT button to receive GWPA information about the township and section you selected in the county(s) chosen, or click the RESET button to clear your selection.

5.3. Water Quality in Areas of Oil and Gas Production – Regional Groundwater Monitoring Program

https://www.waterboards.ca.gov/water_issues/programs/groundwater/sb4/regional_monitoring/index.html#overview

- Salinity mapping.
- Produced water characterization.
- Groundwater potential risk zone analysis.
- Data from USGS, DOGGR, and other state and regional boards.
- Chemical data are available to download. Trendline analysis is feasible.
- Data releases: https://www.waterboards.ca.gov/water_issues/programs/groundwater/sb4/regional_monitoring/index.html#datareleases

Screenshots of website and selected downloadable data:

Reports

The data collected during the exploratory sampling is summarized in the following report: "USGS Open-File Report 2016-1181: Data from Exploratory Sampling of Groundwater in Selected Oil and Gas Areas of Coastal Los Angeles County and Kern and Kings Counties in Southern San Joaquin Valley, 2014–15: California Oil, Gas, and Groundwater Project"

The U.S. Geological Survey sampled water wells in the Los Angeles Basin and southern San Joaquin Valley, California, and oil wells in the San Joaquin Valley for analysis of multiple chemical, isotopic, and groundwater-age tracers. This report summarizes that work to evaluate the utility of using tracers for assessing oil and gas production activities on groundwater quality in California. The report is available at the following: "Preliminary results from exploratory sampling of wells for the California oil, gas, and groundwater program, 2014–15, Open-File Report 2016-1100."

The U.S. Geological Survey compiled data that characterizes the intensity of petroleum resource development and proximity to groundwater resources. This report is available at the following: "Prioritization of oil and gas fields for regional groundwater monitoring based on a preliminary assessment of petroleum resource development and proximity to California's groundwater resources, Scientific Investigations Report 2018-5065."

The U.S. Geological Survey compiled a report to document the preliminary groundwater salinity mapping of 31 oil fields and adjacent aquifers. The data is summarized into 8 sub-regions across major oil-producing areas of central and southern California. This report is available at the following: "Preliminary groundwater salinity mapping near selected oil fields using historical water-sample data, central and southern California. Scientific Investigations Report 2018-5082."

Data Releases

Data collected from collected produced water samples from four petroleum wells in the southern San Joaquin Valley. This digital dataset contains the site information, analyzing laboratories and methods, and water chemistry and quality control results for these samples. The report is available at the following: Produced water chemistry data for samples from four petroleum wells, Southern San Joaquin Valley, California (2014)

Supporting data for the "Produced water chemistry data for samples from four petroleum wells, Southern San Joaquin Valley, California, 2014" (9/6/2016)

Data from the Fruitvale produced water ponds is available at the following link: Historical produced water chemistry data compiled for the Fruitvale Oilfield, Kern County, California (3/20/2018)

Supporting data for the "Produced water chemistry data for the Lost Hills, Fruitvale, and North and South Belridge study areas, Southern San Joaquin Valley, California" (6/7/2018)

Data Analyzed for the Preliminary Prioritization of California Oil and Gas Fields for Regional Groundwater Monitoring (7/23/2018)

Supporting data for the "Water and petroleum well data used for preliminary regional groundwater salinity mapping near selected oil fields in central and southern California" (7/24/2018)

"Groundwater and surface water chemistry results for samples collected near the Lost Hills and North and South Belridge oil fields, Kern County, California" (9/17/2018)

"Geochemical and geophysical data for wells in the Fruitvale and Rosedale Ranch oil and gas fields, Kern County, California, USA" (9/27/2018)

"Water chemistry data for samples collected at groundwater sites near the Fruitvale oil field, September 2016–February 2017, Kern County, California" (9/20/2018)

"Geochemical, geological, and geophysical data for wells in the Poso Creek oil and gas field, Kern County, California" (12/13/2018)

"Geophysical and geochemical data for salinity mapping in the Midway-Sunset oil field area" (12/19/2018)

"Historical produced water chemistry data compiled for the Lost Hills and North and South Belridge Oilfields, Kern County, California" (1/29/2019)

Water chemistry data for samples collected at gr…

View

An investigation was done by the U.S. Geological Survey, in cooperation with the California State Water Resources Control Board's Program of Regional Groundwater Monitoring of Water Quality in Areas of Oil and Gas Production, to assess the effects of oil and gas production activities on nearby groundwater resources. During November 2016–September 2017, 30 samples were collected at groundwater wells and 1 sample was collected at a surface-water site. This dataset contains site information and water chemistry results for samples collected near the Lost Hills and North and South Belridge oil fields, Kern County, California. Samples were analyzed for water-quality indicators, major and minor ions, nutrients, trace elements, volatile organic compounds, naturally occurring radioactive material, geochemical and age-dating tracers, dissolved organic carbon, low molecular weight organic acids, dissolved standard and hydrocarbon gases, and dissolved noble and atmospheric gases. Quality-control samples including replicates; source-solution, equipment, and field blanks; laboratory spikes; and split samples for interlab comparisons were collected and summarized in this data release.

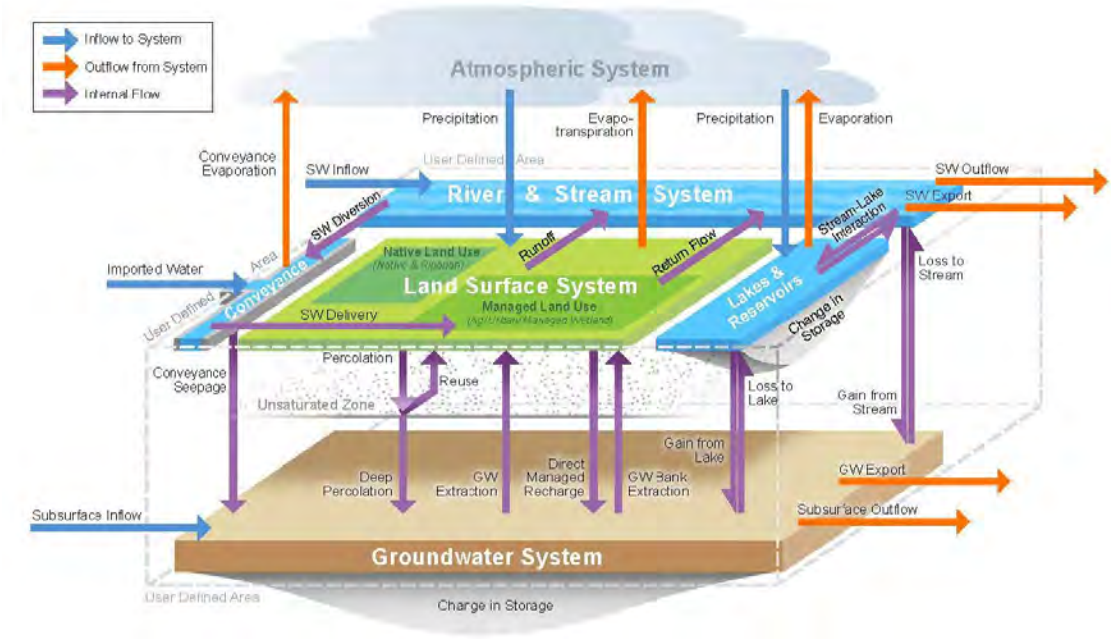
Methods and Data Used in the Water Budget Spreadsheet Model Approach

Appendix G-1

Water Budget Model Overview



APPENDIX G-1
WATER BUDGET MODEL OVERVIEW

A water budget is an accounting of all water inflows to and outflows from a given spatial domain, and enforces the principle of mass balance through use of a change in water storage term. A water budget is expressed by the following simple equation:

Inflows - Outflows = Change in Storage

The above fundamental equation holds true for any defined domain (e.g., parcel, watershed, basin, etc.) and length of time (e.g., day, month, year, etc.) and, when properly constructed using process- and/or physics-based components, serves as a powerful tool for understanding water flow through a system.

Figure G-1-1: DWR Water Budget Schematic (Fig. 7 from DWR's SGMA BMP #4, pg. 30)

Description of Water Budget Framework

A water budget "framework" has been developed to inform the development of a water budget model for the District's service area that is consistent with the requirements of the Sustainable Groundwater Management Act (SGMA) and aligns with the historical, current, and future water budget periods as specified by the Kern Groundwater Authority GSA (KGA GSA) and further described below. The conceptual water budget model is depicted on **Figures WB-1 and WB-2** of the Wheeler Ridge-Maricopa Water Storage District (WRMWSD) Kern Subbasin Management Area Plan, and is further described below.

Water Budget Subdomains

The water budget is divided into five internal subdomains, each influenced by a number of flow components and within which mass-balance is enforced (i.e., the sum of inflow components is balanced by the sum of outflow components and/or a change in storage component). **Figure WB-1** shows the water budget domain, and the following internal subdomains:

a. Artificial channels
b. Agricultural lands
c. Urban lands
d. Natural channels, and
e. Groundwater system

In addition to the five internal subdomains, several external subdomains are incorporated into the spreadsheet model. These include the watersheds that contribute streamflow to streams entering the District, and the atmosphere which is a source of precipitation and sink for evapotranspiration. The spreadsheet model does not explicitly account for the vadose (unsaturated) zone between the land surface and the (saturated) groundwater system, but instead incorporates temporal lag factors to account for the movement of water through this zone. An implicit assumption in this approach, therefore, is that the vadose zone does not experience any change in storage over time.

Water Budget Flow Components

Within and between each subdomain are 31 water budget flow components that route water through WRMWSD. **Figure WB-2** shows a conceptual diagram of the individual water budget flow components between subdomains as well as flow components that are external to the overall water budget domain (i.e., serve only as an inflow or outflow to the entire system, rather than a flow between subdomains). The 31 conceptual water budget flow components are listed in **Table G-1-1**, along with an overview of their estimation methods**.** The general relationship between water budget subdomains, associated flow components, and mass balance relationships is further depicted in **Table G-1-2**.

Certain components are based on "raw" data which are directly measured and based on historical records. These "raw" components are considered to have a relatively high degree of certainty. Other components are estimated using a variety of analytical methods (e.g., Darcy's Law to calculate subsurface flows across the domain's external boundaries) and are thus subject to greater uncertainty based on the parameters used in their estimation. Some components (i.e., groundwater pumping for agricultural use) constitute major proportions of the overall water budget and have thus been given significant attention. Others are relatively minor in magnitude (e.g., seepage from artificial channels) and are, to some degree, less significant to the overall water budget and less well defined.

While the various subdomains and linkages shown on **Figures WB-1** and **WB-2** and in **Table G-1-1** and **Table G-1-2** indicate a highly complex system, the use of such a component-based bottom-up approach allows each component to be considered separately which can benefit model development and application. For example, if new data or methods become available for a certain component, they can be easily plugged into the appropriate component without disturbing the rest of the model.

Water Budget Time Periods

As mentioned above, the water budget spreadsheet model was developed to estimate the magnitude of water budget flow components and the resulting change in groundwater storage to the local aquifer system underlying WRMWSD for three distinct time-periods as defined by the KGA GSA:

- **Historical –** DWR Water Years 1995 – 2014 (i.e., October 1994 – September 2014);
- **Current –** DWR Water Year 2015 (i.e., October 2014 – September 2015); and
- **Future –** 50-year projection of DWR Water Years 2016 – 2065 (see **Appendix G-6**).

Water Budget Spreadsheet Model Functionality

The water budget spreadsheet model was developed using Microsoft Excel. The complete model consists of one Excel (.xlsx) workbook with several individual spreadsheet tabs which can generally be grouped into four categories:

- "Master" Models
- "User Input Parameters" and Model Calibration
- Presentation and Reporting
- "Backend" Data and Calculations

"Master" Models

The final calculations for all historical and current (1994 - 2015) water budget components occur within the following three "master" tabs of the spreadsheet:

- **"Kern_monthly_WB"**
- **"WWB_monthly_WB"**
- **"Combined_monthly_WB"**

These tabs contain the fully populated monthly historical and current water budgets for (1) the District's SGMA management area within the Kern Subbasin[1], (2) the District's SGMA management area within the White Wolf Subbasin, and (3) District's entire SGMA management area, respectively.

Results of the historical and current water budget efforts for the Kern Subbasin were subsequently used to inform the development of three projected (i.e. future) water budget scenarios for the WRMWSD Kern Subbasin Management Area, which are described in greater detail in **Appendix G-6**. The projected water budget "master" spreadsheet models include:

- **"Kern_PROJECTED_baseline"**
- **"Kern_PROJECTED_2030"**
- **"Kern_PROJECTED_2070"**

All master spreadsheets are denoted in green within the Excel workbook. Each column of the master spreadsheets represents an individual water budget flow component or associated calculation. Flow components are grouped by Water Budget Domain/Subdomain, and main flow components are listed by number (1 through 31) near the top of each master tab. Each row of the master spreadsheets (apart from the header rows) represents a single month in the model period, as defined in columns E-F. All values are listed in acre-feet (AF). Monthly values are subsequently summarized by water year at the bottom of each master spreadsheet. The master spreadsheets have been fully populated with data via linkages with the "backend" data and calculation spreadsheets (described in further detail below) and/or through calculations made directly within the master spreadsheet, and in all cases should not be directly edited

[1] This area includes the District's overlap lands with Arvin-Edison Water Storage District (AEWSD) within the Kern Subbasin. Select water budget components are reported for the overlap and non-overlap areas in **Tables WB-1 – WB-5** of the Management Area Plan. WRMWSD is actively coordinating with AEWSD regarding management responsibilities of the overlap lands under SGMA implementation, and associated water budget models will be updated accordingly going forward.

unless intending to override the existing data with updated inputs. Raw data inputs are denoted in blue shaded cells, whereas unshaded cells are calculated inputs.

"User Input Parameters" and Model Calibration

As further described in **Appendix G-5**, various "User Input Parameters" are included to assist in calibration of the historical and current water budgets. These are listed above the header rows of the master tabs, including:

- Irrigation Efficiency Coefficients (for micro-drip, micro-sprinkler, sprinkler, center-pivot sprinkler, and gravity-based irrigation types; see **Appendix G-4**)
- Deep Percolation Lag Period (i.e., approximate time delay for deep percolation to reach groundwater table; see **Appendix G-4**)
- White Wolf Fault Hydraulic Conductivity and Thickness (to estimate transmissivity along the fault; see **Appendix G-3**)
- Kern Subbasin Groundwater to Streamflow Inflow Ratio (to estimate groundwater inflows to the Kern Management Area as a residual to the groundwater subdomain; see **Appendix G-3**)
- Leachate Water Electrical Conductivity (to estimate leaching demands; see **Appendix G-4**)
- Additional Operational Demands (to estimate additional applied water demands [in terms of AFY/irrigated acre] from cultural practices and other operation requirements, e.g. dust abatement, frost control, etc.; see **Appendix G-4)**
- Ineffective Precipitation Deep Percolation Coefficient (to estimate deep percolation from ineffective precipitation; see **Appendix G-4**)
- Kern & White Wolf Watershed Consumptive Use Fractions (to estimate residual streamflows into the District; see **Appendix G-2**)
- Kern & White Wolf Watershed Precipitation Thresholds for Runoff (to estimate residual streamflows into the District, see **Appendix G-2**)
- Municipal & Industrial Consumptive Use Fraction
- Artificial Canals Seepage Rate
- Natural Channels Seepage Fraction (see **Appendix G-2**)

Many of these "User Input Parameters" have been adjusted within the model to reflect best available information and/or calibrated to optimize model response, but can be adjusted manually to reflect updated information or to test model response. Adjustments to the User Input Parameters are made within the **"Calibration"** tab of the model, and the listed values within the master tabs will update automatically.

As further described in **Appendix G-5**, The **"Calibration"** tab is the active module used to qualitatively calibrate the water budget by aligning the historical change in storage calculated in the master model tabs to change in storage values estimated via historical water level records collected within the model domain. This is principally done via adjustment of select "User Input Parameters" specified above, and subsequent

assessment of the resulting fit of the model-calculated change in storage to analogous estimates made from water level records collected at two "bookend" periods in time within the model period. The water level-calculated change in storage estimates used for this analysis are listed in the **"WL_storage_change"** spreadsheet of the Excel workbook. All calibration-related spreadsheets are denoted in yellow.

Presentation and Reporting

Live tables and figures that have been developed for inclusion in the Kern Management Area Plan, as well as several associated presentation & reporting related tabs, can be found in the blue shaded tabs within the water budget Excel workbook. These include:

- Exhibits used in the Kern Management Area Plan, including:
  - **"Table WB-1_Kern"** – Annual Surface Water Inflows and Outflows by Source Type
  - **"Table WB-2_Kern"** – Annual Inflows to and Outflows from the Groundwater System, and Change in Storage
  - **"Table WB-3_Kern" –** Annual and Cumulative Change in Groundwater Storage between Seasonal Highs
  - **"Table WB-4_Kern" –** Annual Change in Groundwater Storage vs. DWR Water Year Type
  - **"Table WB-5_Kern" –** Annual Total Inflows, Outflows, and Change in Groundwater Storage
  - **"Table WB-6_Kern" –** Summary of Projected Water Budget Results (with/without) Project & Management Action Implementation
  - **"Table_G-1-1_WB_Components"** – Summary of Analytical Water Budget Components
  - **"WB_graphs_Kern"** – includes all graphs used to develop Figures WB-1 through WB-20 of Kern Management Area Plan
  - **"Fig_WB-18" –** Figure WB-18 of Kern Management Area Plan
  - **"Fig_G-4-2" –** Agricultural Subdomain Water Budget Schematic
- Spreadsheets supporting development of Management Area Plan exhibits, including:
  - **"horiz_bar_chart"** – used to summarize water budget components for reporting in Tables WB-1 through WB-5
  - **"horiz_bar_chart_proj" –** used to summarize projected water budget components for reporting in Table WB-6
  - **"change_storage_figs" –** used to develop Figures WB-10 through WB-14, GWC-8
  - **"SW_cum_import_71_15" –** used to help develop Figure WB-4
  - **"data_as_values_for_combined_hyd" –** used to help develop Figure WB-18

"Backend" Data and Calculations

All other tabs within the Excel workbook contain various input data and calculations used to support water budget calculations in the master water balance tabs and should not be edited. Uncolored tabs correspond to various raw input data that are directly linked to the historical and current master model tabs. These include:

- **"Monthly_SW_deliveries" –** records of monthly surface water deliveries to WRMWSD customers in the Kern and White Wolf portions of the District (1999 – 2015)
- **"Monthly_GW_Pumping" –** records of monthly District and annual Private User Input groundwater pumping into the California Aqueduct (2001 – 2015)

- **"M_I_deliveries" –** records of annual WRMWSD deliveries to Municipal and Industrial (M&I) customers (1994 – 2015)
- **"Monthly_precip_WR" –** monthly precip rates [in] at WRMWSD and NOAA climate stations (1994 – 2015)
- **"C2VSim_FG_Boundary_Params" –** average transmissivity and depths of C2VSim-FG Layers 1 and 2 extracted along WRMWSD boundary lines, for use in approximating groundwater flux (see **Appendix G-3**)
- **"raster_based_gradients" –** average groundwater elevations along boundary gradient lines extracted from historical groundwater elevation raster data (see **Appendix G-3**)
- **"S1b. SWP Historic"** – record of annual historical SWP contract versus total imports, maintained by WRMWSD

Raw input data inputs to the water budget model also include spreadsheets imported directly from the R processing software, which was used predominantly to process land use and ITRC-METRIC data for integration into the Agricultural Lands subdomain (see **Appendix G-4**). These are denoted as light grey tabs in the Excel workbook, and include:

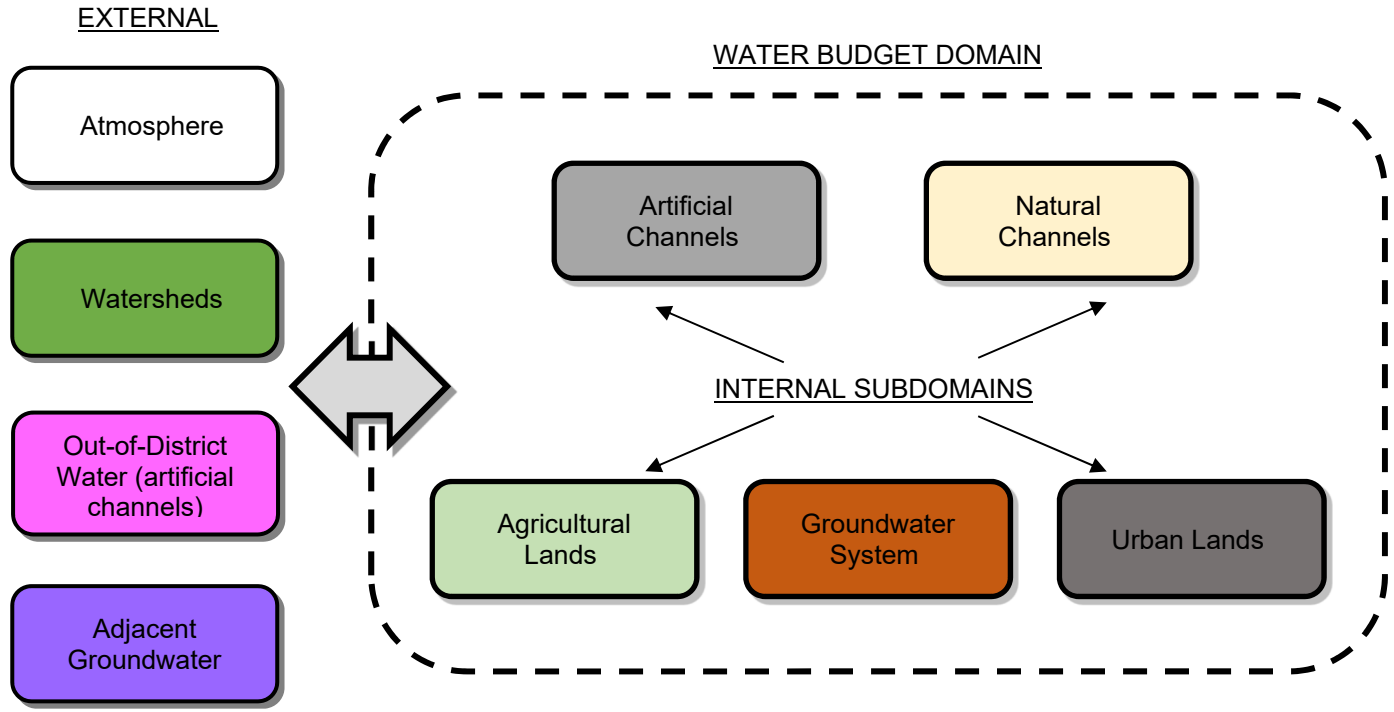
- **"monthly_ITRC_CROPS_R" –** WRMWSD monthly ITRC data by irrigation type, 2001 - 2015
- **"monthly_ITRC_CROPS_pre2k_R" –** WRMWSD monthly ITRC data by irrigation type, 1993 - 2000
- **"monthly_ITRC_channels_R" –** monthly ITRC data along California Aqueduct and 850 Canal, 1993 - 2015
- **"monthly_ITRC_Basin_unadj_R" –** monthly ITRC within WRMWSD by Basin, un-adjusted for non-coverage areas (see **Appendix G-4**), 1993 - 2015

Dark grey tabs represent spreadsheets involving a calculation or series of calculations for incorporation into the historical & current master model tabs. These include:

- **"climate_parser_master_WR**" – used to estimate precipitation on District lands and within surrounding watersheds (see **Appendix G-2**)
- **"GW_Fluxes" –** used to estimate subsurface fluxes across District boundaries (see **Appendix G-3**)
- Various tabs used to calculate components within the Agricultural Lands subdomain (see **Appendix G-4**), including:
    - **"Monthly _adjusted_ET_by_zone" –** parses monthly ITRC data into different land use subdomains and estimates ET for the in-District areas outside ITRC coverage
    - **"Monthly_acreages" –** parses seasonal crop data into different land use subdomains
    - **"Monthly_irr_eff" –** calculates monthly irrigation efficiency coefficients based on seasonal irrigation types
    - **"leaching_master" –** calculates monthly leaching volumes based on seasonal crop types
    - **"operational demands" –** calculates monthly operational demands based on irrigated acreage
    - **"effective_precip" –** calculates monthly effective precipitation using raw precipitation, ET data
    - **"2012_AgDomain" –** estimates monthly ET for calendar year 2012, where ITRC-METRIC data was unavailable
    - **"pre2k_operations"** – estimates monthly surface water deliveries, District groundwater pumping rates based on annual data from FAA Table IV records for 1994 - 2000

- **"native yield" –** used for KGA "native yield" discussions (no impact on water budget functionality)

Purple shaded tabs correspond to raw data inputs and calculations used to delineate select water budget components in the overlap and non-overlap areas of the Kern and White Wolf portions of the District. These tabs do not effect the water budget functionality, and are used for reporting purposes in **Tables WB-1 – WB-5** of the Management Area Plan only. They include:

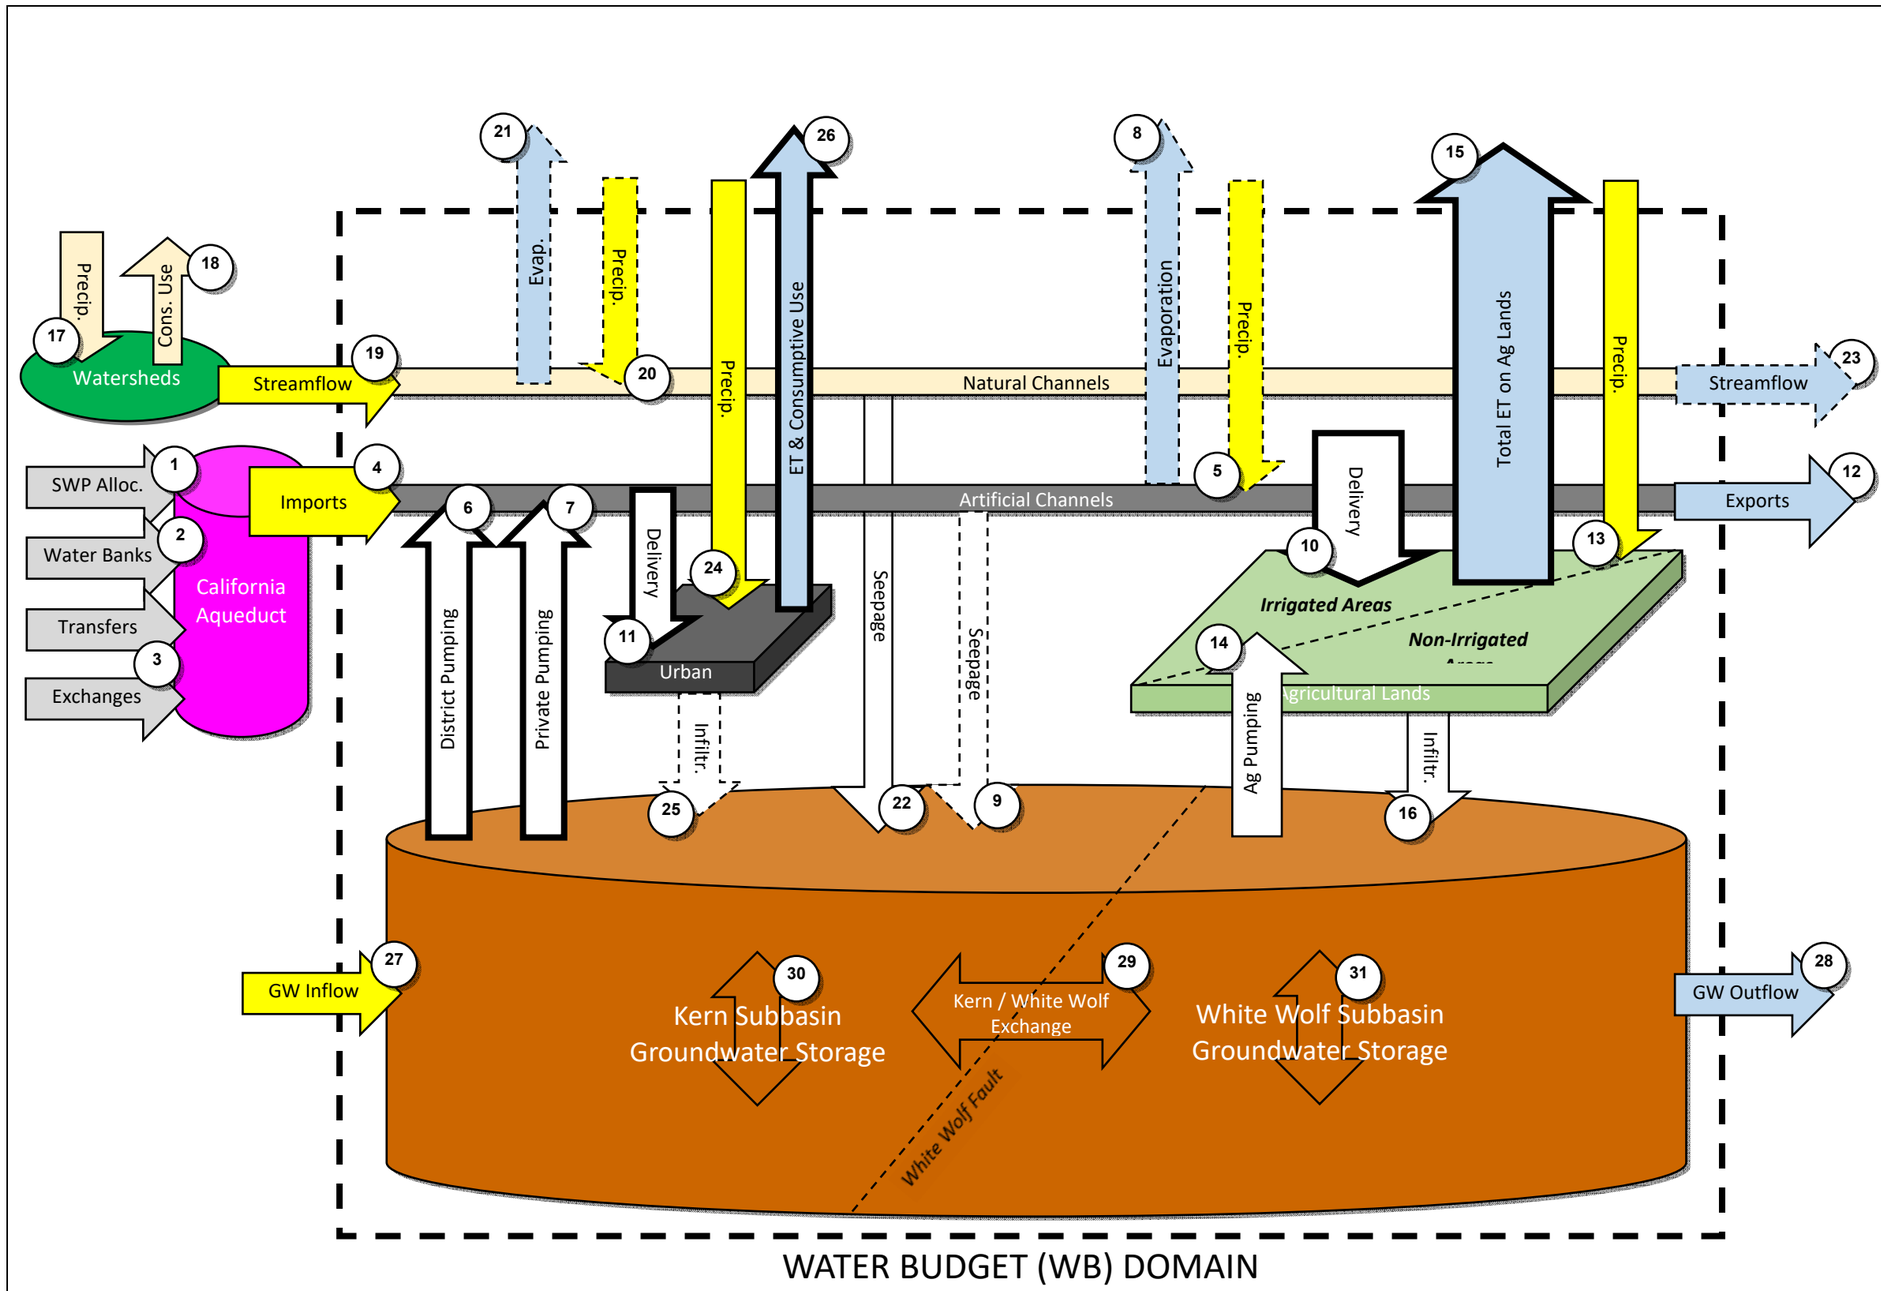


- "**ET_total_v_non-overlap"** – compares monthly ITRC ET signal for the full District and the non-overlap area only
- "**WRMWSD_Overlap_Deliveries_AE**" – monthly WRMWSD surface water delivery records to the WRMWSD-AEWSD overlap area
- **"Monthly_ET_by_zone_WR_no_overla" –** parses monthly ITRC data on the non-overlap area into different land use subdomains
- **"Monthly_acreages_WR_no_overlap" –** parses seasonal crop data in the non-overlap area into different land use subdomains
- **"2012_AgDomain_WR_no_ove" –** estimates monthly ET in the non-overlap area for calendar year 2012, where ITRC-METRIC data was unavailable
- **"MONTHLY_ITRC_Basin_WR_no_ove" –** monthly ITRC within non-overlap area by Basin, un-adjusted for non-coverage areas (see **Appendix G-4**), 1993 - 2015
- **"MONTHLY_ITRC_CROPS_no_overlap" –** WRMWSD monthly ITRC data in non-overlap area by irrigation type, 2001 - 2015
- **"MONTHLY_ITRC_CROPS_pre2k_no_ove" –** WRMWSD monthly ITRC data in non-overlap area by irrigation type, 1993 - 2000
- **"leaching_master_WR_no_overlap" –** calculates monthly leaching volumes in non-overlap area based on seasonal crop types
- **"operational_demands_WR_no_over" –** calculates monthly operational demands in non-overlap area based on irrigated acreage

Finally, brown shaded tabs correspond to raw data inputs and calculations used to inform development of three projected model scenarios (see **Appendix G-6**). These include:

- KGA climate change factors and surface water delivery assumptions for projected water budget scenarios, including:
  - **"SWP Baseline" –** Projected State Water Project supply change factors under "baseline" scenario
  - **"SWP 2030" –** Projected State Water Project supply change factors under "2030 Climate Change" scenario
  - **"SWP 2070" –** Projected State Water Project supply change factors under "2070 Climate Change" scenario
  - **"Precipitation 2030 SR 21" –** Projected precipitation change factors under "2030 Climate Change" scenario
  - **"Precipitation 2070 SR 21" –** Projected precipitation change factors under "2070 Climate Change" scenario
  - **"ET 2030 SR 21" –** Projected evapotranspiration change factors under "2030 Climate Change" scenario

- **“ET 2070 SR 21” –** Projected precipitation change factors under “2070 Climate Change” scenario



- **“Kern_PROJECTED_analog” –** Kern master water budget under 50-yr analog period (no adjustments to supplies, climate assumptions) – not used as a unique projected scenario, only to assist in calculations for baseline/2030/2070 projected scenarios
- **“P&MA_scenarios” –** used to input P&MA supply augmentation and demand reduction targets for 2030 and 2070 climate change scenarios to assess impacts on projected change in storage under full SGMA implementation

30	Kern Basin Reduction in Groundwater Storage	Accumulation Term									In/Out	Calculated as Residual of Groundwater Basin subdomain within the Kern monthly budget
31	White Wolf Basin Reduction in Groundwater Storage	Accumulation Term									In/Out	Calculated as Residual of Groundwater Basin subdomain within the White Wolf monthly budget

Abbreviations:

Ag. = agricultural
AFY = acre-feet per year
CU = consumptive use
ET = evapotranspiration
Evap. = evaporation
GW = groundwater
M&I = municipal and industrial
Precip. = precipitation
WB = water budget

Notes:

1. Water budget subdomains outlined in dashed line are considered part of the overall water budget domain.
2. "Raw" components are those that generally are best quantified based on actual data.
3. The Artificial Channels Subdomain includes the CA Aqueduct, 850 Canal, and the District's delivery pipeline network
4. "Evapotranspiration" includes all estimated crop and vegetative evapotranspirative demands as well as evaporation of excess rainfall and from open water bodies within the District.

Mass Balance Equations

Subdomains that Must "Balance" (i.e., Inflows = Outflows); external fluxes shown in blue (inflow) or pink (outflow) text; internal fluxes shown in black text

Irrigated Ag Lands (SW and GW)	**Inflows** (Precipitation + [District] Ag Deliveries + [Private] GW Pumping for Ag Use) **= Outflows** (Applied Water ET + Effective Precip. ET + Evap. Of Ineff. Precip. + Applied Water Runoff + Applied Water Perc. + Perc. Of Ineff. Precip.)
Irrigated Ag Lands (GW only)	**Inflows** (Precipitation + [Private] GW Pumping for Ag Use) **= Outflows** (Applied Water ET + Effective Precip. ET + Evap. Of Ineff. Precip. + Applied Water Runoff + Applied Water Perc. + Perc. Of Ineff. Precip.)
Non-Irrigated Ag Lands (dry farming)	**Inflows** (Precipitation) **= Outflows** (Effective Precip. ET + Evap. Of Ineff. Precip. + Perc. Of Ineff. Precip.)
Native Lands	**Inflows** (Precipitation) **= Outflows** (Effective Precip. ET + Evap. Of Ineff. Precip. + Perc. Of Ineff. Precip.)
Urban Lands (GW only)	**Inflows** (Precipitation + [District & Dom.] GW Pumping for M&I Use + [M&I] Imports) **= Outflows** (Applied Water ET + Effective Precip. ET + Evap. Of Ineff. Precip. + WW Effluent Discharges + Applied Water Perc. + Perc. Of Ineff. Precip.)
Natural Channels	**Inflows** (Precipitation + Streamflow from Adjacent Uplands) **= Outflows** (Evaporation + Perc. Of Streamflow + Ag Diversions + M&I Diversions + Streamflow to Adjacent Lowlands)
Artifical Channels	**Inflows** (Precipitation + [District] Imports) **= Outflows** (Evaporation + Exports + [District] Ag Deliveries)

Subdomains that are not required to "Balance" (i.e., can have a change in storage); external fluxes shown in blue (inflow) or pink (outflow) text; internal fluxes shown in black text

Deep (Production) Aquifer	**Inflows** (GW Inflows from Adjacent Areas + Applied Water Perc. + Perc. Of Ineff. Precip. + Streamflow Perc. + Artificial Channel Seepage Losses + Banking "Leave Behind") - **Outflows** (GW Outflows to Adjacent Areas + GW Pumping for Ag Use + GW Pumping for M&I Use + Seepage to Native Lands (GDEs) + Seepage to Channels (GDEs) + GW Pumping to Artificial Channels ("Pump-in") + GW Bank "Deposits") = **Change in Storage**
Groundwater Bank "Account"	**Inflows** (Banking "Deposits") - **Outflows** (Banking "Leave Behind" + Recovery Pumping "Withdrawals") = **Change in Storage** ("Bank Balance")
Outside of Water Budget Domain	*tracking the mass balance of external domains is not applicable to the water budget*
Atmosphere	*tracking the mass balance of external domains is not applicable to the water budget*

Precipitation (total) gets divided into: Effective Precip. ET + Evap. of Ineff. Precip. + Perc. of Ineff. Precip.
Applied Water gets divided into: Applied Water ET + Applied Water Perc.

Appendix G-2

Description of Precipitation and Contributing Streamflow Estimates

APPENDIX G-2
DESCRIPTION OF PRECIPITATION AND CONTRIBUTING STREAMFLOW ESTIMATES

This appendix documents the process used to derive estimates of precipitation on Wheeler Ridge-Maricopa Water Storage District (WRMWSD or District) lands and the surrounding watersheds contributing to streamflow within the District.

Selection of Climate Stations

Precipitation on District lands and to surrounding watersheds is estimated from the six local climate stations maintained by and located within the District, and two additional climate stations located outside of the District maintained by the National Oceanic and Atmospheric Administration (NOAA). Each of these stations report measurements of monthly precipitation (inches per month [in/mo]) during the water budget period of interest (1993 – 2015), although data availability varies by station and includes sporadic missing monthly values which were filled with estimated values, as described below.

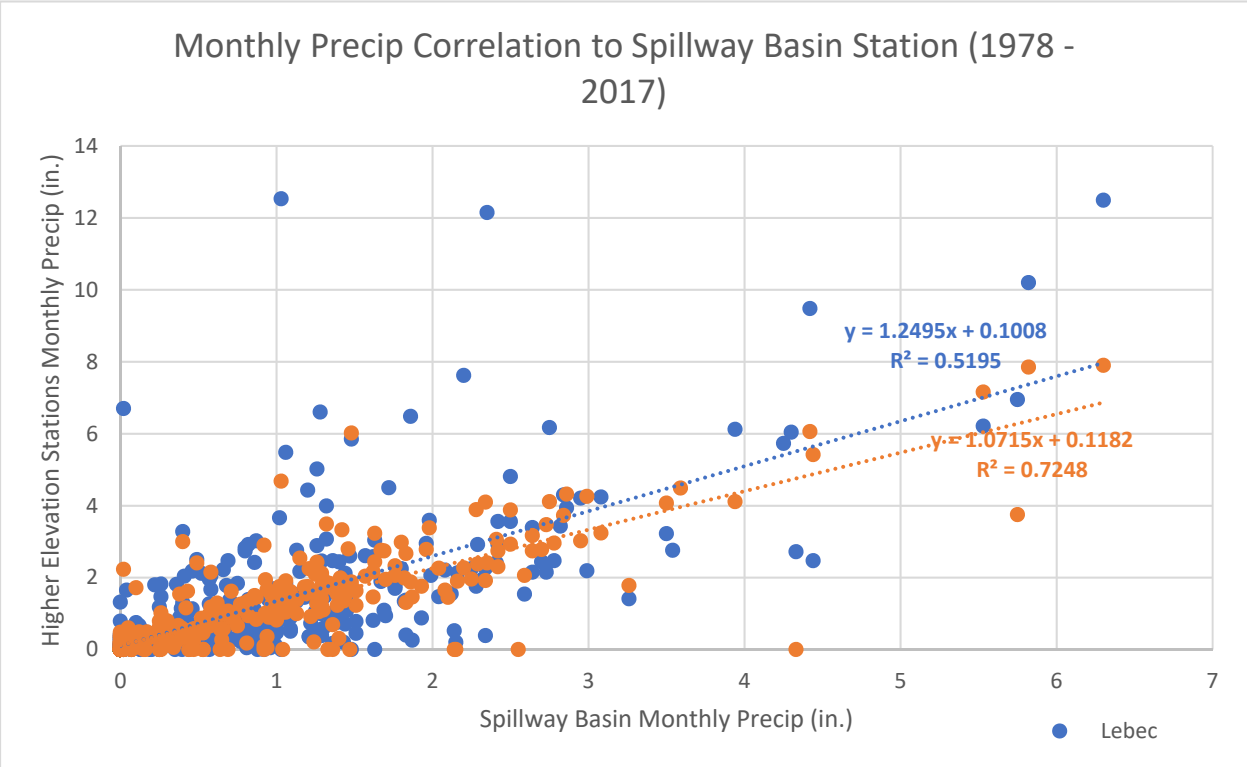
The six local climate stations maintained by the District include:

- **Greenlee's Pasture** (*January 1971 – December 2017)*
- **District Headquarters** (*January 1978 – December 2017)*
- **WRM-2 Pumping Plant** (*January 1978 – December 2017)*
- **5P-P2 Pumping Plant** (*January 1978 – December 2017)*
- **PA-2 Pumping Plant** (*January 1978 – December 2017)*
- **Spillway Basin** (*January 1978 – December 2017)*

The additional climate stations maintained by NOAA employed for this analysis include:

- **Tejon Rancho, CA [NOAA Coop. ID #48839]** (*January 1895 – December 2017)*[1]
- **Lebec, CA [NOAA Coop. ID #44863]** (*July 1948 – December 2017)*[2]

NOAA stations were incorporated into this analysis because there is significant topographic difference (i.e., nearly 8,000-foot elevation difference) between the District lands and the peaks of the surrounding watersheds in the San Emigdio and Tehachapi mountains to the southwest and southeast, respectively, that contribute to streamflow within the District. This elevation difference results in an orographic effect whereby precipitation in the surrounding watersheds is significantly greater than precipitation measured at the six local climate stations within the District. In order to account for this precipitation difference, data from the two additional NOAA climate stations were used. NOAA climate stations were selected based on the following criteria:



1) Data availability & continuity within the time-period of interest (1993 – 2015);
2) Location within the District's surrounding watersheds; and
3) Ground surface elevation (relative to the elevation range within surrounding watersheds).

[1] Data retrieved from NOAA's National Climatic Data Center (NCDC) online portal (https://www.ncdc.noaa.gov/cdo-web/datasets/GSOM/stations/GHCND:USC00048839/detail)
[2] Data retrieved from NOAA's National Climatic Data Center (NCDC) online portal (https://www.ncdc.noaa.gov/cdo-web/datasets/GSOM/stations/GHCND:USC00044863/detail)

Interpolation of Missing Monthly Precipitation Data

NOAA stations employed in this analysis contained several missing monthly values within the period of interest. For these months, precipitation was estimated based on a linear correlation model developed with a District-operated climate station. The District-operated climate station that most directly aligned with both the Tejon Rancho and Lebec stations was the Spillway Basin (elevation ~840 feet above mean sea level [ft msl]). As shown on **Figure G-2-1** below, over the entire period of record (1978-2017), monthly precipitation records collected from the Spillway Basin station showed an **85% correlation** ($R^2 = 0.72$) with data collected from the Tejon Rancho station (elevation ~1,370 ft. msl), and a **72% correlation** ($R^2 = 0.52$) with data collected from the Lebec station (elevation ~3,600 ft. msl).

Figure G-2-1. Long-term Correlation between Spillway Basin Station and NOAA Stations

As such, monthly precipitation values for months with missing precipitation data within the Tejon Rancho and Lebec records were estimated using the linear regression models derived for each station with respect to the Spillway Basin station.

Spatial Representation of Precipitation Data

Precipitation is a spatially variable phenomenon and can usually only be directly observed at discrete points within a domain (i.e., at climate station locations). Additionally, precipitation is affected by surrounding topography, and the orographic effect must be considered when deriving rainfall estimates over watershed areas with significant elevation range. As mentioned previously, the nearly 8,000 ft difference in elevation between District lands and the peaks of the surrounding watersheds in the San Emigdio and Tehachapi mountains results in an orographic effect. As such, it is practical to employ

precipitation data from higher-elevation climate stations to estimate precipitation within these surrounding watersheds contributing to streamflow into the District.

Table G-2-1 presents the approximate elevation of each climate station used in this analysis, as derived from the U.S. Geological Survey National Elevation Dataset (NED):

Table G-2-1. Climate Stations and Corresponding Ground Surface Elevations

Climate Station	Operator	Ground Surface Elevation (ft msl)
Greenlee's Pasture	WRMWSD	400
District Headquarters	WRMWSD	490
WRM-2 Pumping Plant	WRMWSD	500
5P-P2 Pumping Plant	WRMWSD	590
Spillway Basin	WRMWSD	840
PA-2 Pumping Plant	WRMWSD	940
Tejon Rancho	NOAA	1,370
Lebec	NOAA	3,590

Based on the distribution of locations and elevations from the eight climate stations employed for this analysis, a two-fold approach was employed to represent precipitation on District lands and from surrounding watersheds:

1) **Theisen polygons** were used to delineate the representative area for each of the six District-operated climate stations within the District.

2) **Elevation cutoffs** were used to delineate the representative area for the higher-elevation NOAA climate stations.

This analysis is based on the following assumptions:

- The six District-operated climate stations are located within the floor of the Central Valley at relatively similar elevations; thus, precipitation within the District is best represented spatially using the closest climate station to each point within the District.

- The two NOAA climate stations are located within surrounding watersheds to the District or near the southern boundary of the White Wolf portion of the District, and at significantly higher elevations than the District climate stations (see **Table G-2-1** above); thus, precipitation on the surrounding watersheds (and the southern-most portion of the District) is best represented by the NOAA climate station at the nearest elevation to each point within the surrounding watershed area.

Figure G-2-2 (attached) shows the location and coverage area represented by each climate station within the District and its surrounding watersheds. The following elevation cutoffs were used to determine which NOAA station (if any) would be employed in these areas:

- Elevations less than 1,155 ft msl are represented by the District climate station network (i.e., delineated by the Theisen polygon lines);
- Elevations between 1,115 ft msl and 2,480 ft msl are represented by the Tejon Rancho climate station; and
- Elevations greater than or equal to 2,480 ft msl are represented by the Lebec climate station.

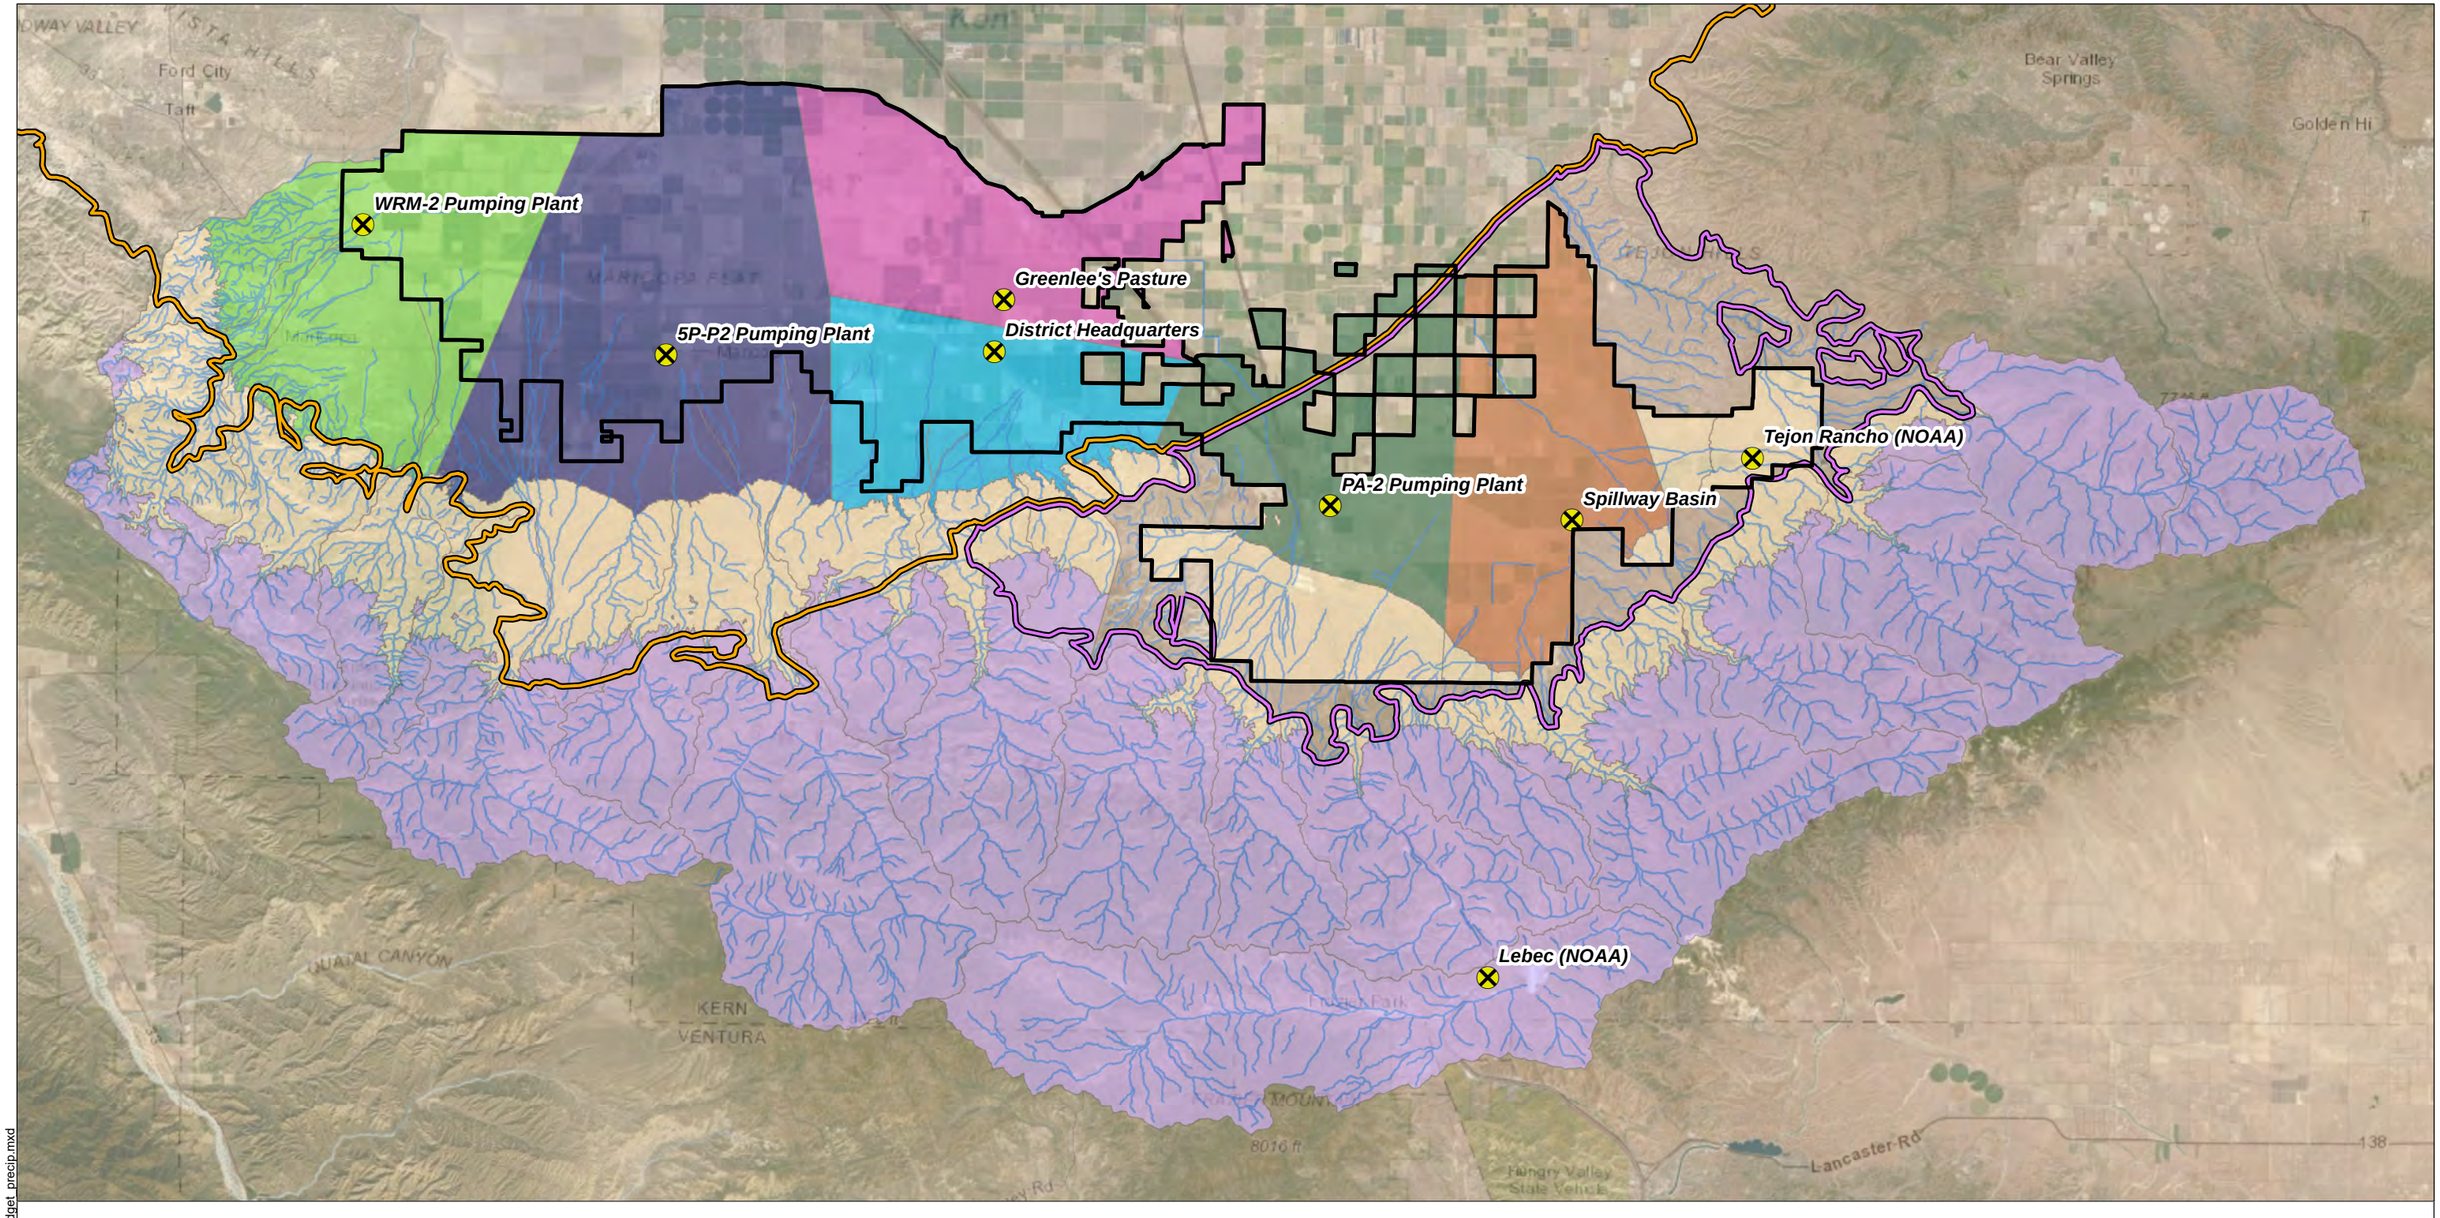
Calculation of Rainfall and Contributing Streamflow

Following the spatial delineation process described above, total areas represented by each climate station were calculated for in-District lands (in both the Kern and White Wolf Subbasins), as well as for the surrounding watershed area.

The volume of monthly rainfall (acre-feet per month; [AF/mo]) on the District and on surrounding watersheds is then estimated as follows:

$$Rainfall = \sum \frac{p_{station}}{12} * A_{station} \quad (1)$$

where $p_{station}$ = monthly precipitation [in/mo] and $A_{station}$ = total area represented by the station [acres].



Contributing streamflow into the District is then calculated from the Rainfall on Watersheds using a linear equation with two parameters: a "Precipitation Threshold for Runoff Initiation" and a "Watershed Consumptive Use Fraction". These parameters are defined in the "User Input Parameters" of the water budget model (see Appendix G-1). Contributing streamflow into the District is calculated as:

$$Streamflow\ into\ District = max\left(0, Rainfall\ on\ Watersheds - \frac{p_{threshold}}{12} * A_{watershed}\right) * (1 - CU_{watershed}) \quad (2)$$

where $p_{threshold}$ = Precipitation Threshold for Runoff Initiation [in], $CU_{watershed}$ = Watershed Consumptive Use Fraction [dimensionless], and $A_{watershed}$ = total area of surrounding watersheds [acres].

Ultimately, based on water budget calibration, Watershed Consumptive Use Fractions of **98%** and **95%** and Precipitation Thresholds of **0.5** inches were used to estimate contributing streamflow into the Kern Subbasin and White Wolf Subbasin portions of the District, respectively. This resulted in contributing streamflow estimates of **3,104 AFY** and **8,416 AFY** for the Kern and White Wolf portions of the District, respectively, over the historical water budget period (DWR WY 1995 – 2014). These estimates align very closely with the United States Geological Survey's Basin Characterization Model[3] (USGS-BCM) estimates for the same contributing watersheds (3,480 AFY and 9,730 AFY for the Kern and White Wolf areas) over 1981 – 2010. See **Appendix G-5** for further details regarding the water budget calibration process.

Appendix G-3

Description of Subsurface Cross Boundary Flow Estimates

APPENDIX G-3
DESCRIPTION OF SUBSURFACE CROSS-BOUNDARY FLOW ESTIMATES

This appendix documents the process used to estimate subsurface cross-boundary flows as a means of quantifying groundwater inflows and outflows to the aquifer system underlying Wheeler Ridge-Maricopa Water Storage District (WRMWSD or District) lands. As shown in **Figure G-3-1**, cross-boundary groundwater fluxes were calculated for three segments along the District perimeter:

- **White Wolf Fault Boundary (Exchange with AEWSD) –** to represent groundwater flux across the fault into Arvin Edison Water Storage District (AEWSD) lands in the Kern Subbasin;
- **White Wolf Fault Boundary (Internal Exchange)** – to represent groundwater flux across the fault into WRMWSD's lands in the Kern Subbasin; and
- **Kern Boundaries (Net Exchange)** – to represent net groundwater fluxes to/from the Kern Subbasin portion of the WRMWSD service area (i.e. the "Kern Management Area") resulting from (1) subsurface recharge from surrounding watersheds to the south of the Kern Management Area, and (2) groundwater exchange between WRMWSD and Kern Delta Water District (KDWD) lands and the Buena Vista Lake Bed area.

As further described below, estimates of subsurface cross-boundary flows across the White Wolf Fault were calculated using Darcy's Law, while estimates of net groundwater inflows to the Kern Management Area were calculated as a residual to the groundwater subdomain during the water budget calibration process (see **Appendix G-5** for more details).

Estimation of Groundwater Fluxes Across the White Wolf Fault

Monthly groundwater fluxes across the two segments of the White Wolf fault described above were calculated using Darcy's Law, which states that:

$$Q = T * i * L \quad (1)$$

where Q = groundwater flowrate [feet cubed per day; ft^3/d], T = aquifer transmissivity [feet squared per day; ft^2/d], i = hydraulic gradient [dimensionless], and L = length of boundary perimeter used to calculate groundwater flux [feet; ft].

Methods used to derive values for *T, I,* and *L* along each boundary segment are further documented below.

Estimation of Aquifer Transmissivity

Aquifer transmissivity (*T)* is calculated as the product of aquifer hydraulic conductivity (K) [feet per day; ft/d] and aquifer thickness (b) [ft]:

$$T = K * b \quad (2)$$

There is significant uncertainty associated with each of these parameters across the White Wolf fault segments described above. As such, initial estimates for each parameter were chosen based on associated values reported in historical hydrogeological studies, numerical models, and water budgets conducted within the region, including:

- Dibblee and Oakeshott, 1953. Dibblee, T.W. Jr. and G.B. Oakeshott, *White Wolf fault in relation to geology of the southeastern margin of San Joaquin Valley, California*, GSA Bulletin, vol. 64, p. 1502-1503, 1953.
- Wood and Dale, 1964. Wood P.R. and R. H. Dale, *Geology and Ground-Water Features of the Edison-Maricopa Area, Kern County, California*, USGS Water Supply Paper 1656, 1964.

- EKI, 2016. *White Wolf Basin Technical Report*, 77 pp.

Final aquifer hydraulic conductivity and depth values were subsequently determined through water budget calibration. See **Table G-3-1** below for initial and final (calibrated) estimates of *K* and *b* along the Kern Northern Boundary and White Wolf Fault.

Table G-3-1. Aquifer Hydraulic Conductivity and Depth Estimates

Boundary Segment	Initial *K* [ft/d]	Calibrated *K* [ft/d]	Initial *b* [ft]	Calibrated *b* [ft]
White Wolf Fault (to AEWSD)	1	3	1,000	1,000
White Wolf Fault (to WRMWSD)	1	3	1,000	1,000

Estimation of Aquifer Gradients and Perimeter Length

As mentioned previously, cross-boundary groundwater fluxes across the White Wolf fault were separated into two segments:

- White Wolf Fault Boundary (Exchange with AEWSD)
- White Wolf Fault Boundary (Internal Exchange)

To calculate boundary lengths (*L)* and hydraulic gradients (*i)*, a GIS-based methodology was employed that uses interpolated groundwater elevation rasters, polylines representing the District boundaries, and the "Zonal Statistics" toolbox to estimate average hydraulic heads across each boundary.

Groundwater elevation rasters for various seasons within the period of interest were generated through Kriging interpolation of water level data contained in the District's "WL" Access database. Based on data availability and quality, water levels from wells within the District and in the nearby area north of the District boundary were interpolated to produce groundwater elevation rasters for the following seasons:

- Spring 2003
- Fall 2005
- Spring 2006
- Fall 2006
- Spring 2009
- Fall 2009
- Spring 2011
- Fall 2011
- Spring 2013
- Fall 2013
- Spring 2014
- Fall 2014
- Spring 2015
- Fall 2015

A simplified set of "gradient line" polylines were then drawn in GIS that generally traced both sides of the two White Wolf Fault boundary segments described above (four polylines in total, see **Figure G-3-1**). The distance between polylines for each pair was 10,000 feet, and lengths were set consistently for each polyline in a pair to deduce the approximate boundary length (*L*) for the two boundary segments listed above.

Subsequently, for a given season and year, an average groundwater elevation (in feet above mean sea level [ft msl]) was deduced for each polyline on either side of the District boundary segment using the Zonal Statistics raster processing toolbox. Finally, the dimensionless hydraulic gradient (*i)* across the boundary segment for each season and year was calculated as follows:

$$i = \frac{GWE_2 - GWE_1}{10{,}000\ ft} \qquad (3)$$

where GWE_1 and GWE_2 are the average groundwater elevations along the two polylines for each boundary segment.

Estimation of Monthly Groundwater Flux in the Water Budget Model

After deducing aquifer transmissivity (*T*), boundary length (*L*) and gradient parameters for a given season and year, groundwater flux was calculated using Darcy's Law (see equation 1). Fluxes were converted from ft^3/d to acre-feet per month (AF/mo) to provide a representative "monthly" flux estimate associated with that season and year.

To populate the water budget model with a monthly groundwater flux for the entire period of interest (1994 – 2015), the "monthly" groundwater fluxes calculated for the season and year closest to the month in question within the model were used. Groundwater elevation rasters created for "Spring" seasons represent water level measurements collected in between January 15 – April 15; therefore, March 1 is used as the representative date for "Spring" groundwater flux calculations. Groundwater elevation rasters created for "Fall" seasons represent water level measurements collected in between August 15 – November 15; therefore, October 1 is used as the representative date for "Fall" groundwater flux calculations.

As an example, groundwater fluxes reported in the water budget for the month of May 2015 were represented by the calculated fluxes from the "Spring 2015" raster, whereas groundwater fluxes reported for the month of August 2015 were represented by the calculated fluxes from the "Fall 2015" raster. This allows the water budget to provide a continuous (monthly) estimate of cross-boundary groundwater fluxes that is most representative of current conditions as estimated from actual groundwater elevation data included in the District's records.

Estimation of Net Groundwater Fluxes to the Kern Management Area

Use of raster-based gradients and Darcy's law to estimate groundwater fluxes, as described above, is well suited for approximating fluxes across the White Wolf Fault, as this hydrogeologic barrier to flow is considerably well-defined and groundwater flow moves in a generally consistent southeast-to-northwest direction perpendicular to the fault line (see White Wolf Fault studies mentioned above for further details). This allows for reasonably straight-forward estimation of groundwater gradients across the fault, as the "gradient lines" can be drawn parallel to the fault line and consistent with the general direction of groundwater flow in the area.

As evident in **Figure G-3-1** and in the local groundwater elevation surfaces derived for earlier dates within the historical water budget timeframe, groundwater flow directions are much more variable along the District perimeter within the Kern Subbasin, with certain sections indicating an inflow gradient, others an outflow gradient, and still others indicating a gradient that is nearly parallel to the boundary line. Another complicating factor is that very little groundwater elevation data exists for the regions to the south and west of the WRMWSD boundary, making it challenging to accurately estimate average groundwater elevations immediately outside the District. Consequently, the average groundwater gradient across each major boundary of the WRMWSD Kern Management Area is much harder to define. Furthermore, the WRMWSD Kern Management Area boundary is highly complex in geometry, making the use of generalized "gradient lines" to approximate fluxes across each boundary segment less applicable to this particular scenario.

Given the constraints mentioned above, an approach was used that approximates net groundwater fluxes to/from the Kern Management Area as a residual in the groundwater subdomain deduced via calibration of the water budget model. After constraining all other groundwater inflow and outflow variables within the model (e.g., infiltration, pumping, etc.), a monthly groundwater flux rate was calculated that resulted in the closest fit to change in groundwater storage calibration targets developed via comparison of observed water levels between "bookend" dates within the water budget timeframe (see **Appendix G-5**).

Ultimately, it was found that the modeled change in groundwater storage achieved a closest fit to all calibration targets when net monthly groundwater fluxes to the Management Area were tied to the

estimated streamflow signal into Management Area. Specifically, it was determined that setting a "**Groundwater to Streamflow Inflow**" ratio of **3:1** within the Kern Management Area resulted in the best overall calibration of the water budget model (see **Appendix G-5**) and produced net groundwater inflow volumes on the order of **9,300 AFY** on average through the historical water budget period (DWR WY 1995 – 2014). This net inflow estimate is conservative relative to how the C2VSim-FG Kern Subbasin numerical model (developed by KGA and other Basin GSAs, see **Section 9** of the Management Area Plan) quantifies net groundwater inflows to the Management Area (31,200 AFY) over the same historical period.

This observed correlation between groundwater inflows and streamflow behavior could be in part due to the fact that the southern border of WRMWSD abuts several alluvial fans receiving recharge from various ephemeral creeks draining into the Kern Subbasin from the San Emigdio mountains to the south. Given the variable gradients observed along the northern and western boundaries of the Management Area, this subsurface recharge mechanism from the south may be the dominant groundwater flow component along the WRMWSD Kern Subbasin boundaries and would thus result in a net groundwater inflow to the Management Area. Further quantification of subsurface inflows across the southern boundary would necessitate the collection of additional groundwater elevation data to the south of the District, where very little historical data currently exist. See **Appendix G-5** for further details regarding the water budget model calibration process and results.

Description of the Agricultural Lands Water Budget Subdomain

APPENDIX G-4
DESCRIPTION OF THE AGRICULUTRAL LANDS WATER BUDGET SUBDOMAIN

This appendix describes the process for calculating water budget components within the Agricultural Lands subdomain of the Wheeler Ridge-Maricopa Water Storage District (WRMWSD or "District") Long-term Water Budget (currently populated for 2001–2015). This analysis was based on the following data sources:

- **Satellite Evapotranspiration (ET) Data** from the Irrigation Training & Research Center (ITRC)[1] "Mapping Evapotranspiration at High Resolution with Internalized Calibration" (ITRC-METRIC) Study, funded by the Kern Groundwater Authority (KGA)[2]
    - *monthly resolution, January 1993 – December 2015* [3]

- **WRMWSD Land Use Surveys** from the District's "CROPS.shp" shapefile
    - *seasonal (spring and fall) resolution*, *Spring 2001 – Spring 2017*

- **WRMWSD Surface Water Delivery Records** from the District's "WRM_DataMDB" Access databases (i.e., "WLEDGER" tables)
    - *monthly resolution, January 1999 – December 2016*

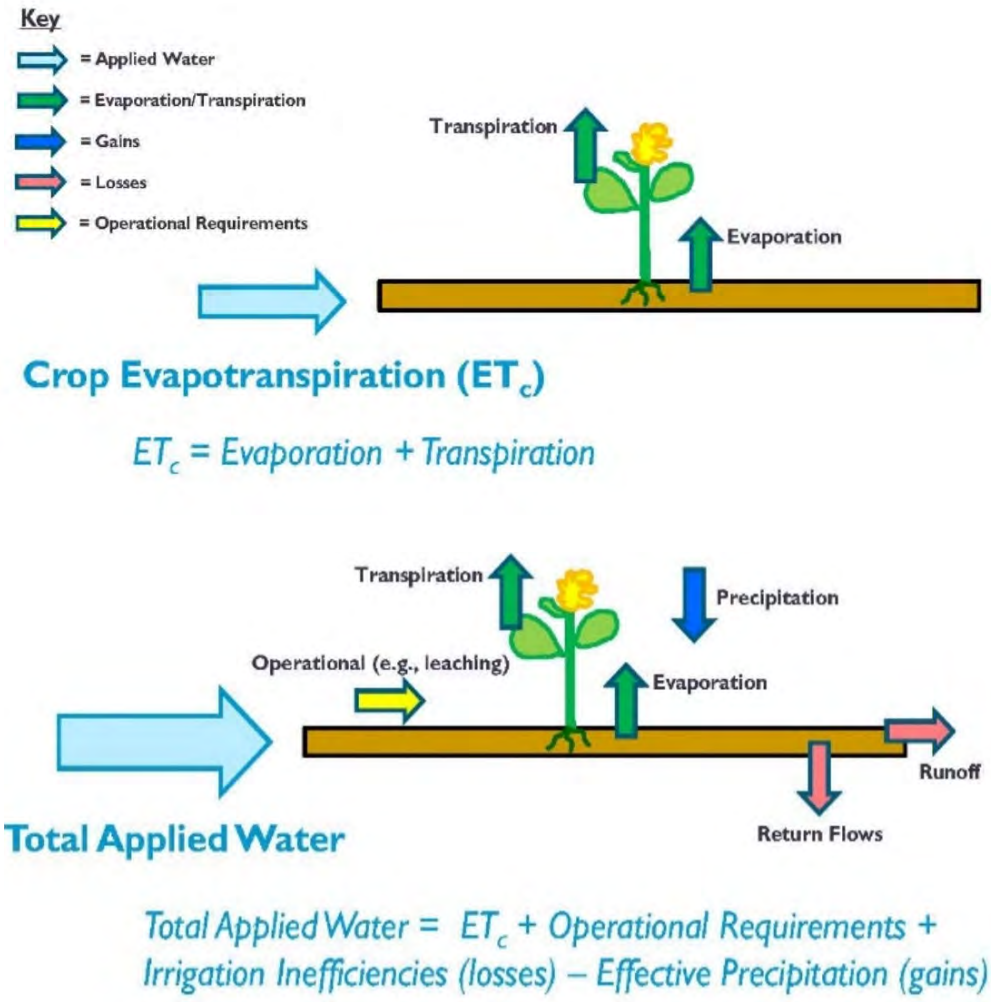
- **Precipitation Records** from the six local climate stations maintained by and located within the District, and two additional climate stations located outside of the District maintained by the National Oceanic and Atmospheric Administration (NOAA)[4]
    - *monthly resolution, January 1971 – December 2017 (data availability varies by station)*

Description of ITRC-METRIC ET Dataset

The ITRC-METRIC ET Dataset uses satellite-based remote sensing of radiant energy and the METRIC energy balance theory to quantify actual water flux to the atmosphere from the land surface (including ET and evaporation from bare soil and open water). This approach differs from other commonly-used methods that estimate ET based on land use (i.e., cropping) patterns and reference ET data and/or crop water use coefficients. There are several advantages of the ITRC-METRIC approach over conventional crop coefficient methods:

- ITRC-METRIC provides the ability to measure actual ET over large areas without any previous knowledge of land use or climate variables, whereas crop coefficients will estimate ET based on known cropping acreages and assumed crop water use properties.

[1] The Irrigation Training & Research Center is part of the California Polytechnic State University, San Luis Obispo.
[2] Howes, D., 2018, *1993-2015 ITRC-METRIC ETc for Kern County*, prepared for the Kern Groundwater Authority on behalf of the Cal Poly Irrigation Training & Research Center. (see **Attachment G-4-1**)
[3] There is no ITRC satellite ET data for calendar year 2012, as the Landsat satellite system employed in the METRIC analysis was out of order during this period. See **Attachment G-4-1** for further details.
[4] See **Appendix G-2** for a detailed description of how climate stations are used to estimate precipitation on District lands and surrounding watersheds.



- ITRC-METRIC provides semi-continuous (i.e., rasterized) ET data at a high spatial resolution (satellite image pixel size of 30 x 30 meters) for an area of study, whereas crop coefficient-based ET estimates are limited to the resolution of the land use dataset being employed.
- ITRC-METRIC allows for ET measurement at a relatively frequent temporal resolution (e.g., approximately every 10 days), whereas crop coefficient methods are typically only available on a seasonal, or at best monthly, basis.

Due to these advantages, ET data developed using the ITRC-METRIC method will intrinsically reflect spatial and temporal variabilities in ET due to factors that cannot be fully accounted for using conventional crop coefficient methods. For example, the ITRC-METRIC ET rasters (image files) will reflect impacts on ET due to crop stresses from drought conditions, ET for crops at various stages of growth, ET for land parcels with multiple growing seasons (i.e., double cropping) and/or interbedded crops, and evaporation from surface water features (such as canals, reservoirs, spreading basins, etc.).

However, the ITRC-METRIC dataset has a significant limitation for water-budgeting purposes in that it does not provide an estimate of ***total applied water***, only ***actual (observed) ET***. *Total applied water* is a term used by water resource engineers to estimate how much water is actually being applied to the land. This differs from ET in that it includes not only water applied to satisfy crop water demand, but also unintentional over-irrigation due to irrigation inefficiency and water intentionally applied for other operational requirements or cultural practices (e.g., leaching, dust abatement, field preparation, frost control). During the main growing season from spring through fall, when precipitation is minimal and ET is greatest, total applied water is nearly always greater than evapotranspiration for any irrigated land, as no irrigation method is 100 percent efficient[5]. Calculation of total applied water must also consider water added to the land surface via precipitation, as this will reduce the irrigation demand for a given area. **Figure G-4-1** illustrates the difference between actual (crop) ET (ET_c) and total applied water.

[5] Irrigation efficiency is defined as the fraction of total applied water that is used by the crop to satisfy its vegetative water demand.

Figure G-4-1. Crop Evapotranspiration (ET or ETc) vs. Total Applied Water

Land Surface Processes within the Water Budget

From a holistic water budgeting perspective, total applied water that does not go towards satisfying crop ET will be subject to four main processes once it is applied to the land surface:

1) Evaporation to the atmosphere
2) Land surface runoff
3) Infiltration and accumulation in the root zone
4) Deep percolation below the root zone to the groundwater table (i.e., return flows)

Although this water budget model allows for temporary carry-over storage of excess effective precipitation in the root zone for subsequent uptake by crops (see below), it is assumed that there is no net long-term accumulation of water within the root zone. Accurate simulation of soil moisture changes would require detailed spatial information on soil properties and root zone depth, as well as data for precipitation, irrigation, and ET on the timescale of hours to days. As the current water budget is designed to reflect monthly changes on a District scale, this level of detail is beyond the current scope of the effort. Furthermore, assuming quasi-steady state conditions within the root zone mimics the approach of the

MODFLOW Farm Process package, which has proven that "simulated inflows into the root zone converged to outflows after time intervals of several days"[6]. Therefore, the assumption of steady-state soil moisture within the root zone is justified.

Similarly, as this water budget was developed on a District scale, and given the generally low topographic slope and lack of significant permanent streams along District boundaries, we have assumed that land surface runoff of applied water is negligible for the purposes of this water budget. Though runoff may occur between parcels within the District service area, there is no continuous receiving water body (i.e., "Natural Channels" such as streams) that could transport surface water runoff outside of the District in any significant volume. Therefore, we have assumed that all land surface runoff occurring between parcels within the District will either (1) evaporate or (2) infiltrate into the subsurface before leaving District boundaries.

Under the above assumptions, excess water applied to the ground surface on District lands will predominantly either (1) evaporate from the wetted bare soil or (2) percolate below the root zone into the deeper subsurface (eventually recharging groundwater) before leaving District boundaries. Considering that landowners within WRMWSD generally employ highly efficient irrigation techniques (such as micro-drip irrigation) and follow irrigation schedules designed to minimize evaporation of excess irrigation water, it is further assumed that evaporation of excess irrigation water is considered to be a negligible flux component of the ITRC-METRIC ET signal, and thus all "inefficient irrigation" of these lands will infiltrate through the root zone and eventually make its way down into the underlying principal aquifer.

Building the Agricultural Lands Subdomain Water Budget

As mentioned above, deep percolation is the only major component of total applied water not measured by the ITRC-METRIC dataset within the agricultural lands subdomain. Deep percolation is likely to result from three main applications of excess water to the ground surface:

1) Intentional operational and/or cultural processes, such as soil leaching and dust abatement
2) Irrigation inefficiencies
3) Excess (i.e. "ineffective") precipitation

Excess water from operational processes and irrigation inefficiencies are only relevant to the irrigated portion of the District, whereas precipitation in excess of crop water demands must be considered across the entire District area. Therefore, for purposes of this water budget, we have separated the irrigated portion of the District from the non-irrigated portion of the District (i.e., including agricultural and native vegetation lands as well as urban lands) before estimating deep percolation and total applied water.

[6] Dogrul, E. C., Schmid, W., Hanson, R., Kadir, T., & Chung, F. 2011. Integrated Water Flow Model and Modflow-Farm Process: A Comparison of Theory, Approaches, and Features of Two Integrated Hydrologic Models. prepared by California Department of Water Resources, Bay-Delta Office in conjunction with the U.S. Geological Survey.

Determining Irrigated vs. Non-Irrigated and Urban Lands

As mentioned above, historical land use data for parcels within the WRMWSD service area were provided by the District for Spring and Fall, 1994 – 2015 in a shapefile entitled "CROPS.shp"[7]. Land use for each parcel was classified on a biannual "seasonal" (i.e., Spring/Fall) basis using crop categories defined in the District's "BAL_XREF" and "CROP_XREF" spreadsheets within the "WRMData_MDB" access database. For the Fall seasons, parcels without crop category information were assumed to have the same crop as was indicated in the Spring season of that same water year (per direction from the District's GIS technician). Parcels were then classified into Irrigated, Non-Irrigated, and Urban categories for each season as follows:

- **"Non-Irrigated"** – land parcels marked as:
  - "NV" – Native Vegetation
  - "DEF" – Idle Lands
  - "FAL" – Fallowed Lands
  - "EUC" – Eucalyptus (not irrigated)
  - "WHD" – Wheat (dry farmed)
  - N/A (i.e., Spring parcels with blank entries)
- **"Urban"** – land parcels marked as "OTH" – Other Lands[8]
- "**Irrigated"** – all other land parcels included in the CROPS.shp

This analysis was performed in R software to facilitate data processing and reproducibility of results.

Determining Irrigation Methods and Irrigation Efficiency Coefficients

As mentioned above, the contribution of "unintentional overwatering" resulting from irrigation inefficiency must be accounted for in estimating total applied water and deep percolation within the agricultural lands subdomain. As such, a representative irrigation efficiency coefficient must be associated with each irrigation type listed in the land use records.

In addition to providing seasonal crop categories, the WRMWSD "CROPS.shp" shapefile also included information on parcel-specific irrigation methods for the years 2011, 2012, and 2013. Irrigation methods listed in this shapefile included:

- "MD" – Micro-Drip
- "MS" – Micro-Sprinkler
- "SP" – Sprinkler
- "CP" – Center-Pivot Sprinkler
- "Fur" – Furrow (Gravity)
- "NON" – Not Irrigated

[7] Before the year 2001, the "CROPS.shp" shapefile only contained cropping information for Spring/Fall 1995 and 1997. These were used to infer general land use categories (e.g. "irrigated", "non-irrigated", "urban") for all years before 2001, where Spring/Fall 1995 crops were used to infer land use for Spring/Fall 1994 – 1996, and Spring/Fall 1997 were used to infer land use for Spring/Fall 1997 – 2000.

[8] "OTH" parcels were classified as "urban lands" based on observations from Google Earth, in which most cases "OTH" parcels were recognized as built structures or paved surfaces.

For parcels marked as "irrigated" based on the reclassification procedure described above, irrigation methods were assigned as follows:

- For years 1994— 2011, Irrigation Method = "IRR_METH_11" (2011 irrigation data)
- For year 2012, Irrigation Method = "IRR_METH_12" (2012 irrigation data)
- For years 2013—2015, Irrigation Method = "IR_METH_13" (2013 irrigation data)

This analysis was performed in R software to facilitate data processing and reproducibility of results.

From here, an area-weighted average irrigation efficiency coefficient was calculated for each season in the record within each basin, which was then later incorporated into the calculation of deep percolation on irrigated lands. Irrigation efficiencies were initially estimated for each irrigation method based on representative values reported by the Food and Agricultural Organization of the United Nations (FAO)[9] and other commonly used resources, as follows:

- Micro-Drip (MD) – **85%**
- Micro-Sprinkler (MS) – **80%**
- Sprinkler (S) – **75%**
- Center-Pivot Sprinkler (CS) – **70%**
- Furrow (Gravity) (F) – **65%**

These values were included as "User Input Parameters" in the budget to facilitate easy adjustment, but were ultimately left unchanged during the calibration process. Parcels marked "NON" (Not Irrigated) in 2011 – 2013 almost always fell into the "Not Irrigated" category based on the crop category classification as described above. However, for years where irrigation methods were not explicitly reported in the data, various parcels may have been irrigated for that year (based on the crop type information) and attributed a "NON" irrigation type if they were not irrigated during 2011 – 2013. For these parcels, the irrigation efficiency coefficient of "NON" was determined as the long-term (2011-2016), acreage-weighted average irrigation efficiency coefficient across the District for all known irrigation types. This weighted average was calculated as **83%** based on the given data, reflecting a dominance of micro-drip irrigation systems within the District.

The resulting irrigation efficiency coefficient (e_{irr}^{i}) for agricultural lands in any month *i* in the water budget period is then calculated as:

$$e_{irr}^{i} = \frac{\sum(0.85*Acreage_{MD}^{i}+0.80*Acreage_{MS}^{i}+0.75*Acreage_{S}^{i}+0.70*Acreage_{CS}^{i}0.65*Acreage_{F}^{i}+0.83*Acreage_{NON}^{i})}{Acreage_{Irrigated\ Lands}^{i}} \quad (1)$$

where $Acreage_{x}^{i}$ = acreage of irrigated lands supplied by *x* irrigation type for month *i*, and where *x* = micro-drip (MD), micro-sprinkler (MS), sprinkler (S), center-pivot sprinkler (CS), furrow (F), and NON (unknown type) irrigation types.

[9] Brouwer, C., Prins, K., & Heibloem, M., 1989, Annex I – Irrigation efficiencies. *Irrigation Water Management Training Manual No. 4 – Irrigation Scheduling*, prepared by the Food & Agricultural Organization of the United Nations.

Linking Reclassified Land Use Information to ITRC-METRIC ET Data

Monthly ITRC-METRIC data was processed using a GIS model (i.e., automated procedure) that sums observed ET values for each parcel based on its geometry as mapped in the District's "CROPS.shp" shapefile. The GIS model employs a Spatial Analyst tool known as "Zonal Statistics" to sum the ET values from each 30 x 30 meter raster pixel within a parcel to determine the total ET value (in inches per month; [in/mo]) for each parcel included "CROPS.shp." This is then multiplied by the raster resolution (900 m^2) and converted into acre-feet per month (AF/mo) to provide a volumetric estimate of ET (in AF/mo) for each parcel on a given month. This process was iterated for the entire set of monthly ITRC-METRIC ET rasters (265 in total) resulting in monthly ET values for each for the entire period of record of the ITRC-METRIC dataset (1993 – 2011, 2013 – 2015). These values were then joined to the reclassified crop information using a unique parcel-based key incorporated into both datasets. Because the crop classification data is reported biannually, whereas the ITRC data is collected monthly, the following time periods were employed to link reclassified land use data to the ITRC-METRIC dataset:

- **"Spring"** – March through August of the calendar year
- **"Fall"** – September through February of the following calendar year

As an example, under this scenario an ITRC raster developed for July 2003 would be linked to the "Spring 2003" land use dataset, whereas an ITRC raster developed for February 2003 would be linked to the "Fall 2002" dataset.

The result of this process is an aggregated monthly dataset containing parcel-based information on:

- Basin location (i.e., Kern Basin or White Wolf Basin)
- Acreage
- Crop type
- Irrigation type (irrigated, not irrigated, urban)
- Irrigation method (if irrigated)
- Monthly ET

A complicating factor in this process is that the ITRC rasters do not cover the entire District area, leaving approximately 1,012 acres of land (~0.6%) without associated ET data. To account for this gap in coverage, a value for "unused acreage" by parcel was developed based on the difference in acreages of the original and joined datasets. ET was then estimated for the area of each parcel outside of ITRC coverage (if any) by applying the average per-acre ITRC ET rate for each of the three irrigation types (irrigated, not irrigated urban) from the covered area. This ensured that the entirety of the District contained an ET estimate for each month.

Determining Additional Irrigation Demands

As mentioned above, ITRC-METRIC data provides a reasonable estimate of actual ET occurring within the District but should not be considered to represent total applied water on District lands. In addition to accounting for irrigation inefficiencies, estimates of total applied water must also consider the additional irrigation demands associated with crop leaching and other operational water requirements, as well as account for any contributions of effective precipitation in meeting the ET demand measured by ITRC-

METRIC. The following subsections detail how additional irrigation demands are estimated within the analytical water budget model.

Crop Leaching Requirements

As mentioned above, soil leaching is a common practice that can significantly increase the volume of applied water required for long-term operations beyond the ET demands estimated by ITRC-METRIC data. As no specific information on leaching practices (i.e., amounts, locations, timing) was available from the District, a conventional approach outlined by the FAO was used to determine leaching requirements based on crop-specific salinity thresholds and estimates of leaching water salinity[10]. For a given crop, the "leaching fraction" (i.e. the incremental portion of irrigation water in excess of crop ET demands required to maintain the soil salinity at ideal conditions for crop yield) is defined as follows:

$$LF = \frac{EC_w}{5(EC_e) - EC_w} \quad (2)$$

where *LF* = leaching fraction [dimensionless], EC_w = electrical conductivity of the irrigation water [deciSiemens per meter; dS/m], and EC_e = crop salinity threshold [dS/m].

From here, the volumetric "leaching requirement" can be calculated as the incremental volume of water needed to satisfy the leaching demand:

$$LR = \frac{ET_c * LF}{1 - LF} \quad (3)$$

where *LR* = leaching requirement [AF] and ET_c = crop evapotranspiration [AF].

For the purposes of this analysis, leaching demands are calculated for the entire irrigated lands portion of the agricultural lands subdomain for each month. To achieve this, an area-weighted crop-salinity threshold is calculated for the irrigated lands area for each basin based on the relative acreages of each crop category included in "CROPS.shp." (see **Attachment G-4-2** for the list of indicative crop salinity thresholds used in this methodology). A leaching fraction (*LF*) is then calculated per equation (2) above within the water budget based on the area-weighted crop salinity threshold and an assumed electrical conductivity of irrigation water (EC_w). The EC_w is implemented as a user-adjustable input parameter within the water budget spreadsheet, and was ultimately set at 500 microsiemens per centimeter (µS/cm) in line with the general water quality profile of WRMWSD's imported surface water supplies. Crop evapotranspiration (ET_c) is estimated from the monthly ITRC-METRIC ET data for irrigated lands, and a monthly leaching requirement (*LR*) is calculated using equation (3) above.

Other Operational Demands

As mentioned above, in addition to soil leaching, other operational practices that require additional applied water are commonly employed for purposes such as pre-irrigation requirements, harvesting, pest control, frost control, crop uniformity, germination, and dust control. As no specific information on specific operational water uses (i.e., amounts, locations, timing) was available from the District, these additional "operational demands" are estimated from *JMLord, Inc.'s* historical agricultural demand

[10] Tanji, K.K., & Kielen, N.C., 2002, Annex I – Crop salt tolerance data. *Agricultural drainage water management in arid and semi-arid areas*, prepared by the Food & Agricultural Organization of the United Nations.

reports[11] provided for the District's neighbor, Arvin-Edison Water Storage District (AEWSD), who is known to have a similar land use profile and distribution to WRMWSD.

Based on the *JMLord, Inc.* reports, it was determined that on a District scale, agricultural water users were historically applying an additional **0.16 AFY/acre** to their lands on average (over Water Years 1994 – 2015) to meet additional operational demands beyond leaching. This value was employed for the "Additional Operational Demands" User Input Parameter within the analytical water budget model to estimate operational water demands within the District for any given month:

$$OD^i = \frac{0.16}{12} * Acreage^i_{Irrigated\ Lands} \quad (4)$$

where OD^i = operational demands for month *i* [AF] and $Acreage^i_{Irrigated\ Lands}$ = irrigated acreage for month *i*.

Processing Precipitation Data

As mentioned above, estimates of total applied water should also take into account any contribution of effective precipitation in meeting ET demands on District lands. The residual "ineffective precipitation" (i.e., the portion of precipitation which is not considered available to meet ET demands) may also contribute to groundwater recharge to a certain degree and should thus be quantified and routed to appropriate subdomains within the analytical water budget to ensure mass balance is fully conserved within the model.

Calculating Effective Precipitation

Effective precipitation as defined as "the part of rainfall that can be used to meet the evapotranspiration of growing crops. It does not include surface runoff or percolation below the crop root zone." (USDA-SCS, 1970)[12]. Since limited data exists to quantify historical rates of effective precipitation within the District, we have chosen to employ an empirical equation developed by the United States Department of Agricultural Soil Conservation Service (USDA-SCS)[13] which factors in measurements of monthly rainfall, evapotranspiration (i.e. crop consumptive use), and estimated depth of application (or "usable soil water storage" depths) to approximate effective rainfall (in inches) for any given month[14]. The resulting equation for estimating monthly effective precipitation [in] is:

$$p_e = f * (0.70917 * p_t^{0.82416} - 0.1156) * 10^{0.02426 * ET_c} \quad (5)$$

where p_e = effective precipitation [in], p_t = total precipitation [in], ET_c = crop evapotranspiration [in], and f = correction factor for irrigation application depths different from 3 inches, where:

---

[11] JMLord, Inc., 1998 – 2015. *Arvin-Edison Storage District – Assessment of Reasonable Water Requirements.* Internal Reports.

[12] United States Department of Agriculture – Soil Conservation Service (USDA-SCS), 1970. *Irrigation Water Requirements*. USDA-SCSC Technical Release No. 21. 88 pp

[13] *Ibid [17].*

[14] "SCS scientists analyzed 50 years of rainfall records at 22 locations throughout the United States to develop a technique to predict [monthly] effective precipitation (USDA 1970). A daily soil moisture balance incorporating crop [ET], rainfall, and irrigation was used to determine the ET effectiveness." (USDA-SCS, 1993).

$$f = (0.531747 + 0.295164 * D - 0.057697 * D^2 + 0.003804 * D^3) \quad (6)$$

where *D* = net depth of application during irrigation [in].

Effective precipitation (p_e) was calculated for each month for both irrigated and non-irrigated lands, where *D* was set to the default value of 3 inches for irrigated lands and set to zero inches for non-irrigated lands. These normalized values were subsequently converted into volumetric effective precipitation rates (in AF per month) using the acreages of irrigated and non-irrigated lands for the given month. For example:

$$P_{e\,Irrigated\ Lands}^{\ i} = \frac{p_{e\,Irrigated\ Lands}^{i}}{12} * Acreage_{Irrigated\ Lands}^{i} \quad (7)$$

where $P_{e\,Irrigated\ Lands}^{\ i}$ = effective precipitation on irrigated lands for month *i* [AF]. A similar calculation was used for the non-irrigated lands.

Effective Precipitation Carryover Term

While a soil moisture balance is not explicitly modeled in this analytical water budget, it is recognized that excess effective precipitation in the rainy winter months of the year may be retained temporarily in the root zone and can help contribute to meeting ET demands in the early growing season, thus reducing the irrigation demand during these months. To account for this phenomenon, we have included an effective precipitation "carryover" term to allow for any residual effective precipitation in excess of ITRC-METRIC ET signal to remain available for meeting ET demands in the following month(s) throughout the model period. This effective precipitation carryover term is defined as:

$$P_{e\,Carryover}^{\ i} = \max(0,\ P_e^i - ET^i) \quad (8)$$

where $P_{e\,Carryover}^{\ i}$ = carryover of excess effective precipitation from month *i* [AF], P_e^i = effective precipitation for month *i* [AF], and ET^i = ITRC-METRIC measured ET for month *i* [AF].

This effective precipitation carryover term is subsequently added to the effective precipitation value calculated for the following month:

$$P_e^{i+1} = +P_{e\,initial}^{\ i+1} + P_{e\,Carryover}^{\ i} \quad (9)$$

where P_e^{i+1} = adjusted effective precipitation for month *i + 1* [AF], $P_{e\,initial}^{\ i+1}$ = initial effective precipitation for month *i +1* (calculated from equations 5 – 7) [AF], and $P_{e\,Carryover}^{\ i}$ = effective precipitation carryover term from month *i* [AF] (calculated from equation 8).

Parsing Ineffective Precipitation

As mentioned above, "ineffective precipitation" is defined as the portion of total (direct) precipitation that is not considered available to meet ET demands:

$$P_{ineff}^{i} = P_t^i - P_{e\,initial}^{\ i} \quad (10)$$

where P_{ineff}^{i} = ineffective precipitation for month *i* [AF], P_{t}^{i} = total precipitation for month *i* [AF], and P_{e}^{i} = initial effective precipitation for month *i* [AF] (calculated from equations 5 – 7).

Ineffective precipitation can either (1) runoff as a surface outflow from the water budget domain; (2) evaporate from the land surface before infiltrating into the root zone; or (3) percolate from the root zone into the vadose zone, where it eventually becomes groundwater recharge. As mentioned above, (1) surface runoff outside of the District is considered negligible in this water budget, leaving (2) evaporation and (3) deep percolation as the only pathways for parsing ineffective precipitation. Very little historical data or reference information exists for quantifying the proportions of evaporation versus deep percolation for ineffective precipitation, so we have chosen to define an **"ineffective precipitation deep percolation coefficient"** (f_{DP}) user input parameter to apportion these flux components within the model. Here, the portion of ineffective precipitation contributing to deep percolation for a given month (P_{DP}^{i}) is defined as:

$$P_{DP}^{i} = P_{ineff}^{i} * f_{DP} \tag{11}$$

where P_{ineff}^{i} = ineffective precipitation for month *i* [AF], and f_{DP} = ineffective precipitation deep percolation coefficient [-].

Consequently, the portion of ineffective precipitation that will evaporate from the land surface for a given month (P_{evap}^{i}) is defined as:

$$P_{evap}^{i} = P_{ineff}^{i} * (1 - f_{DP}) \tag{12}$$

Notably, P_{evap}^{i} is included as a unique evaporative flux component from the water budget domain in addition to ITRC-METERIC derived ET, as opposed to assuming that evaporation of ineffective precipitation was included in the ITRC-METRIC signal. Though the ITRC-METRIC method is considered a generally reliable estimator of actual ET over large spatial domains, it faces certain limitations, particularly in the winter months where usable LANDSAT satellite imagery may not be available due to the presence of clouds, etc., and/or satellite imagery may not adequately capture the evaporation occurring from wetted soils immediately following a precipitation event[15]. With this constraint in mind, and under the observation that ITRC-METRIC measured ET in the winter months (i.e., November – February) was usually significantly lower than pan evaporation measured at the District's nearby (5P-P2 Pumping Plant, District Headquarters, and PA-2 Pumping Plant) climate stations for the same months, it was determined that an additional "evaporation of ineffective precipitation" term (P_{evap}^{i}) was warranted for estimating evaporation of ineffective rainfall during the winter months when it is likely to be underestimated by the ITRC-METRIC method. Inclusion of P_{evap}^{i} also results in a more reasonably conservative estimate of groundwater recharge from ineffective precipitation (P_{DP}^{i}) during the wet season.

The ineffective precipitation deep percolation coefficient (f_{DP}) user input parameter was ultimately determined via calibration of the water budget model, as described further in **Appendix G-5**. A constant

[15] *Ibid [2].* See full ITRC-METRIC report for further details.

value of f_{DP} = 0.5 (i.e., 50% deep percolation of ineffective precipitation) was used for the WRMWSD analytical water budget model.

Calculating the Total Irrigation Demand and Agricultural Groundwater Pumping

Following the above methodologies to calculate the monthly ET demand, irrigation efficiency, leaching and other operational demands, and contributions of effective precipitation, the total irrigation demand within the District can be determined. After accounting for the volume of District surface water deliveries to irrigated lands from the District's "WLEDGER" tables, the volume of groundwater pumping for irrigation (otherwise termed "agricultural groundwater pumping") can also be estimated for any given month during the water budget period.

For any given month (*i)*, the unadjusted irrigation demand is defined as the ET demand on irrigated lands minus any contributions of effective precipitation:

$$I^i_{demand} = \max(0, ET^i_{Irrigated\ Lands} - P_{e}{}^{i}_{Irrigated\ Lands}) \quad (13)$$

where I^i_{demand} = unadjusted irrigation demand [AF], $ET^i_{Irrigated\ Lands}$= ITRC-METRIC ET on irrigated lands [AF], and $P_{e}{}^{i}_{Irrigated\ Lands}$ = effective precipitation on irrigated lands [AF] (equation 9) for month *i*.

The adjusted irrigation demand is then computed as follows:

$$I^i_{demand,adj} = I^i_{demand} * (1 + (1 - e^i_{irr})) + LR^i + OD^i \quad (14)$$

where e^i_{irr} = irrigation efficiency coefficient (equation 1), LR^i = leaching requirement (equation 3), and OD^i = operational demands (equation 4) for month *i.*

As seen in equations (13) and (14), if the unadjusted irrigation demand (I_{demand}) is less than zero (i.e., if there is effective precipitation in excess of the measured ET on irrigated lands) than I_{demand} is set to zero and the adjusted irrigation demand only includes the leaching requirements & operational demands for that given month.

From here, we can calculate agricultural groundwater pumping ($GW^i_{pumping}$) for month *i* as the residual of the surface water deliveries to irrigated lands and the adjusted irrigation demand:

$$GW^i_{pumping} = \max(0, I^i_{demand,adj} - SW^i_{deliveries}) \quad (15)$$

where $SW^i_{deliveries}$= surface water deliveries[16] [AF] for month *i*.

If surface water deliveries to irrigated lands are greater than the adjusted irrigation demand, then there is no additional need for irrigation water and agricultural groundwater pumping is thus set to zero.

[16] The term "surface water deliveries" is used here to refer to deliveries by the District to its customers within the Surface Water Service Area through the District's conveyance system. These deliveries may in fact include some groundwater recovered from storage by the District's recovery wells.

Calculating Instantaneous and Time-Averaged Deep Percolation

Using the above methodology, total applied water (*TAW)* [AF], is intrinsically calculated within the water budget as follows:

$$TAW^i = SW^i_{deliveries} + GW^i_{pumping} \quad (16)$$

For the irrigated lands, *TAW* includes groundwater pumping and surface water deliveries after accounting for effective precipitation on the irrigated portion of the District (see equation 13). The *TAW* term therefore inherently reflects all assumptions about irrigation efficiency, leaching, operational requirements, and effective precipitation, as these values are included in the calculation of groundwater pumping within the irrigated portion of the District. TAW reduces to zero for non-irrigated lands, while for urban lands TAW will only include surface water deliveries to municipal & industrial (M&I) customers, and/or any M&I groundwater pumpage.

From here, the total instantaneous deep percolation on irrigated lands ($DP^i_{inst_{Irrigated\ Lands}}$) [AF] for month *i* is calculated as:

$$DP^i_{inst_{Irrigated\ Lands}} = TAW^i - ET^i_{Irrigated\ Lands} + P^i_{DP_{Irrigated\ Lands}} \quad (17)$$

where $ET^i_{Irrigated\ Lands}$ = ITRC-METRIC ET on irrigated lands [AF] and $P^i_{DP_{Irrigated\ Lands}}$= portion of ineffective precipitation contributing to deep percolation on irrigated lands (equation 11) [AF].

For the irrigated lands, this term will reflect all deep percolation resulting from inefficient precipitation, irrigation inefficiency, leaching demands and any other operational water uses.

For the non-irrigated lands, TAW is, by definition, zero and the total instantaneous deep percolation on non-irrigated lands ($DP^i_{inst_{Non-Irrigated\ Lands}}$) can be re-written as:

$$DP^i_{inst_{Non-Irrigated\ Lands}} = P^i_{e_{Non-Irrigated\ Lands}} - ET^i_{Non-Irrigated\ Lands} + P^i_{DP_{Non-Irrigated\ Lands}} \quad (18)$$

Note that in equation 18 deep percolation includes a contribution from effective precipitation on non-irrigated lands ($P^i_{e\ Non-Irrigated\ Lands}$). This term is included in equation 18 as a mass-balance closure term, since it is not intrinsically considered in the calculation of TAW as it is for the irrigated lands subdomain. By definition of P^i_e in equation 9, this term should include all carryover effective precipitation from previous months where $P^i_{e\ Non-Irrigated\ Lands} > ET^i_{Non-Irrigated\ Lands}$ so as to prevent any effective precipitation from percolating below the root zone, thus reducing equation (18) to only include $P^i_{DP\ Non-Irrigated\ Lands}$. However, it has been noted that the ITRC-METRIC measured $ET_{Non-Irrigated\ Lands}$ routinely exceeds $P_{e_{Non-Irrigated\ Lands}}$ estimates during the dry season, thus resulting in a negative $DP^i_{inst_{Non-Irrigated\ Lands}}$ during the summer months. Whether or not this high ET signal in the non-irrigated portions of the District is an artifact of the ITRC-METRIC method or is in fact a

real signal, for the purposes of this water budget a negative $DP^{i}_{inst\,Non-Irrigated\ Lands}$ value results in a net reduction of groundwater storage from the non-irrigated subdomain for the given month.[17]

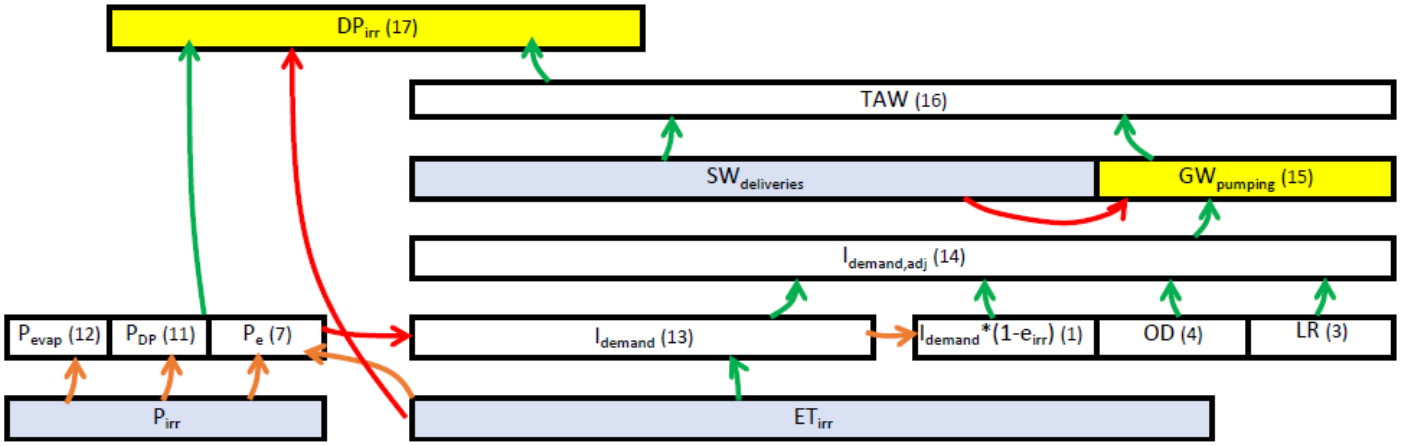
Though the instantaneous deep percolation value serves as a closure term within the irrigated and non-irrigated lands water budget subdomains, in reality, because the groundwater table can occur several hundred feet below the ground surface, it may take a considerable time for deep percolation to travel through the thick vadose zone before it actually reaches the groundwater table and adds to groundwater storage. For the purposes of this water budget, this "lag effect" is represented by including a "Deep Percolation Lag Period" as a user input parameter within the water budget. This allows the user to specify an estimated time (in months) that it would take for any deep percolation water to travel through the vadose zone and reach the groundwater table. The resulting "time-averaged" deep percolation, DP_{avg} [AF], is thus calculated as a moving average as follows:

$$DP_{avg} = \frac{\sum_{i-N}^{i} DP^{i}_{inst}}{N+1} \qquad (19)$$

where *N* = the deep percolation lag period [months].

This value represents the estimated volume of "deep percolation" that actually reaches the groundwater table on a given month. For the WRMWSD water budget, a final deep percolation lag period of **11 months** was selected, so the amount of deep percolation recharging the groundwater basin for a given month would equal the time-averaged deep percolation (DP_{avg}) percolation for the past 11 months up to the present. Use of this time-averaged deep percolation (i.e., use of a moving average) results in a smoothed-out time series of recharge. This method was also applied to the recharge from stream flows into the District, seepage from man-made channels (negligible), and return flows from urban water use.

[17] It should be noted that the excess non-irrigated demand likely does not come from groundwater storage depletion, but is rather made up by a combination of local runoff from adjacent irrigated lands, contributions from streamflows, and/or seepage from natural and artificial water systems. Functionally, it is justified to attribute this demand to groundwater storage depletion, because if it were to come from surface water it would then reduce the amount of surface water available for delivery to agricultural lands which would increase the demand for pumping, and so the same result is achieved.



Conclusions

The result of the above processing steps is a water budget for the agricultural lands subdomain that:

- Incorporates direct measurements of ET from the land surface using ITRC-METRIC data as well as estimates of direct precipitation from local climate stations;
- Links monthly ITRC-ET data to seasonal, parcel-based land use details;
- Parses ET into buckets of (1) irrigated lands, (2) non-irrigated lands, and (3) urban lands;
- Calculates estimates of agricultural pumping and deep percolation on irrigated lands due to ineffective precipitation, irrigation inefficiencies, leaching, and operational demands;
- Calculates estimates of deep percolation on non-irrigated lands due to ineffective precipitation;
- Factors in a user-defined lag period to represent the time lag effect of vadose-zone flow on groundwater recharge due to deep percolation; and
- Accounts for evaporation of ineffective precipitation in the winter months where ITRC-METRIC ET data may not fully capture evaporation after rain events due to gaps in imaging frequency and/or less-reliable interpolations between imaging dates.

The attached **Figure G-4-2** provides a schematic of the irrigated agricultural lands subdomain equations and their interrelationships as described above.

Kern Groundwater Authority
1993-2016 ITRC-METRIC

Introduction

The Irrigation Training & Research Center (ITRC) at California Polytechnic State University, San Luis Obispo was contracted by the Kern Groundwater Authority (KGA) to compute actual evapotranspiration (ETc) from the Southern San Joaquin Valley within and near the Kern Groundwater Basin. The area of interest is shown in Figure 1 with a "natural color" image in the background.

ITRC uses a modified Mapping of EvapoTranspiration with Internal Calibration (METRIC™) procedure to compute actual evapotranspiration using LandSAT Thematic Mapper (LandSAT) data. The original METRIC procedure was developed by Dr. Richard Allen (University of Idaho). ITRC has made a number of modifications to the original procedures including using a grass reference evapotranspiration instead of alfalfa, a semi-automated calibration procedure, spatially interpolated ETo, modifications to the aerodynamic resistance and albedo computations for certain crops, improved open water evaporation algorithm, etc.

Figure 1. Aerial image of the area of interest within which actual evapotranspiration was provided to KGA

This report will describe the general process and some results of the modeling over the timeframe. The monthly and annual results of ITRC-METRIC for this project have been transmitted to KGA (care of Eric Averett, General Manager, Rosedale-Rio Bravo WSD).

ITRC- METRIC Procedures

This *Procedures* section will discuss the information that was gathered and used to compute the actual crop evapotranspiration (ET) in the Delta. The ITRC-METRIC process is based on a surface energy balance and includes corrections for aerodynamic resistance. It depends upon both accurate and frequent LandSAT satellite thermal images and understanding of the cropping systems within a region. The METRIC programs have gradually evolved from research in the US and other countries with the objective of being able to directly estimate actual ET over large areas with limited data availability (such as crop type, irrigation method, irrigation practices, etc.). The image processing is relatively fast; however, the collection of significant background data (besides the satellite images) that are necessary to start the processing in a new area can be somewhat time-consuming. Proper use of METRIC also requires expert input/interpretation by those who run the program.

LandSAT 5, 7, and 8 image pixel resolution is 30 meters by 30 meters for all but the thermal band. The thermal band pixel resolution is 120 meters by 120 meters for LandSAT 5, 60 meters by 60 meters for LandSAT 7, and 100 meters by 100 meters for LandSAT 8. For this project, the thermal band was sharpened to 30 meter by 30 meter resolution using the nominal cubic spline that is provided in the raw images by USGS. ITRC has a more advanced thermal sharpening process, but that was not used because of time and budget constraints for this project. Inputs into the ITRC-METRIC model included:

- LandSAT imagery
- Digital elevation maps
- NASS CropScape data
- Corrected weather station data (hourly and daily)
- Corrected spatial grass reference evapotranspiration (ETo) maps (daily)
- Spreadsheet calculated values
- Tabulated constants

A critical benefit of using ITRC-METRIC to determine actual evapotranspiration is that land use/crop type information is not needed. Therefore, inaccuracies of determining land use are not part of the uncertainty in ETc output. General land use information (row crop, orchard, etc.) is used to correct for aerodynamic influences on ETc. The information provided through the NASS CropScape is of sufficient accuracy for this piece of the process.

Satellite Images

LandSAT 5, LandSAT 7, and LandSAT 8 images available from the United States Geological Survey (USGS) on sixteen-day intervals were used for the METRIC process. Table 1 shows the time frame of available images from each satellite.

Table 1. Time frame of available images for LandSAT 5, 7, and 8

LandSAT 5	LandSAT 7**	LandSAT 8
November 1982 – October 2011	June 1999 – Present	April 2013 – Present

***After May 2003, LandSAT 7 began producing images with missing data, or "bandgaps" because of a defective sensor/mirror. LandSAT 7 is only used as a backup if other LandSAT data is missing. Bandgaps are filled using interpolation techniques in GIS as described in the METRIC Application Manual Version 2.0.7 (Allen et al. 2010)*

The area of interest is covered by the LandSAT image path 42, rows 35 and 36**.** Each path identifies a path, or single trip the LandSAT takes, and the rows are different portions of that path. The rows along the same path are taken on the same day and the center of the row image is taken at approximately the same time of the day (approximately 11 a.m. Pacific Standard Time).

The METRIC modeling process relies on surface temperature data from the LandSAT thermal band. Actual ETc cannot be computed for the regions covered by clouds or fog. Figure 2 compares a non-clouded image with a cloud-covered LandSAT image. The best quality (minimal clouds and fog) LandSAT images were selected for processing. Every LandSAT image available throughout the study period was evaluated manually.

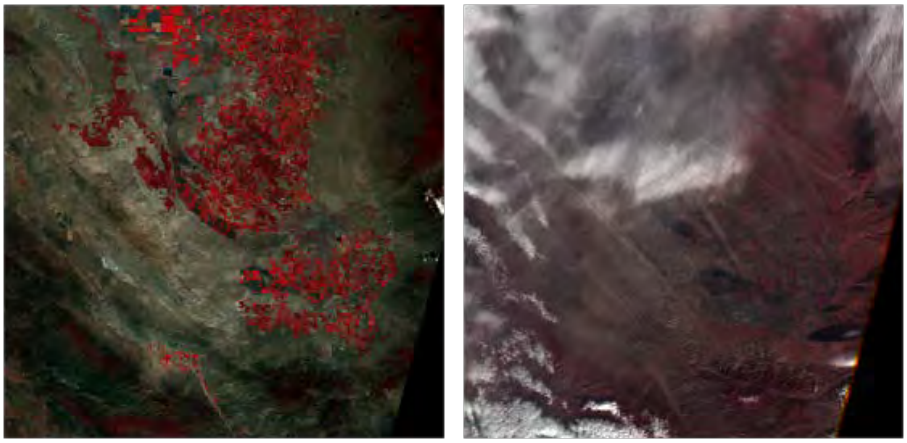

Figure 2. Cloud free LandSAT image (left) and LandSAT image with clouds (right)

All relatively cloud-free available images were used for the modeling process. Table 2 lists the images processed from late 1992 through early 2016. A total of 234 images were used to cover the study period.

If a cloud-free image was not available during a month, the image with the fewest clouds was selected or LandSAT 7 imagery was used. If an image with clouds had to be used, the clouds were masked out of the results and replaced with interpolated results from images processed before and after the image date. For the cloud masking interpolation, the two previous and three subsequent processed images were used to estimate the actual crop coefficient for the cloudy region.

Some months (generally during winter) had no usable images because of significant cloud cover. Available images, before and after the month with no data, were selected to be used to interpolate the missing image.

For those cases when three or more consecutive months did not have usable images, the closest available image was used in combination with a correction factor, to get an average estimated Kc map for the missing month. Those correction factors were established based on data from years with usable winter images. Because this process was used only for winter months, which have low ET, the overall accuracy should not be influenced significantly. However, users should understand that the uncertainty of the data for these months is greater than if LandSAT images were available. The months when this process was used can be seen in Table 3.

Weather Data

ITRC-METRIC utilizes daily spatially varied grass reference ETo for interpolation between image dates. SpatialCIMIS is a product provided by the California Irrigation Management Information System (CIMIS) maintained by the California Department of Water Resources (DWR). Spatially varied ETo is developed by interpolating ETo between CIMIS weather stations, which measure and compute the ETo on an hourly basis. However, the collected data could have errors. Therefore, ITRC quality controls the hourly weather data at each weather station in the Central Valley (Redding to south of Bakersfield) and corrects the daily Spatial CIMIS data.

ITRC-METRIC also relies on hourly weather data from a station within the area of interest for processing the instantaneous images (prior to interpolation). The Shafter and Famoso CIMIS stations were utilized as the "primary" weather stations. These stations were selected because of their centralized locations within the primary area of interest. Shafter was used from 1992-1997 and Famoso was used from 1998-2015. The same quality control procedure was used at all weather stations, as will be described.

Hourly weather data for the project time frame was collected from CIMIS weather stations located throughout the project area. Forty-nine weather stations were used for the METRIC modeling process. Figure 3 shows the majority of weather stations used in this project. Not all stations were available during the entire analysis period. Each station is listed in Table 4 showing the approximate range of time that the station was utilized. A station may have become active or inactive within this timeframe.

The weather component data collected from the weather stations included:

1. Solar radiation (W/m^2)
2. Vapor pressure (kPa)
3. Air temperature (ºC)
4. Wind speed (m/s)
5. Precipitation (mm)
6. Relative humidity (%)
7. Dew point temperature (ºC)
8. PM ETo (mm)

* “Primary” stations

All collected **hourly** weather data from the stations went through a quality control check and correction procedure. A detailed procedure on the quality control conducted can be found in FAO Irrigation and Drainage Paper No. 56[1] along with correction procedures. The main variable needing correction to accurately compute the hourly ETo is solar radiation. However, relative humidity was also examined using the procedures described in Allen et al. (1998). Figure 4 contains a graph of the corrected solar radiation for the Famoso CIMIS station for 2010-2014. This weather parameter is often in error if a pyranometer becomes covered with dust or debris, or if it loses calibration. This can be identified by comparing the daily incoming solar radiation with the maximum potential solar radiation (computed based on elevation, latitude, and time of year). If the measured value does not approach or become equal to the maximum potential over a time frame of several weeks, this could indicate an error in the measurement. Day-to-day variability is expected, but during a clear day, the measured should approach the potential. High values of solar radiation can be caused by incorrect sensor calibration.

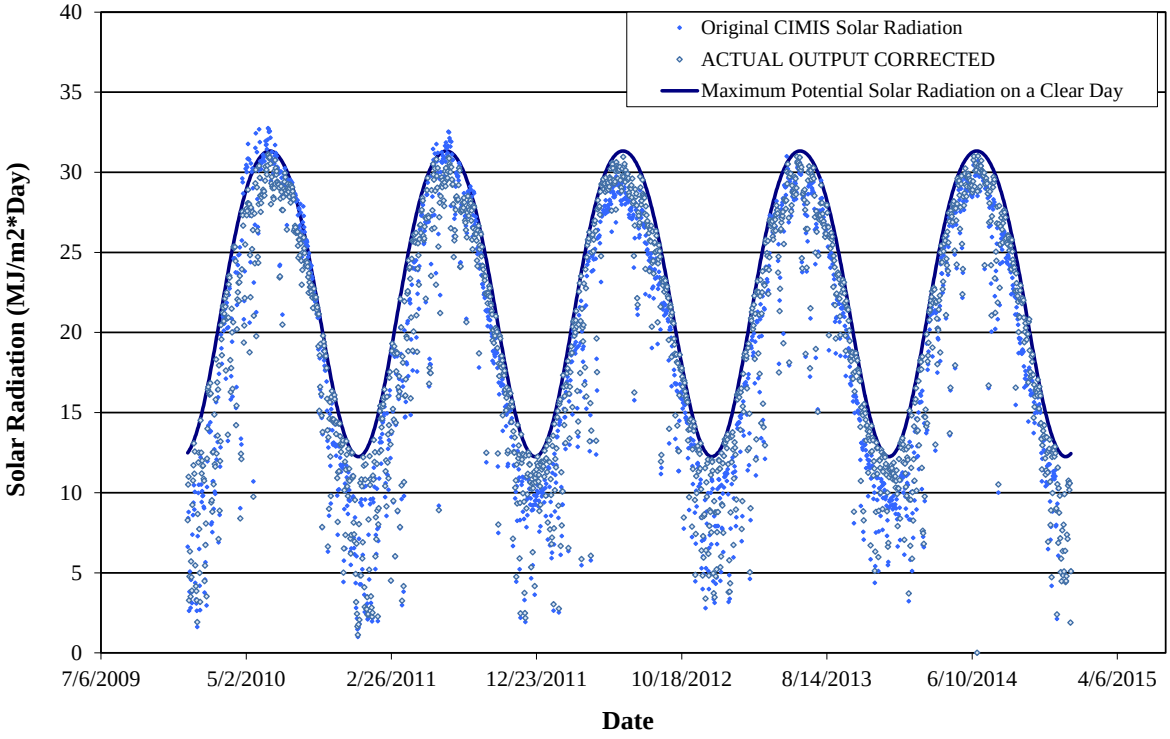

Figure 4. Example of solar adjustments made on Famoso CIMIS Station for 2010-2014. The same analysis was conducted for all weather stations in the Central Valley.

For missing data, or if an error was flagged on the CIMIS station signifying missing, incomplete, or odd data results, data were examined for general consistency. Missing data and data believed to be in error were corrected. The correction procedure used in this analysis replaced the missing or flawed data with the averages from nearby weather stations. Once all hourly data was corrected, the data was input into REF-ET™ (Dr. Richard Allen, University of Idaho) to compute the corrected hourly ASCE Standardized ETo that was used in this study.

[1] Allen, R.G.; Pereira, L.S.; Raes, D. & Smith, M. (1998). Crop evapotranspiration – Guidelines for computing crop water requirements. FAO Irrigation and Drainage Paper, No. 56, FAO, Rome

ETo and individual weather data are used within the ITRC-METRIC process to compute inputs into the software. METRIC computes the instantaneous ETc for every pixel within the LandSAT image at the instant the image is taken. Knowing the ETo at that instant from the local weather station, a **crop coefficient (Kc)** can be computed (Kc = ETc/ETo). It has been shown that this instantaneous actual Kc at the time of image acquisition (approximately 11 a.m.) is a very good representation of the Kc for that entire day. These instantaneous Kc results are interpolated using a cubic spline procedure between image dates. The interpolated pixel Kc for each day is then multiplied by the daily corrected spatial ETo discussed in the next section.

Corrected Spatial ETo

Spatial CIMIS ETo is a relatively new resource available through the DWR. A specialized algorithm uses weather station data, elevations and other inputs to interpolate ETo between stations. However, Spatial CIMIS ETo rasters rely on CIMIS weather data that could have errors. In order to improve accuracy, ITRC incorporated the corrected CIMIS weather data into the Spatial CIMIS ETo raster images using a model we developed for ArcGIS 10.1.

The basic correction procedure first included adding the locations of all 49 stations into GIS. The uncorrected Spatial ETo at the weather station location was extracted for each day over the time frame investigated. The difference between the corrected daily ETo for each station and the uncorrected Spatial ETo was computed. These differences were used to generate a difference raster using Inverse Distance Weighting (IDW) interpolation. The difference raster was combined with the uncorrected Spatial ETo to generate the corrected Spatial ETo image.

Figure 5 shows a comparison of the uncorrected Spatial CIMIS ETo and the corrected Spatial ETo for July 15, 2015. The corrected Spatial ETo represents the combination of our corrected ETo data blended with the original Spatial CIMIS ETo.

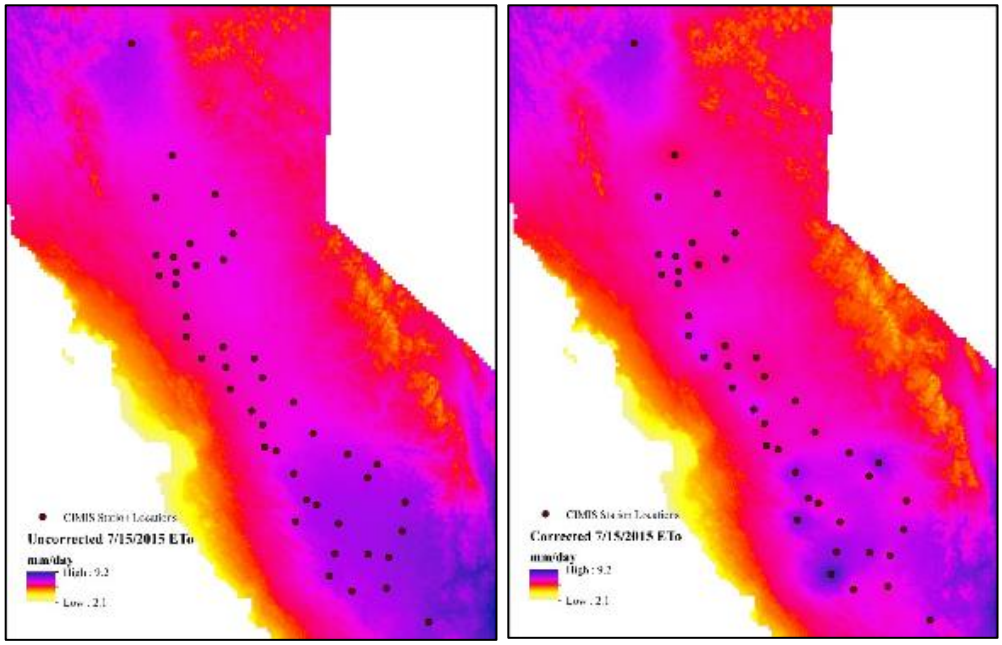

Figure 5. Example of uncorrected Spatial CIMIS ETo compared to corrected Spatial ETo for July 15, 2015

Calibration near Primary Weather Station

The METRIC process requires calibration of the hot and cold pixel for each image processed. The calibration should be conducted near a primary weather station within the image. Therefore, a primary weather station was selected for each image path. The stations selected (Shafter (1993-1997) and Famoso (1998-2015)) were chosen on the basis of the stations' history of reliable, relatively error-free data. Other reasons for choosing primary stations included:

- The location within intensive agricultural areas.
- Relatively representative of weather throughout the agricultural regions in the path.

Shafter was used as a primary station for the years 1993 through 1997. Famoso was used as a primary station for the remainder of the study period.

For the semi-automated calibration process, an area of interest (AOI) is created around the primary weather station. This AOI is generally within a 5 to 10 mile radius of the primary station and urban areas, or large non-agricultural areas are avoided. Figure 6 shows the calibration AOI for the Famoso CIMIS station.

Figure 6. Famoso CIMIS station calibration area of interest (AOI)

Elevation Data

A Digital Elevation Model (DEM) obtained from the USGS was used to adjust the model outputs based on the surface elevation throughout the area of interest. The DEM used had a resolution of 10m (1/3 arc second) which was then re-projected into a 30m × 30m pixel size to match the resolution of the LandSAT images.

Land Use Map

As previously mentioned, accurate land use/crop types are not necessary for ITRC-METRIC. General information on whether land is natural vegetation, row/field crops, orchards, or vineyards is used to adjust for aerodynamic resistance of the canopy, and is also a function of leaf area index. NASS CropScape provides sufficient accuracy for this information.

Land Use Data 2007 to Present

For years 2007 to present, only the land use data from the NASS annual rasters were used. While this information is sufficient for METRIC, there are issues with consistency within fields. Land use surveys were conducted by the California DWR on a field-by-field basis for all of the counties located in the Central Valley. DWR land use survey shapefiles were downloaded for each county, some of which may have last been surveyed in the 1990s. The shapefiles contain field boundaries or in some cases boundaries of the same crop that cover multiple fields. All non-agricultural areas in the DWR land use surveys were removed from the shapefile. Using the zonal statistics tool in ArcGIS, the NASS land use was summarized for each DWR agricultural field boundary in the Central Valley. The crop that made up the majority of the field area was assumed to cover the entire field area.

The final corrected land use maps went through a quality control check to ensure that a single land use value was uniform across an entire field. Figure 7 shows an example of the original uncorrected NASS land use compared to the land use used in this analysis, which is much more consistent. The inconsistent "pixelated" areas in the corrected land use were identified as non-cropped areas in the DWR land use survey. Therefore, these non-ag areas use the original NASS data.

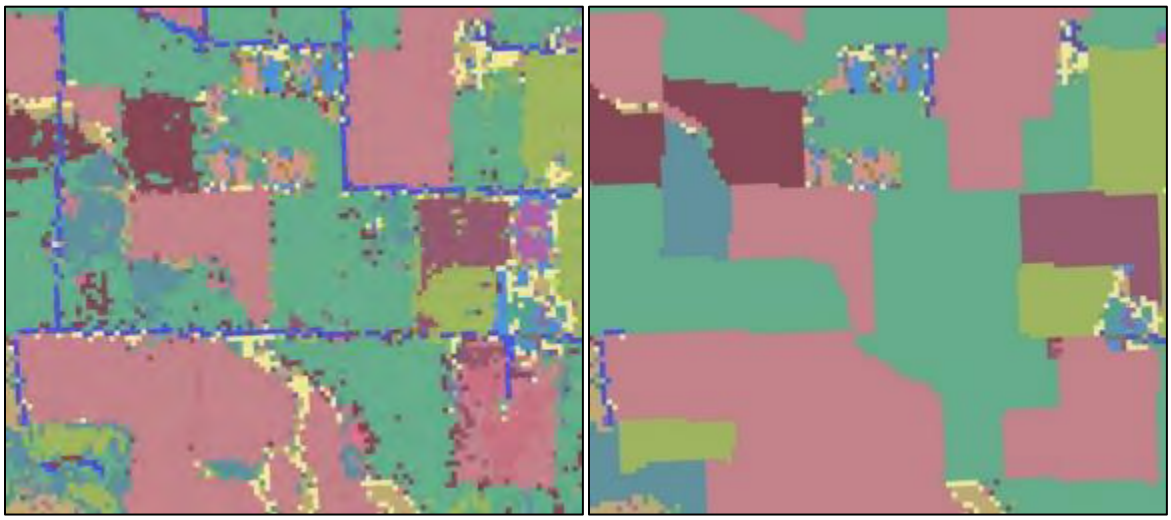

Figure 7. Example original NASS land use (left) compared to corrected land use based on the majority crop type within each agricultural field (right). Each color identifies a different land use type (i.e., almonds, alfalfa, developed, etc.)

Land Use Data 1997 to 2006

The earliest NASS land use raster available for California is from 2007. The County of Kern Agriculture and Measurement Standards provides land use shapefiles only for agricultural fields in the county from 1997 to present. The shapefiles did not provide land use data outside of the agricultural fields. Therefore, information from the last available NASS land use raster (2007) was used to fill in the missing background. The following process was used to combine the two sources to create land use maps for 1997 through 2006:

1. The crop data for each individual field from the Kern County data was converted to a specific value to match the crop identification value used by NASS. For example, a field containing alfalfa in the Kern County data was converted to the NASS crop value of 16.
2. The Kern County shapefile, with the added NASS crop value, was then converted to a raster image to represent the crop value.
3. The DWR survey shapefile was used to quality control the 2007 NASS land use raster so that the raster values within the field boundaries were all uniform.
4. The new Kern County raster was then mosaicked with the corrected 2007 NASS raster. The land use values from the Kern County raster had top priority over the 2007 NASS values and therefore were utilized in the final land use raster. Then 2007 NASS values were used in the non-agricultural areas as well as the background portion of the image.

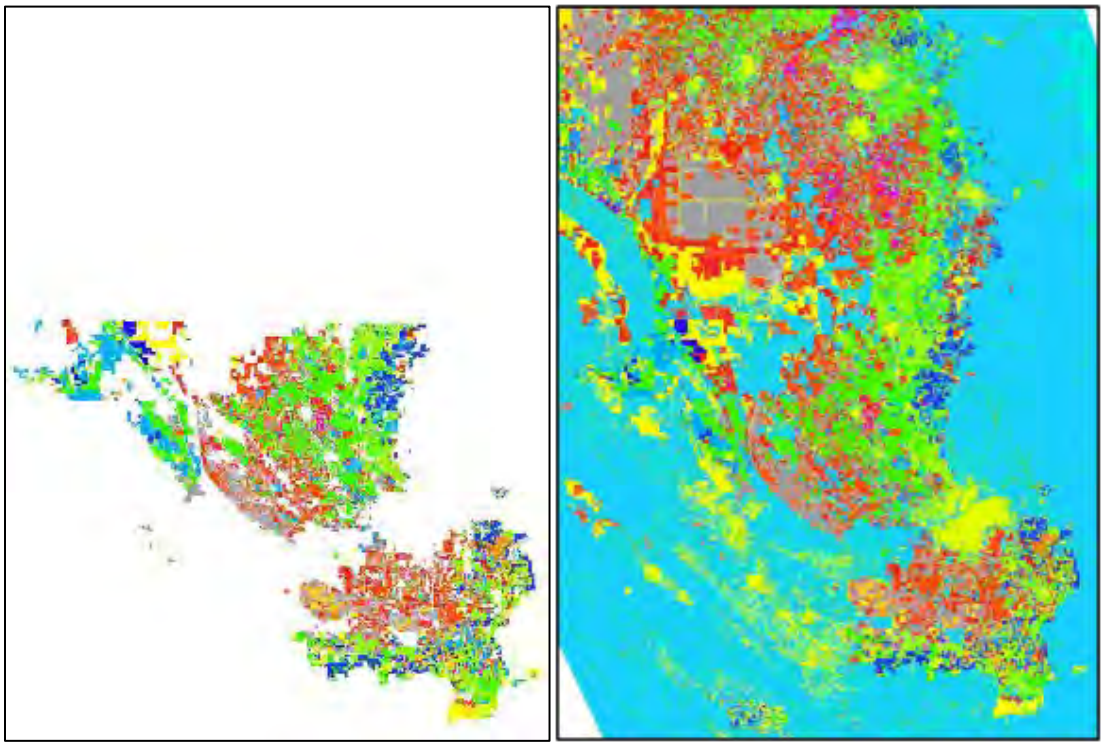

Figure 8. County of Kern agricultural land use fields (left). Combined County of Kern and NASS land use image (right)

Land Use Data 1993-1996

No land use data was available prior to 1997. Therefore, the final quality controlled 1997 land map was used for 1993 through 1996.

Interpolation between Image Dates

The selected images were processed, resulting in instantaneous actual crop coefficients (Actual Kc) on those dates for each pixel. The crop coefficient has been shown to remain constant during the majority of the daylight hours. Therefore, the instantaneous actual Kc was used as a surrogate for the daily actual Kc. In order to estimate the actual ETc between dates that images are available, actual Kc's are interpolated between image dates. A modified cubic spline approach is used to examine images within the month to be computed, prior to that month, and after that month. For example, to interpolate the ETc in the month of July, the July image(s) would be used along with May and June, and August and September. Cubic spline interpolation provides a smooth, non-linear interpolation between image dates. The interpolation takes place for every pixel in the image and the results are temporary Kc images for every day in the month. The daily pixel actual Kc values are then multiplied by the daily corrected Spatial ETo previously discussed to compute the daily actual ETc for each pixel. These daily ETc images are summed together for each month. Finally, the corrected Spatial ETo is summed for each month and the monthly ETc is divided by the ETo to generate the final monthly Kc image.

Monthly actual Kc and actual ETc results for Kern County for the period 1993-2016 have been provided to the Kern Groundwater Authority in GIS raster (image) format.

Accuracy of ITRC-METRIC ETc Estimates

Uncertainty is the quantification of accuracy in measurements and estimates. The most accurate method to estimate ETc is using a weighing lysimeter (correctly) but this is not feasible except in research situations. There are various methods that can be used to estimate ETc, each with different levels of uncertainty:

1. Traditional crop coefficient models (not used here but common in groundwater modeling) have uncertainty due to the assumptions that ETc is constant within a field and between fields in a region. Additionally, errors in land use determination (acreage of each crop), planting and harvest dates (or budbreak and dormancy for permanent crops), and crop management (irrigation, pruning, etc.) all impact the ETc uncertainty. Errors in weather data collection to determine grass reference ETo also impact the uncertainty. As a reference, uncertainties with crop coefficient methods are in the range of 20-25%.
2. Sensor-based measurements such as eddy covariance and surface renewal only measure a small footprint in a field and have potential for sensor errors due to improper calibration, loss of calibration over time, or sensor fouling. Additionally, the sensors must be adjusted, installed correctly, and some (e.g., surface renewal) depend on assumptions that may not hold. Data management and technical support make these infeasible when examining ETc over many fields.
3. NDVI-based ETc estimates have some advantages over (1) and (2) in that they provide spatial variation over a field and field to field. But these still rely on accurate crop surveys. Additionally, this method does not account for crop stress, unless that stress is so severe that it impacts the vegetative index. As with (1) above, the ETo errors translate to ETc uncertainty.
4. ITRC-METRIC ETc overcomes many of the issues with other methods, which is why it was developed. This method does not rely on accurate crop surveys. It also accounts for crop stress before it impacts the vegetation. Spatial variation in ETc throughout a field and between fields is accounted for. ETo continues to be an important part of ITRC-METRIC, which is why quality control of the data is important. In order to limit errors in ETo, ITRC conducts an extensive quality control of the weather station data and utilize spatially varied ETo to account for different climates within a region. As with other methods, it is imperative that the person doing the processing understands agronomic aspects

within the region being evaluated. Errors in processing will generate errors in ETc estimation. All ITRC-METRIC images are reviewed by project managers with many years of experience in farming, irrigation, and crop water use estimation to ensure that the outputs are correct. This overcomes potential errors in LandSAT sensor data since each image is calibrated independently.

ITRC-METRIC uncertainty is estimated to be +/-7 to 10% in this study. On a large scale (GSA or county-wide ETc volumes) the error is on the lower end of this range. On a field scale, it may be on the upper end currently. We have continued to make improvements to our methodology and feel that in the future field-scale ETc will be on the lower end of the range provided. Additionally, the launch of LandSAT 9 (planned for December 2020) will improve the temporal resolution, providing images every 16 days, offset by 8 days from LandSAT 8 (potential for images on an 8 day interval). There are no other ETc computational methods available with uncertainties on both a large scale and field scale within these ranges.

Summary of Results

The annual results have been summarized for the Kern County Valley floor and the field boundaries (majority) within the Valley floor of Kern County. Figure 9 shows the boundaries used for the data extraction for the summaries discussed in this section. Average annual ITRC-METRIC ETc was extracted using the Zonal Statistics tool in ArcGIS. The average ETc from the extracted area was multiplied by the area within the boundaries (overall boundary or each field boundary for the fields) to compute volumes. Over the 23-year period, the field boundaries and overall boundary were the same.

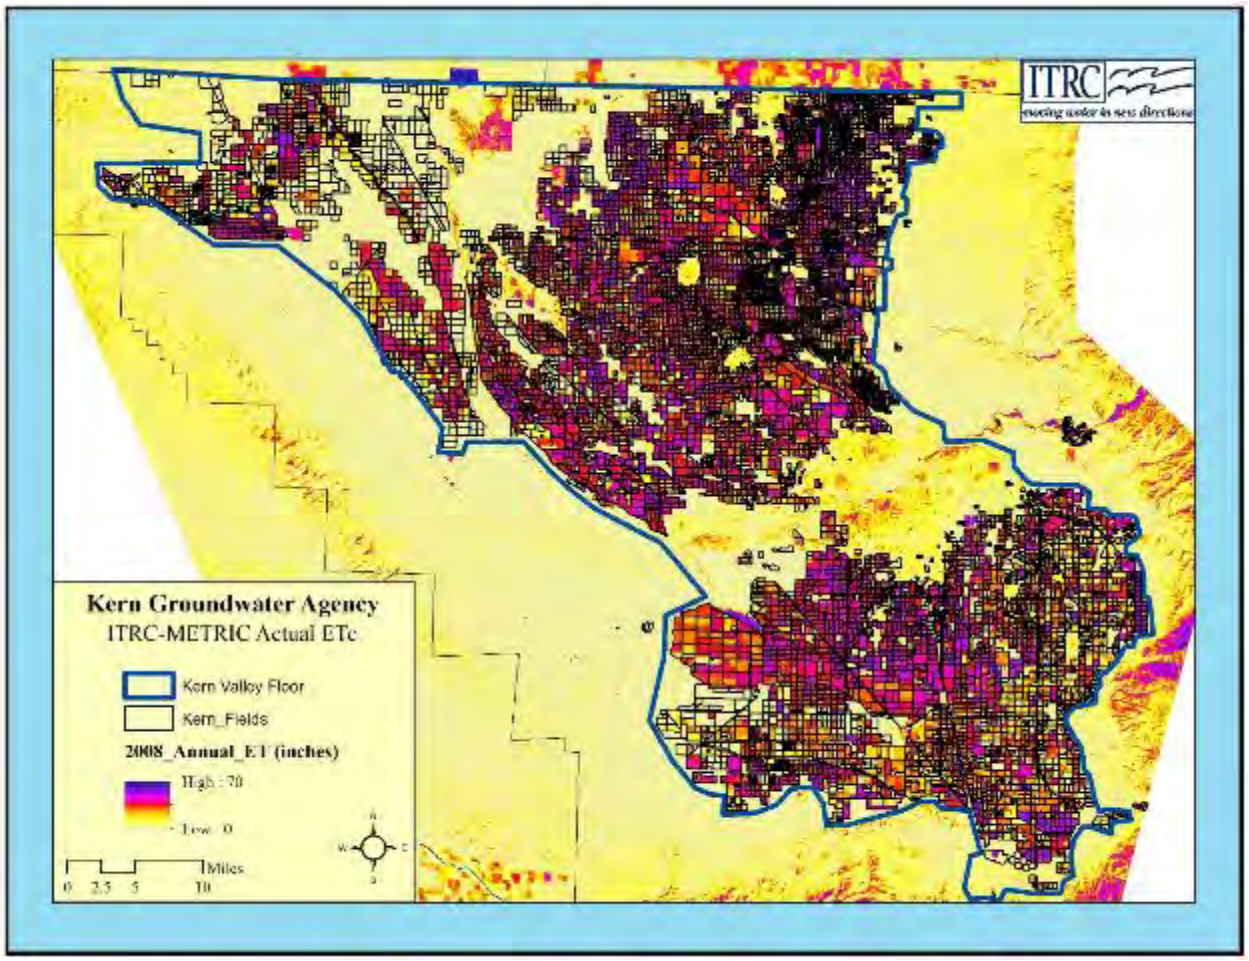

Figure 9. 2008 ETc image with Valley floor and field boundaries used for the summary analysis

The volume of actual ETc for the overall area and only within fields is shown in Figure 10. For reference, the grass reference evapotranspiration (ETo) and precipitation from the Shafter CIMIS station (1992-1997) and Famoso CIMIS (1998-2015) are also shown. ETo provides an idea of the weather conditions that drive evapotranspiration. Hotter, drier years have a higher ETo.

Figure 11 shows the volume of ETc for all water districts in Kern County and Kern Groundwater Authority members. The acreage of all districts is greater than the "Valley Floor Area" because of district boundaries covering areas outside of the valley floor (e.g., West Kern W.D.). Some districts with

substantial overlap of other districts were removed from the evaluation to limit double counting. However, some minor overlap may cause the estimates to be slightly higher than the actual volume of ETc.

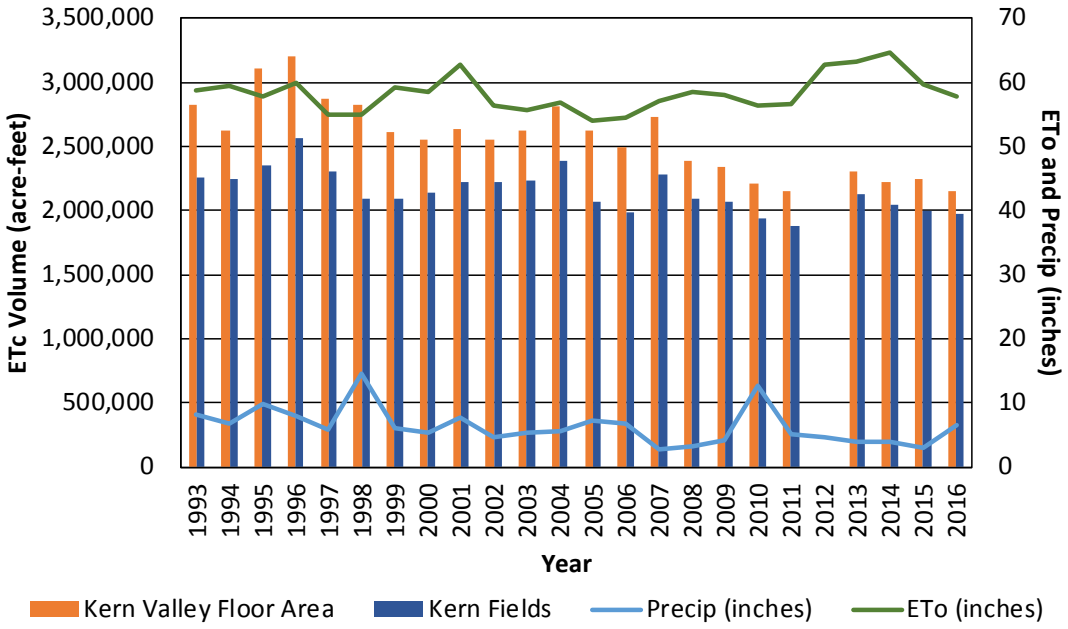

Figure 10. Annual volume of ETc for the Kern County Valley floor and within fields in Kern County. Grass reference ETo and precipitation depths are shown for each year as a reference.

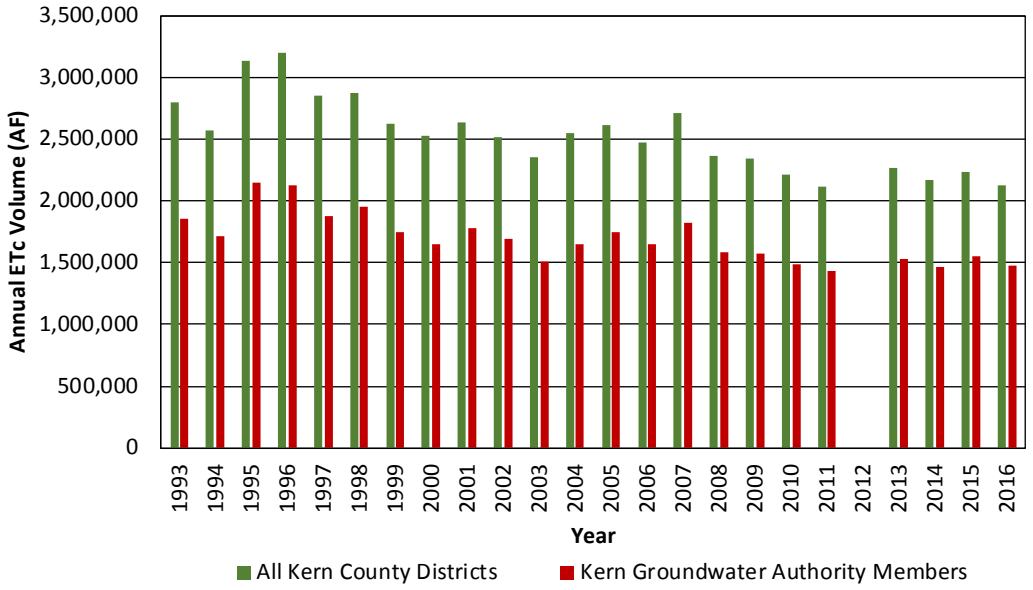

Figure 11. Annual volume of ETc for irrigation/water districts in Kern County and just Kern Groundwater Authority member districts

Evaluation of ETc Variation

In general, there is an overall decline in ETc volume from the Valley floor starting over the 23 years that the ET analysis covers. The field ETc decline is not as significant but does trend downward. The difference between the Valley floor and field ETc is due to ET and evaporation occurring outside of field boundaries. Year to year variability in ETc volume might be explained by weather differences between years. To examine this, the data was normalized to exclude weather variation by examining the annual crop coefficient (Kc), computed as the actual ETc divided by ETo (ETo is computed based on weather data, not including precipitation). Annual Kc values are shown in Figure 12 for the study period (bar graphs) for the entire Kern valley floor area (includes urban, streets, undeveloped areas, etc.) and within fields only (only agricultural fields in the same area).

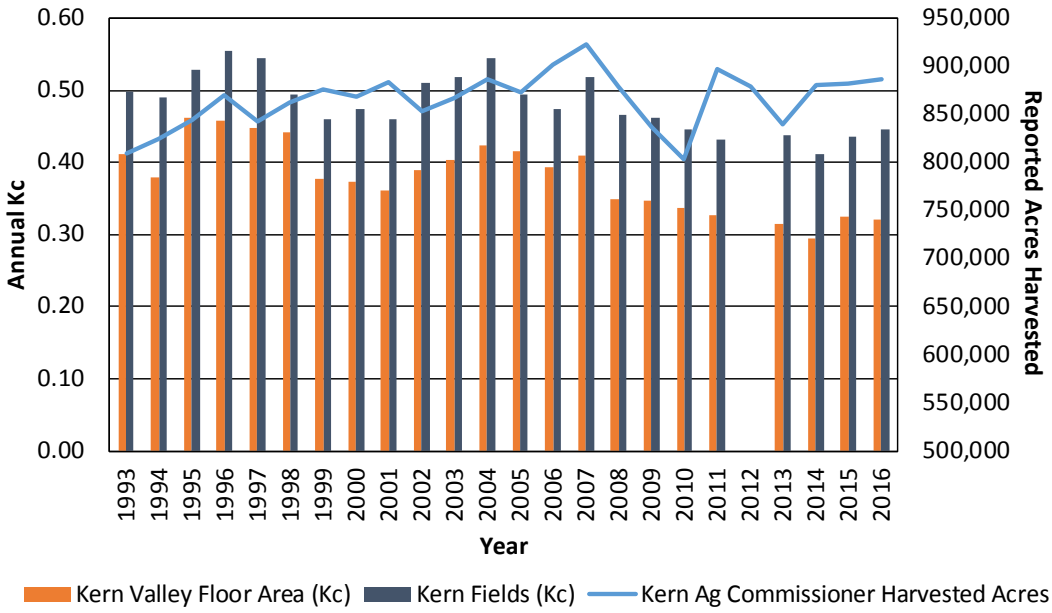

Figure 12. Annual crop coefficient (Kc) for the Kern County Valley floor and within fields in Kern County. Reported Ag Commissioner total harvested acres per year on the right axis of the graph.

As expected, the Kc is higher when only looking within field boundaries compared to the entire Valley floor of Kern County. Areas outside of the fields are in large part reliant on precipitation or are a mix of landscape and residential areas. Urban areas and open water are also included. As with the volume, there seems to be a general decline in overall Kc over the 23 years.

In the mid-2000s the Kc increases. Figure 12 also includes the Kern County Ag Commissioners total harvested acres over the 23 year period for reference and to possibly explain some of the variation. Interestingly, the Ag Commissioners' total harvested acreage increases from 1993 to 2016. While there are some general trends indicating that the annual Kc increases as the acreage increases, the trends do not follow as closely as one might expect. This could be due to the types of crops harvested over the period or the age of permanent crops being grown. It is important to restate that crop types are not used to determine ETc using ITRC-METRIC. They are only shown here as a reference to potentially explain the variation in ETc.

To delve further into the theory that crop type shifts may explain ETc variation, crop acreages of the major crops in Kern County (Kern County Agricultural Commissioner Reports) are shown in Figure 13. The higher ETc and Kc values in the mid-2000s are likely due to the increase in alfalfa acreage during this period in combination with the higher almond acreage. However, the higher ETc and Kc values in the mid-1990s are more challenging to explain. Obviously there is more cotton acreage and likely more double cropping of different row crops (although cotton is not commonly double cropped). Other crops in the cotton rotations likely include double cropping, such as corn and grain hay, which are not shown.

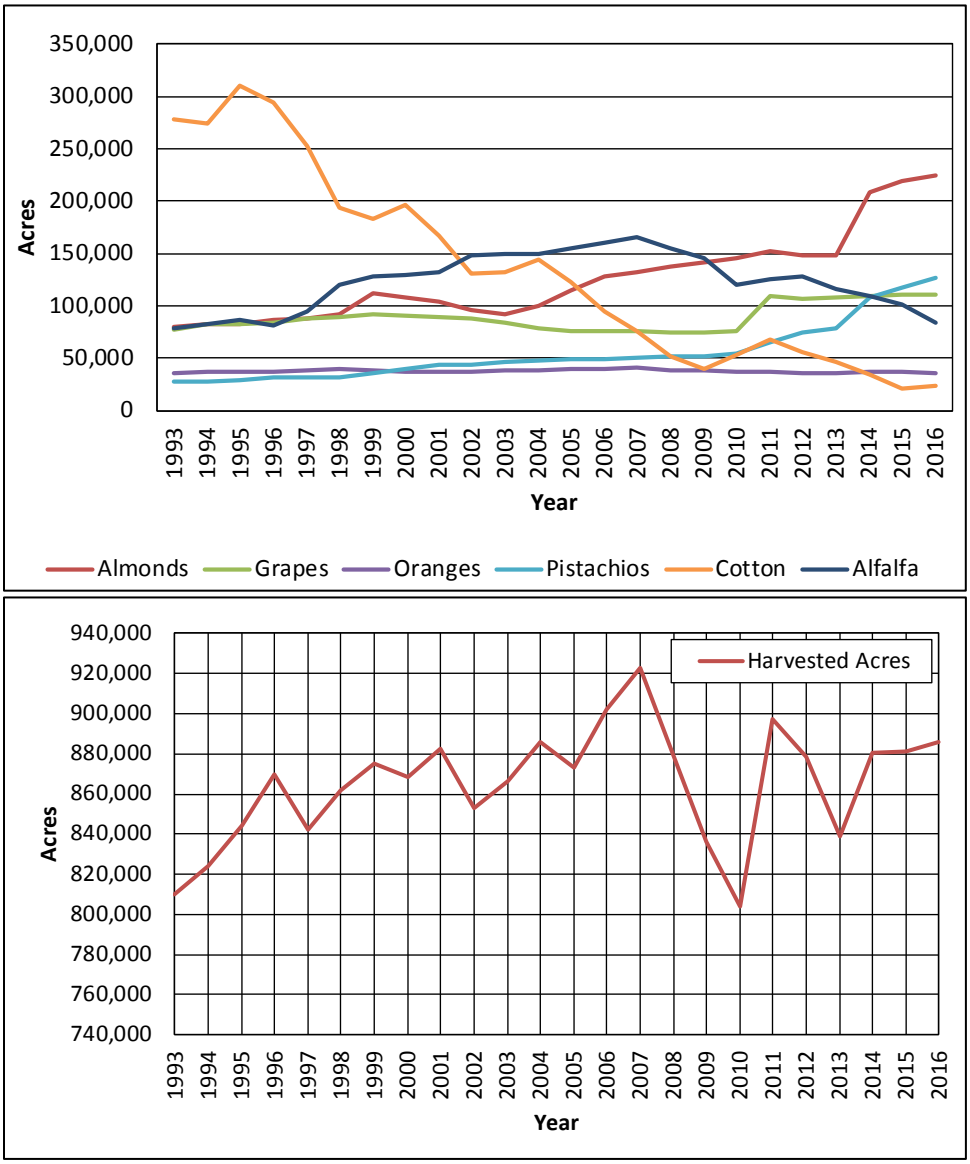

Figure 13. Crop acreage for major crops in Kern County from 1993-2016 (top) and total harvested acres (bottom) from Ag Commissioner Reports

As previously discussed, the Kern County Ag Commissioner reports showed an overall increase in harvested acreage from 1993 to 2015. The Ag Commissioner reports showed the 1993 total harvested acres at approximately 809,700 compared to the 2015 harvested acreage of 881,000. Year-to-year variations are shown in Figure 12.

There are also some unexplainable anomalies in the Ag Commissioner data, such as the increase in almond acreage from 2013 to 2014. Figure 13 shows that total acres (bearing and non-bearing) for almonds increased by over 50,000 acres from 2013-2014. The bearing acreage showed the most significant increase from 2013 to 2014 even though only 1,600 acres of non-bearing trees were reported for 2013. The bottom line is that over 50,000 acres of bearing almonds showed up in 2014 without explanation. This could be due to an error in the Ag Commissioner's reporting or a shifting methodology of accounting for certain crops.

The annual Kc by field in Kern County from ITRC-METRIC was plotted from lowest to highest Kc for four selected years (Figure 14). The fields with the lowest Kc would be fallow or young orchards/vineyards. Notice that there are more fields with Kc values below 0.2 in 2008 and 2015 than in 1993 or 1996. Of these, 1996 has the fewest low Kc fields while 2015 has the most. Different fields have different Kc values each of these years. The key point is that the lower Kc values in 2014 and 2015 (Figure 12) are likely driven down by increased fallowing or young orchards. Additionally, Figure 14 indicates that the overall field acreage was probably lower in 2015 than in 1993. While field acreage is not the same as harvested acreage because it does not account for double-cropping, it is unlikely that double cropping accounts for the full difference in reported acreage.

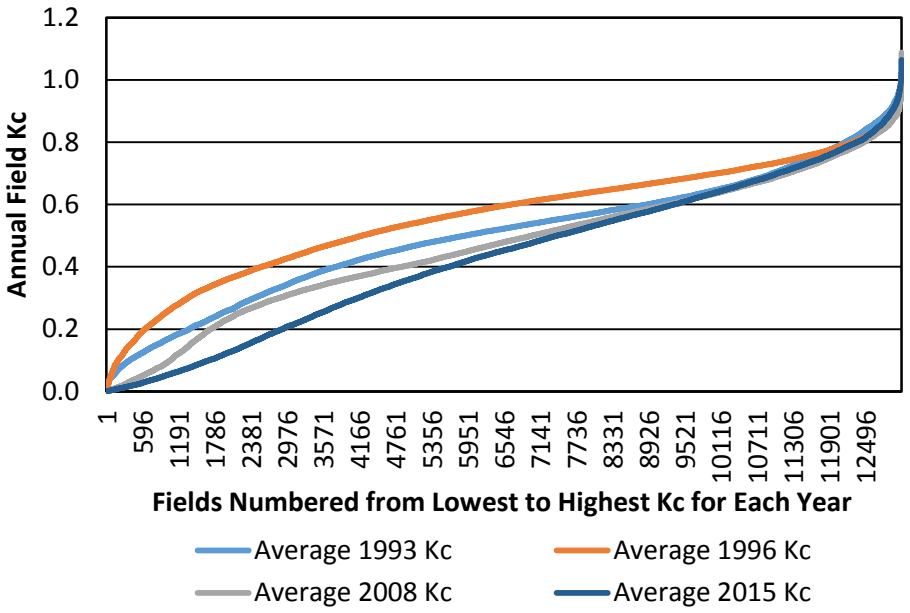

Figure 14. Annual Kc by field sorted from lowest to highest for four different years

Visually, significantly more non-cropped fields can be seen in 2015 than in 1993 (Figure 15). Portions of Kern County (red circles which include portions of Lost Hills Water District, Buena Vista WSD, and Henry Miller WD) show much lower ET in 2015 than 1993. These areas were fallowed or not cropped during the drought. In other areas, new permanent crop plantings may be the cause of lower ET. Additionally, the Kern Lake and areas south of Bakersfield have much lower ET values indicating new permanent crops or fallowing.

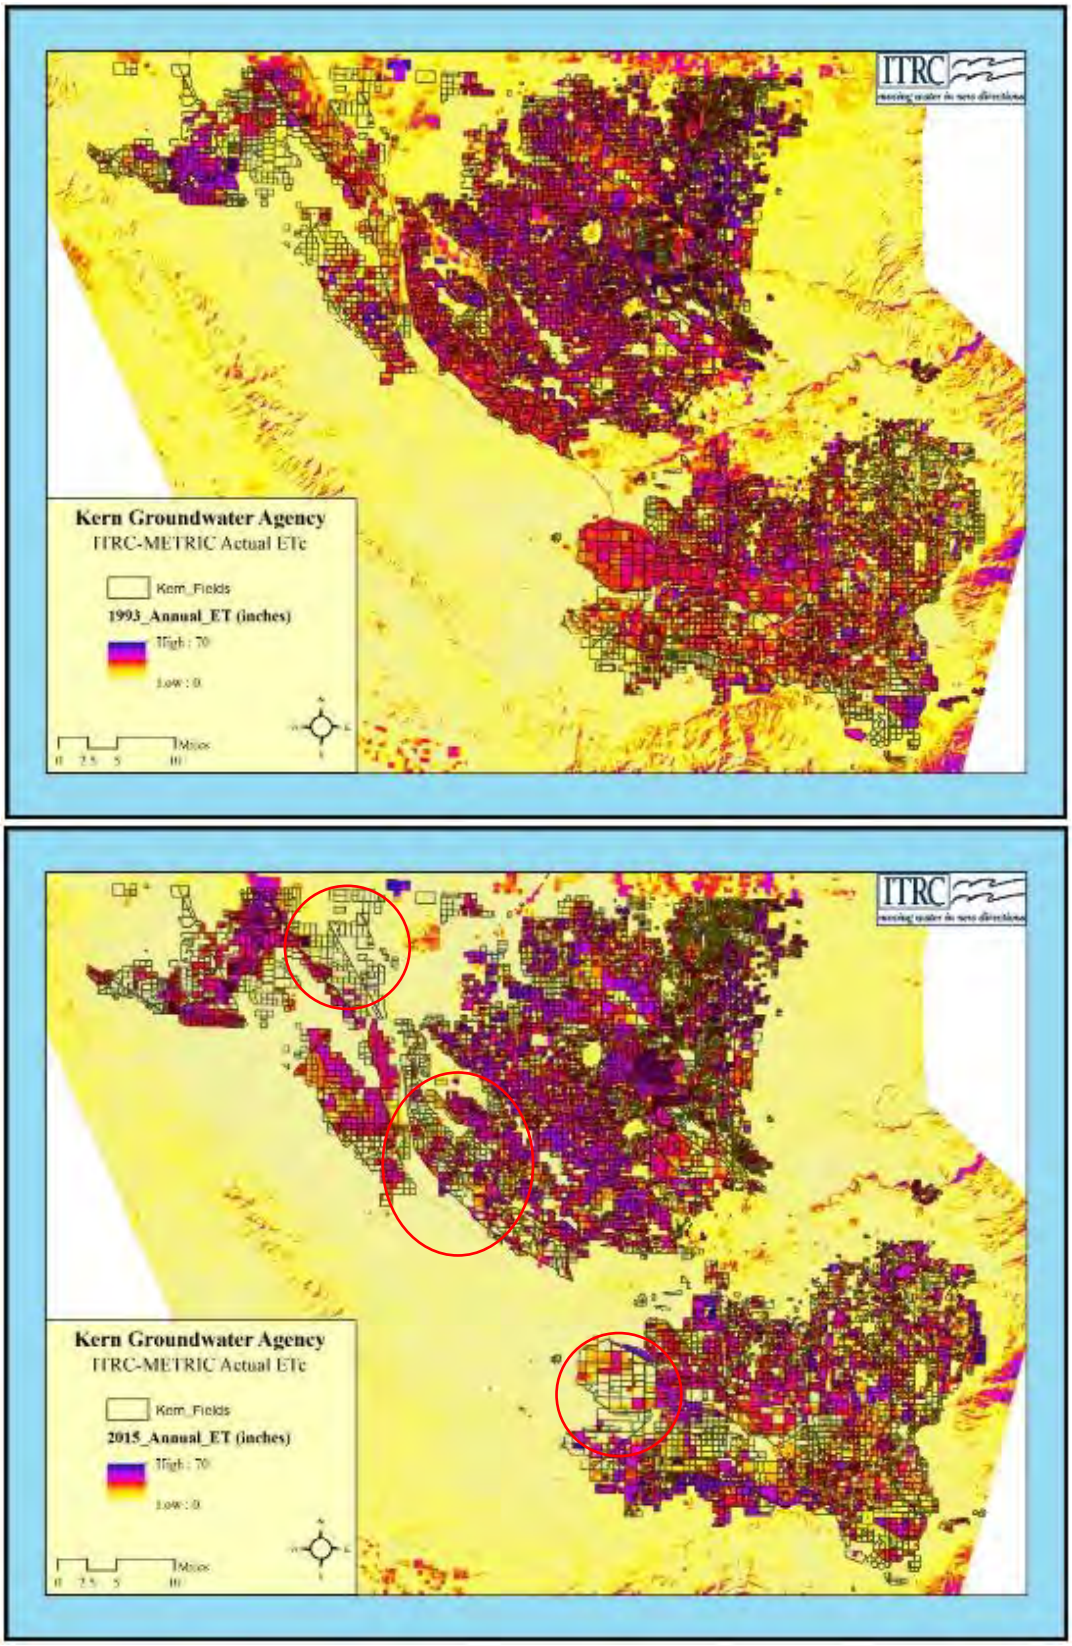

Figure 15. Annual ITRC METRIC ET in 1993 (top) and 2015 (bottom) with field boundaries

Conclusion

Over the 1993-2016 period, the volume of evapotranspiration from fields within the valley floor of Kern County ranged from approximately 2-2.5 million acre-feet. Evapotranspiration varies year to year in the valley floor portion of Kern County. This is caused by several factors including weather, crop mix, water availability, precipitation, and land fallowing. It was beyond the scope of this study to investigate exactly why evapotranspiration varied. However, the previous figures indicate that there seems to be increased fallowing or young orchards and vineyards planted in more recent years, resulting in lower evapotranspiration in this period. This acreage reduction does not coincide with Kern County Ag Commissioner's reported harvest acreage changes over the period.

The monthly and annual evapotranspiration and Kc imagery in GIS format has been transmitted to Kern Groundwater Authority.

Future Work

Net To/From Groundwater (NTFGW)

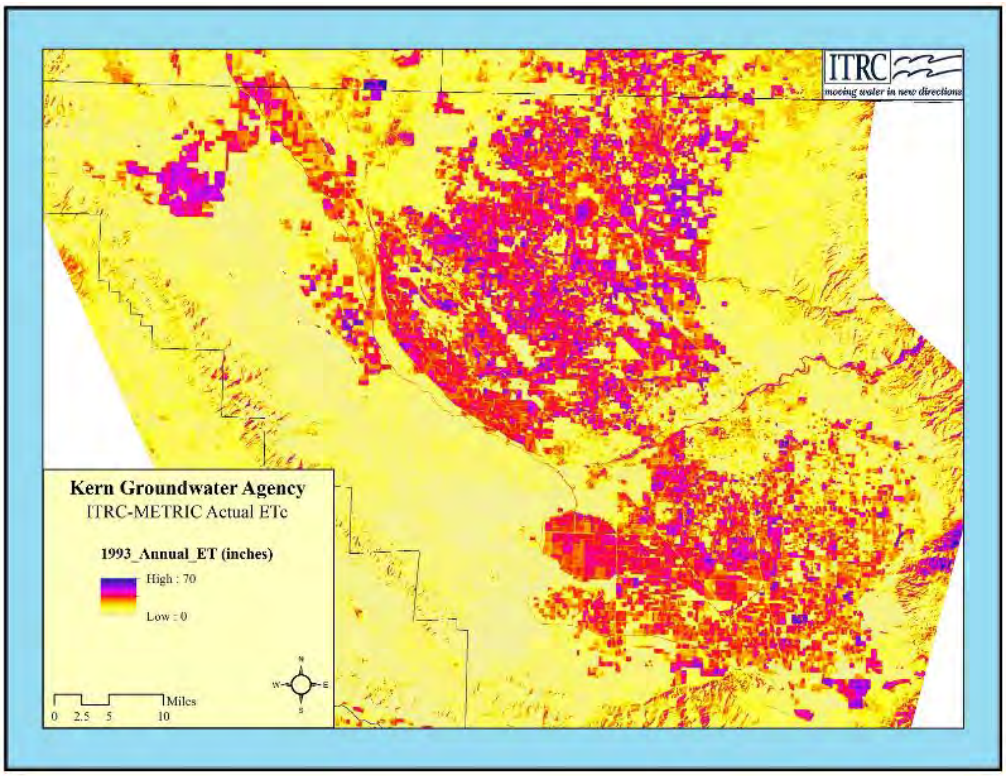
ITRC has developed a process to examine net groundwater use without the need to monitor groundwater pumping. This process is called the Net To and From Groundwater (NTFGW) and can be conducted at various scales from the farm/field, GSA, and Basin. This method incorporates surface water diversions, turnout deliveries (for farm/field scale), surface outflows, and precipitation with the monthly ETc to determine net groundwater use. Basically, if precipitation and surface water deliveries exceed ETc, the excess water would be stored in the root zone or moves to the groundwater (net to groundwater). If ETc exceed surface supplies, there is a net extraction from the groundwater to make up the difference. Results are provided spatially at the 30 meter pixel resolution. NTFGW is being used for two purposes:

1. Using historical data, to assist in calibration/verification of groundwater models. Equally important, the results provide a directly computed future ETc with net zero extraction.
2. For future management and regulation of groundwater use within the GSA. Monthly results will be provided to each GSA participant in near real-time (approximately 15 days after surface delivery information is provided to ITRC). Some GSAs are planning on providing this to farmers via a web mapping portal.

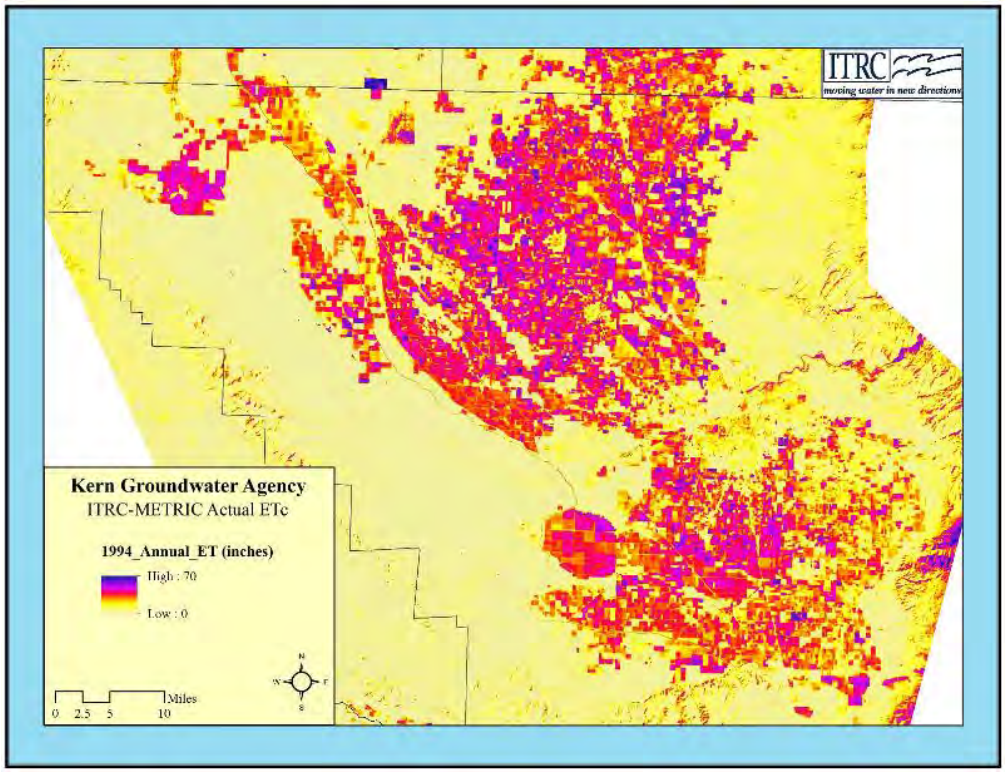
The benefits of NTFGW include:

- No groundwater metering program with meters at each well is needed. DWR has approved the method as a best-available science alternative.
- No estimates on irrigation efficiency are needed. Irrigation efficiency estimates have a high level of uncertainty, vary from field to field, and will change over time. NTFGW simplifies the evaluation of sustainable yield because inherently sustainable yield is a net value of how much groundwater can be consumed in a GSA. There is no need to estimate leaching requirements or other non-consumptive uses of groundwater. Comparing net values eliminates many uncertainties.
- It offers the ability to track net canal seepage and net recharge basin recharge by basin.
- It offers the ability to continuously track banked or over-drafted groundwater on a farm, district, and GSA level.
- It is cost-effective: the anticipated cost will be $30,000-$50,000 per year per district/GSA. Actual cost will depend on the district/GSA size and the level of evaluation.

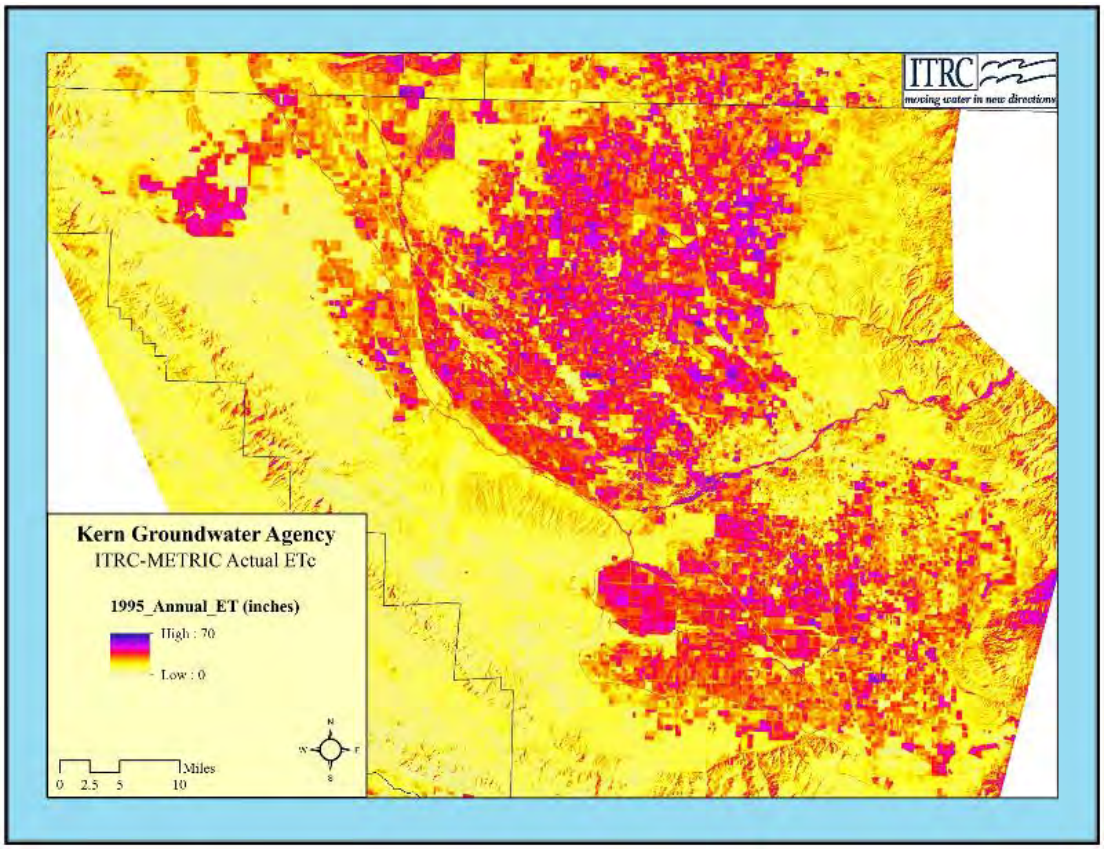
ITRC-METRIC ETc



There are several options moving forward. ITRC-METRIC ETc will be an important tool. Over the past several years there have been lessons learned which will impact the process in the future:



1. Thermal sharpening has not been extensively used because it is time-consuming. However, ITRC is working on expediting this process. Currently, the thermal sharpening process increases the overall processing cost by a factor of 50%. It is expected that this cost will be reduced in the future. On a larger scale it is not important because the overall ETc is not increased or decreased. On a field level, it may be more important.
2. In the past we used at least 1 image per month to compute ETc. ITRC now uses all available good-quality images (mostly cloud/fog free, some cloud coverage is okay). Again, on a large scale (over a district for example) it is not as critical, but for individual fields, especially for row and field crops, it is critical to have images at least on a 16-day interval to capture harvests appropriately.



Future implementation of continuous ETc will be important for groundwater management in the Kern subbasin. The historical data generated as part of this project is being implemented in the groundwater modeling efforts in the subbasin. The next steps are towards monitoring sustainable use of the groundwater into the future. ITRC believes that NTFGW is the best methodology to monitor groundwater use since net groundwater use is more important than gross groundwater pumping. Pilot projects using NTFGW compared to groundwater pumping have been successfully implemented in a subbasin just north of Kern. ITRC would be pleased to share these results with interested parties.

Appendix G-5

Water Budget Model Calibration

APPENDIX G-5
WATER BUDGET MODEL CALIBRATION

This appendix documents the processes used to calibrate the Wheeler Ridge-Maricopa Water Storage District (WRMWSD) long-term water budget spreadsheet model and reports the final water budget calibration results.

Calibration Process

As described in **Appendix G-1**, the water budget model is a spreadsheet-based tool that quantifies 31 individual hydrologic flow "components" and then uses mass balance principles to link components and calculate a residual change in storage from the groundwater system at a monthly timestep.

Included in the water budget spreadsheet model are various "User Input Parameters" that can be adjusted to improve model performance. Values for these adjustable parameters were initially set to reasonable values based on review of previous relevant studies and local information, where possible (see **Appendices G-1** through **G-4**), and were subsequently adjusted to minimize the difference between model-calculated change in storage and the change in storage derived from rasterized groundwater elevation monitoring data.

Development of Groundwater Storage Change Rasters

The change in groundwater storage was estimated within the District's SGMA jurisdictional area[1] between various time periods using local groundwater elevation data provided by the District[2] along with data downloaded from the DWR's "CASGEM" portal. Local groundwater level data within and proximate to the District boundaries were interpolated using kriging[3] to create continuous groundwater elevation surfaces (rasters) for several "bookend" years of interest within the water budget period[4]. Interpolated water level surfaces were subsequently compared between bookend years to calculate the change in storage, as follows:

$$GW\ Storage\ Change_{t1 \rightarrow t2} = (GWEL_{t2} - GWEL_{t1}) * Specific\ Yield$$

[1] WRMWSD's "SGMA jurisdictional area" includes the portions of the District within the Kern Groundwater Authority Groundwater Sustainability Agency (KGA GSA) area within the Kern Subbasin and all portions of the District within the White Wolf Subbasin.

[2] Local groundwater level data also included records from Arvin-Edison Water Storage District (AEWSD) for wells located in the AEWSD-WRMWSD "overlap area".

[3] Data were interpolated using kriging, a geostatistical method commonly used to interpolate groundwater elevation data, in the software package Surfer. The output of this interpolation process is a raster file with 100-ft by 100-ft pixels, which can be subtracted from or multiplied by other raster files covering the same area, and for which total volume can be calculated.

[4] The interpolated surfaces vary significantly depending on which well data sets are used. Based on significant analysis, we have more confidence in the change in storage estimates generated from surfaces constructed using groundwater elevation data from paired and/or "nearby" wells within a 1-mile buffer radius between each other between datasets (i.e., when groundwater elevation data from each season and year were only selected if the same well or a "nearby" well also had a measurement for the other season and year used for the storage change analysis). Use of the full dataset would allow for greater data density in each bookend year, but, because of historically variable groundwater monitoring patterns, the groundwater storage change estimates are then impacted by changes in monitoring locations.

where *GWEL* is the groundwater elevation and the subscripts *t1* and *t2* refer to the beginning and ending bookend years, respectively. For the purposes of this analysis, a uniform specific yield value of **0.08** was used to calculate groundwater storage change from the rasterized water level data, in line with the representative average specific yield value of the unconfined aquifer (i.e., Layer 1) within the District used in DWR's California Central Valley Groundwater-Surface Water Simulation model, "fine-grid" Beta version (C2VSim-FG)[5].

Using this approach, groundwater storage change was calculated within the District's SGMA jurisdictional area for the following four periods, each of which representing unique timescales and/or climatic conditions within the historical/current water budget time period:

- Fall 1994 – Fall 2015 (entire KGA water budget period)
- Spring 2003 – Spring 2012: (representative long-term "wet" period)
- Spring 2003 – Spring 2015: (representative long-term "dry" period)
- Fall 2014 – Fall 2015: (representative short-term "dry" period)

Water Budget Calibration to Change in Storage Rasters

User input parameters specified within the water budget spreadsheet model (see **Appendix G-1**) were subsequently adjusted within reasonable limits to improve the fit between the water budget-calculated change in storage and the water level-based change in storage estimates for each of the four time periods mentioned above[6].

First, a sensitivity analysis was conducted to determine the most "critical" user input parameters (i.e., those that have the greatest effect on the water budget) for adjustment during model calibration. The most "critical" input parameters identified were those related to subsurface inflows and outflows, streamflow, and contributing precipitation to the District, including:

- **Kern Groundwater to Streamflow Inflow Ratio**, which controls the residual groundwater inflow term into the Kern Management Area (see **Appendix G-3**);
- **Hydraulic conductivity of the aquifer near the White Wolf Fault,** which controls the rate of groundwater flux across the fault (see **Appendix G-3**);
- **Watershed Consumptive Use Fraction and Watershed Precipitation Threshold for Runoff**. These parameters determine the amount of precipitation on contributing watersheds that runs off and becomes streamflow recharge within the District service area (see **Appendix G-2**);
- **Ineffective Precipitation Deep Percolation Coefficient**. This parameter controls how much ineffective precipitation is expected to percolate back into the groundwater subdomain, with the remainder assumed to evaporate from the wetted land surface (see **Appendix G-4**).

[5] C2VSim-FG beta is the latest release of C2VSim from DWR and is currently being used for SGMA planning and GSP development within the Kern Subbasin. Note, this model is currently uncalibrated. C2VSim input files downloaded 13 June 2018 from: https://data.cnra.ca.gov/dataset/c2vsimfg-beta-model

[6] March 1st was chosen as the representative date for which to compare "Spring" water level data to within the water budget model spreadsheet.

The above parameters were used as the primary calibration parameters to achieve an acceptable fit with the storage change estimated using the water level change method. Calibration was conducted by systematically adjusting the values of these key parameters to try to minimize the difference (in terms of root-mean-squared error [RMSE]) between the "observed" (i.e., based on water level records) change in storage for a given time period and the water budget model-calculated change in storage. Other user input parameters are less sensitive and were therefore left at their initial values in the final calibration.

Calibration Results

Table G-5-1 below reports the final calibrated values of each "User Input Parameter" included in the water budget model spreadsheet. Parameters listed in **bold** are those whose values were adjusted during the calibration process; all other parameters were held at their initial values during calibration.

Table G-5-1. Final Calibrated Values of User Input Parameters

User Input Parameter	Calibrated Value
Kern Groundwater to Streamflow Inflow Ratio (-) [1]	**3**
White Wolf Fault Hydraulic Conductivity (ft/day) [1]	**3**
Kern Watershed Consumptive Use Fraction (-)	**0.98**
Kern Watershed Precipitation Threshold for Runoff (in)	**0.5**
White Wolf Watershed Consumptive Use Fraction (-)	**0.95**
White Wolf Watershed Precipitation Threshold for Runoff (in)	**0.5**
Ineffective Precipitation Deep Percolation Coefficient	**0.5**
Irrigation Efficiency Coefficients (-)	Variable, ranging from 0.65 for furrow to 0.85 for micro-drip
Deep Percolation Lag Period (months)	11
Leaching Water EC (uS/cm)	500
Artificial Channel Seepage Rate (ft/day)	0.01
Additional Operational Demands (AFY/irrigated acre)	0.16
M&I Consumptive Use Fraction (-)	1
Natural Channels Seepage Fraction (-)	1

Abbreviations:

AFY = acre-feet per year; EC = electrical conductivity; ft/day = feet per day; in = inches; M&I = municipal and industrial; uS/cm = microSiemens per centimeter;

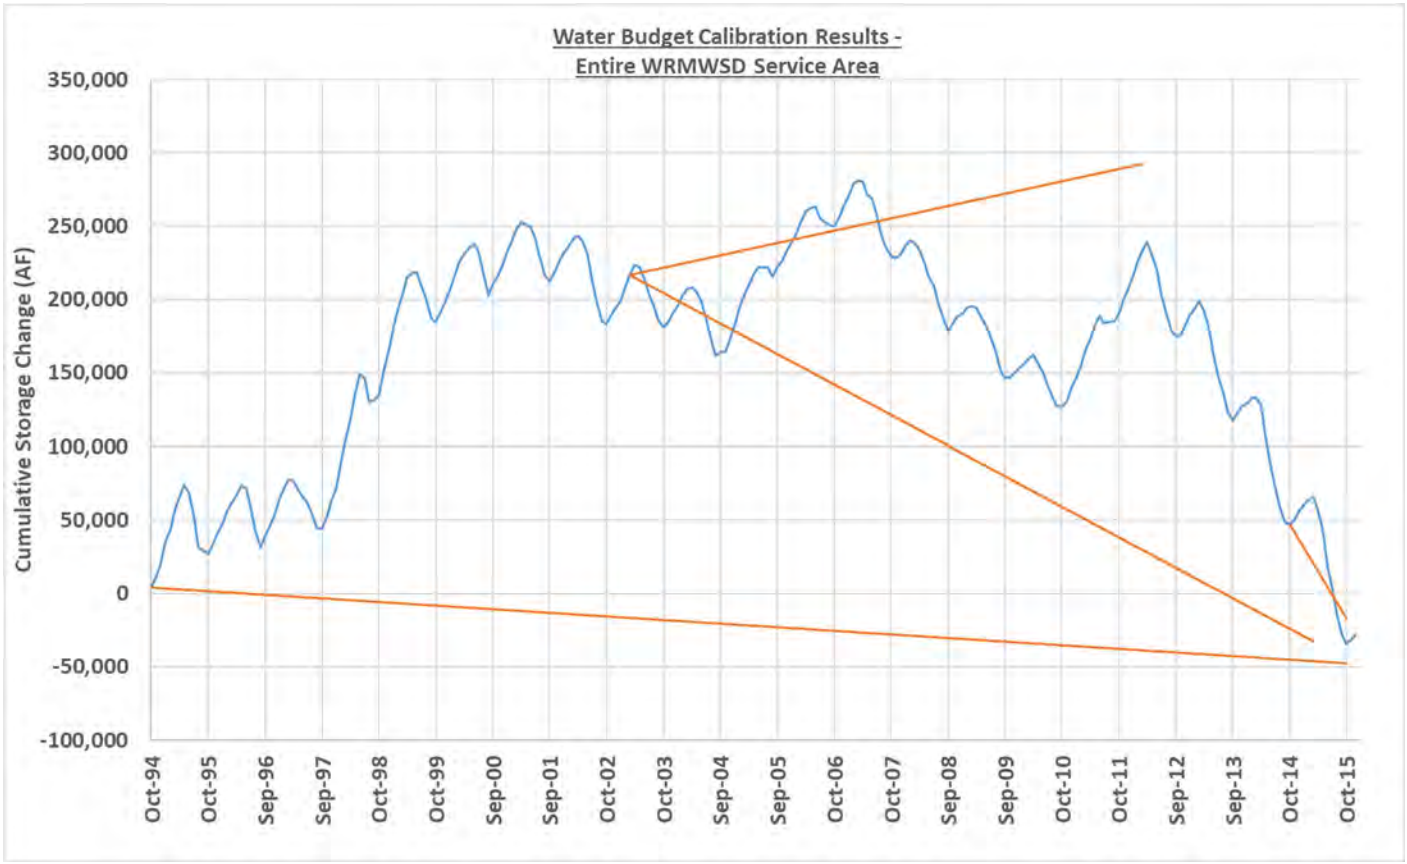
Notes:

1. The hydraulic conductivity values for the Wolf Fault were adjusted as calibration parameters for the groundwater inflow/outflow components. Other factors affecting this component (i.e., vertical saturated thickness of the inflow/outflow boundary) are assumed to be fixed for the purposes of calibration.

Table G-5-2 and **Figure G-5-1** (attached) present the results of the water budget model calibration in terms of the water budget spreadsheet model-calculated change in storage compared to the change in storage estimated using the water level change method for all four calibration periods mentioned above.

Table G-5-2. Water Budget Calibration Results to Raster-Based Storage Change Estimates

Time Period[1]	Rationale for Selection of Time Period Employed for Model Calibration	Average Annual Groundwater Storage Change Calculated from Water Level Rasters (AFY)[2,3]	Average Annual Groundwater Storage Change Calculated from Water Budget Model (AFY)[2,3]	Difference (Relative to Water Level Raster Method) (AFY)
Fall 1994 – Fall 2015	Entire KGA Water Budget Period	-2,500	-1,300	1,200
Spring 2003 – Spring 2012	A representative long-term "wet" period	8,500	1,900	-6,600
Spring 2003 – Spring 2015	A representative long-term "dry" period	-20,700	-12,100	8,600
Fall 2014 – Fall 2015	A representative short-term "dry" period	-63,700	-76,900	-13,100



Notes:

1. March 1st was chosen as the representative date for which to compare "Spring" water level data to within the water budget model spreadsheet.
2. Results shown are rounded to the nearest 100 AFY.
3. Storage change estimates are calculated assuming of a uniform storage coefficient of 0.08.

Table G-5-2 and **Figure G-5-1** demonstrate the successful calibration of the water budget spreadsheet model to change in storage estimates deduced from the water level change method. Adjustment of the "critical" user input parameters resulted in a model calibration with a RMSE between "observed" and model-calculated annual change in storage of **8,500 AFY** when considering all four calibration targets, and **6,300 AFY** when only considering the three long-term calibration targets (i.e., Fall 1994 – 2015, Spring 2003 – 2012, and Spring 2003 – 2015). For context, the residuals in calculated vs. "observed" change in storage estimates for the three long-term periods (approximately -13,100 to 8,600 AFY) represent **0.67% to 7.36%** of the total annual average inflows into the District, thus demonstrating the spreadsheet model's accuracy in simulating long-term changes in groundwater storage relative to the total magnitude of the water budget domain.

Figure G-5-2 (attached) demonstrates the water budget-calculated change in water levels relative to a set of long-term hydrographs compiled from the District's local groundwater elevation records. This figure

further demonstrates the general agreement between observed and model-calculated changes in water levels, both in terms of magnitude and directionality, throughout the 22-year water budget timeframe.

Appendix G-6

Overview of Projected Water Budget Models

APPENDIX G-6
OVERVIEW OF PROJECTED WATER BUDGET MODELS

As described in **Appendix G-1**, results from the historical and current (California Department of Water Resources [DWR] Water Years 1994 – 2015) analytical water budget were subsequently used to inform development of three projected (i.e. future) water budget scenarios for the Wheeler Ridge-Maricopa Water District (WRMWSD) Kern Subbasin Management Area. These scenarios are consistent with the Kern Subbasin-wide projected water budget modelling effort that WRMWSD is participating in as a member of the KGA. A basic description of the projected water budget model assumptions and framework is provided below.

Description of Projected Water Budget Timeline

As described in **Section 9.4.1.** of the WRMWSD Management Area Plan, per 23-CCR § 354.18(e)(2)(A), the projected water budgets must use 50 years of historical precipitation, evapotranspiration, and streamflow information as the basis for evaluating future conditions under baseline and climate-modified scenarios. The process by which a 50-year period of precipitation, evapotranspiration and streamflow information was developed is based on the process adopted by all GSAs within the Basin, as described in the KGA Umbrella GSP and the Coordination Agreement. That process is briefly summarized here.

To develop the required 50 years-worth of hydrologic input information, first an "analog period" was created from the 20 years-worth of historical information (DWR Water Years 1995-2014) by combining the years in a specific way that, on average, maintained the long-term average hydrologic conditions. This approach, which was used for both the spreadsheet water budget model approach and the basin-wide C2VSim-FG modeling approach, allowed for the creation of a complete 50-year period to inform the projected water budget analysis, even when certain component datasets were not available for that length of time. The sequence of actual years that were combined to create the 50-year analog period is as follows:

Analog Years 1-12:	Based on actual years 2003-2014
Analog Years 13-32:	Based on actual years 1995-2014
Analog Years: 33-50:	Based on actual years 1995-2012

The above mapping of actual years to analog years within the required 50-year projected water budget period applies to precipitation and ET datasets. It also applies to datasets of imported surface water with some additional modifications as described in the following section.

Description of Projected Water Budget Scenarios

As described in **Section 9.4.2.** of the WRMWSD Management Area Plan, using the 50-year analog period, three projected water budget scenarios were developed for this analysis:

- **Baseline Scenario –** uses "the most recent water supply information as the baseline condition for estimating future water supply", per 23-CCR § 354.18(e)(2)(C);
- **2030 Climate Change Scenario –** uses 2030 climate change factors developed by DWR and the Friant Water Authority to estimate future water supplies, changes to precipitation and evapotranspiration; and

- **2070 Climate Change Scenario –** uses 2070 climate change factors developed by DWR and the Friant Water Authority to estimate future water supplies, changes to precipitation and evapotranspiration.

Development of the three scenarios was done consistent with the agreed-upon process being used basin-wide. Further details of the scenario development are contained within **Section 9.4.2.** of the WRMWSD Management Area Plan, in the KGA Umbrella GSP, and in the Coordination Agreement.

Description of Projected Water Budget Model Framework

A projected water budget was developed for each of the three scenarios described above under the same framework and methodologies used to develop the historical and current water budget model. Given the scope of this effort was limited to completion of water budget requirements for the WRMWSD Management Area Plan, projected scenarios were only developed for the portion of WRMWSD contained within the Kern Subbasin.

Building the 50-year Analog Period

As described above, a 50-year "analog" period was first created using partial repeats of the 20-year historical WRMWSD water budget model (DWR Water Years 1995 – 2014) for the development of projected water budget scenarios. This was accomplished in the "master" projected water budget tabs of the spreadsheet model (see **Appendix G-1**) by creating a 50-year monthly sequence (i.e., 600 months) where, for any given month, each water budget component within the spreadsheet model directly referenced the analogous "analog" month of the historical Kern budget.

Applying Change Factors

After the 50-year "analog period" was replicated in the projected water budget "master" tabs, monthly change factors were applied to selected water budget components to incorporate projected changes to surface water supply availability, as well as precipitation and evapotranspiration intensity under each of the (3) projected water budget scenarios. These monthly change factors were provided directly from the KGA and are being used for the Basin-wide C2VSim-FG projected water budget effort[1]. In summary, the following change factors were applied to the WRMWSD projected water budget model:

- Changes to State Water Project (SWP) imports, based on data from DWR's CalSim water resources planning model and the 2008/2009 Long-Term Operations Criteria and Plan (OCAP) Biological Opinion[2];
- Changes to precipitation and evapotranspiration, based on DWR's "gridded change factors for precipitation and reference evapotranspiration" for 2030 and 2070 climate change projections[3].

[1] For more information see **Section 9.4.2.** of the WRMWSD Management Area Plan, the KGA Umbrella GSP, and in the Coordination Agreement

[2] CalSim deliveries data from: https://data.cnra.ca.gov/dataset/sgma-climate-change-resources; SWP operational data from: https://water.ca.gov/Programs/State-Water-Project/Operations-and-Maintenance/Monthly-and-Annual-Operations-Reports; new operations regulations pursuant to the 2008-2009 OCAP BOs used as basis for calculation of SWP impacts by KGA's consultant.

[3] https://data.cnra.ca.gov/dataset/sgma-climate-change-resources/resource/f86f75e8-0de6-4232-968d-83521116496e

Change factors were provided by KGA as a monthly multiplier to each analog month within the projected water budget period. These change factors were applied to their respective water budget components within the WRMWSD projected water budget models to evaluate the projected impacts to groundwater storage underlying the District given the estimated changes to surface water supply availability and climate under each projected scenario.

Modeling Projects & Management Actions

After developing the projected water budget scenarios through the methodologies described above, the approximate groundwater storage deficits resulting from each projected scenario (see **Table WB-6**) were used to inform the development of Projects and Management Actions (P&MA) for the WRMWSD Kern Subbasin Management Area. These proposed P&MAs were subsequently simulated under the 2030 and 2070 projected water budgets to assess how proposed P&MA implementation would address the groundwater storage change deficits identified from the model (see **Table WB-7**).

P&MAs were incorporated in the model as either (1) increases in surface water deliveries to the irrigated portion of the District, to simulate supply augmentation benefits, or (2) reductions in evapotranspiration from irrigated lands, to simulate demand reduction benefits. Both surface water supply augmentation and demand reduction P&MAs were applied uniformly for each year of the projected water budget model scenarios, so as to simulate the projected impacts of "full P&MA implementation" under each scenario. For each year, additional surface water supplies were delivered on a monthly basis according to WRMWSD's average historical monthly delivery patterns, whereas reductions in evapotranspiration were performed in line with the average historical breakdown of monthly ET within the irrigated portion of the District.

Appendix H

WRMWSD Long-Term Monitoring Access Agreement

MONITORING WELL ACCESS AGREEMENT

This Monitoring Well Access Agreement ("Agreement") is made and entered into by and between the Wheeler Ridge-Maricopa Water Storage District (hereafter "District") and _____ (hereafter "Landowner"), both of whom shall be referred to individually as a "Party" to this Agreement and collectively as the "Parties" to this Agreement.

RECITALS

WHEREAS, the District is a member of the Kern Groundwater Authority ("KGA") which has adopted or will adopt a Groundwater Sustainability Plan ("GSP") to comply with the Sustainable Groundwater Management Act ("SGMA"); and

WHEREAS, the District has developed and is responsible for implementing a chapter of the KGA GSP; and

WHEREAS, SGMA requires the long-term monitoring of static groundwater levels and water quality; and

WHEREAS, to comply with this requirement, the District may need access rights from Landowners within its service area to monitor groundwater elevations and water quality; and

WHEREAS, Landowner's Land (as described and depicted in Exhibit A) contains one or more groundwater wells ("Monitoring Well(s)") in the District GSP chapter area for which the District is required to monitor for groundwater elevation and water quality monitoring activities; and

WHEREAS, Landowner has agreed to grant the District limited access onto Landowner's Land, subject to the terms and conditions as set forth in this Agreement.

NOW, THEREFORE, the Parties have entered into this Agreement to allow the District to access to Landowner's Land under the following terms and conditions:

TERMS AND CONDITIONS

1. Incorporation of Recitals. The foregoing recitals are incorporated herein as terms and conditions of this Agreement.

2. Right of Entry. Landowner grants to the District and its employees, agents, consultants, and contractors a non-exclusive year-round license to enter onto Landowner's Land (as described and depicted in Exhibit A) to obtain groundwater elevation and water quality data from Landowner's Monitoring Well(s). Unless otherwise agreed to by the Parties in a written amendment to this Agreement, the Parties agree that the District's access to Landowner's Land shall be limited to wells described in Exhibit A's "Monitoring Well Locations" and in compliance with any conditions listed under "Access Instructions."

3. Access and Control. Except as otherwise provided in this Agreement, Landowner retains the exclusive right of access to and control over the Landowner's Land. Nothing contained in

this Agreement shall be construed as affording the public a right of access to any portion of the Landowner's Land or precluding Landowner's right to grant access to third parties across the Landowner's Land, provided that such access is not inconsistent with this Agreement.

4. Duration of Right. The Parties agree that this Agreement shall remain in effect until either of the following occurs: (a) Termination of the Agreement by either Party, or (b) Change in Ownership of Landowner's Land.

a. Termination by a Party. The Parties agree that this Agreement may be terminated at any time, with or without cause, by either Party upon sixty (60) days written notice to the other Party.

b. Landowner's Land: Change in Ownership. The Parties agree that this agreement shall terminate upon any change in ownership of Landowner's Land. Thereafter, the District acknowledges that it will need to enter into a new access agreement with the new owner(s) of Landowner's Land.

5. No Easement. The Parties agree that this Agreement does not grant the District a possessory right, easement, or other land interest with respect to Landowner's Land.

6. Costs. The Parties agree that all groundwater elevation and water quality monitoring performed by the District under this Agreement shall be funded by the District. The Landowner shall continue to be responsible for County well inspection fees. District agrees to provide a small concrete pad, a welded water-tight cover, and a locking cap at the Monitoring Well site if the wellhead is not already provided with a water-tight cover or pump head. The District also agrees to repair any defects in the integrity of the well collar, cap, lock, and pad above the ground surface, excepting damage caused by the sole negligence or intentional misconduct of the landowner, so long as this Agreement is in effect.

7. No Storage. The right of entry does not include permission to store soil, groundwater, or measurement apparatus on the Landowner's Land.District shall remove its materials and tools from the Landowner's Land at the end of each working day.

8. Maintenance of Landowner's Land. The Parties acknowledge that this Agreement grants the District a non-exclusive year-round license to access Landowner's Land for the limited purpose of obtaining groundwater elevation and water quality data from Landowner's Monitoring Well(s). Accordingly, except as provided in section 5 of this Agreement below ("Damage/Restoration"), the Parties agree that the District (including its employees, agents, consultants, and contractors) is under no obligation to maintain or otherwise repair the Landowner's Land.

9. Damage/Restoration. The District (including its employees, agents, consultants, and contractors) shall take all reasonable precautions to avoid damaging Landowner's Land. If any

DRAFT

damage is caused to Landowner's Land by the District in the course of performance of this Agreement, the District shall notify the Landowner immediately. In addition, the District will, at its sole cost and expense and with the Landowner's consent, take all action reasonably necessary to repair the damage and restore Landowner's Land to the condition that existed immediately prior to the damage caused by the District. It is understood and agreed that the District shall not be responsible for maintenance of the Monitoring Well(s) below the ground surface. The Parties agree that the District shall not be liable in the event that groundwater contamination or unauthorized waste disposal is eventually attributed to the well(s), or in the event that destruction of the well(s) (e.g., by grouting) is ultimately required.

10. Schedule or Notice of Access. The District may develop a schedule of dates/times it will access Landowner's Land for the purposes of well monitoring. Upon reasonable notice, the Landowner shall endeavor to refrain from pumping from the Monitoring Well(s) for at least 48 hours prior to the scheduled access date. If the District does not provide a schedule, it shall undertake reasonable efforts to notify the Landowner at least twenty-four (24) hours in advance of accessing Landowner's Land pursuant the access rights granted under this Agreement.

11. Indemnity. The District agrees to defend, indemnify, and hold harmless Landowner for any costs, claims, damages, losses or other liabilities arising out of the District's (including any employees, agents, consultants, and contractors) actions on Landowner's Land under this Agreement, with the exception that the District shall not be responsible for defending, indemnifying, or holding harmless Landowner with regard to costs, claims, damages, losses, or other liabilities arising out of the sole negligence or intentional misconduct of Landowner.

12. Insurance. Prior to entering onto Landowner's Land, District shall provide to Landowner a certificate that the District or District's consultant a certificate evidencing general liability insurance in the amount of at least $1,000,000 Dollars aggregate limit.

13. Written Notices. Written notices between the Parties shall be sent via U.S. mail to the addresses listed below:

[District Name]	[Landowner's Name]
[Address]	[Address]
[City,] CA [zip code]	[City,] CA [zip code]

14. Entire Agreement. This Agreement contains the entire understanding of the Parties and supersedes all prior agreements and understandings among the Parties related to the subject matter of this Agreement.

15. Amendment. Amendments to this Agreement shall become effective upon execution of a written amendment signed by both Parties.

DRAFT

16. Severability. If any provision of this Agreement is held to be unenforceable for any reason, it shall be adjusted, rather than voided, if possible, to achieve the intent of the Parties, and the balance of the Agreement shall remain in full force and effect.

17. Governing Law. This Agreement shall be interpreted and enforced pursuant to the laws of the state of California.

18. Effective Date. This Agreement shall become effective as of the latest date of execution below.

19. Confidentiality. By executing this Agreement, the Landowner authorizes the District to release the location and construction details of Landowner's Monitoring Well(s) together with any and all groundwater elevation and water quality data obtained pursuant to this Agreement to the Kern Groundwater Authority, the State of California, and their agents. It is understood and agreed that data obtained from Landowner's Monitoring Well(s) pursuant to this Agreement may be published from time to time in the District's GSP chapter, in GSP updates, or in other forms, written and electronic, that will be available to the general public.

Board Resolution

BEFORE THE BOARD OF DIRECTORS OF
WHEELER RIDGE-MARICOPA WATER STORAGE DISTRICT

IN THE MATTER OF: **RESOLUTION NO. 2019-18**

RESOLUTION APPROVING MANAGEMENT AREA PLAN FOR WHEELER RIDGE-MARICOPA WATER STORAGE DISTRICT MANAGEMENT AREA

WHEREAS, the Kern Groundwater Authority (the "Authority") is duly formed and existing under and pursuant to that certain Second Amended and Restated Agreement Joint Powers Agreement (the "JPA"), for the purposes of carrying out the Sustainable Groundwater Management Act (Water Code § 10720 *et seq.*) (SGMA), including the development, adoption and implementation of a Groundwater Sustainability Plan (GSP) for lands within the boundaries of the Authority's members and elsewhere within the Tulare Lake Groundwater Basin;

WHEREAS, the District is a member of the Authority;

WHEREAS, pursuant to Section 7.01 of the JPA, the District has exercised its option under the JPA to develop a chapter governing SGMA implementation within the boundaries of the District for inclusion in the Authority's GSP, which is titled *Groundwater Sustainability Plan-* Wheeler Ridge-Maricopa *Water Storage District Management Area* (the "WRMWSD Chapter"); and,

WHEREAS, the District has conducted public outreach, solicited public input on, and, as appropriate, has responded and/or will respond to public comments on, the WRMWSD Chapter as required under SGMA; and

WHEREAS, following such outreach, solicitation and response, the District's Board of Directors reviewed and evaluated the WRMWSD Chapter.

NOW, THEREFORE, THE BOARD OF DIRECTORS OF THE WHEELER RIDGE-MARICOPA WATER STORAGE DISTRICT does hereby resolve, declare and order as follows:

1) Each of the matters set forth above is true and correct and the Board so finds and determines.

2) The Board finds that the WRMWSD Chapter is consistent with the requirements of SGMA, and pursuant to Section 2.03(b) of the JPA approves the Chapter for inclusion in the Authority's GSP.

3) The Board hereby authorizes District staff to undertake such actions as are necessary and appropriate to transmit the WRMWSD Chapter to the Authority and to present the WRMWSD Chapter to the Authority's Board of Directors for consideration of inclusion in the Authority's GSP.

ALL THE FOREGOING being on motion of Director Reiter, seconded by Director Marin, and authorized by the following vote, to wit:

AYES: Atkinson, Blaine, Fry, Marin, Mettler, Reiter, Richardson.

NOES: None.

ABSTAIN: None.

ABSENT: Valpredo.

I HEREBY CERTIFY that the foregoing resolution is the resolution of said District as duly passed and adopted by said Board of Directors on the 11th day of December 2019.

WITNESS my hand and seal of said Board of Directors this 11th day of December 2019.

(District Seal)

Mark Valpredo
Vice-President of the Board of Directors

Executive Summary

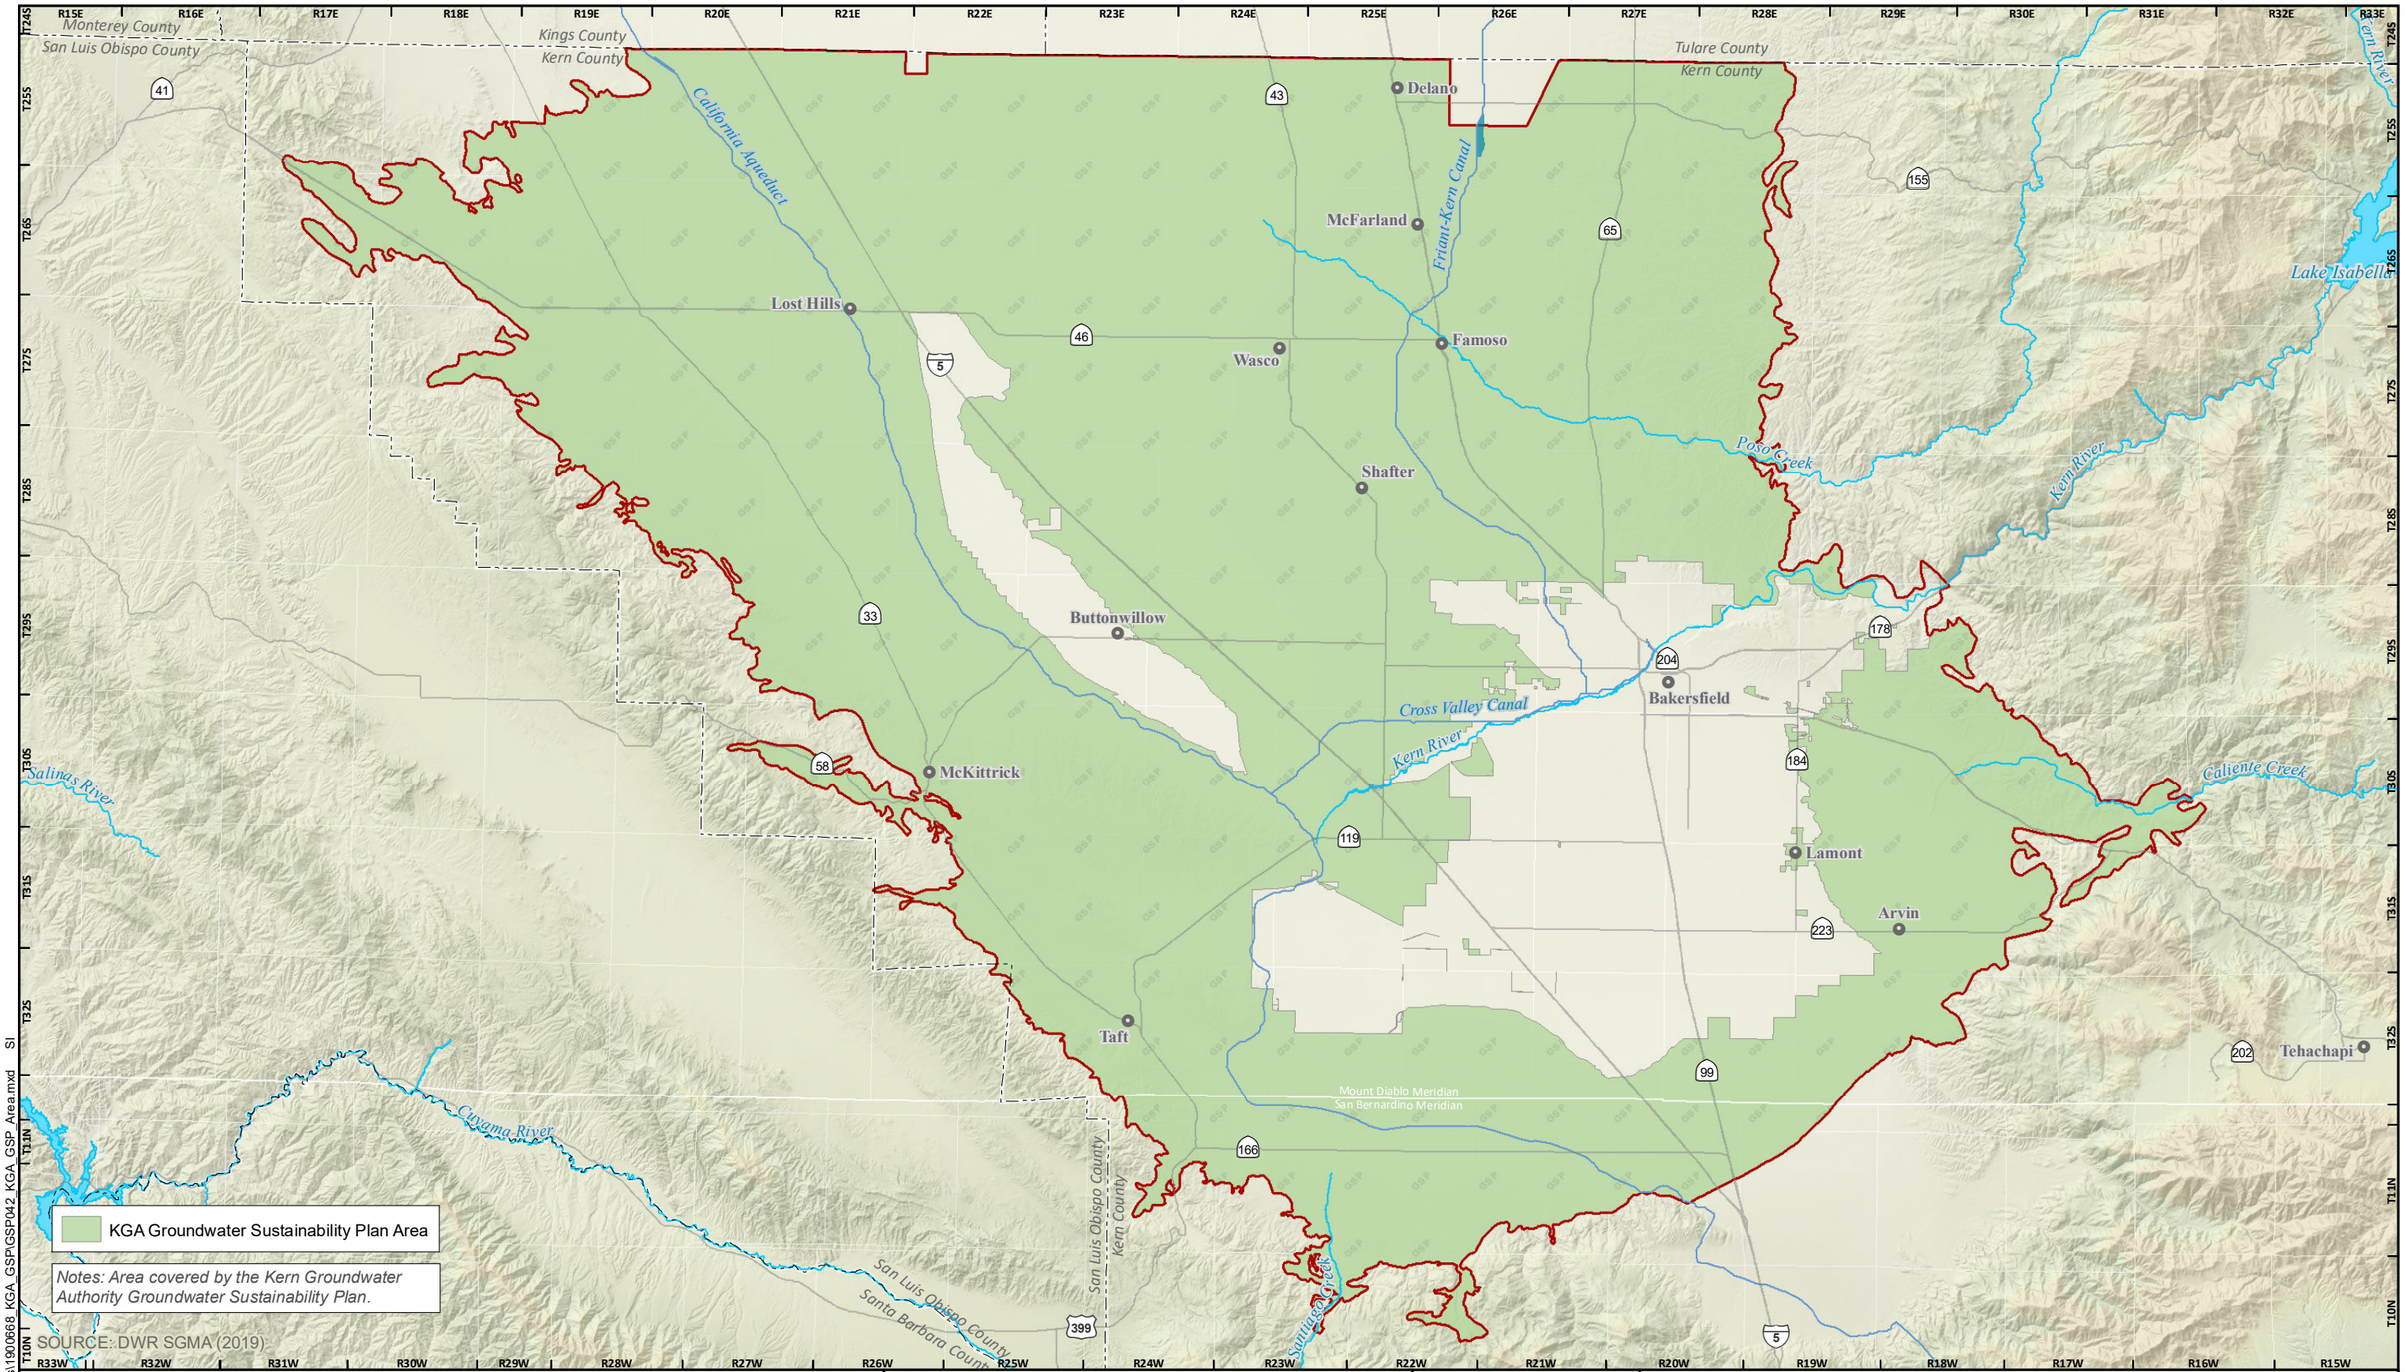
The Kern Groundwater Authority (KGA) Groundwater Sustainability Agency (GSA) covers approximately 1.2 million acres of the Kern County Subbasin's (Subbasin) approximate 1.8 million acres, as defined by the California Department of Water Resources (DWR) Bulletin 118 (see Figure E-1). DWR has identified the Kern Subbasin as a "critically overdraft basin". The Kern Groundwater Authority includes 16 member entities made up of water districts/agencies, groundwater banking projects, and organized nondistricted lands. The 16 member entities also constitute the KGA Board, with one representative from each member entity. Its boundary stretches along the northwest, northeast, and southern parts of the Subbasin. The KGA was formed for the purpose of:

- Coordinating groundwater management programs and activities;
- Identifying and addressing issues pertaining to sustainable groundwater management;
- Establishing a framework for local groundwater management; and
- Coordinating with other GSAs in the Subbasin.

The KGA provides, through a Joint Powers Agreement, each member the sole right and responsibility to implement SGMA within its respective boundaries and/or management areas, in a manner determined by the member. However, the implementation actions can not interfere with the surrounding members or GSAs in their ability to comply with SGMA. The KGA, as such, provides the critical mechanism for coordination of SGMA related activities between its members as well as with the other GSAs in the Subbasin.

The Subbasin includes 11 organized GSAs. Of these, six GSAs have elected to be included in the Groundwater Sustainability Plan (GSP) of the KGA and two are included in the Kern River Groundwater Sustainability Agency GSP. Three additional district-specific GSPs have been prepared in the Subbasin by Buena Vista Water Storage District, Henry Miller Water District, and Olcese Groundwater Sustainability Agency. The five GSAs submitting GSPs have coordinated throughout the development of the GSPs in the Subbasin as indicated in the executed Coordination Agreement and will continue through the implementation of the GSPs.

Kern County produces a wide variety of crops on approximately 900,000 acres, making it a major contributor to California's agricultural economy. One important honor that Kern County is known for is its agricultural industry ranking. Kern County is currently ranked the #1 agricultural producing county in the United States and has been for the last three years with gross value of all agricultural commodities produced in 2017 estimated at $7.25 billion. The top five commodities are grapes, almonds, citrus, milk, and pistachios, which make up more than $4.5 billion (63 percent) of the total value. With this, Kern County agriculture is the largest employer in the region with 1 in every 5 jobs related to agriculture. The communities, economy, and local governments are and have been reliant on Kern County agriculture and are dedicated to preserving the viability of agriculture into the future.



As stated, all the GSAs in the Subbasin have coordinated and collaborated on the development of water modeling budgets (historical, baseline and projected) in the Subbasin. Considerable effort and resources were expended to update the C2VSim model with local data to better represent Subbasin conditions, as described in this GSP. Subbasin-wide water budget results from the numerical model-based water budget show the Subbasin, as a whole, has an overdraft of 324,326 acre-feet per year over the baseline conditions of which the KGA is approximately 256,281 of the deficit.

In response to this level of overdraft the KGA members, in coordination with the other GSAs in the Subbasin, have developed Subbasin-wide Sustainable Management Criteria. This includes required Measurable Objectives and Minimum Thresholds for the Sustainability Indicators relevant to the specific management areas of the Subbasin to protect against the occurrence of Undesirable Results that would cause unreasonable impacts the beneficial users and uses of groundwater in the Subbasin.

The KGA members have sources of water supplies such as local streams (Caliente, Poso Creek), Kern River, State Water Project and Central Valley Project sources. Each member addresses their own individual water supply sources in greater detail in their individual management area plans along with how the beneficial users in their jurisdiction will participate in achieving sustainability.

The KGA members have also identified more than 150 projects and management actions ranging from expansion of local and regional conveyance and recharge facilities to take advantage of surplus supplies; new conveyance and recharge projects; and participation in the California WaterFix or other thru-Delta improvement projects. Management actions range from implementing district level fee structures to incentive reduced groundwater pumping; participation in local, regional, and state-wide water markets; and setting allocation for groundwater use by landowner, based on the sustainable yield of management areas.

The coordinated modeling effort shows that implementation and completion of the identified projects and management actions during the implementation period of 2020 to 2040, as stated in the individual management area plans and GSPs from the other GSAs in the Subbasin, would result in an average surplus of 85,578 acre-feet per year over the projected baseline condition simulation.

1 Introduction

The Kern County Subbasin is located at the southern end of the San Joaquin Valley and is known for its rich soil and Mediterranean-like climate, which has made Kern County one of the top producing agriculture regions in the nation. The Kern County Subbasin (Subbasin) is bounded by the Kern County Line and the Tule Groundwater Subbasin on the north; the granitic bedrock of the Sierra Nevada foothills on the east; the Tehachapi mountains on the southeast; and by the marine sediments of the San Emigdio Mountains and Coast Ranges on the southwest and west (DWR, 2006).

California is the nation's largest agricultural producer and is the nation's sole exporter of many agricultural commodities, supplying nearly 99 percent of the almonds, artichokes, and garlic. Recent study by the University of California (November 2019) highlighted the contribution of agriculture to California's economy. Agricultural production, agricultural support, agricultural distribution, and agricultural processing employ nearly 1.2 million people and generated approximately $264 billion in sales in 2018. The San Joaquin Valley is the major contributor to California agricultural economy as can be shown in Table 1-1.

Table 1-1: San Joaquin Valley Contribution to California's Agricultural Economy (2018)

	Agricultural Production	Agricultural Support	Agricultural Distribution	Agricultural Processing
San Joaquin Valley				
Jobs	131,700	116,900	33,700	62,900
Earnings ($ billion)	$6.5	$4.2	$1.9	$4.0
Sales ($ billion)	$24.0	$7.7	$6.4	$31.7
California				
Jobs	325,200	320,000	304,00	245,000
Earnings ($ billion)	$16.2	$18.0	$17.8	$16.0
Sales ($ billion)	$61.0	$32.0	$57.4	$113.0

Sources: California's Working Landscapes, University of California, November 2019

In Kern County a wide variety of crops are produced on approximately 900,000 acres, making it a major contributor to California's agricultural economy. One important honor that Kern County is known for is its agricultural industry ranking. Kern County currently is ranked the #1 agricultural producing county in the United States and has been for the last three years with gross value of all agricultural commodities produced in 2017 estimated at $7.25 billion (Kern County Department of Agriculture and Measurement Standards, 2018). The top five commodities are grapes, almonds, citrus, milk, and pistachios, which make up more than $4.5 billion (63 percent) of the total value. With this, Kern County agriculture is the largest employer in the region with 1 in every 5 jobs related to agriculture. The communities, economy, and local governments are and have been reliant on Kern County agriculture and are dedicated to preserving the viability of agriculture into the future.

Bulletin 118 published by California Department of Water Resources (DWR) in January 1980 states that "The Kern County Water Agency, which covers the Kern County Basin, presently receives about half of its maximum annual entitlement from the State Water Project. If no new lands were to go into production, and the full entitlement from the State Water Project were delivered today, there would be no overdraft in Kern County as a whole." Harvested acres in Kern County have remained relatively steady at an average of 858,000 acres a year with only a 10 percent annual fluctuation from that average between 1980 and 2017.

Since the operation of the State Water Project (SWP) in 1968 until 2007, SWP contractors received on average 86 percent of their entitlement. However, in May 2007, Federal Judge Oliver Wagner overturned a federal scientific study that aimed to protect Delta Smelt in the Sacramento-San Joaquin Delta (Delta) resulting in curtailing Delta export pumping operations to protect the continued existence of the fish. In addition, the State of California experienced a historic extended drought from 2012 to 2016. As a result, SWP contractors received on an average only 48 percent of their entitlement from 2008 to 2016.

Despite the reduction in SWP deliveries, the groundwater overdraft in the entire Subbasin declined from 600,000 acre-feet per year in 1980 (Bulletin 118-80) to a current estimate of 324,300 acre-feet in 2015 (Todd, 2019). This decrease in amount of overdraft per year was achieved through change in crop patterns; increase in agriculture efficiency; and increase in conjunctive use and banking projects throughout the Subbasin.

The current baseline condition estimates that the Subbasin has an average annual overdraft of 324,326 acre-feet per year (Todd, 2019 projected water model). However, with the proposed projects and management actions slated for development and implementation in the Subbasin, it is forecasted that the Subbasin will achieve sustainability by 2040 with an estimated 42,144 acre-feet of annual surplus (see Attachment H). The projects and management actions are described in this Groundwater Sustainability Plan (GSP) and the individual management area plans, attached to this GSP, and the 4 other GSPs prepared within the Subbasin. Collectively, the projects and management actions currently proposed provide a reasonable approach for sustainable management of the groundwater Subbasin and can be adaptively managed to meet future challenges as necessary.

1.1 Sustainable Groundwater Management Act

During the height of the last drought in 2014, the State Legislature passed the Sustainable Groundwater Management Act (SGMA), which consists of a three-bill package of Assembly Bill (AB) 1739 (Dickinson), Senate Bill (SB) 1168 (Pavley) and SB 1319 (Pavley). SGMA as it is called, provides for the local control of groundwater resources while requiring the sustainable management of that groundwater resource. One of the first requirements under the SGMA law was to form/establish a local governance body called a Groundwater Sustainability Agency (GSA) with the local authority to develop, adopt, and implement a GSP. GSPs must document monitoring conditions and establish management criteria to avoid undesirable results and identify potential actions which either maintain and/or achieve sustainable groundwater management by 2040 or 20 years from the date of the adoption of the GSP. The KGA, through a

Joint Powers Agreement, is a recognized GSA in the Subbasin for the purpose of developing a GSP.

Sustainable management of groundwater is defined under SGMA as the "management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results" (California Water Code (CWC) Section 10721(v)). The undesirable results under SGMA include the significant and unreasonable lowering of groundwater levels; loss of groundwater storage and supply; degradation of water quality; land subsidence; surface water depletion; and sea water intrusion.

Further, under the SGMA law, water basins throughout California were determined or classified to be of "high" or "medium" priority by DWR. The Subbasin was determined or classified to be a "high" priority basin, which triggers the requirement of submittal of its GSP by January 31, 2020.

1.2 Purpose of the Groundwater Sustainability Plan

The purpose of this GSP is to comply with SGMA and serve as a comprehensive foundation for groundwater management within areas of the Subbasin covered by the Kern Groundwater Authority (KGA) by providing information on the current groundwater conditions; establishing the sustainability goals to be achieved through the implementation of management actions and projects; and demonstrating how sustainability will be achieved through the 20-year implementation period.

In the Subbasin, there are four other established GSAs who are submitting GSPs: the Kern River Groundwater Sustainability Agency (KRGSA), Buena Vista Water Storage District (BVGSA), Henry Miller Water District (HMGSA), and Olcese Groundwater Sustainability Agency (Olcese GSA).

Throughout the development process for this GSP, the KGA has considered and coordinated with the other four GSAs in the Subbasin to comply with the requirement of developing and utilizing consistent data and methodologies throughout the Subbasin, especially the development of a basin-wide basin setting. Additionally, the GSAs within the Subbasin coordinated the respective elements of their GSPs necessary for achieving the sustainability goals for the Subbasin.

1.3 Sustainability Goal

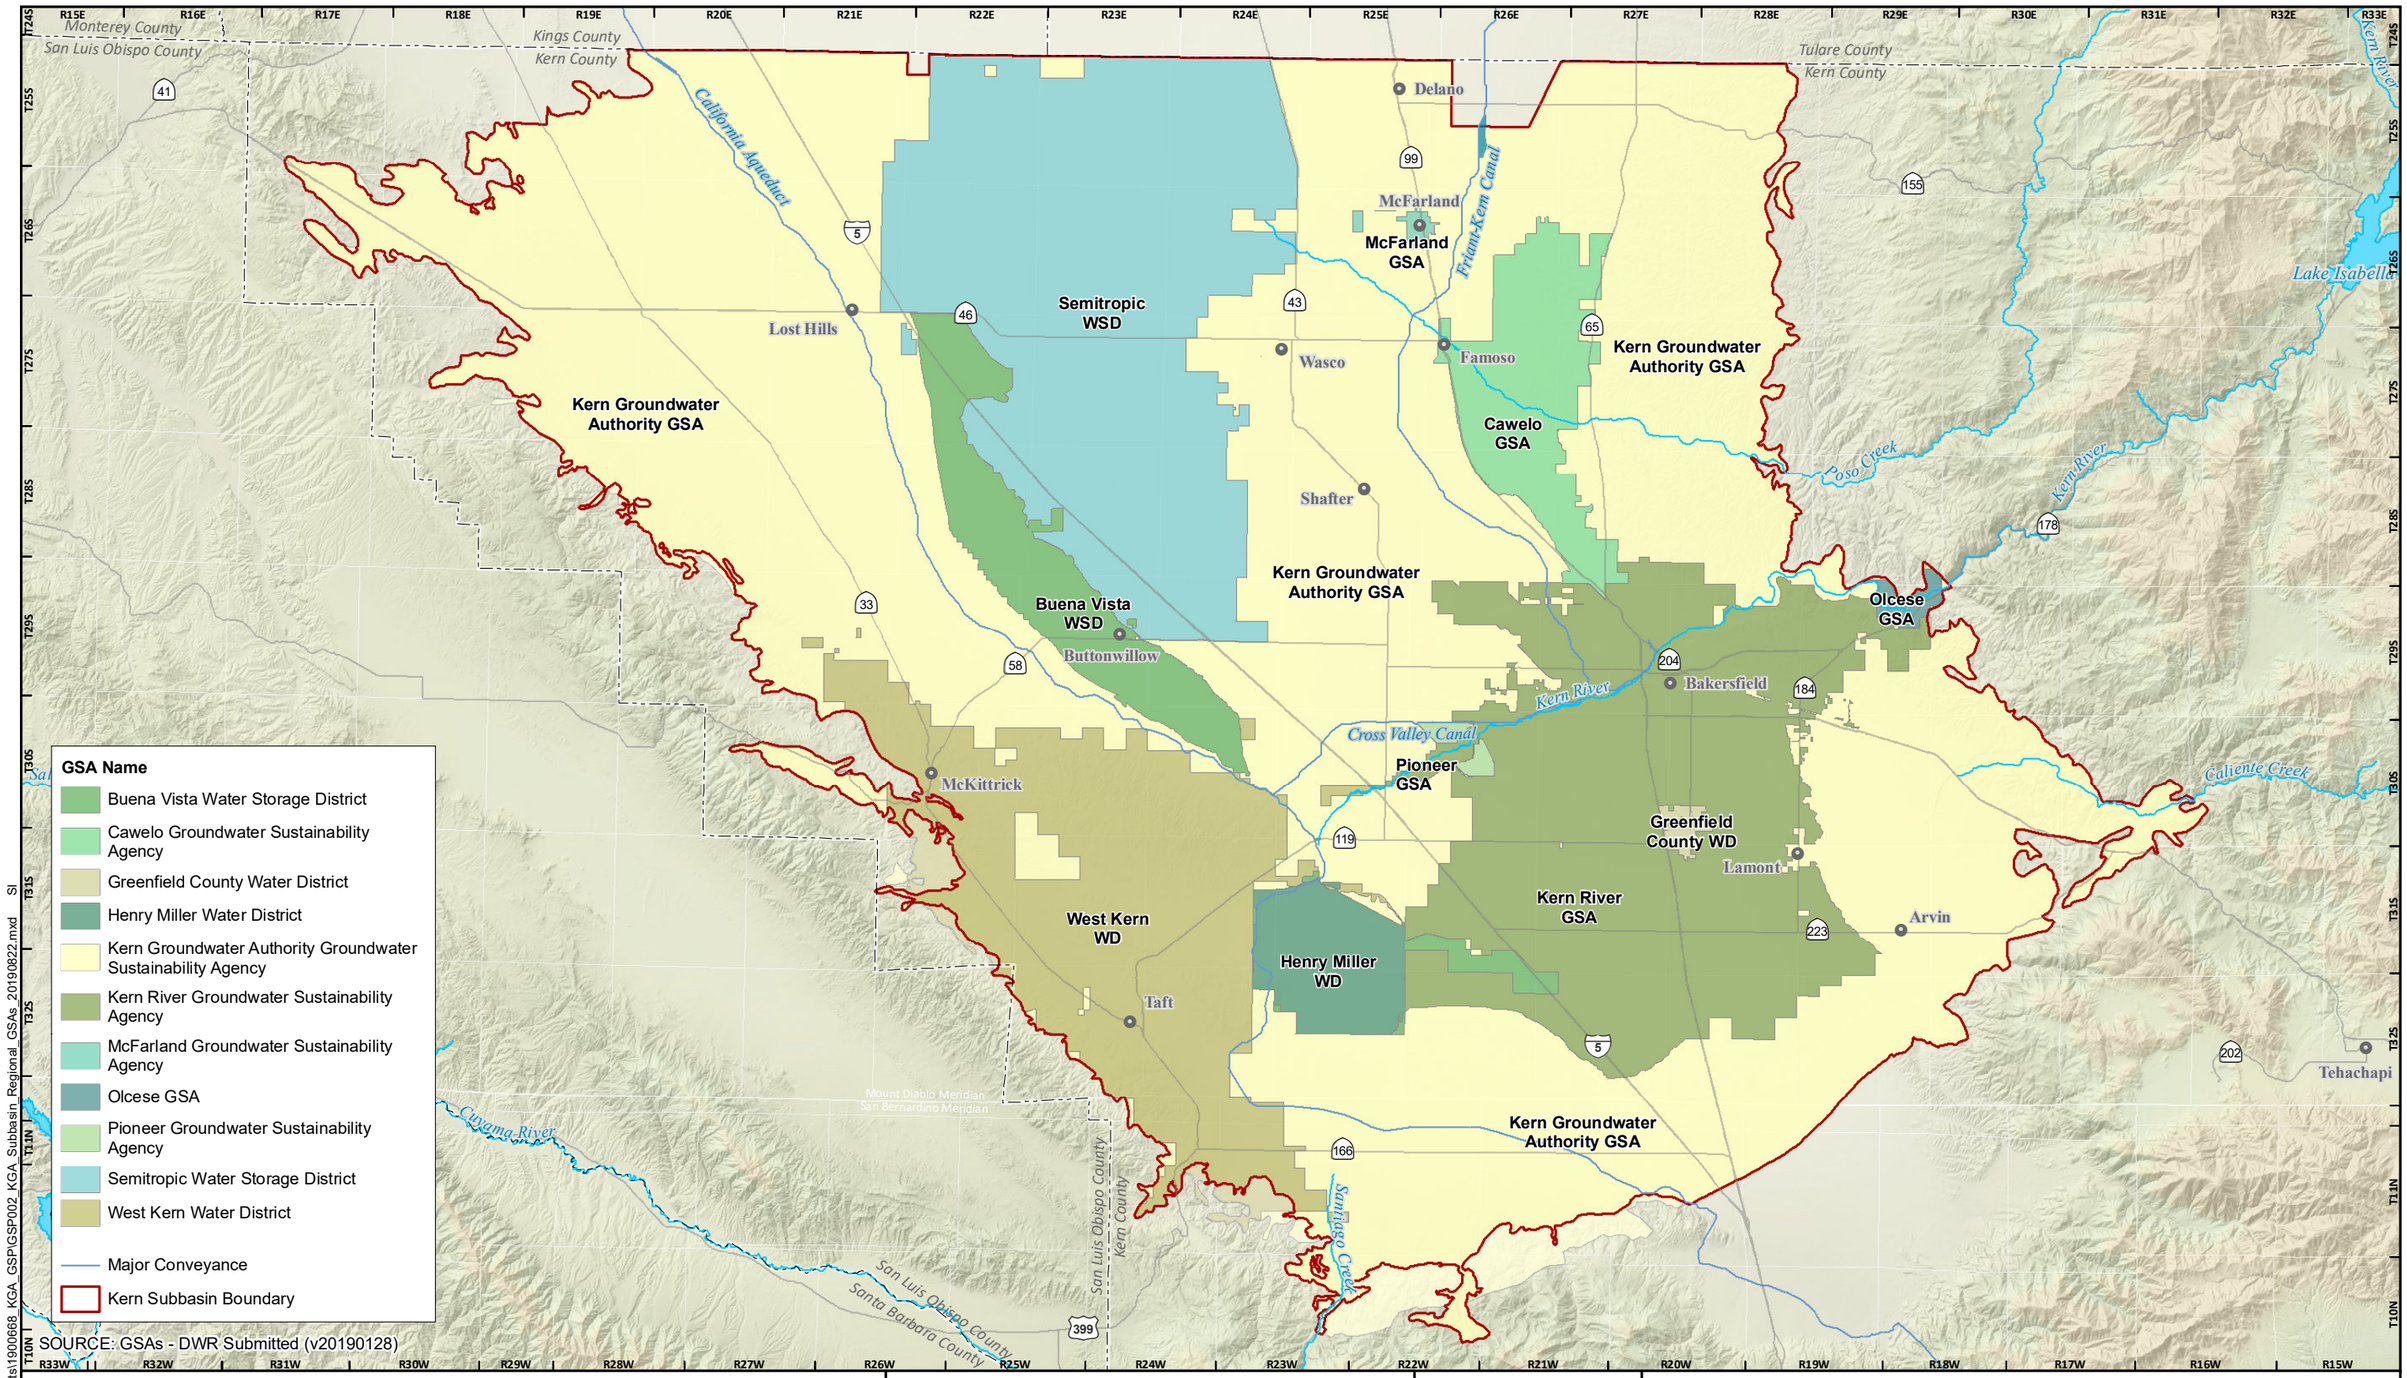
Under Section 354.24 of the GSP emergency regulations, each agency shall establish in its GSP a sustainability goal for the basin that culminates in the absence of undesirable results within 20-years of the applicable statutory deadline. This GSP and the GSPs of the other GSAs in the Subbasin have collaborated on the development of the following sustainability goal for the Kern County Subbasin.

The sustainability goal of the Kern County Subbasin is to:

- *Achieve sustainable groundwater management in the Kern County Subbasin through the implementation of projects and management actions at the member agency level of each GSA.*
- *Maintain its groundwater use within the sustainable yield of the basin as demonstrated by monitoring and reporting groundwater conditions.*
- *Operate within the established sustainable management criteria, which are based on the collective technical information presented in the GSPs in the Subbasin.*
- *Collectively bring the Subbasin into sustainability and to maintain sustainability over the implementation and planning horizon.*

1.4 Agency Information

In complying with Section 354.6 of the GSP emergency regulations, the following section provides agency information, legal authority, and estimated cost of plan implementation for the KGA and its members in the Subbasin.



Agency's Name:	Kern Groundwater Authority
Agency's Address:	1800 30th Street, Suite 280
Agency's Phone Number:	(661) 479-7171
Agency's Website:	http://www.kerngwa.com/index.html
Contact Person:	Patty Poire
Contact Person's Title:	Planning Manager, KGA

1.4.1 Organization and Management Structure of the KGA GSA

The Subbasin includes 11 organized GSAs, as shown in Figure 1-1. Of these, several GSAs have elected to be included in the GSP of either the KGA or the KRGSA. Table 1-2 indicates if the GSA have elected to prepare an independent GSP or if they are part of either the KGA or KRGSA. In total, 11 GSAs in the Subbasin are developing five GSPs.

Table 1-2: Groundwater Sustainability Agencies in Kern County Subbasin

This Page Left Blank Intentionally

The KGA, as a Subbasin coordination group, was created prior to the enactment of SGMA with the intent of establishing a framework for the coordinated management of the groundwater basin underlying the San Joaquin Valley portion of Kern County, including the preservation and maintenance of local control over groundwater resources and to provide future certainty for basin users. With the passage of SGMA, the KGA elected to form a GSA under a Joint Powers Agreement (JPA) (Attachment A), thereby assuming responsibility for development of a comprehensive GSP for an area which includes agricultural lands, urban and industrial development as well as oil fields.

The KGA GSA covers approximately 1.2 million acres of the Subbasin's approximate 1.8 million acres and includes 16 member agencies (Table 1-3 and Figure 1-2). The 16 member agencies also constitute the KGA Board, with one representative from each agency. Its boundary stretches along the northwest, northeast, and southern parts of the Subbasin. The KGA also includes a single associate member, the Eastside Water Management Authority, who consistent with SGMA, is a non-voting member of the GSA and represents lands outside of a KGA member agency boundary.

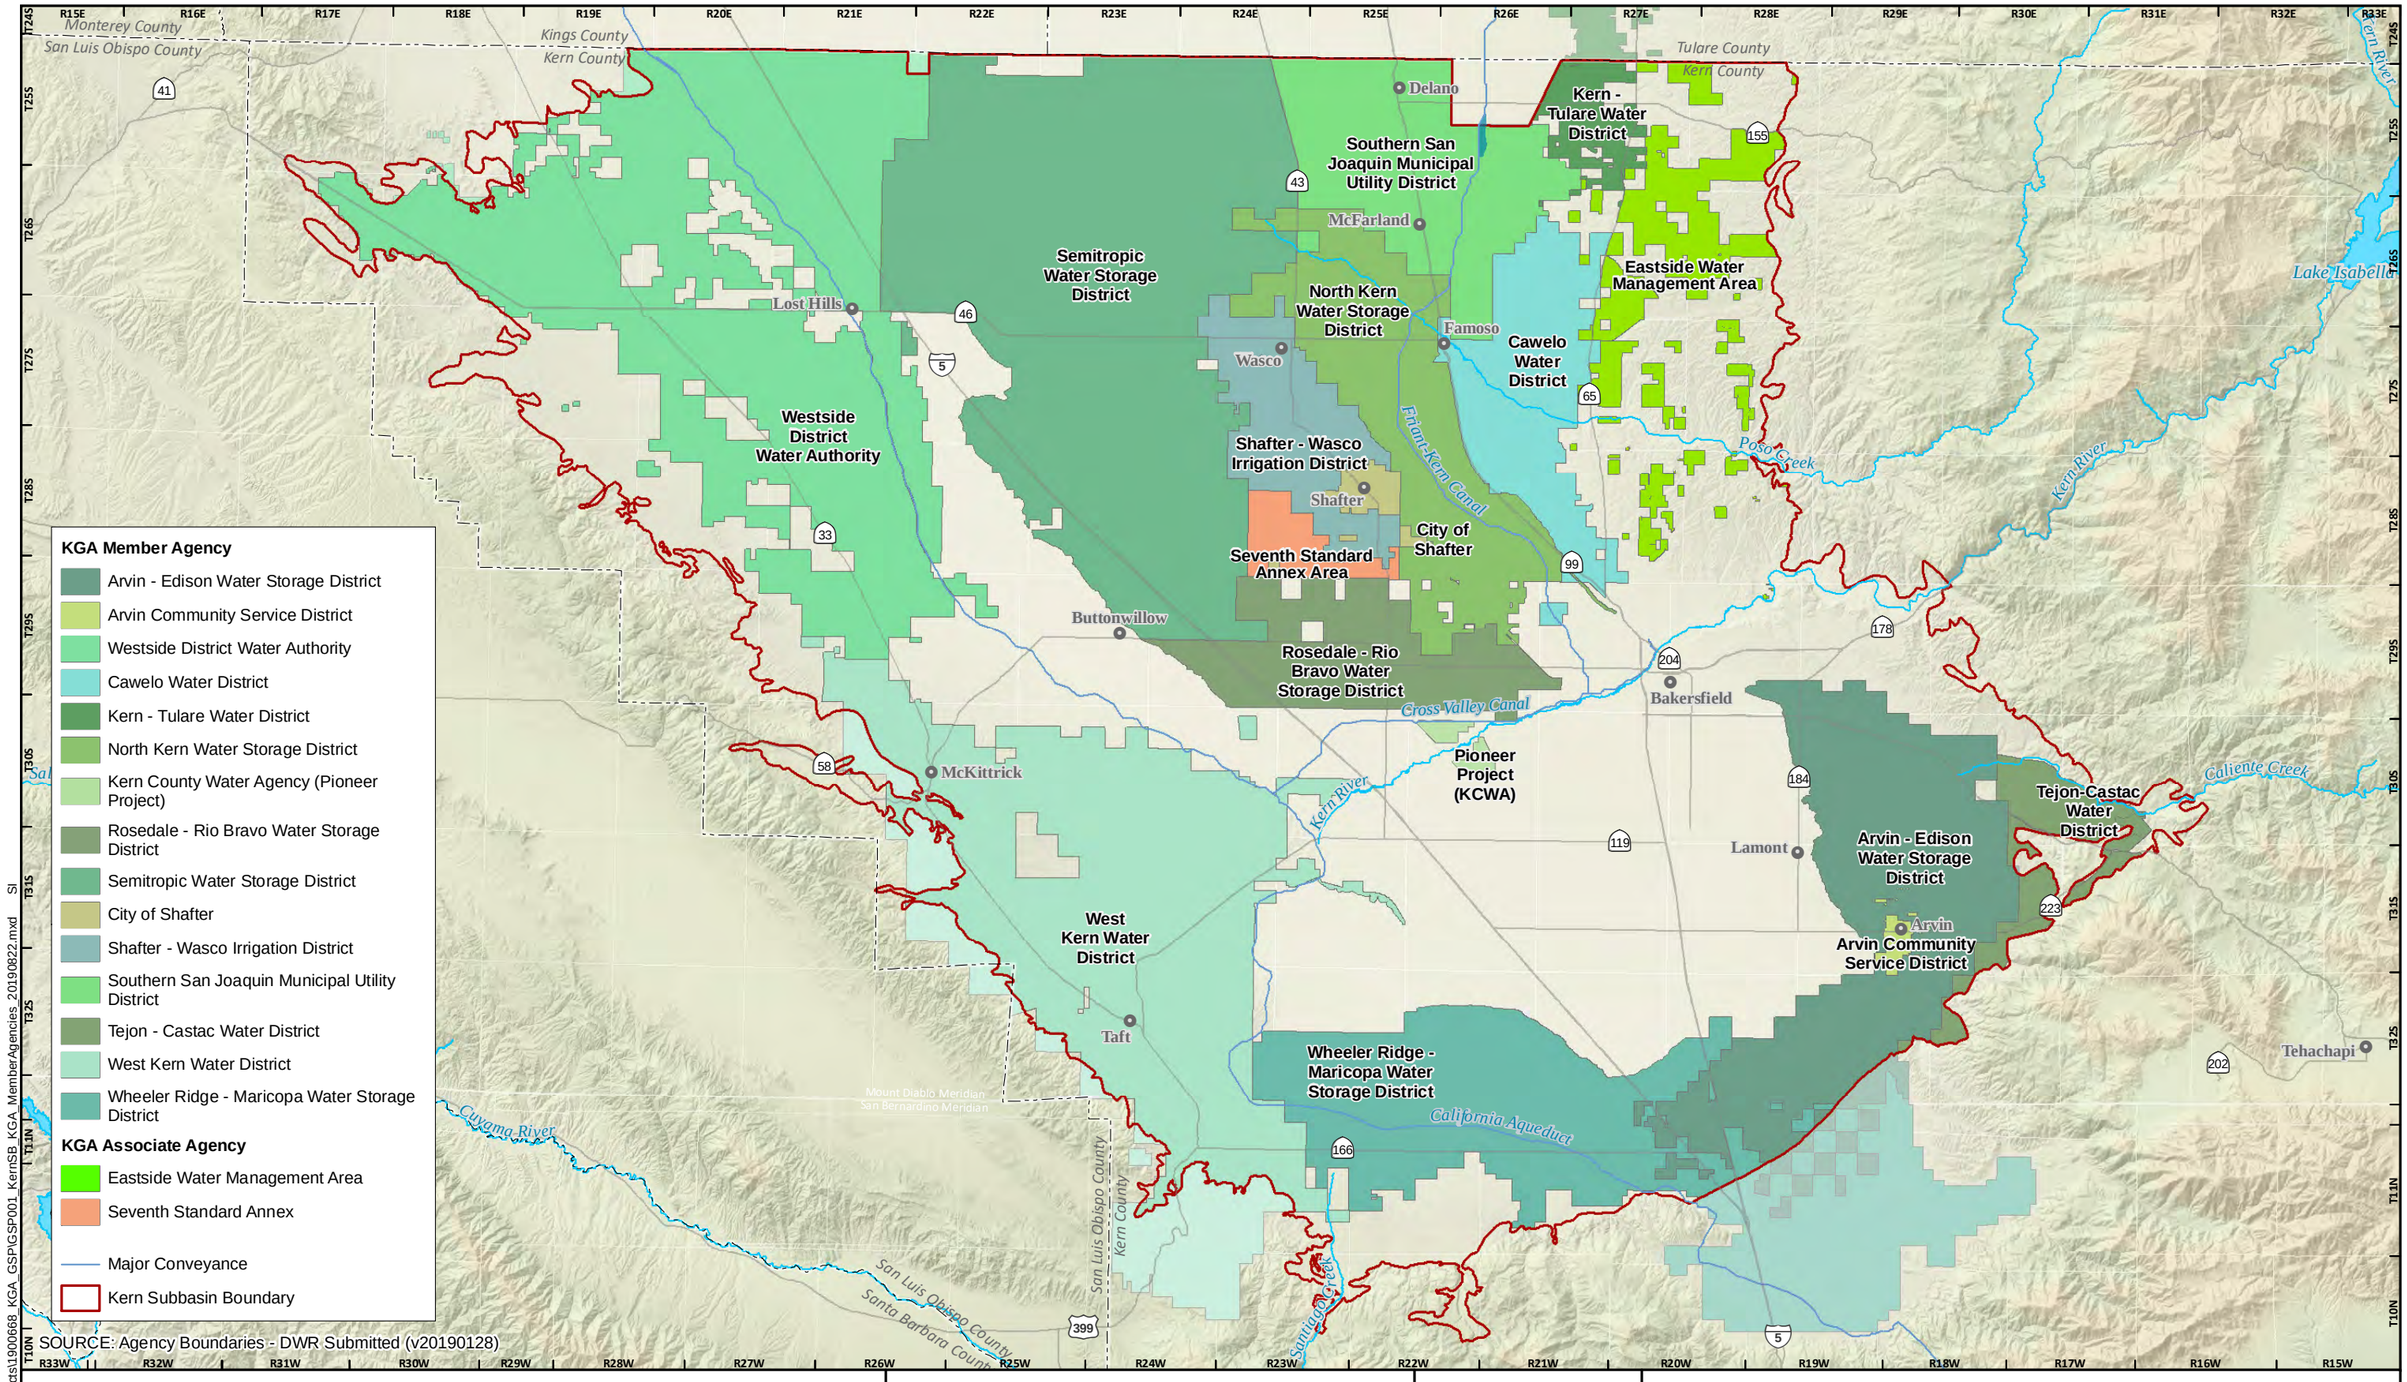
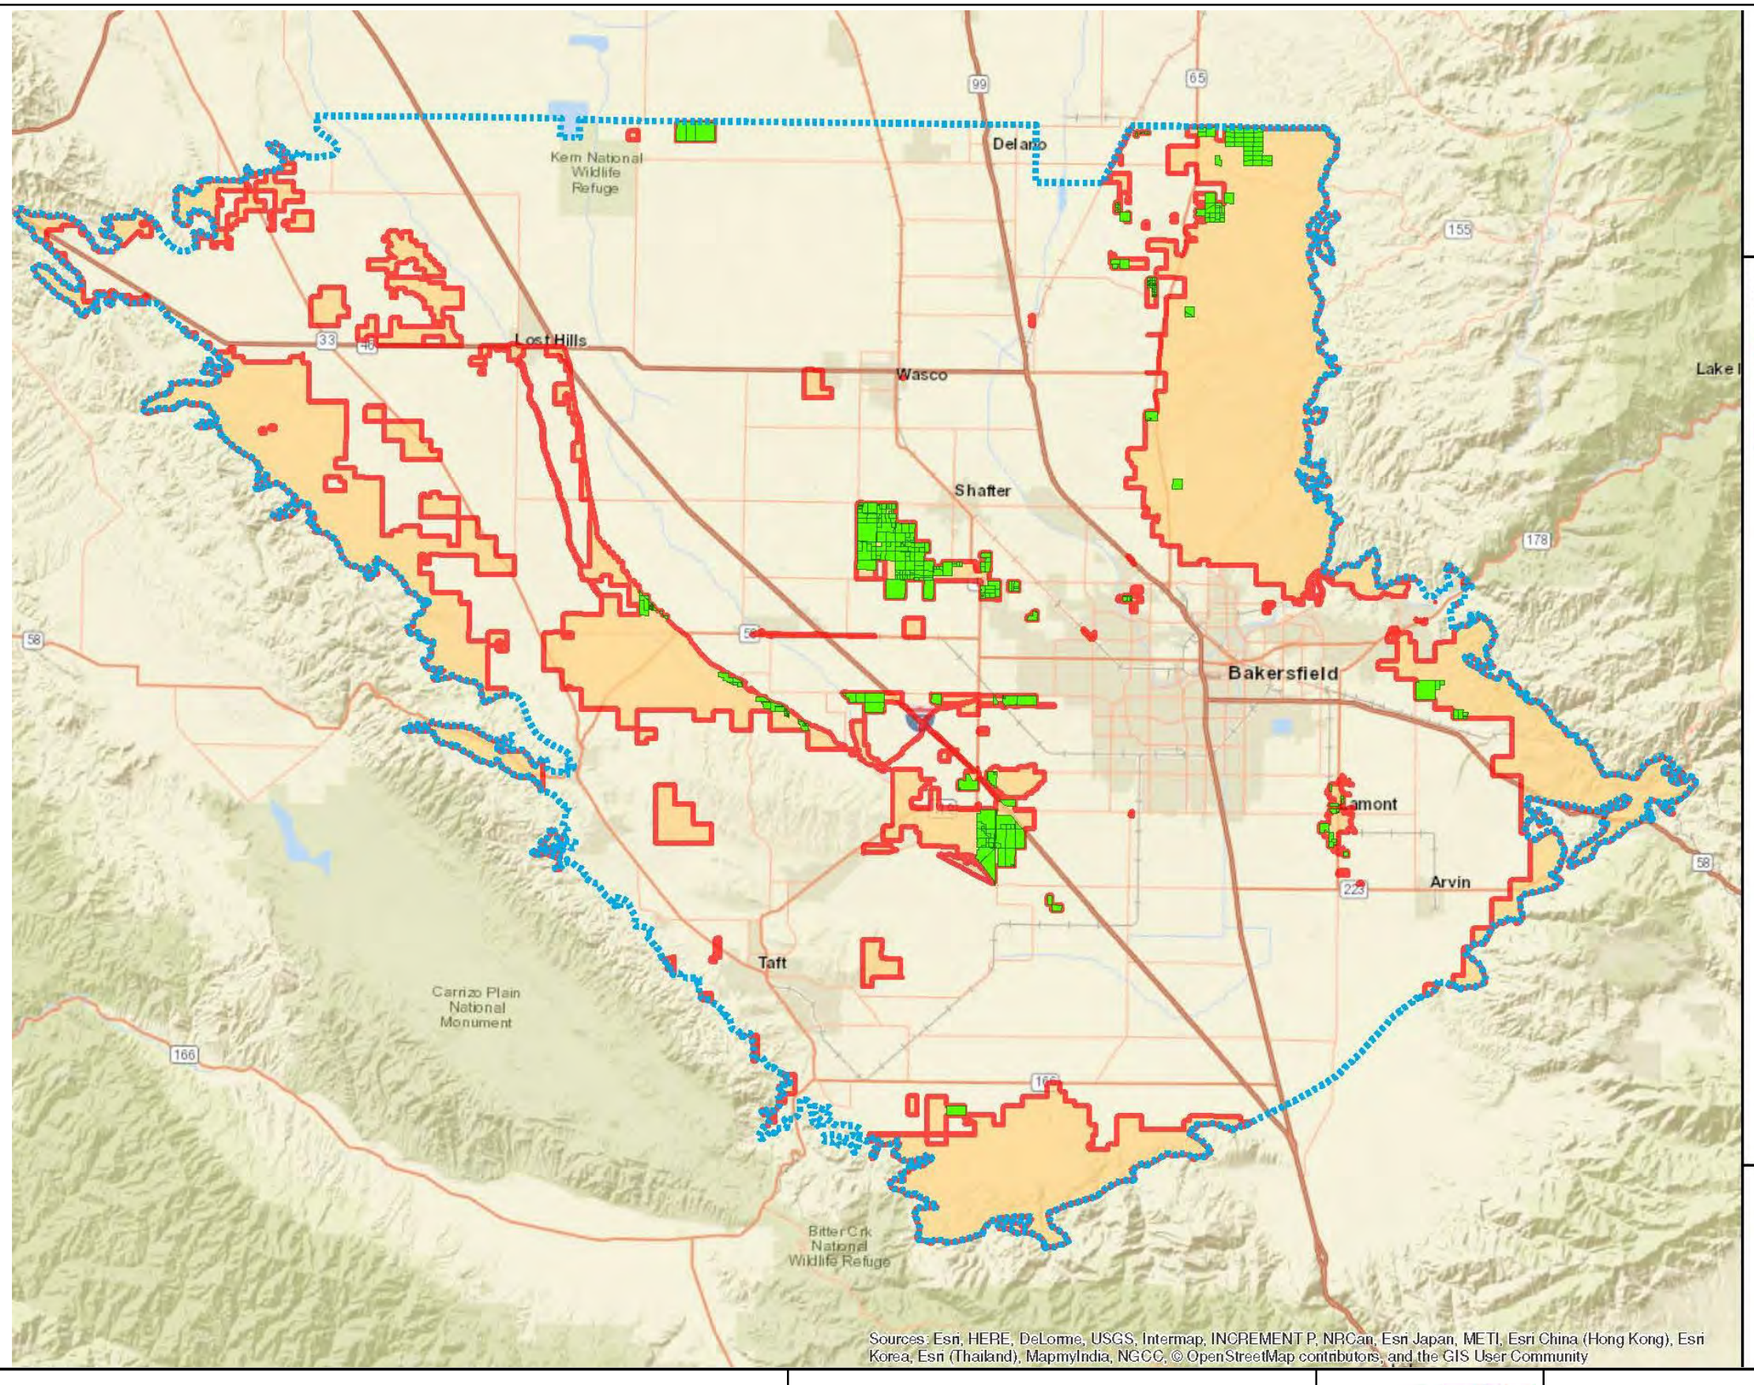
Eastside Water Management Authority	

1 – Groundwater Sustainability Agency



At the inception of the KGA, Kern County was a member of the KGA to represent lands within the Subbasin and outside of the jurisdiction of a local agency participating in a GSA in the Subbasin – non-districted lands. However, in December 2018, Kern County supervisors elected to withdrawal from the KGA and from that action, approximately 440,950 acres of non-districted lands became not covered by a GSA (Figure 1-3). At the December 19, 2018 KGA Board meeting, the direction provided by the Board was to reach out to the non-districted landowners and extend coverage; however, those non-districted landowners who are not wanting to participate will be eventually removed from the KGA GSA boundary and will then be required to report directly to the State Water Resources Control Board (State Water Board). The KGA reached out to those landowners via a mass mail-out to advise of the County's decision and extended the opportunity to participate in SGMA through the member agencies of the KGA. The coverage to the non-districted lands was handled by the landowners entering into agreements



with the KGA member agencies, including associate members, for SGMA coverage under the KGA members' respective management area plans. Assistance from Kern County Water Agency made this coverage possible by lending its jurisdiction under SGMA to the KGA members' who have agreements with those non-districted landowners. Through the efforts by the member agencies of the KGA, approximately 242,180 acres of the non-districted lands will be covered and will be compliant with SGMA. The remaining 198,770 acres not covered are typically grazing lands or lands associated with oil production where minimal or no groundwater usage exists (Figure 1-4). The decision to extend SGMA coverage and to revise the KGA GSA boundary to remove non-districted lands not participating with KGA member agencies has been presented and discussed openly at public KGA board meetings since the initial discussion at the December 2018 board meeting.

For those non-districted lands not covered by a member of the KGA, the five Subbasin GSAs have coordinated to cover all those non-districted lands in the water modeling effort for the historic, baseline, and future projections. Today, the future projection water modeling results demonstrate that the entire Kern Subbasin (including the non-districted lands) will be sustainable with implementation of proposed projects and management actions activities by 2040. Also, the Kern Subbasin GSAs have agreed to continue to coordinate on the monitoring of those non-districted lands going forward and to include the monitoring data in the annual reporting requirements of the Subbasin, thus covering the entire basin in the GSP.

To facilitate the implementation of the KGA GSP, KGA's jurisdictional area is divided into management areas formed by the portion of the Subbasin that underlies the boundaries of each member agency and any associated non-districted lands. Each member agency of KGA has developed its own management area plan to support the development of this KGA Umbrella GSP and collectively are used as reference for details regarding the variances between management areas throughout this report. Southern San Joaquin Municipal Utility District entered into an agreement with McFarland Groundwater Sustainability Agency to include them as part of its management area plan. As Southern San Joaquin Municipal Utility District became a member agency of KGA GSA, the McFarland GSA is also included in the KGA GSP even though they are not a member agency.

KGA includes two disadvantages communities (DAC) as full voting member agencies from the beginning of the formation of the exclusive GSA, the Arvin Community Services District and the City of Shafter. Sustainable management for the Arvin Community Services District is covered in the management area plan developed by Arvin-Edison Water Storage District. The City of Shafter is covered in North Kern Water Storage District & Shafter-Wasco Irrigation management area plan. Both DACs have been actively engaged with the KGA and their respective management area plans development.

The KGA has been working proactively to coordinate with all GSAs and its associated GSP within the Subbasin to ensure that all GSPs developed within the Subbasin meet the requirements of the Kern County Subbasin Coordination Agreement. All the GSAs in the Subbasin have collaborated in the development and adoption of a Coordination Agreement, as required under SGMA, for the coordinated management and implementation of the five GSPs prepared in the Subbasin. Attachment B provides a copy of the Kern Subbasin Coordination Agreement. Table 1-4 provides the additional information of the five GSPs in the Subbasin.

1.4.2 Legal Authority of the GSA

The KGA was granted the legal authority of a GSA by complying with CWC Section 10723.8 (see Attachment A). The KGA held the required public hearings regarding the establishment of a GSA as stated in CWC Section 10723(b) and passed a resolution to form the KGA GSA (Attachment C). The authority granted to the KGA is to develop, adopt, and implement a GSP that would be available to those lands within the boundaries of the KGA members. KGA provided the required notification of intent to prepare a GSP to DWR on December 20, 2017 (Attachment D). Under CWC Section 10723.2, the KGA within its boundaries shall consider the interests of all beneficial uses and users of groundwater, as well as those responsible for implementing GSPs.

The KGA was formed for the purpose of:

- Coordinating groundwater management programs and activities;
- Identifying and addressing issues pertaining to sustainable groundwater management; and
- Establishing a framework for local groundwater management.

The intent of the members under this JPA is to provide each member the sole right and responsibility to implement SGMA within its respective boundaries and/or management areas, in

a manner determined by the member. Members expressly intend that the KGA will not have the authority to limit or interfere with the respective members rights and authorities over their own internal matters, including, but not limited to, a member's surface water supplies, groundwater supplies, facilities, operations, water management, and water supply matters.

1.4.3 GSP Implementation Costs & Funding

The KGA has developed the costs in Table 1-5 for its own administrative and coordination efforts as it serves as the coordination entity for the KGA member agencies. These costs will be funded through cost share agreement with the KGA member agencies.

The cost of implementing SGMA at the member agency level can be found in the management area plans attached to this GSP.

Table 1-5: Estimated Costs for GSP Implementation

Item	Description	Estimated Cost
Annual Administration	Administrative activities for ongoing coordination among Member Agencies and other GSA in the Subbasin and coordination with DWR.	$659,700
Sustainability Management and Coordination	KGA coordination with Member Agencies for coordinated implementation of sustainability management practices	$230,000
Coordinated Monitoring Activities	Basin-wide coordinated monitoring activities, such as, subsidence and evapotranspiration monitoring.	$200,000
Annual Report	Data collection and consolidation from Member Agencies to facilitate annual reporting to DWR	$350,000
5-Year GSP Update and Report	Data collection, consolidation and report generation of KGA 5-year update	$500,000

1.5 GSP Organization

The KGA Umbrella GSP provides SGMA coverage for all the Subbasin lands covered in the management areas of its member agencies. The members of the KGA have prepared management area plans that provide details for all GSP required elements, including the technical detail for setting sustainable management criteria specific for their respective management area. The KGA Umbrella GSP provides an overview and summary, a roll-up concept, of the GSP elements developed in the management area plans. There is a total of 15 management area plans attached to this GSP. This GSP is organized as follows:

2. Introduction
3. Plan Area and Basin Setting
4. Sustainable Management Criteria
5. Projects and Management Actions
6. Plan Implementation

7. References

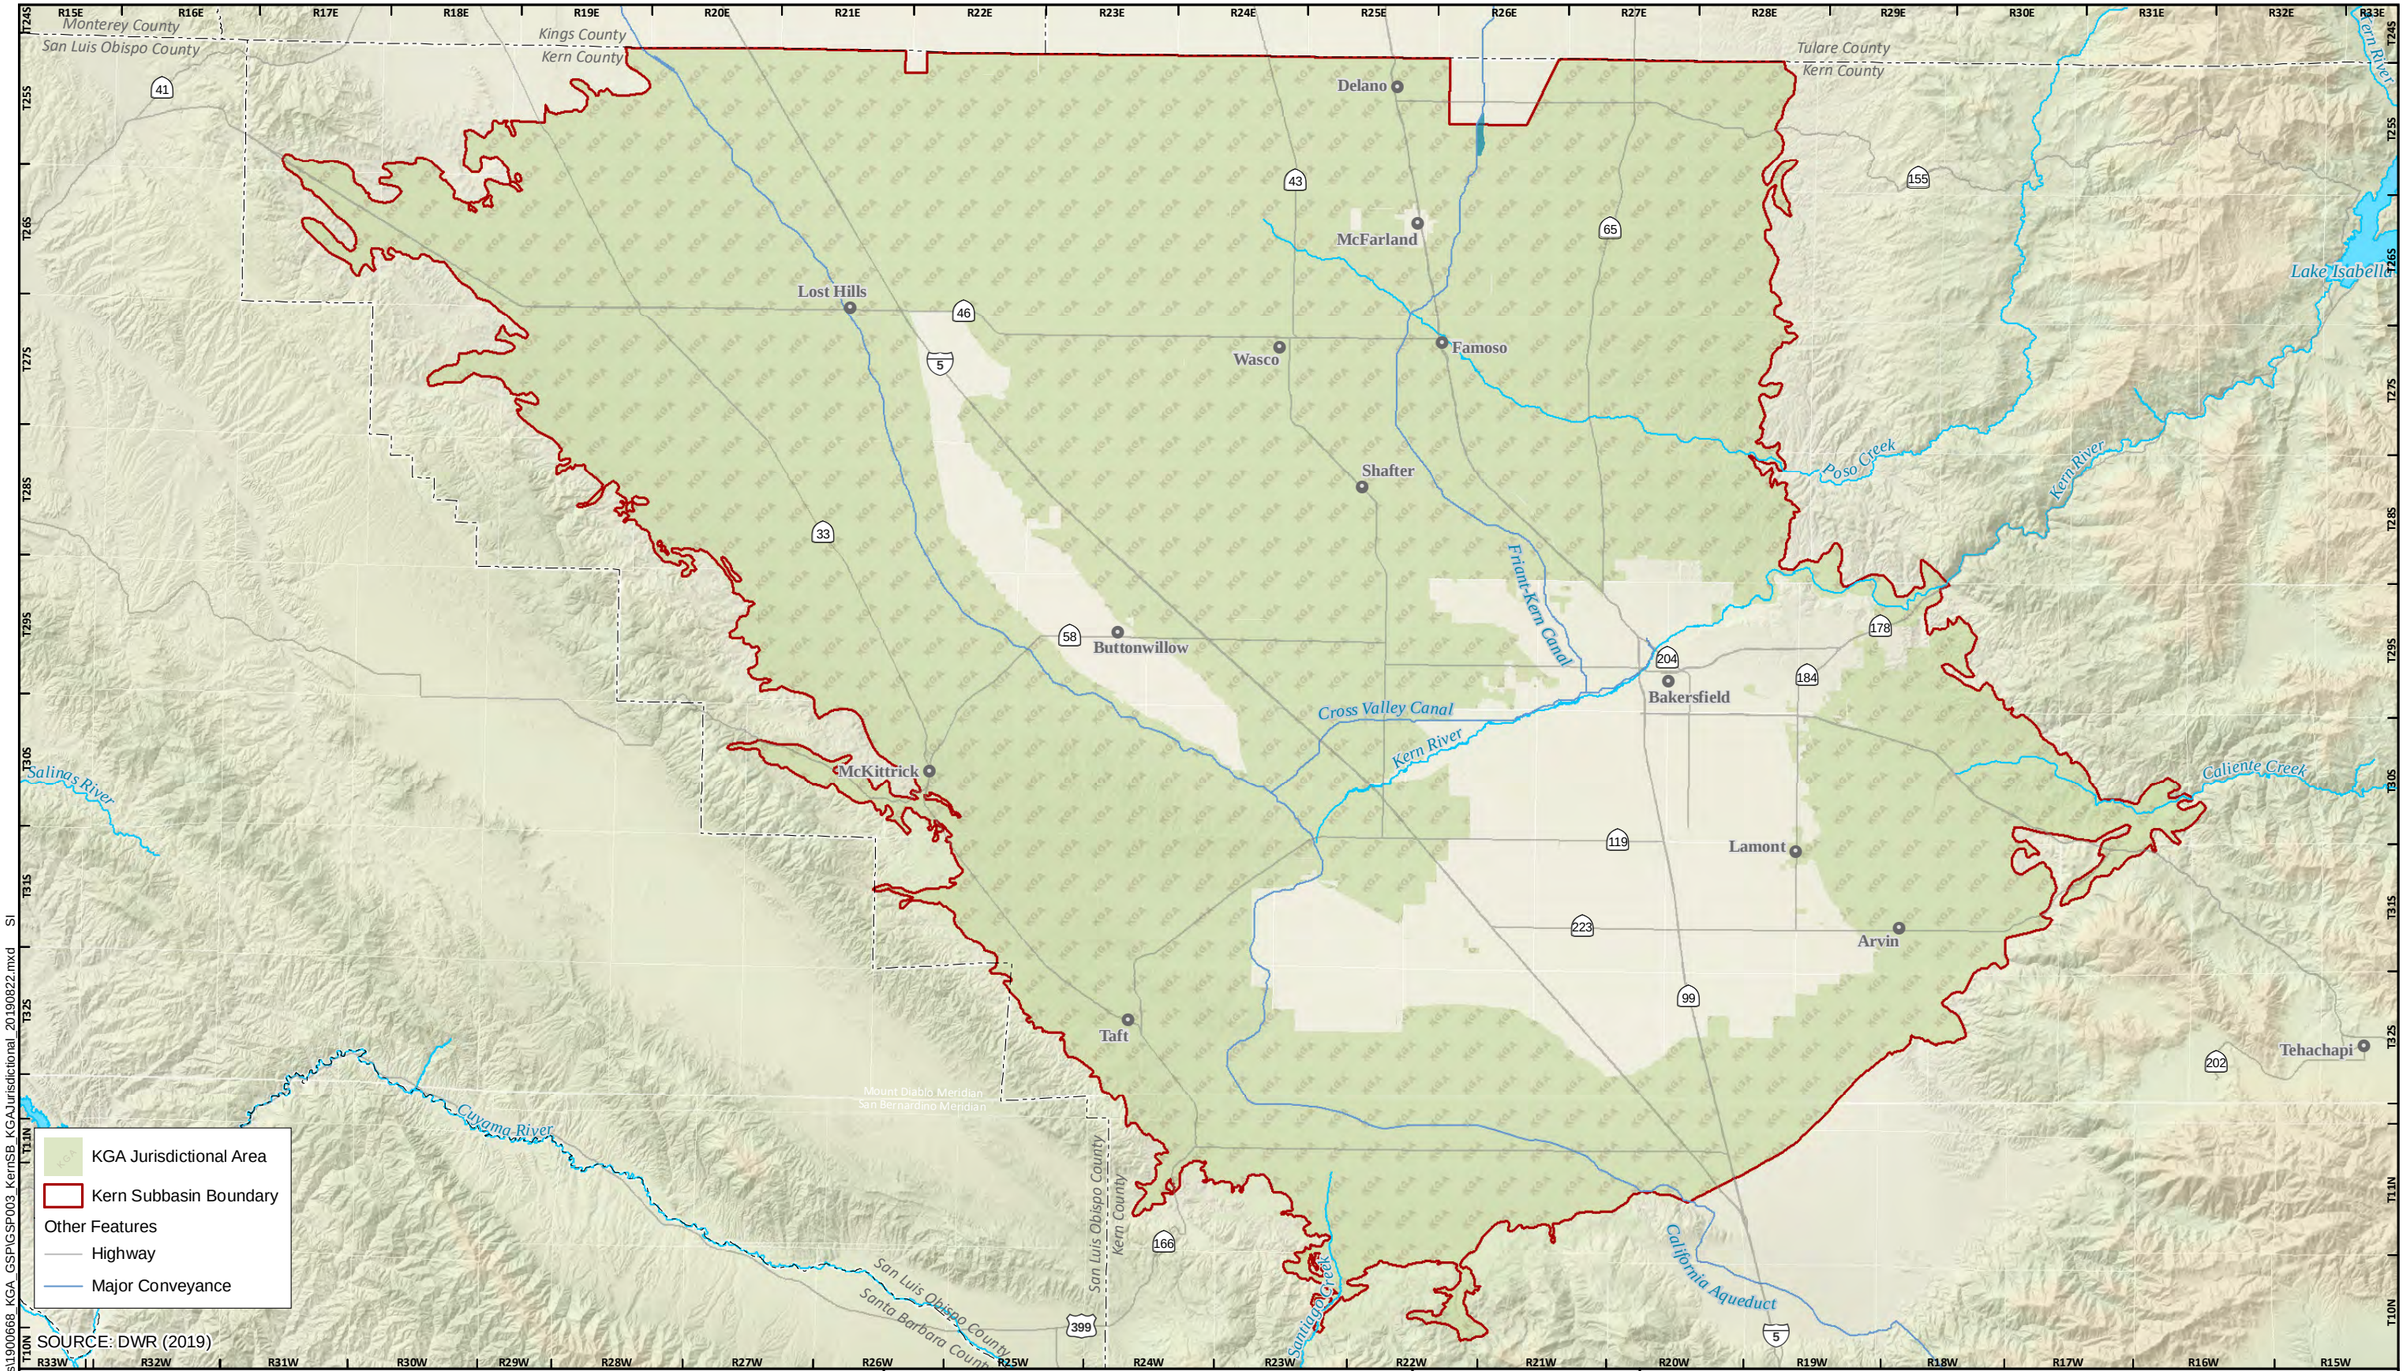
2 Plan Area and Basin Setting

2.1 Description of Plan Area

KGA's jurisdictional boundary is entirely within the Subbasin, as defined in DWR Bulletin 118, South of the Tulare Lake Hydrologic Region of the San Joaquin Valley Groundwater Basin. The following section describes the area covered by the KGA GSP.

2.1.1 Summary of Jurisdictional Areas and other Features

The Subbasin is located within the southernmost portion of the Tulare Lake Hydrologic Region of the San Joaquin River Basin and is bounded by the Sierra Nevada on the east; by the Tehachapi Mountains, San Emigdio Mountains, and White Wolf Subbasin on the South; and the Coast Range (Temblor Range) on the west. As shown in Figure 2-1, KGA's jurisdictional boundary represents 1,617 square miles or approximately 58 percent of the Subbasin. There are no Adjudicated Areas within the Kern County Subbasin.



Hydrologic systems in the Subbasin include numerous rivers, lakes, and canals, many of which are located in the KGA boundaries or are used to supply water to the entire Subbasin. The prominent natural surface water body in the Subbasin is the Kern River, which originates in the Sierra Nevada to the northeast of the Subbasin. Canals and conveyance systems within the Subbasin supply water for beneficial uses throughout the Subbasin. A detailed description of these hydrologic systems is included in Section 2.2 of the basin setting of this Umbrella GSP.

There are several incorporated cities within KGA's jurisdictional boundary as shown in Figure 2-1. There are a number of de minimis domestic water users and multi-parcel water systems located within the KGA jurisdictional area, which will be covered under the management area GSPs.

2.1.2 Plan Area Setting

Land use designations within the KGA jurisdictional boundary are predominantly agricultural (Figure 2-2). Most urban and incorporated land use areas are in the eastern portion of the Subbasin while the agricultural lands dominate the northern, western, and southern portions. For lands covered by a water district, source of water is a combination of surface water and groundwater, as shown in Figure 2-3. Generally, all other lands not covered by a district are dependent on groundwater.

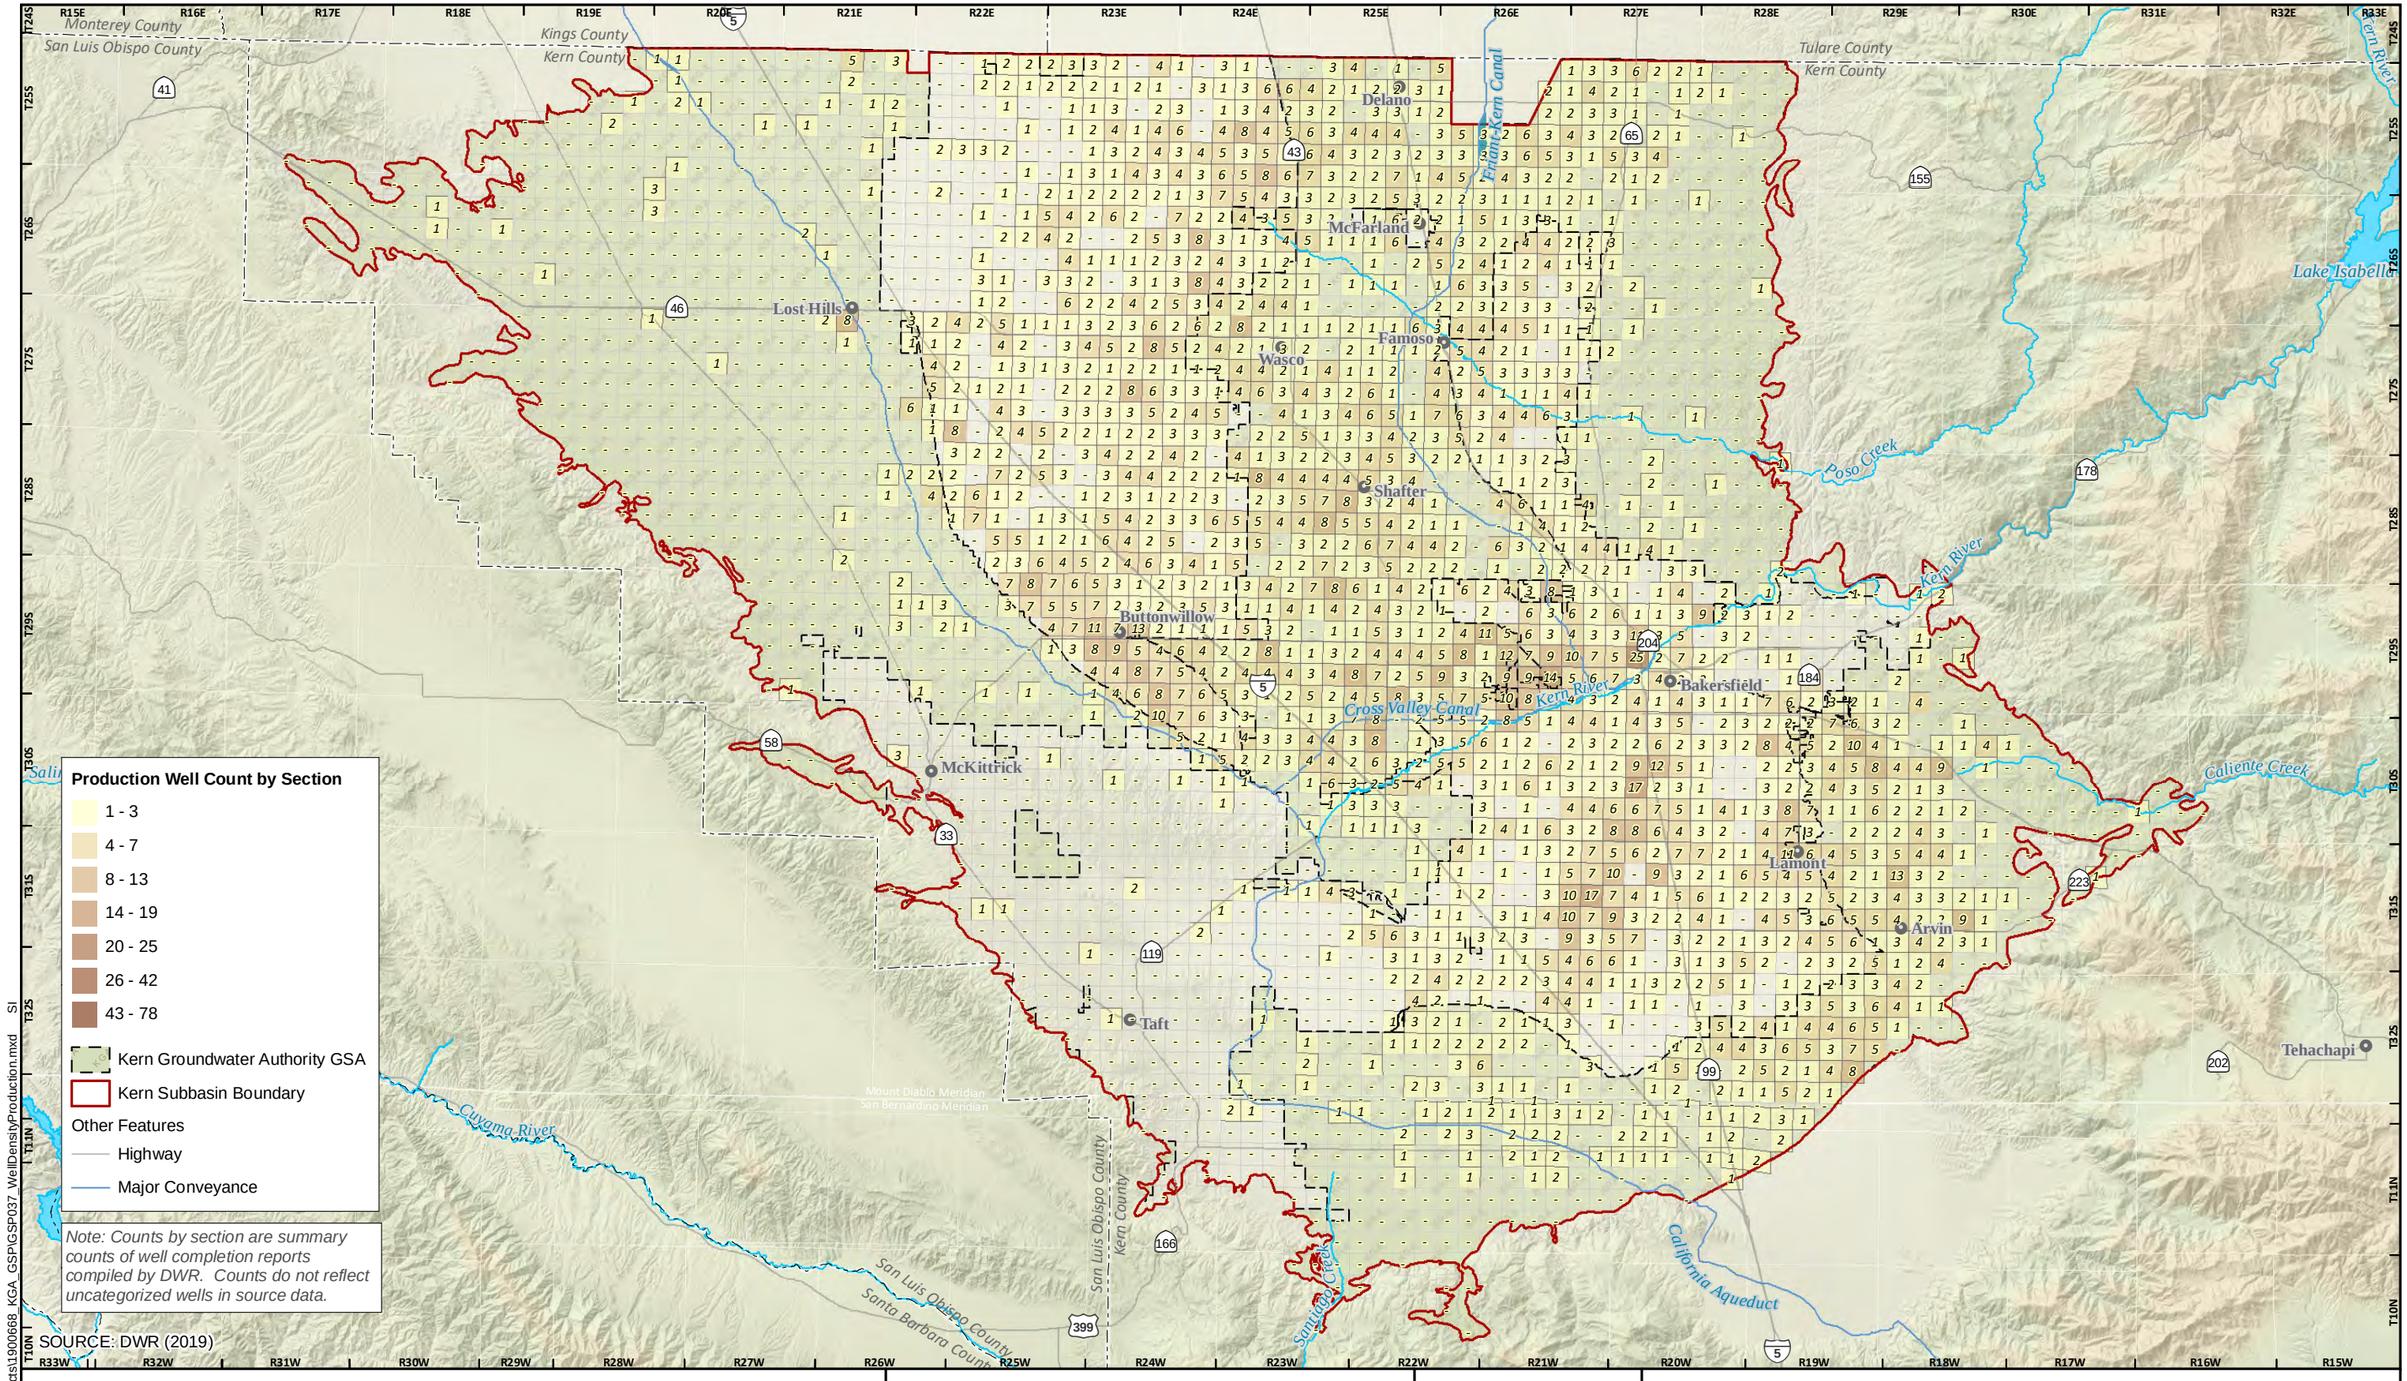
Well densities for production, domestic, and public supply wells within the Subbasin are presented on Figures 2-4 through 2-6, respectively. This dataset is based on well statistics provided by DWR (2019) from the Online System for Well Completion Reports and is intended to be for qualitative informational purposes. Production wells include those described in completion reports as irrigation, municipal, public, or industrial wells. In summary, higher well densities can be found in the central portion of the Subbasin whereas moderate to lower densities are found in the north-east and south-east regions. The western region ranges in areas of low densities to no wells at all. For further information on well types and densities for each management area within the Subbasin, refer to the individual management area plans.

Under the KGA jurisdictional boundary, there are state, small multi-parcel water systems, and domestic water users that are groundwater dependent. In addition, there are incorporated cities within the KGA jurisdictional boundary as shown in Figure 2-7.

2.1.3 Existing Plans in the Plan Area

In general, the goals, policies, and implementation measures established by existing plans (e.g. the Kern County General Plan) are complementary to sustainable groundwater management of the local management areas relative to future land use development and conservation. The plan encourages development of the County's groundwater supply to ensure that existing users have access to high quality water, and states that future growth should be accommodated only while ensuring that adequate high-quality water supplies are available to existing and future users. Below is a list of all existing general plans within the Subbasin. The agencies that developed and adopted the general plans below have retained their jurisdiction over land use and zoning as well as the elements included into their respective general plans. The KGA nor its members have any jurisdiction over the development of general plans within the Subbasin, however, as general plans are being updated in the future, the KGA and its members will actively participate in the coordination of general plan update with the GSP implementation. The descriptions of plans associated with specific management areas are described in greater detail in the management area plans.



- **Kern County General Plan –** This plan was adopted in 2004 and is being updated through the year 2040. Its overall goal is to ensure the county can accommodate anticipated growth and development while maintaining a safe and healthful environment and a prosperous economy by preserving valuable natural resources and assuring the provision of adequate public services (Kern County, 2009).
- **Metropolitan Bakersfield General Plan –** The current plan was first adopted in 2002. This plan aims to achieve goals related to new development, protecting natural resources from environmental damage, as well as preserving agricultural land (City of Bakersfield, 2016) The Metropolitan Bakersfield General Plan is mostly located within the Kern River GSA. There also exists a Metropolitan Habitat Conservation Plan that is mostly located within the Kern River GSA jurisdiction.

- **City of Arvin General Plan –** This plan aims to promote the protection, stewardship, and use of the city's natural resources and to prevent wastefulness, unsustainable usage, and neglect (City of Arvin, 2012).
- **City of Shafter General Plan –** This plan's goals include, but is not limited to, recognizing and retaining commercial agriculture as a desirable land use and as a major segment of the community's identity and economic base (City of Shafter, 2005).
- **City of Wasco General Plan –** This plan was adopted in 2002 and contains objectives, policies and standards specific to the protection of groundwater resources as well as soils and air quality within the City of Wasco and its planning area.
- **City of Delano General Plan –** This plan was adopted in 2005 and aims to protect natural resources, including groundwater, soils, and air quality.
- **City of McFarland General Plan –** This plan was adopted in 1991; however, current versions of the plan do not specifically address groundwater.
- **City of Taft General Plan –** This plan was adopted in 2010; however, the adopted version does not specifically address groundwater.
- **City of Maricopa General Plan –** This plan was adopted in pieces with the last piece adopted in July 2017; however, there is no water element section in the General Plan that specifically addresses groundwater

Successful implementation of this GSP will help to ensure that the Subbasin's groundwater supply is managed in a sustainable manner. Implementation of existing policies are expected to be compatible with management areas strategies in the Subbasin to achieve groundwater sustainability. It is anticipated that implementation of this GSP, while consistent with existing plans and policies to protect water resources, will alter the water supply assumptions and potentially land use plans over the planning horizon. Given that the existing plans are being updated concurrently with the development of this GSP, it is anticipated that future plans would take into account this GSP and utilize consistent water supply assumptions over the 2040 planning horizon.

Land use plans vary between each management area, as they implement policies which best fit their communities. Management area plans provide specific information regarding land use plans and effects of those plans in the individual management areas.

The implementation of land use plans outside of the Subbasin could potentially affect the ability of the KGA to achieve sustainable groundwater management, especially to the north of the Subbasin. However, at this stage, coordination with neighboring Subbasin's has been limited. Future activities of the KGA include increased coordination with neighboring groundwater Subbasins, which will be documented in future updates to this GSP.
