2.1.4 Existing and Ongoing Water Resource Programs

Per Section 354.8(c) of the GSP regulations, this section identifies and describes existing water resources programs in the KGA jurisdictional area. This section provides an overview of each program being implemented within the KGA. Table 2-1 provides a matrix showing which programs are being implemented within each management area. Additional details are provided in the individual management area plans.

2.1.4.1 Management Plans

The State of California has pre-SGMA programs for the management of groundwater supply and quality. These programs are managed at various levels of government by existing public agencies, either individually or collaboratively with neighboring agencies within the same groundwater basin. The following section provides an overview of these management programs and the elements addressed in each.

Groundwater Management Plans

In 1992, the State of California passed the Groundwater Management Act (AB 3030). This legislation provided guidelines for the agencies and districts to provide planned and coordinated monitoring, operation, and administration of groundwater basins with the goal of long-term sustainability. There are several types of Groundwater Management Plans, which are described below.

Pre-SB 1938 Plans: These plans, typically adopted before 2002, could be prepared by a local agency in a Bulletin 118-desginated basin on a voluntary basis. The voluntary components of these plans include:

- The control of saline water intrusion.
- Identification and management of wellhead protection areas and recharge areas.
- Regulation of the migration of contaminated groundwater.
- The administration of a well abandonment and well destruction program.
- Mitigation of conditions of overdraft.
- Replenishment of groundwater extracted by water producers.
- Monitoring of groundwater levels and storage.
- Facilitating conjunctive use operations.
- Identification of well construction policies.
- The construction and operation by the local agency of groundwater contamination cleanup, recharge, storage, conservation, water recycling, and extraction projects.
- The development of relationships with state and federal regulatory agencies.
- The review of land use plans and coordination with land use planning agencies to assess activities which create a reasonable risk of groundwater contamination.

Table 2-1: Summary of KGA Water Resources Programs

SB 1938 Plans: These plans were generally adopted during or after 2002, incorporating the elements of the Pre-SB 1938 Plans. With the passage of SB 1938, the following components were required as part of any Groundwater Management Plan:

- Basin Management Objectives: The Groundwater Management Plan shall include Basin Management Objectives relating to the monitoring and management of groundwater levels within the groundwater basin, groundwater quality degradation, inelastic land surface subsidence, and changes in surface flow and surface water quality that directly affect groundwater levels or quality or are caused by groundwater pumping in the basin.
- Agency Cooperation: The local agency shall prepare a plan to involve other agencies that enables the local agency to work cooperatively with other public entities whose service area or boundary overlies the groundwater basin.
- Mapping: The local agency shall prepare a map that details the area of the groundwater basin, as defined in DWR's Bulletin 118, and the area of the local agency, that will be subject to the Groundwater Management Plan, as well as the boundaries of other local agencies that overlie the basin in which the agency is developing a Groundwater Management Plan.
- Monitoring Protocols: The local agency shall adopt monitoring protocols that are designed to detect changes in groundwater levels, groundwater quality, inelastic surface subsidence (in basins for which subsidence has been identified as a potential problem), and flow and quality of surface water that directly affect groundwater levels or quality or are caused by groundwater pumping in the basin.
- Located outside Bulletin 118 Groundwater Basins: Plans located outside DWR Bulletin 118 alluvial groundwater basins will incorporate the above components and shall use geologic and hydrologic principles appropriate to those areas.

AB 359 Plans: When AB 359 was enacted in 2013, it required additional technical components related to groundwater recharge areas and modification to several of the existing groundwater management plan adoption procedures in place as part of SB 1938. The additional technical components are as follows:

- The groundwater projects to which these requirements apply include projects that are part of an integrated regional water management program or plan.
- Groundwater projects require a description of how recharge areas identified in the plan substantially contribute to the replenishment of the groundwater basin and a map identifying the recharge areas, as defined, for the groundwater basin to be included in a groundwater management plan for purposes of the state funding requirements.
- Require the local agency to provide the map of the recharge areas to local planning agencies and notify the department and other interested persons when a map is submitted to those local planning agencies.

Integrated Regional Water Management Plans

In 2002, the Regional Water Management Planning Act (SB 1672) created the Integrated Regional Water Management (IRWM) Program. The IRWM Program is used as a collaborative effort to identify and implement water management solutions on a regional scale that increase regional self-reliance, reduce conflict between agencies and users, and manage water to concurrently achieve social, environmental, and economic objectives. By collaborating on projects, participants in the IRWM Program can provide these benefits and meet their water supply and quality goals. In the Kern County Subbasin, there are two IRWM Plans: the Poso Creek IRWM Plan and the Kern County IRWM Plan.

USBR Water Management Plans

The Central Valley Improvement Act of 1992 and Section 210(b) of the Reclamation Reform Act of 1982 requires certain entities to prepare and submit a Water Management Plan. Entities required are those that enter into a repayment contract or water service contract with the Bureau of Reclamation. Not all member agencies under KGA are required to have a plan under USBR. Refer to management area plans for specific details.

Irrigated Lands Regulatory Program

The Tulare Lake Basin General Order (Order R5-2013-0120) was passed by the Regional Water Quality Control Board (RWQCB) in 2006. This order requires that any irrigated land having the potential to discharge to surface water or groundwater must comply with the requirements set by the RWQCB. Compliance includes membership in a Coalition or obtaining coverage through an Individual Order from the RWQCB. Several districts in the KGA jurisdictional area are members of the Kern River Watershed Coalition Authority, which was formed in 2011.

Groundwater Export Ordinance

Kern County adopted a groundwater export ordinance in 1998, which requires a Conditional Use Permit for export of water to areas both outside the County and within watershed areas of underlying aquifers in the County. The ordinance applies only to the southeastern drainage of the Sierra Nevada and Tehachapi mountains in the South Lahontan Hydrologic Region in eastern Kern County.

Title 22 Drinking Water Program

The Division of Drinking Water regulates public drinking water systems, which include municipal and state small water systems. These systems are required to comply with the standards set forth in Title 22 of the California Code of Regulations. For single parcel/single-connection systems, Kern County Environmental Health Services provides regulation and oversight to meet the requirements of Title 22.

2.1.4.2 Conjunctive Use Programs

Conjunctive use or "the coordinated use of surface water and groundwater" has been used for many years in Kern County, for the benefit of water users, to allow for flexibility in the way water is delivered, whether climatic conditions allow for imported surface water, or if

groundwater is needed in any given year. Conjunctive use is further described by the Water Education Foundation with the following: "In its passive form, also called in-lieu conjunctive use, surface water is used in wet years and groundwater is used in dry years. In active conjunctive use, surface water is directly injected into aquifers and wells to be used as needed as part of groundwater banking" (Water Education Foundation, 2019).

In the Kern Subbasin, conjunctive use plays a vital role for all beneficial users to coordinate the use of surface water and groundwater to improve the overall reliability of water supply. Whether it be water used to irrigate crops or to service communities for drinking water purposes, all users benefit from conjunctive use programs throughout the Subbasin. Conjunctive use programs in the Subbasin have been developed to capture and transport wet year surface water for the purpose of groundwater recharge and offset use of groundwater pumping. In turn, this prepares the basin for dry periods when groundwater may be limited. Projects such as interties, pipelines, and recharge basins have been developed, financed, and implemented by districts within the Kern Subbasin to deliver, bank, and return surface water, as well as replenish aquifers to better prepare for and manage during times of dry periods when beneficial users are more reliant on groundwater. Many of these types of projects have been incorporated in other state programs, such as the IRWM program. In the Kern Subbasin, there are two IRWM regions including the Poso Creek IRWM Region and the Kern IRWM Region. Both regions have developed plans to manage water use and delivery as well as the development of water related projects. Further information on the types of conjunctive use programs in the Kern Subbasin can be found in each of these plans. Additionally, many of the projects captured in the IRWM plans are included in the management area plans as project and management actions to be implemented within the Kern Subbasin to achieve groundwater sustainability.

The majority of the KGA member agencies partake in groundwater banking and recharge programs. The purpose of these programs is to bring surface water into the Subbasin to recharge groundwater levels and better prepare for and manage water during times of dry periods or in wet periods where water is of excess. Groundwater banking refers to recharging specific amounts of water in a groundwater basin that can later be withdrawn and used by the entity that deposited the water.

KGA member agencies have banking agreements amongst each other. For example, members of the Poso Creek IRWM such as Semitropic WSD and North Kern WSD, operate long-term water banking programs that allow banking partners, including districts outside of the Poso Creek IRWM Region, to store surplus water in another district and to recover their water when needed. These districts receive surface water from the banking partners in years of ample supplies and deliver it to their landowners for irrigation use in-lieu of groundwater pumping (*Poso Creek Integrated Regional Water Management Plan, 2019 Update*). Once banked, the entity depositing the water receives a credit and groundwater which otherwise would have been pumped remains in storage. In the Poso Creek IRWM Region alone, there is approximately 25,000 acre-feet per month of recharge capacity that can be used to bank imported surface water.

In addition to banking programs within the Poso Creek IRWM Region, other prominent groundwater banking facilities in the Kern Subbasin include the Kern Water Bank and Kern

County Water Agency - Pioneer Project. These are facilities managed by the Kern Water Bank and the Kern County Water Agency, respectively. Kern Water Bank contains approximately 7,000 acres of recharge ponds, which can recharge up to 72,000 acre-feet per month. When water is available to the Kern Subbasin which cannot be absorbed, these water banking projects provide additional storage facility for otherwise potentially lost surplus surface supplies available during wet years. Most members of the KGA participate in banking and recharge programs in one way or another. For further explanation of banking and recharge programs as well as district involvement, refer to individual management area plans.

2.1.4.3 Well Permitting Process

Well permits within the Subbasin are issued by the Kern County Public Health Services Department Water Well Program and will continue under SGMA. Kern County will continue to retain jurisdiction over the water well permitting process. The Water Well Program issues permits to construct, reconstruct, and destroy water wells. All wells must be constructed in accordance with Kern County Ordinance Code, Section 14.08, and the State Department of Water Resources' Bulletin 74-81 and Bulletin 74-90, except as modified by subsequent revisions. The ordinance requires, among other things, that domestic and agricultural wells be installed a minimum distance from potential pollution and contaminant sources; water quality be tested for new and reconstructed wells; an NSF 61 approved flowmeter be installed; and the final well construction be inspected by Kern County staff.

Through a collaborated process, the Kern Subbasin GSAs, with the KGA taking the lead, worked with the Kern County Public Health Services Department to develop a supplemental well application for wells to be installed within the Kern Subbasin (Figure 2-8). This new form requires the applicant to provide additional information regarding construction of the well, proposed use, and amount of water to be pumped. If the applicant knows the water district and GSA in which the well will be located, it is indicated on the form. The application is completed and submitted to the Kern County Public Health Department where it is forwarded to the appropriate water district or GSA, through the KGA Planning Manager. The district in which the well is located is able to provide comments on the application advising the applicant of sustainability criteria that may impact the operation of the well. This process has been in place since January 2019 and demonstrates coordination between Kern County Public Health Services requirements and SGMA requirements concerning water well permitting processes.

2.1.4.4 Plan Elements from CWC Section 10727.4

Per Section 354.8(g) of the GSP regulations, each plan shall include a description of any additional GSP elements included in Water Code Section 10727.4 appropriate to the region. While management area plans provide full details for each element, this section provides a brief overview.

(a) Control of saline water intrusion.

- Because the Kern County Subbasin is located far from coastal areas, saline water intrusion is not considered to be an issue.

Figure 2-8. Kern County Public Health Services – Overdrafted Basin Supplemental Well Application

(b) Wellhead protection areas and recharge areas.

- Kern County Public Health Services Department Water Well Program issues permits to construct, reconstruct, and destroy water wells (see Section 2.1.4). Recharge areas are managed by individual water districts in the Subbasin to bring in surface water to recharge the groundwater aquifers. Many districts engage in banking programs and work conjunctively to exchange water to support the sustainability of the Subbasin.

(c) Migration of contaminated water.

- The mitigation, remediation, and management of groundwater contamination plumes is regulated in the Subbasin by the Central Valley Regional Water Quality Control Board (CVRWQCB) and the County of Kern. Groundwater contamination plumes have been identified by individual districts, which actively monitor groundwater sampling and work with the CVRWQCB to address groundwater contamination issues. Contamination plumes are not found in every district under KGA, refer to management area plans for specific information.

(d) A well abandonment and well destruction program.

- Kern County Public Health Services Department Water Well Program issues permits to construct, reconstruct, and destroy water wells (see Section 2.1.4).

(e) Replenishment of groundwater extractions.

- KGA member agencies actively manage the groundwater basin within their respective boundaries through conjunctive use and other programs. For specific details pertaining to each management area refer to their management area plan.

(f) Activities implementing, opportunities for, and removing impediments to, conjunctive use or underground storage.

- KGA member agencies actively manage the groundwater basin within their respective boundaries through conjunctive use and other programs. Refer to management area plans for specific details pertaining to each management area.

(g) Well construction policies.

- Kern County Public Health Services Department Water Well Program issues permits to construct, reconstruct, and destroy water wells. To see how this process is coordinated under SGMA with the Subbasin GSAs, see Section 2.1.4.3.

(h) Measures addressing groundwater contamination cleanup, groundwater recharge, in-lieu use, diversions to storage, conservation, water recycling, conveyance, and extraction projects.

- Oversight of groundwater contamination cleanup is provided by the CVRWQCB and the County of Kern.

- Recharge policies exist across the Subbasin that allows on-farm banking as well as banking and exchanges with other districts in the region.
- Conservation and irrigation efficiency practices have been encouraged and incorporated both at the district and grower level.
- In-lieu use, diversions to storage, water recycling, conveyance, and extraction projects on managed on a district level in the Kern Subbasin.

(i) Efficient water management practices, as defined in Section 10902, for the delivery of water and water conservation methods to improve the efficiency of water use.

- KGA Member Agencies are constantly pursuing efficiency with their water management practices through management plans as outlined in the management area plans.

(j) Efforts to develop relationships with state and federal regulatory agencies.

- Many of the member agencies under KGA hold state and federal water contracts as well as work closely with DWR on projects and management practices. Refer to management area plans for further details.

(k) Processes to review land use plans and efforts to coordinate with land use planning agencies to assess activities that potentially create risks to groundwater quality or quantity.

- There are a number of water use and land use programs member agencies are involved in within the Kern Subbasin that require land use plans. Refer to management area plans for further details.

(l) Impacts on groundwater dependent ecosystems.

- This element is covered in the KGA Umbrella Chapter, Section 2.3.8, as well as the individual management area plans.

2.1.5 Notice and Communication

SGMA requires that GSAs consider the interests of all beneficial uses and users of groundwater and to encourage and include them in the GSP development process. To capture the intent of SGMA, as legislation better served under local control, KGA member agencies played a vital role in the development of this GSP. This process included communication and outreach at the local level, with each KGA member agency engaging with its beneficial users to gather vital input, data, and feedback to ensure the success of this GSP and individual management area plans.

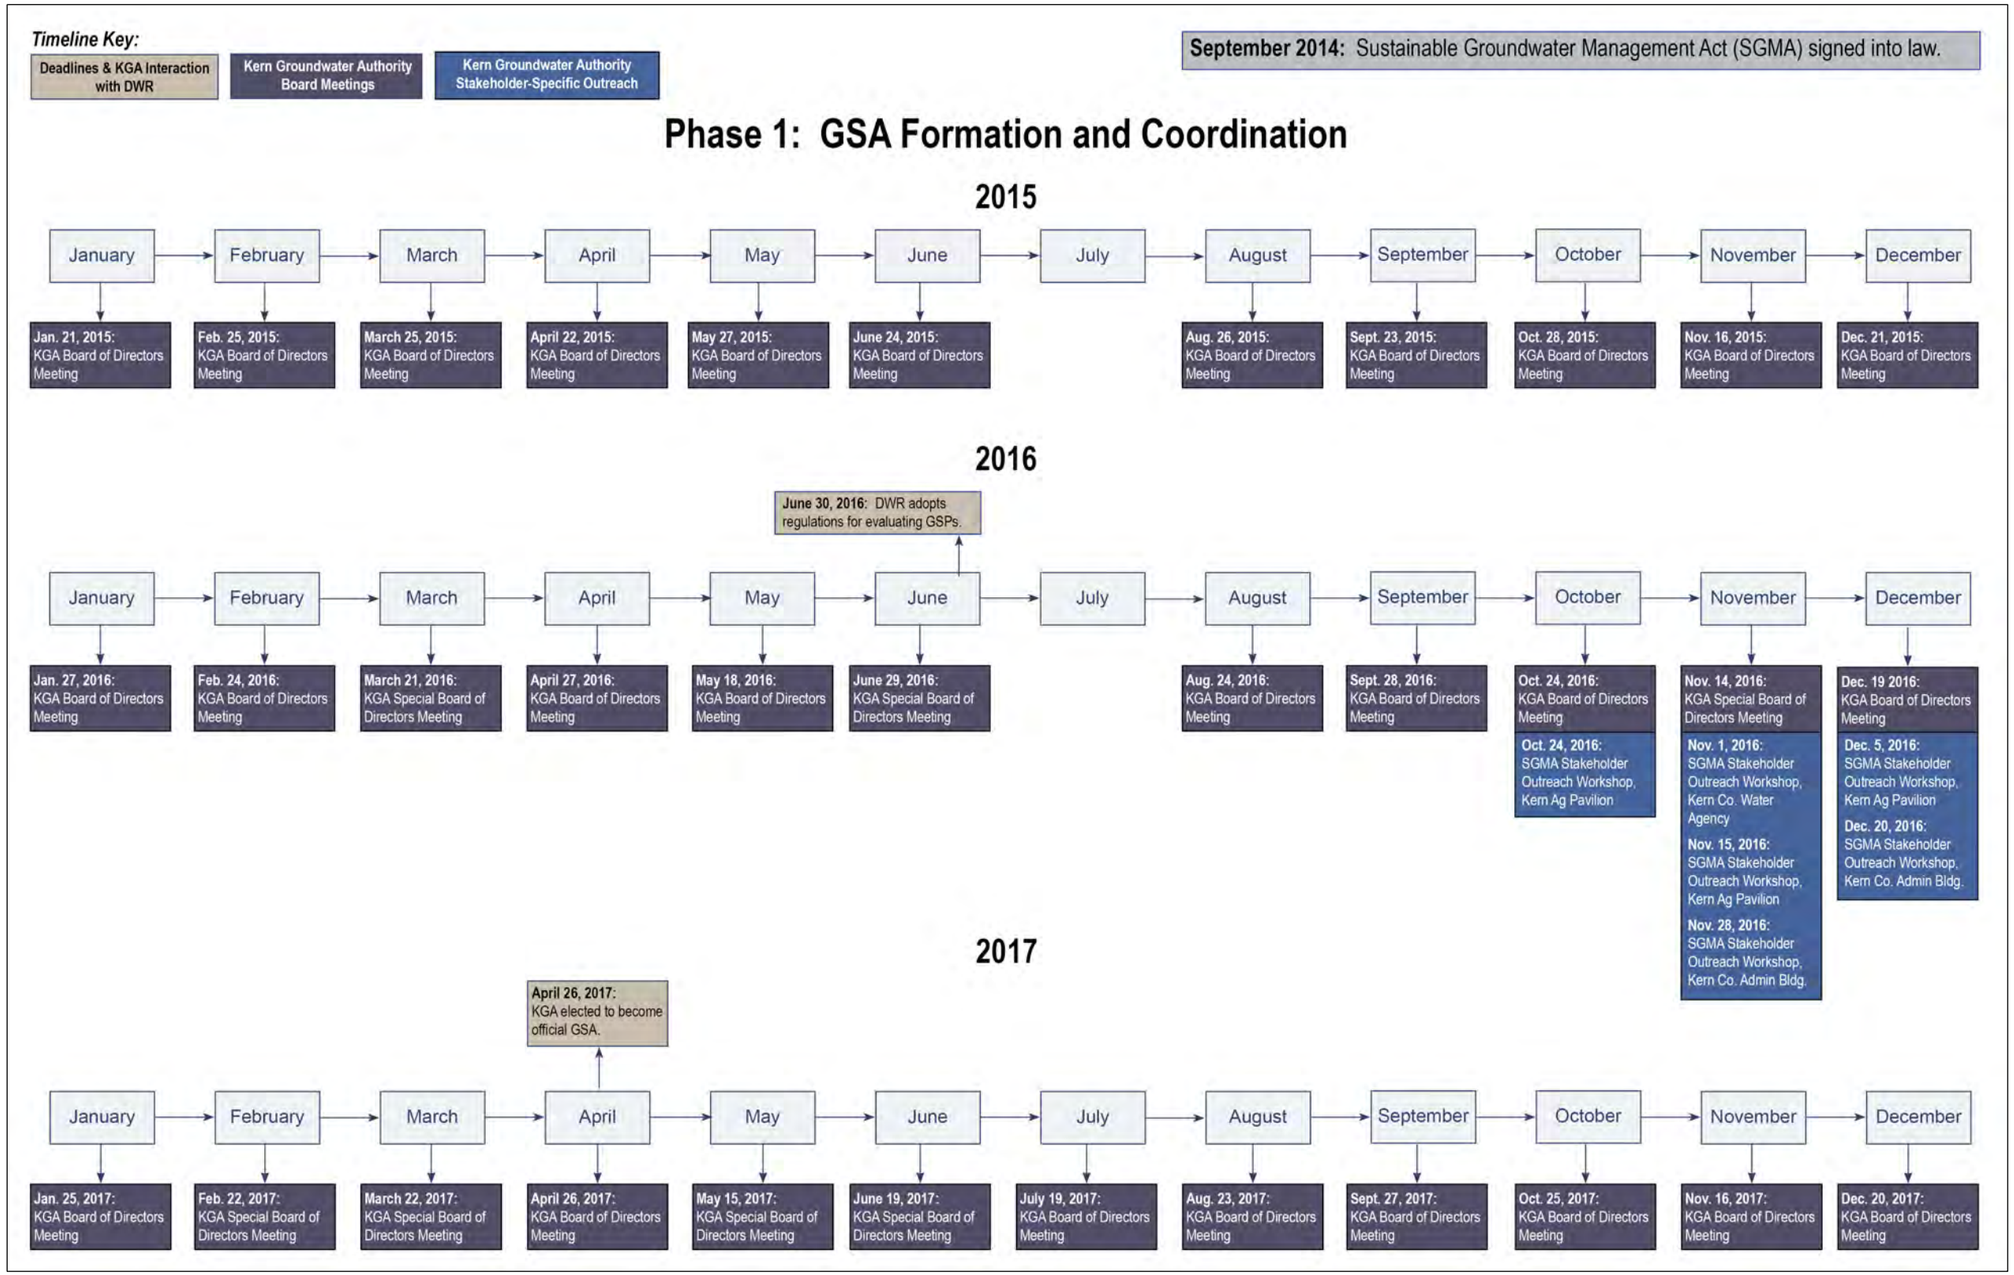
In May of 2018, the KGA initiated the development of a Communication and Engagement Plan (C&E Plan) (Attachment E) to facilitate and assist KGA member agencies in stakeholder engagement and outreach. KGA communication and outreach consisted of stakeholder meetings and workshops; maintaining an interested parties list for KGA events; and development of a Stakeholder Survey and Agricultural Survey for the benefit of KGA member agencies. In

addition to outreach and communication through the KGA, each member agency was tasked with conducting their own communication and outreach to better capture the diverse needs of their beneficial users within their jurisdictional areas. By receiving information directly for member agencies using a local control approach, users greatly benefitted.

For more detailed information on KGA member agency communication and outreach efforts please see the member agencies' management area plans.

2.1.5.1 Description of Beneficial Uses and Users in the Subbasin

As was previously stated, as required by SGMA, GSAs must consider the interests of all beneficial uses and users of groundwater and include them in the GSP development process. For the KGA and its member agencies, beneficial users are stakeholders who have an interest or a need in groundwater use within the boundaries of the KGA. With the development of the C&E Plan the focus was to address the opportunities for engagement and to encourage participation by beneficial users. Located within the C&E Plan are lists of beneficial users as well as a stakeholder engagement timeline based on phases of the GSP development and implementation processes. The engagement timeline for the KGA are shown in the following figures; Figures 2-9, Phase 1: GSA Formation and Coordination; Figure 2-10, GSP Preparation and Submission; and Figure 2-11, GSP Review and Evaluation.



Another component of the C&E Plan was the development of the interest parties list. The interested parties list began development immediately and is constantly updated to include all interested parties who sign in/attend any of the monthly meetings held by the KGA and/or its member agencies.

The development of the Stakeholder Survey and Agricultural Survey was a vital instrument in the KGA outreach during the process of the development of the management area plans. To capture as many diverse beneficial users as possible, the Stakeholder Survey was developed in both English and Spanish and was available at workshops, stakeholder meetings, and both were accessible on the KGA website where they could be completed online. The information provided by the beneficial user assisted the KGA member agencies in the development of their projects and management actions. These surveys are located on the KGA website and can be completed online anytime during the process of the development of the management area plans. Monthly, the KGA took the information provided from those surveys and provided a summary report to the KGA Board of Directors, the KGA member agency managers, and to the public for their consideration.

2.1.5.2 Communication

Decision-Making Process

KGA was formed by a JPA that stipulates that each member agency has the sole right and responsibility to develop and implement SGMA within its respective boundaries; however, the KGA Board is the final decision-maker for the KGA and its member agencies, except for the implementation of SGMA within a management area. Implementation of SGMA is to be governed by the member agency within its jurisdiction.

Provost & Pritchard Consulting Group • Updated December 2019

Figure 2.11. Kern Groundwater Authority's Communication & Engagement Timeline – Phase 3: GSP Review and Evaluation

This Page Left Blank Intentionally

The JPA is written to provide open and transparent communication to all beneficial users; thus, the KGA's decision-making process consists of several public meeting opportunities:

- The KGA Board of Directors public meetings are on the fourth Wednesday of every month and include presentations regarding the development of the GSP as well as decisions on coordinated SGMA requirements with the other GSAs in the Subbasin. Public meetings also include administrative and financial decisions. Meeting notification includes public posting of the board agenda and background materials on the KGA website and an email notification to the interested parties list a week prior to the meeting, which also includes all relevant meeting materials.
- As the Subbasin GSPs were developed, KGA and the other GSAs established coordination meetings. These meetings began in July 2018 to coordinate each of the five GSPs scheduled to be developed and submitted to DWR. These meetings are held every Friday morning and are attended by all KGA member agency managers and the other four GSA managers. These meetings included discussions to obtain an understanding and consensus on the data and methodologies used in the five GSPs. Once an understanding and consensus was reached, the data and methodology were then discussed at the Kern GSA Coordination Committee meeting, where each of the five GSAs are represented by a policy or board member and a staff manager, as well as at stakeholder public meetings.
- Stakeholder public meetings were held on the first Monday of every month where presentations were made concerning the development of this GSP as well as items that need to be coordinated under SGMA with the other GSAs. These meetings began under the name of the Coordination Committee and then changed to Stakeholder meetings in 2018. Typically, meetings were open discussions with occasional presentations for specific GSP elements. If there were no new developments on the GSP, meetings were cancelled to take into consideration beneficial users' time. All meeting dates and presentation materials are located on the KGA website with email notifications sent out to the interested parties list prior to meetings, which included all relevant meeting materials.
- Kern GSA Coordination Committee meetings were established to coordinate the data and methodologies at a policy-level. These meetings were held on the third Wednesday of every month and were attended by one policy decision-maker from each of the GSAs and staff members to assist in the discussion. These meetings were established to maintain the coordination as well as the requirement of utilizing the same data and methodologies throughout the development of the five GSPs.

Public Engagement Opportunities

As previously stated, each KGA member implemented its own outreach programs to provide opportunities for beneficial users to participate in the development of individual management area plans. The details of these outreach programs can be found in the management area plans. However, the KGA held several public workshops, stakeholder meetings (mentioned above),

Farm Bureau meetings discussions, and media outreach. These meetings are listed in the C&E Plan and are also indicated in the list below.

2.1.5.3 Informing the Public about GSP Development Progress

KGA Website

The website was established immediately upon approval as an exclusive GSA and is updated monthly with materials from all the meetings including presentation materials and board packages. There is also a Resource & Outreach tab that provides the technical reports and workshop materials.

Interested Parties List

An email distribution list of stakeholders and beneficial users was developed and is constantly updated for outreach and notices throughout the GSP planning process. The list is maintained and updated by the KGA and is included in the C&E Plan.

Media

The KGA has participated in several media segments televised by Kern Golden Empire Television (KGET) Channel 17 – Kern County in Depth segment. There have been three tapings since the establishment of SGMA, one for the formation of the GSAs, the withdrawal of Kern County impacts to SGMA and the beginning process of the GSP, and the release of the GSP and the process moving forward. These are televised for a month and are also located on KGET Channel 17 website.

2.1.5.4 Public Comments

Public comments were collected throughout GSP development process and incorporated into the development of KGA Umbrella GSP and the management area plans of the KGA members, as described above. Additionally, the KGA prepared a Public Draft Kern Groundwater Authority Groundwater Sustainability Plan in August 2019. The draft KGA GSP was made available during a noticed public comment period from August 30, 2019 to November 28, 2019. Comments received were considered and responded to either in this final version of the KGA GSP or were forwarded to the appropriate KGA member agency for their consideration. All comments received and responded to those comments are included in Attachment F.

2.2 Basin Setting

This basin setting focuses on the area encompassed within the jurisdiction of the KGA, its participating members agencies, and collaborators. Figure 2-1 presents the current extent of the KGA jurisdictional area and member agencies. Due to the proximity of adjacent GSAs, details and data from adjacent GSAs are included herein. This basin setting is intended to represent an overview of the entire Subbasin. Additional details are included in the basin setting description of other GSPs prepared in the Subbasin and in the management area plans prepared by KGA member agencies.

2.2.1 Hydrogeologic Conceptual Model

Numerous descriptions and reports of local hydrogeologic conditions are available for the Subbasin. Details from previous investigations relating to the regional geologic and structural setting of the Subbasin; geologic features affecting groundwater flow; vertical and lateral boundaries; primary aquifers and aquitards; groundwater elevations and flow direction over time; and water quality are described below. This information is the foundation for the hydrogeologic conceptual model (HCM).

This HCM has been prepared under the supervision of Matthew Mayry, Certified Hydrogeologist.

2.2.1.1 Kern County and Lateral Boundaries

The Kern County Subbasin (5-022.14) (Figure 2-12), is within the southernmost portion of the Tulare Lake Hydrologic Region of the San Joaquin River Basin (5-022). The Subbasin encompasses a surface area of 1,792,000 acres (2,800 square miles) and contains approximately 32,000 feet (6 miles) of marine and continental sediments (DWR, 2006; Page, 1986). The Subbasin has approximately 40,000,000 acre-feet (AF) of groundwater storage with another 10,000,000 AF of storage capacity, including areas where water levels have declined (DWR, 2006). A recent U.S. Geological Survey (USGS) estimate of sediment thickness is 3 miles for the San Joaquin Valley (Faunt et al., 2009). Continental sediments comprise up to approximately 3,400 feet of the material along the Kern River near the town of Tupman (western side of the valley), and the base of the fill is over 18,000 feet deep (Davis et al., 1959).

The lateral boundaries of the Subbasin, are defined by various jurisdictional and geomorphic segments, as presented by DWR (2016b). The Subbasin is bounded by the Sierra Nevada on the east; by the Tehachapi mountains, San Emigdio mountains, and White Wolf Subbasin (5-022.18) on the south; and the Coast Range (Temblor Range) on the west. To the north of Subbasin are the following Subbasins: Kettleman Plain (5-022.17), Tulare Lake (5-022.12), and Tule (5-022.13).

Figure 2-12. Kern County Subbasin and Vicinity

2.2.1.2 Regional Geologic and Structural Setting

A brief description of the evolution of valley sediments and fill is included below, as it relates to the regional aquifer system of the Tulare Lake Region of the San Joaquin Valley Basin.

During pre-Tertiary time granitic rocks were deposited in the present-day area of the Sierra Nevada and Tehachapi Mountains (eastern and southeastern flanks of the Subbasin). Plutonic and tectonic activity also formed metamorphics that occur along the margins of the Subbasin. As tectonic activity uplifted these granitic and metamorphic deposits, erosion with subsequent transport of sediment into the basin occurred. These rocks form an almost impermeable boundary for the groundwater basin, but fractures and joints permit small yields of water to wells (Page, 1986).

Near the end of the Late Cretaceous, tectonic movements elevated the Coast Ranges to the west of the Central Valley which created a marine embayment in the present-day Southern San Joaquin region. During the Tertiary, seas advanced and retreated within this southern embayment, resulting in deposits comprised of both continental and marine sediments. The most recent of which are the Pyramid Hills, Vedder Sand, Olcese Sand, Santa Margarita Formation, and San Joaquin and Etchegoin Formations.

During the late Tertiary, uplift of basement occurred near present-day Bakersfield forming what researchers have termed the Bakersfield Arch. The Arch effectively resulted in depocenters for thick sequences of sediment to accumulate to the north and south of the Kern River (Bartow, 1991; Vasconcellos, 2016; Figure 2-13) during later Tertiary and Quaternary time. Tertiary crustal uplift and shifting caused the formation of the Sierra Nevada, Temblor, and Coast Ranges (Bartow, 1991). Crustal deformation along the proto-San Andreas and present-day San Andreas led to the formation of the structural traps for oil and gas accumulation throughout the west-side.

The Quaternary Period (Pleistocene and Holocene), marked a time when the seas retreated, and continental deposits from alluvial and fluvial systems formed (Tulare and Kern River Formations (Page, 1986). Marine rocks and deposits are, in part, the source rocks for the Tulare Formation on the west and the granitic from the Sierra Nevada on the east are the source rocks for the Kern River Formation. Some of the marine deposits on the west, contain saline water, that could have migrated into adjacent and overlying continental deposits (Page, 1986). Overall, the continental rocks make up most of the regional aquifer system in the central and eastern sides of the Subbasin while brackish to freshwater deposits and eroded marine deposits of the Coast Range make up a very small portion of the water-bearing units on the western side of the Subbasin.

The Pleistocene Epoch was dominated by brackish and freshwater lakes within the Subbasin, resulting in thick deposits of clay, as found throughout the upper Tulare Formation. In particular, the Corcoran Clay has been mapped over much of the San Joaquin Valley (including Tulare Lake Region), and its equivalents have been correlated to clays beneath the Kern and Buena Vista dry lake beds in the southern part of the Subbasin, as well as the Tulare Lake sediments on the northern boundary of Kern County (Croft 1972; Page, 1986) (Figure 2-14). This clay makes up a considerable impermeable to semipermeable zone that divides shallower poor-quality water from higher quality water of the regional aquifer system.

APPROXIMATE THICKNESS AND EXTENT OF E-MODIFIED CORCORAN CLAY

JULY 2019

FIGURE 2-14

Since the Pleistocene Epoch, stream channels, lakes, and rivers have deposited alluvium throughout the Subbasin. Alluvial fans have formed on both sides of the valley, but most notably on the eastern side where the Sierra Nevada granitics are the main source of sediment (Poso Creek Fan, Kern River Fan, and Caliente Creek Fan). On the eastern side of the valley, these stream channels are large, laterally migrating distributary channels. Over time, shifting stream channels have created coalescing fans, forming broad sheets of inter-fingering, wedge-shaped lenses of gravel, sand, and finer detritus (Page, 1986), which make up the shallow continental water-bearing deposits of the regional aquifer system. Page (1986) identified various depositional environments for the continental sediments, including alluvial fan and deltaic conditions on the eastern side of the valley, and flood-plain, lake, and marsh conditions on the western side. Consequently, coarse-grained deposits are predominant on the eastern side while fine-grained deposits are predominant within the central and western areas of the Subbasin.

Figure 2-15 is a conceptual block diagram that generally illustrates the highlands surrounding the Subbasin with folded beds separating the west side from the east side. This diagram displays the succession of marine deposition to more recent continental deposition and alluvium with fresher water deposits.

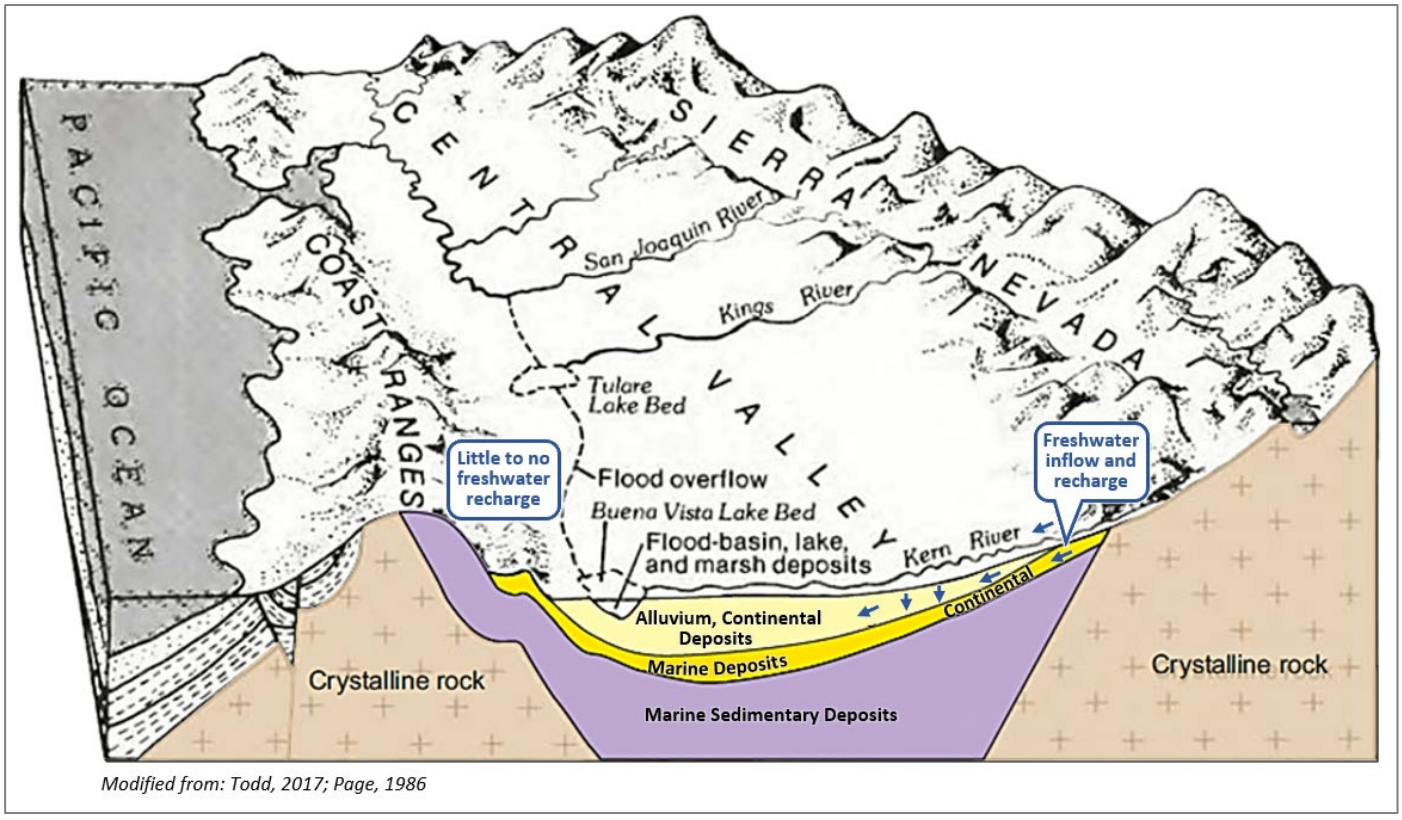

Figure 2-15. Conceptual Block Diagram Looking North from Kern River

The geologic history discussed above is related to the stratigraphy described below, and as summarized in Table 2-2. The description also includes a discussion of the portions of the formations that bear groundwater that have been utilized historically.

Table 2-2. Generalized Hydrostratigraphy of Kern County Subbasin

Age	Geologic Units of Interest	General Description		Deposition		AE	General Hydrogeologic Context
Recent	Alluvium	Discontinuous beds of sand, silt, clay and gravel, becoming finer grained toward the valley.		Continental / Alluvial	Alluvial Fans		Shallow unconfined aquifer in some areas of the subbasin.
Pleistocene	Older Alluvium						
	Tulare Formation	Interbedded gravel, sand, silt, and clay.			Marine, Debris Flows, Fluvial, Semi-arid to arid (West)/ Fluvial-Lacustrine (East)		Major freshwater aquifer of the subbasin.
	Corcoran Clay	Silt and clay. Lacustrine.					Confining/semi-confining aquitard in the west-central and central-southern subbasin.
	Tulare Formation	Kern River Formation Alluvial Fan Deposits. Interbedded gravel, sand, silt, and clay.	Interbedded gravel, sand, silt, and clay.			**AE**	Major fresh water aquifer of the subbasin.
Pliocene	San Joaquin Formation		Siltstone, clayey, diatomaceous with thin lenticular sand beds.	Transitional	Continental and brackish to restrictive marine		Fresh water production limited to deep wells.
Miocene	Etchegoin Formation **AE**	Fresh water production on east side of the valley.	Clay and silt to sand, gravel, and sandstone		Marine to partly continental	**AE**	Fresh water production limited to deep wells.
	Santa Margarita Sandstone **AE**	Chanac Formation Conglomerate with lenses of coarse sand and clays Non-Marine Clastic. Limited fresh water production on east side.	Fine to coarse white sand, gravel, and sandstone.		Shallow Marine Clastic	**AE**	Fresh water aquifer on east/northeast side of the valley
	Round Mountain Silt	Brown siltstone, diatomaceous		Marine	Marine		Aquitard on east side of the subbasin.
	Olcese Sand	Light gray sandstone with a few pebble and siltstone beds.			Marine/ nonmarine clastic wedge	**AE**	Fresh water aquifer on the east/northeast side of the subbasin.
	Freeman-Jewett Silt	Brown siltstone with interbedded ash.			Marine to shallow water	**AE**	Aquitard
Oligocene	Pyramid Hills and Vedder Sands	Interbedded sandstone and siltstone			Marine to shallow water	**AE**	Possible fresh water aquifer on the east/northeast side of the subbasin.

Aquifer Exemptions present (AE) - California Department of Conservation, https://www.conservation.ca.gov/dog/Pages/Aquifer-Exemptions-Status.aspx.

Stratigraphy

The Oligocene Pyramid Hills and Vedder Sands are interbedded sandstone and siltstone deposited in a shallow to deep marine environment and in a limited non-marine environment. They may produce fresh groundwater on the east and southeast sides of the Subbasin (Page, 1986).

The Miocene Olcese Sand and Santa Margarita Sandstone are current sources of drinking water in the northeastern portion of the Subbasin where they occur as confined aquifers (KTWD, 2016). The origin of the Miocene Olcese Sand and Santa Margarita Sandstone varies from continental to marine going from east to west across the Subbasin (Scheirer, et al, 2007a). The Miocene Olcese Sand ranges up to 600 feet in thickness and consists of unconsolidated medium- to coarse-grained sand containing a few pebble and siltstone beds. The formation is exposed in the Poso Creek area (Page, 1986) and is utilized by the Olcese Water District in the Kern River Canyon. The Santa Margarita Sandstone ranges in thickness from 200 to 600 feet and consists of coarse-grained sand (DWR 2006), and includes an upper bed of fine, silty, well sorted gray sand, and a lower bed of brownish-gray and brown fossiliferous micaceous sandy siltstone. According to Page (1986), the sandstone is a major aquifer that reportedly yields as much as 1,950 gallons per minute (gpm) to wells. Croft (1972) reported that the formation also yields water to wells in the foothills southeast of Bakersfield. The Round Mountain Silt is an aquitard that separates the Miocene Olcese Sand from the Santa Margarita Sandstone and acts as a confining unit for the Miocene Olcese Sand (KTWD, 2016). This silt unit consists mostly of a gray and brown siltstone that contains beds of diatomite and silty sand (Page, 1986), and ranges in thickness from 0 to about 200 feet.

The Mio-Pliocene Etchegoin Formation varies considerably, ranging from clay and silt to sand, gravel, and sandstone. It ranges in thickness from a few tens of feet to more than 2,000 feet. Several wells near the foothills and a few deep wells in the valley derive fresh water from the Etchegoin; however, its depth is more than 3,000 feet beneath most of the valley and is limited to deep well production (Page, 1986).

Overlying the Etchegoin Formation is the Pliocene San Joaquin Formation of marine deposition. It contains silt and silty sandstone, with a conglomerate at the base of the formation. In the deep subsurface northeast of the Kettleman Hills, the formation is considered a shoreline deposit because the material is coarser and more permeable than in the Kettleman Hills area and yields fresh water to many wells. The San Joaquin Formation is the youngest marine deposit in the Central Valley (Page, 1986), representing the end of marine deposition in this area. Overlying sediments were deposited by alluvial, fluvial, and lacustrine processes.

The Tulare Formation is Plio-Pleistocene in age, and in conjunction with the Kern River Formation (Mio-Pliocene to possibly early Pleistocene), represents west-east facies change across the Subbasin. The Tulare and Kern River formations are moderately to highly permeable and are major freshwater sources within the Subbasin (Page, 1986; SWSD, 2012).

The Tulare Formation (western-central Subbasin) contains up to 2,200 feet of interbedded, oxidized to reduced sands, gypsiferous clays, and gravels derived primarily from Coast Range

sources. The permeable deposits of the Tulare Formation are divided into upper and lower units, separated by the E-modified Corcoran Clay member (Corcoran Clay) of the formation. Groundwater beneath the Corcoran Clay is typically confined to semiconfined (Page, 1986; SWSD, 2012). In addition to its confining properties, laboratory tests indicate that the clay is highly susceptible to compaction (Faunt, et al., 2009). On the west side of the Subbasin, the Tulare Formation is also divided by upper and lower units by potential equivalents to the Corcoran Clay that are reported locally (Rector, 1983; Geomega, 2001). While the central part of the basin was deposited in a fluvial-lacustrine environment, the west side has lacustrine claystones, fan-delta deposits, debris-flow dominated alluvial-fan deposits, but also paleosols representing an arid to semiarid setting (Nilsen and Campbell, 1996). The difference in Tulare deposition illustrates fundamental differences between the west side and east side aquifer system.

The Corcoran Clay occurs laterally in the north Subbasin (~34 miles wide in extent) from Delano to Lost Hills (Figure 2-14) and narrows to the south where it is not a confining bed in the Kern Fan Area. Although the USGS data present a clay in the western part of the Kern Fan area, local data do not support the presence of an extensive confining clay in the Kern Fan area. A clay in the south part of the Subbasin has been correlated as the Corcoran Clay by many investigators including Croft (1972) and Page (1986). It extends from Buena Vista Lake Beds to just east of Arvin and DiGiorgio (~31 miles wide in extent). In the south Subbasin, the Corcoran Clay is present at depths between 250 and 650 feet (DWR, 1981). Within the central area of the Subbasin between the Kern River and Highway 46, the depth to the Corcoran Clay varies from 300 to 450 feet. Further north to the county line, the depth varies from 200 to 750 feet. The Corcoran Clay, most notably the modified E-clay (Page, 1986) is generally very fine grained; however, isolated, coarser zones are possible, particularly where the clay is less than 20 feet thick. The thickness of the clay is as much as 100 feet in a small area of the southern Subbasin but typically varies between 20 and 40 feet. In the northern Subbasin, the clay might be as thick as 60 to 80 feet in isolated areas, but the thickness typically varies between 10 and 30 feet. The Corcoran Clay does not exist under the Kern Alluvial Fan (Kern Fan), where the shallow unconfined layers are separated from deeper layers by an intermediate zone of interbedded sands and silts which retard vertical groundwater flow and create an increase in semi-confinement with depth. The Corcoran Clay is also not present in the eastern/northeastern part of the Subbasin from the cities of McFarland and Bakersfield, to Edison (Faunt et al., 2009).

The Kern River Formation includes from 500 to 2,000 feet of poorly sorted, lenticular deposits of clay, silt, sand, and gravel derived from the Sierra Nevada. The Kern River Formation crops out in the east Subbasin and reaches its maximum thickness of 2,600 feet in the subsurface west of mapped outcrops (Bartow and Pittman, 1983). The formation consists mostly of poorly sorted fluvial sandstone and conglomerate with interbeds of siltstone or mudstone that becomes finer grained northward and westward. Some of the thicker siltstone or mudstone interbeds may represent deposits of small ephemeral lakes or ponds (Bartow and Pittman, 1983). The Kern River Formation is coarsest in its easternmost exposures, generally the area south of the Kern River, where the composition includes a cobble conglomerate with boulders near the base and pebbly sandstone. (Bartow and Pittman, 1983). Two oil-producing zones occur in the lower part

of the formation where it is believed to have migrated to the Kern River Formation from older marine sediments (Bartow and Pittman, 1983).

The Kern River Formation unconformably overlies the Chanac Formation and may be contemporaneous with the Etchegoin, San Joaquin, and the Tulare formations (Bartow and Pittman, 1983 and Bartow, 1991); however, Graham and others (1988) concluded that the Kern River Formation predates the Corcoran Clay, which has a basal age of about 725,000 years. Radiometric dating of a volcanic ash layer near the top of the Kern River Formation at the Kern River oilfield may agree with the aforementioned basal age; however, others dated this ash bed at 6 million years which would place the Kern River Formation solely in the Miocene (Scheirer et al., 2007a). Nevertheless, the gradational relationship between the Kern River Formation and seemingly younger units such as the Etchegoin, San Joaquin, and Tulare formations would have to be reexamined.

Older alluvium and terrace deposits overly the Tulare and Kern River formations. These deposits also make up a portion of the regional aquifer system. They are composed of up to 250 feet of Pleistocene-age lenticular deposits of clay, silt, sand, and gravel that are loosely consolidated to cemented. These deposits are moderately to highly permeable and yield sufficient water to wells. They are often indistinguishable from the underlying Tulare and Kern River formations (DWR, 2006).

The Holocene-age younger alluvium and flood basin deposits vary in character and thickness in the Subbasin. Along the eastern and southern Subbasin margins, these younger deposits consist of up to 150 feet of interstratified and discontinuous beds of clay, silt, sand, and gravel. In the southwestern portion of the Subbasin, the deposits are finer-grained and less permeable as they grade into fine-grained flood basin deposits underlying the historic lakebeds of Buena Vista and Kern lakes in the southern portion of the Subbasin. The flood basin deposits consist of silt, silty clay, sandy clay, and clay interbedded with poorly permeable sand layers. These flood basin deposits are difficult to distinguish from underlying fine-grained older alluvium (Page, 1986; DWR, 2006).

As described above for the deposition of the Tulare and Kern River formations and Quaternary facies differ from west to east across the basin. The below diagram (Figure 2-16) illustrates the general distribution of facies fluvial-deltaic deposition dominating the east-side; alluvial, lacustrine, and marsh deposition dominating the central portions of the basin, and alluvial and debris flow deposition dominating the western side of the Subbasin during the Quaternary.

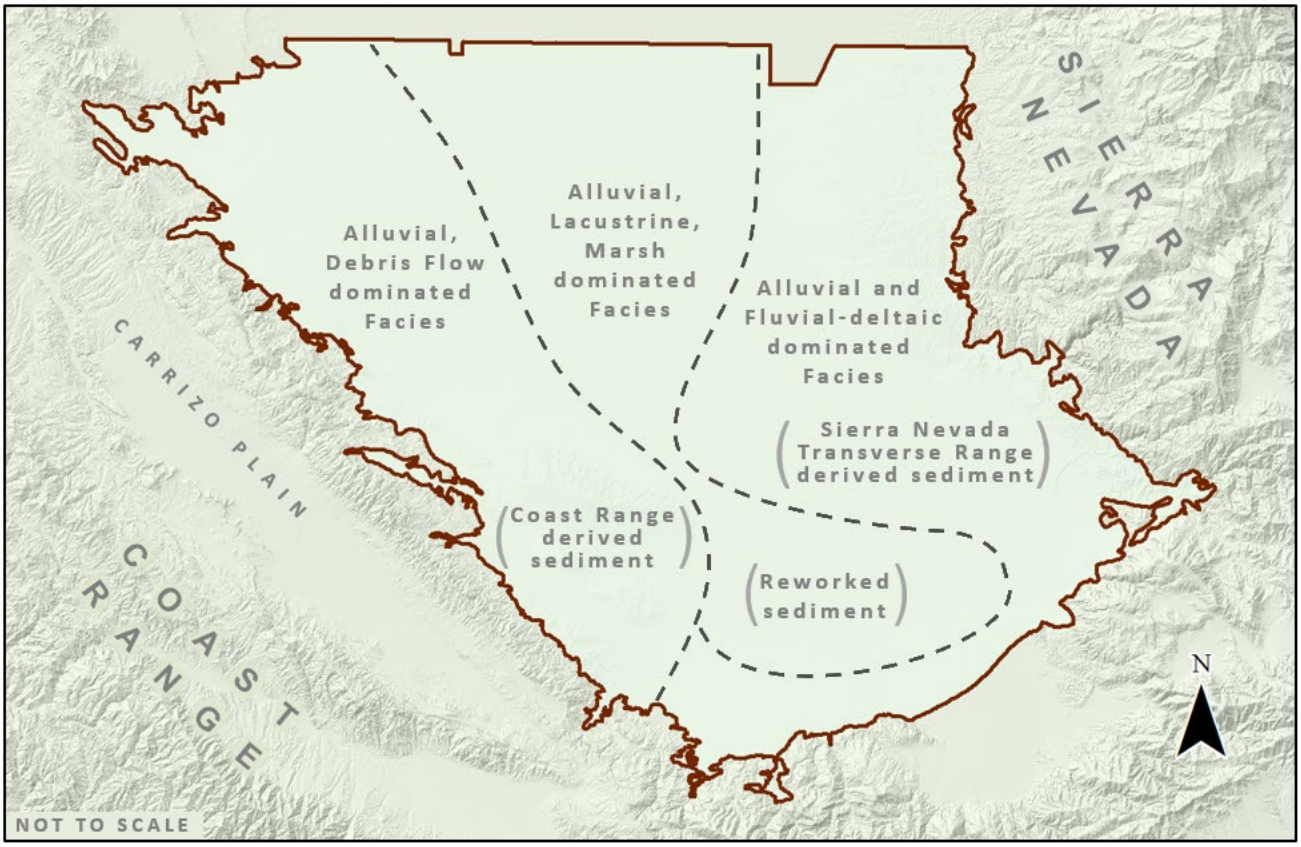

Figure 2-16: Generalized Quaternary Depositional Facies

2.2.1.3 Geologic Features that Significantly Affect Groundwater Flow

The primary structure in the Subbasin that affects groundwater flow is the large asymmetric structural trough (San Joaquin Valley Syncline) that has been the depocenter of thousands of feet of sediments since late Mesozoic time (Bartow, 1991). Groundwater naturally flows northwest along the trend of the syncline. Likewise, the Bakersfield Arch is a broad southwest-plunging arch of basement rock that separates the small Maricopa-Tejon sedimentary basin at the south end with the remainder of the sedimentary basin to the north and west (Figure 2-13, from Bartow, 1991). Groundwater recharging from the Kern River will flow north and south along the flanks of the arch away from the center of the Subbasin.

Numerous faults and folds are located in the Subbasin, as shown in local geologic maps (Figures 2-13, 2-17, and 2-18). Bartow (1991) identified portions of three types of structural regions in Subbasin, excluding the Bakersfield Arch. The northeastern third of the Subbasin, including the north half of the Arch, is located on the minimally-deformed eastern limb of the valley syncline. Normal faulting is associated with the Bakersfield Arch, occurring mostly in the older sediments (QPc; Ts) but extending into and concealed by the younger sediments (Qoa, Q; Qs), notably the Pond-Poso Creek Fault. Fault orientations vary from northwest to northeast due to alternating compressional and extensional forces.

.

DWR Bulletin 118 - San Joaquin Valley Groundwater Basin - Kern County Subbasin

DESCRIPTION OF MAP UNITS

Qs **Sand dunes (Holocene)** Windblown sand and dune sand

Qb **Flood-basin deposits (Holocene)** Clay, silt, and some sand; near Stockton consist of muck, peat, and other organic soils. In places may include part of the Modesto Formation (Pleistocene)

Qr **River deposits (Holocene)** Gravel, sand, silt, and minor amounts of clay deposited along channels, flood plains, and natural levees of main streams. In places may include part of Modesto Formation (Pleistocene)

QTl **Lacustrine and marsh deposits (Pliocene to Holocene)** Clay, silt, and some sand; in subsurface include three widespread clays: A clay (Pleistocene and Holocene?); C clay (Pleistocene); and modified E clay (Pleistocene), includes Corcoran Clay Member of Tulare and Turlock Lake Formations

QTc **Continental rocks and deposits (Miocene to Holocene)** Heterogeneous mix of generally poorly sorted clay, silt, sand, and gravel; some beds of claystone, siltstone, sandstone, and conglomerates. Include some informal units: younger alluvium (Holocene), older alluvium (Pleistocene and Holocene?) and continental deposits (Pliocene and Pleistocene); three formations of Pleistocene age: Modesto, Riverbank, and Turlock Lake; Tulare Formation (Pliocene and Pleistocene) on western side of valley, Laguna Formation (Pliocene) on eastern side, and Kern River Formation (Miocene to Pleistocene?) on southeastern part

Tvd **Volcanic rocks and deposits (Miocene and Pliocene)** Massive tuff with large fragments of vesicular basalt northwest of Tracy; tuff, and volcanic breccia at south end of valley

Tcpm **Continental rocks and deposits (Miocene and Pliocene)** Gravel, sand, silt, clay, conglomerate, sandstone, siltstone, and claystone, contain andesitic material. Principally Mehrten Formation (Miocene and Pliocene) on eastern side of valley; include continental equivalents of Etchegbin Formation (Miocene and Pliocene) on western side of valley, and Chanac Formation (Miocene) on southern part

Tcmo **Continental and marine rocks and deposits (Miocene and Pliocene)** Gravel, sand, silt, clay, silty sandstone, and siltstone. Include continental and marine equivalents of San Joaquin Formation (Pliocene) and Etchegoin Formation (Miocene and Pliocene)

Tm **Marine rocks and deposits (Eocene, Oligocene, Miocene, and Pliocene)** Sand, clay, silt, sandstone, shale, mudstone, and siltstone. On western side of valley include the San Joaquin and Etchegoin Formations, Temblor Formation (Oligocene and Miocene) and Kreyenhagen Formation (Eocene). On southeastern side include the Santa Margarita Formation of various authors, the Round Mountain Silt, the Olcese Sand, the Freeman Silt, and the Jewett Sand (including the Pyramid Hill Sand Member) (all Miocene), and the Vedder Sand (Oligocene)

Tcmo **Continental rocks and deposits (Oligocene and Miocene)** Gravel, conglomerate, sand, tuffaceous sand, clay, and sandy clay; contain rhyolitic material on eastern side of valley. Principally Valley Springs Formation (Oligocene and Miocene) on eastern side of valley; unnamed fanglomerates (Miocene), and Bena Gravel (Miocene) in the southern part

Tcme **Continental rocks and deposits (Eocene to Miocene)** Conglomerate, sandstone, consolidated fanglomerate, claystone, tuff and tuff breccia; near Fresno consist of tuffaceous sand and gravel. Near Bakersfield include the Bealville Fanglomerate (Oligocene and Miocene) and the Walker Formation (Eocene to Miocene)

Tcs **Continental rocks and deposits (Eocene)** Conglomerate and sandstone; along eastern side of valley contain anauxite. Principally Ione Formation (Eocene) on eastern side of valley

Unconformity

pTs **Marine rocks (Pre-Tertiary)** Sandstone, shale, siltstone, and some limestone, chiefly on western side of valley; in places contain abundant secondary gypsum. Include Moreno Formation (Cretaceous and Paleocene) and Panoche Formation (Cretaceous)

pTg **Granitic rocks (Pre-Tertiary)** Chiefly granitic rocks on eastern side of valley, in places consists of mafic intrusive rocks

pTm **Metamorphic rocks (Pre-Tertiary)** Metasedimentary, metavolcanic and other metamorphic rocks on eastern side of valley

AUGUST 2019

FIGURE 2-17

Regional Cross Sections

Geologic Units

Qls - Pleistocene-Holocene: Selected large landslides, such as the Blackhawk Slide on the north side of San Gabriel Mountains; early to late Quaternary.

Q - Pleisto-Holocene: alluvium, lake, playa and terrace deposits; unconsolidated and semi-consolidated

Qoa - Quaternary: older alluvium, lake, playa and terrace deposits

QPc - Plio-Pleistocene: sandstone, shale and gravel deposits; mostly loosely consolidated

P - Pliocene: sandstone, siltstone, shale and conglomerate; mostly moderately consolidated

Mc/M - Miocene: sandstone, shale, conglomerate and fanglomerate; moderately to well consolidated

O - Oligocene: sandstone, shale and conglomerate; mostly well consolidated

E - Eocene: Shale, sandstone, comglomerate, minor limestone; mostly well consolidated.

TC - Undivided Tertiary: sandstone, shale, conglomerate, breccia and ancient lake deposits

m - pre-Cenozoic: Undivided pre-Cenozoic metasedimentary and metavolcanic rocks of great variety. Mostly slate, quartzite, hornfels, chert, phyllite, mylonite, schist, gneiss, and minor marble.

gb - Mesozoic: Gabbro and dark dioritic rocks; chiefly Mesozoic.

grMz - Mesozoic: Mesozoic granite, quartz monzonite, granodiorite, and quartz diorite.

Ku - Lower Cretaceous: Upper Cretaceous sandstone, shale, and conglomerate.

Kl - Lower Cretaceous; Lower Cretaceous sandstone, shale, and conglomerate.

Faults

Several faults have historical displacement or have been identified as features that affect groundwater flow. The following are: Pond-Poso Fault, Edison Fault, White Wolf Fault, Kern Front Fault, Premier Fault, New Hope Fault, and small portions of the Pond Fault (California Geological Survey, 2010a). The Edison Fault and White Wolf Faults also affect the flow groundwater (DWR, 2006).

The southeastern quarter of the Subbasin, including the south half of the Bakersfield Arch, is considered to be "highly deformed" and the "most complex tectonic history" (Bartow, 1991) due to the alternating north-south compressional and extensional forces since the Cretaceous Period. The southern boundary of the Subbasin is delineated by the northeast-trending White Wolf Fault, a reverse fault with active displacement (DMG, 1955), that may have originally been a normal fault (Bartow, 1991). The White Wolf Fault separates the Subbasin from the new White Wolf Subbasin to the south. Two northeast-trending thrust faults are located at the southwestern corner of the Subbasin, including the Wheeler Ridge and Pleito Faults. During the 1952 Bakersfield earthquake, a group of small ground fractures developed in an alignment just north and subparallel to White Wolf Fault. Numerous normal faults are located along the eastern margin of the southern Subbasin, including the Edison Fault and many unnamed fault segments that were active during the 1952 earthquake. More detailed descriptions of local faults and folds of interest are described in the chapters herein.

Folds

Several concealed folds have been delineated in the central Subbasin, the Paloma anticline, Buttonwillow and Semitropic anticlines, San Joaquin Valley syncline, and other unnamed anticlines and synclines in the Subbasin.

West-Side Fold Belt and Groundwater Flow

The west-side fold belt includes anticlines: Kettleman Hills, Lost Hills, Elk Hills, and at the east boundary of the fold-belt, Buttonwillow and Semitropic anticlines (Bartow, 1991) (Figure 2-17; Page, 1986). These structures are oriented toward the northwest, subparallel to the Coast Range and the San Andreas Fault. Page (1986) and DWR (2006), identified the anticlinal folds of the highlands, specifically Lost Hills, as restrictions to groundwater flow within the lowlands, and this condition likely applies to other anticlines in the Subbasin.

Structurally, and to a large degree, lithological, the western side differs from the central and eastern portions of the Subbasin. Western Plio-Pleistocene deposits are derived from weathering and erosion of the Coastal Range made up of marine deposits yielding clays and silts and some sands. On the other hand, the east side is made up of quartzose and feldspathic coarser sized sediments from the Sierra Nevada.

In addition to structure, the thickness of fresh water bearing deposits and the sources of groundwater recharge differ between the west side and the central and east side of the Subbasin. In general, the differences result in more restrictive localized groundwater system with poorer quality water on the west side of the Subbasin.

2.2.1.4 Kern County Subbasin Boundaries

As described above, the lateral boundaries are defined by jurisdictional and structural boundaries (DWR, 2003, 2016a, 2016b). Within the jurisdictional boundaries of the Subbasin, are effective lateral boundaries of usable groundwater or effective extents of the principal aquifers.

These boundaries will be discussed in the remainder of this section, and include the presence or absence of: a sufficient quantity of groundwater for beneficial use; water quality changes rendering groundwater unusable; and aquifer exemptions of portions of the Subbasin that either contain commercially producible hydrocarbons or minerals, are high in total dissolved solids, and/or are otherwise isolated from the rest of the Subbasin by geologic boundaries. The characteristics of the effective groundwater Subbasin, as described above, also apply to the bottom of the groundwater basin and are discussed in Section 2.2.1.5.

Criteria for the Extent of Groundwater with Beneficial Use in the Subbasin

An aquifer may not be suitable for beneficial use if:

- It is not currently serving as a source of drinking water,
- It has commercially producible minerals or hydrocarbons, or
- It is not expected to supply a public water system, and
- It is either economically or technologically infeasible for treatment or recovery now or in the future for domestic, agricultural, or industrial use.

The purpose of this GSP is not to exempt aquifers, nor is it to define the maximum depth or water quality concentration at which groundwater is economically recoverable or treatable now or in the future. However, by applying the criteria of 40 CFR §144.3 and 40 CFR §146.4, active oil and gas aquifers and exempted aquifers are not a part of the groundwater basin for beneficial use.

The groundwater Subbasin's extent, where no exemptions or commercially producible hydrocarbons exist, likely ranges between 3,000 milligrams per liter (mg/l) and 10,000 mg/l total dissolved solids (TDS) depending on the feasibility of treatment and recovery of the groundwater for beneficial use. The estimated lateral extents of the Subbasin are further presented with the bottom of the Subbasin and cross sections of this plan.

2.2.1.5 Bottom of Subbasin

As described above, the following whichever is shallowest, are the lateral and vertical boundaries of the groundwater Subbasin:

- depth to producible minerals or hydrocarbons,
- depth to and aerial extent of exempted aquifers,
- depth that makes recovery of water for domestic, commercial, or industrial purposes no longer economically or technologically feasible, or

- the depth at which groundwater cannot now or in the future serve as a source of drinking water.

For example, water bearing zones below the depth to producible hydrocarbons are not within the groundwater basin; likewise, water bearing zones below an exempted aquifer are not within the groundwater basin.

In some parts of the Subbasin the lateral and bottom boundaries of the groundwater are subject to depths to producible hydrocarbons and extent of depths to aquifer exemptions. As described above, any water bearing zone below these three criteria are outside of the groundwater Subbasin. The available depth to hydrocarbons and aquifer exemptions at the time of this GSP compilation, although possibly generalized, are incorporated into Figures 2-19 and 2-20 for comparison.

As discussed above, it is not the intent of this plan to evaluate at which depth the groundwater is economically recoverable or treatable in the future; but, for discussion purposes only, a TDS of 2,000 mg/l is presented in Figure 2-19, to consider the vertical and lateral distribution of a fresh groundwater dataset in the Subbasin. A TDS of 2,000 mg/l has been mapped throughout the region by Page (1973), historically, it was considered a limiting TDS concentration for the irrigation of most crops (Page, 1973); however, it does not define the bottom of the groundwater Subbasin (or the depth to water that is no longer economically or technologically feasible for groundwater beneficial use). Other local datasets for a TDS of 2,000 mg/l are included in management area plans.

By comparison the depth to TDS of 10,000 mg/l (Gillespie et. al. 2017) (one of the criteria for classification as an underground source of drinking water (USDW)) is presented on Figure 2-20. As discussed above, this depth may not represent the USDW if there are aquifer exemptions or producible hydrocarbons shallower in the subsurface.

In addition to the datasets mentioned above, the SWRCB Resolution Number 88-63 (SRWCB, 1988), has also listed criteria for the suitable sources of drinking water for municipal or domestic water supply. These sources are defined as waters that: have a TDS of less than 3,000 mg/l; are reasonably expected by Regional Boards to supply a public water system, including sufficient yield; are not contaminated or beyond reasonable treatment; and are not exempted by 40 CFR §146.4 (SRWCB, 1988). At this time, there is no dataset developed to present basin-wide correlations of the SRWCB 88-63 base of drinking water.

An additional informal description of the bottom of the Subbasin may be referred to by some researchers, at times, as the “current operational bottom of the Subbasin” which basically describes the depth of active groundwater well pumping; however, this description should not be used to satisfy SGMA requirements § 354.14(b)(3) of the California Code. The range of well depths and perforations generally deepen in the alluvial aquifer system from the margins of the basin toward well discharge points in the south-central and north-central Subbasin. The historical operational bottom of the depth and/or the current operational bottom of the basin are not mapped herein because the operational bottom of the Subbasin has increased with depth as groundwater elevations have decreased over the years. In general, groundwater wells extend to

depths of more than 1,000 feet (Page, 1986), and the maximum thickness of freshwater deposits is calculated at about 4,400 feet, occurring at the south end of the valley (Page, 1986). Cross sections included in this plan provide a representation of current well depths in the Subbasin.

Page (1973) Base of Freshwater

Although, not the bottom of the groundwater basin, the base of fresh groundwater (Figure 2-19) has historically been defined by Page (1973), as the depth at which specific conductance (SpC) is 3,000 micromhos per centimeter (µmhos/cm) or microsiemens per centimeter (µS/cm), and is considered to be generally equivalent to a TDS concentration of 2,000 mg/l. These values have been reported because they may be considered a limiting factor for irrigation. The conversion factor from SpC to TDS used for this determination was 0.67, which is midway between the typical range of 0.55 to 0.75 (Hem, 1985), and is dependent on the composition of groundwater.

The base of fresh groundwater is quite variable in the Subbasin ranging over 4,000 feet, as listed below:

Location			Elevation, feet msl	Depth, feet below ground
Southeast,	T31S/R28E-Section 32,	West of Arvin	> -4400	~ 4700
Northwest,	T26S/R20E-Section 34,	Lost Hills area	0	~ 400
Northeast,	T25S/R27E-Section 6,	South of Richgrove	-2800	~ 3300
East central,	T29S/R27E-Section 12,	Oildale	-2000	~ 2500
West central,	T29S/R24E-Section 16,	East of Buttonwillow	-800	~ 1100

On the east side of the Subbasin, the base of fresh groundwater trends parallel to nearby faulting. The 2,400-foot below mean sea level (bmsl) contour (and other deep contours) on Figure 2-19 represents a northwest-trending trough of fresh groundwater between Bakersfield and Wasco. This trough lies between the concealed Poso Creek fault to the northeast and the pre-Quaternary Greeley Fault on the southwest that extends from the Kern River to the Kern National Wildlife Refuge. This “graben” of deeper fresh groundwater appears to be trending with these faults.

A smaller, northwest-trending trough of fresh groundwater is located east of Delano and south of Richgrove on the west side of several northeasterly-trending faults. This trough of fresh groundwater may be more of an indicator of freshwater in the Santa Margarita and Olcese aquifers.

On the west side of the Subbasin, notably, west of Lost Hills, Buttonwillow, and Elk Hills, Page (1973), reported very little data for groundwater less than 3,000 µmhos/cm. The lack of data is a combination of evidence suggesting that there is very little fresh water (<3,000 µmhos/cm), on the west side as corroborated by other sources (Gillespie et. al., 2017; and Metzger and Landon, 2018), and a potential data gap where additional data may be useful.

NOTES:

(Approximate) Elevation of base of fresh water (Specific conductance generally less than 3,000 micomhos per centimeter) or ~2,000 mg/L TDS.

Hydrocarbon elevations from primacy productive limits represent difference between average surface elevation and minimum depth of productive limit.

Elevation to hydrocarbons and the top of exempted aquifers are generalized. Refer to the report table for details. Exemptions are subject to change as applications are approved.

Per 40 CFR §144.3, exempted aquifers are not USDWs. Based on criteria of 40 CFR §146.4, primacy productive limits are not suitable USDWs.

Gillespie et. al. 10,000 mg/L TDS

The depth to groundwater with a TDS of 10,000 mg/l (Figure 2-20), is the deepest possible USDW. Gillespie et. al. (2017) and Kong (2016) developed these data based on geochemical analysis of water samples and geophysical log analysis. The depth to 10,000 mg/l TDS is generally consistent with regional trends within the Subbasin. Southeast of the City of Bakersfield, the 10,000 mg/l TDS is mapped to a depth of 6000 ft. This is consistent with the knowledge that this area of the Subbasin receives the greatest amount of fresh water recharge from the Sierras.

In the Maricopa depocenter in the south part of the Subbasin a couple miles north of Wheeler Ridge the 10,000 mg/l TDS contour may be as deep as 10,000 ft. No chemical analysis data were available to verify this geophysical log interpretation; however, the results from Page (1973), also mapped the depth to 2000 mg/l groundwater at 4600 ft (which was the deepest fresh water in the Subbasin) (Gillespie et. al., 2017). The Maricopa depocenter appears to have fresh water that extends deeper than anywhere else in the Subbasin.

Salinities in the west Subbasin are much higher, and depths to the base of USDW are more variable (Gillespie et. al., 2017). The structural complexity along the west side of the valley may be a contributing factor to the variable distribution of water salinity in this area. Gillespie et. al. (2017), cite that numerous wells contain waters between 3000 and 10,000 parts per million (ppm) in the nonmarine Tulare Formation and overlying alluvium in the western Subbasin.

Figure 2-21 below is a conceptual profile illustrating the general difference between the shallow and deep aquifer systems (fresh water continental deposits and alluvium, and saline water marine deposits), and the differences between the west and east side aquifer systems. In general, groundwater is more saline on the westside, while the freshwater column is thickened in the eastern-central part of the Subbasin.

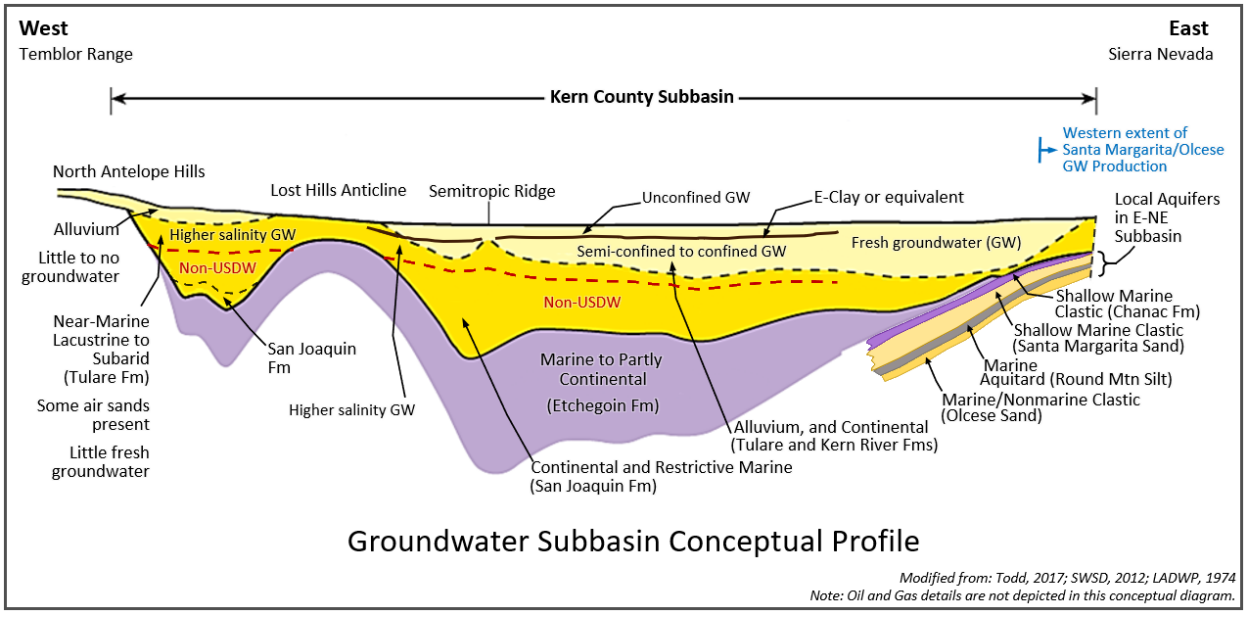

Figure 2-21. Groundwater Subbasin Conceptual Profile

2.2.1.6 Principal Aquifers and Aquitards

The groundwater aquifers of the Subbasin are geologically diverse with differing zones of confined, semiconfined, and unconfined groundwater conditions. As depicted in the below Figure 2-22, the primary aquifer system occurs in the central-northern, central, and central southern portions of the Subbasin. It consists of the Tulare formation, Kern River formation, and overlying alluvium. On the eastern side of the Subbasin are the confined Santa Margarita, Olcese, Pyramid Hills, and Vedder Sands. Groundwater wells extract water where these aquifers are not exempted and where they are feasible for groundwater supply use without hydrocarbons, On the western side of the Subbasin, very little usable groundwater occurs. In the northwest, groundwater supply production is likely limited and may occur in alluvium and/or the Tulare Formation.

In addition to the formations described above, groundwater may also be pumped from the San Joaquin and Etchegoin (Page, 1986; Bartow and Pittman, 1983) in the central portion of the Subbasin; however, little information is available to further document the groundwater characteristics or extraction within these zones.

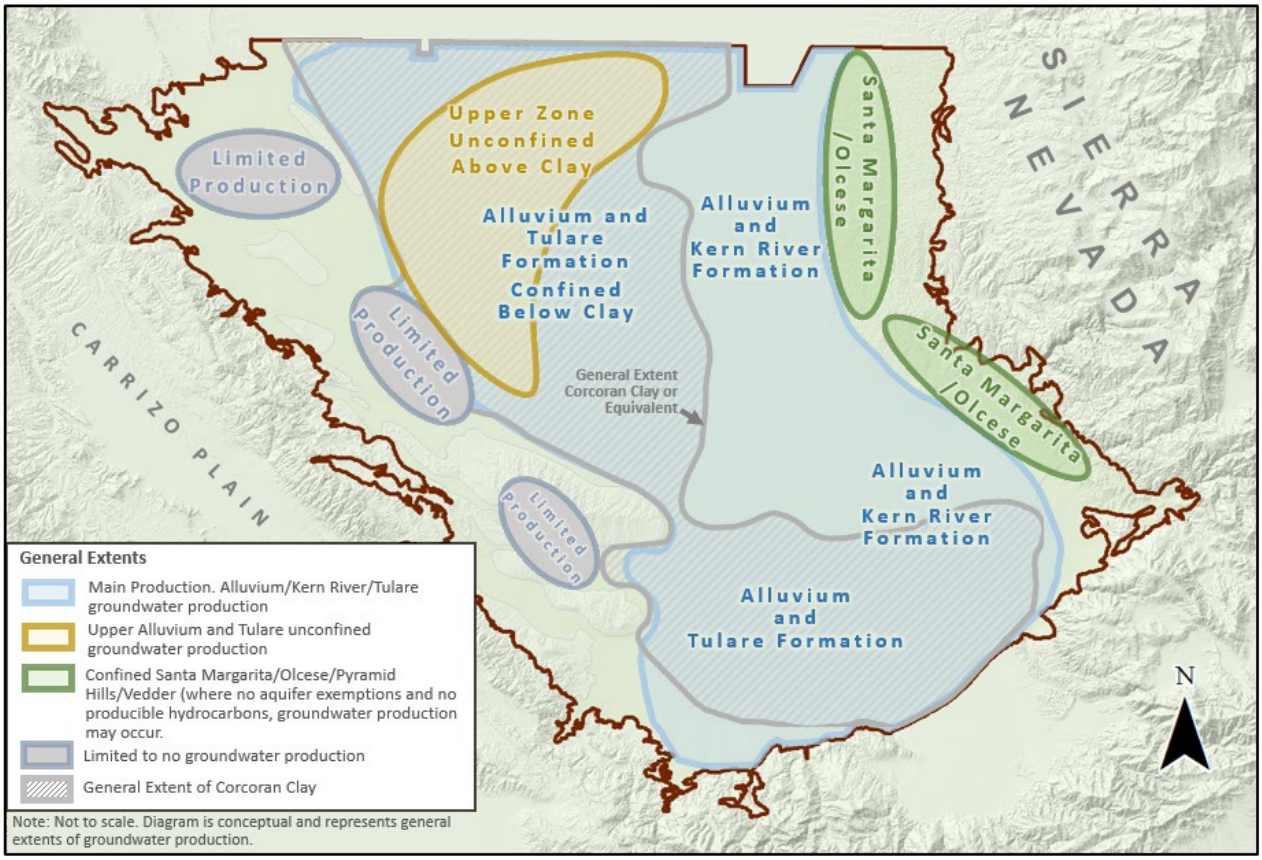

Figure 2-22. General Distribution of Groundwater Aquifer Supply Production in Kern County Subbasin

Formation Names

Table 2-2 presents the hydrostratigraphy and summary of the geologic units of interest with general details and a general summary of deposition and aquifer context.

The Subbasin groundwater system is dominated by alluvial/fluvial deposits on a basin-wide scale and produces an intricate, heterogenous grouping of aquifers. Although formations can be mapped across the Subbasin, much of the material is not distinctive in the subsurface and designation of a particular formation is difficult. Additionally, the E-modified layer of the Corcoran Clay member of the Tulare Formation is correlated across much of the Tulare Lake Hydrologic Region; however, there are still localized debates and questions on the extent and correlation of the E modified clay.

Refer to the discussion on stratigraphy in section 2.2.1.2. for a brief description of the formations and their general context in relation to the aquifer system.

Primary Aquifer System

The primary aquifer system of the Subbasin is within the Tulare and Kern River formations and overlying alluvium. It includes differing zones of confined, semiconfined, and unconfined groundwater conditions, due to the presence of clays that act as local aquitards. The Corcoran Clay and other equivalent clays occur within the Tulare Formation in the central and southern parts of the Subbasin (Page, 1983 and Page, 1986). Where extensive clays are present, some areas of the aquifer system may consist of a deeper confined zone and a shallower unconfined to semi-confined zone. Within the eastern portion of the Subbasin and in the vicinity of the Kern River Alluvial Fan, the aquifer system is made up of an unconfined to semi-confined zone. Shallow zones are also present locally in the northwestern and southern portions of the central Subbasin. The shallow zone is not a part of active groundwater extraction, but data are included in the groundwater conditions section of this report to evaluate changes over time.

Some researchers in the Subbasin define the primary aquifer system as one principal aquifer because the confining beds such as the E-modified Corcoran Clay or equivalent, are not laterally continuous across the Subbasin, or lithologically consistent allowing for continuous confinement. In addition, there are older wells in some parts of the Subbasin, that are screened across the Corcoran Clay which could allow interconnection of water between the upper and lower zones. However, for the past few decades, local county enforcement has worked to eliminate well construction practices with screens across encountered upper unconfined zones and lower confined zones.

In addition, to the aquifer zones described above, there is a shallow groundwater zone occurs above the A-Clay or other shallow clay; however, this zone has poor quality water and is not a part of the groundwater supply aquifer system.

Table 2-3 below is a summary of generalized aquifer characteristics of the primary aquifer system.

Table 2-3. Primary Aquifer System of Kern County Subbasin

Generalized Hydrostratigraphy	Relative Depth	Basin Extent	Water Quality	Corresponding Formations
Unconfined Zone	Middle to Deep	East side "main production zone"	Good	Eastside Alluvium and Kern River Formation
		Central, above the Corcoran Clay	Moderate	Central Subbasin, above the Corcoran Clay Member (E) of the Tulare Formation, or other equivalent fine-grained layers.
Confined, Semi-confined, or Lower Zone		Central "main production zone"	Good to Moderate	Confined to Semiconfined. Alluvium, Kern River Formation, and Tulare Formation

Eastern Confined Aquifers

Along the eastern margins of the Subbasin, other principal aquifers, where classified as USDWs and not exempted, include, semiconsolidated rock such as the Santa Margarita Sandstone, and Olcese Sands. These confined aquifers are hydraulically separated from the Kern River Formation aquifer system by Pliocene marine deposits. Other aquifers to the east, where classified as USDWs and not exempted, include the Pyramid Hills, Vedder Sand, and the Chanac Formation (Page, 1986; Bartow and Pittman, 1983). The extent of groundwater production in these aquifers is limited by the extent of producible hydrocarbons, aquifer exemptions, and increased salinity with depth.

West-side Aquifers

Alluvial aquifer zones on the west side of the Subbasin may contain groundwater that is higher in TDS. This groundwater occurs in the fold belt associated with folded and faulted strata. Where aquifers are classified as USDWs and not exempted per 40 CFR §144.3, groundwater may be pumped for beneficial use. The Tulare Formation makes up most of the aquifer system on the west side; however, the Tulare Formation differs in facies and origin than what is documented in the central portion of the Subbasin. West-side aquifers are described in more details in the management area plans.

Physical Properties of Each Aquifer and Aquitard

Aquifer parameters within the Subbasin are available from both well pumping tests and calibrated groundwater models. Data are summarized in Table 2-4 and Figure 2-23. Aquifer properties reported herein include hydraulic conductivity which is a volume of water that will move in a unit of time, under a unit hydraulic gradient through a unit area, and the specific yield

(unconfined systems) and storage coefficient (confined systems), which are functions of an aquifer's ability to store and release water from storage (storativity).

Table 2-4. Aquifer Parameters for Kern County Subbasin

Data Source	Calculated Horizontal Hydraulic Conductivity (feet/day)	Vertical Anisotropy Kh/Kz	Storage Coefficient	Specific Yield
Kern Pumping Tests Compilation (Todd, 2018)	7 to 250	--	0.0008 to 0.034	--

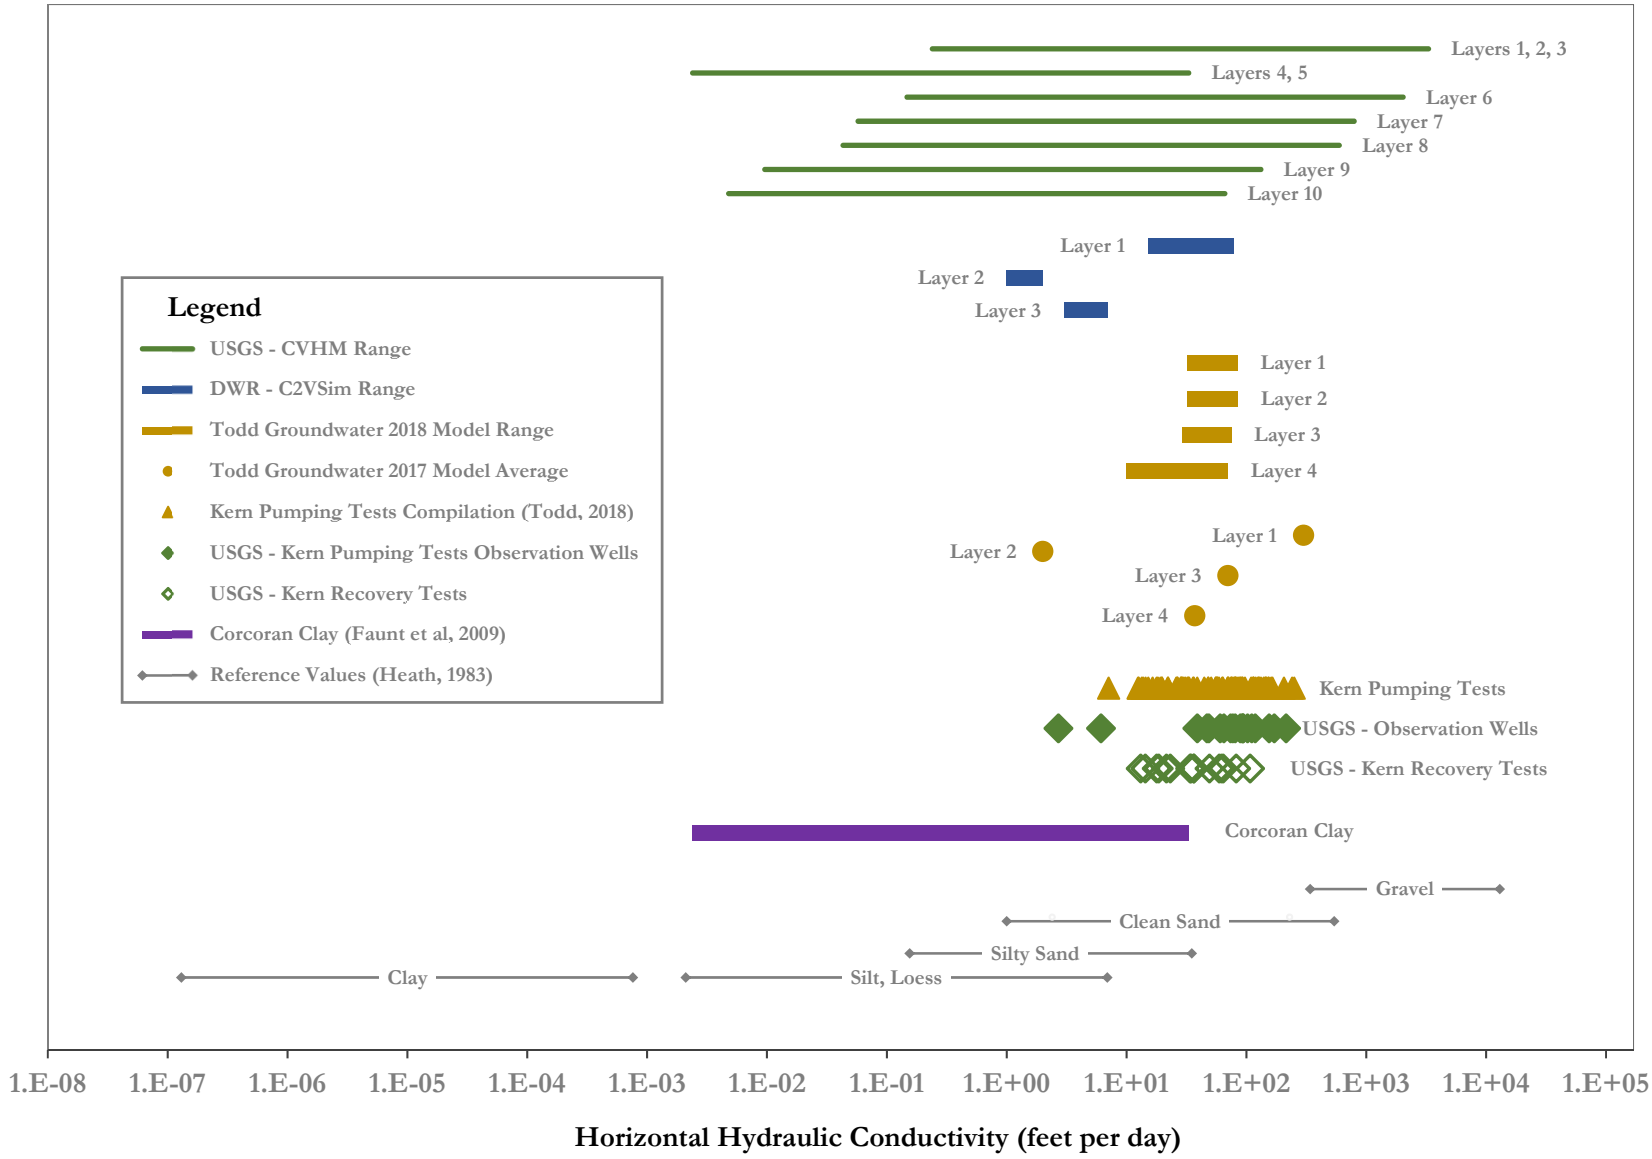

Figure 2-7.pptx

Kern Groundwater Authority Basin Setting	GEI Consultants	HYDRAULIC CONDUCTIVITY VALUES
Kern County, California		AUGUST 2019 FIGURE 2-23

Hydraulic Conductivity

Aquifer data derived from pumping tests were taken from two sources: 1) relatively short (1.5- to 5-hour) pumping tests by the USGS at irrigation wells during the late 1950s and 1960 (McClelland, 1962), and 2) from constant rate pumping tests from engineering consultants in the 2000's (Todd, 2018). The depth of these test wells varied from 98 to 1,500 feet below ground surface (bgs) (median: 650 ft bgs), and pumping rates varied from 44 to 4,480 gpm (median: 2,500 gpm). The analysis included the use of water level recovery data from pumping wells and water levels from observation wells. From these tests, the hydraulic conductivity was estimated and ranges from 3 to 250 feet per day (ft/d; median: 60 ft/d), which is consistent with published ranges for clean, medium- to coarse-grained sand (Heath, 1983), or for a fine sand to coarse gravel (Schwartz & Zhang, 2003). These values also fall within the range of the groundwater models that were partially calibrated with these data (C2VSim; CVHM; Todd, 2018; Todd, 2017) (Figure 2-23).

The Corcoran Clay of the Tulare Formation is most commonly known for its fine-grained beds; however, lithology does vary from fine (clay and silt) to coarse (sand) texture (Page, 1986; Faunt et al., 2009). These coarser-grained beds are isolated and principally occur where the Corcoran Clay is less than 20 feet thick. Faunt et al., (2009) compiled and estimated horizontal hydraulic conductivities within the range of 0.0024 to 33 ft/d, which is within the range of silt to fine/medium sand (Figure 2-23) (Heath, 1983). A range of vertical hydraulic conductivity was estimated from permeameters and field tests between 6.6×10^{-6} ft/d to 1.5×10^{-3} ft/d (Faunt et al., 2009), representing a potential vertical anisotropy range of 3.6×10^{2} to 2.2×10^{4}. As noted by Faunt et al., (2009) laboratory permeameter tests may have underestimated the hydraulic conductivity while field testing may have overestimated hydraulic conductivity due to potential for intra-borehole flow across the clay. Additionally, recent inelastic compaction of the Corcoran Clay in areas of subsidence may have further reduced vertical hydraulic conductivity (Faunt et al., 2009).

Specific Yield and Storage

Storage of an aquifer is primarily described and quantified by the storativity or the volume of water released from storage per unit surface area of the aquifer per unit decline in hydraulic head (Heath, 1983). It is important to note that while storativity applies to both confined and unconfined systems, it can be further simplified for these two systems. Storativity accounts for aquifer compression and water expansion (specific storage components), which are the primary factors for estimating storage in confined systems; thus, for confined systems, the specific storage or storage coefficient is most often reported. In contrast, for unconfined systems, the specific yield or effective porosity (gravity-driven dewatering of an aquifer) better represents storativity because aquifer compressibility and water expansion are somewhat negligible in unconfined systems. For unconfined systems, specific yield is most often reported, and is a function of porosity and specific retention.

For confined systems, the aquifer compressibility of the storage coefficient can be further defined as elastic and inelastic skeletal specific storage, where inelastic storage will be lost once compression and dewatering occur. It is estimated that in the Central Valley, the inelastic

specific storage typically is 30 to several hundred times larger than the elastic skeletal specific storage (Faunt et al., 2009; Ireland et al., 1984). Where fine-grained deposits with inelastic storage are thick in the aquifer system, water released could be a major source of water, but could also result in a permanent loss in storage capacity of fine-grained sediments.

Specific yield of unconfined zones and the storage coefficient of confined zones within the Subbasin have been estimated by laboratory testing of sample cores, calculation based on lithology type, and groundwater model calibration (Dale, 1966; Davis et al., 1959; Davis et al., 1964; Faunt et al., 2009; DWR, 2013; Todd, 2017 and 2018). A range is presented in Table 2-4 and is within the range of values published for similar grain sizes and lithology (Heath, 1983; Morris and Johnson, 1967) (generally 0.02-0.40).

General Water Quality of Principal Aquifers

As required in the regulations, this section is a general summary of water quality of the principal aquifers in the Subbasin. This section does not replace the discussion of water quality issues under Groundwater Quality Section 2.3.3.

This discussion provides a high-level description of water quality variation in the principal alluvial aquifer system of the Subbasin, both laterally (from west to east across the Subbasin) and vertically (shallow–deep within the Subbasin). For local details on water quality for specific areas of an aquifer, refer to the management area plans.

Total dissolved solids are discussed in this section only for the purpose of comparing and contrasting different portions of the aquifer system for Subbasin characterization. For details regarding water quality issues and current groundwater conditions, refer to Section 2.3.3 and individual management area plans. In general, water quality is higher in TDS in the western third of the Subbasin than in the rest of the Subbasin. Higher nitrate and other solutes concentrations are typically present in shallow perched zones and in the unconfined zone above the Corcoran Clay. Groundwater is progressively fresher and lower in TDS below the Corcoran Clay, toward the center of the basin, and in the eastern half of the Subbasin. In contrast, arsenic concentrations increase with depth and in close proximity near portions of the Corcoran Clay. Arsenic and salinity progressively increase with depth approaching the base of USDW.

Kern County Water Agency Water Supply Reports which end in 2011 presented groundwater quality maps using data pre-1997. These maps report that unconfined groundwater (typically above the E-modified Corcoran Clay) in the central portion of the Subbasin generally ranges from less than 500 to 1,500 ppm for TDS, while the west side unconfined groundwater ranges from 1,000 to 5,000 ppm for TDS. The confined aquifer zone (typically below the E-modified clay) in the central portion of the Subbasin generally ranges from less than 200 to 500 ppm for TDS, while west side confined water typically ranges from 1,000 to 4,000 ppm.

The high TDS groundwater in the west side with respect to the east side has recently been reported in a preliminary groundwater salinity mapping study conducted by the USGS (Metzger and Landon, 2018). Within the Subbasin, the study reported much higher TDS in west side water when compared with east side groundwater. Metzger and Landon suggest that higher TDS could

be related to a combination of natural conditions (west side sediments derived from marine deposits with some connate water) and anthropogenic factors such as infiltration from disposal ponds and/or agricultural drainage ponds. The researchers suggest that groundwater on the east side of the Subbasin have the lowest TDS and greatest depths to non-USDWs because they are adjacent to Sierra Nevada that is a source of low TDS (fresh water Ca-HCO_3 type) recharge, whereas, aquifer zones on the west side of the Subbasin have higher TDS values. The west side aquifer zones likely receive very little recharge from the Temblor Range which is made up of marine deposits, and west side aquifer zones such as the west side Tulare Formation likely contain connate water derived from marine deposits (Wood & Dale, 1964). This higher TDS water (Na/Ca-SO_4 type) in west side water is consistent with historical reports and is documented for more than 60 miles from north to south in the Subbasin (KCDEH, 1980; KCDEH and KCWA, 1982; Sierra Scientific Services, 2013). Additional sections of this GSP provided by west side entities, discuss further details on the west-side Subbasin aquifer system.

Primary Use of Each Principal Aquifer

The unconfined zone in the eastern portion of the Subbasin and in the Kern Fan, and the confined zone below the Corcoran Clay are the primary production zones of the Subbasin aquifer system. In addition, the upper unconfined zone is pumped for beneficial use in the north central and west central areas of the Subbasin. The primary uses of the Subbasin aquifer system include agricultural, municipal, domestic, and storage for the banking of surface water.

Summary of Beneficial Uses and Users of Groundwater

Land use in the Subbasin includes agriculture, urban/industrial/residential, and open space use. According to the 2014 SGMA legislation, beneficial users of groundwater and property interests potentially affected by the use of groundwater include:

- Agricultural Users
- Domestic Users
- Municipal Well Operators
- Public water systems
- Local Land Use Planning Agencies
- Environmental Users

According to DWR well completion reporting and the CASGEM program, groundwater wells are constructed for a variety of uses including:

- Domestic / Residential
- Irrigation
- Stock
- Municipal / Public
- Monitoring / Observation

- Industrial
- Cathodic Protection
- Other / Unknown

2.2.1.7 Data Gaps and Uncertainty

The primary data gaps in the hydrogeologic conceptual model include:

- Physical properties of the westside aquifers and eastside aquifers,
- Physical properties of the upper zone of the primary aquifer system,
- Groundwater characterization on the eastern and western flanks of the Subbasin and in the upper and shallow zones, and
- Groundwater quality of the primary aquifer zones and confined zones on the eastern and western flanks of the Subbasin, from wells screened solely in a single aquifer zone.

As improvements to monitoring networks are made, data can be used to fill data gaps in the Subbasin.

2.2.1.8 Cross Sections

A general summary of regional subsurface information is provided below in the context of cross sections developed for this plan. Where applicable, detailed discussions of the subsurface are included in some management area plans of the Subbasin.

Cross sections were developed to illustrate the subsurface conditions of the Subbasin. The locations of the cross sections discussed below are provided on Figure 2-18. Section A-A' north of the Kern River (Figure 2-24a) is northeast-trending and perpendicular to the numerous faults and folds within the valley. Section B-B' north of the Kern River (Figure 2-24b) is northwest-trending to be parallel to the axis of the valley. Geologic and hydrogeologic data were compiled from DWR well logs, DOGGR well logs, Page (1973), Gillespie et al (2017), *California Oil and Gas Fields* (DOGGR, 1998), and other regional investigations.

Cross sections spanning the southern and southeastern portions of the Subbasin were developed for management area plans and are included herein (Figures 2-24c to 2-24g). For a discussion of the subsurface across the White Wolf Fault, data including a cross section are presented in the *White Wolf Subbasin Technical Report* (EKI, 2016), that was a part of the 2016 Basin Boundary Modification Request.

This Page Left Blank Intentionally

A-A' North of the River

A-A' north of the river illustrates the change in hydrogeology from west to east. The westside has a thin fresh water zone due to a shallow base of fresh water. The geology on the westside is dominated by marine deposits and the overlying Tulare formation consists of alluvial fan and debris flow facies primarily from sediments derived from the Coast Range marine deposits. To the east of the California Aqueduct, the Corcoran Clay of the Tulare includes diatomaceous clay and other fine-grained deposits associated with basin center facies. Section A-A' includes seismic form lines from the PGA (1991) investigation that show general structure of bedding that are consistent with mapped Buttonwillow and Semitropic folds and the structure of the base of the Tulare. In contrast, traditionally mapped Corcoran Clay layers which are available through the USGS and DWR (C2VSIM on Section A-A'), correlate clays that do now follow the general bedding forms observed in seismic lines. Future investigation may clarify the discrepancies between these interpretations.

The upper zone groundwater elevation is plotted on section A-A' which is generally considered to pertain to wells screened above the Corcoran Clay. Section A-A' displays wells screened in the upper zone above the Corcoran Clay which is the primary groundwater production zone to the west of Interstate 5 (I-5). Some groundwater production in the upper zone occurs east of I-5 with wells screened above the mapped Corcoran Clay and other wells screened across the Corcoran Clay. The upper zone likely extends further west and east; however, additional data were not available to continue the correlation.

The main regional groundwater surface is plotted across the basin. The groundwater is generally confined where wells are below the Corcoran Clay and semiconfined where wells are outside the extent of the Clay. As described in section 2.2.1.3, Pond-Poso Fault has been documented to affect groundwater flow. High resolution water level data across the fault, however, were not available for this cross section.

The central portion of the Subbasin (just west of the Pond-Poso Fault), has a much thicker aquifer zone with a deeper base of freshwater and thicker deposits of continental sediments (Kern River formation) derived from the Sierra Nevada where freshwater recharge into the Subbasin predominates.

Further to the east, wells have been drilled deeper (greater than 2000 feet) in order to extract fresh groundwater from the Santa Margarita formation and Olcese Sand. Although these aquifers are separate from the main alluvial aquifer system of the valley by Plio-Miocene Marine Deposits, some wells are screened across the continental deposits (Kern River formation), extending through marine and into the Santa Margarita formation and Olcese Sand.

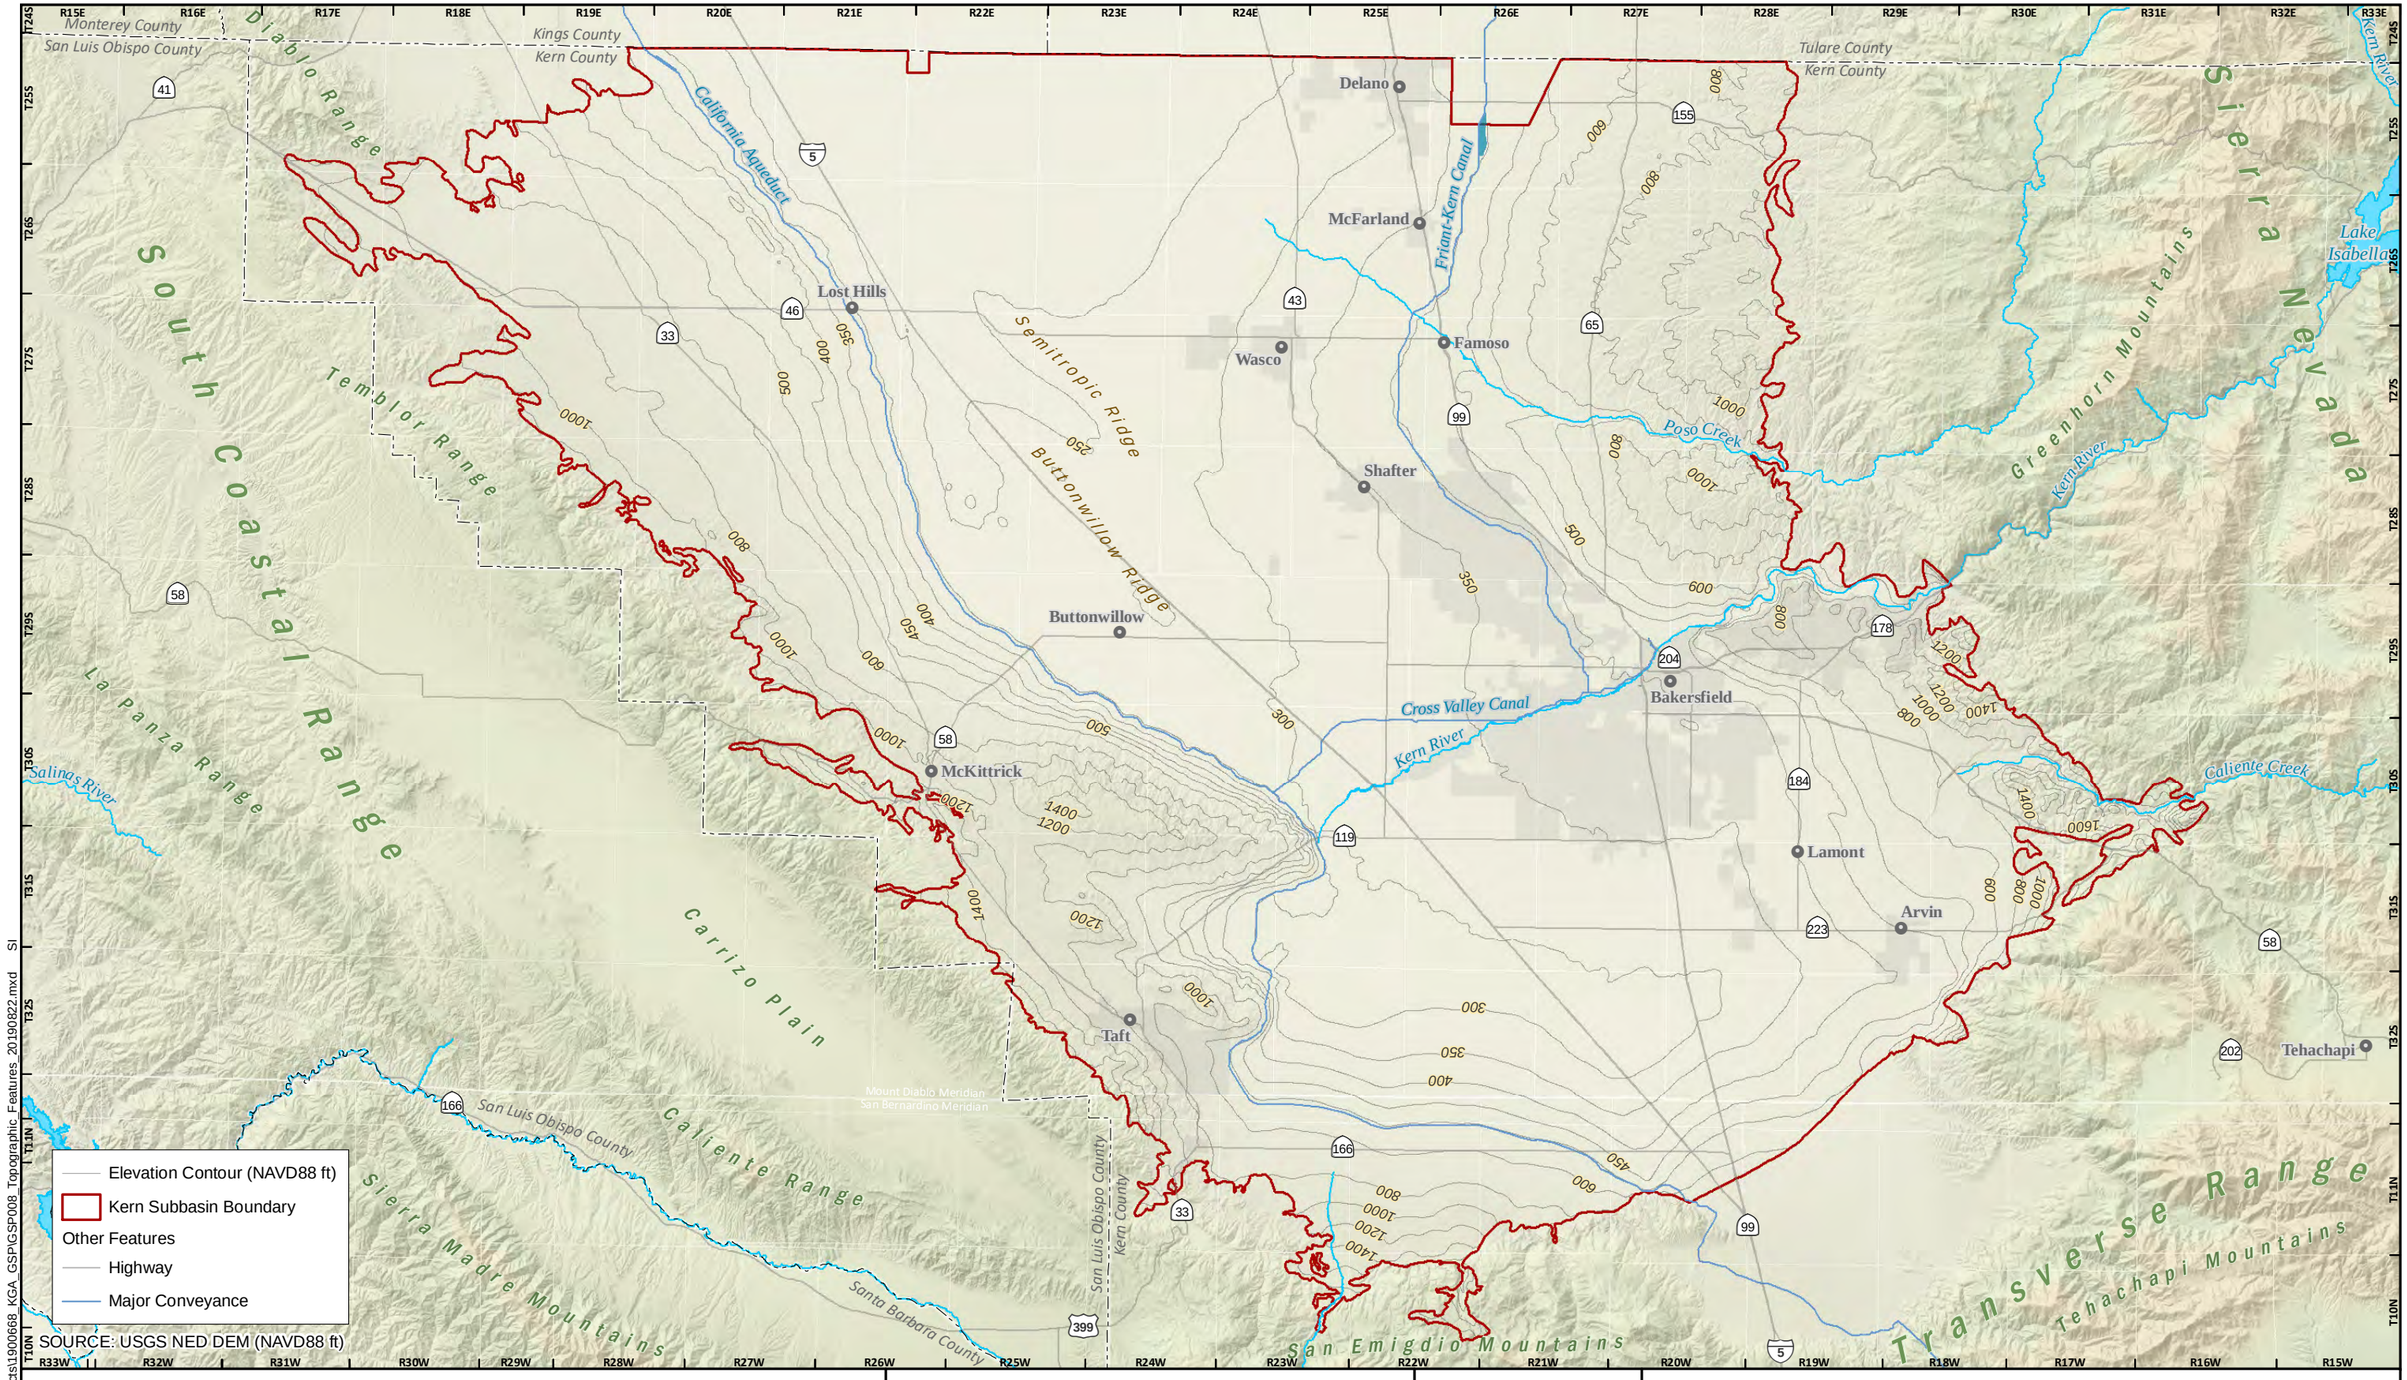
B-B' North of the River

Section B-B' from northwest to southeast trends through a portion of the Subbasin with a deep base of freshwater. Seismic form lines confirm bedding gradually rise to the south onto the Bakersfield Arch beginning from just north of the City of Shafter southward toward the City of Bakersfield and the Kern River. The alluvium and Kern River formation become thicker toward the south where the Kern River has been a major source of the sediment input into the Subbasin.

South of the River Cross Sections

Cross sections developed for management area plans in the southern portion of the Subbasin are included herein (Figures 2-24c to 2-24g). These sections present the base of fresh water where it is deepest in the central southern area of the Subbasin southwest of the City of Arvin. They also present the White Wolf Fault and Edison Fault which alter groundwater flow. In general, water wells are screened in the upper 1000 feet of the subsurface across the southern portions of the Subbasin, in the Kern River Formation and Tulare Formation. In the southeastern portion of the Subbasin, faulting and folding has created a thinner column of Kern River Formation deposits to the east of Lamont. The top of the Chanac Formation may be as shallow as 900 feet below ground surface in T31S-R29E. Consequently, data on the base of fresh water were not readily available for plotting in the southeastern portion of the Subbasin.

Cross sections across the White Wolf Fault are provided in the *White Wolf Subbasin Technical Report* (EKI, 2016). Historical sections document change in groundwater elevations (generally a 50 feet decline) across the fault from south to north. Displacement of beds across the fault increases with depth. In general, groundwater aquifer thickness is not significantly affected by displacement across the fault. Additional information is available at the Basin Boundary Modification website: https://sgma.water.ca.gov/basinmod/basinrequest/preview/34.



2.2.1.9 Mapped Physical Characteristics

Topographic Information

Figure 2-25 presents a basin-wide topographic map of the Subbasin. The rim elevation of the Subbasin varies from approximately 600 feet msl along the White Wolf Fault on the south to over 2,000 feet in the foothills of the adjacent San Emigdio Mountains. On the east and west sides, the rim elevations vary between 1,000 and 2,000 feet msl. As such, the topography of the Subbasin slopes toward the center of the valley on three sides, and the 400-foot contour line generally defines a long and narrow valley floor, which slopes to the northwest. The lowest land surface elevations are approximately 210 feet msl and are located along the County line between Highway 43 and Interstate 5 (18 of 24 miles). Within the Subbasin, prominent topographic features include the Elk Hills, and the Buttonwillow and Semitropic ridges.

Surficial Geology (Including Location of Geologic Sections)

The surficial geology of the Subbasin has been documented in a variety of previous investigations and is presented on Figures 2-13, 2-17, and 2-18 (Bartow, 1991; Page, 1986; and CGS, 2010b) According to the California Geological Survey (2010b), the center of the basin consists mainly of Pleistocene to recent unconsolidated and semi-consolidated alluvial (Q of Figure 2-17), lake, playa, and terrace deposits. Older Pleistocene alluvium (Qao) is present in the eastern portion of the basin on top of Pliocene-Pleistocene deposits (QPc) of sandstone, shale and gravel deposits, including the Kern River Formation. The QPc unit includes the Tulare Formation and occurs as islands, surrounded by recent alluvium, within the center of the northern Subbasin along the western side and within the alluvium. Small remnants of older continental sediments are included along the southeastern flank of the Subbasin, including undivided

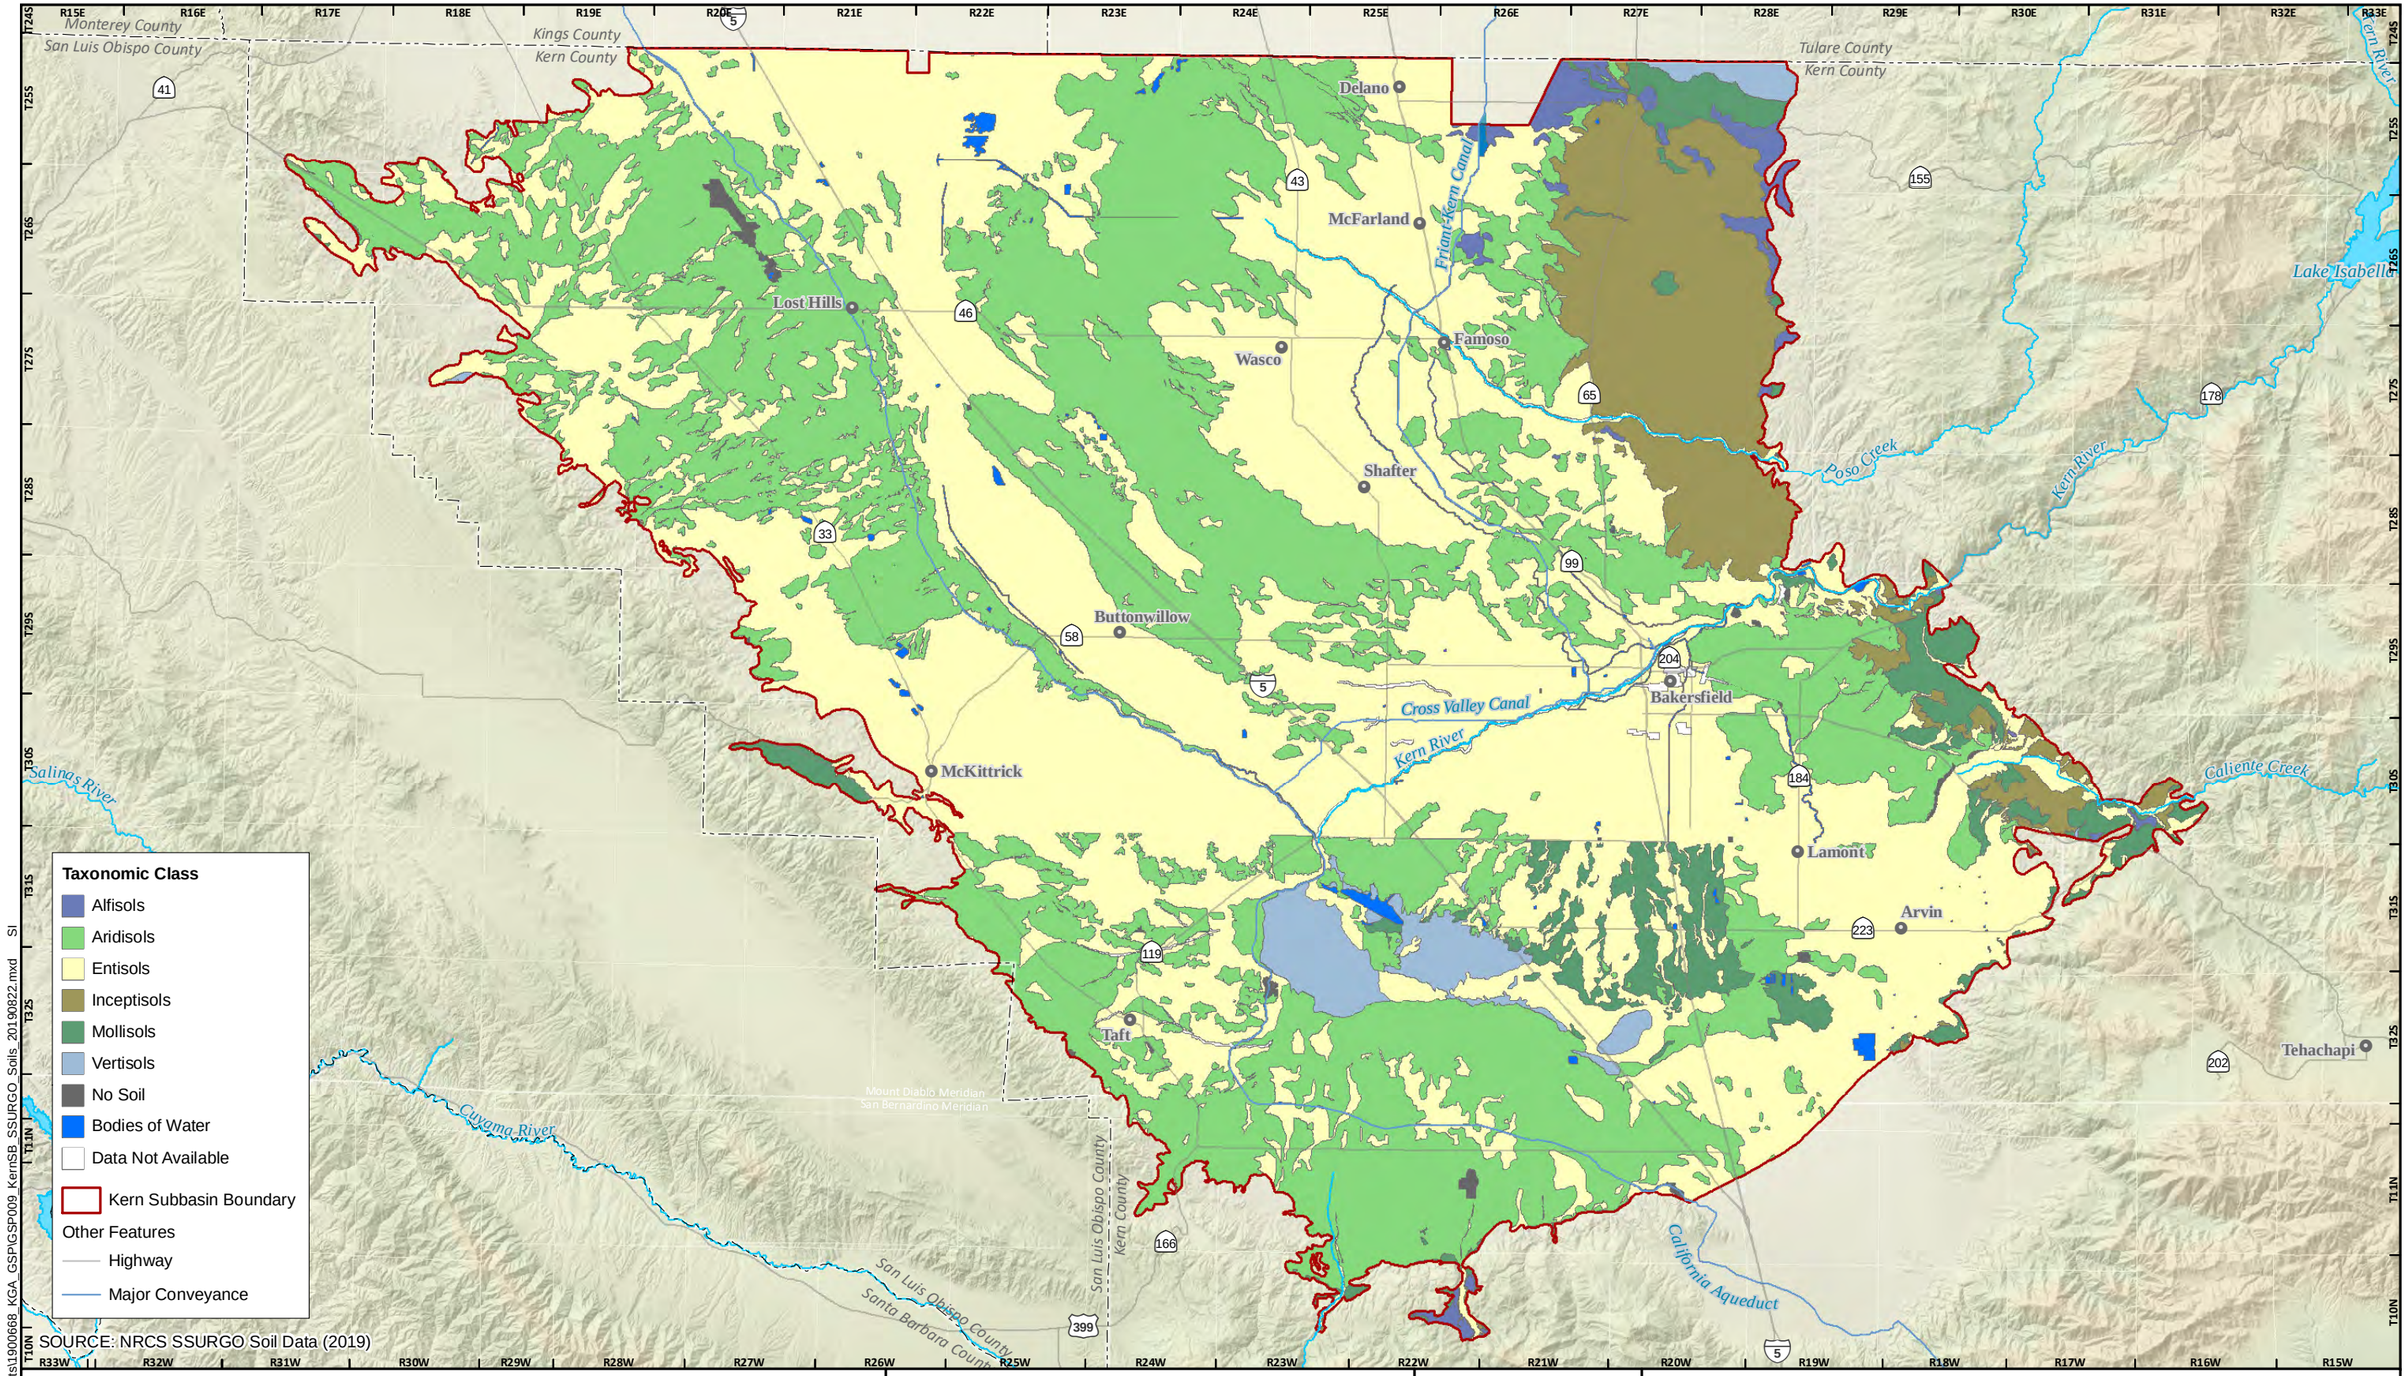
Tertiary-age sandstone, shale, conglomerate, breccia, and lake deposits (Tc) and Miocene-age sandstone, shale, conglomerate, and fanglomerate (Mc) plus smaller remnants of older marine sediments: Miocene-age sandstone, siltstone, shale, conglomerate, breccia (M). These remnant units would include the Santa Margarita Formation, Round Mountain Silt, and Olcese Sand.

Bartow (1991) provides a similar map (Figure 2-13) as the California Geological Survey map but refers to Quaternary alluvial and lacustrine sediments (Qs) on the valley floor and Tertiary sedimentary rocks (TS) along the flanks and for the islands of older rocks in the valley center. As discussed further below, the map shows the location of the Bakersfield Arch as well as three structural regions within the Subbasin.

Page's (1986) presentation of the surficial geology, as shown by Figure 2-17 better display the lakebed deposits. Recent river deposits (Qr) associated with the present-day Kern River, are shown as a long, narrow strip from the mouth of the Kern Canyon, and are comprised of gravel, sand, silt, and minor amounts of clay. The center of the valley floor is underlain by Recent flood basin (Qb) – clay, silt, and some sand; and by Pliocene to Recent lacustrine and marsh deposits (QTl) – clay, silt, and some sand with extensive subsurface clay layers (A, C, E/Corcoran). The former unit is associated with the original Kern River drainage and flood basin while the latter unit is associated with the historical Kern Lake Bed, Buena Vista Lake Bed, Goose Lake Beds, and the southern edge of the Tulare Lake Bed. The remainder of the valley is underlain by Miocene to recent continental deposits (QTc) – a heterogenous mixture of gravel, sand, silt, and clay with some layers of conglomerate, sandstone, siltstone, and claystone. Like the other maps, remnants of older continental deposits are shown along the rim of the Subbasin, primarily the southeastern side, including Oligocene to Miocene deposits (Tcmo) of gravel, conglomerate, sand, and clay; and Eocene to Miocene deposits (Tcme) of conglomerate, sandstone, fanglomerate, claystone, and breccia plus limited occurrences of undifferentiated marine deposits (Tm) of sand, clay, silt, sandstone, shale, mudstone, and siltstone of Eocene to Pliocene ages.

Soil Characteristics



Soils within the Subbasin have two general origins that are approximately delineated by the trough of the valley, which also mirror depositional patterns as mapped in surficial geology. The eastern alluvial fans were deposited primarily by runoff from the Sierra Nevada, Tehachapi, and Transverse mountain ranges. These soils are of igneous and metamorphic origin; are typically well drained, very low in salinity, and ideal quality for agriculture. The northwestern alluvial fans originated from Coast Range sedimentary rock formed on the sea bottom. This northwest region tends to have more areas with poorly drained soils of relatively marginal quality (Provost & Pritchard, et al., 2015). The Groundwater Quality Assessment Report (Provost & Pritchard, et al., 2015) describes five areas of different soil texture in the Subbasin: the clay rim area of fine grained texture near the historical lake beds, the foothills of medium texture, the Kern Fan region derive from river deposition, northern areas with some alluvium and other sources, and Wheeler Ridge/Arvin Edison with coarse soil. These five areas contain the different soil types described below.

Soils in the center of the Subbasin are generally categorized into three types according to texture. Fine-grained soils are found in the southwest, the historical lake beds, and northwest corners of

Subbasin. Coarse grained soils within the Poso Creek fan, Kern River fan, and Caliente creek fan. And the moderate infiltration of soils along the distal edges of the fans. The lake bed areas are composed of fine-grained soils of the historical Buena Vista and Kern lakebeds, and swamp and overflow lands, which continue north along the historical drainage paralleling the Goose Slough, Goose Lake, and southern edge of the Tulare Lake depositional environment. Medium to coarse grained soils are distributed in the Poso Creek and Kern River drainage beds as well as the proximal and medial portions of the Kern Fan, and the south boundary of the Subbasin.

Figure 2-26 and 2-27 present the soil distribution within the Subbasin as defined by U.S. Dept. of Agriculture (USDA), National Resources Conservation Service, Soil Survey Geographical Database (SSURGO) as obtained from the DWR SGMA Data Viewer website (2018). Figure 2-26 shows that six soil orders are present in the Subbasin, including Aridisols and Entisols throughout most of the Subbasin, with Inceptisols along the eastern highland, and much lesser amounts of Alfisoils, Mollisols, and Vertisols. According to the online Encyclopedia Britannica (EB, 2018), Ardisols are dry soils characterized by a low humus, light-colored surface horizon with a subsurface accumulation of soluble salts, silicate clays, and possibly a cemented layer of calcium carbonate, calcium sulfate (gypsum) or silica. Entisols are characterized by the absence of soil horizons due to recent deposition or active erosion under extreme wet or dry conditions (EB, 2018). Inceptisols exhibit a weak appearance of soil horizons overlying a weathering-resistant parent material. Alfisols are characterized by well-developed soil horizons enriched with aluminum- and iron-bearing (Al/Fe-) minerals but depleted of calcium carbonate (EB, 2018). Translocated clays typically form a layer with relatively high amounts of mineral nutrients (calcium, magnesium, sodium, and potassium). Mollisols are characterized by a thick, dark surface horizon of humus, which typically originates from native grass vegetation, and mineral nutrients are present in most horizons (EB, 2018). Humus and Al/Fe-bearing minerals do not migrate to subsurface layers. Vertisols are clay-rich soils (>30 percent) with significant cracking during the dry season due to the shrink-swell response of the clay minerals during the dry and wet seasons (EB, 2018). The shrink-swell action produces significant vertical mixing of the soil.

Figure 2-27 shows the distribution of hydrogeologic soil groups, which is based largely on four categories of infiltration rates: high, moderate, slow, and very slow. Group A soils have a high infiltration rate due to well drained sands or gravelly sands. Group B soils are moderately well drained due to moderately fine to coarse textures. These soils are present on the east, west, and south sides of the valley floor. Group C soils have a low infiltration rate due to their fine texture or because of a layer that impedes downward movement of water. These soils are present along the valley floor, along the eastern highlands, and at various locations along the northwestern side of the Subbasin. Group D soils have a very slow infiltration rate due to the presence of clay and are located primarily along the northern Subbasin boundary within the valley floor. More detailed soil survey data can be found in four USDA reports on various portions of the Subbasin: *Soil Survey of Kern County, California* (USDA, 1981, 1988, 2007, and 2009), including recent online updates.

FIGURE 2-27

Natural Recharge, Direct Recharge Areas, and Potential Recharge Areas

Direct recharge and potential recharge areas are differentiated in this section from natural recharge. Natural recharge occurs by groundwater underflow from adjacent sources, precipitation outgaining evapotranspiration in a Subbasin, or from natural surface waters flowing into the Subbasin. On the other hand, direct recharge is either planned or unplanned application of surface water by unlined conveyance, field application, managed recharge, and spreading operations. This section focuses mainly on direct recharge and potential recharge to the Subbasin, but briefly discusses natural recharge to the Subbasin. In-lieu recharge is not discussed in this section because it does not provide an actual input to the groundwater system for budgeting purposes, but only curtails or reduces the amount of groundwater that would have been pumped. In-lieu recharge is discussed in other sections of this GSP. This section may not include all localized recharge activities and facilities, but these local activities and facilities are further described within the individual management area plans.

Natural recharge to the Subbasin occurs mainly by underflow or surface recharge from the eastern and southern highlands (Sierra Nevada and Tehachapi Mountains). The surface water bodies as a source of recharge are discussed in the next section. In general, natural in-situ recharge by precipitation is absent in Subbasin, and may only occur in extreme wet years, because typically evapotranspiration outgains the amount of natural precipitation to the Subbasin (Provost and Pritchard et. al., 2015). The absence of natural recharge by in-situ precipitation in the Subbasin further illustrates the lack of recharge to the west side of the Subbasin where it is likely that very little if any freshwater underflow recharges the west side. In contrast, the east side is dominated by recharge from the Kern River and the Sierra Nevada.

Significant direct recharge to groundwater in the Subbasin occurs through managed recharge and water banking (storage) projects; as well as unmanaged recharge through natural waterways, unlined spill basins and regulating (balancing) reservoirs, percolation of applied water to crops that descend below the root zone, and unlined canals. Numerous sources of water are recharged by various projects, including local surface water (Kern River, Poso Creek, and other drainages) and imported water (State Water Project [SWP] and Central Valley Project [CVP]).

The major areas of direct recharge (facilities and drainages) are presented in Figure 2-28. Additional areas of unmanaged or managed recharge may include agricultural land where excess irrigation water percolates below the root zone, wastewater treatment spreading areas, and urban drainage spreading areas. Additional locations of natural recharge from surface water features may include springs, seeps, ephemeral/intermittent streams flowing into the Subbasin (Figure 2-29). The surface water features are described in more detail in the following section.

Since the late 1980s, large-scale groundwater recharge/banking operations have been constructed along the Kern River. Given the permeable nature of sediments within the Kern River Fan, most of the enhanced recharge projects involve surface spreading through ponds, low-lying fields, or basins. Some projects are dedicated to the replenishment of the groundwater basin, while other projects store surplus SWP and CVP water for subsequent extraction; and some banking projects do both. (Todd, 2017).

The Soil Agricultural Groundwater Banking Index (SAGBI), can further estimate groundwater recharge suitability to quantify recharge of deep percolated applied irrigation water and potential recharge from future managed recharge within the Subbasin. The California Soil Resource Lab at University of California Davis has developed an online application (https://casoilresource.lawr.ucdavis.edu/sagbi/) to present the SAGBI, which estimates groundwater recharge suitability based on five major factors: deep percolation, root zone residence time, topography, chemical limitations, and soil surface condition. The application includes mapping coverage of the SAGBI and indicates a moderately good to excellent rating for the Poso Creek alluvial fan in the north central Subbasin, the Kern River alluvial fan in the central area, and in much of the southeastern to southwestern corners of the Subbasin. SAGBI ratings are moderately poor to very poor along the eastern margin, central western margin, as well as the center of the valley from the former Kern and Buena Vista lake beds, north along the Goose Neck Slough to the Tulare Lake Bed. While moderately good to good SAGBI is shown for much of the western margin, this area is underlain by marine sediments and is not likely to be a useful area for recharge. The SAGBI ratings generally agree with mapped soil data where higher rated SAGBI soil corresponds with moderate to high infiltration soils. Note that an abrupt east-west alignment of good versus poor SAGBI occurs in the southern central Subbasin and is likely due to the methods and results of historical soil surveys.

Groundwater discharge areas in the Subbasin are limited due to the depth of usable groundwater, typically greater than 100 feet throughout the Subbasin. Shallow, poor-quality groundwater (above the A-clay) does occur in the west central and southern areas. These shallow groundwater areas may support salt-tolerant vegetation. Effects of a shallow water table and evapotranspiration may discharge poor quality shallow groundwater from these areas to the surface. Historically, flowing wells were present throughout much of the valley floor (Mendenhall, 1916), including the Buena Vista and Kern lakes and the area to the north (>180 square mi), and from Buttonwillow north beyond the county line (>400 square mi). Over 100 flowing wells were identified in 1905 and reductions in flow were recognized in the following years. According to the USGS groundwater model (Faunt, 2009), the Kern River is a groundwater discharge area along a nominal 7-mile reach within Bakersfield, east of Highway 99; however, the City of Bakersfield measures flow at six weirs along the river across the valley and shows an overall loss of flow (seepage) from the Kern River.

Surface Water Bodies

Figure 2-29 presents the location of surface water bodies in the Subbasin according to the National Hydrography Dataset. These water bodies include the California Aqueduct (SWP) and federal Friant-Kern Canal, and other local canals that help convey Kern River water and imported surface water to beneficial users in the Subbasin. This dataset also includes the Kern River, Poso Creek, Caliente Creek, and other significant ephemeral streams, spring, and seeps, that are sources of recharge from the mountains on the east, southeast, and south sides of the Subbasin. The National Hydrography Dataset also includes wetlands delineations around the Kern Wildlife Refuge. The refuge is now sustained by imported surface water typically wheeled from the California Aqueduct and conveyed by the Goose Lake Canal to the refuge (USFS, 2005).

The most important source of naturally occurring surface water for the Subbasin is the Kern River, which has been regulated by the Isabella Dam and Reservoir since 1954. The dam and reservoir are operated by the U.S. Army Corps of Engineers and the distribution of water is administered by the Kern River Watermaster. The Kern River is approximately 164 miles long and is fed by rain and snowmelt from the Southern Sierra Nevada, including Mount Whitney. The last 35 to 40 miles of river crosses the Subbasin.

Local streams, many of which are ephemeral, provide additional local surface water during the wet season and during above normal and wet water years. A very small percentage of minor stream runoff is collected and used for irrigation; the majority of these irregularly occurring flows likely serve to recharge local groundwater basins (Kennedy and Jenks, 2011).

Source and Point of Delivery for Imported Water Supplies

Imported water is supplied by the Central Valley Project's (CVP) Friant-Kern Canal and California Department of Water Resources through the SWP. CVP water from the Friant Division is conveyed to users in the Subbasin through the Friant-Kern Canal, and SWP water is conveyed through the California Aqueduct together with CVP water from the Delta Division. Treated produced water is also used as an imported source of water to the groundwater Subbasin for beneficial use.

Central Valley Project – Friant Division

The CVP Friant-Kern Canal diverts water from Millerton Reservoir, created by Friant Dam on the San Joaquin River, and extends southward a distance of 152 miles through Fresno, Tulare and Kern counties to its terminus at the Kern River in Bakersfield. The capacity of Millerton Reservoir is about 520,000 AF, but 130,000 AF of this storage lies below the intake for the Friant-Kern Canal.

Water districts along the east side of the San Joaquin Valley entered into long-term water supply contracts with Reclamation, which provide for the delivery of three types of water; Class 1, Class 2, and Section 215.

Class 1 Water is the supply of water stored in or flowing through Millerton Lake which, subject to the contingencies described in the Contracts, will be available for delivery from Millerton Lake and the Friant-Kern and Madera Canals as a dependable water supply during each Contract Year.

Class 2 Water is the supply of water which can be made available subject to the contingencies described in the Contracts for delivery from Millerton Lake and the Friant-Kern and Madera Canals in addition to the supply of Class 1 Water. Because of its uncertainty as to availability and time of occurrence, such water will be undependable in character and will be furnished only if, as, and when it can be made available as determined by the Contracting Officer.

Section 215 Water is a temporary supply of water, other than Class 1 Water or Class 2 Water, made available to the Contractors in addition to water provided pursuant to water service contracts, including water made available that is not subject to acreage limitation pursuant to

Section 215 of the Reclamation Reform Act of October 12, 1982 (96 Stat. 1263), as amended. The historical allocation priorities for Section 215 Water are as follows:

- Long-term contractors
- Cross Valley contractors
- Other parties within the Friant Division service area with direct delivery capabilities
- CVP contractors outside of the Friant Division service area
- Other parties

Central Valley Project – Delta Division

In 1973, DWR completed the initial facilities of the SWP, including the main line of the California Aqueduct. Portions of the SWP were constructed for use in conjunction with the facilities of the CVP. As the state and federal projects developed, a group of water users planned the Cross-Valley Canal as a means of taking delivery of CVP water conveyed through the California Aqueduct. The Cross-Valley Canal was completed in 1975 and, in 1976, the water users entered into three-party contracts with DWR and Reclamation. Under these contracts, CVP water available to Reclamation in the Delta can be pumped by the SWP's Harvey O. Banks Pumping Plant into the California Aqueduct for delivery to the Tupman turnout where this water is diverted into the Cross-Valley Canal. This federal water, conveyance of which is subordinate to conveyance of SWP water, can then be delivered to water users in the Subbasin.

State Water Project

The Kern County Water Agency was formed in the 1960s to contract with the DWR for the importation of SWP water to Kern County. The California Aqueduct, the SWP's principal conveyance feature, transports water from the Delta along the west side of the San Joaquin Valley to the Subbasin. Individual water districts holding contracts with Kern County Water Agency have turnouts directly from the aqueduct into their service areas or receive water via the Cross-Valley Canal.

Two types of water are available from the SWP, including relatively firm Table A Water and surplus Article 21 Water. Table A Water takes its name from an exhibit to the contract between the DWR and the SWP contracting agencies that serves as the basis for allocating water among the agencies.

While the reliability of SWP water is less than was anticipated when the contracts were executed, a contract amendment, introduced in the Monterey Agreement of 1994, put agricultural and urban contractors on equal footing respecting the allocation of water supply during shortages. Prior to the amendment, agricultural contractors were burdened with a larger share of any shortages.

Article 21 Water, unlike Table A water, cannot be scheduled; rather, it must be taken at the time it is declared to be available and is analogous to Section 215 Water for the CVP-Friant contractors. The following conditions govern the availability of Article 21 Water:

- Available only when deliveries do not interfere with Table A allocations and SWP operations
- Available only when excess water is available in the Delta
- Available only when conveyance capacity is not being used for SWP purposes or scheduled SWP deliveries
- Cannot be stored within the SWP system. In other words, the contractors must be able to use the Article 21 water directly or store it in their own system

Due to these conditions, Article 21 Water is only available during the wet months of the year, typically December through March.

Produced Water

Water brought to the surface when oil is extracted is often referred to as "produced water." Produced water is groundwater that is commingled with hydrocarbons and located within the hydrocarbon bearing reservoir. Produced water is generated as oil is extracted for use. Often, produced water is returned to the original geological formation for enhanced oil recovery or disposal. Some produced water is suitable for beneficial use with treatment, though most is higher in salinity and must undergo extensive treatment and be blended with other water before use. New technology and the need to find new sources of water are driving the ability to process and treat produced water for beneficial use.

2.3 Groundwater Conditions

Annual groundwater elevation contour maps covering much of the Subbasin have historically been prepared by Kern County Water Agency in Water Supply Reports since before the 1990s until 2012. These maps provide seasonal high groundwater level conditions from spring water level data, and generally depict groundwater flow conditions over time consistent with flow directions observed in 2015. Groundwater conditions are also monitored through a number of local and joint district activities, as well as state mandated programs, such as CASGEM.

2.3.1 Groundwater Trends

Based on historical groundwater trends from USGS and the Kern County Water Agency (Page, 1986; and KCWA), groundwater flows into the Subbasin mostly from the uplands along the south and east margins of the Subbasin. Below is a generalized diagram depicting groundwater flow into the Subbasin (Figure 2-30). In the absence of pumping or significant barriers, groundwater naturally flows from high elevation points of recharge to lower elevation points with less recharge. In general, groundwater flow diverges to the north and south away from natural and managed recharge points along the Kern River. The river flows into Subbasin roughly along the axis of the Bakersfield Arch, which has a broad topographical rise that gradually dips to the north and south; thus, the rough alignment of the river effectively splits the Subbasin into northern and southern groundwater flow regimes. Groundwater to the south of the river flows toward discharge points at pumping wells within the south-central areas of the Subbasin, and groundwater to the north of the river migrates toward the northwest discharge points at pumping wells and continues north until it leaves the Subbasin as subsurface underflow.

Figure 2-30 presents the approximate location of the San Joaquin Valley (Buttonwillow) Syncline which likely affects the flow of westside groundwater from significantly impacting the main production zone of the Subbasin. In general, groundwater elevation trends near the river may be highly variable due to high volumes of managed groundwater recharge and extractions associated with groundwater banking projects. Groundwater elevation patterns further away from banking operations show more seasonal responses from pumping and recharge, and, an overall, long-term decline in groundwater level in the majority of the Subbasin.

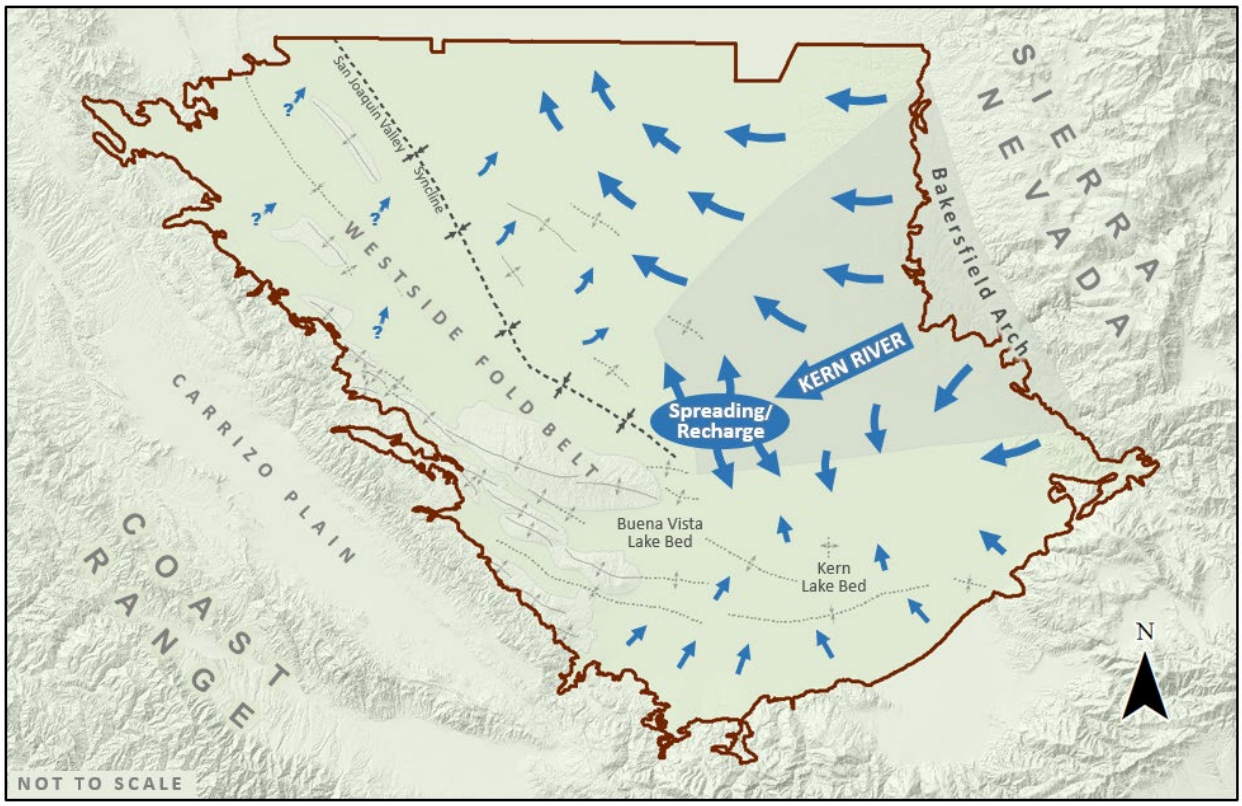

Figure 2-30. Generalized Diagram of Groundwater Flow in Kern County Subbasin

2.3.1.1 Elevation and Flow Directions

Groundwater elevation contour maps were prepared for Spring 2015 to provide relatively current groundwater flow trends across the Subbasin since the inception of SGMA. Contours were prepared for Spring 2015 (seasonal high) in the primary aquifer zone or "main production zone" which is generally confined below the E-clay or Corcoran and unconfined to semiconfined outside the extent of the E-clay (Figure 2-31). Contours for the "Upper Zone" by Schmidt and Associates (2018) are presented on Figure 2-32 for Spring 2015 data. They represent the upper unconfined to semiconfined zone (above the E-clay or equivalent) underlying the northwest-central part of the Subbasin. A Fall 2015 contour map was also developed to represent seasonal low groundwater conditions in the primary aquifer zone (Figure 2-33). At this time, there is insufficient data to contour a fall 2015 upper zone map. In addition, to production zones, depth contours developed by the Kern County Water Agency (2012) for the shallow unconfined zone (above the A-clay or equivalent) are presented on Figure 2-34.

SUMMER 2011 UPPER ZONE GROUNDWATER ELEVATIONS

AUGUST 2019

FIGURE 2-34

These contours were developed from Summer 2011 and are generally representative of 2015 conditions. In general, shallow elevations are fairly constant over time.

Regional Contours

In general, groundwater flow directions reported are consistent with historical trends, with groundwater flowing from the uplands on the south, east, and west of the Subbasin toward the center of the Subbasin. Groundwater tends to diverge at the Kern River with flow to the south of the river toward pumping well discharge points, and flow to the northwest of the river toward pumping wells, and further north until it leaves the Subbasin. Based on 2015 groundwater elevations, the divergence to the North and to the South along the river is less notable due to the drought conditions which resulted in greater groundwater use with very little recharge during 2013 to 2015. Depressions in the groundwater potentiometric do occur south of the river; however, a general trend of flow toward the north and center "trough" of the Subbasin is apparent.

Groundwater elevations during Spring 2015 in the main production zone of the aquifer system ranged from less than minus 100 ft msl in the north-central part of the Subbasin to greater than 300 ft msl in the eastern and southeastern part of the Subbasin.

Groundwater elevation data for the Fall 2015 were limited in availability due to the high demand for pumping; therefore, the data range is incomplete, it may be affected by pumping, and it represents only a partial dataset; however, general groundwater flow trends are consistent with historical trends. Groundwater elevation data for the Fall 2015 in the main production zone of the aquifer system ranged from less than minus 150 ft msl (north-central Subbasin) to greater than 250 ft msl (south-southeast Subbasin). Contours in the upper unconfined zone of north-central Subbasin and shallow zone of Subbasin were not prepared for Fall 2015 due to a lack of sufficient data.

Upper Zone Contours

Groundwater elevations during Spring 2015 in the upper zone of the north central part of the Subbasin ranged from 220 ft msl to 160 ft msl. Within Townships 27S and the northern half of 28S, groundwater in the Upper Zone flows northeasterly. Within the southern half of Township 28S and 29S, groundwater flows southeasterly. Some of this flow may be affected by the Buttonwillow Syncline and Buttonwillow Ridge (anticline). As observed in Cross Section A-A' of North of the River (Figure 2-24A), beds from this groundwater aquifer system are deformed (folded).

Shallow Depth Contours

Groundwater depths in the shallow zone historically range from approximately 20 to 25 ft bgs to less than 5 ft bgs (ranging from 200 ft msl to 245 ft msl). Representative contour maps were chosen from the Kern County Water Agency's 2011 Water Supply Report (KCWA, 2012) (Figure 2-34), because more recent data from 2011 to 2015 are limited in extent; nonetheless, the recent data agree with DWR published maps of shallow perched groundwater in the San Joaquin Valley (DWR, 2009), and with the Kern County Water Agency's historical water supply reports.

Shallow groundwater is not significantly impacted by groundwater pumping in the production zone, as observed by the relatively consistent shallow groundwater depths and extents in historical water supply reports from the Kern County Water Agency and DWR across multiple water year types. The source of shallow groundwater as mapped by the Kern County Water Agency, is derived from the percolation of applied irrigation water, as well as historical natural percolation during large storm events. The extent of shallow groundwater, which is typically perched on shallow fine-grained sedimentary units and likely disconnected from the productive aquifer system, is relatively consistent with Page's (1986) extent of mapped surficial fine-grained flood deposits (Figure 2-17 and shallow clay units related to the "A" Clay of the Corcoran Clay (KCWA, 1976). During the mid to late 1980's, sufficient data were collected for the Kern County Water Agency's water supply report to show that, at times, the perched shallow groundwater units to the north of the river and to the south of the river have been joined at the northwest of the Kern River Fan, generally following the extent of flood plain deposits as mapped by Page (1986).

While shallow groundwater data is collected in certain regions of the Subbasin, the current data collection effort does not provide sufficient data to understand the interconnection between the lower production aquifer and the shallow purged groundwater system that existing in portions of the basin. This data gap will be addressed in projects and management actions identified in individual management area plans.

Horizontal Gradients

The following is a summary of general regional groundwater flow direction and general regional horizontal gradients based on the contour maps presented herein. For more detailed trends, refer to management area plans.

Groundwater in Spring 2015 for the main production zone (confined below the E-clay and semi-confined outside of the clay) in the east-northeast flows southwesterly at a gradient of 0.011 ft/ft. In the north-central area, groundwater flows northwesterly at a gradient of 0.002 ft/ft. In the central area of the Subbasin near the Kern River and banking activities, groundwater flows north to northwesterly at a gradient of 0.002 to 0.004 ft/ft. In the southeast, groundwater flows southwesterly at a gradient of 0.025 ft/ft. In the south, groundwater flows northwesterly to southeasterly at gradients of 0.004-0.012 ft/ft and 0.004 ft/ft respectively. In the southwest, groundwater flows northeasterly at a gradient of 0.001 ft/ft. Groundwater in the Bakersfield area flows away from the river from 0.005 to 0.011 ft/ft in a southeasterly to northwesterly gradient.

Groundwater in Fall 2015 for the main production zone (confined below the E-clay and semi-confined outside of the clay) in the east-northeast flows west to southwesterly at a gradient of 0.015 ft/ft. In the north-central area, groundwater flows northwesterly at a gradient of 0.002 ft/ft. In the central area of the Subbasin near the Kern River groundwater flows toward the banking activities northeasterly and southwesterly at gradients of 0.006 ft/ft and 0.003 ft/ft respectively. In the southeast, groundwater flows southwesterly at a gradient of 0.016 ft/ft. In the south, groundwater flows northwesterly to southeasterly at gradients of 0.007 ft/ft and 0.008 ft/ft respectively. In the southwest, groundwater flows northwesterly at a gradient of 0.005 ft/ft.

Groundwater in Spring 2015 for the upper unconfined zone (unconfined above the E-clay) in the north half of Township 28S and 27S flows northeasterly at a gradient of 0.002 ft/ft. In the south half of T28S and T29S, groundwater flows southeasterly at a gradient of 0.003 ft/ft. In the far north mapped area of the upper unconfined zone, groundwater flows at a gradient of 0.001 ft/ft northwesterly and 0.004 ft/ft westerly.

2.3.1.2 Hydrographs and Vertical Gradients

Hydrographs presenting change in groundwater elevation over time and vertical groundwater gradients for specific areas of the Subbasin are provided in the chapters herein for local management areas. In general, hydrographs presented in the management area plans indicate that groundwater elevations decline during below normal water years (as defined by the water year index), and groundwater elevations begin recovering during above normal water years. Additional information can be found Section 2.4, Water Budget Information.

2.3.2 Seawater Intrusion

The Subbasin is located in the Central Valley, more than 40 miles from the Pacific Ocean. Seawater intrusion will not affect the Subbasin.

2.3.3 Groundwater Quality

To characterize groundwater quality in the Subbasin, a literature review was conducted using USGS studies and other technical reports, as well as data extracted from GeoTracker and EnviroStor to identify contaminant plumes. The SWRCB's Human Right to Water portal was used to identify contaminants that are commonly violating drinking water standards and an evaluation of the groundwater water quality was conducted using data from local Water Districts and the State Drinking Water Information System (SDWIS), which collects sample results from all State regulated public water systems. This section of the report provides a brief introduction to the contaminants most commonly found in the Subbasin. A more focused evaluation of the groundwater is provided in the management area plans for each member agency that comprises the KGA.

Characterization of groundwater quality was conducted to comply with (California Code of Regulations – Title 23 – Waters; Subarticle 2 §354.16(d) – Groundwater Conditions: groundwater quality issues that may affect the supply and beneficial uses of groundwater, including a description and map of the location of known groundwater contamination sites and plumes. Constituents evaluated and the methodology used were consistent with guidance provided in:

- Assembly Bill 1249 (AB 1249) which states that "if the IRWM region has areas of nitrate, arsenic, perchlorate, or hexavalent chromium contamination, the (IRWM) Plan must include a description of location, extent, and impacts of the contamination; actions undertaken to address the contamination, and a description of any additional actions needed to address the contamination" (Water Code §10541.(e)(14)).

- Division of Drinking Water's (DDW) Human Right to Water (HR2W) portal, which identifies the contaminants that public water systems have received maximum contaminant level (MCL) violations. Commonly found contaminants were trended and occurrence data was evaluated.
- Water Quality Control Plan for Tulare Lake Basin (Basin Plan), dated May 2018, which is the State Board's implementation plan for Water Code §106.3. The amended Basin Plan requires permittees to "address the immediate needs of those drinking groundwater that exceeds the drinking water standard for nitrate."

Incorporating guidance from these sources was intended to incorporate the major constituents of concern and characterize groundwater in a manner that is consistent with current water quality focused programs. Of the regulated drinking water constituents considered, the most common water quality issues within the Subbasin are: nitrate, arsenic, boron, hexavalent chromium, dibromochloropropane (DBCP), 1,2,3-trichloropropane (TCP), total dissolved solids (TDS), sodium, and chloride. This water quality discussion is divided by constituent to explain the drinking water and agricultural standards and how these constituents impact beneficial uses in the different regions of the Subbasin. Since the predominant land use in the Subbasin is for agricultural purposes, agricultural Water Quality Goals (as established by Ayers and Westcott) are referenced for evaluation of groundwater salinity (SWRCB, 2016a). The most applicable standard, Drinking Water Standard or agricultural goals will be used as a reference point when discussing each constituent.

Maps created to show constituent prevalence were developed using data extracted from the Groundwater Ambient Monitoring and Assessment (GAMA) Groundwater Information System. Only wells from the Public Water System dataset were used because they provide more consistent results since compliance monitoring frequency is regulated by DDW. To depict the highest contaminant values, the maximum concentrations were plotted, rather than average concentrations, from each public water system spanning a 10-year timeframe (2009-2019). These maps are intended to provide a general overview of constituent prevalence and concentrations. They should not be interpreted as indicating contamination throughout the region because constituent concentrations typically vary depending on well construction and local hydrogeologic conditions. More detailed analysis of water quality trends is discussed in the individual management area plans.

2.3.3.1 Arsenic

Arsenic has a primary drinking water MCL of 10 parts per billion (ppb) and an agricultural goal of 100 ppb. Reports published by the Department of Pesticide Regulation and USGS studies and the hydrogeology of the Subbasin indicate that the major source of arsenic in this Subbasin is naturally occurring from erosion of natural deposits. Throughout the southern San Joaquin Valley, arsenic-rich minerals such as arsenopyrite, a common constituent of shales and apatite, and phosphorites are the most common sources of arsenic leaching materials in the aquifer (Burton et al, 2012). In the Subbasin, these minerals are mostly found in lake bed deposits or the Corcoran Clay. USGS reports that most of the highest arsenic detections are near the City of Delano and at the southwest extents of the Kern Fan, near the City of Bakersfield.

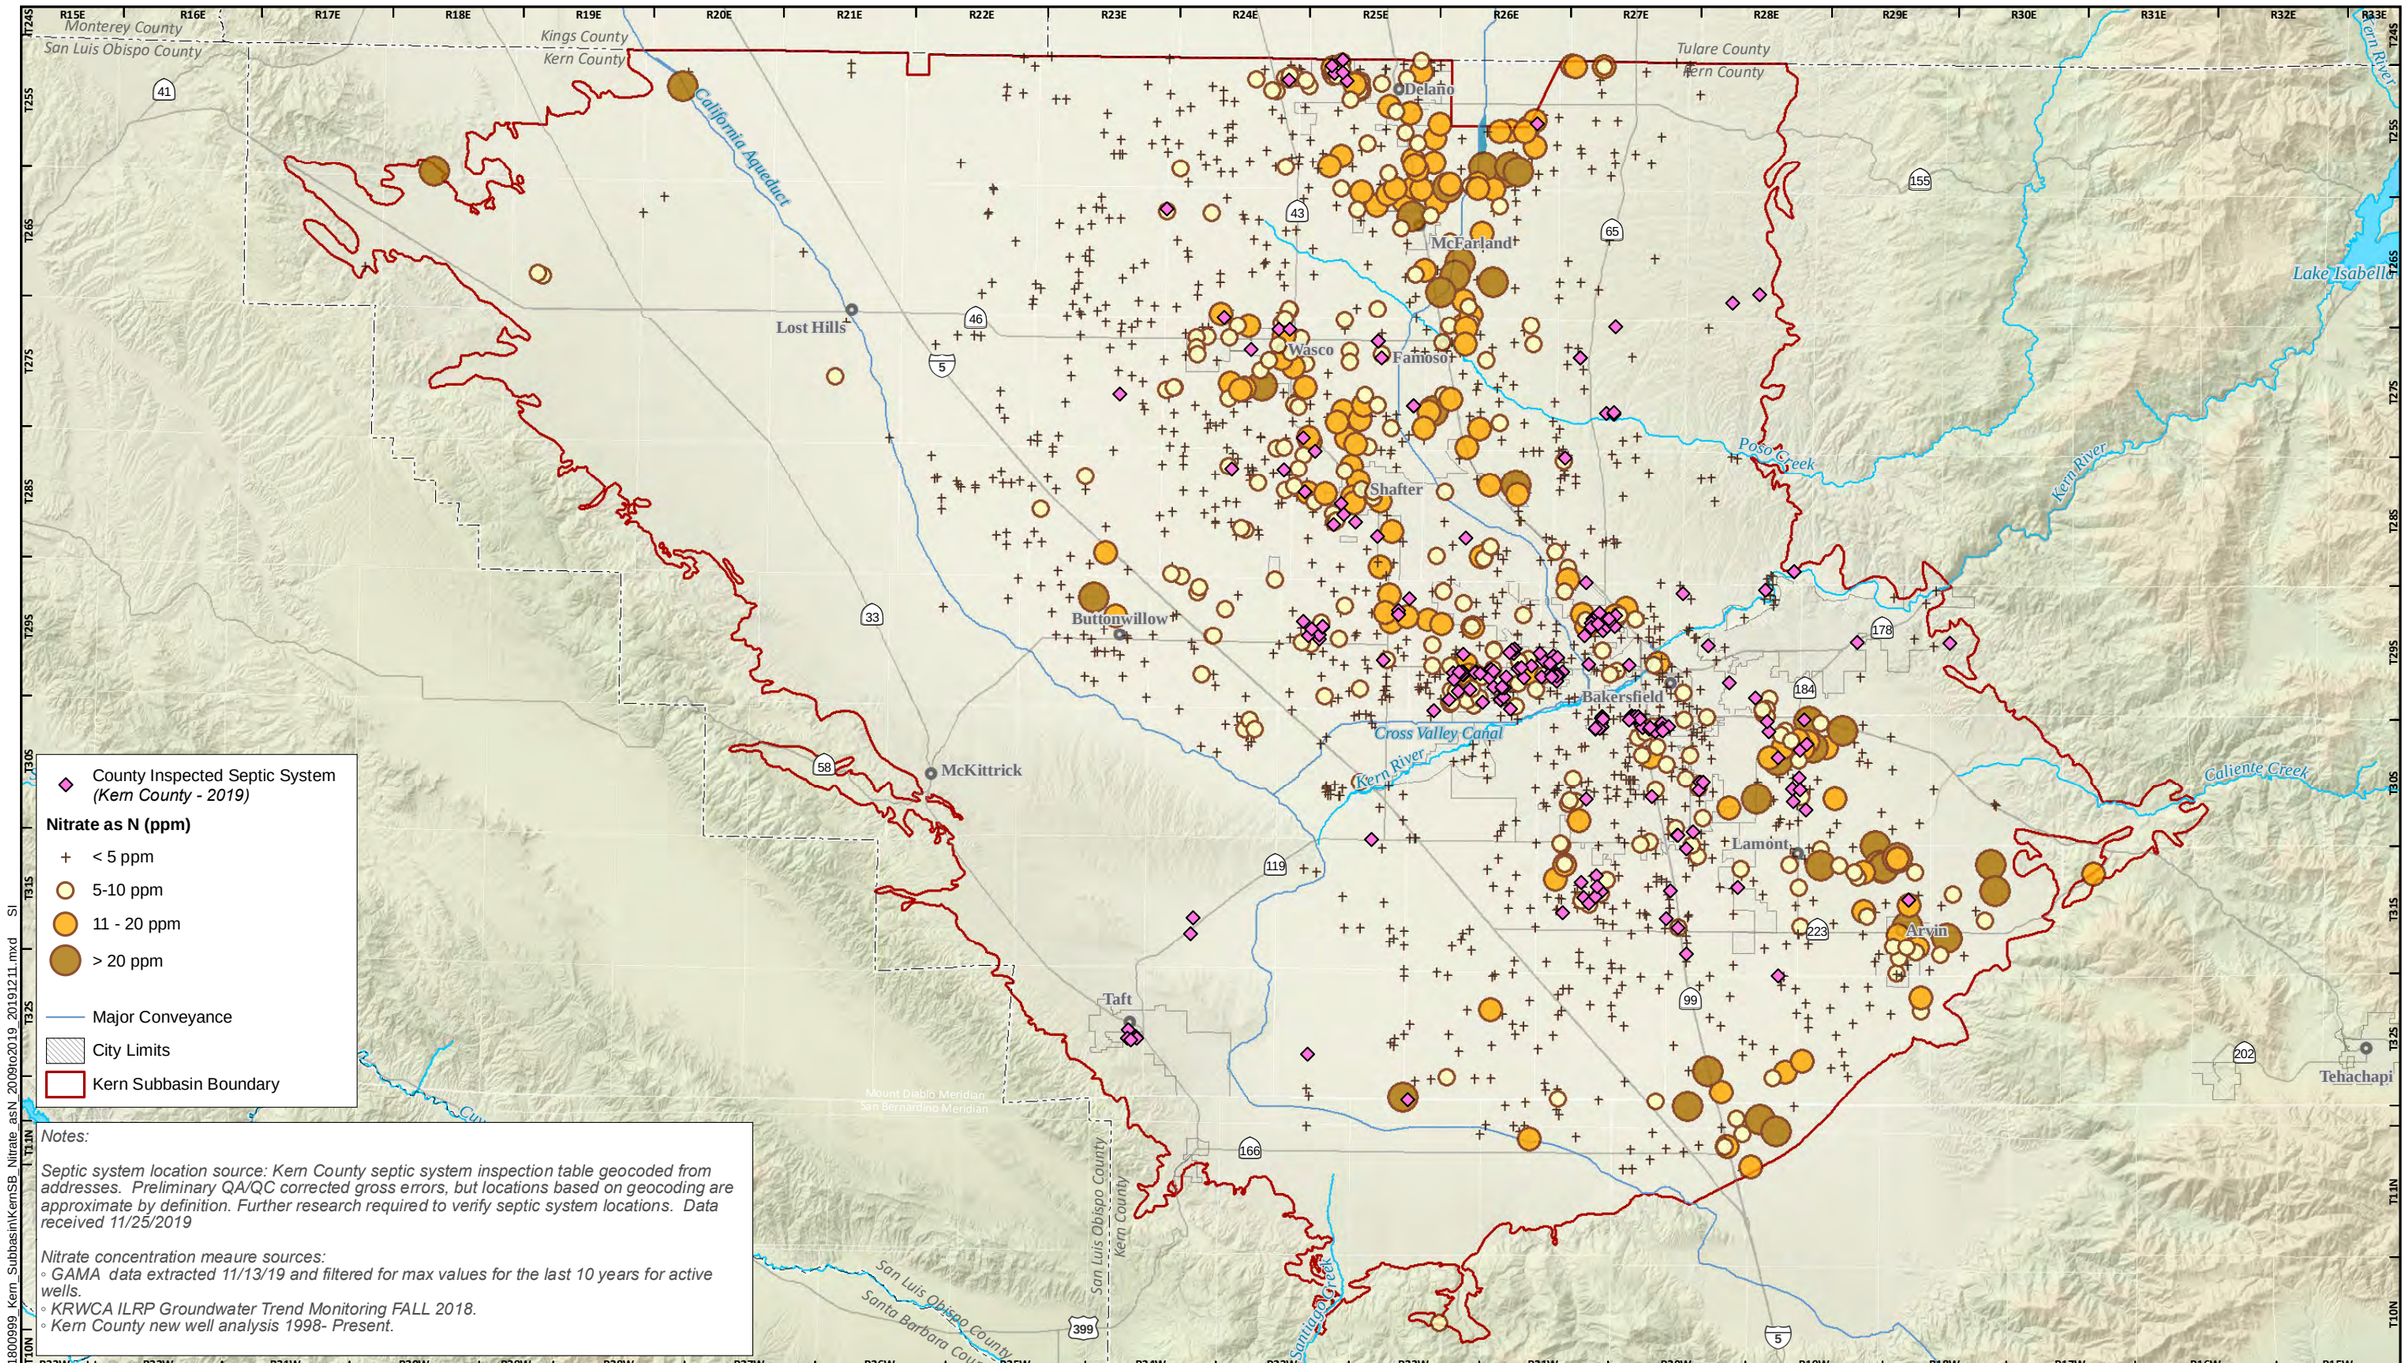
Since arsenic is mostly derived from natural geochemical processes, elevated concentrations are localized and appear to be associated with lake bed areas where there are thick clay deposits: Tulare Lake, Kern Lake, and Buena Vista Lake (Bulletin 118, DWR). In the Subbasin, consistently high concentrations generally concentrate in the center of the valley along the north margin of Buena Vista lake bed. Data trending indicates that its predominately found in wells constructed deeper than 1,000 feet below ground surface (bgs). Trending of the public water system wells in the Kern Fan indicates elevated arsenic is consistently found in wells constructed deeper than 650 feet bgs, and when groundwater elevations decline. A study conducted by USGS reports that arsenic is the trace element most frequently present at high concentrations in the Subbasin. Concentrations found in nearly 1,400 samples ranged from 10 to 30 ppb (Burton et al, 2012).

Severe drought conditions from 2012 through 2016 resulted in groundwater levels significantly declining throughout Kern County; subsequently, wells located in the Kern Fan are showing higher concentrations of arsenic from the deeper aquifers into the pumping zone due to the proportion of water from the deeper screened intervals increasing. Consequently, higher concentrations of arsenic have been observed in municipal wells. As groundwater levels temporarily recovered in 2017, there was a noticeable correlation to lower arsenic concentrations.

Findings from a study conducted by Negrini et. al (2008) explain that the thickest part of the coarsening-upward unit in the Kern Fan is in the same region as the wells with elevated arsenic concentrations. The study identified a large-scale sedimentary sequence (a specific geologic sequence) that was primarily prevalent in most of the wells in this study area. This sequence unit consists mostly of uniformly fine-grained silts and clays and the unit abruptly thickens basin-wide. The thickest part of this unit was found to have groundwater arsenic concentrations above 50 ppb. Depth interval containing sediments from this unit generally coincide with intervals having elevated arsenic concentrations. It was also found that at the same depth interval, arsenic is in an easily exchangeable state in the bulk sediment where oxidizing geochemical conditions dissolve the pyrite and release arsenic into the groundwater.

In addition to the lake bed areas, there is common arsenic detections associated with the Corcoran Clay. Mineral deposits transported by rivers into the San Joaquin Valley, from the Sierra Nevada and the coastal mountain ranges, became enriched with arsenic mineral deposits then adsorbed on the clay surfaces that were buried over time. When the oxygen deprived mineral deposits come into contact with oxygenated water, the result is dissolution of arsenic within the clay pore and into the groundwater. These deposits typically begin at depths greater than 180 feet bgs. Occurrence of arsenic in groundwater and any associations to the Corcoran Clay are addressed at the management area plans water quality sections.

2.3.3.2 Nitrate



Nitrate as nitrogen has an acute drinking water MCL of 10 parts per million (ppm); there is no agricultural goal. Sources of nitrate contamination in groundwater are runoff and leaching from fertilizer use; leaching from septic systems and sewage; confined animal facilities; and very

small concentrations from erosion of natural deposits. Typically wells in the San Joaquin Valley have higher nitrate concentrations in the shallower zones. However, higher nitrate concentrations can also occur in deep wells, depending on source concentrations, lithology, and well construction. Dubrovsky et al (2010) considers background nitrate concentrations above 1 ppm to indicate human activity.

Although the agricultural industry is believed to be a primary contributor to nitrate contamination of the groundwater basins in the Central Valley, based on mass loading calculations, irrigation practices in this Subbasin have been improved to reduce nitrate leaching into groundwater. In a study conducted for the Kern River Watershed Coalition Authority (KRWCA, 2013), it is acknowledged that nitrate leaching from agricultural irrigation is not like other basins to the north because irrigation practices are more efficient here, which reduced nitrate leaching into the groundwater. This assessment is supported by a comparison of the Nitrate Hazard Index results from 1990 and 2012, which shows a significant reduction in nitrate risk to groundwater.

KRWCA is leading the Irrigated Lands Regulatory Program (ILRP) for the Subbasin and have provided results from the initial groundwater sampling that took place in fall of 2018 (KRWCA, 2019). Their groundwater trend monitoring program requires nitrate sampling of first encounter groundwater during spring and fall each year. Trends are not ascertained yet since fall of 2018 was the first year of monitoring and these are the only results that are publicly available. Of the 26 representative wells sampled (14 domestic and 12 irrigation), nitrate results ranged from 1.1 to 21 parts per million (ppm) with a median value of 9.9 ppm. Nine of the wells sampled exceed 10 ppm: of these, seven wells are domestic and two are used for irrigation. Nitrate concentrations of these wells is included in Figure 2-35, although they are not specifically labeled as first encounter groundwater wells.

In addition to studies evaluating agricultural impacts of nitrate contamination, studies investigating the correlation of other potential nitrate sources were also reviewed. Dubrovsky et al (2010) finds that domestic wells located in agricultural areas are not only influenced by irrigation practices and/or livestock as a potential nitrate source, but also from septic systems. A USGS study (Burton et al, 2012) was conducted in the Southeast San Joaquin Valley and the Kern County Subbasin. This study used statistical analysis of land uses, well construction data, water quality parameters and number of septic systems around each study well to determine that land uses fairly represent nitrate sources impacting the well. Some of the data obtained for the Burton et. al, (2012) study were from the State Water Board's GAMA Domestic Well Project, where wells were sampled in 2006 (Shelton, 2006). The Project analyzed 29 of the 181 domestic study wells in the Kaweah Subbasin study area, for stable isotopes of nitrogen and oxygen. Wells with higher nitrate concentrations (median of 5 ppm and mean of 11 ppm) were targeted for this study. Testing showed that 28 of the 29 impacted wells have nitrate characteristics consistent with a dairy manure or septic system source. Septic systems elevate groundwater nitrate concentrations since they only remove half of the nitrogen in the wastewater, leaving the remaining half to percolate to groundwater (McCalasand, 2019). One of the 29 wells showed an isotopic composition indicative of a synthetic fertilizer. While the isotopic composition of nitrate

varies with land use, it is consistent between nitrate source (soil, fertilizer, manure, septic or community wastewater). Private well sampling for stable isotopes of nitrate was not conducted in the Kern County Subbasin.

Kern County Environmental Health Department (EHD) updated their program and ordinance with the development of the County's Local Agency Management Program (LAMP) to comply with the State Water Board's policy on septic systems (SWRCB, 2012). This was adopted to allow local agencies to continue use of septic systems, while protecting water quality and public health. An analysis was conducted to estimate baseline septic systems in Kern County. Four basic elements used in their analysis were parcel development status; general soil/septic systems suitability mapping; hydrologic areas; and groundwater basins. Since it was assumed that incorporated areas have municipal sewer systems that either serve or are available to these parcels, only non-sewerage unincorporated areas of the County were included in the analysis. This study revealed that approximately 30 percent of developed parcels within the Subbasin rely on septic systems. KGA is working with Kern County to document the location of these septic systems. A partial list of system recently inspected was provided and is shown in Figure 2-35.

Prior to the State's policy, EHD has been collecting water quality data on newly drilled wells to gain an understanding of groundwater quality. Initial assessment showed about eight percent of the wells tested are above the nitrate MCL; data from 1998 through 2019 are included in Figure 2-35. While there is currently a data gap, it is anticipated that continued work with Kern County and through the implementation of their LAMP that the domestic well water quality data and location of septic systems will be available to KGA. Although not all septic system location data is available at the time of this evaluation, it is noted areas with septic systems and domestic wells, generally show elevated nitrate concentrations.

Studies conducted by UC Davis, Center for Watershed Sciences have evaluated nitrate sources in the Tulare Lake Basin and documented that on a regional scale, groundwater nitrogen loading from sewer collection system leaks and septic systems is negligible compared to fertilizers. However, when looking at a local level, septic systems can be a significant source of nitrate contamination to domestic wells in peri-urban areas surrounding cities, or in areas of relatively high rural household density (Viers et. al, 2012). Findings also indicate that disadvantaged communities with water quality issues are in these same areas. Septic systems are considered low-hanging fruit (Dzurella et al, 2012), but is an important issue to address due to its impact to localized drinking water sources.

Data gaps often identified in these studies include lack of localized data such as location of septic systems, proximity of domestic wells to septic systems, and water quality of unregulated domestic wells. Reports such as Viers et al, (2012) and the initial assessment for the LAMP report have acknowledged these data gaps. To better assess nitrate sources, future monitoring programs should be geared towards better data collection methods to conduct a more comprehensive evaluation on septic system impacts to groundwater. Additionally, nitrate issues need to be evaluated on a local level rather than regional approach, especially when looking at the impacts to human health and consumption of water from unregulated domestic wells.

2.3.3.3 Boron

There is no federal or state MCL for boron. However, California does have a Notification Level of 1,000 ppb, and there is an agricultural goal of 700 ppb. The agricultural goal is set to protect various agricultural uses of water, including irrigation of various types of crops and stock watering. These levels are used as a baseline to compare against and are not intended to represent an acceptable maximum value for the Subbasin. Since most of the land use in the Subbasin is irrigated lands, the agricultural goal for boron is used as a reference point, rather than the drinking water Notification Level. The most prevalent sources of boron in drinking water are from leaching of rocks and soils, wastewater, and fertilizer/pesticides applications.

According to the USGS Scientific Investigations Report 2011-5218 (Burton et al, 2012) boron is most commonly found in the southern part of the Subbasin near the Tehachapi Mountains. Even though the USGS study for boron was limited to the southern part of the Subbasin, it was concluded that elevated concentrations of boron may be naturally occurring. Boron is potentially associated with sediments in the aquifer derived from marine deposits that are naturally high in boron from the Coast Ranges and San Emigdio Mountains. Saline waters have also been found to contain relatively high concentrations of boron, groundwater that underlies the freshwater aquifer could contribute high boron concentrations in deep wells.

2.3.3.4 Hexavalent Chromium

There is no federal MCL for hexavalent chromium. In July 2014, California adopted a primary MCL of 10 ppb, which was invalidated as of September 2017. While DDW is repeating the regulatory process for adopting a new MCL, the federal MCL of 50 ppb for total chromium applies. There is no agricultural goal for hexavalent chromium.

Hexavalent chromium can come from anthropogenic and natural sources. Anthropogenic sources include discharges of dye and paint pigments, wood preservatives, chrome-plating liquid wastes, and leaching from hazardous waste sites into the environment. Naturally occurring chromium is a metal found in ore deposits containing other elements, mostly as chrome-iron ore. Chromium is also prevalent in soil and plants: the phenomenon of releasing chromium into groundwater is believed to be similar geochemical processes to arsenic. Generally, natural chromium in the environment occurs as trivalent chromium (Cr3) then is oxidized to a hexavalent state (Cr6+). This typically occurs in oxidizing conditions such as alkaline pH range (between 8 and 14 units) or in the presence of manganese dioxide; in these conditions, naturally occurring hexavalent chromium is likely to exist.

The presence of manganese oxide minerals within ultramafic and serpentinite derived soils and/or sediments can trigger the oxidation of chromium, leading to the presence of naturally occurring hexavalent chromium in the aquifers (SWRCB, 2017; Groundwater Information Sheet 2017). While studies have not been conducted on the types of soils and sediments in the Subbasin where hexavalent chromium is present, the relatively low concentrations (typically in the range of 5 – 13 ppb) indicate the source is naturally occurring (GAMA). Additionally, GeoTracker and EnviroStor databases were searched for open contamination cleanup sites and do not identify any point source contamination in the Subbasin.

2.3.3.5 Synthetic Organic Chemicals

Synthetic organic chemicals predominately found in the Subbasin are dibromo-3-chloropropane (DBCP) and 1,2,3-trichloropropane (TCP). Both chemicals have very low drinking water MCLs. There are no agricultural goals. DBCP has a primary MCL of 0.2 ppb; sources of contamination are a banned nematicide that is still present in soils and groundwater due to runoff or leaching from former use on soybeans, cotton, vineyards, tomatoes, and tree fruit. Since its use was banned in 1977, groundwater contaminant concentrations in municipal wells have shown either steady or decreasing trends. In 2008 the Department of Public Health (transferred to State Water Board as DDW in July 2014) estimated the median half-life of DBCP in the Central Valley is 20 years. This is consistent with the public well data that has been evaluated for this Subbasin.

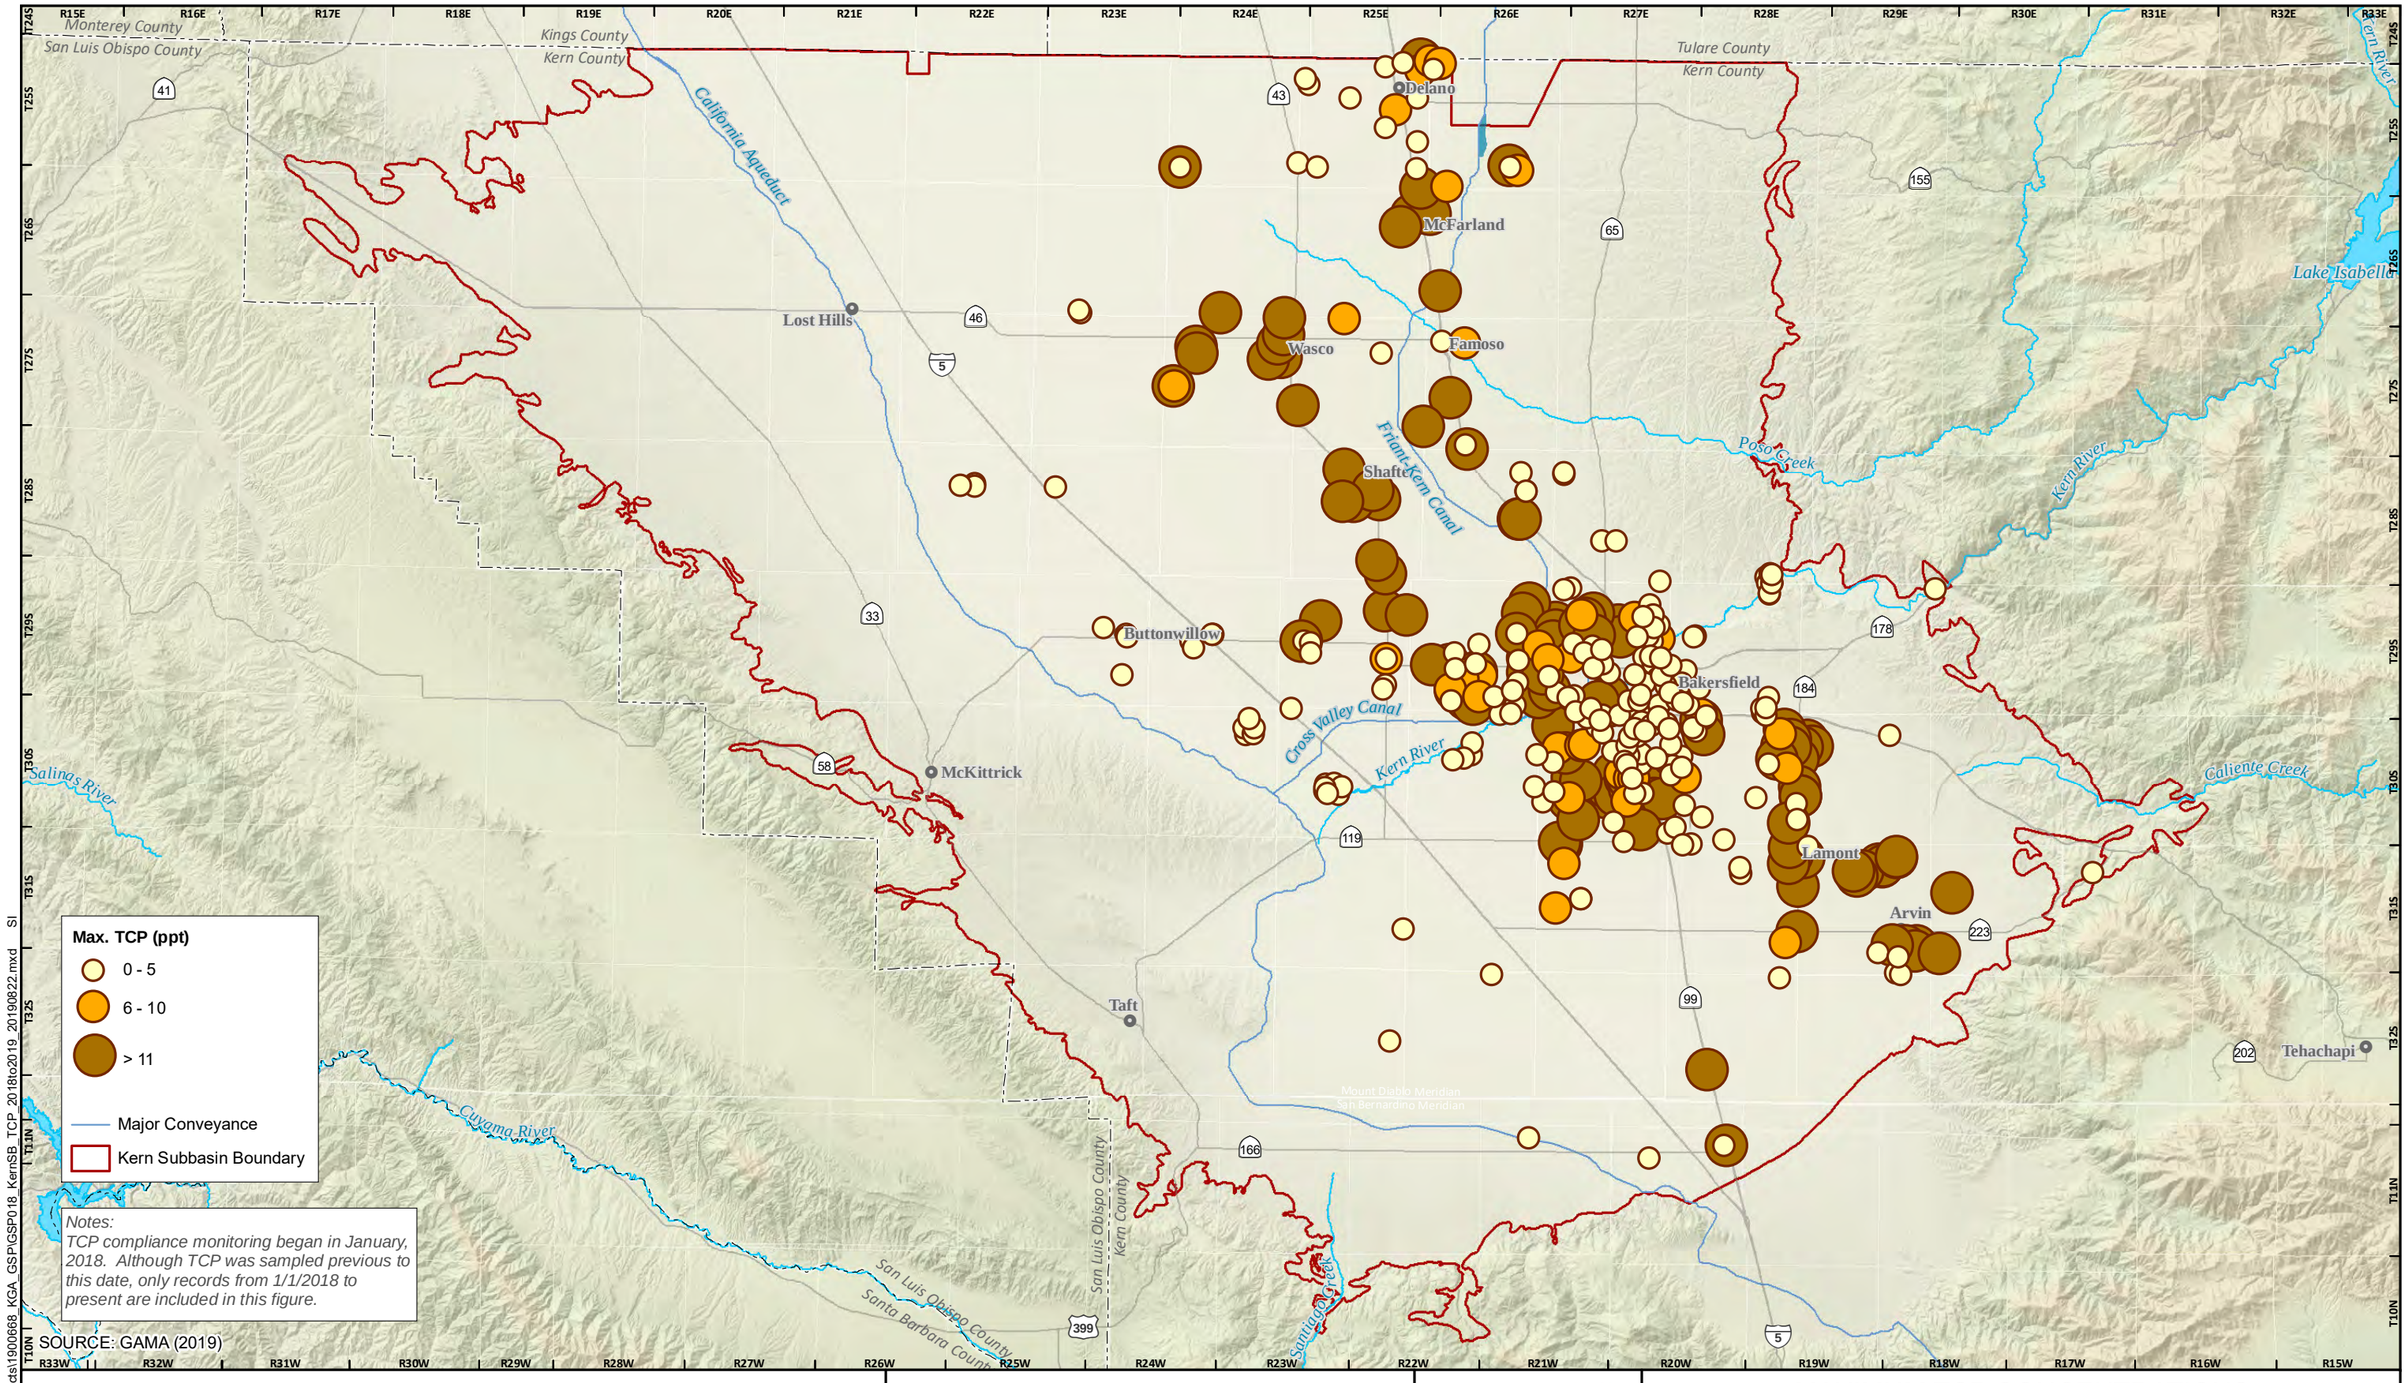
TCP has a primary MCL of 5 parts per trillion (ppt), which became effective in January 2018 and requires all active drinking water sources are tested at least quarterly during 2018. Since the MCL is set at the detection limit, any well with a detection is identified as exceeding the standard. According to the Water Boards Q1 Report, there is a clear correlation between the location of the of drinking water sources contaminated with TCP and agricultural activities (State Water Resources Control Board, TCP Sampling in Q1 2018).

In the past, TCP was present as an impurity in certain soil fumigants (1,3-D soil fumigants) used to kill nematodes. TCP also has some limited industrial uses. Throughout the Central Valley, most of the TCP found in groundwater was introduced through agricultural application of soil fumigants sold under the trade names of D-D and Telone. In the mid-1970s, Telone was reformulated and the name changed to Telone II. D-D was discontinued in 1984. Telone II remains on the market today but no longer contains TCP. Because TCP was an impurity in these soil fumigants, the potential groundwater contamination was not disclosed to distributors or users, by the product manufacturers. Application rates were not tracked, making it difficult to determine where groundwater contamination is likely to occur. TCP is a highly stable compound, meaning that it is resistant to degradation and has a half-life of hundreds of years (Samin et. al. 2012).

Many large public water systems (serving more than 10,000 population) began sampling their wells for TCP using a low-level analytical method around 2003, as a requirement of the Unregulated Chemical Monitoring Rule. From this data, DDW determined that the most impacted counties are Kern, Fresno, Tulare, Merced, and Los Angeles. Since a primary MCL was adopted, all water systems were required to test their wells quarterly beginning January 2018. Occurrence data from the State Water Board's DDW shows 94 of California's public water systems have 562 TCP impacted wells (DDW, June 2016). In Kern County, 18 water systems have 124 impacted wells, or approximately 52 percent of their total wells (State Water Board, June 2016).

Figure 2-36 provides a graphical representation of TCP concentrations for the public water system wells within the Subbasin (data extracted on April 29, 2019). To simplify the figure, only the maximum concentrations from January 2018 to April 2019 are shown. Results from the initial compliance monitoring indicates that increased testing requirements directly increased the prevalence of TCP impacted wells in the Subbasin.

the maximum concentrations from January 2018 to April 2019 are shown. Results from the initial compliance monitoring indicates that increased testing requirements directly increased the prevalence of TCP impacted wells in the Subbasin.



2.3.3.6 Total Dissolved Solids (TDS), Sodium and Chloride

Based on drinking water standards, the recommended secondary maximum contaminant level (SMCL) of total dissolved solids is 500 parts per million with an upper limit of 1,000 ppm and chloride is 250 ppm with an upper limit of 500 ppm. There is no drinking water standard for sodium; however, Water Quality Goals for Agriculture, published by the Food and Agriculture Organization of the United Nations in 1985, has set agricultural goals for TDS, sodium, and chloride at 450 ppm, 69 ppm, and 106 ppm, respectively. The criteria identified are protective of various agricultural uses of water, including irrigation of various types of crops and stock watering. These levels are used as a baseline to compare against and are not intended to represent an acceptable maximum value for the Subbasin. Since a majority of the land use in the Subbasin is irrigated lands, the agricultural goals for TDS, sodium, and chloride are used for this portion of the water quality evaluation.

The Burton et. al (2012) report states that in general the higher concentrations of TDS may be affected by sediments from the Tehachapi and San Emigdio Mountains and the Coast Ranges which contain marine deposits. Report findings showed positive correlations between agricultural land use and TDS levels but concluded that higher concentrations of TDS in the Subbasin may primarily be from natural sources as well as human activities. The same findings were true for chloride concentrations.

In a preliminary groundwater salinity mapping study conducted by USGS Scientific Investigations (Report 2018-5082, Metzger and Landon, 2018), groundwater salinity related to the distribution of 31 oil fields and adjacent aquifers was mapped across major oil-producing areas of central and southern California. The objective of this mapping study was to define groundwater with TDS concentrations less than 10,000 ppm using data from petroleum and groundwater wells, and to document data gaps. The study concluded that there is no hydrogeological connection between oil wells and water wells in the mapped regions. This conclusion is based on salinity mapping and well construction: the top perforation of the oil wells is deeper than the bottom perforation of water wells, except for oil fields in the north eastern part of Kern County. Well perforations in the north eastern part showed little to no vertical separation. Additionally, the study found that the west side of the San Joaquin Valley (in in Kern County) generally has the highest TDS levels at the shallowest depths.

Salinity defined in the chapters of this report are sometimes general, referring to TDS levels, or may be more specific to address the ions of concern based on predominant land uses. TDS is comprised of several dissolved minerals (calcium, phosphates, nitrates, sodium, potassium, and chloride), most of which have minimal impact on beneficial uses of the groundwater. Throughout the Subbasin, sources of salinity identified include a combination of naturally occurring marine deposits; infiltration from produced water disposal ponds; perched water subject to evaporative pumping; or agricultural drainage ponds.

Sodium and chloride ions contribute to TDS and in this region are more important to evaluate due to its impact to the agricultural industry. Both sodium and chloride show similar trends in the wells evaluated; therefore, some sections of the water quality evaluation collectively refer to these ions as salinity. There is slightly more focus on sodium since it is an important measurement to crop yield.

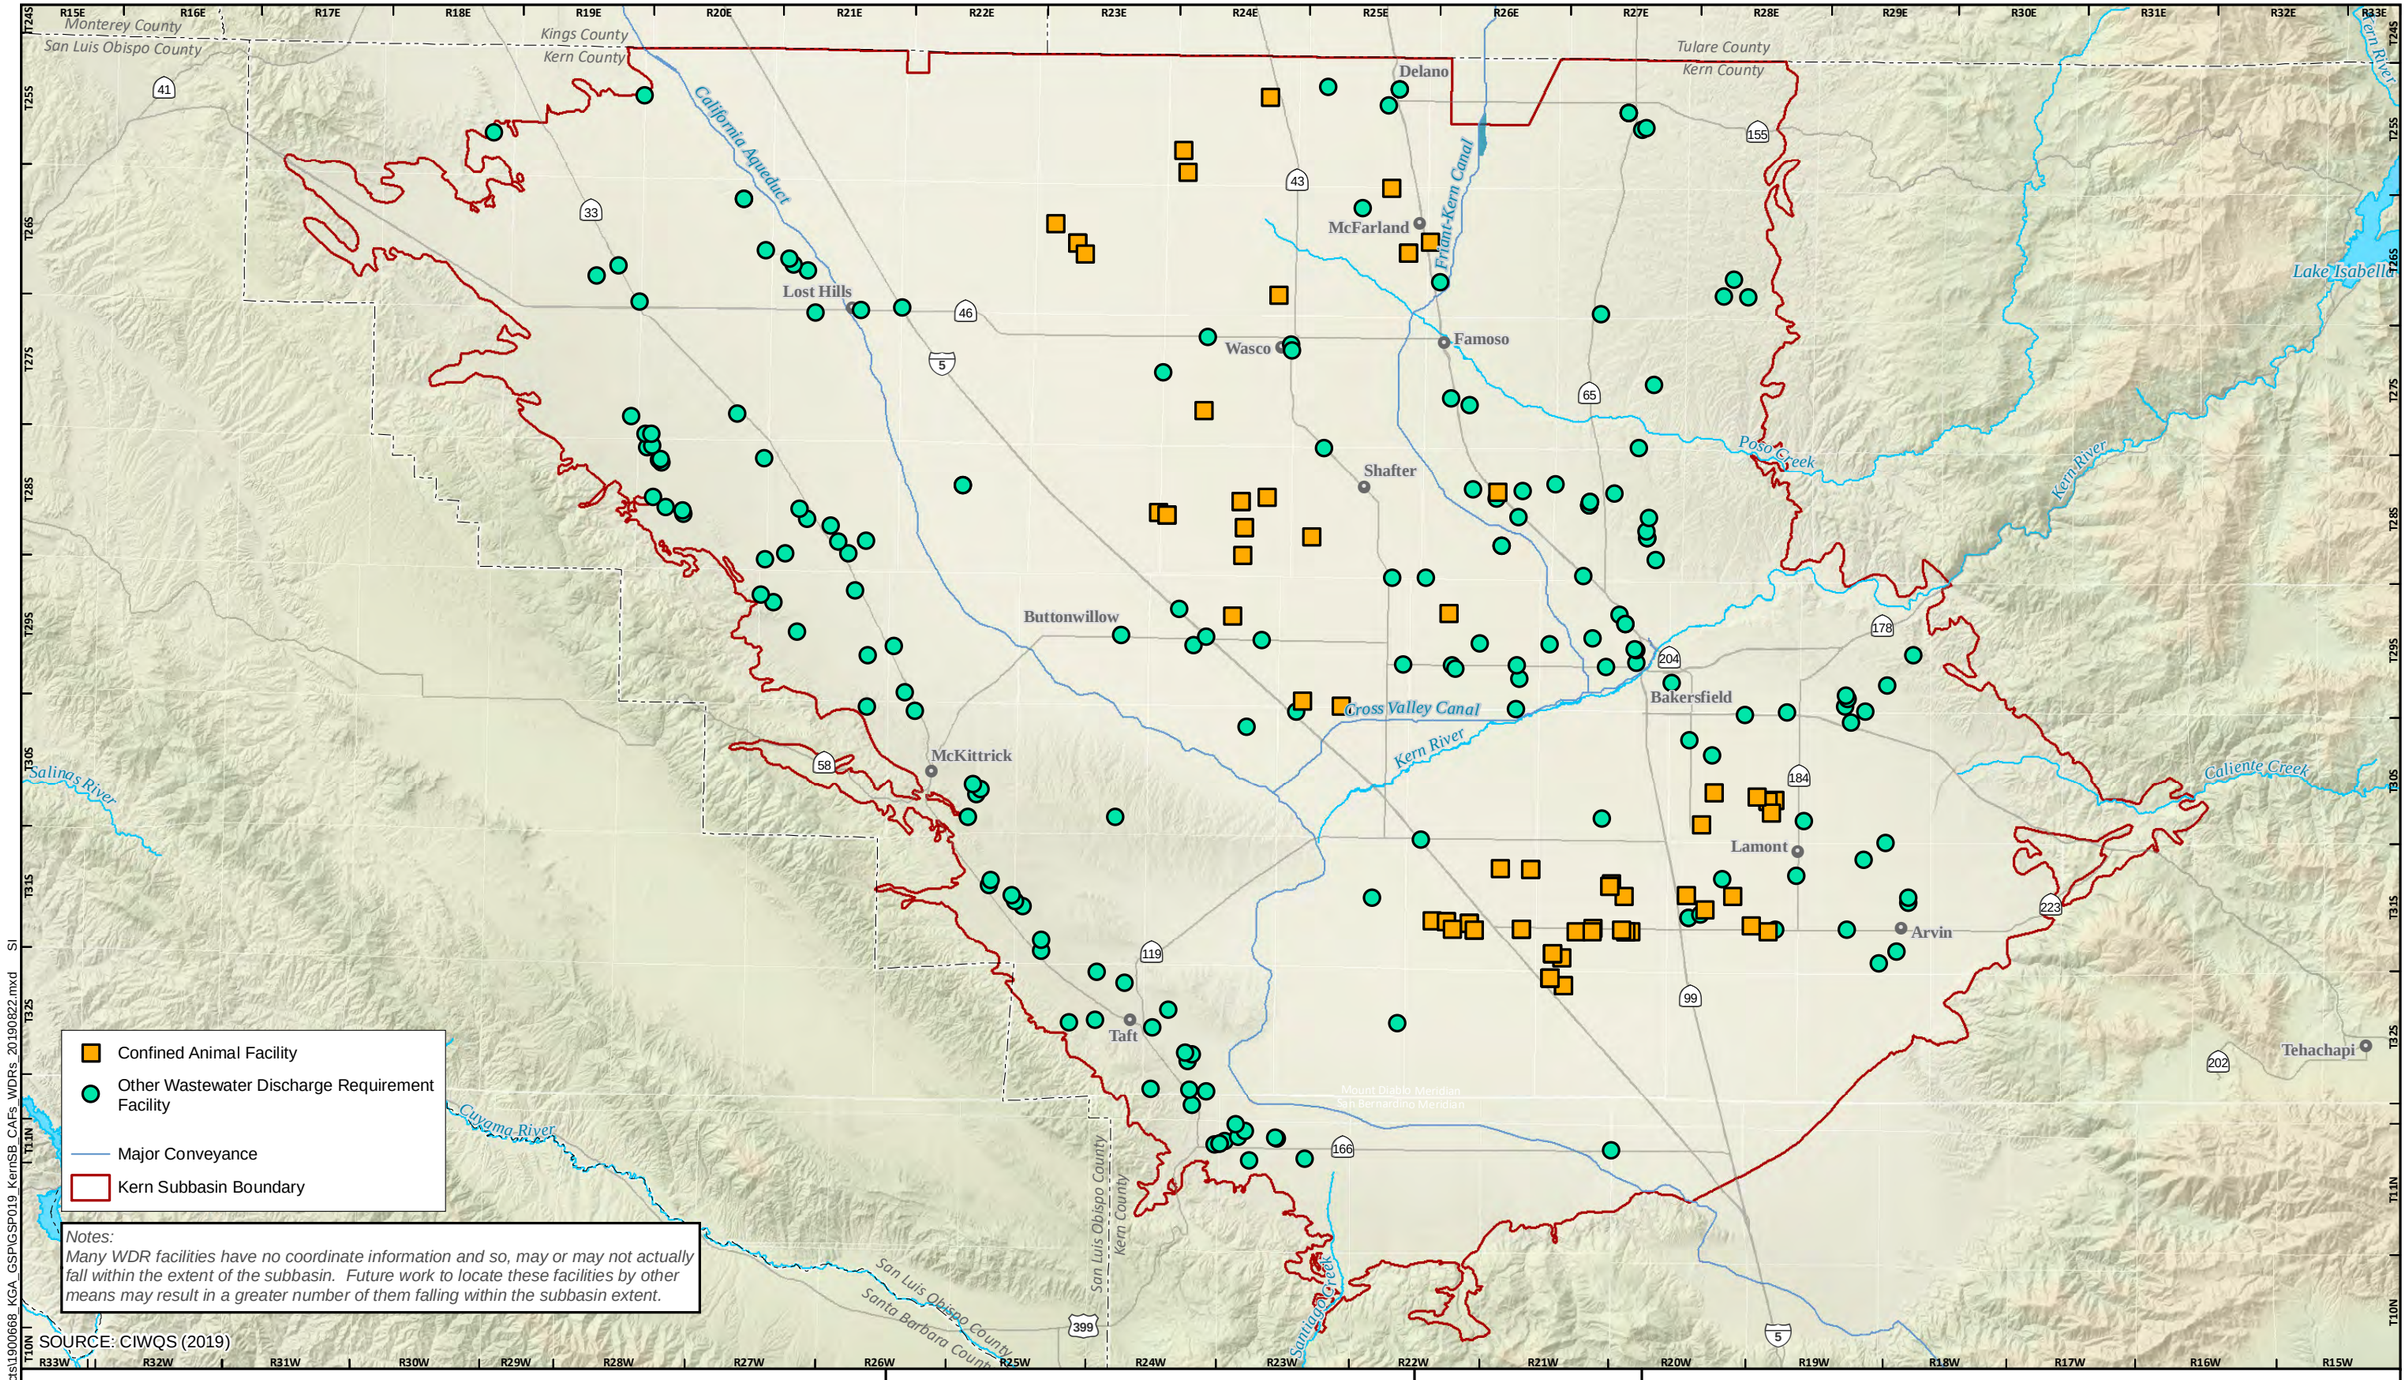
2.3.3.7 Groundwater Contaminant Sites

An evaluation of documented groundwater contaminant sites in the Subbasin were identified through the GAMA Groundwater Information System. GAMA contains information from other programs and databases, such as SWRCB – GeoTracker and Department of Toxic Substances (DTSC) – EnviroStor databases. The data included in this basin setting is in response to the emergency regulations § 354.16(d), that requests within the GSP, "a description and map of the location of known groundwater contamination sites and plumes." However, it is not the intent of this section to evaluate or confirm whether any of these sites as listed by regulatory agencies are impacting groundwater with beneficial use. Furthermore, this GSP cannot guarantee the accuracy of the data acquired from these regulatory sources. This section presents cases as were listed from the regulatory databases that may document potentially impacted groundwater sites. Programs listed below were reviewed from GAMA. There are two figures to graphically represent the distribution of sites; Figure 2-37 shows permitted facilities and Figure 2-38 shows clean-up sites.

- Waste Discharge Requirements (WDR)
- Underground Storage Tank (UST)
- Leaking Underground Storage Tank (LUST)
- Cleanup Program Sites
- DTSC Hazardous Waste Sites
- Department of Pesticide Regulation
- Underground Injection Control (UIC) Wells
- Oil and Gas Sites
- Irrigated Lands Regulatory Program Sites
- Confined Animal Site

Permitted Facilities with Waste Discharge Requirements Orders

While GeoTracker does not include water quality data for WDRs a list of sites and their general location is accessible through the State Board's California Integrated Water Quality System (CIWQS). The general location of Confined Animal Facilities is also available through this database. Figure 2-37 is a graphical representation of the known WDRs and Confined Animal Sites in the Subbasin. A total of 264 sites were identified; however, 43 sites are not included in this figure because latitude/longitude coordinates were not available to confirm that the site are within the Subbasin. The intent of mapping the location of the sites is to provide an idea of where the WDRs and Confined Animal Sites are located throughout the Subbasin.



Irrigated Lands Regulatory Program (ILRP) is permitted as a third-party WDR, like the WDR permit for Confined Animal Sites. However, site specific information is not publicly available because there are too many enrolled parcels under the Order. The Kern River Watershed Coalition Authority reports on the program. Relevant reports were reviewed and incorporated into the water quality discussion.

Underground Injection Control Permitted Wells

UIC permitted wells are not included in the list of groundwater contaminant sites because the UIC program's objective is to confine injected fluid to the approved injection zone so that injected fluid does not migrate to a zone where it could degrade valuable groundwater or hydrocarbon resources. Wells permitted under the State's Class II UIC program are presented on Figure 2-39. The UIC program's objective is to confine injected fluid to the approved injection zone so that injected fluid does not migrate to a zone where it could degrade valuable groundwater or hydrocarbon resources (DOGGR, April 2019). This program requires that any injection well have at least two cemented strings of casing across any underground source of drinking water located above a proposed injection zone, an annual Mechanical Integrity Test (MIT) and an annual step-rate test to ensure that groundwater is protected.

Data acquired from the regulatory sources listed above are included in Table 2-5 (Envirostor and Geotracker Databases) only if they applied to the following criteria in the order listed below:

1. potential media of concern defined as "groundwater," "other groundwater," or "drinking groundwater,"
2. potential contaminant of concern defined, or "unknown,"
3. the site/case reported as "not closed", and had one of the following statuses:
    - active cleanup
    - active land use restrictions
    - open remediation
    - open site assessment
    - open – eligible for closure
    - inactive-action required
    - other evaluation

Major Conveyance
Kern Subbasin Boundary
Notes: Disposal wells as identified in "List of Permitted Wells Sent to EPA.xlsx" file published February, 2015. Addtionally, the 176 wells identified as injecting to potential USDW sites was contained in a subsequent letter to the EPA, "US EPA 5-15-2015 Update.pdf" dated May, 2015. Both of these sources were located on the DOGGR UIC FTP site (ftp://ftp.consrv.ca.gov/pub/oil/UIC Files).

There is a total of 77 sites identified within the Subbasin. Figure 2-38 and Table 2-5, with cross referenced Map IDs, present the locations and details of known impacted groundwater or potentially impacted groundwater within the Subbasin. Table 2-5 provides the Site/Facility Name, Site Regulatory Identification and Status, associated site address and latitude/longitude, CalEnviroScreen Score (if applicable), as well as any identified constituents of concern impacting the groundwater at these sites.

2.3.4 Land Subsidence

Inelastic (irrecoverable) land subsidence (subsidence) is a sustainability indicator that often occurs in the region due to over pumping of aquifers with a high percentage of fine-grained deposits. Inelastic land subsidence has the potential to alter the land surface in ways that could increase flood risk in low lying areas; and damage well casing, canals, and other linear infrastructure. This section summarizes land subsidence data collected within the Subbasin and discusses documented impacts and potential impacts of land subsidence in or near the Subbasin.

2.3.4.1 Processes Leading to Land Subsidence

Several processes contribute to land subsidence in the Subbasin and include, in order of decreasing magnitude: aquifer compaction by overdraft; hydrocompaction (shallow or near-surface subsidence) of moisture deficient deposits above the water table that are wetted for the first time since deposition; petroleum reservoir compaction due to oil and gas withdrawal; and subsidence caused by tectonic forces (Ireland et al., 1984). Subsidence associated with oil and gas activities may be included on datasets in figures and tables of this GSP due to the regional method of data collections such as LANDSAT and InSAR. If significant impacts to critical infrastructure associated with oil and gas activities are identified by regional subsidence monitoring, they will be communicated to DOGGR to address as appropriate pursuant to Public Resources Code 3315.

Inelastic compaction or land subsidence occurs in the fine-grained beds of the aquifer system. Clays and silts, although not very permeable, are typically highly porous. In many of these fine-grained layers, pore spaces are supported by water at the time of deposition. This water is essentially groundwater storage to the Subbasin, although the majority of it is a component of inelastic storage, and therefore, it is not reusable. During over-pumping conditions, groundwater is pumped from pore spaces between grains of sand and gravel. Once the aquifer system is pumped beyond the sustainable yield, the lowered water pressure in the sand and gravel causes slow drainage of water from the clay and silt beds. The subsequent release of water and water pressure from the clay and silt beds result in compaction (the beds become thinner) as clay particles supported by water in pore spaces rearrange and collapse. Groundwater cannot re-enter the clay structure after the collapse.

This condition represents a permanent loss of the water storage volume in the clay layers. The effects of compaction are also seen as a lowering of the land surface, otherwise known as land subsidence.

2.3.4.2 Impacts due to Land Subsidence

There are various impacts of land subsidence on surface land uses and groundwater use that are documented in Kern County and adjacent study areas. Some of these references are from historical investigations while others are current. Both provide examples of potential future impacts of long-term subsidence in the study area.

Loss in Groundwater Storage and Increased Pumping Lifts

As described above, inelastic land subsidence can lead to the reduction in storage of fine-grained units. The reduction in storage ultimately leads to increased pumping lifts. Ireland et. al. (1984), explained that during compaction of fine-grained units caused by overdraft, there is a one-time release of water that is a short-term benefit to users because it results in extra water released from clay storage that is not renewable. Figure 2-40 below provides a conceptual diagram illustrates how over-pumping and subsidence leads to increased pumping lifts.

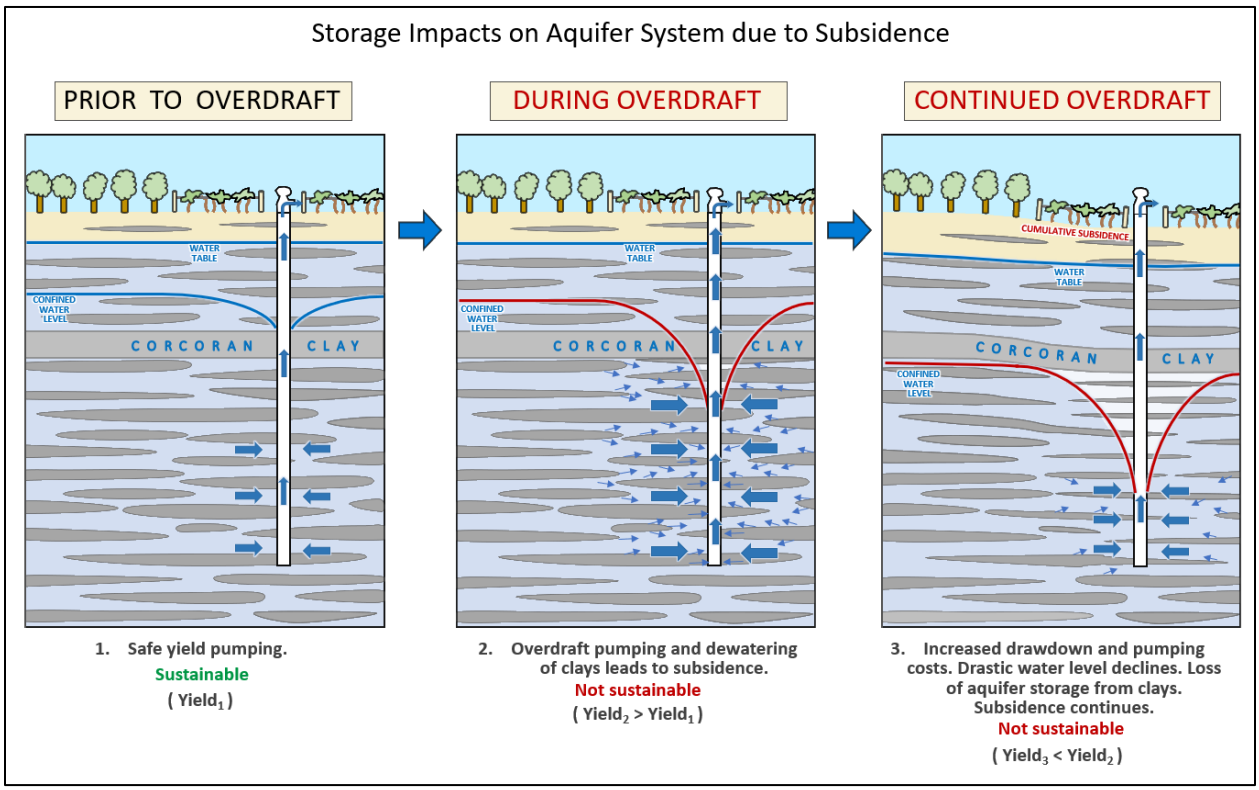

Figure 2-40. Conceptual Diagram of Impacts of Over-Pumping and Subsidence

Ireland et. al. (1984) documented the above phenomenon in the Los Banos-Kettleman City area. In the late 1960's, water levels were drawn down to historical lows with subsidence rates that exceeded 1 ft per year. Water levels subsequently recovered, and subsidence nearly ceased in the middle 1970's with the delivery of surface water. During the drought of 1976-1977, a second

cycle of overdraft and subsidence occurred. Water level declines were more rapid during the second cycle due to the loss of one-time storage from the first event. In addition, subsidence rates typical of those during the first event were observed (Ireland et al, 1984). In 1980, wet conditions and more available surface water resulted in groundwater levels recovering to pre-drought conditions and subsidence rates nearly ceased (Ireland et al, 1984).

Ojha et. al. (2019), references recent studies suggesting that subsidence between 2007 and 2015 in the Central Valley (primarily San Joaquin Valley) resulted in losses of 0.4% to 5.25% storage capacity in the aquifer system. However, this storage reduction does not substantially decrease usable or renewable storage for groundwater because the clay layers do not typically store significant amounts of recoverable, usable groundwater (LSCE, 2014). Nonetheless, it is estimated in the past, that by the mid-1970s, about one-third of the volume of water pumped from storage in areas such as Los Banos-Kettleman City, came from compaction of fine-grained beds (Poland and others, 1975; Faunt et al, 2009). Although the largest body of clay is the Corcoran Clay, a relatively insignificant volume of water has been released from storage in the Corcoran Clay (Faunt et al, 2009), likely because of its large thickness and low permeability.

Ojha et. al. (2019) suggests that loss in storage due to subsidence may impact the overall aquifer system by increasing the replenishment time of the aquifer which could pose challenges to water management in the future.

Surface Linear Infrastructure

Large-scale linear infrastructure is most susceptible to the regional subsidence caused by regional groundwater withdrawal. When subsidence rates are not equal across a region, differential compaction can occur. This differential compaction or subsidence may result in the formation of new low-lying areas for which canal designs have not taken into account. Newly formed low-lying areas are what impact large-scale linear infrastructure such as canals; often reducing freeboard and capacity. Examples of infrastructure that have been impacted by subsidence in the Southern San Joaquin Valley include the Friant-Kern Canal and California Aqueduct.

CVP

The Friant Kern Canal impacts have been well documented to the north of the Subbasin in an approximate five-mile stretch across Deer Creek (FWA, 2018). Subsidence was roughly 2 feet of the canal invert. Due to land subsidence the canal's water delivery capability has been reduced by nearly 60% to some contractor's (FWA, 2018). In contract, within the Subbasin, the Friant Kern Canal has experienced a few inches subsidence near Poso Creek (Mileposts 127 to 137).

SWP

The California Aqueduct was constructed in some areas with historical subsidence. "In an effort to prevent future subsidence from affecting the operation of the Aqueduct (and future water deliveries), extra freeboard was also added to [certain stretches] of the Aqueduct" (DWR, 2017c). During initial operation, only a few places experienced lining cracks including an area

with a concrete culver undercrossing just downstream of the Buena Vista Pumping Plant experienced settlement (DWR, 2017c).

Two segments of the Aqueduct were raised in 1989 and 1996 in Kern County (Table 2-6; DWR, 2017c). The first between MP 194.94 and 197.05 (T25S-R20E) in 1989, and the second between MP 206.10 and 207.94 (T27S-R21E). In general, this northwest portion of the basin is far from the main groundwater production in the central part of the Subbasin, so it is uncertain if groundwater supply extraction contributes to land subsidence in this area. Swanson (1998) also reported subsidence in this area along a 29-mile reach of the California Aqueduct, the cause of which was uncertain. The subsidence rates increased during dry periods and decreased during wet periods. Swanson (1998) recommended that observation wells and an extensometer be installed along this reach "to determine the cause of the subsidence because there is little ground-water pumping in the immediate area."

Table 2-6: 1989 and 1996 Canal Raise in the San Joaquin Field Division

Year	Pool	Spec	Milepost		Station		Length (miles)	Maximum Raise (inches)
			From	To	From	To		
1989	22	89-26	182.39	184.82	718+00	846+00	2.43	30
1989	22	89-26	194.94	197.05	1373+41.59	1485+00	2.11	39
1996	22	96-19	206.10	207.94	1962+84	2059+99.2	1.84	30

Fault Movement

Within the Subbasin, Pond-Poso Fault movement has been detected during dry years. Although the impact to infrastructure is unknown. Holzer (1980) observed fault movement along the Pond-Poso Fault from February 1977 to March 1979. This fault movement was observed during seasons of water level decline, and he concluded that 9 inches of offset had occurred along the Pond-Poso Fault System since the 1950's. In addition, Holzer (1980) observed that fault offset of groundwater levels was greater during dry years when the lowest seasonal water level low occurred.

Impacts to Well Casing

Although not in the Subbasin, just north of Subbasin, Wilson (1968) documented well casing failures attributed to land subsidence. Wilson reported that during 1950-1961 in a part of the Los Banos-Kettleman Hills area, wells that were screened primarily below the Corcoran Clay experienced screen failures associated with compaction or land subsidence.

Degraded Water Quality

Degradation of water quality due to land subsidence has been studied in the San Joaquin Basin to the north of the Subbasin. Smith et. al. (2018), hypothesizes that poor water quality in clays may be released to the aquifer system during over pumping and compaction of clays. Specifically, data north of the Subbasin in the San Joaquin Valley may indicate that areas with a thicker Corcoran Clay extent have seen an increase in arsenic concentrations as subsidence rates have increased due to over pumping (Smith et. al., 2018).

2.3.4.3 Land Subsidence Monitoring

Historical documentation of subsidence has relied on various types of data, including ground surveys, declining groundwater levels, and borehole extensometers. Recent subsidence studies have relied on ground surveys, borehole extensometers, continuous GPS stations, and remote sensing to collect data.

Each method has advantages and drawbacks. An extensometer measures a discrete subsurface interval, or typically the interval of the ground surface to the total depth of the extensometer. On the other hand, CGPS and InSAR monitor overall change in ground surface relative to a datum such as sea level, regardless of the depth interval. Moreover, InSAR provides information over a wide area.

Remote Sensing

Within the Central Valley, and in particular the Subbasin, researchers have utilized remote sensing techniques such as satellite-based Interferometric Synthetic Aperture Radar (InSAR) and aircraft-based L-band SAR or Unmanned Aerial Vehicle Synthetic Aperture Radar (UAVSAR). These surveys have been led by the National Aeronautics and Space Administration (NASA) and Jet Propulsion Laboratory (JPL), as well as other international researchers. The benefit of remote sensing is that large areas of land can be surveyed with no invasive actions or land surface access complications. DWR has commissioned studies (TRE Altamira, 2019) to evaluate the accuracy of remote sensing and identify additional processing and calibration methods for accuracy.

The following is a summary of recent remote sensing findings with respect to the TRE Altamira report:

- InSAR data with nearby UNAVCO CGPS have been processed and calibrated for northern Kern County Subbasin to the north of Visalia using the TRE Altamira-patented method SqueeSAR.
- InSAR calibration by TRE Altamira reports accuracy to 20 mm (0.07 feet) at 95% confidence interval.
- The calibration points include UNAVCO CGPS points (subsidence results as great as 8 inches over the time period of 2015 to 2018).
- Other points in the SOPAC network including Corcoran and Lemoore stations were not included in calibration; however, Ojha et al (2019) demonstrated that LEMA Lemoore and CRCN Corcoran (high subsidence areas) (at least 50 inches of subsidence between 2015 to 2018) may correlate well with InSAR.

Filling data gaps in the San Joaquin Valley with high subsidence areas lacking calibration monitoring points such as CGPS may be beneficial for future remote sensing work and calibration.

2.3.4.4 Historical Subsidence Results

Within the Subbasin, subsidence has been documented from leveling by the National Geodetic Survey at up to 12 feet from 1926 to 1970 (Ireland et al., 1984). USGS estimates that about 75 percent of the subsidence occurred in the 1950s and 1960s, corresponding to extensive groundwater development (Galloway, et al., 1999). Water levels during this period were continuing to fall to historic lows each year, for the first time, which were associated with larger amounts of subsidence (Todd, 2017).

Subsidence was also measured by USGS borehole extensometers in the west Subbasin from 1978 to 1983 (26S/23E-16H2 and 16H3) and to the south of Bakersfield from 1963 to 1978 in Extensometer 32S-28E-20Q1). These two extensometers have since been abandoned; however, a couple new extensometers have been installed in the Subbasin.

2.3.4.5 Recent Subsidence Results

Recent subsidence data is summarized in Table 2-7. In addition, time-series plots of subsidence monitoring points are included in Attachment G. Table 2-4 includes a summary of InSAR data published in a subsidence study commissioned by the California Water Foundation. Subsidence was measured at 0 to 0.5 feet from 2007 to 2011 across the Subbasin (LSCE, 2014). Subsidence was measured from 2005 to 2017 in the north and west Subbasin (based on six continuous GPS (CGPS) stations (BVPP, P544, P545, P563, P564, P565). These CGPS stations are monitored as a part of UNAVCO's Plate Boundary Observation (PBO).

Two extensometers have produced current data: 25S/22E-35B1 and 30S/25E-16L. Data for these extensometers are also included in Table 2-7.

JPL provided a progress report of InSAR subsidence monitoring in California (Farr et al., 2015), for data processed from the Japanese PALSAR for 2006 to 2010, Canadian Radarsat-2 for the period May 2014 through January 2015. From April 2014 to January 2015, subsidence was measured along the California Aqueduct from State Route 58 south to White Wolf Fault. Additional InSAR subsidence monitoring was reported by JPL (Farr et al., 2016) in 2016 for data from the European Space Agency's satellite-borne Sentinel-1A from the period May 2015 through September 2016, and NASA airborne UAVSAR for the period March 2015 through June 2016. The ESA's Sentinel-1A surveyed the entire San Joaquin and Tulare Basins, and subsidence was estimated between 4 and 8 inches in the north central portion of Subbasin as well as in the south of the Subbasin. The UAVSAR southern flight line along the California Aqueduct measured as much as 12 inches of subsidence, from April 2014 to June 2016, between east of Buena Vista Pumping Plant and Wind Gap Pumping Plant near Old River Road.

According to Luhdorff & Scalmanini Consulting Engineers (LSCE), Borchers and Carpenter (2014), subsidence is on-going and leading to significant impairment of the California Aqueduct and the Friant-Kern Canal. According to DWR (2014) the Subbasin was rated at a high risk for future subsidence due to 1) a significant number of wells (51%) with water levels at or below historic lows; 2) documented historical subsidence; and 3) documented current subsidence. Moreover, greater amounts of subsidence are occurring to the north of Subbasin in the Tulare

Subbasin. The amount of future subsidence will depend on whether future water levels decline below previous low levels and remain low for a considerable amount of time. Maintaining water levels above the previous low water levels may limit the risk of future subsidence.

2.3.4.6 Annual Rate of Subsidence

The following tabulated data includes cumulative inches of subsidence within Subbasin, and a calculated approximate annual rate for the time period for the data collection period.

Table 2-7 Land Subsidence Data

Subbasin Area	Date Range	Cumulative Subsidence (inches)	Calculated Annual Rate of Subsidence (inches/year)	Source
Historical Range in the Subbasin	1926 - 1970	12 - 96	~ 0.3 - 2.2	Ireland, 1984. Topographic Maps and Leveling Data.
North Central Subbasin	1978 - 1983	-0.04 – 1.5	-0.001 – 0.03	Extensometer 26S/23E-16H2 and -H3, USGS
South of Bakersfield	1963 – 1977	23.3	~0.14	Extensometer 32S-28E-20Q1, USGS
North and West Subbasin	2005 - 2017	0.1 – 11.7 0.2	~0 – 1.3	CGPS PBO. (BVPP, P544, P545, P563, P564, P565).
South central Subbasin	2006-2016	9.8 - 11.5	~1.1	CGPS (BKR1/BKR2, ARM1)
West Subbasin and South of Bakersfield	Jan. 2007 – Mar. 2011	6.0	~1.4	LSCE, 2014. Compiled from InSAR.
North Central Subbasin	Dec. 2013 – Mar. 2018	3.2	~0.8	SWSD Extensometer 25S22E35B001M
Central Subbasin	July 1994 - June 2018	-3 (negative value indicates uplift)	Not Presented Here.	Kern Fan Extensometer 30S/25E-16L According to AECOM (2016), data from extensometer show “little response to changes in water level changes during recharge or recovery operations.”
Southwest Subbasin along California Aqueduct	Apr. 2014 – Jan. 2015	0.5 - 5	~0.7 – 6.7	UAVSAR. InSAR Canadian Radarsat-2 (Farr et al., 2015)
North Central Subbasin	May 2015 – Sep. 2016	~1 - 12	~1.3 – 9.2	InSAR ESA Sentinel-1A (Farr et al., 2016)
Southwest Subbasin along California Aqueduct	Apr. 2014 – Jun. 2016	0 - 16	~0 – 7.4	UAVSAR (Farr et al., 2016)

2.3.4.7 Map of Subsidence Locations

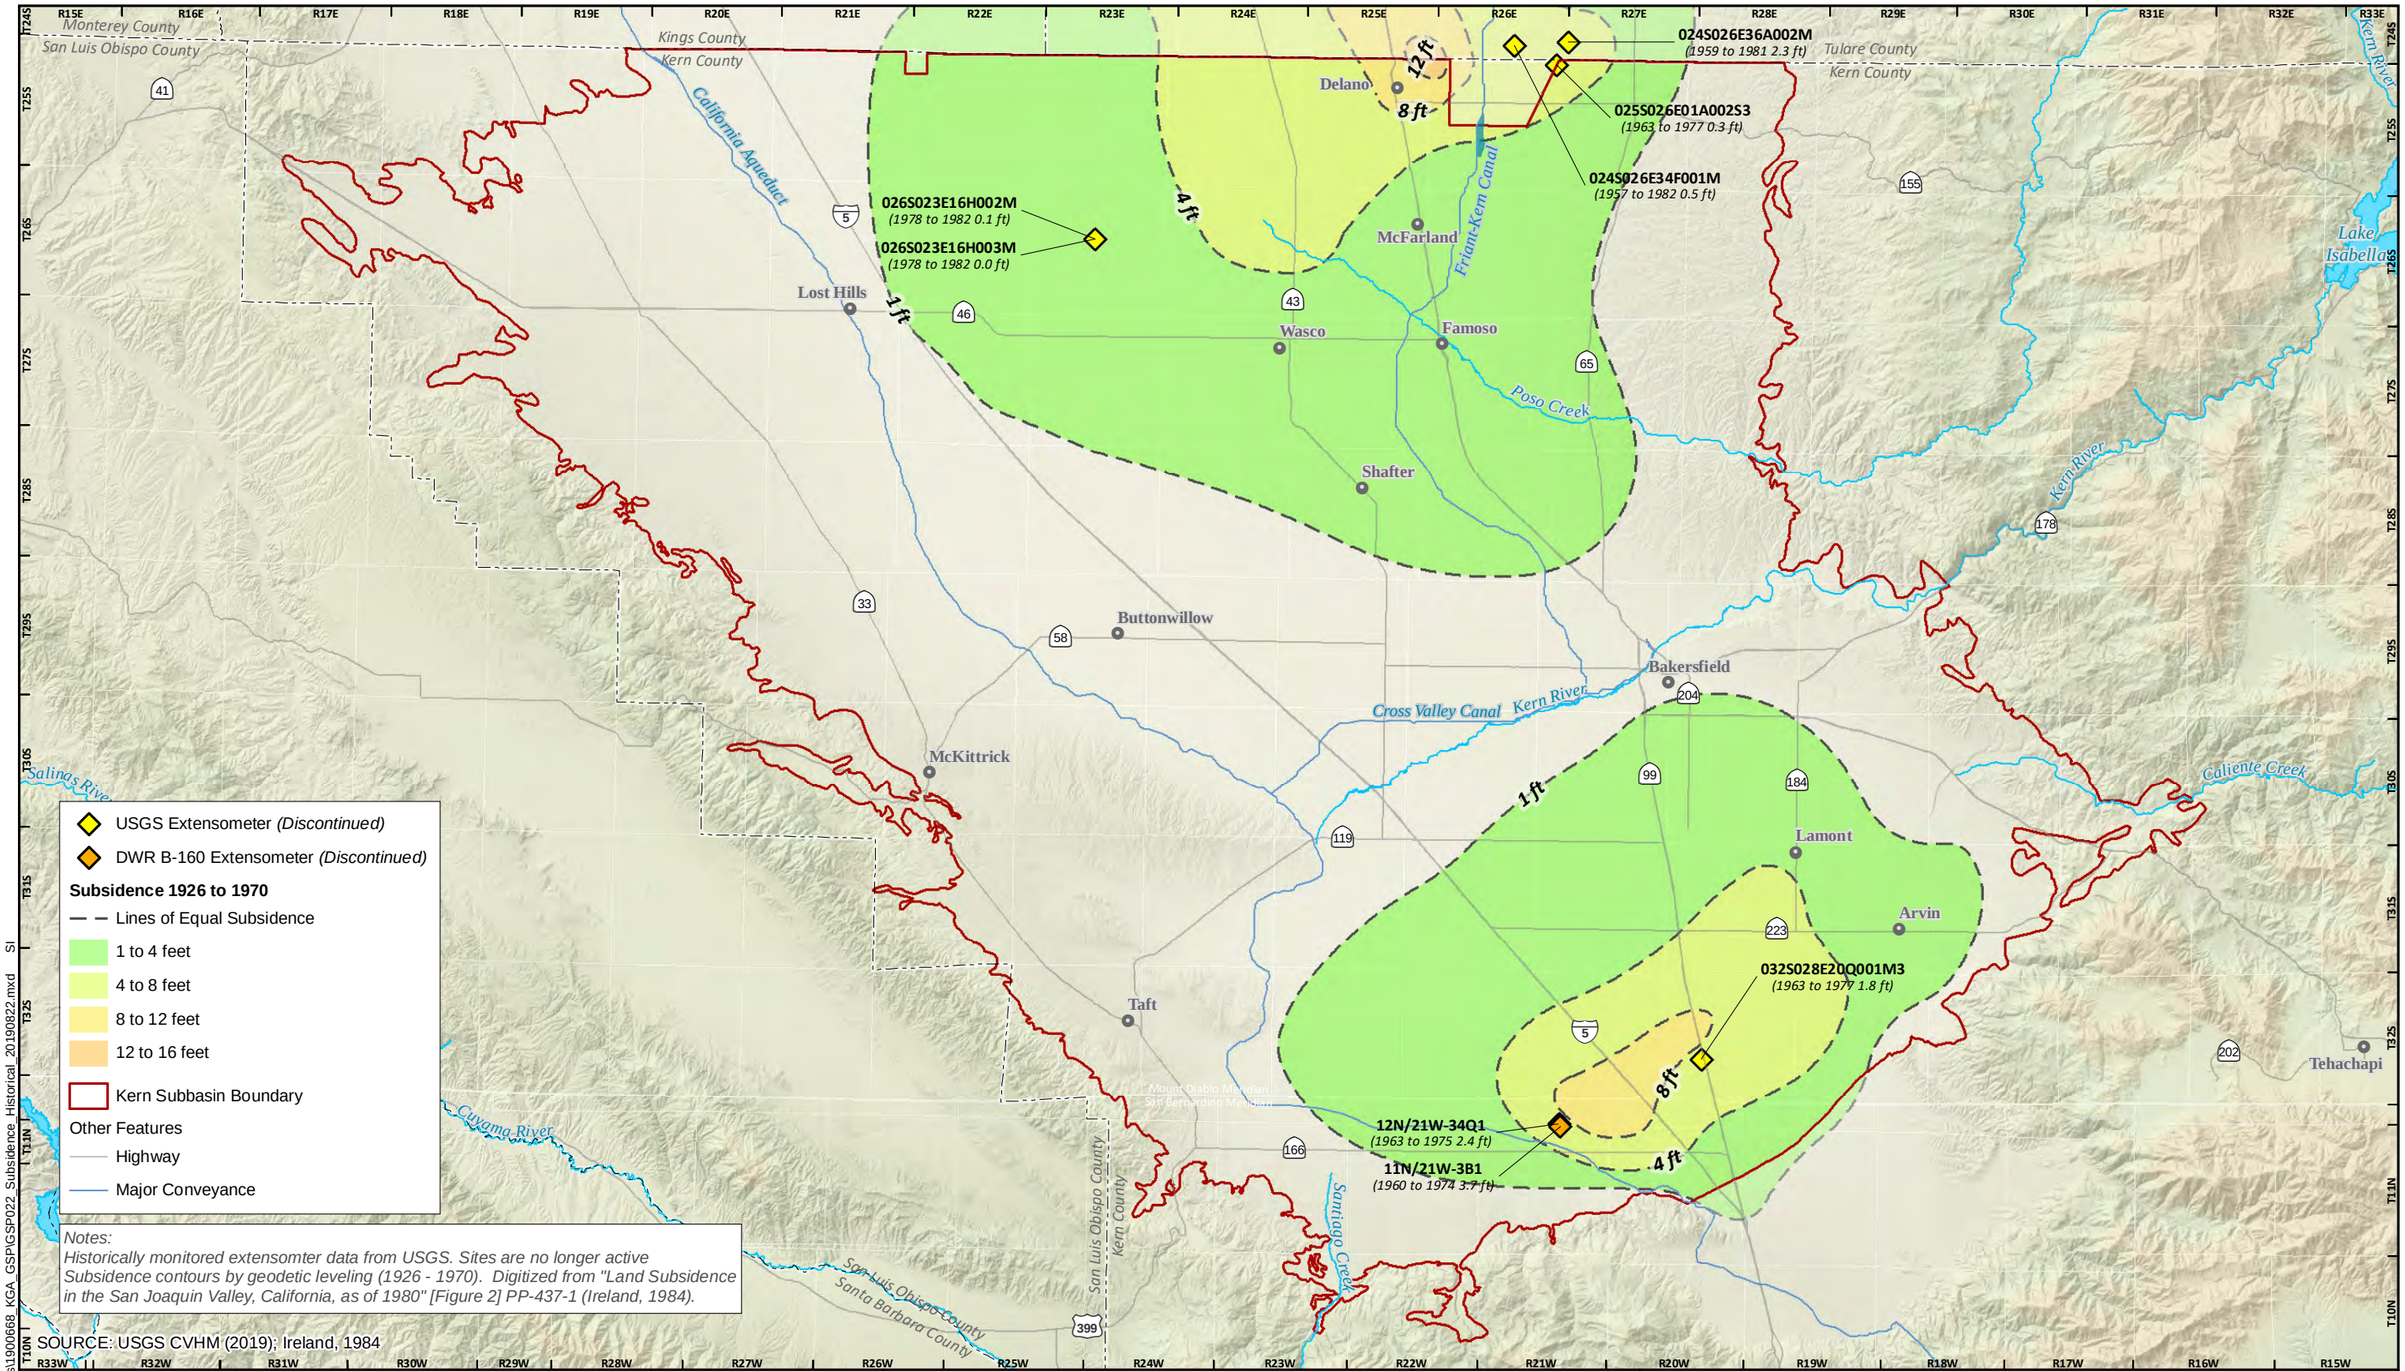
Subsidence within the Subbasin measured by historical studies is plotted on Figure 2-41. Subsidence as measured by recent studies and monitoring points including the UAVSAR and InSAR datasets is plotted on Figures 2-42 and 2-43, respectively. Corresponding rates of subsidence are presented on Figures 2-44 and 2-45. CGPS data locations, which are monitored continuously by UNAVCO, are plotted with recent calculated subsidence.

2.3.4.8 Data Gaps in Subsidence Understanding

There are data gaps in land subsidence that will be considered for future data collection. These data gaps include subsidence monitoring along points of critical infrastructure such as the Friant Kern Canal and California Aqueduct.

As described herein, there are a valuable dataset of CGPS monitoring points with which to pair water level monitoring data; however, InSAR data show that many of the CGPS points are not in zones of high subsidence, nor adjacent to critical infrastructure. Therefore, CGPS points alone are useful as quality control points, but they are likely not situated in areas of high subsidence or near critical infrastructure to facilitate decision making on sustainable management criteria.

InSAR is a dataset that may be able to fill the gaps between CGPS points. Continued InSAR data collection can fill the temporal data gap in the record. Correlations between CGPS and InSAR could confirm InSAR results in high subsidence areas near Subbasin, as they have been demonstrated in low subsidence and other areas (Tre Altamira, 2019; and Ojha et al, 2019).



As the water level monitoring network is established in the Subbasin, collocated temporal water level data with CGPS data can be collected to evaluate the relationship between active subsidence and residual subsidence with respect to water level change over time. The understanding of residual subsidence will better inform sustainable management criteria for setting thresholds.

2.3.5 Interconnected Surface Water Systems

Interconnected surface water systems are surface waters that are hydraulically connected by a continuous saturated zone to an underlying aquifer 23-CCR § 351(o). Within the Subbasin, there are no interconnected natural surface water systems in monitored areas associated with the pumping zone of the regional aquifer system.

The following are naturally occurring surface water bodies within the Subbasin:

- Kern River: Flows within the Subbasin (located within the Olcese and Kern River GSAs) are a function of hydrologic conditions in the Kern River watershed and regulation by Isabella Dam and Reservoir; and
- Poso Creek and other minor streams: Streamflow is unregulated and is ephemeral within the Subbasin, principally occurring during “wet” months of “wet” years.

Notes:
Vertical ground surface displacement rates are derived from Interferometric Synthetic Aperture Radar (InSAR) data that are collected by the European Space Agency (ESA) Sentinel-1A satellite and processed by the National Aeronautics and Space Administration (NASA) Jet Propulsion Laboratory (JPL), under contract with to the California Department of Water Resources (DWR). JPL presented preliminary processing results in the Progress Report: Subsidence in California, March 2015 – September 2016, and submitted a later version of the processing results that are still preliminary to the California Department of Water Resources (DWR). These files provided by JPL to DWR are multiband floating point GeoTIFFs with each band representing a date. GeoTIFF pixel values are in inches equal to the cumulative vertical displacement from the first date. JPL processed Sentinel-1A InSAR data separately for three different geographic regions; The Sacramento Valley, the San Joaquin Valley, and the South Central Coast. DWR temporarily interpolated the JPL data to end-of-month values, merged the resulting rasters from all three regions into a single raster for each month, and clipped all rasters to Bulletin 118 groundwater basins. Processing results that are still preliminary. (JPL/CIT Farr et al, 2017)

This Page Left Blank Intentionally

Other surface water bodies, such as the Buena Vista Aquatic Recreation Area lakes, are situated in former basins of natural surface water bodies but are now dependent on managed water deliveries.

Since the advent of groundwater pumping in the Subbasin and subsequent impoundment and regulation of flow of the Kern River, groundwater levels near the river are no longer connected with the river bed by a continuous saturated zone. Water quality data suggest that some portion of the recharge to the principal water-bearing aquifer underlying the far eastern portion of the Subbasin (the Olcese Sand Aquifer) may come from percolation of Kern River surface water via seepage through the Kern Gorge Fault and/or through the overlying shallow alluvium. However, such recharge occurs independent of groundwater production in the principal aquifer, and there is no known pumping from the shallow alluvium zone itself. Thus, there is no interconnected surface water under the influence of groundwater pumping in the principal aquifer in this area and no impacts to interconnected surface water have been observed.

The observation that there are now no interconnected surface water systems in the Subbasin is reflected in the aquifer characterization found in locally developed groundwater models. For example, groundwater levels in the Kern Delta Water District Superposition Model are indicated to be disconnected from the Kern River and other simulated streams (Todd, 2017). See the Kern River GSA GSP, which addresses in more detail the lack of interconnected surface water around the Kern River bed, as the area in around the Kern River bed is located within the jurisdiction of the Kern River GSA. The information below, as required by GSP regulations, is provided for completeness of the KGA GSP basin setting, however, for a more detailed discussion of interconnected surface water systems related to the Kern River, see the Olcese and Kern River GSAs GSPs, as the Kern River is outside of the jurisdictional area of the KGA.

2.3.5.1 Groundwater Elevation and the Kern River

Recent maps of groundwater contours developed by the Kern County Water Agency Improvement District 4 indicate there is a significant separation between the potentiometric surface near the river channel and the elevation of the river bed in areas where groundwater elevations have been mapped near the Kern River. The Hydrologic Profile from the most recent *Kern Fan Operations Report* (KCWA, 2018), illustrates prevailing groundwater conditions both spatially and temporally near the Kern River. This profile, which is transverse to the axis of the Kern River, indicates that during “wet” years, such as 1998 and 2006, groundwater elevations are highest directly below the Kern River bed while, during “dry” years, groundwater levels have declined to depths greater than 200 feet below the river bed. This prevailing pattern suggests that, during wet years, recharge to groundwater from the Kern River channel and nearby water banking operations forms a groundwater mound that gradually flows away from the river to the north and the south. Conversely, in dry years, there is an overall decrease in groundwater levels due to the lack of recharge from the Kern River and nearby water banking operations.

2.3.5.2 Hydrographs

Upstream of the Improvement District 4 monitoring coverage is a segment of the river, near Hart Park and the First Point of Measurement within Subbasin, that has available groundwater elevation data from the Kern County Water Agency for supply wells 29S/28E-02A01 and 29S/28E-10K01. These wells are located upgradient of Rocky Point Weir, and groundwater elevation data are plotted against the elevation of the adjacent river bed. In general, water levels in the wells consistently ranged from approximately 27 to 49 feet lower than the river bed between 1995 to 2016 (Figure 2-46). The Kern River is outside of the KGA jurisdictional area. For more information see the Olcese and Kern River GSA GSPs.

2.3.5.3 Stream Gaging

Stream gaging data for the Kern River are available for stations upstream of the Subbasin at Democrat Springs (USGS 11192500 and USGS 11192000), as well as at the First Point of Measurement upstream of Beardsley River Weir and Rocky Point Weir. Differences in annual flow volumes were calculated between Democrat Springs and the First Point of Measurement (factoring in diversions between these points) for water years 1990 through 2016. In general, streamflow tends to increase between Democrat Springs and the First Point of Measurement during wet years (i.e. 1993, 1998, 2005, and 2011), which in part reflects surface water inflow from tributaries along this segment of the River. In contrast, Kern River flows decrease during some dry years such as 2001, 2008, 2009, and 2013, but also exhibit gains during the periods from 2001 to 2002 and from 2013 to 2014.

The Kern River is outside of the KGA jurisdictional area. For more information see the Olcese and Kern River GSA GSPs.

2.3.5.4 Data Gaps

Although available data confirm that the Kern River is not interconnected with the underlying groundwater downstream of the First Point of Measurement, it appears that the Kern River from Democrat Springs to the First Point of Measurement may be gaining flow, with accretion from groundwater being one of the sources contributing to these gains. However, available data between these two locations (approximate 22 1/2-mile reach) are not adequate to refine the assessment of gaining and losing segments from the east boundary of the Subbasin to the First Point of Measurement (approximate 10-mile reach). In this regard, there are several mapped springs throughout the Kern River Canyon, with an absence of any mapped springs below the mouth of the canyon within the Subbasin, indicating that the majority of gains are likely within the canyon. For additional information see the Olcese and Kern River GSA GSP.

2.3.6 Groundwater Dependent Ecosystems

Groundwater Dependent Ecosystems (GDEs) are ecological communities that depend on groundwater emerging from aquifers or groundwater occurring near the ground surface (shallow water table). In the Kern Subbasin, potential GDEs are likely to be associated with wetlands and riparian areas that are supported either by shallow groundwater or by a combination of shallow groundwater and surface water. As discussed previously, shallow groundwater is present in west-central and southern portions of the Subbasin. Ephemeral wetlands covered by water seasonally are likely to be supported by irrigation deliveries and precipitation and are unlikely to be surface expressions of groundwater. For example, the Kern National Wildlife Refuge, is now sustained by imported surface water (USFS, 2005). Other features having the potential to provide habitat, such as groundwater recharge basins that are artificially flooded with surface water, also depend on diversion of surface water rather than a shallow groundwater table. The distribution of potential GDEs in the Kern Subbasin was assessed based on DWR's Natural Communities Commonly Associated with Groundwater (NCCAG) data.

The following is taken from the DWR Natural Communities dataset website for NCCAG (DWR, 2019):

> *"*The Natural Communities dataset is a compilation of 48 publicly available State and Federal agency datasets that map vegetation, wetlands, springs, and seeps in California. A working group comprised of DWR, the California Department of Fish and Wildlife (CDFW), and The Nature Conservancy (TNC) reviewed the compiled dataset and conducted a screening process to exclude vegetation and wetland types less likely to be associated with groundwater and retain types commonly associated with groundwater, based on criteria described in Klausmeyer et al., 2018. Two habitat classes are included in the Natural Communities dataset: (1) wetland features commonly associated with the surface expression of groundwater under natural, unmodified conditions; and (2) vegetation types commonly associated with the sub-surface presence of groundwater (phreatophytes)."

The data included in the Natural Communities dataset do not represent DWRs determination of a GDE. However, the Natural Communities dataset can be used by GSAs as a starting point when approaching the task of identifying GDEs within a groundwater basin."

Figure 2-47 shows CDFW lands in the Central Region. Similarly, Figure 2-48a and 2-48b shows potential location of wetlands and GDEs in the Subbasin, respectively, as identified in the National Hydrography Dataset. In addition, the surface water bodies from the National Hydrography Dataset are also discussed in relation to potential GDEs.

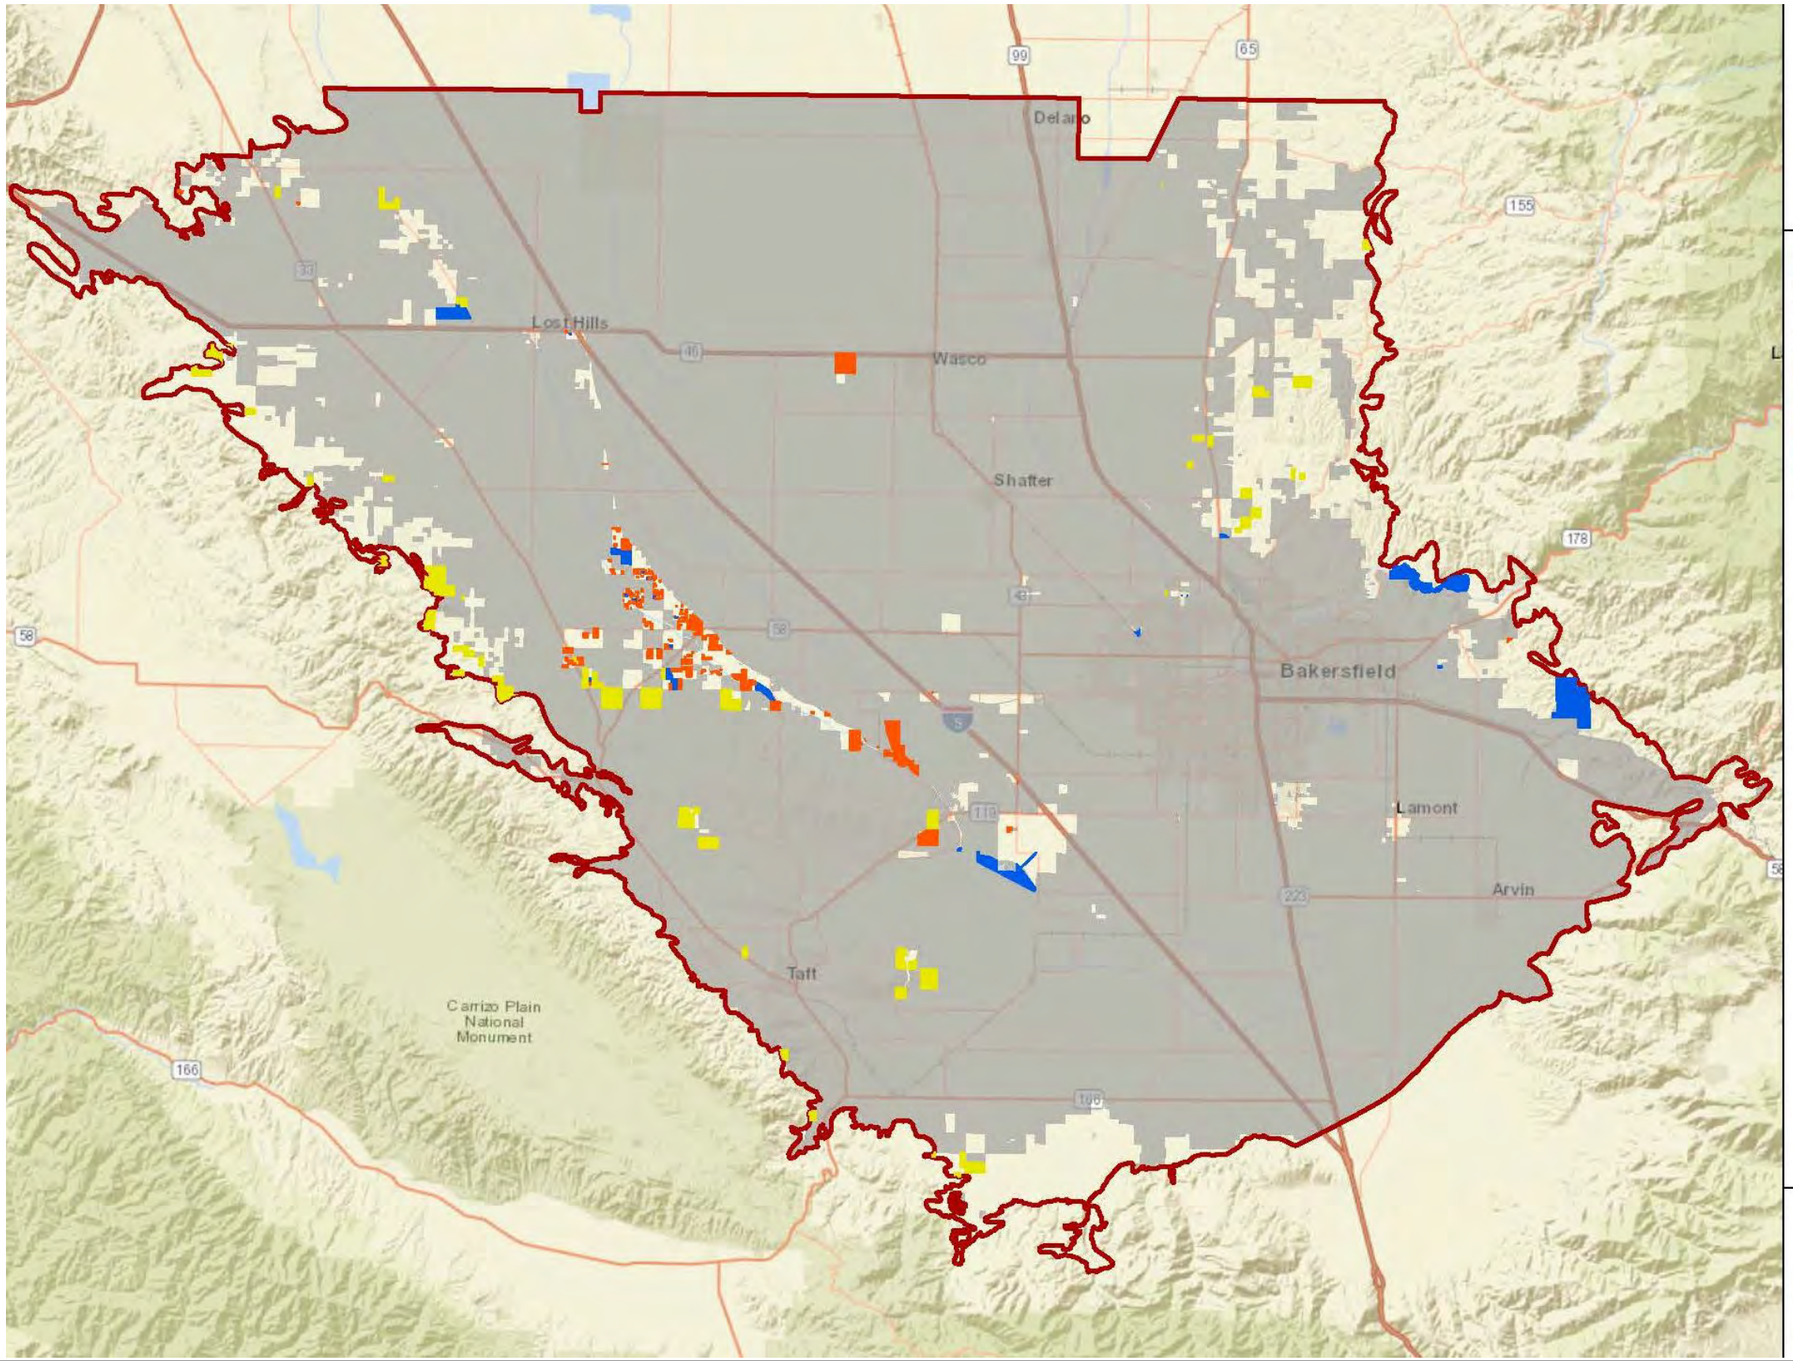
The below discussion presents NCCAG dataset of the Subbasin. Any further details regarding these mapped datasets are provided in the management area plans. Where data gaps exist, future monitoring and GSP updates will seek to fill these gaps, as described in the management area plans of the individual KGA members.

2.3.6.1 NCCAG Mapped Data

Figure 2-29 displays the locations of seeps and springs based on data extracted from the National Hydrography Dataset at the base of the mountains and foothills in the southeast, southwest, and northwest edges of the Subbasin.

Figure 2-48a and 2-48b displays NCCAG data in the Subbasin. NCCAG features are mapped along spring-fed streams in the southwest along the perimeter of the Subbasin: Santiago Creek to San Emigdio Creek situated in the Wind Wolves Preserve. Toward the east, Pleitito and Pleito Creeks have mapped NCCAG datasets. Potential spring-fed streams to the southeast of Sycamore Canyon Golf Course may have associated NCCAG mapped data. In the southeast corner of the Subbasin, in the highlands along the Caliente Creek drainage are mapped NCCAG features. On the eastern side of the Subbasin, NCCAG wetlands and vegetation are mapped along the Kern River and Poso Creek. On the northern boundary of the Subbasin, NCCAG wetlands and vegetation are mapped in the Kern River channel to the southwest of Kern Wildlife Refuge. Along the western edges of the Subbasin, there are mapped NCCAG features.

Groundwater potentiometric surfaces from Kern Fan Monitoring Reports (KCWA, 2016) indicate that underlying aquifers are not connected with stream channels. Some flow in the Kern River, as well as in Poso Creek and other mountain-front creeks, is likely to be sustained periodically by release of bank storage (surface water stored in stream banks), but the underlying groundwater is too deep to sustain flow in the valley floor.



2.3.6.2 Evaluation of NCCAG Results

The conditions in the center of the Subbasin suggest that the groundwater production aquifer does not reach the shallow subsurface. The production aquifer lies at depths that prevent surface water expressions or accessibility for vegetation. The respective chapters within this GSP may present additional data regarding NCCAG mapped dataset.

Based on the NCCAG dataset along the margins of the Subbasin where spring-fed streams exist, further confirmation is needed to evaluate the presence of GDEs. Chapter-level GSPs, where necessary, provide local details regarding the current understanding of potential GDEs in the respective area.

In the west-central and southern-central Subbasin, shallow groundwater levels are present. These clays have historically been a concern regarding encroachment of poor-quality perched groundwater into crop root zones. The shallow groundwater in the west-central and southern-central Subbasin is not well suited for agricultural or domestic water supply; therefore, existing water management practices and practices that may be introduced through the implementation of SGMA are unlikely to draw on the shallow groundwater that may support potential GDEs.

2.4 Water Budget Information

All GSAs in the Subbasin coordinated and collaborated on the development of water modeling budgets (historical, baseline and projected). The GSAs entered into a Cost Share Agreement with the Kern River GSA who took the lead and contracted with Todd Groundwater to develop a groundwater model on behalf of the Subbasin. The contract required that Todd Groundwater use the California Central Valley Groundwater-Surface Water Simulation Model (C2VSim) provided by DWR. Considerable effort and resources were expended to update the C2VSim model with local data to better represent Subbasin conditions, as described below. The process Todd Groundwater used to update C2VSim is more fully described in the Historical and Projected Future Water Budget Development (Attachment H). Subbasin -wide water budget results from the numerical model-based water budget are provided in Attachment H and show the Subbasin, as a whole, has a total storage deficit of 324,326 acre-feet per year (AFY) over the baseline period.

The Subbasin's dynamic conjunctive use programs, water banking operations, and water transfers/exchanges made it necessary to coordinate a separate water accounting system using Subbasin specific values for supply, demand and net results. The C2VSim model results reflect Subbasin-wide conditions and does not allocate water shortages/surpluses, nor do the results allocate the "ownership" of water. As a result, the GSAs, through a coordinated effort, developed water budgets that estimate current conditions for each GSA that are generally consistent with the C2VSim model results under baseline condition. These GSA-level budgets are based upon best available information, recognizing however, each estimate includes data gaps and has varying degrees of accuracy and/or reliability. Table 2-8 reflects the coordinated development the GSA-level water budgets for the Kern Subbasin and is also included in the Coordination Agreement for the Kern Subbasin.

Table 2-8: Kern Subbasin GSA-Level Water Budgets

Entity	Total Water Demand (acre-feet)	Total Water Supply (acre-feet)	Net Water Budget (acre-feet)
Kern Groundwater Authority	1,939,409	1,683,128	-256,281
Henry Miller GSA	40,884	35,791	-5,093
Olcese Water District GSA	2,650	3,202	552
Kern River GSA	305,310	276,157	-29,153
Kern River GSA – App K Properties	1,308	0	-1,308
Buena Vista GSA	103,950	126,936	22,986
Non-Districted Lands*	18,013	0	-18,013
TOTALS:	**2,411,524**	**2,125,214**	**-286,310**
Todd Groundwater Model Results for Baseline Condition:			**-324,326**
Todd Groundwater Model Results for Historical Change in Groundwater Storage:			**-277,114**

*Most of the irrigated non-districted lands are now managed /covered under SGMA by GSAs.

To ensure the KGA individual water budgets reflected actual conditions, the KGA members developed a coordinated water accounting methodology. The result of that effort indicates a current baseline shortage/deficit for KGA members of -256,281 AFY[1]. This reflects the difference between a total demand for KGA members of 1,939,409 AFY, and a total supply of 1,683,128 AFY. Each KGA member agency management area plan reflects their consistent management area water budget in their individual water budget sections.

2.4.1 Model Development

SGMA regulations require that water budget analyses for GSPs be conducted on a basin-wide basis. DWR developed C2VSim to simulate water demands and supplies in the Central Valley. The C2VSim Fine Grid Beta Model (C2VSimFG-Beta) is derived from a series of Central Valley hydrologic models developed by DWR and other agencies beginning in the early 1990s. C2VSimFG Beta includes historical input data for WY1922-2015 in the Kern Subbasin. These data include monthly precipitation and annual land use for each model element and estimated monthly evapotranspiration for each modeled land use type and agricultural crop. Historical surface water data include monthly surface water inflow for each river entering the model boundary and monthly surface water diversions.

C2VSimFG Beta input files have been modified to incorporate locally-derived managed water supply and demand data to better represent the local water balance for the Subbasin. known as C2VSimFG-Kern model. This model includes revised data for the Kern County subbasins to better represent local water conditions. To comply with the SGMA water budget requirements (Section 354.18), the KGA and the other four GSAs in the Subbasin engaged in a basin-wide effort to develop a basin-wide groundwater model. The results of this effort are provided in Attachment H - TODD Groundwater C2VSimFG-Kern Report and Results, which is summarized below.

2.4.2 Data Compilation

Historical surface water diversions, water bank recharge and water bank withdrawal information were collected from Kern County water purveyors. Urban land use was restricted to developed areas, and urban populations and per-capita water demands were updated. Detailed description of data compilation methodology, assumptions and sources are provided in Attachment H: Historical and Projected Future Water Budget Development with C2VSimFG-Kern.

[1] The water supplies available to each KGA member from the Pioneer and Kern Water Bank banking programs are incorporated into the listed total available supplies. Note that both programs only store surface supplies, and do not have consumptive demands that contribute to the listed shortages. For more detail on the banking projects, please see the respective chapters.

2.4.3 Historical and Current Water Budget

C2VSimFG-Kern was used to develop historical (WY1995 to WY2014) water budget for the Kern County Subbasin and is presented in Figure 2-49. The results are summarized as follows:

- **Deep Percolation –** This is defined as precipitation and applied water that reaches the groundwater after simulated transport across the unsaturated zone. The simulated historical 20-year average resulted in a net inflow of 669,398 AFY.
- **Managed Recharge and Canal Seepage –** This is defined as combined groundwater recharge from managed aquifer recharge operations, groundwater banking, and seepage from canals and other conveyance. The simulated historical 20-year average resulted in a net inflow of 583,598 AFY.
- **Net Groundwater-Surface Water (GW/SW) Interactions –** This is defined as net volumetric exchange of surface water and groundwater between the aquifer and streams: Positive represents a net groundwater recharge, and negative represents a net groundwater discharge to the stream. The simulated historical 20-year average resulted in a net inflow of 98,606 AFY.
- **Groundwater (GW) Pumping –** This is defined as total groundwater pumping by wells. Groundwater banking recovery pumping is specified as fixed input values and agricultural and municipal pumping is calculated by C2VSimFG-Kern based on demand minus surface water diversions. The simulated historical 20-year average resulted in a net outflow of 1,590,373 AFY.
- **Small Watershed Inflow –** This is defined as runoff, small stream inflow and subsurface inflow from the small watersheds and areas surrounding the groundwater basin. The simulated historical 20-year average resulted in a net inflow of 48,760 AFY.
- **Subsurface Flow with Adjacent Groundwater (GW) Basins –** This is defined as net subsurface groundwater flow to and from the Subbasin with adjoining groundwater basins: negative is a net flow out of the Subbasin and positive is a net flow into the Subbasin. The simulated historical 20-year average resulted in a net outflow of 87,102 AFY.
- **Change in Groundwater Storage –** This is the sum of the inflow components (positive numbers) plus the outflow components (negative numbers): positive is an increase in storage typified by a rise in groundwater levels whereas a negative is a decrease in storage typified by a decline in groundwater levels. The simulated historical 20-year average resulted in a decline in groundwater storage of 277,114 AFY.

Figure 2-50 presents the average annual historical water budget for the Subbasin that includes the out-of-basin groundwater banking obligation of 85,965 AFY.

Figure 2-51 shows the simulated annual and cumulative change in groundwater storage over the 20-year historical period. It was observed that during the periods of WY1995 to WY2000, WY2005 to WY2006 and WY2010 and WY2011, the groundwater storage volume was stable to

increasing and correlates to the above average rainfall and surface water availability during these times. Similarly, during the periods WY2001 to WY2004, WY2007 to WY2009 and WY2012 to WY2015, groundwater storage volume decreased, correlated to periods of drought and low surface water availability. Figure 2-52 shows the simulated historical groundwater recharge by source that also reflects a climatic pattern with high deep percolation to groundwater and steep increases in managed aquifer recharge and canal seepage during the above average rainfall periods and lower groundwater recharge during the drought years.

As a result, groundwater pumping for agriculture shows a general increasing trend from WY1995 to WY2014; however, groundwater pumping is lower in above average rainfall years and higher during droughts as shown in Figure 2-53. This general increasing trend follows a comparable decreasing trend in surface water deliveries over the same period as shown in Figure 2-54.

2.4.3.1 Sustainable Yield

SGMA defines Sustainable Yield as "the maximum quantity of water, calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result". To determine the sustainable yield for the Kern Subbasin, the results of the C2VSimFG-Kern model were used with two methods to estimate the amount of groundwater pumping that would avoid the undesirable result of a reduction in groundwater storage over the historical base period 1995 to 2014.

- **Sustainable Yield from Groundwater Pumping** – The model results produced an average annual groundwater pumping in the Kern Subbasin of 1,590,373 AFY with a decline in groundwater storage of 277,114 AFY. Subtracting the groundwater storage decline from groundwater pumping produced a sustainable yield of approximately 1,313,000 AFY for the Kern Subbasin.
- **Sustainable Yield from Groundwater Recharge** – The model results produced an average annual groundwater recharge in the Kern Subbasin of 1,400,362 AFY. The subsurface outflow from the GSA totals 87,102 AFY. Subtracting these losses from the groundwater recharge produced a sustainable yield of approximately 1,331,000 AFY.

Using WY1995 to WY2015 as the base period, C2VSimFG-Kern results show declining groundwater levels and long-term reduction of groundwater storage. During this period, average annual inflow to the aquifer is 1,400,362 AFY, and outflow is 1,677,475 AFY. This yields an average annual deficit of 277,144 AFY. Based on these historical C2VSimFG-Kern results, the sustainable yield of the basin is approximately 1,313,000 AFY, plus or minus 10%.

2.4.3.2 Native Yield

SGMA does not require the native yield to be considered or addressed, however, in the process of working on the Sustainable Yield, water budget allocations, and the water modeling for the entire Kern Subbasin, the discussion of the native yield and how best to address it in the Kern Subbasin occurred. The C2VSimFG-Kern results does model the concept of native yield,

however, as described in section 4.2.2 of Attachment H, the Native Yield at this time is based on available data. However, there exists in this area data gaps and as such, as those data gaps are eliminated and management actions are implemented, the estimate of native yield is likely to change. With the current available data for input to the C2VSimFG-Kern, the model provides the following results:

- The volume of precipitation that recharges the groundwater in the irrigated agricultural areas is 77,780 AFY
- The volume of precipitation that recharges groundwater in the other areas is 132,981 AFY
- The volume of inflow from unallocated small watersheds that recharges the groundwater in the irrigated agricultural areas is 48,760 AFY
- The above inputs resulted in a native yield for the Kern Subbasin of 259,520 AFY which resulted in the native yield estimate of 0.144 acre-feet per acre for the total area of the Kern County Subbasin.

During the process of working through the water budget allocations for the entire Kern Subbasin with all GSAs, the native yield was one of the most critical supply source to be coordinate. Acknowledging the presence of data gaps and implementation of projects and management actions, the GSAs of the Kern Subbasin have agreed to the continued analysis and refinement of the native yield, from a technical and legal basis. This has been identified as a management action for the KGA, in coordination with all other Kern Subbasin GSAs, in 2020.

2.4.4 Projected Future Water Budgets without SGMA Implementation

Projected future water budgets for the Subbasin were developed using the C2VSimFG-Kern for future baseline conditions and 2030 and 2070 Climate Conditions over a 50-year planning and implementation horizon. These scenario models provide a basis of comparison for evaluating proposed sustainability management actions and projects over the SGMA planning and implementation horizon.

- **Future Baseline Conditions:** Repeat historical hydrology with future water supply reliability provided by DWR.
- **2030 Climate Conditions:** Adjust historical hydrology for 2030 climatic conditions and water supply reliability provided by DWR.
- **2070 Climate Conditions:** Adjust historical hydrology for 2070 climatic conditions and water supply reliability provided by DWR.

Detailed description of assumptions, hydrology estimations, precipitation rates, surface water deliveries, sources of data and groundwater banking conditions are provided in Attachment H: Historical and Projected Future Water Budget Development with C2VSimFG-Kern.

2.4.4.1 Future Baseline Water Budget

The Baseline Scenario simulates how the Subbasin aquifer would respond if the recent hydrology were repeated with current expected surface water availability and current land use. The primary difference between historical conditions and the projected future baseline is a nearly 20% decrease in imported surface water deliveries primarily from the SWP due to the long-term Operational Criteria and Plan (OCAP) Biological Opinion and is replaced with additional groundwater pumping. As a result, total net aquifer outflows increase by about 35,600 AFY, total net aquifer inflows decrease by about 11,600 AFY with the average groundwater pumping of 1,625,000 AFY, which includes agricultural pumping, urban pumping and exported water. This results in an additional loss of groundwater storage of about 47,200 AFY over the 50-year projected future baseline. Baseline simulation results indicate that the Subbasin has an average annual overdraft of 324,326 AFY, however, with the implementation and completion of projects and management actions as stated in the individual management area plans and GSPs from the other GSAs in the Subbasin, the baseline simulation results show that the Subbasin has an average surplus of 85,578 AFY.

2.4.4.2 2030 Climate Change Water Budget

The 2030 Scenario simulates how the Subbasin aquifer would respond assuming hydrologic conditions representing a potentially drier climate (no or limited amount of snow pack) and are based on the DWR Climate Change Guidance (DWR 2018). The 2030 DWR climate change factors were applied to the Baseline Scenario Conditions. Additional adjustments were made to the imported surface water supplies from the SWP, CVP and Kern River, accounting for about an additional 2% decrease from the Baseline Conditions.

The results show a net increase in aquifer inflows of about 44,700 AFY along with an increase in aquifer net outflows of about 101,200 AFY. This is mostly attributed to the climate shift to earlier rainfall making more surface water available for managed aquifer recharge during the winter but less available for irrigation in the summer resulting in higher groundwater pumping. The net change in groundwater storage is an additional decline of about 56,600 AFY due to the climate change impacts. 2030 Climate Change simulation results indicate that the Subbasin has an average annual overdraft of 372,120 AFY with the net change in groundwater storage showing an additional decline of about 47,794 AFY, compared to the Baseline, due to the climate change impacts. However, with the implementation and completion of management actions/projects as stated in the individual management area plans and GSPs from the other GSAs in the Kern Subbasin, 2030 Climate Change simulation results indicate that the Subbasin has an average deficit of approximately 46,829 AFY.

2.4.4.3 2070 Climate Change Water Budget

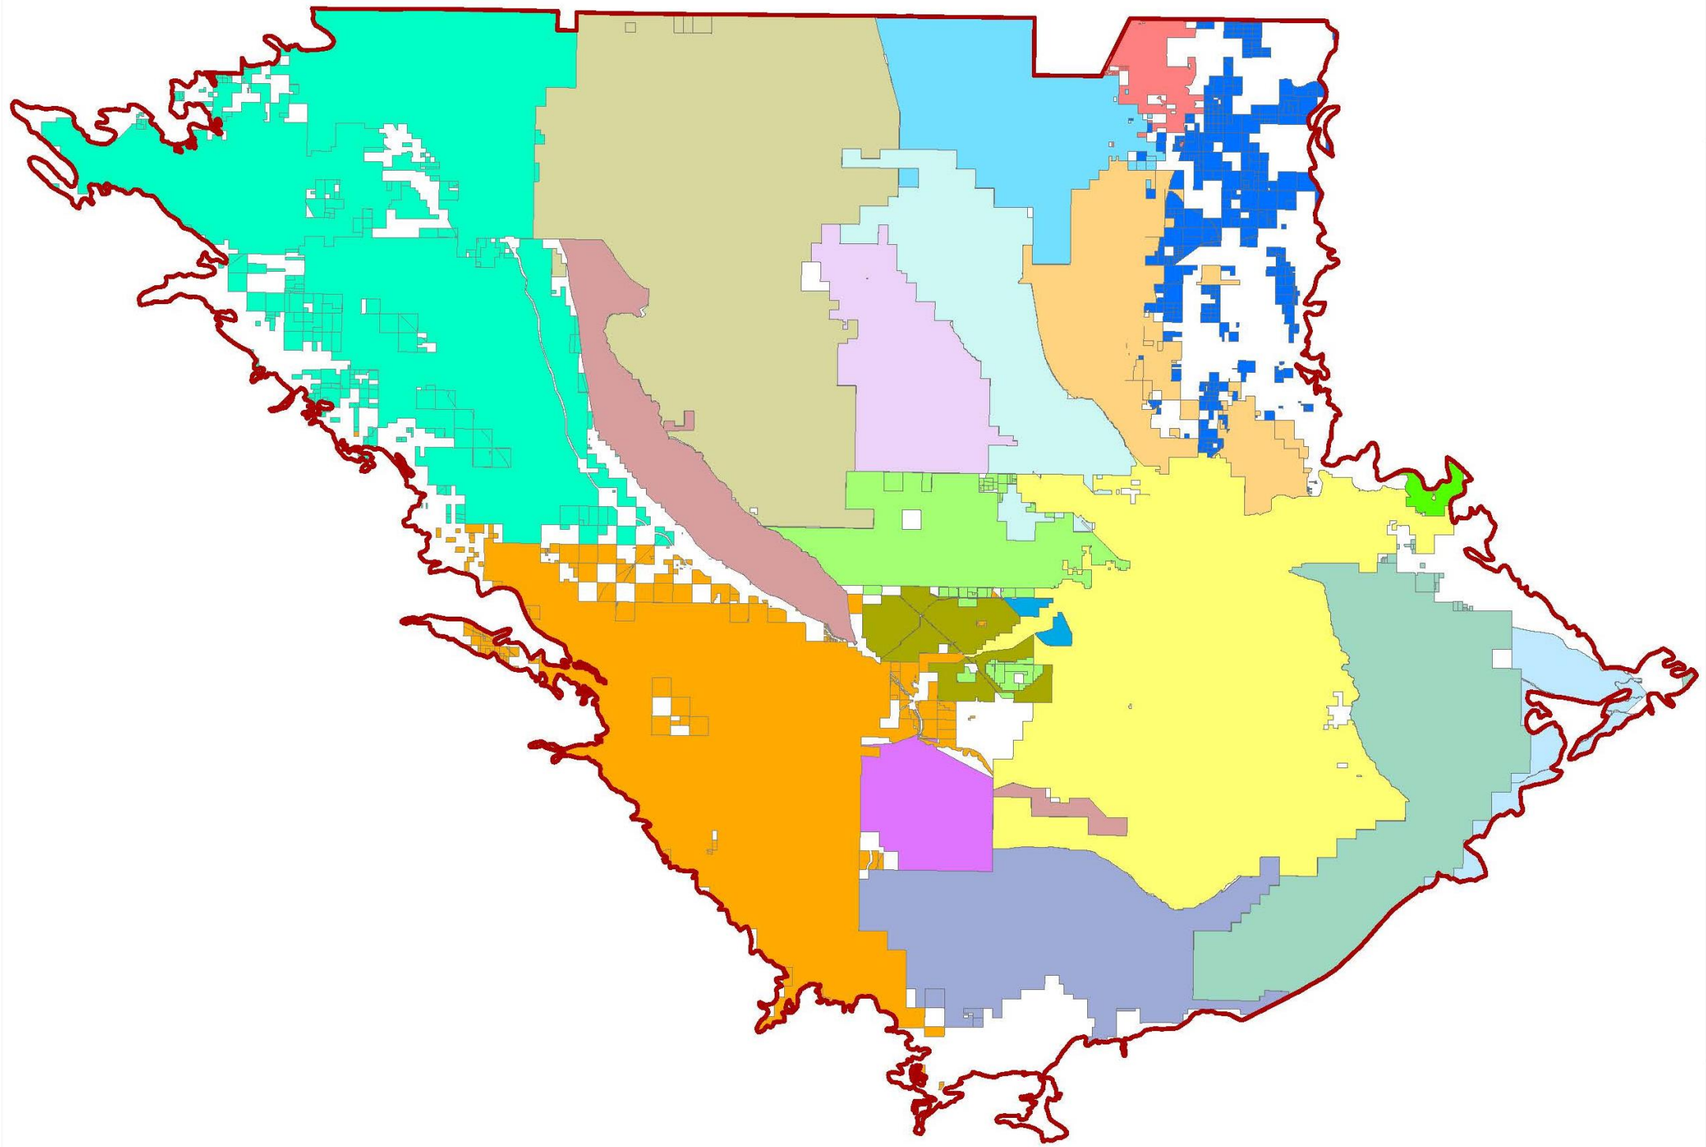
The 2070 Scenario simulates how the Subbasin aquifer would respond assuming hydrologic conditions representing a potentially very dry climate and are based on the DWR Climate Change Guidance (DWR 2018). The 2070 DWR climate change factors were applied to the Baseline Scenario Conditions. Additional adjustments were made to the imported surface water supplies from the SWP, CVP and Kern River, but these accounted for an additional 6% decrease from the Baseline Conditions. The 2070 Climate Change Scenarios were run both with and without SGMA Projects.

The results show a net increase in aquifer inflows of about 66,100 AFY along with an increase in aquifer net outflows of about 231,600 AFY. This is mostly attributed to an even greater climate shift to earlier rainfall making more surface water available for managed aquifer recharge during the winter but less available for irrigation in the summer resulting in higher groundwater pumping. 2070 Climate Change simulation results indicate that the Kern County Subbasin has an average annual overdraft of 472,336 AFY with the net change in groundwater storage showing an additional decline of about 148,010 AFY due to the climate change assumptions. As indicated in the above model simulations, with the implementation and completion of management actions/projects as stated in the individual management area plans and GSPs from the other GSAs in the Kern Subbasin, the 2070 Climate Change model results unfortunately still indicate a average deficit of 45,969 AFY.

2.5 Management Areas

KGA members worked together to establish management areas within the Subbasin to implement projects and management actions as well as better capture local groundwater conditions. In order to prevent undesirable results in adjacent management areas, members have established minimum thresholds consistent with each other.

The Subbasin consists of many entities with land use or water management authority. While a majority of these entities are members of the KGA who have water management authority as explained in Section 1.4, they retain their local responsibility for compliance with SGMA. The County of Kern and municipalities located within the management areas retain their land use



jurisdiction. Ultimately the members of the KGA have the responsibility to implement projects and management actions, as described in Section 4 of this GSP and in the individual management area plans, to achieve sustainability within their management areas. The management areas are summarized in Table 2-9 and presented on Figure 2-55. A detailed explanation of each management area under the KGA is provided in their respective management area plans. The following section provides a brief overview of how and why management areas were created as well as how each area will be managed.

Management areas were created by the districts/member agencies under the KGA to support groundwater sustainability in the Subbasin. Due to the size and variability of water supplies in the region, 25 management areas were created to better manage groundwater. While there is no one approach, majority of the management areas in the region maintain respective district boundaries. Districts and member agencies under the KGA already maintain/manage water rights, contracts, and governing agreements in their regions. By creating their own management areas, Districts/members can maintain/manage maximum flexibility and control over SGMA compliance within its service area, allowing them to implement projects and management actions applicable to their respective areas.

Management areas are designated within the Subbasin to leverage existing relationships with water users for local water accounting and management actions of imports; exports; water consumption and conservation; and groundwater pumping. While most were created from district boundaries, other management areas were developed based off groundwater and geological conditions in each respective service area, which is why some districts have multiple management areas as shown in Table 2-9. These management areas will preserve groundwater management practices and implement additional requirements set forth in this GSP. The JPA with KGA allows for each district or member agency to establish individual management areas and manage them to support the sustainability of the region.

3 Sustainable Management Criteria

3.1 Sustainability Goal

SGMA requires that a sustainability goal be defined for the basin (23-CCR § 354.22), and that the sustainability goal be defined on a basin-wide basis. As introduced in Section 1.3, the KGA, working with all GSAs and its member agencies in the Subbasin have developed the following sustainability goals for the Kern County Subbasin:

- *Achieve sustainable groundwater management in the Kern County Subbasin through the implementation of projects and management actions at the member agency level of each GSA.*
- *Maintain its groundwater use within the sustainable yield of the basin as demonstrated by monitoring and reporting groundwater conditions.*
- *Operate within the established sustainable management criteria, which are based on the collective technical information presented in the GSPs in the Subbasin.*
- *Collectively bring the Subbasin into sustainability and to maintain sustainability over the implementation and planning horizon.*

3.2 Undesirable Results

Undesirable results for each sustainability indicator have been developed through a collaborative process with all the GSAs in the Subbasin, compliant with GSP emergency regulations, which state that undesirable results are to be defined consistently throughout the basin (23-CCR § 354.20). Seawater intrusion and depletion of interconnected surface water were determined not to be present in the Subbasin; therefore, undesirable results for these sustainability indicators were not defined. Justification for these determinations is provided in Sections 3.2.4 and 3.2.5.

The undesirable results developed for this Subbasin represent a condition creating unreasonable impacts to the beneficial uses and users of groundwater over a broad area of the Subbasin. The undesirable results definition for the Subbasin allows flexibility for each management area within the Subbasin to define minimum thresholds that protect against significant and unreasonable impacts to the beneficial uses and users of groundwater within specific management areas. The minimum thresholds within a management area, which define undesirable results, have also been coordinated with other management areas and/or other GSAs to ensure that undesirable results are avoided across management areas and over broad areas of the Subbasin. Each management area plan provides details for minimum thresholds for their respective management areas and how an exceedance of those will be mitigated should they occur.

3.2.1 Criteria Used to Define Undesirable Results

Within the KGA, the criteria used to characterize an undesirable result within each management area was developed by each member of the KGA for their respective management area(s), which

is also coordinated with other management areas and/or GSAs to prevent impact to neighboring areas of the Subbasin and ensure that all areas can be sustainably managed. In all cases the undesirable result is defined as occurring when minimum thresholds within a management area are exceeded at representative monitoring sites. However, the exceedance of a minimum threshold at a single representative monitoring site does not constitute an undesirable result for the Subbasin. Each management area has defined the criteria for the number of representative monitoring sites to exceed their minimum threshold for the management area to become an undesirable result watch area and potentially an undesirable result at the basin level. For example, a management area may adopt criteria specifying that if 50% of the representative monitoring sites within the management area exceed their minimum thresholds it becomes an undesirable result watch area. The criteria used to define undesirable results for each management areas varies and is explained in each individual management area plans.

3.2.2 Undesirable Result for Chronic Lowering of Groundwater Levels

The basin-wide definition for undesirable results for chronic lowering of groundwater levels is as follows:

> *The point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users.*
>
> *This is determined when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each management area). Minimum thresholds shall be set by each of the management areas through their respective management area plans or Groundwater Sustainability Plans.*

This undesirable result definition at the Subbasin level provides flexibility at the management area level to identify the appropriate users and uses of groundwater and the levels of impacts important in that area of the Subbasin. Consistent with DWR's Draft BMP for Sustainable Management Criteria, the Subbasin recognizes that: "overdraft during a period of drought is not sufficient to establish a chronic lowering of groundwater levels if extractions and groundwater recharge are managed as necessary to ensure that reductions in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods." The Subbasin has agreed that a drought period of greater than 10-years would constitute prolonged drought and the lowering of groundwater levels or groundwater storage to below minimum thresholds resulting from a prolonged drought will not constitute an undesirable result.

Within the Subbasin, a management area will be considered an undesirable result watch area for the chronic lowering of groundwater levels when it exceeds its minimum threshold criteria, as determined by each management area. For example, one management area can be considered an undesirable result watch area when 51% of the representative monitoring sites in the management area violates their minimum threshold for groundwater levels. Similarly, another

management area can set this at 75% of their representative monitoring sites. However, if multiple undesirable result watch areas meet the criteria for a Subbasin undesirable result, as defined above, the Subbasin would be experiencing an undesirable result. To prevent the Subbasin from triggering an undesirable result as defined above, once an undesirable results watch area occurs, the Kern SGMA Coordination Committee will review and may provide direction to the effected management area(s).

Establishment of specific measurable objectives and minimum thresholds based on the above definition for this undesirable result can be found in Section 3.3 and with additional regional detail provided within each management area plan.

3.2.2.1 Potential Cause of Chronic Lowering of Groundwater Levels

Section 354.26(b)(1) of the GSP Regulations requires identification of potential causes of an undesirable result for each sustainability indicator. Potential causes of undesirable results for chronic lowering of groundwater levels vary throughout the Subbasin. Lowering groundwater levels can be attributed to increased groundwater pumping, reduced imported water supplies, reduced groundwater inflows from adjacent areas, and/or climate change that results in more frequent and extreme droughts and dry periods. For more specific information regarding the cause of chronic lowering of groundwater levels in the regions of the Subbasin, refer to the management area plans.

3.2.2.2 Potential Effects of Chronic Lowering of Groundwater Levels

Section 354.26(b)(3) of the GSP regulations requires identification of potential effects of an undesirable result for chronic lowering of groundwater levels. Potential effects of an undesirable result due to the chronic lowering of groundwater levels is the potential to affect the reasonable and beneficial use of, and access to, groundwater by overlying users. As previously mentioned, the beneficial uses and users of water varies across the Subbasin and each management area plan address the potential effects on those uses and users. Also, as previously mentioned, these plans are coordinated to avoid impacts the neighboring GSAs or management areas. As mentioned in Section 2.5 Management Areas and the reason why management areas were established, for more detailed information on how the effects or impacts to the beneficial users concerning the chronic lowering of groundwater levels in specific areas refer to the individual management area plans.

3.2.3 Undesirable Result for Reduction of Groundwater Storage

The basin-wide definition of an undesirable result for reduction of groundwater storage is as follows:

> *The point at which significant and unreasonable impacts, as determined by the amount of groundwater in the basin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended 10-year drought period.*

This is determined when the volume of storage (above the groundwater level minimum threshold) is depleted to an elevation lower than the groundwater level minimum threshold in at least three (3) adjacent management areas that represent at least 15% of the subbasin or greater than 30% of the subbasin (as measured by the acreage of each management areas). Minimum thresholds shall be set by each of the management area through their respective management area plans or Groundwater Sustainability Plans.

As with chronic lowering of groundwater levels, the above basin-wide definition allows for local determination of potentially effected uses and users and the level of impacts important to the various management areas in the Subbasin. As groundwater levels are used as proxy for groundwater storage, an undesirable result watch area for reduction of groundwater storage is defined similar to the undesirable result watch area for chronic lowering of groundwater levels.

Establishment of specific measurable objectives and minimum thresholds based on the above definition for this undesirable result can be found in Section 3.3 and with additional regional detail provided within each management area plan.

3.2.3.1 Potential Cause of Reduction of Groundwater Storage

Section 354.26(b)(1) of the GSP regulations requires identification of potential causes of undesirable results for each sustainability indicator. Potential causes of an undesirable result for reduction of groundwater storage vary throughout the Subbasin, specifically the volume of storage need to manage through a drought period. Reduction of groundwater storage can be attributed to increased groundwater pumping; reduced imported water supplies; reduced surface water and banking; reduced groundwater inflows from adjacent areas; and/or climate change that results in more frequent and extreme droughts and dry periods. Similar to the chronic lowering of groundwater levels, for more specific areas of the Subbasin and to determine the potential cause of reduction of groundwater storage, refer to the management area plan for the specific area.

3.2.3.2 Potential Effects of Reduction of Groundwater Storage

Section 354.26(b)(3) of the GSP regulations requires identification of potential effects of an undesirable result for reduction of groundwater storage. Potential effects of reduction of groundwater storage could lead the limited groundwater availability during a prolonged drought.

3.2.4 Undesirable Result for Degraded Water Quality

The basin-wide definition of an undesirable result for degraded water quality is as follows:

The point at which significant and unreasonable impacts over the planning and implementation horizon, as caused by water management actions, that affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

This is determined when the minimum threshold for a groundwater quality constituent of concern is exceeded in at least three (3) adjacent management areas that represent at least 15% of the subbasin or greater than 30% of the designated monitoring points within the

basin. Minimum thresholds shall be set by each of the management areas through their respective management area plans or Groundwater Sustainability Plans.

As with chronic lowering of groundwater levels, the above basin-wide definition allows for local definition, within each management area of the Subbasin, of the minimum thresholds that constitute a significant and unreasonable impact to the reasonable and beneficial use of groundwater by overlying users. Similar to reduction of groundwater storage, groundwater levels are also used as proxy for degraded water quality. An undesirable result watch area for degraded water quality is defined similar to the undesirable result watch area for chronic lowering of groundwater levels.

Establishment of specific measurable objectives and minimum thresholds based on the above definition for this undesirable result can be found in Section 3.3 and with additional regional detail provided within each management area plan.

An overview of the existing water quality conditions in the Subbasin is provided in the basin setting section of this GSP. More specific information regarding current water quality conditions can be found in each individual management area plan. Additionally, details of the water quality monitoring in the KGA can be found in Section 3.4.7.2.

3.2.4.1 Potential Cause of Degraded Water Quality

Section 354.26(b)(1) of the GSP regulations requires identification of potential causes of undesirable results for each sustainability indicator. Potential causes of an undesirable result for degraded water quality vary throughout the Subbasin. Water quality in the Subbasin has been historically sustainable with few exceptions. In the future, water quality can be degraded by significant increase in groundwater pumping or unforeseen point source contamination issues caused by natural or human activity. Each management area plan addresses the cause of degraded water quality in their management area differently since the Subbasin has dynamic differences in hydrology and water supplies and uses. For detailed causes of degraded water quality in a specific area, refer to the management area plans.

3.2.4.2 Potential Effects of Degraded Water Quality

Section 354.26(b)(3) of the GSP regulations requires identification of potential effects of an undesirable result for degraded water quality. An undesirable result for degraded water quality could affect beneficial users. This could potentially reduce the amount of usable supply delivered to groundwater users and require the need for treatment systems, which could potentially have a negative economic effect. As mentioned above for the cause of degraded water quality, the effects or impacts vary in the Subbasin and the management area plans provide more detailed information for their specific areas.

3.2.5 Undesirable Result for Land Subsidence

The basin-wide definition of an undesirable result for land subsidence is as follows:

The point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.

This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan.

As with chronic lowering of groundwater levels, the above basin-wide definition allows for local definition, within each management area of the Subbasin, of the minimum thresholds that constitute a significant and unreasonable impact to the reasonable and beneficial use of groundwater by overlying users. However, as described in Section 3.3.3, the determination of minimum thresholds for land subsidence has not been completed for the Subbasin and is identified as a data gap. While it is generally acknowledged that subsidence exists in portions of the Subbasin, there are generally no significant impacts to infrastructure within the Subbasin. It is unclear whether subsidence occurring in the northern portion of the Subbasin is the results of groundwater pumping from within the Subbasin or from the Tule and Tulare Lake subbasins to the north, where subsidence has been documented to significantly impact critical water infrastructure. As detailed in the monitoring plan, the KGA along with the other GSAs in the Subbasin will develop a joint subsidence monitoring program to better understand the cause and impacts of subsidence. The intent of the KGA and the other GSAs in the Subbasin is to develop minimum thresholds for subsidence for inclusion in the 2025 GSP update. The Monitoring Network section of this GSP provides a description of the proposed basin-wide land subsidence monitoring strategy that has been adopted by the KGA and all other GSAs in the Subbasin.

Establishment of specific measurable objectives and minimum thresholds based on the above definition for this undesirable result can be found within each management area plan. Additional details on subsidence monitoring can be found in 3.4.7.4.

3.2.5.1 Potential Cause of Land Subsidence

Section 354.25(b)(1) of the GSP regulations requires identification of potential causes of an undesirable result for land subsidence. Potential causes of land subsidence vary throughout the Subbasin. While subsidence is not a widespread issue in the Subbasin, potential causes for future subsidence could be tied to significant increases in groundwater pumping, resulting in dewatering of compressible clays in the subsurface. Recent reports of damage to critical infrastructure due to land subsidence are provided in detail in the management area plans. Data gaps and challenges to setting sustainable management criteria and monitoring for undesirable results due to land subsidence are presented in Section 3.4.

3.2.5.2 Potential Effects of Land Subsidence

Section 354.26(b)(3) of the GSP regulations requires identification of potential effects of an undesirable result for land subsidence. Potential effects of land subsidence include damage to critical infrastructure including pipelines, roads, building, water conveyance systems, and flood control facilities. Damage to these systems could impact water delivery to surface water, resulting in increased groundwater use.

3.2.6 Seawater Intrusion

The Subbasin is located approximately 60 miles from the Pacific Ocean, separated by the Coastal Range and other geologic features that prevent seawater from migrating into the Subbasin. Details of the geologic structure of the Subbasin can be found in the basin setting of this GSP. Based on the separation of the Subbasin from any source of seawater, the Subbasin has not developed sustainable management criteria for this sustainability indicator.

3.2.7 Interconnected Surface Water

As defined in the California Code of Regulations (§ 351. Definitions), "Interconnected Surface Water" refers to water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted." A discussion on interconnected surface water is included in Section 2.3.5. As there are no known natural interconnected surface water systems within the KGA boundary, this sustainability indicator is not included in this GSP.

3.3 Minimum Thresholds and Measurable Objectives

The SGMA planning effort began in 2013, prior to the enactment of SGMA, as districts in the Subbasin recognized the need to begin coordination of groundwater management activities. The initial efforts focused on developing an understanding of the significant issues facing groundwater management at the Subbasin and at the district level. Particularly important to this process was understanding the unique conditions that existed in the Subbasin. These conditions include, but are not limited to:

- Not all district's or areas have equal access to groundwater resources (quantity or quality).
- Each district has variable imported or local water supplies (State Water Project, Friant Project, Kern River) each with their own management and reliability challenges.
- The ability to implement water management programs within district's varies by the authorities of the district and in some cases challenges coordination between districts.
- The beneficial uses and users of groundwater varied across the Subbasin.

Despite these unique conditions, the districts within the Subbasin understood the need to coordinate the development of groundwater management activities and common technical materials on which to develop future management activities.

The KGA was formed under a JPA in 2017 and through that process the KGA/GSA Managers Group was formalized. The KGA/GSA Managers Group includes representatives from all KGA member agencies, typically the district general managers and technical experts, as well as representatives from each of the other GSAs developing a GSP in the Subbasin; Kern River GSA, Buena Vista GSA, Henry Miller GSA and Olcese GSA. The measurable objectives and minimum thresholds within the Subbasin were developed in a collaborative process, starting with the KGA/GSA Managers Group. The Managers Group has been meeting on a weekly basis to

address coordination issues; develop and share technical information; identify and resolve potential conflicts; and, where appropriate, elevated issues to the Board of Directors of their respected GSAs and/or the Kern SGMA Coordination Committee comprised of representatives of all GSAs in the Subbasin.

Through the Managers Group, the process for developing minimum thresholds and measurable objectives for the entire subbasin was initiated. This process involved review of the SGMA requirements for thresholds and objectives, including their relationship and coordination to management areas; presentation of technical methods for establishing thresholds and objectives; and coordination between districts and GSAs through the establishment of draft and final thresholds and objectives.

The process was facilitated by the KGA/GSA Planning Manager and technical team with input and identification of issues from member agencies and GSA representatives. The general process for developing minimum thresholds and measurable objectives is outlined below:

Step 1: Regulatory and technical review of minimum threshold and measurable objectives requirements.

- **KGA/GSA Managers Group:** Provided overview of regulatory and technical requirements.
- **Member agencies and GSA representatives and technical consultants:** Sharing of technical approaches to establishing thresholds and objectives for their respective management areas.

Step 2: Defining roles and responsibilities for GSAs and management areas (district areas).

- **KGA/GSA Managers Group:** Presentations on roles and responsibilities for managing resources through proposed thresholds and objectives.
- **Member agencies and GSA representatives and technical consultants:** Identification of potential management area conflicts and opportunities for joint resource management strategies.

Step 3: Development of first draft minimum thresholds and measurable objectives for all Subbasin management areas.

- **KGA/GSA Managers Group:** Facilitate review of draft thresholds and objectives, including development of contour maps and cross-sections of thresholds and objectives.
- **Member agencies and GSA representatives and technical consultants:** Develop and execute technical approach for developing thresholds and objectives with presentation to the KGA Managers Group for review.

Step 4: Development of second draft thresholds and objectives for all Subbasin management areas.

- **KGA/GSA Managers Group:** Facilitate review of draft minimum thresholds and measurable objectives, including development of contour maps and cross-sections of thresholds and objectives.

- **Member agencies and GSA representatives and technical consultants:** Develop and execute technical approach for developing thresholds and objectives and presentation to the KGA Managers Group for review. Identify areas of potential conflicting minimum thresholds and measurable objectives in adjacent management areas and coordinate resolution with adjacent management area.

Step 5: Adoption of final minimum thresholds and measurable objectives.

- **KGA/GSA Managers Group:** Facilitate review of final thresholds and objectives and presentation of thresholds and objectives to KGA Board of Directors.
- **Member agencies and GSA representatives and technical consultants:** Resolve any outstanding conflicts and review thresholds and objectives with management area Boards of Directors and stakeholder groups
- **GSA Boards:** KGA/GSA managers presented to their specific boards for policy board approval

As demonstrated in the steps above, the KGA/GSA Managers Group facilitated the coordination and review of the Subbasin's minimum thresholds and measurable objectives. The technical work required to establish thresholds and objectives at the management area level was completed by the member agencies or GSAs. For the details of the technical processes utilized by KGA member agencies see their respective management area plans. One item to note, that during this entire process the KGA held several stakeholder/beneficial users workshops to roll-out the minimum thresholds and measurable objectives for their input at each step. Also, at the KGA Board meetings, the minimum thresholds and measurable objectives appeared as discussion items.

3.3.1 Chronic Lowering of Groundwater Levels and Reduction of Groundwater Storage

The final Subbasin minimum thresholds and measurable objectives for the chronic lowering of groundwater levels sustainability indicator at each representative monitoring site are presented in listed in Table 3-1 and the representative monitoring sites are shown in Figure 3-1. Figure 3-2 show only the minimum thresholds for the groundwater levels sustainability indicator with elevation contours between each of the representative monitoring sites. This figure provides an indication of how the thresholds values at each representative monitoring site relate to adjacent monitoring site values. Contour maps such as these were used in the review of draft thresholds to determine areas of potential conflicting thresholds between neighboring management areas, such as drastically differing threshold values, elevation gradients steeper than typically observed gradients, or elevation gradients contrary to typically observed gradients.

Figure 3-3 shows only the measurable objective values for groundwater levels sustainability indicator at each representative monitoring site, with elevation contours between monitoring site. The draft measurable objectives were reviewed in the same manner as minimum thresholds.

The chronic lowering of groundwater level minimum thresholds and measurable objective values serve as proxy for the reduction of groundwater storage in the entire Subbasin. Through the

KGA/GSA Managers Group process, it was generally agreed that the withdrawal of groundwater from the Subbasin would not create impacts to beneficial uses or users of groundwater in the Subbasin if groundwater elevations are maintained above the minimum threshold values. Further, the KGA/GSA Managers Group agreed that the measurable objective for groundwater levels should be set sufficiently higher than the minimum threshold for groundwater levels to support groundwater extractions through a 10-year drought cycle, like that experienced from 2006 to 2016, as an example. As a result, the measurable objective for chronic lowering of groundwater levels and reduction in groundwater storage are the same or the measurable objective for groundwater levels serves as a proxy for groundwater storage. The exact methodology and planned drought period used by each management area is described in the management area plans.

3.3.2 Degraded Water Quality

The minimum thresholds and measurable objectives for degraded water quality were established by each of the management areas. All the representative monitoring sites for water quality are also shown in Figure 3-4 and summarized in Table 3-1. In many instances, the minimum threshold and measurable objectives values for groundwater levels serves as a proxy for water quality. In other words, no water quality degradation, migration of contaminate plumes, or other indicators of water quality impairment would be experienced at the groundwater level minimum threshold value at that representative monitoring site.

The details, methodologies, and justification of the water quality minimum threshold and measurable objectives can be found in the management area plans.

3.3.3 Land Subsidence

Land subsidence due to groundwater withdrawal is generally correlated with declining groundwater levels. Land subsidence is currently monitored by extensometers, CGPS stations, and level surveying with benchmarks throughout the Subbasin. The development of minimum thresholds for land subsidence at the basin level is ongoing due to data gaps in monitoring and identification of undesirable results in the Subbasin. Some management areas have not set minimum thresholds for land subsidence pending development of additional data and monitoring, other management areas have established preliminary minimum thresholds.

A combination of water level monitoring and land subsidence monitoring will be used to help set sustainability criteria. As detailed in the monitoring plan section of this GSP, the existing network of subsidence monitoring will be expanded to better understand the causes and impacts of subsidence in the Subbasin. The monitoring plan also provides a plan for filling data gaps to support future establishment of minimum thresholds and measurable objectives for the land subsidence sustainability indicator.

Additional details regarding land subsidence can be found in the groundwater conditions section of this GSP and in the management area plans.

Table 3-1: Summary of Minimum Thresholds and Measureable Objectives

3.3.4 Seawater Intrusion

As described above, the Subbasin is located approximately 60 miles from the Pacific Ocean, separated by the Coastal Range and other geologic features that prevent seawater from migrating into the Subbasin. Details of the geologic structure of the Subbasin can be found in the basin setting of this GSP. Based on the separation of the Subbasin from any source of seawater, the Subbasin has not developed sustainable management criteria for this sustainability indicator.

3.3.5 Depletions of Interconnected Surface Water

As described above the Subbasin, has not identified any areas of interconnected surface waters. Though many studies have been conducted in the Subbasin, including in areas such as the Kern River and Poso Creek, results do not show evidence of surface water within the Subbasin to be interconnected. As there are no known natural interconnected surface water systems within the KGA boundary or the Subbasin, this sustainability indicator is not included in this GSP. Additional information can be found in basin setting section of this GSP and in the management area plans.

3.4 Monitoring Network

The monitoring networks, protocols, and standards described within this section and in the respective management area plans meet the requirements of §352.2, and §354.32 to §354.40 of the California Code of Regulations.

3.4.1 Monitoring Network Description

Management areas within the KGA generally align with member agency boundaries and represent areas of common water management practices. Management areas are designated and managed by KGA member agencies (Table 2-9) and shown in Figure 2-61. KGA member entities are best suited to leverage existing relationships with water users for local groundwater monitoring and site access.

The monitoring network for the KGA represents the coordination of the monitoring networks and activities of the KGA member agencies within their respective management areas. Each member agency will implement its monitoring plan, as described in their management area plan. The KGA will coordinate the annual collection and reporting of monitoring data to DWR and will ensure the monitoring network and protocols are compliant with SGMA.

The monitoring network for the KGA represents the coordination of the monitoring networks and activities of the KGA/GSA Managers Group within their respective management areas. Each member agency will implement its monitoring plan, as described in their management area plan. The KGA will coordinate the annual collection and reporting of monitoring data to DWR and will ensure the monitoring network and protocols are compliant with SGMA.

Monitoring Network is capable of collecting sufficient data to demonstrate short-term, seasonal, and long-term trends in groundwater and related surface conditions, and yield representative

information about groundwater conditions as necessary to evaluate Plan implementation. The monitoring network objectives accomplish the following:

1) Demonstrate progress toward achieving measurable objectives described in the management area and throughout the Subbasin
2) Monitor impacts to the beneficial uses and users of groundwater
3) Monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds
4) Quantify annual changes in water budget components

3.4.2 Monitoring Network Objectives

The objectives of the KGA monitoring network are to:

- demonstrate progress toward achieving measurable objectives summarized in this GSP and detailed in the attached management area plans;
- monitor impacts to the beneficial uses of groundwater and stakeholders within the Subbasin; monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds; quantify annual changes in water budget components; and
- monitor changes for the following pertinent sustainability indicators in the Subbasin;
    - Groundwater Potentiometric Surfaces, or Groundwater Levels,
    - Groundwater Storage,
    - Groundwater Quality, and
    - Land Subsidence.

Seawater intrusion and depletions of interconnected surface water are not pertinent to the monitoring network as they were not considered pertinent sustainability indicators, as described in the basin setting.

3.4.3 Monitoring Data Quality Objectives

As described in DWR's *Groundwater Monitoring Protocols, Standards, and Sites BMP* (DWR, 2016c), the processes for maintaining quality control and quality assurance are iterative, and, as such, will be evaluated every 5 years for effectiveness. The monitoring networks implemented as part of this GSP include the analytical approaches to obtain acceptable data that can monitor the sustainability indicators against minimum thresholds and interim milestones. Where necessary, revisions can be made every 5 years as this GSP is updated.

The monitoring network (see Figures 3-4 and Table 3-1) will be capable of collecting sufficient data to demonstrate seasonal, short-term (1 to 5 years), and long-term (5 to 10 years) trends in groundwater and related surface conditions and yield representative information about groundwater conditions as necessary to evaluate Plan implementation. The frequency at which data will be collected for each network will be described herein.

3.4.4 Monitoring Progress Toward Measurable Objectives

As described in Section 3.2, groundwater levels in the KGA are the key sustainability indicator to monitor undesirable results. Seasonal groundwater levels in selected monitoring wells will be used to monitor progress towards identified measurable objectives. While most of the management areas have used groundwater level as a proxy to monitor other sustainability indicators, certain management areas have defined specific interim milestones for other primary sustainability indicators such as degraded water quality and groundwater storage. The details of these milestones can be found in the management area plans.

After adopting this GSP, the KGA and its member agencies will monitor the progress towards reaching interim milestones for groundwater levels. This progress will be compared with monitoring data for storage, land subsidence, and water quality as well as their respective minimum thresholds, to evaluate the effectiveness of groundwater level as proxies for these other the sustainability indicators. Where needed, interim milestones for groundwater levels or other sustainability indicators may be adjusted to maintain the objectives of the GSP.

The proposed monitoring networks will provide data used to monitor impacts of sustainable groundwater management to beneficial uses and users of groundwater. The proposed approach for monitoring impacts to beneficial uses and users of groundwater are described in Table 3-2.

Table 3-2. Monitoring Impacts to Beneficial Uses and Users

Potential impacts on beneficial uses and users of groundwater	Monitoring Network	Notes
Groundwater elevation decline may result in increased pumping costs and or dry wells.	Groundwater Level Monitoring	Groundwater levels will be compared with well screen construction and pump depth settings
Groundwater storage is reduced to less than minimum threshold affecting future supplies for use.	Groundwater Level Monitoring	Data will be incorporated into the Subbasin model to quantify and monitor storage outlooks and minimum thresholds and interim milestones.
Land subsidence due to overdraft results in infrastructure damage and loss in aquifer storage.	Groundwater Level and Land Subsidence Monitoring	Groundwater levels and land subsidence data will be evaluated against minimum thresholds and interim milestones.
Groundwater quality is degraded and is not suitable for use without additional treatment costs.	Groundwater Quality Monitoring	Data from all water quality reporting sources will be evaluated for the Subbasin to compare against minimum thresholds and objectives.

3.4.5 Coverage of Sustainability Indicators

As mentioned previously, the monitoring plan for each management area plan addresses all pertinent sustainability indicators of the Subbasin: chronic lowering of groundwater levels, reduction in groundwater storage, degraded water quality, and land subsidence. Figure 3-1 and 3-4 provides the current distribution of representative monitoring wells for water elevations and water quality, respectively, to be included in the monitoring network for the KGA by its member agencies. Based on the BMP for monitoring networks, the well density goal is to be between 4 to 10 wells per 100 square miles (DWR, 2016c). In the Subbasin, the KGA covers approximately

2,800 square miles of which, approximately 60% (or ~1,700 square miles) has active groundwater wells. Based on DWR's BMP recommended density goal, the KGA monitoring network should contain between 70 to 280 monitoring wells. The KGA's proposed monitoring network includes 194 well locations for groundwater elevation and storage and 188 well locations for water quality, nearly all of which are groundwater elevation monitoring locations.

3.4.6 Scientific Rational for Site Selection

The monitoring network for the KGA member agencies was designed using the following scientific rational for site selection:

- Aquifer representation –Per DWR's Emergency Regulations CCR § 354.34 (c) (1), monitoring wells were chosen to adequately represent each underlying aquifer within the KGA.
- Potential impacts to beneficial users of groundwater
- Availability of site-specific historical data and technical information
- Spatial and vertical representation of the underlying aquifers
- Precedence of dedicated monitoring wells over production wells
- Site accessibility

While this outlines the general procedure followed by the KGA member agencies to identify their respective monitoring networks, the detailed scientific rational for each monitoring network can be found in the respective management area plan.

3.4.7 Monitoring Protocols for Data Collection and Monitoring

3.4.7.1 Groundwater Level Monitoring Network Protocol and Standards

The existing monitoring network in the KGA includes production wells and dedicated monitoring wells. Until enough dedicated monitoring wells are installed to fill data gaps, production wells will be used to expand the spatial coverage of the existing network.

As referenced in §352.4 of the regulations, monitoring sites/wells will conform to best management practices for geographic locations, identification, and details on well construction. Table 3-3 provides the requested standards.

Table 3-3: Standards for Required Monitoring Well Information

Well Identification	Use the CASGEM well identification number. If a CASGEM well identification number has not been issued, appropriate well information shall be entered on forms made available by DWR.
Well/Site Location	Geographic locations shall be reported in GPS coordinates by latitude and longitude in decimal degree to five decimal places, to a minimum accuracy of 30 feet, relative to NAD83, or another national standard that is convertible to NAD83. Reference point elevations shall be measured and reported in feet to an accuracy of at least 0.5 feet, or the best available information, relative to NAVD88, or another national standard that is convertible to NAVD88, and the method of measurement described.
Well Type and Construction Details	A description of the well use/type, whether the well is active or inactive, and whether the well is a single, clustered, nested, or other type of well. Casing perforations, borehole depth, and total well depth shall be reported. Well completion reports will be provided, if available, from which the names of private owners have been redacted. Geophysical logs, well construction diagrams, or other relevant information will be provided, if available, including any other relevant well construction information, such as well capacity, casing diameter, or casing modifications.
Monitoring Zone	Identification of principal aquifer or aquifer zones monitored.

Requirements for well selection

- A long-term access agreement that includes year-round site access to allow for increased monitoring frequency
- A unique identifier that includes a general written description of the site location, date established, access instructions and point of contact, type of information to be collected, latitude, longitude and elevation
- Monitoring location should also track all modifications to the site in a modification log

Monitoring Protocols

As referenced in §352.4 of the GSP regulations, "monitoring protocols shall be developed according to BMP. Monitoring protocols shall be reviewed at least every five years as part of the periodic evaluation of the Plan and modified as necessary."

As per DWR's Monitoring Protocol BMP (DWR, 2016c) and the Subbasin's Coordination Agreement for Groundwater Elevation Data:

- Groundwater level data shall be sufficient to produce seasonal maps of potentiometric surfaces or water table surfaces throughout the basin that clearly identify changes in groundwater flow direction and gradient.
- Use the Kern Subbasin Well Data form.
- Groundwater level data shall be collected from each principal aquifer in the basin.

- Collection of data between the approved time frames only.
    - January 15th to March 30th
    - September 15th to November 15th
- A weighted water level meter will be used to measure the depth to groundwater.
- Depth to groundwater must be measured relative to an established Reference Point on the well casing. If no mark or reference point is apparent, the person performing the measurement should measure the depth to groundwater from the north side of the top of the well casing.
- The elevation of the Reference Point of the well must be surveyed to the North American Vertical Datum of 1988. The elevation must be accurate to within 0.1 foot.
- Each well's Reference Point will be cataloged to ensure identical procedures are followed for subsequent measurements.
- The data collector should remove the appropriate cap, lid or plug that covers the monitoring access point listening for pressure release. If a release is observed, the measurement should follow a period of time to allow the water level to equilibrate.
- Depth to groundwater must be measured to an accuracy of 0.1 foot below the Reference Point.
- The water level meter shall be decontaminated after measuring each well.
- The data collector shall calculate the groundwater elevation as:
    - GWE = RPE – DTW
    - GWE = Groundwater Elevation
    - RPE = Reference Point Elevation
    - DTW = Depth to Water
- The data collector must ensure that all measurements are consistent units of feet, tenths of feet or hundredths of feet. Measurements and Reference Point Elevations should not be recorded in feet and inches.

Pressure Transducers

As per DWR's Monitoring Protocols BMP (DWR, 2016c), groundwater levels and/or calculated groundwater elevations may be recorded using pressure transducers equipped with data loggers installed in monitoring wells. When installing pressure transducers, care will be exercised to ensure that the data recorded by the transducers is confirmed with hand measurements.

The following general protocols will be followed when installing a pressure transducer in a monitoring well:

- The sampler will use an electronic sounder or chalked steel tape and follow the protocols listed above to measure the groundwater level and calculate the groundwater elevation in the monitoring well to properly program and reference the installation.
- The sampler will note the well identifier, the associated transducer serial number, transducer range, transducer accuracy, and cable serial number.
- Transducers will be able to record groundwater levels with an accuracy of at least 0.1 foot. Consideration of the battery life, data storage capacity, range of groundwater level fluctuations, and natural pressure drift of the transducers will be included in the evaluation.
- The sampler will note whether the pressure transducer uses a vented or non- vented cable for barometric compensation. Vented cables are preferred, but non- vented units provide accurate data if properly corrected for natural barometric pressure changes. This requires the consistent logging of barometric pressures to coincide with measurement intervals.
- Follow manufacturer specifications for installation, calibration, data logging intervals, battery life, correction procedure (if non-vented cables used), and anticipated life expectancy to assure that data quality objectives are being met for the GSP.
- Secure the cable to the well head with a well dock or another reliable method. Mark the cable at the elevation of the reference point with tape or an indelible marker. This will allow estimates of future cable slippage.

The transducer data will periodically be checked against hand measured groundwater levels to monitor electronic drift or cable movement. This will happen during routine site visits, at least annually or as necessary to maintain data integrity.

The data will be downloaded as necessary to ensure no data is lost and entered into the basin's DMS following the QA/QC program established for the GSP. Data collected with non-vented data logger cables will be corrected for atmospheric barometric pressure changes, as appropriate. After the sampler is confident that the transducer data have been safely downloaded and stored, the data will be deleted from the data logger to ensure that adequate data logger memory remains.

As mentioned above, for specific details regarding the monitoring network for groundwater level and change in groundwater storage for each management area, please refer to the respective individual management area plans. The data gaps and steps for improvement of the respective monitoring networks have also been identified in those management area plans.

3.4.7.2 Water Quality Monitoring Network Protocol and Standards

Groundwater Quality Monitoring Network Protocol and Standards

The existing monitoring network in the KGA includes production wells and dedicated monitoring wells. Until enough dedicated monitoring wells are installed to fill data gaps,

production wells will be used to expand the spatial coverage of the existing water quality network.

As referenced in §352.4 of the GSP emergency regulations, monitoring sites/wells will conform to best management practices for geographic locations, identification, and details on well construction.

Requirements for Well Selection

- A long-term access agreement that includes year-round site access to allow for increased monitoring frequency
- A unique identifier that includes a general written description of the site location, date established, access instructions and point of contact, type of information to be collected, latitude, longitude and elevation
- Monitoring location should also track all modifications to the site in a modification log
- The use of existing water quality data within the basin should be done to the greatest extent possible
- Monitoring network should consist largely as a supplemental monitoring locations where known groundwater contamination plumes are under existing regulatory management

Monitoring Protocols

The monitoring protocols will follow, at a minimum, the sampling guidelines as provided in DWR's *Groundwater Monitoring Protocols, Standards, and Sites BMP* (2016c).

Groundwater quality sampling protocols will ensure that:

- Groundwater quality data are taken from the correct location,
- Groundwater quality data are accurate and reproducible,
- Groundwater quality data represent conditions that inform appropriate basin management and are consistent with the data quality objectives,
- All important information is recorded to normalize, if necessary, and compare data, and
- Data are handled in a way that ensures data integrity.

The following points are general guidance in addition to the techniques presented in the previously mentioned USGS *National Field Manual for the Collection of Water Quality Data.*

Standardized protocols include the following:

- Monitor groundwater quality data from each principal aquifer in the basin.
- Data should be sufficient for mapping movement of degraded water quality.
- Data should be sufficient to assess groundwater quality impacts to beneficial uses and users.

- Data should be sufficient to evaluate whether management activities are contributing to water quality degradation.
- All analyses should be performed by a laboratory certified under the State Environmental Laboratory Accreditation Program.
- Samples will be collected according to the standards listed in the Standard Methods for the Examination of Water and Wastewater, USGS National Field Manual for the Collection of Water Quality Data.
- Prior to sampling, the sampler must contact the laboratory to schedule laboratory time, obtain appropriate sampler containers, and clarify any sample holding times or sample preservation requirements.
- Each well used for groundwater quality monitoring must have a unique identifier. This identifier must appear on the well housing or the well casing to avoid confusion.
- In the case of wells with dedicated pumps, samples should be collected at or near the wellhead. Samples are not to be taken/collected from storage tanks, at the end of long pipe runs or after any water treatment infrastructure.
- Samples will be taken/collected only after the appropriate volume of water has been purged from the casing and field parameters have stabilized.
- Sampler will clean the sampling port and/or sampling equipment. The sampling port and/or sampling equipment must be free of any contaminants.
- Groundwater elevation in the well should be measured following the protocols described in the groundwater level measuring protocols.
- Field parameters of pH, electrical conductivity and temperature should be collected for each sample. Lab pH analysis are typically unachievable due to short hold times.
- All field instruments should be calibrated daily and evaluated for drift throughout the day.
- Sample containers should be labeled prior to sample collection. The sample label must include:
    - Sample ID (well ID)
    - Sample date and time
    - Sample personnel
    - Sample location
    - Preservative used
    - Analytes and analytical method
- Samples shall be collected under laminar flow conditions. This may require reducing pumping rates prior to sample collection.
- Samples requiring preservation must be preserved as soon as practically possible.

- Samples to be analyzed for metals should be field-filtered prior to preservation. Do not collect an unfiltered sample in a preserved container.
- Samples will be chilled and maintained at 4 C to prevent degradation of the sample
- Samples will be shipped under a chain of custody documentation to the appropriate laboratory promptly to avoid violating holding time restrictions.
- Custody Seal will be used by the field technician if a third-party transportation service is used.
- A Field Sampling Log will be maintained for each sampling event and will include:
    - Sampler's identification
    - Well identification
    - Climatic conditions
    - Depth to water prior to purging
    - Type of purging and sampling device
    - Purging rate and volume
    - Relative well yield volume
    - Field parameter measurements (pH, temperature, EC, DO)
    - Type and number of samples collected
    - Date and time collected

As mentioned above, for specific details regarding the monitoring network for groundwater quality for each management area, please refer to the respective individual management area plans. The data gaps and steps for improvement of the respective monitoring networks have also been identified in those chapters.

3.4.7.3 Reduction of Groundwater Storage

The reduction of groundwater storage provides an estimate of the change in annual groundwater storage. Since the groundwater storage is not a directly measurable condition, it relies heavily on the collection of accurate groundwater level data. The changes in groundwater levels reflect changes in storage and can thus be estimated with assumptions of thickness of subsurface geologic units, porosity, and connectivity. These observations will be essential for use in calculating the water budget.

A water budget is a foundational tool used to compile water flows (supplies) and outflows (demands). It is an accounting of the total groundwater and surface water entering and leaving a basin or user-defined area. The difference between flows and outflows is a change in the amount of water stored.

Coordination of water budget data to comply with groundwater storage include:

- Surface water supply

- Total water use
- Water budget
- Sustainable yield

The change in the annual volume of groundwater storage between seasonal high conditions shall be quantify in the water budget calculations.

3.4.7.4 Land Subsidence Monitoring Network

The current regional subsidence monitoring network includes regional subsidence screening by InSAR conducted by the USGS and monitoring points at existing continuous GPS (CGPS) stations and available data from SOPAC, as described in the basin setting. These monitoring points include: P544, P545, P563, P564, P565, BFLD, ARM1/2, TAFT, and BVPP. In addition, local extensometers for Semitropic Water Storage District (25S22E35B001M) and Kern Water Bank (30S25E16L) and benchmark monuments of North Kern Water Storage District are included in the network. Data from leveling surveys of the California Aqueduct and Friant-Kern Canal are also valuable points that have some historical data, but which have not been formally incorporated into the local Subbasin network.

Subsidence monitoring is needed to understand the causes of subsidence, the potential risk of damaging critical infrastructure, and how to set minimum thresholds to avoid significant impacts to critical infrastructure in the Subbasin.

Regional coordination of monitoring is key to the design of the network in the Subbasin because regional groundwater extraction is a main driver for regional-scale subsidence, along with subsurface geologic conditions. In addition, if significant impacts to critical infrastructure due to subsidence associated with oil and gas activities identified through regional monitoring, they will be communicated to DOGGR to address as appropriate pursuant to Public Resources Code 3315.

The basis for the design of land subsidence monitoring in the Subbasin is CWC 23 CCR § 354.34. Below are excerpts of the code with pertinent requirements to the Subbasin monitoring network.

Based on 23 CCR § 354.34, the following are some of the key criteria considered for Subbasin monitoring:

- The monitoring will collect sufficient data for seasonal, short-term, and long-term trends in groundwater and related surface conditions.
- The monitoring network will focus on collecting subsidence data (rate and extent) to avoid undesirable results, which for subsidence is defined as "…the point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, affects the surface land uses or critical infrastructure…".
- The monitoring network will be based on scientific rationale.

§ 354.34. Monitoring Network

(a) Each Agency shall develop a monitoring network capable of collecting sufficient data to demonstrate short-term, seasonal, and long-term trends in groundwater and related surface conditions, and yield representative information about groundwater conditions as necessary to evaluate Plan implementation.

…

(c) Each monitoring network shall be designed to accomplish the following for each sustainability indicator:

…

(5) Land Subsidence. Identify the rate and extent of land subsidence, which may be measured by extensometers, surveying, remote sensing technology, or other appropriate method.

…

(g) Each Plan shall describe the following information about the monitoring network:

(1) Scientific rationale for the monitoring site selection process.

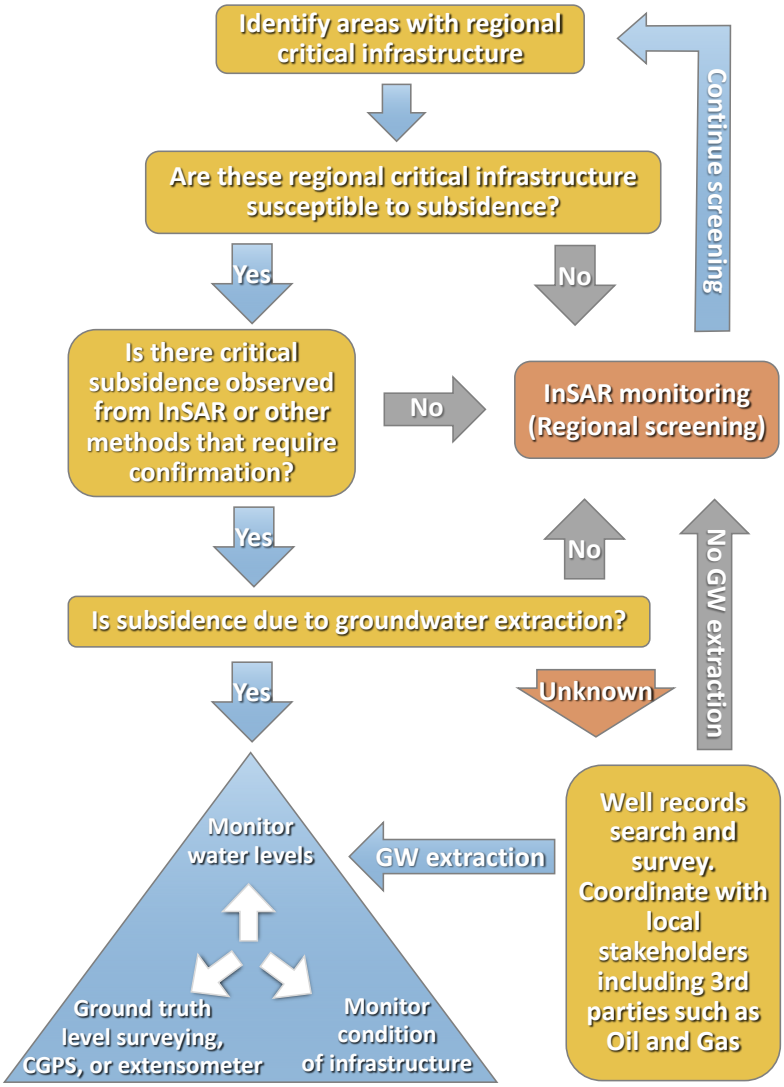
….

(j) An Agency that has demonstrated that undesirable results related to one or more sustainability indicators are not present and are not likely to occur in a basin, as described in Section 354.26, shall not be required to establish a monitoring network related to those sustainability indicators.

Monitoring Protocols

The preliminary monitoring network is based on the following decision-making process (Figure 3-5), which represents continuous screening for land subsidence in the Subbasin by InSAR and ground truthing where necessary. Where critical infrastructure is potentially susceptible to regional subsidence and subsidence is evident, then a determination is needed as to whether groundwater extraction is causing the subsidence. If groundwater extraction is causing the subsidence, then the following actions should be taken:

1. groundwater level monitoring,
2. additional ground-truthing of subsidence, and
3. monitoring of the critical infrastructure.



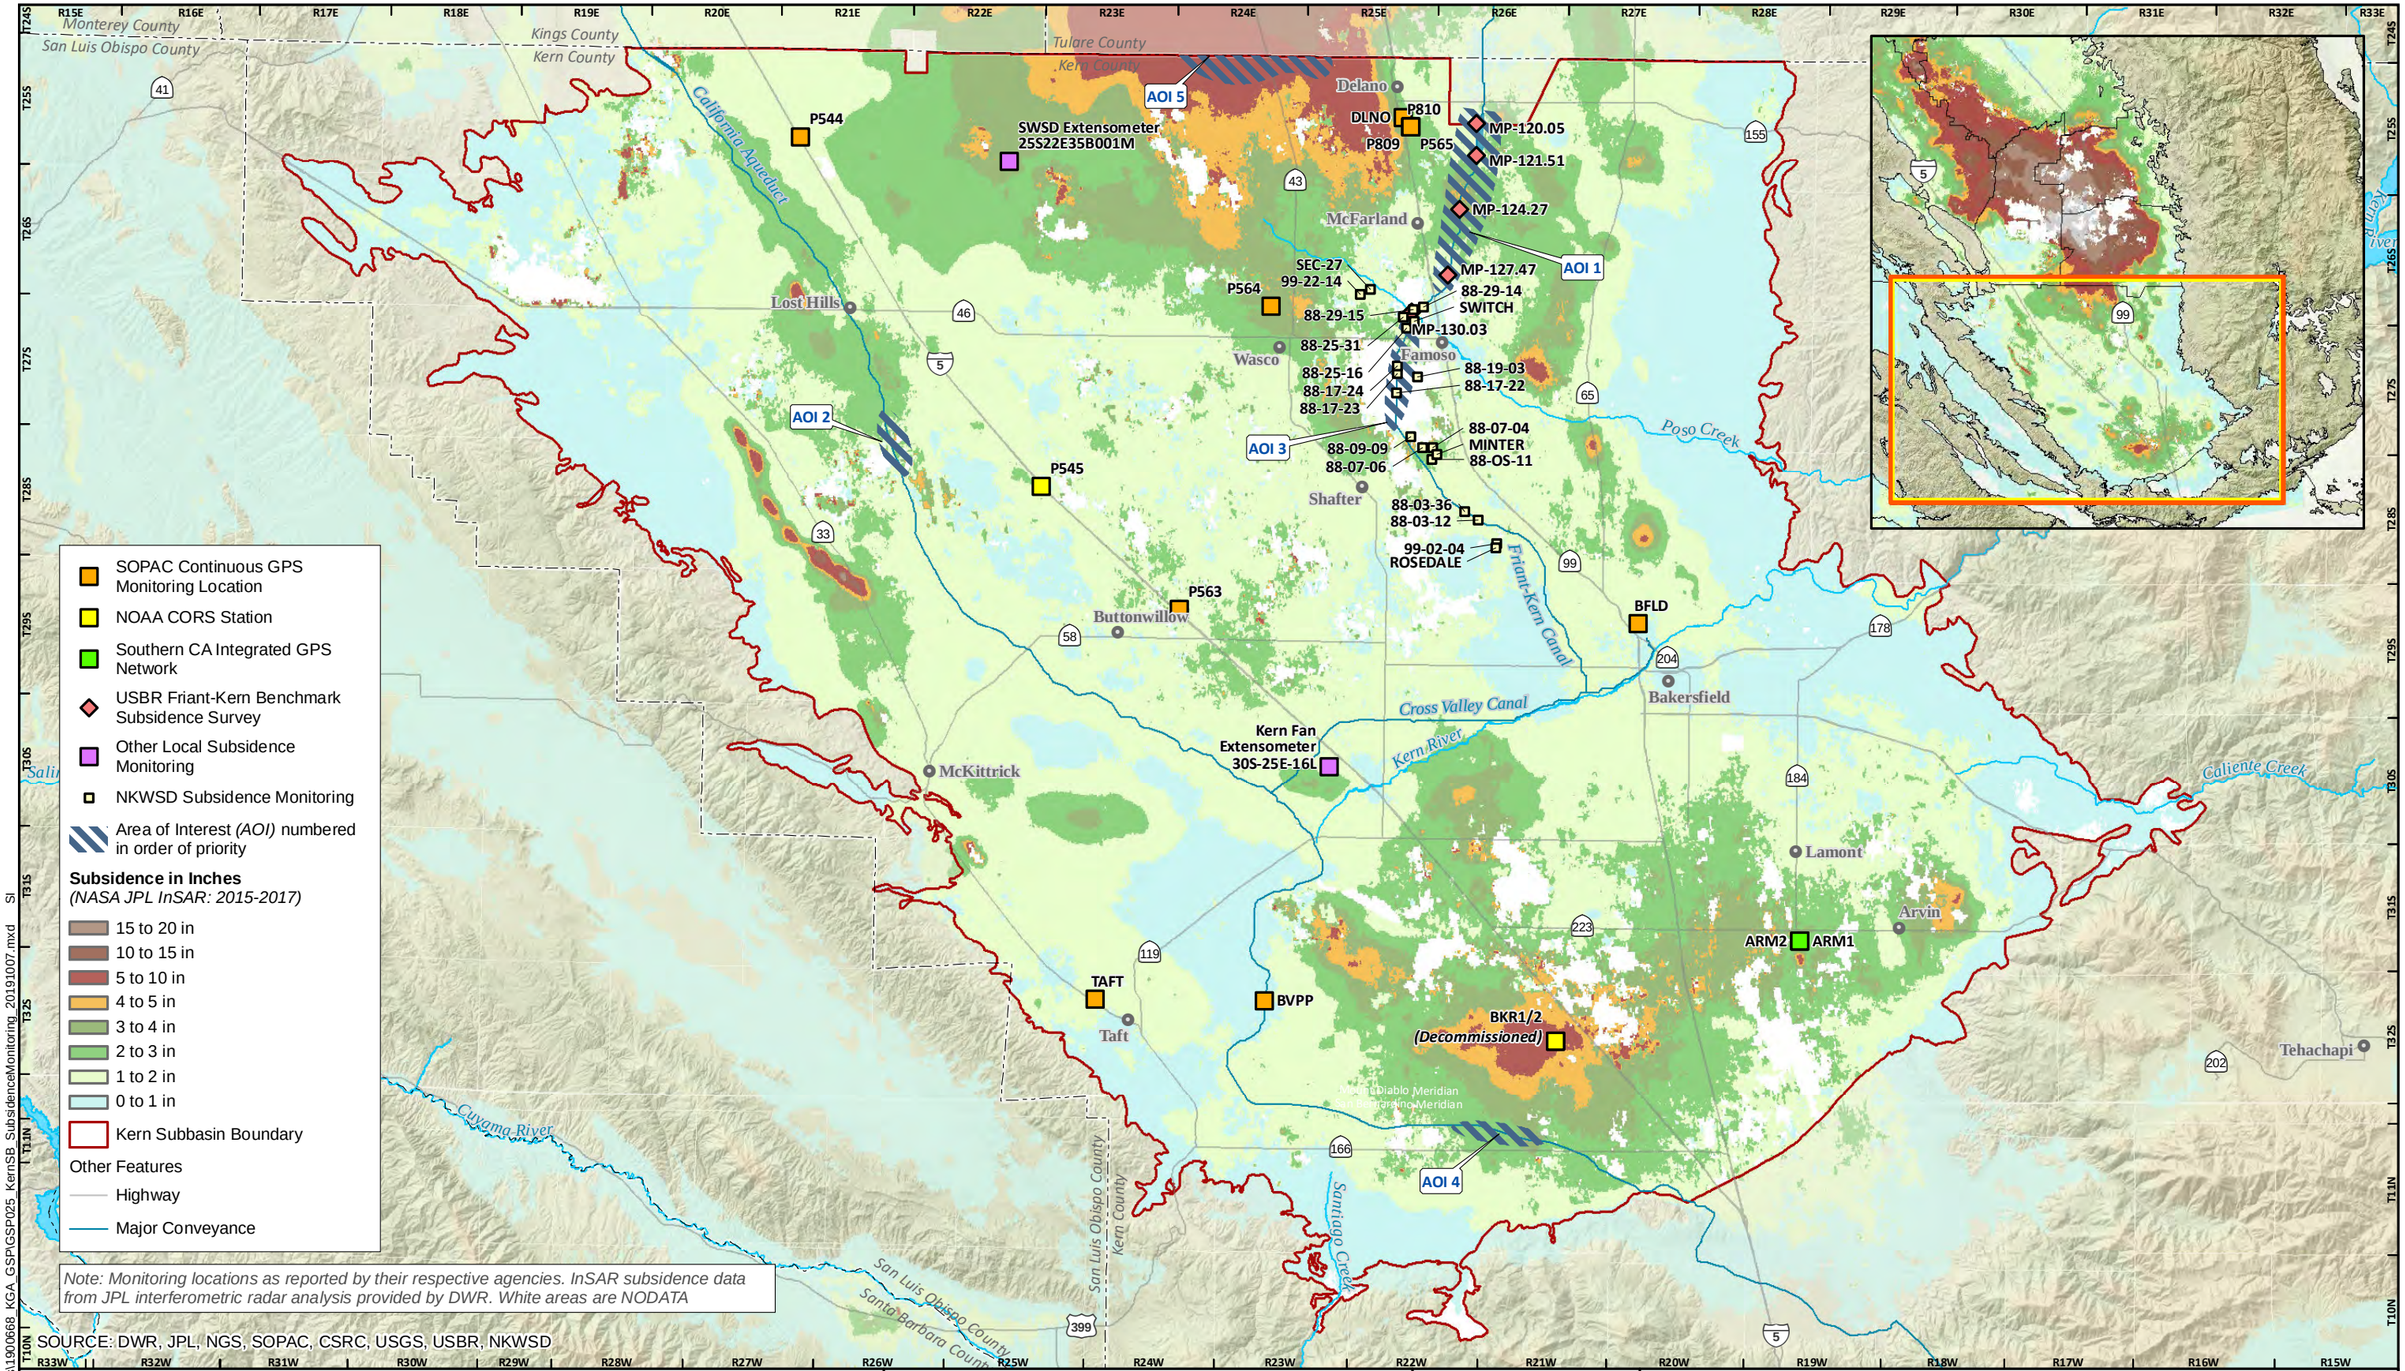


Figure 3-5. Subsidence Monitoring Design Approach

Subsidence Monitoring Network within Areas of Interest

The subsidence monitoring network areas of interest (AOI) are shown in Figure 3-6. Five AOIs were identified, in order of priority, to improve the subbasin monitoring network (AOI-1 to AOI-5). Two of these areas are located along the Friant-Kern Canal, two are along the California Aqueduct, and one area is for monitoring changes in land surface elevation along the northern boundary of the subbasin where a significant amount of subsidence has been reported in the InSAR data.

This Page Left Blank Intentionally

Water Level Elevations

The collection of water level elevations should eb coordinated with subsidence monitoring points. If no wells within the water level monitoring network of the Subbasin are located near AOIs then monitoring wells at these locations will be identified for installation.

Five Areas of Interest

Based on the above monitoring design approach and recent InSAR and level surveying data from State Water Project, Central Valley Project, and North Kern Water Storage District as scientific rationale, four subsidence AOIs associated with critical infrastructure have been identified. In addition, a fifth AOI has been identified at the north boundary of the Subbasin. These AOIs will be covered by the monitoring network. Of these five, the stretch along CA Aqueduct MP 196 to 215 and MP 267 to 271 will be investigated to confirm if groundwater extraction is the cause of subsidence.

Where groundwater extraction is not causing subsidence in an AOI, groundwater management will not be a mitigating factor; therefore, the area will be removed from the AOI list for subsidence monitoring.

Friant-Kern Canal (AOI 1)

This high priority area is located along the Friant Kern Canal between Mileposts 120 to 130, east-northeast of the City of McFarland. The purpose of this AOI is to monitor subsidence along the Friant Kern Canal and its related infrastructure. At times, InSAR monitoring has reported up to 5 inches per year of subsidence in areas surrounding this segment of the Friant Kern Canal. At present, no significant impacts to the Friant Kern Canal have been reported along this portion of the canal's alignment. According to leveling survey data from Friant Water Authority (FWA, 2019), the Friant Kern Canal invert may have subsided from 2 ft to 3 ft below original as-built elevations between mileposts 120 to 135. Continued lowering of the canal invert can decrease freeboard from the original as-built conditions, which may contribute to reduction in emergency storage capabilities and delivery options of the Canal.

In contrast, beyond the Subbasin's northern boundary, subsidence has caused significant impacts to the Friant Kern Canal conveyance capabilities between mileposts 101 to 108.

Existing Monitoring

Currently, this area is screened by InSAR, and previous level surveying was performed by Friant Water Authority at mileposts 120 to 135. There are no other active monitoring points except for InSAR along this stretch.

New Monitoring Approach

A new CGPS station that monitors at the ground surface any subsurface subsidence, regardless of the depth interval, is recommended in this area. Monitoring at this location will assist in the KGA and its member to determine the causes of subsidence. If is it is reasonability determined that local agricultural extractions are the cause of subsidence at this location, the appropriate management area will work towards establishing appropriate measurable objectives and

minimum thresholds. This CGPS data will complement any manual level surveys that may incorporate the Friant Water Authority reported measuring points. CGPS data may also provide on-demand data as needed.

Coordination of Monitoring

Subsidence monitoring along the Friant Kern Canal benefits local stakeholders, CVP contractors, and the Friant Water Authority. It is anticipated that this monitoring can be coordinated with Friant Water Authority to share data as well as potentially share resources and cost.

Any level surveying along the canal from the United States Bureau of Reclamation Friant-Kern benchmarks will require coordination with the Friant Water Authority.

CA Aqueduct Milepost 196 to 215 (AOI 2)

This high priority area is the segment of the California Aqueduct where an embankment failure occurred at Milepost 208 in June 2011 (DWR, 2017c). This failure is partially attributed to subsidence. The cause of this subsidence is unknown and is therefore a subject of monitoring at this location. This area is along the Aqueduct between Mileposts 196 to 215 in the western central subbasin (Figure 3-5). In addition to embankment failure, other consequences of subsidence include loss in freeboard in the Aqueduct. This area has experienced at least 2 feet of subsidence since the Aqueduct was constructed.

Existing Monitoring

Currently, this area is screened by InSAR and is monitored with level surveys every three to seven years by the DWR's DOE. There are no other active monitoring points along this stretch.

New Monitoring Approach

The source of subsidence, either by groundwater extraction activities or oil activities, will be investigated by performing well records searches from DWR well completion records, the Kern County Public Health Department well permit records, and the DOGGR's databases. If necessary, a field well survey may be performed. Coordination may be needed with local stakeholders to confirm the magnitude of groundwater extracted within 1 mile of this portion of the Aqueduct's alignment and the volume of fluids extracted and injected by oil and gas activities within 1 mile of this alignment. A third potential source for subsidence in this area could be hydrocompaction, which was identified during the initial design and construction of the Aqueduct. Pre-consolidation of soil was performed during initial construction so hydrocompaction is likely not significant, however, it cannot be ruled out at this time.

If it is determined that groundwater extraction is playing a role in subsidence for this area, a monitoring point should be installed away from the footprint of the Aqueduct to avoid potential signatures of hydrocompaction if any exist. If there is question of whether some of the subsidence is related to nearby oil and gas activities, then an extensometer should be installed in the interval where groundwater production occurs. An extensometer will provide data of subsidence pertaining to intervals with groundwater production, whereas a CGPS would capture any subsidence regardless of the depth interval.

Coordination of Monitoring

Subsidence monitoring along the Aqueduct benefits local stakeholders, State Water Project (SWP) contractors, and the DWR's DOE. It is anticipated that this monitoring can be coordinated with DWR to share data as well as potentially share resources and cost.

Friant-Kern Canal Milepost 130 to 137 (AOI 3)

This medium priority area is located along the Friant Kern Canal between Mileposts 130 to 137, southwest of Famoso and Poso Creek. The purpose of this AOI is to monitor subsidence along the Friant Kern Canal infrastructure where InSAR and local stakeholders have reported subsidence in the surrounding area. As with AOI-1, no significant impacts to the Friant Kern Canal have been reported along this stretch. According to leveling survey data from the Friant Water Authority (2019), the Friant Kern Canal invert may have subsided from 2 ft to 3 ft below original as-built elevation between Mileposts 120 to 135. Continued lowering of the canal invert can decrease freeboard from the original as-built conditions, which may contribute to reduction in emergency storage capabilities and delivery options of the Canal.

Existing Monitoring

Currently, this area is screened by InSAR, and previous level surveying was performed by the Friant Water Authority at Mileposts labeled on Figure 3-5. Local districts monitor this stretch regularly. Currently there are no continuous monitoring points along this stretch.

New Monitoring Approach

A CGPS station that monitors from the ground surface, any subsurface subsidence regardless of the depth interval, is recommended because the only known cause of subsidence in this area is attributed to groundwater extraction. This CGPS data will complement manual level surveys from local district surveys. CGPS data will also provide nearly on-demand data as needed.

Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the Friant Kern Canal benefits local stakeholders, CVP contractors, and the Friant Water Authority. It is anticipated that this monitoring can be coordinated with Friant Water Authority to share data as well as potentially share resources and cost.

Any level surveying along the canal from the Friant-Kern Canal benchmarks will require coordination with the Friant Water Authority.

CA Aqueduct Milepost 267 to 271 (AOI 4)

This medium priority area is located along the Aqueduct between Milepost 267 to 271 near Old River Road. InSAR data report subsidence southwest and along I-5 and southwest toward the Aqueduct along Old River Road. A former CGPS station (BKR1/2) located about 5 miles north of the Aqueduct along Old River Road also reported significant subsidence; however, this station has since been decommissioned (2016).

Existing Monitoring

Currently, this area is screened by InSAR, and is monitored by level surveying every three to seven years by the DWR's DOE. There are no other active monitoring points along this stretch.

New Monitoring Approach

Groundwater extraction is potentially the source of subsidence, so a continuous monitoring station such as a CGPS or extensometer will be installed. Other potential sources could be oil and gas extraction and hydrocompaction. A DOGGR records search may provide sufficient information to understand the extent of oil and gas extraction in this area. Although hydrocompaction may not be significant because of pre-consolidation practices during Aqueduct construction, nonetheless, in order to avoid potential signatures of hydrocompaction, a monitoring point should be installed away from the footprint of the Aqueduct. If feasible during the siting study, the site location may be selected to the north between the Aqueduct and former BKR1/2.

Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the Aqueduct benefits local stakeholders, SWP contractors, and the DWR's DOE. It is anticipated that this monitoring can be coordinated with DWR to share data as well as potentially share resources and cost.

North Boundary of Subbasin (AOI 5)

This medium priority area is in the northern quarter of T25S-R24E and T25S-R25E. Currently, this AOI does not have recognized susceptible critical infrastructure. It has significant subsidence reported both historically (USGS level surveys) and recently (InSAR). A CGPS station in this area will provide a needed ground truthing point to confirm InSAR readings and will act as a useful monitoring point to gauge progress of groundwater management along the border of the subbasin in relation to neighboring subbasins to the north.

Existing Monitoring

Currently, this area is screened by InSAR. There are no other active monitoring points along this stretch.

New Monitoring Approach

Monitoring at this location will assist in the KGA and its members to determine the causes of subsidence. If is it is reasonability determined that local agricultural extractions are the cause of subsidence at this location, the appropriate management area will work towards establishing appropriate measurable objectives and minimum thresholds. If local groundwater extraction is determined to be the source of subsidence more detailed subsidence monitoring will be undertaken. a CGPS or extensometer monitoring station should be installed. Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the subbasin boundary benefits local stakeholders in Kern County subbasin and adjacent subbasins. In the future, data may be shared with neighboring GSAs for coordination.

3.4.8 Assessment and Improvement of Monitoring Network

The following section describes data gaps and improvements for groundwater elevations, groundwater quality, and land subsidence. While this section provides the overall data gaps observed within the KGA, details for each management area can be found in the respective management area plan.

3.4.8.1 Groundwater Elevation and Storage

As referenced in § 352.4 of the regulations, "*If an Agency relies on wells that lack casing perforations, borehole depth, or total well depth information to monitor groundwater conditions as part of a Plan, the Agency shall describe a schedule for acquiring monitoring wells with the necessary information, or demonstrate to the Department that such information is not necessary to understand and manage groundwater in the basin."*

Well types and construction details will need to be determined to improve on the monitoring network. Downhole well surveys and desktop surveys will be utilized for existing wells to fill in the well construction details gap. New dedicated monitoring wells and converted monitoring wells from production wells will be utilized to fill in the monitoring network spatial extent and density. Plans for improvement will be developed during the next few years to be ready for proposal.

Currently, groundwater elevation and sampling measurements are not scheduled according to the 1 to 2-week period during the middle of Spring and middle of Autumn, as recommended by DWR's Monitoring Protocol BMP. Consequently, groundwater elevations and hydraulic gradients in the Subbasin are reported according to a broader range of time between Spring and Fall.

To minimize the effects of a temporal data gap in the future, it will be necessary to coordinate the collection of groundwater elevation data such that it occurs within a two-week window during the key reporting periods of mid-March and mid-October.

3.4.8.2 Groundwater Quality

New dedicated monitoring wells and converted monitoring wells from production wells will be utilized to fill in the monitoring network spatial extent and density. Plans for improvement will be developed during the next few years to be ready for proposal.

3.4.8.3 Land Subsidence

As described above, the Subbasin has agreed to a joint effort of monitoring subsidence at critical location in the Subbasin. The proposed monitoring program is to understand the causes of

subsidence, the potential risk of damaging critical infrastructure, and how to set minimum thresholds to avoid significant impacts to critical infrastructure in the Subbasin.

3.4.9 Monitoring Summary

The monitoring networks as described above will leverage existing networks for groundwater elevations and storage, groundwater quality, and land subsidence. The networks will be improved upon with data reported semiannually to meet the objectives of this plan. The networks will be evaluated as often as possible to consider improvements and adjustments, and at a minimum, every 5 years, the network reports will summarize the results against measurable objectives. The network improvement plan is provided below.

4 Projects and Management Actions

4.1 Proposed Projects and Management Actions

Projects and management actions for the KGA have been developed at the management area level. Table 4-1 (provided at the end of this section) provides a summary list of all projects and management actions being considered for implementation by each member agency, including the project title, implementation status, a brief description of the project, and benefits associated with the project. The details of each proposed project and management action can be found in each member agency's management area plan.

In addition to the projects and management actions that are proposed by the KGA members, the KGA has identified projects and management actions that it will implemented to further the coordination of groundwater management in the Subbasin. Table 4-2 list these proposed projects and management actions. These efforts will be managed by the KGA and will be cost-share through agreements with KGA members and other GSAs in the Subbasin, as appropriate.

Table 4-2: Kern Groundwater Authority Projects and Management Actions

Project Name	Project Description
Subsidence Monitoring (basin-wide)	Improve the understanding of the causes and impacts of subsidence in the Subbasin. Implementation Period: 2020 to 2025
Groundwater Modeling (basin-wide)	Improve the understanding of groundwater reactions to the implementation of projects and management actions, relationship to minimum thresholds and measurable objectives, determination of the native yield of the Subbasin, and subsurface flow within and out of the Subbasin. Implementation Period: 2020 to 2025
Study of Native Yield of the Subbasin	Studies to refine the understanding and allocation of the available native groundwater yield within the Subbasin. Implementation Period: 2020 to 2025
KGA Monitoring Network Improvement Program	The KGA will work with its member entities, and other Subbasin GSAs, to continue to improve and reach SGMA compliance for identified representative monitoring sites. The KGA will work to identify joint projects and programs to ensure efficient installation and/or rehabilitation of monitoring wells and data collection and reporting efforts. Implementation Period: 2020 to 2025.
Basin-wide Coordination	Continuation of the Kern Subbasin Managers Group to coordinate water management activities in the Subbasin, including technical analysis, project management and coordination, identification of joint management opportunities and coordination of SGMA reporting requirements to DWR. Implementation Period: 2020 to ongoing
Annual Reporting	Coordination and facilitation of annual SGMA reporting requirements. Implementation Period: 2020 to ongoing

The Subbasin includes a complex environment of various local and imported surface water supplies; variable access to groundwater supplies based on quantity and quality; water

management authorities; extent and capacity of water management infrastructure; and fiscal relationship with local landowners for participation in water management programs. Each of the member agencies within the KGA has identified projects and management actions best suited to meet the conditions of sustainability within their respective management areas within the water management and authorities of its entity. Collectively these projects and management actions are designed to maintain or achieve sustainability and the avoidance of undesirable results, first within the management area and then collaboratively throughout the Subbasin. The KGA, the KGA/GSA Managers Group and the Kern SGMA Coordination Committee will monitor the progress of project and management action implementation against reported groundwater conditions and performance to measurable objectives and interim milestones. Through this coordination effort opportunities will be explored for collaboration in implementing projects and management actions, as has been historically accomplished in the Subbasin, for joint conveyance as well as recharge and banking projects, as an example.

Table 4-1 list more than 150 projects and management actions. This includes management projects ranging from expansion of local and regional conveyance and recharge facilities to take advantage of surplus supplies; new conveyance and recharge projects; and participation in the California Water Fix or other thru-Delta improvement projects. Management actions range from implementing district level fee structures to incentive reduced groundwater pumping; participation in local, regional, and state-wide water markets; and setting allocation for groundwater use by landowner, based on the sustainable yield of the management area.

Table 4-1 also demonstrates the tremendous capacity of the entities in the Subbasin to implement projects and management actions to manage the Subbasin sustainably. As the KGA and the other Subbasin GSAs progress to 2040, the implementation of projects and management actions will be adaptively managed to ensure that the proper mix of projects or management actions are developed to avoid undesirable results. Each management area plan as developed its own adaptive management strategy, which often entails some level of groundwater pumping reductions if proposed project or management action are not realized or are not as effective as anticipated.

4.2 Projected Future Water Budgets with SGMA Implementation

Projected water budgets with implementation of the projects and management actions described in the previous section were developed using the C2VSimFG-Kern to evaluate the performance with respect to achieving groundwater sustainability. Proposed projects and management actions were simulated under Baseline conditions, 2030 Climate Conditions and 2070 Climate Conditions using the C2VSimFG-Kern. Detailed description of proposed SGMA projects, and management actions are provided in *Attachment H: Historical and Projected Future Water Budget Development with C2VSimFG-Kern*.

4.2.1 Future Baseline Water Budget with SGMA Implementation

The Baseline Scenario with Projects simulates the implementation of proposed projects and management actions applied to the Baseline Scenario. No other changes were made except for the addition of the projects to provide a direct comparison of the relative benefits of the over

400,000 AFY of proposed SGMA projects and management actions. The change in groundwater storage for projected future baseline with SGMA Projects improves by about 409,904 AFY. This change results in a net gain in groundwater in aquifer storage over the WY2041 to WY2070 sustainability period of about 85,578 AFY.

Figure 4-1 shows the comparison of the average annual water budget components for the two different Baseline Scenarios. Over this period, the average groundwater pumping of 1,354,000 AFY for the Baseline Scenario with SGMA Projects (which includes agricultural pumping, urban pumping and exported water) is over 270,000 AFY less than the Baseline Scenario.

4.2.2 2030 Climate Change Water Budget with SGMA Implementation

The 2030 Climate Scenario with SGMA Projects simulates the implementation of proposed projects and management actions applied to the 2030 climate change conditions. No other changes were made to this scenario. A comparison of the average annual water budget components for the two 2030 Climate Scenarios is presented in Figure 4-2. The change in groundwater storage for projected 2030 Climate Scenarios condition with SGMA Projects improves by about 418,949 AFY. This change results in a net deficit in groundwater in aquifer storage over the WY2041 to WY2070 sustainability period of about 46,829 AFY. Over this period, the average groundwater pumping of 1,444,300 AFY for the 2030 Climate Scenario with SGMA Projects, which includes agricultural pumping, urban pumping and exported water, is over 290,000 AFY less than the 2030 Climate Scenario without SGMA Projects.

4.2.3 2070 Climate Change Water Budget with SGMA Implementation

The 2070 Climate Scenario with SGMA Projects simulates the implementation of proposed projects and management actions applied to the 2070 climate change conditions. No other changes were made to this scenario. A comparison of the average annual water budget components for the two different 2070 Climate Scenarios is presented in Figure 4-3. The change in groundwater storage for projected 2070 Climate Scenarios condition with SGMA Projects improves by about 426,367 AFY. This change results in a net deficit in groundwater in aquifer storage over the WY2041 to WY2070 sustainability period of about 45,969 AFY. Over this period, the average groundwater pumping of 1,559,000 AFY for the 2070 Climate Scenario with SGMA Projects, which includes agricultural pumping, urban pumping and exported water, is over 307,000 AFY less than the 2070 Climate Scenario without SGMA Projects.

A comparison of the annual change in groundwater storage over the 50-year hydrologic period for the baseline conditions, 2030 and 2070 climate condition for with and without projects is presented in Figure 4-4. The time series shows that change in groundwater storage has stabilized to slightly increasing over the period from WY2041 to WY2070 for with Projects condition.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
Arvin-Edison Water Storage District				
AEWSD	AEWSD Sunset Spreading Works	Land acquisitions has been completed. To be implemented upon adoptions of AEWSD GSP Chapter and grant funding acquisition.	The Sunset Spreading Works, approximately 150 acres, is located on the boundary between AEWSDand KDWD, adjacent to KDWD's Eastside Canal. The Project will take surface water (Federal CVP,State Water Project, or local supplies) diverted through KDWD's Eastside Canal and recharge thesurface supplies as part of AEWSD's and KDWD's joint water management programs. The Project will include the construction of exterior and interior dikes for a direct recharge facility, a new turnout and pump station from the KDWD Eastside Canal, and interbasin structures.	Project enhances recharge relevant to groundwater levels, storage, and quality. Prima benefits include water supply augmentation of 2,000-3,000 AFY of recharge and a water demand reduction of 410 AFY.
AEWSD	Private and Caltrans Basin Connections	Not yet initiated. Implementation upon receipt of grant funding.	This project involves the construction of pipelines to connect several on-farm private basins and Caltrans sumps near AEWSD to utilize for groundwater recharge.	Project enhances recharge relevant to groundwater levels and storage. Primary benefits include water supply augmentation of 50-500 AFY of recharge.
AEWSD	Sycamore Creek Detention & Sedimentation Basin	Not yet initiated. Implementation upon receipt of grant funding.	The proposed basin would serve to intercept sediment from Sycamore creek flows to prevent constriction where sediment deposits downstream, reduce the peak outflow, and prevent the likelihood of a canal and spreading basin breach. Detained water could be recirculated for irrigation demands or recharged for groundwater supply augmentation.	Project enhances recharge relevant to groundwater levels, storage, and quality. Primary benefits include water supply augmentation of 200-300 AFY of stormwater capture.
AEWSD	AEWSD South Canal Flood Study / Improvements	Study to be initiated upon GSP adoption and grant funding acquisition.	The South Canal Flood Study would review and possibly revise the FEMA floodplain in this area in order to increase the height of the canal bank to provide additional operational freeboard and accordingly reduce the potential for canal spills and subsequent flooding.The additional canal storage could allow for the caputure and use of additional floodwater in-lieu of groundwater pumping.	Project enhances recharge relevant to groundwater levels and storage. Primary benefits include water supply augmentation of 100-200 AF of increased storage capacity and stormwater capture.
AEWSD	Stormwater Management and Flood Control Improvements	To be decided upon available funding. Excessive flooding or further damages may expedite intiation.	Potential construction of new sedimentation/detention basins, flood ditch erosion protection, Spillway Basin expansi lengthening the South Canal's siphon under David Road or extension of the South Canal liner through designated floodplain reaches.	Project enhances recharge relevant to groundwater levels, storage, and quality.
AEWSD	On-Farm Recharge	Underway	The program will encourage individual growers to perform on-farm recharge for individual and aggregated benefits. Water may be recharged on-farm in private basins and/or distributed through irrigation systems across irrigated acreage in excess of current crop ET.	Project enhances recharge relevant to groundwater levels and storage.
AEWSD	Caliente Creek Habitat Mitigation and Gorundwater Recharge	Not yet initiated. Implementation upon receipt of grant funding.	Restoration of agricultural lands to native vegetation to provide flood mitigation. Two alternatives are being considered, of which Alternative 1 is partial agricultural and 2 is non-agricultural.	Project provides immediate flood control benefits of local stormwwater.
AEWSD	AEWSD Intake Canal / KDWD Buena Vista Canal Intertie	Not yet initiated. Implementation to be decided.	Improvement of existing and/or construction of new interties between AEWSD Intake Canal and KDWD's Buena Vis Canal to facilitate water exchanges between the two districts and Kern County partners.	Project to increase surface storage capacity and delivery flexibility in relation to groundwater levels and storage. Primary benefits include water supply augmentation of 8,000 AFY increased transfer and exchange potential.
AEWSD	AEWSD Intake Canal / KDWD Farmer's Canal Intertie	Not yet initiated. Implementation to be decided.	Improvement of existing and/or construction of new interties between AEWSD Intake Canal and KDWD's Farmer's Canal to facilitate water exchanges between the two districts and Kern County partners.	Project to increase surface storage capacity and delivery flexibility. Primary benefits include water supply augmentation of 4,000 AFY increased transfer and exchange potential.
AEWSD	AEWSD Wasteway Basin Improvements	Project to be implemented upon FEMA grant approval.	The primary use of the existing AEWSD Wasteway Basin is to provide emergency water storage in the event of power failure. Additionally, it works as a detention facility for the City of Bakersfield stormwater. This project would include construction of a HDPE liner along the levees, installation of recirculation pumps, and basin grading. These improvements would allow the basin to serve as a location to divert and clarify sediment.	Project to increase surface storage capacity and delivery flexibility in relation to groundwater levels and storage. Primary benefits include water supply augmentation of 1,550 AFY of stormwater capture.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
AEWSD	Forrest Frick Pipeline / KDWD Eastside Canal Intertie	Not yet initiated. Implementation upon receipt of grant funding.	This project would connect the Forrest Frick Pipeline to the KDWD Eastside Canal to send AEWSD SW supplies through KDWD to serve portions of the AEWSD GWSA with temporary water contracts, utilizing existing infrastructure (turnouts, pipelines that are both District and landowner owned). With the District's new 9(d) contract, certain provisions of Reclamation law are no longer applicable and all lands within the service area can now be served with federal water supplies.	Primary benefits include water supply augmentation of 10 AFY of recharge, 3 AFY/ac of land served.
AEWSD	AEWSD North Canal Balancing Reservoir Expansion & Discharge Pipelines	To be initiated upon completion of feasibilty	The proposed project will consist of the installation of a pipeline system that will convey flows from the four (4) wells within the AEWSD Balancing Reservoir directly to the basin discharge structure and no longer through the basin low flow channels. Infiltration and evaporation losses on well discharge flows will be eliminated and power efficiency for the wells (kwh/af) will be significantly enhanced since all water pumped will be discharged into the North Canal.	Primary benefits include water supply augmentation of 16 AF of increased storage capacity and 100 AFY of recharge. In addition, water demand is expected to be reduced by 50 AFY in evaporative losses.
AEWSD	AEWSD Lateral Capacity Improvement Projects	Not yet initiated.	Increase delivery capacity of the AEWSD N-55 lateral system. Some examples of the actions considered for this project are: replacement of lateral system and landowner pipelines, renovation of storage tanks, construction of pump stations, etc.	Primary benefits include water supply augmentation of 2,000 AFY of of increased delivery capacity.
AEWSD	Conversion of Granite Quarry to Sycamore Reservoir	Study to be initiated upon GSP adoption and grant funding acquisition.	The Granite Co. quarry, located upstream of the Sycamore Spreading Basins, is approaching the end of its operational life and could be converted into a balancing / detention / spreading reservoir. Excess flows in the North Canal could be pumped into the quarry reservoir, so the detained water could be recirculated for irrigation demands in lieu of groundwater pumping and/or recharged.	Primary benefits include water supply augmentation of 3,000-6,000 AFY of recharge and an additional 2,500 AF increased storage capacity.
AEWSD	AEWSD South Canal Balancing Reservoir	Not yet intiated.	Creation of a reservoir to allow water storage for flow mismatches in the AEWSD canal system during operation or emergencies. Depending on the location, this reservoir would increase storage capacity by ~500 AF.	Primary benefits include water supply augmentation of 500 AF increased storage capacity.
AEWSD	Frick Unit In-Lieu Project	Not yet intiated. To be implemented upon grant funding.	This project would increase the ability of the District to provide surface water supplies to the Groundwater Service Area (GWSA) to help meet crop irrigation requirements. With the Project, the District will supply surface water when available through new facilities to the GWSA to meet crop irrigation requirements with the intent of reducing District wide groundwater use.	Primary benefits include water supply augmentation of 3,500 AFY of increased surface water deliveries.
AEWSD	DiGiorgio Unit In-Lieu Project	Completed Phase I. Future phases intiated upon grant funding.	The District will supply SW when available through new facilities to the GWSA to meet its water requirements with the intent of reducing District-wide GW use. However, when SW is in short supply and under agreement, the landowners could recover and return GW from their own wells to the District canal system through new pipelines once they have satisfied their own water needs.	Primary benefits include water supply augmentation of 4,250 AFY in increased surface water deliveries.
AEWSD	General In-Lieu Banking Program	Not yet initiated. To be implemented upon grant funding.	The In-Lieu Banking Program consists of suppling surface water to landowners that previously relied only on groundwater (GWSA). New infrastructure would have to be built to facilitate the implementation of this program.	Primary benefits include water supply augmentation of 2.75 AFY/ac increased surface water deliveries every 2.5 years.
AEWSD	Reclamation of Oilfield Produced Water	To be implemented upon adoptions of AEWSD GSP Chapte and agreement with partnering oil field.	Reclaiming water from oil production facilities for irrigation purposes is currently an untapped water source in AEWSD. After treatment and cooling, produced water could be pumped into AEWSD facilities to serve irrigation demands in-lieu of groundwater pumping.	The primary expected benefit is water supply augmentation.
AEWSD	Wastewater Reclamation with City of Arvin & Bakersfield	To be implemented upon adoptions of AEWSD GSP Chapte and agreement with City of Arvin and City of Bakersfield.	Reclaiming water from Cities of Arvin and Bakersfield wastewater treatment facilities for irrigation purposes is currently an untapped water source in AEWSD. After wastewater treatment, the effluent could be pumped into AEWSD facilities to serve irrigation demands in-lieu of groundwater pumping.	The primary expected benefit is water supply augmentation of 10,000 AFY.
AEWSD	Incentives for Land Conversion	To be implemented upon adoptions of AEWSD GSP Chapter.	The District would provide subsidies to incentivize groundwater users to convert land to alternative land uses (e.g. solar farms) and reduce groundwater extractions. The District may consider a subsidy structure study to determine which subsidies would result in the greatest expected annual benefit in acre-feet per year.	The primary expected benefit is water demand reduction of 2.75 AFY/ac of land converted.
AEWSD	On-farm Water Conservation	To be implemented upon stakeholder interest and acuisition of grant funding.	The NRCS is offering landowner incentive programs to assist in implementing various conservation activities, including but not limited to: irrigation system improvements, water/nutrient/pest management, and pump engine replacement. Interested landowners can call (661) 336-0967 or visit the website (www.ca.nrcs.usda.gov) for more information.	The primary expected benefit is water demand reduction of 50 - 500 AFY.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
AEWSD	Groundwater Fee Increase	Contingent on the Frick Unit In-Lieu Project, Digorgio Unit In-Lieu Project, and General In-Lieu Banking Program.	Increase GWSA costs to incentivize groundwater users to reduce groundwater extractions and take surface water when available. The District may consider modifying its fee structure study to determine the best strategy for curbing groundwater overdraft without causing inequitable economic impact.	The primary expected benefit is water demand reduction.
AEWSD	Groundwater Extraction Quantification Method	To be implemented upon adoptions of AEWSD GSP Chapter.	Application of a new policy to specify an approved method to quantify the individual and aggregated groundwater extractions for the required SGMA annual reporting. Some methods to consider (or a combination of them) are the following: (1) Irrigated Acreage determined by aerial imagery; (2) Irrigated area hybrid determined by annual crop survey alongside aerial imagery; (3) Calibrated energy records; (4) Volumetric flow measurement; (5) Remote sensing of vapotranspiration; (6) Other.	This Project is expected to improve water management flexibility and efficiency as well as data gap filling and monitoring.
AEWSD	Groundwater Allocation per Acre	To be implemented upon adoptions of AEWSD GSP Chapte and initiated as needed to meet milestones if other new supplies are not developed as anticipated.	This program would provide a finite groundwater allocation on a per acre basis. The policy would identify and forecast the demands associated with existing water rights, domestic and environmental uses. The sustainable yield and ultimate groundwater allocation would take into consideration the applicable beneficial uses and users of groundwater. Once an individual groundwater allocation is determined, the District may adopt a policy which provides a gradual “ramp-down” wherein an allocation would decrease over time to arrive at the actual roundwater allocation to allow growers time to adjust to the concept of an allocation and, for some growers, a reduction in groundwater use. The policy would detail the number of years and amount of reduction each year.	The primary expected benefit is water demand reduction.
AEWSD	Groundwater Marketing & Trading	Contingent on Management Actions; Groundwater Extraction Quanitification Method and Groundwater Allocation per Acre.	Contingent on the GW extraction quantification and allocation programs, the District would pursue a groundwater market and trading program to provide uses and beneficial users more flexibility in utilizing a groundwater allocation. The District may adopt a policy to define a groundwater trading program, acknowledging that many complexities and considerations required to successfully initiate and manage a trading program may arise. Therefore the District should discuss any other water bank/credit systems in existence. The District may adopt a groundwater trading structure and consider a variety of structures including: (1) Bilateral contracts or "coffee shop" markets; (2) Brokerage; (3) Bulletin boards; (4) Auctions and reverse auctions; (5) Electronic clearing-houses or "smart markets" ; (6) Other trade structures.	This Project is expected to improve water management flexibility and efficiency.
AEWSD	Education of Groundwater Use per Acre	To be implemented upon adoptions of AEWSD GSP Chapter.	This program would provide groundwater users an expected groundwater volume, as an education tool, prior to enforcement actions on groundwater allocations, with the goal of providing awarness of overdraft conditions. This information would be provided in an annual letter, along with average crop demand, GSA average extraction, GW overdraft, and reminders of GSA powers and authorities.	The primary expected benefit is water demand reduction of 100 AFY.
AEWSD	ACSD Emergency 1,2,3-TCP Treatment at Well No. 13	Implementation is underway.	The project involves the installation of emergency 1,2,3-TCP treatment at the well head. The work will include installation of a skid mounted treatment system with two granular activated carbon media vessels for removal of 1,2,3-TCP, connection to the existing well discharge piping, installation of below ground and above ground influent and effluent piping and appurtenances, electrical and controls, and modifications to the existing well site PLC programming.	This Project is expected to imrpove water quality.
AEWSD	ACSD Arsenic Mitigation Project - Phase II	Implementation is underway.	The purpose of the project is to bring the ACSD water system into compliance for Arsenic. All five of the ACSD active wells exceed the maximum contaminant level (MCL) of 10 ppb for Arsenic. The project was separated into two phases. Phase II involves drilling three new wells, constructing a 1.0 MG storage tank and booster pumping plant, and connecting the facilities to the existing distribution system. The original five (5) water wells will then be abandoned and destroyed in accordance with Kern County Standards.	This Project is expected to imrpove water quality.
Cawelo Water Storage District				
CWD	Voluntary Land Conversion	2020 to 2040 Implementation	The Cawelo GSA will develop a program to incentivize landowners to reduce their total crop demand by converting farmed land to groundwater recharge areas. This would reduce demands and the increased recharge capability could increase supplies. It could also reduce the potential of currently fallow land being used for future crops. This Management Action could be implemented conjunctively with Project #2: Increase GW Recharge and Banking Capacity	Range of annual benefit is 2,000 AFY with an average annual benefit at 2040 of 2,000 AFY.
CWD	Crop Conversion and Irrigation Efficiency	2020 to 2040 Implementation	The Cawelo GSA will evaluate potential programs to incentivize growers to convert from relatively high water demand crops to crops that require less water and to improve the efficiency of irrigation practices. The Cawelo GSA will partner with Federal, State and local organizations such as the California Department of Food and Agriculture, U.S. Department of Agriculture, and Natural Resources Conservation Service to provide landowners information and access to conservation programs. The programs would educate the landowners on the potential economic savings from conversion to lower water demand crops and increased irrigation efficiencies and incentivize them to seek improved economically viable agricultural operations.	Range of annual benefit is less than 2,000 AFY with an average annual benefit at 2040 of 3,8000 AFY.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
CWD	Land Acquisition	2020 to 2040 Implementation	The Cawelo GSA will evaluate and potentially implement a program to acquire land that is actively farmed to reduce irrigated acreages within the Cawelo GSA. This would directly eliminate demands and free up the associated water supplies to meet other demands. This could be a very long-term program seeking to acquire appropriate land when available or to reduce the financial burden. Another method for pot ential conservation programs will be developed that could place certain easements on land that would minimize potential future increased water demands. These programs could also be implemented by contracts or other types of agreements.	Range of annual benefi is 2,500 AFY with an average annual benefit at 2040 of 2,400 AFY.
CWD	New Water Supply Purchases	Begin program in 2020.	The Cawelo GSA would implement programs that will acquire long-term new water purchase contracts and/or establish a water purchase fund if contracts are difficult to secure because of high demand and competition and resulting high costs. The main goal would be to secure long-term new water contracts but compliance with SGMA will impact future water management practices and could make the availability of new long-term contracts scarce. If long-term contracts can't be secured then a new water fund would be established to build funding reserves for water purchases. These purchases could occur during favorable times such as hydrologically wet years when water will be more readily available at lower costs. While the Cawelo GSA would likely not need this water in wet years, these types of purchases could be in the form of banked water that the Cawelo GSA could request at a future date. Alternatively, the funds could be used to make annual water purchases and the revenue for the fund would be consistent from year to year regardless of the hydrological conditions. Therefore, during wet or average hydrologic years the water would cost less and reserves would be built up for more costly water purchases during the drier years. It is estimated that an additional 5,000 AFY to 23,000 AFY of water could be imported into the Cawelo GSA area through new long-term contracts or establishing a new water purchase fund or both.	Securing new long-term contracts or establishing a water purchase fund or both could result in an additional 5,000 AFY to 23,000 AFY of water that could be imported into the Cawelo GSA area. This additional water would increase the amount of water in the basin and decrease overdraft.
CWD	Increase Groundwater Recharge and Banking Capacity	Target 2030 Implementation	The Cawelo GSA will implement projects or programs to increase recharge capacity to capture and recharge additional wet year high flow waters to store for future use. The Cawelo GSA has limited groundwater recharge facilities and has not been able to capture and recharge all available water under wet hydrological conditions. This project would entail building additional Cawelo GSA-owned recharge facilities and/or improve the distribution system to increase the capacity to capture more water, especially during wet hydrologic events. Some facilities could be strategically located to capture storm runoff that may otherwise leave the Cawelo GSA area. It is estimated that approximately 200 to 570 acres of new recharge and banking facilities could be developed. Additionally, the Cawelo GSA will consider implementing a program to incentivize landowners to use their land for recharge. This could provide an opportunity for landowners to bank their private-owned water for future recovery and possibly allow the Cawelo GSA access to their lands for additional recharge. This program would not only increase recharge capacities during wet years but could also reduce water demand by replacing crops with recharge facilities. The privately-owned water could be purchased under Project #1, New Water Supply Purchases, described above.	There are significant regions within the Cawelo GSA with soil properties that could achieve percolation rates of up to 0.5 AF per day. Assuming an average percolation rate of 0.35 AF/day and approximately 200 to 570 acres of potential new recharge and banking land, about an average of 500 AFY to 1,500 AFY of new water could be recharged for future recovery. It is not clear what magnitude landowner-owned recharge facilities would have on importing additional waters into the Cawelo GSA are It could be anywhere between an average of 50 AFY to 500 AFY.
CWD	New Cawelo GSA Banking Partners	Begin program in 2020.	The Cawelo Water District benefits from a banking program partnership with the Zone 7 Water Agency. Located in the Livermore-Amador Valley, which is outside of the Kern County Subbasin. The District stores water for Zone 7 and keeps half of the water that it stores. For example, for every 2 AF feet of water delivered to District recharge facilities, the District is obligated to only return 1 AF. The currently banking program with Zone 7 could be modified to increase the amount of water stored for Zone 7 and/or a new banking programs and partners could be considered to fund the construction of new facilities and/or to improve existing facilities. It is estimated this could increase the annual average water supply up to 500 AFY.	The expansion of the existing banking contract with Zone 7 and/or the development of additional banking partners would be a beneficial way the Cawelo GSA could increase its groundwater supply by the portion of water each partner agrees to essentially leave in the Cawelo GSA area. Zone 7 has agreed to leave 50 percent of all that is spread. It is estimated that this program would generate about 500 AFY.
CWD	Water Treatment Facilities	Begin program in 2020.	The Cawelo GSA is currently evaluating projects to install water treatment facilities that will allow the Cawelo GSA to acquire wastewater and treat it to a level that is safe for crop irrigation. Wastewater is exempt from SGMA regulation and the treated wastewater would be considered new water. There is a substantial volume of oilfield produced water (OPW), a byproduct of oil production, available in the vicinity of the Cawelo GSA. The salinity of OPW can range from moderate to high, although even the best quality still requires some level of blending with fresh water before it can be used on crops. Reverse osmosis or distillation would generally be needed to remove enough salts to make the OPW usable for irrigation. Near the Cawelo GSA, approximately 20,000 AFY of wastewater is injected into exempt groundwater aquifers well below the base of fresh water. The Cawelo GSA is evaluating potential projects to treat anywhere from 7,500 AFY to 20,000 AFY of OPW.	The treated OPW would be a new source of about 7,500 AFY to 20,000 AFY of water for irrigation.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
CWD	Friant Pipeline Project	Construction in 2019.	The Cawelo GSA is currently developing the Friant Pipeline Project that would increase water importation capacity into the Cawelo GSA area. Currently, the amount of imported water that the Cawelo GSA can import into the area is limited by conveyance capacity, not by irrigation demand or recharge basin capacities. The Friant Pipeline Project would increase the total capacity by 100 cubic feet per second (cfs) and connect Cawelo's Famoso Recharge Basins directly to the Friant-Kern Canal. The increased capacity would allow greater access to high flow water and support banking programs with Friant Contractors. The Friant Pipeline Project would result in an additional 1,500 AFY to 2,500 AFY of water brought into the Cawelo GSA area on an average annual basis.	The Friant Pipeline Project would increase the total capacity into the Cawelo GSA by 100 cfs and increase access to CVP high flow waters and allow for banking programs with Friant Contractors. It would result in an additional 1,500 AFY to 2,500 AFY of water brought into the Cawelo GSA area on an average annual basis.
CWD	Poso Creek Flood Water Capture	Target 2030 Implementation	The CWD has appropriative rights to divert water from Poso Creek, an ephemeral stream, when there are flows into the Cawelo GSA area. Additionally, there are downstream districts that also have subsequent appropriative rights and certain adjacent landowners that exercise their riparian rights. CWD also has additional diversion rights to divert supplementary water when high flows occur. The Poso Creek Flood Water Capture Project would consist of the construction of additional facilities to take advantage of those additional rights and divert supplementary water from creek during times of high flow. In addition to making more water available to the Cawelo GSA, this capture of additional high flows could reduce potential downstream flooding impacts. Participation from downstream right holde would be needed due to potential water right impacts. The estimated net water gain is up to 150 AFY on average.	The Poso Creek Flood Water Capture Project would provide up to 150 AFY on average of additional water and could reduce potential downstream flooding impacts.
CWD	Surface Water Storage	Target 2030 Implementation	The Cawelo GSA has several existing reservoirs with a combined storage capacity of 800 AF. This project would consist of constructing a new 5,000 AF reservoir within the Cawelo GSA boundary. This would provide additional storage capacity to bring more water into the Cawelo GSA area during wet years. It is estimated that this new reser would provide approximately 500 AFY on average. This program would likely only be implemented conjunctively with other water management programs.	A new reservoir would provide approximately 500 AFY on average.
CWD	Out of Cawelo GSA Banking	Begin program in 2020.	The Cawelo GSA will evaluate groundwater banking projects that are outside the Cawelo GSA but within the Kern County Subbasin and also groundwater banking projects outside of the Kern County Subbasin. Potential banking projects outside of the Cawelo GSA are likely to have multiple participants and therefore offer a limited share of pro benefits.	This Project could yield an average annual benefit of 500 AFY to 4,000 AFY through out of Cawelo GSA banking programs.
Eastside Water Management Area				
EWMA	Project-1	Not yet initiated; Timetable TBD.	Development of oilfield produced-water supplies to potentially reduce groundwater demand.	Potential additional external source of water for the basin (annual volume TBD).
EWMA	Project-2	Not yet initiated; Timetable TBD.	Investigation of groundwater quality by compilation and analysis of (a) available water quality data, and (b) borehole geophysical data.	Improved HCM and understanding of 3-D distribution of TDS in specific aquifers or regions.
EWMA	Project-3	Not yet initiated; Timetable TBD.	Improved estimation of local (EWMA) native yield by use of additional field-collected data and analysis.	Improved HCM and understanding of groundwater recharge in specific aquifers c regions.
EWMA	Project-4	Not yet initiated; Timetable TBD.	Construction of aquifer-specific monitoring wells in locations with data gaps, to better understand hydraulic heads and gradients.	Improved ability to monitor groundwater conditions in specific aquifers or areas.
EWMA	Project-5	Not yet initiated; Timetable TBD.	Installation of pressure transducers in selected wells of the monitoring network, to collect high-resolution cost-effect data.	Improved ability to monitor groundwater conditions in EWMA.
EWMA	Project-6	Not yet initiated; Timetable TBD.	Surface runoff capture and enhanced infiltration in impoundments.	Reduced groundwater pumping (annual volume TBD) to meet sustainability goals, as needed.
EWMA	Management Action-7	Not yet initiated; Timetable TBD.	Reduction of irrigated acreage, or modification of irrigation techniques or crop types to reduce water usage.	Reduced groundwater pumping (annual volume TBD) to meet sustainability goals, as needed.
EWMA	Management Action-8	Not yet initiated; Timetable TBD.	Assess fees for groundwater use to encourage reduced pumping or curtailment.	Reduced groundwater pumping (annual volume TBD) to meet sustainability goals, as needed.
EWMA	Management Action-9	Not yet initiated; Timetable TBD.	Establish a system of transferrable water credits.	Reduced groundwater pumping (annual volume TBD) to meet sustainability goals, a needed.
EWMA	Management Action-10	Not yet initiated; Timetable TBD.	Legal and administrative review: effects of CEQA and water law on joint management of native yield.	Clarification of constraints on sustainable groundwater management in EWMA.
Kern Water Bank Authority				
KWB	Temporary Lowering of Groundwater Levels	Ongoing	KWB operations can cause a temporary lowering of groundwater levels in adjacent areas toward the end of extended droughts. In order to mitigate the potential impacts that might arise from those temporary changes, DWR has developed mitigation measures for the project, which have now been coordinated with other adjacent water banking projects and incorporated into a Joint Operations Plan. The Joint Operations Plan designates measures to prevent, eliminate or mitigate significant adverse impacts resulting from project recovery operations.	

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
KWB	Reduction of Groundwater Storage	Ongoing	KWBA cannot recover water beyond those volumes previously stored less appropriate losses. When storage accounts reach zero, recovery pumping will stop. Given due consideration to this mitigation measure, no other management actions are necessary	
KWB	Degraded Water Quality	Ongoing	Groundwater monitoring from 1994 through 2018 indicates groundwater quality is not being degraded by KWB water banking activities, and in fact the removal of salts is benefitting the aquifer. DWR developed mitigation measures to ensure that continued KWB operations do not degrade groundwater quality.	
KWB	Subsidence	Ongoing	Subsidence has not occurred in over twenty years of KWB operations. DWR has also concluded that subsidence is not likely to occur as the result of future operations. Monitoring will continue, and if subsidence begins to develop appropriate mitigation measures will be developed.	
KWB	Project	Not yet initiated.	KWBA intends to construct an additional 1,025 acres of recharge basins.	Project will allow KWBA capture more water in the future, furthering the conservation goals of SGMA.
Kern Tulare Water District				
KTWD	Action 1: Modify District Pricing Structure	ction 1 could be executed during the first 5 years of implementing the Plan (2020-2025).	The most affordable way to reduce groundwater pumping is to provide a pricing mechanism that causes groundwater to cost more than surface water. This could be accomplished by implementing a “groundwater charge” for every acre-foot pumped. Water Code §35533 provides the District the authority to collect groundwater charges. Revenue from the groundwater charge could be used to implement management actions or to reduce the cost to deliver surface water from the District.	5,580 AF/yr reduction in groundwater pumping.
KTWD	Action 2: CRC Pipeline Project - Produced Water Project	The District and CRC are in the process of acquiring permits, preparing an anti-degradation analysis and acquiring a WDR from the Regional Board. Project pipelines have been designed and plan and profile drawings have been prepared. The District is negotiating an agreement with CRC and obtaining rights-of-way. The pipeline construction is expected to be completed prior to 2025.	The District has historically accepted produced water to provide surface water to the District and is in the process of obtaining an additional source of produced water from California Resources Corporation (CRC). Produced water from CRC will be transported through 12 miles of 15-inch pipeline to the Guzman Reservoir. From the Guzman Reservoir water will be transported through 1.8 miles of 30-inch pipeline to the District’s existing Big 4 Reservoir, from which it will be blended with water from the Friant-Kern Canal and distributed in existing facilities to existing irrigated agriculture located within the District.	3,000 AF/yr of additional surface supplies (results in a reduction of 1,440 AF/yr in groundwater pumping).
KTWD	Action 3: In-District Surface Storage	The project is still in the preliminary design phase and will require additional steps before construction. The District has selected two potential reservoir sites, completed exploratory borings, and conducted a geotechnical evaluation of the two potential sites. The District has yet to acquire land and rights of way, permits, environmental documentation, or project financing. It is estimated that these facilities will be constructed between 2025 and 2030 if they are determined to be feasible and found to be necessary.	There are times when affordable water supplies are available, but the District has little to no irrigation demand and no available spreading capacity in its existing out-of-district banking programs. Construction of off-stream surface storage will allow the District to acquire water when it is available and store it to meet future irrigation demands. The District has selected two potential reservoir sites with a total capacity of 8,000 AF to capture wet year water. The sites are located to the east of the District in both the north and south portions. A location map of facilities and detailed description is not provided due to the confidential nature of the property and rights of way acquisition.	Based upon annual water supply modeling herein, the project yields only 530 AF/yr. However, a monthly analysis will need to be conducted to provide a better estimate of project yield, which could be as much as 2,000 AF/yr (assumes the reservoirs are used once every 4 years).
North Kern Water District & Shafter-Wasco Irrigation District				
NKWSD	Calloway Canal Improvements: Lining Snow Rd. to 7th Standard Rd.	Calloway Canal Lining is an ongoing project. NKWSD is in the process of acquiring adequate funding to complete the next one-mile lining of the project. The proposed project schedule includes a start date of October 2019 and completion within 36-months.	Calloway Canal Improvements is part of NKWSD’s continued effort of the recently completed 1.1-mile long canal lining. The first phase of this project consists of concrete lining approximately 2,200 LF of currently unlined portion of the Calloway Canal to increase surface water reliability and prevent seepage.. Phase two of this project includes water delivery improvements (WDI) that consist of installing magnetic flowmeters (or magmeters) at a total of 50 of the District owned production wells. Each magmeter will include a totalizer capable of measuring the volume of groundwater pumped through the wells. Further, water level sensors will also be installed in each of the 50 production wells and four additional monitoring wells to quantify the depth-to-water data. Additionally, the District proposes to implement telemetry upgrades at each of the production well sites, each of the monitoring well sites, and 14 remote Terminal Unity (RTUs-used to measure canal levels) sites. The final part of the water delivery improvements integrating these sites with NKWSD’s Supervisory Control and Data Acquisition (SCADA) setup.	Lining the canal will reduce the irrecoverable losses that result when high quality surface water seeps to poor quality groundwater, which cannot be recovered for later use without substantial treatment. Reducing these losses enhances NKWSD’s capability to deliver increased volumes of water from the Kern River to irrigators for existing demand. The integration of the telemetry system with the SCADA setup will enable the District to control well operation and access their groundwater pumping data remotely. Water conserved by lining the canal and implementing WDI is estimated at 1,576 AFY.
NKWSD	Expanded Water Banking Program	This program is an expansion of the District’s ongoing groundwater banking program. Environmental documents are being prepared to carry out the program in a timely manner.	Due to historically low groundwater levels, requirements under SGMA, and potential reductions in its historical water supplies, NKWSD is proposing a new program to increase its existing conjunctive use (or water banking) facilities a subsequently expand these facilities. Phase I of this program would primarily rely on unused capacity in existing facilities which is available from time to time (with some additional conveyance) and would seek to increase the utilization of the District’s proven recharge and recovery assets. Phase II would involve the construction of additional direct recharge and recovery facilities to further expand water banking in the District. Both the District and District landowners will receive water supply benefits from this program.	Implementation of this program would bring additional water supplies that would help offset potential losses of the District’s historical supplies, support the District’s mission of maintaining economic pumping lifts for its landowners, and maintain supplies to be used for municipal and industrial purposes by the city of Shafter. Quantitative benefits include 50,000 AFY (Phase I) and 72,000 AFY (Phase II) for a total of 122,000 AFY of water for the District.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
NKWSD	Groundwater Banking Conveyance Improvements to NKWSD Recharge and Recovery	NKWSD is in the process of acquiring adequate funding to complete this project. The proposed project schedule includes a start date of October 2019 and completion by the end of 2021.	The proposed project involves the drilling and equipping of three replacement wells and connecting two other deep wells (five total) to NKWSD's existing network to improve return capacity of recharged water for the District's neighbors. Proposed project is to construct the necessary pipelines to connect five deep wells to the District's recovery network system that improves the capacity to return water supplies multiple districts in the region during dry years.	Implementation of this project is anticipated to return previously stored water into the FKC and NKWSD's conveyance system at a rate of approximately 27 cfs. This equates to a total estimated average of 1,660 acre-feet per month, or an annual capacity of 9,961 acre-feet per year for the seasonal use of the wells (six months in a year) to improve the return capacity for the Poso Creek IRWM CVP Contractors to meet irrigation demands during a critically dry year. Two of the five wells will discharge into the District's canals and the remaining three will connect to the District's manifold pipeline, which ultimately discharges to the FKC.
NKWSD	Beneficial Reuse of Oilfield Produced Water	This is an ongoing project. NKWSD is interested in expanding the amount of oilfield produced water being brought into the district; however, no decision has been made at this time.	Since 2015, NKWSD has made beneficial reuse of oilfield produced water by blending produced water with other surface supplies for irrigation use. The California Resources Corporation (CRC) discharges 58 acre-feet per day of produced water from CRC's Kern Front Oil Field to NKWSD. The blended water is used directly for irrigation or is discharged to spreading basins in NKWSD for groundwater recharge.	Currently, this project has an important beneficial impact on water resources in the local area. One impact of the project is the annual recycling of up to 11,000 AF of oilfield produced water to the District. This flow is blended with other water sources and used for irrigation and groundwater recharge. Produced water increases the District's water supply and partially replaces groundwater that would otherwise be pumped. During the winter season, produced water is discharged to the Rosedale Spreading Basins along with any available Kern River water to recharge groundwater supplies. This has the added benefit of decreasing the rate of groundwater decline and lowering pumping costs.
NKWSD	SCADA Automation and Evapotranspiration Measurement Improvements	This is an ongoing project. The District is in the process of switching from SCADA to Wonderware Software and plans to implement upon approval from Reclamation.	The proposed project includes the installation of Supervisory Control and Data Acquisition (SCADA) Automation software along with Evapo-transpiration (ET) measurement stations. This project is divided into two components, the purpose of the first component is to remotely monitor and control the District owned and operated groundwater wells and Canal level transmitters. The second component of this project is to install evapo-transpiration (ET) stations in strategic locations within the District. The District anticipates that the crop specific ET measurements will help the District and its growers to correlate the ET and the applied water with the crop yield.	With these modernization efforts, the District can automatically record the instantaneous groundwater pumping rate, depth to groundwater, canal level, water quality parameters, and ET data.
NKWSD	Poso Creek Weir	Currently, this project is in preliminary stages. This project is part of the projects planned to meet the sustainability goal of the District by 2040. NKWSD may implement this at any time over the planning horizon to reach its sustainability goal.	NKWSD plans to construct a weir on the Poso Creek Flood channel to divert water into their facilities. The District currently has an earthen plug that works to divert water; however, the plug is not reliable and has proven to be inefficient for the District. Implementation of this project will provide a more reliable management of flows, allow water to be measured as it is diverted, and reduce the velocity and sediment loading prior to diversion. Diverted water will be used to increase groundwater banking activities in NKWSD to help prevent further lowering of groundwater levels.	Construction of a weir will provide the ability to drop out sediment prior to flood water entering the District's distribution system or direct spreading facility. By slowing the velocity and allowing sediment to drop out, higher water quality is diverted into the district.
NKWSD	Spreading Pond Facility	No Data	No Data	No Data
RRID	Expanded Recharge	Project is in the conceptual phase; however, the pre-existing conveyance pipeline allows for swift project implementation if needed.	RRID will expand their recharge to include on-farm spreading to maximize recharge capability. To ensure adequate delivery of supplies, water delivery infrastructure improvements will be included in this project. Improvements to the CRC pipeline will be made before on-farm recharge occurs.	An estimated 6,000 AFY would be added to the already 5,000 AFY provided by CRC for the purposes of beneficial reuse.
RRID	Allocation of Available NKWSD Supplies	This project is ongoing as NKWSD already allocates produced water to their facility; however, water spread in the Rosedale facility will now exclusively benefit RRID.	Oilfield produced water will be allocated to North Kern's Rosedale spreading facility for RRID's exclusive benefit.	
SWID	Diltz Intertie Lateral Piping and WMI	Design plan specifications have been completed for the proposed later improvements coinciding with the Diltz Intertie mainline design. Project is in its pre-construction phase and will be fully implemented in 2020.	The proposed project includes installing pressurized pipe laterals to connect the Diltz Intertie mainline to serve 380 acres of irrigated land. Project will consist of a 1.5-mile long, 30 cfs, 36- inch diameter, bi-directional, intertie pipeline which will allow for the efficient conveyance of surface water supplies to spreading ground facilities located in SWID.	Component 1 is expected to decrease groundwater pumping in the SWID by providing growers with pressurized surface water deliveries at a greater capacity and frequency. Decreased groundwater pumping in SWID will all for the recovery of groundwater elevations. This project will save 1,927 AFY of water following project completion.
SWID	Bell Recharge Project	Project is currently in planning phase and still requires final pipeline alignment selection to begin other project components such as easement acquisition, final design, and bidding.	Implementation of this project includes the construction of a 12 cfs conveyance improvement along SWID's existing distribution system that will allow CVP-Friant supply to be delivered from the FKC to the Bell Recharge site. Bell project will allow for delivery of surface water to the new Bell Recharge facilities form the CVP, for increased water storage.	Proposed Bell Project pipeline connection is anticipated to convey CVP wet period water into SWSD at a rate of 12 CFS with estimated annual benefits of 1,728 AFY.
SWID	Kimberlina Recharge Project	Already being implemented. To be completed by 2022.	Construction of a 285-acre recharge site for CVP surface water.	Water suuply augmentation of approximately 19,000 AFY

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
SWID	Leonard Avenue Conveyance Improvement Project	Project is currently in planning phase and still requires final pipeline alignment selection to begin other project components such as easement acquisition, final design, and bidding.	This project involves the construction of 1.5 miles of pipeline to connect SWID with Semitropic Water Storage District (SWSD). Implementation of a new pipeline will provide SWID with the operational flexibility to absorb surface water when it is available for delivery to SWSD's distribution system, connecting the supply to in-lieu and direct recharge facilities in SWSD, generally during wet periods, so that water delivered can later be recovered for irrigation in peak demand months, or dry periods.	When implemented, this project will provide added capacity to absorb surplus water from the CVP during wet periods. It is estimated that this project will capture 2,880 AFY of surface supply, predominately from the CVP surface floodwater conveyed via the FKC, through SWID and into SWSD. Additional water absorbed into the groundwater basin will be split 50/50 between SWID and SWSD. The total average annual water saving to SWID is 1,440 AFY. Captured water will directly offset SWID's reliance on San Joaquin River supplies to the Bay-Delta and help conserve local groundwater supplies.
SWID	Improved Water Level Measurement of District Recharge Facility	This project is in the planning phase. Implementation of this project may begin as soon as 2020.	Proposed project includes the construction of a 400 to 500-feet deep, 8-inch diameter PVC monitoring well and the conversion of an existing older well to an 800-feet deep, 6-inch diameter monitoring well both equipped with both w level sensors and located within the District's recharge facility. Both monitoring wells will help manage and collection information on groundwater levels which can be used to document site performance as well as monitor the effects of the groundwater aquifer levels.	Implementation of this project will contribute to improving the district's drought resiliency and preserving groundwater levels by monitoring groundwater levels in the facility and improving efficiency of recharge operations.
NKWSD	Refinement of Water Budget Components	Ongoing	Improvement of monitoring and measurements to refine the accuracy of measurement or calculation of inflow a outflow components of district level water budget. Will also refine Subbasin Model and water budg	This management action is conceptual; a volume of water associated with th management action has not been calculate
NKWSD/SWID	"Surface Water First" Incentive Program	This Management Action is in the preliminary stages of consideration by the districts. It has not been formally adopte but is under consideration.	Both NKWSD and SWID have access to imported surface water to supply their respective jurisdictional areas. However, there instances in which growers have historically opted to pump groundwater, rather than receiving deliveries of surface water from the district which services their properties. When this occurs, the district must either use that water for groundwater recharge or enter into exchanges with other districts (either in the KCS or in another basin). While this may be an economic decision for the grower, it has the potential to cause local impacts to groundwater in the district over the long-term. To prevent local impacts to groundwater due to the use of groundwater over available surface water, the districts may explore a fee structure in which growers with access to surface water may be assessed for the use of groundwater when surface water is available for use. The fees collected for such activities would be applied to the expansion of existing recharge projects or the development of new recharge projects to accommodate the additional surface water that would be brought into the district to replace the additional groundwater pumped.	A reduction of groundwater extraction would result from the implementation of this incentive program. The fees collected in this incentive program have not been quantified but would also provide a source of funding for the expansion of existing recharge or the development of new recharge projects within the districts.
NKWSD/SWID	On-Farm Efficiency/Deficit Irrigation Practices Incentive Program	The provisions of the conservation laws are being complied with by both NKWSD and SWID. Ag water management plans, as required by SB 7, are being regularly updated by these districts for submittal to DWR. Plans will be updated to include the applicable requirements of AB 1668 and SB 606.	As agricultural water service providers, both NKWSD and SWID comply with all provisions of SB 7 (amending Division 6, Part 2.55 of the Water Code) passed into law in November 2009 regarding agricultural water conservation and management. Efficient management practices in the law, related to SGMA objectives, include volumetric water pricing, incentives for conjunctive use and increased groundwater recharge, and development of an overall water budget. AB 1668 and SB 606 passed in 2018 did not materially add to these objectives, save for those districts serving between 10,000 and 25,000 acres who must now prepare water management plans under the newer laws.	There are no direct benefits to be derived and quantified from compliance with the aforementioned agricultural conservation laws at the present time. The districts will continue to divert for beneficial use all local and imported water supplies to which it is entitled. Should agricultural demands for irrigation water diminish as a result of some the conservation provisions, a larger portion of diverted supplies will be devoted to groundwater recharge in the future.
NKWSD/SWID	On-Farm Recharge Activities Incentive Program	This Management Action is in the preliminary stages of consideration by the districts. It has not been formally adopte but is under consideration.	In wet years, when the districts have utilized the full capacity of their respective recharge basins and spreading grounds, it may be necessary for the districts to seek other locations for the application of available surface water for groundwater recharge. The districts will develop an incentive program to encourage landowners to take delivery of available water that is in excess of customer demand and the districts' capacity for recharge projects for application to fallow land and/or over-irrigation of crops to facilitate further groundwater recharge. Landowners will receive a groundwater credit in exchange for participation in this program, for their use within the district which has provided the water for on-farm recharge activities.	A increase of groundwater recharge would result from theimplementation of this incentive program.
NKWSD/SWID	Subsurface Recharge Feasibility Study	This Management Action is in the preliminary stages of consideration by the districts. It has not been formally adopte but is under consideration.	Both NKWSD and SWID have been approached by landowners within their respective districts about the efficacy and use of subsurface recharge methods. While subsurface recharge is being tested in neighboring districts, neither NKWSD nor SWID have taken an official position on the use of such methods. Before the implementation of any program which would supply water to landowners for use in subsurface recharge practices, the districts will conduct a feasibility study to evaluate whether or not these practices are appropriate for the hydrogeologic conditions and/or land uses within their respective jurisdictions. The scope of the feasibility study is yet to be determined, but it will include evaluation of subsurface recharge methods, the soil types located within each district, the effectiveness of subsurface recharge compared to other recharge methods, and its compatibility with existing land uses.	No benefits have been quantified for this Management Action at this time. Potential benefits gained through the use of subsurface recharge will be determined as a result of this Management Action.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
NKWSD/SWID	Land Conversion from Agricultural Use to Urban Use	The conversion of land use from agricultural to urban is an ongoing process, the pace of which is determined by external factors such as the demand for land based on each city's growth and need for additional housing and/or property to support business, industrial, or municipal use. The projected growth for each city is based upon the current General Plans and may be subject to change when the cities update their respective plans.	As described in the General Plans for the cities of Shafter and Wasco, anticipated population growth is expected to lead to changes in land use within the limits of each city and in the Sphere of Influence for each city. The conversion of land use from agricultural to urban use generally leads to an overall reduction in groundwater use due to the decreased demand, in terms of volume per unit area.	For NKWSD's jurisdiction, there is an anticipated reduction of water by 2030, based o the conversion of land use as the city of Shafter expands. In SWID's jurisdiction, the anticipated reduction of water by 2030 reflects the anticipated growth of both Shafter and Wasco.
NKWSD/SWID	Urban Water Conservation Program	The cities of Shafter and Wasco are currently evaluating their respective compliance measures for indoor use and are awaiting additional information and guidelines concerning regional outdoor and landscape compliance measures. The cities presently are complying with the 2020 mandates contained in SB 7X-7 and as embodied in their respective UWMPs. As the SWRCB establishes its compliance deadlines for both indoor and outdoor usage, anticipated to occur by 2025, the municipal KGA Members will have a clearer picture of an implementation schedule.	As referenced in the Umbrella Basin Setting (Chapter 2), urban water usage in the future is expected to comply with the conservation mandates contained in SB 606 and AB 1668, both bills signed into law in May 2018. Based on that legislation, indoor residential use is to be capped at 55 gpcd in 2019 and ramp down to 50 gpcd by 2030, and outdoor residential use is to be capped in the future based on local climate and size of landscaped areas. Standards for outdoor usage are to be defined in a SWRCB rule-making process to be completed by June 2022.	Given the early implementation stages of AB 1668 and SB 606, its benefits in terms of reduced groundwater pumping by Shafter and Wasco can only be roughly approximated. The Pacific Institute, in its 2014 report "Urban Water Conservation and Efficiency Potential in Calif." estimated that indoor usage could be reduced by 33-40 gpcd, and that outdoor/landscape usage could be reduced by 20-50 gpcd. These values are on a statewide basis and likely unrealistic in some regions; however, the report postulates that total urban water usage could be reduced by as much as 30-60%. Savings of this magnitude would represent a significant reduction in groundwater pumping by both cities. The Measurable Objectives to be partially met with additional urban conservation include groundwater level stabilization and, by proxy, groundwater storage stabilization.
SWID	Mitigation Program for Potential Impacts to Domestic Wells	Upon implementation of the law.	In coordination with other KGA members, develop a mitigation program to offer financial assistance for the replacement of domestic wells which are impacted by groundwater management to the proposed SMCs. Coordinate development of eligibility criteria for participation in mitigation program.	Since this management action is conceptual, a volume of water associated with this management action has not been calculated.
NKWSD/SWID	In-District Allocation Structure	This Management Action is in the conceptual stages, having been discussed with various stakeholder groups. However, an actual structures and fee schedules have yet to be devised for either district.	At the time of this draft of the GSP, neither NKWSD nor SWID have an established allocation structure and fee schedule for groundwater extraction. As SGMA is implemented throughout the KCS, the districts are required to manage to the Sustainable Management Criteria (SMCs). One of the ways to manage for the SMCs is to allocate the Sustainable Yield for their respective districts to the landowners within their districts. While the specifics of such an allocation structure may vary between the districts, a baseline groundwater extraction volume would be allocated to each parcel based on its size and the Sustainable Yield for the district. If a landowner were to extract more water than the baseline volume for that parcel or for the aggregate of all of their parcels within the district, they would be required to pay an extraction fee which would be applied toward projects and programs implemented by the district to reach and/or maintain sustainability.	The benefits to sustainable groundwater management have not been quantified at this time. However, the development and implementation of an allocation structure for each district would allow for the districts to utilize their Sustainable Yield as a management tool for reaching and maintaining their SMCs.
NKWSD/SWID	Voluntary Land Fallowing	At this time, this Management Action is conceptual. The districts will develop their respective fallowing programs during the SGMA implementation period.	In the event of a drought, the districts may not be able to entirely meet in-district demand by increasing the volume of imported water. The combination of decreased availability in surface water to supply to the district and decreased recharge from other sources in the subbasin has the potential to lead to violations of SMCs at the Representative Monitoring Sites, in the absence of decreased demand. To facilitate the districts' ability to maintain sustainability at their respective monitoring sites, the districts will develop and implement their own voluntary land fallowing programs for their jurisdictions.	The decrease in water demand will be dependent upon the land being fallowed and its existing land use at the time of fallowing. Agricultural demand for water is generally estimated to be 3 AF/acre. Fallowing or land retirement would reduce the demand to zero for the lands participating in the program.
NKWSD/SWID	Pumping Restrictions	At this time, this Management Action is conceptual. The districts will develop their respective processes to implement pumping restrictions within their jurisdictions.	In the event that the districts or the entire subbasin are nearing a condition where they are at risk of triggering an Undesirable Result, even with the implementation of the projects and management actions described in this Plan, it may be necessary for the districts to limit groundwater pumping. The volume of groundwater extraction permitted under this Management Action would be determined by the districts based on the Sustainable Yield for the district and the SMCs at the Representative Monitoring Sites.	Pumping restrictions based on the Sustainable Yield of the district, could decrease groundwater demand if applied to NKWSD. If applied to SWID, pumping restrictions could decrease groundwater demand.
Pioneer Groundwater Sustainability Agency				
Pioneer	Project 1: Participation in California WaterFix	Participation in California WaterFix is within the authority of KCWA as an SWP contractor and its decision to fully, partially or not participate would require coordination with its Member Units.	California WaterFix may be implemented by DWR in partnership with the Delta Conveyance Design and Construction Joint Powers Authority (JPA) to increase the amount of water that can safely be diverted from the Delta by constructing a diversion in the upper Delta and conveying it through a tunnel(s) to the existing SWP and CVP pump stations. Under current operations, the SWP and CVP are unable to consistently deliver full contract amounts of wa because of environmental and water quality concerns. Diverting a portion of Delta supplies at a point further upstream and further from the ocean would reduce water quality issues because the source water is high quality, and is less likely to cause seawater intrusion in the lower Delta. It will also help reduce diversion-specific impacts on the environment by reducing direct impacts of pumping on aquatic species, such as reversal of Delta flow and entrapme in screens on the diversion pumps (CNRA, 2018).	The new monitoring well cluster will address an identified data gap in the Pioneer GSA Area. The monitoring well cluster will also help Pioneer GSA evaluate maintenance o its sustainability goals and monitor groundwater conditions in that portion of the Pione GSA Area.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
Pioneer	Project 2: Install Monitoring Well in North Pioneer	Implementation of this project entails planning, permitting, design and currently, construction of the monitoring well cluster. KCWA and/or its consultants will secure necessary permits and plan, design and construct the wells. KCWA will monitor the wells as part of normal Pioneer Project operations.	A data gap for groundwater monitoring north of the Kern River was identified during development of this Chapter GS and a monitoring well cluster is being constructed in the northwest triangle-shaped parcel of the Pioneer Project (i.e. the area of the GSA north of Kern River). The triangle shaped parcel is in the northwest portion of the North Pioneer Area, and does not include a recharge pond. This area is in the southeast quarter of section 6, T 30S/R26E. The monitoring well cluster will allow groundwater monitoring at multiple depths using three separate boreholes.	The new monitoring well cluster will address an identified data gap in the Pioneer GSA Area. The monitoring well cluster will also help Pioneer GSA evaluate maintenance of its sustainability goals and monitor groundwater conditions in that portion of the Pione GSA Area.
Pioneer	Management Action 1: Continued Balanced Pumping and Recharge	This management action would be accomplished through continuation of existing groundwater recharge and recovery operations. Surplus water would be banked either for overdraft recovery or future use. Banked groundwater would be used to supplement water supplies in dry years or during years of shortages	Continued balanced pumping and recharge is the standard operating procedure for the Pioneer GSA. Under this management action, long-term pumping would be balanced by long-term recharge activities in the Pioneer GSA Area. Pioneer GSA would continue to closely monitor water that is pumped from the Subbasin and water that recharges the Subbasin with the goal of a balanced groundwater budget over the long term.	The Pioneer Project is operated in a manner that results in more water being recharg than recovered from the Subbasin in the Pioneer GSA Area. Therefore, continuing operation of the Pioneer Project in the same manner would provide a net positive increase of groundwater volume in the Pioneer GSA Area. Full benefits of this management action would be evaluated through accounting of water recharge volumes compared to groundwater pumping.
Pioneer	Management Action 2: Continued Participation in Basin-Wide Coordination with other GSAs	This management action would be accomplished through continued attendance at KGA coordination meetings and by arranging periodic coordination meetings with the Kern River GSA, the Henry Miller GSA, the WKWD GSA and the Buena Vista GSA. Meetings would be attended by one or more representatives of Pioneer GSA and may include the GSA manager or their designated staff. Decisions made in coordination meetings would not be binding until approved by the appropriate authority, such as the Pioneer GSA manager or by KCWA's Board of Directors.	Pioneer GSA is one of 11 GSAs in the Subbasin. Sustainable management of the Subbasin as a whole requires coordination among GSAs and their respective GSPs. During development of the GSPs in the Subbasin, GSAs have been discussing sustainability thresholds, potential projects and management actions and specific issues and concerns. The KGA is a JPA composed of member agencies that was established in 2014 to develop and implement a groundwater management plan in the Subbasin and the neighboring Tulare Lake Groundwater Basin (KGA, 2017). This management action would involve attending monthly KGA manager and coordination meetings, as well as KGA stakeholder meetings, which are held as needed. Quarterly coordination meetings would be held with the Kern River GSA, and annual coordination meetings would be held with the Henry Miller GSA, the WKWD GSA and the Buena Vista GSA.	This management action would continue existing coordination activities between GSA managers, and help to build and maintain relationships with neighboring GSAs. Through coordination activities and ongoing communication, potential conflicts among GSAs regarding groundwater management would be mitigated because GSAs would better understand the challenges facing each other and how these challenges are being addressed. It will also provide an opportunity for GSAs to inform each other of potential issues that may require intra-Subbasin coordination, and to inform neighboring GSAs of management actions and projects under way that may affect decisions of other GSAs.
Pioneer	Adaptive Management Strategy: Increase Surface Spreading Losses from 6 to 10 Percent	Coordination would be initiated by KCWA with the Pioneer Project Participants.	Under the *Pioneer Project Participation Agreement*, all surface water diverted to the Pioneer Project for spreading is assessed a 6 percent loss factor. All losses assessed are non-recoverable. This provision was set up to "prevent, eliminate or mitigate significant adverse impacts" resulting from project recovery operations. The intent of losses assessed is to assist in mitigating impacts to adjoining entities. This adaptive management strategy would explore feasibility of increasing the fixed loss rate from 6 percent to a fixed loss rate of 10 percent.	This adaptive management strategy would provide KCWA and the Pioneer Project Participants an understanding of the feasibility of increasing lossess assessed to diverted surface water. If increasing losses is deemed feasible, it would provide the Pioneer Project and the opportunity to mitigate and avoid undersirable results and support the for sustainability indicators relevant to the Pioneer GSA as follows: chronic lowering of groundwater levels (direct), reduction of groundwater storage (proxy), degraded water quality (proxy), and subsidence (proxy).
Rosedale Rio Bravo Management Area				
RRBMA	West Basin Improvements	RRBWSD purchased the properties in 20092015. Project construction was completed in 2016	The improvement of existing recharge ponds and development of an additional 50 acre project west of Bakersfield designed to recharge, store and recover water to provide a cost-effective and reliable water supply for landowners within the RRBWSD.	This project has the potential to recharge up to 5,000 AF of water in wet years. This could provide the RRBWSD with up to 1,000 AFY.
RRBMA	Stockdale East Groundwater Storage and Recovery Project	RRBWSD purchased the property in 2010. Project is 90% complete, it will be operational by 2020.	Project is a developed 200-acre project west of Bakersfield designed to recharge, store and recover water to provide a cost-effective and reliable water supply for landowners within the RRBWSD.	This project has the potential to recharge up to 25,000 AF of water in wet years. This could provide the RRBWSD with up to 4,000 AF per year on average.
RRBMA	Pilot Projects	These continued GRAT projects could be on-line as early as 2025.	In 2017 the RRBWSD developed four pilot recharge projects under which it leased properties for temporary recharge activities. Since that time the District has invested in a Groundwater Recharge Assessment Tool (GRAT) in order to identify similar projet sites in the future.	Approximately 10,000 AF was recharged during that year of implementation in these four projects. The GRAT implementation could provide RRBWSD up to 2,000 AF per year.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
RRBMA	Onyx Ranch	The project is currently undergoing a feasibility and environmental analysis. The project could be on-line as early as 2025.	The RRBWSD owns several parcels of land and the associated water rights for the Onyx Ranch and the Smith Ranch. These parcels are located along the South Fork of the Kern River in the Kern River Valley, in and around the communities of Weldon and Onyx, in an unincorporated area of northeastern Kern County. These parcels together comprise the 4,109.18-acre project site. The RRBWSD is currently conducting an analysis of a proposed change in the point of diversion and place of use of the water rights associated with these parcels so that the water can be delivered in the RRBWSD service area on the San Joaquin Valley floor and used for irrigation and groundwater recharge. The project would reduce the diversion of water on the project site and convert the irrigated fields to lower water use crops, or allow the fields to return to their native vegetative state. With the proposed project, RRBWSD would allow the water that would have been diverted on the project site to remain in the South Fork of the Kern River and flow downstream. This could result in a net increase in flows within the South Fork of the Kern River, and the Isabella Reservoir where the water would be released through the Isabella Dam and flow downstream in the lower Kern River until the water is diverted at the RRBWSD diversion point. From there, the RRBWSD would deliver the water to recharge basins and channels within and near its service area west of the City of Bakersfield (City) in unincorporated Kern County within the San Joaquin Valley.	The net increase in water supplies to the RRBWSD's service area as a result of the proposed project would help mitigate the shortages in RRBWSD's contracted State Water Project (SWP) water supply from the State of California, which has steadily reduced due to environmental constraints in the Sacramento/San Joaquin Delta. The proposed project would provide the RRBWSD with approximately 6,500 AF per year.
RRBMA	James Groundwater Storage and Recovery Project	Rosedale and Buena Vista Water Storage District jointly purchase the property in 2011. Current project status is feasibility and environmental analysis. This project could be online as early as 2025.	The James Groundwater Storage and Recovery Project is a proposed 2,078-acre project in southwest Bakersfield designed to recharge, store and recover water to provide a cost-effective and reliable water supply for landowners within the RRBWSD (and elsewhere).	This project has the potential to recharge up to 150,000 AF of water in wet years. This could provide the RRBWSD with up to 3,000 AF per year.
RRBMA	Kern Fan Groundwater Storage Project.	Project status is feasibility analysis. This project could be on-line as early as 2030.	The District has evaluated a conceptual Kern Fan Groundwater Storage Project (Kern Fan Project). This project would serve to develop a regional water bank in the Kern Fan to capture and store Article 21 water via the State Water Project (SWP) during conditions when surface water is abundant. A two-phased approach would be taken to the development of the Kern Fan Project. The first phase would be to develop a project site, including the purchase of approximately 640 acres of land in the Kern Fan area. The first phase would also include constructing conveyance facilities, recharge facilities, and recovery facilities as necessary to develop a fully functioning water banking project. The second phase of the Kern Fan project would involve acquiring an additional 640 acres of land for expansion of the water banking facilities and developing the associated recharge and recovery facilities.	This could provide the RRBWSD with up to 10,000 AFY.
RRBMA	Western Rosedale In-Lieu Service Area	Project status is shovel ready; feasibility and environmental analysis is complete. This project could be on-line as early as 2035.	The Western Rosedale Lands In-Lieu Service Area Project (the Project) includes construction and operation of up to ten miles of water conveyance pipelines, including appurtenant facilities (such as pumps and valves), and a joint service area agreement between RRBWSD and BVWSD in order to provide surface water to agricultural water users within the portion of RRBWSDs service area located westerly of Interstate 5 in close proximity to Buena Vista Water Storage Districts East Side Canal.	This could provide the RRBWSD with up to 1,000 AFY.
RRBMA	Ten Section Water Recharge Project	No implementation date is known at this time.	The owners of Ten Section located within the South of the River Monitoring Zone are currently studying the feasibility of a 200+ acre groundwater recharge, storage and recovery project.	It is estimated that approximately 2,200 AF/month could be recharged into the aquifer.
RRBMA	Water Charge Demand Reduction	This management action could be on-line as early as 2025.	The Water Charge would be expected to result in demand reduction in the RRBWSD. For market reasons it is probable that landowners will opt to fallow ground in order to trade water supplies to other District landowners, as well as fallow lands (or limit double cropping) to avoid the Water Charge all together.	With an agricultural water consumptive use demand of about 84,000 AF per year we conservatively expect a 5% demand reduction as a result of the water charge which results in about 4,000 AFY of reduced demand
RRBMA	RRBWL (White Land) Water Supplies and Demand Imbalance Reduction	This management action could be on-line as early as 2020.	White Lands (non-RRBWSD lands) within the RRBMA that are not used for groundwater banking will correct the water supply imbalance on a linear basis over the planning period of 2020-2040. Like RRBWSD lands, the white lands will start with the native yield of 0.15 AF/acre. The total annual demand for white lands in the RRBMA is about 10,300 AFY with a water supply imbalance (or deficit) of 3,618 AFY. The average agricultural demand is 2.6 AF/acre according to METRIC studies. While agricultural demands in the White Lands range from 1.4-4.9 AF/acre the initial allowable demand will be the average demand of 2.6 AF/acre. It is expected that white lands would seek to acquire water supplies for in-lieu and direct groundwater recharge via banking agreements with RRBWSD or others to offset demands.	Demand reduction will occur as follows over the 2020-2040 period; the imbalance will be reduced by 1/20 of the current imbalance each year (5%). This approach will result in about 217 AF of imbalance reduction each year and 2,170 AFY by 2030 and a total of 4,335 AFY by the 2040 sustainability planning period.
RRBMA	RRBWD 3rd Party Recharge and Storage Program	This management action could be on-line as early as 2020.	The RRBWSD will assist 3rd parties (white lands, districts, and private parties) in recharging water supplies for use in the RRBMA or other down gradient areas in the Kern Sub-basin. RRBWSD would offer existing conveyance and recharge facilities in exchange for a portion of the imported water supply and payments of yet-to-be developed costs and/or fees.	It is expected that the RRBWSD would provide this service in exchange for 20-33% of the imported water supply and that an average amount of 5000 AFY would be imported. This management action could bring an additional supply of 1,250 AFY to RRBDL lands.
Southern San Joaquin Municipal Utility District				

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
SSJMUD	In-District Spreading and Recovery Facility	SSJMUD is in the process of purchasing land and applying for construction funding. Once these steps are complete, the District will implement this project immediately.	This project will include construction of 80-acres of spreading ponds and the installation of two recovery wells within district boundaries. The proposed recharge ponds have an anticipated annual capacity of 3,240 AFY. Prior to this project, the district has not had any in-district direct recharge facilities. Implementation of this project will allow SSJMUD the opportunity to capitalize on wet period storage of CVP supplies and allow them to bypass less favorable out-of-district banking agreements to store water that would increase the District's and the subbasin's water reliability and drought resiliency.	The proposed recharge ponds have an anticipated annual capacity of 3,240 AFY. Estimated amount of water to deliver to recharge is at least 4,200 AFY. If the available surplus is delivered to an out-of-district facility, it is expected that North Kern will keep one-third of the water as part of banking agreements and SSJMUD will realize an average water benefit of 2,800 AFY. Captured water will directly offset the District's reliance on the San Joaquin River supplies to the Bay-Delta and help conserve local groundwater.
SSJMUD	SSJMUD and Semitropic Schuster Intertie	This project is in the conceptual stage of development and is included in the 2019 Poso Creek IRWM Plan Update.	The proposed project is to construct an intertie in coordination with SWSD. This pipeline will allow for SSJMUD to bank or return water to Semitropic previously delivered to Semitropic's groundwater banking program. SSJMUD could deliver wet period water from the FKC for groundwater banking to Semitropic or return water for irrigation purposes during dry years. This Project removes the need to involve a third-party in an agreement with Semitropic for banking since it establishes a direct connection to return water to SSJMUD from Semitropic, thereby increasing operational flexibility and reliability to deliver previously stored water from groundwater storage at times of drought.	Considering the frequency of surplus 'Other Water' in the Central Valley Project and the existing design limit of 50 cfs, the Project will allow for an expected average annual amount of 3,622 AF to be put into storage with 1,811 AF credited to SSJMUD for return. Given that recently the District became a member of the Poso Creek Integrated Regional Water Management Group (IRWM) in spring 2016, interties such as this pipeline were identified as the first step in the District's efforts towards banking water with their neighboring districts to add drought resiliency.
SSJMUD	SSJMUD and CWD Intertie Pipeline	This project is in the conceptual stage of development and is included in the 2019 Poso Creek IRWM Plan Update.	SSJMUD and CWD propose to construct a bidirectional intertie connecting their respective water conveyance systems. This pipeline is a regional opportunity to improve flexibility, reliability, and conjunctive use of water supplies.	The estimated annual yield of this project is approximately 50 to 500 AF, depending on the selected project size. Project size will be determined by greatest benefit yielded that is economically feasible and sustainable.
SSJMUD	SSJMUD and North Kern WSD 9-28 Intertie Pipeline	This project is in the planning stage of development, in conjunction with NKWSD, and is defined in the Poso Creek IRWM Plan.	Project proposal includes the construction of the 9-28 Intertie pipeline with NKWSD. This pipeline will allow for the return of CVP Class I, Class II, and surplus floodwater that was previously delivered to the District's groundwater banking partner (NKWSD) from the FKC for groundwater banking or irrigation purposes during wet years. The pipeline is the conveyance mechanism for return of previously stored water to the District during dry years. This project removes the need to involve a third-party in an agreement with North Kern for banking since it established a direct connection to return water to SSJMUD from NKWSD, thereby increasing operational flexibility and reliability to deliver previously stored water from groundwater storage during times of drought.	This project would allow for SSJMUD to better capture and utilize wet period supplies by increasing the District's capacity to return banked wet period water during dry periods. Considering the frequency of surplus Other Water in the Central Valley Project, the Project will allow for an expected annual amount of 10,000 AF to be put into storage with 6,667 AF credited to SSJMUD for return. The pipeline capacity to return water from North Kern to SSJMUD is 4,284 AFY, which will require roughly 1.5 years to return the water for each 10,000 AF of water banked and 6,667 AF credited.
SSJMUD	Southeast Delano Spreading Grounds	This project is in the planning stage of development. SSJMUD has already begun the process of developing a CEQA document to assess the potential impacts of the construction and operation of spreading grounds in the areas identified by the district.	SSJMUD proposes the purchasing of land holdings, with possible partnering agencies (to be identified later), in and around the eastern most portion of the District. The District is currently exploring the potential for capturing excess surface water deliveries in the FKC. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand, typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class I contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.	Implementation of this project has the potential for contributing water supplies to SSJMUD, the City of Delano (which qualifies as a DAC), and Poso Creek IRWM water users. Specifically, SSJMUD will use a portion of these captured flows to offset their groundwater use in dry years by moving the surplus water to this banking facility using either the Friant Kern Canal other existing infrastructure. Wet year water supplies captured in the spreading grounds and storage locations will be utilized by SSJMUD, City of Delano, and potentially other Poso Creek stakeholders, during years where other water supplies are limite
SSJMUD	City of Delano Spreading Grounds	This project is in the planning stage of development. SSJMUD has already begun the process of developing a CEQA document to assess the potential impacts of the construction and operation of spreading grounds in the areas identified by the district.	SSJMUD proposes identifying and evaluating potential land suitable for developing recharge basins, with possible purchase with private and/or public partnering agencies within the City of Delano. The purpose of this project is to capture surface water deliveries that are delivered through the FKC. Excess available surface supply, or those flows beyond the quantity of water that satisfies immediate water demand within a service area, typically occurs in wet years when precipitation in contributing watersheds is large enough to induce surface water available above Friant Class 1 contract supplies. Potential flows to capture consists of water which is currently discharged during wet years, during flood conditions and for water that needs to be delivered due to changes in timing to meet environmental water management goals for the San Joaquin River Restoration.	Implementation of this project has the potential for contributing water supplies to SSJMUD, the City of Delano (which is classified as DAC), and Poso Creek IRWM water users. Specifically, SSJMUD will use a portion of these captured flows to offset their groundwater use in dry years by moving the surplus surface water to this banking facility from the FKC or other existing infrastructure. Wet year water supplies captured in the spreading grounds and storage locations will be utilized by SSJMUD, City of Delano, and potentially other Po Creek stakeholders, during years where other water supplies are limite
SSJMUD	Pond Road Spreading Grounds	This project is in the planning stage of development. SSJMUD has already begun the process of developing a CEQA document to assess the potential impacts of the construction and operation of spreading grounds in the areas identified by the district.	SSJMUD proposes identifying and evaluating potential land holdings to be purchased, with possible private and/or public partnering agencies. The District is currently exploring the potential for capturing excess surface water deliveries in the Friant-Kern Canal. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand, typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class 1 contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.	Implementation of this project has the potential for contributing water supplies to SSJMUD, the City of Delano, and Poso Creek IRWM water users. Specifically, SSJMUD will use a portion of these captured flows to offset their groundwater use in dry years by moving the surplus water to this banking facility using either the California Aqueduct or other existing infrastructure. Wet year water supplies captured in the spreading grounds and storage locations will be utilized by SSJMUD, City of Delano, and potentially other Poso Creek stakeholders, during years where other water suppli are limited.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
SSJMUD	In District Spreading Grounds	This project is in the planning stage of development. SSJMUD has already begun the process of developing a CEQA document to assess the potential impacts of the construction and operation of spreading grounds in the areas identified by the district.	SSJMUD proposes identifying and evaluating potential land holdings to be purchased, with possible private and/or public partnering agencies. The District is currently exploring the potential for capturing excess surface water deliveries in the FKC. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand, typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class 1 contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.	Implementation of this project has the potential for contributing water supplies to SSJMUD, the City of Delano, and Poso Creek IRWM water users. Specifically, SSJMUD will use a portion of these captured flows to offset their groundwater use in dry years by moving the surplus water to this banking facility using either the California Aqueduct or other existing infrastructure. Wet year water supplies captured in the spreading grounds and storage locations will be utilized by SSJMUD, City of Delano, and potentially other Poso Creek stakeholders, during years where other water suppli are limited.
SSJMUD	Conversion of Dairy to Recharge Facility	This project is in the conceptual stage of development, with potential sites being evaluated based on data available through the RWQCB's GAMA Geotracker program, the district's recharge feasibility study, and other state and local agencies.	SSJMUD proposes identifying and evaluating potential purchase of a dairy, with possible private and/or public partnering agencies. The District is currently exploring the potential for capturing excess surface water deliveries in the FKC. Excess surface supply, or those flows beyond the quantity of water that satisfies immediate water demand typically occur in wet years where precipitation in applicable watersheds is large enough to induce surface water available above Class 1 contract supplies. Potential captured flows consist of water which is currently discharged during wet year and flood conditions.	Implementation of this project has the potential for contributing water supplies to SSJMUD, the City of Delano, and Poso Creek IRWM water users. Specifically, SSJMUD will use a portion of these captured flows to offset their groundwater use in dry years by moving the surplus water to this banking facility using either the California Aqueduct or other existing infrastructure. Wet year water supplies captured in the spreading grounds and storage locations will be utilized by SSJMUD, City of Delano, and potentially other Poso Creek stakeholders, during years where other water suppli are limited.
SSJMUD	"Surface Water First" Incentive Program	This Management Action is in the preliminary stages of consideration by the districts. It has not been formally adopte but is under consideration.	SSJMUD has access to imported surface water to supply its jurisdictional area. However, there instances in which growers have historically opted to pump groundwater, rather than receiving deliveries of surface water from the distri which services their properties. When this occurs, the district must either use that water for groundwater recharge o enter into exchanges with other districts (either in the KCS or in another basin).	An estimated reduction of 1,800 AFY of groundwater extraction would result from the implementation of this incentive program. The fees collected in this incentive program have not been quantified but would also provide a source of funding for the expansion of existing recharge or the development of new recharge projects within the districts.
SSJMUD	On-Farm Efficiency/Deficit Irrigation Practices Incentive Program	The provisions of the conservation laws are being complied with by both NKWSD and SWID. Ag water management plans, as required by SB 7, are being regularly updated by these districts for submittal to DWR. Plans will be updated to include the applicable requirements of AB 1668 and SB 606.	As an agricultural water service provider, SSJMUD complies with all provisions of SB 7 (amending Division 6, Part 2.55 of the Water Code) passed into law in November 2009 regarding agricultural water conservation and management. Efficient management practices in the law, related to SGMA objectives, include volumetric water prici incentives for conjunctive use and increased groundwater recharge, and development of an overall water budget. AB 1668 and SB 606 passed in 2018 did not materially add to these objectives, save for those districts serving between 10,000 and 25,000 acres who must now prepare water management plans under the newer laws.	There are no direct benefits to be derived and quantified from compliance with the aforementioned agricultural conservation laws at the present time. The districts will continue to divert for beneficial use all local and imported water supplies to which it is entitled. Should agricultural demands for irrigation water diminish as a result of some the conservation provisions, a larger portion of diverted supplies will be devoted to groundwater recharge in the future.
SSJMUD	On-Farm Recharge Activities Incentive Program	This Management Action is in the preliminary stages of consideration by the districts. It has not been formally adopte but is under consideration.	In wet years, when the district has utilized the full capacity of their respective recharge basins and spreading grounds, it may be necessary for the districts to seek other locations for the application of available surface water for groundwater recharge. The district will develop an incentive program to encourage landowners to take delivery of available water that is in excess of customer demand and the district's capacity for recharge projects for application to fallow land and/or over-irrigation of crops to facilitate further groundwater recharge. Landowners will receive a groundwater credit in exchange for participation in this program, for their use within the district which has provided the water for on-farm recharge activities.	An estimated increase of 1,200 AFY of groundwater recharge would result from the implementation of this incentive program.
SSJMUD	Conversion of Agricultural Land to Urban Use	The conversion of land use from agricultural to urban is an ongoing process, the pace of which is determined by externa factors such as the demand for land based on each city's growth and need for additional housing and/or property to support business, industrial, or municipal use. The projected growth for each city is based upon the current General Plans and may be subject to change when the cities update their respective plans.	As described in the General Plans for the cities of Delano and McFarland, anticipated population growth is expected lead to changes in land use within the limits of each city and in the Sphere of Influence for each city. The conversion of land use from agricultural to urban use generally leads to an overall reduction in groundwater use due to the decreased demand, in terms of volume per unit area. The City of Delano and the surrounding areas have a projected increase of 2,100 acres in urban use; the City of McFarland and its surrounding areas have a projected increase of 1,100 acres.	For SSJMUD's jurisdiction, there is an anticipated reduction of 900 AF of water by 2030, based on the conversion of land use as the cities of Delano and McFarland expand. By 2040, the projected reduction is 1750 AF.
SSJMUD	Urban Water Conservation Program	The cities of Delano and McFarland are currently evaluating their respective compliance measures for indoor use and are awaiting additional information and guidelines concerning regional outdoor and landscape compliance measures. The cities presently are complying with the 2020 mandates contained in SB 7X-7 and as embodied in their respective UWMPs. As the SWRCB establishes its compliance deadlines for both indoor and outdoor usage, anticipated to occur by 2025, the municipal KGA Members will have a clearer picture of an implementation schedule.	As referenced in the Umbrella Basin Setting (Chapter 2), urban water usage in the future is expected to comply with the conservation mandates contained in SB 606 and AB 1668, both bills signed into law in May 2018. Based on that legislation, indoor residential use is to be capped at 55 gpcd in 2019 and ramp down to 50 gpcd by 2030, and outdoor residential use is to be capped in the future based on local climate and size of landscaped areas. Standards for outdoor usage are to be defined in a SWRCB rule-making process to be completed by June 2022.	Given the early implementation stages of AB 1668 and SB 606, its benefits in terms of reduced groundwater pumping by Delano and McFarland can only be roughly approximated. The Pacific Institute, in its 2014 report "Urban Water Conservation and Efficiency Potential in Calif." estimated that indoor usage could be reduced by 33-40 gpcd, and that outdoor/landscape usage could be reduced by 20-50 gpcd. These values are on a statewide basis and likely unrealistic in some regions; however, the report postulates that total urban water usage could be reduced by as much as 30-60%. Savings of this magnitude would represent a significant reduction in groundwater pumping by both cities. The Measurable Objectives to be partially met with additional urban conservation include groundwater level stabilization and, by proxy, groundwater storage stabilization.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
SSJMUD	In-District Allocation Structure	This Management Action is in the conceptual stages, having been discussed with various stakeholder groups. However, a actual structures and fee schedules have yet to be devised fo either district.	At the time of this draft of the GSP, SSJMUD does not have an established allocation structure and fee schedule for groundwater extraction. As SGMA is implemented throughout the KCS, the districts are required to manage to the Sustainable Management Criteria (SMCs) established in Section 5 of this Chapter GSP. One of the ways to manage for the SMCs is to allocate the Sustainable Yield for their respective districts to the landowners within their districts. The allocation structure would allow for the transfer of groundwater pumping credits within each district's jurisdiction provided that it does not lead to localized impacts to at the Representative Monitoring Sites defined in Sections 4 and 5 of this Chapter GSP.	The benefits to sustainable groundwater management have not been quantified at this time. However, the development and implementation of an allocation structure for each district would allow for the districts to utilize their Sustainable Yield as a management tool for reaching and maintaining their SMCs.
SSJMUD	Voluntary Land Fallowing	At this time, this Management Action is conceptual. The district will develop its fallowing program during the SGMA implementation period.	In the event of a drought, the district may not be able to entirely meet in-district demand by increasing the volume of imported water. The combination of decreased availability in surface water to supply to the district and decreased recharge from other sources in the subbasin has the potential to lead to violations of SMCs at the Representative Monitoring Sites, in the absence of decreased demand. To facilitate the district's ability to maintain sustainability at its monitoring sites, the district will develop and implement a voluntary land fallowing program.	The decrease in water demand will be dependent upon the land being fallowed and its existing land use at the time of fallowing. Agricultural demand for water is generally estimated to be 3 AF/acre. Fallowing or land retirement would reduce the demand to zero for the lands participating in the program.
SSJMUD	Pumping Restrictions	At this time, this Management Action is conceptual. The district will develop its process to implement pumping restrictions within the plan area.	In the event that the districts or the entire subbasin are nearing a condition where they are at risk of triggering an Undesirable Result, even with the implementation of the projects and management actions described in this Plan, it may be necessary for the district to limit groundwater pumping. The volume of groundwater extraction permitted under this Management Action would be determined by the district based on the Sustainable Yield for the district and the SMCs at the Representative Monitoring Sites.	The benefits of mandatory pumping restrictions have not yet been quantified, as the guidelines for such a management action have not been established.
Shafter-Wasco Irrigation District - 7th Standard				
SWID - 7th Standard	Evaluation of Potential to Utilize SWID Kimberlina Ponds for Recharge or other Facilities	Status: Conceptual, have begun initial discussions; Initiation: 2020-2024 Completion: Ongoing Accrual of Benefits: Annual-basis	SWID operates the Kimberlina Ponds groundwater recharge facility. The Annex Area will evaluate opportunities with SWID to utilize Kimberlina Pond storage capacity for recharge. The Annex Area will evaluate opportunities to purchase non-SWID water for recharge in the Kimberlina Ponds facilities, when the Ponds have unused capacity (i. likely in nonwet and non-drought years).	Up to 4,500 AFY of imported supply, in combination with other recharge projects. Increased groundwater levels.
SWID - 7th Standard	Evaluation of Potential to Partner in Kern Fan Groundwater Storage Project	Status: Conceptual, have begun initial discussions with RRBWSD; Initiation: 2030 Completion: 2035 Accrual of Benefits: 50 years after constructio	The Kern Fan Groundwater Storage Project is under development by RRBWSD and would serve to develop a regio water bank in the Kern Fan to capture and store Article 21 water via the State Water Project (SWP) during conditions when surface water is abundant. The Annex Area could potentially become a funding partner in this project and have access to recharge and storage capacity in the Project.	Up to 4,500 AFY of imported supply, in combination with other recharge projects. Increased groundwater levels.
SWID - 7th Standard	7th Standard Annex Management Area Storage Pond Project	Status: Conceptual, have begun initial discussions with RRBWSD; Initiation: 2030 Completion: 2035 Accrual of Benefits: 50 years after construction	This project would improve water supply reliability and groundwater conditions in the Management Area. Benefits of developing a groundwater recharge facility within the Mangement Area include effective conveyance of surface water supplies when they are available, facilitation of water banking and exchange arrangements, and avoidance of direct water quality impacts. A conveyance mechanism, such as the Flat Rocks Canal would be necessary to bring such water to the Mangement Area.	Up to 1,463 AFY of recharge capacity for purchased surface water within the Management Area (assumes 320-acre basin). Increased groundwater levels.
SWID - 7th Standard	Identify Opportunities to Utilize Existing Infrastructure	Status: Conceptual, have begun initial discussions; Initiation: 2020-2024 Completion: ongoing Accrual of Benefits: annua	Several entities in the vicinity of the Annex Area have existing groundwater recharge infrastructure, which have unused capacity, particularly in nonwet years. The Annex Area will evaluate potential opportunities with these entities to utilize the unused capacity for recharge of purchased water.	Up to 4,500 AFY of imported supply, in combination with other recharge projects. Increased groundwater levels.
SWID - 7th Standard	On-Farm Groundwater Recharge	Status: Conceptual, have begun initial discussions; Initiation: 2020-2024 Completion: ongoing Accrual of Benefits: annua	In May 2019, the SWID Board adopted a new Buried Recharge policy that will allow for on-farm water banking, which will allow Annex Area landowners to purchase and recharge non-SWID water on their own properties, as well as th within the original SWID boundary.	Up to 4,500 AFY of imported supply, in combination with other recharge projects. Increased groundwater levels.
SWID - 7th Standard	Flat Rock Canal Extension	Status: Conceptual, have begun initial discussions; Initiation: 2030 Completion: 2035 Accrual of Benefits: 50 year period following construction	The Management Area will assess the feasibility of this project and seek partnership with other interest entities. This project would provide connection from the Annex Area to the Kern Water Bank Canal, Cross Valley Canal, and Goose Lake Slough. Phase 1 of this project is to distribute Kern River water to the north using gravity from Goose Lake Slough.	Improve ability to delivery surface water supplies to the District for irrigation or recharge. Benefits to neighboring entities, who would be key partners in this regional project.
SWID - 7th Standard	Develop New Interconnections Within SWID's Conveyance System (and Improve "Bottleneck" Issues)	Status: Conceptual, will require evaluation of options an benefits; Initiation: TBD Completion: TBD Accrual of Benefits: TBD	The Annex Area can work with SWID to increase the capacity and flexibility of SWID's current conveyance system, to allow access to additional supplies.	Improve operational flexibility within the SWID conveyance system to allow for increased capacity to accept surface water supplies when available.
SWID - 7th Standard	Increased Recycled Water Deliveries and Recharge	Status: In discussions for increased purchases; Initiation: In progress Completion: Anticipated 2019-2020 Accrual of Benefits: Annual	Secondary-treated municipal wastewater is from the North of the River Sanitary District is currently used for irrigation and infiltrated into groundwater within the Annex Area. The Annex Area is discussion options to increase recycled water deliveries and recharge of groundwater with secondary-treated wastewater within the Annex Area. Growth ra projected at 2% and output expected to increase to 14,000 AFY.	Up to 8,180 AFY of treated effluent (based on project increased WWTP flows), to be used for irrigation to offset groundwater demand.
SWID - 7th Standard	On-farm Water Conservation	Status: not yet initiated; Initiation: Upon stakeholder interest Completion: TBD Accrual of Benefits: 1-3 years after initiation	The NRCS is offering landowner incentive programs to assist in implementing various conservation activities, including but not limited to: irrigation system improvements, water/nutrient/pest management, and pump engine replacement. Interested landowners can call (661) 336-0967 or visit the website (www.ca.nrcs.usda.gov) for more information.	Reduce on-farm water demands.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
SWID - 7th Standard	Voluntary Rotational Land Fallowing Program	Status: not yet initiated; Initiation: Upon approval of funding mechanism Completion: Anticipated 2020-2024 Accrual of Benefits: 1 years after initiation	In order to reduce demand within the Management Area, this project would incentivize landowners to fallow their previously farmed lands voluntarily on a rotational basis. This potential project would be implemented on a voluntary rotational basis. Incentives have not yet been established, but would be anticipated to be funded by the Annex Area landowners through the same funding mechanism used for other SGMA related activities.	Up to 1,443 AFY of reduced water demand (assumed 430 acres fallowed per year).
SWID - 7th Standard	Education of Groundwater Use per Acre	Status: not yet initiated; Initiation: Upon GSP implementation Completion: Until overdraft ends/other programs initiated Accrual of Benefits: 1 year after initiation	This program would provide groundwater users an expected groundwater volume, as an education tool, prior to enforcement actions on groundwater allocations, with the goal of providing awareness of overdraft conditions. This information would be provided in an annual letter, along with average crop demand, GSA average extraction, GW overdraft, and reminders of GSA powers and authorities.	Reduce on-farm water demands.
Semitropic Water Storage District				
SWSD	Landowner Water Budgets	Under Development; Initiation expected 2020.	Establish individual water budget for landowners by landowner classes	Water demand reduction of an estimated 60,000 af total (3,000 af/yr to 2040)
SWSD	Tiered Pricing for Groundwater Pumping	Not yet started; to be implemented in 2020 after implementation of MA 1	Develop pricing structure to incentize groundwater users to manage groundwater extractions to MA1 water Budgets	Water demand reduction consistent with MA1 (Landowner Water Budgets)
SWSD	District Fallowing Program	Not yet started; to be implemented in 2020 after implementation of MA 1	Support land fallowing as a District action and by individual landowners or groups of landowners.	Water demand reduction consistent with MA1 (Landowner Water Budgets)
SWSD	Enhanced Groundwater Recharge	Status is ongoing and expected to be initiated in 2020 upon adoption of Semitropic GSP.	Development of surface and subsurface recharge projects underlying developed agricultural lands to increase groundwater recharge capacity	Water supply augmentation up to 20,000 af average annual
SWSD	Monitoring Network Improvement Plan	Not yet started; Expected to be initiated in 2020 upon adoptic of Semitropic GSP.	Assess and identify monitoring network requirements for full compliance with SGMA and development of i implementation plan for achieving full compliance	Improved groundwater monitoring in support of SGMA
SWSD	Evaluation and Assessment of GDEs within the Semitropic Area	Not yet started; Expected to be initiated in 2020 upon adoptic of Semitropic GSP.	Conduct additional analysis to verify the prescence and extent of GDE's in the Semitropic and, if present, devel appropriate monitoring protocols	
SWSD	Brackish Water Desalination	Initiated planning; expected to be initiated in 2022 upon completion of environmental and regualtory requirements.	Development of a braackish water treatment facility to treat locally sourced brackish water for District use.	Expected water supply augmentation of 1,800 af/year
SWSD	In-District Water Markets and Transfers	Not yet started; Expected to be initiated in 2022 upon adoptic of Semitropic GSP.	District will allow for the development of market for in-district transfers	Water supply augmentation TBD.
SWSD	Poso Creek MAR	Upon completion of feasibility and permitting requirements; Expected initiation in 2020	Development of floodwater capture and recharge program ffrom Poso Creek flood flows	Water supply augmentation of 1,200 af average annual
SWSD	Tulare Lake Project	Under Development since 2018; Initiated upon completion of water rights determination	Development of conveyance facilities to divert Kings River flood flows for direct use and recharge in the SWSD	Water supply augmentation of 70,000 af average annual
SWSD	Water Market Acquitions	Status is ongoing and expected to be initiated in 2020 upon adoption of Semitropic GSP.	Increased participation in state-wide water markets for spot market and long-term water transfers	Water supply augmentation of 4,000 af average annual
SWSD	Stored Water Recovery Unit	Initiated; 2025 Upon approve by SWSD BOD and identification of funding	Development of water storage to expand in-lieu service areas	Increases capacity & flexibility of conveyance for recharge
SWSD	Pond-Poso Spreading Grounds, Phase II	Inititated; Upon adotion of Semitropic SWSD; 2020.	Development of spreading facililiteis to increase groundwater recharge capacity	Increases groundwater recharge capacity
SWSD	Pond-Poso Entrance Ponds	Initiated; 2025 upon approval by SWSD BOD and identification of funding.	Development of spreading facililiteis to increase groundwater recharge capacity	Increases capacity & flexibility of conveyance for recharge
SWSD	Multi-District Conveyance (CA to Friant-Kern Canal)	Ongoing; Implementation upon approval by SWSD BOD and identification of funding.	Development of a conveyance system to deliver surface water for groundwater recharge and irrigation	Increases capacity & flexibility of conveyance for recharge
SWSD	Schuster Spreading Grounds	Not yet started; Expected initiation 2030 upon approval by SWSD BOD and identification of funding	Development of spreading facililiteis to increase groundwater recharge capacity	Increases groundwater recharge capacity
SWSD	Leonard Avenue System	Inititated 2019; Upon adotion of Semitropic SWSD.	Development of an intertie system to provide east to west surface water conveyance to for supply in groundwater dependent areas	Increases capacity & flexibility of conveyance for recharge
SWSD	Diltz Intertie	Ongoing 2018; Upon adoption of Semitropic SWSD.	Connection of an intertie to provide surface water converyance for agricultural irrigation	Increases capacity & flexibility of conveyance for recharge
SWSD	Cox Canal	Ongoing 2018; Upon adoption of Semitropic SWSD.	Developed canal for the conveyance of surface water for groundwater recharge	Increases capacity & flexibility of conveyance for recharge
SWSD	Stored Water Recovery Unit- XYZ	Ongoing 2019; Upon adoption of Semitropic SWSD.		Increases capacity & flexibility of conveyance for recharge
Tejon-Castac Water District Management Area				

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
TCWDMA	Conversion of Granite Quarry to Sycamore Reservoir	The timeframe for initiation and completion of this P/MA are not certain, but presumably would begin once the Granite Quarry facility ceases operations, which is anticipated in one to four years. Construction duration is to-be-determined.	This P/MA entails repurposing of the Granite Quarry excavation into a storage reservoir upon cessation of mining operations at the facility which is expected in the next one to four years. The P/MA is being considered and developed in conjunction with Arvin-Edison Water Storage District (AEWSD), and the source of water to fill the new reservoir would likely be surplus imported surface water, brought to the reservoir by AEWSD during wet years, with possible additional contribution from local stormflow runoff. In addition, TCWD may choose to store some of its State Water Project water supplies in the facility at times, supplies which would be wheeled through the AEWSD canal system. The facility is anticipated to serve as a storage basin for water added to it, as well as a location for recharge.	AEWSD has estimated the net benefit of this P/MA to be approximately 2,500 acre-fe (AF) of increased storage capacity (which aids in delivery flexibility for AEWSD), and between 3,000 and 6,000 acre-feet per year (AFY) of increased recharge. As a secondary benefit, recharge of imported surface water would likely have a positive effect on local groundwater quality.
TCWDMA	Recharge of Carrot Wash Water	The status of this P/MA currently underway, and the timeframe to accrual of benefits is likely on the order of one year.	Tejon Ranchcorp (TRC) recharges carrot wash water generated at a nearby carrot processing facility to a 75.5-acre parcel located just outside of the TCWD MA (Township 32S Range 30E Section 6). The site, which has been in operation since 2016, receives carrot wash water from a nearby carrot processing facility which is discharged to a se of recharge ponds. A total of over 1,000 AF has been recharged at these ponds between 2016 and early 2019. This project is anticipated to continue in the future, and results in a local recharge benefit. A production well may be installed in the future at the site to allow for recovery of recharged groundwater.	Based on the amount of water recharged since operations began in 2016, the annual benefit from this P/MA is estimated at approximately 300 AFY.
West Kern Water District				
WKWD	Project 1: Automatic Meter Reading Project	The circumstance of implementation for this project would be current conditions, once funding is secured or committed and the project approved by WKWD's Board of Directors, it could be implemented.	In 2015, WKWD began installing AMR systems for all industrial and outlying customers. To further achieve sustainability goals, WKWD would install AMR systems on the remainder of its primarily residential customer meters. The AMR system selected by WKWD for its industrial and outlying customers uploads data every 24 hours to a website where customers can access their accounts and view water use data, compare their current water use to their historical water use, and receive leak alerts.	AMR provides potential water savings through early leak detection and increased awareness of water use among customers. Upgrading meters also reduces unaccounted-for losses related to accuracy degradation in older meters. WKWD estimates that AMR will save an average 8 percent of water f each metered connection, based on savings experienced by nearby agencies. The City of Sacramento had an average 4 percent water savings based on a pilot AMR project, while the Golden Hills Community Services District realized 12 percent in average savings (WKWD, 2014). WKWD's 2015 UWMP shows residential water use ranges between 2,169 AF in 2015 to a projected high of 2,597 AF in 2040, and applying the projected 8 percent conservation, anticipated water savings from this project is estimated to be 173 to 208 AFY (WKWD, 2016). Conservation achieved by the AMR project would be measured by the reduction in water deliveries to customers with AMR meters.
WKWD	Project 2: Participation in California WaterFix	Long-term	California WaterFix is intended to address the challenges of pumping water from the Delta by diverting water upstream of the current diversion points and conveying it to existing pump stations for the SWP and the Central Val Project (CVP). Under current operation, the SWP and CVP are unable to consistently deliver state and federal water contractors their full contract supplies. California WaterFix is intended to address some of the conditions that impact the ability to export water from the Delta.	The primary benefit of this project would be the increased reliability of imported water supplies and to expand groundwater banking opportunities to meet customer demands. Additional supplies could be 1) banked in WKWD's recharge facilities, 2) used for GWE protection if monitoring shows unexpected declines in elevation, or 3) transferred to neighboring agencies to help offset groundwater pumping in the Subbasin.
WKWD	Project 3: Buena Vista Recreation Area Water Supply Management Coordination	Implementation of this project is already underway and is likely to remain an ongoing project until such time as the BVARA no longer requires water from the GSA area.	BVARA is in and adjacent to the WKWD GSA area. The 1,585-acre BVARA is home to two manmade lakes, Lake Webb and Lake Evans, boating facilities, playgrounds and volleyball courts, camp sites, and picnic areas. The lakes lie outside of the GSA area but the park facilities such as picnic areas, restrooms, and parking areas are within the GSA area. When constructed, the lakes had a combined storage capacity of over 6,800 AF. Shoreline camping and picnic areas are landscaped with grass and are irrigated during the dry season (County of Kern Parks and Recreation Department, 2019). With no outlet, water from the lakes either evaporates or percolates into the groundwater basin. Kern County pumps groundwater from wells located within the GSA area to supplement losses at the lake. Supplemental water delivered to the lakes is not metered and is not included in WKWD GSA's water balance.	Managing water supply for the BVARA would include a focused effort on monitoring pumping in that portion of the GSA area, and identifying which projects or manageme actions are needed to eliminate undesirable results in the Subbasin. Securing additional supplemental supplies would reduce the potential impacts to groundwater levels, storage, and water quality for this portion of the GSA area. Improved management of the BVARA water supply would also support ongoing use of the BVARA, a popular recreation area. The project does not have a directly measurable benefit unless implementation actions arise from these meetings.
WKWD	Management Action 1: Continued Balanced Pumping and Recharge	The circumstance of project implementation would be current conditions and would remain unless conditions indicated a different management approach was needed to achieve sustainability indicators.	Continued balanced pumping of groundwater and recharge of imported supplies has and will continue to be the operational norm for WKWD. Under this management action, recharge and recovery activity will continue to be monitored closely by WKWD to maintain balanced conditions.	This management action would allow WKWD to continue operating groundwater recharge and recovery in balance, resulting in a long-term net-zero balance in the Subbasin for the areas under WKWD's control.
WKWD	Management Action 2: Implement Water Shortage Response Plan	The circumstance of implementation for this project would be times of water shortage, supply interruption, or drought, as declared by WKWD's Board of Directors. Implementation would cease when shortages are no longer being experienced, and as approved by the WKWD's Board of Directors.	WKWD's Water Shortage Response Plan (WSRP) is incorporated into the 2015 UWMP and includes triggers for when the WSRP would be implemented. The WSRP describes management actions and use restrictions that would be implemented if water shortages were declared. Because current operation of groundwater recharge and recover the GSA area has shown a long-term increase in banked groundwater, and normal water years are projected to have a surplus of supply that can be banked, it is not expected that the WSRP would go into effect during normal or wet years. During extended dry periods, groundwater pumping would increase, and WKWD would use banked supplies to meet demands in excess of available imported and surface water supplies.	The WSRP is designed to reduce customers' overall water use by implementing restrictions on when and how water may be used. As a result, implementation of this management action would reduce overall demand, which offsets demand for imported water and groundwater. Each Response Level is designed to help achieve a specific conservation target, and would reduce overall demands between 0 and 6,900 AF (i.e. to 50 percent conservation) (Table 8-3). Conservation achieved by this management action would be measured by the reduction in metered water deliveries after this management action is implemented.

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
WKWD	Management Action 3: Continued Participation in Basin-Wide Coordination	The circumstance of implementation for this project is ongoing.	The WKWD GSA is one of 11 GSAs in the Subbasin. Coordination among these GSAs is necessary for sustainable management of the Subbasin as a whole and has been ongoing during development of their respective GSPs. Coordination during GSP development has included regular in-person meetings and calls to discuss sustainability thresholds, potential projects and management actions, and to discuss specific issues and concerns. As described in this Chapter GSP, the KGA is developing an Umbrella GSP for the Subbasin, while the other GSAs in Kern County are developing Chapter GSPs.	This management action would continue existing coordination activities among GSA managers, helping to build and maintain relationships with neighboring GSAs. Potent conflicts between GSAs regarding groundwater management would be reduced because GSAs would better understand the challenges experienced in each GSA are and how these challenges are being addressed. Coordination meetings will also prov an opportunity for GSAs to inform each other of potential issues that may require intra-Subbasin coordination to address, and to notify neighboring GSAs of management actions or projects that might affect a decision made by another GSA.
WKWD	Adaptive Management Strategy 1: Taft Recycled Water Program	This project would be implemented through an agreement between WKWD, the City of Taft, and FCTHSD.	The Taft Recycled Water Program would create up to 423 AFY of tertiary recycled water suitable for Title 22-approv applications for recycled water. This project would be implemented in partnership between WKWD, the City of Taft, and the Ford City-Taft Heights Sanitation District (FCTHSD). WKWD provides water within the WKWD GSA area, but sanitation services are provided by the City of Taft and FCTHSD, which jointly own the Taft Wastewater Treatment Facility (WWTF). The Taft WWTF currently produces undisinfected secondary effluent that is suitable for and applied to feed crops, specifically alfalfa. This effluent is not suitable for wider recycled water use, but through upgrade to tertiary treatment, it could be used more widely for non-potable applications, such as landscape irrigation, which currently use potable water to meet demands (WKWD, 2018).	The project would create up to 423 AFY of tertiary recycled water, offsetting an equal volume of potable water (WKWD, 2018). Available and unused potable water is currently banked for future use during imported and surface water supply shortages. This project would both reduce demand for groundwater pumping during dry years and allow for additional water to be banked during wet years. Tertiary recycled water would be a local supply with high supply reliability, even during drought years. The volume of water offset by this project would be measured by quantifying the amount of tertiary recycled water both produced and delivered.
WKWD	Adaptive Management Strategy 2: Shift Balance of Pumping between North and South Wellfields	Implementation would require easy-to-implement operational changes and could be implemented quickly once triggered.	In 2010, WKWD's North Wellfield (wells within the North Project Management Area) was constructed in response to falling groundwater levels at the South Wellfield (wells within the South Project Management Area). Despite a surplus of banked groundwater, local levels at the South Wellfield showed a trending decline associated with groundwater recovery activities. A single wellfield for recovery activities also limited WKWD's operational flexibility. To combat these two management challenges, the North Wellfield was constructed along with additional recharge basins. Under current operation of the two wellfields, 11,300 AFY are pumped from the South Wellfield and 12,700 AFY are pumped from the North Wellfield. The North Wellfield has an annual pumping capacity of 24,000 AFY (WKWD, 2010).	This adaptive management strategy would reduce groundwater pumping in a localized area, allowing water levels in that area to recover or to decline less sharply during times of drought. Minimizing groundwater level declines reduces the potential for localized subsidence and long-term decrease in groundwater storage capacity. It also helps to maintain well efficiency, allowing for improved wellfield longevity. Local recovery of GWEs would be determined by standard monitoring activities that are part of regular wellfield management. Local groundwater level recovery from this strategy would be measured by monitoring of groundwater levels in the vicinity of the two wellfield
WKWD	Adaptive Management Strategy 3: Implemer Permanent Demand Management Measures	As needed	According to the 2016 WSRP, Response Level 1 is ongoing, and all water use restrictions are strictly voluntai These actions only become mandatory if a Response Level 2 is declared, which requires a declaration by the WKWD's Board of Directors. This adaptive management strategy would convert the Response Level 1 actions in the WSRP from voluntary to mandatory. These water restrictions would require a 25 percent reduction in large landscape watering from 2007 levels, prohibit water waste, and reduce non-contracted industrial water use by 15 percent from 2007 levels. WKWD may choose to implement these or a different set of permanent demand management measures as appropriate at the time this adaptive management strategy is approved	Project benefits are expected to be like those achieved under Management Action 2 (Implement WSRP), though they will have long-term benefits because they are permanent measures rather than temporary ones under the WSRP. Conservation achieved by this management action would be measured by the reduction in metered water deliveries after this management action is implemented.
Westside District Water Authority				
WDWA	Collect Representative Hydrogeologic Data	The PMA No.1 will be implemented beginning with acceptance of the MNP, and directly support WDWA MT/MOs by providing foundational data to monitor and manage adaptive management projects that are designed and implemented to ameliorate the potential for significant reduction of ground water elevations and groundwater in storage	Historically, because of the brackish and naturally degraded quality of groundwater in the WDWA, growers have rel almost exclusively on surface water from the SWP for their irrigation needs. Groundwater is used primarily for blending when annual SWP deliveries are less than expected. As a result, there is currently little representative hydrogeologic data in the WDWA. This lack of data represents a significant data gap that must be addressed in order to refine the current understanding of the WDWA Conceptual Hydrogeologic Model, including key elements such as groundwater elevations, pumping and changes to groundwater in storage and the overall water budget.	The ability to generate representative data for use in updating water budget elements; Improved numerical groundwater modeling results; and Better forecasting and planning of adaptive management projects and management actions.
WDWA	Water Resource Coordination	The implementation of the disparate Water Resource Coordination Programs vary, some as described above are already in place and ongoing. Others, like a KCS-wide coordination program would likely begin with planning during the first five-year reassessment period after KCS Plan implementation. Coordination between the WDWA and its immediately adjacent GMAs would likely be structured to begin with meetings shortly after Plan approval.	The member growers in the WDWA have historically made significant investment in efficient irrigation technologies and methods that promote water conservation and sustainable management. They have also coordinated amongst themselves as individuals or via the various Water Districts to implement focused reduction demand measures, trade or purchase surplus water when deliveries from the SWP have been reduced. It is assumed that these effective ad hoc arrangements will continue after Plan implementation. In addition, the WDWA will work cooperatively and in close consultation with its members, the KGA and adjacent GMAs to coordinate water resource monitoring, testing and future water trading as part of its overall strategy for the sustainable management of all its available water resources.	More reliability and flexibility in water availability; Drought resiliency; and Sustainable water strategies for both short and long-term planning horizons.
WDWA	Conjunctive Reuse of Naturally Degraded Brackish Groundwater	Preliminary planning for a Project Engineering FS for the first phase of the project has already begun. It is expected there will be at a minimum two phases of distributed treatment facility construction.	To further enhance the sustainable and adaptive management strategies for the Westside, the WDWA is evaluating the feasibility of an innovative phased project that will integrate the treatment and conjunctive reuse of naturally degraded brackish groundwater and oilfield produced water for multiple beneficial uses.	When operational, the Project will result in multiple potential beneficial uses, including many of the "One Water" concepts enumerated in the State's California Water Action Plan.
Wheeler Ridge-Maricopa Water Storage District				

Table 4-1. Kern Groundwater Authority Member Entities List of Projects and Management Actions

Entity	Project Title	Implementation Status	Description	Benefits
WRMWSD	On-Farm Recharge	Not yet initiated; To be implemented upon adoption of WRMWSD GSP Chapter - 2020	Study and implement on-farm recharge where viable.	approx. 2,000 AFY (10,000 AF every five years)
WRMWSD	In-District Banking Facilities	Not yet initiated; To be implemented upon adoption of WRMWSD GSP Chapter - 2020	Program to promote private and/or District-owned banking facilities within the District.	approx. 2,000 AFY (10,000 AF every five years) approx. 2.75 AFY per acre of land converted to basins
WRMWSD	Increase Out-of-District Banking Operations	Not yet initiated; To be implemented upon adoption of WRMWSD GSP Chapter - 2020	Increase size/participation in out-of-District banking facilities (i.e., Kern Water Bank and Pioneer Project). Increased banking of wet year supplies outside of the District would support deliveries of imported water into the District in normal/dry years.	TBD; depends on recharge basin area
WRMWSD	Expand District Distribution System	Not yet initiated; TBD	Project to expand District distribution system into area currently using only private groundwater.	approx. 2,000 AFY
WRMWSD	Purchase Additional Supplies	Ongoing	Continue purchase of additional supplies, as available, for banking outside of the District or direct delivery within the District.	Increase purchases by 5,000 AFY
WRMWSD	Desalination Facilities	Not yet initiated; TBD	Desalination facilities to allow for use of additional poor quality groundwater for agricultural use, easing demand on principal aquifer.	No net supply augmentation, but minimizes local GW pumping impacts
WRMWSD	"Thru Delta" Facility	State-led effort underway	Particpation of some sort of "Thru Delta" Facility to increase access to contracted (SWP) supplies.	up to 25,000 AFY
WRMWSD	Acreage Assessment	Not yet initiated; To be implemented upon adoption of WRMWSD GSP Chapter - 2020	Set policy to implement an acreage assessment to fund purchase of additional supplies, purchase of land for fallowing, and other investments to support SGMA compliance.	
WRMWSD	Groundwater Allocation and Market	Not yet initiated; To be implemented upon adoption of WRMWSD GSP Chapter - 2020	Develop a groundwater pumping allocation methodology, including a market system for trading and/or transfering of allocations.	
WRMWSD	Voluntary Pumping Limitations	Not yet initiated; To be implemented upon adoption of WRMWSD GSP Chapter - 2020	Set non-binding pumping limitations in conjunction with a fee for pumping above limits.	up to 21,000 AFY
WRMWSD	Mandatory Pumping Limitations	Not yet initiated; 2030	Set binding pumping limitations in conjunction with a fee for pumping above limits.	up to 21,000 AFY
WRMWSD	Land Retirement	Not yet initiated; 2035	Purchase and permanently fallow previously irrigated acreage within District to reduce overall water demand and groundwater extractions.	up to 21,000 AFY

Kern Groundwater Authority Groundwater Sustainability Agency
Groundwater Sustainability Plan

ATTACHMENT A

Joint Powers Agreement

KERN GROUNDWATER AUTHORITY
FOR THE TULARE LAKE BASIN PORTIONS OF KERN COUNTY
SECOND AMENDED AND RESTATED JOINT POWERS AGREEMENT

THIS SECOND AMENDED AND RESTATED AGREEMENT ("Agreement") is made and effective as of 7-22, 2019, pursuant to the Joint Exercise of Powers Act (Government Code Sections 6500, *et seq.)* by and between the public agencies listed on the attached Exhibit A.

This Agreement is made with reference to the following facts and understandings.

A. Each of the parties to this Agreement (the "Members") provides water service to landowners and/or residents and/or provides water to retail water entities within its respective service area..

B. Pursuant to Joint Powers Agreements dated May 27, 2014 (the "Original Agreement") and March 22, 2017 (the "Amended and Restated Agreement"), the Kern Groundwater Authority (the "Authority") was created to carry out the purposes of Part 2.75 of Division 6 (commencing at Section 10750 of the California Water Code) and develop, adopt and implement a groundwater management plan that would be available to those lands within the boundaries of the Authority's members and within the Tulare Lake Groundwater Basin.

C. On August 29, 2014, the California Legislature passed comprehensive groundwater legislation contained in SB 1168, SB 1319 and AB 1739. Collectively, those bills, as subsequently amended, enacted the "Sustainable Groundwater Management Act" ("SGMA"). Governor Brown signed the legislation on September 16, 20 I 4 and it became effective on January I, 2015. In adopting SGMA, the Legislature intended "[t]o provide local groundwater agencies with the authority and technical and financial assistance necessary to sustainably manage groundwater." (California Water Code Section 10720(d).)

D. SGMA anticipates that each affected groundwater basin or subbasin will be regulated separately by one or more Groundwater Sustainable Agencies (each, a "GSA"). A local agency or combination of local agencies may elect to be the GSA for a basin or sub-basin. SGMA generally provides that a combination of local agencies may form a GSA through a joint powers agreement, memorandum of understanding or other legal agreement. (California Water Code Section 10723.6)

E. Groundwater sustainability under SGMA is to be achieved through Groundwater Sustainability Plans ("GSPs"). Under SGMA, a GSP can be a single plan developed by one or more GSAs, or multiple coordinated plans within a basin or subbasin by multiple GSAs (California Water Code Section 10727).

F. The Members, individually and collectively, have the goal of cost-effective, sustainable groundwater management in the Kern County Subbasin that considers the interests and concerns of the Members and other stakeholders.

G. As used in this Agreement "Kern County Subbasin" means such basin as defined in Department of Water Resources Bulletin 118, as its boundaries may be modified from time to time through the procedures described in California Water Code Section I 0722.2.

H. The intent of the Members under this Agreement is to provide each Member with the sole right and responsibility to implement SGMA within its respective boundaries and/or Management Areas, as defined herein, in a manner determined by the Member, whether through the Authority or as a GSA. To facilitate coordination within the Kern County Subbasin, the Members desire for the Authority to have the authority to serve as a GSA for some or all of the Members within the Kern County Subbasin in a manner that allows the Members (individually or collectively) to directly implement SGMA and a GSP within their respective Management Areas as defined herein, while the Authority serves primarily a coordinating and administrative role in order to provide for sustainable groundwater management through the subbasin. The Members expressly intend that the Authority will not have the authority to limit or interfere with the respective Members' rights and authorities over their own internal matters, including, but not limited to, a Member's surface water supplies, groundwater supplies, facilities, operations, water management, and Water Supply Matters, as defined herein. Nothing in this Agreement is intended to modify or limit Members' police powers.

I. The Members expressly intend that neither SGMA, nor this Agreement, nor any GSP adopted by the Authority shall be construed as authorizing the Authority, or any dispute resolution process contained herein, to:

(i) determine or alter surface water rights or groundwater rights (California Water Code Section 10720.5 (b));

(ii) make binding determinations of the water rights of any person or entity (California Water Code Section 10726.8 (b)); or

(iii) supersede the existing land use authority of cities or counties, including the city or county general plan, within the overlying basin (California Water Code Section I 0726.8 (f)).

J. In light of the enactment of SGMA together with the goals and intent described above, the Members wish to amend and restate the Original Agreement in its entirety as provided herein.

THEREFORE, in consideration of the mutual promises, covenants and conditions herein set forth, it is agreed by and among the Members that the Amended and Restated Agreement effective as of March 22, 2017 is hereby amended and restated to read in its entirety as follows:

Article I: Definitions

As used in this Agreement, unless the context requires otherwise, the meaning of the terms hereinafter set forth shall be as follows:

(a) "Associate Members" shall mean those Members of the Authority admitted in accordance with the terms and provisions of this Agreement that are not General Members. The Board of Directors may from time to time admit Associate Members on terms and conditions consistent with SGMA and as determined by the Board. Representatives of Associate Members may not serve on the Board and/or Board Committees. Likewise, while the Board of Directors welcomes their input, the representatives of Associate Members shall be non-voting, their presence shall not be counted in determining whether a quorum is present, and they shall not be permitted in closed sessions of the Board of Directors.

(b) "Authority" shall mean the Kern Groundwater Authority, being the separate entity created pursuant to the provisions of Government Code sections 6500 *et seq.* by this Agreement.

(c) "Board of Directors" or "Board" shall mean the governing body of the Authority as established by Section 3.0I of this Agreement.

(d) "Committee" shall mean any committee established pursuant to Section 3.03 of this Agreement.

(e) "Cooperative Members" shall mean those members of the Authority admitted in accordance with the terms and provisions of this Agreement, but are not General Members or Associate Members. The Board of Directors may from time to time admit Cooperative Members on terms and conditions consistent with SGMA and as determined by the Board and/or Board Committees. Cooperative Members shall not have any obligation to fund the Authority or otherwise pay money to the Authority under Article IV of this Agreement. Cooperative Members shall have no seat or voting rights on the Authority's Board of Directors, no responsibility to draft a GSP chapter, or any other responsibility under this Agreement unless otherwise agreed to in writing.

(f) "Fiscal Year" shall mean that period of 12 months established as the Fiscal Year of the Authority pursuant to Section 4.01 of this Agreement.

(g) "General Members" shall mean those Members of the Authority more particularly identified as General Members on Exhibit A, and any parties which shall hereafter become General Members in accordance with the terms and provisions of this Agreement. A local agency as defined by SGMA may participate as a General Member on its own behalf or join with one or more agencies as a single General Member. Multiple agencies which elect to coordinate their representation as one General Member shall, for purposes of this Agreement, be treated as one General Member.

(h) "GSA" shall mean Groundwater Sustainability Agency as defined in SGMA.

(i) "GSA Notice Date" shall mean March 1, 2017.

(j) "Kern County Subbasin" means the groundwater subbasin described in Recital G of this Agreement.

(k) "GSP" shall mean Groundwater Sustainability Plan as defined in SGMA.

(l) "Management Area" shall mean the area within the boundaries of a Member or group of Members to be managed by that Member or group of Members under any GSP adopted by the Authority.

(m) "Members" shall mean the General Members, Associate Members, and Cooperative Members.

(n) "SGMA" shall mean the Sustainable Groundwater Management Act.

(o) "Special Activities" shall mean activities that are consistent with the purpose of this Agreement, but which are undertaken by fewer than all the Members in the name of the Authority pursuant to Section 3.07.

(p) "Water Supply Matters" shall mean a Member's surface water supplies, groundwater supplies, facilities, operations, water management, water supply projects and financial affairs.

Article II: Creation of Authority

Section 2.01 Creation.

The Members hereby reaffirm that, pursuant to their joint exercise of powers under the provisions of Government Code sections 6500 *et seq.*, they have created a public entity to be known as the "Kern Groundwater Authority."

Section 2.02 Term.

This Agreement is an amendment of the Amended and Restated Agreement dated March 17, 2017, and shall therefore become effective, including without limitation on General Members not executing it, upon its execution by at least 75% of the General Members and will remain in effect until terminated by agreement of a majority of then participating General Members. Notwithstanding the above, once the Authority has adopted and approved a GSP for some or all of the Kern County Subbasin, this Agreement shall not be terminated except by agreement of 75% of the General Members (as described in Section 3.05 below). Unless it is terminated, this Agreement shall remain in effect and be binding upon the Members and upon all future Members for such a period as the Authority engages in any activities under this Agreement, except as to any party which withdraws or is terminated from its participation in the Authority in accordance with this Agreement. This Agreement shall supersede the Original Agreement and the Interim Funding Agreement effective 2013. Any monies collected pursuant to the Interim Funding Agreement which have not been expended as of the date of this Agreement shall be credited towards each Member's financial commitment as identified herein.

Section 2.03 Purpose.

(a) The purposes of this Agreement are to:

(i) provide for the joint exercise of powers common to each of the Members and powers granted pursuant to SGMA (subject to the restrictions contained in this Agreement), through the Authority, to cooperatively carry out the purposes of SGMA and develop, adopt and implement a legally sufficient GSP covering those portions of the Kern County Subbasin that are within the

jurisdictional boundaries of the Members, subject to the limitations set forth herein; and

(ii) provide a mechanism for the coordination of groundwater management activities by and among the Members, in accordance with SGMA.

(b) Each of the General Members (or group of General Members) shall have the sole and absolute right, in its sole discretion, to:

(i) become a GSA individually or collectively within the General Member's boundaries or the Management Area managed in whole or in part by such General Member;

(ii) approve the portion, section or chapter of the GSP adopted by the Authority as applicable within the General Member's boundaries or the Management Area managed in whole or in part by such General Member, as provided for in Section 7.01 of this Agreement; and

(iii) implement SGMA and the GSP adopted by the Authority within the General Member's boundaries or the Management Area managed in whole or in part by such General Member.

(c) Except to the extent requested by a General Member with respect to the lands within its boundaries, the Authority shall serve primarily a coordinating and administrative role in order to provide for sustainable groundwater management of the Kern County Subbasin in a manner that does not limit any Member's rights or authority over its own water supply matters, including, but not limited to, a Member's Water Supply Matters. Subject to the provisions, limitations and restrictions contained in this Agreement, activities unrelated to coordinating and administrative tasks necessary for groundwater management and sustainability shall not be undertaken by the Authority.

(d) Notwithstanding any other provision of this Agreement, the Authority shall not seek status as a GSA or approve a GSP prior to the GSA Notice Date.

(e) Not later than the GSA Notice Date, or such later date as determined by the Board of Directors, each Member shall provide the Authority with written notice that such Member will:

(i) continue as a Member and request the Authority to act as the GSA within such Member's boundaries or for the Management Area managed in whole or in part by such Member pursuant to a separate agreement between the Authority and the Member setting forth the terms and conditions of the Authority's role as the GSA within such Member's boundaries or for the Management Area managed in whole or in part by such Member;

(ii) continue as a Member and confirm that it will implement the GSP adopted by the Authority within such Member's boundaries or for the Management Area managed in whole or in part by such Member continue as a Member;

(iii) continue as a Member but seek GSA status within its boundaries or within the Management Area managed in whole or in part by such Member in order to implement SGMA and the GSP adopted by the Authority therein; or

(iv) seek GSA status within its boundaries or within the Management Area managed in whole or in part by such Member and adopt its own GSP, in which case such Member shall be deemed to have withdrawn from the Authority pursuant to Article VI but will endeavor in good faith to develop and execute a coordination agreement with the Authority in accordance with SGMA. Such Member may still be eligible to become an Associate Member pursuant to Section 6.02 (a).

Section 2.04 Powers.

(a) Subject to the limitations and restrictions contained within this Agreement, the Authority shall have the power to take any action, for the benefit of its Members, to carry out the purposes of this Agreement, including, but not limited to, applying for loans and grants, becoming a GSA for any or all of the Kern County Subbasin except the portions thereof for which Members become the GSA, and developing, adopting and implementing a GSP, subject to the paramount right of Members to become GSAs as specified in Section 2.03. The Authority shall have the power to sue and be sued. Notwithstanding the foregoing, the Authority shall not have the power to control, limit or empower a Member's rights and authorities over its own Water Supply Matters. Likewise, unless a Member requests it, the Authority shall have no power to interfere with (i) the Member's rights, use or management of the Member's water or water supply or (ii) the rights of individual landowners within the Member's boundaries to utilize, apply, store, or otherwise use surface or groundwater. Subject to the limitations and restrictions contained in this Agreement, the Authority is authorized, in its own name, to do all acts necessary for the exercise of said powers provided that said acts are duly adopted by the then seated Board of Directors and are consistent with this Agreement. Except as provided in Section 4.05, the Authority may not levy assessments on its Members. In accordance with California Government Code Section 6509, the foregoing powers shall be subject to the restrictions upon the manner of exercising such powers pertaining to the Cawelo Water District.

(b) Notwithstanding anything to the contrary in this Agreement, the Authority shall not (i) undertake any activities within any Member's boundaries, or within a Management Area managed in whole or in part by such Member, unless the Member formally and expressly requests, consents to and agrees, in writing, to the activity proposed in accordance with Section 7.4 or (ii) acquire or seek to acquire by eminent domain any property of a Member. Nothing in this Agreement shall modify or limit the police powers of Members, if any.

Article III: Internal Organization

Section 3.01 - Governing Body.

(a) The Authority shall be governed by a Board of Directors which is hereby established and which shall be initially composed of representatives of the General Members, as shown on Exhibit A. Membership on the Authority's Board of Directors shall not include Representatives from Associate and Cooperative Members. Without amending this Agreement, the Board of Directors composition shall be altered from time to time to reflect the termination and/or admission of any new General Members.

(b) Each General Member's governing board shall select a representative from its governing body or the governing body of one of the agencies within the General Member to serve as their Board member. A General Member may designate from its governing body or the governing

body of one of the agencies within the General Member to serve as its alternative Director. The role of each alternate Director shall be to assume the duties of the Director appointed by his/her Member entity in case of the absence or unavailability of such Director, including without limitation such Director's duties as a member of any Committee established pursuant to Section 3.03. The Directors and alternates so named shall continue to serve until their respective successors are appointed.

(c) Nothing in this Agreement shall preclude a future amendment of this Agreement to reconfigure the Board of Directors into a smaller body comprised of representatives of General Members or other individuals, all as defined in such amendment.

Section 3.02 Officers.

The Board shall select a Chair from among the Board of Directors who shall be the presiding officer of the Board meetings. The Board shall select a Vice Chair from among the Board of Directors who shall serve as the presiding officer in the absence of the Chair. The Board shall also select a Secretary, who need not be a member of the Board of Directors. The terms of such Officers shall be established by the Board of Directors from time to time and as necessary.

Section 3.03 Committees.

There shall be established such Committees as the Board of Directors shall determine from time to time. Each such Committee shall be comprised of representatives of General Members, shall exist for the term specified in the action establishing the Committee, shall meet as directed by the Board of Directors, and shall make recommendations to the Board of Directors on the various activities of the Authority. The Board of Directors may delegate authority to the Committee to administer and implement the various activities of the Authority, subject at all times to the limitations on the Authority set forth in this Agreement; provided, that no power to enforce any aspect of SGMA or the GSP adopted by the Authority shall be delegated to a Committee.

Members shall be given reasonable advance notice of all Committee meetings, including without limitation ad hoc Committee meetings, all of which meetings shall be open to Members and their representatives.

Section 3.04 Seal; Bylaws.

The Board may (but need not) adopt an official seal for the Authority and adopt such bylaws as it may deem necessary to regulate the affairs of the Authority in accordance with this Agreement. The bylaws may be amended from time to time by a majority vote of the Board of Directors as it may deem necessary.

Section 3.05 Voting; Quorum.

(a) Subject to Section 3.05(c), each member of the Board of Directors shall be entitled to a vote determined as follows:

(i) Each member of the Board shall have one (I) vote on matters with respect to which such member is entitled to vote.

(ii) Voting on actions related to Special Activities shall be weighted as determined by each Special Activity agreement.

(b) Directors holding two-thirds of the voting power on the entire Board of Directors on a matter shall constitute a quorum for the transaction of Authority business. Any Board member abstaining from a vote shall be counted for purposes of determining the existence of a quorum, but shall not be deemed to be voting.

(c) A Director (including a Director serving as a member of a Committee) shall be entitled to vote on any matter or action (i) that would affect the General Member represented by such Director, (ii) relating to the general business or administration of the Authority, or (iii) that would impact any land or landowners within the boundaries of the General Member represented by such Director or the Management Area managed in whole or in part by such General Member.

(d) Examples of matters and actions on which a Director shall be entitled to vote include without limitation matters or actions relating to the implementation of SGMA within the boundaries of the General Member represented by such Director, amounts to be paid by the General Member represented by such Director to the Authority, the imposition of fees or charges within the boundaries of the General Member represented by such Director, the adoption or amendment of the Authority's GSP.

(e) In the event of a disagreement as to whether a Director is entitled to vote on a matter or action coming before the Board or a Committee, such Director shall be entitled to vote on the matter or action unless 75% of the Directors present at the meeting determine that such Director is not so entitled.

(f) Except as otherwise provided in this Agreement, any action by the Board of Directors shall require a two-thirds vote of the Directors entitled to vote thereon that are present at the meeting. Any amendment of this Agreement shall be governed by Section 8.0 I.

(g) Two-thirds of the members of a Committee entitled to vote thereon shall constitute a quorum for a matter or action before the Committee. All questions and matters of any nature whatsoever coming before any Committee shall be determined, provided a quorum is present, by the concurrence of75% of the members of such Committee entitled to vote thereon present and voting on such matter. Any Committee member entitled to vote thereon abstaining from a vote shall be counted for purposes of determining the existence of a quorum, but shall not be deemed to be voting.

(h) This Section 3.05 shall not apply to matters affecting implementation of SGMA within a particular Management Area. Such matters shall be governed by the Member or Members implementing SGMA within that Management Area, except to the extent otherwise agreed upon by such Member(s) pursuant to 2.04(b) or in a Special Activity agreement.

Section 3.06 - Meetings.

Meetings of the Board of Directors and any Committee (to the extent applicable) shall be conducted in accordance with the Ralph M. Brown Act, California Government Code Sections 54950, *et seq.*

Section 3.07 - Special Activities.

With the prior approval of the entire Board of Directors, Members may undertake Special Activities in the name of the Authority. All Members shall be given the opportunity to participate in each Special Activity of the Authority unless the Special Activity is an action described in Section

7.04. Prior to undertaking a Special Activity, the Members electing to participate in the Special Activity shall enter into an activity agreement. Such activity agreement shall provide that (i) no Special Activity undertaken pursuant to such agreement shall conflict with the terms of this Agreement and (ii) the Members to the activity agreement shall indemnify, defend and hold the Authority, and the Authority's other Members, harmless from and against any liabilities, costs or expenses of any kind arising as a result of the Special Activity described in the activity agreement. All assets, rights, benefits, debts, liabilities and obligations attributable to a Special Activity shall be assets, rights, benefits debts, liabilities and obligations solely of the Members that have entered into the activity agreement for that Special Activity, in accordance with the terms of the activity agreement, and shall not be the assets, rights, benefits, debts, liabilities and obligations of those Members that have not executed the activity agreement.
Members not electing to participate in the Special Activity shall have no rights, benefits, debts, liabilities or obligations attributable to such Special Activity.

Article IV: Financial Provisions

Section 4.01 - Fiscal Year.

The Fiscal Year of the Authority shall be from January I through December 31 of each

Section 4.02 - Funds: Accounts.

(a) The North Kern Water Storage District shall serve as the Fiscal Agent and Treasurer or the Authority unless otherwise determined by the entire Board. The Fiscal Agent shall be responsible for all money of the Authority from whatever source. The Board may compensate the fiscal agent for services rendered.

(b) All funds of the Authority shall be strictly and separately accounted for and regular reports shall be rendered of all receipts and disbursements at least quarterly during the Fiscal Year. The books and records of the Authority shall be open to inspection by the Members.

(c) The Authority shall contract with a certified public accountant to make an audit or review of the accounts and records of the Authority which shall be conducted in compliance with Section 6505 of the California Government Code. The Fiscal Agent shall have the right to reject any proposed certified public accountant. All costs associated with this Audit will be the full responsibility of the Authority.

Section 4.03 - Property: Bonds.

The Board of Directors shall from time to time designate the officers and persons, in addition to those specified in Section 4.02 above, who shall have charge of, handle, or have access to any property of the Authority. Each such officer and person shall file a bond in an amount designated by the Board of Directors.

Section 4.04 - Budget.

By a date set by the Board of Directors each Fiscal Year, the Board of Directors shall adopt a budget for the Authority for the ensuing Fiscal Year; provided, that except as provided in Section 4.05,

the Authority shall not impose assessments or other charges on Members. Notwithstanding the foregoing, by its execution of this Agreement, each Member confirms that it has authorized its Director and Alternate Director to approve actions and expenditures by the Authority over and above the approved annual budget of the Authority for a Fiscal Year that do not create a fiscal obligation greater than $5,000 on such Member without further action of such Member.

Section 4.05 - Payments To The Authority.

(a) Except as otherwise provided, all fees, costs and expenses incurred by the Authority for general administrative services, such as legal, preparation of audits, and other general administrative functions shall be funded (i) from permissible contributions from third parties and (ii) assessments on the General Members, levied from time to time by the Board of Directors to carry out the activities of the Authority generally applicable to all General Members, which shall be equal per General Member, as shown on Exhibit A.

(b) No Member shall be bound, financially or otherwise, by any obligation, contract or activity undertaken by the Authority unless and except to the extent agreed upon by the Member, except that each Member shall be obligated to fund its then current annual share of the general basic budget of the Authority, provided such budgets are otherwise approved as provided herein. Funding of other matters shall be through Special Activity agreements or as otherwise agreed to by the Members in writing.

(c) Cooperative Members shall not be assessed by the Authority and are under no obligation to fund or otherwise pay money to the Authority.

Section 4.06 - GSP Fees.

The Authority may impose reasonable fees, charges, assessments and other levies to implement its GSP and/or SGMA; provided, that the Authority shall have no authority to impose any such fees, charges, assessments or other levies on any of its Members or within a Management Area without the express consent and approval of the affected Member(s), or the Member or Member implementing the Authority's GSP and SGMA within such Management Area.

Article V: Management

Section 5.01 - Management.

In addition to, or in lieu of, hiring employees, the Authority may engage one or more General Member(s) or third party(ies) to manage any or all of the business of the Authority on terms and conditions acceptable to the Board of Directors. Any General Member or third party so engaged shall have such responsibilities as are set forth in the contract for such General Member's or third party's services.

Article VI: Relationship of Authority And Its Members

Section 6.01 - Separate Entity: Property.

In accordance with California Government Code Sections 6506 and 6507, the Authority shall be a public entity separate and apart from the parties to this Agreement. Unless, and to the extent

otherwise agreed herein, the debts, liabilities and obligations of the Authority shall not be debts, liabilities or obligations of the Member entities. The Authority shall own and hold title to all funds, property and works acquired by it during the term of this Agreement.

Section 6.02 - Admission, Withdrawal and Termination of Members.

(a) Additional qualified parties may join in this Agreement and become General Members upon the approval of the entire Board of Directors, subject to terms and conditions as may be established by the Board of Directors. Associate Members may be admitted on terms and conditions established by the entire Board of Directors. Prior to being admitted as a new Member, an entity shall execute an agreement to be bound by the terms of this Agreement and any other terms and conditions established by the Board of Directors.

(b) Notwithstanding anything herein to the contrary, any Member may withdraw from this Agreement by giving 30 days written notice of its election to do so, which notice shall be given to the Board of Directors and to each of the other parties.

(c) Upon withdrawal, the Member shall not be relieved of all obligations for assessments to pay costs or liabilities of the Authority which were incurred prior to the date of the withdrawing Member's notice of withdrawal, but shall remain responsible for all obligations for assessments to pay costs or liabilities of the Authority which were incurred prior to the date of the withdrawing Member's notice of withdrawal.

(d) Subject to any contrary provisions of SGMA, a Member may be terminated by a three-fourths vote of the Directors representing Members not subject to the termination vote if such Member is then in breach of this Agreement and the breach is identified in the vote of the Board of Directors. Upon termination, the breaching Member shall no longer be a Member of the Authority; provided, that such termination shall become effective no earlier than 90 days after such vote of the Board of Directors and shall only be effective if the breach identified in the vote of the Board of Directors has not be cured by the effective date for the termination.

(e) Upon termination, the Member shall be entitled to a reimbursement for all assessments collected within 12 months prior to the termination vote and they shall be relieved of all ongoing obligations for assessments to pay costs or liabilities of the Authority which were incurred prior to the date of the termination.

(f) Upon withdrawal or termination as a Member, the provisions of Section 2.04(b) shall remain applicable to any such withdrawing or terminated Member. The withdrawing or terminated Member will also be entitled to copies of all documents, information, and material developed by the Authority and paid for in whole or in part by the Member prior to the Member's withdrawal or termination.

(g) Upon withdrawal or termination as a Member, whether occurring before or after the GSA Notice Date and/or the date the Authority becomes a GSA as provided for in SGMA, or whether occurring before or after June 30, 2017, it is contemplated the withdrawing or terminated Member would concurrently become (or designate) a GSA for the lands within its boundaries (or a Management Area managed in whole or in part by such Member), so that such lands of the withdrawing or terminated Member would continue to be subject to a GSA and if applicable a GSP and the powers of such withdrawing Member within its boundaries would not

be limited by this Agreement. In such event the Authority and its remaining Members shall (i) not object to or interfere with the lands in the withdrawing or terminated Member's boundaries (or a Management Area managed in whole or in part by such Member) being in a GSA, as designated by such withdrawing or terminated Member, (ii) facilitate such transition to the extent reasonably necessary, and (iii) in cooperation with the withdrawing or terminated Member, withdraw from managing the Kern County Subbasin as a GSA (if it has already elected to be a GSA) for that portion of the Basin within the boundaries of the withdrawing or terminated Member and so notify the Department of Water Resources.

Section 6.03 - Disposition Of Property Upon Termination Or Determination By Board Of Directors Of Surplus.

(a) Upon termination of this Agreement or upon determination by the Board of Directors that any surplus money is on hand, such surplus money shall be returned to the Members of the Authority. The distribution of said surplus shall be proportionate to the current year percentages as shown in Exhibit A, or as modified after the inclusion of new Members.

(b) The Board of Directors shall first offer any surplus properties, works, rights and interests of the Authority for sale to the Members and the sale shall be at the Authority's actual cost unless otherwise required by law. If no such sale is consummated, then the Board of Directors shall offer the surplus properties, works, rights and interests of the Authority for sale in accordance with applicable law to any governmental agency, private entity or persons for good and adequate consideration.

Section 6.04 - Liability For Debts.

The Members do not intend hereby to be obligated either jointly or severally for the debts, liabilities or obligations of the Authority, except as may be specifically provided for in California Government Code Section 895.2 as amended or supplemented. Provided, however, if any General Member(s) of the Authority are, under such applicable law, held liable for the acts or omissions of the Authority caused by negligent or wrongful act or omission occurring in the performance of this Agreement, such parties shall be entitled to contribution from the other Members so that after said contributions each General Member shall bear an equal share of such liability, as shown on the then-current Exhibit A. This Section 6.04 does not apply to acts or omissions of a Member in implementing the GSP adopted by the Authority within such Member's boundaries or a Management Area managed in whole or in part by such Member.

Section 6.05 - SGMA-Related Expenses Incurred by Members.

Expenses incurred by a Member, or group of Members, for the implementation of the SGMA within a Management Area shall be borne solely by that Member or group of Members. Neither the Authority nor its other Members shall be liable for such expenses.

Article VII - Implementation of SGMA Section

7.01 - Development of GSP.

Any Member or group of Members may create its or their own chapter or provisions

governing SGMA implementation within their respective boundaries or a Management Area managed in whole or in part by such Member(s) for inclusion by the Authority into the Authority's GSP. Cooperative Members shall be under no obligation to prepare or otherwise contribute to the preparation of any GSP chapter(s). The Authority shall promptly review the proposed chapter or provisions for consistency with the Authority's GSP and to determine that it meets the requirements of SGMA. If the Authority determines by a vote of 75% of the Directors that a Member's proposed chapter or provisions is/are consistent with SGMA and the Authority's GSP, it shall incorporate such chapter or provisions into the Authority's GSP. Such chapter or provisions may include operating conditions and criteria for groundwater banking projects that have previously been negotiated with other Members or agencies within the Basin and/or are contained within approved environmental documents, and in reviewing a Member's chapter the Authority shall not reject or fail to approve a Member's chapter based solely upon such operating conditions and criteria. The Authority shall not adopt a GSP that will be implemented within any Member's boundaries or Management Area without the prior approval of the Member.

Section 7.02 - Authorization to Carry Out the Terms of the GSP.

The Authority is authorized to carry out any of the following powers for the benefit of its Members that are included in the GSP adopted by the Authority without any further approval of the Board of Directors, subject at all times to the limitations and restrictions contained within this Agreement:

(a) Collection and maintenance of water extraction information and other technical data.

(b) Coordination of actions within, and reporting by, a Management Area.

(c) Carrying out studies and other technical investigations.

(d) Establishment and administration of conjunctive use and land fallowing programs.

(e) Requiring permitting of water extraction facilities.

(f) Requiring installation of meters.

(g) Buy, sell, exchange, recharge, and/or store water if the benefits thereof are made available to all General Members.

(h) Fix and collect rates for replenishment and other activities as a regulatory or service fee provided for at Water Code Sections 10730 through 10731.

Section 7.03 - Actions Requiring Additional Approval.

Subject to the limitations of this Agreement, the Authority shall not do any of the following without the approval of 75% of the voting power of the Board of Directors:

(a) Restrict or otherwise limit extraction of native groundwater other than through economic incentives and disincentives.

(b) Fund capital construction projects.

Notwithstanding any other provision of this Agreement, the Authority shall not restrict or otherwise limit the extraction of water stored (whether through direct recharge or in lieu deliveries) in the Kern County Subbasin as a part of any banking or recharge project or program, or otherwise seek to regulate the operation any such project or program.

Section 7.04 - Management Areas.

Any General Member (or group of General Members) may request that the Authority directly assume the responsibility of implementing SGMA and the Authority's GSP within its Management Area by giving written notice to the Authority, which notice may be given at any time. Where the service areas of multiple General Members overlap a Management Area, the General Members within the Management Area shall unanimously join the request. The Board of Directors shall take action to accept or reject such request. If the Authority accepts such request, the Authority and the requesting General Member(s) shall develop a mutually acceptable agreement describing the respective roles and responsibilities of the Authority and the requesting General Member(s) with respect to such implementation.

Except as otherwise expressly provided, the Authority's role within a Management Area, unless otherwise unanimously requested by the General Member(s) managing such Management Area, shall be primarily coordinating and administrative. In particular, the roles and responsibilities for implementing SGMA and the GSP within a Management Area shall be the subject of a Special Activity agreement between the General Member(s) and the Authority.

Article VIII: Miscellaneous Provisions

Section 8.01 - Amendment.

This Agreement may be amended from time to time by the concurrence of 75% of the General Members. To provide non-concurring parties an opportunity to withdraw from the Authority as provided herein, an amendment shall be binding on all parties 60 days after the required concurrence has been obtained.

Section 8.02 Severability And Validity Of Agreement.

Should the participation of any party to this Agreement, or any part, term or provision of this Agreement be decided by a courts or the Legislature to be illegal, in excess of that party's authority, in conflict with any law of the State of California, or otherwise rendered unenforceable or ineffectual, the validity of the remaining portions, terms or provisions of this Agreement shall

not be affected thereby and each party hereby agrees it would have entered into this Agreement upon the remaining terms and provisions.

Section 8.03 - Assignment.

Except as otherwise provided in this Agreement, the rights and duties of the parties to this

Agreement may not be assigned or delegated without the advance written consent of the Authority (as evidenced by a majority vote of the Board of Directors), and any attempt to assign or delegate such rights or duties in contravention of this section shall be null and void. Any assignment or delegation permitted under the terms of this Agreement shall be consistent with the terms of any contracts, resolutions or indentures of the Authority then in effect, including without any Special Activity agreement to which the assigning or delegating Member is a party. This Agreement shall inure to the benefit of and be binding upon the successors and assigns of the parties hereto. This section does not prohibit a party from entering into an independent agreement with another agency regarding the financing of that party's contributions to the Authority or the disposition of proceeds which that party receives under this Agreement so long as such independent agreement does not affect, or purport to affect, the rights and duties of the Authority or the parties under this Agreement.

Section 8.04 - Execution In Parts Or Counterparts.

This Agreement may be executed in parts or counterparts, each part or counterpart being an exact duplicate of all other parts or counterparts, and all parts or counterparts shall be considered as constituting one complete original and may be attached together when executed by the parties hereto. Facsimile or electronic signatures shall be binding.

Section 8.05 - Notices.

Notices authorized or required to be given pursuant to this Agreement shall be in writing and shall be deemed to have been given when mailed, postage prepaid, or delivered during working hours to the addresses set forth for each of the parties hereto on Exhibit "A" of this Agreement, or to such other changed addresses communicated to the Authority and the Member entities in writing, and to such other entities that become Members.

Section 8.06 - Dispute Resolution.

(a) A dispute resolution group shall be established by the Board of Directors to resolve disputes and/or controversies through mediation relating to the interpretation, construction, performance, termination, breach of, or withdrawal from this Agreement (the "Dispute Resolution Group"). The Dispute Resolution Group shall meet with the parties involved no later than 30 days following notification of the dispute or controversy. Thereafter, the Dispute Resolution Group will have 90 days to endeavor to resolve the dispute.

(b) Following conclusion of the dispute resolution process as herein provided, any Member may pursue any judicial or administrative remedies otherwise available. Notwithstanding this Section 8.06, a Member may seek a preliminary injunction or other interlocutory judicial relief if necessary to avoid irreparable damages or to preserve the status quo.

IN WITNESS WHEREOF, the parties hereto, pursuant to resolutions duly and regularly adopted by their respective Board of Directors or governing board, have caused their names to be affixed by their proper and respective officers as of the day and year first above-written.

Coordination Agreement

Kern County Subbasin Coordination Agreement

THIS COORDINATION AGREEMENT (the "Agreement") is made effective as of JANUARY 20, 2020 by and among the Groundwater Sustainability Agencies ("GSA") within the Kern County Subbasin that are developing a Groundwater Sustainability Plan ("GSP") (each a "Party" and collectively the "Parties"), each of which is identified in Appendix 1 and is made with reference to the following facts:

WHEREAS, on September 16, 2014, Governor Jerry Brown signed into law Senate Bills 1168 and 1319 and Assembly Bill 1739, known collectively as the Sustainable Groundwater Management Act ("SGMA"); and

WHEREAS, SGMA requires all groundwater basins designated as high or medium priority by the Department of Water Resources ("DWR") to manage groundwater in a sustainable manner; and

WHEREAS, the Kern County Subbasin (Basin Number 5-22. 14, DWR Bulletin 118) ("Basin") within the San Joaquin Valley Groundwater Basin, has been designated as a high-priority basin by DWR; and

WHEREAS, the Basin includes eleven (11) GSAs that are managing the Basin through five (5) different GSPs; and

WHEREAS, SGMA allows local agencies to engage in the sustainable management of groundwater, but requires GSAs intending to develop and implement multiple GSPs within a basin to enter into a coordination agreement;

WHEREAS, the Agreement does not prevent any Party from providing comments on a GSP, or otherwise coordinating among parties with regard to specific items in a GSP outside this Agreement, on issues including but not limited to specific border conditions between GSP's and/or the timing and/or effect of projects and management actions contained within another GSP; and

WHEREAS, nothing in this Agreement represents or should be construed as the determination of any claim or assertion of a groundwater right; specifically, the coordinated water budget information or data does not amount to an allocation, or otherwise represent a determination, validation, or denial of any claimed or asserted groundwater right.

THEREFORE, in consideration of the facts recited above and of the covenants, terms and conditions set forth herein, the Parties agree as follows:

SECTION 1 – PURPOSE

The purpose of this Agreement is to comply with SGMA coordination agreement requirements and ensure that the multiple GSPs within the Basin are developed and implemented utilizing the same methodologies and assumptions as required under SGMA and Title 23 of the California Code of Regulations, and that the elements of the GSPs are appropriately coordinated to support sustainable management.

The Parties intend that this Agreement be a description of how the multiple GSPs, developed by the individual GSAs, are implemented together to satisfy the requirements of SGMA. The Parties intend this Agreement to be incorporated as part of each individual GSP developed by the Parties.

SECTION 2 – GENERAL GUIDELINES

2.1 Responsibilities of the Parties

The Parties shall work collaboratively to comply with SGMA and this Agreement. Each Party to this Agreement is a GSA and acknowledges it is bound by the terms of the Agreement. This Agreement does not otherwise affect each Party's responsibility to implement the terms of their respective GSP. Rather, this Agreement is the mechanism through which the Parties will coordinate portions of the multiple GSPs to ensure such GSP coordination complies with SGMA.

2.2 No Adjudication or Alternative Plans in the Basin

As of the date of this Agreement, there are no portions of the Basin that have been adjudicated or have submitted for DWR approval an alternative to a GSP pursuant to Water Code Section 10733.6.

SECTION 3 – GOVERNANCE

3.1 Basin Coordination Committee

The Basin Coordination Committee (BCC) will oversee the activities described in section 3.1.5 of this Agreement. The Basin Coordination Committee will consist of one representative appointed from each GSP.

3.1.1 Each Basin Coordination Committee member's compensation for service on the Basin Coordination Committee, if any, is the responsibility of the appointing Party.

3.1.2 Each Basin Coordination Committee member shall serve at the pleasure of the appointing GSP and may be removed or substituted from the Basin Coordination Committee by the appointing GSP at any time.

3.1.3 The Basin Coordination Committee will meet periodically as it deems necessary to carry out the activities described in this Agreement

3.1.4 The Basin Coordination Committee may suggest subcommittees, workgroups, or otherwise request staff of the Parties to develop technical data, supporting information and/or recommendations.

3.1.5 The purposes of the Basin Coordination Committee are to (1) recommend to their respective GSAs the appointment of a Plan Manager who will act in accordance with this Agreement, and (2) provide a forum wherein the Parties may discuss basin coordination activities, which may include the development, planning, financing, environmental review, permitting, implementation, and long-term monitoring

of the multiple GSPs in the Basin, pursuant to SMGA requirements ("Coordination Activities").

3.2 Plan Manager

The Plan Manager shall be appointed by unanimous agreement by the Parties for a term of one calendar year, and annually thereafter, and may be removed by unanimous agreement of the Parties with or without cause. The Plan Manager shall serve as the point of contact for DWR as specified in 23 CCR § 357.4, subd. (b)(1). The Plan Manager shall submit or assist with the submittal of all GSPs, plan amendments, supporting information, monitoring data and other pertinent information, Annual Reports, and periodic evaluations to DWR when required. The Plan Manager has no authority to take any action or represent the Basin Coordination Committee or a particular GSA without the specific direction and authority of the Basin Coordination Committee or the particular GSA, respectively. The Plan Manager is obligated to immediately disclose all communications he/she receives in his/her capacity as Plan Manager to the Basin Coordination Committee and the affected GSA, as appropriate under the circumstances.

SECTION 4 – EXCHANGE OF DATA AND INFORMATION

4.1 Procedure for Exchange of Information

4.1.1 The Parties may exchange information through collaboration and/or informal requests made at the Basin Coordination Committee level or through subcommittees suggested by the Basin Coordination Committee. However, to the extent it is necessary to make a written request for information to another Party, each Party shall designate a representative to respond to information requests and provide the name and contact information of the designee to the Basin Coordination Committee. Requests may be communicated in writing and transmitted in person or by mail, facsimile machine or other electronic means to the appropriate representative as named in this agreement.

4.1.2 Nothing in this Agreement shall be construed to prohibit any Party from voluntarily exchanging information with any other Party by any other mechanism separate from the Basin Coordination Committee.

4.2 Non-Disclosure of Confidential Information

Pursuant to Section 4.1 of this Agreement, a Party may provide one or more of the other Parties with confidential information. To ensure the protection of such confidential information and in consideration of the agreement to exchange said information, appropriate arrangements may be made to restrict or prevent further disclosure.

SECTION 5 – METHODOLOGIES & ASSUMPTIONS

Pursuant to California Water Code section 10727.6 and 23 CCR, § 357.4, the Parties will meet and agree upon the methodologies used in their respective GSPs with respect to utilizing the same data and methodologies for the following assumptions: 1) groundwater elevation data; 2) groundwater extraction data; 3) surface water supply; 4) total water use; 5) change in groundwater storage; 6) water

budget; and 7) sustainable yield, and that such methodologies and assumptions will continue to be used in the future development and implementation of such GSPs, except to the extent modified by the Parties in the future. Information regarding the agreed upon Basin methodologies and assumptions shall be attached as Appendix 2 to this Agreement when approved by all Parties.

SECTION 6 – MONITORING NETWORK

6.1 The Parties shall develop a monitoring network and monitoring network objectives for the Basin in accordance 23 CCR, §§ 354.32 – 354.40. Each network shall facilitate the collection of data in order to characterize groundwater and related surface water conditions in the Basin and evaluate changing conditions that occur from implementation of the individual GSPs. The individual GSPs shall include monitoring objectives, protocols, and data reporting requirements as necessary under SGMA and SGMA Regulations.

6.2 The monitoring network(s) will demonstrate short-term, seasonal, and long-term trends in groundwater and related surface water conditions. Each Party's GSP will describe the monitoring network's objectives for the Basin, including an explanation of how the network will be developed and implemented to monitor groundwater and related surface water conditions, and the interconnection of surface water and groundwater, with sufficient temporal frequency and spatial density to evaluate the affects and effectiveness of GSP implementation. The Parties shall implement the monitoring network objectives to accomplish the following: a) demonstrate progress toward achieving measurable objectives described in the GSPs; b) monitor impacts to the beneficial uses or users of groundwater; c) monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds; and d) quantify annual changes in water budget components. Information regarding the agreed upon Basin monitoring network shall be attached as Appendix 3 to this Agreement when approved by all Parties.

6.3 The Parties shall design a monitoring network that will achieve the following for the enumerated sustainability indicators:

6.3.1 Chronic Lowering of Groundwater Levels:

The network shall collect information sufficient to demonstrate groundwater occurrence, flow directions, and hydraulic gradients between principal aquifers and surface water features by the following methods: a) density of monitoring wells to collect measurements through depth-discrete perforated intervals to characterize the groundwater table or potentiometric surface for each principal aquifer; and b) take static groundwater elevation measurements, at least two times a year, representing seasonal low and high conditions.

6.3.2 Change in Groundwater Storage:

The network will provide sufficient data for the GSAs to estimate the change in annual groundwater in storage.

6.3.3 Degraded Water Quality:

The network will collect sufficient spatial and temporal data from each GSA to determine groundwater quality trends for water quality indicators, as determined by the GSA, to address known water quality issues.

6.3.4 Land Subsidence:

The network will identify the location, rate and extent of land subsidence, which may be measured by extensometers, surveying, remote sensing technology, or any other appropriate method.

6.3.5 Seawater Intrusion/Depletion of Interconnected Surface Water:

The network will not be designed to monitor Seawater Intrusion and/or Depletion of Interconnected Surface Water because these issues are not applicable to the Basin.

6.4 The Parties shall determine the density of monitoring sites and frequency of measurements required to demonstrate short-term, seasonal, and long-term trends based upon the following factors: a) the amount of current and projected groundwater use; b) aquifer characteristics, including confined or unconfined aquifer conditions or other physical characteristics that affect groundwater flow; c) impacts to beneficial uses and users of groundwater and land uses and property interests affected by groundwater production, and adjacent basins that could affect the ability of that basin to meet the sustainability goal; d) whether individual GSAs have adequate long-term existing monitoring results or other technical information to demonstrate an understanding of aquifer response.

6.5 Parties may designate a subset of monitoring sites as representative of conditions in the Basin or a portion of the Basin.

6.6 The Parties shall identify data gaps where the Basin does not contain sufficient monitoring sites, where the frequency of monitoring is insufficient, or sites are unreliable. If such gaps are identified, the Parties shall describe the reason for the gap and describe actions that may be taken to remedy such gaps.

6.7 The Parties shall share information necessary to create a Basin map displaying the location and type of each monitoring site within the Basin, and a report in tabular format, including information regarding the monitoring site type, frequency of measurement, and purpose for which the monitoring site is being used.

SECTION 7 – COORDINATED WATER BUDGET

7.1 In accordance with 23 CCR, § 357.4 subd. (b) the Parties shall prepare a coordinated water budget for the Basin as described in this sub-section, as required by 23 CCR, § 354.18. The water budget will provide an accounting and assessment of the total annual volume of groundwater and surface water entering and leaving the Basin, including historical, current, and projected water budget conditions, and the change in the volume of water stored. Information regarding the agreed upon coordinated water budget shall be attached as Appendix 4 to this Agreement when approved by all Parties.

7.2 Each Party for its respective GSP shall endeavor to provide the information required by 23 CCR, § 356.2 to the Basin Coordination Committee by March 1 for the preceding calendar year.

7.3 The Parties shall use the projected water budgets to estimate future baseline conditions of supply, demand, and aquifer response to their GSP implementation, and to identify the uncertainties of these projected water budget components. The Parties shall use the following methodologies and assumptions to estimate future baseline conditions concerning hydrology, water demand and surface water supply availability or reliability over the planning and implementation horizon for the projected water budget.

7.3.1 To the extent available, use 50 years of historical precipitation, evapotranspiration, and streamflow information as the baseline condition for estimating future hydrology. The projected hydrology information shall also be applied as the baseline condition used to evaluate future scenarios of hydrologic uncertainty associated with projections of climate change and sea level rise.

7.3.2 Projected water demand shall utilize the most recent reliable land use, population growth, evapotranspiration, and crop coefficient information as the baseline condition for estimating future water demand. The projected water demand information shall also be applied as the baseline condition used to evaluate future scenarios of water demand uncertainty associated with projected changes in local land use planning, population growth, and climate.

7.3.3 Projected surface water supply shall utilize the most recent reliable water supply information as the baseline condition for estimating future surface water supply. The projected surface supply shall also be applied as the baseline condition used to evaluate future scenarios of surface water supply availability and reliability as a function of the historical surface water supply as identified in the historical water budget and the projected changes in local land use planning, population growth, and climate.

SECTION 8 – COORDINATED DATA MANAGEMENT SYSTEM

The Parties will develop and will maintain a data management system that is capable of storing and reporting information relevant to the development and/or implementation of the GSPs and monitoring network of the Basin as required by SGMA and the SGMA Regulations. Information regarding the agreed upon coordinated data management system shall be attached as Appendix 5 to this Agreement when approved by all Parties.

SECTION 9 – ADOPTION AND USE OF THE COORDINATION AGREEMENT

9.1 Cooperative Implementation of GSPs

The Parties intend that their individual GSPs will be implemented together in order to satisfy the requirements of SGMA. The collective GSPs in a coordinated manner will utilize the groundwater models, a description of the physical setting and characteristics of the separate aquifer systems within the Basin, the methodologies and assumptions as specified in Water Code section 10727.6, a description

of the undesirable results, the minimum thresholds, the measurable objectives, and monitoring protocols that together provide a description of the sustainable yield of the Basin(s) as a whole, and how it will be sustainably managed.

9.2 GSP and Coordination Agreement Submission

The Parties shall submit their respective GSPs to DWR through the Plan Manager in accordance with SGMA and SGMA Regulations. The Parties intend that this Agreement suffice to fulfill the requirements of providing an explanation of how the GSPs implemented together satisfy Water Code sections 10727.2, 10727.4 and 10727.6 for the entire Basin.

9.3 In Event Entire Basin Not Covered by GSP

In the event it appears that the entire Basin may not be covered by one or more GSPs as of January 31, 2020, each Party may take such action as deemed necessary or appropriate by such Party with respect to filing its GSP and/or other documents with DWR.

9.4 Duration of Coordination Agreement

This Coordination Agreement shall be reopened for amendment at the at the submission of the next round of GSP's covering the Kern Subbasin (no later than 5 years from January 31, 2020). Unless amended at that time, the Coordination Agreement shall be automatically renewed every 5 years. The parties may agree to unanimously amend this Coordination Agreement at any time.

SECTION 10 – Modification and Termination of the Agreement

10.1 Modification

This Agreement shall be reviewed as part of each five year assessment and may be supplemented, amended, or modified only by the written agreement of all the Parties. No supplement, amendment, or modification of this Agreement shall be binding unless it is in writing and signed by all Parties.

10.2 Withdrawal, Termination, Adding Parties

10.2.1 A Party may unilaterally withdraw from this Agreement without causing or requiring termination of this Agreement, effective upon 30 days' notice to the other Parties.

10.2.2 A new GSA or group of GSA's may be added as a Party to this Agreement if such entity or entities is submitting a GSP within the Basin.

10.2.3 This Agreement may be rescinded by unanimous written consent of all the Parties. Nothing in this Agreement shall prevent the Parties from entering into another coordination agreement.

SECTION 11 – Dispute Resolution

11.1 Procedures for Resolving Conflicts

In the event that any dispute arises among the Parties relating to the rights and obligations arising from this Agreement, the aggrieved Party or Parties shall provide written notice to the other Parties of the dispute. Within thirty (30) days after such written notice, the Parties shall attempt in good faith to resolve the dispute through informal means. If the Parties cannot agree upon a resolution of the dispute within thirty (30) days from the providing of written notice specified above, the dispute will be elevated to the BCC for consideration, along with the notice of dispute and any other relevant supporting documentation produced and shared by the disputing parties pursuant to their informal meet and confer process. The BCC may issue a recommendation concerning resolution of the dispute. If the Parties cannot agree upon a resolution of the dispute following the input of the BCC, the disputing Parties will meet and confer to determine if other alternative dispute resolution methods are agreeable, including voluntary non-binding mediation, which may include the Department of Water Resources dispute resolution process, arbitration, or appointment of a panel of technical experts prior to commencement of any legal action. The cost of alternative dispute resolution shall be paid in equal proportion among the Parties to the dispute, otherwise the Parties shall bear their own costs. Upon completion of alternative dispute resolution, if any, and if the controversy has not been resolved, any Party may exercise any and all rights to bring a legal action relating to the dispute.

11.2 Litigation

In the event a dispute or claim is not resolved by a mutually agreeable settlement through informal negotiation or voluntary mediation, the aggrieved Party may file suit in a County Superior Court with jurisdiction to provide a binding decision on the matter.

In the event that any dispute arises among the Parties relating to the rights and obligations arising from this Agreement, the aggrieved Party or Parties shall provide written notice to the other Parties of the dispute. Within thirty (30) days after such written notice, the Parties shall attempt in good faith to resolve the dispute through informal means. If the Parties cannot agree upon a resolution of the dispute within thirty (30) days from the providing of written notice specified above, the dispute will be elevated to the BCC for consideration, along with the notice of dispute and any other relevant supporting documentation produced and shared by the disputing parties pursuant to their informal meet and confer process. The BCC may issue a recommendation concerning resolution of the dispute. If the Parties cannot agree upon a resolution of the dispute following the input of the BCC, the disputing Parties will meet and confer to determine if other alternative dispute resolution methods are agreeable, including voluntary non-binding mediation, which may include the Department of Water Resources dispute resolution process, arbitration, or appointment of a panel of technical experts prior to commencement of any legal action. The cost of alternative dispute resolution shall be paid in equal proportion among the Parties to the dispute, otherwise the Parties shall bear their own costs. Upon completion of alternative dispute resolution, if any, and if the controversy has not been resolved, any Party may exercise any and all rights to bring a legal action relating to the dispute.

11.2 Litigation

In the event a dispute or claim is not resolved by a mutually agreeable settlement through informal negotiation or voluntary mediation, the aggrieved Party may file suit in a County Superior Court with jurisdiction to provide a binding decision on the matter.

From: Michael Maley, Todd Groundwater
Charles Brush, Hydrolytics LLC

Re: **SGMA Water Budget Development using C2VSimFG-Kern in support of the Kern County Subbasin Groundwater Sustainability Plans (GSPs)**

1. INTRODUCTION

In compliance with the Sustainable Groundwater Management Act (SGMA), the multiple Groundwater Sustainability Agencies (GSAs) of the Kern County Subbasin (**Figure 1**) have successfully coordinated on the development of Groundwater Sustainability Plans (GSPs). The Kern County Subbasin, the largest in the State, was designated as critically-overdrafted by the California Department of Water Resources (DWR). Water management in the Kern County Subbasin is complex. It involves more than 30 water districts/systems, contains large groundwater banking projects of State-wide importance, and provides large quantities of groundwater to support both large urban centers and one of the top agricultural-producing areas in the country. In addition, most agencies are involved in conjunctive management of local surface water, imported state and federal water, and groundwater.

Within this complex water management setting, GSAs recognized that a numerical modeling tool would be needed to meet GSP regulations for assessment of historical, current, and future projected water budgets that are developed on a Subbasin-wide basis (§357.4(b)(3)). The California Central Valley Groundwater-Surface Water Simulation Model (C2VSim) is anticipated to be DWR's primary tool for evaluating water management in the Central Valley and is specifically referenced in the GSP regulations for application to GSP water budgets (§354.18(f)); therefore, C2VSim was selected by the GSAs for GSP compliance.

This technical memorandum describes the process and approach for selection, revisions, and application of the C2VSim to the Kern County Subbasin. The memorandum documents the development of Subbasin water budgets and presents the results. This document is being prepared as an attachment to Subbasin GSPs and as an attachment to the Kern County Subbasin GSAs' coordination agreement.

1.1 Background

During late 2016 and 2017, Subbasin GSAs held a series of meetings and workshops to evaluate potential modeling tools for GSP application. Although numerous existing models had been developed by various entities in the Subbasin over time, none of those models covered the entire Subbasin or incorporated all of the local water budget components necessary to meet GSP requirements.

During the time that the Subbasin was evaluating various modeling alternatives, DWR was in the process of updating the regional C2VSim model through water year (WY) 2015. In particular, the GSP regulations stated that DWR would provide the C2VSim model "for use by Agencies in developing the water budget." Todd Groundwater developed an approach for review, revisions, and application of the C2VSim model to the Kern County Subbasin. In March 2017, the Kern River GSA (KRGSA), on behalf of the Subbasin GSAs, entered into a contract with Todd Groundwater to conduct the proposed scope of work. The Kern Groundwater Authority (KGA), on behalf of the Subbasin GSAs, also retained Woodard & Curran to conduct a peer review of the Todd Groundwater C2VSim model revisions and application for the Kern County Subbasin.

DWR released the C2VSim Fine Grid Public Beta model (C2VSimFG-Beta) on May 18, 2018 (CNRA, 2018). An initial model review indicated that the C2VSimFG-Beta generally had good historical precipitation, streamflow, land use and crop acreage for the entire Central Valley. Historical water supply and demand data were also generally good in the Sacramento Valley and San Joaquin River hydrologic regions; however, data were considered less reliable in the Tulare Lake hydrologic region including Kern County. To address this concern, Todd Groundwater – working with all Subbasin GSAs –revised the Kern County portion of C2VSimFG-Beta for WY1985 to WY2015. This revised version of C2VSim for the Kern County Subbasin, referred to herein as the C2VSimFG-Kern model, was used to develop historical, current and projected-future water budgets in accordance with the requirements in the GSP regulations.

The Central Valley portion of Kern County contains two groundwater subbasins, the Kern County Subbasin (5-022.14) and the White Wolf Subbasin (5-22.18) based on DWR Bulletin 118 (DWR, 2016A). All of the agencies that deliver water in White Wolf Subbasin also deliver water in the Kern County Subbasin and participated in the C2VSim revision. The White Wolf Subbasin portion of C2VSimFG-Beta model was included in this update to ensure coordination of groundwater conditions between the two subbasins. These are considered separate groundwater basins under SGMA with the Kern County Subbasin listed by DWR as critically-overdrafted with a GSP deadline of January 30, 2020, whereas the White Wolf Subbasin is listed as medium priority with a GSP deadline of January 30, 2022. Therefore, only the model results for the Kern County Subbasin are evaluated and reported here.

1.2 General Approach

The current C2VSim model has a detailed finite element mesh that closely follows local hydrologic features. As a regional model, the C2VSimFG-Beta may over-generalize local conditions within the Kern County Subbasin so as to be inconsistent with local site-specific data and knowledge. To address this concern, the managed water supply and demand inputs were updated to better represent the local water balance. To do this, the more general assumptions in C2VSimFG-Beta were replaced with local data and knowledge that are regionally or locally significant over the WY1995 to WY2015 Hydrology Period. Local managed water supply input data (e.g., surface water deliveries, land use, irrigation demand, return flows, and groundwater banking) were collected and applied to C2VSim. Improvement of Kern County data focused on incorporating:

- Surface water delivery volumes, application areas and use by water district,
- Groundwater banking recharge, recovery and application of recovered water,
- Irrigation demand from recent analyses of remote sensing data of evapotranspiration in the Kern County Subbasin based (ITRC, 2017),
- Urban demand for the Subbasin focusing on Metropolitan Bakersfield, and
- Data on other water sources and demands of local significance to individual districts/GSAs.

Compiling the data needed for the model revision required a coordinated effort from the Subbasin GSAs (**Figure 1**) to provide locally derived data on managed water supply and demand that was used to revise the C2VSimFG-Beta for the Kern County Subbasin. The Subbasin GSAs also coordinated on selection of consistent study periods for the C2VSimFG-Kern water budget analyses. Based on technical considerations and a review of regional data, the following study periods were selected:

- Historical Water Budget - WY1995 through WY2014 (Section 3.2), and
- Current Water Budget - WY2015 (Section 3.2),
- Projected Water Budget - WY2021 through WY2070 using 50 years of hydrologic data based on historical data (Section 6.1).

Todd Groundwater also coordinated data collection and model revision efforts with a Technical Peer Review Team and local agencies to ensure input data were accurately represented in the model. Tabulated input data, model files and model-derived water budgets were provided to the Technical Peer Review Team for review of accuracy and appropriateness. Model input data and results were also provided to Kern County Subbasin water districts and local water purveyors for their review. Comments and data issues were reconciled and incorporated into the revised C2VSimFG-Kern model.

1.3 Acknowledgements

These regional model revisions were enhanced by the participation of the many agencies that provided local water budget input data. Todd Groundwater worked with the member agencies, and their consultants, including the Kern River GSA, Kern Groundwater Authority GSA, Henry Miller Water District GSA, Olcese Water District GSA, and Buena Vista GSA to coordinate acquisition of input data from other agencies in formats that could be easily incorporated into the C2VSim model. On-going review of interim model results by these agencies, including local zonal water budgets, groundwater hydrographs and other model results, helped ensure that the revised model reproduced local mass balance estimates across the Subbasin.

Woodard & Curran conducted an on-going peer review of model input files at the request of the GSAs in the Kern County Subbasin. Todd Groundwater worked with Woodard & Curran throughout the historical model revision process. The C2VSimFG-Kern input files for the Kern County Subbasin revised historical simulation were provided to DWR for incorporation into future C2VSim public releases.

Dr. Charles Brush of Hydrolytics LLC was added to the Todd Groundwater modeling team. As an early developer of C2VSim for DWR, he provided his experience and expertise with the C2VSim. This collaborative effort provided further assurance that the significant model revisions could be managed in an efficient manner to meet the expedited schedule for water budget development.

2. C2VSIM

C2VSim uses DWR's modeling code *Integrated Water Flow Model* (IWFM) and covers the entire California Central Valley. Kern County is located at the far southern end of the Central Valley (**Figure 2**). C2VSim simulates the full hydrologic cycle, calculating water demands and tracking water movement through surface water and groundwater systems, and is therefore well suited to support GSP development.

2.1 C2VSim Background

DWR developed C2VSim to simulate water demands and supplies in the Central Valley. C2VSim is an application of DWR's IWFM software. IWFM is an integrated hydrologic model that simulates water flows on the linked land surface, unsaturated zone, groundwater, and surface water flow systems. A key feature of IWFM is DWR's agricultural and urban water supply and demand management module that dynamically simulates the delivery of both surface water and groundwater supplies based on both water availability and calculated water demands, as affected by usage and climatic conditions.

The C2VSim is derived from a series of Central Valley hydrologic models developed by DWR and other agencies beginning in the early 1990s. Each model in this series has incorporated significant improvements over the previous version (Brush, Dogrul and Kadir, 2013). The groundwater flow system is modeled in IWFM using the finite element method and uses a highly efficient solver developed at UC Davis. The IWFM Demand Calculator (IDC) and land surface simulation process were developed with input from California irrigation management professionals. Given DWR's emphasis on water management, detailed water budgets produced by C2VSim provide strong representations of the surface water and groundwater flow systems and make it a preferred platform for developing water budgets.

2.2 C2VSImFG-Beta Model

DWR's 2018 release of C2VSimFG-Beta includes historical input data for WY1922 to WY2015. C2VSimFG-Beta includes historical precipitation, stream inflow, land use and crop acreage for the entire Central Valley. These data include monthly precipitation and annual land use for each model element and estimated monthly evapotranspiration for each modeled land use type and agricultural crop. Historical surface water data include monthly surface water inflow for each river entering the model boundary and monthly surface water diversions and deliveries.

The C2VSimFG-Beta finite element grid divides the Central Valley into 32,537 model elements (**Figure 2**). Element areas are small near streams and in developed areas and expand to larger sizes in undeveloped areas. Element sizes average 407 acres and range from 4 to 1,770 acres. Central Valley rivers and streams are represented with a network of 110 stream reaches. Surface water and groundwater inflows from uplands along the model boundary are simulated with 1,033 small watersheds. Within the Kern County Subbasin, the land surface elevation varies from 208 feet above mean sea level (msl) in the north to 3,922 feet above msl in the foothills.

The groundwater aquifer system is represented with four aquifer layers and one regional confining layer. The aquifer thickness in the Kern County Subbasin varies from 857 to 9,054 feet and the deepest aquifer location is 8,752 feet below msl. The Central Valley aquifer is simulated with the following hydrostratigraphic layers, listed from top to bottom:

- Shallow, unconfined aquifer,
- Regional confining layer,
- Active confined aquifer (contains high level of pumping),
- Inactive confined aquifer (contains limited pumping), and
- Saline confined aquifer.

C2VSimFG-Beta includes annual land use and crop acreages and monthly precipitation, evapotranspiration, stream inflows, surface water deliveries and specified groundwater pumping rates for WY1922 to WY2015. C2VSimFG-Beta uses IDC to dynamically calculate distributed monthly water demands, allocate available water supplies to meet these demands, and calculate unmetered groundwater pumping necessary to satisfy unmet demands. C2VSimFG-Beta produces detailed monthly water budgets for arbitrary sets of elements grouped into zones.

Water demands are calculated dynamically for each model element using the IWFM Demand Calculator (IDC) for agricultural, urban, native and riparian land use types. Agricultural demand is calculated based on annual crop type distribution mapping and user-specified evapotranspiration rates for 20 irrigated crop types and managed seasonal wetlands at the Kern National Wildlife Refuge. Agricultural water demand is determined based on a soil moisture balance that uses local soil properties to assess the amount of applied water (precipitation and specified surface water applications) available to meet the crop demand. If water demands in an element are not satisfied from these sources, the C2VSim model calculates the groundwater pumping needed to eliminate any deficit.

Urban demands are calculated based on population and per-capita water demands. Water demands for native, undeveloped, fallow or riparian settings are calculated from monthly evapotranspiration rates and the amount of precipitation. If water demands in an element are not satisfied, no applied water is provided to these areas, and the vegetation is assumed to be in a stressed state. Runoff of precipitation in developed and undeveloped areas within the Subbasin and surrounding small watersheds is calculated using methodology included in IWFM that is based on the Soil Conservation Service Curve Method (NRCS, 2004).

C2VSimFG-Beta was released after a preliminary model calibration. The distribution of aquifer parameters was based on a texture analysis of lithologic well logs compiled by the US Geological Survey (USGS, 2009) from Well Completion Reports submitted to DWR by well drillers. The texture analysis interpolated the percentage of coarse-grained material at each well location and depth of the C2VSimFG-Beta mesh. Aquifer parameters were then calculated for the model mesh based on the percentage of coarse-grained material and estimated properties for pure coarse- and fine-grained materials. Transmissivities were estimated using specific capacity tests, where available. Soil properties for each model element were derived from digitized soil maps published by the US Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS, 2018).

3. KERN COUNTY REVISIONS

C2VSimFG-Beta input files were revised to incorporate locally-derived managed water supply and demand data to better represent the local water budgets for the Kern County Subbasin. Additional revisions were made to C2VSimFG-Beta model to address issues that were identified with the physical representation of the Kern County Subbasin. The result of these Kern County specific modifications is a local version of C2VSimFG-Beta that is referred to here as C2VSimFG-Kern. The following provides a summary of the model modifications.

3.1 C2VSimFG-Kern Model

C2VSimFG-Kern input files incorporate locally-derived historical data for the Kern County and White Wolf subbasins to better represent local water conditions. These are two separate groundwater subbasins in the Kern County portion of the San Joaquin Groundwater Basin. The Kern County Subbasin is listed as critically-overdrafted by DWR with a GSP deadline of January 30, 2020, whereas the White Wolf Subbasin is listed as medium priority by DWR with a GSP deadline of January 30, 2022. C2VSimFG-Kern was not changed for areas outside of the Kern County Subbasin.

Historical surface water diversion, water bank recharge and water bank withdrawal information were collected from local GSAs, management areas, water agencies and purveyors. Urban land use was restricted to developed areas, and urban populations and per-capita water demands were updated. Model structure (elements, streams, stratigraphy, etc.) was not modified. Model parameters were not calibrated, although some model parameters were adjusted to improve model performance in specific geographic areas.

3.2 Simulation Time Period

GSP requirements indicate a need to identify an average hydrologic study period for purposes of the groundwater analyses in the basin-wide water budgets. In order to select a consistent study period, the Kern County Subbasin GSAs agreed upon an historical hydrologic study period covering WY1995 through WY2014 (October 1, 1994 through September 30, 2014). The selection of the historical hydrologic study period was based on a variety of technical criteria including:

- Covers at least 10 years consistent with GSP regulations (§354.18(c)(2)(B)),
- Contains 10 years characterized as above normal or wet years based on precipitation; also contains 10 years of below normal or dry years, including four critically dry years,
- 100 percent of the long-term average streamflow conditions on the Kern River, as indicated by an average annual Kern River Index of 100 percent (**Figure 4**),
- About 104 percent of long-term average precipitation (NOAA Bakersfield Meadows Field Airport Station),
- Widely-available high-quality data available across the Subbasin,
- Time period with current water management practices, intensive groundwater banking operations, and more recent land use patterns,
- Begins in a time of relatively stable water levels (October 1994), and
- Overlaps a time period with consistently developed basin-wide contour maps by Kern County Water Agency (KCWA).

For the historical water budget, it is desirable to define a base period when natural hydrology represents average conditions. C2VSimFG-Kern incorporates this 20-year base period of WY1995 through WY2014 with a 10-year spin-up period (WY1985 to WY1994).

Kern County water agencies provided locally-derived water budget data for WY1993 to WY2015 for this study so that data input extended beyond the historical base period. Additional water budget data prior to WY1993 were also collected where available and input into the model.

The simulation period for C2VSimFG-Kern was set to WY1986 to WY2015 (October 1, 1985 through September 30, 2015), allowing a 10-year spin-before the start of the historical base period. The C2VSimFG-Beta simulation period ran from October 1973 through September 2015 (WY1974 to WY2015). The period from October 1973 to September 1985 was not included in the simulation due to concerns about lack of comparable data from these earlier periods.

3.3 Data Compilation

Participating agencies compiled water budget input data sets (using their staff, consultants or other resources) and provided them to Todd Groundwater. Where appropriate, Todd Groundwater developed data templates that conformed to IWFM model data needs and used them to facilitate obtaining input data from local agencies. This included monthly data for the following:

- Surface water imports and diversions (inflows and outflows) by source, conveyance and application area,
- Groundwater banking and managed aquifer recharge by water district or agency,
- Groundwater recovery pumping of groundwater bank recharge for export from the basin,
- Groundwater recovery pumping of managed aquifer recharge for local use,
- Urban area population and per capita water use, and
- Crop evapotranspiration (ET) rates based an analysis of satellite data (ITRC, 2017).

In addition, groundwater banking data were compiled for the large Kern Fan banking projects. Recently developed crop ET rates derived from remote sensing data were used to develop monthly crop ET rates for agricultural crops. Urban land use was restricted to developed areas, urban populations and per-capita water demands were updated, and urban wastewater recharge operations were added.

3.4 Surface Water

Kern County surface water diversions in C2VSimFG-Beta were grouped by project or water source, and some surface water deliveries were applied to large regions rather than to individual districts. In addition, some local surface water deliveries were missing from C2VSimFG-Beta. For C2VSimFG-Kern, the 43 Kern County surface water diversions from C2VSimFG-Beta were replaced with 113 surface water diversions developed with data provided by local agencies.

The Arvin-Edison WSD, Wheeler Ridge-Maricopa WSD and Tejon-Castaic WD overlie both the Kern County and White Wolf subbasins. Surface water deliveries for these districts were apportioned to either the Kern County and White Wolf subbasins, based on data provided by Arvin-Edison WSD and Wheeler Ridge-Maricopa WSD, so that surface water deliveries to those areas could be tracked separately for the water budgets.

3.4.1 River and Stream Inflow

Inflows to the Kern River and Poso Creek at the Subbasin boundary are based on historical gauge data. Kern River inflows at the First Point gauge and downstream gauges were verified and updated based on the annual Kern River Hydrographic Reports produced by the City of Bakersfield (COB, 1985-2015). C2VSimFG-Beta contained Poso Creek inflows for WY1961 to WY1986. Poso Creek inflows for WY1987 to WY2015, based from flow records for the Coffee Canyon and Trenton stream gauges, were added to C2VSimFG-Kern based on data provided by the local agencies.

3.4.2 Surface Water Diversions

Monthly surface water diversion data for WY1995 to WY2015 were collected for 21 agencies and recharge projects in Kern County. The data from each water district or agency included monthly surface water inflow by source and monthly surface water outflow by destination.

The monthly surface water inflow and outflow data collected for this study did not have sufficient detail to track this water and create an accurate historical water budget for each canal for each month. The data did provide sufficient information to identify monthly surface water diversions from each source and deliveries to each end use. Therefore,

- All diversions from the Kern River were exported from the model and treated as imports at delivery locations,
- Diversions from Poso Creek and the Kern River Flood Channel (or Main Drain) were diverted from the appropriate stream nodes, and
- All other surface water deliveries (State Water Project (SWP), Central Valley Project (CVP), oil field recovery water, etc.) were treated as imports.

Each C2VSim surface water diversion is linked to two groups of model elements: the elements of the end use and the elements receiving the recoverable losses. A single set of elements was used for both purposes in C2VSimFG-Kern. Model elements for agricultural, urban and refuge deliveries were selected by overlaying the model grid on delivery areas maps. Model elements for recharge diversions were selected by overlaying the model grid on recharge basin maps.

Monthly water delivery data for the SWP, CVP and Kern River were also provided by the agencies. Monthly turnout-level deliveries for the SWP were also compiled from the monthly SWP Report of Operations published by DWR. Monthly CVP deliveries were compiled from the USBR Report of Operations. Monthly Kern River flow and diversions were compiled from Kern River Hydrographic Reports. Water agencies in the Kern County Subbasin trade and wheel water in real time to maximize water utilization, minimize waste and energy consumption, and meet immediate water needs. Water delivery reports from water suppliers (such as the CVP and SWP) generally identify the owner of delivered water, not where it was actually delivered.

Some surface water conveyances discharge water into stream or river channels for re-diversion downstream. A key part of the surface water system in Kern County is the Kern River. Kern River operations data were reviewed for calendar years 1970 to 2015. While **Table 1** summarizes surface water deliveries, **Table 2** summarizes Kern River diversions by turnout location as applied in C2VSimFG-Kern.

3.4.3 Surface Water Deliveries

Water flow through the Kern River and its associated canal system is very complex. Water is diverted from the Kern River into a parallel canal system at several locations, with some diverted water flowing

back to the river. Some water from the CVP and SWP are discharged into the Kern River for diversion downstream. Some water agencies are served from multiple diversion points along the Kern River. Several canals that receive water diverted from the Kern River also exchange water with other canals and receive some water from groundwater pump-in, so deliveries from many canals cannot be attributed to a single source. **Figure 5** shows the locations of the primary streams, regional surface water canals, and groundwater recharge locations in the Kern County Subbasin.

Each surface water diversion in C2VSim is allocated to a specified destination and water use. Five water use types are simulated in C2VSimFG-Kern: agricultural, urban, refuge, recharge and export. Agricultural and refuge diversions are applied to a group of model elements that corresponds to a surface water service area within a specific water agency or refuge. Urban diversions are allocated to an urban service area. Groundwater recharge diversions are allocated to the model element or elements where the receiving recharge basin is located. Three delivery fractions apportion each surface water diversion to application, loss to groundwater (recoverable loss), and loss to evaporation (non-recoverable loss). **Table 1** summarizes the annual surface water deliveries for agricultural use by water district in Kern County. **Table 3** summarizes surface water diversions for urban use, wastewater land disposal and wildlife refuge management in Kern County.

3.5 Groundwater Banking and Managed Aquifer Recharge Operations

In our preliminary discussions with the C2VSim developers at DWR, it was revealed that significant model uncertainty was related to incomplete data regarding groundwater banking and other managed aquifer recharge (MAR) operations in the Kern County Subbasin. Recognizing the importance of these groundwater banking projects for simulating groundwater conditions, the groundwater banking and MAR operations data was updated using the earliest available records.

3.5.1 Recharge and Recovery Data

A monthly time-series of recharge rates was determined for each recharge project. Recharge rates were allocated to individual recharge basins using the initial data whenever possible or were shared proportionally between basins based on historical rates. All Kern County recharge basin surface water deliveries were simulated as imports.

Recharge basin locations and recovery well locations were provided by each agency or project (**Figure 6**). The C2VSim finite element grid was overlaid onto a map of recharge basins to determine the model elements for each recharge location. Well location coordinates were added to C2VSimFG-Kern.

Monthly volumes for recharge at groundwater banking and managed aquifer recharge facilities were compiled for 16 agencies and projects (**Table 4**). This information originated from multiple sources, and included data provided by agencies, compiled from agency reports, and compiled from Kern River Hydrographic Reports. The data includes monthly recharge for years prior to 1995 for many projects. Several agencies and projects provided data for multiple recharge basins. Some groundwater wells used for recovery of banked water are also used for other purposes such as supplementing agricultural or urban surface water deliveries.

Recognizing that several of the large groundwater banking projects (especially those on the Kern Fan) pre-date the 20-year base period, and that future studies might simulate periods prior to 1985, all available historical data for groundwater banking operations was reviewed and updated. This included incorporating pre-1985 data for banking operations at

- Arvin-Edison WSD (1966-2015),
- Berrenda Mesa Project (1977-2015),
- Buena Vista WSD (1963-2015),
- City of Bakersfield 2800 Recharge Facilities (1973-2015),
- North Kern WSD (1956-2017), and
- Rosedale-Rio Bravo WSD (1980-2015).

3.5.2 Groundwater Recovery

Two types of recovery wells were added to the C2VSimFG-Kern. These include district-operated water wells that were used for out-of-district transfers or out-of-basin exports of groundwater, and wells used for recovering banked groundwater and distributing the pumped groundwater via the district's water conveyance system to provide water supply, typically for agricultural use, within the district. The locations of the specified groundwater recovery wells are shown on **Figure 6**. The specified groundwater recovery pumping input into C2VSimFG-Kern is summarized as follows:

- 229 time series for Kern County groundwater banking withdrawals were added,
- 313 simulated pumping wells and 225 pumping time series for local groundwater pumping by district-operated recovery wells were added, and
- Elemental agricultural, refuge and urban pumping was eliminated in areas where it has not historically occurred.

Recharge and withdrawal data for the Kern Fan banking projects, including the Kern Water Bank, Berrenda Mesa Project, Pioneer Project, and the City of Bakersfield 2800 Recharge Facilities were shared with the local banking authorities for verification. Banking data for district-specific groundwater banking projects were provided by these districts. A summary of the data input for groundwater recovery pumpage added to C2VSimFG-Kern is provided in **Table 5**.

3.5.3 Model Application

A separate diversion was created to deliver surface water to each recharge basin or set of geographically close jointly managed basins. A diversion time series of monthly application rates was then created for each recharge diversion from the available data. Each recharge diversion delivers water to the model elements coinciding with the receiving recharge basin(s). Recharge basins were simulated in C2VSimFG-Kern by setting the application delivery fraction to zero, the recoverable loss fraction to 94% and the evaporation loss to 6%.

Monthly groundwater recovery was generally provided by well field and destination (e.g., agriculture, urban, canal pump-in, or export). This information was used to develop a pumping time series for each well field and destination. Groundwater pumped for export from the Kern County Subbasin is summarized in **Table 6**. Recovery well locations and screen intervals were used to enter each recovery well into C2VSimFG-Kern. Recovery pumping time series were then allocated equally to all of the wells in each field.

Some well fields supply water to two different end uses, for example supplementing surface water deliveries within the district in some months and exporting water from the district in other months. This is handled in C2VSimFG-Kern by entering the well two times. Each entry is associated with a separate time series of pumping rates and delivery destination.

3.5.4 Groundwater Banking Obligations

The general operation of groundwater banking facilities is to recharge excess available surface water supplies during wet years by recharging to the groundwater and recovering this water by pumping in dry years when surface water supplies are limited. Groundwater banking programs store water in the Kern County Subbasin for use by local agencies and for export to out-of-basin entities.

For evaluating the groundwater sustainability, any water stored in the Kern County Subbasin that is contractually obligated to an out-of-basin entity does not contribute to the long-term groundwater sustainability because the owner of that water could call for its return at any time. However, this can be difficult to track because a common practice is to recover groundwater for local use to replace imported surface water that was sent to the out-of-basin entity.

C2VSimFG-Kern does not have a mechanism to track these complex contractual exchanges, so the tracking is done as a post processing step by assigning the portion of the groundwater recharge as an out-of-basin banking obligation.

The Kern County Subbasin GSAs provided the total out-of-basin banking obligation for their operations as of September 2014 for the historical assessment. As of September 2014, the out-of-basin banking obligation for the Kern County Subbasin totaled of 1,719,307 acre-feet, which, when averaged over the 20-year period, was 85,965 acre-feet per year (AFY). The 85,965 AFY is applied during post-processing of C2VSimFG-Kern historical water budget results.

3.6 Urban Water Demand

C2VSim calculates urban water demands for specified urban delivery zones, allocates specified surface water and groundwater supplies to meet these demands, and can optionally pump additional groundwater to satisfy unmet urban demands in each zone. Urban demands were represented with nine urban zones in C2VSimFG-Beta. These zones were reconfigured, and a tenth urban zone was added representing Metropolitan Bakersfield in C2VSimFG-Kern. Historical urban populations and per capita water use rates were reviewed and updated.

3.6.1 Urban Zones

C2VSimFG-Kern dynamically calculates urban water demands for urban zones using time-series data of urban populations and monthly per capita water use. The urban delivery zones of C2VSimFG-Beta were modified to better represent Kern County population centers, jurisdictional boundaries and urban water sources. Although Kern County urban water delivery systems are operated by many diverse entities, their water generally comes from two sources: surface water deliveries and agency-operated groundwater wells.

The nine Kern County urban zones in C2VSimFG-Beta for Kern County were numbered 97-105. The Urban Zone boundaries were adjusted, as shown on **Figure 7**, as follows:

- Portions of Urban Zones 97, 99, 100, and 102 in C2VSimFG-Beta were used to create Urban Zone 106 representing the Metropolitan Bakersfield area,
- Urban Zone 98 was extended southeast to near the Stockdale Highway to include unincorporated urban areas,
- The boundary of Urban Zone 99 was extended eastward to California State Route 65 to include small communities in this area, removing them from Urban Zone 100, and

- The northern boundary of Urban Zone 104 was moved north to correspond to the West Kern WD service area.

3.6.2 Urban Population and Per Capita Use

Historical annual urban populations for the urban zones were estimated using United States Census total population data from 1990, 2000 and 2010 (US Department of Commerce, 2018). Tabular historical census data and census block shapefiles were obtained from the IPUMS National Historical Geographic Information System Database (IPUMS 2018). These data were combined to produce maps of the geographic distributions of populations within Kern County. The historical populations for each Urban Zone were estimated by mapping census block centroids to the ten Urban Zones using ArcGIS. The 1990, 2000 and 2010 populations of each Urban Zone were then estimated as the sum of the populations of the associated census blocks. Populations for other years were estimated using interpolation and extrapolation. The population values by Urban Zone used for C2VSimFG-Kern are listed in **Table 7**.

3.6.3 Urban Water Use Specifications

Monthly historical urban water demands for Urban Zone 106 were calculated using water delivery data from the water purveyors in the Metropolitan Bakersfield area. Monthly historical urban water demands for the other urban zones in the Kern County Subbasin were estimated using available water use data from published urban water management plans for the communities served in those zones. The historical monthly water use in each zone was then divided by the historical population to obtain the monthly per capita urban water demand. Monthly historical per capita water demands for zones without urban water management data were estimated using the per capita water demand from zones with similar demographics.

The urban water use specifications indicate the portion of total urban water that is used indoors. In C2VSimFG-Kern, the portion used indoors becomes urban return flow, and the remainder is added to the urban root zone where it contributes to evapotranspiration and deep percolation. C2VSimFG-Beta included monthly urban water use specifications for each model subregion. The urban per capita water use was based on local water supply data and urban water management plans. **Table 8** lists the per capita water use data used for C2VSimFG-Kern.

3.6.4 Urban Wastewater

Urban wastewater for the Metropolitan Bakersfield area is treated at local wastewater treatment plants; however, wastewater disposal is primarily evaporation ponds or land disposal at locations outside of the Metropolitan Bakersfield area. C2VSimFG-Beta does not have a direct means to redirect wastewater to an outside location. Urban wastewater, based as the indoor use, is applied uniformly within the urban zone. To get around this limitation, application of wastewater for the Metropolitan Bakersfield area was turned off in C2VSimFG-Kern. The wastewater deliveries to evaporation ponds and land disposal areas from the wastewater treatment plants was assigned to the appropriate location using data provided by the plants. This conserved the water balance by not double counting wastewater, and it was applied at the appropriate locations for evaluating groundwater levels.

3.6.5 Model Application

Historical annual urban population estimates were placed in the C2VSimFG-Kern urban population input file. Historical monthly urban per capita water demand estimates for each urban zone were placed in the C2VSimFG-Kern urban per capita water use file. Urban demand was calculated by C2VSimFG-Kern and the water supply to meet these demands was met first by specified surface water and groundwater

pumping deliveries for urban use. The remaining water demand in each model element was met with groundwater pumped from the aquifer portion of that element.

3.7 Agricultural Crop Water Demand

C2VSim dynamically calculates agricultural crop water demands and allocates supplies to meet these demands for each model element. Agricultural demands are calculated for 20 crops using historical crop acreage data and crop evapotranspiration (ETc) rates. Crop water demands in each model element are first met with stored soil moisture, surface water deliveries and specified groundwater deliveries. If the agricultural demands are not satisfied, the model can optionally calculate the additional groundwater pumping required to satisfy the unmet demands and extract that water from the groundwater component of the model element.

C2VSimFG-Beta contained one set of monthly ETc rates for each model subregion that were applied to all years despite climatic variation. New monthly ETc rates for three model subregions (northeast, northwest, south) in Kern County were calculated for 1993-2015 using monthly remote sensing imagery and detailed annual crop maps. ETc for 1974-1992 were estimated from 1993-2015 values by using the values for similar water year types based on the San Joaquin Index. Satellite data were not available for 2012, so ITRC was unable to provide METRIC data for 2012. In C2VSimFG-Kern, 2013 was applied as an appropriate proxy for ETc data in 2012 because of their hydrologic similarity.

A remote sensing study of historical ETc rates across the entire Kern County Subbasin by the Irrigation and Training Research Center (ITRC, 2017) provided detailed basin-wide agricultural demands that corresponded to the WY1995 to WY2014 base period. These data were used to develop monthly ETc rates for the Kern County portion of the model.

3.7.1 ET Rates

The Irrigation Training and Research Center (ITRC) at California Polytechnic State University, San Luis Obispo, has developed a procedure to use remote sensing imagery from Landsat satellites to calculate historic ETc rates (ITRC, 2017). The Mapping of Evapotranspiration with Internal Calibration (METRIC) method was originally developed by Richard Allen of the University of Idaho. ITRC made several modifications to the original METRIC method to better match California data and conditions (named the ITRC-METRIC method). These modifications include using grass for reference evapotranspiration (ETo), incorporating a semi-automated calibration procedure and spatially interpolating ETo rates. An example of the METRIC ET data for the total annual ET in 2013 is provided in **Figure 8**.

ITRC used Landsat imagery for 1994-2015 (except 2012 when no imagery was available) and the ITRC-METRIC method to develop monthly raster maps of ETc at 30 x 30-meter resolution for the Kern County portion of the Central Valley (ITRC, 2017). The monthly ETc raster maps were used with annual DWR crop maps to calculate the average ETc by crop type for the three Kern County C2VSim subregions. ITRC-METRIC raster data were used to determine the exact areas of applied irrigation and total annual ETc. A raster pixel was assumed to be irrigated if the total annual ETc was greater than 20 inches.

The following data processing steps were used to determine monthly ETc rates for each crop and C2VSim subregion:

- Create irrigation coverages – ITRC-METRIC monthly ETc raster data were summed to calculate total annual ETc for each year for each raster location. The ArcGIS Reclassify tool was then used on each annual ETc raster to create a binary polygon coverage for each year for 1994-2015

(except 2012), setting the attribute "IRR" to 1 if total annual ETc was over 20 in/year, and to 0 if total annual ETc was equal to or less than 20 in/year.

- Create land use coverages – Annual DWR land use rasters were converted to polygon coverages with the attribute "Crop" set to the corresponding integer crop value used in C2VSimFG-Kern. The land use rasters were checked against GIS maps produced by the Kern County Agricultural Commissioner and errors in the DWR land use rasters were corrected. DWR land use maps for 1994-1997 were missing large areas of data, so the 1998 land use map was used to approximate the land use for 1994-1997.
- Create monthly zone maps – One zone shapefile was created for each month by using the ArcGIS Union tool to combine a shapefile of the three C2VSim subregions with the irrigation coverage (produced in step 1) and the land use coverage (produced in step 2). Each monthly zone polygon shapefile has three attributes: C2VSim subregion, binary irrigation indicator, and a land use crop value. The dissolve function was used to combine zones with identical parameters.
- Calculate average monthly ETc for each zone – The ArcGIS Zonal Statistics by Table tool was used to calculate the average ETc value for each zone for each month. The individual pixels in each monthly ETc raster were averaged within each zone (produced in step 3). ITRC-METRIC data for 2013 were used in place of missing data for 2012.
- Combine tables – The MS Access Append function was used to combine the monthly ETc tables into a master table of monthly ETc by crop and C2VSim subregion.
- Output data – Data from the Access database was exported in a form consistent with the C2VSimFG-Kern input files. The output was also summarized to show the average monthly ETc for the irrigated area of each crop type in each model subregion.

The monthly ETc rates for the three Kern County subregions for WY 1993-2015 were then replaced with the monthly ETc rates calculated using ITRC-METRIC data. The annual ETc rates applied to C2VSimFG-Kern by crop are listed in **Table 9**.

3.7.2 Irrigation Periods

The C2VSim Irrigation Periods file contains monthly parameters for each crop and subregion that indicate whether or not the crop is irrigated in that month. C2VSimFG-Beta irrigation periods for the three Kern County subregions were adjusted to match crop irrigation practices from ITRC-METRIC water usage. Refuge irrigation periods for the three Kern County subregions were also adjusted to match Kern NWR practices. Simulated irrigation water usage for the C2VSimFG-Kern better reflects observed irrigation practices.

3.8 Model Modifications

In general, the scope of work was to revise the managed water supply and demand for the Kern County Subbasin. During the course of this revision, several issues were identified with the hydrogeological conceptual model and simulation parameters that affected the historical water budget. The following summarizes modifications made in C2VSimFG-Kern to improve the model performance. Other issues identified regarding the hydrogeological conceptual model, model setup and simulation parameters that were not addressed in C2VSimFG-Kern but are recommended to be modified for future model updates, are listed in Section 8.5. A summary of the changes that were made in C2VSimFG-Kern are provided below.

3.8.1 Streambed Parameters

In the Kern County Subbasin, the Kern River and Poso Creek are the two largest streams. Both have multiple stream gauges along their courses including ones near where they enter the Kern County Subbasin from the Sierra Nevada. These are the only two streams that are simulated in the model using the IWFM stream module. Both are predominantly losing streams where surface water recharges groundwater, except during limited periods near the major groundwater banking operations west of Bakersfield when multi-year periods of recharge operations produce high groundwater levels.

As a part of the C2VSimFG-Kern update, the simulated recharge from the Kern River and Poso Creek were compared to changes in stream gauge measurements and estimated streambed losses to evaluate how well the model was simulating streambed seepage. For much of the Kern River, the amount of streambed seepage is estimated based on daily weir information and is documented in the annual Kern River Hydrographic Reports. The streambed parameters used in C2VSimFG-Beta were not providing a comparable volume and distribution of seepage along the Kern River streambed. In dry years, streamflow as not getting far enough downstream whereas in wet years the seepage was too low. Similarly, the Poso Creek streambed seepage showed similar issues based on comparisons to differences in stream gauge data along its course.

To address this, the Kern River and Poso Creek streambed parameters were manually modified until a reasonable approximation of the measured streambed seepage was achieved by C2VSimFG-Kern. In general, the streambed conductance was lowered whereas the stream wetted perimeter was increased. This provided the best balance in matching the measured dry, average and wet years flows in both streams.

Part of this issue is that C2VSimFG-Beta uses a simple form of the stream module in the simulation. This approach appears to work sufficiently well for the continuously flowing streams in the northern parts of the Central Valley but is not sufficient for simulating the highly variable flows that occur on the Kern River and Poso Creek. It is recommended that future revisions to C2VSimFG-Kern further evaluate issues in simulating streamflow and seepage in the Kern River and Poso Creek (see Section 8.5). This may include incorporating more advanced streamflow simulation features that are available in IWFM but that have not been utilized in C2VSimFG.

3.8.2 Small Watershed Runoff

In reviewing the small watershed contributions, it was determined that the runoff was not representing the variable nature of runoff in an arid region. Although this was not part of the originally planned model revisions, it affected the model results. Todd Groundwater revised the corresponding model parameters to be more representative of the local arid conditions in Kern County.

Runoff of precipitation from the surrounding small watersheds was calculated within C2VSimFG-Kern using methodology included in IWFM that is based on the SCS Curve Method (NRCS, 2004). The C2VSimFG-Beta results showed a steady baseflow that contributed water to the Kern County Subbasin continuously and did not show the appropriate variation in runoff expected between wet, average and dry years in the arid environment.

Two major issues were identified and revised. First, the SCS curve number was changed to allow a higher percentage of runoff in wet years to capture the flashy nature of runoff from these watersheds during differing climatic conditions. Second, IWFM uses a localized soil moisture water budget; however, soil, ET and other parameters were set that allowed for the continuous outflow from the

basins. These were changed to more appropriate values that limited baseflow from the very small watersheds while allowing baseflow from the larger watersheds. Parameters were varied to better match estimated watershed runoff from a local USGS study (Nady and Larragueta, 1983).

3.8.3 Root Zone Parameters

Areas of overly high root zone hydraulic parameters led to high volumes of deep percolation that required additional groundwater pumping to meet the overall water demand for irrigation. This issue was noted by local water district staff who recognized that the groundwater pumping and deep percolation from preliminary model results were significantly higher than what was found in practice. A review found areas of overlying hydraulic conductivity and other hydraulic parameters that caused this high percolation rate. Two types of issues were found. First, very high parameters were found in parts of the basin that were not consistent with local soil data. Second, the root zone parameters for lakebed and other heavy clay soil areas were too high. These areas were manually adjusted to be more in line with observed conditions. A more rigorous development of root zone parameters should be considered in the future as this issue demonstrates that it is a sensitive parameter.

3.8.4 Land Use Modifications

The agricultural land use and crop type distribution in the model for early period (1974-1990 and 1992-1996) from C2VSimFG-Beta used a regional distribution and did not accurately represent historical practices. This resulted in agricultural water use being distributed across the entire Kern County Subbasin including areas that did not have irrigated agriculture. To correct for this, land use and crop type data were modified to conform with irrigated agricultural areas in the early 1990s. The crop types were adjusted to be consistent with the Kern County Agricultural Commissioner reports for these years. This included capturing the appropriate crop types present in the Kern County Subbasin in the periods from 1974 through 1996. For example, there was a higher percentage of cotton produced during that period and a lower percentage of nut trees, which became one of the major crop types in the 2010s.

3.8.5 Westside Pumping Limits

Western Kern County contains large areas with poor groundwater quality. As a result, little or no agricultural or urban groundwater pumping occurs in this area. To simulate this, groundwater pumping was turned off in C2VSim-Kern in most of the area with poor groundwater quality. However, in the Westside District Water Authority Management Area, limited groundwater pumping does occur. The poor-quality water is mixed with surface water to supplement the imported water supply. To simulate this condition, the groundwater pumping rate in the Westside District Water Authority Management Area was estimated to be 10% of the surface water deliveries, and the automated groundwater pumping adjustment in C2VSimFG-Kern was turned off for these areas.

Subsequent to the completion of the historical model, GSP developers in the Westside area refined their estimate of pumping used to mix with delivered surface water to about 3,000 AFY, which is considerably lower than that used in the historical model. The Westside GSP developers included a management action to further refine the estimated groundwater use in the Westside GSP water districts. Therefore, the original assumption was left in this version of the historical model. The Westside District Water Authority Management Area GSP identifies a management action to further evaluate the groundwater pumping in their area. The results of their evaluation will be included in in future model updates.

3.8.6 Kern Wildlife Refuge pumping

C2VSimFG-Beta enabled groundwater pumping in the model elements representing the Kern National Wildlife Refuge. The Kern National Wildlife Refuge Water Management Plan (USBR, 2011) indicates that

during the simulation time period, the refuge was sustained entirely on imported surface water and occasional diversions of Poso Creek flood waters. No groundwater was pumped at the refuge during the simulation period 1985-2015. Groundwater pumping was used at some time in the past. Groundwater pumping and automated groundwater pumping adjustment were turned off for all model elements in the Kern National Wildlife Refuge.

In addition to the Kern National Wildlife Refuge, former rice fields and other areas are currently used for sustaining ponds at private duck hunting clubs in the northwestern portion of the Kern County Subbasin. Water use data for these operations were not available during the development of the historical model. This water includes a combination of surface water and groundwater, and this volume is considered to be very small relative to the overall basin water use. GSP developers included a management action to further refine the estimated water use for these facilities that will be addressed in future updates.

3.9 C2VSimFG-Beta Modifications

Minor changes were made to the C2VSimFG-Kern hydrogeological conceptual model and natural water budget components and are listed in **Table 10**. The architecture of the model including layering, discretization, boundary conditions, and aquifer properties was not revised. Aquifer parameters were adjusted in several areas to better match observed historical conditions, especially in areas with high historic recharge volumes such as the Kern Fan. Extremely high soil hydraulic conductivities in a small set of elements were reduced to more reasonable values. Stream-bed conductance values were modified in some stream reaches to better match simulated stream gains and losses to observed values. Minor adjustments to small watershed parameters were also made to match surface runoff to observed values.

Due to the number of modifications that were identified with the hydrogeological conceptual model and aquifer parameters during the C2VSimFG-Kern update, it is recommended that a more rigorous model update be conducted that will update the hydrogeological conceptual model and aquifer parameters to be consistent with that presented in the Kern County Subbasin GSPs. In addition, further calibration of C2VSimFG-Kern is recommended to update aquifer parameters in the Kern County Subbasin. Future calibration is further discussed in Section 8.5.

4. HISTORICAL AND CURRENT WATER BUDGETS FROM C2VSIMFG-KERN

C2VSimFG-Kern was used to develop historical (WY1995 to WY2014) and current (WY2015) water budgets for the Kern County Subbasin. The following summarizes the simulated water budgets from C2VSimFG-Kern. A summary of these results is provided below.

4.1 Historical and Current Water Budget

The simulated historical and current water budgets based on C2VSimFG-Kern are presented in **Tables 11A** and **11B** and are presented graphically on **Figures 9**. **Figure 10** presents the average annual historical water budget for the Kern County Subbasin. The results for the historical water budget are summarized under the following categories that are defined as:

- **Deep Percolation** – Precipitation and applied water that reaches the groundwater after simulated transport across the unsaturated zone. The simulated historical 20-year average is a net inflow of 669,398 AFY.
- **Managed Recharge and Canal Seepage**- Combined groundwater recharge from managed aquifer recharge operations, groundwater banking, and seepage from canals and other conveyance. The simulated historical 20-year average for Managed Recharge and Canal Seepage is a net inflow of 583,598 AFY. On Figure 10, this total is subdivided between out-of-basin groundwater banking obligations (85,965 AFY) and the remaining local recharge of 497,633 AFY.
- **Net Groundwater-Surface Water (GW/SW) Interactions** - Net volumetric exchange of surface water and groundwater between the aquifer and streams: Positive represents a net groundwater recharge, and negative represents a net groundwater discharge to the stream. The simulated historical 20-year average is a net inflow of 98,606 AFY.
- **Small Watershed Inflow** – Runoff, small stream inflow and subsurface inflow from the small watersheds and areas surrounding the groundwater basin. The simulated historical 20-year average is a net inflow of 48,760 AFY.
- **Groundwater (GW) Pumping** - Total groundwater pumping by wells. Groundwater banking recovery pumping is specified as fixed input values and agricultural and municipal pumping is calculated by C2VSimFG-Kern based on demand minus surface water diversions. The simulated historical 20-year average is a net outflow of 1,590,373 AFY.
- **Subsurface Flow with Adjacent Groundwater (GW) Basins** - Net subsurface groundwater flow to and from the Kern County Subbasin with adjoining groundwater basins: negative is a net flow out of the Subbasin and positive is a net flow into the Subbasin. The simulated historical 20-year average is a net outflow of 87,102 AFY.
- **Change in Groundwater Storage** - Sum of the inflow components (positive numbers) plus the outflow components (negative numbers): positive is an increase in storage typified by a rise in groundwater levels whereas a negative is a decrease in storage typified by a decline in groundwater levels. The simulated historical 20-year average is a decline in groundwater storage of 277,114 AFY.

The simulated change in groundwater storage varies over the 20-year historical period and is closely related to climatic conditions and surface water supply availability (**Figure 11**). During the periods

WY1995 to WY1999, WY2005 to WY2006 and WY2011, the groundwater storage volume was stable to increasing and correlates to the above average rainfall and surface water availability during these times. During the periods WY2000 to WY2004, WY2007 to WY2010 and Y2012 to WY2015, groundwater storage volume decreased, correlated to periods of drought and low surface water availability. The simulated historical groundwater recharge also reflects this climatic pattern with high deep percolation to groundwater and steep increases in managed aquifer recharge and canal seepage during the above average rainfall periods and lower groundwater recharge during the drought years (**Figure 12**).

Groundwater pumping for agriculture shows a general increasing trend from WY1995 to WY2014; however, groundwater pumping is lower in above average rainfall years and higher during droughts (**Figure 13)**. This general increasing trend follows a comparable decreasing trend in surface water deliveries over this same period. As shown on **Figure 14**, surface water deliveries show a general decreasing trend from WY1995 to WY2014; however, the surface water deliveries are higher in the above average rainfall years and lower during the droughts.

4.2 Sustainable Yield

Section 354.18(b)(7) of the GSP Regulations requires that an estimate of the basin's sustainable yield be provided in the GSP (or in the coordination agreement for basins with multiple GSPs). SGMA defines "sustainable yield" as:

> "the maximum quantity of water, calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result."

SGMA does not incorporate sustainable yield estimates directly into sustainable management criteria. Sustainable yield is referenced in SGMA as part of the estimated basinwide water budget and as the outcome of avoiding undesirable results. Basinwide pumping within the sustainable yield estimate is neither a measure of, nor proof of, sustainability. Sustainability under SGMA is only demonstrated by avoiding undesirable results for the six sustainability indicators.

4.2.1 Determination of Sustainable Yield

To determine the sustainable yield for the Kern County Subbasin, the results of the C2VSimFG-Kern model were used with two methods to estimate the amount of groundwater pumping that would avoid the undesirable result of a reduction in groundwater storage over the historical base period 1995 to 2014. The results are shown in **Table 12** and are summarized below:

- **Sustainable Yield from Groundwater Pumping –** The model results produced an average annual groundwater pumping in the Kern County Subbasin of 1,590,373 AFY with a decline in groundwater storage of 277,114 AFY. Subtracting the groundwater storage decline from groundwater pumping produced a sustainable yield of approximately 1,313,000 AFY.

- **Sustainable Yield from Groundwater Recharge –** The model results produced an average annual groundwater recharge in the Kern County Subbasin of 1,400,362 AFY. The subsurface outflow from the GSA was estimated to be 87,102 AFY. Subtracting these outflow losses from the groundwater recharge produced a sustainable yield of approximately 1,313,000 AFY.

Sustainable yield estimates are part of SGMA's required basinwide water budget. In general, the sustainable yield of a basin is the amount of groundwater that can be withdrawn annually without causing undesirable results. This sustainable yield estimate can be helpful for evaluating the projects and programs needed to achieve sustainability. Although the SGMA regulations require a single value of sustainable yield calculated basinwide, it should be noted that the sustainable yield can be changed by implementation of recharge projects, variations in climate, or changes in stream flow conditions.

Using WY1995 to WY2014 as the base period, C2VSimFG-Kern results show declining groundwater levels and long-term reduction of groundwater storage. During this period, average annual inflow to the aquifer is 1,400,362 AFY, and outflow is 1,677,476 AFY (**Table 11A**). This yields an average annual deficit of 277,114 AFY. Based on these historical C2VSimFG-Kern results, the sustainable yield of the basin is approximately 1,313,000 AFY, with an estimated level of uncertainty on the order of plus or minus 10% to 20%.

4.2.2 Native Yield

Although not a SGMA requirement, the native yield is being used by Kern County GSAs for determining a portion of the groundwater allocation within the basin. The native yield is comparable to the sustainable yield except that the only recharge that is included in the calculation is the natural, unallocated portion of the groundwater recharge. For the Kern County Subbasin, this includes the groundwater recharge derived from precipitation and runoff from unallocated streams. The Kern River and Poso Creek, however, are allocated streams where specific agencies or parties have rights to specific volumes of flow.

The C2VSimFG-Kern model results over the historical base period WY1995 to WY2014 was again used for estimation of native yield. The model results were used to determine the amount of precipitation recharge over irrigated agricultural areas and the native/urban/undeveloped areas. The total and average annual volume of precipitation that percolates to groundwater during the WY1995 to WY2014 base period are listed in **Table 13**. The basinwide contribution is the relative proportion of the runoff along the basin margins from small, unallocated watersheds and inflow from the surrounding basin margin (from areas not defined as DWR groundwater basins). The results of this assessment based on the C2VSimFG-Kern results are shown in **Table 13** and are summarized below:

- The volume of precipitation that recharges the groundwater in the irrigated agricultural areas is 77,780 AFY.
- The volume of precipitation that recharges groundwater in the other areas is 132,981 AFY.
- The volume of inflow from unallocated small watersheds that recharges the groundwater in the irrigated agricultural areas is 48,760 AFY.

Totaling these inputs results in a native yield for the Kern County Subbasin of 259,520 AFY. The annual contribution per acre of approximately 0.144 acre-feet per acre is estimated by dividing the average annual contribution by the total area of the Kern County Subbasin (**Table 13**).

Similar to the sustainable yield, the native yield at this time is based on the available data. However, as data gaps are eliminated and management actions/plans are implemented, the native yield could change, and any changes to native yield will be included in future GSP amendments.

4.2.3 Application of Sustainable and Native Yield

In general, the sustainable yield of a basin is the amount of groundwater that can be withdrawn annually without causing undesirable results. The native yield is comparable to the sustainable yield except that the only recharge that is included in the calculation is the natural, unallocated portion of the groundwater recharge. The following estimates of the Kern County Subbasin sustainable and native yields are derived from the C2VSimFG-Kern historical model results for the purpose of supporting GSP assessment of the types and magnitude of projects and programs needed to achieve sustainability.

The C2VSimFG-Kern estimates of sustainable and native yield presented here are based on available data and the current level of model calibration. Therefore, these estimates are considered appropriate as guides to SGMA planning. However, the C2VSimFG-Kern sustainable and native yield estimates are initial water budget estimates that are not intended for determination of individual landowner allocations or groundwater rights. Additional technical and legal analysis, along with stakeholder involvement, is necessary to fully quantify the sustainable and native yields.

5. APPROACH FOR PROJECTED FUTURE WATER BUDGETS

Projected future Baseline water budgets for the Kern County Subbasin were developed using the C2VSimFG-Kern. These projected water budgets establish expected Baseline conditions to evaluate the impacts of GSP implementation. Three predictive scenarios were developed for the Kern County Subbasin, each representing a different expected future hydrologic condition, by adapting C2VSimFG-Kern as follows:

- Future Baseline Conditions: Repeat historical hydrology with expected future water supply,
- 2030 Climate Conditions: Adjust historical hydrology for 2030 climatic conditions and expected water supply, and
- 2070 Climate Conditions: Adjust historical hydrology for 2070 climatic conditions and expected water supply.

Projected future water budgets were developed for Baseline conditions and expected 2030 Climate Conditions and 2070 Climate Conditions over a 50-year planning and implementation horizon. These scenario models provide a basis of comparison for evaluating proposed sustainability management actions and projects over the SGMA planning and implementation horizon.

5.1 Assumptions

C2VSimFG-Kern was modified to incorporate projected future hydrology and land use using analog data from the historical C2VSimFG-Kern model. This approach meets GSP requirements using:

- A 50-year time-series of historical precipitation, evapotranspiration and stream flow information as the future Baseline hydrology conditions,
- The most recent land use, METRIC-based evapotranspiration, crop coefficient and urban population growth information as the Baseline condition for estimating future water demands,
- The most recent water supply projections as the Baseline condition for estimating future surface water supply,

- DWR Climate Change Guidance and Data Sets to incorporate estimated climate change conditions for the Kern County Subbasin,
- Specialized analysis of the Kern River watershed and estimated runoff volumes under climate change conditions,
- Specialized analysis of CVP deliveries to Kern County under climate change conditions incorporating implementation of the San Joaquin River Restoration Program, and
- Specialized analysis of SWP deliveries to Kern County under climate change conditions incorporating implementation of the OCAP Biological Opinion and recent changes in Table A and Article 21 allocations.

5.2 Projected Future SGMA Projects

Projected water budgets for the Kern County Subbasin were developed using the C2VSimFG-Kern to evaluate the performance of proposed management actions with respect to achieving groundwater sustainability. Participating agencies provided a list of projected future management actions to be implemented between WY2021 and WY2040. These projects were simulated under Baseline conditions, 2030 Climate Conditions and 2070 Climate Conditions through WY2070 using the C2VSimFG-Kern.

Proposed future projects and management actions were provided by GSAs. The types of proposed SGMA projects and management actions are summarized as follows:

- Demand Reduction is the volume of water reduced by changing the land use; these include:
    - Agricultural demand reduction projects through incentives or actions to reduce crop water use,
    - Fallowing of agricultural land and conversion of agricultural land to recharge basins, and
    - Conversion of agricultural land to urban land.
- New Supply groups together planned increases in imported water supplies; these include:
    - Increased surface water imports generally resulting from projected water purchases,
    - New water conveyance facilities including pipelines and reservoirs to increase flexibility, and
    - Expansion of surface water delivery areas to reduce groundwater usage.
- Other Supply groups together proposed projects to increase local water supplies; these include:
    - Recharging treated waste waters derived from both urban areas and oil production operations; increased recharge occurs in both existing and new locations,
    - Increased stream flow diversions; these include exercising riparian water rights and diverting flood flows,
    - Reallocation of water; generally reducing sales of surface water and banked groundwater and using this water within the agency, and
    - Brackish groundwater in areas not currently overdrafted will be treated and mixed with surface water to augment surface water supplies.

Some management actions are implemented gradually over many years, with savings increasing each year over the implementation period. Some management actions are implemented only in certain years (wet years, for example). The anticipated average-annual water supply benefit of the proposed SGMA projects and management actions steadily increases over the 20-year period from WY2021 to WY2040 to represent the implementation of the Kern County Subbasin GSPs. This increasing trend, as shown as

the average-annual water supply benefit over five-year increments on **Figure 15**, is summarized as follows:

- about 116,000 AFY over the first five-year period (WY2021-WY2025),
- about 216,000 AFY over the second five-year period (WY2026-WY2030),
- about 343,000 AFY over the third five-year period (WY2031-WY2035), and
- about 361,000 AFY over the fourth five-year period (WY2036-WY2040).

The anticipated water supply benefit of the proposed SGMA projects and management actions included in the C2VSimFG-Kern projected future simulations is 422,000 AFY over the period from WY2041 to WY2070. Benefits of implementing these projects and management actions over the 20-year implementation period are summarized in **Figure 15**.

6. PROJECTED FUTURE BASELINE DEVELOPMENT

Projected water budgets are required by GSP regulations to represent future conditions over a 50-year GSP planning and implementation horizon. A Baseline condition was developed that projects water supply, demand and operations based on current land use and expected water supply availability over 50 years. The Baseline then serves as a basis of comparison for evaluating proposed sustainability management actions and projects for achieving sustainability over the planning and implementation horizon. Each predictive scenario model simulates the 50-year planning and implementation period WY2021 to WY2070. Development of the projected future Baseline conditions is summarized below.

6.1 Projected Future Time Period Development

WY1995 to WY2014 was chosen as a historical hydrology period because detailed demand and supply data are available for this period, and most Subbasin water delivery infrastructure was fully developed by the middle of this period. The average Kern River inflow for this period is also very close to the long-term average Kern River inflow.

The projected future simulation period is based on repeating the WY1995 to WY2014 historical study period. This period is only 20 years long, so a 50-year sequence of historical hydrology was developed by repeating data from this period in the sequence as shown in **Table 14**. The development of this sequence is summarized as follows:

- Simulation period WY2021 to WY2032 used the historical period WY2003 to WY2014,
- Simulation period WY2033 to WY2052 used the historical period WY1995 to WY2014, and
- Simulation period WY2053 to WY2070 used the historical period WY1995 to WY2012.

This sequence was developed to match long-term average flows on the Kern River, and to ensure that the Baseline does not end in an extreme drought or extreme wet year. By starting the projected future simulation time sequence with WY2003, the 50-year hydrology period has approximately 100 percent of the long-term average streamflow conditions on the Kern River, as indicated by an average annual Kern River Index of 100 percent. The sequence includes the appropriate range of hydrologic conditions including extremely wet years and extended periods of drought.

C2VSimFG-Kern simulation results for the last timestep of the historical simulation (September 30, 2015) were used as initial conditions for all projected future simulations, including initial conditions for the root zone, saturated and unsaturated aquifer zones, and small watersheds. Since the historical C2VSimFG-Kern simulation period ends with WY2015, all projected future scenarios also include estimated hydrology for WY2016 to WY2020. Model input data for WY2016 to WY2020 was developed by repeating model input data for recent years based on correlation with the San Joaquin Index (DWR, 2019).

6.2 Development of Key Baseline Data Sets

Key required components for the Projected Future Baseline, as summarized in the DWR *Water Budget Best Management Practices* guidance document (DWR, 2016B) include the following:

- The projected Baseline hydrology conditions were developed using 50-years of historical precipitation and streamflow following the sequence outlined in Section 6.1.
- Surface water supplies are based on available information from DWR and others to project future water imports from the SWP, CVC - Friant-Kern Canal (FKC) and Kern River diversions. For the Kern River, recent diversion practices based on entitlements were used to develop water use consistent with the Baseline hydrology.
- WY2013 land use was used as current land use for all scenarios as drought conditions likely reduced agricultural production in WY2014 and WY2015.
- Consumptive use for agriculture and undeveloped lands was based on the recent land use and METRIC-based evapotranspiration. Following DWR guidance, METRIC data over the Baseline period was varied according to varying hydrologic conditions (e.g., water year type).
- Urban water demand was based on projections from recent urban water management plans to meet regulations for future water use. Urban demand was estimated in the model based on projected urban population growth and per capita water demand information (including recent regulatory guidance).
- Small watershed inflows used the same parameters as the historical C2VSimFG-Kern model; however, volumes varied based on changes in the precipitation and ET under the 2030 and 2070 climate change conditions.

Time-series input data were first developed for the Baseline scenario model for WY2021 to WY2070. Development of this time-series input data generally involved repeating time-series data from the historical C2VSimFG-Kern in the appropriate sequence. The following time-series data were developed for each scenario:

- Precipitation rates,
- Evapotranspiration rates,
- Surface water inflow rates,
- Surface water diversion and delivery rates, and
- Specified groundwater pumping rates.

Baseline scenario model time-series data files were then modified following DWR guidelines to produce time-series input data for the 2030 Climate Conditions and 2070 Climate Conditions scenario models. C2VSim input data were modified only in Kern County. C2VSim input data for areas outside of Kern County were not modified.

The baseline data sets were incorporated into the model files to develop the projected future water demand and supply under Baseline, 2030 Climate and 2070 Climate conditions. A summary of the development of the projected future water demand and supply is discussed below.

6.3 Projected Future Water Demand

The projected future water demand was developed using fixed WY2013 land use areas with historical evapotranspiration rates for the Baseline and modified evapotranspiration rates for the 2030 and 2070 climate scenarios and increasing urban populations.

6.3.1 Agricultural Water Demand

Evapotranspiration rates for the Baseline scenario model were developed by repeating input evapotranspiration rates from C2VSimFG-Kern in the appropriate sequence. DWR provided monthly change factors for ETo values under 2030 and 2070 central tendency climatic conditions on a 6 km x 6 km VIC grid for calendar years 1915 through 2011. The VIC grid IDs for each C2VSim subregion in the Kern County Subbasin Zone of Interest were identified and area weighted monthly ETo change factors were calculated for each subregion. Baseline scenario ETc rates for each subregion were then multiplied by the appropriate area-weighted ETo change factors to produce time-series ETc rates for the 2030 Climate Conditions and 2070 Climate Conditions scenarios. Factors for calendar years 1959-1961 were used as analogs for calendar years 2012-2014.

6.3.2 Urban Water Demand

Urban water demand calculations include an indoor component and an outdoor component. Indoor urban water demands are based on the urban population and monthly per capita water demand. Future urban populations for Kern County urban areas were estimated using California Department of Finance population projections. Future per capita urban water demands were estimated using projections from urban water management plans and California urban water conservation regulations, including SB 606 and AB 1668. Future outdoor urban water demands are based on ETc rates, which were modified as described in the Agricultural Water Demand section above.

6.3.3 Groundwater Banking Recovery

Future groundwater banking recovery rates were developed by repeating historical recovery rates in the appropriate sequence. No adjustments were made to Baseline rates or to rates for 2030 and 2070 climatic conditions.

6.4 Projected Future Water Supply

Projected future precipitation, stream inflow and surface water import time series were developed following DWR guidelines. Baseline future water supplies were developed by repeating historical values in the appropriate sequence. Surface water diversions were then adjusted to account for operational changes. Baseline water supplies were then modified to simulate 2030 and 2070 central tendency climatic conditions.

6.4.1 Precipitation Rates

Precipitation rates for the Baseline scenario model were developed by repeating input precipitation rates from C2VSimFG-Kern in the appropriate sequence. DWR provided monthly change factors for precipitation under 2030 and 2070 central tendency climatic conditions on a 6 km x 6 km VIC grid for calendar years 1915 through 2011. The VIC grid ID for each C2VSim element in the Kern County Subbasin Zone of Interest was identified and the Baseline scenario precipitation rates were multiplied by

the appropriate factors to produce time-series precipitation rates for the 2030 Climate Conditions and 2070 Climate Conditions scenarios. Factors for calendar years 1959-1961 were used as analogs for calendar years 2012-2014.

6.4.2 Surface Water Inflow Rates

Surface water inflow rates for Poso Creek and White River for the Baseline scenario model were developed by repeating input inflow rates from C2VSimFG-Kern in the appropriate sequence. DWR provided unimpaired streamflow change factor datasets for Central Valley streams, and an Excel spreadsheet tool to modify basin unimpaired streamflow using these change factors. The unimpaired streamflow change factors and spreadsheet were used to modify Baseline inflows to produce 2030 Climate Conditions and 2070 Climate Conditions scenario time series inflows for Poso Creek and White River.

Surface water inflow rates for Kern River at First Point for the Baseline scenario model were developed by repeating historical inflow rates from C2VSimFG-Kern in the appropriate sequence. Flows on the Kern River are regulated, so the unimpaired streamflow method was not appropriate for estimating future flows under 2030 and 2070 climatic conditions. Projected Kern River flows at First Point under 2030 and 2070 central tendency conditions were estimated by GEI (2018) for calendar years 1956-2010 hydrology. This analysis considered the impacts of changed runoff in each sub-watershed contributing to the Kern River to develop revised streamflow estimates for Kern River at First Point. Future scenario Kern River at First Point flows for calendar years 2011-2014 were estimated using flows for analog years with similar annual flows and monthly flow pattern. Analog years 1986, 1991, 1990 and 1961 respectively were used for 2011-2014 in the future scenarios.

6.4.3 Surface Water Deliveries

Surface water delivery rates for the Baseline scenario model were developed by first repeating input surface water delivery rates from the C2VSimFG-Kern in the appropriate sequence, and then modifying selected data sets. Surface water deliveries from in-basin sources such as Oil Field Recovery were held constant at WY2015 rates for all future scenarios.

The Kern County Subbasin is served by both the CVP and the SWP. Recent changes in CVP and SWP operations and their impacts on future surface water supplies are reflected in surface water diversion rates for the three scenarios. Future CVP deliveries will be affected by implementation of the San Joaquin River Restoration Program (SJRRP) that included the 2008 U.S. Fish & Wildlife Service biological opinion (BO) on the Long-Term Operational Criteria and Plan (OCAP) for coordination of the CVP and SWP. Future SWP deliveries will be affected by operational changes implemented between 2004 and 2008 including the OCAP BO, reduced Table A contract amounts and reduced Article 21 deliveries. DWR provided projected future deliveries from the CVP and SWP for WY1922 to WY2003, derived from CalSim-II modeling conducted for the Water Supply Investment Program (WSIP) (California Water Commission, 2016). DWR's CVP projections as provided do not fully incorporate these SJRRP operational changes. DWR's SWP delivery projections do not include the OCAP BO operational constraints, the reduced Table A amounts and reduced Article 21 water.

Future CVP delivery projections developed by the Friant Water Authority (FWUA) were used in place of DWR's CVP projections. FWUA (2018) used CalSim-II to develop projected surface water deliveries with SJRRP implementation under hydrological conditions representing the Current Baseline, 2030 and 2070 climate conditions by delivery class for WY1922 to WY2003, and estimated allocations to each CVP contractor. The 2015.c data set was used for Baseline scenario CVP deliveries, the 2030.c data set was

used for 2030 Climate Conditions scenario CVP deliveries, and the 2070.c data set was used for the 2070 Climate Conditions scenario CVP deliveries. CVP deliveries for WY2004 to WY2014 were estimated using deliveries for analog years WY1951 to WY1961; these analog years have a similar distribution of water availability.

The SWP projections provided by DWR for WY1995 to WY2003 and historical deliveries for WY2004 to WY2014 were modified to incorporate the impacts of SWP operational changes in the three scenarios. 2019 SWP Table A contract amounts were used to allocate these SWP deliveries to individual districts. In summary:

- Baseline Hydrologic Conditions
  - WY1995 to WY2003 conditions are based on 2030-Level CALSIM increased by 3.03 %,
  - WY2004 to WY2007 conditions are based on historical data adjusted for OCAP BO, and
  - WY2008 to WY2014 conditions are based on historical data with the assumption that OCAP BO adjustments are already factored into the data.
- 2030 Climate Change Hydrologic Conditions
  - WY1995 to WY2003 conditions are based on the 2030-Level CALSIM Projection,
  - WY2004 to WY2007 conditions are based on OCAP BO adjustment reduced by 3.03 %, and
  - WY2008 to WY2014 conditions are based on historical data reduced by 3.03%.
- 2070 Climate Change Hydrologic Conditions
  - WY1995 to WY2003 conditions are based on the 2070-Level CALSIM Projection,
  - WY2004 to WY2007 conditions are based on OCAP BO adjustment reduced by 8.09%, and
  - WY2008 to WY2014 conditions are based on historical data reduced by 8.09%.

Within the Kern County Subbasin, water users engage in complex real-time water trading and wheeling activities to maximize water utilization, minimize waste and energy consumption, and meet immediate water needs. It would be difficult to project future surface water deliveries in the Kern County Subbasin without the use of a surface water allocation model that simulates these water trading and wheeling activities. Therefore, for this modeling effort, monthly future scenario agricultural, urban and recharge deliveries from sources originating outside the basin were estimated by adjusting historical deliveries by the ratio of (total scenario inflows)/(total historical inflows) for each month, where total inflows are the sum of CVP deliveries, SWP deliveries and Kern River at First Point. In addition, Kern River at First Point flows above historical flows under the 2030 Climate Conditions and 2070 Climate Conditions scenarios were proportionally added to selected recharge deliveries. This method is deemed adequate for subbasin-level future scenario analyses.

Some future scenario data sets did not cover the entire period from October 1994 through September 2014. In these cases, data from an analog historical period with similar water availability was used to fill in the missing data. The analog years for each data type are summarized as:

- For CVP deliveries (CalSim-II data), WY1951 to WY1961 were used as analogs for missing WY2004 to WY2014 data; these analog years have a similar distribution of water availability.
- Projected future Kern River at First Point flows for calendar years 1986, 1991, 1990 and 1961 were used as analogs to missing calendar years 2011 through 2014; each of these analog years had a similar historical annual flow volume and monthly distribution.

- For climatic data adjustment factors, calendar years 1959-1961 were used as analogs to missing calendar years 2012-2014.

6.5 Development of Climate Change Conditions

Input data for the C2VSimFG-Kern were modified to simulate three future climatic scenarios. Historical precipitation, evapotranspiration, land use, population, surface water inflow and surface water delivery rates were replaced with projected future values for WY2016 to WY2070 for Future Baseline Conditions. The Future Baseline Conditions for WY2021 to WY2070 were then modified to simulate 2030 Climate Conditions and 2070 Climate Conditions. Water management agencies in the Kern County Subbasin provided a broad suite of proposed water management and conservation projects to increase water supplies and reduce water management demands. These projects are added to the C2VSimFG-Kern to assess the long-term impacts of these projects under the Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios.

Projected water budgets under Future Baseline Conditions, 2030 and 2070 Climate conditions are used to evaluate the potential effects of future Baseline and extended dry conditions with respect to achieving sustainability. DWR published a *Modeling Best Management Practices* Guidance Document (DWR, 2016B) that outlines DWR recommendations for developing and running predictive scenarios. The C2VSimFG-Kern was modified following these recommendations to develop the Baseline scenario model. DWR also issued the *Guidance for Climate Change Data Use During Sustainability Plan Development* Guidance Document (DWR 2018A) that outlines how DWR recommends that climate change be addressed under SGMA. Baseline scenario data sets were modified using DWR climate change data sets for Kern County following procedures outlined in the guidance documents to develop the 2030 Climate Conditions and 2070 Climate Conditions scenario models. The adjustment factors for Baseline, 2030 Climate Change and 2070 Climate Change for SWP deliveries were developed based on consistent CalSim operations studies at current, 2030 and 2070 climate levels developed for Bay Delta Conservation Plan evaluation and provided by DWR Bay Delta Office staff. The WSIP studies provided on DWR's SGMA web site were not used due to the unavailability of a Baseline study with assumptions consistent with the 2030 and 2070 climate change studies.

6.6 Groundwater Banking Assumptions

Groundwater banking operations are simulated in the C2VSimFG-Kern with surface water diversions to recharge basins and specified pumping rates for groundwater extractions. All surface water deliveries were adjusted under the Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios. Surface water deliveries to recharge basins were first adjusted by the same ratio as other surface water deliveries, then increased if Kern River flows were greater than historical flows. Specified pumping rates for groundwater extraction were not modified.

The out-of-basin banking obligations were assumed to follow a similar pattern where groundwater banking recharge would be affected by the limitation on surface water deliveries, but that banking recovery would remain similar to historical volumes. Therefore, the historical groundwater banking obligations were adjusted under the Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios by the same percentage as the surface water deliveries; however, the groundwater banking recovery was assumed to remain the same. Based on the historical banking obligations and using that as a foundation going forward, no banking partner has ever requested the full amount of the water banked at any particular time even in the most recent drought years. All the banking obligation

agreements require limitations on amounts to be requested and delivered as well as "leave in" amounts that remain in the Kern County Subbasin. This historical management of banking obligations provides the Kern County Subbasin more flexibility for use of water as well as delivery of the obligations. For the projected future scenarios, the out-of-basin banking obligations were calculated as follows:

- For the Baseline scenarios, the out-of-basin banking obligations were calculated as 69,632 AFY based on surface water deliveries of about 81% of historical deliveries.
- For the 2030 Climate scenarios, the out-of-basin banking obligations were calculated as 67,913 AFY based on surface water deliveries of about 79% of historical deliveries.
- For the 2070 Climate scenarios, the out-of-basin banking obligations were calculated as 64,474 AFY based on surface water deliveries of about 75% of historical deliveries.

Tracking of banked groundwater obligations was done using the same post processing process as applied to the historical groundwater assessment by assigning the portion of the groundwater recharge as an out-of-basin banking obligation.

7. PROJECTED FUTURE C2VSIMFG-KERN SIMULATION RESULTS

The C2VSimFG-Kern was run for three scenarios that estimate hydrologic conditions of Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios both with and without the proposed SGMA projects and management actions for a total of six projected future scenarios.

7.1 Projected Future Water Budgets

C2VSimFG-Kern calculates water budget components each month of the simulation period for each future scenario. Projected future water budgets developed based on the C2VSImFG-Kern simulation results with the proposed SGMA management actions were then compared to results for the future scenarios without the management actions to assess how these changes enhance groundwater sustainability within the Kern County Subbasin.

The average annual value of each water budget component summarizes the impacts over 50 years with current water demands. The water budget results for the six Projected Future Scenarios are presented in **Tables 16 through 21**, and include averages over three different periods, which include:

- **WY2021 to WY2040** – Implementation Period representing the 20-year period required by the SGMA regulations to implement projects and management actions to achieve sustainability.
- **WY2041 to WY2070** – Sustainability Period representing the 30-year hydrologic period following the Implementation Period to assess the long-term sustainability of the proposed projects and management actions with variable climatic conditions including periods with above average rainfall and extended droughts.
- **WY2021 to WY2070** – Simulation Period representing the entire 50-year projected future hydrologic conditions.

Changes to surface water diversions under the proposed projects and management actions included monthly increases or reductions to 37 model diversions and the addition of 7 new diversions. Ten new groundwater pumping wells were added to simulate a new groundwater pumping program. Agricultural

land use was converted to native vegetation in ten management areas, and to urban land use in three management areas. The projects and management actions included in the C2VSimFG-Kern scenarios with SGMA projects are described in the individual GSPs and management area plans. These changes were applied to a series of six C2VSimFG-Kern scenarios for Baseline, 2030 Climate Conditions and 2070 Climate Conditions both with and without SGMA projects. The results of these simulations are summarized in **Table 15** below.

Baseline simulation results indicate that the Kern County Subbasin has an average annual overdraft of 324,326 AFY. By implementing the proposed projects and management actions, the Subbasin is forecasted to achieve sustainability by 2040 with an estimated 42,144 AFY of annual surplus. With adjustments to account for limitations in the simulation (discussed in Section 7.2.1), the adjusted change in storage increases to 85,578 AFY.

Collectively, the C2VSimFG-Kern simulation results indicate that the currently proposed SGMA projects and management actions, once fully implemented, provide a reasonable approach to achieve sustainable management of the groundwater basin and can be adaptively managed to meet future challenges as necessary. A brief summary of each of the six projected future water budgets from C2VSimFG-Kern is provided below.

Table 15: Summary of Simulated Change in Groundwater Storage Results over the 2041 to 2070 Sustainability Period

C2VSimFG-Kern Model Scenario	Change in Groundwater Storage (AFY)	
	C2VSimFG-Kern Model Results	Adjusted Model Results
Historic	-277,114	-277,114
Baseline	-324,326	-324,326
Baseline with Projects	42,144	85,578
2030 Climate Change	-380,900	-372,120
2030 Climate with Projects	-12,861	46,829
2070 Climate Change	-489,828	-472,336
2070 Climate with Projects	-118,273	-45,969

7.1.1 Baseline Condition Water Budgets

The Baseline Scenarios simulate how the Kern County Subbasin aquifer would respond if the recent hydrology were repeated with current expected surface water availability and current land use. The Baseline Scenarios were run both with and without SGMA projects.

For the Baseline Scenario without SGMA Projects, the groundwater budget for WY2021 to WY2040 (**Table 16**) repeats the 20-year historical hydrologic period so it provides a direct comparison of the differences between the projected future Baseline without SGMA Projects and the historical condition. The primary difference between historical conditions and the projected future Baseline is a nearly 20% decrease in imported surface water deliveries primarily from the SWP due to the OCAP Biological

Opinion. This is replaced with additional groundwater pumping. As a result, total net aquifer outflows increase by about 20,200 AFY and total net aquifer inflows decrease by about 76,500 AFY. This is mostly because of increased groundwater pumping and decreased managed aquifer recharge due to a decline in imported SWP water. Over this period, the average groundwater pumping is 1,581,000 AFY, which includes agricultural pumping, urban pumping and exported water. This results in an additional loss of groundwater storage of about 56,300 AFY over the 50-year projected future Baseline period.

The Baseline Scenario with SGMA Projects simulates the proposed SGMA projects and management actions (Section 5.2) applied to the Baseline Scenario. No other changes were made except for the addition of the SGMA projects to provide a direct comparison of the relative benefits of about 422,000 AFY of proposed SGMA projects and management actions. The groundwater budget for the Baseline Scenario with SGMA Projects is provided in **Table 17**. Comparing the groundwater budget for WY2041 to WY2070 (**Table 17**) with the same period from the Baseline Scenario (**Table 16**) provides an evaluation of groundwater conditions after the SGMA projects and management actions have been fully implemented. As a result, total net aquifer inflows increase about 135,400 AFY due to increased managed aquifer recharge and deep percolation. The total net aquifer outflows decrease about 231,100 AFY due mostly to decreased groundwater pumping with agricultural demand reduction management actions.

The change in groundwater storage for the Baseline Scenario with SGMA Projects improves by about 366,500 AFY compared to the Baseline Scenario without SGMA Projects. This change results in a net gain in groundwater in aquifer storage over the WY2041 to WY2070 sustainability period of about 42,100 AFY. A comparison of the annual change in groundwater storage over the 50-year hydrologic period is presented in **Figure 16**. The time series shows that change in groundwater storage has stabilized to slightly increasing over the period from WY2041 to WY2070.

A comparison of the average annual water budget components for the two different Baseline Scenarios is presented in **Figure 17**. Over the WY2041 to WY2070 period, the average groundwater pumping of 1,354,000 AFY for the Baseline Scenario with SGMA Projects (which includes agricultural pumping, urban pumping and exported water) is over 270,000 AFY less than in the Baseline Scenario.

7.1.2 2030 Climate Change Water Budgets

The 2030 Scenarios simulate how the Kern County Subbasin aquifer would respond assuming hydrologic conditions representing a potentially drier climate and are based on the DWR Climate Change Guidance and Resource Guide (DWR, 2018A and 2018B). The 2030 DWR climate change factors were applied to the Baseline Scenario conditions. Additional adjustments were made to the imported surface water supplies from the SWP, CVP and Kern River, accounting for about an additional 2% decrease from the Baseline Conditions. The 2030 Climate Change Scenarios were run both with and without SGMA projects. Results for climate change budgets are illustrated in **Figures 18, 19, and 20**.

The groundwater budget for the 2030 Climate Scenario without SGMA Projects for WY2041 to WY2070 (**Table 18**) is compared the same period for the Baseline Scenario without SGMA Projects to assess the relative change due to the climate change assumptions. The results show a net increase in aquifer inflows of about 44,700 AFY, however, the aquifer net outflows increase by about 101,200 AFY. This is mostly attributed to the climate shift to earlier rainfall making more surface water available for managed aquifer recharge during the winter but less available for irrigation in the summer, resulting in higher groundwater pumping. The net change in groundwater storage is an additional decline of about 56,600 AFY due to the climate change impacts.

The 2030 Climate Scenario with SGMA Projects simulates the proposed SGMA projects and management actions (Section 5.2) applied to the 2030 climate change conditions. No other changes were made to this scenario. The groundwater budget for the 2030 Climate Scenario with SGMA Projects is provided in **Table 19**. Comparing the groundwater budget for WY2041 to WY2070 (**Table 18**) between the two 2030 Climate Scenarios, the total net aquifer inflows increase about 118,700 AFY due to increased managed aquifer recharge and deep percolation. The total net aquifer outflows decrease about 249,300 AFY due mostly to decreased groundwater pumping with agricultural demand reduction management actions.

The change in groundwater storage for the 2030 Climate Scenario with SGMA Projects improves by about 368,000 AFY. This change results in a net decline in groundwater in aquifer storage over WY2041 to WY2070 of about 12,900 AFY. A comparison of the annual change in groundwater storage over the 50-year hydrologic period is presented in **Figure 20**. The time series shows that change in groundwater storage has stabilized to slightly increasing over the period from WY2041 to WY2070, but at a level below the results for the Baseline Scenario with SGMA Projects.

A comparison of the average annual water budget components for the two 2030 Climate Scenarios is presented in **Figure 18**. Over this period, the average groundwater pumping of 1,444,000 AFY for the 2030 Climate Scenario with SGMA Projects, which includes agricultural pumping, urban pumping and exported water, is over 290,000 AFY less than in the 2030 Climate Scenario without SGMA Projects.

7.1.3 2070 Climate Change Water Budgets

The 2070 Scenarios simulate how the Kern County Subbasin aquifer would respond assuming hydrologic conditions representing a potentially very dry climate and are based on the DWR Climate Change Guidance (DWR, 2018A and 2018B). The 2070 DWR climate change factors were applied to the Baseline Scenario Conditions. Additional adjustments were made to the imported surface water supplies from the SWP, CVP and Kern River, and these accounted for an additional 6% decrease from the Baseline Conditions. The 2070 Climate Change Scenarios were run both with and without SGMA Projects.

The groundwater budget for the 2070 Climate Scenario without SGMA Projects over WY2041 to WY2070 (**Table 20**) is compared the same period for the Baseline Scenario without SGMA Projects to assess the relative change due to the climate change assumptions. The results show a net increase in aquifer inflows of about 66,100 AFY, however, the net aquifer outflows increase by about 231,600 AFY. This is mostly attributed to an even greater climate shift to earlier rainfall making more surface water available for managed aquifer recharge during the winter but less available for irrigation in the summer resulting in higher groundwater pumping. The net change in groundwater storage is an additional decline of about 165,500 AFY due to the climate change assumptions.

The 2070 Climate Scenario with SGMA Projects simulates the proposed SGMA projects and management actions (Section 5.2) applied to the 2070 climate change conditions. No other changes were made to this scenario. The groundwater budget for the 2070 Climate Scenario with SGMA Projects is provided in **Table 21**. Comparing the groundwater budget for WY2041 to WY2070 (**Table 20**) between the two 2070 Climate Scenarios, the total net aquifer inflows increase about 106,300 AFY due to increased managed aquifer recharge and deep percolation. The total net aquifer outflows decrease about 265,300 AFY due mostly to decreased groundwater pumping due to agricultural demand reduction management actions.

The change in groundwater storage for 2070 Climate Scenario with SGMA Projects improves by about 371,600 AFY. This change results in a net decline of groundwater in aquifer storage over WY2041 to WY2070 of about 118,300 AFY. A comparison of the annual change in groundwater storage over the 50-year hydrologic period is presented in **Figure 20**. The time series shows that change in groundwater storage has stabilized to slightly increasing over the period from WY2041 to WY2070, but at a level below the results for the Baseline and 2030 Scenarios with SGMA Projects.

A comparison of the average annual water budget components for the two different 2070 Climate Scenarios is presented in **Figure 19**. Over this period, the average groundwater pumping of 1,559,000 AFY for the 2070 Climate Scenario with SGMA Projects, which includes agricultural pumping, urban pumping and exported water, is over 307,000 AFY less than in the 2070 Climate Scenario without SGMA Projects.

7.2 Projected Future Sustainability Assessment

To assess the sustainability of the proposed GSP plans, the C2VSimFG-Kern model future scenario input files were modified to incorporate all the proposed SGMA projects and management actions.

7.2.1 Change in groundwater storage

Groundwater sustainability for the Kern County Subbasin was assessed using annual changes in groundwater storage. As discussed in Section 7.1, the decline in groundwater storage of the three future Baseline scenarios is significantly mitigated by the implementation of the proposed SGMA projects and management actions. An assessment of the projected future groundwater storage change for the six projected future scenarios is summarized in **Table 22**.

The Change in Groundwater Storage presented in **Table 22** provides the net difference in aquifer inflows and outflows without consideration of subsurface flow to and from adjacent groundwater basins. This provides a measure of the natural and managed water supply within the groundwater basin without being influenced either positively or negatively by the subsurface flow. For the Kern County Subbasin, the net operational flow differs from the change in groundwater storage by about 50,000 to 75,000 AFY for the scenarios without SGMA projects, indicating that most of the groundwater storage change is due to conditions within the basin.

The Adjustments to Groundwater (GW) Storage Change are made to account for limitations in either the underlying conceptual model of C2VSimFG-Kern or the setup of the projected future scenarios. The two adjustments made to the projected future water budgets include:

- **Adjustment for Excess Basin Outflows** is the difference in simulated basin outflow that is attributed to addition of SGMA projects in Kern County without comparable SGMA projects added to adjacent basins. Adjustment assumes that this difference is due to limitation of the simulation, and that this difference would remain in Kern County Subbasin when SGMA projects from adjacent basins are included in the simulation.
- **Adjustment for Excess Kern River Outflow** is the increase in simulated groundwater outflows to the Kern River relative to Baseline condition that are attributed to SGMA projects and climate change. The model is not optimized for river management. Because the Kern River is a highly managed system, the assumption is that in practice this water would be recovered for beneficial use and not allowed to flow from the basin.

These adjustments resulted in an overall improvement in the change in groundwater storage for the projected future water budgets. For the scenarios that include the SGMA Projects, the change in groundwater storage improves by 43,400 AFY (Baseline), 59,700 AFY (2030 Climate Change), and 72,300 AFY (2070 Climate Change). As a result of these adjustments, the adjusted change in groundwater storage for the three scenarios with SGMA Projects varied as follows:

- the Baseline Scenario with SGMA Projects changes from an increase of 42,100 AFY to an increase of 85,600 AFY.
- the 2030 Climate Scenario with SGMA Projects changes from a decline of 12,900 AFY to an increase of 46,800 AFY.
- the 2070 Climate Scenario with SGMA Projects changes from a decline of 118,000 AFY to a decline of 46,000 AFY.

These adjustments indicate areas of improvement for C2VSimFG-Kern. Future updates to the model will address how to better simulate these conditions directly to limit the use of post-simulation adjustments.

7.2.2 Sustainability Assessment

As defined by SGMA, the sustainable yield of a basin is the amount of groundwater that can be withdrawn annually without causing undesirable results. Although the SGMA regulations require that a single value of sustainable yield must be calculated basinwide, it should be noted that the sustainable yield can be changed with implementation of recharge projects, variations in climate, or changes in stream flow conditions. For the projected future scenarios, both the climate and the managed water supply operations are significantly affected which would lead to a change in the sustainable yield for the basin.

For the sustainability assessment, the sustainable yield was recalculated using the method described in Section 4.2, and the results are presented in **Table 23**. Without the SGMA projects and management actions, the percentage of the Average Annual Difference to the total groundwater pumping provides context to compare the significance of the level of groundwater pumping for the basin. For the scenarios without SGMA projects and management actions, the groundwater pumping exceeds the sustainable yield on the order of 25% to 34% (**Table 23**). However, with the proposed SGMA projects and management actions, the groundwater pumping is less than the sustainable yield of the Subbasin for the Baseline and 2030 climate scenarios and is within 3% of the sustainable yield for the 2070 climate scenario (**Table 23**). This assessment indicates that the proposed SGMA projects and management actions for the Kern County Subbasin are of sufficient magnitude that, if fully implemented, would lead to groundwater sustainability for the Kern County Subbasin after WY2040.

7.2.3 Minimum Thresholds and Measurable Objectives

Another requirement of SGMA is for groundwater levels not to cross their minimum thresholds to the extent that undesirable results would occur in the basin, and moreover, that proposed SGMA projects and management actions would lead to meeting the measurable objectives. The Kern County Subbasin GSAs have defined 186 representative monitoring well (RMW) locations spread across the Kern County Subbasin. A minimum threshold and measurable objective have been assigned each of the 186 locations, and the hydrographs for all 186 locations are provided in **Attachment A**. The RMW locations are shown on **Figure 21**.

The C2VSimFG-Kern results were used to assess whether the simulated groundwater levels would meet the minimum threshold and measurable objective for each monitoring well. Because C2VSimFG-Kern is

not fully calibrated, the results are presented as relative change (which does not require calibration) instead of simulated groundwater levels using the superposition method. Future change in groundwater level was determined for each of the 186 locations for each of the six projected future simulations. The change was calculated from the simulated March 2015 groundwater levels from the model. The change in groundwater level was then applied to the measured March 2015 groundwater level at the monitoring location. The result was to superimpose the simulated change in groundwater levels from the projected future C2VSimFG-Kern scenarios relative to the measured March 2015 groundwater level.

Figure 22 provides four representative examples of the simulated hydrographs using this method. Hydrographs of the simulated groundwater levels relative to the minimum thresholds and measurable objectives for all 186 locations were provided to the various GSAs and water districts for inclusion in their respective GSPs. In general, across most areas of the basin, groundwater levels fall near or below the minimum thresholds without the SGMA projects but are typically above the minimum threshold for the simulations that include the SGMA projects.

The groundwater hydrographs for some locations, especially along the eastern and western basin margins, show an unusual pattern that is likely influenced by issues with the hydrogeological conceptual model incorporated into C2VSimFG-Kern for these locations. The hydrographs for these areas are not considered to be representative of actual conditions that would physically occur. This is a limitation to the model. It is recommended that a more rigorous model update be conducted to revise the hydrogeological conceptual model to be consistent with that presented in the Kern County Subbasin GSPs. In addition, further calibration of C2VSimFG-Kern is recommended to update aquifer parameters in the Kern County Subbasin. The recommendations for revisions to the hydrogeological conceptual model and additional calibration are further discussed in Section 8.5.

8. VALIDATION OF C2VSIMFG-KERN PERFORMANCE

The C2VSimFG-Kern performs well within the central part the Kern County Subbasin. The model does not perform as well east of the Friant-Kern Canal or west of the California Aqueduct. The geologic and hydrogeologic conceptual models within the central part of the Kern County Subbasin appear to be generally realistic. The geologic and hydrogeologic conceptual models appear to be very poor in the areas where the model does not perform well.

8.1 C2VSimFG-Kern Validation

One of the concerns for the modeling is the overall calibration of C2VSimFG-Beta in Kern County. As discussed above, the assumption is that C2VSimFG-Beta was developed using reasonable care in developing the geologic framework and developing a consistent regional methodology for determining aquifer properties. An identified weakness of the C2VSimFG-Beta is the quality of data used in developing the overall water balance such as the extent of the groundwater banking operations in Kern County. The issues with the water balance are considered the primary contributing factor affecting the calibration of the C2VSimFG-Beta; the hydrogeologic conceptualization is reasonably accurate for a regional planning analysis.

To address these concerns, a validation analysis was performed for C2VSimFG-Kern by comparing simulations results to field measured groundwater level data collected during the Study Period and comparing those to a similar set of residuals from the C2VSimFG-Beta model. The statistical results of

this analysis should be comparable, if not better, for C2VSimFG-Kern compared to the C2VSimFG-Beta results.

The analysis used 42,058 groundwater levels measurements collected from 558 monitoring wells in the Kern County Subbasin. The data were collected by Kern County Water Agency, the Kern Fan Monitoring Committee, the DWR Water Data Library, and local agencies. For each location, the residual was calculated as the simulated groundwater level minus the measured groundwater level based on the well measurement data. A brief summary of the statistical measures used to evaluate the calibration results (shown on **Table 24**) is provided below:

- The residual mean is computed by dividing the sum of the residuals by the number of residual data values. The closer this value is to zero, the better the calibration especially as related to the water balance and estimating the change in aquifer storage. The residual mean of 17.3 feet for C2VSimFG-Kern is an improvement of 47% over the 32.6 feet from C2VSimFG-Beta.
- The absolute residual mean is the arithmetic average for the absolute value of the residual, so it provides a measure of the overall error in the model. The absolute residual mean of 37.4 feet for C2VSimFG-Kern is an improvement of 34% over the 56.8 feet from C2VSimFG-Beta.
- The residual standard deviation evaluates the scatter of the data. A lower standard deviation indicates a closer fit between the simulated and observed data. The standard deviation is 45.5 feet for C2VSimFG-Kern, which is an improvement of 16% over the 54.0 feet from C2VSimFG-Beta.
- The Root Mean Square (RMS) Error is the square root of the arithmetic mean of the squares of the residuals and provides another measure of the overall error in the model. The RMS Error is 50.0 feet for C2VSimFG-Kern, which is an improvement of 32% over the 73.5 feet from C2VSimFG-Beta.
- The correlation coefficient ranges from 0 to 1 and is a measure of the closeness of fit of the data to a 1 to 1 correlation. A correlation of 1 is a perfect correlation. The correlation coefficient of 0.76 for C2VSimFG-Kern is an improvement of 47% over the 0.52 from C2VSimFG-Beta.
- Another statistical measure is the ratio of the standard deviation of the mean error divided by the range of observed groundwater elevations. This ratio shows how the model error relates to the overall hydraulic gradient across the model. The ratio for C2VSimFG-Kern is 0.061 feet, which is an improvement of 34% over the 0.092 from C2VSimFG-Beta.

Considering these results in context with the overall range of measurements of 616 feet, the residual mean of 17.3 feet represents a relative percentage difference of less than 3%. For the absolute residual mean of 37.4 feet, the relative percentage difference is about 6%. Despite this improvement in model performance, the model is not considered fully calibrated. However, C2VSimFG-Kern is reasonably validated for assessing groundwater level changes on the subbasin scale for the purposes of SGMA planning.

8.2 Sensitivity Analysis

The C2VSimFG-Kern model was not formally calibrated. Some physical parameters were adjusted to improve model performance in specific areas. A sensitivity analysis was conducted on the adjusted model to understand how variations in model parameters affect model results. Eight physical parameter sets were systematically varied, and model results compared to the base model for a

selected group of groundwater hydrographs. C2VSimFG-Kern parameter sensitivities evaluated for Kern County Subbasin include:

- Horizontal hydraulic conductivity of aquifer (Kh)
- Vertical hydraulic conductivity of aquifer (Kv)
- Vertical hydraulic conductivity of Corcoran Clay aquitard (Kcorc)
- Streambed conductance of Kern River (Cstm)
- Specific storage of aquifer (Ss)
- Specific yield of aquifer (Sy)
- Soil hydraulic conductivity in root zone (Ksoil)
- Soil pore size distribution index in root zone (λ)

The Root Mean Squared Error between observed and simulated values was calculated for the original parameter set and after varying each parameter set upward and downward by a set factor. Results are presented in **Figure 23**. This sensitivity analysis shows that the hydrologic parameter values in the C2VSimFG-Kern model are generally within an acceptable range. A full model calibration would likely improve model performance.

8.3 Peer Review Process

Todd Groundwater worked with Woodard and Curran (W&C) throughout the model development process as W&C conducted an on-going peer review of model input files. W&C staff have developed several IWFM-based models and worked with DWR to develop C2VSimFG-Beta. Their reviews helped ensure that the model update used best practices when incorporating new data. The peer review process was documented in a series of meeting summaries to the KGA and KRGSA. The updated C2VSimFG-Kern input files for the Kern County Subbasin were shared with DWR for incorporation into future C2VSim public releases.

The more general assumptions in C2VSimFG-Beta were replaced with local data and knowledge that are regionally or locally significant for WY1995 to WY2015. This update employed a phased approach with regular peer reviews.

1) Phase 1 revisions address components of Regional Significance that require significant changes to the overall model input file structure. These include:
   a) Surface water delivery volumes, application areas and use by water district,
   b) Groundwater banking recharge, recovery and application of recovered water,
   c) Evapotranspiration rates and irrigation demand based on ITRC METRIC data (ITRC 2017),
   d) Urban population and per capita demand, including addition of an urban zone for Metropolitan Bakersfield, and
   e) Addition of groundwater extraction wells for groundwater banking projects.
2) Interim Review
   a) The Woodard & Curran Peer Review Team
   b) Kern County Subbasin water districts and purveyor's local data review
   c) Stakeholder input
3) Phase 2 revisions address components of Local Significance that generally require modifications of input data and parameters within the existing C2VSim model input file structure. These include:

a) Local water sources and demands of significance to individual Districts/GSAs,
b) District pumping for in-district delivery via surface water canals where significant,
c) District recharge operations utilizing canals, stream channels, and basins,
d) Wastewater disposal and land application, and
e) Review and limited adjustment of model parameters.

4) Interim Review by same reviewers listed in item 2

5) Phase 3 revisions include addressing comments and incorporating new data from the Interim Reviews

6) Interim Review by same reviewers listed in item 2

7) Tabulate model-derived water budgets for Peer-Review and GSP Use

In each update phase, historical and current water budgets for zones representing water agency service areas were produced with the revised C2VSimFG-Kern model incorporating corrected local data. These water budgets were shared with participating agencies for review, to ensure that C2VSimFG-Kern correctly represented local water balances. Where necessary, participating agencies provided additional data which was incorporated into C2VSimFG-Kern.

8.4 Internal Review Process

Todd Groundwater and Hydrolytics LLC worked collaboratively on this model revision, water budget development and the projected future scenarios. Throughout this work, efforts were applied to improve data management to develop a systematic process for generating model input files. Using this approach, internal review could be conducted with each firm reviewing the contributions from the other. The goal was to accurately represent the data provided by the Kern County agencies in the model.

Due to schedule constraints, a thorough internal review of the projected future model scenarios was not completed prior to the submission of the Public Review Draft of the model results in August 30, 2019. A thorough review of all input for the projected future scenarios was conducted in September and October 2019. During this review, several issues were identified and corrected. As a result, the results in this report vary from those provided in the August 2019 Public Review Draft. Although the numbers changed, the overall conclusions from the C2VSimFG-Kern simulations remained essentially the same.

8.5 Recommendations for Future Improvements to C2VSimFG-Kern

The C2VSimFG-Kern performs well in the Kern County Subbasin, producing simulated water budget components that generally match historical values compiled by local agencies. C2VSimFG-Kern simulated groundwater levels provide a reasonable approximation of observed groundwater levels in the central part of the Kern County Subbasin. The model is well suited for estimating the impacts of management actions on the Subbasin groundwater storage and is also well suited as a planning tool in meeting compliance of SGMA.

During the model update, several outstanding issues were identified that should be addressed in future updates to C2VSimFG-Kern. The following actions and model improvements are recommended:

- **Improve streamflow simulations of the Kern River and Poso Creek.** Flows in the Kern River channel, including local stream-groundwater interactions, are not well replicated and surface water diversions are not dynamically simulated. Some rejected recharge occurs in the Kern Fan

area in very wet years, with significant outflow of groundwater to the Kern River especially in the Kern Fan banking area (i.e., rejected recharge). This has been an ongoing issue and needs to be addressed for the projected future water budgets so that banking recharge volumes can be better matched in the model. It is recommended that future revisions to C2VSimFG-Kern further evaluate issues in simulating streamflow and seepage in the Kern River and Poso Creek (see Section 8.5). This may include incorporating more advanced streamflow simulation features that are available in IWFM but that have not been previously utilized in developing C2VSim models by DWR. Changing the stream simulation feature may require development of a local Kern County Subbasin model.

- **Improve the geologic and hydrogeologic conceptual model of the Kern County portion of the Central Valley.** A hydrogeologic conceptual model is a framework for understanding where groundwater exists, where it flows, and how groundwater interacts with surface water bodies and the land surface. A geologic conceptual model provides a framework for understanding the geologic features that control groundwater movement. Quantitative analysis of Kern County Subbasin groundwater flow is severely hampered by the lack of detailed geologic and hydrogeologic conceptual models of the areas outside the central alluvial basin. Geologic and hydrogeologic conceptual models will provide a foundation for the quantitative analysis of the groundwater flow system, and the framework for modeling the system. Key steps are:
    - Develop detailed geologic and hydrogeologic conceptual models of the Kern County Subbasin.
    - Differentiate the four Principal Aquifers that have been identified in the Kern County Subbasin based on definitions from local management area GSPs.
    - Identify the locations and characteristics of natural features that affect groundwater recharge and movement (faults, ridges, clays).
    - Understand water occurrence and movement in areas outside the central Kern County Subbasin.
    - Develop water quality maps (natural constituents and anthropogenic constituents).
    - Modify the Kern County Subbasin model to conform to the updated conceptual models.
- **Simulation of deep percolation and small watersheds.** Unreasonably high deep percolation (return flows) of the applied water in some areas has led to unreasonably elevated pumping rates to compensate. One problem is high root zone hydraulic parameter values in certain areas that were identified and corrected to better reflect local soil conditions. Because the excess pumping was returning to groundwater, the change has little effect on the basin change in storage, but the pumping and deep percolation are now more in line with local estimates. Root zone hydraulic parameters should be redeveloped throughout the subbasin to assure model values are representative of actual values.
- **Root Zone Parameters,** Areas of overly high root zone hydraulic parameters led to high volumes of deep percolation that required additional groundwater pumping to meet the overall water demand for irrigation. A review found areas of overlying high soil hydraulic conductivity and other soil parameters produced percolation rate that were too high. These areas were manually adjusted to be more in line with observed conditions. A more rigorous development of root zone parameters should be considered in the future as this issue demonstrates that it is a sensitive parameter.

- **Investigate development of a stand-alone Kern County Subbasin model.** The C2VSim model provided by DWR and updated with local data is adequate for GSP preparation. However, this model may not meet all of the groundwater modeling needs of Kern County Subbasin stakeholders. In addition, running a full Central Valley simulation model imposes longer model run times and reduces model flexibility. Stakeholders should undertake a comprehensive study to develop a list of their integrated (groundwater and surface water) modeling needs, and then decide whether further improving C2VSimFG-Kern or developing a new integrated hydrologic model is the best way to address the Subbasin modeling needs. This decision should be made before the end of 2020 to allow sufficient time to develop a new model or improve C2VSimFG-Kern in time for use in development of the 2025 GSP.
- **Adjust the finite element grid to honor water management boundaries.** The C2VSimFG-Kern model grid is a randomly generated grid that does not conform to any local features other than natural surface water channels. This limits the spatial accuracy of model inputs and the precision and flexibility of water budget outputs. Adjusting the grid to match district and agency boundaries, historical delivery areas, water management units within districts, and geologic and hydrologic features would greatly enhance model capabilities.
- **Quantify boundary flows.** Significant uncertainty exists regarding the rates and timing of groundwater flows into the Kern County Subbasin from surrounding watersheds, and groundwater flows from the Kern County Subbasin to Kings and Tulare counties to the north. Reliable estimates of boundary flows will improve model performance in boundary areas.
- **Kern County Subbasin Boundary.** The GSAs in the basin should consider when DWR updates the Bulletin 118 in 2020 to investigate the "actual" Kern County Subbasin and to remove those peripheral lands where aquifer connectivity does not exist.
- **Utilize more complex water management features of IWFM.** The Kern Update process modified information within the existing C2VSimFG-Beta model structure to improve model performance within the Kern County Subbasin. The IWFM application has several features that could be further utilized to improve model performance.
    - Adjust the agricultural crops to better match the Kern County crop mix (for example, create separate crop categories for carrots, young and mature almonds, young and mature pistachios, etc.).
    - Implement multi-cropping with semiannual or quarterly land use.
    - Some C2VSim data are organized by DWR subregions, which represent heterogeneous areas with homogeneous data. Developing Kern County Subbasin subregions and organizing model input data by these subregions may provide a better representation of local hydrologic conditions.
- **Calibrate the improved model for the Kern County Subbasin**. DWR did not fully calibrate the Kern County portion of the C2VSim model, owing to both poor historical input data and a lack of calibration data sets. The Kern Update process significantly improved the historical data in the model, developed some calibration data sets, and included limited adjustment of model parameters. The updated model performs adequately in the central part of the Kern County Subbasin and poorly in areas outside the central part of the basin. Once the above improvements are completed, the Kern County portion of the resulting model should be fully calibrated to ensure that it performs well throughout the Kern County Subbasin.

9. CONCLUSIONS

This brief summary provides an overview of the findings and conclusions of the modeling results for the Kern County Subbasin using C2VSimFG-Kern.

9.1 Findings of the C2VSimFG-Kern Application and Results

The subbasin-wide update of C2VSimFG-Kern incorporated data from many local agencies. Each participating agency provided data for their jurisdiction for use in improving the model. This included managed water supply data (e.g., surface water deliveries, land use, irrigation demand, return flows, and groundwater banking), stream and groundwater monitoring data, geologic data, and other relevant data. This information was compiled and used to improve C2VSimFG-Kern performance in the Kern County Subbasin.

The historical water budget analysis indicates that the Kern County Subbasin was in a state of overdraft equivalent to the long-term decline in groundwater storage from WY1995 to WY2014 of 277,144 AFY. Projected Future simulations indicate that the proposed SGMA projects and management actions in the Kern County GSPs are sufficient for the Kern County Subbasin to achieve sustainability under Baseline and 2030 Climate Change conditions.

C2VSimFG-Kern was used to evaluate the change in groundwater in storage for projected future conditions using a baseline condition that projects current water supply, water demand and land use over a 50-year period based on historical hydrology. The baseline was adapted following DWR climate change guidance to develop 2030 and 2070 climate change simulations. The proposed SGMA projects and management actions were compiled from all of the Kern County Subbasin GSAs and management areas. The total projects total about 421,000 AFY after implementation. This assessment indicates that the proposed SGMA projects and management actions for the Kern County Subbasin are of sufficient magnitude that, if fully implemented, would lead to groundwater sustainability for the Kern County Subbasin after WY2040.

The historical C2VSimFG-Kern performs well in the Kern County Subbasin, producing simulated water budget components and groundwater levels that generally match historical values compiled by local agencies. C2VSimFG-Kern simulated groundwater levels provide a reasonable statistical approximation of observed groundwater levels in the Kern County Subbasin that show significant improvement relative to C2VSimFG-Beta. Therefore, C2VSimFG-Kern is well suited as a planning tool to estimate the impacts of the proposed SGMA projects and management actions on groundwater conditions in the Kern County Subbasin.

The C2VSimFG-Kern model development and the water budget analysis were designed to fulfill the GSP requirement for a coordinated subbasin-wide water budget analysis, while also providing information required to fulfill other GSP requirements. The C2VSimFG-Kern was provided to DWR so the Kern County Subbasin revisions can be incorporated into their master version of the C2VSim model.

9.2 C2VSimFG-Kern Compliance with Coordination Agreement Requirements

Subbasin GSAs coordinated on the development and application of the C2VSimFG-Kern to ensure that the model was incorporating comparable data sets and the best available information; as such, the model meets numerous technical requirements for Subbasin-wide coordination, including for

Coordination Agreements in §357.4. As demonstrated throughout this memorandum, the C2VSimFG-Kern model documents the use of "the same data and methodologies" for water budget development.

Specifically, groundwater extraction data were coordinated through the use of ET METRIC data for all irrigated lands over the entire Subbasin to estimate private irrigation pumping. Monthly metered data from District, municipal, and banking pumping were incorporated as available. Surface water supply data were provided in similar units and formats using consistent templates for data collection and management in the model. Total water use and change in groundwater in storage were developed through consistent methodologies as applied in the C2VSimFG-Kern model. Calibration targets also incorporated consistent data sets for groundwater elevation data throughout the Subbasin as compiled in the DWR Water Data Library, KCWA water level database, and supplemented with local data, as needed. This memorandum documents coordination efforts in subsequent sections that demonstrates compliance with GSP requirements in §354.18, §357.4, and other portions of the regulations.

9.3 Limitations and Uncertainty of C2VSimFG-Kern

The C2VSimFG-Kern performs well in the Kern County Subbasin, producing simulated water budget components that generally match historical values compiled by local agencies. C2VSimFG-Kern simulated groundwater levels provide a reasonable approximation of observed groundwater levels in the central part of the Kern County Subbasin. The model is well suited to estimating the impacts of management actions on subbasin groundwater storage.

The C2VSimFG-Kern update was limited in scope, and some model components do not perform well. These components do not reduce model capabilities with respect to GSP development but limit the usefulness of the model for other types of studies. Flows in the Kern River channel, including local stream-groundwater interactions, are not well replicated and surface water diversions are not dynamically simulated. The Kern County Subbasin portion of the C2VSimFG-Kern is not calibrated, and although the land surface water budget components are generally accurate, groundwater conditions and stream flows are poorly simulated in much of the Subbasin. Some rejected recharge occurs in the Kern Fan area in very wet years, but this is not significant as it is a very small volume.

The C2VSimFG-Kern is a reliable and defensible tool to support planning future groundwater conditions and estimating the potential hydrological impacts of future climate conditions and management actions at the subbasin level. It is currently the best available quantitative tool for assessing projected future groundwater conditions under SGMA. DWR recommends updating and refining models used in GSPs to incorporate new data including that in annual GSP updates. Refining Kern County Subbasin hydrologic modelling tools to replicate district-level historical conditions will provide a reliable means of assessing future effects of management actions at the district level for future GSP development.

9.4 Applicability of C2VSimFG-Kern Simulation Results

Based on the model validation, C2VSimFG-Kern provides a useful planning tool to evaluate potential future trends in groundwater in the Kern County Subbasin. The model validation demonstrated the capability of C2VSimFG-Kern to reasonably simulate the groundwater elevations and trends during the period from WY1995 through WY2015 based on the comparison to measured data.

The ability to reasonably simulate historical conditions provides confidence that C2VSimFG-Kern can be used to simulate potential future conditions. The model has the capability to simulate the most beneficial application of water projects that would provide the long-term benefit to the area. For the

future case scenarios, the general practice is to evaluate model results with respect to long-term trends. Therefore, as a planning tool, it is most beneficial to run the model in relation to a base case and to evaluate the relative difference between the model scenario and the base case. The base case would assume a selected set of climatic, hydrologic and pumping conditions. Commonly, the calibration base period is assumed to repeat; however, any number of variations can be constructed.

It is important to note that in some cases the model results may vary from those measured in individual wells due to the geologic complexity of the Kern County Subbasin. However, the model is capable of evaluating the impacts of changes in pumping and water use practices in the Kern County Subbasin that are useful for SMGA planning purposes.

The conclusions and recommendations presented herein are professional opinions based on the C2VSimFG-Kern revisions and simulations as described herein. The findings and professional opinions presented in this letter are presented within the limits prescribed by the client contract, in accordance with generally accepted professional engineering, geologic and modeling practices, to support development of GSPs within the Kern County Subbasin. There is no other warranty, either expressed or implied, regarding the conclusions, recommendations, and opinions presented in this report.

TABLE 10 - Summary of C2VSimFG-Beta modifications in the Kern County Revision applied to C2VSimFG-Kern by IWFM model input file

File Name	Change to Model Input File
C2VSimFG.in	
*	Change simulation starting time to 09/30/1985_24:00
C2VSimFG_Unsat.dat	
*	Replaced initial condition values with more representative values for revised starting
C2VSimFG_SWatersheds.dat	
*	Modified parameters to improve stream discharge match to historical values
C2VSimFG_Groundwater1985.dat	
*	Added hydrologic flow barrier at White Wolf Fault
*	Set Corcoran Clay thickness to 0 ft in areas where it is not present
*	New 10/1/1985 initial condition
*	Modified hydraulic conductivity and specific storage in Layer 1 in the Kern Water Bank
*	Kern County observation wells
C2VSimFG_ElemPump.dat	
*	FRACSK and DSTSK modified for Kern County elements with limited pumping
C2VSimFG_WellSpec.dat	
*	Added Kern County groundwater water bank recovery wells
*	Added Kern County In-District and Urban wells
C2VSimFG_PumpRates.dat	
*	Added Kern County groundwater water bank recovery pumping
*	Added Kern County In-District and Urban pumping
C2VSimFG_StreamInflow.dat	
*	Exteneded Poso Creek inflow through WY2015
C2VSimFG_DiverionSpec.dat	
*	Removed all Kern County diversions and renumbered remaining diversions to 1-371
*	Added Kern County diersions 372-484
C2VSimFG_Diverions.dat	
*	Removed all Kern County diversions and renumbered remaining diversions to 1-371
*	Added Kern County diersions 372-484
*	Updated diversion data for all diversions to Kern County
C2VSimFG_BypassSpecs.dat	
*	Removed bypass #17
C2VSimFG_RootZone.dat	
*	Native return flow is sent to either nearby stream nodes as runoff or out-of-model as ET
C2VSimFG_IrrPeriod.dat	
*	Adjusted Kern County irrigation periods
C2VSimFG_ReturnFlowFrac.dat	
*	Modified Kern County Ag return flow fraction
C2VSimFG_Urban.dat	
*	Added zone 106 for Metro Bakersfield and adjusted other Kern County zone areas
*	Applied estimated September 1985 initial condition

TABLE 10 - Summary of C2VSimFG-Beta modifications in the Kern County Revision applied to C2VSimFG-Kern by IWFM model input file

File Name	Change to Model Input File
C2VSimFG_Urban_Area.dat	
*	Changed Kern County oil fields from urban to native vegetation
C2VSimFG_Urban_PerCapWaterUse.dat	
*	Updated population for Kern County Urban Zones based on 1990, 2000, 2010 Census
*	Developed demands from historical data and water management plans
C2VSimFG_Urban_Population.dat	
*	Updated population for Kern County Urban Zones based on 1990, 2000, 2010 Census
C2VSimFG_Urban_WaterUseSpecs.dat	
*	Set fractions for SRs 19-21 based on local info
C2VSimFG_NonPondedCrop.dat	
*	Return flow = 0 for Kern County
C2VSimFG_NonPondedCrop_Area.dat	
*	Revided crop distributions to match historical distribution
C2VSimFG_PondedCrop_Area.dat	
*	Modified distribution of rice to be limited to areas in northwest Kern County with
C2VSimFG_NativeVeg_Area.dat	
*	Rebalanced native veg distribution after redistribution of non-ponded crop area to

Table 11A - Historical Groundwater Budget for the Kern County Subbasin for Water Years 1995 to 2014 based on the C2VSimFG-Kern Historical Simulation

Water Year	Deep Percolation	Managed Recharge and Canal Seepage	Net GW/SW Interactions	GW Pumping	Small Watershed Inflow	Subsurface Flow with Adjacent GW Basins	Change in Groundwater Storage
Units	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft
1995	880,480	944,800	185,777	-946,782	122,287	-75,299	1,111,263

Table 11B - Current Groundwater Budget for the Kern County Subbasin for Water Year 2015 based on the C2VSimFG-Kern Historical Simulation

Water Year	Deep Percolation	Managed Recharge and Canal Seepage	Net GW/SW Interactions	GW Pumping	Subsurface Flow within GW Basin	Subsurface Flow with Adjacent GW Basins	Change in Groundwater Storage
Units	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft
2015	429,983	89,744	46,344	-2,740,237	0	-51,201	-2,225,366

NOTES:

Deep Percolation	Precipitation and applied water that reaches the groundwater after simulated transport across the unsaturated zone
Managed Recharge and Canal Seepage	Combined groundwater recharge from managed aquifer recharge operations, groundwater banking, and seepage from canals and other conveyance
Net GW/SW Interactions	Net volumetric exchange of surface water and groundwater from streams: Positive represents a net groundwater recharge, and negative represents a net groundwater discharge to the stream
GW Pumping	Total groundwater pumping by wells. Groundwater banking recovery pumping is specified input whereas agricultural and municipal pumping is calculated by C2VSim based on demand
Subsurface Flow within GW Basin	Net subsurface groundwater flow into a neighboring water district or area within the Kern County Subbasin: negative is a net flow out of the district and positive is a net flow into the district
Subsurface Flow with Adjacent GW Basins	Net subsurface groundwater flow from the Kern County Subbasin with an adjoining groundwater basin: negative is a net flow out of the Basin and positive is a net flow into the Basin
Change in Groundwater Storage	Sum of the inflow components (positive numbers) plus the outflow components (negative numbers): positive is an increase in storage typified by a rise in GW levels whereas a negative is a decrease in storage typified by a decline in GW levels

TABLE 12: Estimated sustainable yield for Kern County Subbasin for WY1995 to WY2014 Base Period based on C2VSimFG-Kern Historical Simulation

Water Year	Total Average Annual Volume	Agricultural Average Annual Volume	Agricultural Average Annual Volume per Ag Acre	Urban Average Annual Volume
Units	Acre-ft	Acre-ft	ft/acre	Acre-ft
	Sustainable Yield from Groundwater Pumping			
Groundwater Pumping	1,590,373	1,239,931	1.59	176,146
Percentage of Pumping		78%		11%
Change in Groundwater in Storage	-277,114	-216,051	-0.28	-30,692
Percentage of Pumping		-17%		-17%
Sustainable Yield	**1,313,259**	**1,023,880**	**1.31**	**145,453**
Average Annual Difference	**-277,114**	**-216,051**	**-0.28**	**-30,693**
Percent Difference	**-21%**	**-21%**	**-21%**	**-21%**
	Sutainable Yield from Basin Recharge and Outflow			
Groundwater Recharge	1,400,362	1,091,789	1.40	155,101
Subsurface Outflow	-87,102	-67,909	-0.09	-9,647
Sustainable Yield	**1,313,260**	**1,023,880**	**1.31**	**145,453**
Average Annual Difference	**-277,114**	**-216,051**	**0**	**-30,692**
Percent Difference	**0**	**0**	**0**	**0**

NOTES:

Sustainable Yield from Groundwater Pumping Approach assumes that adjusting total groundwater pumping by the change in storage provides an reasonable approximation of the Basin Sustainable

Sutainable Yield from Basin Recharge and Outflow Approach assumes that the Basin Sustainable Yield can be reasonably approximated by adding up the different recharge components and non-

TABLE 13: Estimate of potential native yield for Kern County Subbasin for WY1995 to WY2014 based on C2VSimFG-Kern Historical Simulation

	Ag Precipitation Recharge			Other Area Precipitation Recharge			Small Watershed Inflows			
Water Year	Precipitation in Agricultural Area	Precipitation to ET Demand	Precipitation to Groundwater in Agricultural Area	Precipitation in Other Areas	Precipitation to ET Demand	Precipitation to Groundwater in Other Areas	Small Watershed Subsurface Inflow	Small Watershed Runoff Percolation	Small Watershed Recharge to Groundwater	Native Yield
Units	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft

NOTES:

Simulation of Recharge	IWFM applies two processes to simulate the movement of water from the surface to the groundwater. The root zone simulates calculates the volume of water that will percolate below the root zone based on local soil properties. This water bases to the unsaturated zone that applies a 1-D vadose zone flow that simulates the rate that water will reach the groundwater based on subsurface properties and soil moisture content.
Percolation from Agricultural Area	Total volume of rainfall and applied water calculated to meet the total agricultural demand that percolates below the root zone in irrigated agricultural areas based on C2VSim simulation.
Percolation from Urban Area	Total volume of rainfall and applied water calculated to meet urban outdoor use that percolates below the root zone in urban areas based on C2VSim simulation.
Percolation from Native, Undeveloped or Fallow Areas	Total volume of rainfall and applied water that percolates below the root zone in native, undeveloped and fallow areas based on C2VSim simulation.
Percolation to Unsaturated Zone	Total volume of rainfall and applied water that percolates below the root zone from all areas based on C2VSim simulation.
GW Recharge from Unsaturated Zone	Volume of water going from the unsaturated zone to groundwater
GW Banking, Managed Recharge and Canal Seepage	Managed aquifer recharge and groundwater banking is simulated in C2VSim by applying a high recoverable loss factor for surface water diversions. For Kern County, these operations generally assumes that 88% to 94% of surface water deliveries physically recharge groundwater. This recharge is applied directly to the groundwater without passing through the unsaturated zone.
Net GW/SW Interactions	Net volumetric exchange between surface water in Kern River or Poso Creek and the groundwater. A positive number is surface water to groundwater, and a negative is groundwater discharge to the stream. This recharge is applied directly to the groundwater without passing through the unsaturated zone.
Total GW Recharge	Total volume to water reaching the groundwater as recharge

TABLE 22: Assessment of change in groundwater storage from C2VSimFG-Kern model results for historical and future scenarios for the Kern County Subbasin

Scenario	Model Results 2041-2070 Sustainability Period		Adjustments to GW Storage Change 2041-2070 Sustainability Period		
	Change in Groundwater Storage	Change in Net Operational Budget	Adjustment for Excess Basin Outflows	Adjustment for Excess Kern River Outflow	Adjusted Change in GW Storage
units	**AFY**	**AFY**	AFY	AFY	**AFY**
Historic	**-277,114**	**-190,012**	0	0	**-277,114**
Baseline	**-324,326**	**-253,629**	0	0	**-324,326**
Base Projects	**42,144**	**152,353**	26,327	17,108	**85,578**
2030 Climate	**-380,900**	**-318,260**	0	8,780	**-372,120**
2030 Projects	**-12,861**	**90,282**	27,056	32,634	**46,829**
2070 Climate	**-489,828**	**-429,035**	0	17,492	**-472,336**
2070 Projects	**-118,273**	**-15,861**	28,077	44,227	**-45,969**

NOTE:

"Change in *Groundwater Storage* " DOES include subsurface flow with adjacent basins

"*Operational Storage* " DOES NOT include subsurface flow with adjacent basins

"Adjustment for *Excess Basin Outflows* " is the difference in simulated basin outflow that is attributed to addition of SGMA projects in Kern County without comparable SGMA projects added to adjacent basins**.** Adjustment assumes that this difference is due to limitation of simulation, and that this difference would remain in Kern County when SGMA projects from adjacent basin are included in simulation.

"Adjustment for *Excess Kern River Outflow* " is the increase in simulated groundwater outflows to Kern River relative to Baseline condition that are attributed to SGMA Projects and Climate Change. Model is not optimized for river management. Since the Kern River is a highly managed system, the assumption is that in practice this water would be recovered for beneficial use rather than be a loss of water from the basin.

"*Adjusted Change in GW Storage* " Change in GW Storage plus modifications listed as adjustments to provide a more realistic Change in GW Storage estimate for the simulation.

TABLE 23: Evaluation of Sustainable Yield for Projected-Future scenarios based on C2VSimFG-Kern Model Results for Kern County Subbasin

Scenario	C2VSimFG-Kern Model Results 2041-2070 Sustainability Period					
	Groundwater Pumping	Change in Groundwater in Storage	GW Storage Adjustments	Sustainable Yield	Average Annual Difference of Pumping to Yield	Percent Difference of Pumping to Sustainable Yield
units	AFY	AFY	AFY	AFY	AFY	AFY
Historic	**1,590,373**	**-277,114**	**0**	**1,313,259**	**-277,114**	**-21%**
Baseline	**1,624,694**	**-324,326**	**0**	**1,300,369**	**-324,326**	**-25%**
Baseline Projects	**1,354,088**	**42,144**	**43,434**	**1,439,666**	**85,578**	**6%**
2030 Climate	**1,734,001**	**-380,900**	**8,780**	**1,361,881**	**-372,120**	**-27%**
2030 Projects	**1,444,144**	**-12,861**	**59,690**	**1,490,974**	**46,829**	**3%**
2070 Climate	**1,866,239**	**-489,828**	**17,492**	**1,393,902**	**-472,336**	**-34%**
2070 Projects	**1,559,343**	**-118,273**	**72,304**	**1,513,373**	**-45,969**	**-3%**

NOTES:

Groundwater Pumping	Total groundwater pumping by wells. Groundwater banking recovery pumping is specified input whereas agricultural and municipal pumping is calculated by C2VSim based on demand
Change in Groundwater in Storage	Sum of the inflow components (positive numbers) plus the outflow components (negative numbers): positive is an increase in storage typified by a rise in GW levels whereas a negative is a decrease in storage typified by a decline in GW levels
Adjusted Banking	Adjustment that assumes that recharge operations are affected by reductions in imported water sources, but
GW Storage Adjustments	Adjustment to GW Storage that reflect artifacts of the simulation. For Kern County, adjustments made to reflect no SGMA projects simulated north of Kern County, and that Kern River operations are not optimized to
Sutainable Yield	Sustainable yield is defined is the amount of pumping that can be sustained in the groundwater basin without the undesirable effect of a decline in groundwater storage that serves as a proxy for other undesirable effects
Average Annual Difference	The difference between the sustainable yield and the simulated groundwater pumping. A negative value is pumping in excess of the sustainable yield
Percent Difference	The percentage of the Average Annual Difference to the total groundwater pumping to provide context and a method to compare the significance of the difference in the pumping copmared to the sustainable yield.

TABLE 24: Summary of Statistical Analysis for Validation of C2VSimFG-Kern Historical Simulation

Validation Measure	C2VSimFG-Kern	C2VSimFG-Beta	Percent Change
Units	Feet	Feet	Percent
Residual Mean	17.3 ft	32.6 ft	47%
Residual Standard Deviation	45.5 ft	54.0 ft	16%
Absolute Residual Mean	37.4 ft	56.8 ft	34%
Root Mean Square (RMS) Error	50 ft	73.5 ft	32%
Scaled Absolute Residual Mean	0.061	0.092	34%
Correlation Coefficient	0.76	0.52	47%
Number of Monitor Wells	558	558	same
Number of Observations	42,075	42,075	same

Notes

Observation Point	Location in the model where measured data from well is compared to simulated model results
Residual	Difference between measured and simulated groundwater elevations at an observation point
Residual Mean	Statistical measure of fit of simulated to measured data using sum of the residuals divided by the number of residual data values
Residual Standard Deviation	Statistical evaluation of the scatter of the data by calculating standard deviation of residuals
Absolute Residual Mean	Statistical measure of fit of simulated to measured data using sum of the absolute value residuals divided by the number of residual data values
Root Mean Square (RMS) Error	Statistical measure of fit of simulated to measured data using square root of the quotient of sum of squares of residuals by the number of observations
Scaled Absolute Residual Mean	Statisical measure to provide scale of validation using ratio of the absolute residual mean divided by the range of observed groundwater elevations
Correlation Coefficient	Scaled measure of the closeness of fit of simulated to measured data from -1 to 1 correlation with 1.0 a perfect correlation
Number of Monitor Wells	Number of wells where measured groundwater level data was compared to C2VSimFG-Kern simulation results for model validation
Number of Observations	Number of groundwater level measurements that were compared to C2VSimFG-Kern simulation results for model validation

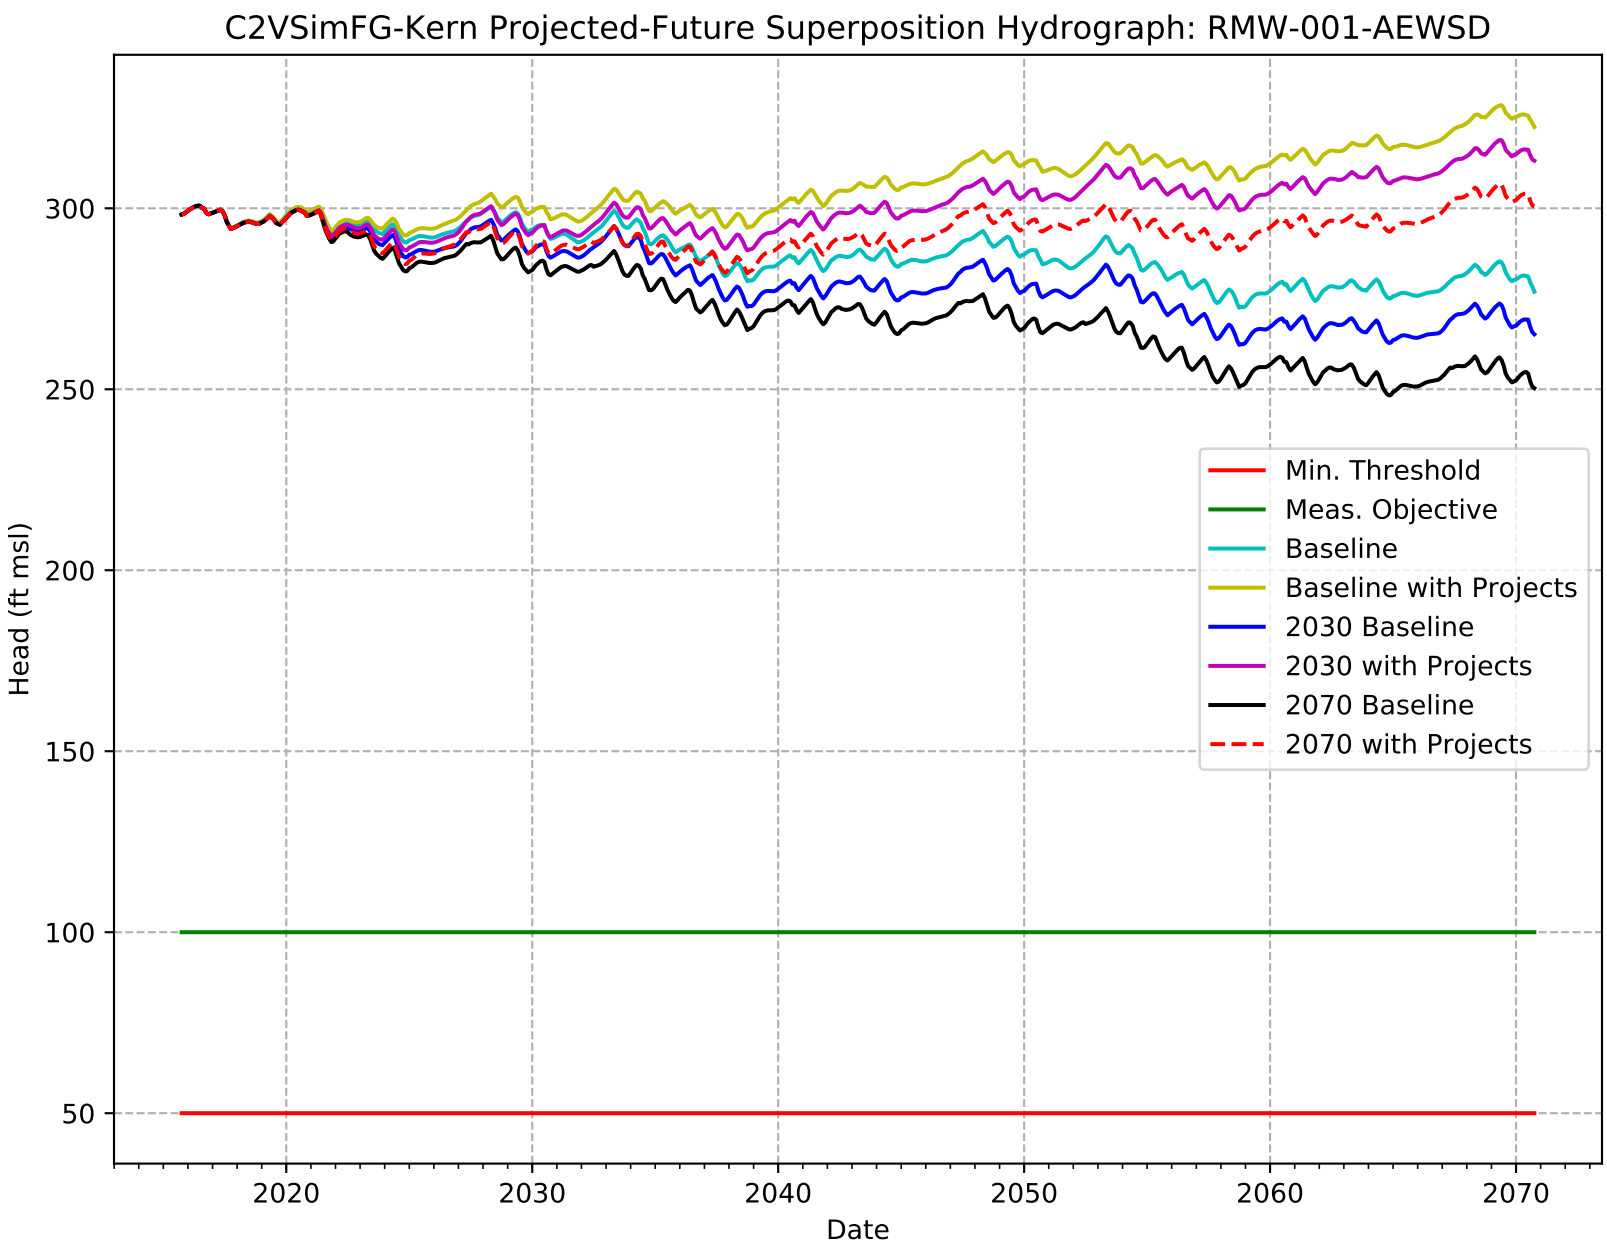
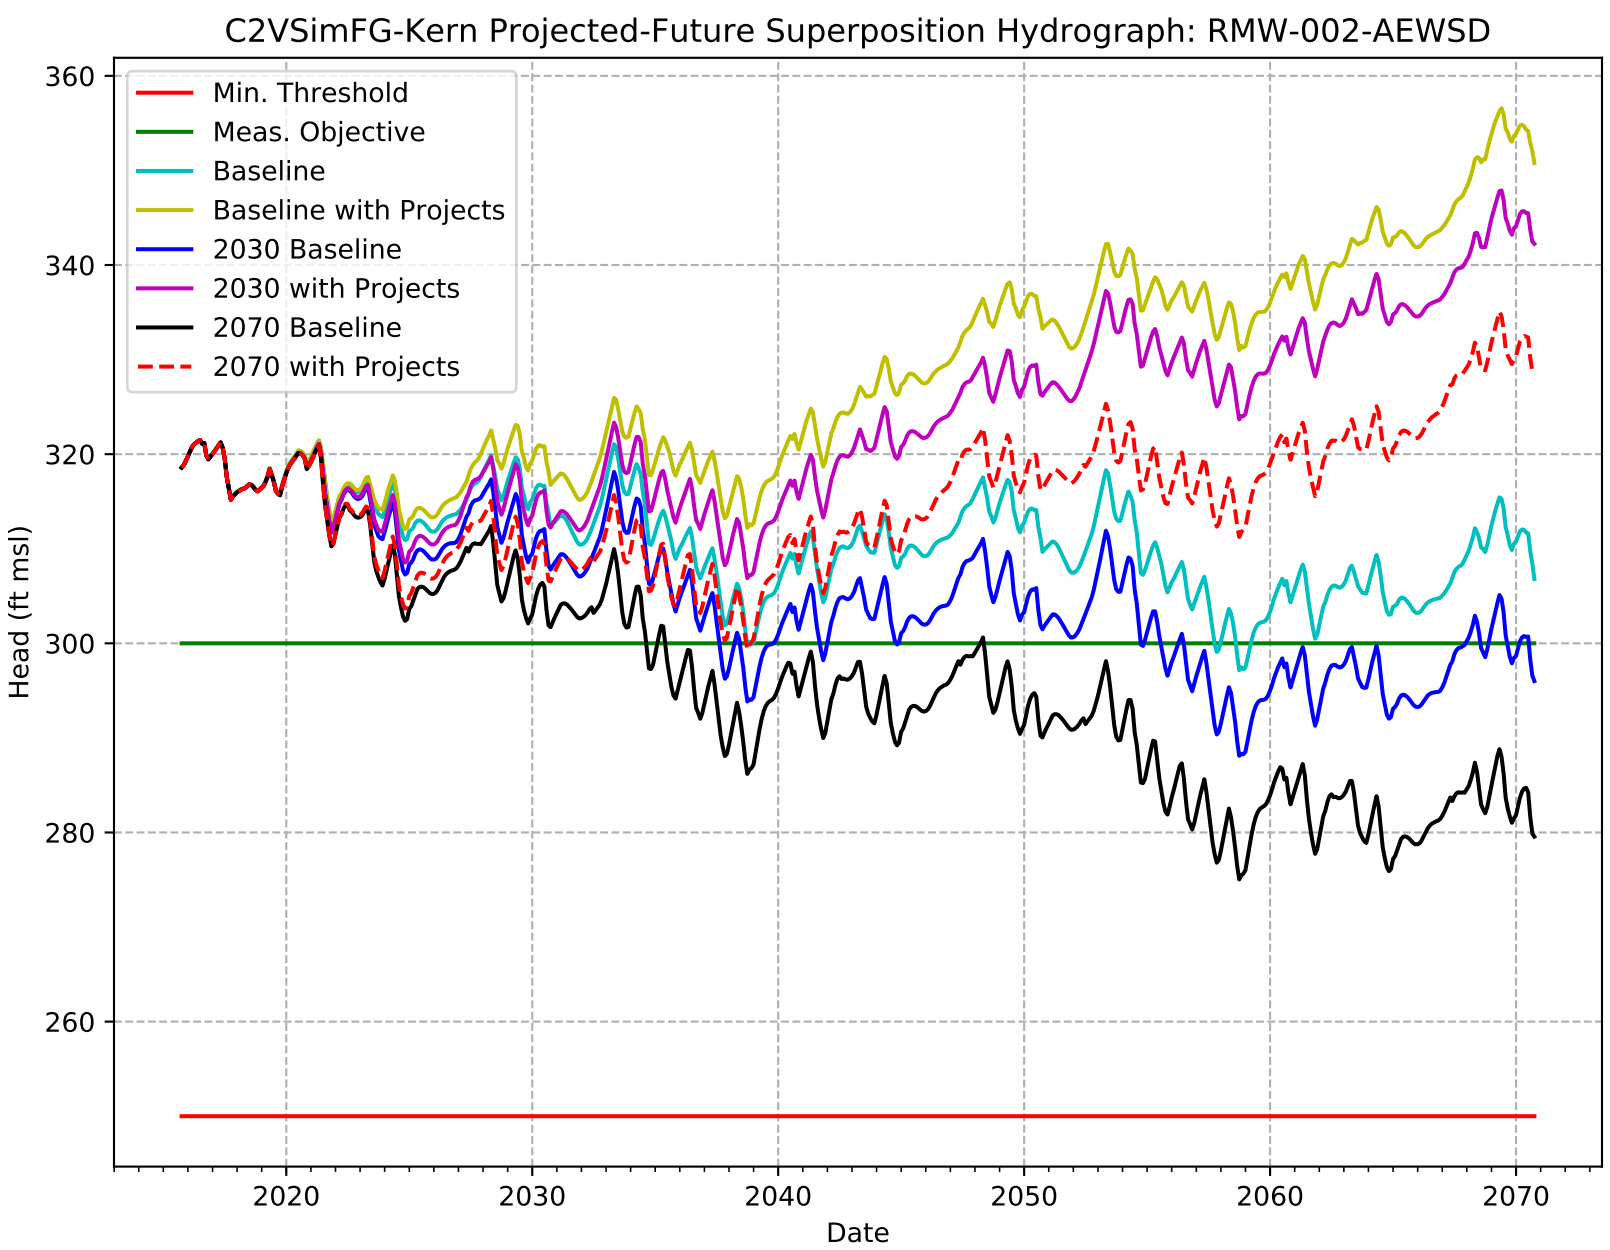
Notes:
Sensitivity parameters modified and evaluated for Kern County Subbasin
Kh – horizontal hydraulic conductivity of aquifer
Kv – vertical hydraulic conductivity of aquifer



Kcorc - horizontal hydraulic conductivity of Corcoran Clay aquitard or equivalent
Cstm – streambed conductance of Kern River and Poso Creek
Ss – specific storage of aquifer



Sy – specific yield of aquifer
Ksoil –soil hydraulic conductivity in root zone
Λ –soil pore size distribution index in root zone

Kern River GSA - App. K Properties	1,308		-1,308
Buena Vista GSA	103,950	126,936	22,986
Non-districted lands*	18,013		-18,013
Totals	2,411,524	2,125,214	**-286,310**

Todd Groundwater Modeling Result for Baseline Condition: **-324,326**

Todd Groundwater Modeling Result for Historical Change in Groundwater in Storage: **-277,114**

***Most of the irrigated non-districted lands are now being managed/covered under SGMA by the GSAs**

The Kern County Subbasin GSAs have collaboratively developed the above water budget table to present an inventory of supply and demand using a "checkbook approach". The checkbook approach provides a mechanism for coordinated water accounting among the GSAs and does not include subsurface flows. The table was used to examine local water budget conditions and to prevent double-counting of water supplies. Although developed separately from the C2VSimFG-Kern model, the sum of the water budget deficits compares relatively well with model results; model deficits shown at the bottom of the table are larger due to inclusion of Subbasin subsurface outflows, which are not included in the checkbook approach.

APPENDIX 3

Undesirable Results Definitions

Introduction:

- **Management areas shall be identified by the basin and shown on exhibit "A".**
- **Representative Monitoring Locations shall mean the locations within the basin which are identified and designated by the GSA's for purposes of monitoring sustainability indicators.**
- **Critical Infrastructure shall mean facilities which are utilized to provide public services such as water, utilities, and or transportation service for a region.**
- **Prolonged Drought – The undesirable results herein take into account the accommodation of a prolonged drought as defined in DWR's BMP.**

Chronic Lowering of Water Levels –
The point at which significant and unreasonable impacts over the planning and implementation horizon, as determined by depth/elevation of water, affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

This is determined when the minimum threshold for groundwater levels are exceeded in at least three(3) adjacent management areas that represent at least 15% of the subbasin or greater than 30% of the subbasin (as measured by each Management Area). Minimum thresholds shall be set by each of the management areas through their respective Groundwater Sustainability Plans.

Groundwater Storage –
The point at which significant and unreasonable impacts, as determined by the amount of groundwater in the basin, affect the reasonable and beneficial use of, and access to, groundwater by overlying users over an extended drought period. (10-years?)

This is determined when the volume of storage (above the groundwater level minimum thresholds) is depleted to an elevation lower than the groundwater level minimum threshold in at least three(3) adjacent management areas that represent at least 15% of the subbasin or greater than 30% of the subbasin (as measured by the acreage of each Management Area).

Minimum thresholds shall be set by each of the management areas through their respective Groundwater Sustainability Plans.

Degraded Water Quality Trends –
The point at which significant and unreasonable impacts over the planning and implementation horizon, as caused by water management actions, that affect the reasonable and beneficial use of, and access to, groundwater by overlying users.

This is determined when the minimum threshold for a groundwater quality constituent of concern is exceeded in at least three(3) adjacent management areas that represent at least 15% of the subbasin or greater than 30% of the designated monitoring points within the basin. Minimum thresholds shall be set by each of the management areas through their respective Groundwater Sustainability Plans.

Land Subsidence Trends –
The point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.

This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan.

Monitoring Network & Protocols

Monitoring Network shall be developed to be capable of collecting sufficient data to demonstrate short-term, seasonal, and long-term trends in groundwater and related surface conditions, and yield representative information about groundwater conditions as necessary to evaluate Plan implementation. The monitoring network objectives shall be implemented to accomplish the following:

1) Demonstrate progress toward achieving measurable objectives described in the Plan
2) Monitor impacts to the beneficial uses and users of groundwater
3) Monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds
4) Quantify annual changes in water budget components

Monitoring Network shall be designed to ensure adequate coverage of sustainability indicators. If management areas are established, the quantity and density of monitoring sites in those areas shall be sufficient to evaluate conditions of the basin setting and sustainable management criteria specific to that area. To the extent possible, the use of existing monitoring data and infrastructure should be utilized to meet the needs for characterization, historical record documentation and continued monitoring requirements.

Monitoring Network shall describe the scientific rationale for the monitoring site selection and for each sustainability indicator, the quantitative values for the minimum threshold, measurable objective and interim milestones shall be indicated at each monitoring site.

Monitoring Protocols developed shall include a description of technical standards, data collection methods, and other procedures or protocols for monitoring sites or other data collection facilities to ensure that the monitoring network utilizes comparable data and methodologies. There is no definitive rule for the density of groundwater monitoring points needed in a basin. The table below provides guidance for the density of monitoring wells per hundred square miles. One important item to consider is how the definitions of undesirable results will be impacted to provide the necessary information to indicate compliance.

Reference	Monitoring Well Density (wells per 100 miles2)
Heath (1976)	0.2 - 10
Sophocleous (1983)	6.3
Basins pumping more than 10,000 acrefeet/year per 100 miles	4.0
Basins pumping between 1,000 and 10,000 acre-feet/year per 100 miles	2.0
Basins pumping between 250 and 1,000 acre-feet/year per 100 miles	1.0
Basins pumping between 100 and 250 acre-feet/year per 100 miles	0.7

Measuring Groundwater Levels

Given the significant variations in groundwater elevations throughout the Kern subbasin which are due to variations in hydrologic conditions, no single groundwater elevation surface should be considered a representation of groundwater flow directions in this basin.

Requirements for well selections:

- A long-term access agreement that includes year-round site access to allow for increased monitoring frequency
- A unique identifier that includes a general written description of the site location, date established, access instructions and point of contact, type of information to be collected, latitude, longitude and elevation
- Monitoring location should also track all modifications to the site in a modification log

The following data collection protocols are to be followed within the Kern subbasin:

- Groundwater level data shall be sufficient to produce seasonal maps of potentiometric surfaces or water table surfaces throughout the basin that clearly identify changes in groundwater flow direction and gradient.
- Use the Well Data form provided (see attached)
- Groundwater level data shall be collected from each principal aquifer in the basin
- Collection of data between the approved time frames only
    - January 15th to March 30th
    - September 15th to November 15th
- A weighted water level meter or other CASGEM approved measuring device will be used to measure the depth to groundwater
- Depth to groundwater must be measured relative to an established Reference Point on the well casing. If no mark or reference point is apparent, the person performing the measurement should measure the depth to groundwater from the north side of the top of the well casing
- The elevation of the Reference Point of the well must be referenced to the North American Vertical Datum of 1988. The accuracy of the reference point should be consistent with CASGEM established guidelines.
- Each well's Reference Point will be cataloged to ensure identical procedures are followed for subsequent measurements.
- The data collector should remove the appropriate cap, lid or plug that covers the monitoring access point listening for pressure release. If a release is observed, the measurement should follow a period of time to allow the water level to equilibrate.
- Depth to groundwater must be measured to the accuracy associated with the approved monitoring method or device.
- The water level meter shall be decontaminated after measuring each well.
- The data collector shall calculate the groundwater elevation as:
    - GWE = RPE – DTW
    - GWE = Groundwater Elevation

    - RPE = Reference Point Elevation
    - DTW = Depth to Water
- The data collector must ensure that all measurements are consistent units of feet, tenths of feet or hundredths of feet. Measurements and Reference Point Elevations should not be recorded in feet and inches.

Groundwater Quality

Groundwater quality monitoring networks shall be designed to demonstrate that the degraded water quality sustainability indicator is being observed for the purpose of meeting the definition of the sustainability goal.

Requirements for well selections:

- A long-term access agreement that includes year-round site access to allow for increased monitoring frequency
- A unique identifier that includes a general written description of the site location, date established, access instructions and point of contact, type of information to be collected, latitude, longitude and elevation
- Monitoring location should also track all modifications to the site in a modification log
- The use of existing water quality data within the basin should be done to the greatest extent possible
- Monitoring network should consist largely as a supplemental monitoring locations where known groundwater contamination plumes are under existing regulatory management

The following data collection protocols are to be followed within the Kern subbasin:

- Monitor groundwater quality data from each principal aquifer in the basin
- Data should be sufficient for mapping movement of degraded water quality
- Data should be sufficient to assess groundwater quality impacts to beneficial uses and users
- Data should be sufficient to evaluate whether management activities are contributing to water quality degradation.
- All analyses should be performed by a laboratory certified under the State Environmental Laboratory Accreditation Program
- Samples will be collected according to the standards listed in the Standard Methods for the Examination of Water and Wastewater, USGS National Field Manual for the Collection of Water Quality Data
- Prior to sampling, the sampler must contact the laboratory to schedule laboratory time, obtain appropriate sampler containers, and clarify any sample holding times or sample preservation requirements
- Each well used for groundwater quality monitoring must have a unique identifier. This identifier must appear on the well housing or the well casing to avoid confusion
- In the case of wells with dedicated pumps, samples should be collected at or near the wellhead. Samples are not to be taken/collected from storage tanks, at the end of long pipe runs or after any water treatment infrastructure

- Samples will be taken/collected only after the appropriate volume of water has been purged from the casing and field parameters have stabilized
- Sampler will clean the sampling port and/or sampling equipment. The sampling port and/or sampling equipment must be free of any contaminants
- Groundwater elevation in the well should be measured following the protocols described in the groundwater level measuring protocols
- Field parameters of pH, electrical conductivity and temperature should be collected for each sample. Lab pH analysis are typically unachievable due to short hold times.
- All field instruments should be calibrated daily and evaluated for drift throughout the day
- Sample containers should be labeled prior to sample collection. The sample label must include:
    - Sample ID (well ID)
    - Sample date and time
    - Sample personnel
    - Sample location
    - Preservative used
    - Analytes and analytical method
- Samples shall be collected under laminar flow conditions. This may require reducing pumping rates prior to sample collection
- Samples requiring preservation must be preserved as soon as practically possible
- Samples to be analyzed for metals should be field-filtered prior to preservation. Do not collect an unfiltered sample in a preserved container
- Samples will be chilled and maintained at 4 C to prevent degradation of the sample
- Samples will be shipped under a chain of custody documentation to the appropriate laboratory promptly to avoid violating holding time restrictions
- Custody Seal will be used by the field technician if a third-party transportation service is used
- A Field Sampling Log will include:
    - Sampler's identification
    - Well identification
    - Climatic conditions
    - Depth to water prior to purging
    - Type of purging and sampling device
    - Purging rate and volume
    - Relative well yield volume
    - Field parameter measurements (pH, temperature, EC, DO)
    - Type and number of samples collected
    - Date and time collected

Change in Groundwater Storage

Since the groundwater storage is not a directly measurable condition, it does rely heavily on the collection of accurate groundwater levels. The changes in groundwater levels reflect changes in storage and can thus be estimated with assumptions of thickness of units, porosity, and connectivity. These observations will be essential for use in calculating the water budget.

A water budget is a foundational tool used to compile water flows (supplies) and outflows (demands). It is an accounting of the total groundwater and surface water entering and leaving a basin or user-defined area. The difference between flows and outflows is a change in the amount of water stored.

Coordination of Water Budget Data to comply with groundwater storage:

- Surface water supply
- Total water use
- Water budget
- Sustainable yield

The change in the annual volume of groundwater storage between seasonal high conditions shall be quantified in the water budget.

Land Subsidence

Land subsidence protocols are to be set up to identify the rate and extent of land subsidence, which maybe measured by extensometers, surveying, remote sensing technology, or other appropriate method. To the extent possible, the use of existing data should be utilized.

Prior to development of a specific subsidence monitoring network a screening level analysis should be conducted. The screening of subsidence occurrence should include:

- Review of the HCM and understanding of grain-size distributions and potential for subsidence to occur
- Review of any known regional or correlative geologic conditions where subsidence has been observed.
- Review of historic range of groundwater levels in the principal aquifers of the basin
- Review of historic records of infrastructure impacts, including but not limited to damage to pipelines, canals, roadways or bridges or well collapse potentially associated with land surface elevation changes
- Review of remote sending results such as InSAR or other land surface monitoring data
- Review of existing CGPS surveys

This basin has decided to work together on this protocol with a consultant to obtain the required data.

See the attached for the coordinated effort by all the GSAs in the Kern Subbasin pertaining to Land Subsidence.

TO: Kern County Subbasin GSAs

FROM: GEI Consultants, Inc.

DATE: October 25, 2019

RE: IMPROVEMENTS TO REGIONAL SUBSIDENCE MONITORING IN THE KERN COUNTY SUBBASIN

This memorandum was prepared, in coordination with the Kern County Subbasin GSAs, to fill data gaps in the Kern County Subbasin subsidence monitoring network. It prioritizes areas of interest, at a subbasin-level, that require additional subsidence monitoring. It also includes the design approach and parameters to be monitored, and references DWR guidelines regarding subsidence monitoring design.

Background and Purpose

The development of a network to monitor sustainability indicators, including subsidence, is one of the requirements of the Groundwater Sustainability Plans (GSPs) to be submitted to the Department of Water Resources (DWR) for compliance with the Sustainable Groundwater Management Act (SGMA).

To achieve and comply with the requirements of SGMA as it pertains to subsidence and knowing that in the Kern County Subbasin there lacks sufficient data, this memo was generated for the benefit of the entire Kern Subbasin GSAs as a coordinated effort. In each individual GSPs of the Kern Subbasin, existing land surface elevation and land subsidence monitoring is identified, along with data gaps within the existing network. This memo describes the process and rationale for identifying subsidence areas of interest (AOIs) to address data gaps, the current monitoring network, and the location of future monitoring points. The memo includes the following objectives for monitoring, which are applicable to land subsidence:

1. Demonstrate progress toward achieving measurable objectives described in the management area and throughout the Subbasin;
2. Monitor impacts to the beneficial uses and users of groundwater, surface land uses, and critical infrastructure; and
3. Monitor changes in groundwater conditions (or land subsidence) relative to measurable objectives and minimum thresholds.

The monitoring network is designed to monitor impacts to surface land uses or critical infrastructure as stated in the Subbasin-wide definition of undesirable results for land subsidence (KGA, 2019 emphasis added):

> *The point at which significant and unreasonable impacts, as determined by a subsidence rate and extent in the basin, that affects the surface land uses or critical infrastructure.*
>
> *This is determined when subsidence results in significant and unreasonable impacts to critical infrastructure as indicated by monitoring points established by a basin wide coordinated GSP subsidence monitoring plan.*

One of the purposes for improving the subsidence monitoring network is to collect additional data at each AOI to fill data gaps so that sustainable management criteria (SMCs) can be set. As more data are gathered for the AOIs, Kern County Subbasin GSAs and stakeholders can establish SMCs to avoid undesirable results stemming from subsidence.

AOI Screening and Monitoring Approach

The first step in the subsidence monitoring approach is to identify AOIs based on the presence of critical infrastructure or other surface land uses. These AOIs can then be evaluated based on the decision-making criteria listed below to determine if monitoring is required. This process is illustrated in Figure 1.

An AOI requires monitoring if the following three criteria apply:

1. Infrastructure or surface land uses are susceptible to land subsidence.
2. Significant land subsidence has been observed in screening from Interferometric Synthetic-Aperture Radar (InSAR) or other remote sensing techniques.
3. The subsidence is caused by groundwater extraction.

Where data gaps exist in evaluating the criteria, additional investigation may be necessary. For example, further investigation at AOI-2 is necessary to evaluate if groundwater extraction is causing subsidence.

Monitoring Parameters

If the area is identified as an AOI that requires monitoring, then the following actions should be taken:

A. Groundwater level monitoring near the AOI,
B. Ground-truthing of subsidence detected by InSAR (CGPS, extensometer, or level surveying), and
C. Monitoring of the critical infrastructure.

As depicted in Figure 1, the process for establishing monitoring points includes locations with susceptible critical infrastructure where InSAR and/or other historical and recent monitoring has detected recent subsidence that is likely caused by groundwater extraction.

Regional Coordination

Regional coordination of monitoring is key to the design of the network in the subbasin because regional groundwater extraction is a main driver of subsidence. In addition, many of the critical infrastructure are regional and may require coordination for access within the vicinity and data sharing.

Subsidence associated with oil and gas activities may also occur in the subbasin. However, any subsidence potentially associated with oil and gas activities is regulated by the California Division of Oil, Gas, and Geothermal Resources (DOGGR) under the California Public Resources Code and is therefore separate from SGMA requirements. Coordination between groundwater and oil and gas stakeholders may be needed where there is potential for both activities to cause subsidence that impacts critical infrastructure.

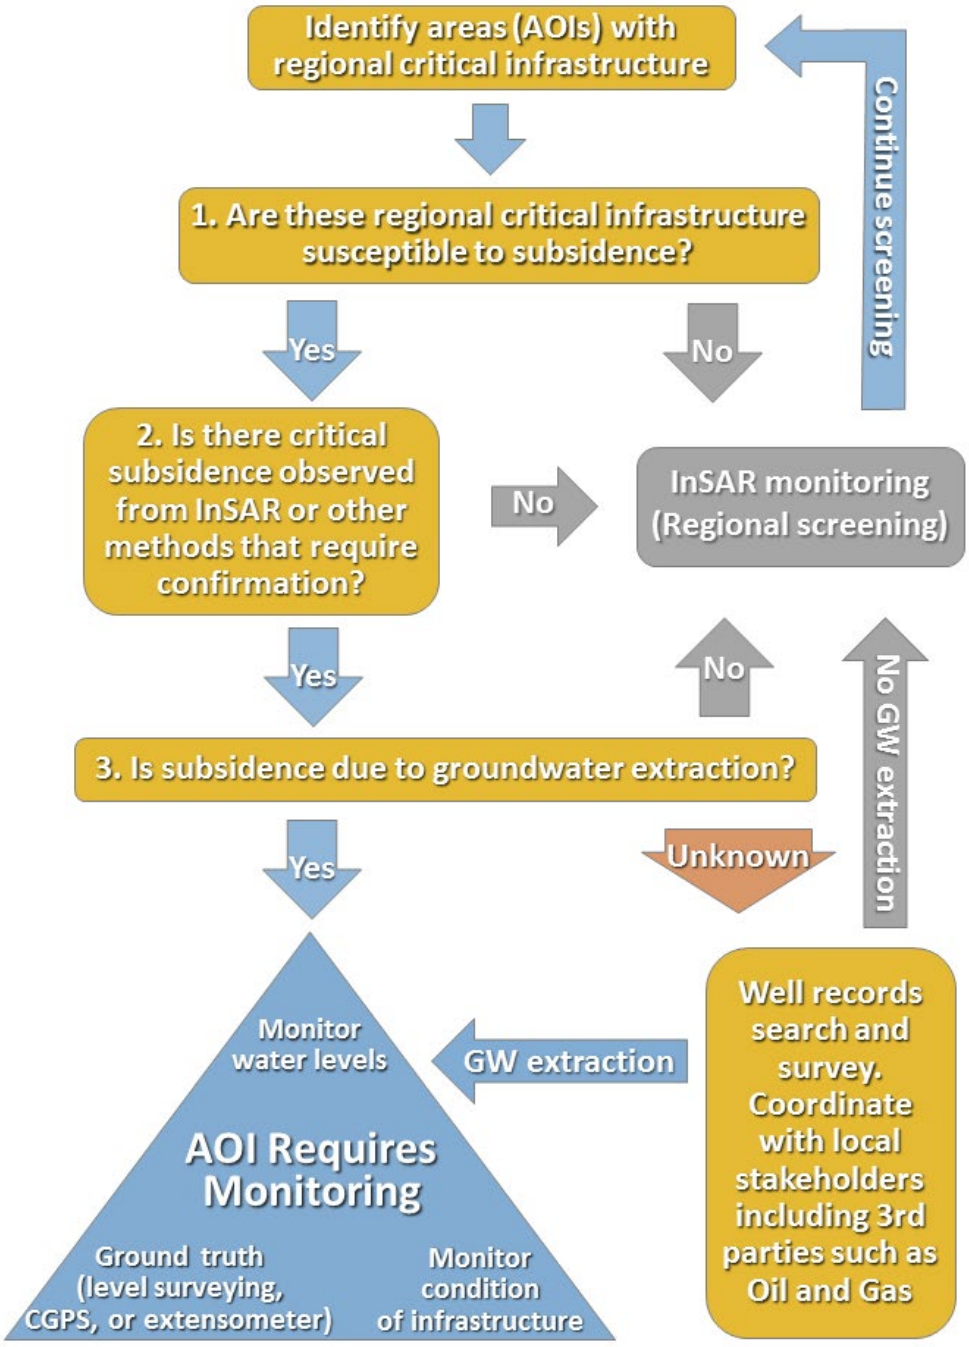

Figure 1. Subsidence Monitoring Decision Making Process and Criteria.

Improvements to Monitoring Network

Timeline and Approach

Five AOIs were identified, in order of priority, to improve the subbasin monitoring network (AOI-1 to AOI-5). Two of these areas are located along the Friant-Kern Canal (FKC), two are along the California Aqueduct, and one area is for monitoring changes in land surface elevation along the northern boundary of the subbasin where a significant amount of subsidence has been reported in the InSAR data.

It is anticipated that these sites will be evaluated in order of priority and may take up to several years to design and implement monitoring points.

Each monitoring site design will consider the following:

1. Confirm groundwater extraction is the cause of subsidence (if necessary),
2. Land siting and ownership,
3. Site access,
4. Monitoring design (CGPS or extensometer),
5. Confirmation that data for all three monitoring parameters can be collected (a. groundwater elevations, b. subsidence, and c. condition of infrastructure), and
6. Connection to the monitoring network and data sharing.

The subsidence monitoring network AOIs are presented on Figure 2. AOI-1 was selected to monitor along the FKC where subsidence has been detected near the northern boundary of the subbasin. AOI-2 was selected where the California Aqueduct has had historical impacts partially attributed to subsidence. AOI-3 along the FKC south of Poso Creek has had subsidence detected and reported by the North Kern WSD. AOI-4 along the California Aqueduct has had subsidence reported by DWR Division of Engineering (DOE) and InSAR, and AOI-5 along the northern boundary of the subbasin is not associated with critical infrastructure but is the location of high cumulative subsidence at the boundary of the subbasin and may be indicative of conditions in the neighboring subbasins which have the potential to impact the conditions of the Kern County Subbasin.

Groundwater Elevations

A key parameter in evaluating subsidence as a sustainability indicator for groundwater management is understanding groundwater level changes with respect to subsidence, particularly regional changes in water level. Figure 3 presents the regional water level monitoring points (RMWs) from the draft GSP with respect to the five AOIs for subsidence monitoring. The following are observations of RMWs within AOI vicinity:

- AOI-1 has a few surrounding RMWs; however, none are within 1 mile of the FKC.
- AOI-2 has one RMW within a mile of the Aqueduct and the AOI.
- AOI-3 has one RMW in the central portion about 1 mile from FKC.
- AOI-4 has two RMWs within the vicinity of the Aqueduct.
- AOI-5 has no RMWs within 1 mile.

Recommendation

Where possible, subsidence monitoring stations should be installed within 1 mile of a reliable RMW. If necessary, a new RMW may be installed to provide a point at which groundwater level may be collected in proximity to the land surface elevation monitoring point.

AOIs listed on subsequent pages

AOI-1. FKC Milepost 120 to 130

This high priority area is located along the FKC between Mileposts 120 to 130 (Figure 2), east-northeast of the City of McFarland. The purpose of this AOI is to monitor subsidence along the FKC and its related infrastructure. At times, InSAR monitoring has reported up to 5 inches per year of subsidence in areas surrounding this segment of the FKC. At present, no significant impacts to the FKC have been reported along this portion of the canal's alignment. According to leveling survey data from Friant Water Authority (FWA, 2019), the FKC invert may have subsided from 2 ft to 3 ft below original as-built elevations between Mileposts 120 to 135. Continued lowering of the canal invert can decrease freeboard from the original as-built conditions, which may contribute to reduction in emergency storage capabilities and delivery options of the Canal.

In contrast, beyond the subbasin's northern boundary, subsidence has caused significant impacts to the FKC conveyance capabilities between Mileposts 101 to 108.

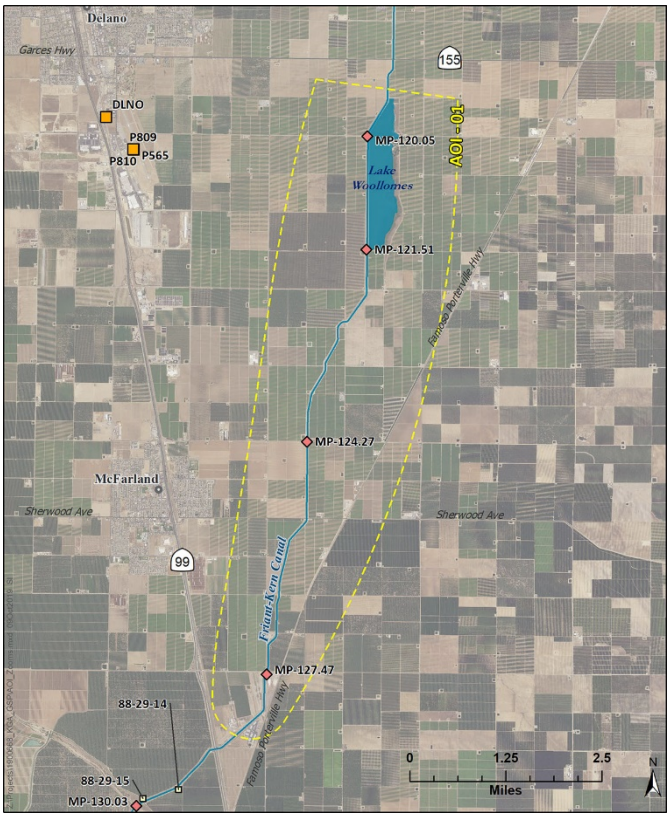

Figure 4. AOI-1. FKC Milepost 120 to 130
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR, and previous level surveying was performed by FWA at the mileposts labeled on Figures 2 and 4. There are no other active monitoring points except for InSAR along this stretch.

New Monitoring Approach

A new CGPS station that monitors at the ground surface any subsurface subsidence, regardless of the depth interval, is recommended because the only known cause of subsidence in this area is attributed to groundwater extraction. This CGPS data will complement any manual level surveys that may incorporate the FWA reported measuring points. CGPS data may also provide on-demand data as needed.

Coordination of Monitoring

Subsidence monitoring along the FKC benefits local stakeholders, CVP contractors, and the FWA. It is anticipated that this monitoring can be coordinated with FWA to share data as well as potentially share resources and cost.

Any level surveying along the canal from the United States Bureau of Reclamation (USBR) Friant-Kern benchmarks (Figure 2) will require coordination with the FWA.

AOI-2. California Aqueduct Milepost 196 to 215

This high priority area is the segment of the California Aqueduct where an embankment failure occurred at Milepost 208 in June 2011 (DWR, 2017). This failure is partially attributed to subsidence. The cause of this subsidence is unknown and is therefore a subject of monitoring at this location. This area is along the Aqueduct between Mileposts 196 to 215 in the western central subbasin (Figure 2). In addition to embankment failure, other consequences of subsidence include loss in freeboard in the Aqueduct. This area has experienced at least 2 feet of subsidence since the Aqueduct was constructed.

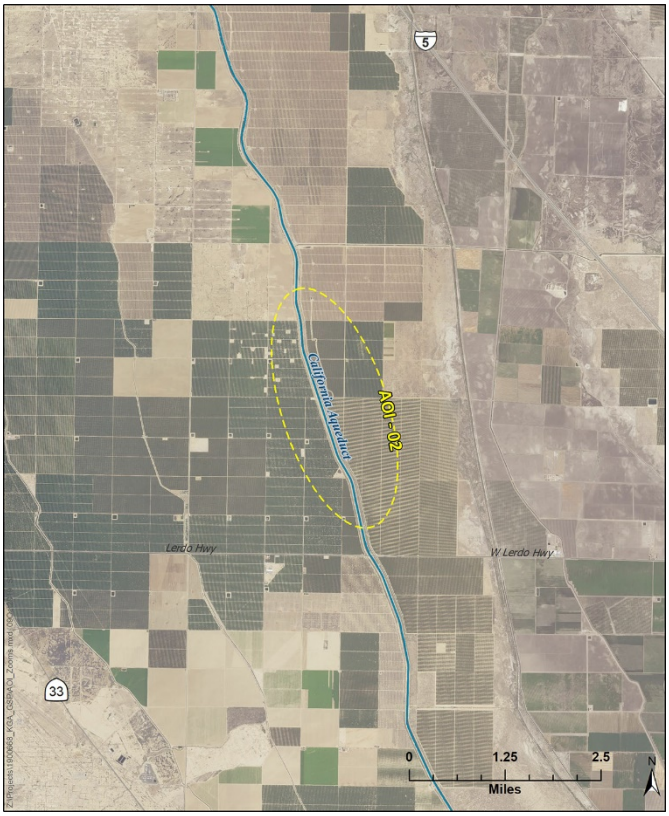

Figure 5. AOI-2. CA Aqueduct Milepost 196 to 215
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR and is monitored with level surveys every three to seven years by the DWR's DOE. There are no other active monitoring points along this stretch.

New Monitoring Approach

The source of subsidence, either by groundwater extraction activities or other activities, will be investigated by performing well records searches from DWR well completion records, the Kern County Public Health Department well permit records, and the DOGGR's databases. If necessary, a field well survey may be performed. Coordination may be needed with local stakeholders to confirm the magnitude of groundwater extracted within 1 mile of this portion of the Aqueduct's alignment and the volume of fluids extracted and injected by oil and gas activities within 1 mile of this alignment. A third potential source for subsidence in this area could be hydrocompaction, which was identified during the initial design and construction of the Aqueduct. Pre-consolidation of soil was performed during initial construction so hydrocompaction is likely not significant, however, it cannot be ruled out at this time.

If it is determined that groundwater extraction is playing a role in subsidence for this area, a monitoring point should be installed away from the footprint of the Aqueduct to avoid potential signatures of hydrocompaction if any exist. If there is question of whether some of the subsidence is related to nearby oil and gas activities, then an extensometer should be installed in the interval where groundwater production occurs. An extensometer will provide data of subsidence pertaining to intervals with groundwater production, whereas a CGPS would capture any subsidence regardless of the depth interval.

Coordination of Monitoring

Subsidence monitoring along the Aqueduct benefits local stakeholders, State Water Project (SWP) contractors, and the DWR's DOE. It is anticipated that this monitoring can be coordinated with DWR to share data as well as potentially share resources and cost.

AOI-3. FKC Milepost 130 to 137

This medium priority area is located along the FKC between Mileposts 130 to 137 (Figure 2), southwest of Famoso and Poso Creek. The purpose of this AOI is to monitor subsidence along the FKC infrastructure where InSAR and local stakeholders have reported subsidence in the surrounding area. As with AOI-1, no significant impacts to the FKC have been reported along this stretch. According to leveling survey data from the FWA (2019), the FKC invert may have subsided from 2 ft to 3 ft below original as-built elevation between Mileposts 120 to 135. Continued lowering of the canal invert can decrease freeboard from the original as-built conditions, which may contribute to reduction in emergency storage capabilities and delivery options of the Canal.

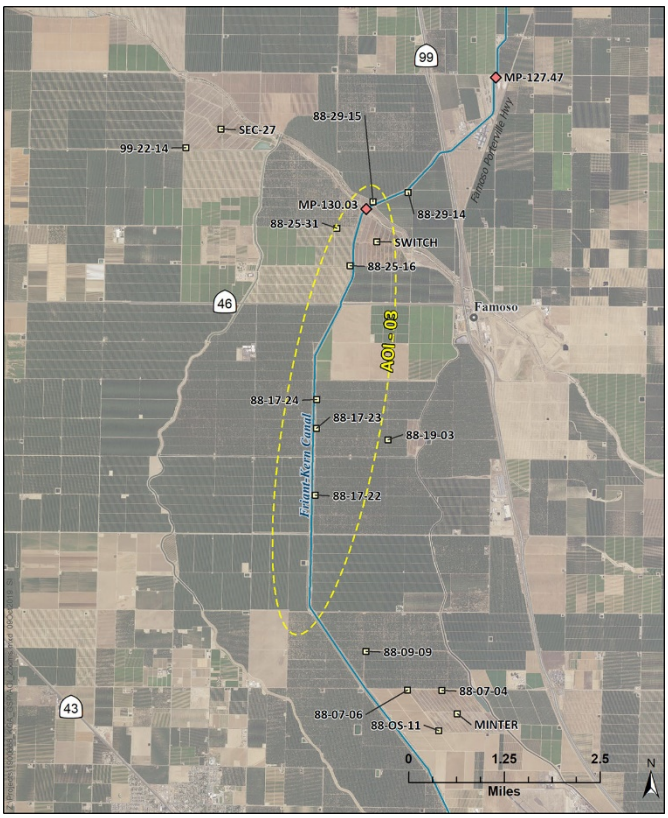

Figure 6. AOI-3. FKC Milepost 130 to 137
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR, and previous level surveying was performed by the FWA at Mileposts labeled on Figure 2. Local districts monitor this stretch regularly as labeled on Figures 2 and 6. Currently there are no continuous monitoring points along this stretch.

New Monitoring Approach

A CGPS station that monitors from the ground surface, any subsurface subsidence regardless of the depth interval, is recommended because the only known cause of subsidence in this area is attributed to groundwater extraction. This CGPS data will complement manual level surveys from local district surveys. CGPS data will also provide nearly on-demand data as needed.

Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the FKC benefits local stakeholders, CVP contractors, and the FWA. It is anticipated that this monitoring can be coordinated with FWA to share data as well as potentially share resources and cost.

Any level surveying along the canal from USBR Friant-Kern benchmarks (Figures 2 and 6) will require coordination with the FWA.

AOI-4. California Aqueduct Milepost 267 to 271

This medium priority area is located along the Aqueduct between Milepost 267 to 271 near Old River Road. InSAR data report subsidence southwest and along I-5 and southwest toward the Aqueduct along Old River Road. A former CGPS station (BKR1/2) located about 5 miles north of the Aqueduct along Old River Road also reported significant subsidence; however, this station has since been decommissioned (2016).

Figure 7. AOI-4. CA Aqueduct Milepost 267 to 271
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR, and is monitored by level surveying every three to seven years by the DWR's DOE. There are no other active monitoring points along this stretch.

New Monitoring Approach

Groundwater extraction is potentially the source of subsidence, so a continuous monitoring station such as a CGPS or extensometer will be installed. Other potential sources could be oil and gas extraction and hydrocompaction. A DOGGR records search may provide sufficient information to understand the extent of oil and gas extraction in this area. Although hydrocompaction may not be significant because of pre-consolidation practices during Aqueduct construction, nonetheless, in order to avoid potential signatures of hydrocompaction, a monitoring point should be installed away from the footprint of the Aqueduct. If feasible during the siting study, the site location may be selected to the north between the Aqueduct and former BKR1/2.

Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the Aqueduct benefits local stakeholders, SWP contractors, and the DWR's DOE. It is anticipated that this monitoring can be coordinated with DWR to share data as well as potentially share resources and cost.

AOI-5. Central-Northern Boundary of Subbasin

This medium priority area is in the northern quarter of T25S-R24E and T25S-R25E. Currently, this AOI does not have recognized susceptible critical infrastructure. It has significant subsidence reported both historically (USGS level surveys) and recently (InSAR). A CGPS station in this area will provide a needed ground truthing point to confirm InSAR readings and will act as a useful monitoring point to gauge progress of groundwater management along the border of the subbasin in relation to neighboring subbasins to the north.

Figure 8. AOI-5 Central-Northern Boundary of Subbasin
(symbol legend on Figure 2)

Existing Monitoring

Currently, this area is screened by InSAR. There are no other active monitoring points along this stretch.

New Monitoring Approach

Groundwater extraction is potentially the source of subsidence, so a CGPS or extensometer monitoring station should be installed. Where possible, this station should be tied in to benchmark surveys performed by local districts.

Coordination of Monitoring

Subsidence monitoring along the subbasin boundary benefits local stakeholders in Kern County subbasin and adjacent subbasins. In the future, data may be shared with neighboring GSAs for coordination.

Monitoring and Design Guidelines

According to the BMP (DWR, 2016), Leveling surveys and CGPS surveys must follow, at a minimum, guidelines in the *CalTrans Survey Manual*: https://dot.ca.gov/programs/right-of-way/surveys-manual-and-interim-guidelines. Extensometer resources from USGS are also listed in the BMP (DWR, 2016).

In addition to CalTrans guidance, UNAVCO has provided many CGPS design specifications on their website. UNAVCO offers a robust CGPS monument design (deep drill based monument [DDBM] that minimizes interference in data recording from soil expansion and temperature effects. Attachments 1 and 2 include example specifications for CGPS stations from CalTrans and UNAVCO, respectively. Attachment 3 includes sample extensometer designs for reference.

Rough Costs to Consider

For subbasin-wide monitoring to be implemented with the recommended AOIs in this memorandum, Kern Subbasin stakeholders will coordinate how the work will be implemented. Below is a brief summary of rough costs expected for the installation of each monitoring solution. Costs do not include ongoing management and maintenance of the stations. Actual costing will be confirmed during procurement and the planning process.

Level Surveying and Benchmarks (not proposed in this memo, but is an alternative approach).

- Install benchmarks where none available along linear features every 1/8 to 1/4 mile in area of interest.
- Each ~$500 to $2500 installation
- Initial Survey (5 to 8 monuments per day). ~$1500-$2500 per day (includes reporting).
- Subsequent Surveys (8 to 10 monuments per day). ~$1500-$2500 per day (includes reporting).

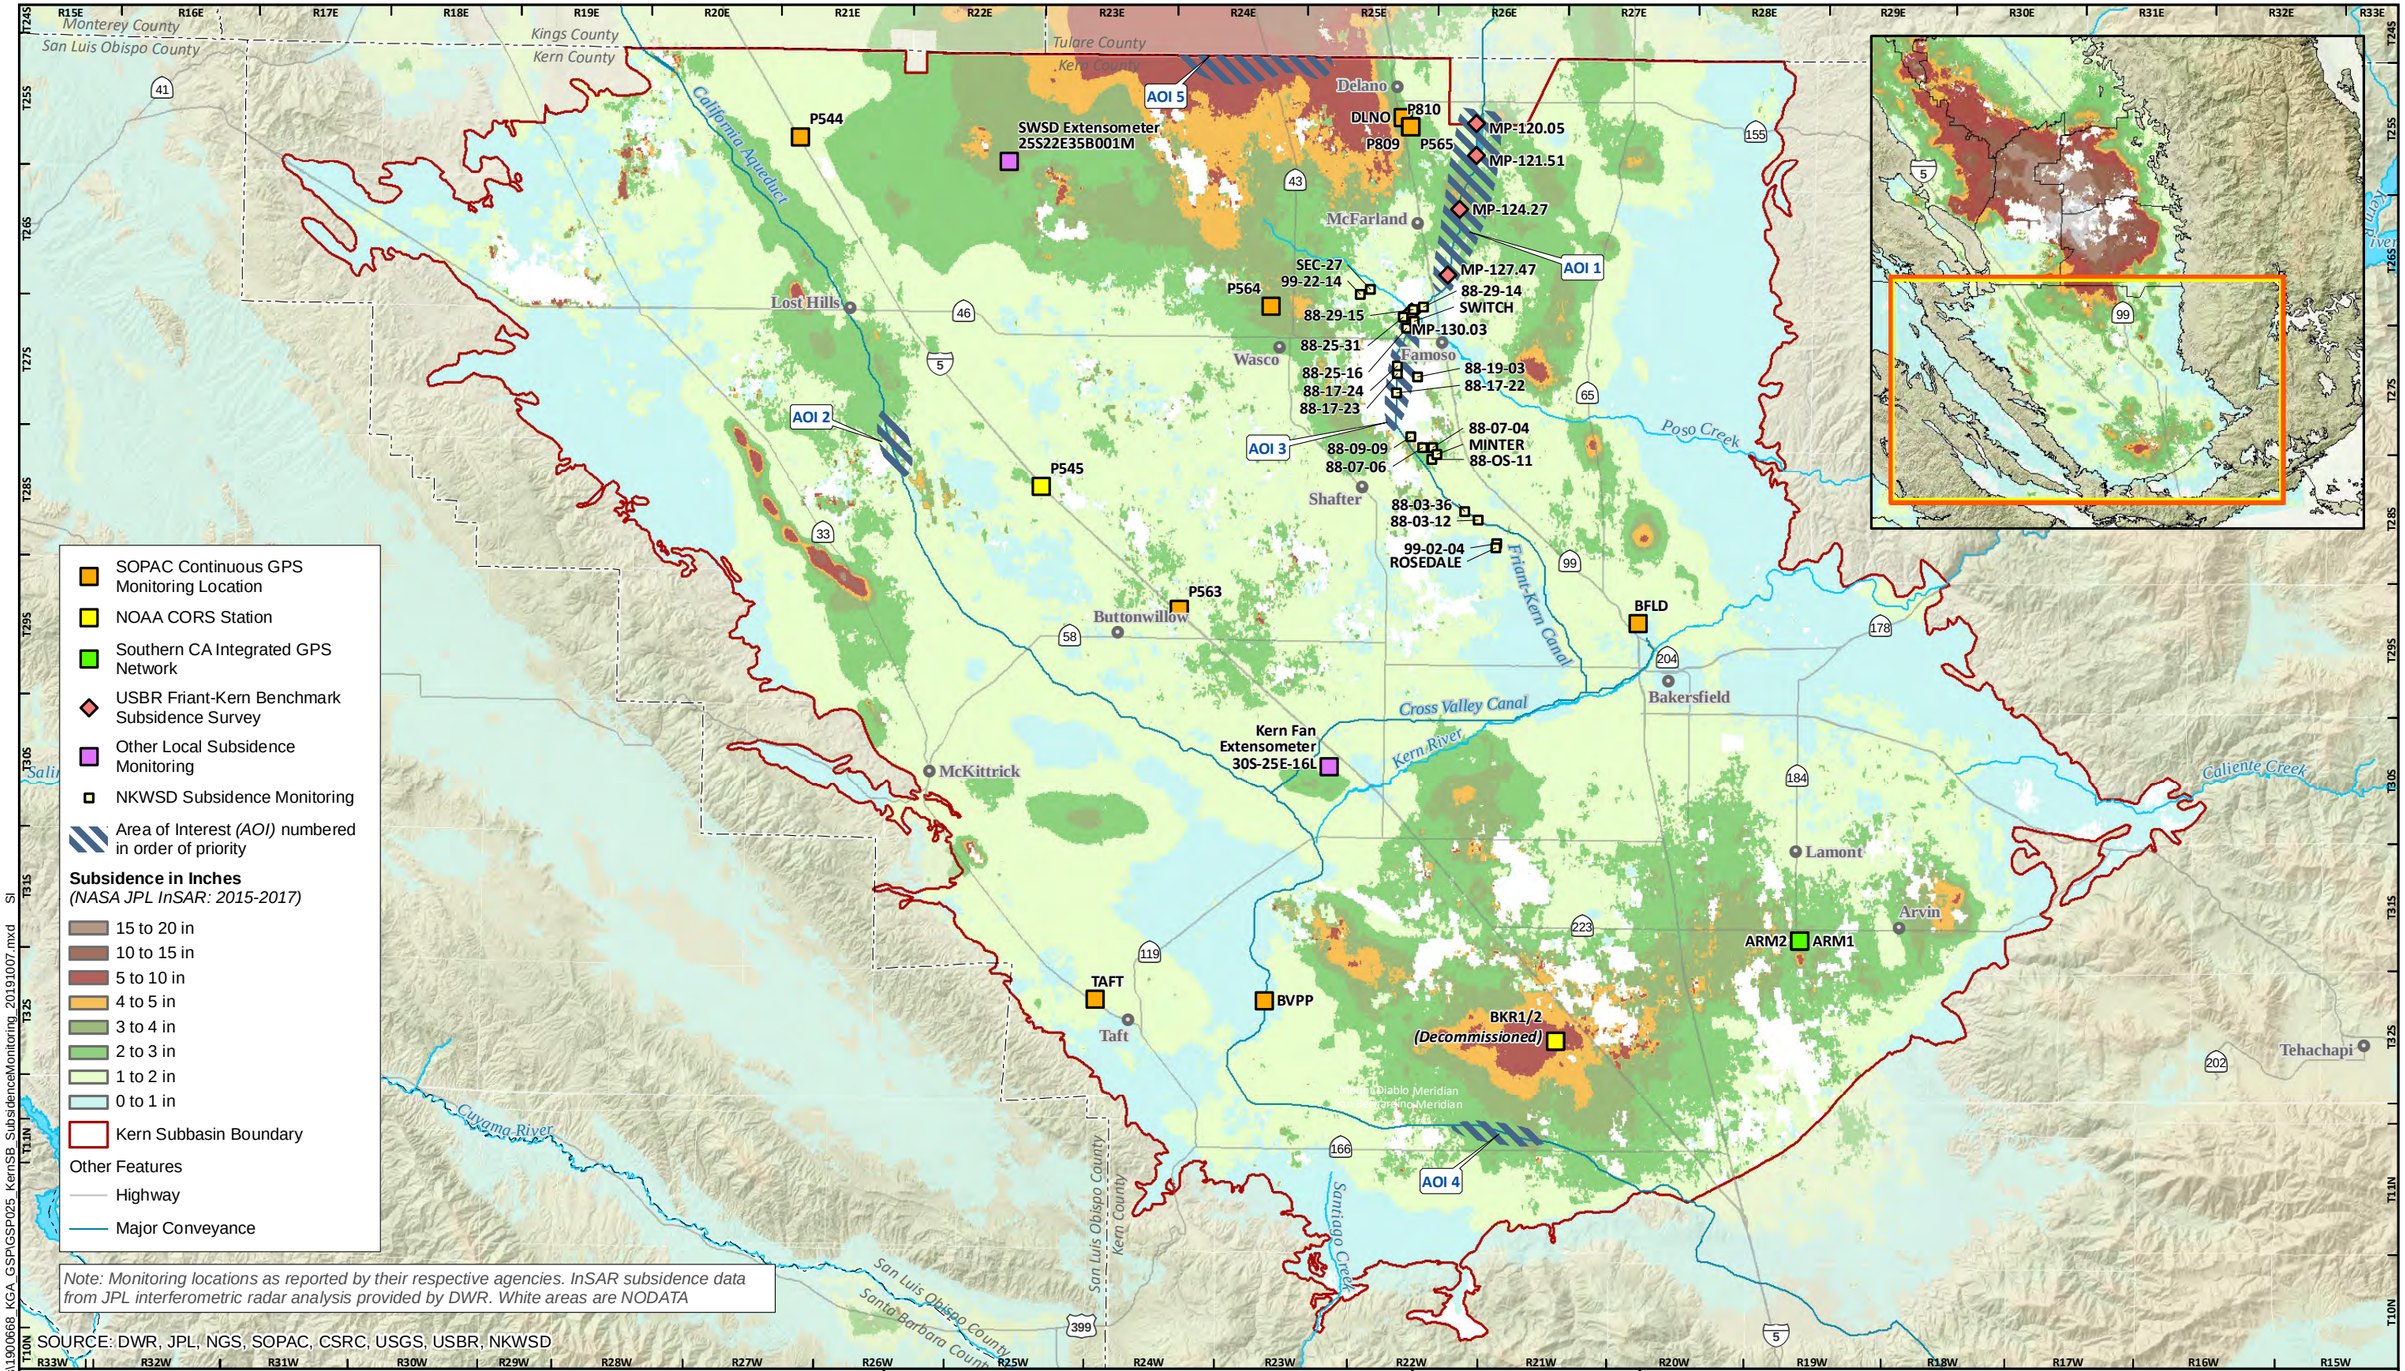
CORS CGPS Station

- ~$30k to $100k depending on equipment (purchase and installation). This may not include programming and digital network setup.
- DWR may be able to provide technical assistance, and at a minimum, review design specifications if DWR concurrence is wanted. DWR has not at this time offered any current specifications or assistance in developing designs.
- Optional outside consulting may be recommended for design and programming.

Extensometer

Drilling and installation costs ~$200k to $300k (design and operation not included).

Conclusions



This memorandum was prepared, in coordination with subbasin stakeholders, to improve the Kern County Subbasin subsidence monitoring network. It prioritizes areas of interest, at a subbasin-level, that require additional subsidence monitoring. Figures 2 and 3 present the AOIs for future monitoring points and associated water level monitoring wells (RMWs). AOIs are listed in order of highest priority for investigation and monitoring installation. Figures 4 to 8 present aerial images of these areas. In AOIs where groundwater extractions and oil and gas activities may be contributing to subsidence, extensometers will be installed in lieu of CGPS points in order to monitor the depth interval of groundwater extractions. Where subsidence monitoring is required, monitoring water levels and the condition of infrastructure is necessary. Where groundwater extraction is not causing subsidence, the AOI can be screened by the region-wide InSAR subsidence monitoring network.

Deep Drilled Braced Monument Overview

Article ID: 300 | Rating: Unrated | Last Updated: Wed, Oct 26, 2011 at 6:49 PM

Deep Drilled Braced Monument

Back to comparison table	Mount Commonly Used	Stability	Cost	Install Time	Labor	Substrate	Site Impact
	 SCIGN mount	high	$7,500-15,000	2-4 d	3-4	BR, U	high

The deep drilled braced monument (UNAVCO DDBM*) provides for a high degree of stability and longevity and can be anchored in bedrock or unconsolidated material. It is in the form of a tripod, each leg extending into the ground up to about 40 feet and welded at the top with gusset reinforcements. If site access is an issue and bedrock is available, the short drilled braced monument is the next best alternative to this type. The UNAVCO DDBM is used throughout the PBO network. It is based on the SCIGN design used at older installations in the SCIGN, BARGEN, PBO and PANGA networks.

* Modified from the original SCIGN DDBM design of Duncan Agnew and Frank Wyatt.

Site ASHM of the BARGEN network, Nevada, Utah, and California.

Pros

- high stability
- longevity
- can be installed in either bedrock or unconsolidated materials

Cons

- labor and tool intensive (requires a drilling rig and crew)
- expensive (can be $7,500 to $15,000, depending on drilling)
- time intensive (requires 2-4 days)
- may not be able to install in some remote locations... depends upon ease of site access
- large construction disturbance footprint

Design and Construction

A drilling contractor is required to install this monument. The cost of installation can typically range between $6,000 and $10,000 depending upon factors such as the type of drilling rig used, distance the drill rig and crew need to travel to site (mobilization/de-mobilization), foundation material (ground) being drilled, etc.

  - sign-01-02-020.pdf
  - sign-01-02-030.pdf

Installation Photos

- Construction Photos

Approximate Cost

$7,500-15,000 depending principally on drilling (substrate, distance drill rig needs to travel to and from the site)

This cost is for the monumentation only; the antenna mount (e.g. SCIGN mount) is not included.

Materials

- 21-foot 1.25" diameter schedule 40 stainless steel pipe, threaded (5 per site)

- 10-foot 1.25" diameter schedule 40 stainless steel pipe, threaded (5 per site)
- 1.25" schedule 40 stainless steel threaded adapters (5 per site)
- 3 weld gussets
- threaded adapter (if using the SCIGN antenna mount; see below)
- 2.5" diameter schedule 40 PVC (for each leg and for center post)
- foam wrapper (for each leg and for center post)
- rebar (for each leg and for center post)
- duct tape (for foam)
- concrete (provided by drillers)
- water (provided by drillers)
- welding rod
- gas for the generator (if there is no AC hookup)
- string, paint, nails, and wood stakes (for marking legs)

Tools

- generator (if there is no AC hookup)
- compass
- reel measuring tape (30m/100ft)
- leg alignment tool
- mallet
- large vice grips (2 or more)
- grinder
- vertical and angle level(s)
- welder
- file, pick, brush, gloves, helmet, long-sleeved shirt, hat (for welding)

Mount Commonly Used

The SCIGN mountis the antenna mount most commonly used with the deep drilled braced monument, although it is only required when using the SCIGN radome. Otherwise, any other leveling mount, such as the SECO 2072-series antenna mount, is acceptable.

GPS Deep Drilled Braced Monument Installation
Driller Instructions

Overview

The deep drilled braced GPS monument (DDBM) is designed to create a highly rigid and immobile structure isolated from surface soil movement and cemented in place at depth. The monument consists of 5 legs (stainless steel pipes) placed into drilled holes, and welded together above the surface to create a "tripod" frame. Of the 5 legs, the center leg is vertical and the 4 other legs are installed at angles to brace the vertical leg.

The Plate Boundary Observatory (PBO) project will require the installation of at least 600 of these DDBM monuments throughout the Western US and Alaska. We hope to locate a small number of highly skilled contractors throughout the Western US and Alaska to install these monuments during the next five years. This scope of work is for a one-time installation project consisting of a small number (1-5) of these installations. This will allow us to evaluate the contractor for possible future work within PBO. Please provide a quote for services based upon the scope of work outlined below.

Material

Contractor to supply to the following material:

1) A sufficient amount of grout to fill 5-35 foot deep holes (4.5"-6" diameter) will be used. Contractor will assure the following:

   a) Type I, II Portland cement and Class F Flyash shall be used for grout materials.
   b) Flyash shall replace 10-15% of the volume of Portland cement.
   c) Grout shall be proportioned to have a water to cementitious material ratio of 0.50.
   d) If using pre-packaged grout, grout shall be 1118 Grout supplied by Surecrete, Seattle, WA, or an approved equal meeting these specifications. Grout 1119 should be used for applications when water is present in the hole.

2) Water sufficient to mix grout. Final mix should be consistency of a milk shake.

All other material will be supplied by UNAVCO.

Construction Procedure

<u>Drilling/Casing/Pipe Placement</u>

1) Drill rig type and size selection shall be determined by contractor such that equipment used is most suited to site geology and hole precision requirements.

2) UNAVCO shall provide to the contractor a summary of expected site conditions such as surface topography and subsurface material.

3) Contractor shall drill 5 holes of 4.5" diameter to minimum depths of 35 ft.
   a) Center hole shall be drilled at vertical orientation plus/minus 2 degrees.
   b) Four angled holes shall be drilled at 35 degrees from vertical plus/minus 2.5 degrees.

4) Holes drilled at precise locations specified by UNAVCO engineering staff. Frequent measurement of hole inclination during drilling shall be made to ensure holes are drilled to exact specifications. The centerlines of all 5 holes shall intersect at a single point plus/minus 3". This point of intersection shall be located 62" above the surface, at the center leg. On level ground, each of the 4 angled legs will enter the ground at 43.5" from the center leg.

5) All holes shall be drilled straight enough so that PVC casing can be installed in the top 15.5 ft of each hole, and that the steel pipe can be freely lowered, not forced, for its entire 35 ft length.

6) Hole depth is to be determined by actual measurement after drilling. If necessary, loose material may need to be removed from the bottom of the holes to achieve required depth.

7) 2.5" PVC casing (wrapped with insulation) shall be installed in upper 15.5 ft of each hole immediately after drilling. It may be necessary to use drill rig to push casing into hole.

8) Contractor shall assist UNAVCO staff in placement of steel piping immediately after drilling and casing installation. 1.25" schedule 40 steel pipe shall be installed inside casing in each hole to a depth of 32-38 ft.

9) A single 5 foot vertical hole shall be drilled for the equipment enclosure.

10) UNAVCO is responsible for siting and alignment.

11) Contractor shall assist in the clearing of cuttings from the hole, during the drilling operation.

Grout Installation

1) Contractor shall provide grouting material and water for mixing.

2) All five legs are to be cemented in place with expansive grout.

3) Contractor shall prepare the pumpable grout to a "milkshake" consistency. Jobsite conditions may affect actual quantities of water needed.

4) Following steel pipe installation, contractor shall pump grout down steel pipes until grout fills pipe and pipe-casing annulus, and is seen emerging from top of annulus. Due to small clearances within pipe and at pipe-casing annulus, high pressures may be encountered during grout placement.

5) Contractor shall place grout such that no air bubbles are introduced. Ensuring a continuous flow of grout through pipe and back up through annulus requires proper grout handling, mixing, and pumping equipment and procedures.

6) Contractor shall neatly finish grout at surface of casing such that water will not puddle around monument legs.

Site Documentation and Cleanup

Contractor shall assist UNAVCO personnel in compiling site documentation including:

1) Depths of holes. All drilling documentation including drilled, measured, tamped, and shimmed pipe depths shall be recorded by contractor.

2) Grout information. Time of day, grout sack ID#, grout amount sifted, mixed, pumped, and lost shall all be monitored by contractor and reported to UNAVCO engineer for recording.

3) Contractor shall be responsible for removal of hazardous materials (i.e. hydraulic fluid, diesel fuel and/or contaminated soil) and debris. Site shall be left in suitable condition.

4) Contractor shall be responsible for containing and disposing of excess grouting material and debris such as cement bags, trash, and cigarette butts.

5) Contractor shall be responsible for leveling and raking of areas that were disturbed by drill rig and support vehicles at the site.

Miscellaneous

1) Contractor is responsible for hotel and per diem for the drilling crew.

2) Contractor shall assist UNAVCO personnel in any tasks related to GPS site installation such as pipe/coupling preparation, installation of pipe and insulation piping.

3) UNAVCO will mark for Underground Services Alert.

4) UNAVCO will provide maps, directions and relevant access information for drilling access.

5) Contractor's equipment and tools are the sole responsibility of the contractor. UNAVCO will not reimburse the contractor for any lost or damaged equipment.

All work shall be done to highest professional standards.

Available as special buy: Special pricing is available to UNAVCO members and associate members on select equipment. For more information see the GNSS Equipment Purchase Information page.
Available on loan: UNAVCO maintains a large pool of GPS and related equipment, available on loan to member and associate member institutions and NSF-funded programs. To submit a request, fill out the Online Support Request Form .
Serviceable at UNAVCO: UNAVCO is licensed to repair select GNSS receivers and antennas. For more information see the Equipment Repairs page.
File size (24 hr, 15 s): File size for a 24 hour-long file collected at a 15 second sample rate. File size is approximate and varies based on # of satellites tracked and frequencies recorded. File sizes shown here were taken from site data in the UNAVCO data archive.
Memory: Memory for receivers from the dealer may vary; values are given for UNAVCO-owned receivers.
Time last recording at 15 s: Estimated length of time the receiver can record at its given internal memory at a sample rate of 15 seconds.
Power draw: Estimated power draw in Watts. The power draw varies depending on the other equipment e.g. antenna(s) connected to the receiver.
Time lasts on 18 amphr battery: Estimated length of time the receiver can operate on the 12 volt, 18 amphr battery standard for UNAVCO campaign systems, without a solar panel. Time will vary based on temperature and battery health.

UNAVCO Resources: Permanent GNSS Station Enclosures

Article ID: 381 | Rating: 1/5 from 2 votes | Last Updated: Wed, Aug 24, 2016 at 8:36 PM

UNAVCO Resources: Permanent GNSS Station Enclosures

UNAVCO has installed and supports a large variety of equipment enclosures for both AC and DC GNSS sites, from enclosures specifically designed for solar systems (the SunWize battery enclosure) to simple storage containers modified to accommodate cable pass-throughs. We can work to find the most suitable enclosure given the budget and the location of each permanent or semi-permanent GNSS installation. Below is a list of enclosures used within the last several years in UNAVCO-supported projects; click on the photographs to see sample content lists and more photos of actual installations. For standard UNAVCO campaign enclosures, check out UNAVCO Campaign GNSS Systems .

	SunWize Premium F-Series Battery Enclosure	The SunWize F-Series 4-battery enclosure is used throughout the Plate Boundary Observatory network, as well as in several other permanent GPS station networks in the US. Benefits include reasonable strength (the enclosure is made of aluminum), security (two key locks secure the enclosure), both internal and external knockouts for passing wires and cables, weatherproof seals, and a generous amount of space. Drawbacks include cost ($700-$1000 as of February 2009), size (if on-site space is limited or if equipment must be shipped), and mounting requirements (enclosure is designed to be mounted on a post, which must be cemented into the ground and strong enough to support batteries).
	Hardigg Case	Hardigg (now owned by Pelican Products) makes rugged, well-sealed plastic enclosures which are stackable, easy to handle, and UV resistant. Connectors are recessed within the ribs of the case to reduce the risk of damage during shipping.

	JOBOX	JOBOX chests, made by Delta Consolidated Industries, Inc. , are durable, weatherproof metal enclosures that UNAVCO has used in several long-term installations, including the EarthScope-sponsored Rio Grande Rift network. Chests are secured with key locks. The major drawback of the JOBOX is weight; boxes are heavy and cumbersome, thus not ideal for shipping and for transporting by foot over long distances. Cost of the box shown here is approximately $300-400 (as of February 2009).
	Pelican Case (large)	The Pelican case is easily portable, can be used to transport equipment, and is weatherproof. The case shown here, as deployed in the EarthScope-sponsored Rio Grande network, contains 2 100 amphr batteries in addition to the GPS receiver. The case is difficult to destroy and can be locked with padlocks. Cost is approximately $250-$300 (February 2009). Smaller cases are available (see below), and have been used in networks with year-round, reliable sunlight where large battery banks are not required.
	Pelican Case (small)	Like the larger Pelican cases (above), the smaller Pelican case is weatherproof and can be used to transport equipment. A smaller case is ideal if space is not an issue--specifically, if the requirement for amount of power stored is small (e.g. in a year-round sunny environment, as is common near the equator). The case is difficult to destroy and can be locked with padlocks. Networks utilizing small Pelican cases include Afar, Ethiopia, and Sierra Negra, Galapagos. Cost for the case shown here is approximately $125 (February 2009).
	Commercial Electrical Enclosure	Electrical boxes can be often purchased 'locally,' in major cities, rather than being shipped. Boxes may include knock-outs for passing cables through and locking options, like the box shown here. Electrical boxes are often sturdy, made of either strong plastic or of metal, and may or may not be weatherproof. Networks utilizing local electrical enclosures include Calabria, Italy and Bangladesh. Typical price range is about $100-$300.

	Storage Container	A heavy-duty storage container, such as the Contico Tuff Box, designed for the back of a truck or other outdoor use may work well for an equipment enclosure. They are generally low cost (about $70 for the container shown here, as of February 2009), available in most US cities, rugged, and lockable with padlocks. The case shown here fits four sealed 100 Amphr batteries along with the GPS and communications equipment. Used as enclosures in the Peatland Bog, Minnesota network.

Cellular Modem Summary

Article ID: 357 | Rating: Unrated | Last Updated: Wed, Oct 28, 2009 at 3:12 PM

Cellular Modem Summary

Cellular modems need to be very robust as the inherent disadvantages of the analog cellular phone system become especially evident with high speed data transfers. Cellular coverage could be of a quality not compatible with high speed data transfers and handshaking protocols. Often more than one cellular provider offers coverage in an area and it is worthwhile to investigate several options. A good voice communication does not translate into an acceptable data communication. Your choice of cellular modem and cellular phone should be able to run off 12VDC, even if AC power is available, to facilitate DC (battery) backup.

Suggested Minimum Requirements

- 12 VDC power
- V.32, V.32bis communication protocols
- V.42, MNP error correction/data compression
- RTS/CTS hardware flow control
- High speed baud rates (2.4-19.2 kbps)
- Compatible with CCITT and Bell standards
- Support industry-standard AT command set
- Compatible with RS-232 Control Signals

APPENDIX 5

At this time, the Kern subbasin is working on the development of a basin-wide coordinated Data Management System. Please see the following documents related to that development of an application to DWR Prop 68 Grant requesting funds for the development. For the current year of annual reporting, see the following document related to a coordinated basin-wide cost share agreement.

Kern County Subbasin Groundwater Sustainability Plan Support 2019 Grant Application

Proposition 68

Sustainable Groundwater Management Grant Program

Groundwater Sustainability Plans and Projects

Proposal Solicitation Package 2019

Proposal Full View

Applicant Information				
Organization Name*	Kern River GSA			
Point Of Contact	**First Name:***	Kristin	**Last Name:***	Pittack
	Email:*	kpittack@bakersfieldcity.us		
	Division Name:	City of Bakersfield	**Phone:***	(661) 3263646 Ext:
	Address Line 1:*	1600 Truxtun Avenue	**Address Line 2:**	
	City:*	Bakersfield	**State:***	California
	Zip:*	93301		
Point Of Contact Position Title*	Water Resources Planner			
Proposal Name*	Kern County Subbasin Groundwater Sustainability Plan Support - Phase II			
Proposal Objective*	The Kern County Subbasin is a critically overdrafted groundwater basin of high priority, located in the Southern San Joaquin Valley. The Proposal covers the entire Kern County Subbasin and is submitted by the Applicant, the Kern River Groundwater Sustainability Agency (KRGSA), on behalf of all the GSAs and participating entities in the Subbasin. The overarching goal of the proposed Subbasin Data Management System (DMS) Development project is to initiate the key steps to develop and build a Subbasin DMS. This DMS will ultimately support SGMA compliance by Subbasin GSAs by providing (1) improved coordination of groundwater monitoring and management actions and (2) the ability to meet the reporting and implementation requirements of SGMA for the Kern County Subbasin. To meet this goal, the project objectives are to retain a contractor to develop, manage, and coordinate use of the DMS with the GSAs and participating agencies; identify the data types that would be required to monitor GSP implementation and Subbasin progress toward sustainability; and investigate, select, and procure a commercially available or custom-designed DMS with an appropriate configuration that combines technical rigor, flexibility, ease of use, and expansion capabilities to store data in text, spreadsheet, graphical, and map-based formats. Some aspects of the DMS project, such as development of a User's Manual and DMS review and assessment, will be funded by the grant but may also be subject to GSA funding if needed. These tasks are included in the project Work Plan to provide context for the work to be completed under this Round 3 Planning funding request.

Project Information

Project Name: Subbasin Data Management System Development Project	
Implementing Organization	Kern River GSA
Secondary Implementing Organization	All of the Kern County Subbasin GSAs
Proposed Start Date	2/1/2020

Proposed End Date	7/31/2022
Scope Of Work	The scope of the project includes Grant Administration, Stakeholder Engagement / Outreach, GSP Development: Subbasin DMS Scoping and Development, and Review and Assessment. Deliverables include: executed contract with database development consultant; list of data types to be collected; report and recommendation on available formats for required information; and possibly recommendation and GSA Boards' decision to select a DMS package.
Project Description	The Kern County Subbasin is the largest Subbasin in California, with a complex water management structure, a large portfolio of local and imported water sources, and numerous large groundwater banking projects, collectively providing local and State-wide benefits for water supply. Given this framework, numerous structures for data management have been developed by local agencies for their own objectives, resulting in disparate data sets and isolated pieces of information. The Kern County Subbasin GSAs recognize the need to develop a centralized, Subbasin-wide DMS. Accordingly, the GSAs are cooperating on this proposal to support monitoring, evaluation, reporting, management, and, importantly, GSP implementation. The Subbasin GSAs have previously coordinated and collaborated on the basin-wide water modeling for GSP development and thus believe that this is the next step forward. The immediate need for a centralized DMS is highlighted by the GSAs' ongoing cooperative efforts for annual reporting. In order to comply with the requirements of SGMA for standardized reporting, and to coordinate on a Subbasin-wide basis for consistent data evaluation, it is crucial that a DMS be developed for the entire Subbasin that will allow the various GSAs to gather and share information regarding local groundwater conditions. The proposed DMS planning and scoping project will ultimately support Subbasin GSAs by providing (1) improved coordination of groundwater monitoring and management actions and (2) the ability to meet the reporting and implementation requirements of SGMA for the Kern County Subbasin.
Project Objective	The project objectives are to retain a contractor to develop, manage, and coordinate use of a Subbasin-wide DMS; identify the data types required to monitor the Subbasin's progress toward sustainability; and investigate, select, and procure a DMS with an appropriate configuration that combines technical rigor, flexibility, ease of use, and expansion capabilities to store data in text, spreadsheet, graphical, and map-based formats.

Section : Questions

Q1. Project Description:

Provide a brief abstract of the proposal. This abstract must provide an overview of the proposal including the main issues and priorities addressed in the proposal. (25 words or less)*

This Proposal develops a data management system (DMS) that covers the Kern County Subbasin and allows Subbasin GSAs to improve GSP coordination, and implementation.

Q2. Previous Funding:

Has the applicant received prior funding through the Proposition 1 SGWP Round 2 grant?*

a) • Yes
b) No

If so, how much funds did the applicant receive?

$1,500,000

Q3. Project Representative:

Provide the name and details of the person responsible for signing and executing the grant agreement for the applicant. Persons that are subcontractors to be paid by the grant cannot be listed as the Project Representative. Other entities included in the GSA can be listed here.*

Rodney Palla
Chair, Kern River Groundwater Sustainability Agency
1600 Truxtun Avenue
Bakersfield, California, 93301
(661) 326-3767

Q4. Project Manager:

Provide the name, title, and contact information of the Project Manager from the applicant agency or organization that will be the day-to-day contact on this application.*

Kristin Pittack
Water Resources Planner, City of Bakersfield
1600 Truxtun Avenue
Bakersfield, CA 93301
(661) 326-3646

Q5. Eligibility:

Has the applicant met the requirements of DWR's CASGEM Program?*

a) • Yes
b) No

Q6.1. Eligibility:

Is the applicant an agricultural water supplier?*

a) Yes
b) • No

Q6.1.a Eligibility:

If yes, has the applicant submitted a complete Agricultural Water Management Plan (AWMP) to DWR?

a) Yes
b) No

Q6.1.b Eligibility:

If yes, has the AWMP been verified as complete by DWR?

a) Yes
b) No

Q6.1.c Eligibility:

If the AWMP has not been submitted, explain and provide the anticipated submittal date.

Q7.1. Eligibility:

Is the applicant an urban water supplier?*

a) Yes
b) • No

Q7.1.a Eligibility:

If yes, has the applicant submitted a complete Urban Water Management Plan (UWMP) to DWR?

a) Yes
b) No

Q7.1.b Eligibility:

If yes, has the UWMP been verified as complete by DWR?

a) Yes
b) No

Q7.1.c Eligibility:

If the UWMP has not been submitted, explain and provide the anticipated date for submittal.

Q8.1 Eligibility:

Is the applicant a surface water diverter?*

a) Yes
b) No

Q8.1.a Eligibility:

If yes, has the applicant submitted to the SWRCB their surface water diversion reports in compliance with requirements outlined in Part 5.1 (commencing with §5100) of Division 2 of the Water Code?

a) Yes
b) No

Q8.1.b Eligibility:

If the reports have not been submitted, explain and provide the anticipated date for meeting the requirements.

Q9. Eligibility:

Does the proposal include any of the following activities:

1.) The potential to adversely impact a wild and scenic river or any river afforded protection under the California or Federal Wild and Scenic Rivers Act
2.) Acquisition of land through eminent domain
3.) Design, construction, operation, mitigation, or maintenance of Delta conveyance facilities
4.) Acquisition of water except for projects that will provide fisheries or ecosystem benefits or improvements that are greater than required currently applicable environmental mitigation measures or compliance obligations
5.) Pay any share of the costs of remediation recovered from parties responsible for the contamination of a groundwater storage aquifer
6.) Projects or groundwater planning activities associated with adjudicated groundwater basins.

If yes, the project is not eligible for grant funding.*

a) Yes (not eligible for grant funding)
b) No

Q10. Eligibility: Consistency with California SB 985– Stormwater Resource Planning Act:

To satisfy SB 985 requirements, stormwater and dry weather capture project must be listed in a SWRP that is consistent with the relevant code provisions enacted by SB 985 (Water Code §10562 (b)(7)) as determined by the SWRCB.

a) This Project is Consistent

Q11. DA Cost Share Waiver or Reduction:

Are you applying for cost share waiver or reduction as a DA? Fill out Attachment 6 – DAC, SDAC, and/or EDA, as appropriate.*

a) Yes; See Attachment 6
b) No

Q12. Certification:

By submitting the application, the Project Director is certifying that:
a) The applicant is an eligible entity;
b) He/She is aware that any attachment exceeding the page limit listed in the attachment templates will not be reviewed;
c) He/She is aware that, once the proposal is submitted in GRanTS, any privacy rights and other confidentiality protections offered by law with respect to the application package and project location are waived; and
d) He/She has read and agrees to all of the Terms and Conditions of the grant agreement.*

a) • Yes (Certified)
b) No

Section : Climate Risk in Investments

Climate Risk in Investment

Q13: Does the organization have a strategic business plan?

a) • Yes
b) No

If Yes, please submit a copy.

Last Uploaded Attachments: Q13_Prop 68 Cost Share Packet_combined.pdf

Q14: Has the organization conducted a climate change vulnerability assessment?

a) Yes
b) • No

If Yes, please submit a copy.

Q15: Does the organization have a main contact person for climate change?

a) Yes
b) • No

If Yes, to what position in the origination does that person report?

Q16: Has the organization considered the risk of climate change in its capital reserves and investments? (Open ended; one-three paragraphs, with specific examples, should suffice).

This Proposal involves funding of a planning effort rather than an implementation project. As such, the Subbasin Data Management System Development project would not involve activities that could emit greenhouse gases or affect carbon sequestration. The project would have no effect related to climate change. Therefore, documentation of climate change effects is not applicable for this Proposal, applicant, or project proponents.

KERN RIVER GSA

Rodney J. Palla, Chair
Bob Smith
Gene Lundquist

October 21, 2019

To: Kern Groundwater Authority
Buena Vista WSD GSA
Henry Miller WD GSA
Olcese WD GSA

Re: Reimbursement Agreement for the Kern County Subbasin – DWR Proposition 68 Grant Application Development and Grant Administration.

The Kern River Groundwater Sustainability Agency (KRGSA), the Kern Groundwater Authority (KGA), the Buena Vista WSD Groundwater Sustainability Agency (BVGSA), the Henry Miller WD Groundwater Sustainability Agency (HMGSA), and the Olcese WD Groundwater Sustainability Agency (OGSA) wish to participate in the Reimbursement Agreement for the Kern County Subbasin – DWR Proposition 68 Grant Application Development and Grant Administration (Grant).

On behalf of the Subbasin, the KRGSA has approved a contract with Horizon Water and Environment (Horizon) which includes a scope of work with the following tasks: 1) Develop and Submit Grant Application ($19,950); 2) Support Database Project Lead in Developing RFP for Database Developer ($1,990); and 3) Grant Administration ($27,680). Horizon's proposal for the scope of work is provided as Attachment 1. All parties agree to cost share this effort according to following terms and conditions:

The participant signatories below will pay their share of the proposed budget of $49,620 as shown on Attachment 2. The first two (2) tasks will be invoiced upon approval of this Agreement. Task three (3) will be billed as future Grant Administration work is performed. All payments shall be due 45 days after the receipt of invoice from the City of Bakersfield.

If the above terms and conditions are acceptable, please sign and date all copies of this letter and return them to the KRGSA. A fully executed original will be returned to all GSA's.

Sincerely,

Rodney Palla
Chairman

Kern County Subbasin – DWR Proposition 68 Grant Application Development

Revised Proposal for Consultant Services Provided by Horizon Water and Environment

October 10, 2019

Horizon will develop a Proposition 68 grant application/proposal for the Kern County Subbasin based on the grant requirements provided by DWR. This application will rely heavily on materials Horizon previously developed preparing the Proposition 1 grant application. Horizon will update those materials as appropriate to reflect the status of current GSPs in the Kern County Subbasin.

Using these existing materials as a starting point, Horizon will develop the grant application efficiently and ensure that the information provided for the Prop 68 grant is consistent with, and builds on, the Proposition 1 grant received in 2017.

This scope of work assumes that one project will be included in the grant application:

- Project 1: Subbasin data management system development

Horizon will work with the appropriate GSAs to receive good baseline information or a project description for the project. Horizon will then use our grant application expertise to articulate how the project aligns and supports the primary objectives of the Proposition 68 Grant and why the Kern County Subbasin is an excellent fit for this grant. Following award of grant funding, Horizon will administer the grant reporting and invoicing process.

Horizon's work will be organized into the following tasks:

Task 1: Develop and Submit Grant Application

Develop Draft Application Materials

- Horizon will use the grant application requirements to frame and structure the grant submittal documents.
- Horizon will review DWR-provided templates to collect and organize project information for the grant application forms and Attachments (e.g., Work Plan, Schedule, Budget) and distribute them to the appropriate project leads.
- Horizon will coordinate data requests with the GSA staff members who will be serving as the project leads for the target project. Horizon will edit/adjust the project information as necessary to support the grant application.
- Horizon will generate draft grant application materials, including necessary text to populate the online GRanTS application tabs and required Attachments.
- Horizon will distribute the draft grant application materials to the KRGSA and other project lead GSAs for their review, with a due date to receive requested edits and/or comments.

Finalize Grant Application Materials

- Horizon will finalize the grant application materials based upon GSA review and feedback described above. Horizon will send final grant application materials to KRGSA and other project lead GSAs for final review and approval prior to DWR submittal.

Submit Grant Application to DWR

- Horizon will complete the online GRanTS application information tabs, and upload all Attachments, before DWR's application period deadline of 1 p.m. on November 1.

Task 2: Support Database Project Lead in Developing RFP for Database Developer

- Horizon will coordinate with Basin Database project lead (KGA, KRGSA, or a committee) to confirm the general database objectives and needs.
- Horizon will develop a draft RFP for review by project lead.
- Horizon will revise and develop final RFP for review and use by project lead.

This task assumes that the project lead, rather than Horizon, will administer the proposal process, including distribution of RFP, review and evaluation of proposals, and contracting of selected firm.

Task 3: Grant Administration *(pending award)*

Grant Initiation, Agreements, and Templates

- Following notification of grant award, Horizon will coordinate with DWR, KRGSA, and KGA to finalize grant materials.

Grant Implementation, Reporting, and Invoicing

- Horizon will develop and distribute templates for quarterly reports, invoices, and backup documentation.
- Horizon will identify deadlines for submittal of information from KRGSA and KGA and will review and clarify the submitted information each quarter to ensure that it meets grant requirements.
- Following review and revision, Horizon will submit reports and invoices to DWR.
- Horizon will coordinate with DWR regarding any needed revisions to submitted materials.
- Throughout the grant period, Horizon will communicate regularly with KRGSA and KGA to maintain the flow of information.

Grant Completion and Closeout

- Horizon will coordinate and review the project's draft Project Completion Report.
- Horizon will assist KRGSA and KGA in developing the Grant Completion Report.
- Horizon will coordinate and upload all completion reports to DWR.
- Horizon will develop a post-performance report template.
- Horizon will coordinate with project leads and DWR in grant closeout.

Cost Estimate:

Task		Estimated Cost
1.	Develop and Submit Grant Application	$19,950
2.	Support Database Project Lead in Developing RFP for Database Developer	$1,990
3.	Grant Administration *(pending award)*	$27,680
	Total	**$49,620**

Schedule:

Horizon will complete the grant submittal process on or before the DWR deadline of November 1, 2019, at 1:00 p.m. Tasks 2 and 3 will be completed following notification of grant award.

Attachment 2

Funding Contribution and Participation Percentages

Total Horizon Contract Amount: $49,620.00
Funding Request for App/RFP: $21,940.00

	Funding Entity	Funding Request
1	Arvin-Edison Water Storage District	$953.91
2	Buena Vista Water Storage District	$953.91
3	Bellridge Water Distrct	$953.91
4	Berrenda Mesa Water District	$953.91
5	Cawelo Water District	$953.91
6	City of Bakersfield	$953.91
7	Eastside Water Management Area	$953.91
8	Henry Miller	$953.91
9	Improvement District No. 4	$953.91
10	Lost Hills Water District	$953.91
11	Kern Delta Water District	$953.91
12	Kern-Tulare Water District	$953.91
13	Kern Water Bank Authority	$953.91
14	North Kern Water Storage District	$953.91
15	Olcese Water District	$953.91
16	Rosedale-Rio Bravo Water District	$953.91
17	Semitropic Water Storage District	$953.91
18	Shafter-Wasco Irrigation District	$953.91
18	Shafter-Wasco 7th Standard Annex	$953.91
19	South San Joaquin Municipal Utilities District	$953.91
20	Tejon-Castac Water District	$953.91
21	West Kern Water District	$953.91
22	Wheeler Ridge-Maricopa Water Storage District	$953.91
	Totals	$21,940.00

Note:
Managers/GSAs all agreed to use Horizon and to split the costs per agency.
Above funding request to cover Grant App. DMS RFP. Future Grant Admin to be billed per agency as costs incured (monthly).

Invoices:

KGA:	$16,216.52
KRGSA:	$2,861.74
BV	$953.91
Henry Miller:	$953.91
Olcese	$953.91
	$21,940.00

Kern County Subbasin Groundwater Sustainability Plan Support - Phase II 2019 Grant Application

Attachment 1

Authorizing Documentation

Proposition 68 and Proposition 1

Sustainable Groundwater Management Grant Program

Planning Grants Proposal Solicitation Package - Round 3

Introduction....1
Applicant Authorizing Documentation....1
Authorizing Resolution....2

Introduction

Attachment 1 includes authorizing documentation for submittal of this Proposition 68 and Proposition 1 Sustainable Groundwater Management Grant Program, Planning Grants Proposal Solicitation Package – Round 3 grant application. The applicant has provided a resolution adopted by the applicant's governing body designating an authorized representative to submit the application and execute an agreement with the State of California for a Sustainable Groundwater Management Grant.

Applicant Authorizing Documentation

The Kern River Groundwater Sustainability Agency (KRGSA) is pleased to serve as the applicant for Kern County Subbasin Groundwater Sustainability Plan Support – Phase II grant application. The Kern County Subbasin Groundwater Sustainability Plan Support – Phase II application includes one project led by and supporting all the GSAs in the Kern County Subbasin. The proposed project will benefit the entire Kern County Subbasin.

KRGSA is a Groundwater Sustainability Agency (GSA) formed in 2016 under Section 10723.8 of the California Water Code and is comprised of public agency members including the City of Bakersfield, the Kern Delta Water District, and the Kern County Water Agency Improvement District No. 4. An excerpt from the GSA application package submitted to the California Department of Water Resources' (DWR's) Sustainable Groundwater Management Section on April 12, 2016, is included as supporting documentation with Attachment 2, Appendix A. Further information and the entire GSA application package may be found on KRGSA's website: http://www.kernrivergsa.org.

The Round 3 Planning Grants Proposal Solicitation Package states that eligible applicants are GSAs, member agencies of the GSAs, or member agencies of an approved Alternate to a GSP for the basin for which the application is submitted. The KRGSA is a GSA for a portion of the Kern County Subbasin (Basin Number 5-22.14) and, as such, is an eligible applicant for this Proposition 68 and Proposition 1 Sustainable Groundwater Management Grant Program, Planning Grants Proposal Solicitation Package – Round 3 grant application.

The KRGSA Executive Board adopted Resolution KRGSA 001-19 on October 21, 2019, authorizing KRGSA to submit this application to obtain a grant under the Sustainable Groundwater Management Grant Program and execute an agreement with the State of California to receive a grant under the Proposition 68 and Proposition 1 Sustainable Groundwater Management Grant Program, Planning Grants Proposal Solicitation Package – Round 3 grant opportunity. A copy of the resolution is included on the following pages.

RESOLUTION NO. KRGSA 001-19

A RESOLUTION BY THE KERN RIVER GROUNDWATER SUSTAINABILITY AGENCY (KRGSA) THAT APPLICATION BE MADE TO THE CALIFORNIA DEPARTMENT OF WATER RESOURCES TO OBTAIN A GRANT UNDER THE SUSTAINABLE GROUNDWATER PLANNING GRANT PROGRAM FOR THE KERN COUNTY SUBBASIN GROUNDWATER SUSTAINABILITY PLAN SUPPORT - PHASE II

WHEREAS, the California Department of Water Resources (DWR) is administering the Sustainable Groundwater Management (SGM) Grant Program Planning Grants using funds authorized by the California Drought, Water, Parks, Climate, Coastal Protection, and Outdoor Access for All Act of 2018 (Proposition 68) and the Water Quality, Supply, and Infrastructure Improvement Act of 2014 (Proposition 1); and

WHEREAS, DWR will award $50 million for projects that develop and implement groundwater plans and projects; and

WHEREAS, Proposition 68 requires a minimum cost share of 25% of the total project cost, and Proposition 1 requires a minimum cost share of 50% of the total project cost; and

WHEREAS, only one grant will be awarded per basin; and

WHEREAS, the KRGSA represents all potential applicants in the kern subbasin, and

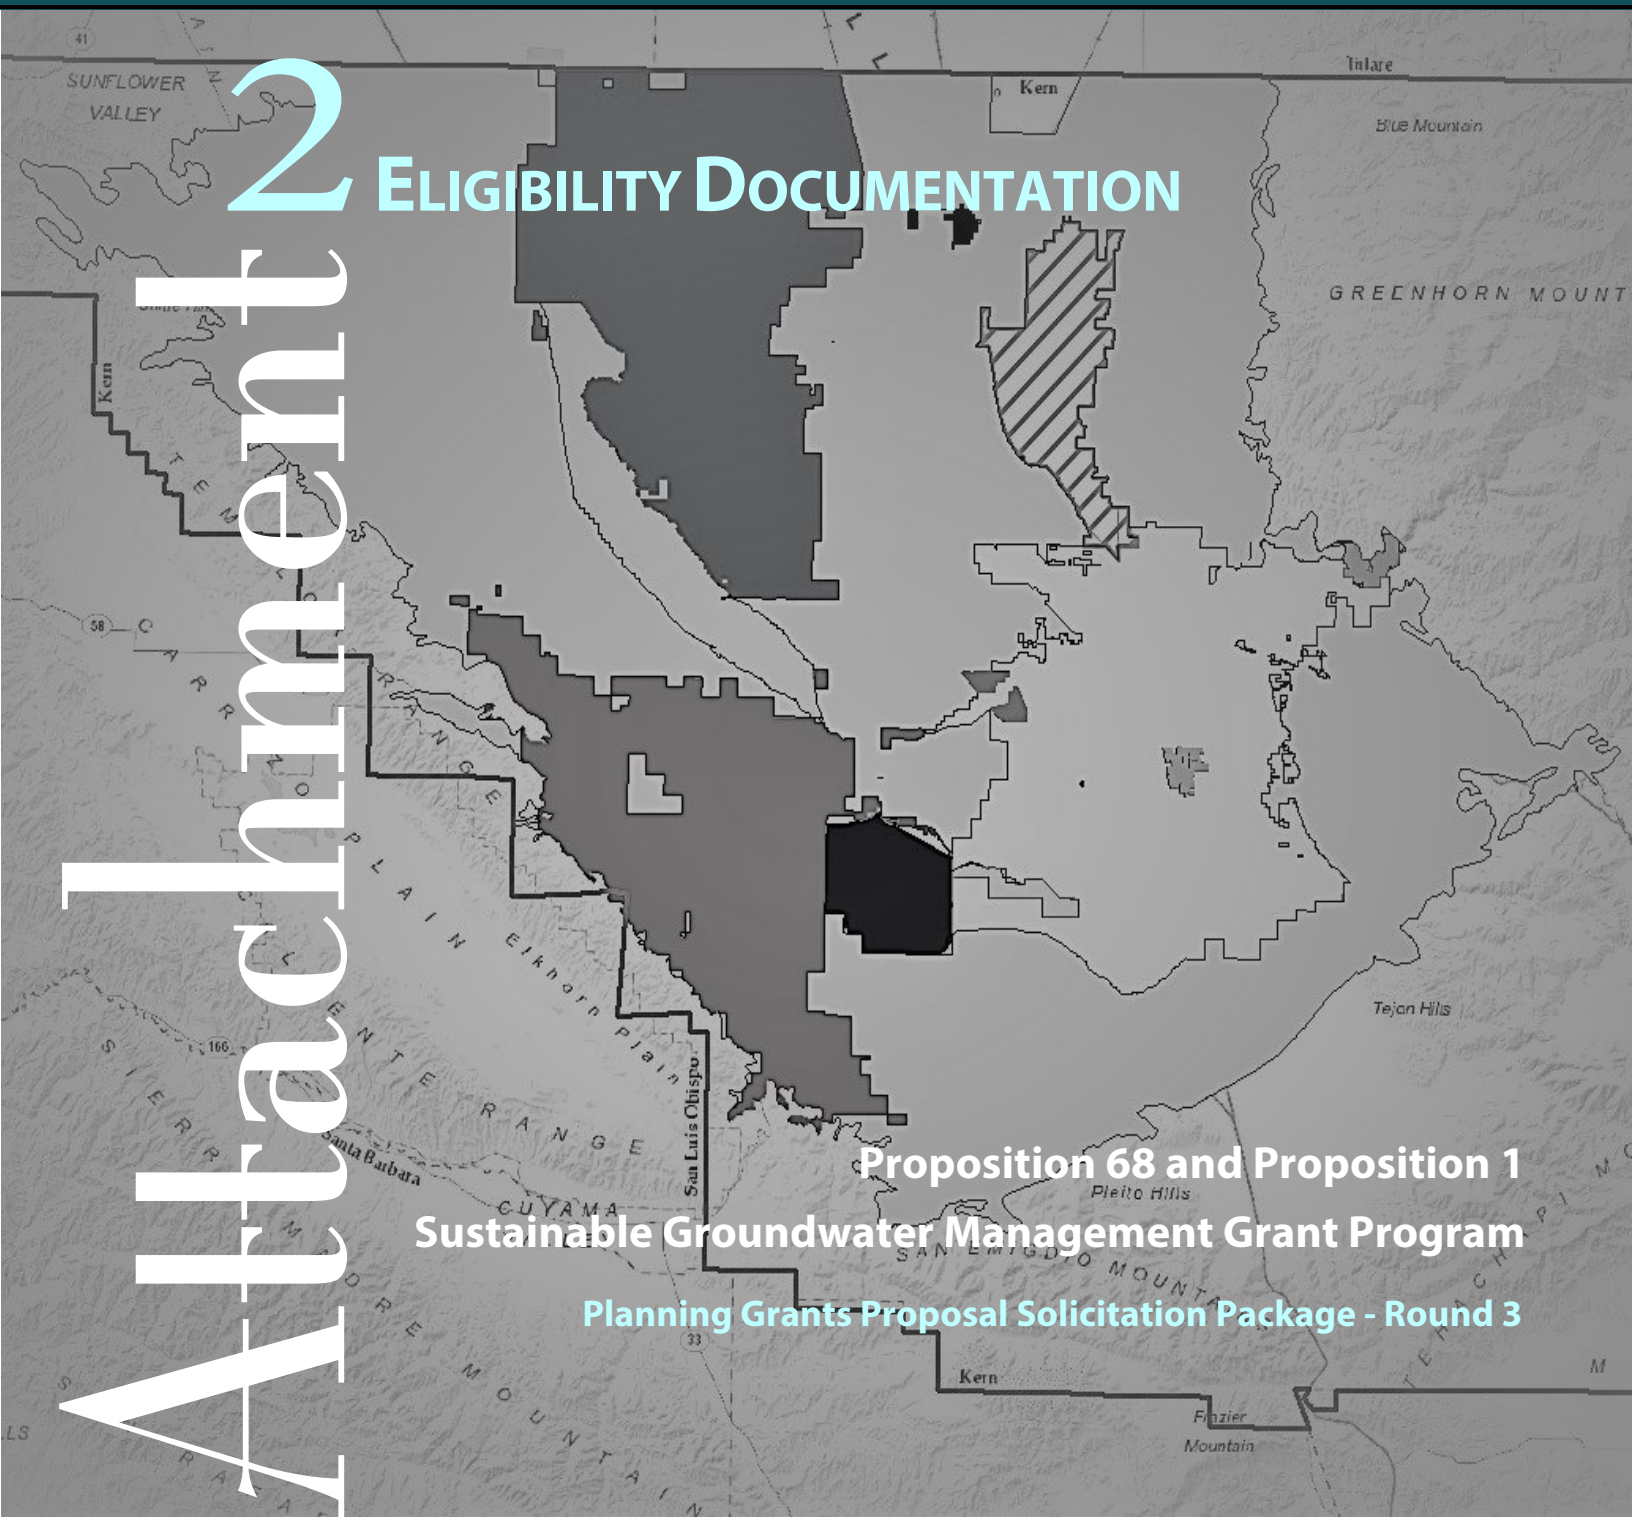
WHEREAS, DWR requires a resolution to be adopted by the applicant's governing body designating an authorized representative to submit the application and execute and agreement with the State of California for a SGM Grant; and

NOW, THEREFORE, BE IT RESOLVED, by the KRGSA as follows:

1. The above recitals and findings are true and correct and are incorporated herein by reference.

2. That application be made to the California Department of Water Resources to obtain a grant under the 2019 Sustainable Groundwater Planning Grant Program pursuant to the Water Quality, Supply, and Infrastructure Improvement Act of 2014 (Proposition 1) (Water Code Section 79700 et seq.) and/or the California Drought, Water, Parks, Climate, Coastal Protection, and Outdoor Access for All Act of 2018 (Proposition 68) for the Kern

County Subbasin Groundwater Sustainability Plan Support - Phase II.



3. That the Board Chair of the KRGSA or his designee is hereby authorized and directed to prepare the necessary data, conduct investigations, file such application, and execute a grant agreement with the California Department of Water Resources and make amendments or changes thereto.

--------oo000oo--------

I HEREBY CERTIFY that the foregoing Resolution was passed and adopted by the Kern River Groundwater Sustainability Agency on OCT 2 1 2019,

Rodney S. Palla, Chairman

Kern County Subbasin Groundwater Sustainability Plan Support - Phase II 2019 Grant Application

Appendices

Appendix A. Kern River Groundwater Sustainability Agency GSA Application Package (excerpt)
Appendix B. Compliance Documentation

Introduction

Attachment 2 includes eligibility documentation for this Groundwater Sustainability Plan Support – Phase II Grant Application. Attachment 2 includes the following sections as required by the Proposal Solicitation Package (PSP):

A. Applicant Information
B. Agricultural Water Management Compliance
C. CASGEM Basin Prioritization and Compliance
D. Climate Change
E. Groundwater Management Compliance
F. Open and Transparent Water Data
G. Public Utilities and Mutual Water Companies
H. Stormwater Resource Plan (SWRP) Compliance
I. Surface Water Diverter Compliance
J. Sustainable Water Use and Demand Reduction
K. Urban Water Management Compliance
L. Water Metering Compliance

A. Applicant Information

The Kern River Groundwater Sustainability Agency (KRGSA) is pleased to serve as the applicant for Kern County's Kern County Subbasin Groundwater Sustainability Plan Support – Phase II grant application. The Kern County Subbasin Groundwater Sustainability Plan Support – Phase II application includes one project led by and supporting all the GSAs in the Kern County Subbasin. . The proposed project will benefit the entire Kern County Subbasin.

The Kern County Subbasin has been identified as a critically overdrafted, high priority groundwater basin. The Proposal objective is to implement a high-priority project that provides direct groundwater planning benefits to the Subbasin, meets Groundwater Sustainability Plan (GSP) regulations, and meets the California Department of Water Resources' (DWR's) evaluation criteria for Sustainable Groundwater Management Grant Program, Round 3 Planning Grants funding.

This project is entitled Subbasin Data Management System Development and it will develop a critical groundwater sustainability planning element encompassing all parts of the Subbasin. The proposed project includes the following primary objectives to initiate developing the Subbasin's Data Management System (DMS): (1) conduct stakeholder outreach and engagement activities, (2) procure consultant assistance for DMS development, (3) identify DMS information requirements, (4) research and select the appropriate DMS approach for the Subbasin, (5) procure or design the DMS and refine and customize the DMS as needed, and (6) develop data protocols and templates (7) train GSA staff . If additional funding is required, the GSAs in the Kern subbasin have agreed to work together to either locate additional funding or to fund. This project is critical to meet immediate Kern County Subbasin GSP planning needs, as well as essential for the next steps in basin coordination and Sustainable Groundwater Management Act (SGMA) compliance requirements.

KRGSA is a Groundwater Sustainability Agency formed in 2016 under § 10723.8 of the California Water Code and is comprised of public agency members including the City of Bakersfield, the Kern Delta Water District, and the Kern County Water Agency Improvement District No. 4. An excerpt from the GSA application package submitted to DWR's Sustainable Groundwater Management Section on April 12, 2016, is included as supporting documentation in Appendix A to this Attachment 2. Further information may be found on KRGSA's website: http://www.kernrivergsa.org.

The Round 3 Planning Grants PSP states that eligible applicants are GSAs, member agencies of the GSAs, or member agencies of an approved Alternate to a GSP for the basin for which the application is submitted. KRGSA is a GSA for a significant portion of the critically overdrafted, high priority Kern County Subbasin (Basin Number 5-22.14) and as such is an eligible applicant for this Proposition 68 and Proposition 1 Sustainable Groundwater Management Grant Program, Planning Grants PSP – Round 3 grant application.

The KRGSA Executive Board adopted Resolution KRGSA 001-19 on October 21, 2019, authorizing KRGSA to submit this application on behalf of the entire Kern subbasin to obtain a grant under the Sustainable Groundwater Management Grant Program and execute an agreement with the State of California to receive a grant under the Proposition 68 and Proposition 1 Sustainable Groundwater Management Grant Program, Planning Grants PSP – Round 3 grant opportunity. A copy of the resolution is included in Attachment 1.

B. Agricultural Water Management Compliance

Agricultural Water Management eligibility for the applicant for this Proposal is discussed in this section.

The applicant, KRGSA, is not an agricultural water supplier. No agricultural water suppliers will receive funding from the proposed grant through a joint-powers agreement or other legal agreement. The project will be implemented by the applicant, KRGSA, and KGA on behalf of all the GSAs in the Subbasin. KGA is also a GSA within the basin, and KGA is not an agricultural water supplier. Neither the applicant nor the additional project proponent, KGA, is an agricultural water supplier, and as such these entities are not required to develop or submit Agricultural Water Management Plans (AWMPs).

Therefore, documentation of Agricultural Water Management Compliance is not applicable for this Proposal, applicant, or project proponents.

It is noted that while the applicant, KRGSA, is not an agricultural water supplier, one of the member agencies of the KRGSA is the Kern Delta Water District, which is required to develop and submit an AWMP. The Kern Delta Water District is in full agricultural water management compliance, having submitted and received DWR approval, with documentation provided in Appendix B.

C. CASGEM Basin Prioritization and Compliance

This section discusses California Statewide Groundwater Elevation Monitoring (CASGEM) eligibility status for the overall Proposal, project proponents, and the proposed project. The Subbasin Data Management System Development project proposed in this application package will benefit the entire Kern County Subbasin, identified as groundwater Subbasin number 5-022.14. Pursuant to Water Code § 10933(b) and Bulletin 118, DWR has designated the Kern County Subbasin as high priority and critically overdrafted.

Determining CASGEM compliance status for the overall Kern County Groundwater Basin (5-022.14) requires identifying:

(1) whether the entirety of the groundwater basin is monitored through identification and establishment of monitoring entities, and

(2) if monitoring data is uploaded to CASGEM regularly each spring and fall, once monitoring entities are established.

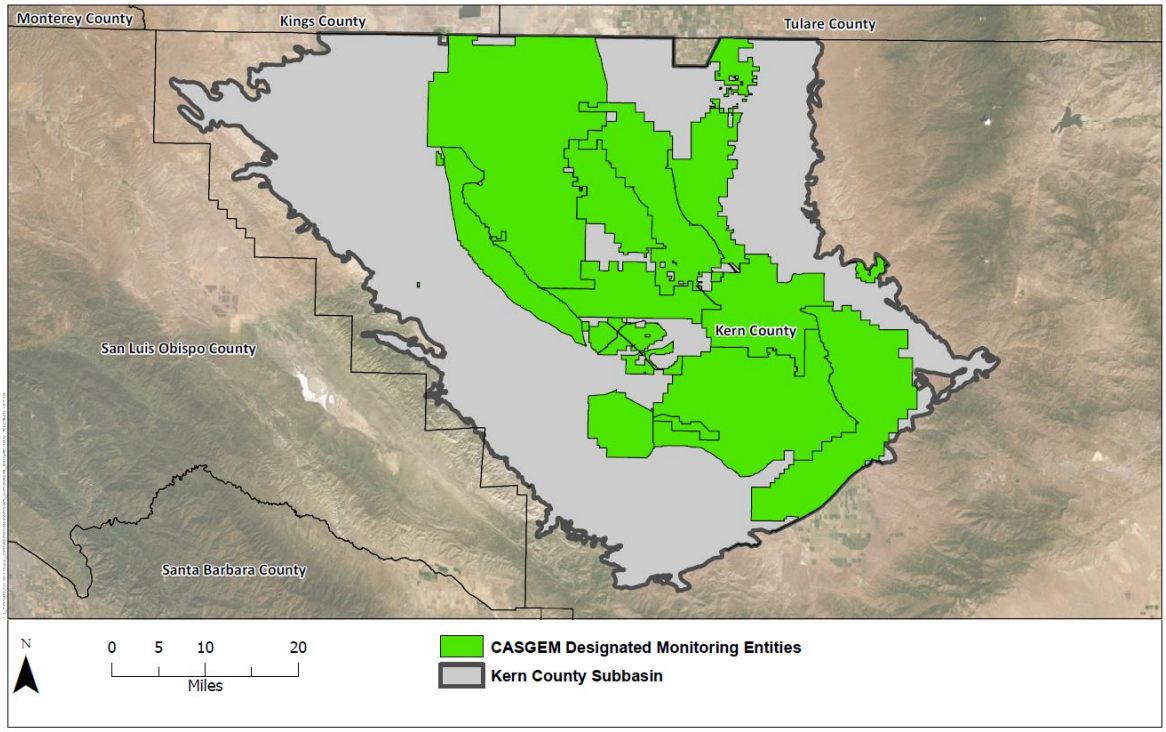
For the portion of high-priority basins that do not have a CASGEM monitoring entity, the grant applicant will not be eligible to receive grant funding (Water Code § 10933.7(a)). Consistent with Water Code § 10933.7(b), if the applicant area is demonstrated to be a DAC or SDAC, the project will be considered eligible for grant funding not withstanding CASGEM compliance.

The Subbasin Data Management System Development project will be implemented by the applicant, KRGSA, in collaboration with KGA on behalf of and in coordination with all the GSAs in the Subbasin. The applicant, KRGSA, is not identified as a CASGEM monitoring entity for the basin. KGA is also a GSA within the Kern County Subbasin. KGA is not a CASGEM monitoring entity. Neither the applicant nor the additional project proponent, KGA, is serving as a CASGEM monitoring entity for the basin. However, approximately 46% of the

Kern County groundwater basin is CASGEM compliant as described below, based on established monitoring entities that provide data to DWR's CASGEM program. This project includes a basin-wide project that will benefit the entire Subbasin, including the 54% non-CASGEM compliant area, of which 90% is characterized as Disadvantaged Community and, as such, is exempt from the requirement for CASGEM compliance.

Figure 2-1, below, depicts the Kern County Subbasin, showing areas where CASGEM monitoring entities have been established (green), and areas where CASGEM monitoring entities are not yet established (gray). This map shows that 46% of the basin is CASGEM compliant in terms of having established monitoring entities that meet CASGEM requirements.

Figure 2-1. Kern County Subbasin Area with Established Monitoring Entities



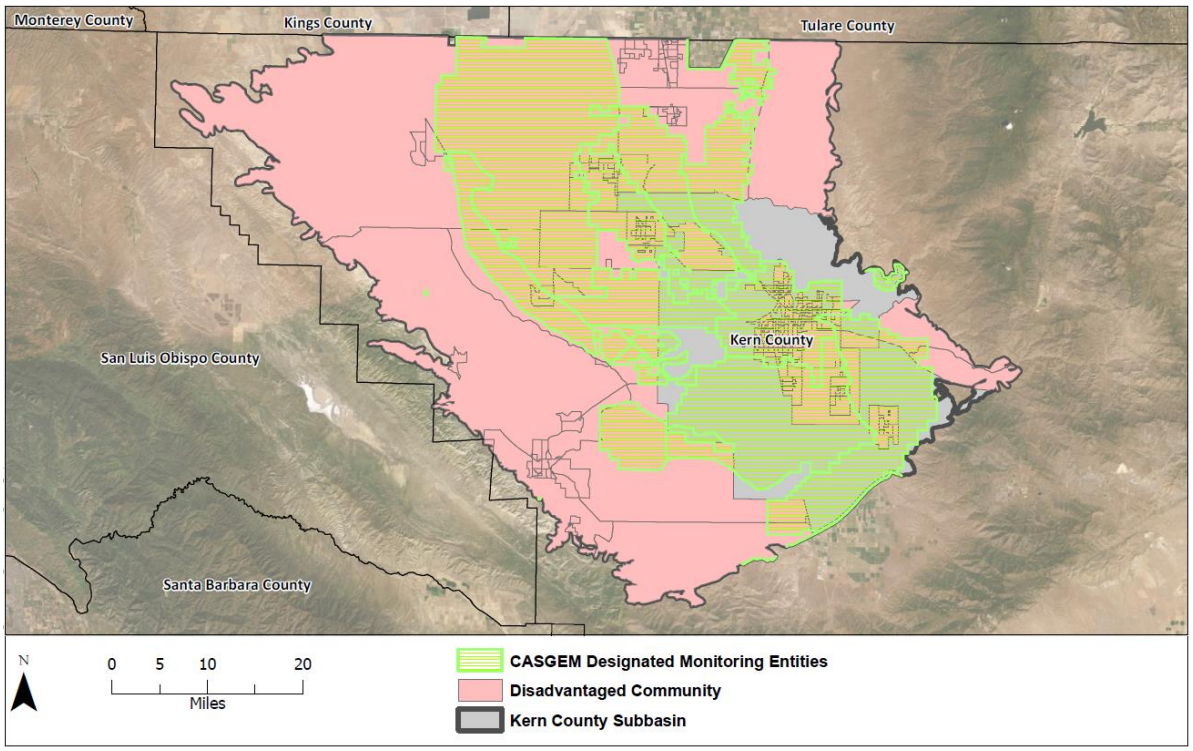


Figure 2-2, below, depicts the Kern County Subbasin, showing CASGEM compliant areas and DAC boundaries within the Subbasin (data acquired from DWR's DAC Mapping tools). This map shows that, within the 54% of the basin that is not CASGEM compliant (in terms of not having established monitoring entities); 90% of that area is characterized as a DAC, and as such, exempt from the PSP requirement for CASGEM compliance. It is noteworthy that only 5.6% of the Subbasin is both not CASGEM compliant and not DAC.

Figure 2-2. Kern County Subbasin Areas with Established Monitoring Entities and DAC Areas

CASGEM Monitoring Data – Current Submittal Status

Table 2-1, below, is featured on DWR's CASGEM website, and presents a list of the established CASGEM monitoring entities for the basin. The table also shows latest elevation data submitted as of October 23, 2019. This table shows that established monitoring entities are providing current elevation data.

Table 2-1. Kern County Subbasin Monitoring Entities and Data Submittal Status

Monitoring Entity	Groundwater Basin/ Subbasin Name	Groundwater Basin/ Subbasin Number	Authority Type	Last Elevation Data Submitted	Associated Well Count
Arvin-Edison Water Storage District	Kern County	5-022.14	Ground Water Management Agency	3/12/2019 5:01:00 PM	41
Cawelo Water District	Kern County	5-022.14	Ground Water Management Agency	3/11/2019 6:48:00 PM	7
Deer Creek & Tule River Authority	Kern County	5-022.14	Local Agency Pursuant to WC Part 2.75	2/25/2019 12:00:00 AM	3
Kern County Water Agency Improvement District No. 4	Kern County	5-022.14	Local Agency Pursuant to WC Part 2.75	3/6/2019 3:46:00 PM	5
Kern River Fan Group	Kern County	5-022.14	Voluntary Cooperative Groundwater Monitoring Association	4/1/2019 12:00:00 AM	34
Kern Water Bank Authority	Kern County	5-022.14	Voluntary Cooperative Groundwater Monitoring Association	7/16/2019 12:00:00 AM	15
Kern-Tulare Water District	Kern County	5-022.14	Local Agency Pursuant to IRWM	10/8/2019 12:00:00 AM	25
North Kern Water Storage District	Kern County	5-022.14	Local Agency Pursuant to WC Part 2.75	5/8/2019 12:00:00 AM	9
Semitropic Water Storage District	Kern County	5-022.14	Local Agency Pursuant to WC Part 2.75	6/8/2019 12:00:00 AM	46
Shafter-Wasco Irrigation District	Kern County	5-022.14	Local Agency Pursuant to WC Part 2.75	2/1/2019 12:00:00 AM	8
West Kern Water District	Kern County	5-022.14	Ground Water Management Agency	8/7/2019 12:00:00 AM	49

Source: DWR's CASGEM website.

The monitoring entities listed in Table 2-1 above are providing elevation data submitted for Kern County Subbasin and encompass approximately 46% of the Subbasin area. The other 54% of the Kern County Subbasin is not yet CASGEM compliant.

Conclusion

As described above, approximately 46% of the Kern County Groundwater Subbasin is CASGEM compliant from the perspective of having established monitoring entities, as well as from the perspective of providing monitoring data to DWR's CASGEM program. Figure 2-2 illustrates that, of the 54% of the basin that is not CASGEM compliant, 90%, or the great majority, is a DAC and, as such, exempt from the PSP requirement for CASGEM compliance. The remaining areas that are still not compliant and not DAC, 5.6% of the Subbasin, will not receive grant funding.

CASGEM compliance is sufficiently demonstrated for the Kern County Groundwater Subbasin for purposes of this grant proposal.

D. Climate Change

This section discusses Climate Change eligibility status for the overall Proposal. The SGM Grant Program 2019 Guidelines document requires that applicants seeking funding must demonstrate that the applicant's project contributes to addressing the risks in the region to water supply and water infrastructure arising from climate change (Water Code § 79742(e)). To the extent practicable, applicants must measure the amount of greenhouse gas emissions reduced and carbon sequestered resulting from an implementation project funded by the SGM Grant Program (Public Resources Code § 80001(b)(7)).

This Proposal involves funding of a planning effort rather than an implementation project. As such, the Subbasin Data Management System Development project would not involve activities that could emit greenhouse gases or affect carbon sequestration. The project would have no effect related to climate change. Therefore, documentation of climate change effects is not applicable for this Proposal, applicant, or project proponents.

E. Groundwater Management Compliance

This section discusses Groundwater Management Compliance eligibility status for the overall Proposal. The SGM Grant Program 2019 Guidelines document requires that, for groundwater implementation projects that directly affect groundwater levels or quality, the applicant must self-certify that one or more option below has been, or is currently, being satisfied.

SGMA (Water Code § 10720 et seq.) specifies actions for critically overdrafted groundwater basins, high and medium priority basins, and low and very low priority basins. Groundwater project proponents must demonstrate how their project is consistent with SGMA efforts in the basin. To be eligible to receive Implementation grant funds, applicants must be from a medium or high priority basin with either:

- An adopted GSP that has been submitted to DWR for review and deemed complete by DWR, or
- An approved Alternative to a GSP.

This Proposal involves funding of a planning effort rather than an implementation project that directly affects groundwater levels or quality. The proposed project, the Subbasin Data Management System (DMS) Development, will develop a critical groundwater sustainability tool encompassing all parts of the Subbasin. The proposed project consists of scoping and development of the DMS including activities such as: (1) conducting stakeholder outreach and engagement activities, (2) procuring consultant assistance for DMS development, (3) identifying DMS information requirements, (4) researching and selecting the appropriate DMS approach for the Subbasin, and (5) procuring and designing the DMS and customizing it as needed. This proposed project is critical to meet Kern County Subbasin GSP, basin coordination, and SGMA compliance needs.

This Proposal is entitled Kern County Subbasin Groundwater Sustainability Plan Support – Phase II. The first phase of this GSP support work is currently underway and is being funded under a Proposition 1 SGMA Round

2 Planning Grant entitled Kern County Subbasin Groundwater Sustainability Support – 2017 Grant Application. Activity under the Proposition 1 grant includes generating a GSP for KRGSA to be submitted to DWR as a deliverable. As of this writing (October 2019) the GSP is in draft form and will be submitted to DWR on or before January 31, 2020.

F. Open and Transparent Water Data

This section discusses Open and Transparent Water Data Compliance for the overall Proposal. The SGM Grant Program 2019 Guidelines document requires that recipients of State funds through grants or contracts for research or projects relating to the improvement of water or ecological data shall, as a condition of the receipt of a grant or contract, adhere to the protocols developed pursuant to subdivision (a) for data sharing, transparency, documentation, and quality control (Water Code § 12406(b)). KRGSA will adhere to all required data sharing, transparency, and documentation protocols.

G. Public Utilities and Mutual Water Companies

This section discusses Public Utilities and Mutual Water Companies Compliance for the overall Proposal. The SGM Grant Program 2019 Guidelines document requires that a project proposed by a public utility regulated by the Public Utilities Commission or a mutual water company shall have a clear and definite public purpose and shall benefit the customers of the water system and not the investors (Water Code § 79712(b)(1)).

This Proposal involves funding of a planning effort rather than an implementation project. The Subbasin Data Management System Development project it will develop a critical groundwater sustainability tool encompassing all parts of the Subbasin. The proposed project consists of scoping and development of the DMS. Once the planned DMS becomes operational, the collected data will inform understanding of existing and projected groundwater levels; consequently, this knowledge will contribute to addressing and reducing risks in the region to water supply and water infrastructure arising from climate change. This is a clear and definite public purpose and benefits the customers and residents of the entire project area, the Kern County Subbasin. There are no investors associated with this project, and there shall be no benefits to investors as a result of this project.

H. Stormwater Resource Plan (SWRP) Compliance

This section discusses Stormwater Resource Plan Compliance for the overall Proposal. The SGM Grant Program 2019 Guidelines document states that Senate Bill (SB) 985 (Water Code § 10563(c)) requires the development of a SWRP or functionally equivalent plan for stormwater and dry weather runoff capture projects to receive grant funds through these provisions.

This Proposal involves funding of a planning effort, not an implementation project. As such, the Subbasin Data Management System Development project would not involve activities that could affect stormwater or dry weather resources. Since this project will conduct no construction, a Stormwater Resource Plan will not be needed.

I. Surface Water Diverter Compliance

Surface Water Diverter eligibility for the overall Proposal is discussed in this section. The SGM Grant Program 2019 Guidelines document states that a diverter of surface water is not eligible for a water grant or loan awarded or administered by the State unless it complies with surface water diversion reporting requirements outlined in Part 5.1 of Division 2 of the Water Code.

The applicant, KRGSA, is not a surface water diverter. No surface water diverters will receive funding from the proposed grant through a joint-powers agreement or other legal agreement. The project included in this proposal will be implemented by the applicant, KRGSA, in collaboration with KGA on behalf of all the GSAs in the Subbasin. KGA is also a GSA within the basin, and KGA is not a surface water diverter. Neither the applicant nor the additional project proponent, KGA, is a surface water diverter, and as such these entities are not required to submit to the State Water Resources Control Board (SWRCB) surface water diversion reports in

compliance with requirements outlined in Part 5.1 (commencing with Section 5100) of Division 2 of the Water Code.

Therefore, documentation of Surface Water Diverter Compliance is not applicable for this proposal, applicant, or project proponents.

It is noted that while the applicant, KRGSA, is not a surface water diverter, two of the member agencies of the KRGSA are surface water diverters. The City of Bakersfield and Kern Delta Water District have longstanding water rights on the Kern River. Both these member agencies are in full compliance with regard to submitting diversion reports with the SWRCB.

J. Sustainable Water Use and Demand Reduction

This section addresses Sustainable Water Use and Demand Reduction eligibility for the overall Proposal. The SGM Grant Program 2019 Guidelines document states that SBx7-7 (Water Code § 10608 et seq.) conditions the receipt of a water management grant or loan for urban water suppliers on gallons per capita per day reduction targets with the end goal of a 20% reduction by 2020.

As discussed below in Section K, Urban Water Management Compliance, the applicant, KRGSA, is not an urban water supplier. No urban water suppliers will receive funding from the proposed grant through a joint-powers agreement or other legal agreement. The Sustainable Water Use and Demand Reduction criterion is not applicable for this Proposal.

K. Urban Water Management Compliance

Urban Water Management eligibility for the applicant for this Proposal is discussed in this section. The applicant, KRGSA, is not an urban water supplier. No urban water suppliers will receive funding from the proposed grant through a joint-powers agreement or other legal agreement. The project included in this proposal will be implemented by the applicant, KRGSA, in collaboration with KGA on behalf of and in coordination with all the GSAs in the Subbasin. KGA is also a GSA within the basin, and KGA is not an urban water supplier. Neither the applicant nor the additional project proponent, KGA, is an urban water supplier, and as such these entities are not required to develop or submit Urban Water Management Plans, to maintain compliance with Sustainable Water Use and Demand Reduction, Part 2.55 of Division 6 (Water Code Section 10608 *et seq*.), or to comply with water metering requirements contained in Water Code Section 525 et seq.

Therefore, documentation of Urban Water Management Compliance is not applicable for this proposal, applicant, or project proponents.

It is noted that while the applicant, KRGSA, is not an urban water supplier, two of the KRGSA member agencies, the Kern County Water Agency Improvement District No. 4 and the City of Bakersfield, are required to develop and maintain an Urban Water Management Plan (UWMP) that is submitted to DWR for review. Kern County Water Agency Improvement District No. 4 is in full urban water management compliance, having submitted and received DWR approval on its 2015 UWMP, which is included in Appendix B. The City of Bakersfield's UWMP was submitted on June 30, 2017. Documentation is also included in Appendix B.

L. Water Metering Compliance

This section addresses Water Metering Compliance eligibility for the overall Proposal. The Round 3 Planning Grants Proposal Solicitation Package states that any urban water supplier applying for State grant funds for wastewater treatment projects, water use efficiency projects, drinking water treatment projects, or for a permit for a new or expanded water supply, shall demonstrate that they meet the water meter requirements in Water Code § 525 et seq.

The applicant, KRGSA, is not an urban water supplier. The project included in this proposal will be implemented by the applicant, KRGSA, in collaboration with KGA on behalf of and in coordination with all the GSAs in the Subbasin. KGA is also a GSA within the basin, and KGA is not an urban water supplier. Neither the applicant nor the additional project proponent, KGA, is an urban water supplier.

This Proposal is not seeking funding for a wastewater treatment project, water use efficiency project, drinking water treatment project, or permit for a new or expanded water supply.

Therefore, the Water Metering Compliance criterion is not applicable for this proposal, applicant, or project proponents.

It is noted that while the applicant, KRGSA, is not an urban water supplier, two of the KRGSA member agencies, the Kern County Water Agency Improvement District No. 4 is a treated water wholesaler and provides a supply to four customers. All connections are metered; however, ID4 is not required to obtain documentation because it is not a retail urban water supplier.

Kern River Groundwater Sustainability Agency
GSA Application Package (excerpt)

April 12, 2016 GSA application package cover letter submitted to DWR's Sustainable Groundwater Management Section

Full application package may be found on KRGSA's website: http://www.kernrivergsa.org

Kern River Groundwater Sustainability Agency

April 12, 2016

Mark Nordberg, GSA Project Manager
Sustainable Groundwater Management Section
California Department of Water Resources
P.O. Box 942836
Sacramento, California 94236-0001

Re: Notice of Decision to Become a Groundwater Sustainability Agency

Dear Mr. Nordberg,

Per Section 10723.8(a) of the California Water Code, the City of Bakersfield, the Kern Delta Water District, and the Kern County Water Agency Improvement District No.4 hereby give notice of their decision to form the Kern River Groundwater Sustainability Agency (GSA) for a portion of the Kern County Subbasin (Basin Number 5-22.14, DWR Bulletin 118) within the San Joaquin Valley Groundwater Basin.

The Sustainable Groundwater Management Act (SGMA), passed in 2014, requires that all basins designated as high- or medium-priority basins that are subject to critical overdraft conditions are to be managed under a groundwater sustainability plan (GSP) or coordinated GSPs (Section 10720.7). The Kern County Subbasin is a high-priority basin and is identified as having critical overdraft conditions. Information regarding the status of groundwater basins is provided by the California Department of Water Resources (DWR) at: http://www.water.ca.gov/groundwater/sgm/cod.cfm.

This GSA notification and supporting materials are submitted to DWR within 30 days of the decision to form the GSA by its member agencies per Water Code §10723.8(a).

Water Code §10723.8(a)(1) requires that this GSA notification include information regarding the service area boundaries of the GSA and the boundaries of the basin the GSA intends to manage. Exhibit 1 includes three maps to satisfy the requirements of Water Code §10723.8(a)(1). Map (A) shows the Kern River GSA boundary. Map (B) shows the Kern River GSA boundary within the Kern County Subbasin. Map (C) shows the boundaries of the service areas of the agencies that comprise the Kern River GSA. The digital GIS data corresponding to the GSA boundary maps shown in Exhibit 1 are included with this submittal and provided on compact disc.

Water Code §10723.8(a)(1) also requires information regarding other agencies managing or proposing to manage groundwater within the basin. At the time of this Kern River GSA Notification submittal to DWR, it is our understanding that the Buena Vista Water Storage District has submitted a Notification to Form a GSA with DWR for a portion of the Kern County Subbasin. Within the Kern County subbasin, we understand that other agencies may be considering or proposing to form GSAs to manage groundwater resources in their own services areas. To our knowledge at this time, the following entities have held either a public hearing or expressed interest in forming a GSA: the Kern Groundwater Authority (KGA) and the Olcese Water District. We understand that the Greenfield County Water District has held a public hearing, passed a resolution to form a GSA, and will be submitting their Notification to Form a GSA with DWR.

On March 1, 2016 the governing Board of the Kern Delta Water District held a public hearing (Water Code §10723.b) regarding formation of the Kern River GSA. On March 15, 2016 the Board passed Resolution 2016-03 wherein the District resolved to become a GSA in cooperation with the City of Bakersfield and Improvement District No.4 of the Kern County Water Agency for the portion of the Kern County Subbasin as shown in Exhibit 1. Exhibit 2 contains a copy of the approved resolution to form the Kern River GSA by the governing Board of the Kern Delta Water District. Exhibit 3 includes details regarding the public noticing of the March 1, 2016 hearing by the Kern Delta Water District. The noticing process was consistent with the requirements of Section 6066 of the California Government Code.

On March 2, 2016 the City Council of Bakersfield held a public hearing (Water Code §10723.b) regarding formation of the Kern River GSA. On March 30, 2016 the City Council passed Resolution 039-16 wherein the City resolved to become a GSA in cooperation with the Kern Delta Water District and Improvement District No.4 of the Kern County Water Agency for the portion of the Kern County Subbasin as shown in Exhibit 1. A copy of Resolution 039-16 is included in Exhibit 2. Details regarding the public noticing of the March 2, 2016 hearing by the City Council are provided in Exhibit 3 and are consistent with the requirements of Section 6066 of the California Government Code.

On March 31, 2016 the Board of Directors of the Kern County Water Agency on behalf of Improvement District No.4 held a public hearing (Water Code §10723.b) regarding formation of the Kern River GSA. On March 31, 2016 the Board of Directors passed Resolution 11-16 wherein the Kern County Water Agency, Improvement District No.4 resolved to become a GSA in cooperation with the Kern Delta Water District and the City of Bakersfield for the portion of the Kern County Subbasin as shown in Exhibit 1. A copy of Resolution 11-16 is included in Exhibit 2. Details regarding the public noticing of the March 31, 2016 hearing by the Board of Directors are provided in Exhibit 3 and are consistent with the requirements of Section 6066 of the California Government Code.

Exhibit 4 provides a memorandum of understanding (MOU) between the Kern Delta Water District, City of Bakersfield, and Kern County Water Agency Improvement District No.4 to form the Kern River GSA and manage groundwater resources sustainably within the GSA boundary. Please note that Exhibit C-1 to the MOU in Exhibit 4 contains a list of additional agencies that have joined the Kern River GSA. Exhibit 5 includes additional supporting documents related to these additional agencies that have joined the Kern River GSA.

Per California Water Code §10723.2, GSAs shall consider the interests of all beneficial uses and users of groundwater within their service area, as well as those responsible for implementing Groundwater Sustainability Plans (GSPs). Exhibit 6 lists interested parties developed pursuant to Water Code §10723.2 and describes how these users and uses will be considered during the development and operation of the Kern River GSA and implementation of the GSP for the Kern River GSA. If additional interested parties are discovered, they too will be included in the development and operation of the GSA and the development and implementation of the agency's sustainability plan (Water Code 10723.8(a)(4)).

Water Code §10723.4 states that a GSA shall also establish and maintain a list of persons interested in receiving notices regarding plan preparation, meeting announcements, and availability of draft plans, maps, and other relevant documents. Any person may request, in writing, to be placed on the list of interested persons. The Kern River GSA will establish and maintain such a list of persons interested in receiving notices.

Except for the authorities granted to a GSA pursuant to Part 2.74 of Division 6 of the California Water Code (SGMA), no new bylaws, ordinances, or authorities have been adopted by the District or City at this time of forming the Kern River GSA (Water Code §10723.8(a)(3)).

The undersigned hereby represents that the information required by California Water Code §10728.3 is included within this notice and that the notification process is complete.

If you have any further questions or require any clarification regarding the information provided in this GSA Notification submittal, please do not hesitate to contact one of our GSA program coordinators as identified on the following page.

Thank you,

Rodney Palla

RE: Urban Water Management Plan Requirements Addressed

Dear Mr. Beard:

The Department of Water Resources (DWR) has reviewed the Kern County Water Agency's 2015 Urban Water Management Plan (UWMP) that was received on June 24, 2016. The California Water Code (CWC) directs DWR to report to the California State Legislature once every five years on the status of submitted UWMPs. In meeting this legislative reporting requirement, DWR reviews all submitted UWMPs.

DWR's review of the Kern County Water Agency's 2015 UWMP has found that the UWMP addresses the requirements of the CWC. DWR's review of plans is limited to assessing whether suppliers have addressed the required legislative elements. In its review, DWR does not evaluate or analyze the supplier's UWMP data, projections or water management strategies. This letter acknowledges that the Kern County Water Agency's 2015 UWMP addresses the CWC requirements. The results of the review will be provided to DWR's Financial Assistance Branch.

If you have any questions regarding the review of the UWMP or urban water management planning please call Gwen Huff at 916-651-9672.

Sincerely,

Vicki Lake

RE: Urban Water Management Plan Submittal

Dear Mr. Chianello:

This is to inform you that the Department of Water Resources has received the 2015 Urban Water Management Plan for City of Bakersfield on June 30, 2017.

DWR reviews Plans as quickly as possible and in the order they are received. If you require an expedited review, please contact me.

Please feel free to contact Gwen Huff at (916) 651-9672 if you have any questions or would like to discuss the review of 2015 Urban Water Management Plans. Contact Ms. Huff, also, if you require an expedited review.

Vicki Lake
Unit Chief
Urban Water Use Efficiency
Department of Water Resources

Work Plan

Grant Proposal Title:	**Kern County Subbasin Groundwater Sustainability Plan Support – Phase II**
Applicant:	**Kern River Groundwater Sustainability Agency**

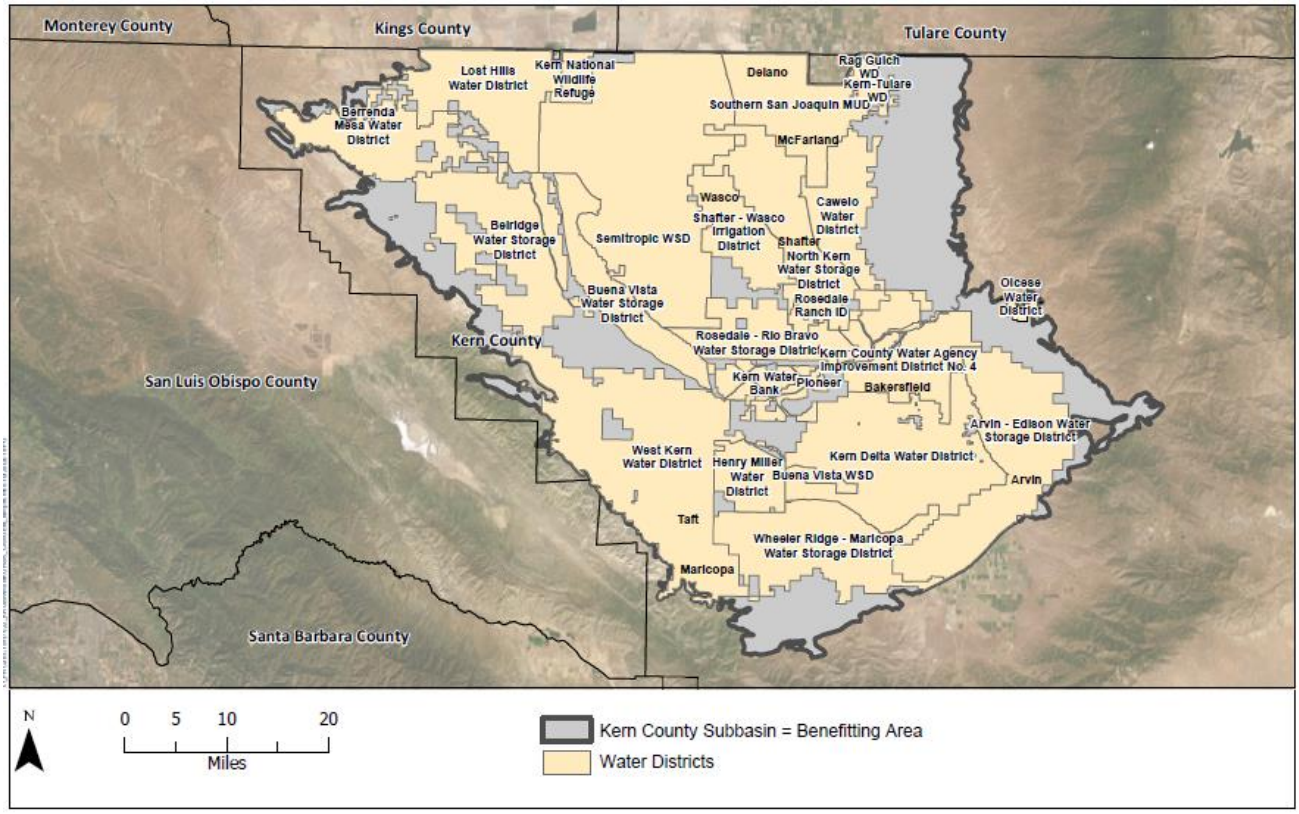
Project Justification

A. Project Description

The Kern County Subbasin (Subbasin 5-022.14) is identified as a critically overdrafted basin where numerous water and irrigation districts, municipalities, industries, mutual water companies, small water systems, and Kern County residents rely on the shared groundwater resources. In compliance with the Sustainable Groundwater Management Act (SGMA), 11 groundwater sustainability agencies (GSAs) have been formed to cooperatively manage local groundwater in a sustainable manner within the Subbasin.

This proposal includes one critically important project, Kern County Subbasin Data Management System Development, which will be implemented by all the GSAs in the Kern County Subbasin. KRGSA is submitting this application on behalf of the entire Subbasin.

KRGSA on behalf of the Kern County Subbasin was awarded $1,500,000 in Proposition 1 SGMA Planning Grant funds for a suite of six GSP Development project components supporting the entire Kern County Subbasin and proposed under the 2017 Round 2 SGMA grant opportunity. These six project components are well underway and successfully nearing completion at the time of this writing. Given the funding guidelines associated with this 2019, Round 3 SGM Planning Grant opportunity, this proposal requests an additional $500,000 in Planning Grant funds, which if awarded, will mean that the Kern County Subbasin will have been awarded the published maximum of $2,000,000 in Proposition 68 and Proposition 1 SGM Planning Grant funding. The Kern County Subbasin is one of the most important groundwater resources in the state, given its large size, high population growth, large number of irrigated acres, reliance on groundwater, and historical groundwater impacts. In light of these relatively high basin prioritization criteria, the Subbasin supports numerous large groundwater banking projects of statewide importance, including the Kern Water Bank, among others. This Subbasin is deserving of earning up to the maximum of grant funding due to the importance of this Subbasin and its various planning needs and challenges.



This project included in this proposal and described below will parlay the available $500,000 in Planning Grant funds to effectively initiate a data management system (DMS) that will benefit all GSAs in the Subbasin and directly support the cross-basin coordination effort.

Background and Need for the Project

Covering about 2,834 square miles, Kern County Subbasin is the largest subbasin in California with a complex water management structure, a large portfolio of local and imported water sources, and numerous large groundwater banking projects, collectively providing both local and State-wide benefits for water supply. The map provided in **Figure 3-1** below shows the boundaries of the Kern County Subbasin, which is also the area that would benefit from the proposed project, as well as the boundaries of the multiple water districts within the Subbasin. The general locations of Disadvantaged

Communities (DACs) are shown in bold-face type; a map showing the areas occupied by DACs is provided as Figure 6-1 in Attachment 6.

Figure 3-1. Kern County Subbasin and Benefitting Area

Given this framework, numerous approaches and systems for data management have been developed over time by each local agency for its own objectives – including regulatory compliance. This has resulted in a myriad of disparate data sets with different organizational structures, temporal and spatial scales, data standards, and assumptions regarding data accuracy and reliability. GSP regulations (Article 3, Section 352.6) require agencies to develop and maintain a data management system that is "capable of storing and reporting information relevant to the development or implementation of the Plan and monitoring of the basin."

The Kern County Subbasin GSAs recognize the need to develop a centralized DMS on a Subbasin-wide basis. Accordingly, the GSAs in the Kern County Subbasin are cooperating on this proposal for a Subbasin-wide DMS to support monitoring, evaluation, reporting, management, and, importantly, GSP implementation. It is recognized that compilation of individual DMSs will require significant manipulation and re-structuring to create a centralized relational DMS that is populated with consistent data sets across the Subbasin.

One of the hallmarks of SGMA is a call for the integrated coordination of groundwater resources across a subbasin planning area. For the Kern County Subbasin, developing a shared, common, and consistent platform across the Subbasin is essential to continue the coordination developed with the C2VSim water modeling, monitoring network, and now annual reporting.

The immediate need for a centralized DMS is highlighted by the GSAs' ongoing cooperative efforts for annual reporting. Specifically, GSAs are working together to collaboratively prepare one Annual Report for each reporting period that covers the entire Subbasin rather than submitting a separate Annual Report from each GSA. As codified in SGMA, Chapter 6, Section 10728 of the California Water Code states:

> "On April 1 following the adoption of a groundwater sustainability plan and annually thereafter, a groundwater sustainability agency shall submit a report to the department containing the following information about the basin managed in the groundwater sustainability plan:
>
> (a) Groundwater elevation data.
>
> (b) Annual aggregated data identifying groundwater extraction for the preceding water year.
>
> (c) Surface water supply used for or available for use for groundwater recharge or in-lieu use.
>
> (d) Total water use.
>
> (e) Change in groundwater storage."

In order to comply with the requirements of SGMA for standardized reporting, and to coordinate on a Subbasin-wide basis for consistent data evaluation, it is crucial that a DMS be developed for the entire Subbasin that will allow the various GSAs to gather and share information regarding local groundwater conditions on a shared and consistent data platform.

Project Goals and Objectives

The overarching goal of the proposed Subbasin Data Management System Development project is to initiate the key steps to develop and build the Subbasin DMS, which will ultimately support Subbasin GSAs by providing (1) improved coordination of groundwater monitoring and management actions and (2) the ability to meet the reporting and implementation requirements of their respective groundwater sustainability plans (GSPs) and the California Department of Water Resources (DWR).

It is noted that the total cost to complete the entire DMS development for the Kern Subbasin will likely exceed the available grant funding of $500,000 under the Sustainable Groundwater Management (SGM) Grant Program, Round 3 (this grant application). This application is submitted to initiate the key steps to develop and build the Subbasin DMS. This Work Plan and the associated Budget and Schedule describe tasks to be funded under this grant and within the available funding, as well as additional tasks that will likely require additional funding, above and beyond this SGM Planning Grant, to be shared among Subbasin GSAs who have already developed successful cost sharing structures for numerous components of the GSP including coordinated development of the Subbasin-wide integrated surface water-groundwater model (C2VSimFG-Kern). The Subbasin GSAs are committed to providing sufficient funds and resources to complete the project.

The work plan steps requested under this grant will provide the necessary DMS framework, addressing needs and processes such as accessibility, transparency, functionality, reliability, and data sharing, among others. The DMS project description, budget, and schedule information provided in Attachments 3, 4, and 5 describe the tasks that will be conducted under the funding support of this grant.

The project objectives are as follows:

- Identify data types to be included in the DMS and required to monitor GSP implementation and Subbasin progress toward sustainability. (funded under this grant)
- Investigate and compare commercially available DMS packages and custom systems to determine the most appropriate and cost-effective format for the Kern County Subbasin DMS. (funded under this grant)

- Select a preferred DMS approach. (funded under this grant)
- Procure or design the DMS and customize as needed with an appropriate configuration that combines technical rigor, flexibility, ease of use, and expansion capabilities to store data in text, spreadsheet, graphical, and map-based formats. (partially funded under this grant; The any additional funding to be provided by Subbasin GSAs)
- Develop data templates that allow each GSA or participating agency to submit the required data in a consistent format that can be combined and adjusted to present information in both local and Subbasin-wide formats to meet DWR reporting requirements. (funded under this grant)
- Develop a DMS User's Manual and train GSA staff to gather, submit, and update the required data on a regular basis and in a consistent format. (funded under this grant
- Coordinate with local stakeholders, non-member agencies, and disadvantaged communities (DACs), such as the Cities of Shafter and Arvin and portions of the City of Bakersfield, that have potential activities, tasks, and/or components that are complementary to the DMS development project. (funded under this grant)

Tools to Be Developed

The proposed Subbasin Data Management System Development project will initiate the key steps to develop and build a critically important DMS for the Kern County Subbasin. Specific tools to be developed during implementation of this grant-funded scoping and development effort include the following:

- A process for identifying necessary data types;
- A comparison/decision-making tool for evaluating commercially available DMS packages and custom systems against the needs and resources of the Subbasin;
- The DMS itself, customized to meet the data needs of the Subbasin GSAs; and
- A DMS User's Manual to train GSA staff in the use of the DMS.

Differentiation from Round 2 Funding

KRGSA is the administering agency for Round 2 funding of six projects under the Kern County Subbasin Groundwater Sustainability Plan Support – 2017 Grant Application (DWR Agreement No. 4600012955):

- Component 1: Grant Administration (KRGSA responsibility)
- Component 2: Groundwater Modeling (KRGSA responsibility)
- Component 3: Groundwater Model Peer Review (KGA responsibility)
- Component 4: Hydrogeologic Conceptual Model and Groundwater Conditions (KGA responsibility)
- Component 5: Groundwater Sustainability Plan Coordination (KGA responsibility)
- Component 6: GSP Development (KRGSA responsibility)

No funding was requested from DWR in Round 2 for the purpose of developing a DMS for the Subbasin, nor is funding being applied to such efforts. The DMS development project included in this proposal is a new and unique project and in no manner duplicative of work included under the six components included in the Round 2 Proposition 1 grant.

Historically, individual GSAs and their member agencies have developed separate systems to comply with various regulations; however, the GSAs in the Kern County Subbasin recognized the need to develop a centralized DMS on a Subbasin-wide basis to specifically conform to the needs of the GSAs and reporting entities to support the Subbasin GSPs. Accordingly, the Subbasin GSAs are cooperating on this proposal for a Subbasin-wide DMS to support monitoring, evaluation, reporting, management, and, importantly, GSP implementation. Compiling the individual DMSs into a coherent system will require significant manipulation and re-structuring to create a centralized relational DMS that is populated with consistent data sets across the Subbasin.

The work being undertaken with Round 2 grant funds, which involves development of GSPs for GSAs in the Subbasin in compliance with SGMA, is proceeding in accordance with DWR-mandated deadlines and will be completed on schedule. No cost overruns have been identified for Round 2 projects, and no additional funding will be required for completion of these projects. No Round 3 funding is intended to be allocated toward these projects.

The Kern County Subbasin Data Management System Project being proposed for Round 3 funding will allow the GSAs to comply with the requirements of SGMA Article 2 (§ 352.6), which requires each GSA to develop and maintain a DMS that is capable of storing and reporting information relevant to the development or implementation of a GSP and monitoring of the basin. Also required under SGMA is the development of a coordinated DMS for the Subbasin (Article 8, § 357.4). The project will assist the GSAs in meeting the requirements of SGMA annual reporting to DWR by April 1 of each year following adoption of its GSP (§ 356.2), as well as the reporting standards provided in Article 3 (§ 352.4) and reporting provisions found in Article 4 (§ 353.4).

B. Project Benefits

Covering about 2,834 square miles, Kern County Subbasin is the largest subbasin in California with a complex water management structure, a large portfolio of local and imported water sources, and numerous large groundwater banking projects, collectively providing both local and State-wide benefits for water supply. Accordingly, the GSAs are cooperating on this proposal for a Subbasin-wide DMS to support monitoring, evaluation, reporting, management, and, importantly, GSP implementation.

The project has two primary benefits that relate to the Subbasin, DACs within the Subbasin area, and all beneficial users of Subbasin groundwater: (1) development of a Subbasin-wide database that will allow consistent collection and comparison of data from multiple GSAs; and (2) improved watershed coordination among the GSAs.

- Database Development: The project will allow the Subbasin GSAs to identify and develop a DMS suitable for collection, storage, and analysis of the various types of data to be generated to support their GSPs. The project will allow the Subbasin GSAs to comply with the requirements of SGMA Article 2 (§352.6), which requires each GSA to develop and maintain a DMS that is capable of storing and reporting information relevant to the development or implementation of a GSP and monitoring of the basin. The proposed project will develop a common data system that all GSAs in the Subbasin can use, and this will enable better coordination across the various GSAs. The goal of the DMS is to support Subbasin GSAs by providing (1) improved coordination of groundwater monitoring and management actions and (2) the ability to meet the reporting and implementation requirements of groundwater sustainability plans (GSPs) and the California Department of Water Resources (DWR).
- Watershed Coordination: Located in the largest county and the southern end of the DWR Tulare Lake Hydrologic Region, the Kern County Subbasin involves numerous large and small watersheds of the Sierra Nevada, San Emigdio and Tehachapi mountains, and the

Coast Ranges. As demonstrated through the Integrated Regional Water Management Planning (IRWMP) Group process, Subbasin agencies associated with these contributing watersheds have coordinated on multiple projects over the years and have continued working together collaboratively during the GSP process. To comply with SGMA requirements SGMA for standardized reporting, and to coordinate on a Subbasin-wide basis for consistent data evaluation, it is crucial that a DMS be developed collaboratively for the entire Subbasin, allowing GSAs to combine and share data and information regarding local groundwater conditions using a consistent and comprehensive data platform.

The Kern County Subbasin Groundwater Sustainability Plan Support – Phase II 2019 Grant Application includes outreach, engagement, and support to benefit DACs throughout the entire Subbasin. During numerous community outreach meetings, DAC representatives have been engaged with questions and comments on Subbasin data.

The following DAC communities within the Kern County Subbasin are identified as cities or Census Designated Places (CDPs) in DWR's DAC database. All communities qualifying as DACs within the Kern County Subbasin will benefit as a result of the DMS project.

Arvin
Buttonwillow CDP
Delano
Edmundson Acres CDP
Ford City CDP
Fuller Acres CDP
Greenfield CDP
Lamont CDP
Lost Hills CDP
Maricopa
McFarland
McKittrick CDP
Mettler CDP
Mexican Colony CDP
Oildale CDP
Richgrove CDP
Shafter
Smith Corner CDP
South Taft CDP
Taft
Taft Heights CDP
Tupman CDP
Valley Acres CDP
Wasco
Weedpatch CDP

The project would include outreach to DAC staff that are required to report under SGMA. Accessibility of data has been a highly sensitive issue to many stakeholders in the Subbasin with concerns about transparency and privacy. Consistent communication and transparency of the DMS development process will be key to obtaining support from the Subbasin's beneficial users of groundwater. To support this budget category for Stakeholder Engagement, technical meetings will be held with the DAC staff that are required to report data to DWR, to obtain buy-in to the Subbasin DMS process.

As part of the IRWMP process, various groups were formed in the Kern County Subbasin as a means of developing a collaborative approach involving the governing group of water management districts, regional Stakeholders, and all other Interested Parties (e.g., landowners, public, local communities), all of which were working on regional water management planning and implementation activities.

DACs are directly represented in the IRWM groups through a DAC Representative, an elected member of the governing Regional Water Management Group who addresses the issues and needs of these areas. Moreover, the DACs are represented by a DAC "Work Group" consisting of individual participants from the following identified groups or communities: Ducor Community Services District, Buttonwillow County Water District, Bishop Acres Mutual Water Community, Semitropic School District, Pond Union School District, City of McFarland, City of Delano, City of Wasco, Lost Hills Utility District, Blackwells Corner, and Earlimart Public Utility District. The IRWM Group gives substantial consideration to the issues and needs of these DACs during all regional planning and implementation activities. The IRWM Group has worked closely with DACs for many years to identify DAC concerns and to promote potential solutions, either as standalone projects or programs or as a component of IRWM grant submissions.

Letters of support for the Kern County Subbasin Groundwater Sustainability Plan Support – Phase II 2019 Grant Application – including a joint letter signed by the agencies required to report under SGMA in the Subbasin – have been provided by several beneficial stakeholders and can be found in Attachment 6, Appendix C. As noted previously, outreach to DACs will continue to occur throughout development of the DMS. With grant funding, the DMS project will be better situated to conduct outreach to, engage, and include DACs and DAC concerns so that DACs will benefit from easier access to groundwater sustainability information.

C. Technical Expertise

The GSAs and participating agencies in the Kern County Subbasin have been working cooperatively for several years to develop GSPs that accurately depict the groundwater management conditions of the Subbasin. Accordingly, the Subbasin GSAs are familiar with the data types and sources in the Subbasin as well as the need to combine and share information. This process will ensure the accuracy of their respective GSPs within the larger Subbasin context and contribute to the success of management actions being proposed for implementation. This need for cooperative and consistent data collection, recordation, management, and use is the impetus for the Data Management System Development project being proposed for this grant.

Agencies involved in this project all involve talented engineers available to lead and assist with this proposed project. All of the agencies are familiar with groundwater data and have experience in groundwater monitoring and management. Thereby, agencies clearly contain the technical expertise to lead in the development of a Subbasin DMS. Many of the agencies also contain web-based technical expertise to provide oversight for potential development of web-based systems and/or complex database structures. GSAs have already demonstrated their collective technical expertise to lead and provide oversight for complex technical projects, including the development of a numerical integrated surface water–groundwater model for GSP applications. Data collection efforts for that model were successfully undertaken by agencies and their technical consultants. GSAs will employ rigorous *Request for Proposal/Qualifications* process to ensure that qualified and competent technical agents are retained for the complex DMS tasks.

KRGSA on behalf of the all the GSAs in the Kern County Subbasin was awarded $1,500,000 in Proposition 1 SGMA Planning Grant funds for a suite of six GSP Development project components supporting the entire Kern County Subbasin and proposed under the 2017 Round 2 SGMA grant opportunity. These six project components supported by the Proposition 1 planning grant have, and continue to, contribute to development of the all the GSPs in the Kern County Subbasin, which are currently undergoing public review and successfully nearing completion at the time of this writing. GSPs are on schedule to comply with the SGMA requirement that all GSPs for critically overdrafted basins be submitted to DWR by January 31, 2020. This success of the technical components of multiple GSPs, funded in part by a DWR grant, again demonstrates the ability of the GSAs to lead a large, complex technical project such as the DMS development, assisted again with DWR funding.

Letters of support for the Kern County Subbasin Groundwater Sustainability Plan Support – Phase II 2019 Grant Application have been provided by several beneficial stakeholders and can be found in Attachment 6, Appendix C.

Project Details

D. Scope of Work and Deliverables

a. Scope of Work

Subbasin Data Management System Development

Implementing Agency: KRGSA

Task (a): Grant Administration (funded under this grant)

This task includes managing and administering the project including invoicing, reporting, and grant contract administration.

1. **Grant Management**
   Coordinate with DWR and conduct administrative responsibilities to execute a Grant Agreement and ensure that all contract requirements are met.
2. **Invoicing**
   Prepare and submit to DWR invoices including back up documentation. Backup will be collected and organized by budget category, along with an Excel compatible summary document detailing the contents of the backup documentation.
3. **Report Preparation**
   Prepare and submit quarterly Progress Reports prepared in accordance with Exhibit F. Prepare and submit draft Grant Completion Report prepared in accordance with Exhibit F. Prepare a Final Grant Completion Report addressing the DWR Project Manager's comments and submit to DWR in accordance with the provisions of Exhibit F.

Deliverables:

- Executed Grant Agreement
- Invoices and associated backup documentation
- Quarterly Progress Reports
- Draft and Final Grant Completion Report

Task (b): Stakeholder Engagement / Outreach (funded under this grant)

Accessibility of data has been a highly sensitive issue to many stakeholders in the Subbasin with concerns about transparency and privacy. Consistent communication and transparency of the DMS development process will be key to obtaining support from the Subbasin's beneficial users of groundwater. To support this budget category for Stakeholder Engagement, technical meetings will be held with the DAC staff that are required to report data to DWR, to obtain buy-in to the Subbasin DMS process.

1. **Technical Meetings**
   Hold technical meetings with staff of DACs that are required to report data to DWR.

Deliverables:

- Meeting agenda with DAC staff
- Workshop presentation documentation

Task (c): GSP Development: Subbasin DMS Scoping and Development

1. **Retain Consultant to Assist with DMS Development** (funded under this grant)

This task includes (a) generating a Request for Proposals (RFP) seeking a qualified professional consulting firm that will assist with development, management, and coordination of the Data Management System (DMS), (b) issuing the RFP, and (c) contracting with the selected firm.

During RFP development, the GSAs will work together in a series of meetings to identify high-level goals and basin needs for ongoing data management. Considerations will include, but not be limited to, data coordination, transparency, sharing, and GSP-required components such as those needed to assist with the Subbasin water budget. Data tracking as required under SGMA will also be considered, including the need to track specific DWR-defined categories for water sources and sectors. In addition, DWR has not yet developed the online forms that may need to be completed for GSP annual reporting and may require specific data formatting in the DMS. Accordingly, the DMS will need to be sufficiently flexible to meet a variety of GSA needs.

The GSA group will discuss and identify a range of alternatives for various DMS levels of sophistication ranging from a relatively simply Subbasin-wide relational database to various web-based platforms with broader functionality and visualization tools. In addition, GSAs will reach out to GSAs in other subbasins to gain insight from "lessons learned" as others use existing DMS structures for SGMA purposes. In this manner, the GSAs will ensure that the RFP is written to target firms capable of providing the required technical services. The GSAs may prefer a phased approach, requiring different consulting services for each phase.

Deliverables:

- RFP
- Executed contract

2. **Identify Information Requirements for DMS** (funded under this grant)

This task involves coordination with all the GSAs in the Subbasin and their groundwater consulting firms, to identify the types and sources of data required to monitor GSP implementation, to evaluate groundwater conditions, and to document Subbasin progress toward sustainability. The DMS consultant will work collaboratively with GSAs, a technical DMS subcommittee, and/or a designated Subbasin consultant to develop a list of necessary data types, sources, and preferred formats (e.g., text, spreadsheet, graphical, and map-based formats) for each, which will be presented to all the GSAs in the Subbasin for input and approval.

Considerations will be given to data structures and formats being used for other monitoring programs in the Subbasin to provide efficiencies for agencies with multiple reporting obligations. The structure of State and local databases may also need to be considered if data will be downloaded periodically from existing sources. Some of this work will be accomplished in parallel with Task (c)(1) above to inform the needs of the RFP. Remaining work will be conducted in consultation with the DMS consultant to bring the required details of the DMS into focus.

Deliverables:

- List of data types and sources to be collected to meet ongoing requirements under SGMA

3. **Investigate and Select an Appropriate DMS** (funded under this grant;

The DMS Consultant (contractor) will investigate and compare commercially available DMS packages and custom systems to determine the most cost-effective and usable format for the DMS. The comparison will focus on DMS features determined to be of highest priority by the GSAs and will include items such as levels of security, data entry and uploading, QA/QC, spatial or graphical visualization, potential linkage to other systems, an appropriate user interface, and, importantly, ease of use. Costs of software, support/upgrades, copyright protections, or other

proprietary restrictions will be documented. The contractor will also consider the technical expertise of those users responsible for entering, uploading, and managing the system for the future. A flexible system that can be readily modified with additional modules or functions in the future may be desirable. Costs will be provided for both development and maintenance of the DMS.

The contractor will prepare a report identifying the commercially available packages and custom systems, detailing the advantages and disadvantages of each and offering a series of recommendations for GSA Boards' consideration.

Deliverables:

- Report with recommendation for GSA Boards' consideration
- GSA Boards' decision to select a DMS package

4. **Procure/Design and Customize the Selected DMS** (funded under this grant; additional funding to be provided by GSAs if needed)

   Following the GSA Boards' decision, the contractor will procure or design the selected DMS and customize as needed with an appropriate configuration that combines technical rigor, flexibility, ease of use, and expansion capabilities to store data in text, spreadsheet, graphical, and map-based formats, as needed. The system will be implemented according to the requirements identified in Task (c)(2).

   Deliverables:

   - Documentation of the Kern County Subbasin DMS

5. **Develop Data Protocols and Templates** (funded under this grant)

   The contractor will develop data templates that allow each GSA or participating agency to submit the required data in a consistent format that can be combined and adjusted to present information in both local and Subbasin-wide formats to meet DWR reporting requirements. Templates and tables will also be developed for DMS output and reporting. Importantly, protocols and a quality assurance/quality control (QA/QC) process will be developed and documented that considers data entry, uploading, downloading, and DMS accessibility. Protocols will also consider data protection and DMS security.

   Deliverables:

   - Data templates and tables

6. **Develop DMS User's Manual and Train GSA Staff** (funded under this grant)

   GSA staff will be trained in data collection, appropriate use of templates, and uploading procedures to ensure that all GSAs are providing consistent information to the DMS. In addition to the system documentation of the DMS system produced in Task (c)(4), the contractor will develop a functional user's manual that describes templates, outlines DMS protocols, and provides step-by-step procedures for a variety of users and uses.

   Deliverables:

   - Training session or module for GSA staff
   - User's Manual

7. **Review and Assessment of DMS** (funded by GSAs as needed)
   Monitoring and assessment activities will include initial review of the DMS by primary users (GSA staff and their groundwater consultants) to determine the suitability of templates for uploading

data and the suitability of the database for combining and using data. Numerous test runs of the new DMS will be conducted to work out system bugs and/or address functional issues. It is anticipated that one reporting period can be managed with the new DMS to provide a test case for future use. After grant completion, the DMS will be assessed on an ongoing basis for potential upgrades, additions or modifications to data, and other DMS adjustments to be funded by the GSAs.

Deliverables:

- Initial review and recommendations for modifications

Task (d): Monitoring / Assessment

This project is a planning effort and does not involve on-the-ground monitoring activities.

Deliverables:

- Initial review and recommendations for modifications

b. Project Deliverables

Deliverables to be provided as a result of implementing the proposed project will include the following items, presented by task:

Task (a): Grant Administration (funded under this grant)

Deliverables:

- Executed Grant Agreement
- Invoices and associated backup documentation
- Quarterly Progress Reports
- Draft and Final Grant Completion Report

Task (b): Stakeholder Engagement / Outreach (funded under this grant)

Deliverables:

- Technical meeting agenda with DAC staff that will be required to report data

Task (c): GSP Development: Subbasin DMS Scoping and Development

1. **Retain Consultant to Assist with DMS Development** (funded under this grant)

   Deliverables:

   - RFP
   - Executed contract

2. **Identify Information Requirements for DMS** (funded under this grant)

   Deliverables:

   - List of data types and sources to be collected to meet ongoing requirements under SGMA

3. **Investigate and Select an Appropriate DMS** (funded under this grant)

   Possible Deliverables to be provided under this grant:

   - Report with recommendation for GSA Boards' consideration

- GSA Boards' decision to select a DMS package

4. **Procure/Design and Customize the Selected DMS** (funded under this grant; additional funding to be provided by GSAs if needed)

   Deliverables:

   - Documentation of the DMS

5. **Develop Data Protocols and Templates** (funded under this grant)

   Deliverables:

   - Data templates and tables

6. **Develop DMS User's Manual and Train GSA Staff** (funded under this grant; additional funding to be provided by GSAs if needed)

   Deliverables:

   - Training session or module for GSA staff
   - User's Manual

7. **Review and Assessment of DMS** (funded by GSAs as part of GSP process)

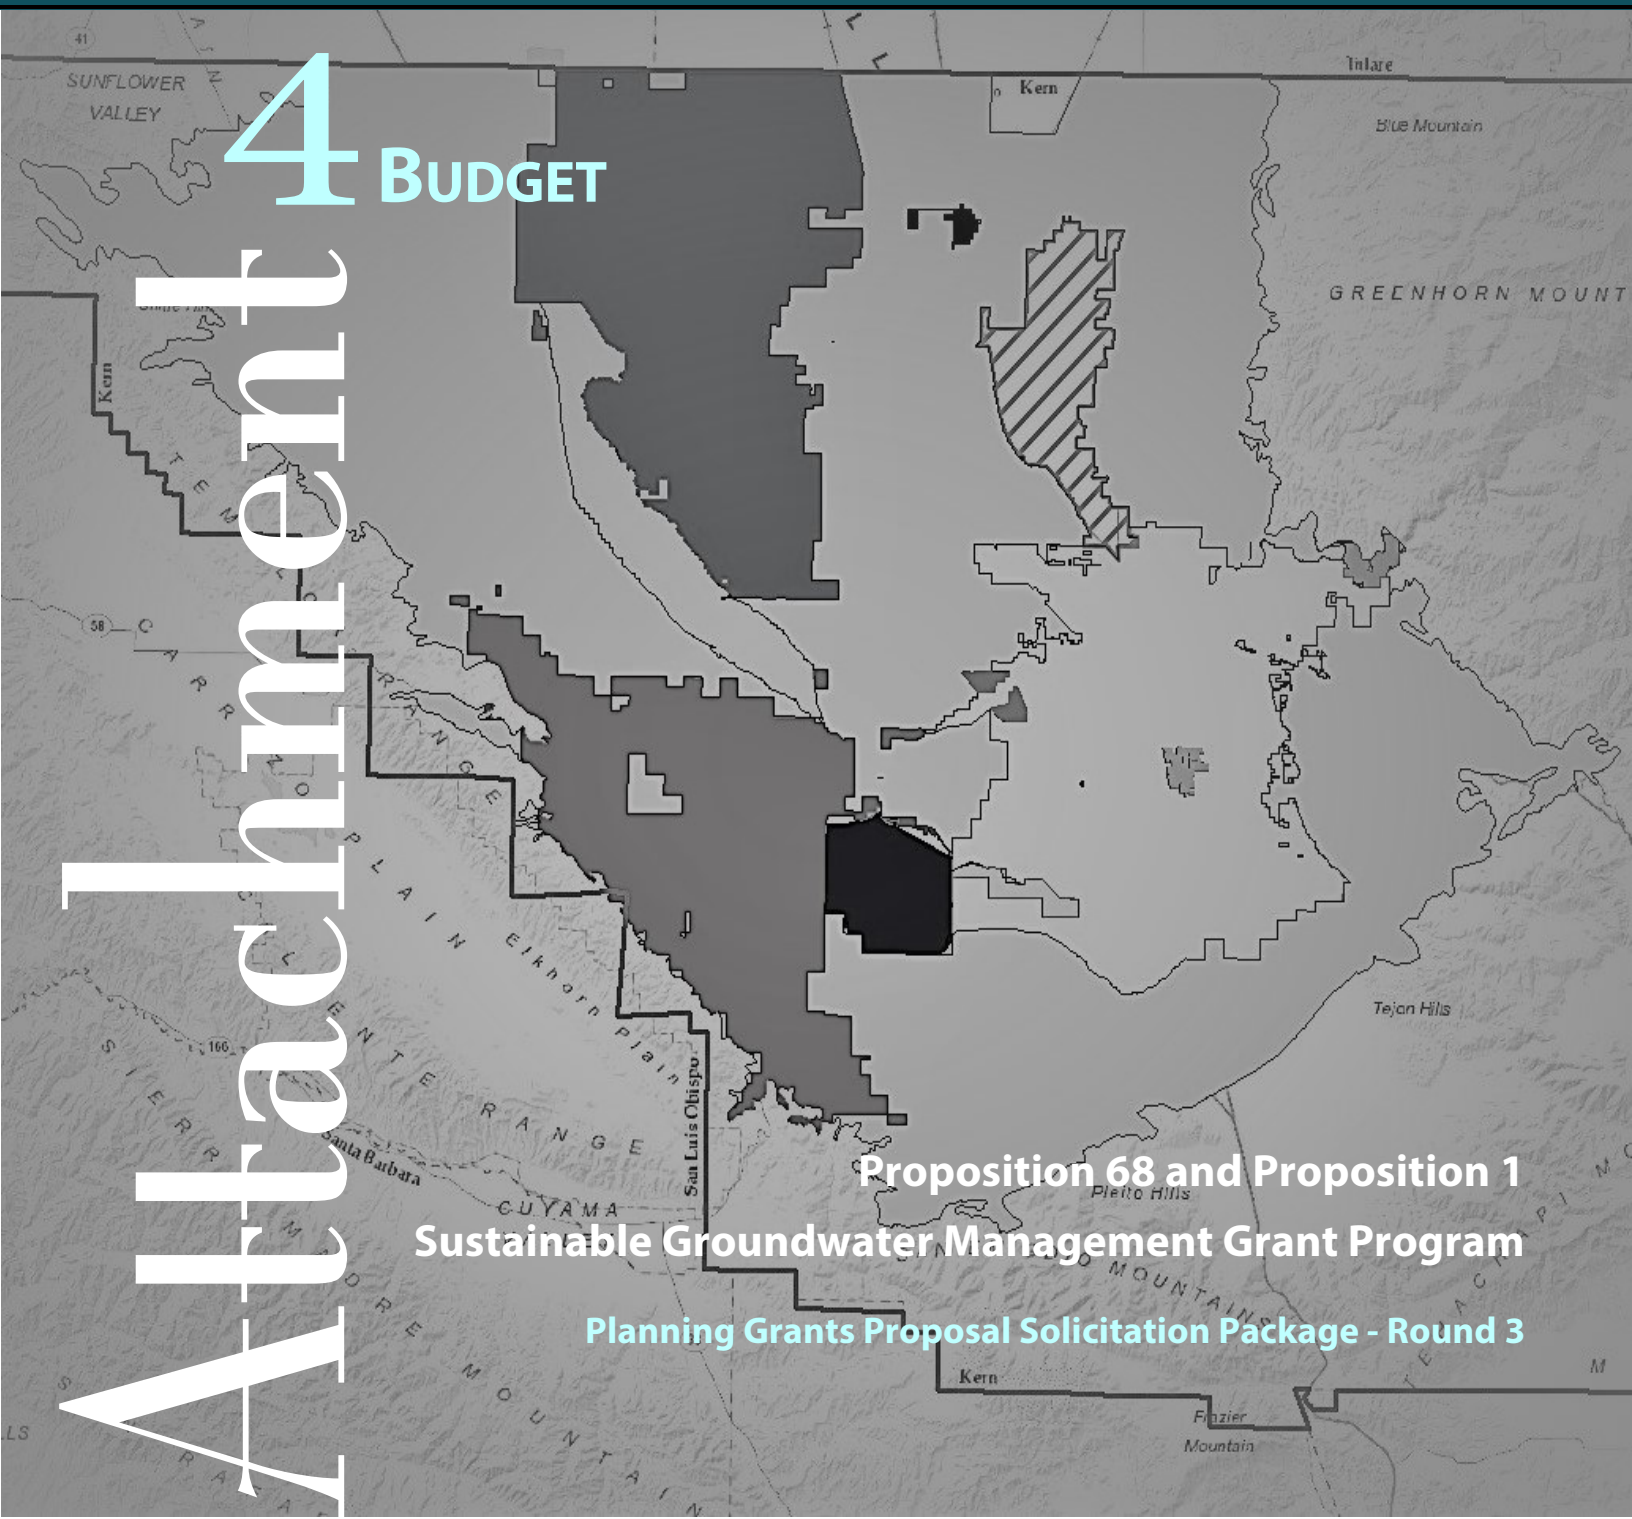
   Deliverables:

   - Initial review and recommendations for modifications

Task (d): Monitoring / Assessment (funded by GSAs as part of GSP process)

This project is a planning effort and does not involve on-the-ground monitoring activities.

Environmental Compliance and Permitting



This Proposal covers the selection and development of a DMS for use by the entire Kern Subbasin to comply with SGMA. The Subbasin Data Management System Development Project does not qualify as a "Project" as defined under CEQA. Under CEQA, a "Project" refers to an action that has the potential to result in a physical change to the environment (Pub. Res. Code § 21065). This proposal consists of research, planning, and data collection and will not result in any foreseeable impact on or alteration of the physical landscape in any shape, matter, or form. Therefore, CEQA does not apply to this Proposal.

Miscellaneous

E. Project Support

A joint letter of support for the project, signed by the members of the entire Kern County Subbasin as well as participating DAC entities, is included in Attachment 6, Appendix C.

Budget Description

The Kern County Subbasin Groundwater Sustainability Plan Support – Phase II proposal includes one project, which will benefit the entire Kern County Subbasin. Since only one component (or project) is proposed, Grant Administration has been included with the budget for the project, and the required budget templates 5A and 6A, intended for proposals that do not include multiple components, have been completed and presented above.

This section summarizes costs included in each budget category and describes how the values included in Table 6A, Proposal Detailed Budget, for the Kern County Subbasin Groundwater Sustainability Plan Support – Phase II were developed.

Budget Category (a): Grant Administration

The Direct Project Administration provided by KRGSA on behalf of all the GSAs in the Kern County Subbasin will support this project and will also oversee the implementation of overall grant funding such as executing a grant agreement with DWR, conducting reporting and invoicing, and ensuring that grant requirements are met. These tasks ensure that the project will be completed, DWR receives Quarterly and Final Project Completion Reports, invoicing and record-keeping are current, and other grant administrative functions are completed.

The Grant Administration budget was developed in order to keep these administration costs to within 5% of the award amount and maximize the grant funding utilized for the Subbasin Data Management System Development project, which is the critical GSP planning need in the Subbasin at this time. The total Budget Category (a) costs are therefore estimated at $25,000 – 5% of the total grant amount of $500,000.

The total of $25,000 for this Budget Category (a) includes $4,000 for Grant Administration, $9,000 for Invoicing, and $12,000 for Report Preparation. The Administration budget is well within DWR's guidance to keep costs to within 10% of the Grant Request. The Grant Administration budget is considered reasonable as it does not exceed 5% of the overall project budget and is consistent with DWR's guidance. This cost estimate is considered standard and was developed based on KRGSA, KGA, and the other GSA experience managing IRWM and SGMA grants in recent years.

The Grant Administration work will include effort from KRGSA's legal and accounting functions, as well as project managers as well as the GSAs in the Kern subbasin who will coordinate with KRGSA, assuring the timely completion of reporting tasks detailed in the Work Plan. A consultant may be added to assist the project team. Grant Administration effort may exceed amounts included in this budget; additional effort and costs required to complete the Grant Administration task will constitute Other Cost Share.

It is anticipated that a full DA waiver for Local Cost Share will be received for this Proposal. In anticipation of the full waiver, no Local Cost Share has been included with the Proposal Budget. Please see Attachment 6 – SDAC, DAC, EDA for documentation and narrative describing Disadvantaged Areas within the Kern County Subbasin project area.

Budget Category (b): Stakeholder Engagement / Outreach

The total cost of Stakeholder Engagement / Outreach, Budget Category (b), is $2,500, included as Grant Request. This cost estimate was developed based on KRGSA, KGA, and other the GSA experience in conducting Stakeholder Engagement and Outreach work in recent years and through development of Groundwater Sustainability Plans for the Subbasin. These costs represent a minimal level of Stakeholder Engagement associated specifically with this proposed grant-funded project, in order that the bulk of available grant funding can be allocated to implementation of the Subbasin Data Management System Development project, which is the critical GSP planning need in the Subbasin at this time.

If the actual level of effort needs to exceed amounts included in this budget to achieve project objectives, the additional costs required to complete the task will be paid by the GSAs.

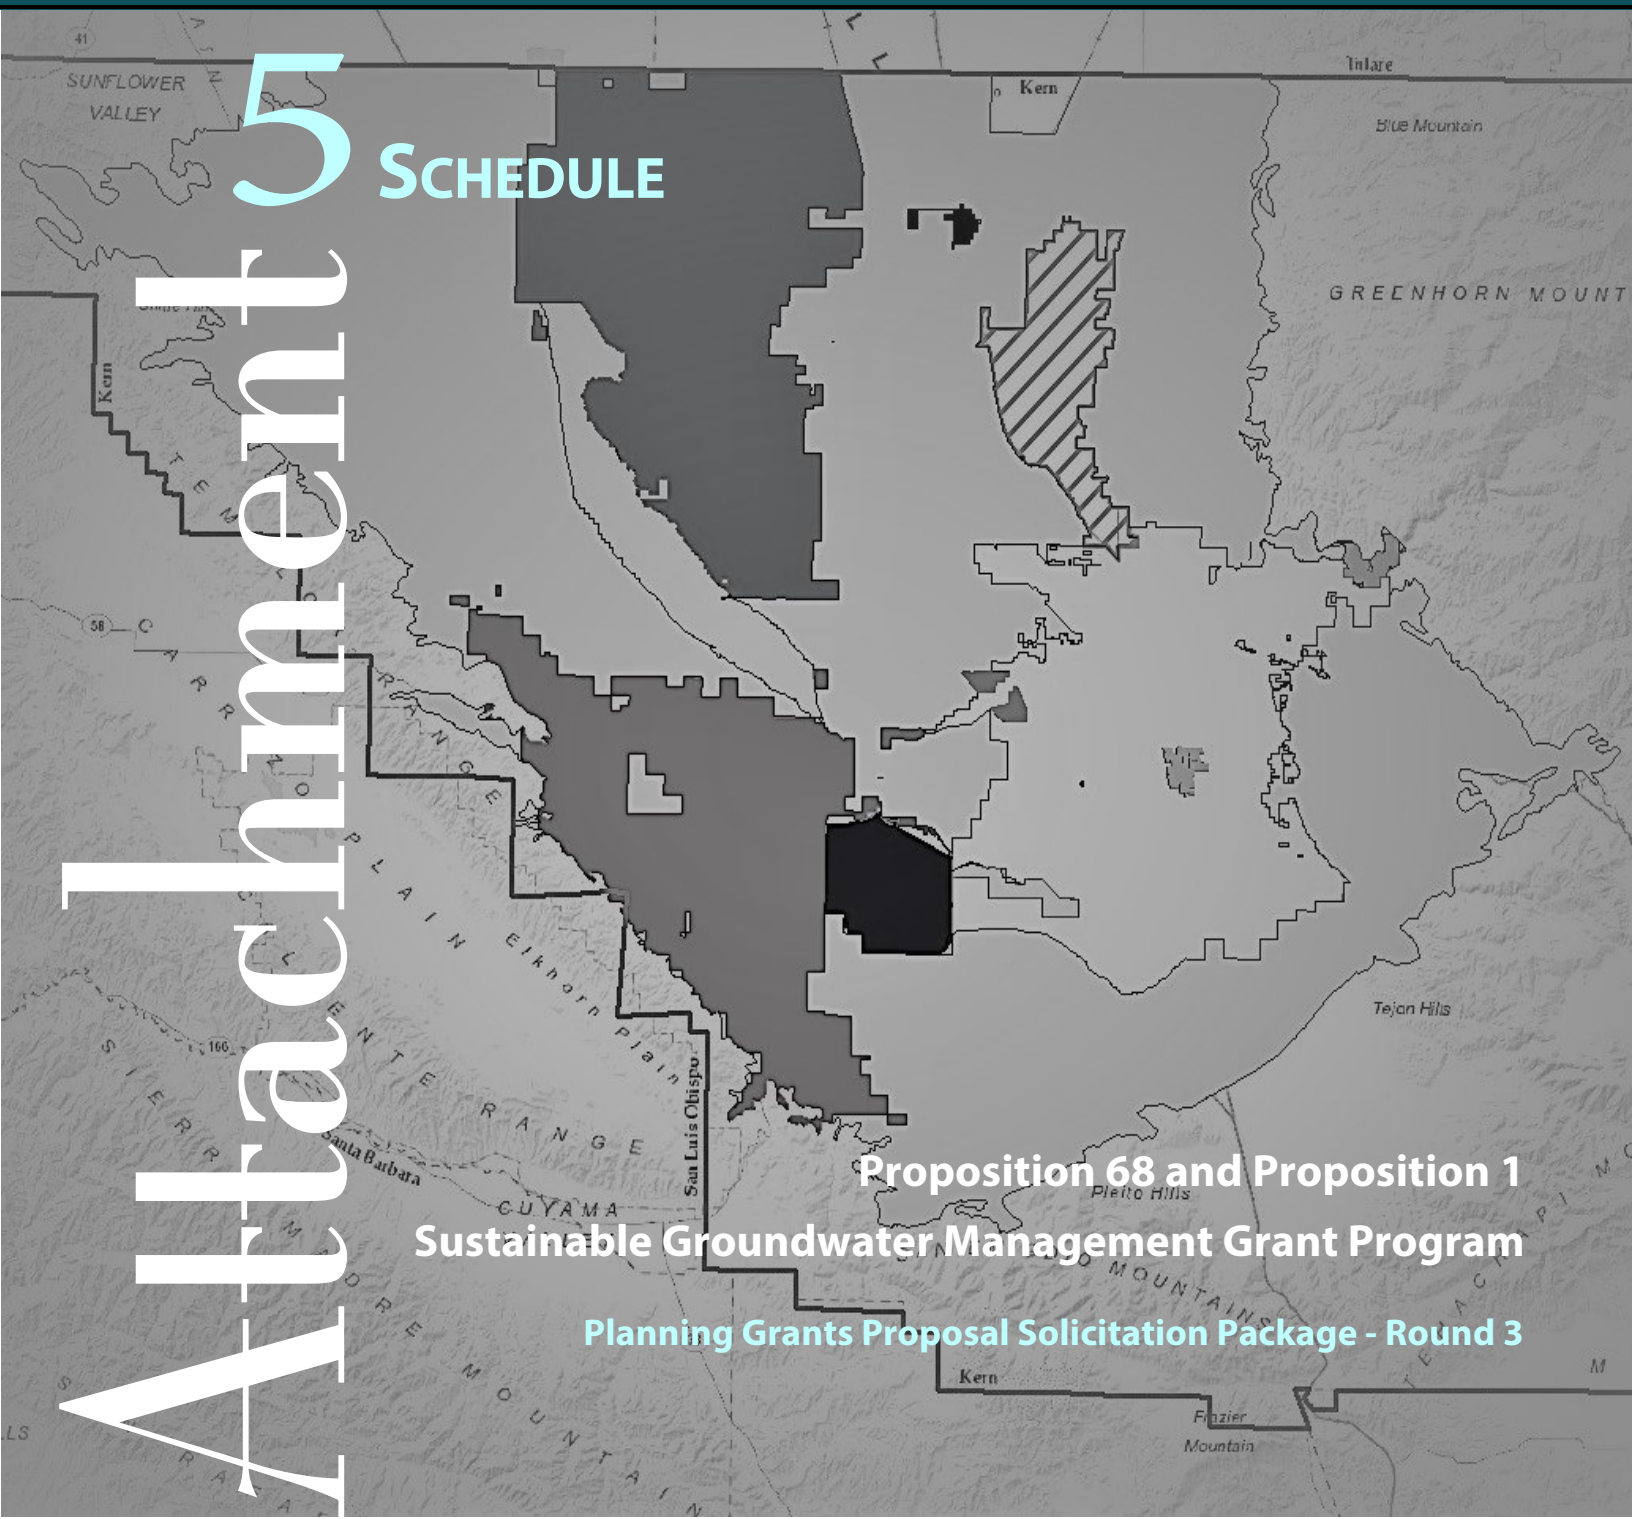
It is anticipated that a full DA waiver for Local Cost Share will be received for this Proposal. In anticipation of the full waiver, no Local Cost Share has been included with the Proposal Budget. Please see Attachment 6 – SDAC, DAC, EDA for documentation and narrative describing Disadvantaged Areas within the Kern County Subbasin project area.

Budget Category (c): GSP Development: Subbasin DMS Scoping and Development

The total cost of GSP Development: Subbasin DMS Scoping and Development, Budget Category (c), is $472,500, included as Grant Request. This total Budget Category (c) cost of $472,500 constitutes the bulk of requested grant funding, in order to launch the scoping and development of the Subbasin's critical GSP planning effort, to develop a DMS for the Subbasin. This $472,500 Category (c) grant request is spread the anticipated seven tasks that will result in a fully functioning DMS. $2,500 is budgeted for Task 1, which includes developing a Request for Proposals and ultimately contracting with a Data Management System professional consultant to lead the DMS development process. Task 2 is budgeted at $2,500 and includes identification of the information requirements for the DMS. Allocated for Task 3, to investigate and ultimately select an appropriate DMS for the Subbasin is $5,000. Task 4 constitutes the bulk of the grant request in the amount of $457,500. Task 4, Procure, Design, and Customize the Selected DMS, is the focus of the Kern County Subbasin to accomplish the coordination of monitoring, management, and annual reporting going forward. Tasks 5 and 6 are supportive tasks to complete the development of a basin-wide coordinated DMS. Each of these tasks is allocated $2,500. Task 7, Review and Assessment of DMS, would be funded by the GSAs as part of their ongoing GSP process.

Budget Category (d): Monitoring / Assessment

This project is a planning effort and does not involve on-the-ground monitoring activities.



As described in Attachment 3, Work Plan, the intent is to make as much progress as possible toward development of a fully functioning DMS. The GSAs have committed to continue ongoing collaborative efforts towards accomplishing Subbasin-wide tasks to support GSP planning and implementation. The GSAs will support each task in the workplan as needed with the necessary level of effort to meet the project goals.

This cost estimate was developed based on KRGSA, KGA, and other GSA experience in contracting with professional consultants in recent years and through development of Groundwater Sustainability Plans for the Subbasin, as well as with input from consultants and industry professionals knowledgeable about DMS development and the data collection needs of the Subbasin's GSAs.

As described in Attachment 3, Work Plan, it is anticipated that the cost to fully develop an operational DMS for the Subbasin will far exceed grant funding available under this Round 3 Planning Grant opportunity. Additional resources beyond the funding available through this grant will be provided by Subbasin GSAs as necessary to complete the project and achieve a workable DMS that meets Subbasin needs. The Subbasin GSAs will coordinate to fund any additional project costs and have a demonstrated track record of doing so on many other GSP-related projects.

It is anticipated that a full DA waiver for Local Cost Share will be received for this Proposal. In anticipation of the full waiver, no Local Cost Share has been included with the Proposal Budget. Please see Attachment 6 – SDAC, DAC, EDA for documentation and narrative describing Disadvantaged Areas within the Kern County Subbasin project area.

(d) Monitoring / Assessment	N/A	N/A

Schedule Description

The Kern County Subbasin Groundwater Sustainability Plan Support – Phase II proposal includes one project, which provides benefits for the entire Kern County Subbasin. Since there are no additional components included with this proposal, Grant Administration has been included with the Work Plan, Budget, and Schedule for the single project, and the required Schedule Table 7A, intended for proposals that do not include multiple components, has been completed and presented above.

This section summarizes the schedule established (and presented in Table 7A) for the Kern County Subbasin Groundwater Sustainability Plan Support – Phase II proposal.

The tasks listed in the schedules align with the same tasks identified and described in the Work Plan (Attachment 3) and Budget (Attachment 4), and use March 2020 as the assumed award date of the grant and launch of Grant Administration. Project implementation will likely begin prior to notification of award, potentially by February 2020.

All project implementation work will be complete by the end of April 2022. The schedule for Grant Administration extends through July 2022 when all final reports and invoicing will be complete for the grant.

The anticipated order of activities for completion of the project is as follows:

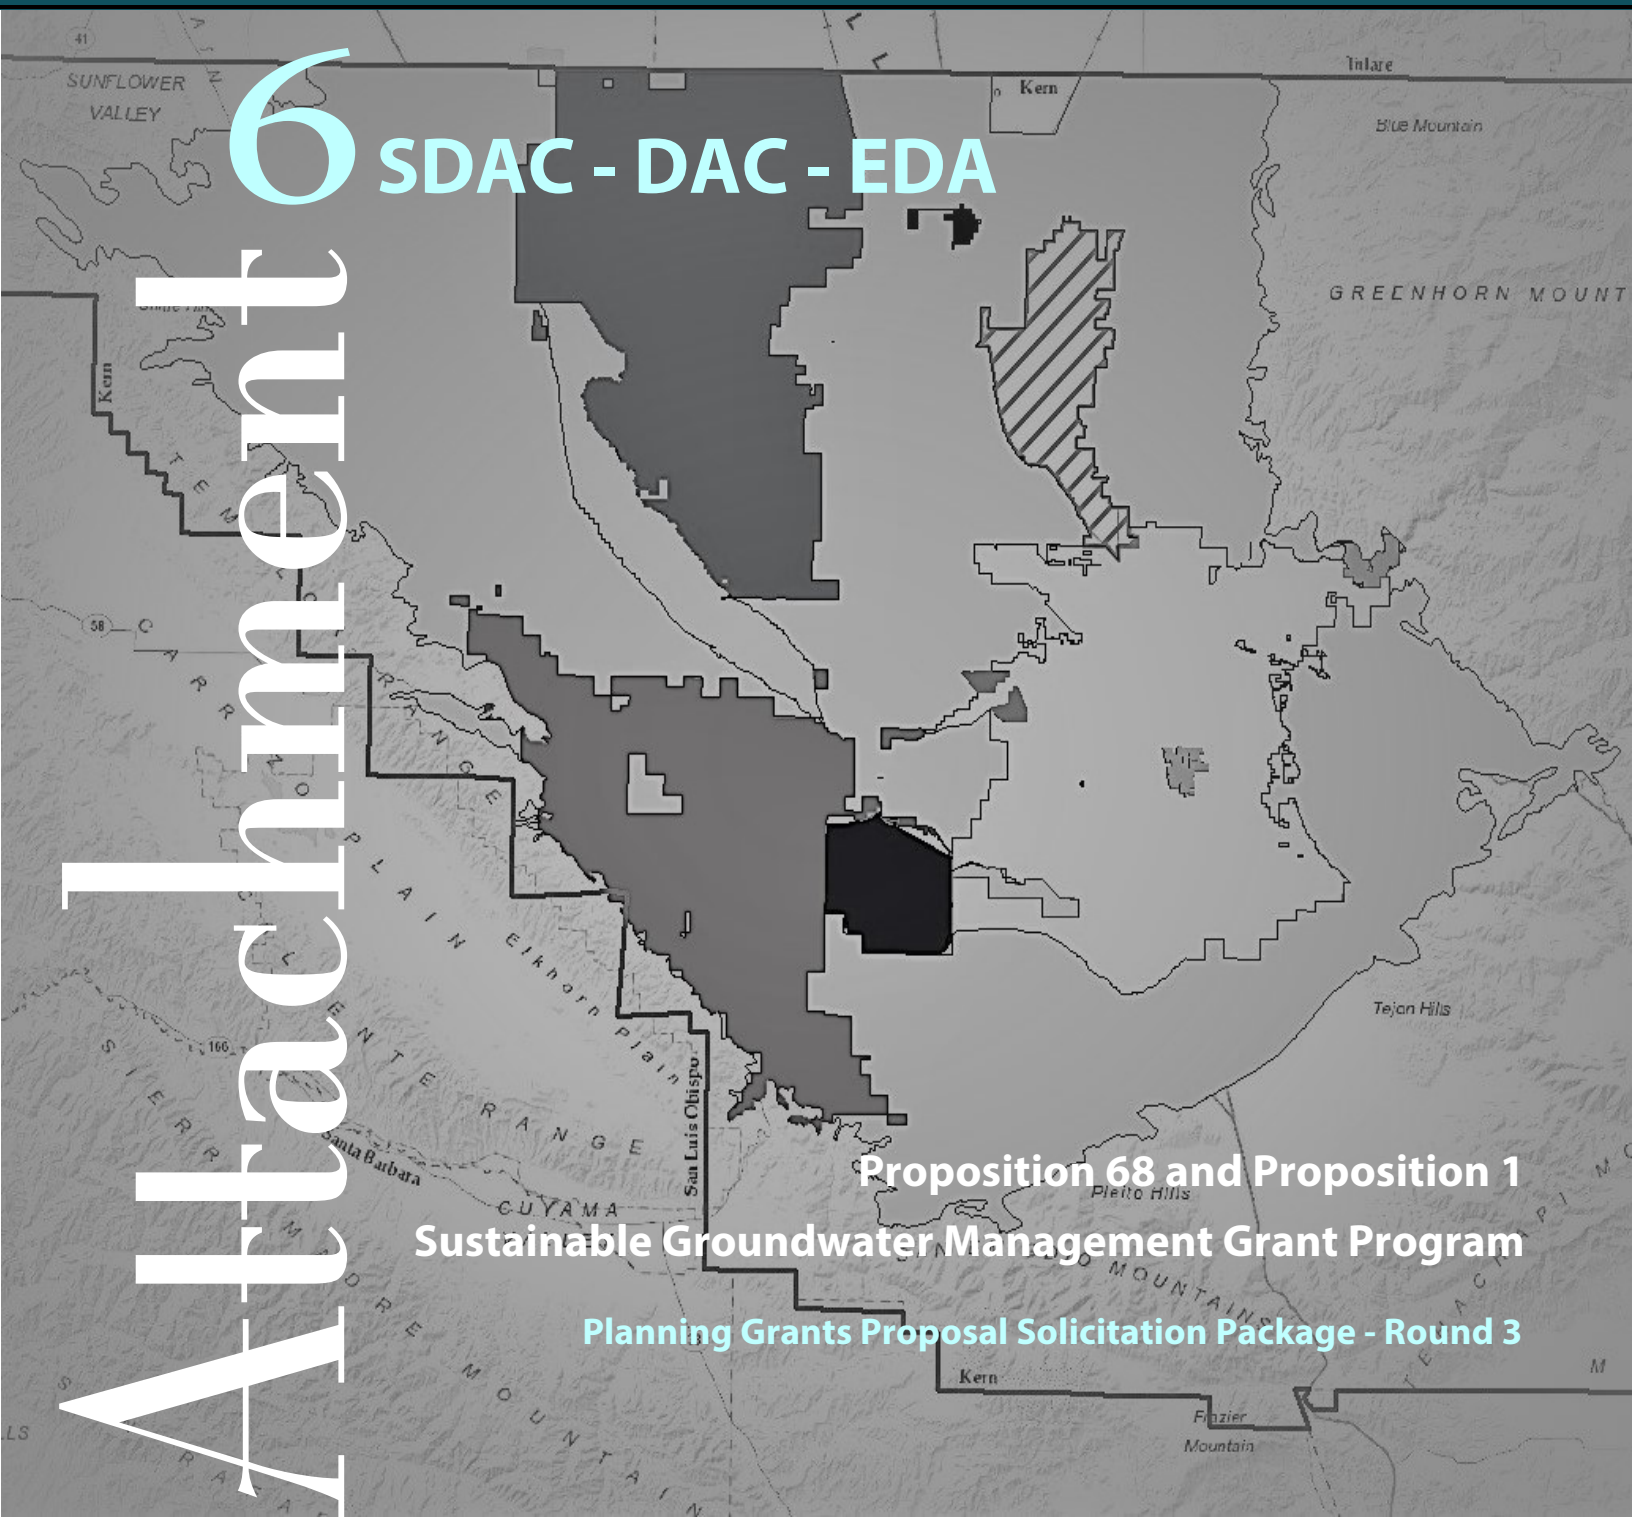
- Category (c), GSP Development: Subbasin DMS Scoping and Development, will begin immediately upon grant award with the process of hiring a DMS consultant (Task 1). The selected consultant will assist the GSAs with identifying information requirements for the DMS (Task 2). Task 2 begins concurrently with Task 1 to allow the identification of requirements to inform the RFP process in Task 1; the task continues to allow communication and consultation with the DMS Consultant on system requirements. After working collaboratively with the GSAs in Task 2, the DMS consultant will then investigate and recommend appropriate DMS options for selection by the GSAs' Boards (Task 3). KRGSA and KGA, on behalf of all the Subbasin GSAs, will procure the selected DMS and the consultant will customize it as needed (Task 4). This process is expected to continue through April 2022 with ongoing adjustments and customization. Task 4 is expected to be partially funded by the GSAs when grant funds are expended for this task. Concurrently with this process, the consultant and GSAs will develop protocols and data templates (Task 5), and will train GSA staff to use and populate the DMS following completion of these tasks (Task 6). Task 7 commences in 2021 when the DMS development is underway and continues throughout the grant period, allowing additional modifications to the DMS as the project is implemented.
- Category (b), Stakeholder Engagement/Outreach, will involve coordination of technical meetings with stakeholders and DACs throughout the process of DMS scoping and development.
- Category (a), Grant Administration, will involve management of the grant, invoicing, and report preparation before, during, and after completion of the grant activities.
- Category (d), Monitoring / Assessment, does not apply to this project as it is a planning effort and does not involve on-the-ground monitoring activities.

Environmental Compliance and Permitting

The Kern County Subbasin Groundwater Sustainability Plan Support – Phase II proposal includes one project, which will benefit the entire Kern County Subbasin. This project, Subbasin Data Management System Development, is effectively a planning effort; no construction will take place under this project.

This grant proposal covers the preparation of Groundwater Sustainability Plans (GSPs) within the Kern County Subbasin. Under Water Code § 10728.6, CEQA does not apply to the preparation and adoption of Groundwater Sustainability Plans. Therefore, this Proposal is exempt from California Environmental Quality Act (CEQA) requirements.

The proposed Subbasin Data Management System Development project will initiate the key steps to develop and build a Subbasin DMS, which will ultimately support Subbasin GSAs by providing (1) improved coordination of groundwater monitoring and management actions and (2) the ability to meet the reporting and implementation



requirements of their respective GSPs and DWR. The development of a DMS does not meet the definition of a "Project" under CEQA, as it will not create any foreseeable impact on or alter the physical landscape in any shape, manner, or form. Under CEQA, a "Project" refers to an action that has the potential to result in a physical change to the environment (Pub. Res. Code § 21065). Therefore, CEQA does not apply to this project.

Development of a Subbasin Data Management System will not require any permits or regulatory agency approvals. Therefore, a process and schedule for securing permits and approvals is not necessary, and has not been included in this Proposal.

Appendix C. Joint Letter of Support 5

Introduction

According to Water Code § 79505.5, a disadvantaged community (DAC) is "a community with an annual median household income that is less than 80 percent of the Statewide annual median household income." These communities, widely dispersed throughout California and the Kern County Subbasin, are especially sensitive to groundwater overdraft and decreases in local water quality such as that in the Kern County Subbasin.

Attachment 6 – SDAC-DAC-EDA addresses the existence of DAC areas located within the Kern County Subbasin, and includes a map showing the Proposal benefit area and the location of DACs.

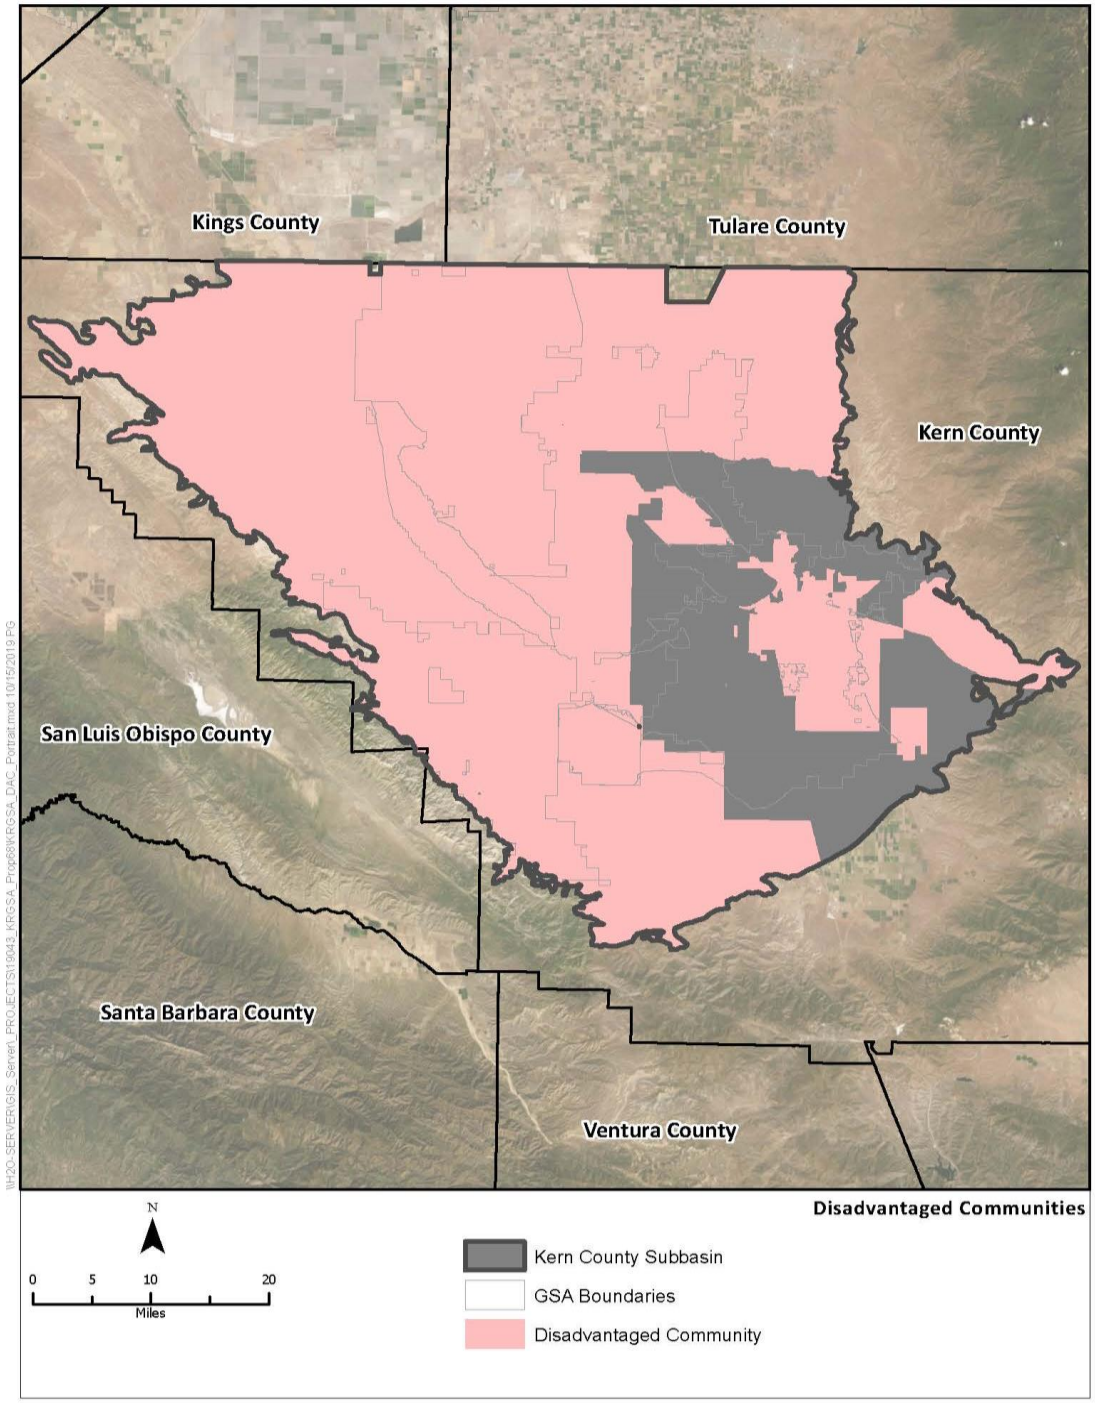
Location of DACs within the Proposal Area

The Kern County Subbasin (Proposal benefit area) is located in the Southern San Joaquin Valley, is a critically overdrafted, high priority groundwater basin and is home to numerous DAC Communities. The GSAs in the Kern County Subbasin identified DACs throughout the Subbasin by using the DWR's DAC Mapping Tool and ArcGIS Map Package. Geographically, the Kern County Subbasin is comprised of 79.5 percent Disadvantaged Communities.

The GSAs in the Subbasin have accurately discerned and mapped where DAC communities exist within the Subbasin. Figure 6-1, below, illustrates the Proposal benefit area and the location of DACs within the Kern County Subbasin.

The DAC Mapping tool and ArcGIS Map Package provide US Census data identifying DACs by "Block Groups", "Tracts", and "Places." The specific dataset used in the tool is the *US Census American Community Survey (ACS) 5-Year Data: 2012 – 2016* (with an MHI of $63,783 and hence calculated DAC threshold of $51,026).

According to the US Census Bureau:



- Block Groups are statistical divisions of census tracts, generally defined to contain between 600 and 3,000 people.
- Census Tracts are small, relatively permanent statistical subdivisions of a county or equivalent entity. Census tracts generally have a population size between 1,200 and 8,000 people, with an optimum size of 4,000 people.
- Places can be defined as either incorporated or designated. Incorporated Places usually consist of a city, town, village, or borough, but can have other legal descriptions or boundaries. Designated Places usually coincide with visible features or the boundary of an adjacent incorporated place or another legal entity boundary, have no legal status, nor do these places have officials elected to serve traditional municipal functions.

For more information on the DAC Mapping Tool or ArcGIS Mapping Package, please visit: http://www.water.ca.gov/irwm/grants/resources_dac.cfm.

All communities qualifying as Disadvantaged Communities within the Kern County Subbasin (block groups, census tracts, and places) will benefit as a result of the Subbasin Data Management System Development project included in this Kern County Subbasin Groundwater Sustainability Plan Support – Phase II Proposal.

Figure 6-1 shows the location and extent of all Disadvantaged Communities within the Kern County Subbasin. These Disadvantaged Areas make up 79.5 percent of the Subbasin and Project area. All communities qualifying as DACs within the Kern County Subbasin will benefit as a result of the proposed project.

Figure 6-1. Disadvantaged Communities in the Kern County Subbasin

DAC Support and Outreach

The Kern County Subbasin Groundwater Sustainability Plan Support – Phase II grant application includes outreach, engagement, and technical support to benefit DACs throughout the entire Subbasin. All the GSAs in the Subbasin conduct regular Board meetings on a monthly basis to support development of their respective GSPs. All the GSAs in the Subbasin have undertaken coordination activities with the DACs in the Subbasin. Several of the DACs are represented by board members on the GSAs in the Subbasin.

The following DAC communities within the Kern County Subbasin are identified as cities or Census Designated Places (CDPs) in DWR's DAC database. All communities qualifying as DACs within the Kern County Subbasin will benefit as a result of the DMS project.

Arvin
Buttonwillow CDP
Delano
Edmundson Acres CDP
Ford City CDP
Fuller Acres CDP
Greenfield CDP
Lamont CDP
Lost Hills CDP
Maricopa
McFarland
McKittrick CDP
Mettler CDP
Mexican Colony CDP
Oildale CDP
Richgrove CDP
Shafter
Smith Corner CDP
South Taft CDP
Taft
Taft Heights CDP
Tupman CDP
Valley Acres CDP
Wasco
Weedpatch CDP

As part of the DMS project, the GSAs in the Subbasin would conduct outreach to all the DACs that will be required to report to DWR under SGMA. GSA staff would work with local DACs within their boundaries, relying on the existing relationships they have established and maintained during the GSP development process.

A joint letter of support for the Kern County Subbasin Groundwater Sustainability Plan Support – Phase II 2019 Grant Application endorsed by the GSAs and stakeholders that would benefit from the project is provided in Appendix C. As noted previously, outreach to DACs will continue to occur throughout development of the DMS. With grant funding, the DMS project will be better situated to conduct outreach to, engage, and include DACs and DAC concerns so that DACs will benefit from easier access to groundwater sustainability information.

Subject: Letter of Support for Kern River Groundwater Sustainability Agency Leading the Kern County Subbasin Proposition 1 Round 3/Proposition 68 Planning Grant Application

Dear Mr. Eusuff and Ms. List:

The undersigned groups are submitting this letter in support of the Sustainable Groundwater Management – Proposition 1 Round 3/Proposition 68 Planning Grant Application submitted by the Kern River Groundwater Sustainability Agency (KRGSA), in coordination with the all the GSAs in the Kern County Subbasin. The demographics of the Subbasin service area establish it as a geographic area of largely disadvantaged communities in need of assistance and support. As representatives and water providers of Disadvantaged Communities (DACs) in the Kern County Subbasin, we jointly support this effort to achieve sustainable groundwater planning in the Kern County Subbasin.

Since the enactment of the Sustainable Groundwater Management Act (SGMA), the Kern County Subbasin GSAs have worked together to achieve sustainable groundwater management. Through a collaborative process involving more than a dozen member agencies and landowner representatives,

GSAs in the Kern County Subbasin have coordinated on numerous GSP activities, including the following milestones:

- Produced a Subbasin-wide Sustainability Goal for achieving and maintaining sustainable groundwater management;
- Developed Sustainable Management Criteria to apply to the entire Subbasin, while allowing flexibility for local GSA control;
- Coordinated on a Subbasin-wide monitoring network and agreed on monitoring protocols for coordinated monitoring and groundwater evaluations;
- Shared costs and tasks for the development of a Subbasin-wide integrated surface water–groundwater model to analyze Subbasin water budgets and to support an evaluation of projects and management actions;
- Held two widely attended SGMA Open Houses to allow stakeholders to discuss the GSP process and requirements directly with GSA managers;
- Hosted numerous community, Board, public outreach, and stakeholder meetings, including many that were focused on the disadvantaged communities in the Subbasin; and
- Organized numerous committees to guide policy decisions, coordinate communication and outreach activities, and provide a forum for GSA managers to discuss and coordinate GSP elements.

While individual GSAs and their member agencies have developed separate Groundwater Sustainability Plans (GSPs) to comply with the SGMA regulations, the Kern GSAs recognized the need to develop a centralized, Subbasin-wide data management system (DMS) to support monitoring, evaluation, reporting, management, and, importantly, GSP implementation. We recognize that compilation of our individual systems will require significant manipulation and re-structuring to create a centralized relational DMS that is populated with consistent data sets across the Subbasin. For this reason, the GSAs of the Kern County Subbasin have agreed to coordinate to submit a Proposition 1 Round 3/Proposition 68 Planning Grant Application to take the first key steps in this process. Participating in the DWR grant funding program through continued Subbasin-wide Groundwater Sustainability Planning efforts is a good and essential step forward for DAC communities in the Kern County Subbasin.

We are pleased and supportive to see the inclusion and participation of Disadvantaged Communities and related stakeholders in the Kern County Subbasin's Groundwater Sustainability Planning efforts, and we believe that funding from this Grant Application will contribute to basin-wide groundwater planning efforts and benefit our community members. By funding the KRGSA's grant application in the full allotment of $500,000, DWR will ensure that all that disadvantaged communities in the Kern County Subbasin will benefit from improved groundwater management and sustainability. The grant funds will be instrumental to the DACs in the Kern County Subbasin by providing the mechanism for meeting their reporting requirements under SGMA and also providing the ability to review each other's data in the Subbasin.

We hope that DWR will fully fund the Kern County Subbasin Round 3 Planning Grant Application, and we look forward to seeing the benefits of this program within all of our service areas in the near future.

Sincerely,

Olcese WD GSA

Re: Reimbursement Agreement for Annual Reporting of the Kern Sub-basin

The Kern Groundwater Authority (KGA), the Kern River Groundwater Sustainability Agency (KRGSA), the Buena Vista WSD Groundwater Sustainability Agency (BVGSA), the Henry Miller WD Groundwater Sustainability Agency (HMGSA), and the Olcese WD Groundwater Sustainability Agency (OGSA) wish to participate in the Reimbursement agreement for the Kern County Subbasin – 2020 Annual Reporting Requirement under SGMA.

On behalf of the Subbasin, the KGA has approved a contract with TODD Groundwater (Attachment 1) which includes a scope of work with the following tasks:
1) Prepare Data Requests and Templates ($10,554)
2) Prepare Groundwater Elevation Contour Maps ($26,749)
3) Review and Compile Hydrographs ($9,458)
4) Compile and Present Water Supply Data ($19,373)
5) Analyze Change in Groundwater in Storage ($32,518)
6) Document Progress in GSP Implementation ($10,639)
7) Prepare Drafts/Final Annual Report and Submit to DWR ($32,322)
8) Communication and Meetings ($33,216)
for a total amount of the contract of $174,830.

Also, on behalf of the Subbasin, the KGA has approved a contract with ITRC (Attachment 2) which includes a scope of work with the following tasks:
1) Provide monthly and annual ITRC-METRIC actual crop evapotranspiration (ETc) for the Kern Subbasin for 2017-2019.
2) Data will be extracted for each GSA within the subbasin and each irrigated field in each GSA monthly for 2017-2019
3) Data will be provided tabularly and monthly ETc images will be provided in GIS format
4) Short report discussing the general process and overall results will be provided
for a total amount of the contact of $16,000

All parties agree to cost share this effort according to following terms and conditions:

1. The participant signatories below will pay their share of the proposed budget of $190,830 as shown on Exhibit 1.
2. All payments from shall be due 45 days after the receipt of invoice from the KGA

If the above terms and conditions are acceptable, please sign and date this letter and return them to the KGA.

Sincerely,

KGA
Vice Chair

TODD GROUNDWATER

November 19, 2019

MEMORANDUM

To: Kern Groundwater Authority (KGA)
Patty Poire, Kern County Subbasin GSP Plan Manager

Cc: Kern River Groundwater Sustainability Agency (KRGSA)
Art Chianello, David Beard, and Mark Mulkay, KRGSA Plan Managers

From: Phyllis Stanin, Vice President

Re: Proposal – Preparation of GSP Annual Report for WY 2019
Kern County Subbasin Groundwater Sustainability Plans (GSP)

The Kern Groundwater Authority (KGA) is leading Subbasin-wide coordination efforts for development of Groundwater Sustainability Plans (GSP) including annual reporting on GSP implementation. Subbasin GSAs are cooperating in preparation of this first GSP Annual Report covering Water Year (WY) 2019 for the Kern County Subbasin. Todd Groundwater has been asked to prepare a proposal to prepare and submit the 2019 Annual Report.

The Kern County Subbasin is required to submit adopted GSPs covering the entire Subbasin to the Department of Water Resources (DWR) by January 31, 2020. Annual Reports are due to DWR "by April 1 of each year following the adoption of the Plan." (§356.2). Accordingly, the 2019 Annual Report is due to DWR by April 1, 2020, only two months after submittal of the GSPs.

1 APPROACH

Collectively, the extensive analyses and hydrogeologic products available in Subbasin GSPs provide a firm foundation for the 2019 Annual Report. Monitoring sites have already been identified, data are being collected, and water budget results are readily available from the historical and current study periods. We envision working cooperatively with Subbasin agencies and their consultants to compile and incorporate information that either is currently available or is being collected as part of GSP implementation.

Preparation of the 2019 Annual Report will follow regulatory guidance. Regulatory requirements for the GSP Annual Reports are provided in Article 7 of the GSP regulations (§ 356). Reporting standards for Annual Report data are provided in Article 3 (§352.4) and reporting provisions can be found in Article 4 (§353.4).

This first Annual Report will require extra analysis of the Subbasin water budget to "bridge" the time period between the end of the Subbasin current Study Period (WY 2015) and the reporting period of WY 2019. Although GSP Annual Reports are designed to describe conditions from the preceding water year only (i.e., WY 2019), regulations also require water budget results (i.e., change in groundwater in storage) to use "historical data to the greatest extent available, including from January 1, 2015 to the current reporting year." (§356.2 (b)(1)(B) and §356.2 (b)(5)(B)). The bridge analysis, combined with the GSP current Study Period, will cover the requirement of "January 1, 2015 to the current reporting year." GSP analyses from the Subbasin-wide historical and current Study Periods –covering WY 1995 through WY 2015 – can be used to satisfy the requirement of "historical data to the greatest extent available."

Regulations only appear to require historical data for hydrographs and change in groundwater in storage. Additional data, including reporting of groundwater extractions, surface water, and total water use by sectors, appear to only refer to the preceding year and not the "bridge" period.

It is anticipated that we will require clarification and interaction with DWR on several issues for the 2019 Annual Report. We recommend working directly with the Subbasin Plan Manager (Patty Poire) on any communications with DWR to ensure that the 2019 Annual Report will comply with regulations. In coordination with the Plan Manager, we will confirm with DWR the specific time period for which these other data sets must cover, seek DWR acceptance of recommended methods to incorporate into the 2019 Annual Report, and work with agencies to comply with DWR requirements.

In our role as the Watermaster Engineer for the Antelope Valley Watermaster, we have been submitting SGMA-compliant annual reports to DWR for several years. Although requirements for adjudicated basins are significantly different from critically over-drafted basins, many of the requested data sets and attachments are the same. This provides us with some insight as to how GSP annual reporting might be managed by DWR; some of these insights are incorporated into this scope of services, as relevant.

2 SCOPE OF SERVICES

In order for Subbasin agencies to begin planning for the required components of the 2019 Annual Report, an example template of the report has been prepared and provided with this proposal as **Attachment 1**. The template has been annotated with a mix of GSP requirements, assumptions for report development, and example text. Annotations also include assumptions and details of our proposed scope of services to allow agencies to better visualize how Subbasin data will be compiled, analyzed, and used in the Annual Report. Accordingly, **Attachment 1** serves as a companion document to this scope of services and is incorporated into the scope by reference.

Tasks associated with the proposed scope of services are summarized below. Also, please refer to **Attachment 1** for GSP requirements and additional assumptions and details for including the information in the 2019 Annual Report.

Table 1: 2019 Annual Report, Kern County Subbasin

Task 1: Prepare Data Requests and Templates

The first step in this process involves development of a data request memorandum by Todd Groundwater, which will provide a list of data requirements from all Subbasin agencies and include data templates to facilitate data compilation and presentation. Todd Groundwater assumes introducing the data request memorandum and templates at a KGA-coordinated Subbasin Managers' Meeting, tentatively scheduled for November 8, 2019 (included in Task 8).

Task 2: Prepare Groundwater Elevation Contour Maps

We will obtain water level data from individual agencies for Spring and Fall 2019 measurements. We assume that data will be provided for the GSP water level monitoring sites but would be pleased to incorporate more data, if available. We will also work with KCWA, who leads an extensive water level monitoring program and may be able to provide additional data to improve map accuracy. Given the need for developing separate maps for each Principal Aquifer, the KCWA supplemental data from wells without construction information may not be included.

It is our understanding that GSAs have identified two primary Principal Aquifers that can be mapped in the Subbasin. Groundwater elevation contour maps will be prepared for each Principal Aquifer for Spring and Fall 2019 (4 total maps). It is also our understanding that two deeper Principal Aquifers, the Olcese Formation and the Santa Margarita Formation, have been identified in limited areas in the eastern Subbasin. If sufficient data are available for contouring groundwater elevations in these aquifers, we can also include them in the Annual Report. We assume that all groundwater elevations available for contouring will be provided by others (except for KRGSA data, which we will produce separately from this proposal).

We assume that groundwater level data will be provided in electronic (Excel) spreadsheets and include, at a minimum, well identifiers (matching hydrographs), date, X/Y or Lat/Long (with datum), depth to water, reference point elevation, water level elevations, and associated Principal Aquifer. GIS shapefiles are also appreciated, if available.

Data will be contoured initially using commercially-available software and then iteratively hand-modified for more accurate representations of groundwater elevations across the Subbasin. We will work directly with individual agencies if data issues are identified or if we require further clarification. If agencies have already developed groundwater elevation contour maps and wish to use the current contours, we can coordinate with the agency to obtain electronic maps or discuss other options. Several drafts of water level contour maps will be developed for review by individual agencies, as needed.

Task 3: Review and Compile Hydrographs

Groundwater elevation hydrographs will be compiled from Subbasin agencies for inclusion in the Annual Report. Hydrographs should be formatted to adhere with the *Data and*

Reporting Standards as prescribed in §352.4(e) of the GSP regulations and summarized in Section 2.2 of **Attachment 1**. In brief, each hydrograph should include a unique site identification number, ground surface elevation, and use the same scale to the greatest extent practical.

We will work with agencies to ensure relatively similar hydrograph formats including the same horizontal scale of October 1, 1994 through September 30, 2019 (WY 1995 – WY 2019), as needed; similar formats may facilitate DWR review. Closely-spaced hydrographs should incorporate the same vertical scales to the extent practicable in adherence with GSP regulations. Hydrographs may also include annotations to allow for easy well identification and understanding by DWR reviewers.

Overall trends and fluctuations as shown by the hydrographs for WY 2016 through WY 2019 will be described briefly in the context of water year type and the groundwater elevation contour maps. A map showing the location of submitted hydrographs will be developed and PDF files of each hydrograph will be included in an appendix of the Annual Report.

Task 4: Compile and Present Water Supply Data

Working with the individual agencies, Todd Groundwater will compile water supply data for the following categories:

- Groundwater Extractions
- Surface Water Supply
- Total Water Use.

For groundwater extractions, total extraction amounts for the preceding year are required, along with a map showing locations and volumes of production. Although data can be combined to report a total extraction from the Subbasin, some local data will be needed to develop groundwater extraction maps. First, we recommend development of a map showing general locations of active wells by type (agricultural, urban, banking recovery, etc.). This will illustrate concentrations of the various extraction types across the Subbasin. To meet the requirement of volumes, we recommend development of various "bubble" maps that illustrate relative volumes for various areas using circles of increasing diameter. We will recommend appropriate illustrations after a review of the available extraction data.

We will emphasize to DWR that management actions are being implemented for estimating groundwater extractions, but those actions were not in place in WY 2019. Therefore, the data will represent estimates, and can potentially be based on extractions associated with recent time periods as provided in the C2VSimFG-Kern model; extractions could be adjusted for current changes in local land use or known changes in extractions, as needed.

In addition to the map, groundwater extractions must be tabulated by water use sector (generally Urban, Agricultural, Managed Recharge, and Other - see Section 3 of **Attachment 1**). Methods and accuracy of measurements must also be included.

Data for total surface water supply (Section 4 in **Attachment 1**) are more likely to be available, but volumes are also required to be tabulated by water use source type. This categorization may be complicated for parties that frequently use water exchanges as part of their ongoing operations. We are assuming that surface water supply data will be provided to us by others (except for the KRGSA agencies), similar to the process conducted for the C2VSimFG-Kern model development.

Groundwater extractions and surface water supply will be combined for Total Water Use in Section 5 of the 2019 Annual Report. As indicated in **Attachment 1**, total water use must be categorized by both water use sector and water source type.

As noted in Sections 3, 4, and 5 of **Attachment 1**, DWR categories of water use sectors, methods/accuracy of measurement, and water use sources have been pulled from the DWR website used for SGMA reporting in adjudicated basins. Given the similarity of the SGMA reporting website organization and the requirements in the GSP regulations of Article 7, it seems reasonable to conclude that this organization will be maintained for reporting data in the GSP annual reports. Data requests and templates will be developed for these water use sectors, measurement methods, accuracy of measurements, and water source types for inclusion, as available (**Attachment 1**).

DWR will recognize that previous data were not likely collected in a manner to differentiate among these categories and some categorization of data will not be available for this first Annual Report. We will confirm with DWR that some data categorization will be unavailable and also that these data only need to be reported for WY 2019; GSP regulations do not indicate that these data need to be provided on an historical basis.

Finally, much of the requested data in this task overlaps with requirements for the updates of Agricultural Water Management Plans (AWMP) and Urban Water Management Plans (UWMPs) for 2020, due in 2021. We will note in the Annual Report that many of these requested data sets are currently being developed/revised in compliance with other planning processes, and data in this Annual Report will be superseded with improved data sets in future annual reports.

Task 5: Analyze Change in Groundwater in Storage

GSP regulations (§ 356.2 (b)(5)(B)) for the Annual Report require both a map and graph of changes in groundwater in storage be developed over the entire groundwater basin that meet the following requirements:

- Graphs depicting the annual and cumulative change in groundwater in storage "based on historical data to the greatest extent available, including from January 1, 2015 to the current reporting year," and
- "Change in groundwater in storage maps for each principal aquifer in the basin".

These requirements presents numerous technical challenges for the Kern County Subbasin (see also the discussion in Section 6.1 of **Attachment 1**).

Based our November 8, 2019, discussion at the Kern County Manager's Meeting, Todd Groundwater will develop change in groundwater in storage maps and graphs for the entire Kern County Subbasin using the C2VSimFG-Kern model. By doing so, we continue to update and use the primary DWR modeling tool with our local Kern County updates for evaluating basin conditions. For this task, we will use a methodology consistent with that used to develop change in groundwater storage graphs for the C2VSimFG-Kern Model Results technical memorandum, which is included in the KGA Umbrella and KRGSA GSPs. Using this approach, we will maintain consistency of method in presenting the basinwide change in groundwater in storage.

For this task, we will request WY2016 through WY2019 data from each district for measured managed water supply and demand data following the methodology used to update the C2VSimFG-Kern model for the Kern County historical water budgets. To meet this Annual Report schedule, this data needs to be delivered to Todd Groundwater no later than January 10, 2020. We will provide data templates to each district to provide monthly data for the following:

- Surface water imports and diversions (inflows and outflows) by source
- Application of surface water imports by category (e.g. irrigated agriculture, urban, managed aquifer recharge, or other uses).
- Groundwater banking and managed aquifer recharge by water district or agency,
- Groundwater banking pumping for export from the basin,
- Metered district groundwater recovery pumping,
- Metropolitan Bakersfield urban water deliveries and wastewater disposal, and
- Any other locally relevant water supply use or demands.

Todd Groundwater will update the natural hydrology for precipitation and flows in gauged streams (Kern River and Poso Creek). Precipitation data will be updated using publicly-available precipitation data from the PRISM Climate Group at Oregon State University. The monthly rainfall data for Kern County for WY2016 through WY2019 will be mapped into C2VSimFG-Kern input files. The Kern River and Poso Creek streamflow for WY2016 through WY2019 will be updated based on locally measured weir data.

Kern County GSAs will also separately contract with the Irrigation Training & Research Center (ITRC) at Cal Poly San Luis Obispo to deliver evapotranspiration (ET) using remote sensing data across the entire subbasin for determining agricultural demand corresponding to the WY 2016 through WY 2019. Todd Groundwater will utilize the ITRC ET data to develop ET rates for Kern County for this period for model input. To meet this Annual Report schedule, this data needs to be delivered to Todd Groundwater no later than January 17, 2020.

As mentioned previously, GSP regulations require a graph depicting the annual and cumulative change in groundwater in storage "based on historical data to the greatest extent available, including from January 1, 2015 to the current reporting year." (§ 356.2 (b)(5)(B)). To meet this requirement, the updated C2VSimFG-Kern subbasin-wide results will be appended to the historical C2VSimFG-Kern results for WY 1995 – WY 2015. One annual

change in groundwater storage map will be developed for each year from WY2016 through WY2019 for the entire Kern County Subbasin using the C2VSimFG-Kern model results.

We will work with agencies to determine the best method for meeting this requirement and then coordinate through the Plan Manager to confirm acceptance of the method by DWR. Additional details are provided in Section 6.2 of **Attachment 1**.

Task 6: Document Progress in GSP Implementation

For this section, Todd Groundwater will work with individual agencies to obtain descriptions and information relating to GSP implementation plans and progress. For the 2019 Annual Report, this section will likely be relatively brief. DWR will recognize that the GSPs were only submitted two months prior to the preparation of this Annual Report and will understand that there will not be substantial progress in plan implementation. Nonetheless, we will document any ongoing activities toward plan implementation that agencies would like to include. In particular, the collection of the preceding year monitoring data and preparation of this First Annual Report are significant steps toward implementation.

Task 7: Prepare Administrative Draft, Draft, and Final Annual Report and Submit to DWR

Based on the tasks above, an Administrative Draft will be prepared for review by Subbasin agencies. Given the condensed schedule, this Administrative Draft will be provided in early February to allow agency input into the development process. It is recognized that the Administrative Draft will contain deficiencies, but the early release will allow comments on analysis methods and results prior to finalization of the technical analysis.

Comments will be incorporated into the Administrative Draft to develop a Draft Annual Report (probably release in early March). This will provide a more complete document for agency review and comment. A Final Draft will also be available prior to submittal for any last-minute minor additions or corrections. The target for the Final Draft is March 13. Todd Groundwater will coordinate with the Plan Manager on submittal of the report prior to the deadline of April 1.

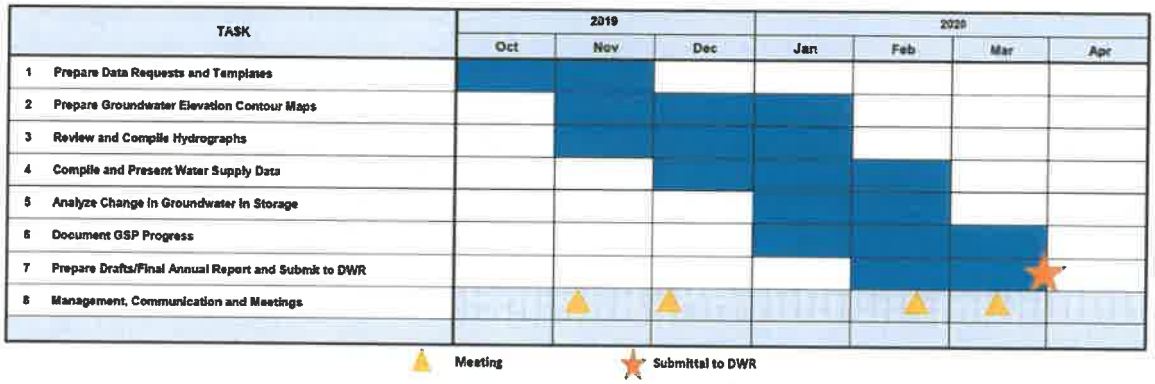
Task 8: Communications and Meetings

As indicated above, there will be a need for communication with Subbasin GSAs and KGA member agencies to obtain comparable data across the entire Subbasin for inclusion in the 2019 Annual Report. Communications will include individual calls/emails with Subbasin agencies, conference calls during periodic meetings of GSA managers, and local in-person meetings to present progress to date and discuss outstanding items or issues.

The preparation of the Annual Report will occur at a busy time for Subbasin agencies. Finalization of GSPs and preparation for GSP submittals will be ongoing. To keep to the expedited schedule of the 2019 Annual Report, a significant amount of communication will be needed to allow Subbasin agencies to focus on required details of the 2019 Annual Report.

To expedite the process, Todd Groundwater will coordinate directly with the Subbasin Plan Manager, Patty Poire, to ensure timely data compilation, review, and incorporation of the required analyses to meet GSP Annual Report requirements. In particular, any questions or contacts with DWR regarding clarifications of Annual Report requirements will be coordinated through the Subbasin Plan Manager.

For budget and planning purposes, four in-person meetings are assumed as part of this scope. Because of the large number of attendees, the KGA Managers Meetings – typically held on Friday mornings – will be used as a forum for data requests, discussion, and comments regarding the Annual Report preparation process. These four meetings, along with the primary objectives and tentative dates, are summarized as follows:



- Meeting No. 1: Provide data request memorandum and templates to agencies and discuss approach for technical analyses including historical change in groundwater in storage; tentatively scheduled for November 8, 2019
- Meeting No. 2: Finalize technical approach for Change in Groundwater in Storage and other technical analyses; tentatively scheduled for December 6, 2019
- Meeting No. 3: Review Administrative Draft Annual Report and address deficiencies; tentatively scheduled for February 21, 2019
- Meeting No. 4: Review Final Draft Annual Report; tentatively scheduled for March 13, 2019.

3 BUDGET AND SCHEDULE

Execution of the scope of work described herein is estimated to cost $174,830. This cost allows for a variety of technical methods to be considered and employed to meet regulatory requirements and the condensed schedule for Annual Report development. Table 1 shows costs by task, along with estimated labor hours and rates.

Our work on the Annual Report can begin in October with additional work on approach for Annual Report items. Technical work can begin in November when water level data from Fall 2019 have been collected and requested data have been compiled. With a submittal date of April 1, 2020, most of the work on the 2019 Annual Report will occur over four months (November through February) with final review and edits of the report targeted for March 2020. A proposed schedule, including the four meetings described in Task 8 is shown below.

Proposed Schedule for 2019 Annual Report, Kern County Subbasin

Please let us know if you have questions regarding this proposal. For the 2019 Annual Report, time is of the essence, and we stand ready to move the effort forward as soon as possible.

DRAFT

EXECUTIVE SUMMARY

*Provide an **executive summary** and **location map** depicting the basin covered by the report (Reg. § 356.2(a)).*

DRAFT

1 INTRODUCTION

Include general information and location map for the basin covered by the report (Reg. § 356.2(a)).

This First Annual Report (2019 Annual Report) for the collective implementation of the Groundwater Sustainability Plans (GSPs) in the Kern County Subbasin is being prepared under the guidance of Water Code Section 10728. The 2019 Annual Report provides data and information for the entire Kern County Subbasin, including 11 GSAs that have cooperated in the preparation of five GSPs. Subbasin GSAs and GSP are shown on Figures 2 and 3, respectively.

1.1 PURPOSE OF THE 2019 ANNUAL REPORT

The purpose of the 2019 Annual Report is to demonstrate that the GSPs in the Kern County Subbasin are being implemented in a manner that will achieve the sustainability goals that have been developed for the Subbasin and individual GSAs. The 2019 Annual Report provides an update on the groundwater conditions for **Water Year 2019**, and documents progress on GSP implementation. Data and analyses cover the period from October 1, 2018 through September 30, 2019; historical analyses are provided for context for some components, as required by the regulations.

Specifically, for this First Annual Report, some additional analyses have been required to cover the time period from October 1, 2015 through September 30, 2019 (WY 2016 through WY 2019). Inclusion of data from this four-year period provides a bridge between the end of the Current Study Period (WY 2015) of the Subbasin GSPs and the reporting period for this 2019 Annual Report (i.e., WY 2019).

1.2 COORDINATED SUBMITTAL

Describe process by which Subbasin data were submitted and compiled.

All of the GSAs in the Kern County Subbasin have cooperated to prepare and submit this First Annual Report.

Figures and tables will be included for the GSAs and GSPs in the Subbasin.

As required by GSP regulations, this Annual Report contains... ***summarize organization and contents***.

DRAFT

2 GROUNDWATER ELEVATIONS

§ 356.2(b)(1)(A) Describe and present graphically, groundwater elevation data from monitoring wells identified in the monitoring network.

2.1 GROUNDWATER ELEVATION CONTOUR MAP FOR EACH PRINCIPAL AQUIFER

§ 356.2(b)(1)(A) ...illustrating, at a minimum, seasonal high and seasonal low. Assume submittal of 2 sets of maps with this Annual Report – Spring and Fall 2019, with a map per Principal Aquifer (4 maps total). Will we have Santa Margarita maps from Kern Tulare and others on the Eastside?

Assume that water level data will be provided in Excel and include, at a minimum, well identifiers (matching hydrographs), date, depth to water, reference point elevation, and water level elevations.

Data will be contoured initially using commercially-available software and then iteratively hand-modified for more accurate representations of groundwater elevations across the Subbasin. Multiple drafts of water level contour maps will be developed for review by individual agencies, as needed.

2.2 HYDROGRAPHS FROM WY 1995 THROUGH SEPTEMBER 2019

Assume that wells in the GSP monitoring networks used for GSP compliance monitoring will be provided by each agency for inclusion in the 2019 Annual Report. Hydrographs can be provided as pdf, described briefly in this section, and incorporated in an appendix.

Section will include and describe:

- Table of Wells and Submitting Agencies
- Figure 8: Hydrograph Location Map.
- Hydrographs to be included in Appendix A.

Hydrograph requirements for Annual Report *§ 356.2(b)(1)(B)*:

- Groundwater elevations
- Water Year Type
- Historical data to the greatest extent possible (WY 1995 – WY 2019)
- Locations, tied to the same datum

Hydrograph requirements from Data and Reporting Standards §352.4(e):

- Hydrographs shall be submitted electronically in accordance with the procedures in Article 4.
- Hydrographs shall include a unique site identification number and the ground surface elevation for each site
- Hydrographs shall use the same datum and scaling to the greatest extent practical

We assume that all submitted hydrographs from each agency will have the same horizontal scale beginning with October 1, 1994 and ending with September 30, 2019. The horizontal axis will have major tick marks for each water year (WY 1995 through WY 2019).

DRAFT

3 GROUNDWATER EXTRACTIONS

GSP requirements in § 356.2(b)(2).

3.1 SUMMARY EXTRACTIONS BY SUBBASIN FOR WY 2019

Total groundwater extractions for the Subbasin for the preceding water year (WY 2019) will be summarized and provided in this section. Data should be collected by "best available measurement methods."

3.2 TABLE OF EXTRACTIONS

Based on our SGMA reporting in Adjudicated Basins, we anticipate the following formats from DWR regarding extraction data reporting. Data may not be available for all sectors for this first report.

- Water Use Sector (including volume, explanation, and uncertainty)
    - Urban
        - Large Landscape
        - Commercial
        - Industrial
        - Residential
    - Agricultural
    - Managed Wetlands
    - Managed Recharge
    - Other Sector

- Measurement Method (direct or estimate)
    - Meters
    - Electrical Records
    - Land use
    - Groundwater model
    - Reported by pumper
    - Other

- Accuracy of Measurements
    - Low, medium, high

3.3 EXTRACTIONS MAP

Map that illustrates the general location and volume of groundwater extractions § 356.2(b)(2).

This map will be developed with various formats, depending on the data provided. At a minimum, we assume preparation of a map will showing extraction wells by well type (agricultural, municipal, etc.), using available information from the agencies. To meet the criteria of showing volumes of extractions, we anticipate developing various "bubble" maps showing groundwater extractions for general areas.

DRAFT

4 SURFACE WATER SUPPLY

§ 356.2(b)(3) Surface water supply used or available for use, for groundwater recharge or in-lieu use shall be reported based on quantitative data that describes the annual volume and sources for the preceding water year.

4.1 TOTAL SURFACE WATER USE

Total surface water use will be reported for the Kern County Subbasin, including a summary of the methods used to determine the volume and the associated uncertainty (high, medium, low). These data will be compiled from the individual agencies in the Subbasin.

4.2 SURFACE WATER BY SOURCE TYPE

Tables will be developed to document the volumes and associated uncertainty by Water Source Type:

- Local Surface Deliveries
- Local Imported Deliveries
- Colorado River Deliveries
- CVP Base and Project Deliveries
- Other Federal Deliveries
- State Water Project Deliveries
- Recycled Water
- Desalination Water
- Other

DRAFT

5 TOTAL WATER USE

§ 356.2(b)(4) Total water use.

Provide total volume of water used in the Subbasin for WY 2019, including the method used to determine and the level of uncertainty (low, medium, high)

- Collected using the best available measurement methods
- Table containing total water use by:
    - Water Use Sector
        - Urban
            - Large Landscape
            - Commercial
            - Industrial
            - Residential
        - Agricultural
        - Managed Wetlands
        - Managed Recharge
        - Other Sector
    - Water Source Type
        - Groundwater
        - Surface water
        - Recycled or reused water
        - Other

DRAFT

6 CHANGE IN GROUNDWATER IN STORAGE

6.1 MAP OF CHANGE IN GROUNDWATER IN STORAGE FOR THE SUBBASIN

*§ 356.2(b)(5)(A) Change in **groundwater in storage maps** for each principal aquifer in the basin.*

GSP regulations require an annual change in groundwater in storage map for the entire Kern County Subbasin be included in the Annual Report. We will follow up with DWR whether this requirement is for only the preceding year (WY 2019) or whether it applies to all four intervening water years (WYs 2016 through 2019).

Based our November 8, 2019, discussion at the Kern County Manager's Meeting, Todd Groundwater will develop change in groundwater in storage maps and graphs for the entire Kern County Subbasin using the C2VSimFG-Kern model. By doing so, we continue to update and use the primary DWR modeling tool with our local Kern County updates for evaluating basin conditions. For this task, we will use a consistent methodology to that used to develop change in groundwater storage graphs for the C2VSimFG-Kern Model Results technical memorandum that is included in the KGA Umbrella and KRGSA GSPs. Using this approach, we will maintain consistency of method in presenting the basinwide change in groundwater storage. One annual change in groundwater storage map will be developed for each year from WY2016 through WY2019 for the entire Kern County Subbasin using the C2VSimFG-Kern model results.

6.2 GRAPHS OF CHANGE IN GROUNDWATER IN STORAGE

§ 356.2(b)(5)(A) Graphs of Change of Groundwater in Storage showing:

- Water Year Type (Wet, Above Normal, Below Normal, Dry, Critically Dry)
- Groundwater Use
- Annual Change in groundwater in storage
- Cumulative change in groundwater in storage
- Based on historical data, to the greatest extent available, including from January 1, 2015 to the current reporting year

GSP regulations require a graph depicting the annual and cumulative change in groundwater in storage "based on historical data to the greatest extent available, including from January 1, 2015 to the current reporting year." (§ 356.2 (b)(5)(B)).

For the Kern County Subbasin, this graph will present annual changes in groundwater in storage from the C2VSimFG-Kern model. Model results provide an annual change in groundwater in storage for each year in the historical and current study periods (WY 1995 – WY 2015). New water budget analyses will be developed for the remaining time period WY 2016 – WY 2019. To meet the regulatory requirement for this graph, the updated C2VSimFG-Kern subbasin-wide results will be appended to the historical C2VSimFG-Kern results for WY 1995 – WY 2015.

DRAFT

7 PROGRESS IN GSP IMPLEMENTATION

§ 356.2(b)(5)(C) A description of progress towards implementing the Plan, including achieving interim milestones, and implementation of projects or management actions since the previous annual report.

For this section, we assume receipt of text from each GSAs/Districts that describes ongoing implementation of each GSP. A brief description of the projects and management actions being implemented will be included, as relevant. This section is not meant to repeat information in the recently-submitted GSPs and will simply refer to the GSPs as appropriate.

In particular, this section will describe relevant monitoring data and how these data are being used. GSP monitoring data can be summarized/included in an appendix. We will confirm with DWR how much of the data and formats are required to accompany the submission of the Annual Report.

DRAFT

8 REFERENCES AND TECHNICAL STUDIES

To be listed as needed.

DRAFT

9 APPENDICES

- Hydrographs and other data.
- Possible inclusion of other information, if determined to be needed by DWR.

DRAFT

ATTACHMENT 2

ITRC
moving water in new directions

Agreement for ITRC-METRIC 2017-2019

Date: October 7, 2019

To: Patty Poire, Planning Manager
Kern Groundwater Authority
ppoire@kerngwa.com, Mobile: (661)706-1989

From: Dan Howes, Ph.D., P.E.
Project Manager/Senior Engineer
Irrigation Training and Research Center
Cal Poly/ San Luis Obispo, CA 93407
Cell: 858-354-0504
djhowes@calpoly.edu

Subject: **Proposal for ITRC-METRIC evapotranspiration for Kern Subbasin (2017-2019)**

This proposal is being submitted to Kern Groundwater Authority (KGWA) by the Irrigation Training and Research Center (ITRC) at Cal Poly State University, San Luis Obispo.

Scope of Work

Update of ITRC-METRIC 2017-2019 Water Year and Calendar Year

ITRC will provide monthly and annual ITRC-METRIC actual crop evapotranspiration (ETc) for the Kern Subbasin for 2017-2019. The following items will be completed:

1. Data will be extracted for each GSA within the subbasin and each irrigated field in each GSA monthly for 2017-2019. We can also provide the data for parcels (larger than 5 acres).
2. Data will be provided tabularly and monthly ETc images will be provided in GIS format.
3. Short report discussing the general process and overall results will be provided.

Cost: **$16,000**

Deliverables

ETc data in tabular (MS EXCEL) and other formats (such as imager) provided on a flash drive or file transfer service.

Timeline for Project

Assuming the full 2019 results are desired, report and data will be provided by February 1, 2020. If water year only results are desired, results will be provided by November 20, 2019.

Contract

The person responsible for technical aspects of this contract will be:

Dan Howes
Project Manager, Irrigation Training and Research Center
Cal Poly
San Luis Obispo, CA 93401-0730
djhowes@calpoly.edu

The contract will be administered by:

Cal Poly Corporation
Building #15
One Grand Avenue
San Luis Obispo, CA 93407

Note: Dr. Howes should be the contact person.

Budget

The total budget is a fixed price Fee for Service of $16,000. The full amount will be invoiced when the draft results are transmitted to KGWA. The Cal Poly Corporation requests that a KGWA representative agree to the Standard Terms and Conditions, which are attached to this proposal. The signed approval can be scanned and submitted via e-mail to Dan Howes.

Invoicing and Payment

ITRC will submit to KGWA (Patty Poire), an invoice of the full fixed cost when transmitting the draft results.

Payment should be made payable to "Cal Poly Corporation" and sent to:

Dr. Dan Howes
Irrigation Training and Research Center (ITRC)
One Grand Ave
Bldg 8A
California Polytechnic State University
San Luis Obispo, CA 93407-0730

Authorization/Approval

Name of authorized ITRC representative: Daniel Howes

Signature of ITRC representative — date: 10/7/2019

Named of authorized Kern GWA representative: Patty Poire

Signature of the representative: — date: 11/20/2019

Irrigation Training & Research Center (ITRC)
Standard Terms and Conditions

THIS AGREEMENT is between the **Kern Groundwater Authority ("Client")** and the Cal Poly Corporation, a separate non-profit auxiliary organization for the California Polytechnic State University, hereinafter referred to as **"ITRC."**

1) **Ordering**: Clients may order services (specify a "Scope of Work") by submitting a written purchase order, a written request for services, by sending confirming e-mail, or by placing a telephone order. The Client must subsequently confirm all telephone orders in writing or via e-mail confirmation prior to commencement of work.
2) **Change Orders:** A Client may request additions or changes to an Order, but must be confirmed by written notice. Email is an acceptable form of writing. The Client will remain responsible for all work performed under the original agreement up until the time ITRC is officially notified of the change.
3) **Suspending or Stopping ITRC's Performance**: The Client may direct ITRC to suspend a portion or all of the work to be performed. In such case, the Client will remain responsible for all work performed up until the time ITRC became aware of Client's desire to discontinue the services. Any uncompleted services in progress at the time of discontinuation will be billed on a prorated basis, as determined by ITRC.
4) **Confidentiality:** ITRC shall keep documents and information identified by Client as confidential to the extent permitted by law, and will not disclose any such information to third parties. ITRC may publish announcements and summaries containing *non-confidential information* about this project in campus newsletters and annual report and other published documents on campus.
5) **Warranties**: Client understands that ITRC performs services only as specified by Client in the Services Agreement accepted by ITRC. ITRC does not make any express or implied warranties or guarantees of any kind to the Client. By their very nature, technical services, testing, analysis and other ITRC services are limited to expected measurement variability. ITRC represents that the Services shall be performed within the limits agreed with Client, and in a manner consistent with the level of care and skill ordinarily exercised by other providers of similar services under similar circumstances.
6) **Ownership of Data:** Data or information provided to ITRC by the Client shall remain the Client's property. Upon full payment to ITRC for all services provided by ITRC, data or information generated by ITRC for the Client shall become the Client's property. ITRC will retain exclusive ownership of any and all analytical methods, Quality Assurance/Quality Control protocols, and equipment developed by ITRC for performance of work by ITRC. ITRC Reports are for the exclusive use of the Client to whom they are addressed. The name of ITRC, Cal Poly Corporation, or California Polytechnic State University, or any symbols of them are not to be used by Client without prior written approval by the appropriate authorized representative.
7) **Indemnification:** Client and ITRC agree that by performing services hereunder, ITRC does not assume, shorten, cancel or undertake to discharge any duty or responsibility of Client to any other party or parties. No one other than Client shall have any right to rely on any Report or other representation or conduct of ITRC, and ITRC disclaims any obligations of any nature whatsoever with respect to such person. Client and ITRC agree, in consideration of ITRC under-taking to perform the ordered service(s) to protect, defend, indemnify, same harmless and exonerate each other from any and all claims, damages, expenses, either direct or consequential for injuries to persons or property arising out of or in consequence of the performance of the services hereunder unless caused by the sole negligence of the other party.
8) **Insurance:** Cal Poly Corporation maintains insurance coverage for its employees to perform professional services. If Client seeks greater protection than is provided by Cal Poly Corporation insurance, Client should obtain appropriate protection from suppliers or insurers.
9) **Limitation of Liability:** If ITRC should be found liable for any losses or damages attributable to the services hereunder in any respect, its liability shall in no event exceed the amount of the fee paid by Client for such services and Client's sole remedy at law or in equity shall be the right to recover up to such amount.
10) **Force Majeure:** Whenever performance by either party is delayed or prevented by an extraordinary event beyond the control of Client or ITRC, such delay or prevention shall be excused and the time of performance extended for the duration of the causative factor. In no event shall the occurrence of any such conditions excuse the Client of its obligations hereunder if services have been performed by ITRC.
11) **Payment of Invoices:** Client agrees to pay all invoices to ITRC within 30 days of invoice date, and if payment is not timely received, the Client agrees to pay a late payment charge on the unpaid balance at the maximum allowed by law.
12) **Governing Law**: This Agreement shall be governed in accordance with the laws of the State of California.

Resolution to Form Kern Groundwater Authority Groundwater Sustainability Agency

KERN GROUNDWATER AUTHORITY
RESOLUTION NO. 2
RESOLUTION ELECTING FORMATION OF THE KERN GROUNDWATER AUTHORITY GROUNDWATER SUSTAINABILITY AGENCY

WHEREAS, the California Legislature has adopted, and the Governor has signed into law, the Sustainable Groundwater Management Act of 2014 ("SGMA"), which requires the sustainable management of groundwater; and

WHEREAS, the legislative intent is to provide for sustainable management of groundwater basins, to enhance local management of groundwater, to establish minimum standards for sustainable groundwater management; and

WHEREAS, in order to exercise the authority granted in SGMA, a local agency or combination of local agencies may elect to form a Groundwater Sustainability Agency (GSA); and

WHEREAS, the Kern Groundwater Authority is a joint powers authority composed of local agencies, as SGMA defines that term; and

WHEREAS, specific members of the Kern Groundwater Authority have executed a Special Activities Agreement for the purpose of coordinating and electing to be a GSA under the organization of the Kern Groundwater Authority ("Participating Members"); and

WHEREAS, every member of the Kern Groundwater Authority was provided the opportunity to participate in the formation of a GSA under the Kern Groundwater Authority; and

WHEREAS, the Kern Groundwater Authority overlies a portion of the Kern County Subbasin (designated basin number 5-022.14) in the California Department of Water Resources' (DWR) groundwater basin system, which has been designated by DWR as a high-priority basin in critical overdraft; and

WHEREAS, Section 10723.8 of the SGMA requires that a local public agency electing to be a GSA notify the DWR of its election and intention to undertake sustainable groundwater management within the agency's jurisdictional boundary; and

WHEREAS, pursuant to Government Code 6066, notice of a public hearing on the Kern Groundwater Authority election to elect to be a GSA has been published as required by law; and

WHEREAS, on April 26, 2017, the Kern Groundwater Authority held a public hearing to consider adoption of this Resolution; and

WHEREAS, the Kern Groundwater Authority, pursuant to the vote of the Participating Members, wishes to exercise the powers and authorities of a GSA granted by SGMA and to begin the process of cooperatively preparing a Groundwater Sustainability Plan (GSP) with other GSAs as appropriate.

NOW, THEREFORE BE IT RESOLVED THAT:

1. The Kern Groundwater Authority hereby finds that the facts set forth in the recitals to this Resolution are true and correct, and establish the factual basis for the Kern Groundwater Authority adoption of this Resolution.

2. The Kern Groundwater Authority hereby elects to become a GSA to manage groundwater within the boundaries of the Participating Members.

3. The Board authorizes the General Manager or his designee within 30 days of adopting this Resolution, to inform the Department of Water Resources of the Kern Groundwater Authority election and take such other and further steps as necessary to comply with the SGMA and the Department of Water Resources requirements.

4. This Resolution shall take effect immediately upon its adoption.

PASSED AND ADOPTED at a meeting of the Board of Directors of the Kern Groundwater Authority on April 26, 2017, by the following vote:

AYES: Directors Pascoe, James, Couch, Pandol, Taube, Andrew, Selvidge, Regan, Franz, Poire, MacIlvaine, Mullins, Barraza, Jr.
NOES: None
ABSTAINING: None

ATTEST:

Lori Honea, Secretary

Notification of Intent to Develop a Groundwater Sustainability Plan

KERN
GROUNDWATER AUTHORITY

December 20, 2017

Mr. Trevor Joseph
Sustainable Groundwater Management Section Chief
California Department of Water Resources
P. O. Box 94236
Sacramento, CA 94236

Re: Notification of Intent to Develop a Groundwater Sustainability Plan

Dear Mr. Joseph:

The purpose of this letter is to notify you that the Kern Groundwater Authority Groundwater Sustainability Agency (KGA) intends to develop a Groundwater Sustainability Plan (GSP) pursuant to Water Code Section 10727.8 for its service area within the Kern County Subbasin (Basin Number 5-22.14, DWR Bulletin 118). The KGA is an exclusive GSA whose formation was posted by DWR on April 21, 2016.

The KGA is engaged in several coordination and outreach efforts across the Kern County Subbasin, as well as within the more specific service area of the KGA. The KGA actively participates in technical and planning meetings and forums with other GSAs in the Kern County Subbasin, recognizing that the findings of the KGA's GSP will need to be coordinated with other GSP development efforts occurring in parallel within the Kern County Subbasin. In addition to the monthly KGA Board of Directors meetings, the KGA holds monthly public meetings to review and discuss on-going planning activities in support of the GSA and GSP development process. These meetings welcome public input and feedback to the GSA and the GSP development process.

The KGA will also be holding educational workshops specifically intended for the interested parties and general public living, working and operating farms and businesses in the KGA service area. These additional workshops will have an educational focus to inform attendees on the overall role and purpose of the GSA, describe the method and process to develop the GSP, and solicit input on the development of the GSP. An initial workshop in 2018 will focus on public involvement and seek input on approaches, such as an Advisory Committee, to regularly acquire input from a wide variety of public stakeholders, and from disadvantaged communities in particular. One of the key goals of the public workshops will be to hear comments and feedback from the public that can be used to further inform the GSP development process.

1800 30th Street, Suite 280, Bakersfield, CA 93301 • Tel: (661) 616-6500 • Fax: (661) 616-5890 • www.kerngwa.com

The KGA has established a website at: http://kerngwa.com/. This website is already actively in use and will continue to provide the public with key information regarding the GSA and GSP development process including the dates of public meetings and workshops. The KGA website also makes our resource planning and GSP documents available to the public.

If you have any questions regarding our GSP development process, please don't hesitate to contact me at the phone number or email below.

Sincerely,

Terry L. Erlewine

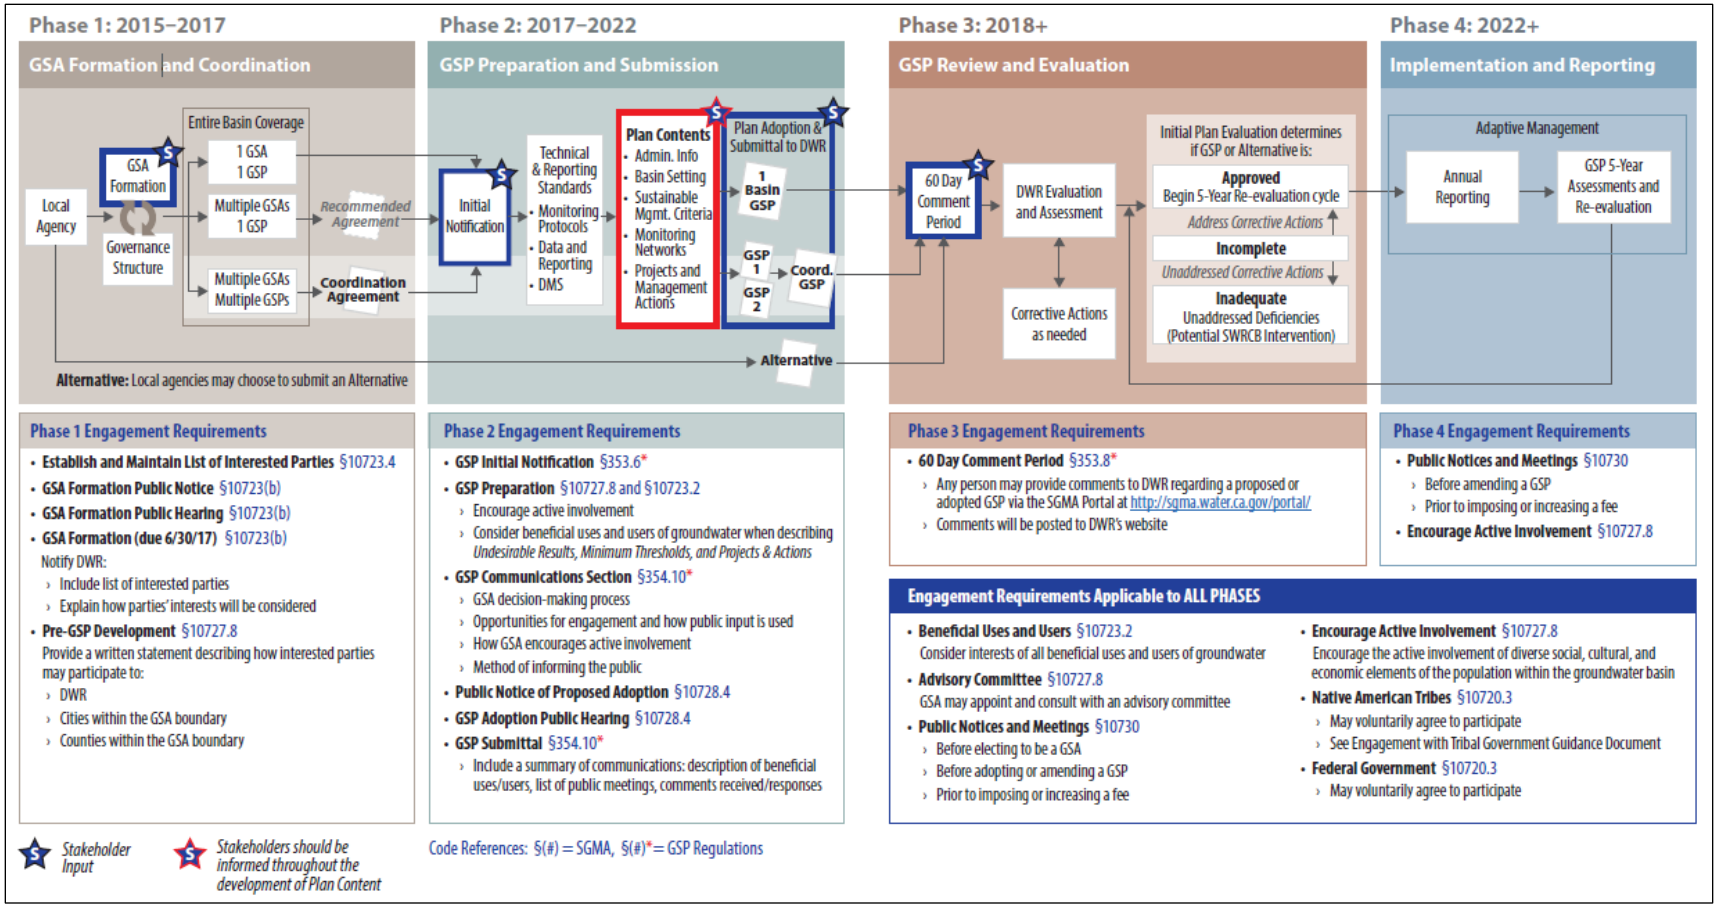
Introduction

SGMA Overview

The Sustainable Groundwater Management Act (**SGMA**) is a combination of three bills signed by California Governor Jerry Brown in 2014: Assembly Bill (**AB**) 1739, Senate Bill (**SB**) 1168, and SB 1319. SGMA provides local agencies with the framework to manage groundwater basins in a sustainable manner. The legislation recognizes that groundwater is most effectively managed at the local level, and local agencies will need to achieve groundwater sustainability by 2040.



In SGMA, sustainable groundwater management is defined as management of groundwater supplies in a manner that can be maintained in planning and implementation phases without causing undesirable results. Undesirable results include significant and unreasonable chronic lowering of groundwater levels, reduction of groundwater storage, seawater intrusion, degraded water quality, land subsidence, and interconnected surface waters.

Implementation of SGMA and outreach requirements are broken down into four phases (**Figure ES-1**):

- **Phase 1: GSA Formation and Coordination –** Phase 1 ranged from 2015 to 2017, and during this phase, local agencies created groundwater sustainability agencies (**GSA**). The responsibility of a GSA is to develop and implement a groundwater sustainability plan (**GSP**) that will consider all beneficial uses and groundwater users within the basin. GSAs were required to be formed by June 30, 2017.
- **Phase 2: GSP Preparation and Submission –** The second phase of SGMA implementation ranged from 2017 to 2019. During this phase, GSAs developed GSPs with measurable objectives and milestones that ensure basin sustainability. A basin may be managed by a single GSP or multiple-coordinated GSPs. The California Department of Water Resources (**DWR**) developed regulations for evaluating GSPs and alternatives to GSPs by June 1, 2016.
- **Phase 3: GSP Review and Evaluation –** For the Kern Groundwater Authority (**KGA**), Phase 3 was held in late 2019, and consisted of a public review period. The public review period was held 90 days prior to the adoption of the GSP. Once the GSP has been submitted to the DWR by January 31, 2020, DWR will hold another 60-day review and comment period for stakeholders.
- **Phase 4: Implementation and Reporting –** Following the submission of the GSP, the KGA will immediately begin the implementation of efforts described in the GSP to reach sustainability within the basin. This will be an ongoing phase, as the goal of SGMA is to reach sustainability by 2040.

Communication & Engagement Plan

As required by SGMA, GSAs must consider the interests of all beneficial uses and users of groundwater and include them in the GSP development process. The Kern Groundwater Authority's Communication & Engagement (**C&E**) Plan addresses how stakeholders within the boundary will be engaged through stakeholder education and opportunities for input and public review during the development and implementation of the GSP. This plan provides an overview of the KGA, its stakeholders, and decision-making process; identifies opportunities for public engagement and discussion of how public input and responses will be used; describes how the KGA encourages the active involvement of diverse, social, cultural, and economic elements of the population within the KGA boundary; and the methods to be used to inform the public stakeholders about the progress of GSP development, public review and implementation.

Figure Intro-1. Stakeholder Engagement Requirements by Phase

I. Goals and Desired Outcomes

This section of the Communication & Engagement Plan provides a description of the Kern Groundwater Authority, defines the goals of how to address the challenges, regulatory requirements and opportunities, and how to reach the desired outcomes of communication efforts.

A. Description and Background of the Kern Groundwater Authority

I.A.1 GSA Description & Boundary

SGMA requires all high- and medium-priority groundwater basins, as designated by the DWR Bulletin 118, to be managed by a GSA or multiple GSAs. Part of the Tulare Lake Basin, the Kern County Groundwater Sub-basin is a high-priority basin that is in critical groundwater overdraft. The Kern County Groundwater Sub-basin currently has 10 GSAs (listed in **Table I-1**).

Table I-1. GSAs in Kern Sub-basin

GSAs within the Kern Sub-basin		
Buena Vista Water Storage District	Cawelo GSA	Greenfield County Water District
Henry Miller Water District	Kern Groundwater Authority	Kern River GSA
McFarland GSA	Olcese GSA – Olcese Water District	Pioneer GSA
Semitropic Water Storage District	West Kern Water District	

On April 26, 2017, the Kern Groundwater Authority, a joint-powers authority (**JPA**), elected to become an official GSA for the portion of the Kern County sub-basin designated in **Figure I-1**. The KGA provides local policy makers, stakeholders and the public with a forum to monitor, report and/or discuss groundwater activities, and identify and address any local groundwater issues. The KGA was formed for the purpose of SGMA, which includes but is not limited to the following activities: coordinating groundwater management programs and activities, identifying and addressing issues pertaining to sustainable groundwater management, and establishing a framework for local groundwater management.

Kern Groundwater Authority's member entities are listed in **Table I-2**. These members overlie the larger portion of the Kern County Subbasin (Basin Number 5-022.14, DWR Bulletin 118) of the San Joaquin Valley Basin, which create the GSA's boundary. The boundary stretches along the northwest, northeast and southern parts of Kern County, California (**Figure I-1**), and includes agricultural lands, urban and industrial areas, and oil fields.

Table I-2. Kern Groundwater Authority Member Entities

Kern Groundwater Authority Member Agencies		
Arvin Community Services District	Arvin-Edison Water Storage District	Cawelo Water District
City of Shafter	Eastside Water Management Area*	Kern County Water Agency
Kern-Tulare Water District	Kern Water Bank Authority	North Kern Water Storage District
Rosedale-Rio Bravo Water Storage District	Semitropic Water Storage District	Shafter-Wasco Irrigation District
Southern San Joaquin Municipal Utility District	Tejon-Castaic Water District	West Kern Water District
Westside District Water Authority	Wheeler Ridge-Maricopa Water Storage District	

*Associate member

Under SGMA, the KGA is responsible for submitting a GSP to the DWR by January 31, 2020 and works cooperatively with the other Kern County Sub-basin GSAs to meet the sustainability requirements for the sub-basin as a whole. The KGA is also working with the other Kern County Sub-basin GSAs, and will continue to do so, on the communication and engagement of all beneficial users.

Throughout the SGMA phases, the KGA's Board of Directors, KGA Planning Manager and general managers of each member agency will be responsible for collecting and organizing data, engaging and retaining experts and consultants, and soliciting feedback from beneficial users of groundwater and interested parties within the GSA boundary. The specific roles of the Board of Directors and committees are described in **Section II.A**.

I.A.2 Industries, DACs, Municipalities

I.A.2.1 Industries

Collaboration meetings will be held with the companies and organizations within the following industries to make sure their organizational visions and groundwater needs for facility operations and conservation efforts are taken into consideration during GSP development and implementation phases.

I.A.2.1.1 Agriculture

The primary industry within the KGA is agriculture, as Kern County is currently the number one agricultural-producing county in the United States. The top five commodities produced in Kern County are grapes, almonds, citrus, pistachios and milk, according to the Kern County Agricultural Crop Report published by the Kern County Ag Commissioner's office. These top five crops comprise over $4.3 billion of the over $7 billion in gross value of crops produced within Kern County. Other top commodities produced in Kern County include: carrots, cattle and calves, potatoes, cherries, pomegranates, alfalfa, and silage and forage. As the primary industry, agriculture is the largest private employer in the county, with on-farm employment accounting for 15 percent of all jobs within Kern County, according to California's State Employment Development Department

With a substantial amount of KGA's acreage in agriculture production, it is important agriculture industry stakeholders are involved and informed during the development and public review phases of the GSP, as implementation will have a significant direct impact on the industry, and ultimately the local, state and national economies. KGA will continue to reach out to the Kern County farmers and will work with them collaboratively.

I.A.2.1.2 Food Processing

Kern County is one of the nation's top agricultural producing counties, and a prime location for the food processors to establish their part of the farm-to-table process. Four of the top 10 food processing companies in Central California are established in Kern County, accounting for nearly 15,000 jobs for the local workforce. Because of their significant impact on the economy within the Kern Sub-basin, direct tie to the agricultural industry and substantial reliance on groundwater supplies to operate their facilities, food processors are a crucial piece of groundwater sustainability management within the KGA boundary.

I.A.2.1.3 Oil Production

Kern County is not only one of the nation's top agricultural producing counties, but also one of the nation's top oil producing counties. Oil and agricultural production have shared the surface of Kern County lands for over 100 years and under current conditions will continue sharing. To be exact, the largest landowners within the county are oil companies who produce oil from those land holdings, and also lease those lands for activities such as grazing and the production of agricultural crops, depending on the location within the Kern subbasin. With the passing of SGMA, the oil industry has participated in many workshops and are considered as one of the beneficial users of groundwater within the county. KGA and its members will continue to seek out the oil industry for participation in the process of the GSP development and implementation and consider their industry not only as a beneficial user of groundwater, but also as the provider of additional water from activities of drilling oil.

I.A.2.1.4 Environmental

There are several environmental organizations within the KGA who focus on land conservation efforts (listed in **Table II-4**). The Kern Wildlife Refuge and Kern River Parkway Foundation are two specific organizations that need to be engaged. The KGA will reach out to these organizations to discuss their land conservation needs so that a healthy regional watershed with ecologically functional waterways can be taken into consideration for GSP development and implementation. Collaboration efforts may be put into place for certain groundwater sustainability projects such as the development of recharge basins.

I.A.2.2 DACs

Communication and educational outreach efforts with disadvantaged communities (**DAC**) and severely disadvantaged communities (**SDAC**) is essential for the development and implementation of the KGA's GSP, and residents are generally dedicated to bettering their communities, particularly when it comes to their water supplies. Important information that will be essential to communicate to and engage DACs will include an explanation of SGMA, water conservation education and soliciting feedback. A composite listing of the 22 DACs and SDACs, along with their populations and number of households, within the GSA boundary are listed in **Table I-3** and laid out in **Figure I-2**.

By including DACs and SDACs in communication efforts during the development, public review and implementation phases of the GSP, residents will be more likely to participate and provide feedback that could be crucial to long-term solutions for groundwater sustainability within their communities. Any feedback received from DAC/SDAC residents will be reviewed by the KGA Board of Directors and Stakeholder Committee and taken into consideration during the GSP development phase. During Phase I: GSA Formation & Coordination, the local DACs were engaged in the process and invited to participate in the formation process and with member-representation on the KGA's Board of Directors. The City of Shafter and Arvin Community Services District currently hold Board of Directors seats.

Table I-3. Disadvantaged Communities within the Kern Groundwater Authority

Community	Population	Households	DAC/SDAC
Buttonwillow	1,371	378	SDAC
City of Arvin	20,028	4,595	SDAC
City of Delano	52,883	10,549	SDAC
City of McFarland	12,784	2,817	SDAC
City of Shafter	17,261	4,434	DAC
City of Wasco	25,865	5,264	DAC
Cherokee Strip	295	68	SDAC
Derby Acres	324	145	SDAC
Dustin Acres	295	128	DAC
Edmundson Acres	274	54	SDAC
Fellows	106	37	DAC
Ford City	4,154	1,323	SDAC
Lost Hills	2,194	452	SDAC
Maricopa	1,158	395	SDAC
McKittrick	112	38	DAC
Mettler	88	31	DAC
Mexican Colony	216	63	SDAC
Smith Corner	661	137	SDAC
South Taft	1,680	471	DAC
Tupman	176	45	DAC
Valley Acres	717	227	DAC
Weedpatch	2,170	583	SDAC

I.A.2.3 Municipalities

The municipalities within the KGA are listed in **Table I-4**. These municipalities will be engaged in outreach efforts throughout the GSP development, public review and implementation phases, as described in **Section II.C**. School districts will be an integral part of outreach efforts, particularly within DACs, and are outlined in **Figure I-4** and **Figure I-5**. Further detail on how school districts will be engaged is described in **Section II.C**.

Table I-4. Municipalities within the Kern Groundwater Authority

Municipalities within the Kern Groundwater Authority			
Arvin Community Services District	City of Delano	City of McFarland	City of Maricopa
City of Shafter	City of Taft	City of Wasco	

I.A.3 KGA's Decision-Making Process

The KGA's decision-making process is broken down by the roles of the Board of Directors and Stakeholder Committee. The roles of these KGA entities and their responsibilities are outlined below and described in more detail in **Section II.A**.

- **Board of Directors –** Adopt general policies regarding development and implementation of the GSP
- **Executive Policy Committee** – Need-only committee to provide direction on finances and other issues
- **KGA/GSA Managers Committee –** Meets weekly to coordinate all of the GSPs within the subbasin, which is then presented at the monthly Stakeholder Committee meeting to seek input.

B. Goals/Desired Outcomes of GSP Development

The overall, main goal of the KGA is to establish and execute a plan that will sustain and manage groundwater within the Kern Sub-basin in a way that is cost-effective with minimal negative impacts to the beneficial uses and users.

C. Communication Objectives to Support the GSP

The ultimate goal of communication objectives during the formation/coordination, GSP development, public review and implementation phases of the SGMA compliance, is to encourage active involvement of diverse, social, cultural, and economic elements of the population within the GSA boundary. The KGA will give beneficial users and users of groundwater opportunities to engage in the GSP process, provide educational outreach opportunities for stakeholders while reaching out through specific communication avenues (**Section V**). As primary stakeholders, members of the Board of Directors and Stakeholder Committee are direct representatives of their districts, communities and industries, and it is important for them to continually gather feedback/input, and concerns/needs of their constituents and report back to their respective meetings. Any primary or secondary stakeholder input received will be reviewed and taken into consideration during GSP development.

I.C.1 Phase 1: GSA Formation and Coordination

Phase 1: GSA Formation and Coordination has been completed. This phase stretched from 2015 through 2018, and consisted of forming the KGA, establishing the List of Interested Parties (**Section II.D**), establishing the Stakeholder Committee, and creating the Communication & Engagement Plan to outline communication efforts for the GSP development, public review and implementation phases. Stakeholder input was utilized during the GSA formation phase, as beneficial users and stakeholders with interests in groundwater usage within the KGA's boundary were notified via public meeting notices as soon as the process began.

I.C.2 Phase 2: GSP Preparation and Submission

Phase 2: GSP Preparation and Submission spanned from 2017 through 2019. With the goal to have the draft GSP in the fourth quarter of 2019, 2018 was primarily the technical development of the plan, while working with the Board of Directors and Stakeholder Committee, as well as primary stakeholders (**Section II.A**), for feedback and input. During 2018 and 2019, public outreach meetings and interaction with secondary

stakeholder groups (**Section II.B**) and other community organizations and entities (**Section II.C**) were held with the purpose of educating and informing stakeholders about SGMA and the GSP process, while also soliciting feedback and input from these groups via Stakeholder Surveys (**Section III.A**) to consider and possibly include feedback and input into the GSP.

I.C.3 Phase 3: GSP Review and Evaluation

During 2019, Phase 3: GSP Review and Evaluation, the communication and engagement efforts continued. Once the draft of the GSP was completed late in the third quarter of 2019, the public review process began in the fourth quarter. A 90-day comment period was held, with the GSP draft posted on the KGA's website for primary and secondary stakeholders to conveniently download and review. Outreach meetings were held and presentations given to stakeholders during this phase at the same locations. These meetings focused on an overview of the GSP content, while giving stakeholders a public forum to provide their feedback and comments.

Once the public review period was complete, public comments were taken into consideration and incorporated into the final version of the KGA's GSP before submission to the DWR by January 31, 2020. Following submittal, stakeholders will be given a second 60-day comment period through the DWR's SGMA portal at http://sgma.water.ca.gov/portal/. Comments will be posted to the DWR's website prior to the state agency's evaluation, assessment and approval.

I.C.4 Phase 4: Implementation and Reporting

Phase 4: Implementation and Reporting will begin once the plan is submitted by January 31, 2020. Even while the DWR is reviewing the GSP, SGMA-implementation at the GSA-level must begin. During the implementation phase, communication and engagement efforts will be shifted to educational and informational awareness of the requirements and processes for reaching groundwater sustainability. Active involvement of all stakeholders is encouraged during this phase, and public notices are required for any public meetings and prior to imposing, and later increasing, any fees.

D. Overriding Concerns, Major Concerns or Challenges

Through preliminary discussions with primary stakeholders during the KGA's Stakeholder Committee meetings, overriding concerns, major concerns or challenges are centralized around economic impacts to the agricultural industry, which will also have a direct impact on DACs. Economic impacts could include loss of jobs and loss of tax revenue due to the decreased land values of fallowed ground. Many of DAC residents are employed by the agricultural industry, and many infrastructure improvement projects within these communities are facilitated by the County of Kern and funded through state and federal funding secured with the assistance of technical providers. The agricultural industry and DACs will be the main target audiences for direct outreach meetings because of the significant impact SGMA implementation will have on these two users of groundwater.

A summary of additional top concerning issues affecting groundwater, and the effect of SGMA on agriculture and rural communities/DACs is listed in **Table III-1**.

II. Audience Identification

A. Primary Stakeholder Groups

The primary stakeholder groups of the Kern Groundwater Authority are members of the Board of Directors and Stakeholder Committee. Their specific roles in the communication and engagement process are discussed in this section.

II.A.1 Role of Board of Directors

The Kern Groundwater Authority's Board of Directors is the governing body of the GSA and was formed to adopt general policies regarding development and implementation of the GSP. The Board is comprised of one representative and an alternate from each of the general member agencies (**Table I-1**).

The Board of Directors meetings are held on the fourth Wednesday of every month at the Kern County Administration Building, located at 1115 Truxtun Avenue in Bakersfield, unless otherwise posted on the KGA's website, www.kerngwa.com/board-of-directors.html.

II.A.2 Role of KGA/GSA Managers Committee

The KGA/GSA Managers Committee meets weekly to coordinate the developments of all five groundwater sustainability plans in the Kern Subbasin. The committee is comprised of KGA management and managers from each GSA. The meetings are held every Friday at 8 a.m. at the Rosedale-Rio Bravo Water Storage District office, located at 849 Allen Road in Bakersfield.

II.A.3 Role of Stakeholder Committee

In Section 10727.8 "Public Notification and Participation; Advisory Committee" of the Sustainable Groundwater Management Act, GSAs may appoint and consult with an advisory committee for the purpose of developing and implementing a GSP. Through this advisory committee, the GSA is able to encourage the active involvement of diverse social, cultural, and economic elements of the population within the groundwater basin prior to and during the development and implementation of the GSP.

In the general interest of encompassing representatives of all interests of the sub-basin, Kern Groundwater Authority established a Stakeholder Committee. These representatives encompass residential, agricultural, environmental, rural, domestic well, and municipal interests. The specific role of the KGA's Stakeholder Committee is to serve as a sounding board for the ideas/concepts developed by the KGA/GSA Managers Committee. Their comments and input have been and will continue to be encouraged and considered in the development of SGMA concepts and implementation.

The Stakeholder Committee meets on the first Monday of every month at 3 p.m. at the Rosedale-Rio Bravo Water Storage District, located at 849 Allen Road in Bakersfield, California, unless otherwise posted on the KGA's website: www.kerngwa.com/stakeholders.html.

B. Secondary Stakeholder Groups

Secondary stakeholder groups have been identified by the Kern Groundwater Authority, based on discussions of interests identified in SGMA, Section 10723.2 "Consideration of All Interests of All Beneficial Uses and Users of Groundwater" (**Table II-1**).

Table II-1. Consideration of All Interests of All Beneficial Uses and Users of Groundwater

SGMA, Section 10723.2. Consideration of All Interests of All Beneficial Uses and Users of Groundwater		
Agricultural Users	Domestic Well Owners	Municipal Well Operators
Public Water Systems	Local Land Use Planning Agencies	Environmental Users of Groundwater
Surface Water Users	Federal Government	California Native American Tribes
Disadvantaged Communities	Entities monitoring and reporting groundwater elevations in all or part of a groundwater basin	

Based on these discussions, secondary stakeholders to be targeted for communication and engagement during the GSP development, public review and implementation phases have been narrowed to those with financial, political, business or personal stakes in the management and sustainability of groundwater within the jurisdiction of the Kern Groundwater Authority. These secondary stakeholders are listed in **Table II-2**.

Table II-2. Secondary Stakeholder Groups with Interests in the Kern Groundwater Authority

Secondary Stakeholder Groups with Interests in the Kern Groundwater Authority		
Agricultural Users	Domestic Well Owners	Municipal Well Operators
Public Water Systems	Local Land Use Planning Agency	Environmental User
Surface Water Users	Native American Tribes	Disadvantaged Communities
City Resident*	Food Processor*	Industrial User/Oil Producer*
Entity monitoring and reporting groundwater elevations in all or part of a groundwater basin		

*Additional secondary stakeholder groups identified by the KGA

Secondary stakeholder groups will be engaged through public outreach meetings and email blasts. These meetings will be held during Phase 2: GSP Preparation and Submission, Phase 3: GSP Review and Evaluation, and Phase 4: Implementation and Reporting.

II.B.1 Native American Tribes

Native American Tribes within the KGA boundary will be invited to participate in GSP development. The KGA will reach out to them by sending them a letter about SGMA and the KGA along with a stakeholder survey. These tribes are listed in **Table II-3**.

Table II-3. Native American Tribes in the Kern Groundwater Authority

Native American Tribe	Contact	Contact Information
Kitanemuk & Yowlumne Tejon Indians (Yowlumne Kitanemuk)	Delia Dominguez, Chairperson	115 Radio Street Bakersfield, CA 93305 Telephone: (626) 339-6785 Email: deedominguez@juno.com

Source: Native American Heritage Commission, Native American Contacts (January 18, 2018)

C. Community Organizations, Public Agencies and Other Entities

There are many community organizations, public agencies and other entities throughout the KGA's boundary that will be utilized to reach out to secondary stakeholders. These resources identified as avenues for outreach opportunities are listed in **Table II-4**. Additional community organizations, public agencies and entities may be added to the list as GSP development and implementation phases move forward, and additional connections are made between the KGA and the communities within its boundary.

The Kern Groundwater Authority will communicate with these resources and request opportunities to give presentations at their respective meetings. If a Board of Director or Stakeholder Committee member is currently involved with or has contacts within a community organization, public agency or other entity, they may present on behalf of the KGA to further outreach efforts. Presentations may include an overview on SGMA and why it is important to the audience, explanation and updates of the GSP development process including an awareness of the public review period, and education of GSP requirements during the implementation phase. In addition, the KGA and the member districts will work with these organizations and agencies to distribute stakeholder surveys, public outreach meeting notices, and educational information via email distribution, social media posts, and printed materials (handouts).

II.C.1 School Districts

School districts within the KGA boundary are also listed in **Table II-4**. While many of the schools receive their water from the cities they are located in, they are an avenue for communicating with stakeholders whose students attend the schools, particularly families within DACs/SDACs.

D. Interested Persons List

SGMA Section 10723.4 "Maintenance of Interested Persons List" states: *"The groundwater sustainability agency shall establish and maintain a list of persons interested in receiving notices regarding plan preparation, meeting announcements, and availability of draft plans, maps, and other relevant documents. Any person may request, in writing, to be placed on the list of interested persons."* In compliance with the SGMA requirement, the Kern Groundwater Authority maintains a list of interested persons, and routinely distributes meeting notices and relevant information to the stakeholders who have requested to be included.

Over 300 individuals have signed up or been added to the Interested Persons List, and the KGA will continue to grow this contact list through the process discussed in **Section V.A.4**.

III. Audience Survey and Mapping

Through ongoing communications and public education and outreach efforts described in **Section V**, primary and secondary stakeholders will have the opportunity to have a voice in the GSP development process. This section discusses in detail the preliminary discussion with primary stakeholders, and implementation of the Stakeholder Survey, which will be a valuable source in collecting feedback from target audiences who have vested interests in how the implementation of the GSP will affect their interests.

A. Stakeholder Survey

III.A.1 Identification of Stakeholder Issues, Interests and Challenges

Stakeholder issues, interests and anticipated challenges are routinely discussed in Board of Directors and Stakeholder Committee meetings. Stakeholder Committee members represent the interests of the secondary stakeholders identified for the KGA (**Table II-2**). Two stakeholder surveys were developed and circulated to solicit input to identify issues, interests and challenges stakeholders are facing and concerned about. **Table III-1** summarizes preliminary responses, which were taken into consideration during the GSP development process and used as a basis for the development of fact sheets and public meeting presentations for secondary stakeholder groups.

Table III-1. Stakeholder Issues, Interests & Challenges

Stakeholder Issues, Interests & Challenges	
Top Concerning Issues Affecting Groundwater:	• Economic impacts (loss of jobs, loss of complete industries, loss of tax revenue due to decrease in land values of fallowed ground) • Overpumping and the subsequent legislation (over-regulation) • Long term quantity and quality • Government regulations and involvement • Fallowing of farmland (loss of production) • Water allocations for domestic use vs. agriculture production with SGMA implementation • Dry wells
Top Concerns of SGMA:	• Economic impacts (loss of jobs, loss of tax revenue due to decrease in land values of fallowed ground) • New regulations (i.e. SGMA and ILRP), and the impacts on investments and livelihoods • Legal rights to groundwater (concerns of unequal representation amongst landowners) • Water usage (surface water vs. groundwater) • Decreased quality of food for California and the United States as a whole • Concerns that the agriculture industry will have to pay for SGMA implementation for all of the beneficial users of groundwater

III.A.2 Survey Questions

Secondary stakeholders needed to have an opportunity to be heard during the GSP development process, in addition to the involvement of the primary stakeholders who represent their interests. The Stakeholder Survey process is a way to gather information from these individuals. The process for conducting the Stakeholder Surveys is discussed in **Section V.A.4**. The final Stakeholder Surveys are included in **Appendix B**, in both English and Spanish.

III.A.2.1 Initial Stakeholder Survey

The initial Stakeholder Survey circulated by KGA and its members was based on survey questions recommended by the DWR, which are listed below. A memorandum with the survey results is included in **Appendix B.** The KGA Board of Directors adjusted the wording on a few of the questions:

1. Are you familiar with Sustainable Groundwater Management Act (SGMA) regulations?
2. Are you currently working on or discussing groundwater management in this region?
3. Do you own or manage/operate land in this region?
4. Do you manage water resources? If yes, what is your role?
5. What is your primary interest in land or water resources management?
6. Do you have concerns about groundwater management? If so, what are they?
7. Do you have requests or recommendations regarding groundwater management? If so, what are they?

The Kern Groundwater Authority incorporated additional questions into the survey to further define the needs and concerns of the users within the GSA boundary:

1. Where are you getting your water supply?: City or Community Water System, Surface, Groundwater, Both Groundwater & Surface Water, Unknown
2. Agriculture & Domestic Well Users: What is your well(s) depth?
3. Agriculture & Domestic Well Users: Has your well(s) ever gone dry? If so, when (month/year)?
4. If you are an Agricultural User, do you: Irrigate, Dry Farm, Graze Livestock, Other
5. How reliable is your current groundwater supply?
6. If you grow crops, do you use irrigation for frost protection?
7. Any other information the Kern Groundwater Authority should be aware of or take into consideration while developing the GSP?

If follow-up questions were needed further into the GSP development phase, a second Stakeholder Survey would have been developed and circulated amongst stakeholders who completed the initial round of surveys.

III.A.2.2 Agriculture-Focused Stakeholder Survey

A second Stakeholder Survey was developed and tailored specifically for agriculture stakeholders. Questions and options from the Ag-Focused Stakeholder Survey are listed below. A memorandum with the survey results is included in **Appendix B**.

1. We have included a map of the Kern Groundwater Authority irrigation and water districts. Please indicate below which districts you have land parcels. (check all that apply)
2. How many total acres do you farm (all land owned, leased and/or managed)?
3. In a typical year, how much of the following crops, animals or land do you manage/own? Options included: fruit trees, nut trees, row crows, seed crops, vegetables, grain, grapes, hay/alfalfa, livestock on pasture/rangeland, dairy (total head), food processor/production, or "other" land use.
4. Which of the following sources of water and management do you typically utilize under the following conditions (dry years, normal years, wet years)? Water source/management options included: irrigation through surface water only, irrigation through groundwater only, irrigation through a mixture of surface and groundwater, wastewater land applied, and no irrigation.
5. If you do use irrigation, which of the following methods of delivery do you use? Option included furrow/flood, sprinklers, drip, microsprinkler, center pivot, and "other."

6. In response to water scarcity, please indicate if you currently use the following practices and your likelihood to use the following practices in the future. Practices listed included: drill more wells, restore existing wells, make existing wells deeper, pump more groundwater than previous years, drip irrigation, water monitoring technology, fallow fields, soil moisture sensors, change to a less water intensive crop, reduce livestock stocking rates, leaf sampling to measure plant-water status, purchase additional water, purchase crop insurance, and "other."
7. Please rate the level of importance these potential groundwater conditions are to you (with "1" being the most concerning, "5" being the least concerning). If you have additional concerns, please indicate them in the "Other" category. Groundwater conditions listed for rating included: lowering of groundwater levels, reduction in groundwater storage, water quality degradation, local subsidence, depletions of surface water, and "other."
8. The following are a list of management options that have been used on the West Coast for water management. Please provide your level of preference for these types of management (ranging from strongly against to strongly support, and not familiar). Management options listed included: individual recharge credits (i.e. winter flooding), water metering, water trading through markets, public program highlighting farmers implementing water saving practices, farmer adoption of water management practices, district investment in conjunctive use infrastructure (i.e. water storage), groundwater replenishment fees, fixed quota for water pumping allocated to each farmer, incentives for water saving practices, moratorium on drilling new wells, permits for drilling new wells, and "other."
9. If groundwater is required in the future, which of the following monitoring methods would you prefer (ranging from strongly not preferred to strongly preferred)? Methods of determining water allocation listed included: well metering, use satellite estimates and ground truth, and use standard crop water requirement indexes.
10. Should disputes arise over SGMA implementation, what is your preferred means of reconciliation (ranging from strongly not preferred to strongly preferred)? Dispute options included: State Water Resources Control Board, groundwater sustainability agency, County Board of Supervisors, Superior Court system, arbitration, and "other."
11. If you have any additional information or feedback regarding SGMA, water management, or farming in Kern County that should be taken into consideration while developing the Groundwater Sustainability Plan, please provide the information below.

III.A.3 Stakeholder Survey Distribution

Printed and online distribution methods for the Stakeholder Survey are described in **Section V.A.3.2** and **Section V.A.4**. Surveys were part of the KGA's Board of Directors agenda every month to review results and discuss submitted stakeholder input. The result summaries from both surveys are include in **Appendix B**.

B. "Lay of the Land" Overview

Results from Stakeholder Surveys will be compiled into a "Lay of the Land Overview" to categorize the feedback received so the technical team can utilize the information during the GSP development phase. This data will be sorted by:

- Type of stakeholder
- Key interests related to groundwater

- Key issues (documented or specific issues of past events)
- Which section of the GSP is this applicable to?

Preliminary results from stakeholder surveys completed in April 2018 are listed in **Table III-1**. These results will be used as a basis for the development of fact sheets and key messages and talking points (**Section IV**).

III.B.1 Types of Stakeholders

Types of stakeholders with the greatest interests in the GSP development and resulting implementation efforts to reach groundwater sustainability include agricultural users, domestic well owners, municipal well operators, public water systems, environmental users, surface water users, and disadvantaged communities.

Stakeholder surveys are geared more specifically for agricultural users, domestic well owners, surface water users, and residents of disadvantaged communities. Representatives of municipal well operators, public water systems and environmental users are integral parts of the primary stakeholder group, and are a more specific, smaller target audience. Surveys will not be tailored specifically for their interests, as information can be more easily gained and addressed through one-on-one conversations and collaborative discussions.

III.B.2 Stakeholder Key Interests Related to Groundwater

The key interests of stakeholders related to groundwater within the KGA boundary include:

- Drinking water
- Domestic, everyday usage
- Agriculture – Farming, ranching (livestock)
- Industrial, food processing, oil production, power generation
- Recreational
- Environmental ecosystem management areas

III.B.3 Key Documented Issues

Several key documented water resources issues have affected, or have the potential to affect, the interests of stakeholders within the Kern Groundwater Authority boundary. As key documented issues arise throughout GSP development, public review and implementation phases, they will be added to this section.

- **Dry Wells –** Several private wells within Kern County have gone dry for various reasons including drought implications and poor infrastructure of the existing wells. Self-Help Enterprises and the County of Kern are working with owners to mitigate the situation.

IV. Messages and Talking Points

Key messages and talking points will be broken down by phases and stakeholder groups, as different factors and issues will affect different groundwater interests. These messages and talking points are also prone to evolve as the GSP is developed, leaving this section open to being amended and finetuned as communication and engagement efforts move forward.

Fact sheets reflecting key messages will be developed and tailored for the specific GSP development, public review and implementation phases, and made available for public education efforts described in **Section V.A.3.2**.

IV.A.1 Key Messages & Talking Points

IV.A.1.1 Universal Key Messages

Universal key messages will be a consistent part of fact sheets and talking points throughout all phases of GSP development, public review and implementation.

- What is SGMA
- Common Uses of Groundwater
- What is the Role of a GSA
- KGA Purpose Statement – Establish and execute a plan that will sustain and manage groundwater within the Kern Sub-basin in a way that is cost-effective, with minimal negative impacts to the beneficial uses and users.

IV.A.1.2 Phase 1: GSA Formation and Coordination

The Phase 1: GSA Formation and Coordination has been completed. During this phase, key messages centered around developing the Board of Directors, official formation of the GSA, and soliciting individuals who represent the interests of all beneficial usages and users of groundwater within the KGA boundary to fill the seats of the Stakeholder Committee.

IV.A.1.3 Phase 2: GSP Preparation and Submission

The first fact sheet will be developed and made available on the KGA website, as well as distributed at public outreach meetings and community organization presentations, and with stakeholder surveys. In addition to the universal key messages, the fact sheet for the GSP development and submission phase will include:

- Timeline of the GSP process
- Industry-related water usage – Common practices and conservation efforts (tailored specific to district stakeholders)
- Industry-related educational statistics for community and economic impacts (tailored specific to district stakeholders)
- Top concerns – Everyday usage/lifestyle impacts, economic impacts, land fallowing
- Direction on providing input/voicing concerns (outreach meetings, stakeholder surveys)
- Importance of imported water for people and economic viability

IV.A.1.4 Phase 3: GSP Review and Evaluation

Once the draft of the KGA's GSP is completed, a second fact sheet will be developed. This fact sheet will also consist of the universal key messages, while the rest of the content will be focused on:

- Timeline of the GSP process
- Main points/overview of the GSP
- Process for public review of GSP draft and providing comments to the KGA
- Additional key messages may be added for this phase.

IV.A.1.5 Phase 4: Implementation and Reporting

Once the KGA's GSP has been submitted to the DWR, the implementation phase will begin, and key messages will be developed with a focus on implementation efforts that affect the secondary stakeholder groups, which will likely result in more than one fact sheet. As with the previous phases, universal key messages will be included.

IV.A.2 Likely Questions or Issues and Responses

The "Likely Questions or Issues" list in **Table IV-1** will evolve through the GSP development, public review and implementation phases. This table will expand as additional questions surface throughout the phases, and responses will be updated as the KGA's GSP is developed and answers are more clearly defined.

Table IV-1. Likely Questions or Issues

Likely Question or Issue	Response	Phase
"Will I have to fallow my land?"	That information has not been determined yet, as we are in the preliminary stages of GSP development.	Phase 1 & 2
"How can I voice my concerns about how SGMA is going to affect me?"	The public is invited to attend Stakeholder Committee meetings and Board of Director meetings to be informed about the progress of GSA and GSP development. Public outreach meetings will be held in 2018, and stakeholder surveys may be completed online via www.kerngwa.com, which will give the public a direct voice into the development of the GSP.	Phase 2
"How much water are we going to be able to pump?"	That information has not been determined yet, as we are in the preliminary stages of GSP development.	Phase 1 & 2
"Are our ag pumps going to be metered? If so, who is going to pay for it?"	That information has not been determined yet, as we are in the preliminary stages of GSP development.	Phase 1 & 2
"What types of management actions and/or projects can improve groundwater conditions?"	That information has not been determined yet, as we are in the preliminary stages of GSP development.	Phase 1 & 2
"Can groundwater management activities improve water challenges in DACs?"	That information has not been determined yet, as we are in the preliminary stages of GSP development.	Phase 1 & 2

V. Venues for Engaging

There are a variety of opportunities, venues and methods for the Kern Groundwater Authority to connect with and engage stakeholders throughout GSA formation, GSP development, GSP review, and GSP implementation phases. Stakeholder groups identified in **Section II** will be engaged in communication efforts as detailed below.

A. Direct Stakeholder Outreach

V.A.1 Collaboration Meetings – Primary Stakeholders

As detailed in **Section II.A**, regular meetings with primary stakeholder groups will be held during their regularly scheduled times. Members of the public and partners from other local agencies are encouraged to attend Board of Directors and Stakeholder Committee meetings to voice their thoughts and concerns throughout the GSP development, public review and implementation phases. Meeting notices and agendas are routinely distributed to the Interested Parties List and are posted on www.kerngwa.com.

Primary stakeholder meetings are held:

- **Board of Directors Meetings –** Fourth Wednesday of every month at 8 a.m. at the Kern County Administration Building, located at 1115 Truxtun Avenue in Bakersfield, California.
- **Stakeholder Committee Meetings –** First Monday of each month at 3:30 p.m. at the Rosedale-Rio Bravo Water Storage District, located at 849 Allen Road in Bakersfield, California.

V.A.2 Educational/Outreach Public Meetings

V.A.2.1 Secondary Stakeholders

Educational/outreach public meetings will be scheduled for Phase 2: GSP Preparation and Submission, Phase 3: GSP Review and Evaluation, and Phase 4: Implementation and Reporting (see **Section VI** for the proposed meeting schedule). These meetings will be important as the GSP will affect all groundwater users within the KGA jurisdiction, and the impact of the SGMA implementation is significant. Stakeholders are already inquiring about the impacts of implementation, while many stakeholders are unaware of the SGMA. Spanish translation services will be available at educational/outreach public meetings.

- **Phase 2: GSP Preparation and Submission –** Public meetings held during Phase 2 were geared towards an overview of SGMA, overview of the GSP development process, public review and implementation (what stakeholders can expect), distribution of stakeholder surveys, and question/answer sessions. This segment of public meetings gave secondary stakeholders an opportunity to be involved in GSP development and share their thoughts and concerns. Possible venues within the KGA are listed in **Table V-1**.
- **Phase 3: GSP Review and Evaluation –** During Phase 3, the draft of the KGA's GSP was distributed for public review. During the public review period, public meetings were held at the same venues as during Phase 2 (**Table V-1**). Presentations included an overview of the GSP and gave stakeholders the opportunity to comment on the draft in a public forum.

- **Phase 4: Implementation & Reporting –** Public meetings will be crucial during Phase 4 and will likely be ongoing to educate stakeholders on implementation requirements and guide them through the steps to compliance and groundwater sustainability.

V.A.2.2 Community Organizations & Others

Community organizations, public agencies and other entities are listed in **Table II-3**, and will be contacted to schedule opportunities to present at their respective meetings throughout the GSP development phase. Presentations will include an overview on SGMA and why it is important to them, an explanation of the GSP development process, including an awareness of the public review period. In addition, the KGA will work with these organizations and agencies to distribute stakeholder surveys, public outreach meeting notices, and educational information via email distribution, social media posts, and printed materials.

V.A.2.3 Meeting Notification Process

Stakeholders will be invited to public meetings through distribution of meeting notices to KGA's district/member agency distribution lists, community organizations' contact lists, and press releases and public service announcements. Press releases will be distributed to local media outlets announcing the meeting dates, times and locations. Local community organizations, such as the Kern County Farm Bureau and Self-Help Enterprises, will be asked to distribute meeting notices via email blasts to their membership/contact lists. When implementation begins, and specific stakeholders need to be informed of upcoming compliance requirements, addresses of property owners within the KGA boundary can be obtained through the County of Kern. Postcards are most cost effective for mailing and can later be used to expedite meeting check-in and track attendance, if required during the implementation phases.

V.A.2.4 Ideal Venues

Venue locations will need to have a capacity to hold large audiences. The location list in **Table V-1** will be updated with additional information and other venue possibilities as meetings are scheduled, and venue availability and rental price is confirmed. KGA will work with disadvantaged communities and community organizations such as Self-Help Enterprises and Leadership Counsel for Justice & Accountability to hold outreach meetings at convenient times and locations within the DACs/SDACs.

Table V-1. Potential Public Meeting Venues & Locations

Venue	Location
Kern Ag Pavilion, Kern High School District	Bakersfield
Wasco Elk's Lodge	Wasco, Shafter
Shafter Veteran's Building	Wasco, Shafter
Arvin Veteran's Hall	Arvin

V.A.3 Printed Communication

V.A.3.1 Branding

Branding is defined as the process of creating distinctive and durable perceptions in the minds of a target audience. A brand is a specific look – a persistent, consistent, unique identity for an organization, making it easy for an audience to identify an organization through its consistent and frequent use of branding. The KGA has developed a brand that will be incorporated in all forms of communication and engagement with the public, which includes consistent usage of the official logo, fonts and colors. The KGA Branding Summary is included in **Appendix A**.

V.A.3.2 Printed Materials

Printed materials will incorporate the visual imagery established through branding efforts and will be tailored for specific means of communication throughout the phases of GSP development, public review and implementation. All printed materials will be translated into Spanish.

- **Fliers –** Fliers will be designed and tailored for secondary stakeholder audiences and will encompass infographics and text with key messages that are pertinent for that phase of GSP development. Distribution will be via website posting, direct mail, email, and direct distribution as handouts at schools, community organization meetings, KGA outreach meetings, or door-to-door. For outreach to DACs/SDACs, any fliers created will be available in both English and Spanish languages.
- **Fact Sheets –** Fact sheets will be developed and updated for each of the GSP phases and will include a section with an overview of SGMA facts, and development, public review and implementation timelines. Fact sheets will be available for download at www.kerngwa.com, distributed at public meetings and community organizations/entities meetings, and emailed to the Interested Parties List and other community organizations' email distribution lists. Fact sheets will be available in both English and Spanish languages.
- **Letter Correspondence –** When letter correspondence is necessary, particularly during the public review and implementation phases, letters will be distributed via email or direct mail. Letters will include pertinent facts and explanations that need to be communicated to specific stakeholder groups.
- **Presentation Materials –** Power Point presentations will be utilized at educational/outreach public meetings. If a Power Point isn't possible to display for a meeting, display boards printed at 24-inch x 36-inch or larger in size will be used and set up on easels. Handouts of presentations and smaller versions of display boards can be distributed to stakeholders in attendance, emailed to the Interested Parties list, and posted on www.kerngwa.com for access by stakeholders as a recap of the meeting.
- **Stakeholder Surveys –** Digital creation and distribution of Stakeholder Surveys is discussed in **Section V.A.4**. For stakeholders who do not have access to the Internet to complete Stakeholder Surveys online, hard copies were available at educational/outreach public meetings and were distributed via direct mail upon request. Water districts distributed surveys in the monthly invoices sent to their customers, and via email blasts sent to their members. A Spanish version was also created for distribution within DACs/SDACs. As hard copy results are received, they were added to the Google Form version of the Stakeholder Survey in-house to efficiently tabulate survey results.
- **Newsletter –** Annual or bi-annual newsletters will be created during the GSP implementation phase to inform stakeholders of compliance requirements and groundwater sustainability updates, opportunities and programs within the Kern sub-basin. The newsletter will be distributed to those on the Interested Parties List and will be finetuned to include others who have specific roles and compliance requirements during GSP implementation.
- **Other Printed Materials –** Other printed materials may be needed to be developed during the GSP development, public review and implementation phases. These documents will also be available in both English and Spanish versions.

V.A.4 Digital Communication

Digital communication outlets will also be designed to incorporate KGA's branding and will be a significant mode of communication through the GSP development, public review and implementation phases.

- **Website –** Public meeting notices, agendas and minutes of the Board of Directors and Stakeholder Committee meetings are posted on the KGA's website, www.kerngwa.com. This website serves as an integral resource for primary, secondary and other community stakeholders within the KGA's boundary. Electronic files of printed materials, presentations and other educational resources, and a direct link to the Stakeholder Survey (English and Spanish versions) are accessible via the website.

  As Fact Sheets are created during the development, public review and implementation phases, a webpage with the same content will be incorporated into the current website sitemap and will be updated as the Fact Sheet is updated/redesigned. This will serve as a way for stakeholders to easily educate themselves on the GSP process and phases.

- **Stakeholder Surveys –** Stakeholder surveys were discussed in **Section III.A**, and were used for the deliberate polling of secondary stakeholders to give them a direct voice in the GSP development phase. Stakeholder surveys were created via Google Forms, and links to English and Spanish versions of the survey are posted on the www.kerngwa.com website and were utilized in email blasts to the Interested Parties list. Google Forms is free of charge to use, and survey results were easily exported into Excel to sort through for the KGA's member agencies and districts. The distribution process of stakeholder hard copies is described in **Section V.A.3.2**, and a copy of the final survey (English and Spanish versions) is included in **Appendix B**.

- **Email Distribution –** As required by SGMA 10723.4 "Maintenance of Interested Persons List," KGA maintains a contact list and regularly distribute emails to those who have expressed interest in the GSA's progress. These emails consist of meeting notices and other documents that are pertinent to the KGA and communication efforts. This process will continue.

  As outreach meetings are held, the email distribution list will grow through direct contact with stakeholders. As this list expands, a Constant Contact account will be established to more easily send out email blasts of news, digital versions of the newsletter, and updates to relevant to the interests of primary and secondary stakeholders within the KGA. A "Stay Informed About the Kern Groundwater Authority" form is posted on www.kerngwa.com/contact-us.html so website visitors can sign up for the email distribution list directly.

  Email blasts for meeting notices, stakeholder surveys, public review notices, and other crucial information will be coordinated with community organizations and stakeholder groups by utilizing their distribution lists. Examples of these organizations are Kern County Farm Bureau, Self-Help Enterprises, chambers of commerce, and irrigation districts within the KGA boundary. A complete working list of organizations are listed in **Table II-3**.

- **Social Media –** Coordination for social media posts announcing upcoming meetings, stakeholder surveys, public review notices, and other crucial information will be coordinated with public agencies, community organizations and stakeholder groups who operate social media sites through Facebook, Instagram, Twitter, and others. A working list of these organizations and the number of followers are listed in **Table V-2**.

Table V-2. Public Agencies & Community Organizations Social Media Outlets

Community Organization	Social Media Outlet/URL	Number of Followers
Arvin Chamber of Commerce	Facebook: @ArvinChamber	101

V.A.5 Media Coverage

Press releases and public service announcements (**PSA**) will be written and distributed to the media list of local newspaper publications, and television/radio stations. These press releases and PSAs will focus on notification of public engagement opportunities such as targeted stakeholder meetings, stakeholder survey circulation, public review/comment processes and opportunities, and GSP implementation.

Direct story pitches will be made when necessary via direct communication with news outlets throughout GSP development and implementation phases. These story pitches will focus on GSP development status

updates, how public input is being used, and general overview of SGMA and how it will affect stakeholders (residents and industry) within the KGA boundary.

Table V-3. Kern County Media Outlets

Media Outlet	Coverage Area
Arvin Tiller	Arvin-Lamont
Bakersfield Californian	Bakersfield
Kern Business Journal	Kern County
Ridgecrest Daily Independent	Ridgecrest
Taft Independent	Taft
Taft Midway Driller	Taft
The Shafter Press	Shafter, Kern County

VI. Implementation Timeline

The timeline for implementing the KGA's Communication & Engagement Plan will be broken down by phase:

- Phase 1: GSA Formation and Coordination – 2015 through 2017 (**Figure VI-1**)
- Phase 2: GSP Preparation and Submission – 2017 through 2019 (**Figure VI-2**)
- Phase 3: GSP Review and Evaluation – 2019 through 2020 (**Figure VI-3)**
- Phase 4: Implementation and Reporting – 2020 and ongoing

The timelines for Phase 1, Phase 2 and Phase are complete, but the timeline for Phase 4 will be developed following as implementation progresses.

Timeline Key:

Deadlines & KGA Interaction with DWR | Kern Groundwater Authority Board Meetings | Kern Groundwater Authority Stakeholder-Specific Outreach

September 2014: Sustainable Groundwater Management Act (SGMA) signed into law.

Phase 1: GSA Formation and Coordination

2015

January	February	March	April	May	June	July	August	September	October	November	December
Jan. 21, 2015: KGA Board of Directors Meeting	**Feb. 25, 2015:** KGA Board of Directors Meeting	**March 25, 2015:** KGA Board of Directors Meeting	**April 22, 2015:** KGA Board of Directors Meeting	**May 27, 2015:** KGA Board of Directors Meeting	**June 24, 2015:** KGA Board of Directors Meeting		**Aug. 26, 2015:** KGA Board of Directors Meeting	**Sept. 23, 2015:** KGA Board of Directors Meeting	**Oct. 28, 2015:** KGA Board of Directors Meeting	**Nov. 16, 2015:** KGA Board of Directors Meeting	**Dec. 21, 2015:** KGA Board of Directors Meeting

2016

June 30, 2016: DWR adopts regulations for evaluating GSPs.

January	February	March	April	May	June	July	August	September	October	November	December
Jan. 27, 2016: KGA Board of Directors Meeting	**Feb. 24, 2016:** KGA Board of Directors Meeting	**March 21, 2016:** KGA Special Board of Directors Meeting	**April 27, 2016:** KGA Board of Directors Meeting	**May 18, 2016:** KGA Board of Directors Meeting	**June 29, 2016:** KGA Special Board of Directors Meeting		**Aug. 24, 2016:** KGA Board of Directors Meeting	**Sept. 28, 2016:** KGA Board of Directors Meeting	**Oct. 24, 2016:** KGA Board of Directors Meeting **Oct. 24, 2016:** SGMA Stakeholder Outreach Workshop, Kern Ag Pavilion	**Nov. 14, 2016:** KGA Special Board of Directors Meeting **Nov. 1, 2016:** SGMA Stakeholder Outreach Workshop, Kern Co. Water Agency **Nov. 15, 2016:** SGMA Stakeholder Outreach Workshop, Kern Ag Pavilion **Nov. 28, 2016:** SGMA Stakeholder Outreach Workshop, Kern Co. Admin Bldg.	**Dec. 19 2016:** KGA Board of Directors Meeting **Dec. 5, 2016:** SGMA Stakeholder Outreach Workshop, Kern Ag Pavilion **Dec. 20, 2016:** SGMA Stakeholder Outreach Workshop, Kern Co. Admin Bldg.

2017

April 26, 2017: KGA elected to become official GSA.

January	February	March	April	May	June	July	August	September	October	November	December
Jan. 25, 2017: KGA Board of Directors Meeting	**Feb. 22, 2017:** KGA Special Board of Directors Meeting	**March 22, 2017:** KGA Special Board of Directors Meeting	**April 26, 2017:** KGA Board of Directors Meeting	**May 15, 2017:** KGA Special Board of Directors Meeting	**June 19, 2017:** KGA Special Board of Directors Meeting	**July 19, 2017:** KGA Board of Directors Meeting	**Aug. 23, 2017:** KGA Board of Directors Meeting	**Sept. 27, 2017:** KGA Board of Directors Meeting	**Oct. 25, 2017:** KGA Board of Directors Meeting	**Nov. 16, 2017:** KGA Board of Directors Meeting	**Dec. 20, 2017:** KGA Board of Directors Meeting

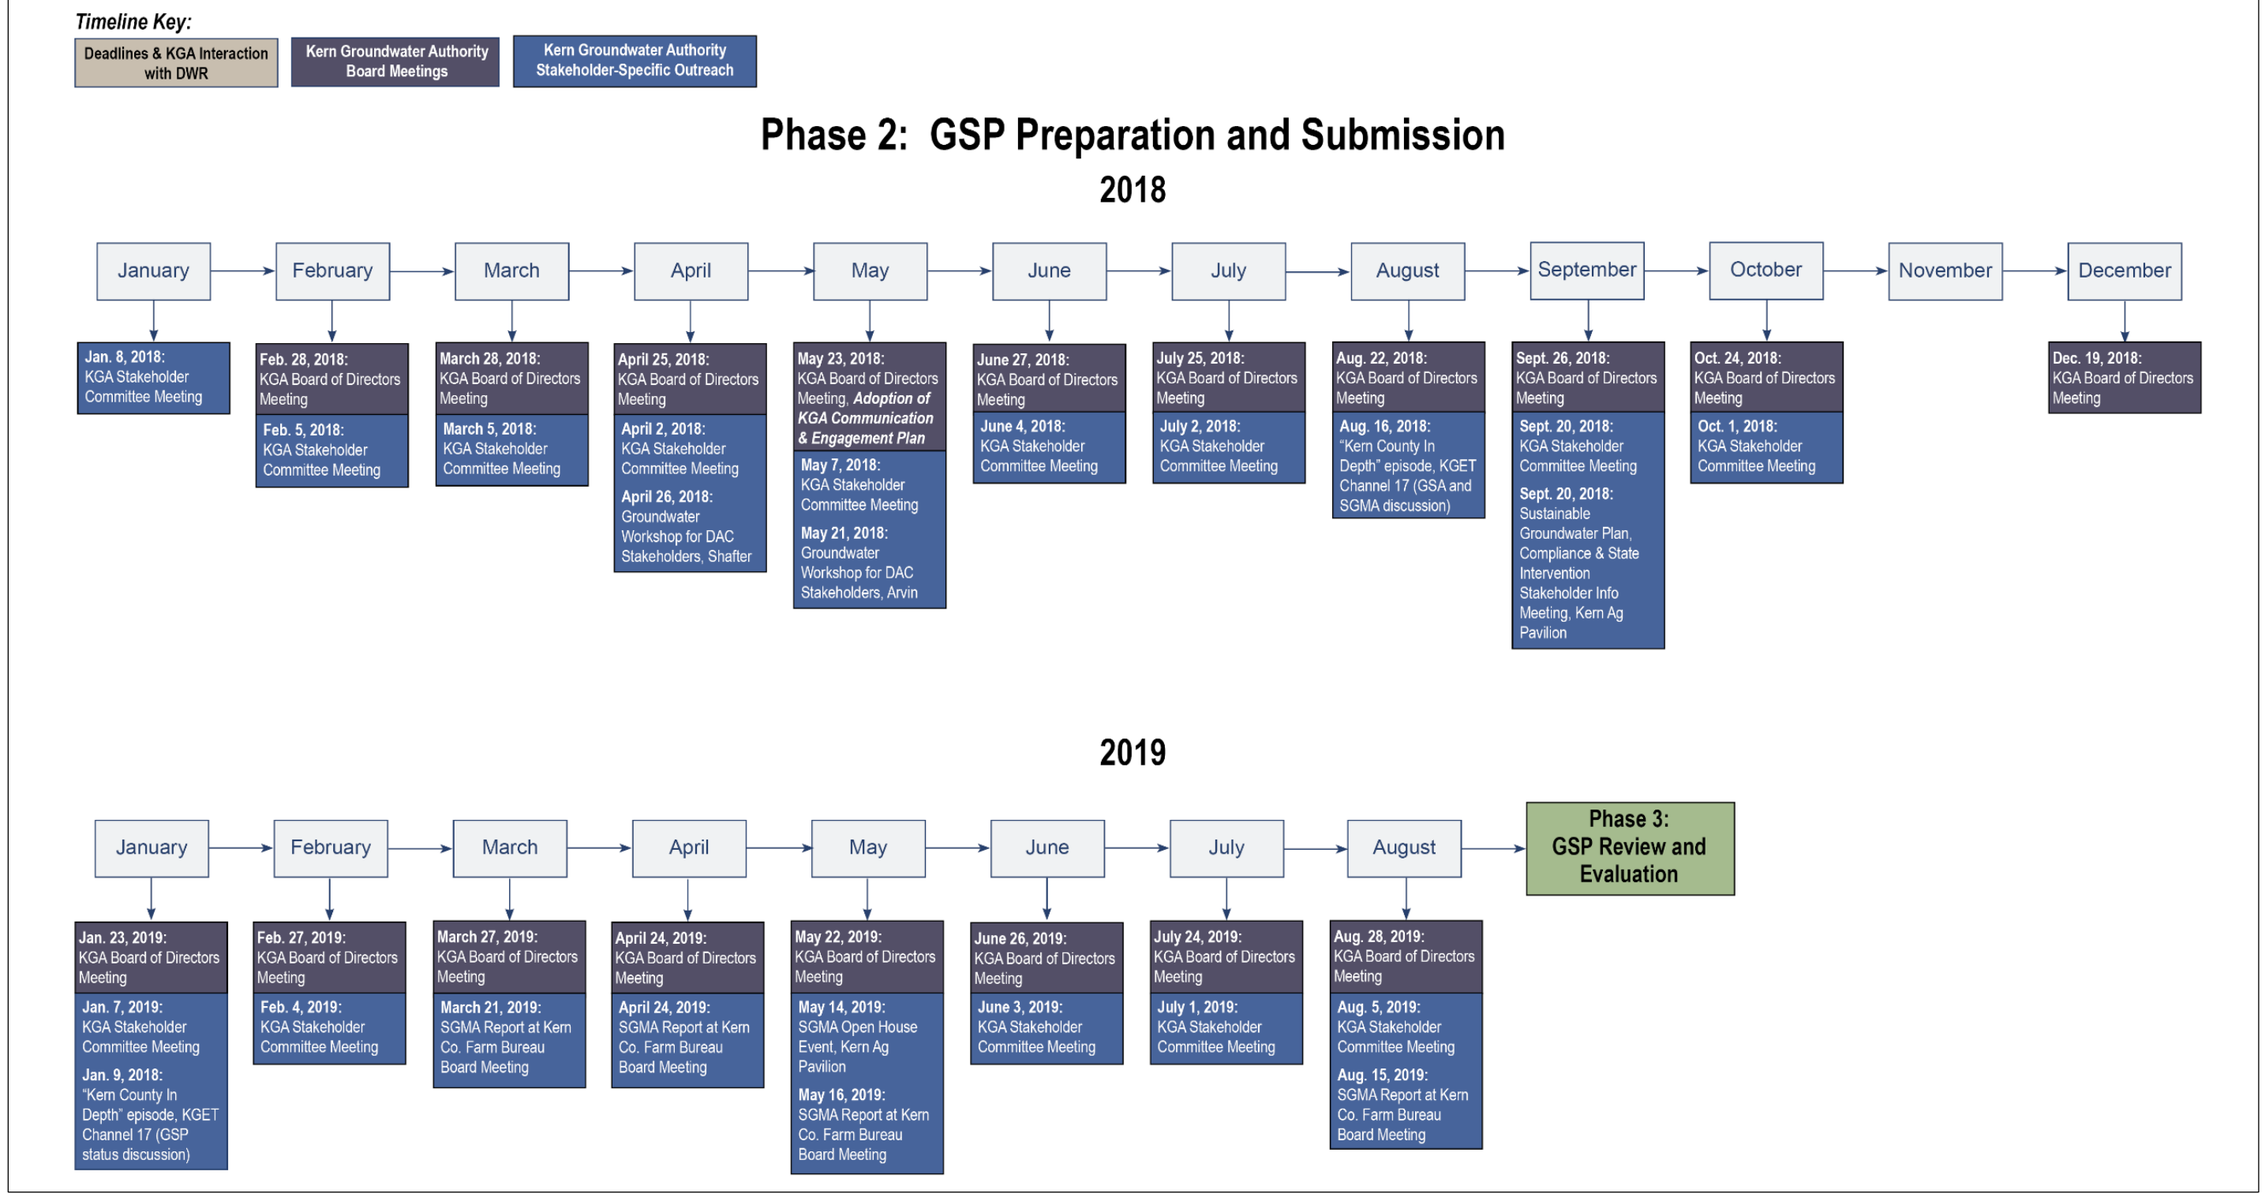

Figure VI-2. Kern Groundwater Authority's Communication & Engagement Timeline – Phase 2: GSP Preparation and Submission, and Phase 3: GSP Review and Evaluation

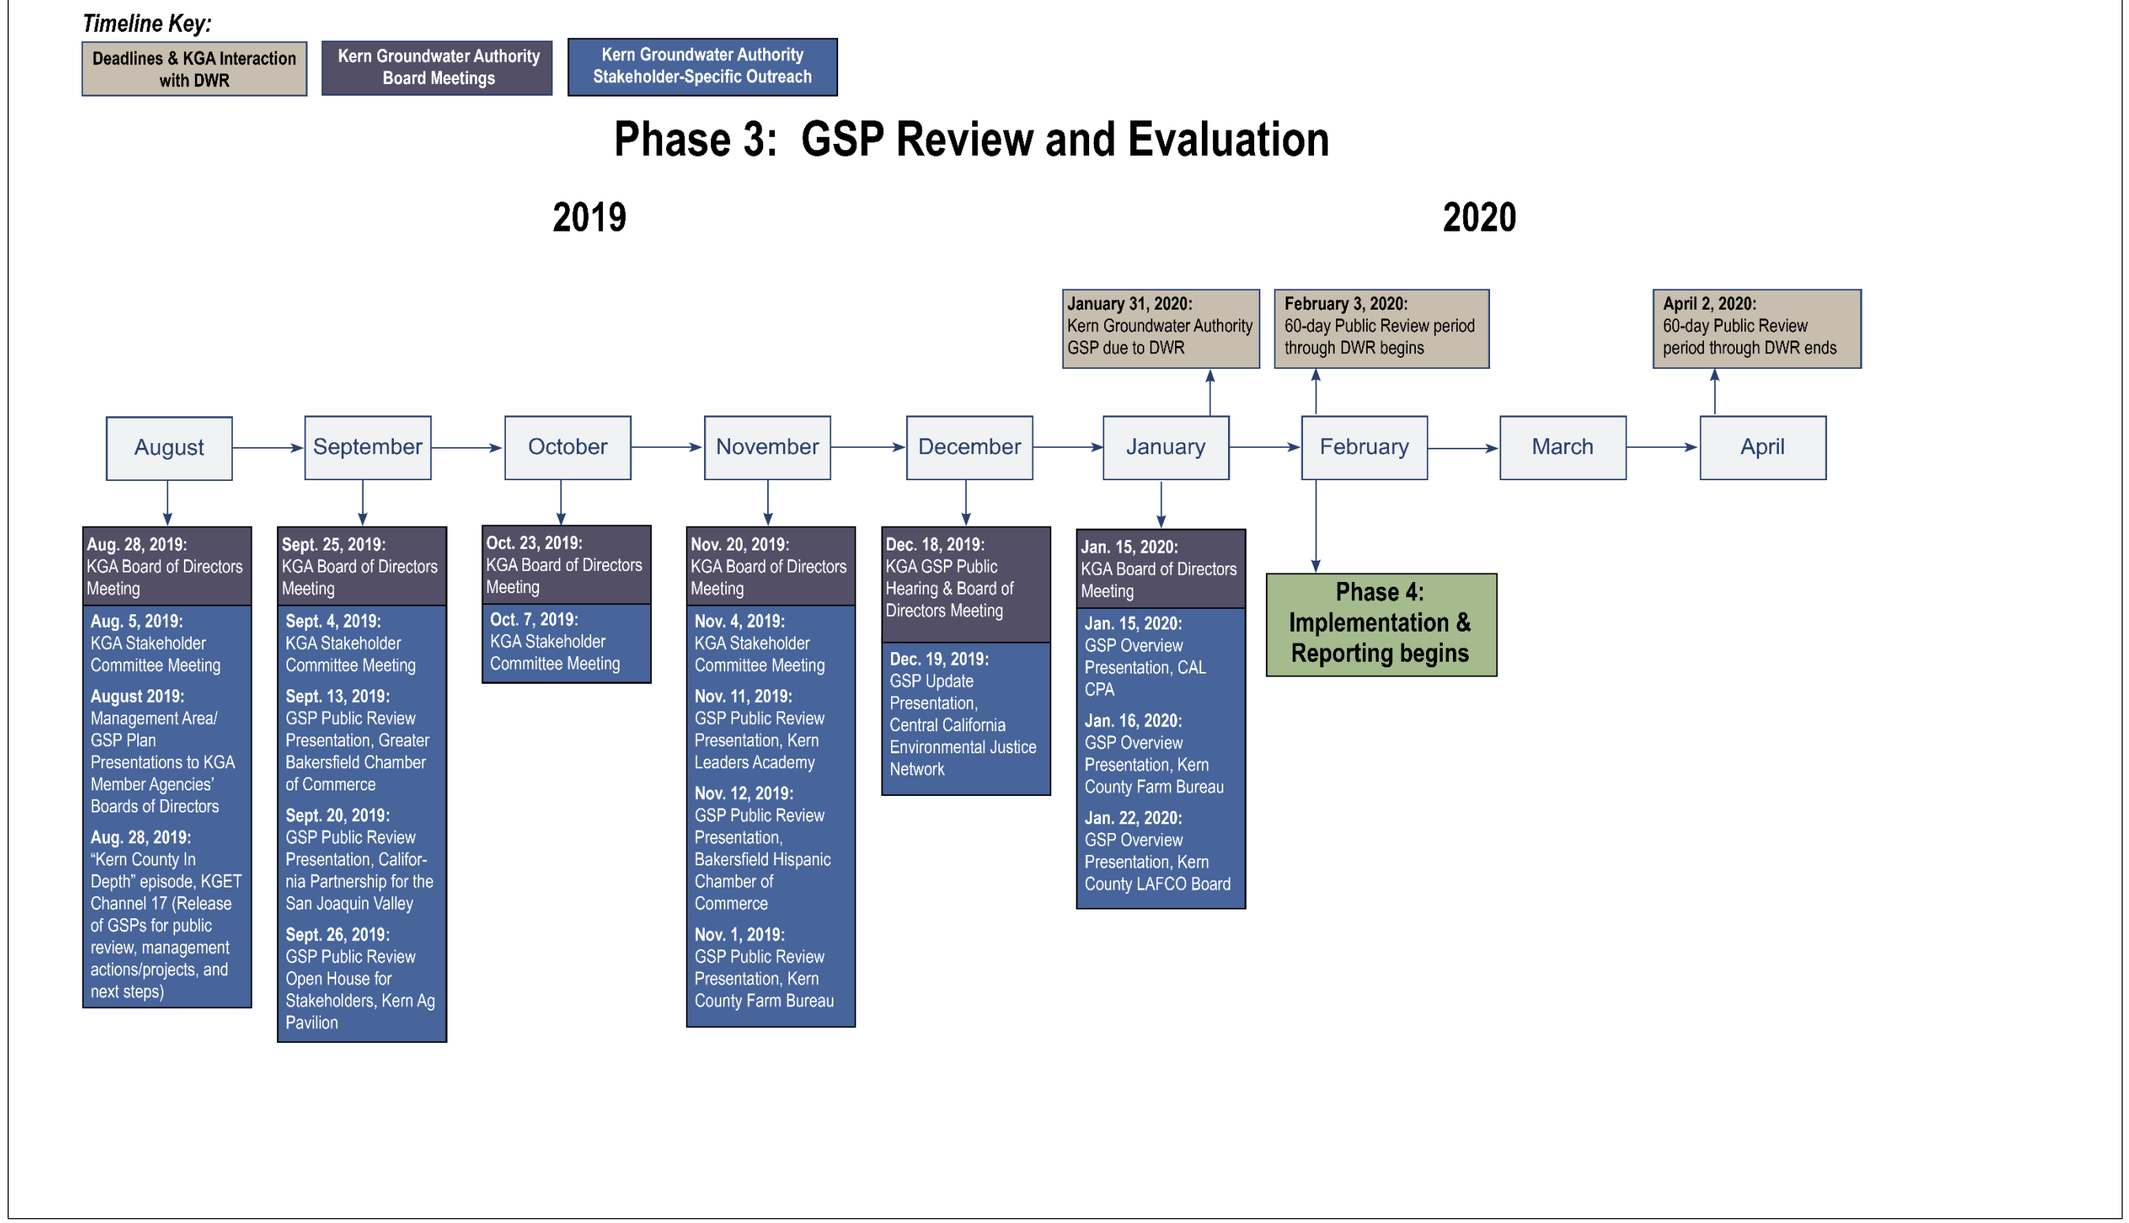

Figure VI-3. Kern Groundwater Authority's Communication & Engagement Timeline – Phase 3: GSP Review and Evaluation

VII. Evaluation and Assessment

A. Evaluation and Assessment Process

Having an established "checks and balances" process is essential in keeping public outreach goals on target. SGMA and the resulting GSP will affect everyone within the sub-basin, and outreach efforts must be all-encompassing. To evaluate and assess how outreach efforts are performing as compared to the goals and objectives detailed in the Communication & Engagement Plan, the Kern Groundwater Authority has established a process:

VII.A.1 Monthly Outreach Reports to Planning Manager

The Public Outreach Coordinator will provide monthly updates to the Planning Manager and Board of Directors (through board meeting attendance or memorandums). These updates will include, but will not be limited to:

- Status of upcoming outreach events, and recaps of past outreach events
- Results and status updates of stakeholder surveys
- Communication & Engagement Plan milestone updates/revisions
- Review/input and approval of printed materials (fliers, fact sheets, talking points, etc.)

VII.A.2 Quarterly Milestone Review

Once per quarter, a more in-depth discussion with the Stakeholder Committee and/or Board of Directors for feedback regarding communication and engagement efforts for the stakeholder groups the specifically represents. These discussions will cover:

- What has worked well?
- What hasn't worked as planned or could be finetuned for more effective results?
- Lessons learned
- Outreach needs that should be added to the implementation timeline
- Next steps

Following the quarterly review with the Stakeholder Committee and/or Board of Directors, the KGA's Planning Manager and Public Outreach Coordinator will meet to review public outreach status updates of tasks outlined in the adopted Communication & Engagement Plan, budget analysis, and feedback from the Board of Directors and/or Stakeholder Committee. Milestone updates will also be discussed, as necessary, to keep up to date with GSP development and implementation phases, and then taken to the Stakeholder Committee for discussion and subsequent approval.

Stakeholder Surveys

KERN GROUNDWATER AUTHORITY

Stakeholder Survey

Date: _____

Stakeholder Type (check all that apply):

☐	Agricultural User	☐	Domestic Well Owner/User	☐	Municipal Well Operator
☐	Public Water Systems	☐	Local Land Use Planning Agency	☐	Environmental User
☐	Surface Water User	☐	Native American Tribe	☐	Disadvantaged/Rural Community Resident
☐	City Resident	☐	Food Processor	☐	Industrial User/Oil Producer
☐	Entity monitoring and reporting groundwater elevations in all or part of the groundwater basin				

Note: Please complete your name and contact information if you'd like to be added to the GSA's email and mailing list for future updates and information regarding Sustainable Groundwater Management Act (SGMA) and the Kern Groundwater Authority.

Name: _____

Address: _____

City: _____ **State:** _____ **Zip:** _____

Email: _____ **Telephone:** _____

1. **Are you familiar with Sustainable Groundwater Management Act (SGMA) regulations?** ☐ Yes ☐ No

2. **Are you currently working on or discussing groundwater management in this region?** ☐ Yes ☐ No

3. **Do you own or manage/operate land in this region?** ☐ Yes ☐ No

4. **Where are you getting your water supply?**
   ☐ City or Community Water System ☐ Surface ☐ Groundwater
   ☐ Both Groundwater & Surface Water ☐ Unknown

5. **Agriculture & Domestic Well Users: What is your well(s) depth?** _____

6. **Agriculture & Domestic Well Users: Has your well(s) ever gone dry?** ☐ Yes ☐ No
   If yes, when (month/year)? _____

7. **If you are an Agricultural User, do you:** ☐ Irrigate ☐ Dry Farm ☐ Graze Livestock
   ☐ Other: _____

8. **How reliable is your current groundwater supply?** _____

   _____

   _____

9. **If you grow crops, do you use irrigation for frost protection?** ☐ Yes ☐ No

10. **Do you manage water resources?** ☐ Yes ☐ No
    If yes, what is your role? _____

11. What is your primary interest in land or water resources management? _____

12. Do you have concerns about groundwater management? ☐ Yes ☐ No

If so, what are they? _____

13. Do you have requests or recommendations regarding groundwater management? ☐ Yes ☐ No

If so, what are they? _____

14. Any other information the Kern Groundwater Authority should be aware of or take into consideration while developing the Groundwater Sustainability Plan (GSP)?

Please return completed surveys to the Kern Groundwater Authority by emailing tbarton@ppeng.com, faxing to (661) 479-7172, or mail to Kern Groundwater Authority, 1800 30th Street, Suite 280, Bakersfield, CA 93301.
Stakeholder Surveys may also be completed online by visiting www.kerngwa.com.

KERN GROUNDWATER AUTHORITY

Encuesta de Partes Interesadas

Fecha: _____

Tipo de Interesado (marque todas que apliquen):

☐	Usuario agrícola	☐	Propietario / usuario de pozo doméstico	☐	Operador municipal de pozos
☐	Sistema de agua público	☐	Agencia local de planificación del uso de la tierra	☐	Usuario ambiental
☐	Usuario de agua superficial	☐	Tribu native americana	☐	Residente de comunidad desventajada/ rural
☐	Residente de la ciudad	☐	Procesador de alimentos	☐	Usuario industrial/Productor de petróleo
☐	Entidad que monitorea y reporta elevaciones de aguas subterráneas en toda o parte de la cuenca de agua subterránea				

Nota: Por favor complete su nombre y la información de contacto si desea ser agregado a la lista de correo electrónico de la GSA y lista de correo para futuras actualizaciones e información sobre la Ley del Manejo Sostenible del Agua Subterránea (SGMA) y la Autoridad de Aguas Subterráneas de Kern (KGA GSA).

Nombre: _____

Dirección Postal: _____

Ciudad: _____ **Estado:** _____ **Código postal:** _____

Correo Electrónico: _____ **Teléfono:** _____

1. **¿Está usted familiarizado con las regulaciones de la ley de Manejo Sostenible del Agua Subterránea (SGMA)?** ☐ Sí ☐ No

2. **¿Está usted actualmente involucrado en actividades o discusiones Sobre el manejo de aguas subterráneas en esta regíon?** ☐ Sí ☐ No

3. **¿Usted es propietario o administra/opera tierra en esta región?** ☐ Sí ☐ No

4. **¿De dónde recibe su suministro de agua?**
   ☐ Sistema de agua de la ciudad o la comunidad ☐ Superficie ☐ Agua subterránea
   ☐ Agua subterránea y superficial ☐ No sé

5. **Usuarios de pozos Agrícolas Y Domésticos: ¿Cuál es la profundidad de su pozo(s)?** _____

6. **Usuarios de poza Agrícolas Y Doméesticos: ¿Alguna vez se ha secado su pozo(s)?** ☐ Sí ☐ No
   ¿Si la respuesta es sí, cuándo (mes/año)? _____

7. **Si eres un usuario agrícola, qual haces:** ☐ Irrigar ☐ Granja seca ☐ Pastoreo
   ☐ Otro: _____

8. **¿Qué tan seguro es su suministro de agua subterránea, corrientemente ?** _____

   _____

   _____

9. **Si cultiva, ¿utiliza el riego para la protección contra las heladas?** ☐ Sí ☐ No

10. **¿Usted administra recursos de agua?** ☐ Sí ☐ No
    Si la respuesta es sí, ¿cuál es su papel? _____

11. ¿Cuál es su interés principal en el manejo de recursos de agua o tierra? _____

12. ¿Tiene preocupaciones acerca el manejo de las aguas subterráneas? ☐ Sí ☐ No

Si la respuesta es sí, ¿cuáles son? _____

13. ¿Tiene used alguna recomendación sobre el manejo de agua subterráneas? ☐ Sí ☐ No

Si la respuesta es sí, ¿cuáles son? _____

14. ¿Tiene used alguna otra información pertinente que debería tener en cuenta el Kern Groundwater Authority GSA para desarroler el Plan de Sostenibilidad de Aguas Subterránease (GSP)?

Por favor regrese la encuesta terminada al Kern Groundwater Authority GSA enviando un corre electrónico a tbarton@ppeng.com , manduando un fax al (661) 478-7172, o por correo a Kern Groundwater Authority GSA, 1800 30th Street, Suite 280, Bakersfield, CA 93301.

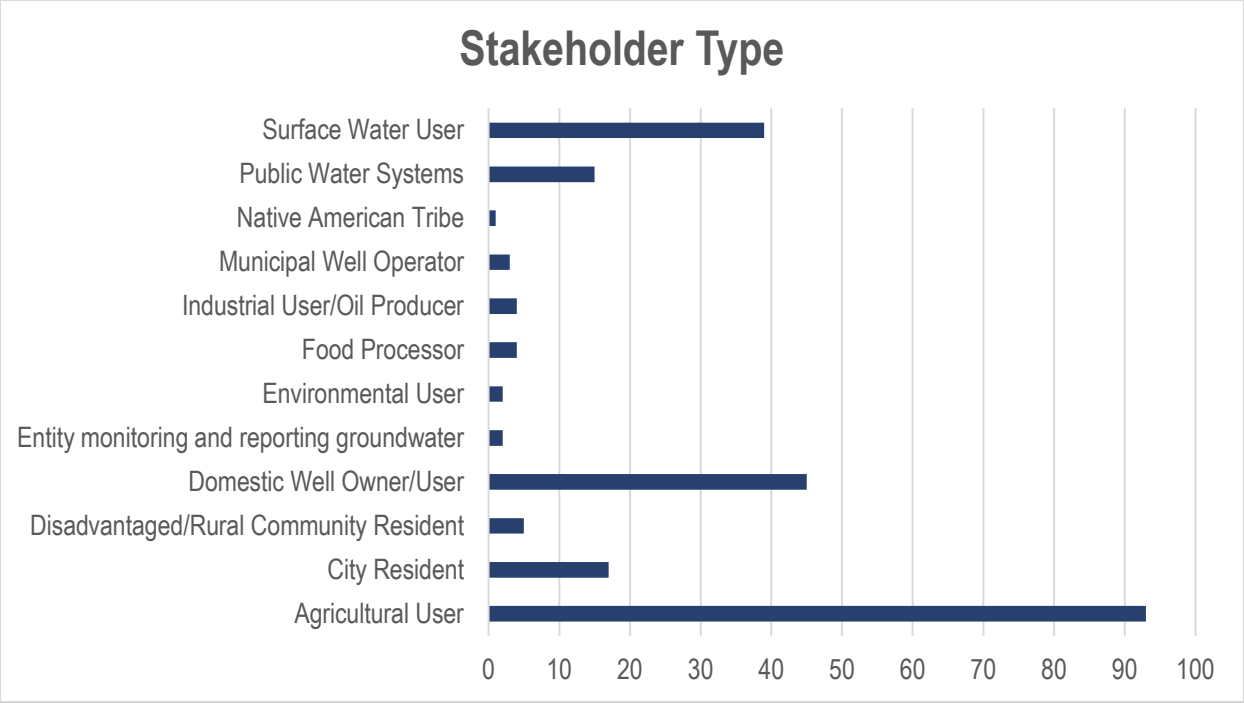
Memorandum

To:	Kern Groundwater Authority Board of Directors
From:	Trilby Barton, Public Outreach Coordinator, Provost & Pritchard Consulting Group
Subject:	Stakeholder Survey Results – Final Report
Date:	December 12, 2018



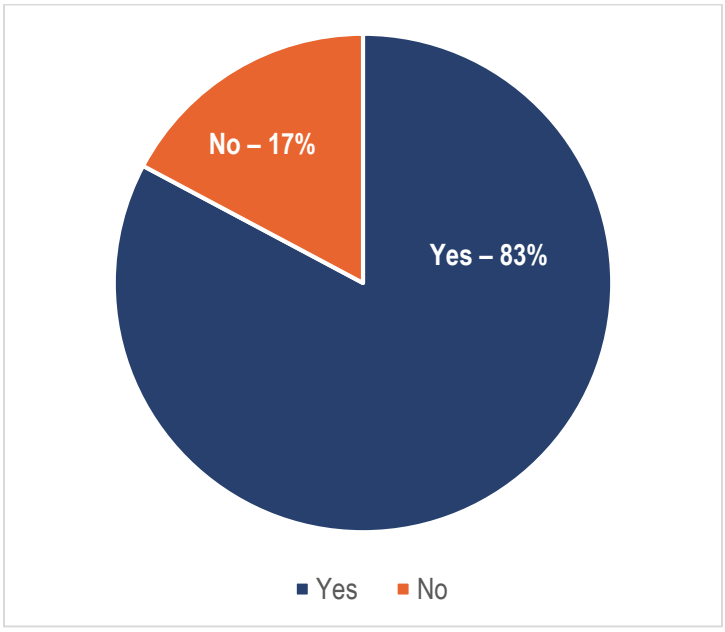
Hard copies and the link to the online version of the Kern Groundwater Authority's Stakeholder Survey (in both English and Spanish) were circulated throughout Kern County. For the final report, the data was sorted through, and duplicate entries were removed. **Kern Groundwater Authority received a total of 123 responses**.

Reponses were received from nearly all stakeholder types identified in the Kern Groundwater Authority's Communication & Engagement Plan. Most responses were received from agricultural users, with domestic well owner/users and surface water users, and city residents following.

Overall, stakeholders are primarily concerned about the economic impacts that SGMA will have on the agriculture and industrial groundwater users within the Kern Groundwater Authority boundaries.

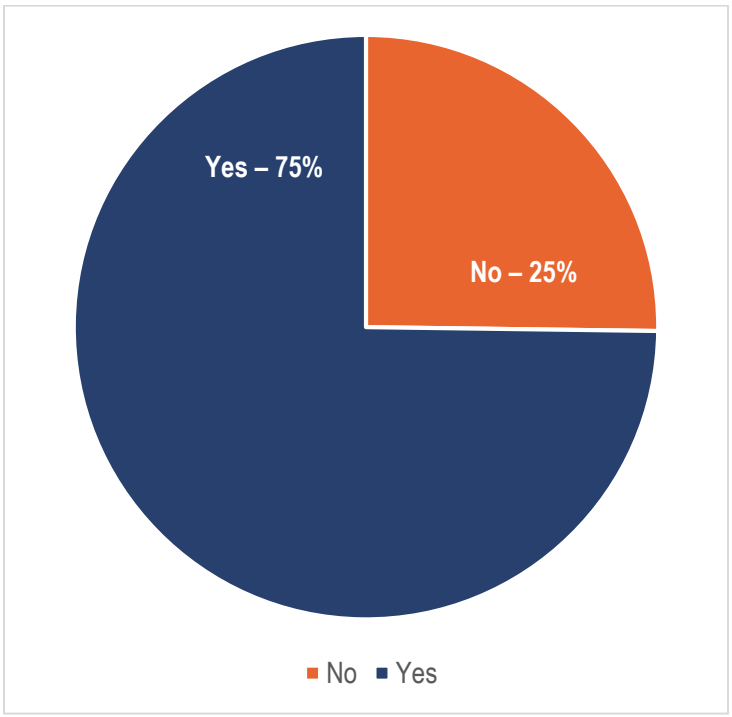
This memo summarizes the data and comments received from the stakeholders who completed the survey.

Final Report of Kern Groundwater Authority Stakeholder Survey Results



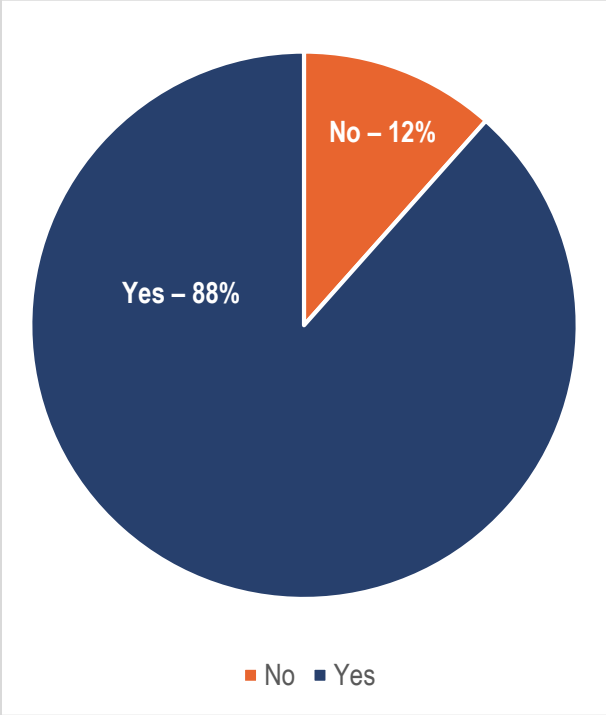
Stakeholder Type Summary:

Agricultural User	93	Domestic Well Owner/User	45
Municipal Well Operator	3	Public Water Systems	15
Local Land Use Planning Agency	0	Environmental User	2
Surface Water User	39	Native American Tribe	1
Disadvantaged/Rural Community Resident	5	City Resident	17
Food Processor	4	Industrial User/Oil Producer	4
Entity monitoring and reporting groundwater elevations in all or part of the groundwater basin			2

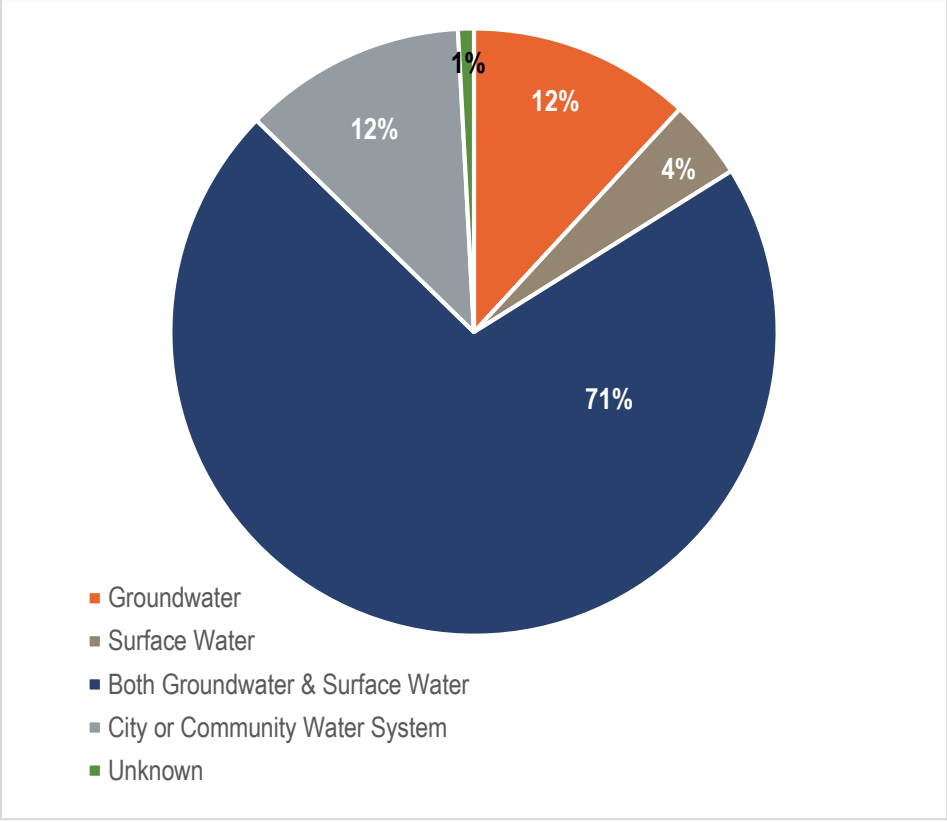


1. Are you familiar with Sustainable Groundwater Management Act (SGMA) regulations?

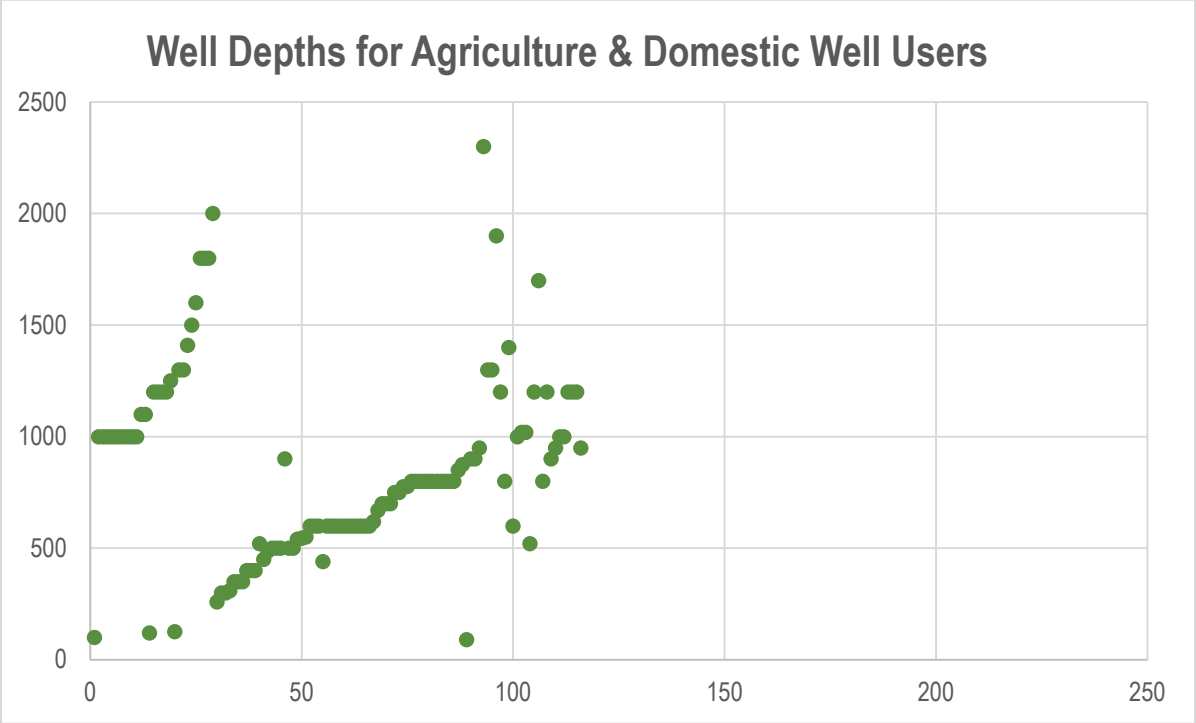
(122 responses)



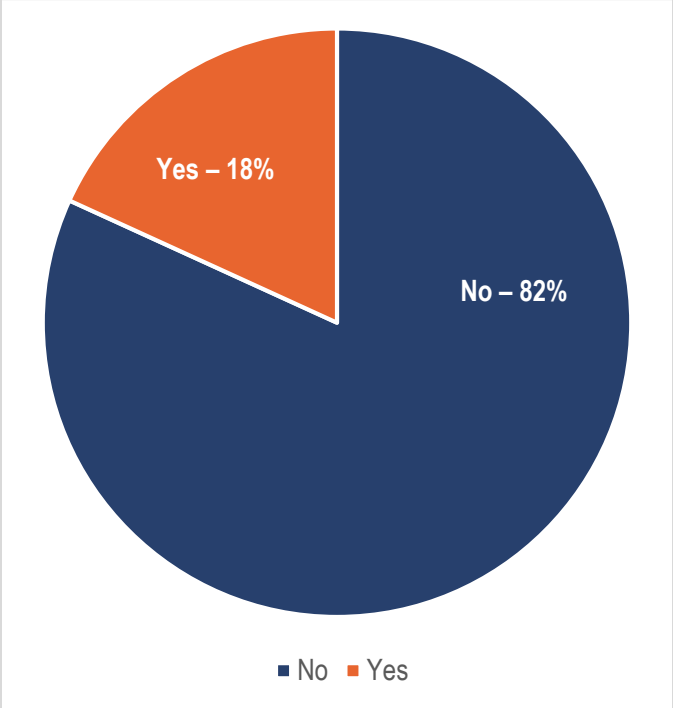
2. Are you currently working on or discussing groundwater management in this region?



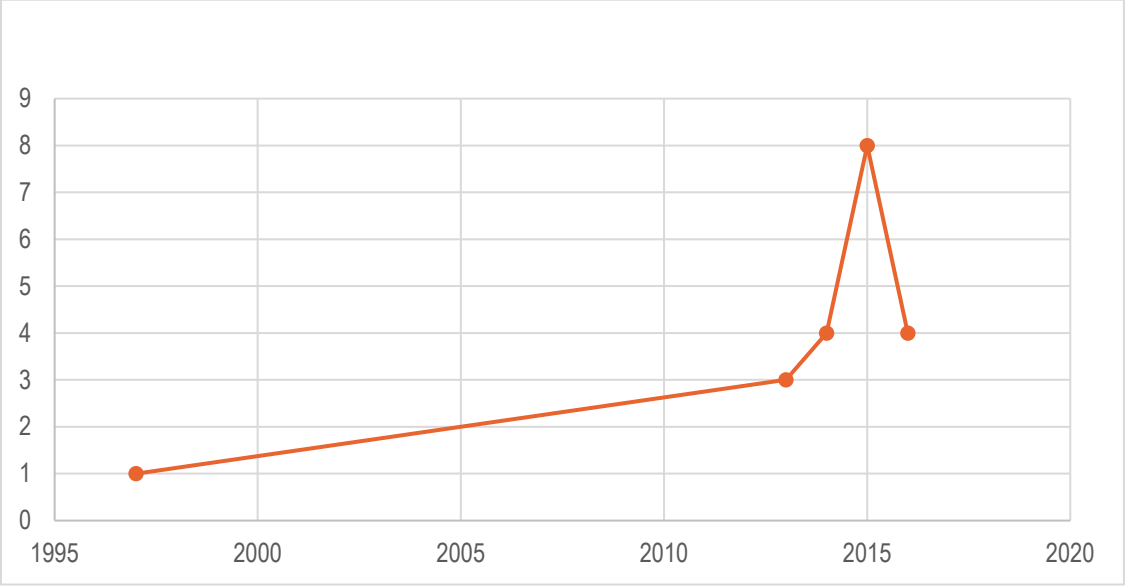
(119 responses)



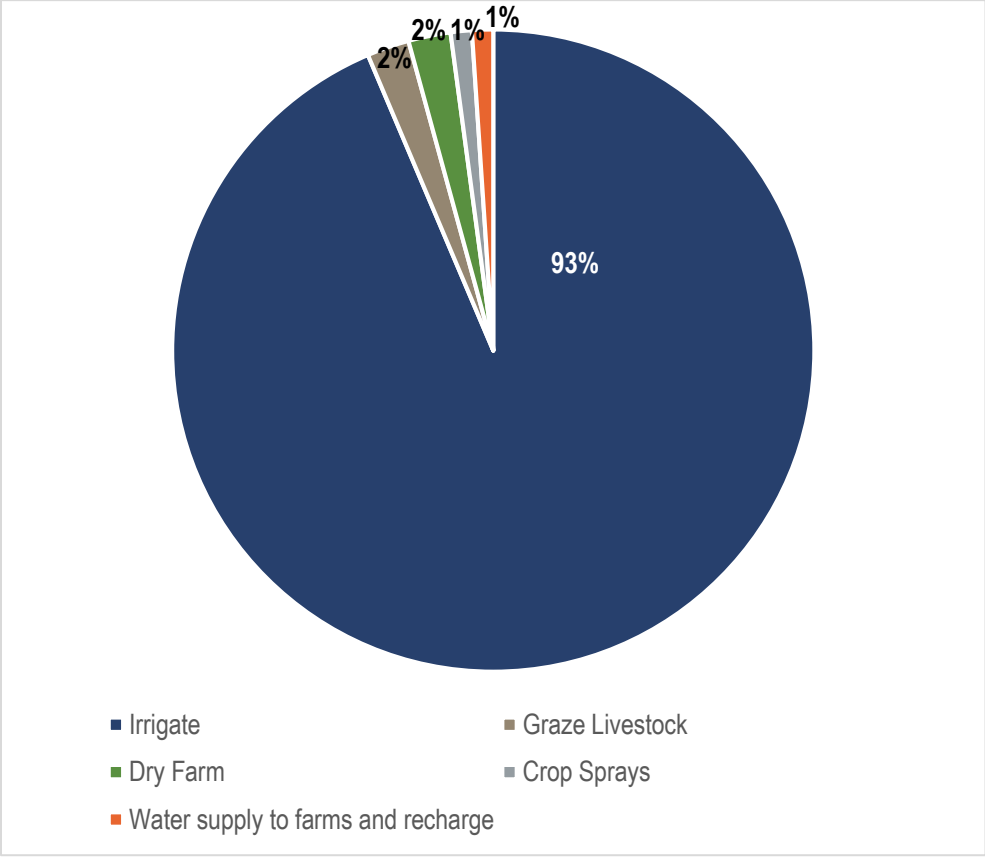
3. Do you own or manage/operate land in this region? *(121 responses)*



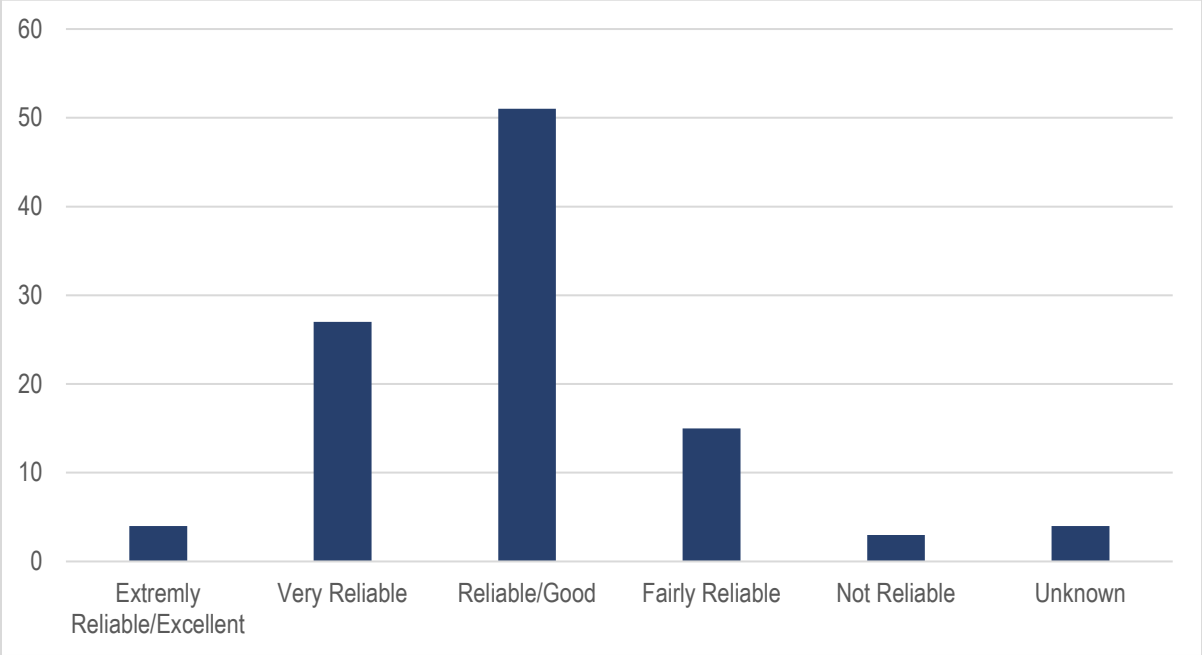
4. Where are you getting your water supply? *(118 responses)*



5. Agriculture & Domestic Well Users: What is your well(s) depth? *(92 responses)*



6. Agriculture & Domestic Well Users: Has your well(s) ever gone dry? *(99 responses)*



If yes, when? *(20 responses)*

7. If you are an Agricultural User, do you: *(94 responses)*

8. How reliable is your current groundwater supply? *(104 responses)*

Additional comments regarding groundwater reliability:

Currently receiving decent district water so not pumping too much, although it's early in our season

We rely on combination of surface water from AEWSD and Wheeler Ridge-Maricopa districts, and groundwater from wells on our property.

Supplied through district

Standing water level did not drop even during drought.

I've only used my well one time in 25 years

It has been reliable. Serves small residential units that do not have yards, one-room units, one-bedroom units, no washer hookup, serves retired and migrant workers.

It is reliable, however lower aquifer levels increase contamination levels for nitrates, which recently forced us to shut down a municipal well.

Part of Arvin-Edison. No wells on our property but have district wells.

Our water districts have historically done a good job providing water to our ranches. While our water levels have dropped, they are still providing adequate water.

Reliable because I've spent money on them and have maintained them

Reliable in conjunction with surface water

Reliable, but water quality is a bit poor on some wells.

Reliable, pump lowered 2016 in response to drought

Production has stayed steady for 10+ years

Well is for domestic use only, poor quality water but reliable

We feel our current groundwater supply is reliable at this time.

Water deep but well are troublesome

Water supply is not a problem it is basin standards not met.

Average 350 gallons

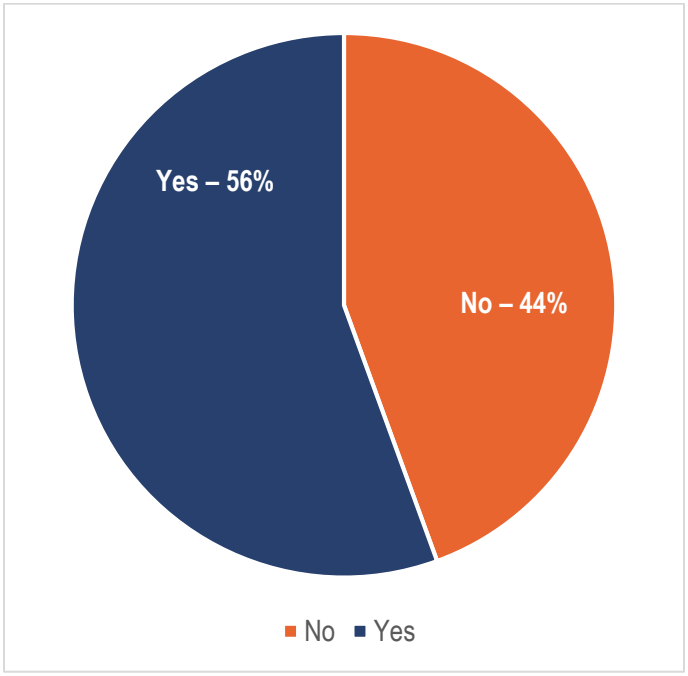
Unknown given the state's undelivered water

Water quality concerns are becoming more important each year for the current groundwater supply.

Fairly reliable as we invested significant capital in 2013 and 2014 to rehab most of our older wells.

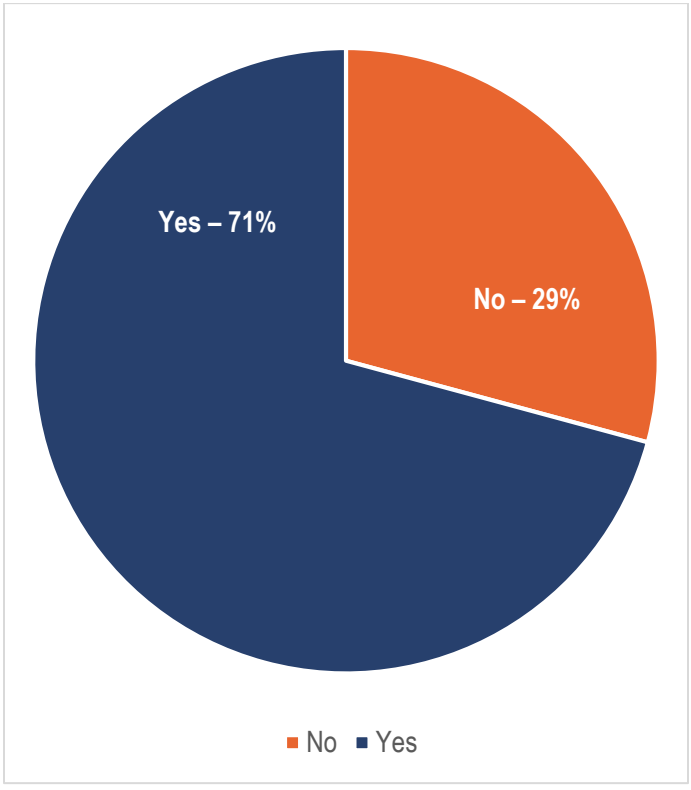
Relatively reliable. Had to extend bowls on one well.

Sufficient for our current needs



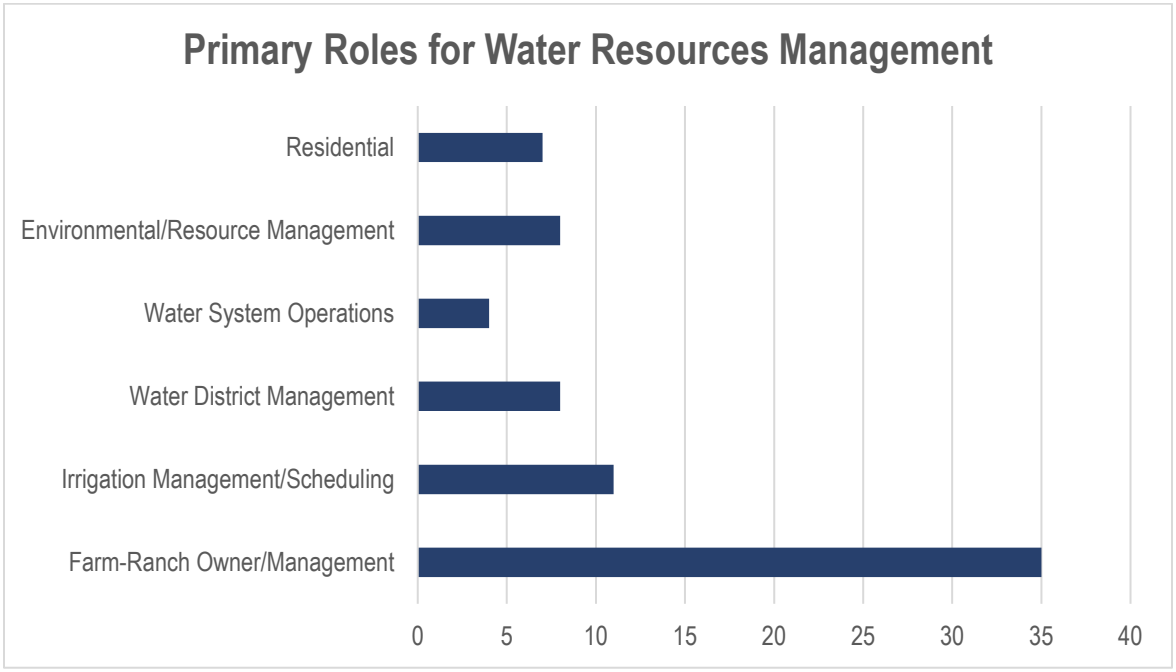
Sufficient for supplemental supply for surface water in most years

Variable. One well is reliable, another is iffy

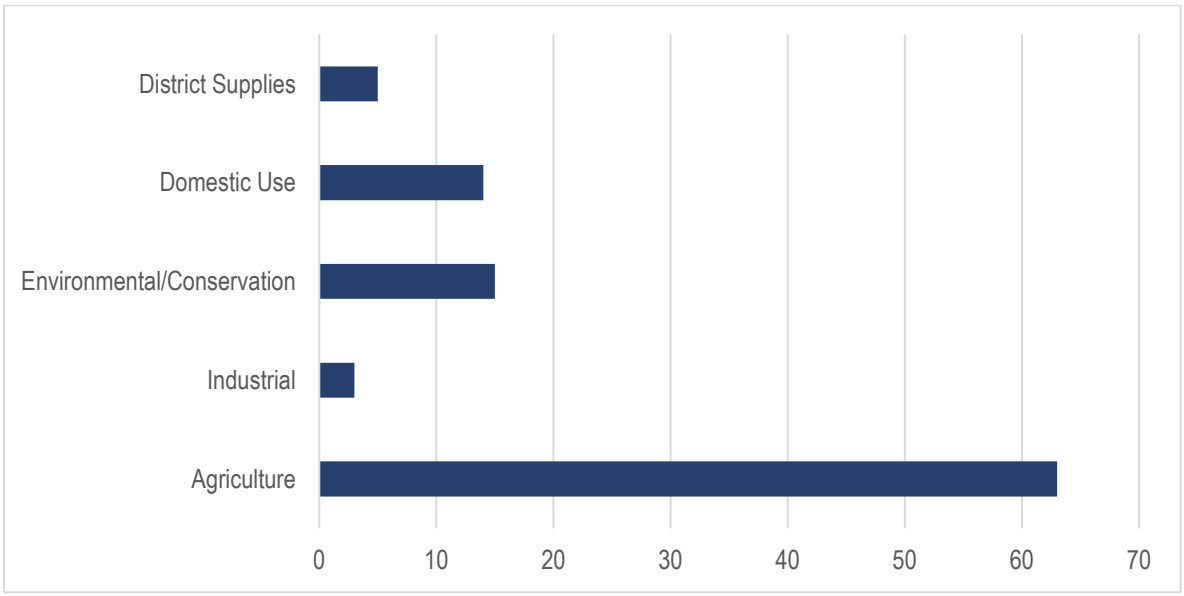


Volume is ok, quality becomes the issue.

Groundwater supply has decreased in quality over the last couple years rapidly.



9. If you grow crops, do you use irrigation for frost protection? *(99 responses)*



10. Do you manage water resources? *(113 responses)*

If yes, what is your role? *(73 responses)*

11. What is your primary interest in land or water resources management? *(100 responses)*

Additional comments regarding primary interests in land or water resources management:

Continued supply of quality & quantity to farm my property

Ensuring our farming operations continue to have access to irrigation water to maintain our crop production.

Farm Management and water for future generations.

Farming is my livelihood. Without water I can't do what I do.

Future availability for my ranch and all other farmers.

Future water availability. Restrictions on pumping groundwater.

Having enough water for personal use and for growing crops

Having enough water to farm our ground

I am a farm banker. SGMA will drastically affect my customers and my bank.

I have a strong interest in water resource management as we farm a large number of permanently planted acreage. We have invested a lot of money into the development of permanent crops and have made efforts to effectively manage our water use as efficiently as possible.

I want to grow crops. I want to continue to live on my farm using well water.

Ensuring adequate supply for our perennial crops

Long term sustainability of farmland (productive)

Maintaining local and personal control with the least outside regulation possible.

My hope is to be able to farm well into the future. If we don't become sustainable in the near future, we won't have a farming option in a couple years.

Producing crops and staying in business

Making sure we have enough water to grow our crops to feed the world

Sustainability and cost, sustainability for future food production, sustainability for water supplies in agriculture

Preparing information on SGMA for CEO and farm managers to make decisions on planting and long-term business planning

That I be able to continue to irrigate my crops

That water remains available for irrigation

To conserve & use less water to get the same production results

To conserve options for water usage when consider crops

To continue to farm without fallowing acreage

Without water land is invaluable. We employ 3,000 people out of a 21,000-person town. If we fallow our lands, we and every other company will not have enough work for the people.

to use water most economically

As an industrial user, need to ensure continued access to volume of groundwater necessary for operations

Keeping water available for my business

Survival of business

Conservation and efficiency of resources

Finite and necessary resource

For water resources to get used properly

Safety, health and environmental professional

My primary interest is managing both surface and groundwater as efficiently and effectively as possible while remaining cognizant of the value of the resources, both land and water.

Need help getting resources for management in using groundwater

Subsidence

Regulation and water

To know & understand the rules/regulations up and coming. Also, to connect with others that are interested in monitoring solutions as we are in this business

Use water wisely

compliance

Follow up with membership in water coalitions.

Continuing to secure, affordable, reliable and high-quality groundwater for the city of Wasco.

Domestic water for low income families

In a community that has a well for our only water source.

Making sure we have enough water to provide the residents of the city

Making sure small systems needs are met and not forgotten alongside larger water users.

Providing quality drinking water and notification to customers

Quality of water.

to do away with the environmentalists and let fish swim for themselves

To have adequate supply of surface and/or ground water to be able to grow and sustain my permanent crops.

To irrigate all the permanent crops, trees and vines with maximum efficiency in use of available water so that I do not run short of water and that trees do not suffer in any way.

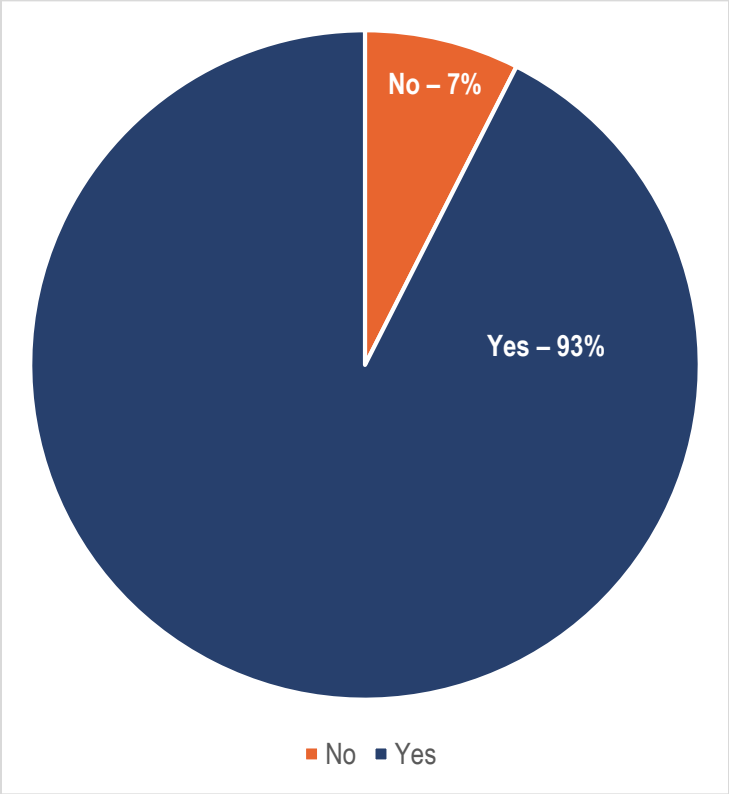
We make our living by growing crops. We have land payments, taxes, high costs in well drilling that we must pay for. Therefore, we must be able to continue to farm so we continue to use our resources in a productive yet not wasteful manner.

We make our living growing crops and we need to be able to maintain our land for survival, therefore, we have always tried to manage our water to our best ability.

We need water to be able to farm in the central valley.

Small disadvantaged community with one well and 18 connections.

That we always have clean and enough water



To continue uninterrupted municipal and farm use.

To have water when needed that is safe for drinking, cooking, etc.

Why do residents have to ration water (weekly watering schedules) while our groundwater is being pumped into the California Aqueduct and sent to LA or elsewhere?

United States

12. Do you have concerns about groundwater management? *(107 responses)*

If so, what are they? *(91 responses)*

That the ability to pump groundwater will be taken away.

Amounts we can pump and quality.

As a white zone owner, I am concerned about how we are going to reach sustainability and still make a living.

As the Public Works Director of a city that provides municipal water, I have a direct interest in groundwater. All of our water is supplied via groundwater wells.

Availability

Bureaucrats can raise my rates or cut me off from water.

Concern with endangered species act and how it's the reason for SGMA.

Concerned that private land owners will be burdened with record keeping and reporting to regulatory agencies.

Defining rainfall as groundwater so land can be taxed

Delivery system statewide

Fallowing ground and hurting the economy

Future groundwater pumping restrictions. Who is going to mandate groundwater pumping restrictions?

Government control

Government interference

Government involvement

Government regulation and interference

Government regulations and involvement

Granite Construction has several rural sites which depend exclusively on groundwater resources. Our concern is primarily that as SGMA rules are implemented our sites' operations are not materially impacted.

How much control will the government enforce upon growers? What practical experience do any of the

Need a great deal of underground water storage programs and a fair, effective water trading mechanism in the San Joaquin Valley basins.

Need more surface water and stop sending rainfall out to the Pacific Ocean.

No new water storage has been constructed in over 50 years, now we will be told how much we can pump. That would be a great idea and a must for the future IF we had enough water storage to farm for the year in tough years too! Legal issues are greatly reducing our surface water also. We make payments on our ground and need to farm every inch of it. We can't be cut short because we don't have water.

Over regulation

Over watering

Overpumping and the subsequent legislation. Over regulation.

Quality and supply

Quality of water

Recycling of wastewater for household and industrial users

Running out of water and creating an enforcement where smaller growers can't compete

Scientifically-based determination of sustainable yield of basin/sub-basin & management areas

SGMA limitations

SGMA poses significant challenges, and the uncertainty around how it will be implemented is concerning

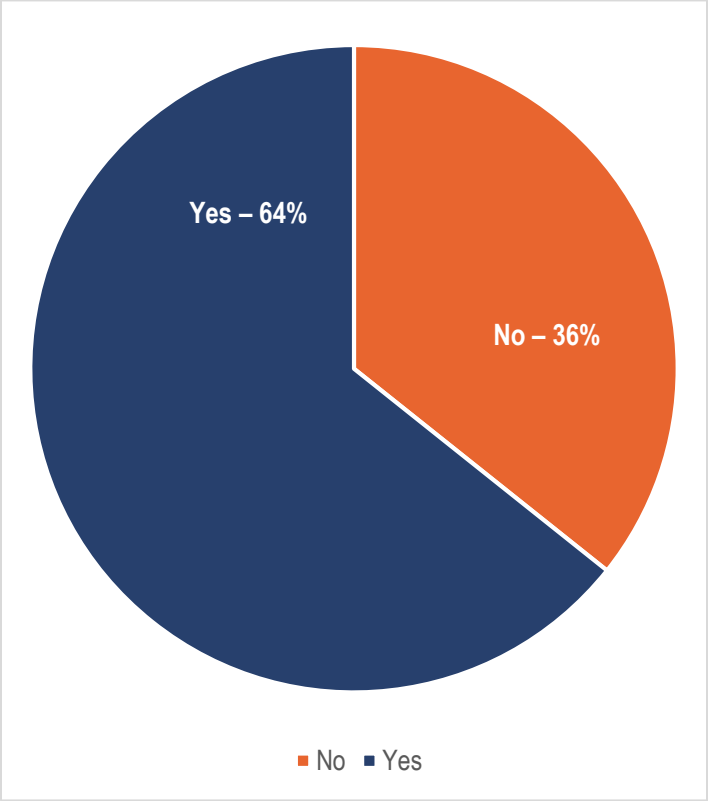
SGMA, Sacramento politicians, Water Quality Control Board, DWR, oil industry contamination, etc.

Shortage

Someone will tell me I cannot pump water for my permanent crops

Subsidence in Tulare County reducing Friant Kern Canal capacity

Sustainability



Sustainability - keeping our groundwater within our basin

government agencies/employees and/or mandator's have in the day to day irrigation practices, field experience?	
How much will government control cost us in money and loss of property rights?	That assumptions made regarding subsidence are in alignment with modeling being done by the subsidence team at DWR.
How will it be regulated? Who is appointed to the committee that ultimately will decide how water will be allocated?	That in dry years when there is inadequate surface water, we won't be able to draw enough groundwater to grow and/or sustain my permanent crops.
I am concerned that in the future I will be restricted in my use of groundwater during periods of drought. I do not consider groundwater as a primary source of water but as a reserve to be used in case of drought to augment restricted surface water availability.	That significant farm land acreage in my region will be taken out of production.
I am concerned that SGMA will become a method for taxation without representation or services.	That the state doesn't come in too heavy-handed, and that they allow us to work into SGMA over time.
I am concerned with our ability to continue to farm the permanent acreage we have developed. I am concerned that a GSP might lack a certain level of flexibility to allow for the transfer of pumping credits across the County or not allow for a proper phase in period that would allow a market to develop for water and/or water credits.	That the underground water basin is sufficient for Kern and not all used for Los Angeles
I fear the overdraft is too big of a problem in the Valley. Subsidence is another major concern.	That the water is protected from any type of contamination
I feel the average person does not feel the importance of farming and would prefer to take away our water and sell it to places like Los Angeles. We seem to already have allowed districts to drill wells and pump water out from underneath us to sell out of our area.	The irrigation canal that has replenished water levels for 100 years has been dry the last several years.
I hope within SGMA we are flexible in amounts we can pump to survive through the dry years	The limits will be put on small domestic users that may not be large enough to be heard.
I think evapotranspiration satellite technology will help balance our water use with taxation to the land user for overuse than trying to meter and police all our wells.	The prioritization of surface water allocation between the public, agriculture and the environment. Need more surface water deliveries to correct groundwater overdraft. Any reduction in irrigable acres needs to allow for viable economic adjustment over an extended timeframe.
I understand the reasoning behind SGMA, and sustainability is needed, but it needs to be combined with advocacy for more surface water. It was lack of surface water that caused the issues we face: if our surface water supply was more reliable, agriculture would not need to use as much groundwater.	To know what the water level is and how much water we can use and for how long
I understand we must manage our groundwater, I do not understand why some districts have been able to pump water out from underneath us and send it to LA. Also growers that have been allowed to plant on the westside where there has never been ag, only to help drain our groundwater. Those of us that have paid high dollars for ground that has both ground and surface water are now being punished.	To make sure water is available to meet demands of farming
If we can actually get a plan in action in time	Water usage is low for almonds
If we do not increase the supply of surface water by raising the level of existing reservoirs and making	We already do a good job with conservation in agriculture. Any more reduction in groundwater

more reservoirs to catch every drop of rain water, no matter how many restrictions we put on groundwater we cannot solve the problem. The only solution to solve the groundwater problem is to make more surface water available.	supply will have a direct correlation to a reduction of jobs. It would decimate many communities throughout the valley.
I'm afraid the government will over regulate and make it impossible to farm efficiently.	We are approaching the deadline for monitoring each location. Self Help will be helping us. Our concern is always the cost. My second concern is that it requires a great deal of time for small mutual water companies to comply with all the regulations.
Individuals vs. subbasin	We must manage water to survive.
Insufficient supply for our perennial crops due to extraction restrictions/limitations and/or restricted surface water.	We need more surface water.
Is SGMA going to limit our availability to access groundwater as a source of agriculture irrigation water? If it does, how will we obtain water in order to maintain our permanent crops of almonds and pistachios?	We need reliable surface water restored to our area so that groundwater recharge can offset groundwater pumping.
It appears that state water management problems are landing squarely on the shoulders of farming. This is going to put most small farmers out of business while corporate farming and municipalities thrive. This is a big mistake.	We paid for our well and shouldn't have to show how we use our water to grow our crops. We are all drip & fan jets, so yes we save and do not waste water
Lack of flexibility upon GSP implementation	What costs will be involved to comply? What limits will there be and on what acreage? Metering and monitoring, reporting regulations.
Long term quantity and quality	What will be the end result in restrictions and when?
Long term sustainable use of groundwater	Will there be a prioritization? Others vs. food? Who decides my future? Will I have enough water to grow my crops? If my surface water is curtailed outside of my control, will I be able to make up for that short fall by using my well as needed? Will there be a water market developed to purchase extra water?
Making sure that the rights of property owners are not over looked to solve this issue.	Will we be stopped from pumping our agricultural wells when our permanent crops need water?
Might run out of water on our domestic well and we don't have another source	Will we get enough water?
Monitor the oil wells because they can pollute the entire underground water system.	Will we have water? What regulatory issues? Loss of production of farm land
More government regulations	Yes, limiting groundwater consumption will limit the acres that can be farmed on well water as a primary source. Surface water quality trends are also in a decline and a higher reliance on low quality water gives me pause.
My concern with SGMA is the fact that our groundwater pumping will be limited in conjunction with not getting full allocation of surface water. I understand overdrafting has caused many issues like poor water quality, land subsidence and a water table that continues to drop. But if our groundwater pumping is cut and our surface water is cut, what are we supposed to do with our investment into permanent crops.	

13. Do you have requests or recommendations regarding groundwater management?

(98 responses)

If so, what are they? *(65 responses)*

Allow farmers more input. We aren't interested in depleting our resources.

Allow more imported water into our region from the north.

An even playing field for all participants

Banking, trades, surface water exchanges, all would help implementation by giving farmers book to adapt

Better communication of GSP development/GSA communication with individual growers

Bring in more surface water to make up for the pending cutbacks on pumping.

Build storage so we can save groundwater!!!

continue communication

Delete land from the Kern water basin that does not have any useable underground water.

Depending on SGMA implementation specifics, we need the ability to bank and trade water as much as possible.

Develop a method of transferring rights to groundwater (i.e. so-called pumping credits). Before

Make it cost effective.

Make sure growers have access to enough groundwater to grow their crops.

More groundwater banking, restore SWP water deliveries to 100%/

More proactive groundwater storage programs within each GSA, including any assessments required for water acquisition and infrastructure.

More water storage reservoirs

None with SWID (who sent us this survey), but many with Semitropic Water District

On-farm recharge is vital to long-term sustainability.

Please continue providing information on SGMA and how it will affect day-to-day farmers who may not be as inclined to "self-education" as most.

Please help local farmers with water or to build new wells.

Possibly opening up a resource or management division for small water mutuals.

Quality of water

limiting extractions outright, attempt to achieve sustainability through the means (i.e. fallowing program, tax on excess extraction, etc.), recharge programs

Develop a water market! Allow water transfers among other water users, farmers. Require the environmentalists to play their part.

Do not constrain groundwater availability to ag users.

Educated, practical, honest people making decisions.

Fixing the Friant so we can receive surface water

Flexibility

Focus on maximum flexibility that will still obtain groundwater equilibrium. GSA should help (where possible) to establish a free market where water and/or water credits can trade among land owners.

Get the state water infrastructure brought up to present day needs and standards.

How will the city manage groundwater so residential usage is managed, not just taxed? Crops before grass.

I admire the GSA's efforts and urge the GSA to continue involving the diverse set of stakeholders that have been engaged so far.

If the state of California wishes to regulate groundwater pumping, then the state and federal systems should guarantee any shortage in the form of surface water deliveries.

Implement groundwater banking credits, ensure areas not within irrigation districts pick up slack as they have not been paying into groundwater banking programs, look at ways to implement wastewater reuse from Bakersfield if possible.

Import more surface water.

Increase surface flows so we are less dependent on groundwater.

Increase surface water flows to reduce dependency on groundwater.

Rely on water districts

Request to be kept in the loop on any issues that may affect the City of Wasco's water supply.

Rural operations and construction projects often only have access to groundwater for operations/dust suppression. We are interested in flexibility of points of extraction (for construction purposes) and insuring that evaluations of current usage include both our construction and mining operations (this is often overlooked in basin usage evaluation as we are neither an agricultural nor residential/municipal service user).

We need flexibility in dry years.

Stop watering the fish.

That we as agricultural water users do our best to utilize surface water but be allowed to pump enough groundwater to grow our crops. I would suggest allowing a certain amount of groundwater to be used annually but averaging it out over a five-year period allow for drier and wetter years.

When we get plenty of surface water, no one would like to pump groundwater by spending so much money in drilling deep wells and electric motors.

The small domestic users keep their water rights.

There should be an equal conservative effort to water storage and infrastructure as regulating SGMA. We can limit pumping but let's figure out a way to capture water throughout the state and increase our efficiency with surface water.

To maintain the right to pump or sell the groundwater now and in the future.

Please put farming as a top priority for water use in the state of California.

To work together to create a plan for a sustainable aquifer

Vote for right-minded politicians, state and federal

We growers conserve as much water as possible. I see the city of Bakersfield wasting water every day – seven days a week, 365 days a year, and nothing has changed since SGMA has come about. What more restrictions will be placed on all farmers? What restrictions will be placed on all non-farm users? Who is exempt? The prison's "CDCR" (California Department of Corrections) wastes millions of gallons

of water per year. Who will address this issue? I am a prior correctional officer, I saw the waste firsthand."

Involve the small communities in decisions

We need to be able to go into this cautiously and not make big cuts at once.

We need to stop allowing our groundwater to leave our county. If its pumped here, it should stay here.

Keep us informed in a timely manner.

We should not over-react and limit that amount of pumping we do too drastically. It should be done slowly and monitored.

We want to see resource management at the basin-level with uniform and consistent methodologies (e.g., accounting, analysis etc.) Sufficient stakeholder engagement and facilitation are of concern as well.

Leave as is, just monitor.

What methods can we use to control groundwater?

Leave me alone. My use of water does not affect anyone in the San Joaquin Basin.

Whatever basin plan is approved, the adjustments to land and water use relationships are implemented over the longest period of time allowed by law.

Less government involvement and flawed environmental agendas

While M&I and ag need to work together, it can't turn into a situation where ag just gets the leftovers that environmental and M&I don't want.

Let us know in advance if you will be stopping us from using our wells.

14. Any other information the Kern Groundwater Authority should be aware of or take into consideration while developing the Groundwater Sustainability Plan? *(41 responses)*

Allow groundwater use averaging over a five-year span.

Quality of water

Board meetings get too in the weeds. Need a place for higher level policy discussion.

Should be district-based not basin-based

Small rural county communities need access to potable water - much of the water is naturally or chemically contaminated. Large cities deal with the problem better due to financial ability. Small systems cannot.

Businesses and livelihoods are at stake. No one is going to be regulated out of business without a fight.

Somehow consider the sizeable investment that growers (perennial crops, especially) have in their crops and development of infrastructure (i.e. irrigation and trellising), and their desire (need) to preserve the value of this investment, such that as many options as possible will need to be explored to accomplish this.

California needs more water storage like dams to help with water management

Stop the west side (that has never had water) from pumping water out from underneath us and sending it to LA and letting the two largest growers in the area from monopolizing it. Stop Semitropic Water District from drilling more wells just to send the water out of Kern County.

Conservation should be for all.

Thank you in advance for you work. You are doing a great service for our industry. It does not go unnoticed.

Continue to provide as much feedback as possible with regards to possible direction of GSP so that we are able to better plan for future knowing how/if a market for water will be developed.

That producing food products are crucial to people of our state and country, whether they realize it or not, and should be protected the best we can.

Do what you can to let public know it's the environmentalists that stop the pumps that have created the current groundwater problems. Work to change the regulations and let the fish fend for themselves.

Don’t have us do unnecessary paperwork. Some of us are just small entities and just want to make a living.

Groundwater should remain a reserve to be used in periods of restricted water availability from the CVP and SWP.

Groundwater pumping should be phased in very slowly (20-50 years): 1) To better monitor groundwater levels and replenishment over time; 2) To better understand where replenishment flows originate for each basin; 3) To allow farmers time to rotate out of permanent crops; 4) To allow water markets and pumping right markets to be formed within basins or water districts.

Groundwater shall not be a marketable resource to be exported or sold across county lines.

I am trying to understand current hydrological inflows and outflows of the area, so not at this point although this will change soon.

I feel that every water user in the state should submit a water management plan just like ag. If you use water in your home and/or business, you should be required to fill out a report just like the state is asking of us (farmers). I feel this is a one-sided implementation of SGMA, I would also like to see the restrictions placed on all consumers be the same across the board. If Sacramento is serious about a fix, this is a fair and impartial way of doing it. I doubt any of this will be taken seriously and implemented across the board, but I remain hopeful

Integration of management areas within basin those with surface vs those dependent on groundwater only.

Is land that is converted from ag to homes helpful for the district?

Much land that has no useable groundwater and has no effect on the basin has been included in the basin boundary.

My groundwater level has not changed substantially in many years.

No, if the action suggested above is taken, we do not need anything else to do at present we are not hitting the target. We are only beating around the bush, or I can say we are putting the cart before the horse.

Our situation took a long time to develop and will take commitment, patience and time to resolve.

Permanent crops are harder to lose than fallowing row crops or alfalfa!

That no restrictions should be put on pumping groundwater from those orchards and vineyards which do not get any district irrigation water, otherwise those orchards and vineyards will die, and part of California will become desert. That will be a big state and national loss.

The loss of jobs, complete industries, the tax base from the working class, housing developments; consumption by more homes means less water for ag.

The required amount of water to farm different crops should not be determined by the GSA or the districts. Farmers/users should have that right.

The runoff from rainfall on the West side of Kern County does not get into the basin groundwater supply. The groundwater that comes from fractured shale formations does not affect the water supply or quality in the basin.

Use common sense, not agenda-driven emotions.

We have several people in our GSA continuing to use groundwater and not surface water. This must be addressed.

We look to be active in developing viable on-farm recharge.

We need transitional pumping.

When I shower, my skin stings, this hasn't always been true. I'm concerned that the water is irritating my skin and making my psoriasis worse.

With so many different standing water depths across the country don't take a one-size fits all.

Without the help from Self Help Enterprises, we would be out of water and with no hope since it is a disadvantaged community. Elizabeth B. has been a wonderful helper.

Yes, now will small growers be able to meet the need of the crop if limits are mandated on how much water we can pump? Large growers and farmers can leave part of their land fallow and use that water on another area of their ranch to meet their water needs.

Yes, start campaigning to do away with saving the delta smelt.

- ☐ Westside District Water Authority (WDWA)
- ☐ Wheeler Ridge-Maricopa Water Storage District (WRMWSD)

2. **How many total acres do you farm (all land owned, leased and/or managed)?:** _____

3. **In a typical year, how much of the following crops, animals or land do you manage/own?**

Crop or Land Type	Acres Managed or Owned
Fruit trees	
Nut trees	
Row crops	
Seed crops	
Vegetables	
Grain	
Grapes	

Crop or Land Type	Acres Managed or Owned
Hay/alfalfa	
Livestock on pasture/rangeland	
Dairy *(total head)*	
Food Processor/Production	
Other land use *(please indicate)*:	

4. **Which of the following sources of water and management do you typically utilize under the following conditions?**

Water Source/Management	Dry Years	Normal Years	Wet Years
Irrigation through surface water only			
Irrigation through groundwater only			
Irrigation through a mixture of surface and groundwater			
Wastewater land applied			
No irrigation			

5. **If you do use irrigation, which of the following methods of delivery do you use?** ***Check all that apply.***

☐ Furrow/flood ☐ Sprinklers ☐ Drip ☐ Microsprinkler ☐ Center pivot

☐ Other *(please indicate)*: _____

6. **In response to water scarcity, please indicate if you currently use the following practices and your likelihood to use the following practices in the future.**

Practice	Currently Use	Future Use					
		Very Unlikely	Unlikely	Somewhat Unlikely	Somewhat Likely	Likely	Very Likely
Drill more wells							
Restore existing wells							
Make existing wells deeper							
Pump more groundwater than previous years							
Drip irrigation							
Water monitoring technology							
Fallow fields							
Soil moisture sensors							
Change to a less water intensive crop							
Reduce livestock stocking rates							
Leaf sampling to measure plant-water status							
Purchase additional water							
Purchase crop insurance							
Other:							

7. **Please rate the level of importance these potential groundwater conditions are to you *(with "1" being the most concerning, 5 being the least concerning)*. If you have additional concerns, please indicate them in the "Other" category.**

Groundwater Condition	Rating of Concern
Lowering of groundwater levels	
Reduction in groundwater storage	
Water quality degradation	
Local subsidence	
Depletions of surface water	
Other *(your opinion)*:	
Other *(your opinion)*:	

8. **The following are a list of management options that have been used on the West Coast for water management. Please provide your level of preference for these types of management:**

Management Option	Strongly Against	Against	Somewhat Against	Somewhat Support	Support	Strongly Support	Not Familiar
Individual recharge credits (i.e. winter flooding)							
Water metering							
Water trading through markets							
Public program highlighting farmers implementing water saving practices							
Farmer adoption of water management practices							
District investment in conjunctive use infrastructure (i.e. water storage)							
Groundwater replenishment fees							
Fixed quota for water pumping allocated to each farmer							
Incentives for water saving practices							
Moratorium on drilling new wells							
Permits for drilling new wells							
Other *(your opinion)*:							
Other *(your opinion)*:							

9. **If groundwater monitoring is required in the future, which of the following monitoring methods would you prefer?**

Method of Determining Water Allocation	Strongly Not Preferred	Not Preferred	Somewhat Not Preferred	Somewhat Preferred	Preferred	Strongly Preferred
Well metering						
Use satellite estimates and ground truth						
Use standard crop water requirement indexes						

10. Should disputes arise over SGMA implementation, what is your preferred means of reconciliation?

Dispute Option	Strongly Not Preferred	Not Preferred	Somewhat Not Preferred	Somewhat Preferred	Preferred	Strongly Preferred
State Water Resources Control Board						
Groundwater Sustainability Agency						
County Board of Supervisors						
Superior Court System						
Arbitration						
Other:						

11. If you have any additional information or feedback regarding SGMA, water management or farming in Kern County that should be taken into consideration while developing the Groundwater Sustainability Plan (GSP), please provide the information below:

Memorandum

To:	Kern Groundwater Authority Board of Directors
From:	Trilby Barton, Public Outreach Coordinator, Provost & Pritchard Consulting Group
Subject:	Ag-Focused Stakeholder Survey Results – Monthly Progress Report
Date:	June 21, 2019

Hard copies and the link to the online version of the Kern Groundwater Authority's Ag-Focused Stakeholder Survey are being circulated throughout Kern County. The survey has been distributed by member districts and is available online at www.kerngwa.com. **To date, Kern Groundwater Authority has received 68 responses**. This memo summarizes the responses received to date.

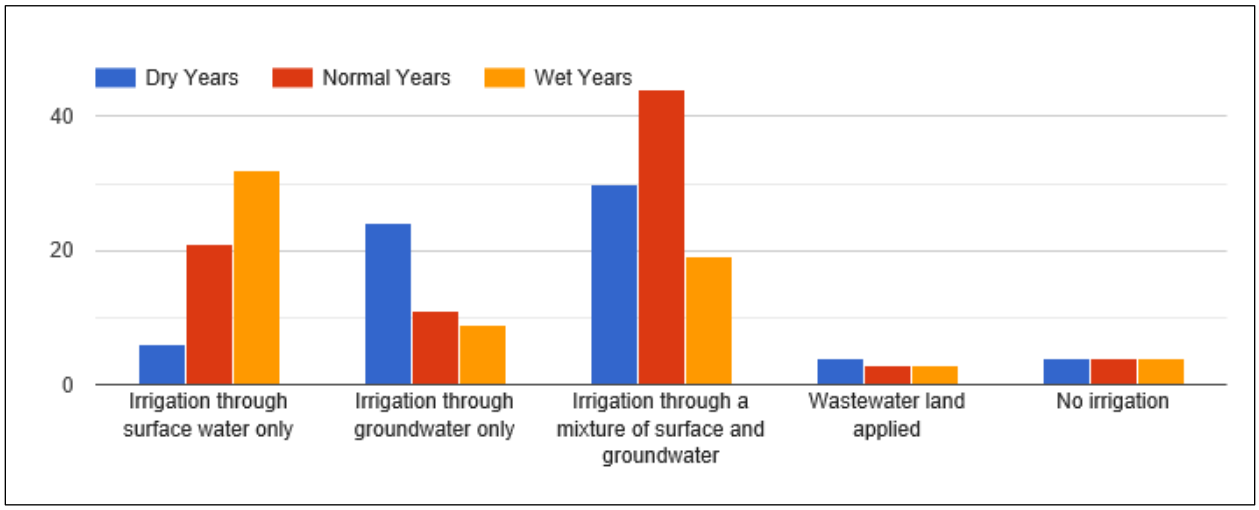
Progress Report of Kern Groundwater Authority Stakeholder Survey Results

1. Please indicate which irrigation/water district in which you have land.

(68 responses, multiple answers per respondent)

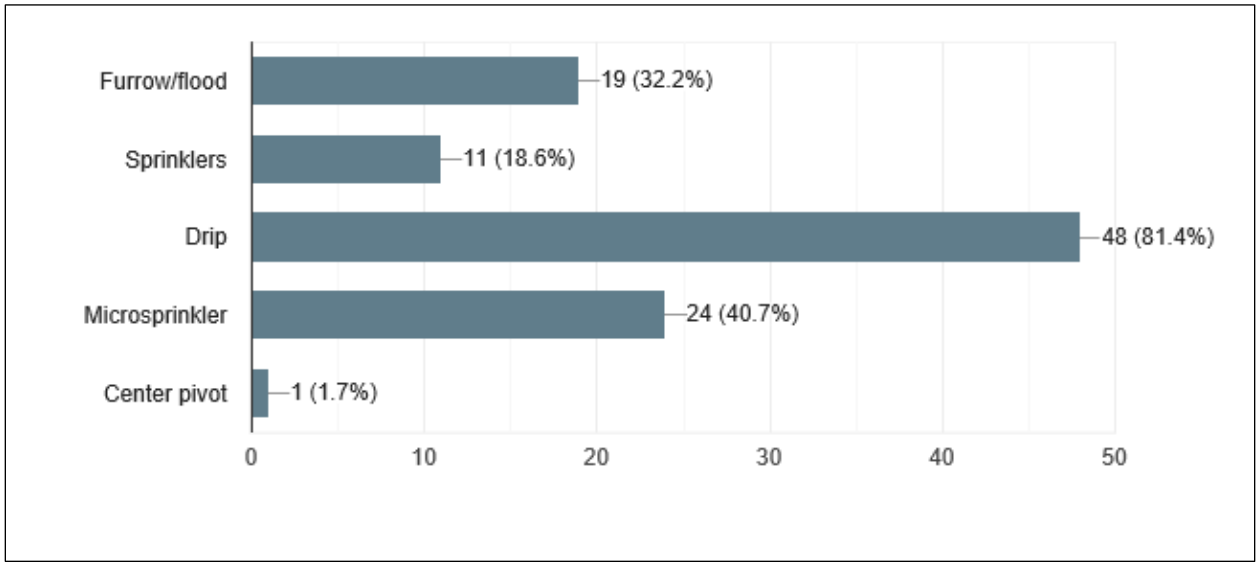
District Name	Number of Responses	District Name	Number of Responses
Arvin Edison Community Services District	0	Rosedale-Rio Bravo Water Storage District	6
Arvin-Edison Water Storage District	10	Semitropic Water Storage District	9
Cawelo Water District	4	Shafter-Wasco Irrigation District	30
City of Shafter	2	Southern San Joaquin Municipal Utility District	31
County of Kern	4	Tejon-Castaic Water District	0
Kern County Water Agency	2	West Kern Water District	2
Kern-Tulare Water District	5	Westside District Water Authority	5
Kern Water Bank Authority	3	Wheeler Ridge-Maricopa Water Storage District	3
North Kern Water Storage District	8		

2. How many total acres do you farm (all land owned, leased and/or managed)?



(58 responses)

Total Acres Farmed	Total Acres Farmed	Total Acres Farmed
4	207	1,000
8	220	1,160
17	230	1,200 (x2)
20	235	1,250 (x2)
35	254	1,500
39.25	257	1,722
40	266	1,921.27
42.21	280	2,044
54	350	2,630
55	370	3,000
56.5	375 (x2)	3,500
100 (x2)	467	4,415
135.33	516	5,000
143	600	6,000
155	640	15,000
156	770	29,000
160	825	
161.82	890	



3. In a typical year, how much of the following crops, animals or land do you manage/own?

Crop or Land Type	Acres Managed or Owned	Crop or Land Type	Acres Managed or Owned
Fruit trees	Ranges from 5-6,000 acres *(23 responses)*	Grapes	Ranges from 100-1,500 acres *(9 responses)*
Nut trees	Ranges from 8-15,000 acres *(47 responses)*	Hay/alfalfa	Ranges from 17-1,000 acres *(8 responses)*
Row crops	Ranges from 65-3,000 acres *(8 responses)*	Livestock on pasture/rangeland	Ranges from 4-17,000 acres *(4 responses)*
Seed crops	*0 responses*	Dairy (total head)	*0 responses*
Vegetables	70-1,500 acres *(2 responses)*	Food Processor/Production	*0 responses*
Grain	Ranges from 250-2,000 acres *(6 responses)*	Other land use (please indicate):	Ranges from 20 to 681 acres of fallowed ground *(3 responses)*

4. Which of the following sources of water and management do you typically utilize under the following conditions?

5. If you do use irrigation, which of the following methods of delivery do you use? Check all that apply. *(59 responses)*

6. In response to water scarcity, please indicate if you currently use the following practices and your likelihood to use the following practices in the future. *(Table lists number of responses.)*

Practice	Currently Use	Future Use					
		Very Unlikely	Unlikely	Somewhat Unlikely	Somewhat Likely	Likely	Very Likely
Drill more wells	6	14	10	6	5	4	6
Restore existing wells	11	12	3	4	9	7	5
Make existing wells deeper	3	14	11	9	8	2	2
Pump more groundwater	7	7	8	3	13	5	7

Practice	Currently Use	Future Use					
		Very Unlikely	Unlikely	Somewhat Unlikely	Somewhat Likely	Likely	Very Likely
than previous years							
Drip irrigation	35	4	1	1	5	5	17
Water monitoring technology	28	2	1	3	6	4	18
Fallow fields	4	11	14	3	4	9	1
Soil moisture sensors	27	2	1	2	7	6	13
Change to a less water intensive crop	4	24	8	7	2	4	1
Reduce livestock stocking rates	1	14	4	1	2	0	4
Leaf sampling to measure plant-water status	13	4	3	2	12	11	4
Purchase additional water	11	5	6	4	7	12	13
Purchase crop insurance	23	3	1	4	6	8	16
Other: *(5 responses)*	Bank water and purchase water credits; Vacant land for sale; Bank water; Groundwater recharge; deep root irrigation						

7. **Please rate the level of importance these potential groundwater conditions are to you** *(with "1" being the most concerning, 5 being the least concerning).* **If you have additional concerns, please indicate them in the "Other" category.** *(Table lists number of responses.)*

Groundwater Condition	Rating of Concern *(1 most concerning, 5 least concerning)*				
	1	2	3	4	5
Lowering of groundwater levels	37	21	2	4	0
Reduction in groundwater storage	28	16	11	4	6
Water quality degradation	13	15	21	9	5
Local subsidence	16	12	11	6	17
Depletions of surface water	43	9	6	2	5

Other *(your opinion)*: There is no potable water under the surface of our land in the white area. We do not have any wells, or use any groundwater, but have been included in the basin anyway. The drinking water for our livestock comes from springs located in the mountains outside of the basin.

It is all politics!!!!! California has plenty of water, use common sense!!

Get rid of the "enviros"; to hell with the fish

Limiting access/use

To rid bureaucratic time wasters; to rid enviros stopping the pumps

Worry about Semitropic groundwater degradation and other areas in our district

Government interferences

8. The following are a list of management options that have been used on the West Coast for water management. Please provide your level of preference for these types of management: *(Table lists number of responses.)*

Management Option	Strongly Against	Against	Somewhat Against	Somewhat Support	Support	Strongly Support	Not Familiar
Individual recharge credits (i.e. winter flooding)	3	2	1	6	17	25	3
Water metering	11	10	8	12	12	8	1
Water trading through markets	4	5	5	8	13	24	4
Public program highlighting farmers implementing water saving practices	2	0	3	12	23	21	1
Farmer adoption of water management practices	2	1	1	9	24	26	0
District investment in conjunctive use infrastructure (i.e. water storage)	3	0	1	3	12	41	1
Groundwater replenishment fees	14	10	13	10	6	3	7
Fixed quota for water pumping allocated to each farmer	24	8	9	11	6	1	2
Incentives for water saving practices	2	2	0	16	18	20	3
Moratorium on drilling new wells	13	12	16	5	3	2	4
Permits for drilling new wells	5	6	8	8	22	10	3
Other *(your opinion)*:	None						

9. If groundwater monitoring is required in the future, which of the following monitoring methods would you prefer? *(Table lists number of responses.)*

Method of Determining Water Allocation	Strongly Not Preferred	Not Preferred	Somewhat Not Preferred	Somewhat Preferred	Preferred	Strongly Preferred
Well metering	17	8	7	9	17	5
Use satellite estimates and ground truth	7	12	15	11	6	2
Use standard crop water requirement indexes	5	10	13	15	6	5

10. Should disputes arise over SGMA implementation, what is your preferred means of reconciliation? *(Table lists number of responses.)*

Dispute Option	Strongly Not Preferred	Not Preferred	Somewhat Not Preferred	Somewhat Preferred	Preferred	Strongly Preferred
State Water Resources Control Board	18	9	5	7	0	13
Groundwater Sustainability Agency	7	2	5	15	16	8
County Board of Supervisors	20	12	4	6	9	2
Superior Court System	23	16	2	4	4	3
Arbitration	3	11	3	9	4	2
Other *(4 responses):* I want the state to delete our land from the basin boundary, then I will not have any dispute to reconcile; Stop running water to the Pacific Ocean; A farmer-controlled Advisory Board						

11. If you have any additional information or feedback regarding SGMA, water management or farming in Kern County that should be taken into consideration while developing the Groundwater Sustainability Plan (GSP), please provide the information below: *(14 responses)*

Allow water banking where it is easiest conveyed and allow those groundwater banking credits to be used in the basin where it is need. If a white area landowner is able to purchase water and can bank it in Arvin or Lost Hills allow this to happen vs spending hundreds of thousands of dollars to convey that water to the particular area where is will be pumped out of. Use the Kern River as a water bank and who ever leaves the water in the river gets the credit for their district no matter where is actually is recharged too. It's one Basin. Why spend millions building additional water banks and conveyance systems when you have the best recharge ground and conveyance system already in place. In addition, think how beautiful our city could be if we had water running though the river more often. WORK TOGETHER for solutions that is best for the basin and allow those benefits to be spread across to all the districts who contribute to the solution.

Important that market is established that allows for creation of an asset (water pumping credit) that can be traded in open market. This would (hopefully) cause water to be used for highest and best use and still allow for flexibility we need in industrial agriculture.

Need ground water

No new water storage has been constructed in over 30 years. Now we will be told how much we can pump. It would of great advantage for our future if we had enough water storage to farm our crop during tough years. Legal issues are greatly reducing our surface water! We make payments on our ground and we need to farm every inch of it. We can't be cut short because of a lack of water. Build a storage so we can save ground water!

Pretty well explained above, we do not have any wells within the basin boundary, do not use any groundwater, do not have any farming and do not want to be included in any of the water wars.

We should have an aggressive program promoting groundwater recharge wherever and whenever possible.

I'm not in support of mega growers only buying farmland in order to resell water to places like L.A. to make a killing off of. Needs to be against the law and downright illegal. The extra water should go to farmers or storage for drought years... not to make profit on!!!

Water trading through markets seems like our best option. Also, connecting farms with conservation easements to facilitate retiring their land.

Work more closely with oil field-produced water and pipe it to other water districts.

Ensure growers fully understand current water consumption. At this point most growers don't have a strong handle on water use which leads to fear of SGMA implementation. Although fearful for agriculture, a program such as this is necessary. With current estimates, groundwater credits and groundwater markets will allow farming to continue in one method or another.

Best to have all district board presidents meet quarterly to work out ways to exchange any surplus water and to work out the details.

Give us the water. Don't send the water out to the ocean. Don't send water to fish that have not been in the area for over 50 years.

I know we can't keep depleting our underground basin, but we need to increase storage and use a more common-sense approach for water. Stop flushing our water to sea.

Some of the proposals presented are ridiculous. Mitigation features presented - farmers paying for municipal wells and housing (rural) well development.

Farmers aren't the end users of water. Consumers are. We are efficient and food is a basic need for survival. It's a shame our state has the best farm land in the world wants to eliminate the profession. We're highly regulated more so than anywhere else in the world. Farming for a century on our land and living on it and investing in, it's hard to move away.

Appendix C

List of Kern Groundwater Authority Public Outreach Efforts

List of Kern Groundwater Authority Public Outreach Efforts

Throughout the SGMA process, the Kern Groundwater Authority held public outreach efforts to engage stakeholders in the development of the Groundwater Sustainability Plan. These KGA-wide meetings and events are listed by phase in a timeline format in Figure VI-1, Figure VI-2, and Figure VI-3, and are listed below in **Table C-1**. Supporting materials for all events and meetings are available at www.kerngwa.com.

The KGA member agencies also held district-specific outreach efforts during the process, and those events and meetings are noted in their specific chapters of the GSP.

Table C-1. List of KGA Public Outreach Efforts

Meeting/Event	Date/Location
2015	
KGA Board of Directors Meeting	January 21, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	February 25, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	March 25, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	April 22, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	May 27, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	June 24, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	August 26, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	September 23, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	October 28, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	November 16, 2015, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	December 21, 2015, Kern County Administration Building, Bakersfield
2016	
KGA Board of Directors Meeting	January 27, 2016, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	February 24, 2016, Kern County Administration Building, Bakersfield
KGA Special Board of Directors Meeting	March 21, 2016, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	April 27, 2016, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	May 18, 2016, Kern County Administration Building, Bakersfield
KGA Special Board of Directors Meeting	June 29, 2016, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	August 24, 2016, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	September 28, 2016, Kern County Administration Building, Bakersfield
KGA Board of Directors Meeting	October 24, 2016, Kern County Administration Building, Bakersfield
SGMA Stakeholder Outreach Workshop	October 24, 2016, Kern Ag Pavilion, Bakersfield
KGA Special Board of Directors Meeting	November 14, 2016, Kern County Administration Building, Bakersfield

Meeting/Event	Date/Location
SGMA Stakeholder Outreach Workshop	November 1, 2016, Kern County Water Agency, Bakersfield
SGMA Stakeholder Outreach Workshop	November 15, 2016, Kern Ag Pavilion, Bakersfield
SGMA Stakeholder Outreach Workshop	November 28, 2016, Kern County Administration Building, Bakersfield

Public Comments

Commentor	Ref #	Comment	Response
Kern Groundwater Authority Received Comments			
Kern County Farm Bureau	FB-1	The Kern County Farm Bureau (KCFB) is submitting this letter on behalf of its members expressing the open and transparent process that the Kern Groundwater Authority (KGA) provided during the development of the Groundwater Sustainability Plan (GSP) required under the Sustainable Groundwater Management Act (SGMA).	Comment Noted.
Kern County Farm Bureau	FB-2	During the last two plus years of the KGA's formation and subsequent development of the GSP, the KGA has attended and presented monthly to the KCFB's board, members, and guests. Most importantly, with the approval of the KCFB, the KGA continuously sought input, recommendations, and suggestions from the KCFB members. In addition to these efforts, the KGA partnered with the KCFB to hold several "Open House" workshops with the Department of Water Resources (DWR) and State Water Board staff in attendance as willing participants thus providing the KCFB's members and all other beneficial users of groundwater in the Kern Subbasin the opportunity to talk one-on-one with staff.	Comment Noted.
Hancock Farmland Services	HFS-1	The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water, for example xxx,xxx acre-feet and not associated with a given gross or net area.	There is no allocation of native yield at this time. The use of the native yield at this time is a component of developing a basic water budget. The water model for the Kern subb describes in detail the native yield and how the water model derives to the Kern subbasin number. There are no determination of any water rights or allocations.
Hancock Farmland Services	HFS-2	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	Comment Noted. See Kern Water Bank Authority Response
Hancock Farmland Services	HSF-3	GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration.	Remote sensing is also another mechanism that is being explored at this time. The KGA is working with DWR to amend a current grant program to accommodate the usage of t funds to begin the development of a program to establish remote sensing systems.
Westchester	WGIM-1	The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water, for example xxx,xxx acre-feet and not associated with a given gross or net area.	Comment noted. See Hancock Farmland Services HFS-1 response.
Westchester	WGIM-2	... GSAs and MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible without creating undesirable results, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity.	Comment Noted: The KGA also agrees with the recommendation to utilize the best available data and science.
Westchester	WGIM-3	As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated and consistent across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).	Comment Noted: Each individual management area and GSA have different water supplies, water amounts and water banking projects thus the coordination occurred during t development of the water model for future projections. SGMA requires to respect water rights.
Westchester	WGIM-4	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	Comment Noted: See Kern Water Bank Authority response
Westchester	WGIM-5	GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater.	The GSAs in the Kern County subbasin are currently engaged in the development of a coordinated basin-wide data management system (DMS). That process has just begun w submittal of an application to DWR for Prop 68 grant funds. As that moves forward, the design of the DMS is vital to the management/tracking of groundwater and surface wa use.
Westchester	WGIM-6	GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration.	Comment Noted: See Hancock Farmland Services HSF-3 response
Wonderful Orchards	WO-1	It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource.	Comment Noted: See Hancock Farmland Services HFS-1 response
Wonderful Orchards	WO-2	In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield.	Comment Noted: See Hancock Farmland Services HFS-1 response
Wonderful Orchards	WO-3	In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin.	Comment Noted: The KGA will continue to hold stakeholder workshops throughout the implementation of the GSP.
Wonderful Orchards	WO-4	Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.	Comment Noted: Water Markets are mentioned in several individual management area plans as management projects/actions. As a basin, the discussion is continuing betwee GSAs. The KGA will continue to hold stakeholder workshops throughout the implementation of the GSP.
Wonderful Orchards	WO-5	GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity	Comment Noted: See Westchester WGIM-2
Wonderful Orchards	WO-6	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	Comment Noted: See Hancock Farmland Services HFS-2 response
Wonderful Orchards	WO-7	GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater.	Comment Noted: See Westchester WGIM-5 response.

Commentor	Ref #	Comment	Response
Dept of Fish and Wildlife	DFW-1	The Department recommends continued data collection to reduce uncertainty around shallow groundwater, and concurrently, around the presence of GDEs. Until such time as a GOE can be verified through field work or increased resolution of groundwater mapping reliant on hydrologically robust baselines, the Department recommends including all potential GDEs in the MAP as beneficial users of groundwater	Comment Noted. The KGA management area plans that have the condition of shallow groundwater have addressed. See Semitropic, Arvin-Edison and Westside management plans for those areas indicated in the comment letter dated 11-25-2019.
Dept of Fish and Wildlife	DFW-2	i. Revise the sustainable management criteria and accompanying narrative by accounting for undesirable results for environmental beneficial users of groundwater. Clarify how species and habitat groundwater needs were considered in the identification of sustainable management criteria. ii. Revise sustainable management criteria to reflect a 'Critically Overdrafted' subbasin designation by seeking to improve current groundwater conditions rather than allowing for continued aquifer depletions over the next two decades.	Comment Noted. The process in developing the Sustainable Management Criteria was an open door policy at several workshops, public KGA board meetings and open house workshop with all the GSAs in the Kern subbasin. Significant and undesirable results are based on local conditions as required not as a best case.
Dept of Fish and Wildlife	DFW-3	The Department recommends that the GSP clarify locations of existing shallow groundwater monitoring wells used to create the shallow groundwater elevation contour map provided within the MAP (Figure 2-27). Additionally, the figure should show overlap potential GDEs with shallow monitoring well locations to vet vegetation groundwater reliance. This figure and associated information would clarify monitoring data gaps and serve as an assessment tool when verifying GDEs.	Comment Noted. The KGA management area plans that have the condition of shallow groundwater have addressed.
Dept of Fish and Wildlife	DFW-4	Many of the Duck Clubs in the MAP area are currently supported by the Department'sCalifornia Waterfowl Habitat Program to ensure the adequate maintenance of habitat critical to wetland-dependent species. Implementation of pumping allowances identified in Figure 5-3 would eliminate all wildlife value associated with these wetlands. To continue to share in the support of this valuable public benefit, the Department recommends that the Semitropic Water Storage District Groundwater Sustainability Agency create additional pumping allowances and/or supplemental water supply opportunities for lands that support wetland habitat. The Department also requests confirmation that all Department-owned lands within Semitropic Water Storage District jurisdiction (see Comment #1) will be granted an equitable native groundwater yield allocation under new Landowner Water Budget management actions (starting page 187).	Comment Noted. The KGA management area plans that have the condition of shallow groundwater have addressed.
The Nature Conservancy	TNC-1	Section 2.1.5.1 Description of Beneficial Uses and Users in the Basin (p. 23) California Water Code §1305(f) defines beneficial uses of waters of the State as including "preservation and enhancement of fish, wildlife, and other aquatic resources and preserves." Section 2.1.5.1 states that beneficial users are stakeholders who have an interest in or need groundwater use. The discussion focuses on active groundwater pumpers but does not mention environmental uses or environmental stakeholders. Section 2.2.1.4 focuses on criteria for determination of groundwater with beneficial use for human consumption or mineral extraction, but omits references in the California Water Code to environmental beneficial uses. **Please describe the other beneficial uses and users of groundwater in the Subbasin identified by the Water Code including: GDEs; managed wetlands; Protected Lands, including preserves, wildlife refuges, conservation areas, recreational areas and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, recreation and navigation.**	Comment Noted. In the KGA Communication and Engagement Plan beneficial users are described including environmental organizations such as the ones that are mentioned i comment.
The Nature Conservancy	TNC-2	Section 2.2.1.4 Kern County Subbasin Boundaries, Criteria for the Extent of Groundwater with Beneficial Use in the Subbasin (p. 40) The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses and users of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. **Please identify any environmental uses and users of groundwater in the plan area, and take particular note of the species with protected status. The following are resources that can be used:** **- Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/;** **- A list of freshwater species located in the Kern County Subbasin in Attachment C of this letter; and** **- The California Department of Fish and Wildlife's California Natural Diversity Database (CNDDB)**.	Comment Noted. See individual management area plans for those areas that have species and habitats.
The Nature Conservancy	TNC-3	Section 2.1.2 Plan Area Setting (pp. 13-14) The GSP provides a description of the groundwater well types and well density; however, there is no discussion of instream flow requirements, if any, or how the water infrastructure is in compliance with regulatory requirements to protect species of concern in the surface waters within the Subbasin. **Please provide a description of any current and planned instream flow requirements or regulatory requirements for protection of species of concern in the Kern River, Poso Creek and Caliente Creek. If there are no requirements in place or planned, then please state that in the GSP.**	Comment Noted. See individual management area plans for those areas that have those surface water indicated. Also, the Kern River is not located within the KGA jurisdictior boundary, see KRGSA for additional information.
The Nature Conservancy	TNC-4	Section 2.1.3 Existing Plans in the Plan Area (pp. 14-15) This section summarizes the Kern County General Plan and general plans for cities within the GSP area. The plan descriptions are focused on goals and policies directly related to groundwater resources and do not include policies and goals related to surface water resources that may be connected to groundwater. **We suggest adding a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. Please include a description of any land use or environmental plans relevant to wetlands, aquatic resources and other GDEs and ISWs and their relationship to the GSP. Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands around the Kern Wildlife Refuge, aquatic resources and other GDEs and ISWs.**	Comment Noted. The General Plan goals and policies are under the jurisdiction of the planning public agency thus the KGA nor any management area plan has the authority to change/adopt any policies requested. The KGA and the individual management area plans where the planning public agenices are located within are communicating about the plan updates coming in 2020 and when there is a general plan amendment occurring.
The Nature Conservancy	TNC-5	Section 2.1.3 Existing Plans in the Plan Area (pp. 14-15) This section is focused on discussion of agriculture and irrigation needs, demands, and types of irrigation, and the groundwater resources policies and goals in general plans. It does not include any other applicable land use or environmental plans that may contain information relevant to the GSP and ISWs. This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**	Comment Noted. The Metropolitan Bakersfield Habitat Conservation Plan is located within the jurisdiction of the KRGSA. Currently, there are no known HCPs or NCCPs adopt within the KGS jurisdiction boundary.

Commentor	Ref #	Comment	Response
The Nature Conservancy	TNC-6	Section 2.1.4 Existing and Ongoing Water Resource Programs (pp. 15-19) Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). In order for this section to provide the appropriate context and help assure integration of GSP implementation with other ongoing regulatory programs, additional information on water use management and monitoring programs relevant to wetlands, sensitive or critical habitat, and GDEs and their relationship to the GSP should be provided. **- Please provide a description of resource management plans, monitoring activities and responsibilities by State, Federal and local agencies and jurisdictions related to aquatic resources and GDEs that could be affected by groundwater withdrawals, and list them in Table 2-1.** **- The Critical Habitat for Threatened and Endangered Species website maintained by US Fish and Wildlife Service (https://fws.maps.arcgis.com/home/webmap/viewer.html?webmap=9d8de5e 265ad4fe09893cf75b8dbfb77) identifies multiple lands with endangered and threatened species in the Subbasin, for instance, Buena Vista Lake Ornate Shrew (Sorex ornatus relictus) occurs within the area. Please review and discuss the potential groundwater reliance of critical species in the Subbasin. Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.** **- Other GDEs and sensitive habitats. Please include a discussion of any monitoring programs related to GDEs and sensitive habitats.**	Comment Noted. Table 2-1 are those programs that the member agencies of the KGA are being implemented within each management area. Since the State and Federal are n members of the KGA their responsbilities are not listed. The table information was provided by the member agencies and for more detail information see individual manageme plans where GDEs and sensitive habitat are located.
The Nature Conservancy	TNC-7	Section 2.1.4.4 Well Permitting Process (p. 20) and Section 2.1.4.5 Plan Elements from CWC Section 10727.4 (g) Well Construction Policies (p. 21) These sections discuss the Kern County Public Health Services Department Water Well Program, which issues permits to construct, reconstruct, and destroy water wells. The discussion does not provide any details regarding the potential effects of the permitting and construction of new wells on aquifer systems, GDEs and ISWs. - **Please discuss that future well permitting and well construction must be coordinated with the GSP to assure achievement of the Plan's sustainability goals.** **- Please state how the well permitting process incorporates protection of GDEs and ISWs within the Subbasin.** **- The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). Please include a discussion of the need for well permitting programs to comply with this requirement.**	Well permits within the Subbasin are issued by the Kern County Public Health Services Department and will continue under SGMA, meaning that Kern County retains jurisdictio the issuing of water well permits. The County has implemented a supplmental well application for SGMA that is distributed to the KGA/GSAs in the Kern subbasin for the individ management area plan or GSA to contact the applicant of the well permit to advise of the local groundwater conditions and consideration of local measurable objectives and mi threasholds prior to the construction of the well. The process developed for well permits was coordinated with all the GSAs in the Kern subbasin and Kern County to limit as m impacts to all beneficial users within the Kern subbasin. The process has been in existence for over a year and has assisted new water well applicants to understand SGMA pric investing in the construction of new water wells.
The Nature Conservancy	TNC-8	Section 2.2.1.5 Bottom of Subbasin (p. 41) The bottom boundary of the Subbasin should be more precisely defined in accordance with DWR guidance. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12- 23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions." Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom. This will prevent the possibility of extractors with wells deeper than the basin boundary (defined by the base of freshwater) from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary. **Please characterize groundwater well extractions from the deepest wells in relation to defining the basin bottom. If the bottom boundary of the Subbasin has not been clearly defined in certain management areas, please identify this as a data gap and elaborate in the monitoring section how and where additional observations can be made to reconcile this data gap.**	Comment Noted. The basin is defined within the Basin Setting. See individual management area plans.
The Nature Conservancy	TNC-9	Section 2.2.1.6 Principal Aquifers and Aquitards (pp. 44-53) The GSP includes a relatively robust description of the geologically diverse aquifers in the Subbasin with differing zones of confined, semiconfined and unconfined groundwater conditions, in addition to "shallow zones" stated to be present locally in the northwestern and southern portions of the central Subbasin. The GSP states these are "not a part of active groundwater extraction, but data are included in the groundwater conditions section of this report to evaluate changes over time." On page 53, environmental users are identified as beneficial groundwater users of the primary aquifers in the Subbasin. Please note that a Principal Aquifer is defined in the GSP regulations as including "aquifers or aquifer systems that store, transmit, and yield significant … quantities of groundwater to … springs, or surface water systems" (23 CCR §351(aa). As such, if the shallow aquifer interacts with surface water systems or provides groundwater necessary to sustain GDEs or other environmental beneficial users, it should be considered a Principal Aquifer. No description, data or information is provided regarding the potential effect of groundwater extraction from groundwater production aquifers on the uppermost shallow aquifers and groundwater bearing zones, whether perched aquifers exist, and how the shallow aquifers or zones are connected to and interact with surface water and GDEs. **Please provide additional description of the shallow aquifers within the Subbasin including characteristics of interconnections with surface water and GDEs, vertical groundwater gradients, connections with underlying production aquifers, and the resulting potential interaction of groundwater pumping with ISWs and GDEs. Please state whether localized perched aquifers are present in the Subbasin. Describe any data gaps. The function and significance of the Shallow Aquifers that provide groundwater to ISWs and GDEs should be summarized in Table 2-3.** **Please describe whether the existence of Aquifer Exemptions has any bearing or implications related to environmental beneficial uses of groundwater.**	Comment Noted. In the Kern subbasin, shallow aquifers are not aquifers that interconnect with the surface as is indicated in the cross sections in the GSP and individual manag area plans. See individual management area plans where shallow aquifers are located within for specific actions to be taken by the management area plan.
The Nature Conservancy	TNC-10	Section 2.2.1.7 Data Gaps and Uncertainty (p. 53) **If data are not present to produce the information requested in the comment above, please clearly identify this as a data gap. Please elaborate in the monitoring section how and where additional observations are to be conducted in order to address this data gap.**	Comment Noted. See individual management area plans where shallow aquifers are located within for specific actions to be taken by the management area plan.
The Nature Conservancy	TNC-11	Section 2.2.1.8 Cross Sections (pp. 54-55) Regional basin-wide geologic cross sections are provided in Figures 2-19a through 2- 19g. These cross-sections do not include a graphical representation of the manner in which the very shallow groundwater or perched water may interact with ISWs or GDEs that would allow the reader to understand this topic. **Please include near- surface cross sections or insets that depict the conceptual understanding of shallow groundwater and ISW interactions at different locations, including perched and regional aquifers and GDEs.**	Comment Noted.
The Nature Conservancy	TNC-12	Section 2.3.1.1 Elevation and Flow Directions (pp. 64-66) This section states that the depth to groundwater in the Shallow Zone ranges from 5 to 25 feet. Inference is made that groundwater levels in the Shallow Zone is relatively constant and is typically perched on fine grained sedimentary units and likely disconnected from the productive aquifer system. No specific data or hydrogeologic analysis is provided to substantiate these important claims. **Please provide any available stratigraphic data, hydrograph data, pumping test data or other information to substantiate these claims. If the data are not available, please identify this as a data gap.**	Comment Noted. Made changes to add additional data references.

Commentor	Ref #	Comment	Response
The Nature Conservancy	TNC-13	Section 2.3.7 Interconnected Surface Water Systems (pp. 88-90) The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted." "At any point" has both a spatial and temporal component. Even short durations of interconnection between groundwater and surface water can be crucial for surface water flow and support of environmental users and uses of groundwater and surface water. ISWs can be either gaining or losing. The text states (p. 88) that "Within the Subbasin, there are no interconnected natural surface water systems in monitored areas associated with the pumping zone of the regional aquifer system" and "Since the advent of groundwater pumping in the Subbasin and subsequent impoundment and regulation of flow of the Kern River, groundwater levels near the river are no longer connected with the river bed by a continuous saturated zone." However, the data provided to substantiate these broad claims cover only portions of the surface water flow system. The models cited as substantiation were not constructed for the purpose of identifying potential ISWs and GDEs, but are regional models constructed for supply management. In fact, the text also states (p. 90) that the Kern River has gained flow during some years and the upper reach of the Kern River in the Subbasin has been identified as gaining. The connection between surface water and groundwater is mentioned as a data gap in Section 2.3.7.4 (p. 90). Furthermore, the depth to water in the shallow aquifer is quite shallow as discussed above (5 to 20 feet below ground surface), which strongly suggests that interaction between the shallow aquifer and surface water may be occurring. Because there are uncertainties in the hydraulic connection between rivers / streams and shallow groundwater, ISWs should not be disregarded in the GSP. The GSP regulations require reliance on the best available information and clear identification of data gaps when sufficient information is not available.	Comment Noted. Kern River is not within the jurisdiction of the KGA. Please review the information related to the Kern River in the KRGSA GSA for further specific details.
The Nature Conservancy	TNC-13 (Cont)	**Please provide additional data or analysis to substantiate the nature of the hydrologic relationship between the shallow aquifer and production aquifers and ISWs. If data are not available to verify that such a connection does not exist, acknowledge where ISWs may exist and identify appropriate sustainable management criteria, monitoring networks and management actions for sustainable ISW management or to address data gaps. Data could include groundwater level data from shallow or nested monitoring wells, comparison of stream stages to groundwater levels, modeling information or additional gaging data. Please elaborate how and where additional observations (shallow monitoring wells, stream gauges, and nested / clustered wells) along surface water features can be used to address data gaps in the Monitoring Network section of the GSP to improve identification of ISWs rather than prematurely disregarding them in the GSP.**	Comment Noted. Additional information provided.
The Nature Conservancy	TNC-14a	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) We applaud KGA for using the NCCAG database, developed through a collaboration between DWR, California Department of Fish and Wildlife (CDFW) and TNC, to identify potential GDEs, and then evaluate the NCCAG results to identify GDEs; however, the approach used is based on narrative analysis and quantitative data are not used. In addition, no determination is presented as to which NCCAG polygons represent GDEs. **Please refer to Attachment D of this letter for best practices in using groundwater data to verify whether NCCAGs are GDEs.**	Comment Noted. During the development of the Basin Setting, several workshops were held to seek input/information from beneficial users to better work together and accommodate their concerns. The Basin Setting was first posted on the KGA website in May 2019.
The Nature Conservancy	TNC-14b	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) The text states (p. 91): "Groundwater potentiometric surfaces from Kern Fan Monitoring Reports (KCWA, 2016) indicate that underlying aquifers are not connected with stream channels. Some flow in the Kern River, as well as in Poso Creek and other mountain-front creeks, is likely to be sustained periodically by release of bank storage (surface water stored in stream banks), but the underlying groundwater is too deep to sustain flow in the valley floor." This contradicts the statements on page 90 that the Kern River has gained flow during some years and the upper reach of the Kern River in the Subbasin are identified as gaining. If there are insufficient groundwater level data in the upper aquifer where gaining reaches are located or where bank storage is inferred to occur, then the NCCAGs in these areas should be included as GDEs in the GSP until data gaps are reconciled in the monitoring network. **Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gaps will be addressed.**	Comment Noted. See response above. See individual management area plans for those plans that are identifying data gaps and how the plans are going to manage going forwa
The Nature Conservancy	TNC-14c	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) The text states (p. 92): "The conditions in the center of the Subbasin suggest that the groundwater production aquifer does not reach the shallow subsurface. The production aquifer lies at depths that prevent surface water expressions or accessibility for vegetation." **Please support this statement with specific groundwater level data that indicate a gap in the saturated zone between the production aquifers and shallow groundwater, and define the extent of the NCCAG dataset polygons that are excluded from consideration as GDEs on this basis.**	Comment Noted. See individual management area plans for more detailed information addressing GDEs in their management area.
The Nature Conservancy	TNC-14d	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) The text states (p. 92): "Based on the NCCAG dataset along the margins of the Subbasin where spring-fed streams exist, further confirmation is needed to evaluate the presence of GDEs." If there are insufficient groundwater level data in the upper aquifer where these stream-fed springs exist, then the NCCAGs in these areas should be included as GDEs in the GSP until data gaps are reconciled in the monitoring network. **Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gap will be resolved.**	Comment Noted. See indivudal management areas plans for specific handling of data gaps.
The Nature Conservancy	TNC-14e	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) Because data gaps have been identified in Section 2.2.1.7 (p. 53) Section 2.3.7.4 (p. 90) and Section 2.3.8.2 (p. 92) related to shallow groundwater conditions and the identification of ISWs and GDEs within the Subbasin, final determination of the extent of GDEs in the Subbasin has yet to be completed. **Please revise the GDE analysis in the GSP by conducting more substantial, data-based evaluation focusing on GDE identification in the GSP, clearly identify which NCCAG polygons are excluded, which polygons are determined to be GDEs and which polygons are uncertain at this time and will be verified as data gaps are address.** SGMA defines GDEs as "ecological communities and species that depend on *groundwater emerging from aquifers or on groundwater occurring near the ground surface* " (emphasis added). **Confirmation of GDEs should be performed based on depth to groundwater in the shallow zone, and additional information provided as to whether the shallow zone may be affected by groundwater withdrawal from the production aquifers. Please refer to Appendix D of this letter for best practices for using groundwater data to verify a connection to groundwater.**	Comment Noted. See response to comments above relating to GDEs and specific impacts/relationship to shallow zones. See individual management area plans for specific ha of data gaps.
The Nature Conservancy	TNC-14f	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) In the scientific literature, it is generally acknowledged that GDEs can rely on groundwater for *some or all* of their requirements (emphasis added). GDEs can rely on multiple water sources simultaneously and at different temporal and/or spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow). SGMA defines GDEs as "ecological communities and species that depend on groundwater *emerging from aquifers* or on groundwater occurring near the ground surface" (emphasis added). **Therefore, we recommend using depth to groundwater contour maps derived from subtracting groundwater levels from a DEM, as described above, to identify whether a potential connection to groundwater exists for the wetlands mapped in Attachment H of the GSP. Please refer to Attachments D and E of this letter for best practices for using local groundwater data to 1) verify whether polygons in the NC Dataset are supported by groundwater in an aquifer, and 2) verify whether ecosystem decline or recovery is correlated with groundwater levels.**	Comment Noted.

Commentor	Ref #	Comment	Response
The Nature Conservancy	TNC-14g	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) Very little description is provided regarding the nature and function of identified GDEs in the west-central and south-central portions of the Subbasin, their potential sensitivity to groundwater and surface water supply changes, or their relative habitat value. **We recommend the inclusion of a discussion regarding the nature and characteristics of GDEs.**	Comment Noted.
The Nature Conservancy	TNC-14h	Section 2.3.8 Groundwater-Dependent Ecosystems (pp. 90-92) **Please provide information on the historical or current groundwater conditions near the GDEs or the ecological conditions present.** Refer to GDE Pulse (https://gde.codefornature.org or Attachment E of this document) or other locally available data (e.g. leaf area index, evapotranspiration or other data developed from remote sensing) and depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC Dataset polygons found in the Subbasin.	Comment Noted.
The Nature Conservancy	TNC-14i	**We recommend an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes vegetation or habitat types and rank the GDEs as having a high, moderate or low value. Explain how each rank was characterized.**	Comment Noted.
The Nature Conservancy	TNC-14j	**Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs. Some organisms rely on uplands and wetlands during different stages of their lifecycle.** Resources for this include the list of freshwater species located in the Subbasin that can be found in Attachment C of this letter, the Critical Species Lookbook, and CDFW's CNDDB database.	Comment Noted.
The Nature Conservancy	TNC-15	Section 2.4 Water Budget (p. 92) The GSP refers to Attachment J for water budget information. In Attachment J, Section 3.7.1 discusses the development of evapotranspiration (ET) rates for each land cover type (p. 11). **Please provide a breakdown of ET for native and riparian vegetation (such as wetlands, riparian vegetation, phreatophytes and other communities). Please evaluate the spatial relationship of native vegetation ET to NCCAG polygons to determine the groundwater use by this beneficial user for inclusion in the water budget. Identify any data gaps and outline the actions needed to address them.**	Comment Noted. The ETc rates for the entire Kern subbasin were coordinated with satellite data and provided to each individual management area and GSA to evaluate their individual areas. The data obtained from the ITRC- METRIC study covers the entire Kern subbasin. The Kern subbasin water modeling budget provides an overview of the data. review more specific ETc beakdown, please see individual management area plans or GSA.
The Nature Conservancy	TNC-16a	Section 3.1 Sustainability Goal (p. 139) The sustainability goal of the Kern County Subbasin is to "Achieve sustainable groundwater management…Maintain its groundwater use within the sustainable yield of the basin…Operate within the established sustainable management criteria…maintain sustainability over the implementation and planning horizon." The GSP regulations (23 CCR §354.24) require that "[t]he Plan shall include a description of the sustainability goal, … a discussion of the measures that will be implemented to ensure that the basin will be operated within its sustainable yield, and an explanation of how the sustainability goal is likely to be achieved … and maintained … ." The stated sustainability goal recites regulatory requirements and does not provide a description of the goal relative to the basin setting and beneficial uses. The goal does not mention environmental uses and users of groundwater and does not mention undesirable results. **Please clarify the sustainability goal and expand its description to ensure that all beneficial uses and users of groundwater are identified as being protected from undesirable results, and in particular, include GDEs, ISWs and related critical habitats.**	Comment Noted. The Sustainability Goal was coordinated/developed for the entire Kern County subbasin which includes all beneficial uses and users located within the Kern C subbasin. The KGA held workshops seeking input into the development of the Sustainability Goal as well as held a Board meeting to seek additional input prior to finalizing. D those meetings, it was addressed that the Sustainability Goal is for the benefit of all beneficial uses and users in the Kern Subbasin and environmental is considered a beneficial
The Nature Conservancy	TNC-16b	**Since GDEs and ISWs may be present in the Subbasin (please see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be specifically included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included.**	Comment Noted. See responses above concerning relationship of beneficial uses and users to the Sustainability Goal. No statement is required concering addressing pre-SGM impacts.
The Nature Conservancy	TNC-16c	The GSP states that there is no ISW connectivity for the Kern River; however, there isn't any data, analysis and / or other information provided to support this broad conclusion. **Please include ISWs in the Sustainability Goal until/unless sufficient data is available and provided to verify the status of ISWs.**	Comment Noted. The Kern River is not located within the jurisdictional boundary of the KGA, see the KRGSA for more detailed information.
The Nature Conservancy	TNC-16d	GDEs are dependent, in part, on suitable water quality; however, the GSP only considers water quality for irrigation and domestic use. **Given that there are potential GDEs in the Subbasin and that they may be affected by water quality, they should be included in the Sustainability Goal and addressed in the Water Quality section.**	Comment Noted. It is stated that water quality could affect beneficial users in the Kern subbasin and are addressed in the GSP as well as in the individual management area pla GDEs are considered beneficial users.
The Nature Conservancy	TNC-17	Section 3.2 Minimum Thresholds and Measurable Objectives (pp. 145-150) Minimum thresholds and measurable objectives for chronic lowering of groundwater levels, reduction of groundwater storage and degraded water quality do not include environmental beneficial users, such as ISWs or GDEs. **For each of these applicable sustainable management criteria, please include a discussion of GDEs (see comments under checklist items 16-20) and whether the minimum thresholds, measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment. Please modify Section 3.2.2 to specifically address impacts from degraded water quality to the plant and wildlife communities within GDEs.**	Comment Noted. The development of the minimum thresholds and measureable objectives were established based on the impacts to all beneficial uses and users within the K subbasin. Specifications to just address plant and wildlife was considered as the thresolds and objectives were being set. For more specific information see indvidual manage area plans.
The Nature Conservancy	TNC-18	Section 3.2.2.2 Potential Effects of Chronic Lowering of Groundwater Levels (p. 141) GDEs are a beneficial user of groundwater in the Subbasin. **Unless evidence is provided to verify the exclusion of GDEs please modify this section of the GSP to identify GDEs as one of the beneficial uses and users of groundwater that could experience significant and unreasonable effects as a result of chronic lowering of groundwater levels.**	Comment noted. See response to comments above.
The Nature Conservancy	TNC-20	Section 3.1.5 (Undesirable Results for depletion of) Interconnected Surface Water (p. 144) The GSP states (p.144) that "Though many studies have been conducted in the Subbasin, including in areas such as the Kern River and Poso Creek, results do not show evidence of surface water within the Subbasin to be interconnected. As there are no known natural interconnected surface water systems within the KGA boundary, this sustainability indicator is not included in this GSP." As noted in the prior comments, several areas have been identified as potential ISWs and GDEs, and substantial data gaps exist. As such, the above statement contradicts other information provided in the GSP, and serves as an acknowledgement of data gaps. It is not an appropriate basis for removing this sustainability indicator from the GSP under the GSP regulations. **Unless evidence is provided to verify the exclusion of GDEs and ISWs, please modify this section of the GSP to include a statement that 1) there are potential ISWs, and 2) provide an assessment of potential undesirable results.**	Comment Noted. See indivudal management areas plans for specific handling of data gaps.
The Nature Conservancy	TNC-21	Section 3.1.5 (Undesirable Results for depletion of) Interconnected Surface Water (p. 144) The GSP states (p.144) that "… there is no interconnected surface water under the influence of groundwater pumping in the principal aquifer in this area and no impacts to interconnected surface water have been observed." As noted in the prior comments, areas of shallow groundwater and gaining stream reaches are known to exist in the Subbasin. No quantitative data have been provided to assess the extent of hydraulic connection between shallow groundwater and the underlying production aquifers. As such, the above statement is insufficiently supported by data and is actually a substantial data gap. **Unless evidence is provided to verify the potential influence of groundwater extraction on GDEs and ISWs, please modify this section of the GSP to include a statement that the data are insufficient to assess whether GDEs can experience significant and unreasonable effects as a result of groundwater extraction in the Subbasin and provide an assessment of potential undesirable results. Please also identify that existing data gaps will be addressed and the presence or absence of GDEs will be verified with monitoring wells screened at the appropriate depths.**	Comment Noted.
The Nature Conservancy	TNC-22	Section 3.2 Undesirable Results (for each sustainability indicator) (pp. 139-144) This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses / users that could be adversely affected by chronic groundwater level decline or other undesirable results. **Please add "possible adverse impacts to potential GDEs and ISWs" to the list of potential undesirable results.**	Comment Noted. As the Undesirable Results were being developed and considered all beneficial uses and users were considered. There were several workshops seeking information/input during the development period.

Commentor	Ref #	Comment	Response
The Nature Conservancy	TNC-23a	Section 3.2 Undesirable Results (for each sustainability indicator) (pp. 139-144) The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC Dataset polygons within the Subbasin. Over the past 10 years (2009- 2018), some NC Dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture in the western portion of the Subbasin. **Please review these spatial patterns and, where possible, correlate them with water level trends. Any indications of adverse trends and any data gaps should be identified.**	Comment Noted.
The Nature Conservancy	TNC-23b	**For each identifiable GDE unit with supporting hydrological datasets, please include the following:** **- Plot and provide hydrological datasets;** **- Define the baseline period in the hydrologic data;** **- Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater; and** **- Explore cause-and-effect relationships between groundwater changes and GDEs.**	Comment Noted.
The Nature Conservancy	TNC-23c	**For identifiable GDE units without supporting hydrological datasets please describe data gaps and / or insufficiencies.**	Comment Noted.
The Nature Conservancy	TNC-23d	**Compile and synthesize biological data for each GDE unit by:** **- Describing biological resources for each GDE unit; and** **- Describing data gaps / insufficiencies.**	Comment Noted.
The Nature Conservancy	TNC-23e	**Describe possible effects on potential ISWs, GDEs, land uses, and property interests, including:** **- Cause-and-effect relationships between potential ISWs and GDEs with groundwater conditions** **- Impacts to potential ISWs and GDEs that are considered to be "significant and unreasonable;"** **- Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities;** **- Land uses should include recreational uses (e.g., fishing/hunting, hiking, boating); and** **- Property interests should include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.**	Comment Noted.
The Nature Conservancy	TNC-24	Section 3.3 Monitoring Network (pp. 150-169) The GSP proposes to coordinate and use existing monitoring networks of Kern Groundwater Authority and its districts / member agencies for groundwater elevations and storage, groundwater quality, and land subsidence. The text (p. 151) states that the monitoring network will monitor impacts to the beneficial uses and users of groundwater and goes on to state that "*depletions of interconnected surface water are not pertinent to the monitoring network.*"(emphasis added) As discussed in previous comments, unless data are provided to support this broad statement, due to uncertainties in the hydraulic connection between rivers / streams and GDEs with shallow groundwater, ISWs and related GDEs should not be disregarded in the GSP. The GSP should include a description of how groundwater conditions will be monitored to assess the potential effects of groundwater withdrawals on ISWs and GDEs. In addition, this section should include a description of how hydrological data gaps and insufficiencies will be addressed in the monitoring network. **Please modify the description of the monitoring network to provide methodologies, data and other information to address the data gaps associated with GDEs and ISWs. This modification should include 1) locating new wells that are appropriately screened to detect changes in groundwater levels in the uppermost water table and the connectivity of GDEs and ISWs with the upper unconfined or shallow zone aquifer; and 2) identifying or installing additional stream gauges in areas where there is potential for ISWs and GDEs. Please expand on the discussion of how the new well and stream data will be used to improve ISW mapping and inform an adequate analysis, and how the data will be used to verify possible GDEs.**	Comment Noted. The development of the monitoring network was established based on the benefits/impacts to all beneficial uses and users within the Kern subbasin. As ha stated previously, environmental is considered a beneficial use in the Kern subbasin and as such was considered in the development of the monitoring network. Several Stakel workshops were held during the development of the monitoring networl seeking input from all beneficial users. The locating of new wells and additional stream gauges are addressed in individual management area plans and GSAs. The monitoring network is considered an adaptive management plan and will be addressed annually as data is obta and submitted to DWR. This data will be available as it becomes available.
The Nature Conservancy	TNC-25	Section 3.3 Monitoring Network (pp. 150-169) As stated above in the comments for Checklist Items 8-10, **please address data gaps along the Kern River and tributary creeks identified earlier in the GSP in this section of the GSP to improve ISW mapping in companion or future GSPs (e.g., through shallow monitoring wells, stream gauges, and nested/clustered wells).**	Comment Noted. The Kern River is not located within the jurisdictional boundary of the KGA, see the KRGSA GSP for more detailed information.
The Nature Conservancy	TNC-23a	Section 4 Projects and Management Actions (p. 175) Table 4-1 in this chapter lists many important projects and management actions including allocation changes, imports, surface water diversions, pumping allowances, conveyance and recharge projects, and addition of percolation basins; however, the descriptions only identify benefits to water level, groundwater storage, water quality and water supply. Maintenance or recovery of groundwater levels and construction of recharge facilities may have potential environmental benefits. It would be advantageous to recognize these benefits so as to demonstrate multiple benefits from a funding and prioritization perspective. - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.** - If ISWs and GDEs will not be adequately protected by the listed projects and management actions, **please consider additional management actions and projects targeted for protecting ISWs and GDEs.** - **Please describe how the projects and management actions will be evaluated to assess whether adverse impacts to GDEs may occur and/or will be mitigated or prevented.** - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/	Comment Noted. Management projects/actions are to the benefit of all beneficial uses and users within the Kern subbasin. The costs associated to the management projects/actions will also be considered as costs to all beneficial uses and users as well. This process will occur during the implementation period of 20 years and with transpar and open conversations/workshops. Please see indivudal management areas plans for specific management projects/actions pertaining to GDEs and ISW.
Leadership Counsel	LC-1	The Draft GSP is Incomplete, and Must Include Additional Information For the Public to Evaluate the GSP	The KGA GSP includes a summary of all the management area plans. For specific information pertaining to drinking water impacts on disadvantaged communities and protecte groups, please review the individual management area plans. During the development of the management area plans, each KGA member engaged in stakeholder out reach to communities/groups located within their area. Also, two disadvantaged communities are represented on the KGA board of directors who have voiced/voted their concerns du the entire process. The KGA held Stakeholder meetings to engage and seek input from all beneficial uses and users during the development of the KGA GSP and management a plans.
Leadership Counsel	LC-2	The Kern Groundwater Authority GSA Is Responsible for the Disproportionate and Disparate Impacts That Its Policies and Activities Will Have on Disadvantaged Communities Belonging to Protected Groups	Comment noted. Please see response LC-1
Leadership Counsel	LC-3	The Coordination Agreement Does Not "Explain How the Plans Implemented Together, Satisfy the Requirements of the Act."	The Coordination Agreement follows the requirements of SGMA and provides a dispute Resolution within the agreement.
Leadership Counsel	LC-4	Inadequate Consideration of Public Input Undermines the Validity and Efficacy of the Draft GSP	Disadvantaged communities are represented on the KGA board of directors. These directors have been active in voicing/voting their concerns through the entire process has b instrumental in providing their insights for their communities. The KGA held several workshops during all hours of the day, provided stakeholder surveys in both English and S at those workshops as well as on-line (see the Communication & Education Plan for those events). As the implementation process moves forward, the KGA and its members p continue the insights from all communities.
Leadership Counsel	LC-5	The Kern Subbasin Undesirable Results Do Not Comply with Existing Law	Comment noted. The KGA developed the GSP in compliance with all requirements and believe it will achieve sustainability as defined by SGMA.

Commentor	Ref #	Comment	Response
Leadership Counsel	LC-6	The GSP's Minimum Thresholds and Measurable Objectives Are Not Adequate	As stated in the response in LC-1, the management area plans provide greater detail on how the minimun thresholds and measurable objectives were developed in their area. T KGA GSA and its management area plans are adaptive planning documents which allow for the adjustment of minimum thresholds and measurable objectives as the implement process begins. Any adaptive management will be the result of stakeholde input and consideration of beneficial use.
Leadership Counsel	LC-7	The Monitoring Network is Inadequate With Respect to Groundwater Levels and Groundwater Quality	Comment noted. The KGA developed the GSP in compliance with all requirements and believe it will achieve sustainability as defined by SGMA.
Leadership Counsel	LC-8	Current Projects and Management Actions are Inadequate	The KGA members developed projects and management actions in order to achieve sustainability as defined by SGMA. The KGA GSP is an adaptive management planning docu that will be reviewed annually with a 5 year update. Each management area plan under the direction of the managers has vented all their individual management projects/acti their workshops looking for input from all beneficial users.
Leadership Counsel	LC-9	The GSA Must Clearly Commit to a Drinking Water Protection Program for the Kern Subbasin	Comment noted. Thank you for your comment and we took it under consideration.
Leadership Counsel	LC-10	Recharge In or Near Disadvantaged Communities and Domestic Well Clusters	Comment noted. Please see response LC-8
Leadership Counsel	LC-11	Establish Pumping Buffer Zones That Protect Disadvantaged Communities and Clusters of Domestic Wells	Comment noted. Please see response LC-1 & LC-8
Leadership Counsel	LC-12	Warning Against a Groundwater Market	Comment noted. The KGA appreciates the comment, considered its content but respectfully does not agree with the conclusion.
Leadership Counsel	LC-13	Multi-benefit projects	Comment noted. Please see response LC-1 & LC-8
Leadership Counsel	LC-14	Funding of Projects and Management Actions	Comment noted. The KGA appreciates the comment, considered its content but respectfully does not agree with the conclusion.
Leadership Counsel	LC-15	The Draft GSP Threatens to Infringe on Water Rights	Comment noted. The KGA appreciates the comment, considered its content but respectfully does not agree with the conclusion.
Leadership Counsel	LC-1	The Draft GSP Conflicts with the Reasonable And Beneficial Use Doctrine	Comment noted. The KGA appreciates the comment, considered its content but respectfully does not agree with the conclusion.
Leadership Counsel	LC-1	The Draft GSP Conflicts with the Public Trust Doctrine	Comment noted. The KGA appreciates the comment, considered its content but respectfully does not agree with the conclusion.
Arvin Edison Water Storage District Received Comments			
Leadership Counsel	3	The Draft GSP is Incomplete, and Must Include Additional Information For the Public to Evaluate the GSP	•The Arvin-Edison MA Plan includes complete information on consideration of drinking water impacts as disadvantaged communities, sustainable management criteria, and Pr and Management Actions (P/MAs) •See further comment responses below. •See KGA response to this comment for further information.
Leadership Counsel	3	The Kern Groundwater Authority GSA Is Responsible for the Disproportionate and Disparate Impacts That Its Policies and Activities Will Have on Disadvantaged Communities Belonging to Protected Groups	•See KGA response to this comment.
Leadership Counsel	4	The Coordination Agreement Does Not "Explain How the Plans Implemented Together, Satisfy the Requirements of the Act"	•See KGA response to this comment.
Leadership Counsel	5	Inadequate Consideration of Public Input Undermines the Validity and Efficacy of the Draft GSP	•See comment response below. •See KGA response to this comment for further information.
Leadership Counsel	6	The GSP states that the JPA was "written to provide open ...communication to all beneficial users," and "each member of the KGA held their own outreach programs and opportunities for beneficial users to participate in the development of their individual management area plans, which is included in their individual management area plans;"17 however, this was not the case. For example, the member agency that has jurisdiction over residents with whom we work in the GSA area, the **Arvin-Edison Water Storage District**, did not adequately reach out to disadvantaged community residents or include their feedback in their GSP. For example, the **Arvin WSD's** website contains no information on SGMA or GSP meetings. We understand from conversations with staff that the agency sent notices to its list serv, but there is no way to sign up for the list serv on the website, and without knowing when and where meetings are occuring the public could not go to a meeting to sign up and be added to the interested parties list serv. Therefore the GSA's choice to delegate GSP development to member agencies did not provide an open and transparent process as required under SGMA.	AEWSD conducted substantial stakeholder outreach and engagement during the Arvin-Edison Management Area Plan (MA Plan) development process. This outreach is describ **Section 5.5** of the MA Plan, as well as the Stakeholder Communication and Engagement Plan (SCEP) included as **Appendix E**. AEWSD outreach efforts included: •letters sent to all landowners and all interested parties; •distribution and compilation of a Stakeholder Survey (direct mail in AEWSD billing statements); •AEWSD website does include an email and AEWSD Executive Secretary maintains a list of interested parties for mass emails regarding notices; •Multiple AEWSD/ACSD informational meetings with flyers mailed and emailed ahead of time, including one to LCJA on 29 May 2019; •Multiple letters sent to all Public Water Systems in the MA Plan area; •Site visits to certain well owners to discuss domestic well status and location and regarding development of a monitoring network; •Letters to "white land" owners; •Multiple public stakeholder workshops, some held in triplicate (including with some outside of regular business hours) in the City of Arvin with Spanish language translation. T group Self Help Enterprises (SHE) attended and presented at three of the workshops. The above outreach efforts are in addition to those performed by the KGA. **A list of meetings during which GSP and SGMA were discussed is included in Appendix E of the M which was updated to reflect additional recent meetings.** This includes 39 public meetings of the AEWSD Board between 2/9/2016 and 11/12/2019 where opportunity was provided for public comment. The topic of stakeholder engagement was also addressed in AEWSD's email response (dated 11/7/2019; attached below) to questions from LCJA **Additional information on the stakeholder engagement process was added to Section 5.5.2.** ACSD's outreach efforts during the MA Plan development process included: •April 3, 2017: ACSD Board Meeting •April 17, 2017 ACSD Board Meeting •May 1, 2017 ACSD Board Meeting •November 6, 2017 ACSD Board Meeting •December 18, 2017 ACSD Board Meeting •January 3, 2018 ACSD Board Meeting •April 2, 2018 ACSD Board Meeting •May 7, 2018 ACSD Board Meeting •May 21, 2018 ACSD Board Meeting •September 24, 2018 ACSD Board Meeting •November 5, 2018 ACD Board Meeting •November 19, 2018 ACSD Board Meeting •January 22, 2019 ACSD Board Meeting •March 4, 2019 ACSD Board Meeting •April 1, 2018 ACSD Board Meeting •July 15, 2019 ACSD Board Meeting •September 3, 2019 ACSD Board Meeting •Since May 6, 2019 General Manager Updates Board of Directors every meeting on all Kern Basin GSA's Manager's Meetings or other meetings and items pertaining to SGMA.

Commentor	Ref #	Comment	Response
Leadership Counsel	6 - 7	The **Arvin-Edison Water Storage District ("Arvin-Edison WSD")** states in its GSP ("**Arvin GSP**") that it considered disadvantaged communities by engaging representatives of the Arvin CSD ("Arvin CSD"), which contains disadvantaged community residents; by creating a Stakeholder Communication and Engagement Plan; and by "welcom[ing] public participation" at stakeholder workshops, **Arvin-Edison WSD** board meetings, **Arvin CSD** board meetings, KGA GSA events and meetings, a stakeholder survey, letters to landowners, and small or one-on-one meetings with individual stakeholders.18 However, as a community-based organization working directly with residents in Arvin, we were not included in these conversations until August 15, 2019 when we attended the **Arvin- Edison WSD** Board meeting where they presented their GSP chapter to its board for approval. Residents we work with did not have any knowledge of the GSP development process in the **Arvin-Edison Management Area.** They had heard about SGMA, but had a minimal understanding of what it entailed and were not aware of their local GSP development.	•ACSD is a co-author of the Arvin-Edison MA Plan and was directly involved in its preparation. Specific portions of the MA Plan that were prepared by and/or pertain to the ACS are listed in **Section 4.** •As described in **Appendix E** of the MA Plan, SHE, a community development organization focused on low-income communities, worked alongside AEWSD and ACSD on stakeh outreach matters and SHE representatives were present at stakeholder workshops. AEWSD provided Spanish language translation services. •Because AEWSD does not provide water service to any Arvin residents, it does not "serve a substantial number of non-English speaking people" and therefore the Bilingual Se Act, mentioned in the LCJA letter, does not apply to AEWSD. •ACSD also worked directly with other community organizations and groups regarding SGMA, including Committee for a Better Arvin (CBA) a subgroup of the Center for Race P and the Environment. CBA sent a support letter on December 3, 2019 describing the active ways in which ACSD/AEWSD involved then in the SGMA process. •Residents of the City of Arvin were sent flyers announcing informational meetings by direct mail and electronic mail (see **Appendix E**). •Records of meeting attendance show that several attendees identified themselves as Arvin residents (see **Appendix E**). •Residents that work directly with LCJA are encouraged to request a meeting with AEWSD/ACSD for a GSP update or other district purposes.
Leadership Counsel	7	Additionally, as mentioned above, **Arvin-Edison WSD** did not maintain a list of interested parties that the public could access; their website contains no sign-up, and no meeting notices or agendas about GSP development meetings were published in any publicly available fora. In addition to this violation of public engagement requirements under SGMA, the members agency did not follow the Brown Act by publishing public meeting notices and agendas before meetings, and does not have agendas or meeting minutes on its website so that such materials are available to the public.19	•The SCEP Section 4 describes the process for stakeholder identification by AEWSD and the KGA. A list of interested parties was identified in the SCEP and continuously update during the MA Plan development process. •AEWSD website does include an email address that would provide anyone to be included as an interested party •All AEWSD customers and interested parties are on the AEWSD list serv and thus receive announcements from AEWSD, including meeting announcements and agendas. •Engagement of ACSD customers was handled by ACSD, in coordination with SHE and other community organizations, including CBA. •AEWSD follows all applicable public noticing requirements. The topic of public noticing and Brown Act compliance was also addressed in AEWSD's email response (dated 11/7 attached below) to questions from LCJA. •References made to Kern River GSA appear to be an error however future stakeholder engagement will follow the SCEP as outlined in **Appendix E**
Leadership Counsel	8	The Kern Subbasin Undesirable Results Do Not Comply with Existing Law	•The Undesirable Results definitions in the Arvin-Edison MA Plan were developed in accordance with existing law (SGMA). •See KGA response to this comment for further information.
Leadership Counsel	11	The GSP's Minimum Thresholds and Measurable Objectives Are Not Adequate	•See comment response below. •See KGA response to this comment for further information.
Leadership Counsel	12	The KGA GSA did not ensure that minimum thresholds created by member agencies considered the interests of all beneficial user groups, or prioritize the security of drinking water in the subbasin, in developing minimum thresholds. For example, the **Arvin-Edison Management Area GSP** did not consider the impact on drinking water users in setting its minimum thresholds. The A**EWSD Management Area Draft GSP** details how it calculated historical water lows and divided the Management Area into four sections based on historical low groundwater levels and agency jurisdiction, and how it adjusted the minimum thresholds to protect the canal that brings surface water to farmers.39 However, in did not evaluate or consider how many wells could go dry from its proposed minimum thresholds, or adjust for effects on drinking water. Therefore it did not consider impacts on drinking water beneficial users, or ensure the protection of drinking water as a the highest beneficial use of water.	•AEWSD did conduct an extensive analysis of water quality based on the available data (see **Section 8.5** and **Figures GWC-9 through GWC-13**, and **Appendix H**) and in consulta with representatives of beneficial users of the water (e.g., ACSD). •Arsenic is the one constituent identified by ACSD as having the potential to be influenced by groundwater management activities, and was thus selected for use as a Sustainat Management Criterion (see **Section 14.4.1**). •As stated in a footnote in the MA Plan, "SGMA does not empower GSAs to develop or enforce water quality standards; that authority rests with the State Water Resources Co Board (SWRCB) Division of Drinking Water and the County. Because of the limited purview of GSAs with respect to water quality, and the rightful emphasis on those constituen may be related to groundwater quantity management activities, the only constituent of concern applicable within the Arvin-Edison Management Area is arsenic in the vicinity of City of Arvin and ACSD. Furthermore, drinking water quality regulations for public water systems apply at the point of delivery to customers, not in the raw water source, and A blends water from its various well sources." •All monitoring sites will be sampled for the constituents identified in the Groundwater Quality Concerns section (**Section 8.5.1**), as well as other relevant groundwater quality parameters (see **Section 16.1.4**). Collection of additional data during plan implementation will be used to refine SMC definitions, as discussed in **Section 13.4**. •All ACSD wells are sampled regularly in accordance with their SWRCB permit. •The Representative Monitoring Site (RMS) was selected by ACSD, based on the list of considerations described in detail in **Section 16.1.4**. •The topic of groundwater quality SMCs and monitoring networks was also addressed in AEWSD's email response (dated 11/7/2019; attached below) to questions from LCJA.
Leadership Counsel	14 - 15	As in the case of groundwater levels, it is clear that the GSA has not considered the potential impact on drinking water users, in particular disadvantaged communities who are less able to afford solutions to treat contaminated drinking water. This has resulted in minimum thresholds and measurable objectives like those in the Arvin GSP, which will only be monitoring for compliance with sustainable management criteria in one well location, and has set the minimum threshold at the drinking water MCL for the contaminant, and the measurable objective at 75% of the MCL. The member agency is only monitoring for compliance with arsenic standards, despite the agency's knowledge of the existence of "nitrate…total dissolved solids (TDS), boron, iron and manganese…within or near the **Arvin-Edison Management Area** above drinking water standards and/or agricultural water quality goals."	
Leadership Counsel	15	The lack of sufficient groundwater quality sustainable management criteria in areas like **Arvin** is likely to lead to critical drinking water impacts, and will be disproportionately felt by disadvantaged communities, who are less able to afford treatment solutions.	•The sustainable management criteria (SMCs) for degraded water quality were developed by AEWSD and ACSD with direct consideration of the drinking water beneficial use (s **Section 14.4**). •The water quality SMCs and monitoring in the MA Plan are in addition to the drinking water standards and monitoring requirements to which ACSD is held under its drinking w permit from the State Water Resources Control Board (SWRCB) Division of Drinking Water (see **Section 14.4**).
Leadership Counsel	15	The GSA has also not specified what actions will be taken if water contamination approaches minimum thresholds, or how minimum thresholds will be triggered. Member agencies such as the **Arvin-Edison WSD** have not specified this in their plans.	•As a public water supplier, ACSD has the responsibility to provide safe drinking water, under regulatory oversight by the SWRCB Division of Drinking Water, which is separate f SGMA. •Under its water system permit from the SWRCB, ACSD provides for water treatment and monitoring of water quality, separate from SGMA. •SGMA does not require that a GSP describe the process that will take place if water quality measurements approach Minimum Thresholds. •**Section 14.4.2** of the MA Plan specifies the Minimum Threshold for groundwater quality as the exceedance of Maximum Contaminant Levels (MCL) for arsenic at the Represer Monitoring Site (i.e., ACSD Well #14). This description of the MT therefore does include a description of "how minimum thresholds will be triggered" (i.e., by an exceedance of t for arsenic over four consecutive bi-annual measurement). •ACSD operates its wells under permit from the SWRCB which has its own monitoring schedule and reporting requirements.
Leadership Counsel	17	The Monitoring Network is Inadequate With Respect to Groundwater Levels and Groundwater Quality	•See comment response below. •See KGA response to this comment for further information.
Leadership Counsel	18	The groundwater quality monitoring network does not adequately capture impacts on drinking water users. In the case of the **Arvin GSP**, the member agency will only monitor for compliance with its minimum threshold and measurable objective for Arsenic once a year in one well, ACSD Well #14, which is one of the wells that provide drinking water to the community of Arvin.	•As described above, ACSD monitors its supply wells for a list of constituents described in and on a schedule set by its drinking water system permit from the SWRCB. The wate quality monitoring in this MA Plan is in addition to the monitoring conducted by ACSD under its permit. •The topic of groundwater quality monitoring networks was also addressed in AEWSD's email response (dated 11/7/2019; attached below) to questions from LCJA.
Leadership Counsel	18	Second, only measuring for compliance with arsenic measurable objectives and minimum thresholds does not protect against increases in other contaminants that exist in other parts of the management area (boron, nitrates, TDS, 123-TCP, iron and manganese). These contaminants could extend, move or increase due to groundwater management activities and pumping patterns. The Arvin GSP does plan to monitor for these contaminants in seven other wells outside of Arvin, but has not set minimum thresholds and measurable objectives for these wells, and does not have plans to do so.	•Arsenic was chosen as the only constituent for defining SMCs because it is currently the only constituent determined to be related to water management activities (i.e., water (see **Section 13.4.2**). Other constituents are either naturally occurring or regulated pursuant to different programs. Additional data collection and analysis, as described in the M Plan, will be used to inform the consideration of water quality issues in the future. •The topic of groundwater quality SMCs was also addressed in AEWSD's email response (dated 11/7/2019; attached below) to questions from LCJA.
Leadership Counsel	18	Furthermore, Arvin is currently experiencing 123-TCP contamination that threatens the health of Arvin residents, so the GSP must monitor for compliance with 123-TCP standards in particular.	•ACSD has recently installed a treatment system for 1,2,3-TCP in one of its production wells to address this occurrence of contamination (see **Section 17.2.3**). •ACSD has also included in this MA Plan, and is currently implementing, a project to mitigate arsenic and 1,2,3-TCP in its raw water supply through well replacement (see **Secti 19.1.2**). •ACSD has never been out of compliance with 1,2,3-TCP as SWRCB set the MCL to take effect January 1, 2018. Wells that contained 1,2,3-TCP were taken offline in January 201 the MCL for 1,2,3-TCP was implemented. Arvin CSD is in litigation with Dow Chemical and Shell Oil Co. to collect on damages to the wells that were affected.

Commentor	Ref #	Comment	Response
Leadership Counsel	19	Third, the well that was chosen, ACSD Well #14, was chosen because it does not have contaminants that are known to exist in wells in the northern part of the management area, which are not currently in use by Arvin CSD, according to our conversation with Arvin-Edison WSD staff at the Kern Subbasin Open House on September 26th, 2019. However, avoiding monitoring contaminated areas defeats the purpose of groundwater quality monitoring under SGMA, which is to measure the concentration and spread of contaminant plumes to ensure that groundwater management activities and pumping do not aggravate existing contamination. The GSA should ensure that the member agency instead monitors for all existing contaminants at minimum throughout the area and especially in areas where contamination is known to exist, and sets minimum thresholds and measurable objectives that apply to all monitoring wells.	•ACSD Well #14 was chosen by ACSD as it is considered representative of wells in the ACSD area that constitute the majority of drinking water beneficial use in the MA Plan are **Section 16.1.4**). •AEWSD staff has never, at the 9/26/2019 Kern Subbasin Open house nor at any other time, ever contended that the reason for selection of the ACSD Well #14 was, as the com states, "because it does not have contaminants that are known to exist in wells in the northern part of the management area." •ACSD chose this well as it is the northern most active well in its water system. This well would serve as an early indicator that would allow detection of any early signs of wate quality degradation. Well #14 does contain levels of Arsenic which are below the MCL, but would be a good indicator of groundwater conditions.
Leadership Counsel	20	Current Projects and Management Actions are Inadequate	•See comment response below. •See KGA response to this comment for further information.
Leadership Counsel	20	The GSA has allowed member agencies like the Arvin-Edison WSD to use a "glidepath" approach that increases surface water and groundwater recharge before demand reduction measures are implemented.67	•Supply augmentation projects and demand reduction management actions (as needed) are to be implemented in a balanced approach under the "glide path" laid out in the Ar Edison MA Plan (see **Section ES.10**; **Section 9.4.5**; **Section 17.1.4**; and **Table PMA-2**).
Leadership Counsel	20	The Arvin GSP contains two projects for treating water quality in Arvin, but these projects were already under way and fully funded so should not be included in the GSP. The GSP has no overall drinking water protection program to protect residents against dry wells and contaminated drinking water from its policies and groundwater management activities.	•These two projects were identified by ACSD as projects to include in the MA Plan because they aim to address the water quality sustainability indicator and relevant beneficial (i.e., drinking water supply).
Leadership Counsel	21	The GSA Must Clearly Commit to a Drinking Water Protection Program for the Kern	•See KGA response to this comment.
Leadership Counsel	22	Recharge In or Near Disadvantaged Communities and Domestic Well Clusters	•See KGA response to this comment.
Leadership Counsel	22	Establish Pumping Buffer Zones That Protect Disadvantaged Communities and Clusters of Domestic Wells	•See KGA response to this comment.
Leadership Counsel	22	Warning Against a Groundwater Market	•See KGA response to this comment.
Leadership Counsel	22	Multi-benefit projects	•See KGA response to this comment.
Leadership Counsel	22	Funding of Projects and Management Actions	•See comment response below. •See KGA response to this comment for further information.
Leadership Counsel	22	Furthermore, any proposed assessments that will pay for projects may not place a disproportionate financial burden on disadvantaged communities. Small disadvantaged communities like Arvin should not be required to pay fees for GSP implementation.	•**Section 17.11** of the MA Plan describes the various funding sources that may be used to pay for the planned P/MAs. •**Section 18.2.2** and **Section 19.2.2** list the funding sources identified by AEWSD and ACSD, respectively, to support general GSP implementation. •The topic of GSP funding was also addressed in AEWSD's email response (dated 11/7/2019; attached below) to questions from LCJA. •ACSD and AEWSD have created a Memorandum of Understanding with regards to SGMA. It shall be noted that ACSD was not asked to contribute financially, which for ACSD s to be a substantial cost savings. •ACSD does participate financially with the KGA, but the KGA is set up for participating agencies to pay based on acreage which made being a voting member readily accessible DAC like Arvin and Shafter.
Leadership Counsel	23	The Draft GSP Threatens to Infringe on Water Rights	•See KGA response to this comment.
Leadership Counsel	23	The Draft GSP Conflicts with the Reasonable And Beneficial Use Doctrine	•See KGA response to this comment.
Leadership Counsel	23	The Draft GSP Conflicts with the Public Trust Doctrine	•See KGA response to this comment.
Wonderful Orchards/Wonderful Citrus	1	**Quantification of Native Yield** It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource. For example, a district or pumper located adjacent to the foothills does not necessarily have a superior claim to native yield over someone located in the center of the basin just because they are geographically closer to the source of mountain front recharge. Similarly, a district or pumper located in a cone of depression does not necessarily have a superior claim to native yield just because groundwater is flowing toward them. Surface water entering the groundwater via seepage in natural channels, including the Kern River and small streams, may be attributable to the native yield depending upon the circumstances of that seepage. A thorough technical and legal analysis is necessary to determine appropriate sources contributing to the native yield and to quantify these supplies.	•"Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). •***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that "the "water accounting" approach described in the Coordinat Agreement and Appendices thereto does attempt to evaluate the water budget using certain management assumptions (e.g., a uniform "native yield component to all lan within the Basin). However, nothing in this water budget information results in or is intended to be a determination of water rights within the Arvin-Edison Management A*** •Implementation of P/MAs, including actions to further refine issues related to water budgets, is described in **Section 18.1.2**. •See KGA response to this comment for further information.
Wonderful Orchards/Wonderful Citrus	2	**Allocation of Native Yield** In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. Appendix J of the GSP indicates the subbasin native yield is approximately 0.144 acre-feet per acre. It is our understanding that subsequent to the release of the draft GSP, all MAPs and other GSPs in the basin agreed to utilize the same number for their water budgets. If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights. Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross or net area. In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and be generally consistent with groundwater rights, recognizing that GSAs do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – Environmental Defense Fund and New Current Water & Land, July 2018.	•***Section 18.1.4 which describes Stakeholder Engagement as part of MA Plan implementation, has been modified to include a statement that any actions to establish lando level allocations of native yield will be conducted through a robust stakeholder engagement process.*** •See KGA response to this comment for further information. •Also see response to
Wonderful Orchards/Wonderful Citrus	2	**Groundwater Markets** Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.	•The MA Plan includes in its portfolio of P/MAs a management action to evaluate and potentially implement a groundwater marketing and trading system (see **Section 17.2.2**). •As described in **Section 18.1.2,** implementation of P/MAs, including the potential establishment of a market-based system, will include performance of any appropriate furthe studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. •See KGA response to this comment for further information.
Wonderful Orchards/Wonderful Citrus	2	**Pumping Restrictions** Wonderful understands that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).	•Demand reduction Management Actions are included in the MA Plan as one element in a portfolio of P/MAs (see **Section 17**). •The P/MA implementation timetable is based on a phased/incremental "glide path" approach (see **Section 17.1.4**). •P/MA implementation will entail, in many cases, performing studies and/or analysis to refine concepts into actionable projects or policies (see **Section 18.1.2**). ***Section 18.1.2 modified to clarify that such studies will be based on using the best available data and science.*** •See KGA response to this comment for further information.

Commentor	Ref #	Comment	Response
Wonderful Orchards/Wonderful Citrus	3	**Groundwater Recharge and Banking** GSAs must develop clear policies and conditions that protect existing investment in groundwater banking and banked inventory, and without interference with existing rules and regulations. GSAs must also find a way to incentivize additional investment, such as on-farm recharge, and allow flexibility for recharged or banked water to be freely transferable (subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results). Where possible, GSPs should also identify management areas that may benefit from additional recharge and banking. We also recommend that GSAs work to develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	•As described in **Section 18.1.2**, implementation of P/MAs, including projects to enhance recharge and projects to manage and/or capture floodwater, will include performanc any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. •See KGA response to this comment for further information.
Wonderful Orchards/Wonderful Citrus	3	**Measurement and Data Management** Finally, GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	•The comment is noted. •***Section 8.1 has been added to the MA Plan to describe data sources used in MA Plan development and how this local DMS will be coordinated with the basin-wide DMS.*** •***Appendix I has been added to the MA Plan to list additional water quality data sources that will be evaluated during MA Plan implementation.*** •The Plan implementation section includes an action to refine the local DMS to comply with (coordinate with) the basin-wide DMS (see **Sections 18.1.1** and **18.1.3**). •See KGA response to this comment for further information.
Farmland Reserves	1	**Allocation of Groundwater Rights.** Though not specifically addressed, we are concerned that the overlying right to extract groundwater will be allocated among all District landowners based on gross acreage. While this is a simple approach to what can be a complex issue, it ignores accepted principles of law intended to more fairly allocate this right among those who have historically used groundwater for irrigation purposes-and made substantial investments based on that use. We wish to at least see identification of this issue in the Chapter and an acknowledgment that it will not be decided now. If the District determines that the issue is broader, then we leave it to the District to address it at the Umbrella GSP level. Any implication that the District has decided to allocate the overlying groundwater rights based simply on gross acreage could invite some to pursue premature legal action to challenge the District's conclusion, which might not be necessary depending on the success of the proposed actions in the Chapter. While this issue certainly affects our interests, we are equally concerned about avoiding unnecessary legal challenges made by others and the instability that would bring to the sub-basin.	•"Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). •***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that "the "water accounting" approach described in the Coordinat Agreement and Appendices thereto does attempt to evaluate the water budget using certain management assumptions (e.g., a uniform "native yield component to all lan within the Basin). However, nothing in this water budget information results in or is intended to be a determination of water rights within the Arvin-Edison Management A*** •Implementation of P/MAs, including actions to further refine issues related to water budgets, is described in **Section 18.1.2**. •See KGA response to this comment for further information.
Farmland Reserves	2	**Native Yield.** The Chapter identifies a coordinated estimated native yield of 0.15-.0.30 acre feet per acre across the KGA. We understand and acknowledge that some number needed to be identified for Water Budget and planning purposes and support the use of these numbers for such purposes. However, these numbers should not be seen as establishing a precedent or used to establish some legal right. Therefore, a statement emphasizing the above points should be made - the planning purpose nature of these numbers and not establishing legal precedent. Additionally, in coordinating with other members of the KGA under the Umbrella GSP, the District should push for a consistent native yield and related methodology across the sub-basin. We understand that this can be a politically charged process, but we are confident the District can provide support for a consistent approach, which will enable a more stable sub-basin.	•"Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). •***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and not a determination of actual legal ground water rights.*** •Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.1.2**. •See KGA response to this comment for further information.
Farmland Reserves	3	**Groundwater Market.** This issue might be premature at this point. However, the Chapter could address the possibility of a market for the exchange or transfer of groundwater credits. If a market system were contemplated, we would encourage such a system to be as flexible as possible (within the requirements of SGMA, the Chapter and the Umbrella GSP) to facilitate the needs of farmers with lands in different areas of the sub-basin and those with the ability to store surface water underground. Again, this might be premature at this time, but a mention of the District's position to support a flexible groundwater market could help move the discussion forward once the Umbrella GSP is submitted to the Department of Water Resources and agencies begin the implementation process.	•The MA Plan includes in its portfolio of P/MAs a management action to evaluate and potentially implement a groundwater marketing and trading system (see Section 17.2.2). •As described in Section 18.1.2, implementation of P/MAs, including the potential establishment of a market-based system, will include performance of any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. •See KGA response to this comment for further information.
Hancock Financial Services	1	**Allocation of Native Yield** The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water, for example xxx,xxx acre-feet and not associated with a given gross or net area. In the event that allocations of any sort are distilled to a landowner or property level, HFS encourages the GSAs in the basin to initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations that are coordinated across the basin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and attempt to be consistent with groundwater rights, recognizing that GSAs do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations, in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – EDF and NCWL, dated July, 2018	•"Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). •***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that "the "water accounting" approach described in the Coordinat Agreement and Appendices thereto does attempt to evaluate the water budget using certain management assumptions (e.g., a uniform "native yield component to all lan within the Basin). However, nothing in this water budget information results in or is intended to be a determination of water rights within the Arvin-Edison Management A*** •Implementation of P/MAs, including actions to further refine issues related to water budgets, is described in **Section 18.1.2.** •***Section 18.1.4 which describes Stakeholder Engagement as part of MA Plan implementation, has been modified to include a statement that any actions to establish lando level allocations of native yield will be conducted through a robust stakeholder engagement process.*** •See KGA response to this comment for further information.
Hancock Financial Services	1	**Groundwater Recharge and Banking** GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	•As described in **Section 18.1.2**, implementation of P/MAs, including projects to enhance recharge and projects to manage and/or capture floodwater, will include performanc any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. •See KGA response to this comment for further information.
Hancock Financial Services	3	**Refinement and Validation of Consumptive Use Calculations Based on ET Measurement** HFS supports use of efficient and accurate systems to determine groundwater use. GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water.	•The comment is noted. •See KGA response to this comment for further information.

Westchester Group Investment Management	1	**Allocation of Native Yield** The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water and not associated with a given gross or net area. In the event that allocations are to be made at a landowner or property level, WGIM encourages the KGA and other GSAs in the basin to initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations that are coordinated across the basin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and attempt to be consistent with groundwater rights, recognizing that GSAs and Management Areas (MAs) do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations, in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – EDF and NCWL, dated July, 2018.	•"Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). ***•Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "the "water accounting" approach described in the Coordi Agreement and Appendices thereto does attempt to evaluate the water budget using certain management assumptions (e.g., a uniform "native yield component to all lan within the Basin). However, nothing in this water budget information results in or is intended to be a determination of water rights within the Arvin-Edison Management A*** •Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.1.2.** ***•Section 18.1.4 which describes Stakeholder Engagement as part of MA Plan implementation, has been modified to include a statement that any actions to establish landa level allocations of native yield will be conducted through a robust stakeholder engagement process.*** •See KGA response to this comment for further information.
Westchester Group Investment Management	1	**Pumping Restrictions** We understand that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs and MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible without creating undesirable results, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated and consistent across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).	•Demand reduction Management Actions are included in the MA Plan as one element in a portfolio of P/MAs (see **Section 17**). •The P/MA implementation timetable is based on a phased/incremental "glide path" approach (see **Section 17.1.4**). •P/MA implementation will entail, in many cases, performing studies and/or analysis to refine concepts into actionable projects or policies (see Section 18.1.2). ***Section 18.1.2 modified to clarify that such studies will be based on using the best available data and science.*** •See KGA response to this comment for further information.
Westchester Group Investment Management	2	**Groundwater Recharge and Banking** GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked water inventory, and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	•As described in **Section 18.1.2**, implementation of P/MAs, including projects to enhance recharge and projects to manage and/or capture floodwater, will include performanc any appropriate further studies and analysis, including engineering, economic/financial, and/or legal, as appropriate.
Westchester Group Investment Management	2	**Measurement and Data Management** GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	•The comment is noted. ***•Section 8.1 has been added to the MA Plan to describe data sources used in MA Plan development and how this local DMS will be coordinated with the basin-wide DMS.*** •Appendix I has been added to the MA Plan to list additional water quality data sources that will be evaluated during MA Plan implementation. •The Plan implementation section includes an action to refine the local DMS to comply with (coordinate with) the basin-wide DMS (see **Sections 18.1.1** and **18.1.3**). •See KGA response to this comment for further information.
Westchester Group Investment Management	3	**Refinement and Validation of Consumptive Use Calculations Based on ET Measurement** WGIM supports use of efficient and accurate systems to determine groundwater use. GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water.	•The comment is noted. •See KGA response to this comment for further information.
California Department of Fish and Wildlife	1	The Plan Area narrative does not identify Department-owned lands.	•The Arvin-Edison MA Plan identifies lands owned by the California Department of Fish and Wildlife in **Section 5.1.3** and on **Figure PA-2.** •See KGA response to this comment for further information.
California Department of Fish and Wildlife	2	The GSP identifies an 'environmental' category of beneficial user but does not specify how impacts to environmental beneficial uses and users of groundwater were considered throughout the GSP.	•The process used to assess the potential occurrence of "environmental" uses/users of groundwater in the Management Area is based on depth to groundwater based on avai data from wells in the principal aquifer, as described in **Section 8.2, 8.7** and **8.8**. This process was informed by the TNC (2019) guidance for evaluation of GDEs. •See KGA response to this comment for further information.
California Department of Fish and Wildlife	3	The GSP identifies the potential for interconnected surface waters but dismisses further evaluation of interconnectivity and abdicates oversight of shallow groundwater-surface water communication.	•The process used to assess the potential occurrence of interconnected surface water in the Management Area is based on depth to groundwater (similar to the process used f evaluation of GDEs, which was done consistent with TNC (2019) guidance; see below) based on available data from wells in the principal aquifer, as described in **Section 8.2** an •See KGA response to this comment for further information.
California Department of Fish and Wildlife	4	The GDE identification section, pursuant to 23 CCR§ 354.16 (g), identifies ecosystems that may depend on groundwater. A report completed by the California Department of Water Resources (CDWR) (1997) shows that a large area of Kern County has 0 to 10 feet to depth to free water below the surface (see CDWR Figures 2, 3 and 5). Based on the presence of shallow groundwater, the Department supports the further investigation of GDEs and recommends including additional references for a more robust GDE evaluation. The Department recognizes that Natural Communities Commonly Associated with Groundwater (NCCAG) (Klausmeyer et al. 2018) provided by CDWR is a good starting reference for GDEs. There are additional resources available for evaluating GDE locations and habitat types, as well as information for State and Federal listed species. These recommended references include, but not limited to the following tools and other resources: the California Department of Fish and Wildlife (CDFW) Vegetation Classification and Mapping Program (VegCAMP) (CDFW 2019A); the CDFW California Natural Diversity Database (CNDDB) (2019B); the California Native Plant Society (CNPS) Manual of California Vegetation (CNPS 2019A); the CNPS California Protected Areas Database (CNPS 2019B); the United States Fish and Wildlife Service (USFWS) National Wetlands Inventory (2018); the USFWS online mapping tool for listed species critical habitat (2019); the United States Forest Service CALVEG ecological grouping classification and assessment system (2019); and other publications by Klausmeyer et al. (2019), Rohde et al. (2018), The Nature Conservancy (TNC) (2014, 2019), and Witham et al. (2014).	•The process used to assess the potential occurrence of GDEs in the Management Area is based on depth to groundwater based on available data from wells in the principal aq as described in **Section 8.2** and **8.8**. ***•Section 8.8 was modified to include mention the use of the TNC (2019) guidance and criteria therein.*** •The criteria used to remove NCCAG from the list of potential GDEs is a depth to water greater than 30 feet, which is based on guidance from The Nature Conservancy (2019). •See KGA response to this comment for further information.

Commentor	Ref #	Comment	Response
California Department of Fish and Wildlife	5	The identification of undesirable results and selection of minimum thresholds are based on an extended 10-year drought period and exclude Sustainable Management Criteria for surface water depletions.	•Because interconnected surface waters are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, sustainable management criteria for Depletion of Interconnected Surface Waters are deemed not applicable/necessary. •See KGA response to this comment for further information.
California Department of Fish and Wildlife	"Other"	Implementation of Future Project Actions Related to SGMA: Comments related to: •The CDFW's role as "Trustee Agency for fish and wildlife resources", and •The CDFW's role as a "Responsible Agency under CEQA" that "may need to exercise regulation authority as provided by the Fish and Game Code for implementation of projects related to the GSP that are also subject to CEQA".	•Comments are noted. •Permitting requirements for each P/MA included in the MA Plan are discussed in **Section 17.6** and in **Table PMA 1**. Work efforts related to P/MA implementation, including stu and environmental (CEQA) documentation, are discussed in **Section 18.1.2**. •See KGA response to this comment for further information.
The Nature Conservancy	9	**Notice and Communication** Please describe the other beneficial uses and users of groundwater in the Subbasin identified by the Water Code including: GDEs; managed wetlands; Protected Lands, including preserves, wildlife refuges, conservation areas, recreational areas and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, recreation and navigation. Please identify any environmental uses and users of groundwater in the plan area, and take particular note of the species with protected status.	•The Arvin-Edison MA Plan identifies lands owned by the California Department of Fish and Wildlife in **Section 5.1.3** and on **Figure PA-2**. •See KGA response to this comment for further information.
The Nature Conservancy	10	**Plan Area Setting** Please provide a description of any current and planned instream flow requirements or regulatory requirements for protection of species of concern in the Kern River, Poso Creek and Caliente Creek. If there are no requirements in place or planned, then please state that in the GSP.	***•Section 7.2.5 of the MA Plan was updated to include a statement that there are no in-stream flow requirements set for any creeks that flow into the Arvin-Edison Manage Area, including Caliente Creek.*** •See KGA response to this comment for further information.
The Nature Conservancy	10	**Existing Plans in the Plan Area** We suggest adding a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. Please include a description of any land use or environmental plans relevant to wetlands, aquatic resources and other GDEs and ISWs and their relationship to the GSP. Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands around the Kern Wildlife Refuge, aquatic resources and other GDEs and ISWs. Please identify all relevant HCPs and NCCPs within the Subbasin and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.	•**Section 5.3** of the MA Plan includes information about land use plans (i.e., General Plans), including a summary of goals, policies and implementation measures related to land water use. •See KGA response to this comment for further information.
The Nature Conservancy	10	**Existing and Ongoing Water Resource Programs** Please provide a description of resource management plans, monitoring activities and responsibilities by State, Federal and local agencies and jurisdictions related to aquatic resources and GDEs that could be affected by groundwater withdrawals, and list them in Table 2-1. Please review and discuss the potential groundwater reliance of critical species in the Subbasin. Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP. Please include a discussion of any monitoring programs related to GDEs and sensitive habitats.	•See KGA response to this comment for further information.
The Nature Conservancy	11	**Well Permitting Process, Well Construction Policies** Please discuss that future well permitting and well construction must be coordinated with the GSP to assure achievement of the Plan's sustainability goals. Please state how the well permitting process incorporates protection of GDEs and ISWs within the Subbasin. Please include a discussion of the need for well permitting programs to comply with this requirement.	•**Sections 5.3.4** and **5.4** of the MA Plan includes discussion of the Kern County Well Permitting Process. •See KGA response to this comment for further information.
The Nature Conservancy	11	**Hydrogeologic Conceptual Model – Bottom of the Subbasin** Please characterize groundwater well extractions from the deepest wells in relation to defining the basin bottom. If the bottom boundary of the Subbasin has not been clearly defined in certain management areas, please identify this as a data gap and elaborate in the monitoring section how and where additional observations can be made to reconcile this data gap.	•**Section 7.1.3** of the MA Plan describes the definition of the bottom of the basin, which includes consideration of the deepest groundwater wells. •See KGA response to this comment for further information.
The Nature Conservancy	12	**Hydrogeologic Conceptual Model – Principal Aquifers and Aquitards** Please provide additional description of the shallow aquifers within the Subbasin including characteristics of interconnections with surface water and GDEs, vertical groundwater gradients, connections with underlying production aquifers, and the resulting potential interaction of groundwater pumping with ISWs and GDEs. Please state whether localized perched aquifers are present in the Subbasin. Describe any data gaps. The function and significance of the Shallow Aquifers that provide groundwater to ISWs and GDEs should be summarized in Table 2-3. Please describe whether the existence of Aquifer Exemptions has any bearing or implications related to environmental beneficial uses of groundwater.	•**Section 7.1.**4 of the MA Plan mentions the occurrence of the "A"-Clay which may result in localized perched groundwater in some areas. •**Section 7.3.2** of the MA Plan mentions that these perched zones are often poor quality and do not yield significant or economic amounts of water to wells, springs, or surface systems, and are therefore not considered part of the principal aquifer. •See KGA response to this comment for further information.
The Nature Conservancy	12	**Hydrogeologic Conceptual Model – Data Gaps and Uncertainty** If data are not present to produce the information requested in the comment above, please clearly identify this as a data gap. Please elaborate in the monitoring section how and where additional observations are to be conducted in order to address this data gap.	•See KGA response to this comment for further information.
The Nature Conservancy		**Hydrogeologic Conceptual Model – Cross-Sections** Please include near-surface cross sections or insets that depict the conceptual understanding of shallow groundwater and ISW interactions at different locations, including perched and regional aquifers and GDEs.	•See KGA response to this comment for further information.
The Nature Conservancy	13	**Hydrogeologic Conceptual Model - Elevation and Flow Directions** Please provide any available stratigraphic data, hydrograph data, pumping test data or other information to substantiate these claims. If the data are not available, please identify this as a data gap.	•See KGA response to this comment for further information.
The Nature Conservancy	14	**Interconnected Surface Water Systems** Please provide additional data or analysis to substantiate the nature of the hydrologic relationship between the shallow aquifer and production aquifers and ISWs. If data are not available to verify that such a connection does not exist, acknowledge where ISWs may exist and identify appropriate sustainable management criteria, monitoring networks and management actions for sustainable ISW management or to address data gaps. Data could include groundwater level data from shallow or nested monitoring wells, comparison of stream stages to groundwater levels, modeling information or additional gaging data. Please elaborate how and where additional observations (shallow monitoring wells, stream gauges, and nested / clustered wells) along surface water features can be used to address data gaps in the Monitoring Network section of the GSP to improve identification of ISWs rather than prematurely disregarding them in the GSP.	•The process used to assess the potential occurrence of interconnected surface water in the Management Area is based on depth to groundwater (similar to the process used f evaluation of GDEs, which was done consistent with TNC (2019) guidance; see below) based on available data from wells in the principal aquifer, as described in **Section 8.2** an •See KGA response to this comment for further information.

Commentor	Ref #	Comment	Response
The Nature Conservancy	14	Groundwater-Dependent Ecosystems Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gaps will be addressed. Please support this statement with specific groundwater level data that indicate a gap in the saturated zone between the production aquifers and shallow groundwater, and define the extent of the NCCAG dataset polygons that are excluded from consideration as GDEs on this basis. Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gap will be resolved. Please revise the GDE analysis in the GSP by conducting more substantial, data-based evaluation focusing on GDE identification in the GSP, clearly identify which NCCAG polygons are excluded, which polygons are determined to be GDEs and which polygons are uncertain at this time and will be verified as data gaps are address. Confirmation of GDEs should be performed based on depth to groundwater in the shallow zone, and additional information provided as to whether the shallow zone may be affected by groundwater withdrawal from the production aquifers. Please refer to Appendix D of this letter for best practices for using groundwater data to verify a connection to groundwater. Therefore, we recommend using depth to groundwater contour maps derived from subtracting groundwater levels from a DEM, as described above, to identify whether a potential connection to groundwater exists for the wetlands mapped in Attachment H of the GSP. Please refer to Attachments D and E of this letter for best practices for using local groundwater data to 1) verify whether polygons in the NC Dataset are supported by groundwater in an aquifer, and 2) verify whether ecosystem decline or recovery is correlated with groundwater levels. We recommend the inclusion of a discussion regarding the nature and characteristics of GDEs. Please provide information on the historical or current groundwater conditions near the GDEs or the ecological conditions present. We recommend an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes vegetation or habitat types and rank the GDEs as having a high, moderate or low value. Explain how each rank was characterized. Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs. Some organisms rely on uplands and wetlands during different stages of their lifecycle.	•The process used to assess the potential occurrence of GDEs in the Management Area is based on depth to groundwater based on available data from wells in the principal aq as described in Section 8.2 and 8.8. •***Section 8.8 was modified to include mention of the use of TNC (2019) guidance and criteria therein.*** •The criteria used to remove NCCAG from the list of potential GDEs is a depth to water greater than 30 feet, which is based on guidance from The Nature Conservancy (2019). •See KGA response to this comment for further information.
The Nature Conservancy	17	**Water Budget** Please provide a breakdown of ET for native and riparian vegetation (such as wetlands, riparian vegetation, phreatophytes and other communities). Please evaluate the spatial relationship of native vegetation ET to NCCAG polygons to determine the groundwater use by this beneficial user for inclusion in the water budget. Identify any data gaps and outline the actions needed to address them.	•ET information used in the water budget analysis is from the ITRC-METRIC study and includes all lands, including non-irrigated lands. •See KGA response to this comment for further information.
The Nature Conservancy	17	**Sustainability Goal** Please clarify the sustainability goal and expand its description to ensure that all beneficial uses and users of groundwater are identified as being protected from undesirable results, and in particular, include GDEs, ISWs and related critical habitats. Since GDEs and ISWs may be present in the Subbasin (please see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be specifically included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included. Please include ISWs in the Sustainability Goal until/unless sufficient data is available and provided to verify the status of ISWs. Given that there are potential GDEs in the Subbasin and that they may be affected by water quality, they should be included in the Sustainability Goal and addressed in the Water Quality section.	•The sustainability goal for the MA Plan area is stated in **Section 2** and **Section 12**, and does include mention of beneficial uses including environmental. •See KGA response to this comment for further information.
The Nature Conservancy	18	**Minimum Thresholds and Measurable Objectives** For each of these applicable sustainable management criteria, please include a discussion of GDEs (see comments under checklist items 16-20) and whether the minimum thresholds, measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment. Please modify Section 3.2.2 to specifically address impacts from degraded water quality to the plant and wildlife communities within GDEs.	•Because GDEs are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, sustainable management criteria for Depl Interconnected Surface Waters are deemed not applicable/necessary. •See KGA response to this comment for further information.
The Nature Conservancy	19	**Undesirable Results** Please add "possible adverse impacts to potential GDEs and ISWs" to the list of potential undesirable results. Please review these spatial patterns and, where possible, correlate them with water level trends. Any indications of adverse trends and any data gaps should be identified. For each identifiable GDE unit with supporting hydrological datasets, please include the following: For identifiable GDE units without supporting hydrological datasets please describe data gaps and / or insufficiencies. Compile and synthesize biological data for each GDE unit by: Describe possible effects on potential ISWs, GDEs, land uses, and property interests, including:	•Because GDEs and ISW are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, sustainable management criteria Depletion of Interconnected Surface Waters are deemed not applicable/necessary. •See KGA response to this comment for further information.

Commentor	Ref #	Comment	Response
The Nature Conservancy	20	**Monitoring Network** Please modify the description of the monitoring network to provide methodologies, data and other information to address the data gaps associated with GDEs and ISWs. This modification should include 1) locating new wells that are appropriately screened to detect changes in groundwater levels in the uppermost water table and the connectivity of GDEs and ISWs with the upper unconfined or shallow zone aquifer; and 2) identifying or installing additional stream gauges in areas where there is potential for ISWs and GDEs. Please expand on the discussion of how the new well and stream data will be used to improve ISW mapping and inform an adequate analysis, and how the data will be used to verify possible GDEs. Please address data gaps along the Kern River and tributary creeks identified earlier in the GSP in this section of the GSP to improve ISW mapping in companion or future GSPs (e.g., through shallow monitoring wells, stream gauges, and nested/clustered wells).	•See KGA response to this comment for further information.
The Nature Conservancy	21	**Projects and Management Actions** For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue. Please consider additional management actions and projects targeted for protecting ISWs and GDEs. Please describe how the projects and management actions will be evaluated to assess whether adverse impacts to GDEs may occur and/or will be mitigated or prevented.	•Because GDEs and ISW are determined to not occur within the MA Plan area, based on depth to groundwater data from the principal aquifer, P/MAs to benefit and protect GD ISW are deemed not applicable/necessary. •See KGA response to this comment for further information.
Cawelo Water District Received Comments			
Grow View Enterprises	CGSA-1	The draft Chapter proposes several projects to help the District and its Groundwater Sustainability Agency achieve your sustainable groundwater management goals. In terms of the potential annual benefit, one of the significant projects is the purchase of new water supplies. We agree.	Cawelo GSA acknowledges the support for the acquisition of new water supplies.
Grow View Enterprises	CGSA-2	Grow View Enterprises recently sent the District a request made on behalf of certain of our affiliated landowners to connect, at their expense, to the District's existing water distribution system to allow for the delivery of surface water to the lands identified in that request. Those lands are currently served exclusively with groundwater. If excess District surface water is available, such a connection would allow these landowners to purchase District water and provide an additional funding source for the District's purchase of new water supplies. At the same time, a connection would allow the landowners to pursue private acquisitions of water supplies for conveyance into the District. Both possibilities would benefit the sustainability efforts of the District by lessening reliance on groundwater and bolstering the identified project to purchase new water supplies. Accordingly, a comment we have on the draft Chapter is that the Chapter should reflect a willingness by the District to allow landowners in the District's non-service area to connect to the District's water distribution system and become part of the District's service area. While individual situations will differ, any unique terms and conditions can be established for each. The Chapter should show the District's willingness to expand its service area as part of the project to allow for an increased delivery of the new water supply purchases the District proposes as a groundwater sustainability project.	As noted in the comment letter, potential connection to the Water District's water distribution system is a Cawelo Water District (CWD) matter. The Cawelo GSA supports landowners' efforts to bring into the GSA or CWD area additional imported water supplies to help meet demand. CWD has a history of allowing its landowners to connect the private systems to the CWD water distribution system and coordinating delivery of landowner owned water per CWD policies and oversite.
Wonderful Orchards/Citrus	CGSA-3	**Quantification of Native Yield**[1] It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource. For example, a district or pumper located adjacent to the foothills does not necessarily have a superior claim to native yield over someone located in the center of the basin just because they are geographically closer to the source of mountain front recharge. Similarly, a district or pumper located in a cone of depression does not necessarily have a superior claim to native yield just because groundwater is flowing toward them. Surface water entering the groundwater via seepage in natural channels, including the Kern River and small streams, may be attributable to the native yield depending upon the circumstances of that seepage. A thorough technical and legal analysis is necessary to determine appropriate sources contributing to the native yield and to quantify these supplies. [1] Native yield as defined in Section 4.2.1 of Appendix J to the GSP.	Cawelo GSA agrees the Native Yield quantification needs to be properly addressed. Currently, for purposes of developing this initial Cawelo GSP/Management Area Plan, the l available data was used to determine an initial Native Yield value for the Cawelo GSA area which is presented in Section 4.7.2. Cawelo GSA acknowledges the Native Yield valu to be refined with additional studies and/or research and endeavors to update the Native Yield quantification as new data becomes available and coordination within the Kern County Subbasin continues.
Wonderful Orchards/Citrus	CGSA-4	**Allocation of Native Yield** In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. Appendix J of the GSP indicates the subbasin native yield is approximately 0.144 acre-feet per acre. It is our understanding that subsequent to the release of the draft GSP, all MAPs and other GSPs in the basin agreed to utilize the same number for their water budgets. If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights. Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross or net area. In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin. The allocation methodology should be consistent with various legal considerations drawn from applicable case law and be generally consistent with groundwater rights, recognizing that GSAs do not have statutory authority to make a final determination of water rights. An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations in addition to acreage owned, to determine a legally defensible allocation. Further information regarding allocation methodology can be found in Groundwater Pumping Allocations Under California's Sustainable Groundwater Management Act – Environmental Defense Fund and New Current Water & Land, July 2018.	The initial Native Yield volume has been updated per Section 4.7.2. At this time, the total volume for the Cawelo GSA has been estimated using best available data and further described by averaging that volume over the acreage within the Cawelo GSA area. This is not an allocation of Native Yield and is merely a method to communicate the average Yield in the Cawelo GSA area. For initial plan purposes, the Cawelo GSA, and in coordination with the KGA and other GSAs, has agreed to use an initial estimate of 0.15 AF per which is roughly equivalent to the Cawelo GSA initial calculations. The Cawelo GSA and other management areas within the Kern County Subbasin need to better understand science supporting the Native Yield and the legal concerns surrounding potential allocation of Native Yield. Cawelo GSA will continue to gather additional information to better inform the Native Yield values and potential allocation of Native Yield. Cawelo GSA will participate in regio coordinated efforts for Native Yield work.

Commentor	Ref #	Comment	Response
Wonderful Orchards/Citrus	CGSA-5	**Groundwater Markets** Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.	It is necessary to gather additional data to better understand groundwater dynamics and how groundwater levels, established Minimum Thresholds and Measurable Objectiv groundwater users in general may be impacted by a potential groundwater transfer market.
Wonderful Orchards/Citrus	CGSA-6	**Pumping Restrictions** Wonderful understands that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).	Cawelo GSA will consistently endeavor to coordinate with other management areas in the Kern County Subbasin on SGMA matters and as they relate to the GSPs. For this initial Plan, there are no proposed management actions to limit pumping in the Cawelo GSA area. Management actions include acquiring additional water supplies and necessary reduce demand.
Wonderful Orchards/Citrus	CGSA-7	**Groundwater Recharge and Banking** GSAs must develop clear policies and conditions that protect existing investment in groundwater banking and banked inventory, and without interference with existing rules and regulations. GSAs must also find a way to incentivize additional investment, such as on-farm recharge, and allow flexibility for recharged or banked water to be freely transferrable (subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results). Where possible, GSPs should also identify management areas that may benefit from additional recharge and banking. We also recommend that GSAs work to develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	The Cawelo GSA has deferred potential groundwater recharge and banking to the CWD. The CWD is currently developing a landowner recharge/banking program.
Wonderful Orchards/Citrus	CGSA-8	**Measurement and Data Management** Finally, GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	The Cawelo GSA anticipates participating in a coordinated Subbasin effort to develop a DMS that is appropriate for the management areas of the Subbasin.
Farmland Reserve	CGSA-9	1. Allocation of Groundwater Rights. Though not specifically addressed, we are concerned that the overlying right to extract groundwater will be allocated among all District landowners based on gross acreage. While this is a simple approach to what can be a complex issue , it ignores accepted principles of law intended to more fairly allocate this right among those who have historically used groundwater for irrigation purposes-and made substantial investments based on that use. We wish to at least see identification of this issue in the Chapter and an acknowledgment that it will not be decided now. If the District determines that the issue is broader, then we leave it to the District to address it at the Umbrella GSP level. Any implication that the District has decided to allocate the overlying groundwater rights based simply on gross acreage could invite some to pursue premature legal action to challenge the District's conclusion, which might not be necessary depending on the success of the proposed actions in the Chapter. While this issue certainly affects our interests, we are equally concerned about avoiding unnecessary legal challenges made by others and the instability that would bring to the sub-basin.	At this time, the total Native Yield volume for the Cawelo GSA has been estimated and further described by averaging that volume over the acreage within the Cawelo GSA are is not an allocation of Native Yield and is merely a method to communicate the average Native Yield in the Cawelo GSA area. For initial plan purposes, the Cawelo GSA, and in coordination with the KGA and other GSAs, has agreed to use an initial estimate of 0.15 AF per acre which is roughly equivalent to the Cawelo GSA initial calculations. The Caw GSA and other management areas within the Kern County Subbasin need to better understand the science supporting the Native Yield and the legal concerns surrounding pot allocation of Native Yield before an allocation can be issued. Cawelo GSA will continue to gather additional information to better inform the Native Yield values and potential allocation of Native Yield. Cawelo GSA will participate in regio coordinated efforts for Native Yield work.
Farmland Reserve	CGSA-10	2. Native Yield. The Chapter identifies a coordinated estimated native yield of 0.15-0.30 acre feet per acre across the KGA. We understand and acknowledge that some number needed to be identified for Water Budget and planning purposes and support the use of these numbers for such purposes. However, these numbers should not be seen as establishing a precedent or used to establish some legal right. Therefore, a statement emphasizing the above points should be made - the planning purpose nature of these numbers and not establishing legal precedent. Additionally, in coordinating with other members of the KGA under the Umbrella GSP, the District should push for a consistent native yield and related methodology across the sub-basin. We understand that this can be a politically charged process, but we are confident the District can provide support for a consistent approach, which will enable a more stable sub-basin.	See the above response
Farmland Reserve	CGSA-11	3. Groundwater Market. This issue might be premature at this point. However, the Chapter could address the possibility of a market for the exchange or transfer of groundwater credits. If a market system were contemplated, we would encourage such a system to be as flexible as possible (within the requirements of SGMA, the Chapter and the Umbrella GSP) to facilitate the needs of farmers with lands in different areas of the sub-basin and those with the ability to store surface water underground. Again, this might be premature at this time, but a mention of the District's position to support a flexible groundwater market could help move the discussion forward once the Umbrella GSP is submitted to the Department of Water Resources and agencies begin the implementation process	It is necessary to gather additional data to better understand groundwater dynamics and how groundwater levels, established Minimum Thresholds and Measurable Objectiv groundwater users in general may be impacted by a potential groundwater transfer market. The Cawelo GSA Board of Directors have publicly stated they believe flexibility is key to the success of SGMA and the GSPs, and that it is necessary for the future of farming.

Commentor	Ref #	Comment	Response
Hancock Farmland Services	HFS-2	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	The KWBA concurs with the comment that existing banking projects need to continue operating as they have. Water banking projects in the Kern County subbasin are critical to reaching the sustainability goals of SGMA. The projects store available surplus surface water during wet years for later recovery in dry years, thereby reducing the reliance on groundwater by others in the subbasin. The projects operate under agreements with other basin stakeholders – developed during the CEQA process – that provide for project monitoring and mitigation measures which reduce any potential impacts to less than significant. Moreover, the projects, by their nature, do not contribute to any of the six undesirable results listed in SGMA.
Westchester	WGIM-4	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	See above comment.
Wonderful Orchards	WO-6	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	See above comment.
North Kern Water Storage District & Shafter-Wasco Irrigation District Received Comments			
Farmland Reserve		"Though not specifically addressed, we are concerned that overlying right to extract groundwater will be allocated among all District landowners based on gross acreage…it ignores accepted principles of law intended to more fairly allocate this right among those who have historically used groundwater for irrigation purposes -- and made substantial investments based on that use."	We have discussed adding language to the Water Budget section of the plan to address the fact that there is currently no in-district allocation of water to the landowners. The language in the Projects & Mgmt Actions section, dealing with in-district allocation as a mgmt action has been revised to address this, as well.
Farmland Reserve		"These numbers should not be seen as establishing a precedent or used to establish some legal right. Therefore, a statement emphasizing the above points should be made."	The discussion on native yield in the Water Budget section of the plan addresses this.
Farmland Reserve		"The Chapter could address the possibility of a market for the exchange or transfer of groundwater credits."	At this time, such a discussion is premature. There is no framework within the districts or the basin at large to allow for the exchange or transfer of groundwater credits. We ca reasonably address this in the plans for 2020 submittal.
Hancock Farmland Services		"The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water, for example xxx,xxx acre-feet and not associated with a given gross or net area."	The discussion on native yield in the Water Budget section of the plan addresses this already. Further emphasis on the "planning budget" role of the Native Yield estimate has b added to the final draft of the plan.
Hancock Farmland Services		"GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.)."	At this time, the framework to offer such incentives does not exist and would require the districts' boards to develop & adopt policy to put it in place. In the time required to pr the 2020 submittal of the plan, we cannot develop the structure and policy required to implement this. However, this is discussed in the Projects & Mgmt Actions section of the and will be considered for implementation after the 2020 plan submittal, when the districts have an opportunity to develop the policy and framework necessary for such progr
Hancock Farmland Services		"GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water."	This is already included in the Projects and Management Actions section and is part of the larger action of refining data for the calculation of Water Budget components in futur updates.
Wonderful Orchards		"The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource."	The districts have identifed as a management action the coordinated effort to further refine water budget components in the Kern County Subbasin Model. The Model and wat budget components will continue to be refined in coordination with the KGA and other GSAs in the basin.
Wonderful Orchards		"In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. Appendix J of the GSP indicates the subbasin native yield is approximately 0.144 acre-feet per acre. It is our understanding that subsequent to the release of the draft GSP, all MAPs and other GSPs in the basin agreed to utilize the same number for their water budgets. If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights. Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross or net area."	The discussion on native yield in the Water Budget section of the plan addresses this already. Further emphasis on the "planning budget" role of the Native Yield estimate has b added to the final draft of the plan. In terms of native yield allocation to the parcel/landowner level, there is no framework currently in place to do so. The development the pol and framework necessary to implement such an allocation cannot be completed in time for the 2020 plan submittal.
Wonderful Orchards		"Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next."	At this time, such a discussion is premature. There is no framework within the districts or the basin at large to allow for the exchange or transfer of groundwater credits. We ca reasonably address this in the plans for 2020 submittal.
Wonderful Orchards		"Wonderful understands that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled)."	As described in the Management Actions subsection of the Management Area Plan, policies for instituting pumping restrictions have not been developed for the 2020 plan subm This has been identifed as a potential management action, should the districts or the basin in general determine that it cannot maintain its path to sustainability through the pro and other management actions to be implemented.

Commentor	Ref #	Comment	Response
Wonderful Orchards		"GSAs must develop clear policies and conditions that protect existing investment in groundwater banking and banked inventory, and without interference with existing rules and regulations. GSAs must also find a way to incentivize additional investment, such as on-farm recharge, and allow flexibility for recharged or banked water to be freely transferrable (subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results). Where possible, GSPs should also identify management areas that may benefit from additional recharge and banking. We also recommend that GSAs work to develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.)."	At this time, the framework to offer such incentives does not exist and would require the districts' boards to develop & adopt policy to put it in place. In the time required to pr the 2020 submittal of the plan, we cannot develop the structure and policy required to implement this. However, this is discussed in the Projects & Mgmt Actions section of the and will be considered for implementation after the 2020 plan submittal, when the districts have an opportunity to develop the policy and framework necessary for such progr
Wonderful Orchards		"GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	A coordinated DMS is already being developed. However, that effort is currently focused at the district/MA level due to the precision of the data being used. Parcel-level alloca not at this time being done in the subbasin. It is premature to consider a basin-wide water market, as the data available does not allow for that level of allocation to be done. Fo consideration in the 2020 plan submittal, we do not have adequate time or resources for the development of such a framework.
Pacific Ag Management		Landowner would like to see RRID's ability to access future water supplies such as flood or highflow water from the Kem River made available to the District or additional waters that may become available. Landowner requests consideration of RRID's right to an ongoing, guaranteed share of such water as it is made available to the District.	This is already addressed in the RRID-specific projects in Section 5.4 of this plan. These projects are conceptual in nature, but they will be further defined as the district impleme SGMA.
Pacific Ag Management		In regard to the produced water available to the District, Landowner requests that RRID be granted increased access to this water to be delivered in the form of pumping credits	This is already addressed in the RRID-specific projects in Section 5.4 of this plan. These projects are conceptual in nature, but they will be further defined as the district impleme SGMA.
Pacific Ag Management		Landowner requests that the District consider using its positive water budget balance (Inflows less Outflows) for the purpose of offsetting any RRID water budget deficit.	The water budget for RRID has been revised based on the addition of the projects into the projected baseline water budget for years 2030 and 2070.
Pacific Ag Management		Landowner understands that recharge opportunities are an integral part of sustaining agricultural operations as the RRID area transitions to urban development. Recharge provides positive hydrological benefits as well as additional pumping opportunities for landowners. Landowner supports the enlargement, creation, and maintenance of recharge facilities within RRID, along with use of the RRID canal system as a recharge area and supplement to RRID water supplies.	This is already addressed in the RRID-specific projects in Section 5.4 of this plan. These projects are conceptual in nature, but they will be further defined as the district impleme SGMA.
Pacific Ag Management		Conveyance capacity is critical in order to effectively and strategically manage the movement of water supplies, both at the agency and at the landowner level. Landowner supports the proposed Calloway Canal improvements. Additionally, Landowner requests that RRID be given greater access to pipeline capacity when surplus water exists and that RRID canals be enhanced and expanded to the benefit of RRID landowners.	Continued maintenance of existing conveyance to RRID is already included as part of the RRID-specific projects discussed in Section 5.4 of this plan.
Pacific Ag Management		As an RRID stakeholder, Landowner is appreciative of North Kern Water Storage District's and Kern Groundwater Authority's support of agricultural land owners and their commitment to the effective management of RRID's water supplies and agricultural lands. The City of Bakersfield and the Kern River Groundwater Sustainability are critical strategic partners for RRID. Landowner is confident that a partnership between the agencies and respective landowners will ensure the continued viability of agricultural operations in RRID and a successful transition to urban development.	Per the terms of the Coordination Agreement between KGA and the other Kern GSAs, and NKWSD and SWID's membership in KGA, the Districts already coordinate with KRGSA Coordination between the Districts and KRGSA will continue through the SGMA implementation process and beyond.
Westchester Group Investment Mgmt		The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water and not associated with a given gross or net area. In the event that allocations are to be made at a landowner or property level, WGIM encourages the KGA and other GSAs in the basin to initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations that are coordinated across the basin.	The discussion on native yield in the Water Budget section of the plan addresses this already. More language can be added to emphasize the "planning budget" role of the Nati estimate.
Westchester Group Investment Mgmt		GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked water inventory, and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	At this time, the framework to offer such incentives does not exist and would require the districts' boards to develop & adopt policy to put it in place. In the time required to pr the 2020 submittal of the plan, we cannot develop the structure and policy required to implement this. However, this is discussed in the Projects & Mgmt Actions section of the and will be considered for implementation after the 2020 plan submittal.
Westchester Group Investment Mgmt		GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	A coordinated DMS is already being developed. However, that effort is currently focused at the district/MA level due to the precision of the data being used. Parcel-level alloca not at this time being done in the subbasin. It is premature to consider a basin-wide water market, as the data available does not allow for that level of allocation to be done. Fo consideration in the 2020 plan submittal, we do not have adequate time or resources for the development of such a framework.
Westchester Group Investment Mgmt		"WGIM supports use of efficient and accurate systems to determine groundwater use. GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water."	This is already included in the Projects and Management Actions section and is part of the larger action of refining data for the calculation of Water Budget components in futur updates.
BDII Investments		"Landowners would like RRID to be able to purchase produced water resources conveyed and/or banked in NKWSD facilities. These volumes appear to be available sources of water in the GSP that could become an integral source of water for acres (sic) within RRID. Landowners would like RRID to improve future water supplies by purchasing flood water or high-flow water from the Kern River when it is available and before that water is offered to areas outside the managed areas within the GSP. Landowners would also like to see RRID purchase surplus water from NKWSD when available to help mitigate the deficit in RRID before these surplus supplies are sold outside the GSP management area. Landowners believe that RRID should continue to improve conveyance and turnout facilities that could be used to supply lands with excess Kern River flow when its available."	This is already addressed in the RRID-specific projects in Section 5.4 of this plan. These projects are conceptual in nature, but they will be further defined as the district impleme SGMA.
BDII Investments		"Landowners would encourage RRID to participate in groundwater banking and the use of recharge facilities in NKWSD for the benefit of RRID. This will allow RRID to develop a more stable long-term supply and pump groundwater in years when there is little or no access to excess Kern River water. Landowners would encourage RRID to explore potential banking and development of recharge facilities within the RRID service area."	This is already addressed in the RRID-specific projects in Section 5.4 of this plan. These projects are conceptual in nature, but they will be further defined as the district impleme SGMA.

Commentor	Ref #	Comment	Response
City of Shafter		"The City's specific comments, concerns, and suggestions have been made to ensure that the description of the City's water system and demond are accurate."	These items were addressed through discussions with the cities and accounted for in the Water Budget: Urban Demand sections of the plan.
City of Shafter		"The City's specific comments, concerns, and suggestions have been made to ensure that [...] the City's beneficial uses are recognized and protected and that the plan does not inadvertently include language that could be misinterpreted to adversely affect the City's water rights or ability to utilize those rights to the benefit of public health and safety."	As described in the plan, SGMA does not alter existing water rights. With input from the cities (through their MOU with the Districts), this comment has been further addressed final draft of the plan.
City of Shafter		"Two critical pieces that the plan should ultimately address are minimum thresholds and measurable objectives set for specific water quality constituents to ensure that water quality does not degrade beyond current conditions."	As discussed in the existing conditions portion of the Basin Setting and the discussions in Section 3 which pertain to water quality, the Sustainable Management Criteria for groundwater levels are being used as a proxy for water quality at this time, in addition to continued monitoring of the constituents of concern coincidental with the monitoring groundwater levels and cooperation and compliance with existing water quality programs.
Leadership Council		"The Draft GSP is incomplete and must include additional information for the public to evaluate the GSP. The Draft GSP omits critical data regarding the consideration of drinking water impacts on disadvantaged communities and protected groups, sustainable management criteria that consider all beneficial users, and projects and management actions that address significant and unreasonable impacts to beneficial users."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with the statement, as the information that Leadership Council claims is missir the GSP is actually included in the management area plans, as appropriate to each respective management area.
Leadership Council		"The KGA is responsible for the disproportionate and disparate impacts that its policies and activities will have on disadvantaged communities belonging to protected groups."	This comment is directed to the KGA GSP and will be addressed by KGA. While the KGA is the GSA entity submitting the plan on behalf of its members, the JPA forming the KGA that each member is responsible for the implementation of SGMA within their respective plan areas. The KGA GSP and its management area plans were developed in considerat all beneficial uses of water and the beneficial users of the groundwater in the subbasin.
Leadership Council		"The Coordination Agreement does not "explain how the plans, implemented together, satisfy the requirements of the Act."	This comment is directed to the KGA GSP and will be addressed by KGA.
Leadership Council		"The GSP was not crafted in a way that adequately considered the input of disadvantaged communities, either at the GSA level or the member agency level."	This comment is directed to the KGA GSP and will be addressed by KGA, pertaining to the KGA level engagement. With respect to the member level engagement, SGMA leaves t manner and frequency of public outreach and engagement to the discretion of the GSA. As described in the introduction of the management area plan, both NKWSD and SWID monthly publicly-noticed meetings which serve as an opportunity for members of the public to provide feedback to the districts regarding the plan's development and implementation. Furthermore, the districts were active participants in the KGA-level outreach activities as well as hosts of their own workshops, which were publicly-noticed, a coordination with the cities of Shafter and Wasco and with Oildale Mutual Water Co on the development of the plan.
Leadership Council		"The Kern Subbasin Undesirable Results do not comply with existing law."	The definitions for undesirable results were developed in coordination with the other GSAs and take into consideration "significant and unreasonable" impacts to the groundwa which affect all beneficial users. Such beneficial uses include agriculture, domestic, and municipal & industrial.
Leadership Council		"It is not clear what the impacts from reaching this undesirable result will be on beneficial users, and instead seems to be an arbitrary determination of what is "significant and unreasonable."	The impact analysis performed by the GSAs in the subbasin contributed to the development of the undesirable results for declining groundwater level.
Leadership Council		"Like the proposed definition of undesirable results for groundwater levels, the proposed definition of undesirable results for degraded water quality are 'when the minimum threshold for when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each management area)."	The comment letter cites an incorrect definition. The definition for the undesirable result for water quality is "when the minimum threshold for a groundwater quality constitue concern is exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the designated monitoring points within Subbasin."
Leadership Council		"The GSP's minimum thresholds and measurable objectives were not established in a way that considered the interests of beneficial users including domestic well owners and disadvantaged communities."	The KGA GSP outlines the methods used by its members to establish the Sustainable Management Criteria (SMCs) within their respective plan areas. For the NKWSD-SWID management plan area, projected groundwater levels based on recent historical hydrology were used to analyze the impact to known agricultural, domestic, and municipal wel While impacts were identified at the minimum thresholds in some management areas, these impacts were determined to not meet the definition of "significant and unreasonat
Leadership Council		"As in the case of groundwater levels, it is clear that the GSA has not considered the potential impact on drinking water users, in particular disadvantaged communities who are less able to afford solutions to treat contaminated drinking water."	As with the groundwater level SMCs, the KGA GSP outlines the methods used by its members to establish the Sustainable Management Criteria (SMCs) within their respective p areas. Based on the analysis in the Basin Setting subsection on existing water quality conditions, it was determined appropriate to use groundwater levels as a proxy for water c in addition to water quality and water level measurement at the representative monitoring sites will be coincidental.
Leadership Council		"GSAs must monitor impacts to groundwater for drinking water beneficial users,54 including disadvantaged communities on domestic wells, and must avoid disparate impacts on protected groups pursuant to state law. The GSA's monitoring network does not comply with SGMA regulations, and fails to capture drinking water impacts to disadvantaged communities and domestic wells[...] To ensure the monitoring network adequately captures impacts to all beneficial users, the GSA must ensure the following: Ensure the proposed monitoring network contains representative monitoring wells in or near all disadvantaged communities and clusters of domestic wells in the GSA area; Ensure that monitoring wells and representative monitoring wells in or near disadvantaged communities and clusters of domestic wells are able to measure the groundwater levels at the depth at which the drinking water wells are screened; Explicitly describe any future representative monitoring wells and identify the proposed locations. When assessing the monitoring network data gaps, the GSP must prioritize installing new monitoring wells in locations where disadvantaged communities, small water systems, and domestic well users reside."	The coordinated basin-wide monitoring network was developed using the DWR BMP on SGMA Monitoring Networks, which discusses recommended well density and what constitutes a "SGMA compliant" representative monitoring site. It also allows for (and encourages) GSAs to use existing monitoring programs already in place for collecting dat the Sustainability Indicators identified in a basin's plan. Domestic wells are typically shallow or in the first occurence of groundwater and are, therefore, not representative of t groundwater conditions of the basin as a whole. Further, there are existing programs with which domestic wells and community wells must comply. These have been identifiec Basin Setting and Monitoring Network sections in the discussions of existing programs. In areas of the basin where the well density does not meet the standards used in the pla proposed well locations have been identified. Per discussion and comments from the cities of Shafter and Wasco, three additional wells have been added to the monitoring net within the NKWSD-SWID management area.
Leadership Council		The groundwater quality monitoring network does not adequately capture impacts on drinking water users.[...] First, measuring for Arsenic (as in Arvin-Edison WSD) only once a year does not provide the member agency or the GSA with frequent enough information to respond to severe drinking water contamination in a reasonable amount of time. If the member agency's management actions, projects, or decisions to let groundwater decline increase drinking water contamination for families in the management area, the member agency could go a whole year without detecting these impacts. [...] Second, only measuring for compliance with arsenic measurable objectives and minimum thresholds does not protect against increases in other contaminants that exist in other parts of the management area (boron, nitrates, TDS, 123-TCP, iron and manganese). These contaminants could extend, move or increase due to groundwater management activities and pumping patterns. [...] However, avoiding monitoring contaminated areas defeats the purpose of groundwater quality monitoring under SGMA, which is to measure the concentration and spread of contaminant plumes to ensure that groundwater management activities and pumping do not aggravate existing contamination.	The monitoring of water quality for the basin will include the use of data from existing programs (e.g. Title 22, ILRP, CV-SALTS) and sampling coincidental with groundwater leve measurements at the representative monitoring sites. As such, the water quality data collected through SGMA will be more frequent than once a year. The constituents of conc be tested in the water quality sampling at representative monitoring sites vary between the management areas. Therefore, the constituents analyzed will differ according to the management area plan. The selection of representative monitoring sites discouraged the use of wells with existing MCL exceedances because of the nature of the definition of undesirable results for degradation of groundwater quality. The occurence of an increase in concentration for constituents of concern in a representative monitoring site will, b of it being a representative site, will be indicative of the migration of existing contamination.
Leadership Council		The projects and management actions set forth in the Draft GSP do not demonstrate a path towards achieving sustainability goals in the plan, and do not adequately account for the needs of disadvantaged communities pertaining to protected groups under state law. The GSA has allowed member agencies like the Arvin-Edison WSD to use a "glidepath" approach that increases surface water and groundwater recharge before demand reduction measures are implemented. This places the majority of the plan's success on surface water resources, which are variable and may not be able to be procured. The GSA should instead ensure that member agencies implement demand reduction strategies from the beginning so that groundwater levels do not plummet. A critical problem with the structure of the GSA is that member agencies cannot share the cost or responsibility for critical GSA-wide projects. Many more financially powerful agricultural and water banking member agencies could and should be part of a strategy to protect drinking water resources in the GSA area, especially given that they use much larger quantities of groundwater and their continued pumping will likely lead to dry wells and groundwater contamination issues for the most vulnerable homes in the GSA area.	The KGA and its members have the authority under SGMA to prioritize projects and management actions, as they see fit, to demonstrate that the basin can reach sustainability 2040. The prioritization of projects to increase imported supply for use by districts' customers or for water banking projects protects groundwater for beneficial use in the basi facilitiating in-lieu banking (where surface water is used whenever it is available, replacing groundwater pumping) or by maintaining groundwater levels through replenishment banking projects. These projects do not run contrary to the mandate to protect groundwater quality. In fact, with groundwater levels as a proxy Sustainability Indicator for wat quality, these projects achieve both the maintenance of groundwater levels and water quality. The agricultural and water banking agencies in the basin, as the customers payin water deliveries and funding projects via land assessments in their respective districts, can and should be a beneficiary of the projects which they are funding.
Leadership Council		"The KGA GSA should implement or incentivize recharge basins or other recharge activities throughout the subbasin wherever DACs and clusters of domestic wells exist. The GSA should encourage these kinds of recharge projects with health co-benefits over on-farm recharge, which is likely lead to accelerate groundwater contamination."	It is at the discretion of the KGA's member agencies to identify projects to fund, as well as opportunities to collaborate with DACs. SWID, since its founding, has used its import supplies to maintain groundwater levels and water quality to the benefit of the beneficial users within the district, including the cities of Shafter and Wasco and domestic well us NKWSD has also operated in the same manner since its founding as a water storage district. Future projects and management actions which deal specifically with the DACs and domestic wells may be considered for subsequent updates to the GSP and management area plans.
Leadership Council		"For areas vulnerable to declining water levels and loss of production capacity, the KGA GSA should adopt management actions that establish geographical protection areas (buffer zones) by establishing bans, pumping limitations or community-specific management areas around disadvantaged communities and domestic well clusters."	The development of these buffer zones would be predicated on the development of a shallow-zone specific monitoring network and SMCs. As discussed in the response to the Monitoring Network comments, these shallow zones are not representative of groundwater conditions throughout the basin. Furthermore, the framework necessary to imple pumping restrictions or bans does not exist within the KGA or its members. Such policy would not be developed or implemented in time for the 2020 submittal.

Commentor	Ref #	Comment	Response
Leadership Council		"We also strongly recommend against a groundwater market in the KGA GSA area. The GSP includes potential groundwater market and trading programs. Groundwater markets raise concerns from the perspective of domestic well users and disadvantaged communities."	At this time, the framework to establish a groundwater market in the basin does not exist. The policies and framework that would need to be developed by the KGA and its mer is too complex to be completed in time for consideration in the 2020 submittal. Additionally, any groundwater market developed by the KGA or its members would have to com with SGMA (i.e. prevent localized impacts to the Sustainability Indicators in its implementation).
Leadership Council		"The GSAs should implement and incentivize multi-benefit projects such as wetlands restoration or stormwater drainage ponds that would eliminate flooding and increase groundwater recharge in disadvantaged communities."	It is at the discretion of the KGA's member agencies to identify projects to fund. Future projects and management actions which provide benefits beyond SGMA may be conside subsequent updates to the GSP and management area plans.
Leadership Council		"Although there are multiple short-term funding sources to leverage for SGMA-related projects, the GSA's and member agencies' operating budgets must be a reliable source of funding over the long-term of GSP implementation, and the GSA and member agencies cannot rely on grant funding for long-term projects and programs that benefit disadvantaged communities. The GSA and member agencies must be responsible for addressing the drinking water issues caused by their policy decisions and activities."	It is entirely appropriate that the KGA's members, when working in collaboration with DACs on a project to benefit groundwater quantity and quality in the basin, seek funding such projects through state and federal grant funding programs. Grant funding, where the districts are eligible, is applied for to defray the cost of projects (which often far exce award amount). The remaining costs of projects and management actions are to be funded with the districts' operating budgets or through special assessments.
Leadership Council		"the Draft GSP allows continued overdraft above the safe yield of the basin, such that drinking water wells (especially domestic wells) will continue to go dry, infringing on the rights of overlying users of groundwater. The GSP must be revised to protect the rights of residents of disadvantaged communities and/or low-income households who hold water rights to groundwater."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with the statement, as the KGA GSP and its included management area plans h demonstrated, the combination of projects, management actions, and established SMCs will bring the basin into balance with its groundwater management by 2040.
Leadership Council		"The reasonable and beneficial use doctrine applies here given the negative impacts of the Draft GSP on groundwater supply and quality, which are likely to unreasonably interfere with the use of groundwater for drinking water and other domestic uses. As the Draft GSP authorizes waste and unreasonable use, it conflicts with the reasonable and beneficial use doctrine and the California Constitution."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with Leadership Council's statement regarding the plan's authorization of "wa and unreasonable use". The beneficial uses of water in the basin include other uses beyond domestic consumption. As such, it is entirely appropriate and in the authority of the that impacts to groundwater be analyzed in consideration of all beneficial uses identified in the plan.
Leadership Council		"The "public trust" doctrine has recently been applied to groundwater where there is a hydrological connection between the groundwater and a navigable surface water body. In Environmental Law Foundation , the court held that the public trust doctrine applies to "the extraction of groundwater that adversely impacts a navigable waterway" and that the government has an affirmative duty to take the public trust into account in the planning and allocation of water resources. The court also specifically held that SGMA does not supplant the requirements of the common law public trust doctrine. In contrast to these requirements, the Draft GSP does not consider impacts on public trust resources, or attempt to avoid insofar as feasible harm to the public's interest in those resources."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with Leadership Council's position in that the Basin Setting of the KGA GSP an management area plans have adequately demonstrated that there are no interconnected surface waters in the basin and that this is the existing condition of the basin.
Rosedale-Rio Bravo Water Storage District Received Comments			
Wonderful Orchards	WO-1	It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource.	See KGA WO-1 Response
Wonderful Orchards	WO-2	In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield.	See KGA WO-2 Response
Wonderful Orchards	WO-3	In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin.	See KGA WO-1 Response
Wonderful Orchards	WO-4	Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.	See KGA WO-1 Response
Wonderful Orchards	WO-5	GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity	See KGA WO-1 Response
Wonderful Orchards	WO-6	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	See KGA WO-1 Response
Wonderful Orchards	WO-7	GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater.	See KGA WO-1 Response
Semitropic Water Storage District Received Comments			
Central Valley Joint Venture	CV1	We hope future proposed allocations and management actions in Semitropic weigh the value of wetlands as beneficial users of groundwater and support their continued existence.	Agree that managed wetlands have value, and there is nothing in the GSP to the contrary. Will weigh the value and reasonable water needs of managed wetla relation to other beneficial uses of groundwater in preparing future water budgets.
California Waterfowl	CW1	The ET water budgets in the GSP are inadequate for continued operation of the managed wetlands. Without an affordable replacement water supply , the water budgets would lead to the complete eradication of managed wetlands in the Semitropic Water Storage District in 20 years.	Agree that managed wetlands have value, and there is nothing in the GSP to the contrary. Will weigh the value and reasonable water needs of managed wetl in relation to other beneficial uses of groundwater in preparing future water budgets.
California Waterfowl	CW2	… recommends that ET allocations for managed wetlands be set on par with agricultural and other users atr 4.2 acre-feet for five years or until a sufficient data on ET rates for managed wetlands becomes available.	Acknowledge the data gap with respect to ET of managed wetlands. Will be including a MA for the continued refinement of ET on managed wetlands. Will a the initial water budget for managed wetlands to 4.2 acre-feet with the approriate ramp-down over the implementation period
California Waterfowl	CW3	Unless a surface water supply can be found to make up the difference between the proposed groundwater budget for managed wetlands, the water budget should be increased to a minimum of 4.2 acre-feet per acre. The cost of surface water should not exceed the cost of pumping groundwater …	Will adjust the initial water budget for managed wetlands to 4.2 acre-feet with the appropriate ramp-down over the implementation period.
California Waterfowl	CW4	How can a surface water supply be provided? … allow flood flows in the Tulare Lake Basin to be used on managed wetlands. … provide access to State Water Project supplies to augment groundwater pumping.	Will consider joint projects for development of Poso Creek flood flows. Will consider access to SWP conveyance capacity for supplemental water supplies, including but not limited to water transfers. These will be included and considered in the development of individual projects and management actions.
California Waterfowl	CW5	The total number of acres in managed wetlands …is very small in comparison to the number of acres in trees and other crops. An increase in the water budget will have a small effect on the groundwater available to agriculture.	All lands will be treated equally with respect to access to native yield and proportionate participation in District programs.
Rancho Visalia	RV1	**The Et Estimates Are Seriously Flawed** The first and most obvious conclusion from the above is that the Et estimates for Rancho Visalia are nowhere near accurate, both as to its undeveloped land and its flooded wetland ponds. This may be because the methodology used to determine the Et works well for agricultural land but does not work for natural, undeveloped land, wetlands or ponds. This is not surprising given that ag land loses water through the much higher Et rates associated with growing and exporting crops whereas duck clubs are composed of only natural, undeveloped land or flooded ponds/wetlands.	ET for undeveloped land is assumed to equal precipitation and therefore there is no net demand for undeveloped properties. Acknowledge the data gap with respect to ET of managed wetlands and duck clubs. Will be including a MA for the continued refinement of ET on managed wetlands. ET is a measurement of consumptive use, not applied water.

Commentor	Ref #	Comment	Response
Rancho Visalia	RV2	**Restricted Water Budgets for Duck Clubs Will Cause Significant and Irreversible Environmental Harm** Imposing duck club water budgets of 1.5 af/ac/yr, as is proposed for the year 2020 in the draft Groundwater Sustainability Plan, will severely impede those clubs' ability to maintain year -round or even seasonal wetlands. Allowing the clubs to only extract .5 af/ac/yr, or worse, just the .15 af/ac/yr Native Yield, when the proposed GSP is fully implemented in 2040, will all but eliminate those wetlands, even for clubs such as Rancho Visalia which only floods about one sixth of its Special GPSC land.	We acknowledge the values of managed wetlands and duck clubs, but are required under SGMA to sustainabily manage the Subbasin without altering the wa rights of landowners. Accordingly, all lands are being treated equally with initial allocation of available native yield in the Subbasin.
Rancho Visalia	RV3	**Any Over-Extraction by Duck Clubs Would Be Insignificant** ….duck club wetlands make up just 2 percent of the 140,000 acres of irrigated land and 1.3 percent of the total acreage within the SWSD. If duck clubs were allowed to extract the 3.5 af/ac/yr necessary to adequately flood their 2,800 acres of ponds, this would total just 9,800 af/yr. This is just .08 percent of the 123,900 af/yr reduction in groundwater pumping required under SGMA. In short, allowing the clubs to extract sufficient water to maintain their wetlands would have no measurable impact on the groundwater levels yet would avoid most of the environmental harm.	It is the expectation that a finite native yield will be developed for the entire Subbasin and that will be allocated among all lands equally. Providing some lanc higher native yields will require a reduction in the native yield allocated to other lands. Moreover, SGMA defines groundwater sustainablity in terms of the avoidance of six (6) defined undesirable results. Allocations of native yield are merely one tool (among many) to achieve sustainability within statutorily-man timeframes.
Rancho Visalia	RV4	**The finalized GSP Should Allow Duck Clubs to Extract Sufficient Groundwater to Sustain Year-round Wetlands on a Perpetual Basis.** **…** allowing duck clubs to extract sufficient water to adequately maintain their ponds would cause virtually no measurable groundwater reduction yet would avoid most of the environmental damage. For these reasons, the example duck club Water Budget should be modified so as to allow clubs to extract 3.5 af/ac/yr for their wetlands.	See Response to Comment RV2. The GSP is predicated on tracking consumptive use (ET), not applied water.
Larry Frey	LF1	Objection to the proposed District plan to not allow a farmer to carry-over from year to year, or a number of years, on a one-to-one basis without a fee the Incremental Pumping allowance portion of his yearly water right.	Comment to be considered through the development process of the Landowner Budgets Management Action.
Fresno Irrigation District	FID1	The project ("Tulare Lake") is fundamentally flawed, as Semitropic has not established that it has the right to export Kings River water to Kern County as the project requires.	The ultimate yield of the Tulare Lake Project will be determined pursuant to the water right proceeding now being conducted by the State Water Resources C Board. Any water supply developed through the implementation of any of the projects identified in Table 5-1 will reduce the District's obligation to retire properties as identified in the third management action.
Kings River Water Association	KR1	The project ("Tulare Lake") is fundamentally flawed, as Semitropic has not established that I has the right to export Kings River water to Kern County as the project requires.	The ultimate yield of the Tulare Lake Project will be determined pursuant to the water right proceeding now being conducted by the State Water Resources C Board. Any water supply developed through the implementation of any of the projects identified in Table 5-1 will reduce the District's obligation to retire properties as identified in the third management action.
North Kings Groundwater Sustainability Agency	NK1	The project ("Tulare Lake") is fundamentally flawed, as Semitropic has not established that I has the right to export Kings River water to Kern County as the project requires.	The ultimate yield of the Tulare Lake Project will be determined pursuant to the water right proceeding now being conducted by the State Water Resources C Board. Any water supply developed through the implementation of any of the projects identified in Table 5-1 will reduce the District's obligation to retire properties as identified in the third management action.
Hancock Farmland Services	HF1	The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water, for example xxx,xxx acre-feet and not associated with a given gross or net area.	Agree that references to native yield are for initial water budget purposes only, are not precedent-setting, and are not a determination of the water rights of individual landowners or other water users.
Hancock Farmland Services	HF2	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	Agree that existing groundwater banking projects and banking inventory should be protected in accordance with contractual requirements and that incentive additional recharge and banking projects should be developed.
Hancock Farmland Services	HF3	GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration.	Agree, Landowner information is important for validating the Et Measurements.
Westchester	W1	The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water, for example xxx,xxx acre-feet and not associated with a given gross or net area.	Agree that references to native yield are for initial water budget purposes only, are not precedent-setting, and are not a determination of the water rights of individual landowners or other water users.
Westchester	W2	… GSAs and MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible without creating undesirable results, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity.	To the extent pumping restrictions are adopted in the future, they will be implemented in accordance with SGMA (including but not limited to the requiremer water rights not be altered) and best available science.
Westchester	W3	As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated and consistent across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled).	To the extent pumping restrictions are adopted in the future, they will be implemented in accordance with SGMA (including but not limited to the requiremer water rights not be altered) and best available science.
Westchester	W4	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	Same as Hancock HF2
Westchester	W5	GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater.	Agree, this is contemplated as an item for coordination relative to all GSA's within the basin

Commentor	Ref #	Comment	Response
Westchester	W6	GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration.	Same as Hancock HF3
Wonderful Orchards	WO1	It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource.	The KGA has identified the "Study of Native Yield for the Kern Subbasin" as a management action that will include all GSAs in the Subbasin. This Management Action will work to develop a common and agreed to native yield value for the entire Subbasin and appropriate methodology for allocation of the native yield accordance with SGMA.
Wonderful Orchards	WO2	In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. .... If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights	Clarification regarding planning level water budget and native yield analysis can be added to the GSP. Agree that references to native yield are for initial wate budget purposes only, are not precedent-setting, and are not a determination of the water rights of individual landowners or other water users.
Wonderful Orchards	WO3	Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross acreage.	Agree with respect to GSA or Management Area; however, utilization of native yield at the landowner level requires an allocation. The initial policy direction allocate native yield equally to all acres within the Subbasin.
Wonderful Orchards	WO4	In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin.	Opportunities for stakeholder input will be provided during the planning and implementation of the Landowner Water Budget Management Action in early 2(
Wonderful Orchards	WO5	An equal-per-gross acre approach to allocations is not likely to be consistent with established water rights doctrine, which must recognize many equitable considerations in addition to acreage owned, to determine a legally defensible allocation.	To the extent pumping restrictions are adopted in the future, they will be implemented in accordance with SGMA (including but not limited to the requiremer water rights not be altered) and best available science. The comment is unclear regarding what is meant by "equitable considerations."
Wonderful Orchards	WO6	Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.	Water markets will be considered as potential future management actions.
Wonderful Orchards	WO7	GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. ... As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled)	Same as Westchester W2 Agreed - is reflected in the development of the IPA and gradual reduction of IPA to 0 by 2040 With regard to ramp-down schedules, not all lands are equal with respect to surface water supplies; therefore the sustainable yield for each property will vary across the Subbasin and accordingly the ramp-down schedules will vary.
Wonderful Orchards	WO8	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	Same as Hancock HF2 Agree and will continue to consider through implementation of projects and management action.
Wonderful Orchards	WO9	GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions.	Same as Westchester W5 1) Agree - however the level of detail (district vs landowner) many vary and will need to be discussed further. 2) Market interface will be considered as markets develop. Should not be limited to just groundwater.
Wonderful Orchards	WO10	GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	Agree - all data needs to be verifiable and defensible at the District and landowner level.
Major Dhillon	MD1	The SGMA draft report(hereinafter as "Report") completely favors the farmers who are getting State water or contracting for surface water. They have access to surface and as well as to the well water, whereas land owners who have no access to surface water are at big disadvantage especially with the new allocation that Semitropic is using	See Section 5.2.3 for clarification. Additonal clarification to be provided in additional information developed through implementation of the Landowner Wate Budget Management Action in early 2020.
Major Dhillon	MD2	The Semitropic water Storage District(hereinafter as "District") did not give any opportunity to land owners if they wish to participate in a program called "Developed land" where a landowner can also pay the water assessment of $137 + per acre. We the land owners who were not provided the opportunity to participate in the Developed land definition MUST BE PROVIDED AN OPPORTUNITY TO PARTICIPATE IF THEY WISH	Disagree - See Prop 218 for New Lands Surcharge
Major Dhillon	MD3	The District has given no consideration to properties which are enrolled in Williamson Act.	Under California law, lands enrolled in the Williamson Act are not exempt from the requirements of SGMA.
Maricopa Orchards	MO1	**Section 2.7.2** 1) Can properties not currently in the in-lieu program enroll? 2) What if growers pay for infrastructure to be part of the program? 3) I don't understand the terminology in the section labeled "Construct additional irrigation distribution systems". What does absorptive capacity and related priorities mean? 4) Water in storage by banking partners may help the groundwater levels generally but any of it can be called upon so should this be recognized? 5) How will the landowner pumping agreement be affected by SGMA? 6) Where is the surface water storage capacity located? 7) On Third Party Banking, how will SGMA affect the in-lieu banking program?	1) yes 2) will be considered 3) one on one discussion for clarification 4) Banked water is not water supply of the District, with the exception of the 10% leave behind. 5) no impact to a landowners Groundwater Pumping Agreement is expected relative to recovery of banked water via the agreement on behalf of the district f bankers. There could be an impact with respect to a landowners ability to wheel water due to compliance with the SGMA Sustainability Indicators 6) Temp storage at Goose Lake under agreement with Goose Lake Holding Co. and surcharge spresding facilities at Scofield. 7) Do not foresee an impact relatative to an existing bankers first priority recharge rights.
Maricopa Orchards	MO2	**Section 3.3.1.1** Does this mean that upper zone pumping is unlimited for now and will just be monitored? How does this effect the Agua Via/WAP projects? There needs to be clear contract language re the assumption of risk for the service providers.	No - This is a data gap. MT and MO for the upper aquifer will be developed in the future

Commentor	Ref #	Comment	Response
Maricopa Orchards	MO3	**Section 3.3.2 and 3.3.3** Seem not to address the issues for MOs/MTs -for example, doesn't SWSD need to monitor subsidence and, if below a specified level, then would require a management action?	The KGA and the District have identified the understanding of subsidence as a data gap and have committed to maintaing existing monitoring sites and establ additonal sites to better understand the specific causes of subsidence in the subbasin. With this information we will establish MO & MT in the District.
Maricopa Orchards	MO4	**General, Water Budget** Allow Growers to determine their order of use. However, with the knowledge that you cannot roll over native yield. Allow Growers to decide if they want to manage their allocation year to year or if they want to opt into the average -How can SWSD guarantee the then current average SWP? Isn't that taking water from the basin to incrementally benefit SWP contract holders? What if contract holders want to bank their surplus water on their own account (either through the SWRU or via the new recharge program?) (Section 5.2.3.2) When will landowners be expected to start using the water budget? 2020 or 2021?	Good input - will consider when developing Landowner Water Budgets
Maricopa Orchards	MO5	**General** The GSP punts to a later 5-year update in many instances. This could be a red flag for DWR. Banking partners should be able to use or sell their banked water in SWSD to growers who have deficits without having to recover from SWSD wells. Query whether there should be a discount to the recovery charge per AF?	Noted
Maricopa Orchards	MO6	**General, Subsidence at the Aqueduct** Additional monitoring should be completed due to subsidence may not be directly linked to Semitropic.	Agree
Maricopa Orchards	MO7	**General, Expiration of Credits on Recharge** Semitropic should not have expiration dates or increasing leave behind factors on water stored via recharge or credit carryover. It will encourage pumping in an effort not to lose stored water.	Good input - will consider when developing Landowner Water Budgets
Maricopa Orchards	MO8	**5.2.3.2, Incremental Pumping Allowance** 1) We are pleased with this glide path approach. This gives growers the opportunity to plan and reach sustainability by 2040. 2) What if the IPA results in undesirable results? 3)Doesn't a larger IPA for non-contract growers reward those that have been benefitting from the overdraft?	1) Comment noted. 2) If IPA results in undesirable results it will require adaptive management. 3) Potentially in the short term, but IPA is reduced to zero by 2040.
Maricopa Orchards	MO9	**Chapter 5** 1) Potentially add ASR as a project that growers/district can use as a tool for recharge. 2) Why is brackish water desalination limited to only 1,800 AF? 3) For Poso Creek MAR, would SWSD allow growers to take flood water and recharge in their own facilities? 4) For SWRU, what type of storage is referenced? 5) Will the pilot program for private recharge continue?	1) Considered as enhanced recharged 2) place holder for proposed project 3) Potentially 4) Primarily in-leu groundwater storage 5) likely yes
Maricopa Orchards	MO10	**Table 5-1** Various spelling errors.	Noted
Maricopa Orchards	MO11	**General, Landowner Classifications** Let landowners that have parcels that are paying a portion of the GPSC to opt in to pay the entirety.	Not at this time
Maricopa Orchards	MO12	**General, Water Markets** Allow basin-wide market and do coordination agreement with neighboring districts (regional).	Will be considered in the future as water market develop within and between districts in the Subbasin. Consideration will need to be given to location of groundwater extractions to avoid concentration of withdrawal and the potential for undesirable results
Maricopa Orchards	MO13	**Kings River Water/ State Water Project** 1) Has any assumption been made regarding there being less Kings River flood water? 2) Has any assumption been made regarding there being less SWP due to projections of long-term allocations being lowered given climate change and expected biological opinion limitations?	1) Planning level estimate. Project yield would reduce obligation to retire lands within the District (MA 3) 2) Currently using DWR provided delivery estimates for 2030 and 2070
Audobon	A1	The proposed consumptive use allocation for duck clubs will result in severe near-term and long-term declines in wetlands in the Semitropic GSA.	Currently, not enough data to make this determination. Additional analysis on consumptive use (ET) and fate of pumped groundwater is required.
Audobon	A2	The evapotranspiration (ET) of flooded wetlands and native uplands is currently poorly understood by Semitropic GSA and should be identified as a data gap. The Incremental Pumping Allowance for wetlands should be set to give an initial ET allocation of 4.2 acre-feet per acre, on par with other irrigated lands, while the ET data gap is addressed in the first five years of the GSP implementation.	Will Modify initial IPA for wetlands to allow up to 4.2AF/Ac of consumptive use Address ET data gap in ongoing ET refinement efforts as an MA
Audobon	A3	Recharge from imported surface water to Kern National Wildlife Refuge should be reflected in proposed water budgets for managed habitat. State and federal lands should be allocated native supply and Semitropic GSA should work with federal and state agencies to develop an appropriate trading system to support habitat *(accounting for recharge from Refuge water supplies)*	Clarification / refinements to the Landowner Water Budget Management Action will be considered as part of the process of approving the same for implemen
Audobon	A4	P. i: Executive Summary, paragraph 2. The beneficial users of water in the Tulare Lake Region are described as "agricultural; municipal and domestic; industrial; and environmental." In the proceeding sentence the environmental users are not included as being supported by groundwater. However groundwater in this region supports managed wetlands that are important migratory bird habitat, provide recreational opportunities, and contribute to the economic viability of local communities.	Agree to change the identified sentence to include managed wetlands
Audobon	A5	P 4. 1.4.1 Plan Area Setting. It is unclear if the "146,000 acres of irrigated lands" includes managed habitat and wetlands. Please clarify if managed wetlands, i.e. 'duck clubs', are included as irrigated lands	Comment noted - numbers ajusted in text
Audobon	A6	Additionally, clarification on how riparian versus native vegetation was classified is absent and would be helpful to understand why the "native vegetation" directly surrounding the Kern River Channel is not "riparian vegetation	Will provide clarification based on sources. I believe this data came from DWR and its their classification system.
Audobon	A7	In Figure 1-2 approximately 1/3 of the area is identified as riparian and native vegetation. This should be noted in the description of land use in this section because of its significance.	Change made to the text to say "Land use within SWSD consists mainly of agricultural production and environmental land uses, as shown in Figure 1-2."
Audobon	A8	1-3 does not show any of the native and riparian vegetation areas from Figure 1-2, many of which are known to be GDEs, as identified by the DWR's Natural Communities Commonly Associated with Groundwater dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) and the Nature Conservancy's GDE Pulse tool (https://gde.codefornature.org/#/home).	Figures have been update to properly reflect areas of the District that are groundwter dependent. No requirement to overlay habitats on that map.
Audobon	A9	P 8. L. Impacts on Groundwater Dependent Ecosystems. Within SWSD there are significant and important habitat areas supported by supplemental water and these managed wetlands heavily rely on pumped groundwater or applied surface water.	Our statement currently is: "There is the potential for Groundwater Dependent Ecosystems (GDE) in the western portion of the District and along Poso Creek. However, the presence of GDE's has not been verified. Section 2.3 of this GSP provides an overview of the available information regarding GDEs in the District. GDEs are not the same as managed wetlands.

Commentor	Ref #	Comment	Response
Audobon	A10	P 9. 1.5.2 Beneficial Uses and Users. DWR Bulletin 118 identifies beneficial uses and users that include the environment. Under the list for "Users of groundwater", "landowners" should include managed habitat and duck clubs, especially since "duck clubs" are identified under section 5.2.3.1 as a unique "Landowner Class" and an example water budget was created for duck clubs in see Figure 5.3.	The change has been made to the text: As required by Section 354.10(a) of the GSP emergency regulations, beneficial use and users in the District's portion of the Subbasin have been identified. The beneficial uses of groundwater in the Plan Area, consistent with the uses identified in DWR Bulletin 118, are: •Agricultural •Municipal and Industrial •Domestic •Environmental Users of groundwater have been identified as landowners, agricultural operations (including farms, dairies, and food processors), rural residents, managed wet and unincorporated
Audobon	A11	P 45. 2.2.7.2 Direct Recharge. It should be noted that percolation not only occurs from "applied water that passes below the crop roots zones, and unlined canals," but may also occur on managed wetlands within the SWSD service area. Managing wetlands to be multiple benefit may provide an opportunity to increase acreage of managed recharge in this region. Direct recharge on managed wetlands should be treated consistent with direct recharge on irrigated agricultural lands.	Noted change was made to the text.
Audobon	A12	P 46. 2.2.9 Sources and Point Delivery for Imported Water Supplies. It should be noted that the Kern National Wildlife Refuge receives water from the State Water Project through agreements with the Bureau of Reclamation, the State, and via conveyance agreements with Buena Vista Water Storage District. As pointed out in 2.2.8 Surface Water Bodies, the Kern National Wildlife Refuge relies on these deliveries of surface water, though these water supplies are becoming less reliable. These surface deliveries have benefited the SWSD management area by providing the use of surface water in-lieu of local groundwater resources, and creating a source for groundwater recharge from the delivered surface water.	Acknowledge that this supply was not accounted for, but neither was the demand or conveyance losses for delivery of Refuge water.
Audobon	A13	P 58. Table 2-4. Land Uses Within SWSD. Duck clubs and overall managed habitat should be a separate land use in this table. It is not clear where the acres for Kern National Wildlife Refuge or the various private duck clubs are represented in this table. This land use, managed habitat, has an applied water demand similar to agriculture and should be included in current and projected water budgets.	Table was removed from text. Numbers inconsistent with other figures
Audobon	A14	P 77. 2.3.7 Interconnected Surface Water Systems. In this section it states that "In order to sustain the managed wetlands in the study area, imported surface water is needed," suggesting that these habitats rely solely on surface water. This is correct for some managed wetlands, such as those found at Kern National Wildlife Refuge. Most private wetlands, operated as duck hunting clubs, pump groundwater to support managed habitat and may access surface water at times. Furthermore, in the proceeding section, 2.3.8 Potential Groundwater Dependent Ecosystems, it describes areas with GDEs being associated with "managed wetlands and riparian areas" that are supported by a "combination of groundwater and imported surface water." These two sections contradict one another and consistency is needed.	Text as been changed as follows: Interconnected surface water systems are surface waters that are hydraulically connected by a continuous saturated zone to an underlying aquifer (DWR, 201 There are no known natural interconnected surface water systems in the study area. ~~The majority of surface water bodies in the study area, such as Jerry Slou Kern River Channel, receive managed surface water deliveries. In order to sustain the managed wetlands in the Semitropic area, imported surface water or pu groundwater is used. For example, the Kern National Wildlife Refuge (KNWR) is now sustained by imported surface water wheeled from the California Aqueduc conveyed by the Goose Lake Canal (USFS, 2005) or from groundwater pumping at the site. Any interconnected surface water systems in the Semitropic area a sustained by managed water deliveries of either Kern River water, imported surface water or local groundwater pumping.~~ The Poso Creek channel is the only channel that experiences natural recharge from the surrounding highlands. However, Poso Creek is ephemeral and only flo during limited wet periods.
Audobon	A15	P 82. Land Use Data. Though Kern National Wildlife Refuge relies solely on surface water, most managed wetlands in SWSD depend solely on groundwater. Some private wetlands do purchase surface water in select years. This distinction should be highlighted in this section.	The section reads as follows. Yellow highlight is suggested addition Land use data surrounding NCCAG vegetation and wetlands indicate actively managed wetlands as well as agricultural land. The agricultural lands may emplo groundwater pumping in dry years; however, it is unknown if pumping occurs in the upper zone. In general, the actively managed wetlands are reliant on a combination of surface water imports and ~~are therefore not dependent solely on~~ pumped groundwater. For example, the KNWR (Figures 2-48 and 2-49), is sustained by surface water imports.
Audobon	A16	P 82-83. 2.3.8.6 Shallow Groundwater and Land Use Discussion (third paragraph). The identification of sources that contribute to shallow groundwater should be identified. This information will be important to understanding how to maintain critical habitat areas and should be prioritized for monitoring efforts.	We state that "It is unknown if or from which aquifer zone groundwater pumping occurs for adjacent agricultural land."
Audobon	A17	P 93-94. 2.6 Management Areas within SWSD. Duck clubs and the Kern National Wildlife Refuge actively apply water to meet consumptive use needs so therefore should not be considered "undeveloped." These lands should be recognized as developed lands within their respective management areas.	Change to: "Management area 3 includes managed wetlands (private duck clubs), the Kern National Wildlife Refuge, undeveloped native lands." Not sure I see a reason to change the statement.
Audobon	A18	P 97. Increased Direct Recharge Capability. Managed wetlands, including Kern National Wildlife Refuge and duck clubs, can potentially provide a unique opportunity for in-lieu recharge while providing waterbird habitat. It is recommended that this be further evaluated for increasing recharge capacity within the service area.	Noted for future consideration
Audobon	A19	P 98. Implemented Third-Party Water Banking. The imported water for the Kern National Wildlife Refuge could be treated similarly to other lands in this section - as a source of continuous surface delivery in-lieu of groundwater use, and a source of recharge with delivery of the surface water through Goose Lake canal.	The refuge is not currently a third party banker. Not appropriate
Audobon	A20	P 154. Table 4-1. Potential Impacts of Overdraft with Corresponding Monitoring. There should be a unique row for managed habitats, as they will have the same impacts as "Irrigated Agriculture." Managed habitats pump groundwater (and when available rely on SWSD surface water) to meet irrigation and habitat needs.	Table 4-1 - In the User Group identification add: Irrigated Agriculture (including managed habitats)
Audobon	A21	P 156. 4.2.2.6 Consumptive Use. We understand that the District is not confident in the consumptive use estimates for managed habitat areas and would like to work together to improve this data set.	Noted - will include a management action for refinement of ET on managed wetlands
Audobon	A22	P 157. 4.3.3 Rationale for Design (paragraph after bullet points). To improve the understanding of how groundwater pumping can impact managed habitat, monitoring well locations may be available within duck clubs or state and federally managed habitats.	Will consider in future updates to monitoring network. No response in document suggested.
Audobon	A23	P 180. Table 5.1. Rows 4 & 7. As specific projects become further developed, managed habitat areas may offer ideal opportunities for recharge or temporary storage of water during high flow events. Projects that utilize habitat lands may lessen negative impacts to cultivated lands from flooding or intentional recharge. We recommend that the GSA investigate opportunities that can allow habitat areas to function both for habitat and to provide recharge or temporary storage. Additionally, knowing that water for recharge likely comes in large quantities over short timeframes, the existing configurations of managed habitat areas can make for useful retention areas, without risking the flooding on irrigated crops such as trees and vines. Expanding priorities that have added benefit, such as habitat and wildlife value, can also lead to non-target benefits (e.g. water filtration or recreation opportunities) and be accomplished through simple actions. This may open the door to additional funding sources that otherwise would not have been available if these benefits were not part of a project. Audubon is interested in helping the GSA investigate these potential opportunities to develop multi-benefit projects.	This concept is captured in the Tulare Lake project and the Poso Creek MAR project. Comment will be considered as projects are developed. No change to te table as suggested.
Audobon	A24	P 185. 5.2.1 Existing Projects and Management Actions (second bullet point). How will managed habitat lands fit into this program and fee structure given the uncertainties of managed habitat consumptive use? (See above comment related to consumptive use). Clarification here is recommended.	To be determined. We are awaiting additional data from Audubon re consumptive use.

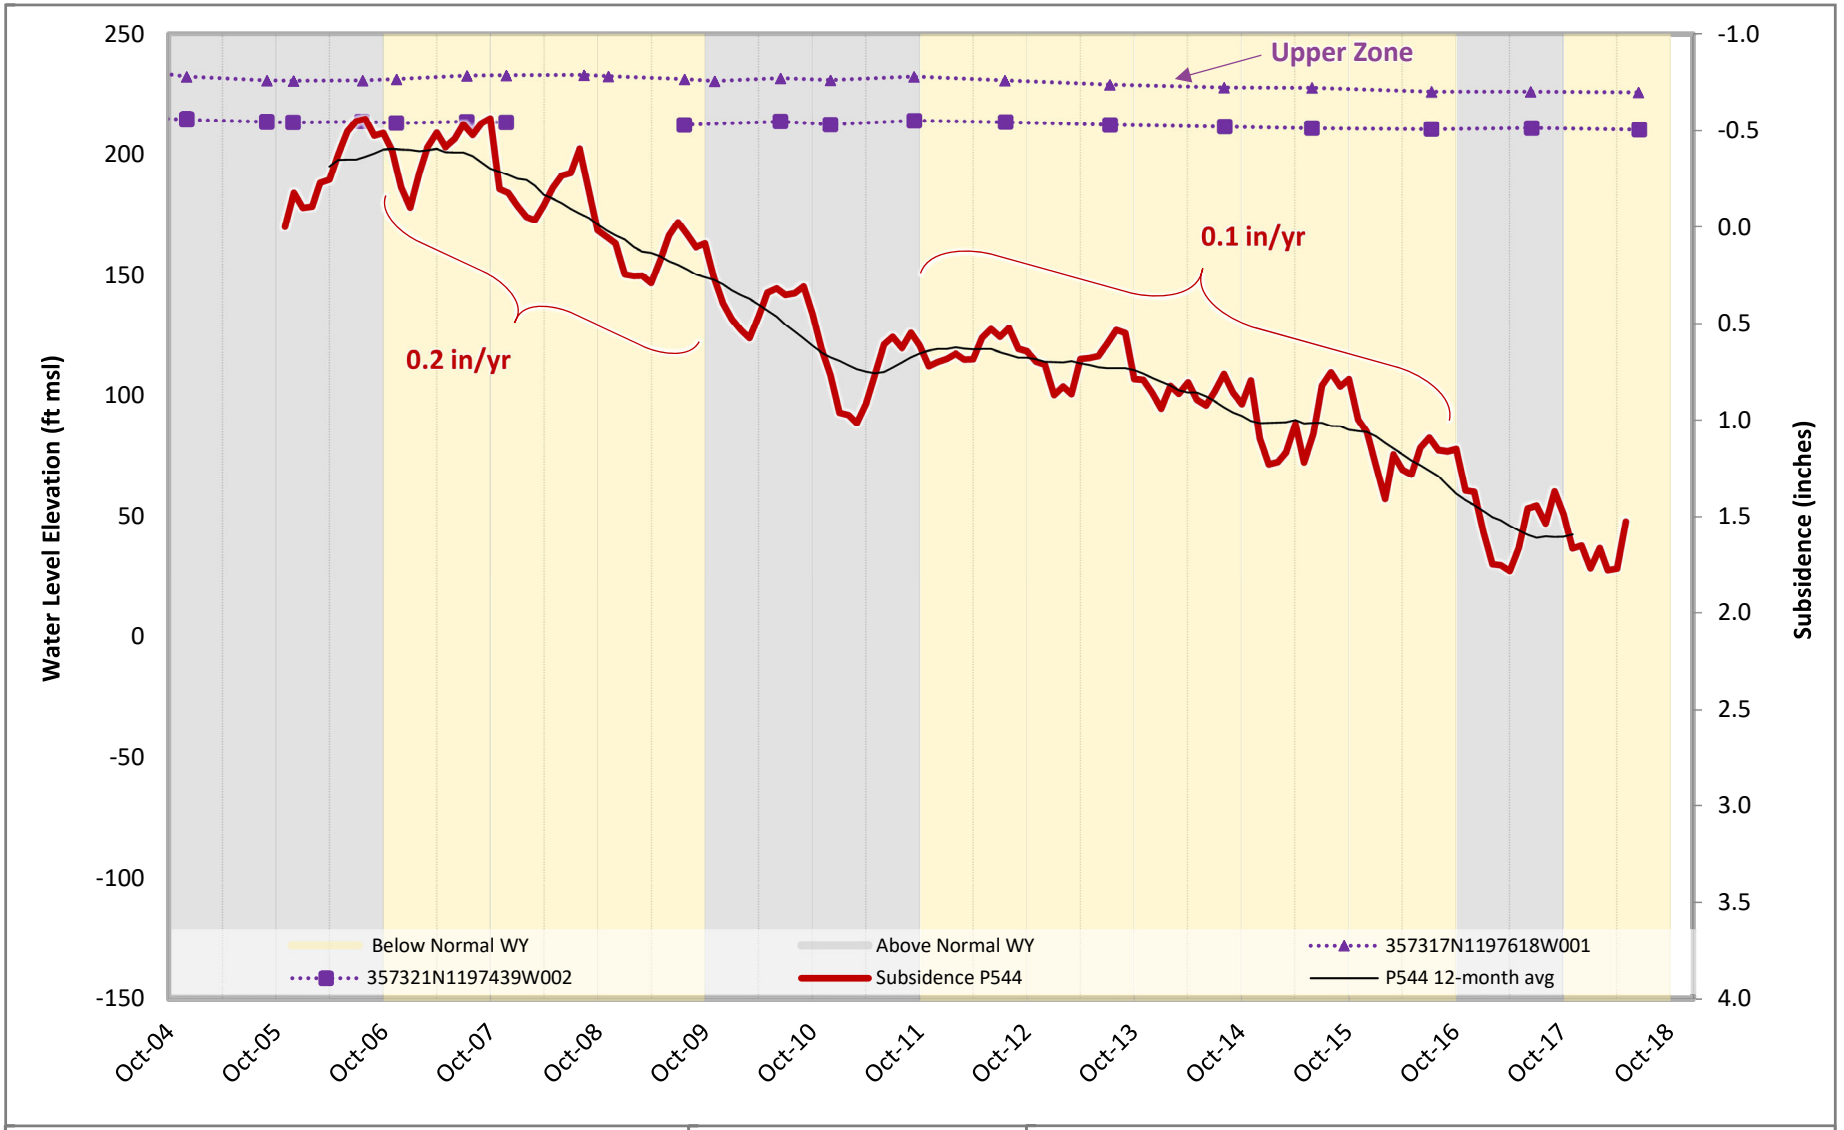
Commentor	Ref #	Comment	Response
Audobon	A25	P 186-187. 5.2.2 Future Projects and Management Actions (bullet #6 and 8). For the management action that "will be developed in a manner which allows for the creation of a 'market' for the transfer of water among District landowners," will this be limited to transfer of Native Yield, or will it also include Incremental Pumping Allowances? Also, please clarify which water supplies this market is intended for. Additionally, what does the management action "equal access to participate proportionate to investment" mean? Managed habitats are a significant benefit to the public resource, are managed to provide critical habitat to migratory birds and other wildlife, and create recreational and economic benefits (i.e. hunting and wildlife viewing) to the community. Please clarify what is the "access" level that may vary by investment?	Water markets will be considered as future management actions.
Audobon	A26	P 189. Incremental Pumping Allowance (IPA). This section states, "The IPA will be established by the District and set such that on average no individual landowner will be short of a water supply at the initiation of the SGMA implementation period." The current estimate of Incremental Pumping Allowance for "duck clubs" is likely insufficient and will make duck clubs "short" at the initiation of the SGMA implementation period. This needs to be addressed to ensure that the duck clubs can continue to provide critical habitat to migratory birds and other wildlife during the transition period of GSP implementation.	Changing IPA to Temprorary Consumptive Use Allowance (TCA)
Audobon	A27	P 192. Special GPSC (Duck Clubs). Details and clarification of how consumptive use amounts were determined for managed habitat is needed. Has the District obtained any data from duck club operators regarding water use per acre? The Incremental Pumping Allowance should be increased to meet the consumptive use needs, similar to the standard GPSC designated lands. Furthermore, for Kern National Wildlife Refuge, the 'banked supplies' should recognize the seepage losses in the Goose Lake Canal that occur from the imported surface water, that is not imported by the SWSD. This is an independent source of surface water imported by the U.S. Bureau of Reclamation and conveyed per agreements with Buena Vista Water Storage District to lands that include a significant portion of Kern National Wildlife Refuge lands within the District. Audubon is interested in working with SWSD to improve information on habitat consumptive use in the management area.	Currently under review.
Dept of Fish and Wildlife	DFW1	The Department recommends continued data collection to reduce uncertainty around shallow groundwater, and concurrently, around the presence of GDEs. Until such time as a GOE can be verified through field work or increased resolution of groundwater mapping reliant on hydrologically robust baselines, the Department recommends including all potential GDEs in the MAP as beneficial users of groundwater	Will include a management action for identification and assesement of GDE and managed habitat water uses and needs. We do identify this as a data gap.
Dept of Fish and Wildlife	DFW2	i. Revise the sustainable management criteria and accompanying narrative by accounting for undesirable results for environmental beneficial users of groundwater. Clarify how species and habitat groundwater needs were considered in the identification of sustainable management criteria. ii. Revise sustainable management criteria to reflect a 'Critically Overdrafted' subbasin designation by seeking to improve current groundwater conditions rather than allowing for continued aquifer depletions over the next two decades.	i) no distinction on landowner use of water ii) NO - Sustainable management critieria developed using concensus position as to what constitutes a significant and undesireable result or worse case scena (not best case)
Dept of Fish and Wildlife	DFW3	The Department recommends that the GSP clarify locations of existing shallow groundwater monitoring wells used to create the shallow groundwater elevation contour map provided within the MAP (Figure 2-27). Additionally, the figure should show overlap potential GDEs with shallow monitoring well locations to vet vegetation groundwater reliance. This figure and associated information would clarify monitoring data gaps and serve as an assessment tool when verifying GDEs.	The District has added a management action to evaluate the presense of GDEs, in order to determine the appropriate level of monitoring required.
Dept of Fish and Wildlife	DFW4	Many of the Duck Clubs in the MAP area are currently supported by the Department's California Waterfowl Habitat Program to ensure the adequate maintenance of habitat critical to wetland-dependent species. Implementation of pumping allowances identified in Figure 5-3 would eliminate all wildlife value associated with these wetlands. To continue to share in the support of this valuable public benefit, the Department recommends that the Semitropic Water Storage District Groundwater Sustainability Agency create additional pumping allowances and/or supplemental water supply opportunities for lands that support wetland habitat. The Department also requests confirmation that all Department-owned lands within Semitropic Water Storage District jurisdiction (see Comment #1) will be granted an equitable native groundwater yield allocation under new Landowner Water Budget management actions (starting page 187)	Semitropic will support the Department in securing additional diversions from the Delta for environmental benefits in Semitropic, with no impacts to Semtrop SWP allocations. All allocations of native groundwater yield will be undertaken in accordance with SGMA, including but not limited to the requirement that v rights not be altered.
Bob Bostick Duck Club	BB1	I support Rancho Visalia's proposal to allow private wetland owners in the Special GPSC to extract 3.5 ac/ft/yr for the acres of land paying the Special GPSC. This would amount to approximately 10,000 ac/ft for the all of the private wetlands in the district and only 0.08 percent of the targeted reduction in groundwater pumping required by SGMA.	The Special GPSC lands have been give a TCA of 4.2 ac-ft per acre.
Bob Bostick Duck Club	BB2	In cooperation with NGOs like CWA and DU, WCB, CA DFW, US Fish and Wildlife, and TBWA develop a written plan and agree to execute the plan to connect all private wetlands to the Pintail Slough water delivery system.	Noted - will be considerd in development of future projects and management actions
Bob Bostick Duck Club	BB3	Agree to support efforts by the private wetland owners to obtain Environmental water to be used only by the wetlands.	Noted - will be considerd in development of future projects and management actions
Clean Water Action	CWA1	Disadvantaged communities are present in the District but are not identified. An ongoing study "Tulare Kern Funding Area Disadvantaged Community Involvement Program" is mentioned but not referenced, nor is there a description of what information is being developed and how it would be used in this plan, particularly since the information won't be available until after the plan is prepared. Instead the plan should use the DWR DAC mapping tool at https://gis.water.ca.gov/app/dacs/ , and identify the program listed above as a refinement of that information that can be used to improve implementation	Noted
Clean Water Action	CWA2	The CA MCLs are cited, however the OEHHA PHG for hexavalent chromium should be used since a standard is unavailable. No other criteria from the RWQCB Plan or Transportation Plan appear to be used.	Noted
Clean Water Action	CWA3	The beneficial uses, including environmental, are listed but no specific groups are mentioned. Kern National Wildlife Refuge (NWR) and Duck Clubs (i.e. private managed wetlands) are identified later in the document, but should be specifically listed as beneficial users of groundwater as Kern NWR uses groundwater for domestic purposes and Duck Clubs use groundwater to provision habitat. There is no mention of involvement in the GSP development by Kern NWR or the Duck Clubs, which is especially important given that this GSP contains one of the largest extents of these environmental beneficial users of all the critical basin GSPs. The Community Portal on the District Website was listed in the GSP as a means of engaging in the development of the GSP, but a more thorough description should be given of actions to engage environmental beneficial users.	Representative from the Kern NWR and private Duck Clubs were notified of all outreach and stakeholder opportunities. Representatives were present at public workshops held District and a GSA Board meetings. Comments were received and responded.

Commentor	Ref #	Comment	Response
Clean Water Action	CWA4	The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses and users of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. The GSP should explicitly identify any environmental uses and users of groundwater in the plan area, and take particular note of the species with protected status. The following are resources that can be used: ● Natural Communities Commonly Associated with Groundwater dataset (NC Dataset): https://gis.water.ca.gov/app/NCDatasetViewer/ ● The list of freshwater species located in the Kern County Subbasin can be found here: https://groundwaterresourcehub.org/sgma-tools/environmental-surface-water-beneficiaries/ ● The California Department of Fish and Wildlife's California Natural Diversity Database (CNDDB): https://www.wildlife.ca.gov/Data/CNDDB ● Land Use Datasets on the Department of Water Resources' SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer	Noted - will consider in proposed management action to evaluate the presense of GDEs
Clean Water Action	CWA5	The GSP does not include a copy of the SCEP. An SCEP should be included in the GSP as an appendix or attachment.	The District has engaged in stakeholder engagement through out the development of the GSP, as documented in the GSP.
Clean Water Action	CWA6	The GSP should clearly identify how DAC beneficial users were engaged in the GSP planning process, by providing detailed information on the number of meetings held, general levels of attendance, what feedback was provided by community members, etc.	GSP identifies all public meetings. District will include attendance sheets from all meeting in Plan updates.
Clean Water Action	CWA7	The draft GSP states that stakeholders' input was considered during decision making processes, however, it does not describe how the input was incorporated. The GSP should provide detailed description about stakeholder input and responses and how are those were addressed by the decisions.	Noted - comments from all stakeholders where considered during the development process.
Clean Water Action	CWA8	Detailed information regarding the location and depths of domestic wells is currently lacking in the GSP. Domestic well location and construction information are essential for evaluating impacts of proposed MOs/MTs on domestic wells. The GSP should provide the locations and depths of all domestic and public supply wells in the GSA area using the best available information, and present this information on maps along with the proposed SGMA-compliance monitoring network so that the public can evaluate how well the monitoring network addresses these key beneficial users. If no better source is available, DWR has made well construction records available through its Well Completion Report Map application website: https://www.arcgis.com/apps/webappviewer/index.html?id=181078580a214c0986e2da28f8623b37	Noted - will consider adding additonal detail on well impact analysis.
Clean Water Action	CWA9	The GSP should provide a more thorough assessment of GDEs, per the discussion provided in Question 2a above. The GSP should provide depth to groundwater contour maps and note the following best practices for doing so: ● Are the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons to reflect local conditions relevant to ecosystems? ● Are the wells used for interpolating depth to groundwater screened within the surficial unconfined aquifer and capable of measuring the true water table? ● Is depth to groundwater contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to contour depth to groundwater.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA10	The GSP should also provide maps of the representative monitoring network overlaid with location of DACs, GDEs, and any other sensitive beneficial users. Such maps will allow the reader to evaluate the adequacy of the network to monitor conditions near these beneficial users, and whether or not the GSP is compliant with 23 CCR § 354.34.(b)(2)	Noted
Clean Water Action	CWA11	The GSP should include a discussion regarding the nature and characteristics of the identified GDEs and potential GDEs, and should provide information on the current and historical groundwater conditions near the GDEs and corresponding GDE ecological conditions. The GSP should include an ecological inventory for all potential GDEs that includes vegetation or habitat types and rank the GDEs as having a high, moderate or low value.	Information is provided in the GSP
Clean Water Action	CWA12	The GSP should identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat have been identified in or near any of theGDEs. Note that some organisms rely on uplands and wetlands during different stages of their lifecycle. Resources for this include the list of freshwater species located in the Subbasin that can be found at https://groundwaterresourcehub.org/sgma-tools/environmental-surface-water-beneficiaries/ , the Critical Species Lookbook, and CDFW's CNDDB database.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA13	The GSP should provide data or analysis to document the statement of the absence of interconnected surface water systems within the GSA area. The GSP should also identify data gaps (e.g., lack of shallow or nested/clustered monitoring wells or stream gauges) and either reconcile them or provide a plan to address them as needed to improve identification of ISWs prior to disregarding them in the GSP.	Groundwater elevation data is presented in the GSP
Clean Water Action	CWA14	The GSP uses a superficial manner of addressing water budgets. Water supplies for the current water budget are presented and the water demand is compared as a total. The available water supply from the State Water Project (SWP) is based on DWR's 2017 Delivery Capacity Report. The quantities related to the SWP are adjusted for 2030.	Noted
Clean Water Action	CWA15	The water demand based on land uses and cropping was not adjusted for 2030. The GSP deferred to the analysis in the KGA Umbrella GSP for 2070 and no summary is provided.	
Clean Water Action	CWA16	The GSP should provide a breakdown of ET for all land-cover types, including managed wetlands, and native and riparian vegetation (such as wetlands, riparian vegetation, phreatophytes and other communities). The GSP should identify any data gaps and outline the actions needed to address them and the schedule for their implementation.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA17	The GSP should design management areas and the associated monitoring network to adequately assess and protect against impacts to all beneficial users, including DACs. It is recommended that the GSP discuss what, if any, differential impacts would be anticipated as a result of the separate management of these areas.	Noted
Clean Water Action	CWA18	The GSP should describe the well network to provide methodologies, data and other information to support the investigation and monitoring of the shallow zone, GDEs and ISWs. This modification should include 1) locating new wells that are appropriately screened to detect connectivity of GDEs and ISWs with the shallow zone, particularly in the northwest management area, and 2) identifying or installing stream gages, if possible, in areas where there is potential for ISWs and GDEs. Please expand on the discussion of how the new well and stream data will be used to improve ISW mapping and inform an adequate analysis, and how the data will be used to verify possible GDEs. The GSP should address data gaps (shallow monitoring wells, stream gages, and nested/clustered wells) to improve ISW mapping in future GSPs.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA19	Based on the presented information, domestic well uses are considered under URs and for the development of water level MOs and MTs, but DAC members are not explicitly considered. More detail and specifics regarding DAC members, including those that rely on smaller community drinking water systems, not only domestic wells, is necessary to demonstrate that these beneficial users were adequately considered.	The District has engaged in stakeholder engagement through out the development of the GSP, as documented in the GSP.
Clean Water Action	CWA20	The information about impacts on domestic wells presented in Appendix D is presented as an average depth. The draft GSP should include more detailed information about the potential impacts on sensitive drinking water users, such as 1) where the likely impacted wells are located, 2) what communities are most affected (including DACs), 3) an estimate of the size of the population that relies on these domestic wells, or 4) if the creation of a new or expanded community water system could address some or all of the population affected by the loss of domestic wells.	Noted

Commentor	Ref #	Comment	Response
Clean Water Action	CWA21	Undesirable results are not clearly identified in the plan. Instead an "undesirable results watch area" is created when 51% of identified representative monitoring sites exceed minimum threshold criteria and when multiple such watch areas are identified. However, there is no discussion of how many watch areas would trigger undesirable results, or whether those watch areas would be for the same sustainable management criteria or a mix. This seems to be contrary to the DWR definition of a minimum threshold in CCR § 351(t), which identifies a minimum threshold as "a numeric value for each sustainability indicator used to define undesirable results."	See section 3.2.2 of District GSP and KGA GSP
Clean Water Action	CWA22	The GSP states (page 158): "A minimum threshold for degraded water quality has not been set because historical data used to evaluate groundwater conditions does not indicate lowered water levels, at least at levels observed to date, resulting in degraded water quality. Regardless, groundwater sampling will continue: monitoring sites and parameters were strategically selected to inform on future degradation." The GSP should present a clear and detailed plan for evaluating and monitoring water quality parameters. Specifically, any plan to recharge groundwater must include groundwater quality monitoring, as recharge even with high quality water can mobilize contaminants.	Noted
Clean Water Action	CWA23	The GSP should include GDEs when developing MOs and MTs and whether the MOs and interim milestones will help achieve the sustainability goal as it pertains to environmental beneficial users. The water quality MOs does not consider the water quality needs of GDEs. The GSP should include impacts from degraded water quality on the plant and wildlife communities within GDEs. The GSP should include all potential MOs and MTs impacts on ISWs and GDEs in the analysis.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA24	The GSP should also discuss any potential undesirable results from degradation of water quality that may impact GDEs and freshwater species in the area.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA25	For each potential GDE unit with supporting hydrological datasets, the GSP should include: ● Plot and provide hydrological datasets for each GDE. ● Define the baseline period in the hydrologic data. ● Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater. ● Explore cause-and-effect relationships between groundwater changes and GDEs.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA26	The GSP should include 1) an assessment of the nature of potential undesirable results to ISWs and GDEs; 2) recognition of the existence of potential ISWs and GDEs, unless adequate data can be provided to dismiss them, 3) a statement that the aquifers will be managed such that there will be no depletion of ISWs that results in a significant and unreasonable impact to GDEs; and 4) recognition of any data gaps and specific steps to verify the presence or absence of ISWs and GDEs with monitoring wells screened at the appropriate depths.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA27	We recommend that the sustainability goal explicitly include drinking water and nature because they are important beneficial uses of groundwater.	Noted
Clean Water Action	CWA28	The likely benefits and impacts to DAC members by the proposed projects and management actions are not clearly identified in the GSP. A discussion should be added for each project or management action to clearly identify the benefits to DAC drinking water users and potential impacts to the water supply. For all potential impacts, the project/management action should include a clear plan to monitor for, prevent, and/or mitigate against such impacts.	Noted
Clean Water Action	CWA29	For the projects already identified, describe and assess how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue. If ISWs will not be adequately protected by those listed, include and describe additional management actions and projects targeted for protecting ISWs.	Noted - District is proposing a management action to evaluate the presense of GDEs and appropropriate monitoring requirements, if needed.
Clean Water Action	CWA30	For projects that construct recharge ponds, the GSP should consider identifying if there is habitat value incorporated into the design and how the recharge ponds can be managed as multiple-benefit projects to benefit environmental users. The GSP should include environmental benefits and multiple benefits as criteria for assessing project priorities. For examples of case studies on how to incorporate environmental benefits into groundwater projects, visit TNC's website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/	Noted
Pat MarchBanks	PM1	In conclusion, I encourage the District to Amend the draft SGMA policy. I request that you be more sensitive and considerate of the future water needs and embrace the value of these important wetlands that are within the District and take proper action to insure their survival.	Noted. Adjusts have been make to the water budget for duck clubs and is reflected in the revised GSP.
Valley Water	VW1	Long-term and sustainable management of California's groundwater basins is important, and Valley Water will encourage the Semitropic GSA's to make efforts towards curbing historic overdraft and other undesirable groundwater impacts in its portion of Kern County. In this regard, Valley Water also recognizes that groundwater bank 'leave behind' (i.e., 10-percent of all stored water provided to Semitropic for their use in local groundwater management), provided by Valley Water and the other banking partners, has proven a positive contribution to local groundwater levels. It is important to Valley Water that existing Semitropic Bank terms and conditions are protected as groundwater managers move forward with the requirements of SGMA. Valley Water will continue to monitor GSP development throughout the DWR review process, and will continue to work with Semitropic regarding annual banking operations. Additionally, as the Semitropic GSA moves forward with SGMA requirements and finalizing the GSP document, Valley Water would appreciate insight or notice from Semitropic on how contemplated actions could directly or indirectly impact the Semitropic Bank	Noted
Shafter-Wasco Irrigation District 7th Standard Annexation Management Area Plan Received Comments			
Rosedale – Rio Bravo Water Storage District (RRBWSD)		Our initial review of the Shafter Wasco & Annex GSP's did not find any statement or commitment to address the respective deficits using a proportional glide path. With that in mind, could you please identify what glide path your respective management areas will be implementing? Specifically, what level of projects and/or demand reduction strategies will be implemented to address any deficit within each of the five (5) year milestones identified within the DWR Guidance Document?	A response was provided to RRBWSD to clarify the location of the requested information in the Annex Area MA Plan (Executive Summary, Section 16, and Table PMA-2).
North of the River Municipal Water District (NORMWD)		We note that throughout the 7th Std Annex Plan, it references the waste water from the NORSD WWTP. In an effort to be concise and frame the comments below, we will not list every section or table that references the waste water; however, we request that you consider our comments directed at every such reference within the 7th Std Annex Plan upon your review of this letter and the plan itself and edit your plan to reflect that NORMWD is the owner of such groundwater and such waste water is being currently utilized via contracts for limited agricultural uses.	The information presented in the SWID Annex Area Management Area (MA) Plan is required by the Sustainable Groundwater Management Act (SGMA) and does not represent groundwater allocation or determination of water rights or claims. The water budget information presented in Section 8 contains both a physical accounting of water flows in a of the Management Area consistent with 23 CCR § 354.18 of the GSP regulations and current Waste Discharge Requirements, and a checkbook methodology consistent with th approach developed by the Kern Groundwater Authority GSA in coordination with other basin GSAs. While water rights are not addressed in the MA Plan, we welcome further discussion of water rights from any Basin landowner as part of SGMA implementation.
Southern San Joaquin Municipal Utility District Received Comments			
Farmland Reserve		"Though not specifically addressed, we are concerned that overlying right to extract groundwater will be allocated among all District landowners based on gross acreage…it ignores accepted principles of law intended to more fairly allocate this right among those who have historically used groundwater for irrigation purposes -- and made substantial investments based on that use."	We have discussed adding language to the Water Budget section of the plan to address the fact that there is currently no in-district allocation of water to the landowners. The language in the Projects & Mgmt Actions section, dealing with in-district allocation as a mgmt action has been revised to address this, as well.
Farmland Reserve		"These numbers should not be seen as establishing a precedent or used to establish some legal right. Therefore, a statement emphasizing the above points should be made."	The discussion on native yield in the Water Budget section of the plan addresses this.
Farmland Reserve		"The Chapter could address the possibility of a market for the exchange or transfer of groundwater credits."	At this time, such a discussion is premature. There is no framework within the districts or the basin at large to allow for the exchange or transfer of groundwater credits. We ca reasonably address this in the plans for 2020 submittal.
Wonderful Orchards		"The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource."	The districts have identifed as a management action the coordinated effort to further refine water budget components in the Kern County Subbasin Model. The Model and wat budget components will continue to be refined in coordination with the KGA and other GSAs in the basin.

Commentor	Ref #	Comment	Response
Wonderful Orchards		"In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield. Currently, the GSP references native yield in terms of acre-feet per gross acre for water budget purposes. Appendix J of the GSP indicates the subbasin native yield is approximately 0.144 acre-feet per acre. It is our understanding that subsequent to the release of the draft GSP, all MAPs and other GSPs in the basin agreed to utilize the same number for their water budgets. If referencing native yield this way is necessary, the GSP should clarify that it is for initial water budget purposes ONLY, is non-precedent setting, and is not a determination of individual landowner allocations or groundwater rights. Alternatively, in the 2020 plans subbasin native yield could be described as a total volume of water and not associated with a given gross or net area."	The discussion on native yield in the Water Budget section of the plan addresses this already. Further emphasis on the "planning budget" role of the Native Yield estimate has b added to the final draft of the plan. In terms of native yield allocation to the parcel/landowner level, there is no framework currently in place to do so. The development the pol and framework necessary to implement such an allocation cannot be completed in time for the 2020 plan submittal.
Wonderful Orchards		"Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next."	At this time, such a discussion is premature. There is no framework within the districts or the basin at large to allow for the exchange or transfer of groundwater credits. We ca reasonably address this in the plans for 2020 submittal.
Wonderful Orchards		"Wonderful understands that there are instances where it may be necessary to restrict pumping in order to achieve basin-wide sustainability. If this becomes a necessity, the GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity. As with native yield allocations, initial pumping allowances and ramp down schedules should be coordinated across the entire basin so that similarly situated pumpers in the basin are treated equitably regardless of their respective MA (some MAPs include a ramp down schedule for groundwater-only lands and others do not; this is a significant difference and should be reconciled)."	As described in the Management Actions subsection of the Management Area Plan, policies for instituting pumping restrictions have not been developed for the 2020 plan subr This has been identifed as a potential management action, should the districts or the basin in general find that it cannot maintain it path to sustainability through the projects an management actions to be implemented.
Wonderful Orchards		"GSAs must develop clear policies and conditions that protect existing investment in groundwater banking and banked inventory, and without interference with existing rules and regulations. GSAs must also find a way to incentivize additional investment, such as on-farm recharge, and allowing flexibility for recharged or banked water to be freely transferrable (subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results). Where possible, GSPs should also identify management areas that may benefit from additional recharge and banking. We also recommend that GSAs work to develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.)."	At this time, the framework to offer such incentives does not exist and would require the districts' boards to develop & adopt policy to put it in place. In the time required to pr the 2020 submittal of the plan, we cannot develop the structure and policy required to implement this. However, this is discussed in the Projects & Mgmt Actions section of the and will be considered for implementation after the 2020 plan submittal, when the districts have an opportunity to develop the policy and framework necessary for such progr
Wonderful Orchards		"GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	A coordinated DMS is already being developed. However, that effort is currently focused at the district/MA level due to the precision of the data being used. Parcel-level alloca not at this time being done in the subbasin. It is premature to consider a basin-wide water market, as the data available does not allow for that level of allocation to be done. Fo consideration in the 2020 plan submittal, we do not have adequate time or resources for the development of such a framework.
Westchester Group Investment Mgmt		The GSP references native yield in terms of acre-feet per gross acre for water budget purposes. If referencing it this way is necessary, the GSP should clarify that these calculations are for initial water budget purposes ONLY, are non-precedent setting, and not a determination of individual landowner allocations or groundwater rights. Alternatively, native yield could be described only as a total volume of water and not associated with a given gross or net area. In the event that allocations are to be made at a landowner or property level, WGIM encourages the KGA and other GSAs in the basin to initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations that are coordinated across the basin.	The discussion on native yield in the Water Budget section of the plan addresses this already. More language can be added to emphasize the "planning budget" role of the Nativ estimate.
Westchester Group Investment Mgmt		GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked water inventory, and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	At this time, the framework to offer such incentives does not exist and would require the districts' boards to develop & adopt policy to put it in place. In the time required to pr the 2020 submittal of the plan, we cannot develop the structure and policy required to implement this. However, this is discussed in the Projects & Mgmt Actions section of the and will be considered for implementation after the 2020 plan submittal.
Westchester Group Investment Mgmt		GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater. The DMS should also include, or be capable of interfacing with, a groundwater market platform that allows for individual users to conduct transactions. Markets will be most effective if there is confidence in the accuracy of the measurements taken, consistency in the data sources relied upon, and flexibility to allow for transactions across the basin. For instance, GSAs using remote sensing to calculate crop evapotranspiration ("ET") as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower provided information to be included into the ET calculation and calibration. Additionally, GSAs should establish criteria and procedures to address any apparent inaccuracies in the ET calculations (e.g., if calculated ET is greater than applied water and precipitation).	A coordinated DMS is already being developed. However, that effort is currently focused at the district/MA level due to the precision of the data being used. Parcel-level alloca not at this time being done in the subbasin. It is premature to consider a basin-wide water market, as the data available does not allow for that level of allocation to be done. Fo consideration in the 2020 plan submittal, we do not have adequate time or resources for the development of such a framework.
Westchester Group Investment Mgmt		"WGIM supports use of efficient and accurate systems to determine groundwater use. GSAs using remote sensing to calculate crop ET as a measurement of consumptive use of groundwater should develop methodologies and quality assurance elements to allow for grower-provided information to be included into the ET calculation and calibration. These methodologies should be developed in consultation with the vendor providing ET data to ensure it is applicable and useful in creating the best available data set. Additionally, GSAs and/or MAs should establish criteria and procedures to address apparent inaccuracies in the ET calculations. An obvious use of the procedure would be in instances where the grower can demonstrate that applied water, plus precipitation, is less than the calculated ET. In these instances, and subject to any requirements established by the GSA, the grower's use of groundwater should be reduced to the applied water total as the ET calculation should not be greater than applied water."	This is already included in the Projects and Management Actions section and is part of the larger action of refining data for the calculation of Water Budget components in futur updates.
Leadership Council		"The Draft GSP is incomplete and must include additional information for the public to evaluate the GSP. The Draft GSP omits critical data regarding the consideration of drinking water impacts on disadvantaged communities and protected groups, sustainable management criteria that consider all beneficial users, and projects and management actions that address significant and unreasonable impacts to beneficial users."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with the statement, as the information that Leadership Council claims is missir the GSP is actually included in the management area plans, as appropriate to each respective management area.
Leadership Council		"The KGA is responsible for the disproportionate and disparate impacts that its policies and activities will have on disadvantaged communities belonging to protected groups."	This comment is directed to the KGA GSP and will be addressed by KGA. While the KGA is the GSA entity submitting the plan on behalf of its members, the JPA forming the KGA that each member is responsible for the implementation of SGMA within their respective plan areas. The KGA GSP and its management area plans were developed in considerat all beneficial uses of water and the beneficial users of the groundwater in the subbasin.
Leadership Council		"The Coordination Agreement does not "explain how the plans, implemented together, satisfy the requirements of the Act."	This comment is directed to the KGA GSP and will be addressed by KGA.

Commentor	Ref #	Comment	Response
Leadership Council		"The GSP was not crafted in a way that adequately considered the input of disadvantaged communities, either at the GSA level or the member agency level."	This comment is directed to the KGA GSP and will be addressed by KGA, pertaining to the KGA level engagement. With respect to the member level engagement, SGMA leaves t manner and frequency of public outreach and engagement to the discretion of the GSA. As described in the introduction of the management area plan, SSJMUD holds monthly noticed meetings which serve as an opportunity for members of the public to provide feedback to the districts regarding the plan's development and implementation. Furthern the districts were active participants in the KGA-level outreach activities as well as hosts of their own workshops, which were publicly-noticed, and coordination with the cities Delano and McFarland on the development of the plan.
Leadership Council		"The Kern Subbasin Undesirable Results do not comply with existing law."	The definitions for undesirable results were developed in coordination with the other GSAs and take into consideration "significant and unreasonable" impacts to the groundwa which affect all beneficial users. Such beneficial uses include agriculture, domestic, and municipal & industrial.
Leadership Council		"It is not clear what the impacts from reaching this undesirable result will be on beneficial users, and instead seems to be an arbitrary determination of what is "significant and unreasonable."	The impact analysis performed by the GSAs in the subbasin contributed to the development of the undesirable results for declining groundwater level.
Leadership Council		"Like the proposed definition of undesirable results for groundwater levels, the proposed definition of undesirable results for degraded water quality are 'when the minimum threshold for when the minimum threshold for groundwater levels are exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the Subbasin (as measured by each management area).”	The comment letter cites an incorrect definition. The definition for the undesirable result for water quality is "when the minimum threshold for a groundwater quality constitue concern is exceeded in at least three (3) adjacent management areas that represent at least 15% of the Subbasin or greater than 30% of the designated monitoring points within Subbasin."
Leadership Council		"The GSP's minimum thresholds and measurable objectives were not established in a way that considered the interests of beneficial users including domestic well owners and disadvantaged communities."	The KGA GSP outlines the methods used by its members to establish the Sustainable Management Criteria (SMCs) within their respective plan areas. For the SSJMUD managem plan area, projected groundwater levels based on recent historical hydrology were used to analyze the impact to known agricultural, domestic, and municipal wells. While impa were identified at the minimum thresholds in some management areas, these impacts were determined to not meet the definition of "significant and unreasonable".
Leadership Council		"As in the case of groundwater levels, it is clear that the GSA has not considered the potential impact on drinking water users, in particular disadvantaged communities who are less able to afford solutions to treat contaminated drinking water."	As with the groundwater level SMCs, the KGA GSP outlines the methods used by its members to establish the Sustainable Management Criteria (SMCs) within their respective p areas. Based on the analysis in the Basin Setting subsection on existing water quality conditions, it was deemed appropriate to use groundwater levels as a proxy for water qual addition to water quality and water level measurement at the representative monitoring sites.
Leadership Council		"GSAs must monitor impacts to groundwater for drinking water beneficial users,54 including disadvantaged communities on domestic wells, and must avoid disparate impacts on protected groups pursuant to state law. The GSA's monitoring network does not comply with SGMA regulations, and fails to capture drinking water impacts to disadvantaged communities and domestic wells[...] To ensure the monitoring network adequately captures impacts to all beneficial users, the GSA must ensure the following: Ensure the proposed monitoring network contains representative monitoring wells in or near all disadvantaged communities and clusters of domestic wells in the GSA area; Ensure that monitoring wells and representative monitoring wells in or near disadvantaged communities and clusters of domestic wells are able to measure the groundwater levels at the depth at which the drinking water wells are screened; Explicitly describe any future representative monitoring wells and identify the proposed locations. When assessing the monitoring network data gaps, the GSP must prioritize installing new monitoring wells in locations where disadvantaged communities, small water systems, and domestic well users reside."	The coordinated basin-wide monitoring network was developed using the DWR BMP on SGMA Monitoring Networks, which discusses recommended well density and what constitutes a "SGMA compliant" representative monitoring site. It also allows for (and encourages) GSAs to use existing monitoring programs already in place for collecting dat the Sustainability Indicators identified in a basin's plan. Domestic wells are typically shallow or in the first occurence of groundwater and are, therefore, not representative of t groundwater conditions of the basin as a whole. Further, there are existing programs with which domestic wells and community wells must comply. These have been identifie Basin Setting and Monitoring Network sections in the discussions of existing programs. In areas of the basin where the well density does not meet the standards used in the pla proposed well locations have been identified. Per discussion and comments from the cities of Delano and McFarland, four additional wells have been added to the monitoring n within the SSJMUD management area.
Leadership Council		The groundwater quality monitoring network does not adequately capture impacts on drinking water users.[...] First, measuring for Arsenic (as in Arvin-Edison WSD) only once a year does not provide the member agency or the GSA with frequent enough information to respond to severe drinking water contamination in a reasonable amount of time. If the member agency's management actions, projects, or decisions to let groundwater decline increase drinking water contamination for families in the management area, the member agency could go a whole year without detecting these impacts. [...] Second, only measuring for compliance with arsenic measurable objectives and minimum thresholds does not protect against increases in other contaminants that exist in other parts of the management area (boron, nitrates, TDS, 123-TCP, iron and manganese). These contaminants could extend, move or increase due to groundwater management activities and pumping patterns. [...] However, avoiding monitoring contaminated areas defeats the purpose of groundwater quality monitoring under SGMA, which is to measure the concentration and spread of contaminant plumes to ensure that groundwater management activities and pumping do not aggravate existing contamination.	The monitoring of water quality for the basin will include the use of data from existing programs (e.g. Title 22, ILRP, CV-SALTS) and sampling coincidental with groundwater leve measurements at the representative monitoring sites. As such, the water quality data collected through SGMA will be more frequent than once a year. The constituents of conc be tested in the water quality sampling at representative monitoring sites vary between the management areas. Therefore, the constituents analyzed will differ according to the management area plan. The selection of representative monitoring sites discouraged the use of wells with existing MCL exceedances because of the nature of the definition of undesirable results for degradation of groundwater quality. The occurence of an increase in concentration for constituents of concern in a representative monitoring site will, b of it being a representative site, will be indicative of the migration of existing contamination.
Leadership Council		The projects and management actions set forth in the Draft GSP do not demonstrate a path towards achieving sustainability goals in the plan, and do not adequately account for the needs of disadvantaged communities pertaining to protected groups under state law. The GSA has allowed member agencies like the Arvin-Edison WSD to use a “glidepath” approach that increases surface water and groundwater recharge before demand reduction measures are implemented. This places the majority of the plan's success on surface water resources, which are variable and may not be able to be procured. The GSA should instead ensure that member agencies implement demand reduction strategies from the beginning so that groundwater levels do not plummet. A critical problem with the structure of the GSA is that member agencies cannot share the cost or responsibility for critical GSA-wide projects. Many more financially powerful agricultural and water banking member agencies could and should be part of a strategy to protect drinking water resources in the GSA area, especially given that they use much larger quantities of groundwater and their continued pumping will likely lead to dry wells and groundwater contamination issues for the most vulnerable homes in the GSA area.	The KGA and its members have the authority under SGMA to prioritize projects and management actions, as they see fit, to demonstrate that the basin can reach sustainability 2040. The prioritization of projects to increase imported supply for use by districts' customers or for water banking projects protects groundwater for beneficial use in the basi facilitiating in-lieu banking (where surface water is used whenever it is available, replacing groundwater pumping) or by maintaining groundwater levels through replenishment banking projects. These projects do not run contrary to the mandate to protect groundwater quality. In fact, with groundwater levels as a proxy Sustainability Indicator for wat quality, these projects achieve both the maintenance of groundwater levels and water quality. The agricultural and water banking agencies in the basin, as the customers payin water deliveries and funding projects via land assessments in their respective districts, can and should be a beneficiary of the projects which they are funding.
Leadership Council		"The KGA GSA should implement or incentivize recharge basins or other recharge activities throughout the subbasin wherever DACs and clusters of domestic wells exist. The GSA should encourage these kinds of recharge projects with health co-benefits over on-farm recharge, which is likely lead to accelerate groundwater contamination."	It is at the discretion of the KGA's member agencies to identify projects to fund, as well as opportunities to collaborate with DACs. SSJMUD is already collaborating with the City Delano to develop in-district recharge facilities which will be made available to the city when there is capacity available. Conversely, Delano will allow the district to utilize an exi stormwater catch basin as a spreading basin, when it is not in use to manage storm flows. Future projects and management actions which deal specifically with the DACs and domestic wells may be considered for subsequent updates to the GSP and management area plans.
Leadership Council		"For areas vulnerable to declining water levels and loss of production capacity, the KGA GSA should adopt management actions that establish geographical protection areas (buffer zones) by establishing bans, pumping limitations or community-specific management areas around disadvantaged communities and domestic well clusters."	The development of these buffer zones would be predicated on the development of a shallow-zone specific monitoring network and SMCs. As discussed in the response to the Monitoring Network comments, these shallow zones are not representative of groundwater conditions throughout the basin. Furthermore, the framework necessary to imple pumping restrictions or bans does not exist within the KGA or its members. Such policy would not be developed or implemented in time for the 2020 submittal.
Leadership Council		"We also strongly recommend against a groundwater market in the KGA GSA area. The GSP includes potential groundwater market and trading programs. Groundwater markets raise concerns from the perspective of domestic well users and disadvantaged communities."	At this time, the framework to establish a groundwater market in the basin does not exist. The policies and framework that would need to be developed by the KGA and its mer is too complex to be completed in time for consideration in the 2020 submittal. Additionally, any groundwater market developed by the KGA or its members would have to com with SGMA (i.e. prevent localized impacts to the Sustainability Indicators in its implementation).
Leadership Council		"The GSAs should implement and incentivize multi-benefit projects such as wetlands restoration or stormwater drainage ponds that would eliminate flooding and increase groundwater recharge in disadvantaged communities."	It is at the discretion of the KGA's member agencies to identify projects to fund. Future projects and management actions which provide benefits beyond SGMA may be conside subsequent updates to the GSP and management area plans.
Leadership Council		"Although there are multiple short-term funding sources to leverage for SGMA-related projects, the GSA's and member agencies' operating budgets must be a reliable source of funding over the long-term of GSP implementation, and the GSA and member agencies cannot rely on grant funding for long-term projects and programs that benefit disadvantaged communities. The GSA and member agencies must be responsible for addressing the drinking water issues caused by their policy decisions and activities."	It is entirely appropriate that the KGA's members, when working in collaboration with DACs on a project to benefit groundwater quantity and quality in the basin, seek funding such projects through state and federal grant funding programs. Grant funding, where the districts are eligible, is applied for to defray the cost of projects (which often far exce award amount). The remaining costs of projects and management actions are to be funded with the districts' operating budgets or through special assessments.
Leadership Council		"the Draft GSP allows continued overdraft above the safe yield of the basin, such that drinking water wells (especially domestic wells) will continue to go dry, infringing on the rights of overlying users of groundwater. The GSP must be revised to protect the rights of residents of disadvantaged communities and/or low-income households who hold water rights to groundwater."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with the statement, as the KGA GSP and its included management area plans h demonstrated, the combination of projects, management actions, and established SMCs will bring the basin into balance with its groundwater management by 2040.
Leadership Council		"The reasonable and beneficial use doctrine applies here given the negative impacts of the Draft GSP on groundwater supply and quality, which are likely to unreasonably interfere with the use of groundwater for drinking water and other domestic uses. As the Draft GSP authorizes waste and unreasonable use, it conflicts with the reasonable and beneficial use doctrine and the California Constitution."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with Leadership Council's statement regarding the plan's authorization of "wa and unreasonable use". The beneficial uses of water in the basin include other uses beyond domestic consumption. As such, it is entirely appropriate and in the authority of the that impacts to groundwater be analyzed in consideration of all beneficial uses identified in the plan.



Commentor	Ref #	Comment	Response
Leadership Council		"The "public trust" doctrine has recently been applied to groundwater where there is a hydrological connection between the groundwater and a navigable surface water body. In Environmental Law Foundation , the court held that the public trust doctrine applies to "the extraction of groundwater that adversely impacts a navigable waterway" and that the government has an affirmative duty to take the public trust into account in the planning and allocation of water resources. The court also specifically held that SGMA does not supplant the requirements of the common law public trust doctrine. In contrast to these requirements, the Draft GSP does not consider impacts on public trust resources, or attempt to avoid insofar as feasible harm to the public's interest in those resources."	This comment is directed to the KGA GSP and will be addressed by KGA. We respectfully disagree with Leadership Council's position in that the Basin Setting of the KGA GSP an management area plans have adequately demonstrated that there are no interconnected surface waters in the basin and that this is the existing condition of the basin.
Tejon-Castac Water District Received Comments			
No Comments Received			
West Kern Water District Received Comments			
Chevron	Letter-1	Include discussion of aquifer lower boundary as above top of the oil/exempt water-bearing zones below oil	Suggested text added to section
Chevron	Letter-2	Provide additional support for removing industrial/non-domestic GW wells in Western Management as "de mimimis extractors" (ES-1.4, Figures 1-13 - 1-15)	Added text to 5-year update to re-evaluate wells in the western management area to review potential uses that may not be de-minimus.
Chevron	Letter-3	In the Western Management Area, how will we evaluate subsidence and undesirable results?	Added text to 5-year update to re-evaluate potential for water use to affect sustainability indicators in the area
Chevron	Comment-1	Same as comment "Letter-2"	Added text to 5-year update to re-evaluate wells in the western management area to review potential uses that may not be de-minimus.
Chevron	Comment-2	Language change: The GSA area includes the WKWD boundary and adjacent oilfield properties owned by corporate and independent operators "*as well as Stateland and privately owned parcels*"	Suggested text added to section
Chevron	Comment-3	Per WC Section 10721(e), "De minimus extractor" defined as "a person who extracts, for domestic purposes, two acre-feet or less per year."	Added text to refine description without relying on 'de minimis'.
Chevron	Comment-4	An aquifer may not be suitable for beneficial use if: a) is not currently serving as a source of drinking water, b) it has commercially producible minerals or hydrocarbons, or c) it is not expected to supply a public water system and d) is either economically or technologically infeasible for treatment or recovery now or in the future for domestic, agricultural, or industrial use. The purpose of this plan is not to exempt aquifers, nor is it to define the maximum depth or water quality concentration at which groundwater is economically recoverable or treatable now or in the future. However, by applying the criteria of 40 CFR §144.3 and 40 CFR §146.4, active oil and gas aquifers and exempted aquifers are not a part of the groundwater basin for beneficial use. The following whichever is shallowest, are the lateral and vertical boundaries of the groundwater Subbasin: a) depth to producible minerals or hydrocarbons or primacy productive limits, b) depth to exempted aquifers, c) depth that makes recovery of water for domestic, commercial, or industrial purposes no longer economically or technologically feasible, or d) the depth at which groundwater cannot now or in the future serve as a source of drinking water. For example, water bearing zones below the depth to producible hydrocarbons are not within the groundwater basin; likewise, water bearing zones below an exempted aquifer are not within the groundwater basin	Suggested text added to section
Chevron	Comment-5	Language change: Separate GW quality and production "There is little or no groundwater production in the Western Management Area, so water quality in that area is not discussed in this section."	GSA's can only manage groundwater quality through groundwater pumping management. If there is no significant groundwater pumping in a region, the GSA cannot effectiveh manage groundwater quality in that area.
Chevron	Comment-6a	1. Consider moving Section 4.9 to this section. 2. Consistent with DWR Water Budget BMP, consider adding language to discuss how this is monitored and how you reach the conclusion it is not impacting GW quality. 3. Please provide reference for "one of the world's largest" or delete it.	Copied content from 4.9 to this section. Removed reference to largeness. Added consideration of coordination with oil producers on an approach to enhance water quali monitoring and reporting of oil produced water to ensure no degradation of groundwater quality due to oil pumping occurs under SGMA.
Chevron	Comment-6b	How have we reached the conclusion that oil production has not impacted groundwater quality?	
Chevron	Comment-6c	Cite "world's largest petroluem producing areas"	
Chevron	Comment-7	Language change: change "produced water ponds" to "percolation ponds"	changed
Chevron	Comment-8	Addition of 4 paragraphs written by Chevron (see comments on pg 120 of draft)	Added majority of text recommended
Chevron	Comment-9	Include a bibliography for cited references	Present in Section 3.9 and at the end of each section
Chevron	Comment-10	change title to "Treated Produced Water"	changed
Chevron	Comment-11	Change "Water produced water" to "treated produced water"	changed
Chevron	Comment-12	Change "evaporation ponds" to "percolation ponds"	changed
Chevron	Comment-13	Consider deleting sentence or providing data to support it: "This water is supplemented by water purchased from WKWD, which indicates that very little water is disposed of, since purchasing fresh water is more expensive than recycling water."	removed
Chevron	Comment-14	Replace last sentence with "Oilfield produced water is sourced from beneath the bottom of the basin."	changed
Chevron	Comment-15	To subsidence bullet point, add "and critical infrastructure."	changed
Chevron	Comment-16	Consider deleting "Most extensometers are located too far from the GSA area to provide useful insight into subsidence trends."	changed
Chevron	Comment-17	Add "critical" before "infrastructure"	changed
Chevron	Comment-18	Replace "large pipelines" with "large-scale linear infrastructure"	changed
TNC	General - 0	Use TNC's online tools and resources and TNC's checklist to better include nature in the GSP (see specifics below)	NCCAG Dataset was used to identify potential locations of GDEs
TNC	General - 1	Actively engage with environmental stakeholders	Outreach is addressed in KGA's Umbrella GSP
TNC	General - 2	For GDEs, utilize: NC Dataset on DWR website, GDE Pulse, and CNDDB	added text stating these uses are not known to exist in the plan area
TNC	General - 3	Potential effects on environmental beneficial users: Use Attachment C for list of freshwater species in Kern County Subbasin	Identification of endangered species is not a requirement under GSP regulations
TNC	General - 4a	ISWs and GDEs are not adequately identified	corrected 2.10.2 to ephemeral, added that there are no known flow requirements
TNC	General - 4b	connectivity of ISWs and GDEs with the Shallow Zone and Upper Unconfined Aquifer was not adequately characterized	There are no GDEs in management areas with non-deminimis pumping (North, South, and Lake Management Areas).
TNC	General - 4c	the plans to address GDE/ISW data gaps in the Subbasin characterization and monitoring networks need to be expanded	There are no GDEs in management areas with non-deminimis pumping (North, South, and Lake Management Areas).
TNC	General - 4d	set sustainable management criteria for all identified and potential GDEs/ISWs	There are no GDEs in management areas with non-deminimis pumping (North, South, and Lake Management Areas).
TNC	Checklist - 1	Describe any environmental beneficial uses and users of groundwater (i.e. GDEs, managed wetlands, fisheries, recreation, etc.) and species with protected status	Beneficial uses are addressed in KGA's Umbrella GSP
TNC	Checklist - 2	Describe current/planned habitat and flow requirements for streams in WKWD (or state if there are none)	Identification of endangered species is not a requirement under GSP regulations, added text about no flow requirements on WKWD GSA area's ephemeral streams
TNC	Checklist - 3	provide a description of monitoring activities and responsibilities by State, Federal and local agencies and jurisdictions related to aquatic resources and GDEs in the GSP plan area that could be affected by groundwater withdrawals	There are no GDEs in management areas with non-deminimis pumping (North, South, and Lake Management Areas).
TNC	Checklist - 4	review and discuss the potential groundwater reliance of critical species in the Subbasin. Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.	Identification of endangered species is not a requirement under GSP regulations, added text about no flow requirements on WKWD GSA area's ephemeral streams
TNC	Checklist - 5	Please include a discussion of monitoring programs related to GDEs and sensitive or protected habitats.	There are no GDEs in management areas with non-deminimis pumping (North, South, and Lake Management Areas).

Commentor	Ref #	Comment	Response
TNC	Checklist - 6	Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources riparian vegetation, and other potential GDEs and ISWs, if applicable.	the General Plan does not have policies regarding the protection of wetlands, aquatic resources riparian vegetation, and other potential GDEs and ISWs,
TNC	Checklist - 7	Please identify all relevant HCPs and NCCPs within the WKWD GSP area, and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.	no HCPs or NCCPs are known to cover the managed management areas (North, South, Lake) of the WKWD GSP
TNC	Checklist - 8	discuss that future well permitting and well construction must be coordinated with the GSP to assure achievement of the sustainability goals, how the process incorporates protection of GDEs, and how well permitting programs must consider the potential impacts of GW extractor on public trust resources	Well permitting is performed by Kern County, not the WKWD GSA
TNC	Checklist - 9	Define the bottom of the boundary from deepest extraction wells. If data unavailable, describe this in data gaps.	Bottom of basin was updated to match KGA's Umbrella GSP
TNC	Checklist - 10	Show cross sections (that could show shallow/perched GW) - (Same as Umbrella comment on Section 2.2.1.6)	Cross Sections for the Kern County Subbasin are included in the KGA's Umbrella GSP
TNC	Checklist - 11	Describe shallow aquifers including interconnections with surface water, vertical GW gradients, and interactions with GDEs and state presence of perched aquifers (or identify as data gap if unavailable)	Section 2.8 contains aquifer information
TNC	Checklist - 12	Support statement of lack of springs with data, or identify as data gap	Figure 2-5 shows locations of springs
TNC	Checklist - 13	Potentially add gaps listed in comments above	None present
TNC	Checklist - 14	Provide more supporting data on why no ISWs are present (including Buena Vista Aquatic Recreational Area and ponds in north central)	Buena Vista Aquatic Recreational Area is not in the WKWD GSA Area. The ponds in the North and South Management areas are managed recharge ponds that are not naturally occuring - effects of pumping in these areas and recharge from the recharge ponds is explained in the water budgets section.
TNC	Checklist - 15	further describe the conceptual understanding of shallow groundwater and stream interactions with the aquifer system at different locations, including perched and unconfined aquifers and GDEs	The only non-managed surface water in the GSA are ephemeral streams, which are not managed, and are in the Western Management Area, which does not have pumping.
TNC	Checklist - 16	elaborate on the relationship between surface water in the BVARA and adjacent shallow and deeper groundwater levels. Since this is identified as a data gap, please describe how and where additional observations (shallow monitoring wells, nested / clustered wells, etc.) along surface water features can be used to reconcile this data gap	the BVARA is outside WKWD GSA, and therefore is not managable by the WKWD GSA. Identifying monitoring in the Lake Management area is identified as a part of implementa
TNC	Checklist - 17	Use GW contours (including seasonal and interannual fluctuations) to verify whether a connection between GDEs and GW exist	Groundwater Contours are provided in the KGA's Umbrella GSP
TNC	Checklist - 18	Expand GDE analysis of using GW data (using their attachments D and E) to verify is ecosystem decline/recovery is correlated with GWLs	NCCAG Dataset showed that there were no potential GDE's in the 3 managed management areas (North, South, Lake)
TNC	Checklist - 19	Provide more data-driven analysis of GDE identification, or identify in data gaps and resolve inconsistency in Umbrella GSP on pg 92	NCCAG Dataset showed that there were no potential GDE's in the 3 managed management areas (North, South, Lake)
TNC	Checklist - 20	Decribe nature and characteristics of GDEs including: GW conditions near GDEs, ecological inventory and ranking, and nearby endangered freshwater species	NCCAG Dataset showed that there were no potential GDE's in the 3 managed management areas (North, South, Lake)
TNC	Checklist - 21	Disaggregate ET of native and riparian vegetation further, or identify as data gap	ET is discussed in the KGA's Umbrella GSP
TNC	Checklist - 22	We recommend an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes vegetation or habitat types and rank the GDEs as having a high, moderate or low value. Explain how each rank was characterized. Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs. Some organisms rely on uplands and wetlands during different stages of their lifecycle.	GSP Regulations do not require these activities.
TNC	Checklist - 23	Please expand the sustainability goal to describe that all beneficial users and GW users will be protected from undesirable results, including GDEs	Sustainability Goal and undesirable results are a coordinated statement that was developed by the KGA, and cannot be changed at this level
TNC	Checklist - 24	Include a statement about any intention to address pre-SGMA impacts	2015 is used as a key function of the identification of minimum thresholds. This is described in Section 7
TNC	Checklist - 25	Address how water quality would affect GDEs	NCCAG Dataset showed that there were no potential GDE's in the 3 managed management areas (North, South, Lake)
TNC	Checklist - 26	For each sustainable management criteria, discuss whether minimum threshold/measureable objectives/interim milestones addresses the environment's sustainability goal	Sustainability Goal and undesirable results are a coordinated statement that was developed by the KGA, and cannot be changed at this level
TNC	Checklist - 27	List GDEs as one of the beneficial users of GW and add "possible adverse impacts to potential GDEs and ISWs" to the list of potential undesirable results	Sustainability Goal and undesirable results are a coordinated statement that was developed by the KGA, and cannot be changed at this level
TNC	Checklist - 28	Correlate trends/spatial patterns of GDEs with GWL trends. Note adverse trends and/or data gaps. (Specific details of trends listed in Appendix B pf 17)	NCCAG Dataset showed that there were no potential GDE's in the 3 managed management areas (North, South, Lake)
TNC	Checklist - 29	Monitoring networks should include proposing (i) new wells to be located in the Western Management Area to be properly screened to analyze GDEs and (ii) stream gages in areas where there is potential for GDEs/ISWs	The western management area does not have significant pumping, and is not managed beyond monitoring for new groundwater use. Will consider monitoring should groundw use increase in the 5 year update.
TNC	Checklist - 30	Modify monitoring network to include water quality impacts on GDEs	Water quality is monitored by proxy, this covers GDEs (which are not present in the 3 managed management areas)
TNC	Checklist - 31	Resolve inconsisency stating "all streams are ephemeral" vs both "ephemeral and perennnial streams"	corrected 2.10.2 to ephemeral, added that there are no known flow requirements
TNC	Checklist - 32	For proposed projects, state how ISWs/GDEs could benefit or list additional management actions to protect GDEs/ISWs and how adverse impacts will be evaluated and mitigated	NCCAG Dataset showed that there were no potential GDE's in the 3 managed management areas (North, South, Lake)
Westside District Water Authority Received Comments			
Wonderful Orchards	WO-1	It is imperative that the final GSP properly address the quantification of native yield. The GSPs, management areas, and other planning units in the subbasin should utilize coordinated methods of determining supply sources for native yield, quantifying the native yield, and accounting for it in individual MAPs' water budgets. Unless there are specific hydrogeologic conditions that differentiate certain portions of the basin from the basin at-large (such as a fault line or barrier to groundwater flow), native yield should be considered a basin-wide resource.	Comment noted. Please see Section 2.7-Water Budget of the WDWA Chapter GSP
Wonderful Orchards	WO-2	In addition to a clear definition of native yield, the final GSP must also include a thorough description of how to calculate the allocation of native yield.	Comment noted. Please see Section 2.7-Water Budget of the WDWA Chapter GSP
Wonderful Orchards	WO-3	In addition, GSAs should initiate a stakeholder-driven process to develop a methodology for establishing landowner-level allocations of native yield that are coordinated across the subbasin.	Comment noted. The WDWA will participate in KGA discussions related to all Subbasin issues.
Wonderful Orchards	WO-4	Markets are essential in facilitating the highest and best use of a limited resource and in giving landowners the most flexibility to minimize the economic impacts of pumping restrictions. To enable a market that works for all landowners in the subbasin, it is imperative that all pumpers know exactly how much marketable water they have available for use or transfer. Unless it is deemed necessary to prevent undesirable results, markets should not place geographic or jurisdictional limitations on transfers within a subbasin and should allow for carry-over of allocations from one year to the next.	Comment noted. The WDWA will participate in KGA discussions related to all Subbasin issues.
Wonderful Orchards	WO-5	GSAs or MAs should implement pumping restrictions when supported by the best available data and appropriate analytical tools. Furthermore, if possible, pumping should be ramped down gradually over the implementation period to avoid a sudden disruption in economic activity	Comment noted. The WDWA will participate in KGA discussions related to all Subbasin issues.
Wonderful Orchards	WO-6	GSAs and MAs must develop clear and understandable policies and conditions that protect existing groundwater banking and banked inventory and allow them to continue operating as they have been under their existing rules and regulations without interference. They must also incentivize additional investment, such as on-farm recharge by providing pumping credits and allow flexibility for recharged or banked water to be freely transferrable subject to the rights and conditions of use associated with the source water and the avoidance of undesirable results. They should develop incentives for public or private investment to expand recharge and banking capacity, as these facilities help to achieve multiple benefits (e.g., habitat, water quality, drinking water, etc.).	Comment noted. The WDWA will participate in KGA discussions related to all Subbasin issues.
Wonderful Orchards	WO-7	GSAs should develop a coordinated basin-wide data management system ("DMS") that is capable of tracking groundwater and surface water use at the landowner, field, or parcel level, and a coordinated methodology for measuring landowner-level use of groundwater.	Comment noted. The WDWA will participate in KGA discussions related to all Subbasin issues. Please also see Setion 6.0- GSP Reporting and Periodic Evaluations of the WDWA Chapter GSP
Department of Fish and Wildlife	DWF-4	The Plan Area narrative does not identify Department-owned lands. … The Department also owns the Buttonwillow, *Lokern* , and Bakersfield Cactus Ecological Reserves, which are also located within the GSP area.	The WDWA has included text and a figure describing DWF lands (Lokern Ecological Resreve) witihn its management area.
Wheeler Ridge-Maricopa Water Storage District Received Comments			

Commentor	Ref #	Comment	Response
Chevron	1	An aquifer may not be suitable for beneficial use if: a) is not currently serving as a source of drinking water, b) it has commercially producible minerals or hydrocarbons, or c) it is not expected to supply a public water system and d) is either economically or technologically infeasible for treatment or recovery now or in the future for domestic, agricultural, or industrial use. The purpose of this plan is not to exempt aquifers, nor is it to define the maximum depth or water quality concentration at which groundwater is economically recoverable or treatable now or in the future. However, by applying the criteria of 40 CFR §144.3 and 40 CFR §146.4, active oil and gas aquifers and exempted aquifers are not a part of the groundwater basin for beneficial use. As described above, the following, whichever is shallowest, are the lateral and vertical boundaries of the groundwater Subbasin: a) depth to producible minerals or hydrocarbons or primacy productive limits, b) depth to exempted aquifers, c) depth that makes recovery of water for domestic, commercial, or industrial purposes no longer economically or technologically feasible, or d) the depth at which groundwater cannot now or in the future serve as a source of drinking water. For example, water bearing zones below the depth to producible hydrocarbons are not within the groundwater basin; likewise, water bearing zones below an exempted aquifer are not within the groundwater basin.	Section 7.1.3 was modified to clarify that in areas where pools in oil fields in the MA Plan area are at shallower depths than the base of fresh water, the bottom of the basin is d as the shallower depth of fresh water from the DOGGR oil field data.
Farmland Reserve	1	**Allocation of Groundwater Rights.** Though not specifically addressed, we are concerned that the overlying right to extract groundwater will be allocated among all District landowners based on gross acreage. While this is a simple approach to what can be a complex issue, it ignores accepted principles of law intended to more fairly allocate this right among those who have historically used groundwater for irrigation purposes-and made substantial investments based on that use. We wish to at least see identification of this issue in the Chapter and an acknowledgment that it will not be decided now. If the District determines that the issue is broader, then we leave it to the District to address it at the Umbrella GSP level. Any implication that the District has decided to allocate the overlying groundwater rights based simply on gross acreage could invite some to pursue premature legal action to challenge the District's conclusion, which might not be necessary depending on the success of the proposed actions in the Chapter. While this issue certainly affects our interests, we are equally concerned about avoiding unnecessary legal challenges made by others and the instability that would bring to the sub-basin.	• "Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see Section 9.1.3). • ***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and no determination of actual legal ground water rights.*** • Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in Section 18.2. • See KGA response to this comment for further information.
Farmland Reserve	2	**Native Yield.** The Chapter identifies a coordinated estimated native yield of 0.15-.0.30 acre feet per acre across the KGA. We understand and acknowledge that some number needed to be identified for Water Budget and planning purposes and support the use of these numbers for such purposes. However, these numbers should not be seen as establishing a precedent or used to establish some legal right. Therefore, a statement emphasizing the above points should be made - the planning purpose nature of these numbers and not establishing legal precedent. Additionally, in coordinating with other members of the KGA under the Umbrella GSP, the District should push for a consistent native yield and related methodology across the sub-basin. We understand that this can be a politically charged process, but we are confident the District can provide support for a consistent approach, which will enable a more stable sub-basin.	• "Native yield", as defined in the Coordinated Water Budget, is applied to all lands in the basin uniformly (see **Section 9.1.3**). • ***Section 9.1.3 was added to clarify the intended purpose of the water budget, and includes a statement that the "native yield" is for planning purposes only and no determination of actual legal ground water rights.*** • Implementation of P/MAs, including actions to further refine issues related to allocations of groundwater, is described in **Section 18.2**. • See KGA response to this comment for further information.
Farmland Reserve	3	**Groundwater Market.** This issue might be premature at this point. However, the Chapter could address the possibility of a market for the exchange or transfer of groundwater credits. If a market system were contemplated, we would encourage such a system to be as flexible as possible (within the requirements of SGMA, the Chapter and the Umbrella GSP) to facilitate the needs of farmers with lands in different areas of the sub-basin and those with the ability to store surface water underground. Again, this might be premature at this time, but a mention of the District's position to support a flexible groundwater market could help move the discussion forward once the Umbrella GSP is submitted to the Department of Water Resources and agencies begin the implementation process.	• The MA Plan includes in its portfolio of P/MAs a management action to evaluate and potentially implement a groundwater marketing and trading system (see **Section 1** • As described in **Section 18.2**, implementation of P/MAs, including the potential establishment of a market-based system, will include performance of any appropriate f studies and analysis, including engineering, economic/financial, and/or legal, as appropriate. • See KGA response to this comment for further information.

SGMA Water Budget Development Using C2VSimFG-Kern in Support of the Kern County Subbasin Groundwater Sustainability Plans

TODD GROUNDWATER

January 7, 2020

MEMORANDUM

To: Mark Mulkay, Kern River GSA
Patty Poire, Kern Groundwater Authority GSA

From: Michael Maley, Todd Groundwater
Charles Brush, Hydrolytics LLC

Re: **SGMA Water Budget Development using C2VSimFG-Kern in support of the Kern County Subbasin Groundwater Sustainability Plans (GSPs)**

1. INTRODUCTION

In compliance with the Sustainable Groundwater Management Act (SGMA), the multiple Groundwater Sustainability Agencies (GSAs) of the Kern County Subbasin (**Figure 1**) have successfully coordinated on the development of Groundwater Sustainability Plans (GSPs). The Kern County Subbasin, the largest in the State, was designated as critically-overdrafted by the California Department of Water Resources (DWR). Water management in the Kern County Subbasin is complex. It involves more than 30 water districts/systems, contains large groundwater banking projects of State-wide importance, and provides large quantities of groundwater to support both large urban centers and one of the top agricultural-producing areas in the country. In addition, most agencies are involved in conjunctive management of local surface water, imported state and federal water, and groundwater.

Within this complex water management setting, GSAs recognized that a numerical modeling tool would be needed to meet GSP regulations for assessment of historical, current, and future projected water budgets that are developed on a Subbasin-wide basis (§357.4(b)(3)). The California Central Valley Groundwater-Surface Water Simulation Model (C2VSim) is anticipated to be DWR's primary tool for evaluating water management in the Central Valley and is specifically referenced in the GSP regulations for application to GSP water budgets (§354.18(f)); therefore, C2VSim was selected by the GSAs for GSP compliance.

This technical memorandum describes the process and approach for selection, revisions, and application of the C2VSim to the Kern County Subbasin. The memorandum documents the development of Subbasin water budgets and presents the results. This document is being prepared as an attachment to Subbasin GSPs and as an attachment to the Kern County Subbasin GSAs' coordination agreement.

1.1 Background

During late 2016 and 2017, Subbasin GSAs held a series of meetings and workshops to evaluate potential modeling tools for GSP application. Although numerous existing models had been developed by various entities in the Subbasin over time, none of those models covered the entire Subbasin or incorporated all of the local water budget components necessary to meet GSP requirements.

During the time that the Subbasin was evaluating various modeling alternatives, DWR was in the process of updating the regional C2VSim model through water year (WY) 2015. In particular, the GSP regulations stated that DWR would provide the C2VSim model "for use by Agencies in developing the water budget." Todd Groundwater developed an approach for review, revisions, and application of the C2VSim model to the Kern County Subbasin. In March 2017, the Kern River GSA (KRGSA), on behalf of the Subbasin GSAs, entered into a contract with Todd Groundwater to conduct the proposed scope of work. The Kern Groundwater Authority (KGA), on behalf of the Subbasin GSAs, also retained Woodard & Curran to conduct a peer review of the Todd Groundwater C2VSim model revisions and application for the Kern County Subbasin.

DWR released the C2VSim Fine Grid Public Beta model (C2VSimFG-Beta) on May 18, 2018 (CNRA, 2018). An initial model review indicated that the C2VSimFG-Beta generally had good historical precipitation, streamflow, land use and crop acreage for the entire Central Valley. Historical water supply and demand data were also generally good in the Sacramento Valley and San Joaquin River hydrologic regions; however, data were considered less reliable in the Tulare Lake hydrologic region including Kern County. To address this concern, Todd Groundwater – working with all Subbasin GSAs –revised the Kern County portion of C2VSimFG-Beta for WY1985 to WY2015. This revised version of C2VSim for the Kern County Subbasin, referred to herein as the C2VSimFG-Kern model, was used to develop historical, current and projected-future water budgets in accordance with the requirements in the GSP regulations.

The Central Valley portion of Kern County contains two groundwater subbasins, the Kern County Subbasin (5-022.14) and the White Wolf Subbasin (5-22.18) based on DWR Bulletin 118 (DWR, 2016A). All of the agencies that deliver water in White Wolf Subbasin also deliver water in the Kern County Subbasin and participated in the C2VSim revision. The White Wolf Subbasin portion of C2VSimFG-Beta model was included in this update to ensure coordination of groundwater conditions between the two subbasins. These are considered separate groundwater basins under SGMA with the Kern County Subbasin listed by DWR as critically-overdrafted with a GSP deadline of January 30, 2020, whereas the White Wolf Subbasin is listed as medium priority with a GSP deadline of January 30, 2022. Therefore, only the model results for the Kern County Subbasin are evaluated and reported here.

1.2 General Approach

The current C2VSim model has a detailed finite element mesh that closely follows local hydrologic features. As a regional model, the C2VSimFG-Beta may over-generalize local conditions within the Kern County Subbasin so as to be inconsistent with local site-specific data and knowledge. To address this concern, the managed water supply and demand inputs were updated to better represent the local water balance. To do this, the more general assumptions in C2VSimFG-Beta were replaced with local data and knowledge that are regionally or locally significant over the WY1995 to WY2015 Hydrology Period. Local managed water supply input data (e.g., surface water deliveries, land use, irrigation demand, return flows, and groundwater banking) were collected and applied to C2VSim. Improvement of Kern County data focused on incorporating:

- Surface water delivery volumes, application areas and use by water district,
- Groundwater banking recharge, recovery and application of recovered water,
- Irrigation demand from recent analyses of remote sensing data of evapotranspiration in the Kern County Subbasin based (ITRC, 2017),
- Urban demand for the Subbasin focusing on Metropolitan Bakersfield, and
- Data on other water sources and demands of local significance to individual districts/GSAs.

Compiling the data needed for the model revision required a coordinated effort from the Subbasin GSAs (**Figure 1**) to provide locally derived data on managed water supply and demand that was used to revise the C2VSimFG-Beta for the Kern County Subbasin. The Subbasin GSAs also coordinated on selection of consistent study periods for the C2VSimFG-Kern water budget analyses. Based on technical considerations and a review of regional data, the following study periods were selected:

- Historical Water Budget - WY1995 through WY2014 (Section 3.2), and
- Current Water Budget - WY2015 (Section 3.2),
- Projected Water Budget - WY2021 through WY2070 using 50 years of hydrologic data based on historical data (Section 6.1).

Todd Groundwater also coordinated data collection and model revision efforts with a Technical Peer Review Team and local agencies to ensure input data were accurately represented in the model. Tabulated input data, model files and model-derived water budgets were provided to the Technical Peer Review Team for review of accuracy and appropriateness. Model input data and results were also provided to Kern County Subbasin water districts and local water purveyors for their review. Comments and data issues were reconciled and incorporated into the revised C2VSimFG-Kern model.

1.3 Acknowledgements

These regional model revisions were enhanced by the participation of the many agencies that provided local water budget input data. Todd Groundwater worked with the member agencies, and their consultants, including the Kern River GSA, Kern Groundwater Authority GSA, Henry Miller Water District GSA, Olcese Water District GSA, and Buena Vista GSA to coordinate acquisition of input data from other agencies in formats that could be easily incorporated into the C2VSim model. On-going review of interim model results by these agencies, including local zonal water budgets, groundwater hydrographs and other model results, helped ensure that the revised model reproduced local mass balance estimates across the Subbasin.

Woodard & Curran conducted an on-going peer review of model input files at the request of the GSAs in the Kern County Subbasin. Todd Groundwater worked with Woodard & Curran throughout the historical model revision process. The C2VSimFG-Kern input files for the Kern County Subbasin revised historical simulation were provided to DWR for incorporation into future C2VSim public releases.

Dr. Charles Brush of Hydrolytics LLC was added to the Todd Groundwater modeling team. As an early developer of C2VSim for DWR, he provided his experience and expertise with the C2VSim. This collaborative effort provided further assurance that the significant model revisions could be managed in an efficient manner to meet the expedited schedule for water budget development.

2. C2VSIM

C2VSim uses DWR's modeling code *Integrated Water Flow Model* (IWFM) and covers the entire California Central Valley. Kern County is located at the far southern end of the Central Valley (**Figure 2**). C2VSim simulates the full hydrologic cycle, calculating water demands and tracking water movement through surface water and groundwater systems, and is therefore well suited to support GSP development.

2.1 C2VSim Background

DWR developed C2VSim to simulate water demands and supplies in the Central Valley. C2VSim is an application of DWR's IWFM software. IWFM is an integrated hydrologic model that simulates water flows on the linked land surface, unsaturated zone, groundwater, and surface water flow systems. A key feature of IWFM is DWR's agricultural and urban water supply and demand management module that dynamically simulates the delivery of both surface water and groundwater supplies based on both water availability and calculated water demands, as affected by usage and climatic conditions.

The C2VSim is derived from a series of Central Valley hydrologic models developed by DWR and other agencies beginning in the early 1990s. Each model in this series has incorporated significant improvements over the previous version (Brush, Dogrul and Kadir, 2013). The groundwater flow system is modeled in IWFM using the finite element method and uses a highly efficient solver developed at UC Davis. The IWFM Demand Calculator (IDC) and land surface simulation process were developed with input from California irrigation management professionals. Given DWR's emphasis on water management, detailed water budgets produced by C2VSim provide strong representations of the surface water and groundwater flow systems and make it a preferred platform for developing water budgets.

2.2 C2VSImFG-Beta Model

DWR's 2018 release of C2VSimFG-Beta includes historical input data for WY1922 to WY2015. C2VSimFG-Beta includes historical precipitation, stream inflow, land use and crop acreage for the entire Central Valley. These data include monthly precipitation and annual land use for each model element and estimated monthly evapotranspiration for each modeled land use type and agricultural crop. Historical surface water data include monthly surface water inflow for each river entering the model boundary and monthly surface water diversions and deliveries.

The C2VSimFG-Beta finite element grid divides the Central Valley into 32,537 model elements (**Figure 2**). Element areas are small near streams and in developed areas and expand to larger sizes in undeveloped areas. Element sizes average 407 acres and range from 4 to 1,770 acres. Central Valley rivers and streams are represented with a network of 110 stream reaches. Surface water and groundwater inflows from uplands along the model boundary are simulated with 1,033 small watersheds. Within the Kern County Subbasin, the land surface elevation varies from 208 feet above mean sea level (msl) in the north to 3,922 feet above msl in the foothills.

The groundwater aquifer system is represented with four aquifer layers and one regional confining layer. The aquifer thickness in the Kern County Subbasin varies from 857 to 9,054 feet and the deepest aquifer location is 8,752 feet below msl. The Central Valley aquifer is simulated with the following hydrostratigraphic layers, listed from top to bottom:

- Shallow, unconfined aquifer,
- Regional confining layer,
- Active confined aquifer (contains high level of pumping),
- Inactive confined aquifer (contains limited pumping), and
- Saline confined aquifer.

C2VSimFG-Beta includes annual land use and crop acreages and monthly precipitation, evapotranspiration, stream inflows, surface water deliveries and specified groundwater pumping rates for WY1922 to WY2015. C2VSimFG-Beta uses IDC to dynamically calculate distributed monthly water demands, allocate available water supplies to meet these demands, and calculate unmetered groundwater pumping necessary to satisfy unmet demands. C2VSimFG-Beta produces detailed monthly water budgets for arbitrary sets of elements grouped into zones.

Water demands are calculated dynamically for each model element using the IWFM Demand Calculator (IDC) for agricultural, urban, native and riparian land use types. Agricultural demand is calculated based on annual crop type distribution mapping and user-specified evapotranspiration rates for 20 irrigated crop types and managed seasonal wetlands at the Kern National Wildlife Refuge. Agricultural water demand is determined based on a soil moisture balance that uses local soil properties to assess the amount of applied water (precipitation and specified surface water applications) available to meet the crop demand. If water demands in an element are not satisfied from these sources, the C2VSim model calculates the groundwater pumping needed to eliminate any deficit.

Urban demands are calculated based on population and per-capita water demands. Water demands for native, undeveloped, fallow or riparian settings are calculated from monthly evapotranspiration rates and the amount of precipitation. If water demands in an element are not satisfied, no applied water is provided to these areas, and the vegetation is assumed to be in a stressed state. Runoff of precipitation in developed and undeveloped areas within the Subbasin and surrounding small watersheds is calculated using methodology included in IWFM that is based on the Soil Conservation Service Curve Method (NRCS, 2004).

C2VSimFG-Beta was released after a preliminary model calibration. The distribution of aquifer parameters was based on a texture analysis of lithologic well logs compiled by the US Geological Survey (USGS, 2009) from Well Completion Reports submitted to DWR by well drillers. The texture analysis interpolated the percentage of coarse-grained material at each well location and depth of the C2VSimFG-Beta mesh. Aquifer parameters were then calculated for the model mesh based on the percentage of coarse-grained material and estimated properties for pure coarse- and fine-grained materials. Transmissivities were estimated using specific capacity tests, where available. Soil properties for each model element were derived from digitized soil maps published by the US Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS, 2018).

3. KERN COUNTY REVISIONS

C2VSimFG-Beta input files were revised to incorporate locally-derived managed water supply and demand data to better represent the local water budgets for the Kern County Subbasin. Additional revisions were made to C2VSimFG-Beta model to address issues that were identified with the physical representation of the Kern County Subbasin. The result of these Kern County specific modifications is a local version of C2VSimFG-Beta that is referred to here as C2VSimFG-Kern. The following provides a summary of the model modifications.

3.1 C2VSimFG-Kern Model

C2VSimFG-Kern input files incorporate locally-derived historical data for the Kern County and White Wolf subbasins to better represent local water conditions. These are two separate groundwater subbasins in the Kern County portion of the San Joaquin Groundwater Basin. The Kern County Subbasin is listed as critically-overdrafted by DWR with a GSP deadline of January 30, 2020, whereas the White Wolf Subbasin is listed as medium priority by DWR with a GSP deadline of January 30, 2022. C2VSimFG-Kern was not changed for areas outside of the Kern County Subbasin.

Historical surface water diversion, water bank recharge and water bank withdrawal information were collected from local GSAs, management areas, water agencies and purveyors. Urban land use was restricted to developed areas, and urban populations and per-capita water demands were updated. Model structure (elements, streams, stratigraphy, etc.) was not modified. Model parameters were not calibrated, although some model parameters were adjusted to improve model performance in specific geographic areas.

3.2 Simulation Time Period

GSP requirements indicate a need to identify an average hydrologic study period for purposes of the groundwater analyses in the basin-wide water budgets. In order to select a consistent study period, the Kern County Subbasin GSAs agreed upon an historical hydrologic study period covering WY1995 through WY2014 (October 1, 1994 through September 30, 2014). The selection of the historical hydrologic study period was based on a variety of technical criteria including:

- Covers at least 10 years consistent with GSP regulations (§354.18(c)(2)(B)),
- Contains 10 years characterized as above normal or wet years based on precipitation; also contains 10 years of below normal or dry years, including four critically dry years,
- 100 percent of the long-term average streamflow conditions on the Kern River, as indicated by an average annual Kern River Index of 100 percent (**Figure 4**),
- About 104 percent of long-term average precipitation (NOAA Bakersfield Meadows Field Airport Station),
- Widely-available high-quality data available across the Subbasin,
- Time period with current water management practices, intensive groundwater banking operations, and more recent land use patterns,
- Begins in a time of relatively stable water levels (October 1994), and
- Overlaps a time period with consistently developed basin-wide contour maps by Kern County Water Agency (KCWA).

For the historical water budget, it is desirable to define a base period when natural hydrology represents average conditions. C2VSimFG-Kern incorporates this 20-year base period of WY1995 through WY2014 with a 10-year spin-up period (WY1985 to WY1994).

Kern County water agencies provided locally-derived water budget data for WY1993 to WY2015 for this study so that data input extended beyond the historical base period. Additional water budget data prior to WY1993 were also collected where available and input into the model.

The simulation period for C2VSimFG-Kern was set to WY1986 to WY2015 (October 1, 1985 through September 30, 2015), allowing a 10-year spin-before the start of the historical base period. The C2VSimFG-Beta simulation period ran from October 1973 through September 2015 (WY1974 to WY2015). The period from October 1973 to September 1985 was not included in the simulation due to concerns about lack of comparable data from these earlier periods.

3.3 Data Compilation

Participating agencies compiled water budget input data sets (using their staff, consultants or other resources) and provided them to Todd Groundwater. Where appropriate, Todd Groundwater developed data templates that conformed to IWFM model data needs and used them to facilitate obtaining input data from local agencies. This included monthly data for the following:

- Surface water imports and diversions (inflows and outflows) by source, conveyance and application area,
- Groundwater banking and managed aquifer recharge by water district or agency,
- Groundwater recovery pumping of groundwater bank recharge for export from the basin,
- Groundwater recovery pumping of managed aquifer recharge for local use,
- Urban area population and per capita water use, and
- Crop evapotranspiration (ET) rates based an analysis of satellite data (ITRC, 2017).

In addition, groundwater banking data were compiled for the large Kern Fan banking projects. Recently developed crop ET rates derived from remote sensing data were used to develop monthly crop ET rates for agricultural crops. Urban land use was restricted to developed areas, urban populations and per-capita water demands were updated, and urban wastewater recharge operations were added.

3.4 Surface Water

Kern County surface water diversions in C2VSimFG-Beta were grouped by project or water source, and some surface water deliveries were applied to large regions rather than to individual districts. In addition, some local surface water deliveries were missing from C2VSimFG-Beta. For C2VSimFG-Kern, the 43 Kern County surface water diversions from C2VSimFG-Beta were replaced with 113 surface water diversions developed with data provided by local agencies.

The Arvin-Edison WSD, Wheeler Ridge-Maricopa WSD and Tejon-Castaic WD overlie both the Kern County and White Wolf subbasins. Surface water deliveries for these districts were apportioned to either the Kern County and White Wolf subbasins, based on data provided by Arvin-Edison WSD and Wheeler Ridge-Maricopa WSD, so that surface water deliveries to those areas could be tracked separately for the water budgets.

3.4.1 River and Stream Inflow

Inflows to the Kern River and Poso Creek at the Subbasin boundary are based on historical gauge data. Kern River inflows at the First Point gauge and downstream gauges were verified and updated based on the annual Kern River Hydrographic Reports produced by the City of Bakersfield (COB, 1985-2015). C2VSimFG-Beta contained Poso Creek inflows for WY1961 to WY1986. Poso Creek inflows for WY1987 to WY2015, based from flow records for the Coffee Canyon and Trenton stream gauges, were added to C2VSimFG-Kern based on data provided by the local agencies.

3.4.2 Surface Water Diversions

Monthly surface water diversion data for WY1995 to WY2015 were collected for 21 agencies and recharge projects in Kern County. The data from each water district or agency included monthly surface water inflow by source and monthly surface water outflow by destination.

The monthly surface water inflow and outflow data collected for this study did not have sufficient detail to track this water and create an accurate historical water budget for each canal for each month. The data did provide sufficient information to identify monthly surface water diversions from each source and deliveries to each end use. Therefore,

- All diversions from the Kern River were exported from the model and treated as imports at delivery locations,
- Diversions from Poso Creek and the Kern River Flood Channel (or Main Drain) were diverted from the appropriate stream nodes, and
- All other surface water deliveries (State Water Project (SWP), Central Valley Project (CVP), oil field recovery water, etc.) were treated as imports.

Each C2VSim surface water diversion is linked to two groups of model elements: the elements of the end use and the elements receiving the recoverable losses. A single set of elements was used for both purposes in C2VSimFG-Kern. Model elements for agricultural, urban and refuge deliveries were selected by overlaying the model grid on delivery areas maps. Model elements for recharge diversions were selected by overlaying the model grid on recharge basin maps.

Monthly water delivery data for the SWP, CVP and Kern River were also provided by the agencies. Monthly turnout-level deliveries for the SWP were also compiled from the monthly SWP Report of Operations published by DWR. Monthly CVP deliveries were compiled from the USBR Report of Operations. Monthly Kern River flow and diversions were compiled from Kern River Hydrographic Reports. Water agencies in the Kern County Subbasin trade and wheel water in real time to maximize water utilization, minimize waste and energy consumption, and meet immediate water needs. Water delivery reports from water suppliers (such as the CVP and SWP) generally identify the owner of delivered water, not where it was actually delivered.

Some surface water conveyances discharge water into stream or river channels for re-diversion downstream. A key part of the surface water system in Kern County is the Kern River. Kern River operations data were reviewed for calendar years 1970 to 2015. While **Table 1** summarizes surface water deliveries, **Table 2** summarizes Kern River diversions by turnout location as applied in C2VSimFG-Kern.

3.4.3 Surface Water Deliveries

Water flow through the Kern River and its associated canal system is very complex. Water is diverted from the Kern River into a parallel canal system at several locations, with some diverted water flowing

back to the river. Some water from the CVP and SWP are discharged into the Kern River for diversion downstream. Some water agencies are served from multiple diversion points along the Kern River. Several canals that receive water diverted from the Kern River also exchange water with other canals and receive some water from groundwater pump-in, so deliveries from many canals cannot be attributed to a single source. **Figure 5** shows the locations of the primary streams, regional surface water canals, and groundwater recharge locations in the Kern County Subbasin.

Each surface water diversion in C2VSim is allocated to a specified destination and water use. Five water use types are simulated in C2VSimFG-Kern: agricultural, urban, refuge, recharge and export. Agricultural and refuge diversions are applied to a group of model elements that corresponds to a surface water service area within a specific water agency or refuge. Urban diversions are allocated to an urban service area. Groundwater recharge diversions are allocated to the model element or elements where the receiving recharge basin is located. Three delivery fractions apportion each surface water diversion to application, loss to groundwater (recoverable loss), and loss to evaporation (non-recoverable loss). **Table 1** summarizes the annual surface water deliveries for agricultural use by water district in Kern County. **Table 3** summarizes surface water diversions for urban use, wastewater land disposal and wildlife refuge management in Kern County.

3.5 Groundwater Banking and Managed Aquifer Recharge Operations

In our preliminary discussions with the C2VSim developers at DWR, it was revealed that significant model uncertainty was related to incomplete data regarding groundwater banking and other managed aquifer recharge (MAR) operations in the Kern County Subbasin. Recognizing the importance of these groundwater banking projects for simulating groundwater conditions, the groundwater banking and MAR operations data was updated using the earliest available records.

3.5.1 Recharge and Recovery Data

A monthly time-series of recharge rates was determined for each recharge project. Recharge rates were allocated to individual recharge basins using the initial data whenever possible or were shared proportionally between basins based on historical rates. All Kern County recharge basin surface water deliveries were simulated as imports.

Recharge basin locations and recovery well locations were provided by each agency or project (**Figure 6**). The C2VSim finite element grid was overlaid onto a map of recharge basins to determine the model elements for each recharge location. Well location coordinates were added to C2VSimFG-Kern.

Monthly volumes for recharge at groundwater banking and managed aquifer recharge facilities were compiled for 16 agencies and projects (**Table 4**). This information originated from multiple sources, and included data provided by agencies, compiled from agency reports, and compiled from Kern River Hydrographic Reports. The data includes monthly recharge for years prior to 1995 for many projects. Several agencies and projects provided data for multiple recharge basins. Some groundwater wells used for recovery of banked water are also used for other purposes such as supplementing agricultural or urban surface water deliveries.

Recognizing that several of the large groundwater banking projects (especially those on the Kern Fan) pre-date the 20-year base period, and that future studies might simulate periods prior to 1985, all available historical data for groundwater banking operations was reviewed and updated. This included incorporating pre-1985 data for banking operations at

- Arvin-Edison WSD (1966-2015),
- Berrenda Mesa Project (1977-2015),
- Buena Vista WSD (1963-2015),
- City of Bakersfield 2800 Recharge Facilities (1973-2015),
- North Kern WSD (1956-2017), and
- Rosedale-Rio Bravo WSD (1980-2015).

3.5.2 Groundwater Recovery

Two types of recovery wells were added to the C2VSimFG-Kern. These include district-operated water wells that were used for out-of-district transfers or out-of-basin exports of groundwater, and wells used for recovering banked groundwater and distributing the pumped groundwater via the district's water conveyance system to provide water supply, typically for agricultural use, within the district. The locations of the specified groundwater recovery wells are shown on **Figure 6**. The specified groundwater recovery pumping input into C2VSimFG-Kern is summarized as follows:

- 229 time series for Kern County groundwater banking withdrawals were added,
- 313 simulated pumping wells and 225 pumping time series for local groundwater pumping by district-operated recovery wells were added, and
- Elemental agricultural, refuge and urban pumping was eliminated in areas where it has not historically occurred.

Recharge and withdrawal data for the Kern Fan banking projects, including the Kern Water Bank, Berrenda Mesa Project, Pioneer Project, and the City of Bakersfield 2800 Recharge Facilities were shared with the local banking authorities for verification. Banking data for district-specific groundwater banking projects were provided by these districts. A summary of the data input for groundwater recovery pumpage added to C2VSimFG-Kern is provided in **Table 5**.

3.5.3 Model Application

A separate diversion was created to deliver surface water to each recharge basin or set of geographically close jointly managed basins. A diversion time series of monthly application rates was then created for each recharge diversion from the available data. Each recharge diversion delivers water to the model elements coinciding with the receiving recharge basin(s). Recharge basins were simulated in C2VSimFG-Kern by setting the application delivery fraction to zero, the recoverable loss fraction to 94% and the evaporation loss to 6%.

Monthly groundwater recovery was generally provided by well field and destination (e.g., agriculture, urban, canal pump-in, or export). This information was used to develop a pumping time series for each well field and destination. Groundwater pumped for export from the Kern County Subbasin is summarized in **Table 6**. Recovery well locations and screen intervals were used to enter each recovery well into C2VSimFG-Kern. Recovery pumping time series were then allocated equally to all of the wells in each field.

Some well fields supply water to two different end uses, for example supplementing surface water deliveries within the district in some months and exporting water from the district in other months. This is handled in C2VSimFG-Kern by entering the well two times. Each entry is associated with a separate time series of pumping rates and delivery destination.

3.5.4 Groundwater Banking Obligations

The general operation of groundwater banking facilities is to recharge excess available surface water supplies during wet years by recharging to the groundwater and recovering this water by pumping in dry years when surface water supplies are limited. Groundwater banking programs store water in the Kern County Subbasin for use by local agencies and for export to out-of-basin entities.

For evaluating the groundwater sustainability, any water stored in the Kern County Subbasin that is contractually obligated to an out-of-basin entity does not contribute to the long-term groundwater sustainability because the owner of that water could call for its return at any time. However, this can be difficult to track because a common practice is to recover groundwater for local use to replace imported surface water that was sent to the out-of-basin entity.

C2VSimFG-Kern does not have a mechanism to track these complex contractual exchanges, so the tracking is done as a post processing step by assigning the portion of the groundwater recharge as an out-of-basin banking obligation.

The Kern County Subbasin GSAs provided the total out-of-basin banking obligation for their operations as of September 2014 for the historical assessment. As of September 2014, the out-of-basin banking obligation for the Kern County Subbasin totaled of 1,719,307 acre-feet, which, when averaged over the 20-year period, was 85,965 acre-feet per year (AFY). The 85,965 AFY is applied during post-processing of C2VSimFG-Kern historical water budget results.

3.6 Urban Water Demand

C2VSim calculates urban water demands for specified urban delivery zones, allocates specified surface water and groundwater supplies to meet these demands, and can optionally pump additional groundwater to satisfy unmet urban demands in each zone. Urban demands were represented with nine urban zones in C2VSimFG-Beta. These zones were reconfigured, and a tenth urban zone was added representing Metropolitan Bakersfield in C2VSimFG-Kern. Historical urban populations and per capita water use rates were reviewed and updated.

3.6.1 Urban Zones

C2VSimFG-Kern dynamically calculates urban water demands for urban zones using time-series data of urban populations and monthly per capita water use. The urban delivery zones of C2VSimFG-Beta were modified to better represent Kern County population centers, jurisdictional boundaries and urban water sources. Although Kern County urban water delivery systems are operated by many diverse entities, their water generally comes from two sources: surface water deliveries and agency-operated groundwater wells.

The nine Kern County urban zones in C2VSimFG-Beta for Kern County were numbered 97-105. The Urban Zone boundaries were adjusted, as shown on **Figure 7**, as follows:

- Portions of Urban Zones 97, 99, 100, and 102 in C2VSimFG-Beta were used to create Urban Zone 106 representing the Metropolitan Bakersfield area,
- Urban Zone 98 was extended southeast to near the Stockdale Highway to include unincorporated urban areas,
- The boundary of Urban Zone 99 was extended eastward to California State Route 65 to include small communities in this area, removing them from Urban Zone 100, and

- The northern boundary of Urban Zone 104 was moved north to correspond to the West Kern WD service area.

3.6.2 Urban Population and Per Capita Use

Historical annual urban populations for the urban zones were estimated using United States Census total population data from 1990, 2000 and 2010 (US Department of Commerce, 2018). Tabular historical census data and census block shapefiles were obtained from the IPUMS National Historical Geographic Information System Database (IPUMS 2018). These data were combined to produce maps of the geographic distributions of populations within Kern County. The historical populations for each Urban Zone were estimated by mapping census block centroids to the ten Urban Zones using ArcGIS. The 1990, 2000 and 2010 populations of each Urban Zone were then estimated as the sum of the populations of the associated census blocks. Populations for other years were estimated using interpolation and extrapolation. The population values by Urban Zone used for C2VSimFG-Kern are listed in **Table 7**.

3.6.3 Urban Water Use Specifications

Monthly historical urban water demands for Urban Zone 106 were calculated using water delivery data from the water purveyors in the Metropolitan Bakersfield area. Monthly historical urban water demands for the other urban zones in the Kern County Subbasin were estimated using available water use data from published urban water management plans for the communities served in those zones. The historical monthly water use in each zone was then divided by the historical population to obtain the monthly per capita urban water demand. Monthly historical per capita water demands for zones without urban water management data were estimated using the per capita water demand from zones with similar demographics.

The urban water use specifications indicate the portion of total urban water that is used indoors. In C2VSimFG-Kern, the portion used indoors becomes urban return flow, and the remainder is added to the urban root zone where it contributes to evapotranspiration and deep percolation. C2VSimFG-Beta included monthly urban water use specifications for each model subregion. The urban per capita water use was based on local water supply data and urban water management plans. **Table 8** lists the per capita water use data used for C2VSimFG-Kern.

3.6.4 Urban Wastewater

Urban wastewater for the Metropolitan Bakersfield area is treated at local wastewater treatment plants; however, wastewater disposal is primarily evaporation ponds or land disposal at locations outside of the Metropolitan Bakersfield area. C2VSimFG-Beta does not have a direct means to redirect wastewater to an outside location. Urban wastewater, based as the indoor use, is applied uniformly within the urban zone. To get around this limitation, application of wastewater for the Metropolitan Bakersfield area was turned off in C2VSimFG-Kern. The wastewater deliveries to evaporation ponds and land disposal areas from the wastewater treatment plants was assigned to the appropriate location using data provided by the plants. This conserved the water balance by not double counting wastewater, and it was applied at the appropriate locations for evaluating groundwater levels.

3.6.5 Model Application

Historical annual urban population estimates were placed in the C2VSimFG-Kern urban population input file. Historical monthly urban per capita water demand estimates for each urban zone were placed in the C2VSimFG-Kern urban per capita water use file. Urban demand was calculated by C2VSimFG-Kern and the water supply to meet these demands was met first by specified surface water and groundwater

pumping deliveries for urban use. The remaining water demand in each model element was met with groundwater pumped from the aquifer portion of that element.

3.7 Agricultural Crop Water Demand

C2VSim dynamically calculates agricultural crop water demands and allocates supplies to meet these demands for each model element. Agricultural demands are calculated for 20 crops using historical crop acreage data and crop evapotranspiration (ETc) rates. Crop water demands in each model element are first met with stored soil moisture, surface water deliveries and specified groundwater deliveries. If the agricultural demands are not satisfied, the model can optionally calculate the additional groundwater pumping required to satisfy the unmet demands and extract that water from the groundwater component of the model element.

C2VSimFG-Beta contained one set of monthly ETc rates for each model subregion that were applied to all years despite climatic variation. New monthly ETc rates for three model subregions (northeast, northwest, south) in Kern County were calculated for 1993-2015 using monthly remote sensing imagery and detailed annual crop maps. ETc for 1974-1992 were estimated from 1993-2015 values by using the values for similar water year types based on the San Joaquin Index. Satellite data were not available for 2012, so ITRC was unable to provide METRIC data for 2012. In C2VSimFG-Kern, 2013 was applied as an appropriate proxy for ETc data in 2012 because of their hydrologic similarity.

A remote sensing study of historical ETc rates across the entire Kern County Subbasin by the Irrigation and Training Research Center (ITRC, 2017) provided detailed basin-wide agricultural demands that corresponded to the WY1995 to WY2014 base period. These data were used to develop monthly ETc rates for the Kern County portion of the model.

3.7.1 ET Rates

The Irrigation Training and Research Center (ITRC) at California Polytechnic State University, San Luis Obispo, has developed a procedure to use remote sensing imagery from Landsat satellites to calculate historic ETc rates (ITRC, 2017). The Mapping of Evapotranspiration with Internal Calibration (METRIC) method was originally developed by Richard Allen of the University of Idaho. ITRC made several modifications to the original METRIC method to better match California data and conditions (named the ITRC-METRIC method). These modifications include using grass for reference evapotranspiration (ETo), incorporating a semi-automated calibration procedure and spatially interpolating ETo rates. An example of the METRIC ET data for the total annual ET in 2013 is provided in **Figure 8**.

ITRC used Landsat imagery for 1994-2015 (except 2012 when no imagery was available) and the ITRC-METRIC method to develop monthly raster maps of ETc at 30 x 30-meter resolution for the Kern County portion of the Central Valley (ITRC, 2017). The monthly ETc raster maps were used with annual DWR crop maps to calculate the average ETc by crop type for the three Kern County C2VSim subregions. ITRC-METRIC raster data were used to determine the exact areas of applied irrigation and total annual ETc. A raster pixel was assumed to be irrigated if the total annual ETc was greater than 20 inches.

The following data processing steps were used to determine monthly ETc rates for each crop and C2VSim subregion:

- Create irrigation coverages – ITRC-METRIC monthly ETc raster data were summed to calculate total annual ETc for each year for each raster location. The ArcGIS Reclassify tool was then used on each annual ETc raster to create a binary polygon coverage for each year for 1994-2015

(except 2012), setting the attribute "IRR" to 1 if total annual ETc was over 20 in/year, and to 0 if total annual ETc was equal to or less than 20 in/year.

- Create land use coverages – Annual DWR land use rasters were converted to polygon coverages with the attribute "Crop" set to the corresponding integer crop value used in C2VSimFG-Kern. The land use rasters were checked against GIS maps produced by the Kern County Agricultural Commissioner and errors in the DWR land use rasters were corrected. DWR land use maps for 1994-1997 were missing large areas of data, so the 1998 land use map was used to approximate the land use for 1994-1997.
- Create monthly zone maps – One zone shapefile was created for each month by using the ArcGIS Union tool to combine a shapefile of the three C2VSim subregions with the irrigation coverage (produced in step 1) and the land use coverage (produced in step 2). Each monthly zone polygon shapefile has three attributes: C2VSim subregion, binary irrigation indicator, and a land use crop value. The dissolve function was used to combine zones with identical parameters.
- Calculate average monthly ETc for each zone – The ArcGIS Zonal Statistics by Table tool was used to calculate the average ETc value for each zone for each month. The individual pixels in each monthly ETc raster were averaged within each zone (produced in step 3). ITRC-METRIC data for 2013 were used in place of missing data for 2012.
- Combine tables – The MS Access Append function was used to combine the monthly ETc tables into a master table of monthly ETc by crop and C2VSim subregion.
- Output data – Data from the Access database was exported in a form consistent with the C2VSimFG-Kern input files. The output was also summarized to show the average monthly ETc for the irrigated area of each crop type in each model subregion.

The monthly ETc rates for the three Kern County subregions for WY 1993-2015 were then replaced with the monthly ETc rates calculated using ITRC-METRIC data. The annual ETc rates applied to C2VSimFG-Kern by crop are listed in **Table 9**.

3.7.2 Irrigation Periods

The C2VSim Irrigation Periods file contains monthly parameters for each crop and subregion that indicate whether or not the crop is irrigated in that month. C2VSimFG-Beta irrigation periods for the three Kern County subregions were adjusted to match crop irrigation practices from ITRC-METRIC water usage. Refuge irrigation periods for the three Kern County subregions were also adjusted to match Kern NWR practices. Simulated irrigation water usage for the C2VSimFG-Kern better reflects observed irrigation practices.

3.8 Model Modifications

In general, the scope of work was to revise the managed water supply and demand for the Kern County Subbasin. During the course of this revision, several issues were identified with the hydrogeological conceptual model and simulation parameters that affected the historical water budget. The following summarizes modifications made in C2VSimFG-Kern to improve the model performance. Other issues identified regarding the hydrogeological conceptual model, model setup and simulation parameters that were not addressed in C2VSimFG-Kern but are recommended to be modified for future model updates, are listed in Section 8.5. A summary of the changes that were made in C2VSimFG-Kern are provided below.

3.8.1 Streambed Parameters

In the Kern County Subbasin, the Kern River and Poso Creek are the two largest streams. Both have multiple stream gauges along their courses including ones near where they enter the Kern County Subbasin from the Sierra Nevada. These are the only two streams that are simulated in the model using the IWFM stream module. Both are predominantly losing streams where surface water recharges groundwater, except during limited periods near the major groundwater banking operations west of Bakersfield when multi-year periods of recharge operations produce high groundwater levels.

As a part of the C2VSimFG-Kern update, the simulated recharge from the Kern River and Poso Creek were compared to changes in stream gauge measurements and estimated streambed losses to evaluate how well the model was simulating streambed seepage. For much of the Kern River, the amount of streambed seepage is estimated based on daily weir information and is documented in the annual Kern River Hydrographic Reports. The streambed parameters used in C2VSimFG-Beta were not providing a comparable volume and distribution of seepage along the Kern River streambed. In dry years, streamflow as not getting far enough downstream whereas in wet years the seepage was too low. Similarly, the Poso Creek streambed seepage showed similar issues based on comparisons to differences in stream gauge data along its course.

To address this, the Kern River and Poso Creek streambed parameters were manually modified until a reasonable approximation of the measured streambed seepage was achieved by C2VSimFG-Kern. In general, the streambed conductance was lowered whereas the stream wetted perimeter was increased. This provided the best balance in matching the measured dry, average and wet years flows in both streams.

Part of this issue is that C2VSimFG-Beta uses a simple form of the stream module in the simulation. This approach appears to work sufficiently well for the continuously flowing streams in the northern parts of the Central Valley but is not sufficient for simulating the highly variable flows that occur on the Kern River and Poso Creek. It is recommended that future revisions to C2VSimFG-Kern further evaluate issues in simulating streamflow and seepage in the Kern River and Poso Creek (see Section 8.5). This may include incorporating more advanced streamflow simulation features that are available in IWFM but that have not been utilized in C2VSimFG.

3.8.2 Small Watershed Runoff

In reviewing the small watershed contributions, it was determined that the runoff was not representing the variable nature of runoff in an arid region. Although this was not part of the originally planned model revisions, it affected the model results. Todd Groundwater revised the corresponding model parameters to be more representative of the local arid conditions in Kern County.

Runoff of precipitation from the surrounding small watersheds was calculated within C2VSimFG-Kern using methodology included in IWFM that is based on the SCS Curve Method (NRCS, 2004). The C2VSimFG-Beta results showed a steady baseflow that contributed water to the Kern County Subbasin continuously and did not show the appropriate variation in runoff expected between wet, average and dry years in the arid environment.

Two major issues were identified and revised. First, the SCS curve number was changed to allow a higher percentage of runoff in wet years to capture the flashy nature of runoff from these watersheds during differing climatic conditions. Second, IWFM uses a localized soil moisture water budget; however, soil, ET and other parameters were set that allowed for the continuous outflow from the

basins. These were changed to more appropriate values that limited baseflow from the very small watersheds while allowing baseflow from the larger watersheds. Parameters were varied to better match estimated watershed runoff from a local USGS study (Nady and Larragueta, 1983).

3.8.3 Root Zone Parameters

Areas of overly high root zone hydraulic parameters led to high volumes of deep percolation that required additional groundwater pumping to meet the overall water demand for irrigation. This issue was noted by local water district staff who recognized that the groundwater pumping and deep percolation from preliminary model results were significantly higher than what was found in practice. A review found areas of overlying hydraulic conductivity and other hydraulic parameters that caused this high percolation rate. Two types of issues were found. First, very high parameters were found in parts of the basin that were not consistent with local soil data. Second, the root zone parameters for lakebed and other heavy clay soil areas were too high. These areas were manually adjusted to be more in line with observed conditions. A more rigorous development of root zone parameters should be considered in the future as this issue demonstrates that it is a sensitive parameter.

3.8.4 Land Use Modifications

The agricultural land use and crop type distribution in the model for early period (1974-1990 and 1992-1996) from C2VSimFG-Beta used a regional distribution and did not accurately represent historical practices. This resulted in agricultural water use being distributed across the entire Kern County Subbasin including areas that did not have irrigated agriculture. To correct for this, land use and crop type data were modified to conform with irrigated agricultural areas in the early 1990s. The crop types were adjusted to be consistent with the Kern County Agricultural Commissioner reports for these years. This included capturing the appropriate crop types present in the Kern County Subbasin in the periods from 1974 through 1996. For example, there was a higher percentage of cotton produced during that period and a lower percentage of nut trees, which became one of the major crop types in the 2010s.

3.8.5 Westside Pumping Limits

Western Kern County contains large areas with poor groundwater quality. As a result, little or no agricultural or urban groundwater pumping occurs in this area. To simulate this, groundwater pumping was turned off in C2VSim-Kern in most of the area with poor groundwater quality. However, in the Westside District Water Authority Management Area, limited groundwater pumping does occur. The poor-quality water is mixed with surface water to supplement the imported water supply. To simulate this condition, the groundwater pumping rate in the Westside District Water Authority Management Area was estimated to be 10% of the surface water deliveries, and the automated groundwater pumping adjustment in C2VSimFG-Kern was turned off for these areas.

Subsequent to the completion of the historical model, GSP developers in the Westside area refined their estimate of pumping used to mix with delivered surface water to about 3,000 AFY, which is considerably lower than that used in the historical model. The Westside GSP developers included a management action to further refine the estimated groundwater use in the Westside GSP water districts. Therefore, the original assumption was left in this version of the historical model. The Westside District Water Authority Management Area GSP identifies a management action to further evaluate the groundwater pumping in their area. The results of their evaluation will be included in in future model updates.

3.8.6 Kern Wildlife Refuge pumping

C2VSimFG-Beta enabled groundwater pumping in the model elements representing the Kern National Wildlife Refuge. The Kern National Wildlife Refuge Water Management Plan (USBR, 2011) indicates that

during the simulation time period, the refuge was sustained entirely on imported surface water and occasional diversions of Poso Creek flood waters. No groundwater was pumped at the refuge during the simulation period 1985-2015. Groundwater pumping was used at some time in the past. Groundwater pumping and automated groundwater pumping adjustment were turned off for all model elements in the Kern National Wildlife Refuge.

In addition to the Kern National Wildlife Refuge, former rice fields and other areas are currently used for sustaining ponds at private duck hunting clubs in the northwestern portion of the Kern County Subbasin. Water use data for these operations were not available during the development of the historical model. This water includes a combination of surface water and groundwater, and this volume is considered to be very small relative to the overall basin water use. GSP developers included a management action to further refine the estimated water use for these facilities that will be addressed in future updates.

3.9 C2VSimFG-Beta Modifications

Minor changes were made to the C2VSimFG-Kern hydrogeological conceptual model and natural water budget components and are listed in **Table 10**. The architecture of the model including layering, discretization, boundary conditions, and aquifer properties was not revised. Aquifer parameters were adjusted in several areas to better match observed historical conditions, especially in areas with high historic recharge volumes such as the Kern Fan. Extremely high soil hydraulic conductivities in a small set of elements were reduced to more reasonable values. Stream-bed conductance values were modified in some stream reaches to better match simulated stream gains and losses to observed values. Minor adjustments to small watershed parameters were also made to match surface runoff to observed values.

Due to the number of modifications that were identified with the hydrogeological conceptual model and aquifer parameters during the C2VSimFG-Kern update, it is recommended that a more rigorous model update be conducted that will update the hydrogeological conceptual model and aquifer parameters to be consistent with that presented in the Kern County Subbasin GSPs. In addition, further calibration of C2VSimFG-Kern is recommended to update aquifer parameters in the Kern County Subbasin. Future calibration is further discussed in Section 8.5.

4. HISTORICAL AND CURRENT WATER BUDGETS FROM C2VSIMFG-KERN

C2VSimFG-Kern was used to develop historical (WY1995 to WY2014) and current (WY2015) water budgets for the Kern County Subbasin. The following summarizes the simulated water budgets from C2VSimFG-Kern. A summary of these results is provided below.

4.1 Historical and Current Water Budget

The simulated historical and current water budgets based on C2VSimFG-Kern are presented in **Tables 11A** and **11B** and are presented graphically on **Figures 9**. **Figure 10** presents the average annual historical water budget for the Kern County Subbasin. The results for the historical water budget are summarized under the following categories that are defined as:

- **Deep Percolation** – Precipitation and applied water that reaches the groundwater after simulated transport across the unsaturated zone. The simulated historical 20-year average is a net inflow of 669,398 AFY.
- **Managed Recharge and Canal Seepage**- Combined groundwater recharge from managed aquifer recharge operations, groundwater banking, and seepage from canals and other conveyance. The simulated historical 20-year average for Managed Recharge and Canal Seepage is a net inflow of 583,598 AFY. On Figure 10, this total is subdivided between out-of-basin groundwater banking obligations (85,965 AFY) and the remaining local recharge of 497,633 AFY.
- **Net Groundwater-Surface Water (GW/SW) Interactions** - Net volumetric exchange of surface water and groundwater between the aquifer and streams: Positive represents a net groundwater recharge, and negative represents a net groundwater discharge to the stream. The simulated historical 20-year average is a net inflow of 98,606 AFY.
- **Small Watershed Inflow** – Runoff, small stream inflow and subsurface inflow from the small watersheds and areas surrounding the groundwater basin. The simulated historical 20-year average is a net inflow of 48,760 AFY.
- **Groundwater (GW) Pumping** - Total groundwater pumping by wells. Groundwater banking recovery pumping is specified as fixed input values and agricultural and municipal pumping is calculated by C2VSimFG-Kern based on demand minus surface water diversions. The simulated historical 20-year average is a net outflow of 1,590,373 AFY.
- **Subsurface Flow with Adjacent Groundwater (GW) Basins** - Net subsurface groundwater flow to and from the Kern County Subbasin with adjoining groundwater basins: negative is a net flow out of the Subbasin and positive is a net flow into the Subbasin. The simulated historical 20-year average is a net outflow of 87,102 AFY.
- **Change in Groundwater Storage** - Sum of the inflow components (positive numbers) plus the outflow components (negative numbers): positive is an increase in storage typified by a rise in groundwater levels whereas a negative is a decrease in storage typified by a decline in groundwater levels. The simulated historical 20-year average is a decline in groundwater storage of 277,114 AFY.

The simulated change in groundwater storage varies over the 20-year historical period and is closely related to climatic conditions and surface water supply availability (**Figure 11**). During the periods

WY1995 to WY1999, WY2005 to WY2006 and WY2011, the groundwater storage volume was stable to increasing and correlates to the above average rainfall and surface water availability during these times. During the periods WY2000 to WY2004, WY2007 to WY2010 and Y2012 to WY2015, groundwater storage volume decreased, correlated to periods of drought and low surface water availability. The simulated historical groundwater recharge also reflects this climatic pattern with high deep percolation to groundwater and steep increases in managed aquifer recharge and canal seepage during the above average rainfall periods and lower groundwater recharge during the drought years (**Figure 12**).

Groundwater pumping for agriculture shows a general increasing trend from WY1995 to WY2014; however, groundwater pumping is lower in above average rainfall years and higher during droughts (**Figure 13)**. This general increasing trend follows a comparable decreasing trend in surface water deliveries over this same period. As shown on **Figure 14**, surface water deliveries show a general decreasing trend from WY1995 to WY2014; however, the surface water deliveries are higher in the above average rainfall years and lower during the droughts.

4.2 Sustainable Yield

Section 354.18(b)(7) of the GSP Regulations requires that an estimate of the basin's sustainable yield be provided in the GSP (or in the coordination agreement for basins with multiple GSPs). SGMA defines "sustainable yield" as:

> "the maximum quantity of water, calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result."

SGMA does not incorporate sustainable yield estimates directly into sustainable management criteria. Sustainable yield is referenced in SGMA as part of the estimated basinwide water budget and as the outcome of avoiding undesirable results. Basinwide pumping within the sustainable yield estimate is neither a measure of, nor proof of, sustainability. Sustainability under SGMA is only demonstrated by avoiding undesirable results for the six sustainability indicators.

4.2.1 Determination of Sustainable Yield

To determine the sustainable yield for the Kern County Subbasin, the results of the C2VSimFG-Kern model were used with two methods to estimate the amount of groundwater pumping that would avoid the undesirable result of a reduction in groundwater storage over the historical base period 1995 to 2014. The results are shown in **Table 12** and are summarized below:

- **Sustainable Yield from Groundwater Pumping –** The model results produced an average annual groundwater pumping in the Kern County Subbasin of 1,590,373 AFY with a decline in groundwater storage of 277,114 AFY. Subtracting the groundwater storage decline from groundwater pumping produced a sustainable yield of approximately 1,313,000 AFY.

- **Sustainable Yield from Groundwater Recharge –** The model results produced an average annual groundwater recharge in the Kern County Subbasin of 1,400,362 AFY. The subsurface outflow from the GSA was estimated to be 87,102 AFY. Subtracting these outflow losses from the groundwater recharge produced a sustainable yield of approximately 1,313,000 AFY.

Sustainable yield estimates are part of SGMA's required basinwide water budget. In general, the sustainable yield of a basin is the amount of groundwater that can be withdrawn annually without causing undesirable results. This sustainable yield estimate can be helpful for evaluating the projects and programs needed to achieve sustainability. Although the SGMA regulations require a single value of sustainable yield calculated basinwide, it should be noted that the sustainable yield can be changed by implementation of recharge projects, variations in climate, or changes in stream flow conditions.

Using WY1995 to WY2014 as the base period, C2VSimFG-Kern results show declining groundwater levels and long-term reduction of groundwater storage. During this period, average annual inflow to the aquifer is 1,400,362 AFY, and outflow is 1,677,476 AFY (**Table 11A**). This yields an average annual deficit of 277,114 AFY. Based on these historical C2VSimFG-Kern results, the sustainable yield of the basin is approximately 1,313,000 AFY, with an estimated level of uncertainty on the order of plus or minus 10% to 20%.

4.2.2 Native Yield

Although not a SGMA requirement, the native yield is being used by Kern County GSAs for determining a portion of the groundwater allocation within the basin. The native yield is comparable to the sustainable yield except that the only recharge that is included in the calculation is the natural, unallocated portion of the groundwater recharge. For the Kern County Subbasin, this includes the groundwater recharge derived from precipitation and runoff from unallocated streams. The Kern River and Poso Creek, however, are allocated streams where specific agencies or parties have rights to specific volumes of flow.

The C2VSimFG-Kern model results over the historical base period WY1995 to WY2014 was again used for estimation of native yield. The model results were used to determine the amount of precipitation recharge over irrigated agricultural areas and the native/urban/undeveloped areas. The total and average annual volume of precipitation that percolates to groundwater during the WY1995 to WY2014 base period are listed in **Table 13**. The basinwide contribution is the relative proportion of the runoff along the basin margins from small, unallocated watersheds and inflow from the surrounding basin margin (from areas not defined as DWR groundwater basins). The results of this assessment based on the C2VSimFG-Kern results are shown in **Table 13** and are summarized below:

- The volume of precipitation that recharges the groundwater in the irrigated agricultural areas is 77,780 AFY.
- The volume of precipitation that recharges groundwater in the other areas is 132,981 AFY.
- The volume of inflow from unallocated small watersheds that recharges the groundwater in the irrigated agricultural areas is 48,760 AFY.

Totaling these inputs results in a native yield for the Kern County Subbasin of 259,520 AFY. The annual contribution per acre of approximately 0.144 acre-feet per acre is estimated by dividing the average annual contribution by the total area of the Kern County Subbasin (**Table 13**).

Similar to the sustainable yield, the native yield at this time is based on the available data. However, as data gaps are eliminated and management actions/plans are implemented, the native yield could change, and any changes to native yield will be included in future GSP amendments.

4.2.3 Application of Sustainable and Native Yield

In general, the sustainable yield of a basin is the amount of groundwater that can be withdrawn annually without causing undesirable results. The native yield is comparable to the sustainable yield except that the only recharge that is included in the calculation is the natural, unallocated portion of the groundwater recharge. The following estimates of the Kern County Subbasin sustainable and native yields are derived from the C2VSimFG-Kern historical model results for the purpose of supporting GSP assessment of the types and magnitude of projects and programs needed to achieve sustainability.

The C2VSimFG-Kern estimates of sustainable and native yield presented here are based on available data and the current level of model calibration. Therefore, these estimates are considered appropriate as guides to SGMA planning. However, the C2VSimFG-Kern sustainable and native yield estimates are initial water budget estimates that are not intended for determination of individual landowner allocations or groundwater rights. Additional technical and legal analysis, along with stakeholder involvement, is necessary to fully quantify the sustainable and native yields.

5. APPROACH FOR PROJECTED FUTURE WATER BUDGETS

Projected future Baseline water budgets for the Kern County Subbasin were developed using the C2VSimFG-Kern. These projected water budgets establish expected Baseline conditions to evaluate the impacts of GSP implementation. Three predictive scenarios were developed for the Kern County Subbasin, each representing a different expected future hydrologic condition, by adapting C2VSimFG-Kern as follows:

- Future Baseline Conditions: Repeat historical hydrology with expected future water supply,
- 2030 Climate Conditions: Adjust historical hydrology for 2030 climatic conditions and expected water supply, and
- 2070 Climate Conditions: Adjust historical hydrology for 2070 climatic conditions and expected water supply.

Projected future water budgets were developed for Baseline conditions and expected 2030 Climate Conditions and 2070 Climate Conditions over a 50-year planning and implementation horizon. These scenario models provide a basis of comparison for evaluating proposed sustainability management actions and projects over the SGMA planning and implementation horizon.

5.1 Assumptions

C2VSimFG-Kern was modified to incorporate projected future hydrology and land use using analog data from the historical C2VSimFG-Kern model. This approach meets GSP requirements using:

- A 50-year time-series of historical precipitation, evapotranspiration and stream flow information as the future Baseline hydrology conditions,
- The most recent land use, METRIC-based evapotranspiration, crop coefficient and urban population growth information as the Baseline condition for estimating future water demands,
- The most recent water supply projections as the Baseline condition for estimating future surface water supply,

- DWR Climate Change Guidance and Data Sets to incorporate estimated climate change conditions for the Kern County Subbasin,
- Specialized analysis of the Kern River watershed and estimated runoff volumes under climate change conditions,
- Specialized analysis of CVP deliveries to Kern County under climate change conditions incorporating implementation of the San Joaquin River Restoration Program, and
- Specialized analysis of SWP deliveries to Kern County under climate change conditions incorporating implementation of the OCAP Biological Opinion and recent changes in Table A and Article 21 allocations.

5.2 Projected Future SGMA Projects

Projected water budgets for the Kern County Subbasin were developed using the C2VSimFG-Kern to evaluate the performance of proposed management actions with respect to achieving groundwater sustainability. Participating agencies provided a list of projected future management actions to be implemented between WY2021 and WY2040. These projects were simulated under Baseline conditions, 2030 Climate Conditions and 2070 Climate Conditions through WY2070 using the C2VSimFG-Kern.

Proposed future projects and management actions were provided by GSAs. The types of proposed SGMA projects and management actions are summarized as follows:

- Demand Reduction is the volume of water reduced by changing the land use; these include:
    - Agricultural demand reduction projects through incentives or actions to reduce crop water use,
    - Fallowing of agricultural land and conversion of agricultural land to recharge basins, and
    - Conversion of agricultural land to urban land.
- New Supply groups together planned increases in imported water supplies; these include:
    - Increased surface water imports generally resulting from projected water purchases,
    - New water conveyance facilities including pipelines and reservoirs to increase flexibility, and
    - Expansion of surface water delivery areas to reduce groundwater usage.
- Other Supply groups together proposed projects to increase local water supplies; these include:
    - Recharging treated waste waters derived from both urban areas and oil production operations; increased recharge occurs in both existing and new locations,
    - Increased stream flow diversions; these include exercising riparian water rights and diverting flood flows,
    - Reallocation of water; generally reducing sales of surface water and banked groundwater and using this water within the agency, and
    - Brackish groundwater in areas not currently overdrafted will be treated and mixed with surface water to augment surface water supplies.

Some management actions are implemented gradually over many years, with savings increasing each year over the implementation period. Some management actions are implemented only in certain years (wet years, for example). The anticipated average-annual water supply benefit of the proposed SGMA projects and management actions steadily increases over the 20-year period from WY2021 to WY2040 to represent the implementation of the Kern County Subbasin GSPs. This increasing trend, as shown as

the average-annual water supply benefit over five-year increments on **Figure 15**, is summarized as follows:

- about 116,000 AFY over the first five-year period (WY2021-WY2025),
- about 216,000 AFY over the second five-year period (WY2026-WY2030),
- about 343,000 AFY over the third five-year period (WY2031-WY2035), and
- about 361,000 AFY over the fourth five-year period (WY2036-WY2040).

The anticipated water supply benefit of the proposed SGMA projects and management actions included in the C2VSimFG-Kern projected future simulations is 422,000 AFY over the period from WY2041 to WY2070. Benefits of implementing these projects and management actions over the 20-year implementation period are summarized in **Figure 15**.

6. PROJECTED FUTURE BASELINE DEVELOPMENT

Projected water budgets are required by GSP regulations to represent future conditions over a 50-year GSP planning and implementation horizon. A Baseline condition was developed that projects water supply, demand and operations based on current land use and expected water supply availability over 50 years. The Baseline then serves as a basis of comparison for evaluating proposed sustainability management actions and projects for achieving sustainability over the planning and implementation horizon. Each predictive scenario model simulates the 50-year planning and implementation period WY2021 to WY2070. Development of the projected future Baseline conditions is summarized below.

6.1 Projected Future Time Period Development

WY1995 to WY2014 was chosen as a historical hydrology period because detailed demand and supply data are available for this period, and most Subbasin water delivery infrastructure was fully developed by the middle of this period. The average Kern River inflow for this period is also very close to the long-term average Kern River inflow.

The projected future simulation period is based on repeating the WY1995 to WY2014 historical study period. This period is only 20 years long, so a 50-year sequence of historical hydrology was developed by repeating data from this period in the sequence as shown in **Table 14**. The development of this sequence is summarized as follows:

- Simulation period WY2021 to WY2032 used the historical period WY2003 to WY2014,
- Simulation period WY2033 to WY2052 used the historical period WY1995 to WY2014, and
- Simulation period WY2053 to WY2070 used the historical period WY1995 to WY2012.

This sequence was developed to match long-term average flows on the Kern River, and to ensure that the Baseline does not end in an extreme drought or extreme wet year. By starting the projected future simulation time sequence with WY2003, the 50-year hydrology period has approximately 100 percent of the long-term average streamflow conditions on the Kern River, as indicated by an average annual Kern River Index of 100 percent. The sequence includes the appropriate range of hydrologic conditions including extremely wet years and extended periods of drought.

C2VSimFG-Kern simulation results for the last timestep of the historical simulation (September 30, 2015) were used as initial conditions for all projected future simulations, including initial conditions for the root zone, saturated and unsaturated aquifer zones, and small watersheds. Since the historical C2VSimFG-Kern simulation period ends with WY2015, all projected future scenarios also include estimated hydrology for WY2016 to WY2020. Model input data for WY2016 to WY2020 was developed by repeating model input data for recent years based on correlation with the San Joaquin Index (DWR, 2019).

6.2 Development of Key Baseline Data Sets

Key required components for the Projected Future Baseline, as summarized in the DWR *Water Budget Best Management Practices* guidance document (DWR, 2016B) include the following:

- The projected Baseline hydrology conditions were developed using 50-years of historical precipitation and streamflow following the sequence outlined in Section 6.1.
- Surface water supplies are based on available information from DWR and others to project future water imports from the SWP, CVC - Friant-Kern Canal (FKC) and Kern River diversions. For the Kern River, recent diversion practices based on entitlements were used to develop water use consistent with the Baseline hydrology.
- WY2013 land use was used as current land use for all scenarios as drought conditions likely reduced agricultural production in WY2014 and WY2015.
- Consumptive use for agriculture and undeveloped lands was based on the recent land use and METRIC-based evapotranspiration. Following DWR guidance, METRIC data over the Baseline period was varied according to varying hydrologic conditions (e.g., water year type).
- Urban water demand was based on projections from recent urban water management plans to meet regulations for future water use. Urban demand was estimated in the model based on projected urban population growth and per capita water demand information (including recent regulatory guidance).
- Small watershed inflows used the same parameters as the historical C2VSimFG-Kern model; however, volumes varied based on changes in the precipitation and ET under the 2030 and 2070 climate change conditions.

Time-series input data were first developed for the Baseline scenario model for WY2021 to WY2070. Development of this time-series input data generally involved repeating time-series data from the historical C2VSimFG-Kern in the appropriate sequence. The following time-series data were developed for each scenario:

- Precipitation rates,
- Evapotranspiration rates,
- Surface water inflow rates,
- Surface water diversion and delivery rates, and
- Specified groundwater pumping rates.

Baseline scenario model time-series data files were then modified following DWR guidelines to produce time-series input data for the 2030 Climate Conditions and 2070 Climate Conditions scenario models. C2VSim input data were modified only in Kern County. C2VSim input data for areas outside of Kern County were not modified.

The baseline data sets were incorporated into the model files to develop the projected future water demand and supply under Baseline, 2030 Climate and 2070 Climate conditions. A summary of the development of the projected future water demand and supply is discussed below.

6.3 Projected Future Water Demand

The projected future water demand was developed using fixed WY2013 land use areas with historical evapotranspiration rates for the Baseline and modified evapotranspiration rates for the 2030 and 2070 climate scenarios and increasing urban populations.

6.3.1 Agricultural Water Demand

Evapotranspiration rates for the Baseline scenario model were developed by repeating input evapotranspiration rates from C2VSimFG-Kern in the appropriate sequence. DWR provided monthly change factors for ETo values under 2030 and 2070 central tendency climatic conditions on a 6 km x 6 km VIC grid for calendar years 1915 through 2011. The VIC grid IDs for each C2VSim subregion in the Kern County Subbasin Zone of Interest were identified and area weighted monthly ETo change factors were calculated for each subregion. Baseline scenario ETc rates for each subregion were then multiplied by the appropriate area-weighted ETo change factors to produce time-series ETc rates for the 2030 Climate Conditions and 2070 Climate Conditions scenarios. Factors for calendar years 1959-1961 were used as analogs for calendar years 2012-2014.

6.3.2 Urban Water Demand

Urban water demand calculations include an indoor component and an outdoor component. Indoor urban water demands are based on the urban population and monthly per capita water demand. Future urban populations for Kern County urban areas were estimated using California Department of Finance population projections. Future per capita urban water demands were estimated using projections from urban water management plans and California urban water conservation regulations, including SB 606 and AB 1668. Future outdoor urban water demands are based on ETc rates, which were modified as described in the Agricultural Water Demand section above.

6.3.3 Groundwater Banking Recovery

Future groundwater banking recovery rates were developed by repeating historical recovery rates in the appropriate sequence. No adjustments were made to Baseline rates or to rates for 2030 and 2070 climatic conditions.

6.4 Projected Future Water Supply

Projected future precipitation, stream inflow and surface water import time series were developed following DWR guidelines. Baseline future water supplies were developed by repeating historical values in the appropriate sequence. Surface water diversions were then adjusted to account for operational changes. Baseline water supplies were then modified to simulate 2030 and 2070 central tendency climatic conditions.

6.4.1 Precipitation Rates

Precipitation rates for the Baseline scenario model were developed by repeating input precipitation rates from C2VSimFG-Kern in the appropriate sequence. DWR provided monthly change factors for precipitation under 2030 and 2070 central tendency climatic conditions on a 6 km x 6 km VIC grid for calendar years 1915 through 2011. The VIC grid ID for each C2VSim element in the Kern County Subbasin Zone of Interest was identified and the Baseline scenario precipitation rates were multiplied by

the appropriate factors to produce time-series precipitation rates for the 2030 Climate Conditions and 2070 Climate Conditions scenarios. Factors for calendar years 1959-1961 were used as analogs for calendar years 2012-2014.

6.4.2 Surface Water Inflow Rates

Surface water inflow rates for Poso Creek and White River for the Baseline scenario model were developed by repeating input inflow rates from C2VSimFG-Kern in the appropriate sequence. DWR provided unimpaired streamflow change factor datasets for Central Valley streams, and an Excel spreadsheet tool to modify basin unimpaired streamflow using these change factors. The unimpaired streamflow change factors and spreadsheet were used to modify Baseline inflows to produce 2030 Climate Conditions and 2070 Climate Conditions scenario time series inflows for Poso Creek and White River.

Surface water inflow rates for Kern River at First Point for the Baseline scenario model were developed by repeating historical inflow rates from C2VSimFG-Kern in the appropriate sequence. Flows on the Kern River are regulated, so the unimpaired streamflow method was not appropriate for estimating future flows under 2030 and 2070 climatic conditions. Projected Kern River flows at First Point under 2030 and 2070 central tendency conditions were estimated by GEI (2018) for calendar years 1956-2010 hydrology. This analysis considered the impacts of changed runoff in each sub-watershed contributing to the Kern River to develop revised streamflow estimates for Kern River at First Point. Future scenario Kern River at First Point flows for calendar years 2011-2014 were estimated using flows for analog years with similar annual flows and monthly flow pattern. Analog years 1986, 1991, 1990 and 1961 respectively were used for 2011-2014 in the future scenarios.

6.4.3 Surface Water Deliveries

Surface water delivery rates for the Baseline scenario model were developed by first repeating input surface water delivery rates from the C2VSimFG-Kern in the appropriate sequence, and then modifying selected data sets. Surface water deliveries from in-basin sources such as Oil Field Recovery were held constant at WY2015 rates for all future scenarios.

The Kern County Subbasin is served by both the CVP and the SWP. Recent changes in CVP and SWP operations and their impacts on future surface water supplies are reflected in surface water diversion rates for the three scenarios. Future CVP deliveries will be affected by implementation of the San Joaquin River Restoration Program (SJRRP) that included the 2008 U.S. Fish & Wildlife Service biological opinion (BO) on the Long-Term Operational Criteria and Plan (OCAP) for coordination of the CVP and SWP. Future SWP deliveries will be affected by operational changes implemented between 2004 and 2008 including the OCAP BO, reduced Table A contract amounts and reduced Article 21 deliveries. DWR provided projected future deliveries from the CVP and SWP for WY1922 to WY2003, derived from CalSim-II modeling conducted for the Water Supply Investment Program (WSIP) (California Water Commission, 2016). DWR's CVP projections as provided do not fully incorporate these SJRRP operational changes. DWR's SWP delivery projections do not include the OCAP BO operational constraints, the reduced Table A amounts and reduced Article 21 water.

Future CVP delivery projections developed by the Friant Water Authority (FWUA) were used in place of DWR's CVP projections. FWUA (2018) used CalSim-II to develop projected surface water deliveries with SJRRP implementation under hydrological conditions representing the Current Baseline, 2030 and 2070 climate conditions by delivery class for WY1922 to WY2003, and estimated allocations to each CVP contractor. The 2015.c data set was used for Baseline scenario CVP deliveries, the 2030.c data set was

used for 2030 Climate Conditions scenario CVP deliveries, and the 2070.c data set was used for the 2070 Climate Conditions scenario CVP deliveries. CVP deliveries for WY2004 to WY2014 were estimated using deliveries for analog years WY1951 to WY1961; these analog years have a similar distribution of water availability.

The SWP projections provided by DWR for WY1995 to WY2003 and historical deliveries for WY2004 to WY2014 were modified to incorporate the impacts of SWP operational changes in the three scenarios. 2019 SWP Table A contract amounts were used to allocate these SWP deliveries to individual districts. In summary:

- Baseline Hydrologic Conditions
  - WY1995 to WY2003 conditions are based on 2030-Level CALSIM increased by 3.03 %,
  - WY2004 to WY2007 conditions are based on historical data adjusted for OCAP BO, and
  - WY2008 to WY2014 conditions are based on historical data with the assumption that OCAP BO adjustments are already factored into the data.
- 2030 Climate Change Hydrologic Conditions
  - WY1995 to WY2003 conditions are based on the 2030-Level CALSIM Projection,
  - WY2004 to WY2007 conditions are based on OCAP BO adjustment reduced by 3.03 %, and
  - WY2008 to WY2014 conditions are based on historical data reduced by 3.03%.
- 2070 Climate Change Hydrologic Conditions
  - WY1995 to WY2003 conditions are based on the 2070-Level CALSIM Projection,
  - WY2004 to WY2007 conditions are based on OCAP BO adjustment reduced by 8.09%, and
  - WY2008 to WY2014 conditions are based on historical data reduced by 8.09%.

Within the Kern County Subbasin, water users engage in complex real-time water trading and wheeling activities to maximize water utilization, minimize waste and energy consumption, and meet immediate water needs. It would be difficult to project future surface water deliveries in the Kern County Subbasin without the use of a surface water allocation model that simulates these water trading and wheeling activities. Therefore, for this modeling effort, monthly future scenario agricultural, urban and recharge deliveries from sources originating outside the basin were estimated by adjusting historical deliveries by the ratio of (total scenario inflows)/(total historical inflows) for each month, where total inflows are the sum of CVP deliveries, SWP deliveries and Kern River at First Point. In addition, Kern River at First Point flows above historical flows under the 2030 Climate Conditions and 2070 Climate Conditions scenarios were proportionally added to selected recharge deliveries. This method is deemed adequate for subbasin-level future scenario analyses.

Some future scenario data sets did not cover the entire period from October 1994 through September 2014. In these cases, data from an analog historical period with similar water availability was used to fill in the missing data. The analog years for each data type are summarized as:

- For CVP deliveries (CalSim-II data), WY1951 to WY1961 were used as analogs for missing WY2004 to WY2014 data; these analog years have a similar distribution of water availability.
- Projected future Kern River at First Point flows for calendar years 1986, 1991, 1990 and 1961 were used as analogs to missing calendar years 2011 through 2014; each of these analog years had a similar historical annual flow volume and monthly distribution.

- For climatic data adjustment factors, calendar years 1959-1961 were used as analogs to missing calendar years 2012-2014.

6.5 Development of Climate Change Conditions

Input data for the C2VSimFG-Kern were modified to simulate three future climatic scenarios. Historical precipitation, evapotranspiration, land use, population, surface water inflow and surface water delivery rates were replaced with projected future values for WY2016 to WY2070 for Future Baseline Conditions. The Future Baseline Conditions for WY2021 to WY2070 were then modified to simulate 2030 Climate Conditions and 2070 Climate Conditions. Water management agencies in the Kern County Subbasin provided a broad suite of proposed water management and conservation projects to increase water supplies and reduce water management demands. These projects are added to the C2VSimFG-Kern to assess the long-term impacts of these projects under the Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios.

Projected water budgets under Future Baseline Conditions, 2030 and 2070 Climate conditions are used to evaluate the potential effects of future Baseline and extended dry conditions with respect to achieving sustainability. DWR published a *Modeling Best Management Practices* Guidance Document (DWR, 2016B) that outlines DWR recommendations for developing and running predictive scenarios. The C2VSimFG-Kern was modified following these recommendations to develop the Baseline scenario model. DWR also issued the *Guidance for Climate Change Data Use During Sustainability Plan Development* Guidance Document (DWR 2018A) that outlines how DWR recommends that climate change be addressed under SGMA. Baseline scenario data sets were modified using DWR climate change data sets for Kern County following procedures outlined in the guidance documents to develop the 2030 Climate Conditions and 2070 Climate Conditions scenario models. The adjustment factors for Baseline, 2030 Climate Change and 2070 Climate Change for SWP deliveries were developed based on consistent CalSim operations studies at current, 2030 and 2070 climate levels developed for Bay Delta Conservation Plan evaluation and provided by DWR Bay Delta Office staff. The WSIP studies provided on DWR's SGMA web site were not used due to the unavailability of a Baseline study with assumptions consistent with the 2030 and 2070 climate change studies.

6.6 Groundwater Banking Assumptions

Groundwater banking operations are simulated in the C2VSimFG-Kern with surface water diversions to recharge basins and specified pumping rates for groundwater extractions. All surface water deliveries were adjusted under the Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios. Surface water deliveries to recharge basins were first adjusted by the same ratio as other surface water deliveries, then increased if Kern River flows were greater than historical flows. Specified pumping rates for groundwater extraction were not modified.

The out-of-basin banking obligations were assumed to follow a similar pattern where groundwater banking recharge would be affected by the limitation on surface water deliveries, but that banking recovery would remain similar to historical volumes. Therefore, the historical groundwater banking obligations were adjusted under the Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios by the same percentage as the surface water deliveries; however, the groundwater banking recovery was assumed to remain the same. Based on the historical banking obligations and using that as a foundation going forward, no banking partner has ever requested the full amount of the water banked at any particular time even in the most recent drought years. All the banking obligation

agreements require limitations on amounts to be requested and delivered as well as "leave in" amounts that remain in the Kern County Subbasin. This historical management of banking obligations provides the Kern County Subbasin more flexibility for use of water as well as delivery of the obligations. For the projected future scenarios, the out-of-basin banking obligations were calculated as follows:

- For the Baseline scenarios, the out-of-basin banking obligations were calculated as 69,632 AFY based on surface water deliveries of about 81% of historical deliveries.
- For the 2030 Climate scenarios, the out-of-basin banking obligations were calculated as 67,913 AFY based on surface water deliveries of about 79% of historical deliveries.
- For the 2070 Climate scenarios, the out-of-basin banking obligations were calculated as 64,474 AFY based on surface water deliveries of about 75% of historical deliveries.

Tracking of banked groundwater obligations was done using the same post processing process as applied to the historical groundwater assessment by assigning the portion of the groundwater recharge as an out-of-basin banking obligation.

7. PROJECTED FUTURE C2VSIMFG-KERN SIMULATION RESULTS

The C2VSimFG-Kern was run for three scenarios that estimate hydrologic conditions of Baseline, 2030 Climate Conditions and 2070 Climate Conditions scenarios both with and without the proposed SGMA projects and management actions for a total of six projected future scenarios.

7.1 Projected Future Water Budgets

C2VSimFG-Kern calculates water budget components each month of the simulation period for each future scenario. Projected future water budgets developed based on the C2VSImFG-Kern simulation results with the proposed SGMA management actions were then compared to results for the future scenarios without the management actions to assess how these changes enhance groundwater sustainability within the Kern County Subbasin.

The average annual value of each water budget component summarizes the impacts over 50 years with current water demands. The water budget results for the six Projected Future Scenarios are presented in **Tables 16 through 21**, and include averages over three different periods, which include:

- **WY2021 to WY2040** – Implementation Period representing the 20-year period required by the SGMA regulations to implement projects and management actions to achieve sustainability.
- **WY2041 to WY2070** – Sustainability Period representing the 30-year hydrologic period following the Implementation Period to assess the long-term sustainability of the proposed projects and management actions with variable climatic conditions including periods with above average rainfall and extended droughts.
- **WY2021 to WY2070** – Simulation Period representing the entire 50-year projected future hydrologic conditions.

Changes to surface water diversions under the proposed projects and management actions included monthly increases or reductions to 37 model diversions and the addition of 7 new diversions. Ten new groundwater pumping wells were added to simulate a new groundwater pumping program. Agricultural

land use was converted to native vegetation in ten management areas, and to urban land use in three management areas. The projects and management actions included in the C2VSimFG-Kern scenarios with SGMA projects are described in the individual GSPs and management area plans. These changes were applied to a series of six C2VSimFG-Kern scenarios for Baseline, 2030 Climate Conditions and 2070 Climate Conditions both with and without SGMA projects. The results of these simulations are summarized in **Table 15** below.

Baseline simulation results indicate that the Kern County Subbasin has an average annual overdraft of 324,326 AFY. By implementing the proposed projects and management actions, the Subbasin is forecasted to achieve sustainability by 2040 with an estimated 42,144 AFY of annual surplus. With adjustments to account for limitations in the simulation (discussed in Section 7.2.1), the adjusted change in storage increases to 85,578 AFY.

Collectively, the C2VSimFG-Kern simulation results indicate that the currently proposed SGMA projects and management actions, once fully implemented, provide a reasonable approach to achieve sustainable management of the groundwater basin and can be adaptively managed to meet future challenges as necessary. A brief summary of each of the six projected future water budgets from C2VSimFG-Kern is provided below.

Table 15: Summary of Simulated Change in Groundwater Storage Results over the 2041 to 2070 Sustainability Period

C2VSimFG-Kern Model Scenario	Change in Groundwater Storage (AFY)	
	C2VSimFG-Kern Model Results	Adjusted Model Results
Historic	-277,114	-277,114
Baseline	-324,326	-324,326
Baseline with Projects	42,144	85,578
2030 Climate Change	-380,900	-372,120
2030 Climate with Projects	-12,861	46,829
2070 Climate Change	-489,828	-472,336
2070 Climate with Projects	-118,273	-45,969

7.1.1 Baseline Condition Water Budgets

The Baseline Scenarios simulate how the Kern County Subbasin aquifer would respond if the recent hydrology were repeated with current expected surface water availability and current land use. The Baseline Scenarios were run both with and without SGMA projects.

For the Baseline Scenario without SGMA Projects, the groundwater budget for WY2021 to WY2040 (**Table 16**) repeats the 20-year historical hydrologic period so it provides a direct comparison of the differences between the projected future Baseline without SGMA Projects and the historical condition. The primary difference between historical conditions and the projected future Baseline is a nearly 20% decrease in imported surface water deliveries primarily from the SWP due to the OCAP Biological

Opinion. This is replaced with additional groundwater pumping. As a result, total net aquifer outflows increase by about 20,200 AFY and total net aquifer inflows decrease by about 76,500 AFY. This is mostly because of increased groundwater pumping and decreased managed aquifer recharge due to a decline in imported SWP water. Over this period, the average groundwater pumping is 1,581,000 AFY, which includes agricultural pumping, urban pumping and exported water. This results in an additional loss of groundwater storage of about 56,300 AFY over the 50-year projected future Baseline period.

The Baseline Scenario with SGMA Projects simulates the proposed SGMA projects and management actions (Section 5.2) applied to the Baseline Scenario. No other changes were made except for the addition of the SGMA projects to provide a direct comparison of the relative benefits of about 422,000 AFY of proposed SGMA projects and management actions. The groundwater budget for the Baseline Scenario with SGMA Projects is provided in **Table 17**. Comparing the groundwater budget for WY2041 to WY2070 (**Table 17**) with the same period from the Baseline Scenario (**Table 16**) provides an evaluation of groundwater conditions after the SGMA projects and management actions have been fully implemented. As a result, total net aquifer inflows increase about 135,400 AFY due to increased managed aquifer recharge and deep percolation. The total net aquifer outflows decrease about 231,100 AFY due mostly to decreased groundwater pumping with agricultural demand reduction management actions.

The change in groundwater storage for the Baseline Scenario with SGMA Projects improves by about 366,500 AFY compared to the Baseline Scenario without SGMA Projects. This change results in a net gain in groundwater in aquifer storage over the WY2041 to WY2070 sustainability period of about 42,100 AFY. A comparison of the annual change in groundwater storage over the 50-year hydrologic period is presented in **Figure 16**. The time series shows that change in groundwater storage has stabilized to slightly increasing over the period from WY2041 to WY2070.

A comparison of the average annual water budget components for the two different Baseline Scenarios is presented in **Figure 17**. Over the WY2041 to WY2070 period, the average groundwater pumping of 1,354,000 AFY for the Baseline Scenario with SGMA Projects (which includes agricultural pumping, urban pumping and exported water) is over 270,000 AFY less than in the Baseline Scenario.

7.1.2 2030 Climate Change Water Budgets

The 2030 Scenarios simulate how the Kern County Subbasin aquifer would respond assuming hydrologic conditions representing a potentially drier climate and are based on the DWR Climate Change Guidance and Resource Guide (DWR, 2018A and 2018B). The 2030 DWR climate change factors were applied to the Baseline Scenario conditions. Additional adjustments were made to the imported surface water supplies from the SWP, CVP and Kern River, accounting for about an additional 2% decrease from the Baseline Conditions. The 2030 Climate Change Scenarios were run both with and without SGMA projects. Results for climate change budgets are illustrated in **Figures 18, 19, and 20**.

The groundwater budget for the 2030 Climate Scenario without SGMA Projects for WY2041 to WY2070 (**Table 18**) is compared the same period for the Baseline Scenario without SGMA Projects to assess the relative change due to the climate change assumptions. The results show a net increase in aquifer inflows of about 44,700 AFY, however, the aquifer net outflows increase by about 101,200 AFY. This is mostly attributed to the climate shift to earlier rainfall making more surface water available for managed aquifer recharge during the winter but less available for irrigation in the summer, resulting in higher groundwater pumping. The net change in groundwater storage is an additional decline of about 56,600 AFY due to the climate change impacts.

The 2030 Climate Scenario with SGMA Projects simulates the proposed SGMA projects and management actions (Section 5.2) applied to the 2030 climate change conditions. No other changes were made to this scenario. The groundwater budget for the 2030 Climate Scenario with SGMA Projects is provided in **Table 19**. Comparing the groundwater budget for WY2041 to WY2070 (**Table 18**) between the two 2030 Climate Scenarios, the total net aquifer inflows increase about 118,700 AFY due to increased managed aquifer recharge and deep percolation. The total net aquifer outflows decrease about 249,300 AFY due mostly to decreased groundwater pumping with agricultural demand reduction management actions.

The change in groundwater storage for the 2030 Climate Scenario with SGMA Projects improves by about 368,000 AFY. This change results in a net decline in groundwater in aquifer storage over WY2041 to WY2070 of about 12,900 AFY. A comparison of the annual change in groundwater storage over the 50-year hydrologic period is presented in **Figure 20**. The time series shows that change in groundwater storage has stabilized to slightly increasing over the period from WY2041 to WY2070, but at a level below the results for the Baseline Scenario with SGMA Projects.

A comparison of the average annual water budget components for the two 2030 Climate Scenarios is presented in **Figure 18**. Over this period, the average groundwater pumping of 1,444,000 AFY for the 2030 Climate Scenario with SGMA Projects, which includes agricultural pumping, urban pumping and exported water, is over 290,000 AFY less than in the 2030 Climate Scenario without SGMA Projects.

7.1.3 2070 Climate Change Water Budgets

The 2070 Scenarios simulate how the Kern County Subbasin aquifer would respond assuming hydrologic conditions representing a potentially very dry climate and are based on the DWR Climate Change Guidance (DWR, 2018A and 2018B). The 2070 DWR climate change factors were applied to the Baseline Scenario Conditions. Additional adjustments were made to the imported surface water supplies from the SWP, CVP and Kern River, and these accounted for an additional 6% decrease from the Baseline Conditions. The 2070 Climate Change Scenarios were run both with and without SGMA Projects.

The groundwater budget for the 2070 Climate Scenario without SGMA Projects over WY2041 to WY2070 (**Table 20**) is compared the same period for the Baseline Scenario without SGMA Projects to assess the relative change due to the climate change assumptions. The results show a net increase in aquifer inflows of about 66,100 AFY, however, the net aquifer outflows increase by about 231,600 AFY. This is mostly attributed to an even greater climate shift to earlier rainfall making more surface water available for managed aquifer recharge during the winter but less available for irrigation in the summer resulting in higher groundwater pumping. The net change in groundwater storage is an additional decline of about 165,500 AFY due to the climate change assumptions.

The 2070 Climate Scenario with SGMA Projects simulates the proposed SGMA projects and management actions (Section 5.2) applied to the 2070 climate change conditions. No other changes were made to this scenario. The groundwater budget for the 2070 Climate Scenario with SGMA Projects is provided in **Table 21**. Comparing the groundwater budget for WY2041 to WY2070 (**Table 20**) between the two 2070 Climate Scenarios, the total net aquifer inflows increase about 106,300 AFY due to increased managed aquifer recharge and deep percolation. The total net aquifer outflows decrease about 265,300 AFY due mostly to decreased groundwater pumping due to agricultural demand reduction management actions.

The change in groundwater storage for 2070 Climate Scenario with SGMA Projects improves by about 371,600 AFY. This change results in a net decline of groundwater in aquifer storage over WY2041 to WY2070 of about 118,300 AFY. A comparison of the annual change in groundwater storage over the 50-year hydrologic period is presented in **Figure 20**. The time series shows that change in groundwater storage has stabilized to slightly increasing over the period from WY2041 to WY2070, but at a level below the results for the Baseline and 2030 Scenarios with SGMA Projects.

A comparison of the average annual water budget components for the two different 2070 Climate Scenarios is presented in **Figure 19**. Over this period, the average groundwater pumping of 1,559,000 AFY for the 2070 Climate Scenario with SGMA Projects, which includes agricultural pumping, urban pumping and exported water, is over 307,000 AFY less than in the 2070 Climate Scenario without SGMA Projects.

7.2 Projected Future Sustainability Assessment

To assess the sustainability of the proposed GSP plans, the C2VSimFG-Kern model future scenario input files were modified to incorporate all the proposed SGMA projects and management actions.

7.2.1 Change in groundwater storage

Groundwater sustainability for the Kern County Subbasin was assessed using annual changes in groundwater storage. As discussed in Section 7.1, the decline in groundwater storage of the three future Baseline scenarios is significantly mitigated by the implementation of the proposed SGMA projects and management actions. An assessment of the projected future groundwater storage change for the six projected future scenarios is summarized in **Table 22**.

The Change in Groundwater Storage presented in **Table 22** provides the net difference in aquifer inflows and outflows without consideration of subsurface flow to and from adjacent groundwater basins. This provides a measure of the natural and managed water supply within the groundwater basin without being influenced either positively or negatively by the subsurface flow. For the Kern County Subbasin, the net operational flow differs from the change in groundwater storage by about 50,000 to 75,000 AFY for the scenarios without SGMA projects, indicating that most of the groundwater storage change is due to conditions within the basin.

The Adjustments to Groundwater (GW) Storage Change are made to account for limitations in either the underlying conceptual model of C2VSimFG-Kern or the setup of the projected future scenarios. The two adjustments made to the projected future water budgets include:

- **Adjustment for Excess Basin Outflows** is the difference in simulated basin outflow that is attributed to addition of SGMA projects in Kern County without comparable SGMA projects added to adjacent basins. Adjustment assumes that this difference is due to limitation of the simulation, and that this difference would remain in Kern County Subbasin when SGMA projects from adjacent basins are included in the simulation.
- **Adjustment for Excess Kern River Outflow** is the increase in simulated groundwater outflows to the Kern River relative to Baseline condition that are attributed to SGMA projects and climate change. The model is not optimized for river management. Because the Kern River is a highly managed system, the assumption is that in practice this water would be recovered for beneficial use and not allowed to flow from the basin.

These adjustments resulted in an overall improvement in the change in groundwater storage for the projected future water budgets. For the scenarios that include the SGMA Projects, the change in groundwater storage improves by 43,400 AFY (Baseline), 59,700 AFY (2030 Climate Change), and 72,300 AFY (2070 Climate Change). As a result of these adjustments, the adjusted change in groundwater storage for the three scenarios with SGMA Projects varied as follows:

- the Baseline Scenario with SGMA Projects changes from an increase of 42,100 AFY to an increase of 85,600 AFY.
- the 2030 Climate Scenario with SGMA Projects changes from a decline of 12,900 AFY to an increase of 46,800 AFY.
- the 2070 Climate Scenario with SGMA Projects changes from a decline of 118,000 AFY to a decline of 46,000 AFY.

These adjustments indicate areas of improvement for C2VSimFG-Kern. Future updates to the model will address how to better simulate these conditions directly to limit the use of post-simulation adjustments.

7.2.2 Sustainability Assessment

As defined by SGMA, the sustainable yield of a basin is the amount of groundwater that can be withdrawn annually without causing undesirable results. Although the SGMA regulations require that a single value of sustainable yield must be calculated basinwide, it should be noted that the sustainable yield can be changed with implementation of recharge projects, variations in climate, or changes in stream flow conditions. For the projected future scenarios, both the climate and the managed water supply operations are significantly affected which would lead to a change in the sustainable yield for the basin.

For the sustainability assessment, the sustainable yield was recalculated using the method described in Section 4.2, and the results are presented in **Table 23**. Without the SGMA projects and management actions, the percentage of the Average Annual Difference to the total groundwater pumping provides context to compare the significance of the level of groundwater pumping for the basin. For the scenarios without SGMA projects and management actions, the groundwater pumping exceeds the sustainable yield on the order of 25% to 34% (**Table 23**). However, with the proposed SGMA projects and management actions, the groundwater pumping is less than the sustainable yield of the Subbasin for the Baseline and 2030 climate scenarios and is within 3% of the sustainable yield for the 2070 climate scenario (**Table 23**). This assessment indicates that the proposed SGMA projects and management actions for the Kern County Subbasin are of sufficient magnitude that, if fully implemented, would lead to groundwater sustainability for the Kern County Subbasin after WY2040.

7.2.3 Minimum Thresholds and Measurable Objectives

Another requirement of SGMA is for groundwater levels not to cross their minimum thresholds to the extent that undesirable results would occur in the basin, and moreover, that proposed SGMA projects and management actions would lead to meeting the measurable objectives. The Kern County Subbasin GSAs have defined 186 representative monitoring well (RMW) locations spread across the Kern County Subbasin. A minimum threshold and measurable objective have been assigned each of the 186 locations, and the hydrographs for all 186 locations are provided in **Attachment A**. The RMW locations are shown on **Figure 21**.

The C2VSimFG-Kern results were used to assess whether the simulated groundwater levels would meet the minimum threshold and measurable objective for each monitoring well. Because C2VSimFG-Kern is

not fully calibrated, the results are presented as relative change (which does not require calibration) instead of simulated groundwater levels using the superposition method. Future change in groundwater level was determined for each of the 186 locations for each of the six projected future simulations. The change was calculated from the simulated March 2015 groundwater levels from the model. The change in groundwater level was then applied to the measured March 2015 groundwater level at the monitoring location. The result was to superimpose the simulated change in groundwater levels from the projected future C2VSimFG-Kern scenarios relative to the measured March 2015 groundwater level.

Figure 22 provides four representative examples of the simulated hydrographs using this method. Hydrographs of the simulated groundwater levels relative to the minimum thresholds and measurable objectives for all 186 locations were provided to the various GSAs and water districts for inclusion in their respective GSPs. In general, across most areas of the basin, groundwater levels fall near or below the minimum thresholds without the SGMA projects but are typically above the minimum threshold for the simulations that include the SGMA projects.

The groundwater hydrographs for some locations, especially along the eastern and western basin margins, show an unusual pattern that is likely influenced by issues with the hydrogeological conceptual model incorporated into C2VSimFG-Kern for these locations. The hydrographs for these areas are not considered to be representative of actual conditions that would physically occur. This is a limitation to the model. It is recommended that a more rigorous model update be conducted to revise the hydrogeological conceptual model to be consistent with that presented in the Kern County Subbasin GSPs. In addition, further calibration of C2VSimFG-Kern is recommended to update aquifer parameters in the Kern County Subbasin. The recommendations for revisions to the hydrogeological conceptual model and additional calibration are further discussed in Section 8.5.

8. VALIDATION OF C2VSIMFG-KERN PERFORMANCE

The C2VSimFG-Kern performs well within the central part the Kern County Subbasin. The model does not perform as well east of the Friant-Kern Canal or west of the California Aqueduct. The geologic and hydrogeologic conceptual models within the central part of the Kern County Subbasin appear to be generally realistic. The geologic and hydrogeologic conceptual models appear to be very poor in the areas where the model does not perform well.

8.1 C2VSimFG-Kern Validation

One of the concerns for the modeling is the overall calibration of C2VSimFG-Beta in Kern County. As discussed above, the assumption is that C2VSimFG-Beta was developed using reasonable care in developing the geologic framework and developing a consistent regional methodology for determining aquifer properties. An identified weakness of the C2VSimFG-Beta is the quality of data used in developing the overall water balance such as the extent of the groundwater banking operations in Kern County. The issues with the water balance are considered the primary contributing factor affecting the calibration of the C2VSimFG-Beta; the hydrogeologic conceptualization is reasonably accurate for a regional planning analysis.

To address these concerns, a validation analysis was performed for C2VSimFG-Kern by comparing simulations results to field measured groundwater level data collected during the Study Period and comparing those to a similar set of residuals from the C2VSimFG-Beta model. The statistical results of

this analysis should be comparable, if not better, for C2VSimFG-Kern compared to the C2VSimFG-Beta results.

The analysis used 42,058 groundwater levels measurements collected from 558 monitoring wells in the Kern County Subbasin. The data were collected by Kern County Water Agency, the Kern Fan Monitoring Committee, the DWR Water Data Library, and local agencies. For each location, the residual was calculated as the simulated groundwater level minus the measured groundwater level based on the well measurement data. A brief summary of the statistical measures used to evaluate the calibration results (shown on **Table 24**) is provided below:

- The residual mean is computed by dividing the sum of the residuals by the number of residual data values. The closer this value is to zero, the better the calibration especially as related to the water balance and estimating the change in aquifer storage. The residual mean of 17.3 feet for C2VSimFG-Kern is an improvement of 47% over the 32.6 feet from C2VSimFG-Beta.
- The absolute residual mean is the arithmetic average for the absolute value of the residual, so it provides a measure of the overall error in the model. The absolute residual mean of 37.4 feet for C2VSimFG-Kern is an improvement of 34% over the 56.8 feet from C2VSimFG-Beta.
- The residual standard deviation evaluates the scatter of the data. A lower standard deviation indicates a closer fit between the simulated and observed data. The standard deviation is 45.5 feet for C2VSimFG-Kern, which is an improvement of 16% over the 54.0 feet from C2VSimFG-Beta.
- The Root Mean Square (RMS) Error is the square root of the arithmetic mean of the squares of the residuals and provides another measure of the overall error in the model. The RMS Error is 50.0 feet for C2VSimFG-Kern, which is an improvement of 32% over the 73.5 feet from C2VSimFG-Beta.
- The correlation coefficient ranges from 0 to 1 and is a measure of the closeness of fit of the data to a 1 to 1 correlation. A correlation of 1 is a perfect correlation. The correlation coefficient of 0.76 for C2VSimFG-Kern is an improvement of 47% over the 0.52 from C2VSimFG-Beta.
- Another statistical measure is the ratio of the standard deviation of the mean error divided by the range of observed groundwater elevations. This ratio shows how the model error relates to the overall hydraulic gradient across the model. The ratio for C2VSimFG-Kern is 0.061 feet, which is an improvement of 34% over the 0.092 from C2VSimFG-Beta.

Considering these results in context with the overall range of measurements of 616 feet, the residual mean of 17.3 feet represents a relative percentage difference of less than 3%. For the absolute residual mean of 37.4 feet, the relative percentage difference is about 6%. Despite this improvement in model performance, the model is not considered fully calibrated. However, C2VSimFG-Kern is reasonably validated for assessing groundwater level changes on the subbasin scale for the purposes of SGMA planning.

8.2 Sensitivity Analysis

The C2VSimFG-Kern model was not formally calibrated. Some physical parameters were adjusted to improve model performance in specific areas. A sensitivity analysis was conducted on the adjusted model to understand how variations in model parameters affect model results. Eight physical parameter sets were systematically varied, and model results compared to the base model for a

selected group of groundwater hydrographs. C2VSimFG-Kern parameter sensitivities evaluated for Kern County Subbasin include:

- Horizontal hydraulic conductivity of aquifer (Kh)
- Vertical hydraulic conductivity of aquifer (Kv)
- Vertical hydraulic conductivity of Corcoran Clay aquitard (Kcorc)
- Streambed conductance of Kern River (Cstm)
- Specific storage of aquifer (Ss)
- Specific yield of aquifer (Sy)
- Soil hydraulic conductivity in root zone (Ksoil)
- Soil pore size distribution index in root zone (λ)

The Root Mean Squared Error between observed and simulated values was calculated for the original parameter set and after varying each parameter set upward and downward by a set factor. Results are presented in **Figure 23**. This sensitivity analysis shows that the hydrologic parameter values in the C2VSimFG-Kern model are generally within an acceptable range. A full model calibration would likely improve model performance.

8.3 Peer Review Process

Todd Groundwater worked with Woodard and Curran (W&C) throughout the model development process as W&C conducted an on-going peer review of model input files. W&C staff have developed several IWFM-based models and worked with DWR to develop C2VSimFG-Beta. Their reviews helped ensure that the model update used best practices when incorporating new data. The peer review process was documented in a series of meeting summaries to the KGA and KRGSA. The updated C2VSimFG-Kern input files for the Kern County Subbasin were shared with DWR for incorporation into future C2VSim public releases.

The more general assumptions in C2VSimFG-Beta were replaced with local data and knowledge that are regionally or locally significant for WY1995 to WY2015. This update employed a phased approach with regular peer reviews.

1) Phase 1 revisions address components of Regional Significance that require significant changes to the overall model input file structure. These include:
   a) Surface water delivery volumes, application areas and use by water district,
   b) Groundwater banking recharge, recovery and application of recovered water,
   c) Evapotranspiration rates and irrigation demand based on ITRC METRIC data (ITRC 2017),
   d) Urban population and per capita demand, including addition of an urban zone for Metropolitan Bakersfield, and
   e) Addition of groundwater extraction wells for groundwater banking projects.
2) Interim Review
   a) The Woodard & Curran Peer Review Team
   b) Kern County Subbasin water districts and purveyor's local data review
   c) Stakeholder input
3) Phase 2 revisions address components of Local Significance that generally require modifications of input data and parameters within the existing C2VSim model input file structure. These include:

a) Local water sources and demands of significance to individual Districts/GSAs,
b) District pumping for in-district delivery via surface water canals where significant,
c) District recharge operations utilizing canals, stream channels, and basins,
d) Wastewater disposal and land application, and
e) Review and limited adjustment of model parameters.

4) Interim Review by same reviewers listed in item 2

5) Phase 3 revisions include addressing comments and incorporating new data from the Interim Reviews

6) Interim Review by same reviewers listed in item 2

7) Tabulate model-derived water budgets for Peer-Review and GSP Use

In each update phase, historical and current water budgets for zones representing water agency service areas were produced with the revised C2VSimFG-Kern model incorporating corrected local data. These water budgets were shared with participating agencies for review, to ensure that C2VSimFG-Kern correctly represented local water balances. Where necessary, participating agencies provided additional data which was incorporated into C2VSimFG-Kern.

8.4 Internal Review Process

Todd Groundwater and Hydrolytics LLC worked collaboratively on this model revision, water budget development and the projected future scenarios. Throughout this work, efforts were applied to improve data management to develop a systematic process for generating model input files. Using this approach, internal review could be conducted with each firm reviewing the contributions from the other. The goal was to accurately represent the data provided by the Kern County agencies in the model.

Due to schedule constraints, a thorough internal review of the projected future model scenarios was not completed prior to the submission of the Public Review Draft of the model results in August 30, 2019. A thorough review of all input for the projected future scenarios was conducted in September and October 2019. During this review, several issues were identified and corrected. As a result, the results in this report vary from those provided in the August 2019 Public Review Draft. Although the numbers changed, the overall conclusions from the C2VSimFG-Kern simulations remained essentially the same.

8.5 Recommendations for Future Improvements to C2VSimFG-Kern

The C2VSimFG-Kern performs well in the Kern County Subbasin, producing simulated water budget components that generally match historical values compiled by local agencies. C2VSimFG-Kern simulated groundwater levels provide a reasonable approximation of observed groundwater levels in the central part of the Kern County Subbasin. The model is well suited for estimating the impacts of management actions on the Subbasin groundwater storage and is also well suited as a planning tool in meeting compliance of SGMA.

During the model update, several outstanding issues were identified that should be addressed in future updates to C2VSimFG-Kern. The following actions and model improvements are recommended:

- **Improve streamflow simulations of the Kern River and Poso Creek.** Flows in the Kern River channel, including local stream-groundwater interactions, are not well replicated and surface water diversions are not dynamically simulated. Some rejected recharge occurs in the Kern Fan

area in very wet years, with significant outflow of groundwater to the Kern River especially in the Kern Fan banking area (i.e., rejected recharge). This has been an ongoing issue and needs to be addressed for the projected future water budgets so that banking recharge volumes can be better matched in the model. It is recommended that future revisions to C2VSimFG-Kern further evaluate issues in simulating streamflow and seepage in the Kern River and Poso Creek (see Section 8.5). This may include incorporating more advanced streamflow simulation features that are available in IWFM but that have not been previously utilized in developing C2VSim models by DWR. Changing the stream simulation feature may require development of a local Kern County Subbasin model.

- **Improve the geologic and hydrogeologic conceptual model of the Kern County portion of the Central Valley.** A hydrogeologic conceptual model is a framework for understanding where groundwater exists, where it flows, and how groundwater interacts with surface water bodies and the land surface. A geologic conceptual model provides a framework for understanding the geologic features that control groundwater movement. Quantitative analysis of Kern County Subbasin groundwater flow is severely hampered by the lack of detailed geologic and hydrogeologic conceptual models of the areas outside the central alluvial basin. Geologic and hydrogeologic conceptual models will provide a foundation for the quantitative analysis of the groundwater flow system, and the framework for modeling the system. Key steps are:
    - Develop detailed geologic and hydrogeologic conceptual models of the Kern County Subbasin.
    - Differentiate the four Principal Aquifers that have been identified in the Kern County Subbasin based on definitions from local management area GSPs.
    - Identify the locations and characteristics of natural features that affect groundwater recharge and movement (faults, ridges, clays).
    - Understand water occurrence and movement in areas outside the central Kern County Subbasin.
    - Develop water quality maps (natural constituents and anthropogenic constituents).
    - Modify the Kern County Subbasin model to conform to the updated conceptual models.
- **Simulation of deep percolation and small watersheds.** Unreasonably high deep percolation (return flows) of the applied water in some areas has led to unreasonably elevated pumping rates to compensate. One problem is high root zone hydraulic parameter values in certain areas that were identified and corrected to better reflect local soil conditions. Because the excess pumping was returning to groundwater, the change has little effect on the basin change in storage, but the pumping and deep percolation are now more in line with local estimates. Root zone hydraulic parameters should be redeveloped throughout the subbasin to assure model values are representative of actual values.
- **Root Zone Parameters,** Areas of overly high root zone hydraulic parameters led to high volumes of deep percolation that required additional groundwater pumping to meet the overall water demand for irrigation. A review found areas of overlying high soil hydraulic conductivity and other soil parameters produced percolation rate that were too high. These areas were manually adjusted to be more in line with observed conditions. A more rigorous development of root zone parameters should be considered in the future as this issue demonstrates that it is a sensitive parameter.

- **Investigate development of a stand-alone Kern County Subbasin model.** The C2VSim model provided by DWR and updated with local data is adequate for GSP preparation. However, this model may not meet all of the groundwater modeling needs of Kern County Subbasin stakeholders. In addition, running a full Central Valley simulation model imposes longer model run times and reduces model flexibility. Stakeholders should undertake a comprehensive study to develop a list of their integrated (groundwater and surface water) modeling needs, and then decide whether further improving C2VSimFG-Kern or developing a new integrated hydrologic model is the best way to address the Subbasin modeling needs. This decision should be made before the end of 2020 to allow sufficient time to develop a new model or improve C2VSimFG-Kern in time for use in development of the 2025 GSP.
- **Adjust the finite element grid to honor water management boundaries.** The C2VSimFG-Kern model grid is a randomly generated grid that does not conform to any local features other than natural surface water channels. This limits the spatial accuracy of model inputs and the precision and flexibility of water budget outputs. Adjusting the grid to match district and agency boundaries, historical delivery areas, water management units within districts, and geologic and hydrologic features would greatly enhance model capabilities.
- **Quantify boundary flows.** Significant uncertainty exists regarding the rates and timing of groundwater flows into the Kern County Subbasin from surrounding watersheds, and groundwater flows from the Kern County Subbasin to Kings and Tulare counties to the north. Reliable estimates of boundary flows will improve model performance in boundary areas.
- **Kern County Subbasin Boundary.** The GSAs in the basin should consider when DWR updates the Bulletin 118 in 2020 to investigate the "actual" Kern County Subbasin and to remove those peripheral lands where aquifer connectivity does not exist.
- **Utilize more complex water management features of IWFM.** The Kern Update process modified information within the existing C2VSimFG-Beta model structure to improve model performance within the Kern County Subbasin. The IWFM application has several features that could be further utilized to improve model performance.
    - Adjust the agricultural crops to better match the Kern County crop mix (for example, create separate crop categories for carrots, young and mature almonds, young and mature pistachios, etc.).
    - Implement multi-cropping with semiannual or quarterly land use.
    - Some C2VSim data are organized by DWR subregions, which represent heterogeneous areas with homogeneous data. Developing Kern County Subbasin subregions and organizing model input data by these subregions may provide a better representation of local hydrologic conditions.
- **Calibrate the improved model for the Kern County Subbasin**. DWR did not fully calibrate the Kern County portion of the C2VSim model, owing to both poor historical input data and a lack of calibration data sets. The Kern Update process significantly improved the historical data in the model, developed some calibration data sets, and included limited adjustment of model parameters. The updated model performs adequately in the central part of the Kern County Subbasin and poorly in areas outside the central part of the basin. Once the above improvements are completed, the Kern County portion of the resulting model should be fully calibrated to ensure that it performs well throughout the Kern County Subbasin.

9. CONCLUSIONS

This brief summary provides an overview of the findings and conclusions of the modeling results for the Kern County Subbasin using C2VSimFG-Kern.

9.1 Findings of the C2VSimFG-Kern Application and Results

The subbasin-wide update of C2VSimFG-Kern incorporated data from many local agencies. Each participating agency provided data for their jurisdiction for use in improving the model. This included managed water supply data (e.g., surface water deliveries, land use, irrigation demand, return flows, and groundwater banking), stream and groundwater monitoring data, geologic data, and other relevant data. This information was compiled and used to improve C2VSimFG-Kern performance in the Kern County Subbasin.

The historical water budget analysis indicates that the Kern County Subbasin was in a state of overdraft equivalent to the long-term decline in groundwater storage from WY1995 to WY2014 of 277,144 AFY. Projected Future simulations indicate that the proposed SGMA projects and management actions in the Kern County GSPs are sufficient for the Kern County Subbasin to achieve sustainability under Baseline and 2030 Climate Change conditions.

C2VSimFG-Kern was used to evaluate the change in groundwater in storage for projected future conditions using a baseline condition that projects current water supply, water demand and land use over a 50-year period based on historical hydrology. The baseline was adapted following DWR climate change guidance to develop 2030 and 2070 climate change simulations. The proposed SGMA projects and management actions were compiled from all of the Kern County Subbasin GSAs and management areas. The total projects total about 421,000 AFY after implementation. This assessment indicates that the proposed SGMA projects and management actions for the Kern County Subbasin are of sufficient magnitude that, if fully implemented, would lead to groundwater sustainability for the Kern County Subbasin after WY2040.

The historical C2VSimFG-Kern performs well in the Kern County Subbasin, producing simulated water budget components and groundwater levels that generally match historical values compiled by local agencies. C2VSimFG-Kern simulated groundwater levels provide a reasonable statistical approximation of observed groundwater levels in the Kern County Subbasin that show significant improvement relative to C2VSimFG-Beta. Therefore, C2VSimFG-Kern is well suited as a planning tool to estimate the impacts of the proposed SGMA projects and management actions on groundwater conditions in the Kern County Subbasin.

The C2VSimFG-Kern model development and the water budget analysis were designed to fulfill the GSP requirement for a coordinated subbasin-wide water budget analysis, while also providing information required to fulfill other GSP requirements. The C2VSimFG-Kern was provided to DWR so the Kern County Subbasin revisions can be incorporated into their master version of the C2VSim model.

9.2 C2VSimFG-Kern Compliance with Coordination Agreement Requirements

Subbasin GSAs coordinated on the development and application of the C2VSimFG-Kern to ensure that the model was incorporating comparable data sets and the best available information; as such, the model meets numerous technical requirements for Subbasin-wide coordination, including for

Coordination Agreements in §357.4. As demonstrated throughout this memorandum, the C2VSimFG-Kern model documents the use of "the same data and methodologies" for water budget development.

Specifically, groundwater extraction data were coordinated through the use of ET METRIC data for all irrigated lands over the entire Subbasin to estimate private irrigation pumping. Monthly metered data from District, municipal, and banking pumping were incorporated as available. Surface water supply data were provided in similar units and formats using consistent templates for data collection and management in the model. Total water use and change in groundwater in storage were developed through consistent methodologies as applied in the C2VSimFG-Kern model. Calibration targets also incorporated consistent data sets for groundwater elevation data throughout the Subbasin as compiled in the DWR Water Data Library, KCWA water level database, and supplemented with local data, as needed. This memorandum documents coordination efforts in subsequent sections that demonstrates compliance with GSP requirements in §354.18, §357.4, and other portions of the regulations.

9.3 Limitations and Uncertainty of C2VSimFG-Kern

The C2VSimFG-Kern performs well in the Kern County Subbasin, producing simulated water budget components that generally match historical values compiled by local agencies. C2VSimFG-Kern simulated groundwater levels provide a reasonable approximation of observed groundwater levels in the central part of the Kern County Subbasin. The model is well suited to estimating the impacts of management actions on subbasin groundwater storage.

The C2VSimFG-Kern update was limited in scope, and some model components do not perform well. These components do not reduce model capabilities with respect to GSP development but limit the usefulness of the model for other types of studies. Flows in the Kern River channel, including local stream-groundwater interactions, are not well replicated and surface water diversions are not dynamically simulated. The Kern County Subbasin portion of the C2VSimFG-Kern is not calibrated, and although the land surface water budget components are generally accurate, groundwater conditions and stream flows are poorly simulated in much of the Subbasin. Some rejected recharge occurs in the Kern Fan area in very wet years, but this is not significant as it is a very small volume.

The C2VSimFG-Kern is a reliable and defensible tool to support planning future groundwater conditions and estimating the potential hydrological impacts of future climate conditions and management actions at the subbasin level. It is currently the best available quantitative tool for assessing projected future groundwater conditions under SGMA. DWR recommends updating and refining models used in GSPs to incorporate new data including that in annual GSP updates. Refining Kern County Subbasin hydrologic modelling tools to replicate district-level historical conditions will provide a reliable means of assessing future effects of management actions at the district level for future GSP development.

9.4 Applicability of C2VSimFG-Kern Simulation Results

Based on the model validation, C2VSimFG-Kern provides a useful planning tool to evaluate potential future trends in groundwater in the Kern County Subbasin. The model validation demonstrated the capability of C2VSimFG-Kern to reasonably simulate the groundwater elevations and trends during the period from WY1995 through WY2015 based on the comparison to measured data.

The ability to reasonably simulate historical conditions provides confidence that C2VSimFG-Kern can be used to simulate potential future conditions. The model has the capability to simulate the most beneficial application of water projects that would provide the long-term benefit to the area. For the

future case scenarios, the general practice is to evaluate model results with respect to long-term trends. Therefore, as a planning tool, it is most beneficial to run the model in relation to a base case and to evaluate the relative difference between the model scenario and the base case. The base case would assume a selected set of climatic, hydrologic and pumping conditions. Commonly, the calibration base period is assumed to repeat; however, any number of variations can be constructed.

It is important to note that in some cases the model results may vary from those measured in individual wells due to the geologic complexity of the Kern County Subbasin. However, the model is capable of evaluating the impacts of changes in pumping and water use practices in the Kern County Subbasin that are useful for SMGA planning purposes.

The conclusions and recommendations presented herein are professional opinions based on the C2VSimFG-Kern revisions and simulations as described herein. The findings and professional opinions presented in this letter are presented within the limits prescribed by the client contract, in accordance with generally accepted professional engineering, geologic and modeling practices, to support development of GSPs within the Kern County Subbasin. There is no other warranty, either expressed or implied, regarding the conclusions, recommendations, and opinions presented in this report.

TABLE 10 - Summary of C2VSimFG-Beta modifications in the Kern County Revision applied to C2VSimFG-Kern by IWFM model input file

File Name	Change to Model Input File
C2VSimFG.in	
*	Change simulation starting time to 09/30/1985_24:00
C2VSimFG_Unsat.dat	
*	Replaced initial condition values with more representative values for revised starting
C2VSimFG_SWatersheds.dat	
*	Modified parameters to improve stream discharge match to historical values
C2VSimFG_Groundwater1985.dat	
*	Added hydrologic flow barrier at White Wolf Fault
*	Set Corcoran Clay thickness to 0 ft in areas where it is not present
*	New 10/1/1985 initial condition
*	Modified hydraulic conductivity and specific storage in Layer 1 in the Kern Water Bank
*	Kern County observation wells
C2VSimFG_ElemPump.dat	
*	FRACSK and DSTSK modified for Kern County elements with limited pumping
C2VSimFG_WellSpec.dat	
*	Added Kern County groundwater water bank recovery wells
*	Added Kern County In-District and Urban wells
C2VSimFG_PumpRates.dat	
*	Added Kern County groundwater water bank recovery pumping
*	Added Kern County In-District and Urban pumping
C2VSimFG_StreamInflow.dat	
*	Exteneded Poso Creek inflow through WY2015
C2VSimFG_DiverionSpec.dat	
*	Removed all Kern County diversions and renumbered remaining diversions to 1-371
*	Added Kern County diersions 372-484
C2VSimFG_Diverions.dat	
*	Removed all Kern County diversions and renumbered remaining diversions to 1-371
*	Added Kern County diersions 372-484
*	Updated diversion data for all diversions to Kern County
C2VSimFG_BypassSpecs.dat	
*	Removed bypass #17
C2VSimFG_RootZone.dat	
*	Native return flow is sent to either nearby stream nodes as runoff or out-of-model as ET
C2VSimFG_IrrPeriod.dat	
*	Adjusted Kern County irrigation periods
C2VSimFG_ReturnFlowFrac.dat	
*	Modified Kern County Ag return flow fraction
C2VSimFG_Urban.dat	
*	Added zone 106 for Metro Bakersfield and adjusted other Kern County zone areas
*	Applied estimated September 1985 initial condition

TABLE 10 - Summary of C2VSimFG-Beta modifications in the Kern County Revision applied to C2VSimFG-Kern by IWFM model input file

File Name	Change to Model Input File
C2VSimFG_Urban_Area.dat	
*	Changed Kern County oil fields from urban to native vegetation
C2VSimFG_Urban_PerCapWaterUse.dat	
*	Updated population for Kern County Urban Zones based on 1990, 2000, 2010 Census
*	Developed demands from historical data and water management plans
C2VSimFG_Urban_Population.dat	
*	Updated population for Kern County Urban Zones based on 1990, 2000, 2010 Census
C2VSimFG_Urban_WaterUseSpecs.dat	
*	Set fractions for SRs 19-21 based on local info
C2VSimFG_NonPondedCrop.dat	
*	Return flow = 0 for Kern County
C2VSimFG_NonPondedCrop_Area.dat	
*	Revided crop distributions to match historical distribution
C2VSimFG_PondedCrop_Area.dat	
*	Modified distribution of rice to be limited to areas in northwest Kern County with
C2VSimFG_NativeVeg_Area.dat	
*	Rebalanced native veg distribution after redistribution of non-ponded crop area to

Table 11A - Historical Groundwater Budget for the Kern County Subbasin for Water Years 1995 to 2014 based on the C2VSimFG-Kern Historical Simulation

Water Year	Deep Percolation	Managed Recharge and Canal Seepage	Net GW/SW Interactions	GW Pumping	Small Watershed Inflow	Subsurface Flow with Adjacent GW Basins	Change in Groundwater Storage
Units	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft
1995	880,480	944,800	185,777	-946,782	122,287	-75,299	1,111,263

Table 11B - Current Groundwater Budget for the Kern County Subbasin for Water Year 2015 based on the C2VSimFG-Kern Historical Simulation

Water Year	Deep Percolation	Managed Recharge and Canal Seepage	Net GW/SW Interactions	GW Pumping	Subsurface Flow within GW Basin	Subsurface Flow with Adjacent GW Basins	Change in Groundwater Storage
Units	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft	Acre-ft
2015	429,983	89,744	46,344	-2,740,237	0	-51,201	-2,225,366

NOTES:

Deep Percolation	Precipitation and applied water that reaches the groundwater after simulated transport across the unsaturated zone
Managed Recharge and Canal Seepage	Combined groundwater recharge from managed aquifer recharge operations, groundwater banking, and seepage from canals and other conveyance
Net GW/SW Interactions	Net volumetric exchange of surface water and groundwater from streams: Positive represents a net groundwater recharge, and negative represents a net groundwater discharge to the stream
GW Pumping	Total groundwater pumping by wells. Groundwater banking recovery pumping is specified input whereas agricultural and municipal pumping is calculated by C2VSim based on demand
Subsurface Flow within GW Basin	Net subsurface groundwater flow into a neighboring water district or area within the Kern County Subbasin: negative is a net flow out of the district and positive is a net flow into the district
Subsurface Flow with Adjacent GW Basins	Net subsurface groundwater flow from the Kern County Subbasin with an adjoining groundwater basin: negative is a net flow out of the Basin and positive is a net flow into the Basin
Change in Groundwater Storage	Sum of the inflow components (positive numbers) plus the outflow components (negative numbers): positive is an increase in storage typified by a rise in GW levels whereas a negative is a decrease in storage typified by a decline in GW levels

TABLE 12: Estimated sustainable yield for Kern County Subbasin for WY1995 to WY2014 Base Period based on C2VSimFG-Kern Historical Simulation

Water Year	Total Average Annual Volume	Agricultural Average Annual Volume	Agricultural Average Annual Volume per Ag Acre	Urban Average Annual Volume
Units	Acre-ft	Acre-ft	ft/acre	Acre-ft
	Sustainable Yield from Groundwater Pumping			
Groundwater Pumping	1,590,373	1,239,931	1.59	176,146
Percentage of Pumping		78%		11%
Change in Groundwater in Storage	-277,114	-216,051	-0.28	-30,692
Percentage of Pumping		-17%		-17%
Sustainable Yield	**1,313,259**	**1,023,880**	**1.31**	**145,453**
Average Annual Difference	**-277,114**	**-216,051**	**-0.28**	**-30,693**
Percent Difference	**-21%**	**-21%**	**-21%**	**-21%**
	Sutainable Yield from Basin Recharge and Outflow			
Groundwater Recharge	1,400,362	1,091,789	1.40	155,101

NOTES:

Sustainable Yield from Groundwater Pumping Approach assumes that adjusting total groundwater pumping by the change in storage provides an reasonable approximation of the Basin Sustainable

Sutainable Yield from Basin Recharge and Outflow Approach assumes that the Basin Sustainable Yield can be reasonably approximated by adding up the different recharge components and non-

NOTES:

Simulation of Recharge	IWFM applies two processes to simulate the movement of water from the surface to the groundwater. The root zone simulates calculates the volume of water that will percolate below the root zone based on local soil properties. This water bases to the unsaturated zone that applies a 1-D vadose zone flow that simulates the rate that water will reach the groundwater based on subsurface properties and soil moisture content.
Percolation from Agricultural Area	Total volume of rainfall and applied water calculated to meet the total agricultural demand that percolates below the root zone in irrigated agricultural areas based on C2VSim simulation.
Percolation from Urban Area	Total volume of rainfall and applied water calculated to meet urban outdoor use that percolates below the root zone in urban areas based on C2VSim simulation.
Percolation from Native, Undeveloped or Fallow Areas	Total volume of rainfall and applied water that percolates below the root zone in native, undeveloped and fallow areas based on C2VSim simulation.
Percolation to Unsaturated Zone	Total volume of rainfall and applied water that percolates below the root zone from all areas based on C2VSim simulation.
GW Recharge from Unsaturated Zone	Volume of water going from the unsaturated zone to groundwater
GW Banking, Managed Recharge and Canal Seepage	Managed aquifer recharge and groundwater banking is simulated in C2VSim by applying a high recoverable loss factor for surface water diversions. For Kern County, these operations generally assumes that 88% to 94% of surface water deliveries physically recharge groundwater. This recharge is applied directly to the groundwater without passing through the unsaturated zone.
Net GW/SW Interactions	Net volumetric exchange between surface water in Kern River or Poso Creek and the groundwater. A positive number is surface water to groundwater, and a negative is groundwater discharge to the stream. This recharge is applied directly to the groundwater without passing through the unsaturated zone.
Total GW Recharge	Total volume to water reaching the groundwater as recharge

TABLE 22: Assessment of change in groundwater storage from C2VSimFG-Kern model results for historical and future scenarios for the Kern County Subbasin

Scenario	Model Results 2041-2070 Sustainability Period		Adjustments to GW Storage Change 2041-2070 Sustainability Period		
	Change in Groundwater Storage	Change in Net Operational Budget	Adjustment for Excess Basin Outflows	Adjustment for Excess Kern River Outflow	Adjusted Change in GW Storage
units	**AFY**	**AFY**	AFY	AFY	**AFY**
Historic	**-277,114**	**-190,012**	0	0	**-277,114**
Baseline	**-324,326**	**-253,629**	0	0	**-324,326**
Base Projects	**42,144**	**152,353**	26,327	17,108	**85,578**
2030 Climate	**-380,900**	**-318,260**	0	8,780	**-372,120**
2030 Projects	**-12,861**	**90,282**	27,056	32,634	**46,829**
2070 Climate	**-489,828**	**-429,035**	0	17,492	**-472,336**
2070 Projects	**-118,273**	**-15,861**	28,077	44,227	**-45,969**

NOTE:

"Change in *Groundwater Storage* " DOES include subsurface flow with adjacent basins

"*Operational Storage* " DOES NOT include subsurface flow with adjacent basins

"Adjustment for *Excess Basin Outflows* " is the difference in simulated basin outflow that is attributed to addition of SGMA projects in Kern County without comparable SGMA projects added to adjacent basins**.** Adjustment assumes that this difference is due to limitation of simulation, and that this difference would remain in Kern County when SGMA projects from adjacent basin are included in simulation.

"Adjustment for *Excess Kern River Outflow* " is the increase in simulated groundwater outflows to Kern River relative to Baseline condition that are attributed to SGMA Projects and Climate Change. Model is not optimized for river management. Since the Kern River is a highly managed system, the assumption is that in practice this water would be recovered for beneficial use rather than be a loss of water from the basin.

"*Adjusted Change in GW Storage* " Change in GW Storage plus modifications listed as adjustments to provide a more realistic Change in GW Storage estimate for the simulation.

TABLE 23: Evaluation of Sustainable Yield for Projected-Future scenarios based on C2VSimFG-Kern Model Results for Kern County Subbasin

Scenario	C2VSimFG-Kern Model Results 2041-2070 Sustainability Period					
	Groundwater Pumping	Change in Groundwater in Storage	GW Storage Adjustments	Sustainable Yield	Average Annual Difference of Pumping to Yield	Percent Difference of Pumping to Sustainable Yield
units	AFY	AFY	AFY	AFY	AFY	AFY
Historic	**1,590,373**	**-277,114**	**0**	**1,313,259**	**-277,114**	**-21%**
Baseline	**1,624,694**	**-324,326**	**0**	**1,300,369**	**-324,326**	**-25%**
Baseline Projects	**1,354,088**	**42,144**	**43,434**	**1,439,666**	**85,578**	**6%**
2030 Climate	**1,734,001**	**-380,900**	**8,780**	**1,361,881**	**-372,120**	**-27%**
2030 Projects	**1,444,144**	**-12,861**	**59,690**	**1,490,974**	**46,829**	**3%**
2070 Climate	**1,866,239**	**-489,828**	**17,492**	**1,393,902**	**-472,336**	**-34%**
2070 Projects	**1,559,343**	**-118,273**	**72,304**	**1,513,373**	**-45,969**	**-3%**

NOTES:

Groundwater Pumping	Total groundwater pumping by wells. Groundwater banking recovery pumping is specified input whereas agricultural and municipal pumping is calculated by C2VSim based on demand
Change in Groundwater in Storage	Sum of the inflow components (positive numbers) plus the outflow components (negative numbers): positive is an increase in storage typified by a rise in GW levels whereas a negative is a decrease in storage typified by a decline in GW levels
Adjusted Banking	Adjustment that assumes that recharge operations are affected by reductions in imported water sources, but
GW Storage Adjustments	Adjustment to GW Storage that reflect artifacts of the simulation. For Kern County, adjustments made to reflect no SGMA projects simulated north of Kern County, and that Kern River operations are not optimized to
Sutainable Yield	Sustainable yield is defined is the amount of pumping that can be sustained in the groundwater basin without the undesirable effect of a decline in groundwater storage that serves as a proxy for other undesirable effects
Average Annual Difference	The difference between the sustainable yield and the simulated groundwater pumping. A negative value is pumping in excess of the sustainable yield
Percent Difference	The percentage of the Average Annual Difference to the total groundwater pumping to provide context and a method to compare the significance of the difference in the pumping copmared to the sustainable yield.

TABLE 24: Summary of Statistical Analysis for Validation of C2VSimFG-Kern Historical Simulation

Validation Measure	C2VSimFG-Kern	C2VSimFG-Beta	Percent Change
Units	Feet	Feet	Percent
Residual Mean	17.3 ft	32.6 ft	47%
Residual Standard Deviation	45.5 ft	54.0 ft	16%
Absolute Residual Mean	37.4 ft	56.8 ft	34%
Root Mean Square (RMS) Error	50 ft	73.5 ft	32%
Scaled Absolute Residual Mean	0.061	0.092	34%
Correlation Coefficient	0.76	0.52	47%
Number of Monitor Wells	558	558	same
Number of Observations	42,075	42,075	same

Notes

Observation Point	Location in the model where measured data from well is compared to simulated model results
Residual	Difference between measured and simulated groundwater elevations at an observation point
Residual Mean	Statistical measure of fit of simulated to measured data using sum of the residuals divided by the number of residual data values
Residual Standard Deviation	Statistical evaluation of the scatter of the data by calculating standard deviation of residuals
Absolute Residual Mean	Statistical measure of fit of simulated to measured data using sum of the absolute value residuals divided by the number of residual data values
Root Mean Square (RMS) Error	Statistical measure of fit of simulated to measured data using square root of the quotient of sum of squares of residuals by the number of observations
Scaled Absolute Residual Mean	Statisical measure to provide scale of validation using ratio of the absolute residual mean divided by the range of observed groundwater elevations
Correlation Coefficient	Scaled measure of the closeness of fit of simulated to measured data from -1 to 1 correlation with 1.0 a perfect correlation
Number of Monitor Wells	Number of wells where measured groundwater level data was compared to C2VSimFG-Kern simulation results for model validation
Number of Observations	Number of groundwater level measurements that were compared to C2VSimFG-Kern simulation results for model validation
