to 500 feet in the Redondo Beach area, and then thin to a featheredge along the north flank of the Palos Verdes Hills. The thicknesses here cited do not include the deposits of dune and beach sand that blanket the coast from Playa del Rey to the Palos Verdes Hills and extend from a few tens of feet above sea level to altitudes as much as 244 feet.

For the several water-bearing zones within the principal water body, general physical character, water-bearing character, extent, thickness, and depth below land surface have been discussed in the geologic section of this report. The quantity of water withdrawn from them is discussed on pages 99–111.

CONFINED AND WATER-TABLE CONDITIONS

Within most of the west basin, the water-bearing zones within the principal water body are separated by substantial thicknesses of relatively impermeable silt or clay. These features have been shown on the gelologic sections previously introduced. The beds of silt or clay confine the water in the several aquifers and prevent free circulation from one to another. For example, between Hawthorne and Gardena, near the axis of the syncline, along the line of section *B–B'* (pl. 3*B*), the "200-foot sand" is separated from the "400-foot gravel" by 50 to 100 feet of silt or clay; and a similar thickness of silt or clay separates the "400-foot gravel" from the Silverado water-bearing zone beneath.

In the Torrance-Inglewood subarea, the water in the several aquifers is almost wholly confined by impermeable deposits, except to the south of Playa del Rey and near Redondo Beach (pl. 11), where a water table occurs. Near Playa del Rey, the water table is in the main water-bearing zone of the San Pedro formation; the top of this water-bearing zone here rises as high as 30 feet above sea level and the confining beds feather out westward in the vicinity of Lincoln Boulevard. West of Lincoln Boulevard and south nearly to Imperial Highway, the main water-bearing zone is directly overlain by permeable beach and dune deposits. Hydrographs introduced later in this report suggest that rainfall passes through these overlying permeable beds directly into the main water-bearing zone (p. 124).

In the Redondo Beach area, south of 190th Street (boundary between Tps. 3 and 4 S.) and west of the center of the city of Torrance, the confining beds that separate the Silverado water-bearing zone and the "200-foot sand" to the east and north are not present (pl. 5). In this area the permeable deposits of Pleistocene age rise above sea level and a water table occurs in what is inferred to be the Silverado water-bearing zone, although its upper part may represent the westward extension of the "200-foot sand."

In the area south of Sepulveda Boulevard and east of Narbonne Avenue, water-table conditions exist in the "200-foot sand," extend eastward about to Alameda Street and beneath much of the Wilmington area. Here, however, the "200-foot sand" is separated from the Silverado water-bearing zone by relatively impervious deposits and from west to east the water table in the "200-foot sand" stands progressively higher than the pressure surface of the Silverado zone.

Elsewhere within the Torrance-Inglewood subarea, the ground water in the Silverado water-bearing zone is wholly confined and in the "200-foot sand" it usually occurs under confined conditions.

In the Culver City subarea the water in the main water-bearing zone of the San Pedro formation commonly is confined, except locally along the north edge of Ballona Gap from the Charnock fault west to the coast, in the Charnock subbasin north of the Charnock well fields, and from the Overland Avenue fault east at least to and beyond the wells in 2/15–1C (pl. 2).

SOURCE AND MOVEMENT

METHOD OF INVESTIGATION

The source of ground water commonly is indicated by the direction of movement. Water generally moves from areas of recharge to areas of discharge. If the water-bearing deposits are homogeneous, the altitude of water level in a number of wells measured within a short span of time can be utilized to construct a map showing contours on the water table or the piezometric surface. Such a map shows conditions of head from place to place. Movement is at right angles to the contours, which connect points of equal altitude on the water table or the piezometric surface. The rate of movement is proportional to the hydraulic gradient and the permeability of the deposits.

As already discussed, the water-bearing deposits in the west basin do not occur as a homogeneous permeable mass but are stratified in several fairly distinct aquifers which are separated at most places by confining layers. Initially the pressure levels in all the water-bearing zones were at about the same altitude. Through the period of use, and largely because of inequalities in draft and replenishment, differences have developed in the pressure levels of the several aquifers. At some places, the maximum differential in water level in shallow and deep aquifers in 1946 was as much as 70 feet. Thus, in order to draw contours on the piezometric surface or water table for a single aquifer, only levels for wells tapping that aquifer can be utilized. A water-level contour map drawn from levels in random wells tapping more than one aquifer would be misleading and inac-

curate and could not be used to determine direction of movement, or source of water.

Within the west basin, the Silverado water-bearing zone south of the Ballona escarpment and its essential correlative to the north currently yield about 90 percent of the ground-water withdrawal, including nearly all the pumpage for industrial use and about 90 percent of the pumpage for domestic use. Thus, with respect to conditions of replenishment and saline contamination, the changes in the form and position of the piezometric surface in these composite water-bearing zones of the San Pedro formation are critical, and the changes in water level in overlying aquifers are of minor importance.

Water-level contour maps showing conditions in 1903-4 and in March 1933 (pl. 9), in April 1941 (pls. 10, 11), and in November 1945 (pl. 12), have been included in this report. Each of these water-level contour maps has been drawn from water-level altitudes in wells tapping the San Pedro formation—that is, the water-bearing zones most intensively utilized. Within almost all the Torrance-Inglewood subarea, the water levels utilized for the maps were those in wells tapping the Silverado water-bearing zone; in the Culver City subarea the water-level data were from wells tapping the main water-bearing zone of the San Pedro formation, the essential correlative of the Silverado water-bearing zone; and inland from the west basin, water levels were from the deeper wells tapping the Silverado or equivalent water-bearing zones of Pleistocene age.

In preparing the water-level contour maps, measurements of depth to water were utilized from all possible sources. For the maps of 1933 and 1941, measurements were made chiefly by the Los Angeles County Flood Control District and by the Los Angeles Department of Water and Power; for the map of 1945, most of the measurements were made by the Flood Control District and by the Geological Survey. All measurements made by the Geological Survey during the cooperative investigation are being published in the annual reports on water levels and artesian pressure in the United States for the years 1944, 1945, and 1946 (U. S. Geol. Survey). The scope of the measurements is discussed on page 112.

Altitudes of measuring points for most of the observation wells in the Torrance-Santa Monica area have been determined by instrumental leveling. For the area immediately west of Long Beach, in T. 4 S., R. 13 W., altitudes for many of the wells were determined by the Geological Survey in 1941–42 through a third-order level net anchored to bench mark "tidal 8" in the Los Angeles Outer Harbor, and by additional levels with transit and stadia or with alidade and level rod, tied to the third-order net (Meinzer, Wenzel, and others, 1944, p. 87–88). In the remainder of the area, altitudes of measur-

ing points for most of the observation wells have been determined by levels of the Los Angeles Department of Water and Power, and these were utilized wherever available. For a few wells, altitudes of measuring points have not been determined instrumentally; however, these altitudes have been interpolated from topographic maps of the Geological Survey having a 5-foot contour interval.

MOVEMENT IN THE TORRANCE-INGLEWOOD SUBAREA

Conditions in 1903–4.—Water-level contours for 1903–4 are plotted on plate 9 for the southern two-thirds of the project area—essentially the Torrance-Inglewood subarea. These contours were constructed from data obtained by Mendenhall and show substantial modification from his water-level contours (Mendenhall, 1905b, pl. 5). The revision has developed for two reasons: (1) The altitude of land surface at the wells measured during the Mendenhall field canvass has been re-interpolated because of recent Geological Survey topographic maps with a land-surface contour interval of 5 feet; in the Torrance area especially, the topography on the later map (1934 edition) differs considerably from that shown by the survey of 1894, which was published with a land-surface contour interval of 25 feet and was the basis for the well altitudes interpolated by Mendenhall. (2) Insofar as possible, only water levels in wells tapping the Silverado water-bearing zone have been utilized in redrawing the water-level contours, whereas the contours of Mendenhall were generalized from all available water levels, including many levels for wells tapping shallower zones.

The reconstructed water-level contours of 1903–4 show coastward movement of ground water across the Newport-Inglewood uplift and a hydraulic discontinuity from about 40 to 50 feet across the inland boundary of the west basin along the 14-mile reach from the Baldwin Hills to Long Beach. Within the west basin movement was also generally coastward. East of Manhattan Beach the 20-foot contour bulges seaward, indicating a flattening of the hydraulic gradient and a diversion of part of the ground-water flow to the northwest and to the south. This configuration of the pressure surface suggests that the known thinning of the Silverado water-bearing zone near the coast at Manhattan Beach (fig. 2) retarded discharge of ground water to the ocean. However, in the vicinity of Manhattan Beach, the dune topography is rough and hilly; and the locations of the wells shown by Mendenhall can be plotted only approximately on the revised topographic map of the Torrance quadrangle. Hence, the computed altitude of the water surface is subject to possible errors of several feet and the contours based on these altitudes are only approximations and are not suitable for exact interpretations.

From Manhattan Beach northward to Playa del Rey, the movement of ground water was westward; inland from Sepulveda Boulevard the coastward gradient was from 6 to 8 feet per mile. Near the coast, however, the gradient was only about 3 feet per mile.

Southward from Manhattan Beach to the Palos Verdes Hills, the movement was generally westward to the coast; from the Palos Verdes Hills to Long Beach the movement was southward. The coastward gradient in 1903–4, both westward toward Redondo Beach and southward toward San Pedro Bay, was about 4 feet per mile.

Thus, the contours of 1903–4 suggest escape of ground water beneath the ocean offshore from Redondo Beach and beneath San Pedro Bay. Although fresh-water springs were reported in San Pedro Bay, under native conditions, these are believed to have developed by escape of water from the ocean-bottom outcrop of the Gaspur water-bearing zone (Poland, Piper, and others, 1956, p. 50). However, escape from the Silverado water-bearing zone under native conditions by upward movement into San Pedro Bay cannot be substantiated by such direct evidence. The writer has heard reports of former fresh-water springs offshore from Redondo Beach but these have not been verified. If such springs did occur, they must have been fed by discharge from the Silverado zone.

From the geologic relations, it would seem that escape could have occurred with much greater facility in the vicinity of Redondo Beach than beneath San Pedro Bay (pls. 5 and 6). If the permeability of the Silverado water-bearing zone is assumed to be about 1,300 gpd per square foot (about two-thirds as great as in the area east of Torrance, as indicated by comparison of yield factors from table 5), the oceanward discharge in the Redondo Beach area under native conditions can be estimated by use of the equation

$$Q = P_f \times I \times A,$$

where Q is gallons per day; P_f is the field coefficient of permeability defined as the number of gallons of water per day that would be conducted through each mile width of the water-bearing bed for each foot of thickness of the bed and for each foot per mile of hydraulic gradient; I is the hydraulic gradient in feet per mile; and A is the cross-sectional area of the water-bearing material in foot-miles. The average thickness of the Silverado water-bearing zone between Hermosa Beach and the Palos Verdes Hills is about 400 feet and the distance about 3.5 miles; thus the estimated discharge $Q = 1{,}300 \times 4 \times 400 \times 3.5$, or about 7.3 mgd, equivalent to about 11 cfs. The presumed gradient of 4 feet to the mile at Redondo Beach is conservative; coastward from the 10-foot water-level contour, a steeper gradient is

suggested by the altitudes of water level in random wells. Because the local control is poor, however, the regional coastward gradient of about 4 feet per mile was utilized in computing the estimate for seaward escape in the Redondo Beach area as of 1903–4. Thus, the annual discharge to the ocean between Hermosa Beach and the Palos Verdes Hills in 1904 is estimated to have been about 8,000 acre-feet per year.

North from Hermosa Beach to Playa del Rey and along San Pedro Bay the data on gradient near the coast in 1903–4 are fragmentary but a rough estimate of oceanward discharge is given on page 147.

Conditions in 1933.—The withdrawals of ground water from the Torrance-Inglewood subarea increased from an estimated 10,000 acre-feet per year in 1904 to about 50,000 acre-feet per year in the early thirties (p. 99–100). The water-level contours for March 1933 (pl. 9) show the changes in position of the water level and in direction of movement that had developed since 1904 as a result of increasing withdrawals from the west basin and from the main coastal basin to the northeast. These changes can be summarized as follows:

1. Immediately inland from the west basin boundary, in the reach from the Baldwin Hills to Long Beach, the water levels had declined about 40 feet in the 29 years but the direction of movement was still coastward into the west basin. The local gradient had been steepened to a small degree. (See also pl. 4 showing water-level profiles for 1904 and 1930.)
2. The pressure differential across the fault boundary ranged from about 30 feet at Inglewood and Dominguez Gap to about 50 feet in the central part of the Rosecrans Hills.
3. Within the area south of Inglewood the pressure level—and, locally, the water table—was below sea level. Everywhere westward from the axis of the pressure trough, about two-thirds of the Torrance-Inglewood subarea, the direction of movement of the water within the Silverado zone had been reversed and was landward—generally southeastward or eastward toward the area of greatest pressure lowering in Dominguez Gap.

Conditions in 1941 and in 1945.—Plate 11 shows water-level contours for April 1941 and plate 10 indicates the rise or fall in water level that had occurred since March 1933 (pl. 9). The general pattern of the contours is similar to that for March 1933. However, attention is directed to four features:

1. The maximum drawdown of water levels in the 8-year period occurred immediately inland from the west basin boundary, east of Inglewood and within the Rosecrans Hills, and was about 30 feet. This drawdown, indicating local overdraft, was noteworthy because almost everywhere else within the main coastal basin (central basin), except in the Huntington Park area, water levels were higher in 1941 than in 1933.
2. In the west basin, north of 190th Street, nearly all water levels were drawn down, but the maximum decline of 16 feet, which developed between Inglewood and Hawthorne, was only about half as great as the drawdown inland beyond the west basin boundary.

3. South of 190th Street, water levels changed only a few feet between 1933 and 1941. In the Wilmington area, a small net rise resulted from the virtual cessation of pumping at the Wilmington and Lomita well fields of the city of Los Angeles (table 7).

4. The axis of the pressure trough moved inland as much as 3 miles between Hawthorne and Gardena, but it was almost stable from 190th Street into Dominguez Gap. This axis marks the boundary between coastward and landward movement of ground water in the Silverado water-bearing zone.

Largely because of demands caused by industrial expansion during the war years, withdrawal of ground water from the Torrance-Inglewood subarea increased about 50 percent between 1941 and 1945 (table 8). The water-level contours of plate 12 indicate conditions in November 1945, essentially at the end of the period of acceleration in draft induced by the war expansion, in relation to distribution of pumping draft.

The contours represent approximate low-water levels for the year, whereas the contours for 1933 and 1941 represent the high-water levels in those years. As is shown on representative hydrographs introduced later in this report, the yearly fluctuation in the Silverado water-bearing zone within the west basin ranges from about a foot near the coast to as much as 30 feet in areas of heavy pumping near the inland boundary. For example, the center of the depression in the piezometric surface immediately north of Hawthorne was 62 feet below sea level in November 1945, but it was only 38 feet below sea level in March 1945 (pl. 13, well 3/14–4N1). Thus, although the contours for November 1945 indicate a maximum decline of more than 30 feet below the contours for April 1941 (pl. 11), much of this is due to seasonal fluctuations. The contours of November 1945 were drawn to show the lowest water levels for the Silverado water-bearing zone that had occurred in the Torrance-Inglewood subarea to the end of 1945. With respect to saline encroachment from the ocean, the average controlling hydraulic gradient is about halfway between the seasonal high and low levels. However, the maximum rate of landward advance of the saline front occurs at the time of autumn low water. In November 1945, the landward gradient from the coast to the minus 20-foot contour was steepest between El Segundo and Hermosa Beach, as much as 20 feet per mile; in the vicinity of Redondo Beach it was only about a third as steep, from 5 to 6 feet per mile.

The axis of the pressure trough did not move appreciably from 1941 to 1945, even though pressure levels along that axis were drawn down locally as much as 30 feet. In November 1945, the greatest differential pressure across the inland boundary of the west basin was about 60 to 70 feet. Differential pressures of this magnitude occurred east of Inglewood across the southern part of the Potrero fault, also in Dominguez Gap across the Cherry-Hill fault.

MOVEMENT IN THE CULVER CITY SUBAREA

Summary of geologic features.—Ballona Gap, a broad trench cut into the Pleistocene deposits by an ancestral Los Angeles River, is floored by deposits of Recent age to a depth of 40 to 80 feet below land surface. These deposits consist of an upper and a lower division. The upper division consists chiefly of clay, silt, and fine sand; it is from 10 to 40 feet thick and of low permeability. The lower division, the "50-foot gravel," is composed almost wholly of gravel, but locally contains lenses of coarse sand. Its thickness ranges from 10 to 40 feet and its average base is about 50 feet below land surface. The "50-foot gravel" blankets most of the gap (pl. 8) and furnishes a thin but permeable ground-water artery from the main coastal basin to the ocean.

Everywhere within the gap, the "50-foot gravel" is presumed to be underlain by the San Pedro formation. Near the coast, the San Pedro largely consists of sand and gravel; but inland beyond the Inglewood fault more than half the formation is made up of layers of silt and clay, which separate and confine the layers of sand and gravel (pl. 3*D*). Within and adjacent to Ballona Gap, three faults divide the San Pedro formation into distinct blocks which are critical with respect to water circulation and to movement of contaminated waters. These three faults are subparallel and trend about north-northwest. So far as known, they do not transect the deposits of Recent age and presumably do not interrupt hydraulic continuity in the "50-foot gravel." (See p. 76 and 78.)

Of the three faults, the Inglewood fault, the farthest inland, passes across the gap about 6 miles from the coast and forms the inland boundary of the west basin in this area. The Sentney plant of the Southern California Water Co. (in 2/14–5D) is a short distance east of this fault and within the main coastal basin. Logs of wells at this plant show that three distinct aquifers in the San Pedro formation yield water to wells and that the three are separated by impervious strata.

The Overland Avenue fault is about 2 miles coastward from the Inglewood fault. Between these two faults, an upthrown block of the San Pedro formation contains water-bearing beds whose thickness ranges from 50 to 100 feet. The subbasin within this block is termed the crestal subbasin.

The Charnock fault is about 1.2 miles west of the Overland Avenue fault and 3 miles from the coast. Between these two faults the San Pedro formation has been dropped and the main water-bearing zone is as much as 350 feet thick. In subsequent discussion, the subbasin within this block will be referred to as the Charnock subbasin. Coastward from the Charnock fault the San Pedro formation is gently

folded and its water-bearing deposits range from 100 to 250 feet in thickness.

Logs of wells indicate that the "50-foot gravel" and the underlying water-bearing deposits of the San Pedro formation are in direct contact locally within each of the blocks here described, and thus, some hydraulic continuity occurs. The complex structure of the San Pedro formation makes it difficult to trace the extent of hydraulic continuity, except where logs of closely spaced wells are available. However, the hydraulic continuity is known to be most free coastward from the Charnock fault, and is very poor to absent inland from the Overland Avenue fault.

North of Ballona Gap, logs of wells show a general southerly dip of the water-bearing beds of Pleistocene age, but the sand and gravel layers are irregular in thickness and position and cannot be correlated from well to well. Only within the dropped Charnock subbasin (to the north), are the water-bearing deposits thick and extensive. The main water-bearing zone extends continuously at least 2 miles north from the gap, to the vicinity of Pico Boulevard, where its top is about 50 feet above sea level and its thickness about 250 feet.

Circulation of ground water.—The Culver City subarea has been defined as including the part of the west basin north of the Ballona escarpment. The ground-water contour maps of the west basin for the selected times between 1904 and 1945, inclusive, indicate that exchange of ground water between the Culver City subarea and the Torrance-Inglewood subarea—that is, across the Ballona escarpment—has been small. Also, in the Culver City subarea, movement has been controlled very largely by fault barriers, which appear to partition the subarea into three essentially separate subbasins. Within these subbasins, movement has been chiefly in response to concentrations of draft at several heavily pumped well fields (pl. 12).

Water-level contours for the Culver City subarea for 1903–4 were reconstructed from basic data by Mendenhall but it was impracticable to reproduce them on plate 9, because of the complexity of the hydrologic pattern for 1933. However, a brief summary of salient features is presented. These contours indicate that in 1903–4 there was a general southward movement of ground water toward Ballona Gap from the upland area flanking the Santa Monica Mountains. In Ballona Gap the contours were drawn chiefly from water levels in shallow wells tapping the "50-foot gravel" because in 1904 very few wells had been drilled to the San Pedro formation below. Here the movement of water was southwestward and essentially parallel with the slope of the land surface. In Ballona Gap, a short distance west of the Inglewood fault, the water-level contours bulge coastward, indicating that water in the "50-foot gravel" was moving coast-

ward from the main basin into the west basin, over the top of the Inglewood fault. Throughout its 6-mile reach within the west basin Ballona Creek was an effluent stream draining water from the Recent deposits of the gap. The reach of effluent seepage extended inland at least half a mile beyond the Inglewood fault and into the area of artesian flow that still existed in 1904 in the main coastal basin.

The water-level contours for March 1933 (pl. 9), April 1941 (pl. 11), and November 1945 (pl. 12), show general similarity in direction of ground-water movement; and all show substantial change from the water-level contours of 1903–4. This change was brought about by (1) heavy draft from well fields in or adjacent to the two subbasins, and (2) the barrier action of the three major faults, which bound those subbasins.

In the main coastal basin, immediately inland from the Inglewood fault and adjacent to Washington Boulevard, heavy withdrawals from the wells at the Sentney plant of the Southern California Water Co. in sec. 5, T. 2 S., R. 14 W., and from nearby wells of the city of Beverly Hills (Cadillac and Castle plants) had developed a substantial cone of pressure relief by the early thirties. In March 1933, the pressure level at the center of this cone as represented by the hydrograph for well 2/14–5D5 (pl. 14), was about 10 feet above sea level; but by April 1941 it had been drawn down as much as 60 feeet below sea level. By 1945 local draft by the city of Beverly Hills had decreased and the water level in the spring of that year at well 2/14–5D5 had recovered substantially; but it was still 30 feet below sea level. Thus the pressure levels at these well fields have been maintained many tens of feet below sea level continuously for the past decade and water in the aquifers of the San Pedro formation has been moving into this cone of depression from the south, east, and north.

Crestal subbasin.—In the crestal subbasin, between the Inglewood and Overland Avenue faults, the movement of water in the San Pedro formation has been consistently southward from the Beverly Hills through 1945. Within this subbasin pumping draft is largely from wells at the Manning plant of the Southern California Water Co. in 2/15–1C and from well 2/15–12B1 of the Metro-Goldwyn-Mayer Corp. (pl. 2). Total draft from this subbasin is believed not to have exceeded 1,600 acre-feet per year. Under native conditions and continuously through the period of withdrawal, replenishment to the San Pedro formation in the crestal subbasin apparently has been supplied almost entirely by runoff from the south flank of the Santa Monica Mountains and by rainfall from the Santa Monica plain. However, in Ballona Gap north of Washington Boulevard, the water-bearing beds of the San Pedro formation are believed to be in direct contact locally with the overlying "50-foot gravel." Hence, ground

water passing westward across the Inglewood fault in the "50-foot gravel" may contribute some replenishment to the underlying San Pedro beds in the crestal subbasin. Within this subbasin, the position of water level in the "50-foot gravel" is not known, except at well 2/15–1P2 near the western boundary; here the water level in this aquifer has been about 30 feet lower than the pressure level of the San Pedro formation for the past 15 years. (See hydrograph for well 2/15–1P2 on fig. 4; pressure levels for San Pedro formation, pls. 9–12.) Thus, near this well, for many years the pressure differential between the two aquifers would not have permitted downward movement from the "50-foot gravel" to the San Pedro formation—if hydraulic continuity exists at all, movement would have been upward.

Charnock subbasin.—In the Charnock subbasin, during the past two decades at least, pumping has been concentrated at the Charnock plant of the city of Santa Monica (2/15–11C), and at the Charnock plant (2/15–11D, E, F) and the Sepulveda plant (2/15–11J) of the Southern California Water Co. The joint withdrawal from these three plants was 7,352 acre-feet in 1933, reached a maximum of 10,448 acre-feet in 1940, and was 7,258 acre-feet in 1941 and 5,005 acre-feet in 1945. The decrease in withdrawal was caused by the gradual decrease in the rate of pumping at the Charnock plant of the city of Santa Monica following 1940 and the complete cessation of pumping by the city late in 1944.

As a result of the concentrated withdrawal at the Charnock well fields and at the nearby Sepulveda well field, the water level in the San Pedro formation has been depressed several tens of feet below sea level since the late twenties. As shown by the water-level contours for the years 1933, 1941, and 1945 (pls. 9–12), and by other data, movement of ground water throughout the subbasin has been toward this focus of withdrawal for the past two decades. To the north (nearly to Pico Boulevard), water levels have been below sea level consistently since 1933, and the steep southward gradient induced by this draft has been as much as 50 feet to the mile (pl. 11). To the south (to and beyond the Ballona escarpment), water levels have been below sea level consistently since 1933, and the average northward gradient has been as much as 25 feet per mile (pl. 11). Thus, at least since 1933, about two-thirds of the water withdrawn from these well fields has come from the north and about one-third from the south. The water-level contours for the San Pedro formation indicate that very little water enters the Charnock subbasin from the east (across the Overland Avenue fault), or from the west (across the Charnock fault), even though the pressure differentials across the two faults have been as much as 110 feet and 90 feet (pl. 11).

The "50-foot gravel" may conduct some water into the Charnock subbasin, from both the east and the west. As shown by geologic section *D–D'* (pl. 3*D*), the "50-foot gravel" is in contact (at least locally) with the water-bearing beds of the San Pedro formation within the Charnock subbasin, and presumably some downward percolation of water occurs. However, fragmentary records of water levels in shallow wells indicate that in the part of the subbasin north of Ballona Creek, the "50-foot gravel" has been essentially dewatered for the past two decades. Southward from Ballona Creek, the base of the "50-foot gravel" locally is as much as 60 feet below sea level, and this water-bearing zone still must be almost wholly saturated.

Coastal area.—Between the Charnock fault and the coast, the "50-foot gravel" of Ballona Gap and the underlying main water-bearing zone of the San Pedro formation are in contact at many places, as shown by logs of wells. Thus, these water-bearing zones may have fair hydraulic continuity (p. 127). The water-level contours of 1903–4 indicate a general oceanward movement of water through these deposits, with a coastward hydraulic gradient of about 10 feet per mile. North of the gap, the water-level gradient was southward, indicating some replenishment from the Santa Monica upland area.

By the late twenties water levels in this coastal part of Ballona Gap had been drawn down as much as 10 to 30 feet and were from 5 to 15 feet below sea level (see pl. 9 for levels in 1933). The water-level contours of March 1933 indicate some continuing contribution from the north, but the underflow to the gap from beneath the Ocean Park and Santa Monica plains must be small because: (1) the water-bearing deposits are thin, and (2) southward movement is impeded by the ground-water barrier about at the north edge of T. 2 S., which is inferred to be a fault zone. Water levels in the gap had recovered to sea level by 1941, probably in part because of the heavy rainfall of that year but chiefly owing to a general decrease of draft for irrigation and cessation of pumping by the Marine plant of the city of Santa Monica in 2/15–9N; both actions were caused by saline encroachment. However, from the early thirties to date, the water level in this coastal part of the gap has been essentially flat and movement of water apparently has been largely in response to local draft. Except for withdrawals from the Marine plant to which reference has been made, that draft has been moderate and widely distributed. Because water levels were below sea level from the middle twenties through the thirties, sea water has advanced inland beyond Lincoln Boulevard and about half the distance from the coast to the Charnock fault (p. 197).

WITHDRAWAL OF GROUND WATER

HISTORY OF DEVELOPMENT

Development of ground water in the coastal plain began about 1870. As of 1904, Mendenhall (1905a, 1905b, 1905c) canvassed and described about 8,200 wells within the coastal plain, of which about 2,500 were flowing in the spring of 1904. Mendenhall estimated that in 1904, the average discharge of all flowing and pumped wells within the coastal plain was about 250 cfs, equivalent to a yearly withdrawal of about 180,000 acre-feet. He did not evaluate withdrawals from the west basin specifically. However, in 1904 there were 134 wells with pumping plants in the west basin, as compared to 282 wells with pumping plants in the Santa Monica and Redondo quadrangles (Mendenhall, 1905b, pls. 5 and 6). The average annual yield of all pumped and flowing wells in these two quadrangles was estimated as about 30,000 acre-feet. If the estimated yield is distributed in proportion to the number of wells with pumping plants, the withdrawals in 1904 were about 14,000 acre-feet per year for all the west basin, and about 10,000 acre-feet per year from the part of the west basin south of Ballona Gap—the Torrance-Inglewood subarea of this report. Because the lands irrigated by ground water within the Santa Monica and Redondo quadrangles amounted to only 12,250 acres in 1904, Mendenhall's over-all figure of 30,000 acre-feet probably is liberal (about 2.5 acre-feet per acre); thus, the estimate of 14,000 acre-feet just derived for the west basin likewise is also believed to be liberal.

During the quarter century following the canvass by Mendenhall, the rate of withdrawal from the west basin increased several fold, owing to: (1) increased demand for water for irrigation, industrial, and domestic use, (2) lack of surface-water sources, and (3) improvement and widespread use of deep-well turbine pumps. Information is not available to indicate the rate at which the withdrawal increased from 1904 to 1930. However, extensive industrial development commenced in the twenties, and water levels in wells tapping the Silverado water-bearing zone began to decline noticeably in the early to middle twenties. Also, a period of low rainfall began about 1919 (table 2), causing an increase in the use of water for irrigation. Thus, it is inferred that the over-all increase in draft was most rapid after 1919. Furthermore, the figures for electrical energy sold on the "agricultural-rate" schedule in the Redondo and Inglewood operating districts of the Southern California Edison Co. are available for the period beginning in 1923. In comparison with the amount of energy sold in 1932, as a base year (p. 104), the amount of energy sold annually in these two operating districts of the Edison Co. from 1923

through 1930 was higher in all years except 1927. The average use in the 8 years was 112 percent of the use in 1932; the peak was in 1923—about 140 percent of the 1932 base. Although water levels in the west basin declined nominally in the twenties, it is believed that pump efficiencies were improved sufficiently to nearly compensate for the increased lift, and that the amount of electrical energy required to raise an acre-foot of water remained nearly constant. Thus, it is concluded that the draft for irrigation in the Torrance-Inglewood subarea was slightly greater from 1923 through 1930 than in 1932 and following years (table 8). Accordingly, the main increase in irrigation draft must have occurred prior to 1923.

As indicated in table 8, by 1931 the withdrawal from the Torrance-Inglewood subarea was about 53,000 acre-feet per year, which incicates an increase of nearly 400 percent in the 26-year period since 1904. Records of withdrawal by the larger plants since 1931 are reasonably complete, and the withdrawal for irrigation and miscellaneous uses can be approximated with fair accuracy. Methods of evaluating this withdrawal are discussed in following pages, and estimates for the yearly over-all draft from the Torrance-Inglewood subarea beginning in 1931 are summarized in table 8.

PUMPAGE FROM MUNICIPAL WELL FIELDS

In 1945, eight cities operated municipal water systems within the Torrance-Santa Monica area. The well fields of the cities of El Segundo, Hawthorne, Manhattan Beach, Santa Monica, and Torrance are located within the west basin. The city of Santa Monica, however, purchased most of its water supply from the Metropolitan Water District, beginning in 1941, and reportedly discontinued the use of its well fields entirely in 1945. The city of Inglewood operated several well fields within the west basin and one (the Centinela Park well field) that was almost entirely in the main coastal basin. The city of Los Angeles operated its Lomita and Wilmington plants, which were within the west basin, and its Manhattan, 99th Street, and Figueroa Street plants in the main coastal basin. In 1945, the city of Beverly Hills pumped all of its water from well fields outside the west basin, partly from the main coastal basin and partly from the Hollywood basin of Eckis (1934, pl. *E*). In addition to these eight municipal systems, Los Angeles County Water Works Districts 13 and 22 withdrew water from plants wholly within the west basin. The distribution of plants producing more than 200 acre-feet of water for public supply or for industrial use in 1945 is shown on plate 12 (also see table 10).

Pumpage records for all these systems except that of Beverly Hills were collected by the Geological Survey from officials of the water

departments or from the city engineers. In some cases these records were extended to earlier years by utilizing estimates made by other agencies, chiefly the Metropolitan Water District (Vail, 1942, table 2). Records of pumpage by the city of Beverly Hills were obtained through the California Division of Water Resources. Available records of the yearly pumpage by each of the eight cities are given in table 7. In this table each record is carried back as far as available data will permit. Except as noted, records are for the calendar year. Total yearly withdrawals from the municipal and county water works district fields within the Torrance-Inglewood subarea from 1931 through 1945 are summarized in table 8, column 2.

WITHDRAWAL FROM THE TORRANCE-INGLEWOOD SUBAREA, 1931–45

METHODS OF EVALUATING WITHDRAWAL

Industrial consumption.—In the southern and central parts of the Torrance-Inglewood subarea, south of El Segundo Boulevard, 20 industrial plants currently obtain their water from wells. The largest use is by petroleum refineries, of which eight are in this area. Most of the records of withdrawal of ground water by each of these industrial plants was obtained from plant representatives. Meter records were available for all plants using large quantities of water. However, estimates that were supplied for several of the smaller plants were based on well performance and hours of operation.

In the central part of the west basin, between El Segundo Boulevard and the Ballona escarpment, there are a number of industrial plants,

but, as far as known, all of these plants purchase their water from municipalities or water companies.

Pumpage by large water companies.—Within the Torrance-Inglewood subarea about 25 private water companies supply water for domestic, irrigation, and industrial uses. Meter records of production are available for several of the larger companies. In connection with its field canvass of wells, the Geological Survey collected meter records from the California Water Service Co., the Dominguez Water Corp., the Palos Verdes Water Co., the Palisades Del Rey Water Co., and the Southern California Water Co. In addition, the pumpage of the Moneta Water Co. has been interpolated from estimates by other agencies in 1931 and 1944. With the exception of the part of the withdrawal by the Dominguez Water Corp. that is sold to industrial plants, total draft by these six companies is given in table 8, column 4.

Pumpage for irrigation and miscellaneous uses.—Withdrawal of ground water by private irrigators and by many small water companies is substantial. However, neither meter records nor estimates are available for most of this use. In its appraisal of withdrawal in the Long Beach-Santa Ana area, the Geological Survey estimated pumpage for agricultural purposes by deriving yearly mean energy factors (energy expended in raising a unit quantity of water) and applying these factors to the quantity of electrical energy expended in pumping from wells. In appraising pumpage for irrigation from the west basin, however, it was found that this method was not readily applicable because: (1) three operating districts of the Southern California Edison Co. extend from the west basin into the main coastal basin, (2) pump-efficiency tests were not sufficiently comprehensive in distribution to define satisfactory yearly energy factors, and (3) many of the smaller water companies are not supplied with energy under the agricultural-rate schedule of the Edison Co.

Because the energy-factor method could not be readily applied, the pumpage for irrigation and for miscellaneous uses in the Torrance-Inglewood subarea was estimated from figures of irrigated acreage, considered together with a plot of electrical energy purchased yearly on the agricultural-rate schedule. Specifically, in 1932 and in 1941, the California Division of Water Resources made crop surveys of the lands in the west basin. Unpublished data in the files of the Division, compiled from these surveys and from maps showing service areas of municipal systems and public utilities, have been utilized by the Geological Survey to estimate the acreage supplied from wells with meter record estimate of pumpage. For the Torrance-Inglewood subarea, it has been estimated from these data that in 1932 an area of about 13,200 acres was so supplied (about 90 percent classified by the Division as irrigated lands and about 10 percent classified as

domestic and industrial areas). Water use on the 13,200 acres in 1932, a year of nearly average rainfall (table 2), is estimated to have been about 13,200 acre-feet, an average use of 1 acre-foot per acre. This figure agrees with estimates made by the Los Angeles County Flood Control District from a field survey in 1931 (Dockweiler, 1932, pl. 11), which indicated that private irrigation and miscellaneous plants in the part of the Torrance-Inglewood subarea west of Vermont Avenue pumped about 9,200 acre-feet in that year. That figure did not include withdrawal from similar plants east of Vermont Avenue, but it is estimated that these plants pumped about 4,000 acre-feet in 1932.

Furthermore, from the crop survey of the California Division of Water Resources made in 1941, it has been estimated that the lands in the Torrance-Inglewood subarea supplied with water from wells for which neither meter records nor estimates are available was about 16,000 acres in that year. About three-quarters of this area—or about the same acreage as in 1932—was classified by the Division as irrigated lands and about one-quarter of the area was classified as domestic and industrial sections. Thus, it is apparent that an increase of about 3,000 acres in lands used for domestic and industrial development supplied with water by noncanvassed withdrawals had occurred since 1932. Data are not available to indicate the rate at which this increase in domestic use took place. Therefore, it is assumed to have been uniform, or about 330 acres per year, and to have required a duty of 1 acre-foot per acre.

To obtain yearly figures for the unmetered irrigation and domestic uses through 1941, it has been assumed that the annual sales of electrical energy under the agricultural-rate classification in the Redondo and Inglewood operating districts of the Southern California Edison Co. furnish an approximate index of water pumped for agricultural use from 1931 through 1941. In that 11-year period the average decline of water level within the Torrance-Inglewood subarea was about 4 feet for the Silverado water-bearing zone, the principal aquifer. The small increase in lift may have been more than offset by improvement in pumping-plant efficiencies. The year 1932, with an estimated withdrawal of 13,200 acre-feet for unmetered agricultural and domestic uses, has been taken as the base year. Thus, for 1931 and the years 1933 through 1941, estimates of withdrawal for unmetered irrigation use in each year have been obtained by multiplying 13,200 by the percentage of electrical energy used in that year in comparison to the 1932 base use. To the figure so obtained has been added the estimated increase in uncanvassed domestic use, prorated as described above. The sum of these two elements has been entered in table 8, column 6.

For the war years 1942–45, agricultural withdrawals decreased substantially but domestic expansion was greatly accelerated, and a considerable part of this increased domestic use of water was met by the smaller water companies. Data are not available to indicate the proportionate changes in area. Therefore, water used for irrigation and for miscellaneous purposes in these 4 years is assumed to have been constant at about 13,000 acre-feet per year.

The estimates entered in table 8 for yearly withdrawals by private irrigators and for miscellaneous use are only approximate. However, these figures constitute less than one-quarter of the total pumpage from the Torrance-Inglewood subarea. Extensive work would have been required to derive a more accurate estimate. In 1948 the California Division of Water Resources began a detailed study of the quantity of ground water drawn from each of the wells or well fields of this subarea, in connection with the pending adjudication of water rights. Accordingly, duplication of work, which the Division must carry out for legal reasons, was not believed to be warranted.

ESTIMATE OF TOTAL PUMPAGE

Table 8 and figure 3 summarize the yearly withdrawal from the Torrance-Inglewood subarea for the 15 years from 1931 through 1945. The estimated over-all draft from this area decreased from 52,600 acre-feet in 1931 to 44,500 acre-feet in 1937, rose to 52,700 acre-feet in 1942, and then increased sharply during the war years to about 78,000 acre-feet in 1945. As shown by the table, most of this expansion was caused by increased industrial demand. Withdrawals for

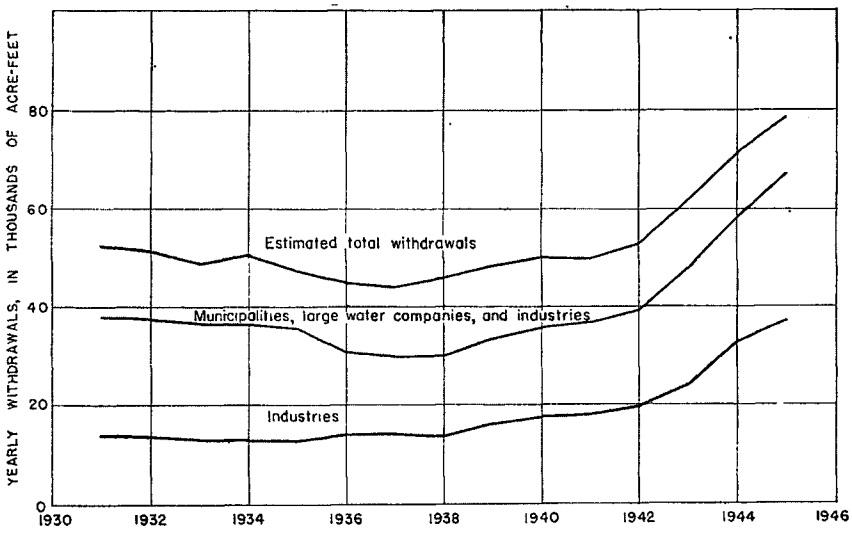

FIGURE 3.—Estimated withdrawals of ground water from the Torrance-Inglewood subarea, 1931–45.

industrial use were nearly constant at 14,000 acre-feet per year from 1931 through 1938, or about 30 percent of the total use; and increased to 19,640 acre-feet in 1942; and to 37,420 acre-feet in 1945, or about 48 percent of the total use. Most of the increase in industrial use of water during the war years was due to the expanded requirements of the oil refineries; in 1945, these refineries accounted for about 88 percent of the industrial demand.

1944	12,000	33,680	13,020	58,700	[5] 13,000	71,700
1945	13,220	37,420	14,770	65,410	[5] 13,000	78,400

[1] For purposes of this report, the part of the west basin south of the Ballona escarpment is called the Torrance-Inglewood subarea.
[2] Includes water pumped by County Water Works Districts 13 and 22.
[3] Includes water sold to industrial plants by the Dominguez Water Corp.
[4] Rounded off to three figures.
[5] Flat estimate only.

The municipal systems accounted for nearly 25 percent of the total draft in 1931 and about 17 percent in 1945. The decrease in use by municipal systems from about 12,000 acre-feet in 1935 to 5,300 acre-feet in 1936 was a result of cessation of withdrawal at the Lomita and Wilmington well fields of the city of Los Angeles, these fields had withdrawn about 8,000 acre-feet per year in the early thirties. Since 1936 the yield from these two well fields has been small.

WITHDRAWAL FROM THE CULVER CITY SUBAREA

Withdrawal of ground water from the Culver City subarea (the part of the west basin north of the Ballona escarpment) has not been appraised in detail. The field canvass of wells was carried only from 1 to 2 miles north of Ballona Gap and collection of records of pumpage from privately owned wells was not attempted for any part of the

Culver City subarea. However, the most heavily pumped well fields have been those of the city of Santa Monica and those of the Southern California Water Co. Table 9 gives the draft from the Culver City subarea by these two agencies yearly from 1931 through 1945.

TABLE 9.—*Withdrawal of ground water, in acre-feet, from the Culver City subarea by the city of Santa Monica and by the Southern California Water Co., 1931–45*

[Sum of pumpage from the Marine, Charnock, and Arcadia plants of the city of Santa Monica, and from the Pacific, Charnock, Sepulveda, and Manning plants of the Southern California Water Co.]

Year	Acre-feet	Year	Acre-feet	Year	Acre-feet
1931	7,111	1936	10,461	1941	8,705
1932	8,066	1937	10,956	1942	4,405
1933	8,607	1938	11,773	1943	5,622
1934	9,238	1939	12,567	1944	6,125
1935	9,312	1940	12,933	1945	6,106

In addition to the withdrawal from the principal well fields, shown in table 9, water from private plants was used to irrigate about 3,300 acres of land in 1932 and about 3,000 acres in 1941 (unpublished data from California Division of Water Resources), chiefly along the south edge of Ballona Gap and in secs. 2 and 3, T. 2. S., R. 15 W. (pl. 2). These irrigated areas were supplied almost exclusively from private wells, although possibly as much as 200 acres of this land have been irrigated with water pumped directly from Ballona Creek (C. E. Bollinger, Los Angeles County Flood Control District, oral communication). About two-thirds of the over-all acreage is planted in garden and field crops and one-third is in irrigated grass. The quantity of ground water pumped to irrigate these lands probably is about 4,000 acre-feet a year.

The privately owned wells yielding water for irrigation in the Culver City subarea in 1945 (excluding the area north of the north boundary of T. 2 S.) were distributed as follows: in the coastal area, 30 wells; in the Charnock subbasin, 24 wells; in the crestal subbasin, 2 wells. If the annual well yields are assumed to be proportional to the distribution, the estimated draft for irrigation (4,000 acre-feet) would be about 2,100 acre-feet from the coastal area, 1,700 acre-feet from the Charnock subarea, and 200 acre-feet from the crestal subbasin. Actually, because yields of wells in the Charnock subbasin are larger than those of wells nearer the coast and because slightly more than half of the irrigated acreage is supplied by water pumped from the Charnock subbasin, it is inferred that the division of draft as of 1945 was about 1,800 acre-feet from the coastal area, 2,000 acre-feet from the Charnock subbasin, and 200 acre-feet from the crestal subbasin.

The larger part of the withdrawal from the Charnock subbasin has been for public supply and has been obtained from the Charnock

well field of the city of Santa Monica and the Charnock well field of the Southern California Water Co.; both fields are in the NW¼ sec. 11, T. 2 S., R. 15 W. (pl. 2). The yearly withdrawal records from these two well fields for the 15 years are graphed on plate 14. The Sepulveda plant of the Southern California Water Co. (well 2/15–11J) also is in this subbasin. The over-all draft from the Charnock subbasin from these three well fields, and from the private irrigation wells previously discussed, is estimated to have been approximately 9,000 acre-feet in 1931, 10,000 acre-feet in 1935, 12,500 acre-feet in 1940 (the peak year), and 7,000 acre-feet in 1945.

In the crestal subbasin, perennial draft has been chiefly by: (1) the Manning plant of the Southern California Water Co. from well 2/15–1C, beginning in the middle twenties; (2) the Metro-Goldwyn-Mayer Corp., from wells 2/15–12B1 and 2/14–7P1, beginning in 1932; (3) the LAC Chemical Co., from well 2/14–6H1, beginning in 1942; and (4) the Holy Cross Cemetery from well 2/14–18Q1, and irrigation wells 2/14–18F1 and F2. The over-all draft from this subbasin did not exceed a few hundred acre-feet per year until the middle thirties; it was about 1,100 acre-feet in 1935 and in 1940, and had increased to about 1,600 acre-feet in 1945.

For the Culver City subarea as a whole, it is estimated that the withdrawal in 1931 was about 13,000 acre-feet. Withdrawal increased to about 20,000 acre-feet in 1940, the peak year of pumpage by the city of Santa Monica. In that year withdrawal was approximately two-fifths as large as it was in the Torrance-Inglewood subarea to the south. In 1945, when draft by the city of Santa Monica had ceased, the withdrawal had decreased to about 12,000 acre-feet per year, or only about one-sixth of that in the Torrance-Inglewood subarea. The over-all use of water in the Culver City subarea is many times greater than the ground-water draft. Current importations (1948) consist chiefly of surface water from the Los Angeles municipal supply, the Colorado River and ground water from the Sentney plant of the Southern California Water Co.

WITHDRAWAL INLAND FROM THE WEST BASIN

About 90 square miles of the Torrance-Santa Monica area is inland from the west basin and almost entirely within the main coastal basin. The over-all withdrawal of ground water from the 90 square miles was not evaluated in this investigation.

Except for the area within the city of Beverly Hills, nearly all of the territory north of Imperial Highway is within the city of Los Angeles and is supplied chiefly by water from the Los Angeles municipal system. Most of the Los Angeles municipal supply to the coastal

plain is imported from the Owens Valley or from the San Fernando Valley, but in this inland area the city currently obtains a minor auxiliary supply of ground water from its Manhattan and 99th Street plants. Some of the area north of Imperial Highway is served by the Sentney, South Los Angeles, and Normandie systems of the Southern California Water Co. The distribution and magnitude of draft from the larger well fields for public supply, as of 1945, are shown on plate 12.

Inland from the west basin, the position and slope of the pressure level are critical with respect to the rate of replenishment by underflow across the west basin boundary. Both the position and slope of the pressure level between Slauson and Rosecrans Avenues are believed to be affected to a major extent by the very heavy withdrawal in the Huntington Park area, a short distance to the east of the east boundary of the Torrance-Santa Monica area. However, the position and slope of the pressure level are affected also by the intensity of local withdrawal. Thus, it is of interest to note that the combined withdrawal from the pumping plants of the city of Los Angeles and of the Southern California Water Co., between Slauson and Rosecrans Avenues, was 4,030 acre-feet in 1931, 3,130 acre-feet in 1938, and 6,440 acre-feet in 1945.

DISTRIBUTION OF DRAFT AS OF 1945

By 1945 most of the withdrawal of ground water from the Torrance-Santa Monica area was concentrated at a number of intensively pumped well fields operated almost entirely for public supply or industrial use. To show the nature of this concentration and its effect on the water levels in the Silverado water-bearing zone and in the correlative aquifers within the San Pedro formation beyond the extent of the Silverado, the magnitude of draft at such plants within the coastal zone of the Torrance-Santa Monica area has been indicated on plate 12 by means of circles whose areas are proportional to the draft. The centers of these circles are plotted at the centers of pumping. For closely grouped wells, the circle commonly encompasses the entire well field; for groups of widely scattered wells which supply a single system, such as the South Los Angeles system of the Southern California Water Co., the circle is plotted approximately at the geographic center of pumping. The circles so plotted on plate 12 are numbered and table 10 identifies the agency withdrawing the water; numbers in this table correspond with those of the plate.

As shown on plate 12, the area of most intensive draft in 1945 was between Dominguez Hill and State Street, approximately along Alameda Street.

TABLE 10.—*Agencies withdrawing ground water from the coastal zone of the Torrance-Santa Monica area in 1945 for public supply or industrial use*

[Numbers identify location and magnitude of draft as indicated on plate 12; well fields withdrawing less than 200 acre-feet not listed]

		29	Stauffer Chemical Co.

PRINCIPAL SOURCES OF GROUND WATER

SOURCES IN THE TORRANCE-INGLEWOOD SUBAREA

In the Torrance-Inglewood subarea, the principal sources of the ground water, in order of increasing age, are: (1) the Gaspur water-bearing zone in the deposits of Recent age (in Dominguez Gap); (2) the "200-foot sand" in the unnamed upper Pleistocene deposits; (3) the "400-foot gravel" in the upper part of the San Pedro formation of Pleistocene age; and (4) the Silverado water-bearing zone in the middle and lower parts of the San Pedro formation. In relation to draft, the Silverado water-bearing zone is of primary importance, and the "200-foot sand," the "400-foot gravel," and the Gaspur water-bearing zone are of secondary importance, and probably in the order listed.

In 1945, the Silverado water-bearing zone was the source of water for: (1) all withdrawals by industries, with the exception of one small plant; (2) essentially all withdrawals from the municipal well fields of Hawthorne, El Segundo, Manhattan Beach, and Torrance, and about one-third of the withdrawal from the well fields of the city of Inglewood within the west basin; (3) all withdrawals by County Water Works Districts 13 and 22; (4) all withdrawals by the California Water Service Co., the Dominguez Water Corp., and the Palos Verdes Water Co., and about 90 percent of the withdrawal by the Lennox, Lawndale, and Gardena systems of the Southern California Water Co.; and (5) at least half of the withdrawals by private irrigators and the

smaller water companies. Of the total withdrawal from the Torrance-Inglewood subarea in 1945—approximately 78,000 acre-feet—about 68,000 acre-feet or 87 percent was taken from the Silverado water-bearing zone.

Of the remaining 13 percent—approximately 10,000 acre-feet—about 8 percent was drawn from the "200-foot sand" and associated aquifers in the unnamed upper Pleistocene deposits, about 3 percent from the "400-foot gravel," and about 2 percent from the Gaspur water-bearing zone in Dominguez Gap.

SOURCES IN THE CULVER CITY SUBAREA

In the Culver City subarea the two principal sources of ground water, in order of increasing age, are (1) the "50-foot gravel" in the deposits of Recent age (in Ballona Gap); and (2) the main water-bearing zone of the San Pedro formation of Pleistocene age—believed to be the essential correlative of the Silverado water-bearing zone to the south. The main water-bearing zone of the San Pedro formation underlies all of Ballona Gap within the west basin and, at least in the Charnock subbasin, extends northward nearly 2 miles beyond the north edge of the Gap, or about to Pico Boulevard. No uniform water-bearing zone seems to exist north of Pico Boulevard. As shown by well logs, the aquifers are thin and discontinuous; as might be expected for alluvial deposits laid down by streams transporting debris from the Santa Monica Mountains.

The main water-bearing zone in the San Pedro formation has been the source of supply for: (1) almost all of the water pumped from the three well fields of the city of Santa Monica; (2) all of the withdrawal from the four well fields of the Southern California Water Co.; (3) nearly all of the withdrawal used for irrigation in the area north of Washington Boulevard, south of Pico Boulevard, and east of Centinela Avenue (pl. 2); and probably more than half of the water pumped for irrigation along the south side of the Ballona Gap. Thus, of the total withdrawal in the Culver City subarea in 1945—some 12,000 acre-feet—it is estimated that about 90 percent was drawn from the main water-bearing zone and associated aquifers within the San Pedro formation; most of the remaining 10 percent was drawn from the "50-foot gravel" in the deposits of Recent age in Ballona Gap.

SOURCES INLAND FROM THE WEST BASIN

As explained on page 108, the withdrawal from the 90 square miles of the Torrance-Santa Monica area inland from the west basin was not evaluated as a whole. However, all of the larger pumping plants draw water almost entirely from deposits of Pleistocene age and from aquifers within the San Pedro formation. These same

aquifers supply a substantial part of the replenishment to the west basin across the crest of the Newport-Inglewood uplift.

WATER-LEVEL FLUCTUATIONS

SCOPE AND UTILITY OF THE RECORDS

In 1903–4 Mendenhall made single measurements of depth to water or of artesian pressure head in several thousand wells on the coastal plain. To extend these data, water-level measurements were made in 41 representative wells at irregular intervals during the next two decades by the Geological Survey. Twenty-six of these wells were within the coastal and inland zones of the present investigation. The records through 1920 have been published by the Geological Survey (Ebert, 1921, p. 13–29); records for three wells for the years 1921–26 have been published by the California Division of Water Resources (Gleason, 1932, p. 62, 77, 104).

In connection with its investigation of water resources of the San Gabriel Valley, the Division of Water Rights in the California Department of Public Works, in cooperation with Los Angeles County and the city of Pasadena, measured depths to ground water periodically from 1923 until 1928 (Conkling, 1927, 1929, p. 171–200). This program superseded the earlier program of the Geological Survey but included only a few wells in the Torrance-Santa Monica area, all of which were in the territory east of Main Street—that is, in the vicinity of Compton and of Dominguez Gap.

The program of water-level measurements by the California Division of Water Rights was accompanied or followed by continuing programs of several agencies, which together extended over all the area of the present cooperative investigation. The two principal programs of periodic water-level measurement in the Torrance-Santa Monica area have been that of the Los Angeles Department of Water and Power, beginning in 1923 and terminating in 1941; and that of the Los Angeles County Flood Control District, beginning in 1928 and continuing to date. These programs have been supplemented by those of many other agencies, especially the following: The San Gabriel Valley Protective Association, beginning in 1928; the city of Pasadena, from 1928 to 1933; the city of Long Beach, beginning in 1929; the city of Beverly Hills, beginning in 1930; the Southern California Water Co., beginning about in 1929; and the California Water Service Co., beginning about in 1933. Periodic measurements have also been made by several other municipalities and water companies, by several industrial plants, and by a few individuals.

Nearly all the water-level records by the agencies listed above have been deposited with the Division of Water Resources in the Cali-

fornia Department of Public Works and are available to the public. Representative records from selected observation wells have been published (Gleason, 1932).

Beginning in 1943, single measurements of depth to water were made by the Geological Survey in several scores of wells in connection with the field canvass of water wells in the Torrance-Santa Monica area. Measurements were continued semiannually until December 1945 in about 60 of these wells. Measurements were made at weekly or biweekly intervals from 1944 to November 1946 in 20 other wells. Water-level recorders were also operated on six wells for periods of a month to 2 years. All the periodic water-level measurements made by the Geological Survey have been published in water-supply papers (see p. 89). Table 11 shows the scope of water-level data available from all agencies, including data taken by the Geological Survey for the coastal zone of the Torrance-Santa Monica area.

TABLE 11.—*Scope of water-level records available from wells in the coastal zone of the Torrance-Santa Monica area, as of July 1946*

Type of record	Number of wells measured		
	Active	Discontinued	Total
Nonperiodic and miscellaneous measurements			266
Semiannual measurements	111	140	251
Monthly measurements	125	350	475
Weekly measurements	16	4	20
Water-level recorder operated	4	27	31
Total	256	521	1,043

These records of depth to water in wells are of inestimable value for the interpretation of the past and present hydrologic conditions, and they reveal the changes in pressure level or water table that have developed as a result of increasing draft. Hydrographs plotted from periodic measurements in single wells show the nature of fluctuations and changes in head within the tapped aquifers. Thus, hydrographs for wells tapping separate aquifers at one place reveal the degree or the lack of hydraulic continuity between those aquifers. Water-level contour maps drawn from data for one or more aquifers known to be hydraulically continuous present the water-level conditions at selected times; discontinuities in the water-level contours define basin boundaries or barrier features. Also, the regional changes in water level shown by comparing maps for separate times can be utilized to obtain estimates of change in storage if the specific yield or storage coefficient is known.

Hydrographs for wells in the Torrance-Santa Monica area show several types of fluctuations, related chiefly to recharge and discharge. Specifically these fluctuations are caused by: (1) recharge from streams, (2) recharge by penetration of rainfall, (3) recharge by underflow, (4) discharge by pumping, and (5) tidal oscillations. Typical fluctuations are illustrated and discussed in following pages.

The water-level contour maps previously introduced (pls. 9–12) show four positions of the water level and directions of water movement in the aquifers of principal draft between 1904 and 1945. Hydrographs for 59 selected wells in the Torrance-Santa Monica area are presented on figures 4 and 5 and plates 13 and 14. The locations of the wells are shown on plate 11; the tapped zones are identified on the individual hydrographs and by symbols on plate 11. Pertinent hydrologic data are given in table 12.

FLUCTUATIONS IN THE TORRANCE-INGLEWOOD SUBAREA

Selected hydrographs assembled on figures 4 and 5 and plates 13 and 14, illustrate the rate of change in pressure head in the several aquifers in the Torrance-Inglewood subarea. Most of the hydrographs concern wells that tap the Silverado water-bearing zone, which supplied about 87 percent of the draft in 1945. Other hydrographs are presented, however, to compare pressure heads in overlying aquifers with that in the Silverado water-bearing zone. These paired hydrographs are of particular interest for three reasons: (1) they furnish proof that the aquifers have substantial hydraulic separation; (2) they indicate the effect of and furnish a clue to the magnitude of draft from each of the aquifers; and (3) they show the differentials in pressure head that have been developed between the several aquifers in the period of most intensive use and are of considerable interest in connection with possible downward migration of contamination, either now or in the future, and with the feasibility of artificial recharge.

DIFFERENCE IN HEAD DEVELOPED BETWEEN THE SEVERAL AQUIFERS

VICINITY OF DOMINGUEZ GAP

The Gaspur water-bearing zone of Recent age in Dominguez Gap occurs from about 60 to 140 feet below the land surface and is separated from the underlying Silverado water-bearing zone of Pleistocene age by several hundred feet of silt and fine sand of low permeability (pl. 6). On figure 5*C*, the composite hydrograph for wells 4/13–14K1 and 4/13–14L1 represents the pressure level in the Gaspur water-bearing zone from 1924 through 1946, and the hydrograph for wells 4/13–21H3 and 4/13–23G2 represents the pressure head in the Silverado water-bearing zone for the same period. Data from the Mendenhall well canvass of 1904 indicate that pressure levels in the two

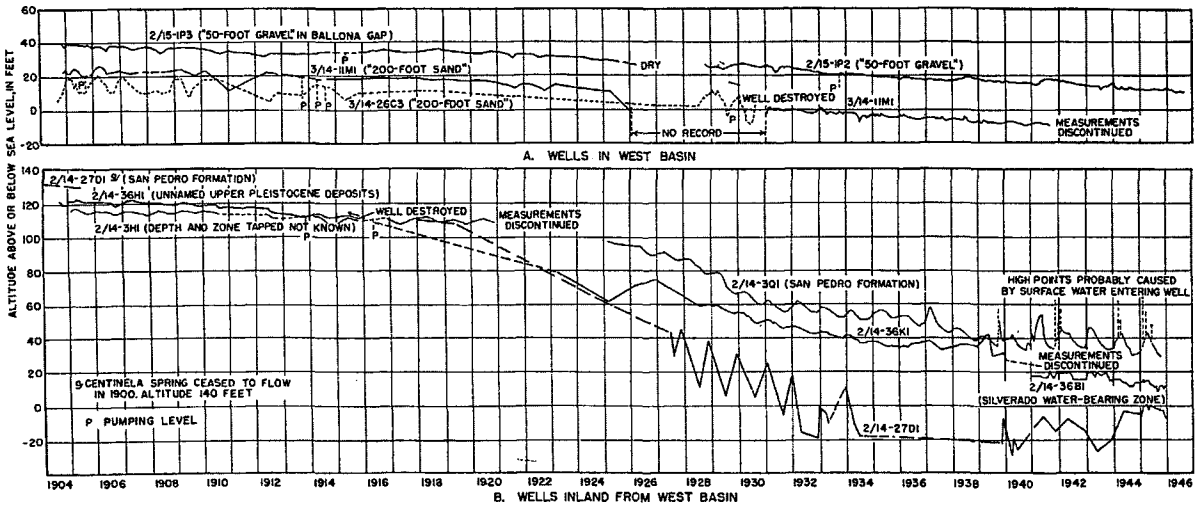

FIGURE 4.—Hydrographs of longest record for wells in and near the west basin.

[1] Number assigned by California Division of Water Resources.
[2] Depths below land-surface datum indicated in whole feet are reported; those to a tenth of a foot are measured by Geological Survey.
[3] Names of agencies used in this table are identified as follows: DWR, Division of Water Resources, State of California; JBL, J. B. Lippincott; LACFCD, Los Angeles County Flood Control District; LADWP, Los Angeles Department of Water and Power; LB, city of Long Beach; SCWC, Southern California Water Water Co.; USGS, U. S. Geological Survey.

water-bearing zones were about equal and were about 20 feet above sea level in 4/13–23D. By 1924, levels for both zones had been drawn down but the level of the Silverado water-bearing zone at well 21H3 was about 20 feet below sea level and some 25 feet below the pressure head in the Gaspur zone (fig. 5*C*). The differential increased to about 40 feet by 1930, remained nearly constant to 1941, and increased to about 60 feet by 1946 (high levels for the year for hydrographs 4/13–14L1 and 4/13–23G2). This increasing differential in pressure levels for the two water-bearing zones is indicative of the lack of hydraulic continuity between them. The Gaspur zone here is highly contaminated by oil-field brine, however (p. 258 to 260), and with this pressure differential, which currently is equivalent to some 25 pounds per square inch, the contamination poses a serious threat to the pure water of the Silverado water-bearing zone. Because the two zones are separated by beds of low permeability, contaminated water is more likely to move downward through wells whose casings are either perforated or rusted through in both zones.

The history of changes in the regimen of the Gaspur water-bearing zone both within and inland from the Dominguez Gap have been treated in some detail in another report (Poland, 1959).

For the semiperched water table in Dominguez Gap, the hydrograph of well 4/13–14P1, from 1941 through 1946 (also plotted on fig. 5*C*) shows that the position of the water table in recent years has been essentially equal to that of the pressure level in the Gaspur zone beneath.

Wells 4/13–29M1 and 33D1, in Wilmington and about 3 miles southwest of well 4/13–23G2, tap the unnamed upper Pleistocene deposits and the lower part of the Silverado zone (table 12). Hydrographs for these wells (fig. 5*C*) illustrate the trends and increasing differential between the water levels in these two aquifers at that place since 1931.

In 1904, under essentially native conditions of head, the water level in both aquifers was about 13 feet above sea level. In the upper Pleistocene deposits the water level had been drawn down to about 20 feet below sea level by 1931, was about constant into 1938, recovered to 17 feet below sea level by 1942, and then declined to 22 feet below sea level by 1946. The pressure level for the lower part of the Silverado water-bearing zone (well 33D1) had been drawn down to 31 feet below sea level by 1932, was about constant to 1942, and then was drawn down to 47 feet below sea level by 1946. Thus, the head differential between these two aquifers increased from nothing in 1904 to about 11 feet in 1932, and to 25 feet in 1946 (high level for the year).

At the Wilmington well field of the city of Los Angeles, a 240-foot section of fine sand and silt separates the upper and lower parts of the Silverado water-bearing zone; this section occurs from about 460 to 700 feet below land surface. Water-level measurements for well 4/13–33E6, not plotted on figure 5, indicate that the pressure level in the upper part of the Silverado water-bearing zone was about 21 feet below sea level in 1927, 24 feet in 1930, and 32 feet in 1946 (high levels for the year). Thus, by 1946, the pressure level for the upper part of the Silverado was about 10 feet below that of the unnamed upper Pleistocene deposits and about 15 feet above that of the lower part of the Silverado water-bearing zone (well 33D1).

GARDENA AREA

Four distinct and separate water-bearing zones in the Gardena area are tapped by wells. These zones and their approximate depths below land surface are as follows: (1) The semiperched water body to about 80 feet; (2) the "200-foot sand" in the unnamed upper Pleistocene deposits from 140 to 260 feet; (3) the "400-foot gravel" in the upper part of the San Pedro formation, from 320 to 400 feet; and (4) the Silverado water-bearing zone in the lower part of the San Pedro formation, from 500 to 700 feet (pl. 3*B*).

On figure 5*B*, hydrographs for wells 3/14–25E2 and 25K3 show the position of the water table in the semiperched water body from 1929 through 1945; the hydrograph for well 3/14–36M3 shows the pressure level in the "200-foot sand" from 1929 through 1946; hydrographs for wells 3/14–14M1 and 23L1 show the pressure level in the "400-foot gravel" for the same period; and hydrographs for wells 3/14–35R1 and 3/14–32F2 show the pressure level of the Silverado water-bearing zone from 1924 through 1946.

The record for the "200-foot sand" is extended back to 1904 by the hydrographs for wells 3/14–11M1 and 26C3 (fig. 4*A*). For the "400-foot gravel," although wells 3/14–14M1 and 3/14–23L1 are a mile apart, and although the hydrograph for well 3/14–23L1 indicates a pressure head about 5 feet below that of well 3/14–14M1 early in 1941 when well 3/14–23L1 was completed and placed in service, the two hydrographs are believed to represent the changes in pressure surface during the period of record. In confirmation, well 3/14–10C1, which also taps the "400-foot gravel" is 2.5 miles northwest of well 23L1; in 1945 the pressure level in well 10C1 (not shown on fig. 5) was only about 2 feet above that for well 3/14–23L1 in March and identical with it in December.

For the Silverado water-bearing zone, well 3/13–32F2 is 2.6 miles east of well 3/14–35R1 and only about a mile from the east boundary of the west basin. Nevertheless, from mid-1944 to the end of 1946, frequent measurements (at least biweekly) of depth to water in each of these wells indicated essentially an identical position of water level throughout the yearly range. In fact, the pressure level of these years in well 3/14–35R1 was not plotted on figure 5*B* because the graph would have been confused with that for well 3/13–32F2. For earlier years also, the levels for both can be considered coequal, as is shown by the position of the random measurements in well 35R1 as related to the hydrograph for well 3/13–32F2.

For the four water-bearing zones in the Gardena area, the changes in water levels that have occurred since 1904 can be summarized as follows, utilizing high level for the year if known:

1. In 1904, Mendenhall's data show that the water levels in the several water-bearing zones were about equal but increased slightly in altitude with depth of zone. For example, the water table of the semiperched zone and the pressure surface of the "200-foot sand" were both from about 15 to 25 feet above sea level, but the pressure surface of the Silverado water-bearing zone was from 25 to 30 feet above sea level.

2. By 1920, the water level in the "200-foot sand" had been drawn down to about 10 feet above sea level (well 3/14–26C3, fig. 4*A*) and that of the Silverado water-bearing zone had been drawn down to sea level (measurement by the Southern California Edison Co. in well 3/14–35R1).

3. In 1929, the water table of the semiperched body was 16 feet above sea level; and the pressure surfaces for the "200-foot sand," the "400-foot gravel," and the

Silverado water-bearing zone were respectively 2, 5, and 18 feet below sea level (fig. 5*B*).

4. By 1941, levels in the four zones were respectively 19 feet above sea level (25E2); 14 feet below sea level (36M3); 15 feet below sea level (14M1); and 22 feet below sea level (32F2).

5. As of 1946, levels were respectively 12 feet above sea level (extrapolated), and 18 feet, 29 feet, and 38 feet below sea level. Thus, as of 1946, and with respect to high levels for the year, the pressure level in the Silverado water-bearing zone was 50 feet below the semiperched water table, 20 feet below the pressure level of the "200-foot sand," and about 9 feet below that of the "400-foot gravel."

VICINITY OF INGLEWOOD

In the vicinity of Inglewood, the hydrographs for wells 2/14–32C1 and 3/14–4N1, shown on plate 13, indicate conditions of change in head in the "200-foot sand" (32C1) and in the Silverado water-bearing zone (4N1) from the early thirties through 1945. These wells are about 2 miles apart. Several hundred acre-feet of water is withdrawn each year from well 3/14–4N1, whereas well 2/14–32C1 is used solely as an observation well. Thus, their hydrographs do not furnish an absolute comparison of static water levels at one place. However, they do indicate the increasing differential in head between the two zones in a general way.

In 1904, water levels in both the "200-foot sand" and the Silverado water-bearing zone near the sites of these wells were about 25 feet above sea level. By 1933, the head in the "200-foot sand" was at sea level and that of the Silverado was about 8 feet below sea level. The pressure heads of both aquifers declined continuously from 1933 to 1945; by 1945, the head in the "200-foot sand" at well 2/14–32C1 was about 17 feet below sea level and the head in the Silverado at well 4N1 was about 40 feet below sea level. Thus, the head differential between the two aquifers, which was zero in 1904 increased by 1945 to 23 feet (high for the year) and about 50 feet (low for the year).

FLUCTUATIONS AND CHANGE IN HEAD IN THE SILVERADO WATER-BEARING ZONE

Figure 5 and plate 13 include hydrographs for 20 wells or groups of wells in the Torrance-Inglewood subarea that tap the Silverado water-bearing zone or correlative aquifers in the San Pedro formation. These wells were selected to give a wide and representative geographic distribution (pl. 11).

AREA SOUTH OF REDONDO BEACH BOULEVARD

With regard to the southern part of the area, figure 5 shows hydrographs for two wells in the water-table reach between Torrance and Redondo Beach—for well 4/14–8E1, 0.9 mile from the coast, and well 4/14–22D1, 2.3 miles from the coast; also for eight wells in the confined or pressure area between Torrance and Long Beach wells 4/14–13F1,

3/14–35R1, 3/13–33E1, 3/13–32F2, and 4/13–15A8, 21H3, 23G2, and 33D1. From west to east, these hydrographs show great differences in (1) the character and amplitude of the seasonal fluctuations, and (2) the rate and amount of decline in pressure head.

The seasonal fluctuations have been small in the water-table area west of Torrance and have become progressively greater to the east in the confined or pressure area. For example, in water-table well 4/14–8E1 the seasonal fluctuation has ranged from 1 to 3 feet, and since 1943, when pumping at this well ceased, the fluctuation has been about 1.5 feet per year. The graph from a water-level recorder operated on this well by the Geological Survey showed a daily fluctuation of as much as 0.1 foot, which was correlated with the tidal fluctuation at Los Angeles Outer Harbor. This correlation indicated a tidal efficiency of about 1.4 percent but with an 8-hour lag in registration. Well 4/14–22D1 is 2 miles farther from the coast and only about 200 feet from a pumped well. Even though the hydrograph shows the effect of the nearby pumping, the seasonal range commonly has not exceeded 4 feet.

Within the pressure area, the seasonal fluctuation has ranged from about 5 feet at well 4/14–13F1 in Torrance to as much as 20 to 25 feet at well 4/13–23G2 (city of Long Beach, Silverado well) in Dominguez Gap. Well 4/13–23G2 is an unused observation well a mile from the nearest active well tapping the Silverado water-bearing zone (4/13–22K1, used for irrigation); also 1.2 and 1.7 miles from the well field of the Dominguez Water Corp. (in 4/13–15A), and the Richfield Oil Corp. (in 4/13–21H). Each of these well fields is a locus of heavy draft (pl. 12, plants 14b and 26). The seasonal range shown by the hydrograph for well 4/13–23G2 was only about 13 feet from 1933 to 1938 but has nearly doubled with the accelerated withdrawal during the forties.

Most of the draft in the vicinity of Dominguez Gap is caused by continuous demands of industrial plants; the draft is about as heavy in winter as in summer. Therefore, the hydrograph for well 4/13–23G2 might be expected to show little, if any, seasonal fluctuation. However, the draft by the Dominguez Water Corp., which is the largest single draft of the area, does vary substantially from winter to summer, because part of the withdrawal is for irrigation and domestic use. The monthly draft by this corporation from January 1943 to June 1944, inclusive, has been plotted on figure 5*C* to show its relation to the seasonal fluctuation in pressure level in well 4/13–23G2. The correspondence is reasonably good, although the pressure level of well 4/13–23G2 is affected by other nearby pumping; it is possibly most strongly affected by the intermittent pumping of irrigation well 4/13–22K1.

The decline in the pressure head of the Silverado water-bearing zone in the southern part of the Torrance-Inglewood subarea has ranged from an average of about half a foot per year near Redondo Beach to as much as 2 feet per year in Dominguez Gap. At well 4/14–8E1 (in Redondo Beach), the water table has declined 10 feet from 1928 to 1946—an average yearly rate of 0.55 foot. In Dominguez Gap, some 10 miles to the east, the decline in the pressure head from 1924 to 1946, shown by the composite hydrograph for wells 4/13–21H3–23G2, has been 46 feet, and has occurred very largely in two widely separate periods. From 1924 to 1927 the decline was 20 feet, or about 7 feet per year; and from 1941 into 1946, during the war period, it was 26 feet, or about 5 feet per year.

AREA BETWEEN GARDENA AND THE BALLONA ESCARPMENT

For the central part of the west basin south of the Ballona escarpment, plate 13 shows hydrographs for eight wells or groups of wells which tap the confined reach of the Silverado, as follows: 3/15–12L1, L6, and L5, at El Segundo; 3/15–25H2 and A1 at Manhattan Beach; 3/14–21B1, 3/14–13J2, 3/13–18G2, and 3/13–20C1, all near Rosecrans Avenue; and 3/14–4N1 and 2/14–34C1 near Inglewood. Wells 2/15–34H1 and 34K1, whose hydrographs also are shown, tap the main aquifer of the San Pedro formation (believed correlative with the Silverado water-bearing zone) in the water-table reach near Playa del Rey (pl. 11).

In the confined reach of the Silverado water-bearing zone, near the coast at the municipal well field of El Segundo, hydrographs for wells 3/15–12L1, L6, and L5 suggest a seasonal fluctuation of about 2 feet if pumping effects are disregarded. Three miles inland and south of Hawthorne, the pressure level at well 3/14–21B1 varied about 10 feet per year in the middle thirties and the annual range increased to about 15 feet by the early forties. The joint discharge of wells 21B1 and 21B2 has ranged between 350 and 711 acre-feet per year since 1940. At the east margin of the west basin, the pressure level in well 3/13–18G2 fluctuated about 10 feet per year in 1945 and 1946, but the range in pumped well 3/14–13J2 has been as much as 23 feet (in 1945).

Throughout the central part of the west basin most of the water is pumped for domestic and irrigation use. Thus, the draft is heaviest late in the summer and it is lightest from December to March. The pressure levels in wells fluctuate in direct ratio to draft demands. This general seasonal fluctuation, which is greatest far within the confined reach of the Silverado water-bearing zone and near the centers of heaviest pumping, may be accompanied by a seasonal compression of the aquifer and the confining beds developed by the re-

duction of artesian pressure in the summer, when pumping is most intensive, and expansion of the beds caused by the gradual increase of pressure as water moves into the compressed parts of the formation during winter months. Such an explanation has been suggested by Fiedler (1944, p. 244–245) for similar fluctuation in the Roswell artesian basin. The subject of compressibility of artesian aquifers has been treated in more detail by Meinzer (Meinzer and Hard, 1925, p. 73–95; Meinzer, 1928, p. 263–291).

As in the water-table area near Redondo Beach, the seasonal fluctuations of the water table near Playa del Rey, at wells 2/15–34H1 and 34K1, have been very small—in most years the range in level has not exceeded 0.5 foot. The nearest heavy draft is at El Segundo, about 2.7 miles southeast from these wells as shown by plate 12. The only local withdrawal is from wells 2/15–34A1 and K1 (wells 3 and 1 of the Palisades del Rey Water Co.). In 1945 their joint draft was about 170 acre-feet.

The drawdown of about 1 foot in the water table at well 2/15–34H1, which persisted from February 1935 to April 1937, was induced by a temporary increase in draft from wells of the Palisades del Rey Water Company, as follows: 89 acre-feet in 1933; 87 acre-feet in 1934; 328 acre-feet in 1935; 147 acre-feet in 1936; 102 acre-feet in 1937; and 99 acre-feet in 1938. An active but temporary drilling program in 1935 in the so-called Del Rey Hills segment of the Playa del Rey oil field received most of its water supply from the wells of this company.

The water table in well 2/15–34K1 consistently stood about 2 feet above sea level in the thirties, but from the end of 1940 to the end of 1941 the level rose from 2.6 to 3.8 feet above sea level. Rainfall was very heavy in the water year 1940–41; at Los Angeles it was about 210 percent of the 68-year average (table 2), and the greatest since 1889–90. The unique rise in water level in well 34K1 was caused by recharge from this rainfall. The peak rainfall was in February and March (12.42 and 8.14 inches at Los Angeles); the water-table peak was in November–December, indicating a 9-month lag in maximum rate of recharge at the water table. The water from rainfall here must pass through about 80 feet of dune sand to reach the water table.

The average rate of downward movement of water from rainfall at well 34K1 in 1941 apparently was about 9 feet per month, only about 3 percent as rapid as the rate of 10 feet per day cited by Sopp (1929, p. 2227) for penetration through 150 feet of Recent alluvium near Pasadena, Calif. Possibly the slow rate of movement was caused by the restraining effect of two beds of clay (7 and 9 feet thick) reported in the log for this well to be present within the dune sand. It is not

known why the water table at well 2/15–34H1, 2,900 feet northeast of well 34K1, did not show a similar response, although a rise and decline may have occurred between the May and October measurements of 1941.

As shown by the hydrographs of plate 13, the decline in the pressure head of the Silverado water-bearing zone in the central part of the west basin (between Gardena and the Ballona escarpment) has differed widely from place to place.

Within the confined reach, about 1.2 miles from the ocean at the main well field of El Segundo, water levels were about 3 feet below sea level in the early thirties and about 4 feet below sea level in 1941 (wells 3/15–12L1–12L6); thus, these levels declined about a foot in 10 years. From 1942 through 1946 the decline was 8 feet, or nearly 2 feet per year. Wells at the main well field of Manhattan Beach (3/15–25A1) have shown about the same character and rate of pressure decline.

On the other hand, near the central synclinal axis of the west basin at well 3/14–4N1 (north of Hawthorne) the decline in pressure head was nearly uniform from 1933 to 1940 at about 2 feet per year, and then increased to more than 3 feet per year to 1946; at well 3/14–21B1, south of Hawthorne, the rate of decline was about 1.3 feet per year from 1930 to 1941 and about 3 feet per year from 1941 to 1946.

In the water-table reach near Playa del Rey (wells 2/15–34H1 and K1), water levels were essentialy stable from 1930 through 1944 but declined about 2 feet in 1945–46. Because water levels to the north, east, and south were below sea level as early as 1933 (pl. 9), the water table of the Playa del Rey area must have been maintained at or above sea level since the early thirties by recharge from rainfall. Thus, the recharge from rainfall in this area is shown to have been more than sufficient to supply the draft from the wells of the Palisades del Rey Water Co. However, in 1945 the regional cone of water-level lowering reached wells 34H1 and 34K1 and caused a steady if slow decline. It is interesting to note that the chloride concentration of water from well 34K1 has increased sharply since January 1945 (fig. 15), coincident with the decline in water level.

FLUCTUATIONS IN THE CULVER CITY SUBAREA

As discussed previously, the part of the west basin in and north of Ballona Gap includes three semi-independent subbasins formed by the partitioning effect of the Overland Avenue and Charnock faults. Water levels in the three subbasins have fluctuated in widely differing fashion. The hydrographs of plate 14 bring out some of the most marked differences.

COASTAL AREA

Wells 2/15–16F1 and 2/15–22B4, respectively, tap the "50-foot gravel" and the San Pedro formation in the coastal area west of the Charnock fault. Hydrographs for these wells (pl. 14) indicate that spring water levels in the two aquifers were essentially equal; in the thirties, the pressure head in the San Pedro formation at well 22B4 had a greater seasonal range than did that of the "50-foot gravel" at well 16F1, but this fluctuation was induced by nearby pumping for irrigation.

In 1904, water levels were about 5 feet above sea level near well 16F1 and 8 feet above sea level near well 22B4. By 1930 the levels had been drawn down about 10 feet below sea level at both wells. Records are not available to define when this drawdown developed; but presumably, most of it occurred in the twenties, when pumping for irrigation was most intensive. By 1930, the front of saline contamination had passed inland beyond both wells (pl. 16), and local draft was decreasing.

The hydrographs show a slow and relatively uniform recovery of water level from 1931 to 1941 in well 16F1, and a similar but irregular recovery in well 22B4; this recovery was caused by a decrease in irrigation draft as saline encroachment became more extensive (pl. 16). In the spring of 1941 the levels rose several feet, coincident with cessation of pumping at the Marine plant of the city of Santa Monica (in 2/15–9N); in 1940 this draft had been 944 acre-feet. Also the recovery of water level in 1941 probably was partly due to the increased replenishment during the wet winter of 1940–41. At well 16F1 the recovery continued until 1944, when the level stood a foot above sea level, and the "ground-water hole" of the early thirties had completely disappeared (pls. 9–12).

Well 2/15–23F1, about 4,000 feet east of well 22B4, taps the semiperched water body overlying the "50-foot gravel." The hydrograph (pl. 14) suggests that, the water table of the semiperched body generally stood a few feet above the water level of the underlying aquifers in the late thirties, but has been essentially coincident since 1941.

CHARNOCK SUBBASIN

Very few of the wells in the Charnock subbasin for which water-level records are available tap only the "50-foot gravel." Many small wells which formerly tapped this aquifer have gone dry and have been abandoned, such as well 2/15–1P3 (fig. 4). The hydrograph for this well indicates that the water level in the "50-foot gravel" declined fairly uniformly from 1904 to 1911 and from 1918 to 1926; the hydrograph for well 2/15–1P2 continues the record of the decline to 1946. Both wells are close to the Overland Avenue fault

which, however, does not interrupt hydraulic continuity within the "50-foot gravel." The hydrographs indicate that this aquifer does not have hydraulic continuity with the main aquifer of the San Pedro formation beneath, because the pressure levels of the latter aquifer have followed an entirely different trend. Hydrographs for wells 2/15–11F4 and 2/15–11E3 at the Charnock plant of the Southern California Water Co. and for well 2/15–24C1, about 2 miles southeast, illustrate the fluctuations since 1930 in the San Pedro formation (pl. 14).

In 1904 the water level in 2/15–11C was from 30 to 35 feet above sea level and in 2/15–24C it was about 16 feet above sea level. In 1925 the level at well 2/15–24C1 was 11 feet above sea level, thus indicating a decline in head of only about 5 feet since 1904.

In 1925 the city of Santa Monica completed its first well at the Charnock municipal field in 2/15–11C; about 1927 the Southern California Water Co. began taking water from its Charnock well field in 2/15–11E and 2/15–11F, and the draft became very heavy before 1930. This concentrated withdrawal from the NW¼ sec. 11 has been the controlling factor in the fluctuation of the pressure level in the main aquifer of the San Pedro formation throughout the Charnock subbasin since 1926. The heavy draft at these fields was supplemented by pumping at the Sepulveda plant of the Southern California Water Co. in well 2/15–11J, which also commenced in 1926. Together, these withdrawals produced a cone of perennial drawdown which rapidly extended to the north and south but was terminated abruptly on the west by the Charnock fault barrier, and was limited on the east by the more distant Overland Avenue fault. A water-level contour map of the high level for 1930 (not included in this report) shows that pressure levels at the Charnock well fields then were 20 to 30 feet below sea level; in addition, the map shows that water levels had been drawn down below sea level southward about 2 miles, or to Ballona Creek (see hydrograph for well 24C1), and northward about three-quarters of a mile, or about halfway to Pico Boulevard.

The hydrographs for wells 2/15–11F4 and 11E3 illustrate the great drawdown of water level that occurred at this center of pumping from 1931 to 1940, inclusive. The combined yearly draft from the Charnock well fields by the city of Santa Monica and by the Southern California Water Co., also illustrated on plate 14, increased from 6,070 acre-feet in 1931 to 9,190 acre-feet in 1940. Withdrawal by Santa Monica decreased about one-half in 1941 and was negligible by 1942 (the total draft from the Charnock fields was 2,505 acre-feet at this time). In response to this variation in concentrated draft, the water level in well 11E3 was drawn down to 100 feet below sea level by 1940 but

recovered about 45 feet by 1945 and became temporarily stabilized about 55 feet below sea level. It should be noted that this well is pumped and is in the midst of other pumped wells; hence the level for this well illustrated on plate 14 represents a "recovery" level observed while well 11E3 was idle but while other wells were pumped. Thus, it shows the over-all drawdown at the well field.

Water levels in other wells tapping the San Pedro formation in the Charnock subbasin have fluctuated primarily in response to the draft at the Charnock well fields. For example, well 2/15–24C1 is 2 miles southeast from the Charnock fields and has not been pumped since 1935. Its pressure-level graph is a reduced replica of the hydrographs for wells 11F4 and 11E3 and shows the same downward trend from 1930 (1925) through 1940 and a gentle recovery of about 4 feet from 1941 to 1945, inclusive.

CRESTAL SUBBASIN

The crestal subbasin occupies the narrow upthrown block between the Inglewood fault to the east and the Charnock fault to the west. In the San Pedro formation within this subbasin, movement of water is southward and the pressure levels now stand far above the drawndown levels to the west and east.

Records of water level by Mendenhall in 1904 and periodic measurements beginning in 1930 show that there was no change in the pressure head of the San Pedro formation in the crestal subbasin from 1904 to 1930. For example, measurements made by the Geological Survey in well 2/15–1F1 (Ebert, 1921, well 16) between 1904 and 1910 indicate that its pressure level then was 60 to 62 feet above sea level; it was still about 62 feet above sea level in 1930, as shown by a water-level contour map for the spring of 1930 prepared as a part of the present investigation. Also, about 2 miles to the south in 2/14–7M, the pressure level was 40 feet above sea level in 1904 and in 1930.

The hydrographs for wells 2/14–7M1 and 18F1 (pl. 14) show the change in pressure head that has occurred from 1930 to 1945, nclusive. The seasonal fluctuation has been less than a foot (a icharacteristic of wells in this subbasin). Decline of head began in 1931, was very gentle until 1936, increased in 1937, and then continued until 1945 at a fairly uniform rate—about 1 foot per year in well 7M1 and 2 feet per year in 18F1. Compared with the great range in water levels to the east and west, the change in pressure head in this subbasin has been suprisingly uniform and completely independent—attesting to a lack of hydraulic continuity within the San Pedro formation across the Inglewood and Charnock faults. The fluctuations of water level have been in response to change in draft within the subbasin. Perennial withdrawal has been chiefly by the Southern California Water Co. at its Manning plant in 2/15–1C,

beginning in the middle twenties; and by the Metro-Goldwyn-Mayer Corp. from wells 2/15–12B1 and 2/14–7P1, beginning in 1932. As described earlier (p. 108), the over-all draft did not exceed a few hundred acre-feet per year until the middle thirties; it was about 1,100 acre-feet in 1935 and in 1940, and about 1,600 acre-feet in 1945.

Water levels in wells at the Manning plant of the Southern California Water Co. show a seasonal fluctuation of as much as 10 feet, but their long-term trend has been in agreement with that of the hydrograph for well 2/14–7M1; water levels at the Manning plant are about 25 feet higher than at well 7M1.

Water levels in the "50-foot gravel" in the crestal subbasin have fluctuated in a different manner from those in the San Pedro formation, presumably because the "50-foot gravel" is hydraulically continuous across the barrier faults that are so effective in damming the older aquifer. Hydrographs for wells 2/15–1P2 and 1P3 (fig. 4) show the long-term decline in head in this aquifer. For the past two decades, draft from the "50-foot gravel" within the crestal subbasin has been negligible; hence the decline has been caused largely by decrease of inflow, and by continued outflow.

FLUCTUATIONS INDUCED BY PUMPING

Seasonal fluctuations related to pumping are discernible in most of the hydrographs for wells measured monthly or more frequently. Pumping draft for irrigation and other uses fluctuates not only with the season but also from day to day. Even wells supplying water to satisfy a reasonably constant industrial demand may be subject to momentary and frequent changes in rate of discharge if the system is operated with an automatic control and substantial storage facilities. These fluctuations of the water level in observation wells induced by such changes in the rate of withdrawal can be determined only by taking a continuous record of water level.

In connection with the operation of water-level recorders in wells, the Geological Survey has obtained many examples of these short-term fluctuations. Two records of particular interest are illustrated in figure 6.

Well 4/13–33D1 (city of Los Angeles, Wilmington plant, well 14) in Wilmington taps the lower part of the Silverado water-bearing zone from 669 to 800 feet below the land surface. The wells of the Texas Co. in 4/13–27M, 6,000 feet to the northeast, tap the full thickness of the Silverado water-bearing zone from 400 to 800 feet below the surface. In December 1941 well 4/13–27M4 (owner's well 6) was being pumped continuously at 850 gpm and well 27M3 (owner's well 5) was on automatic control, pumping intermittently at 3,000 gpm. Thus, the over-all discharge was at the base rate of 850

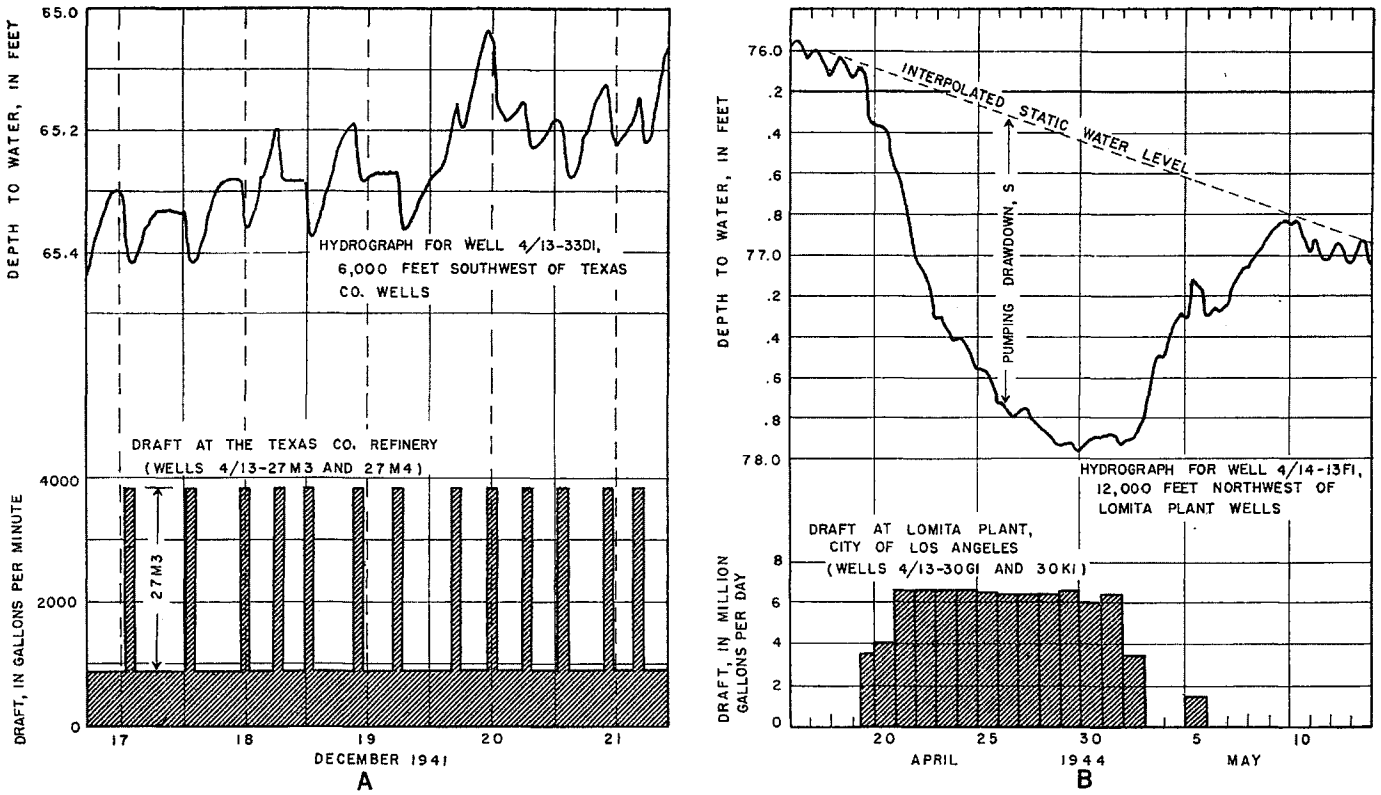

FIGURE 6.—Graphs showing fluctuations of water level in wells 4/13-33D1 and 4/14-13F1 induced by pumping of distant wells.

gpm with intermittent increase to 3,850 gpm (fig. 6). The plot of pressure head in well 4/13–33D1 indicates an immediate response to the pumping of well 27M3. During the time here graphed, the average length of each pumping period for well 27M3 was about 1 hour and the average drawdown in pressure level at well 33D1 induced by this pumping was about 0.08 foot. The drawdown at the pumped well was about 15 feet in 1941. The precise amount of time required for the transmission of the pressure effect through the 6,000-foot distance is not known but the graph indicates registration at well 33D1 within a very few minutes. Before the cause of the fluctuations was identified, the recorder had to be removed from the well and thus an expanded-time graph was not obtained.

Well 4/14–13F1, near Torrance, taps the full thickness of the Silverado water-bearing zone. The fluctuation of pressure head at this well from April 16 to May 13, 1944 is shown on figure 6 together with the combined daily draft from wells 4/13–30G1 and K1 (city of Los Angeles, Lomita plant, wells 6 and 7). The Lomita plant wells, located 12,000 feet southeast from well 4/14–13F1, also tap the Silverado. Their pumps had been idle for about 3 weeks before the beginning of pumping at 9:20 a. m. April 19. In the following 14 days (ending May 2), about 82,620,000 gallons (254 acre-feet) of water was withdrawn from the Silverado water-bearing zone through these wells, at an average discharge rate of 4,340 gpm. The hydrograph for well 13F1 shows that the drawdown of the pressure head caused by this pumping was superimposed on a general declining trend of about 0.04 foot per day. Before, during, and after the operation of the wells at the Lomita plant, the hydrograph for well 4/14–13F1 showed a diurnal fluctuation of about 0.1 foot; its cause is not known. As nearly as can be determined from the recorder graph for well 13F1, the pressure level at this well began to decline about 30 minutes after the pumps were turned on at the Lomita plant, about 2.3 miles distant. Considering the general trend, the drawdown in pressure level induced by the continuous operation of the Lomita plant was 1.1 feet after 4 days and 1.5 feet after 10 days.

Both the rate of response and the magnitude of drawdown at well 4/14–13F1 attest to the complete confinement of the Silverado water-bearing zone between Wilmington and Torrance. If this aquifer were unconfined in that area, it is doubtful if the effect of pumping at a distance of 12,000 feet could be detected from a recorder graph. Certainly a cone of water-table depression of appreciable depth would take many weeks to extend 12,000 feet from the origin.

By plotting on semilogarithmic coordinates the drawdown at well 4/14–13F1 against the time since the pumps at the Lomita plant were started (log scale), the graphical method developed by Cooper and

Jacob (1946, p. 526–534) can be used to determine transmissibility, permeability, and storage coefficient. As discussed on page 54, the transmissibility determined from these data is about 813,000 gpd per foot, and the indicated coefficient of permeability is about 2,000 gpd per square foot. The storage coefficient can be calculated by use of the equation:

$$S=2.25\ T\ t_0/r^2$$

where S is the storage coefficient (volume of water that a unit decline of head releases from storage in a vertical prism of the aquifer of unit cross section), T is the transmissibility, t_0 is the value of time at the drawdown intercept 0, and r is the distance of the observation well from the pumped well. The storage coefficient so derived from the semilogarithmic plot for drawdown in well 4/14–13F1 is 0.0012.

Figures 7 and 8—discussed in detail in the section on barrier features (p. 137 to 141)—also show drawdown fluctuations induced by pumping of nearby wells.

HYDROLOGIC EVIDENCE RELATING TO BOUNDARIES OF THE WEST BASIN

WATER LEVELS ACROSS THE BARRIER FEATURES OF THE NEWPORT-INGLEWOOD UPLIFT

The faults of the Newport-Inglewood uplift produce discontinuities in the pressure surfaces of the aquifers of Pleistocene age. Thus, the location of the fault barriers commonly can best be determined by constructing water-level contour maps and by relating hydraulic discontinuities to geologic or physiographic evidence of faulting. In places where the latter types of evidence are lacking or unknown, the hydraulic discontinuity may furnish the only proof of a fault barrier, and the accuracy of location then depends wholly on the water-level control. The inferred fault barrier passing southeastward along the Rosecrans Hills from the Potrero fault to the Avalon-Compton fault and the similar feature along the crest of Dominguez Hill both have been defined purely from hydrologic data as revealed on plates 9–12, and on hydrographs to be discussed.

The effectiveness of the faults as barriers to water movement can be evaluated in part from the magnitude of the hydraulic discontinuities across them, and by the gradients developed immediately inland and coastward. Both features are shown by the water-level contour maps. The effectiveness can be appraised also from simultaneous water-level fluctuations in two or more wells on opposite sides of such barrier features. In a recent report (Poland, 1959) such an appraisal has been made for the 22-mile reach of the Newport-Inglewood uplift from Dominguez Hill southeast to Newport Mesa.

460508—59——10

From that appraisal and with respect to the reach within Los Angeles County—that is, from Dominguez Hill to the Orange County line near Seal Beach—it has been concluded (Poland, 1959) that:

> In Dominguez Gap there is no barrier to movement through the Gaspur water-bearing zone of Recent age. In the underlying Silverado zone a substantial barrier has been developed but presumably it is not wholly watertight. Along the Signal Hill uplift the barrier features form a reasonably effective barrier to water movement but available evidence suggests that they are not wholly watertight against differential heads of several tens of feet. In Alamitos Gap, no barrier exists within the deposits of Recent age which extend to about 90 feet below land surface. However, the barrier across the underlying San Pedro formation is believed to be essentially watertight.

For the demonstration of the hydrologic evidence from which these conclusions were derived, the reader is referred to that report. In particular, attention is directed to the analysis of hydraulic conditions across the inferred extension of the Cherry-Hill fault in Dominguez Gap, (1) in the semiperched water body, (2) in the Gaspur water-bearing zone, and (3) in the Silverado water-bearing zone (Poland, 1959).

DOMINGUEZ HILL TO THE BALDWIN HILLS

To show hydraulic discontinuities across the 12-mile reach of the Newport-Inglewood uplift from Dominguez Hill northwesterly to the Baldwin Hills, selected data collected or assembled as a part of the present investigation are presented on five pairs or sets of hydrographs, as follows:

1. Across the ground-water barrier on the northwest flank of Dominguez Hill, hydrographs for well 3/13–33B1 (inland side) and well 3/13–33E1 (coastal side). (See fig. 5*B*.)
2. Across the south end of the Avalon-Compton fault, hydrographs for well 3/13–28P1 (inland side) and well 3/13–32F2 (coastal side). (See fig. 5*B*.)
3. Across the north end of the Avalon-Compton fault, hydrographs for well 3/13–17Q1 (inland side) and well 3/13–20C1 (coastal side). (See pl. 13*C*.)
4. Across the ground-water barrier along the central part of the Rosecrans Hills, hydrographs for wells 3/13–8L2 and 7N1 (inland side) and wells 3/13–18G2 and 3/14–13J2 (coastal side). (See pl. 13*C*.)
5. Across the Potrero fault east of the center of Inglewood, hydrographs for wells 2/14–27F1, 2, and 3 (inland side), and well 2/14–34C1 (coastal side). (See pl. 13*D*.)

All these wells tap the Silverado water-bearing zone, therefore the hydrologic data are common to this aquifer. The locations of these wells are shown on plate 11.

On the northwest flank of Dominguez Hill, wells 3/13–33B1 and 3/13–33E1 are about 2,700 feet apart (about 2,300 feet measured normal to the water-level contours). The record for well 3/13–33E1 spans only the years 1931–32. For these years seasonal fluctuation was about the same in both wells, but the pressure head in well 33E1

consistently stood 30 feet lower than that of well 33B1. Thus, the discontinuity shown on plate 9 (March 1933) is known to be an all-year feature. With reference to plate 9, if the approach gradient (inland side) and the escape gradient (coastal side) are projected to the inferred barrier a hydraulic discontinuity of about 25 feet is obtained. Although the measurements at well 33E1 ceased in 1933, the water-level contours of November 1945 (pl. 12) suggest that the actual discontinuity at the barrier had increased in the 12 years to nearly 40 feet.

The hydrographs for wells 3/13–28P1 and 32F2 also span a joint record of about 2 years, from 1944 to 1946. Well 3/13–28P1 is about 700 feet inland from the Avalon-Compton fault, and well 3/13–32F2 is about 4,500 feet coastward. The general character and amplitude of seasonal fluctuation are similar for the two wells. The differential in pressure head, which is about 50 feet, remained about equal throughout the 2 years. Hydrographs for wells 3/13–33B1 and 32F2 furnish a 15-year comparison of the fluctuation in wells which are 6,500 feet apart and on opposite sides of the barrier. They show that the difference between the pressure heads at the two wells has increased from 50 feet in 1931 to 66 feet in 1945.

Wells 3/13–17Q1 and 3/13–20C1, at the northwest end of the Avalon-Compton fault, are only 1,500 feet apart and nearly equidistant from the fault. The hydrographs for these wells, which extend from 1930 to 1945 (pl. 13*C*), show a striking difference in amplitude of seasonal fluctuation; the average for well 17Q1 is about 19 feet and the average for 20C1 is about 6 feet. The greater range in pressure head at well 17Q1 doubtless is caused by more intensive local pumping; however, the pressure effects are not transmitted to well 20C1 because of the fault barrier. The pressure differential at these wells was greatest in the early thirties—about 48 feet in February and 32 feet in August. In 1945 the differential had decreased to about 24 feet for both spring and autumn; this was due almost entirely to decline in head at well 17Q2 (successor to 17Q1 and tapping the same water-bearing beds).

On plate 13*C*, the hydrographs for wells 3/13–8L2 and 7N1 inland from the ground-water barrier along the Rosecrans Hills and those for wells 3/13–18G2 and 3/14–13J2 coastward from the barrier show a striking change during the 17-year period of record. Well 3/14–13J2 is one of the heavily pumped wells in the Gardena system of the Southern California Water Co. Well 3/13–18G2 was pumped by the Union Oil Co. until about 1942. So far as known the two inland wells have not been pumped during the period of record. From 1931 into 1937, the pressure-head differential between wells 3/13–8L2 and 18G2 decreased from 40 feet to 25 feet. In that same period

the head difference between wells 3/13–18G2 and 3/14–13J2 was constant at about 30 feet. From 1937 into 1941, the pressure head in well 3/13–18G2 declined about 30 feet; therefore, in 1941 a pressure differential of 52 feet had developed with respect to well 3/13–8L2. It is inferred that this drawdown of head in well 18G2 was caused by accelerated draft at the Southern plant of the Southern California Water Co. in 3/14–13J. By 1945 the high level for the year in well 18G2 was only about 4 feet above that for 3/14–13J2 and 57 feet below that for well 8L2. The record here discussed is considered to furnish indisputable evidence that well 3/13–18G2 is within the west basin and that it is hydraulically separated from the wells to the northeast by a ground-water barrier.

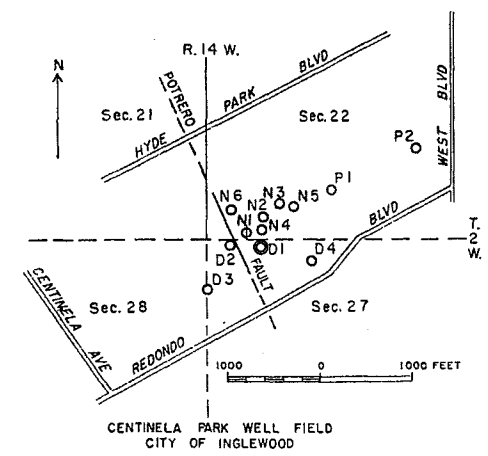
Hydrographs for wells 2/14–27F1, 2, 3, and 2/14–34C1 compare conditions across the Potrero fault at the north edge of the Rosecrans Hills (pl. 13*D*). Although the hydrograph for well 27F1 is shown here only from 1932, earlier measurements indicate a decline of head from 50 feet above sea level in 1930. The amplitude of seasonal fluctuation in well 27F1 has ranged from 5 to 7 feet; that in well 34C1 has ranged from 10 to 35 feet. From 1930 to 1939 the pressure head at well 27F1 was drawn down 49 feet, and the head in well 34C1 declined only 29 feet. On the other hand, from 1940 to 1945 the head in wells 27F2 and F3 (which tap the Silverado water-bearing zone also) declined only 2 feet, whereas the head in well 34C1 was drawn down 27 feet. This greatly accelerated drawdown of pressure head in well 34C1 is believed to reflect the increase in draft on the small subbasin in section 34 which was caused by the pumping of wells 34F1 and L2 (Hollywood Turf Club) beginning about 1941.

For the several pairs of hydrographs here discussed, the evidence indicates a substantial ground-water barrier at each place. The information gained from an appraisal of replenishment, however, indicates that the barrier features are by no means watertight throughout their extent under the range of differential heads that have prevailed across them in the past (see p. 159 to 161).

BALLONA GAP

Across the Inglewood fault in Ballona Gap, a striking hydraulic discontinuity has developed in the pressure head of the San Pedro formation through drawdown of head east of the fault by the joint draft of the Sentney plant of the Southern California Water Co. and the Castle plant of the city of Beverly Hills. Hydrographs are shown on plate 14 for wells 2/14–5D5 and 5F2 at and near the Sentney plant, respectively, inland from the fault, and for wells 2/14–7M1 and 18F1 in the crestal subbasin coastward from the fault. Although the latter two wells are more than a mile from the Inglewood fault and nearly 2

miles from the Sentney plant, their hydrographs represent fluctuation in the crestal subbasin. The contrast in the seasonal pattern and in the long-term trend needs no verbal emphasis. It is concluded from these graphs and from the shape of the water-level contours on plates 9–12 that between the Baldwin Hills and the Beverly Hills, the Inglewood fault presents an essentially water-tight barrier to movement in the San Padro formation.



The water level in the "50-foot gravel" inland from the Inglewood fault was about 62 feet above sea level in 1946 (well 2/14–5D9)—about 90 feet above the pressure level in the San Pedro formation beneath (well 5D5). In the crestal subbasin coastward from the fault, the water level in the "50-foot gravel" as of 1946 was known only for well 2/15–1P2 (fig. 4), and was about 12 feet above sea level. Although the suggested gradient from well 5D9 to well 1P2 in 1946 was 25 feet per mile, it is inferred that no hydraulic barrier transects the "50-foot gravel" at the Inglewood fault. It is of interest to note that the gradient between these two places was 25 feet per mile in 1904 also, although the water level was about 30 feet higher at that time.

PUMPING TEST AT INGLEWOOD WELL FIELD

From January 3 to April 30, 1945, the Geological Survey operated a water-level recorder on well 2/14–27D1 (city of Inglewood, well 7), in the Centinela Park well field of the city of Inglewood, and 200 feet east of the Potrero fault. During the early part of the period of operation, it was noted that the water level in this well was drawn down several feet by the pumping of certain nearby wells in the Centinela Park field. With the cooperation of the Inglewood Water Department, a pumping schedule was arranged for the active wells in the Centinela Park field to determine the effectiveness of the Potrero fault as a barrier to water movement. The Inglewood Water Department kept a careful record of the pumping periods for the active wells in the field. The results of this pumping test are shown on figure 7.

As indicated by the plan of wells in the Centinela Park field (fig. 7), 9 of the 11 active wells in the field are east of the Potrero fault (in the main coastal basin) and 2 are west of the fault (in the west basin). All of the wells tap aquifers in the San Pedro formation, which is correlative with the Silverado water-bearing zone.

Figure 7 shows the drawdown in water level at well 27D1 caused by the pumping of well 22N2, 300 feet to the north. At the time, all other well pumps at the field were idle except those for wells 22P1 and 22P2, which were operated continuously through the period of record on the graph (March 5–12). The drawdown induced by pumping of well 22N2 was 3.8 feet after 46 hours of pumping. Obviously there is free hydraulic movement between these wells. As explained on page

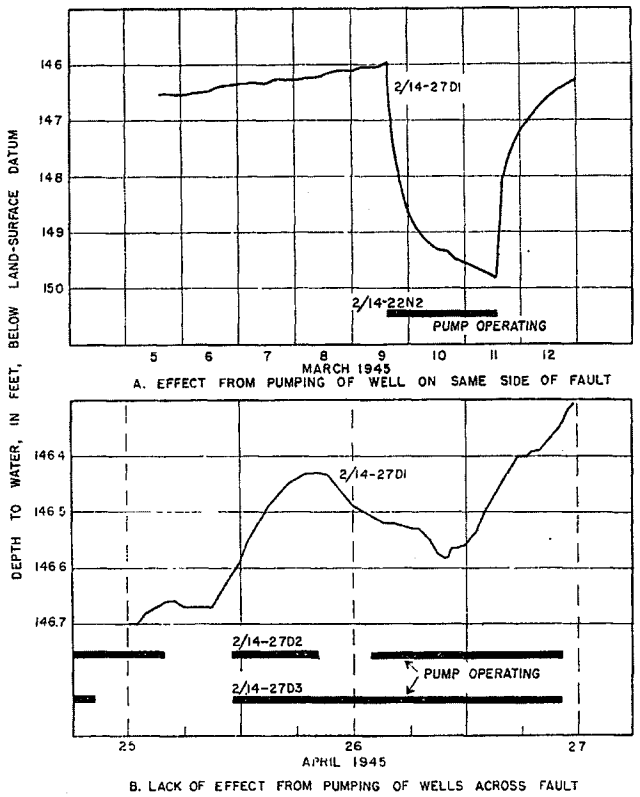
-22N6	20	-27D4	17



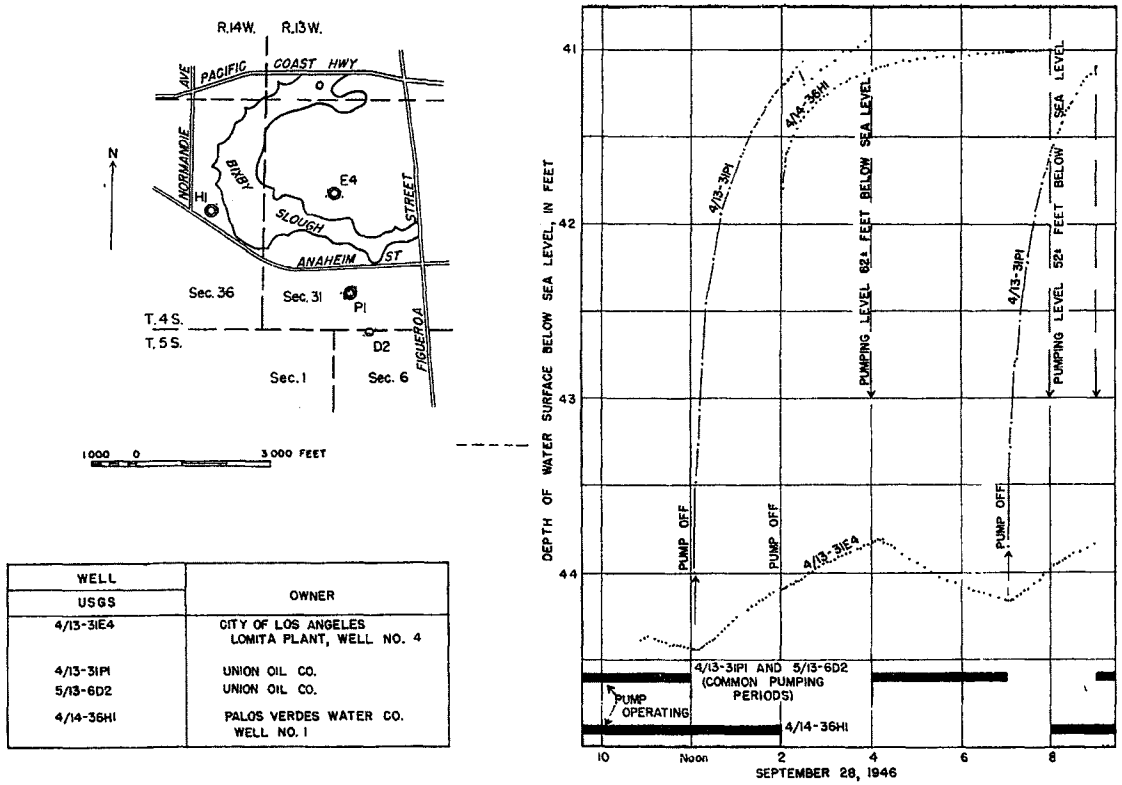


FIGURE 7.—Map of wells, and graphs showing fluctuations of water level in well 2/14-27D1 in Inglewood as related to pumping of nearby wells on opposite sides of Potrero fault.

55, this drawdown of water level in well 27D1 resulting from the pumping of well 22N2 was utilized in computing transmissibility and permeability of the water-bearing beds.

Figures 7 and 8 show the hydrograph for well 27D1 during the intermittent operation of the pumps in wells 27D2 and 27D3 (city of Inglewood, wells 10 and 14); both of these wells are west of the Potrero fault and are 325 and 725 feet, respectively, from well 27D1. For the period here graphed (6 a. m. April 25 to noon, April 27), two of the wells east of the fault 22P1 and 22P2 were operated continuously and all others were idle. Although the hydrograph for well 27D1 indicates drawdown and recovery of the water level in response to pumping, the fluctuations are not related to operation of the pumps in wells 27D2 and 27D3. For example, on April 25 the pumps in these two wells were started at 11:10 and 11:05 p. m., respectively, but the recovering water level in well 27D1 was not affected in the least. Clearly, the Potrero fault is an effective ground-water barrier within the head differentials imposed by this test. The drawdown in well 27D2 at the time of the test is not known. In November 1944 its level was drawn down to 30.7 feet below sea level after pumping for 15 minutes, or about 26 feet below the level in well 27D1. Presumably, the differential of April 25–27 was similar.

PUMPING TEST NEAR WILMINGTON

In September 1946, with the cooperation of the Union Oil Co., the Palos Verdes Water Co., and the Department of Water and Power of the city of Los Angeles, the Geological Survey made a pumping test near Bixby Slough, in Wilmington. This pumping test was made chiefly to determine whether a barrier to ground-water movement existed between the wells of the Union Oil Co. (4/13–31P1 and 5/13–6D2) and nearby wells at (1) the Lomita plant of the city of Los Angeles, in 4/13–31E, and (2) the Palos Verdes Water Co. property, in 4/14–36H. Figure 8 shows the relative locations of the wells, and graphs the results of the pumping test. All of the wells involved in the pumping test tap the Silverado water-bearing zone. Because the wells of the Union Oil Co., beginning with well 5/13–6D1 in 1922, always have yielded water of markedly different chemical quality from that yielded by the wells north of Anaheim Street (fig. 34), it had long been suspected that the Union Oil Co. wells might be separated from the west basin by a hydraulic barrier. For example, from the beginning of 1931 to the end of 1945 about 14,616 acre-feet of water was withdrawn from the Silverado water-bearing zone through the wells of the Union Oil Co. In 1931, the water yielded by well 5/13–6D1 contained about 500 ppm of chloride and 1,200 ppm of dissolved solids; as of 1945, the water from well 5/13–6D2 contained

5/13-6D2	UNION OIL CO.
4/14-36H1	PALOS VERDES WATER CO. WELL NO. 1

FIGURE 8.—Map of wells, and graph showing results of pumping tests to determine presence or absence of barrier features near Bixby Slough.

about 380 ppm of chloride and about 1,000 ppm of dissolved solids. On the other hand, the water withdrawn from the wells in 4/13–31E north of Anaheim Street, has ranged from 42 to 108 ppm of chloride and from 350 to 500 ppm of dissolved solids.

On September 28, 1946, the pumps at the Lomita plant of the city of Los Angeles were idle and had been shut down for several days. The wells of the Union Oil Co. had been pumped continuously for several months before the test, and the wells of the Palos Verdes Water Co. had been pumped intermittently during previous days. During the day, wells 4/13–31P1 and 5/13–6D2 (Union Oil Co.) and well 4/14–36H1 (Palos Verdes Water Co., well 1) were pumped intermittently on an alternating schedule (fig. 8), and water-level measurements were made by the Geological Survey at about 10-minute intervals from 10:00 a. m. to 9:00 p. m. at wells 4/13–31E4, 4/13–31P1, and 4/14–36H1. The fluctuation of water level in these wells is shown on figure 8. During the periods of pump operation as shown, the average joint discharge from the Union Oil Co. wells was about 2,150 gpm, and the discharge from well 4/14–36H1 was estimated by the operator as 1,230 gpm.

Between 12:10 and 4:10 p. m., the water level in well 31E4 recovered along a uniform curve as a result of the shutdown of the pumps in the Union Oil Co. wells from noon to 4:00 p. m. From 4:10 to 7:10 p. m., the water level in well 31E4 declined concurrently with pumping of the Union Oil Co. wells. There is no hydraulic barrier between the Union Oil Co. wells and well 31E4 at the Lomita plant of the city of Los Angeles. On the other hand, the recovering water levels in wells 31E4 and 31P1 did not show any response to the shutdown of the pump in well 4/14–36H1 (Palos Verdes Water Co., well 1) at 2:00 p. m., nor to the starting of the pump again at 8:00 p. m. Also, the recovering level in well 36H1 was not affected by the starting of the pumps in wells 4/13–31P1 and 5/13–6D2 of the Union Oil Co. at 4:00 p. m. Thus, there appears to be a substantial hydraulic barrier somewhere between well 36H1 on the west and wells 4/13–31E4, 31P1, and 5/13–6D2 on the east. The location and direction of this barrier are not known but it is inferred to be a cemented fault zone, because the Silverado water-bearing zone is known to be continuous, highly permeable, and about 700 feet thick between wells 4/13–31E4 and 4/14–36H1. If this barrier should extend northward from the Palos Verdes Hills into the west basin, it would have some effect on local circulation of ground water; but so far as known, it does not separate any of these wells from the main body of ground water in the west basin.

REPLENISHMENT TO THE WEST BASIN

SOURCES AND GENERAL FEATURES

EARLY CONDITIONS

Under the early conditions of ground-water development, replenishment to the water-bearing deposits of the west basin tapped by wells occurred in four ways. In probable relative order of importance they were as follows:

1. By underflow across the Newport-Inglewood uplift (the inland boundary of the west basin) through the deposits of Recent and of Pleistocene age.
2. By direct infiltration from the land surface of (a) water from rainfall, and (b) return water from irrigation, from cesspools, and by leakage from distribution systems.
3. By infiltration of local runoff water from the hills bordering the west basin, including the Santa Monica Mountains and the Santa Monica plain to the north, the hills of the Newport-Inglewood uplift (especially the Baldwin Hills) to the northeast, and the Palos Verdes Hills to the south.
4. By seepage within the west basin from the channels of the Los Angeles River to the south, and from Ballona Creek and its tributaries to the north.

CONDITIONS DEVELOPED BY WATER-LEVEL DECLINE

OCEAN-WATER REPLENISHMENT

During the period of ground-water use, the draft has become large and levels have been drawn down to sea level and below. As a result, in the twenties ocean water began to invade the water-bearing zones along the coast and became a source of recharge. Because of the accelerated decline of water levels in recent years this condition has become critical.

WATER RELEASED BY COMPACTION

Because of the drawdown of water level, water has been withdrawn from storage in the water-table reach, and some water has been derived by compaction of the aquifers and of the surrounding and enclosing fine-grained, relatively impervious sediments. The latter has been called "water of compaction" by Tolman (1937, p. 142–143, 470–472). The quantity so yielded doubtless has been largest in recent years and in areas of greatest drawdown of the pressure head, such as Dominguez Gap.

In certain other areas in California, large quantities of water have been derived by compaction of sediments resulting from regional drawdown of the pressure level. For example, in the Livermore Valley, Alameda County, Calif., Smith (1934; Tolman, 1937, p. 495–498) has estimated from a careful ground-water inventory that some 15,860 acre-feet of water was supplied by compaction of the alluvial materials during a low-water-level period from 1925 to 1930—an

average rate of about 3,200 acre-feet per year, as compared to an average yearly pumping draft of about 12,500 acre-feet. However, the amount of land-surface subsidence was not known, and the volume of compaction could not be determined.

In the Santa Clara Valley of Santa Clara County, Calif., Tolman and Poland (1940, p. 23–35) found that water of compaction, as measured by subsidence of the land surface and inferred equivalent reduction of pore space, was about 230,000 acre-feet from 1919 into 1937. Subsidence developed over an area of about 200 square miles as a result of an average water-level lowering of 100 feet in the 20 years from 1915 to 1935. The maximum subsidence, about 5.5 feet, was at San Jose. Insofar as water was derived from compaction of silt and clay bodies (aquicludes) within or enclosing the aquifers, it represented a nonreplaceable contribution to the usable ground-water supply.

In the west basin no such substantial subsidence of land surface has occurred as a result of ground-water withdrawal. In the vicinity of Terminal Island, near the crest of the Wilmington oil field, the land surface subsided as much as 7 feet between 1928 and 1947.[9] This subsidence was attributed by Gilluly, Johnson, and Grant (1945, also see Gilluly and Grant, 1949) as due almost wholly to the pressure decline and resulting compaction of the oil-bearing sands of Miocene and lower Pliocene age in the Wilmington oil field (which was caused by the removal of oil and gas beginning about 1937). In a recent report, Harris and Harlow (1947, p. 1197–1218) have concluded that the subsidence resulting from the pressure decline has occurred chiefly in the shale and siltstone associated with the oil sands. The publication of these two conflicting concepts on the mechanics of land subsidence emphasizes the need for careful research to resolve the relatively unexplored question of whether subsidence of the land surface associated with the withdrawal of large quantities of fluid is caused primarily by compaction of the permeable reservoir beds or of the relatively impermeable but porous silt, clay, and shale members which are interbedded with or confine the permeable beds, and which, in effect, are a part of the reservoir system.

A large range in the proportion of compaction of coarse-grained permeable deposits to that of fine-grained, relatively impermeable deposits probably will be found, as more examples of land subsidence associated with withdrawal of fluids or gases are studied in detail. The compressibility of each deposit must be in part a function of the physical character; for the fine-grained deposits the rate of com-

[9] Since the present report was released to the open file (1948), the maximum subsidence in the Wilmington area has increased to 22 feet (1955).

paction will also be a function of permeability which determines the rate at which pressure differentials can be equalized—that is, the rate at which fluid can escape from the fine-grained deposits to the more permeable reservoir rocks and permit compaction of the former.

Also in the vicinity of Terminal Island, a land subsidence of as much as half a foot occurred in 1941, concurrently with the dewatering for construction of the large graving dock at the Naval Operating Base on Terminal Island. A brief description of this dewatering operation, its effect on water levels in nearby wells, and the local subsidence of land surface has been given by Grant (1944, p. 149–154).

As summarized elsewhere (Poland, 1959), this dewatering at Terminal Island was carried out by turbine pumps in 36 gravel-envelope wells which tapped the Gaspur water-bearing zone. The dewatering was started on June 27, 1941, and reached a maximum during August, when the average rate of withdrawal was about 35,000 gpm. Pumping operations ceased on April 4, 1942, after the removal of about 26,000 acre-feet of water from the Gaspur zone in 9 months, or slightly more water than was pumped concurrently from this same zone by all water wells from Terminal Island to Whittier Narrows. The lowering of the piezometric level for the Gaspur water-bearing zone was as great as 35 feet in well 5/13–3L1 (Southern California Edison Co., well 4), and 15 feet in well 4/13–35M1, respectively 0.5 mile and 1.7 miles north of the center of pumping at the graving dock. The maximum recorded subsidence was at bench mark 43, at the southwest corner of the Southern California Edison Co. property and 1,650 feet from the center of the graving dock. Records taken by this company indicate that subsidence of bench mark 43 was 0.495 foot relative to bench mark 18, which is about 3,500 feet from the center of the graving dock. As described by Gilluly and Grant (1949, p. 497), substantial recovery of bench-mark altitudes coincided with recovery of water level in observation wells, during the reduced pumping rates of the latter part of the dewatering operation and immediately after cessation of pumping. The recovery of bench-mark altitudes ranged from 14 to 78 percent, with an average recovery of about 42 percent. From these facts, it was concluded by Gilluly and Grant that one-half or more of this subsidence due to the drawdown of the piezometric level of the Gaspur zone was attributable to mineral-grain rearrangement, and the remainder was due to elastic compression. It is of interest to note that the bench marks that underwent the largest subsidence had the smallest percentage of recovery of altitude.

At the center of the greatest drawdown of the pressure level of the Silverado zone within the west basin—at Carson and Alameda Streets in Dominguez Gap—the subsidence of land surface from about the

end of 1933 to 1944–46 was 0.354 foot, according to first-order leveling by the U. S. Coast and Geodetic Survey.[10]

Three miles to the south, on the right-of-way of the Southern Pacific Railroad, about 0.6 mile northeast of the Anaheim Street crossing, bench mark G 33—67 subsided 1.316 feet between 1914 and 1944–46. Of this subsidence, 0.942 foot has occurred since December 1931, and 0.528 foot since July 1941. This bench mark is within the productive limits of the Wilmington oil field and the greater part of the subsidence is believed to have been caused by the compaction which accompanied the withdrawal of oil and gas from that field.

Although the land surface has subsided several tenths of a foot throughout much of the southern part of the west basin, it is not known how much of this subsidence is due to compaction of sediments accompanying the decline of pressure head in the Silverado water-bearing zone. It may have been partly because of tectonic adjustments and partly because of pressure decline in the saline water sands at much greater depth which are hydraulically connected with the producing oil sands of the Wilmington and other oil fields. Accordingly, a direct estimate of subsidence due to compaction of sediments accompanying the decline of pressure head in the Silverado zone has not been attempted in this investigation. However, the quantity of water made available by such compaction of sediments has been estimated on page 151, by use of the empirical storage coefficient determined from the lowering of pressure head in well 4/14–13F1 due to the pumping of the wells at the Lomita plant of the city of Los Angeles (p. 133).

With fully effective confinement, water is yielded from storage only in proportion to the compaction of the water-bearing system (and expansion of the fluid) in response to pressure drop; therefore, it follows that in such cases the storage coefficient must be a measure of the compressibility of the system, and of the land-surface subsidence that will occur with each foot of sustained drawdown of the regional pressure level. However, in the ground-water basins of southwestern United States the water-bearing deposits consist almost entirely of valley fill (Meinzer, 1923, p. 291–303), and confining beds, although abundant, commonly are not extensive. Thus, with prolonged and substantial withdrawal of water, conditions of fully effective confinement are rarely found, and most of the water commonly is withdrawn from storage in the unconfined reaches of the basins by draining of the pore spaces. Only near the coast, where relatively impermeable beds associated with marine deposition are extensive, and in valleys such

[10] Bench mark D-167—At Dolores, at the southeast corner of the intersection of Alameda and Carson Streets, on the Dominguez Water Corp. property, at the pumping-plant building, in the face of the west wall.

as the San Joaquin, where the deeper water wells partly tap aquifers interbedded with fine-grained lacustrine deposits, would reasonably effective confining systems be found. When considered in relation to time intervals of as much as a few years, and possibly even several tens of years, conditions of fully effective confinement presumably are encountered only in the great artesian basins in which the aquifers have been deposited in interior seas. Probably the Dakota sandstone and the overlying plastic shales form the outstanding example of such a basin (Meinzer and Hard, 1925, p. 73–96; Darton, 1896).

Within the west basin, the area of greatest overdraft and of most serious saline contamination is the Torrance-Inglewood subarea. For these reasons, this subarea now (1948) is involved in a pending adjudication of water rights. Thus, the following appraisals of replenishment concern first the magnitude of replenishment to the Torrance-Inglewood subarea and second the replenishment to the smaller subbasins in the Culver City subarea.

REPLENISHMENT TO THE TORRANCE-INGLEWOOD SUBAREA

MAGNITUDE OF REPLENISHMENT IN 1903–4

The average rate of replenishment to the west basin in 1903–4 is believed to have been nearly equivalent to the natural and artificial discharge of that time. Such discharge occurred almost wholly by underflow to the ocean through the undersea extensions of the aquifers of Pleistocene and Recent age and by withdrawal through wells. The water levels were too far below the land surface to afford appreciable opportunity for evapotranspiration losses.

For the Torrance-Inglewood subarea an estimate of the natural discharge to the ocean in 1903–4 can be made by summing up (1) the discharge from the San Pedro formation (Silverado water-bearing zone and correlative aquifers) along the west coast from Playa del Rey to the Palos Verdes Hills, and along the south coast from the Palos Verdes Hills to the Los Angeles River, and (2) the discharge from the Gaspur water-bearing zone to San Pedro Bay. For the Silverado zone, the cross section along the coast is known with reasonable accuracy (pl. 3*C*), but the hydraulic gradient during 1903–4 at the coast cannot be accurately determined. Although water-level contours for the Silverado zone in 1903–4 have been reconstructed from data of Mendenhall (pl. 9 and p. 90), few of the wells in which water-level measurements were made near San Pedro Bay and from Manhattan Beach northward to Playa del Rey tapped the Silverado zone. The permeability of the Silverado zone was determined from pumping tests near Torrance and near Bixby Slough, but it was not determined along the coast. Yield factors for wells near the west coast compared to yield factors for wells between Long

Beach and Torrance (table 5)—where the permeability has been determined as about 2,000 gpm per square foot (p. 54)—suggest a proportion of about 2 to 3, or a permeability of about 1,300 gpm per square foot for the coastal reach from Palos Verdes Hills to Playa del Rey. The following paragraphs sum up the several increments of natural discharge:

1. For the reach from the Palos Verdes Hills to Hermosa Beach, the discharge to the ocean as of 1903–4 has been estimated as about 11 cfs, or about 8,000 acre-feet a year (p. 92).

2. In the same way and only as an approximation, the discharge to the ocean between Hermosa Beach and Playa del Rey can be estimated. The length of this reach is about 7 miles, the average thickness of the aquifer is about 125 feet (pl. 3*C*), the permeability is estimated as about 1,300 gpd per square foot, and the average hydraulic gradient at the coast in 1903–4 was at least 2 feet per mile. Thus, the discharge of that time (north of Hermosa Beach) is estimated to have been at least 2.3 mgd—about 3.5 cfs or about 2,500 acre-feet per year.

3. In regard to discharge from the Silverado water-bearing zone to San Pedro Bay, electric-log data for oil wells on Terminal Island indicate that the aquifers of the Silverado zone along that reach have an average thickness of about 250 feet. From the Los Angeles River west to the non-water-bearing rocks of the Palos Verdes Hills the width of the escape area is about 4 miles. Thus, the effective cross section is about 1,000 foot-miles. The coefficient of permeability for the Silverado zone in this area is not known, but it is probably somewhat lower than that in the Torrance area, where it was determined to be about 2,000 gpd per square foot (p. 54), and near Bixby Slough where it is about 1,400 gpd per square foot. If the permeability beneath Terminal Island is assumed to be about 1,000 gpd per square foot and if the hydraulic gradient of 1903–4 is taken as 4 feet per mile (p. 91), then the oceanward discharge through the Silverado zone beneath Terminal Island can be calculated at about 4 mgd—about 6.2 cfs or approximately 4,500 acre-feet per year.

4. Underflow to San Pedro Bay from the Gaspur water-bearing zone of Recent age is estimated to have been about 2.8 cfs, or about 2,000 acre-feet per year. These figures are based on the assumption that conditions at the coast were as follows: width of water-bearing zone, 2 miles (pl. 8); thickness, 60 feet—or an area of 120 foot-miles; hydraulic gradient, about 5 feet per mile (Mendenhall, 1905a, pl. 4); and an estimated permeability of 3,000 gpd per square foot (see p. 31).

In summation, the estimated yearly discharge to the ocean in 1903–4 from the aquifers beneath the Torrance-Inglewood subarea was about 21 cfs or 15,000 acre-feet from the Silverado water-bearing zone and was about 2.8 cfs or 2,000 acre-feet from the Gaspur water-bearing zone. Thus, the estimated total subsea escape was about 24 cfs or about 17,000 acre-feet per year. When this figure is added to the artificial discharge by pumping—which has been estimated at about 10,000 acre-feet per year during 1903–4 (p. 99)—the suggested over-all discharge was about 27,000 acre-feet per year, and the replenishment was comparable to that figure.

The rainfall record for Los Angeles (table 2) indicates that the 11 years ending with 1903–4 included only 4 years of normal or slightly above normal rainfall. With respect to the 68-year average rainfall of 15.53 inches, at the end of the year 1892–93 there was a cumulated surplus of 43.34 inches of rainfall. By the end of 1903–4 there was a cumulated deficiency of 3.79 inches, indicating an 11-year deficiency of 47.13 inches. The 3 years beginning with 1897–98 were the driest on record. Thus, runoff to the streams and recharge to the main coastal basin must have been continuously deficient during the 11-year period. Largely because of this deficiency, ground-water levels in the intake area near Whittier declined about 14 feet in this period and those near Anaheim declined about 40 feet (Poland, 1958). Also, the pressure level at the Bouton wells 2.5 miles north of Signal Hill and only 2 miles from the west basin boundary, declined about 80 feet in the same period. The decline of pressure head in the Bouton wells was far more than the average for the main coastal basin in Los Angeles County, however. The decline of artesian pressure along the northeast flank of the Newport-Inglewood uplift between Compton and Manchester Boulevard is known to have averaged about 30 feet from the initial historic level to 1904 (Mendenhall, 1905b, pl. 5).

The recharge to the west basin must have been affected in two ways by this deficiency of rainfall. First, there must have been little if any direct penetration of rainwater from the land surface in this period; certainly there was essentially none except in the 4 wettest years. Second, the replenishment by underflow across the Newport-Inglewood uplift must have diminished substantially in the 11-year period, because the pressure levels on the inland side of the barrier faults fell about 30 feet. Draft from the Torrance-Inglewood subarea was not large at that time and it appears doubtful that pressure levels in that subarea of the west basin could have declined in any such amount. Accordingly, the pressure differential across the barrier faults is inferred to have been greatly reduced by the decline in pressure level in the main basin; thus recharge to the Torrance-Inglewood subarea probably was considerably less in 1903–4 than in the eighties. It is believed that under native conditions of average rainfall the recharge to the Torrance-Inglewood subarea was 30,000 to 40,000 acre-feet per year.

MAGNITUDE OF REPLENISHMENT IN 1933–41

The replenishment to an underground basin may be estimated by measurement or calculation of the rate of inflow (intake methods) or the rate of discharge (discharge methods), or by determining changes in ground-water storage. Methods that have been applied to deter-

mine intake and discharge from ground-water reservoirs have been summarized by Meinzer (1932, p. 99–144).

For the west basin, the direct appraisal of the several elements of replenishment would be very tedious, and estimates of rain-water penetration, irrigation return water, and underflow (subsurface recharge) are subject to substantial error unless the basic data are sufficient to furnish reasonable control over the variable factors in the respective equations. Such is not the case at the present time. However, it is understood by the writer that the California Division of Water Resources, as referee in the pending adjudication of water rights, is planning to make a careful estimate of the several elements responsible for replenishment to the basin (California Division of Water Resources 1952).[11]

ESTIMATE BY RELATING PUMPAGE AND CHANGE IN STORAGE

For the purposes of this investigation, the elements of greatest interest are the over-all replenishment, the sea-water contribution, and the underflow across the Newport-Inglewood uplift. It can be assumed that, for years of average rainfall, the contribution by infiltration of water from rainfall and runoff from the land surface will be nearly constant from year to year. The residential and industrial areas are expanding rapidly and the agricultural area is decreasing, but the joint contribution by return water from irrigation of crops and lawns probably will not change appreciably as agricultural lands become residential districts.

The average gross replenishment can be determined most simply by selecting a period of years in which the cumulated rainfall did not markedly digress from the cumulated average, and in which the position of the water level was about equal at the beginning and the end of the period—that is, a period of little or no storage change. If the pumpage is known (or closely estimated) and if the storage change is estimated by the use of the specific yield and storage coefficients, the replenishment can be calculated. If there is no seaward discharge and no change in storage within the period, the gross replenishment is equal to the pumpage.

For the Torrance-Inglewood subarea of the west basin—the area included in the plaintiff's complaint for adjudication of water rights [12]—a relatively small amount of storage change occurred from the spring high-water level of 1933 to the spring high-water level of 1941 (pls. 9 and 11). Accordingly, this period of 8 years has been

[11] Since this report was released to the open file (1948), the California Division of Water Resources has completed its investigation as referee.

[12] California Water Service Co. and others *v.* City of Compton and others, Action No. 506,806 in the Superior Court for Los Angeles County, Calif., Oct. 1945.

460508—59——11

selected for appraisal of the average replenishment to this area before the accelerated draft and decline of water levels in the war years 1942–45.

The average yearly rainfall at Los Angeles in the years from 1933 into 1941 was greater than normal. However, 1940–41 was the only year of greatly excessive rainfall (table 2). With respect to the average rainfall for the 68 years from 1877–78 through 1944–45, as shown in table 2, the average rainfall in the years 1932–33 through 1939–40 was 1.76 inches above normal, and the cumulated surplus for the 8 years was 14.04 inches. For the 9 years from 1932–33 through 1940–41 the yearly average increased to 3.47 inches above normal, and the cumulated surplus was 31.27 inches. Thus, it might be expected that inclusion of the year 1940–41 would yield a nonrepresentative figure for storage change and replenishment. However, most of the water withdrawn from the Torrance-Inglewood subarea is taken from the Silverado water-bearing zone, which is confined by relatively impermeable beds through most of the area. Therefore, it is doubtful that the rainwater penetration of the winter 1940–41 could have had an appreciable effect on the water levels of the Silverado zone or even on the water levels in the shallower "200-foot sand" by April 1941. Examination of the hydrographs introduced on figures 4 and 5 and plates 13 and 14 substantiates this general conclusion. Therefore, it is considered that the period selected is reasonably representative but that rainwater penetration in the 8 years was slightly above average.

The rise or fall of water level in the Silverado water-bearing zone from March 1933 (pl. 9) to April 1941 (pl. 11) is shown by lines of equal change (long dashes) on plate 10; the rise or fall for the "200-foot sand" in this 8-year period also is shown (short dashes). As discussed on pages 87–88, a water table occurs in the Silverado water-bearing zone only in the Redondo Beach area (pl. 10); another water table occurs in the correlative main water-bearing zone of the San Pedro formation in the vicinity of Playa del Rey. It will be noted from the lines of equal change on plate 10 that: (1) the storage change in the water-table reach of the Silverado zone near Redondo Beach did not exceed 5 feet; and (2) the storage change in the water-table reach of the main water-bearing zone near Playa del Rey did not exceed 6 feet. The maximum change (except for the local fall of 20 feet east of Inglewood between the Potrero and Inglewood faults) in the Torrance-Inglewood subarea, east of Hawthorne in the pressure area, was about 16 feet. Inland beyond the west basin boundary, the maximum fall was in excess of 30 feet.

[1] Total change in volume (acre-feet) multiplied by 0.20 (specific yield).
[2] Storage coefficient assumed to be 0.0012 throughout the pressure area.

The storage change in the Silverado water-bearing zone was determined in the following manner:

1. The working copy of plate 10, at a scale of 1:48,000 was superimposed over a map sectionized in the manner of plate 2, each main grid unit representing 1 square mile. For the two water-table areas, a grid subdivided in hundredths of a square mile was utilized to determine the part of each section falling between two lines of equal change. For the larger pressure area, the average change of water level in feet was estimated for each square mile. For each territory the area in square miles lying between lines of equal water-level change (0–2, 2–4, and 4–6) was summed up separately. Cumulative areas so obtained were multiplied by the odd-foot value between the two boundary lines (the average change for the area between the 2- and 4-foot lines was assumed to be 3 feet), giving a volume for storage change in square miles × feet. By summing up all such volumetric elements for each area, the total volume change was obtained for that area.

2. The specific yield for the two water-table areas was assumed to be 20 percent (in accordance with estimates made by Eckis from samples collected in the field and tested in the laboratory) (1934, pl. *E*). The storage coefficient of 0.0012—obtained from the drawdown of water level in well 4/14–13F1 due to pumping of the Lomita plant wells (p. 133)—was applied to the main pressure area. Table 13 presents a summary of water-level changes, volumes dewatered or saturated (or of pressure-level change), and water released from storage.

The storage change has been computed for the "200-foot sand" in the same manner. Contours of the water level in this aquifer were not constructed for the beginning and end of the period of appraisal. Instead, the changes in position of the water level in the period for individual wells were plotted on the working copy of plate 10 and the lines of equal change were drawn from these data. Table 14 summarizes the results of the computation. About one-fourth of the pertinent well logs show water-table conditions at current water levels in the upper Pleistocene deposits ("200-foot sand" and other deposits); therefore, the over-all specific yield was assumed to be about 5 percent.

TABLE 14.—*Estimated storage change in the Torrance-Inglewood subarea, from March 1933 to April 1941, for the "200-foot sand" and correlative deposits of upper Pleistocene age*

Area (sq mi)	Rise (+) or fall (−) (feet)	Change in volume		Storage change (acre-feet of water)
		Square miles × feet	Acre-feet	
16.93	−3	−50.79	−32, 505	----------
19.70	−5	−98.50	−63, 040	----------
10.90	−7	−76.30	−48, 830	----------
8.24	−9	−74.16	−47, 460	----------
55.77	----------	−299.75	−191, 835	[1] −9, 600

[1] Total change in volume (acre-feet) multiplied by 0.05 (specific yield).

The estimated storage change within the Silverado zone in the 8-year period (table 13) is 5,600 acre-feet of which 5,300 acre-feet occurred in the water-table areas. The estimated storage change in the unnamed upper Pleistocene deposits (table 14) is 9,600 acre-feet. Thus, the over-all withdrawal from storage in the 8 years is estimated to have been 15,200 acre-feet, or an average rate of about 2,000 acre-feet per year. Changes in storage in the shallow unconfined body and in the 400-foot gravel probably were inconsequential during this period.

The total withdrawal from the Torrance-Inglewood subarea in the 8 years from 1933 through 1940 (table 8) was 383,100 acre-feet; the average rate of withdrawal was about 47,900 acre-feet per year. There was essentially no natural discharge during this period, therefore, the gross replenishment is equal to the withdrawal less the change in

storage—that is, 383,100 less 15,200 or 367,900 acre-feet. Thus, the average yearly gross replenishment is estimated to have been about 46,000 acre-feet.

CONTRIBUTION FROM THE OCEAN

With the extensive drawdown of water levels to and below sea level, saline waters have invaded the Torrance-Inglewood subarea along the full reach from Playa del Rey to the Palos Verdes Hills. Also, along the south shore from the Palos Verdes Hills to the Los Angeles River channel, saline waters probably have moved northward beyond Terminal Island toward centers of pumping. The water in the Silverado zone beneath Terminal Island is inferred to have been of inferior quality under native conditions (Piper, Garrett, and others, 1953, p. 197). To date, these inferior waters have not advanced sufficiently far northward to reach any actively pumped well fields. As shown by the distribution of withdrawals on plate 12, the first major well fields to receive such inferior waters presumably would be that of the Union Oil Co. in Wilmington (pl. 12, no. 23) and that of the Texas Co. (pl. 12, no. 24) at the west edge of Dominguez Gap. Regardless of the quality of the ground water in the Silverado zone beneath Terminal Island, there must have been a substantial contribution of water to the west basin from the subsea reach south of Terminal Island in response to the landward gradients that have existed since the early thirties. This contribution is not being replaced by water of good quality, and probably it is being followed landward by saline waters, either ocean water entering the outcrop of the Silverado zone beneath San Pedro Bay, or connate saline waters contributed from within the subsea ground-water system, or both.

Ocean water advanced inland in the Gaspur water-bearing zone in the thirties (see p. 259, also pl. 16); the extent of that inland advance has been shown in an earlier report (Piper, Garrett, and others, 1953, pl. 17).

The over-all contribution from the ocean or from the seaward extensions of the water-bearing zones of the Torrance-Inglewood subarea from 1933 to 1941 is estimated in following paragraphs.

The extent of encroachment of saline waters for the reach along the west coast from Playa del Rey to the Palos Verdes Hills is shown on plate 16. The contribution from the ocean can be computed if the assumption is made that the rate of advance of the saline front is a direct measure of the rate of landward inflow of salt water to the water-bearing deposits.

From the appraisal of the rates of saline encroachment as suggested by the advance of the saline front from 1931 to 1946 (pl. 16), and with consideration to the effective hydraulic gradients, it is concluded

(p. 251 to 253) that the average yearly rate of advance of the saline front from Playa del Rey to El Segundo from 1931 to 1941 did not exceed 40 feet, from El Segundo to Hermosa Beach it was about 115 feet, and from Hermosa Beach to the Palos Verdes Hills it was about 90 feet. The effective porosity of the Silverado water-bearing zone and correlative water-bearing deposits along this full reach is estimated to be about 20 percent. The product of the cross-sectional area of water-bearing materials, the average yearly advance, and the effective porosity may be considered to be a measure of the contribution seaward from the front.

The cross-sectional area (pl. 3*C*) for the reach from Hermosa Beach to the Palos Verdes Hills is about 3.5 miles long by 400 feet thick. If the average advance of the front (pl. 16) was 90 feet per year through material with an effective porosity of 20 percent, the quantity of water required to fill the block 3.5 miles long by 400 feet thick by 90 feet wide would be about 3,100 acre-feet. In the same way, the yearly displacement for the reach from Hermosa Beach to Playa del Rey is estimated at about 2,500 acre-feet.

By this method, the average annual contribution to the ground water in the area coastward from the saline front in the reach from Playa del Rey to the Palos Verdes Hills for the years from 1931 to 1941 is estimated to be about 5,600 acre-feet.

By another method, the contribution along this reach can be computed as the product of: (1) the cross-sectional area of permeable material; (2) an estimated permeability of 1,300 gpd per square foot (p. 147); and (3) the average hydraulic gradient. For the reach from Hermosa Beach to the Palos Verdes Hills, where the average landward gradient of the thirties was about 3.5 feet per mile, the contribution so computed is 7,100 acre-feet per year. If the contribution in the reach from Hermosa Beach to El Segundo is computed assuming a permeability of 1,300, a cross-sectional area 4.5 miles long and 150 feet thick, and an equivalent hydraulic gradient of 3.5 feet per mile; and if the small contribution from El Segundo to Playa del Rey is estimated from the rate of saline encroachment, as above, the over-all contribution along the west coast is about 10,800 acre-feet per year.

If the quantities derived by these two independent methods are assumed to indicate the general limits of such a contribution along the west coast in the thirties, the suggested mean is about 8,000 acre-feet per year. Most of this contribution must have been ocean water, but it also included water that descended from the land surface to the water table, in the areas coastward from the saline front, south of Hermosa Beach and north of El Segundo. In the thirties, these two areas included about 3,000 acres, and the average annual contribution of water from the land surface in this dune-sand area may have been

as much as 1,000 acre-feet. If these figures are correct, the ocean-water contribution is estimated to be about 7,000 acre-feet per year.

For the south coast facing San Pedro Bay, the landward movement of water in the Silverado water-bearing zone in the thirties can be estimated in the same manner as the coastward discharge of 1903–4 (p. 147). It is inferred that the Silverado zone or correlative deposits crop out on the ocean floor from 8 to 9 miles southwest of Terminal Island.[13] The average depth of the piezometric level at Terminal Island from 1933 to 1941 was about 30 feet below sea level. Thus, the average inland gradient of those years is inferred to have been about 4 feet to the mile—about equal to the coastward gradient of 1903–4. Therefore, the annual contribution of water moving northward in the Silverado zone from beneath San Pedro Bay in the thirties is estimated to have been about 4,500 acre-feet per year.

The landward movement of salt water in the Gaspur water-bearing zone is known to have underrun about 300 acres from 1931 into 1943 (Piper, Garrett, and others, 1953, pl. 17 and p. 178). The thickness of the Gaspur water-bearing zone is about 60 feet and the effective porosity is about 25 percent. The landward encroachment of the thirties thus was approximately 400 acre-feet per year.

In summation, the average yearly contribution of water to the Torrance-Inglewood subarea from 1933 to 1941 from the ocean or from the subsea extensions of the aquifers is estimated to have been about 12,000 acre-feet per year. Thus, within the limitations of the assumptions made here the average net replenishment of fresh water to the Torrance-Inglewood subarea in these years is 46,000 acre-feet less 12,000 acre-feet, or about 34,000 acre-feet per year.

UNDERFLOW ACROSS THE NEWPORT-INGLEWOOD UPLIFT

Under native conditions of high-water level, the quantity of underflow passing across the Newport-Inglewood uplift from the main coastal basin to the Torrance-Inglewood subarea along the crestal reach from Long Beach to the Baldwin Hills varied in accordance with the differential in the water levels across the fault barriers of the uplift as the one variable (the product of permeability and cross section was a constant). At the crest of the uplift the Silverado water-bearing zone and related deposits in the San Pedro formation then were fully saturated. and the upper Pleistocene water-bearing zones were fully saturated, except at the crests of Dominguez Hill and the Rosecrans Hills, and high on the flank of the Baldwin Hills.

In accordance with the drawdown of water level due to increased withdrawal from the main coastal basin, water levels along the crest of the uplift have declined from 100 to 150 feet below the initial levels

[13] U. S. Coast and Geod. Survey hydrologic chart 5143, Los Angeles harbor and vicinity, 1936.

and substantial dewatering of certain aquifers has occurred. For aquifers almost entirely dewatered along the crest of the uplift, the transmissibility of the saturated cross section has become the primary control on the quantity of water passing into the west basin, and the differentials at the barrier features have become secondary. For aquifers wholly dewatered along the crest, no water passes coastward beyond the crest, and the differentials along the barrier features have no meaning.

DEWATERING ALONG THE UPLIFT CREST

Plate 15 has been prepared for the purpose of appraising the magnitude of dewatering of the water-bearing beds along the crest of the Newport-Inglewood uplift from the Baldwin Hills to Long Beach. The position of the water-bearing beds (pl. 15) has been generalized from plate 3*A*, with slight modification between Manchester Avenue and Imperial Highway, in order to follow the land-surface and inferred subsurface crests. Plate 15*B* shows on an expanded scale, the pressure level and the local water table of the Silverado water-bearing zone and correlative aquifers along the alinement of the section for selected times from 1903–4 to 1945. A partial plot of the water levels of the eighties, inferred from data by Mendenhall, also is shown. The water-level profiles for 1904, 1933, 1941, and 1945 are taken from plates 9–12; the profile for 1930 is from a work map not included in the report. Although the water-level profiles are constructed from data for wells tapping the Silverado zone and correlative deposits, these profiles also can be used to appraise the general order of dewatering of the upper Pleistocene deposits. Part of the generalized position of the top of the Silverado zone has been plotted at the expanded scale of plate 15*B* in order to emphasize the extent of dewatering in this principal aquifer.

As shown by the profiles of plate 15, the upper Pleistocene water-bearing deposits (the "200-foot sand" and correlative deposits) have been extensively dewatered along the crest. On the other hand, the Silverado water-bearing zone and lower Pleistocene correlative deposits have been partly dewatered in the 6-mile reach between the Baldwin Hills and El Segundo Boulevard, but no dewatering has occurred in the 8-mile reach from El Segundo Boulevard to Los Cerritos (Long Beach). The extent of dewatering is summarized as follows:

1. The upper Pleistocene water-bearing deposits initially were fully saturated except at the crests of the Dominguez Hill and Rosecrans Hills and high on the south flank of the Baldwin Hills. By 1945 these deposits had been entirely dewatered along all the crestal reach northwest of El Segundo Boulevard, and had been dewatered nearly to sea level along the crestal reach of Dominguez Hill. Thus, in the early forties, the only segments of these deposits still saturated were: the 3-mile reach between El Segundo Boulevard and Artesia Street, along most

of the Avalon-Compton fault; and the 3-mile synclinal reach beneath and adjacent to Dominguez Gap. The water-bearing beds in the reach along the Avalon-Compton fault are only about 60 feet thick but they are highly permeable and are tapped by many wells; thus, these deposits are believed to transmit substantial underflow through the fault barrier. On the other hand, the water-bearing beds beneath Dominguez Gap, which are composed almost entirely of fine sand (pl. 3*A*), as much as 120 feet thick (well 4/13–2J1), are not tapped by many wells because they are not highly permeable, and their transmissibility is less than that of the thinner aquifers northwest of Dominguez Hill.

In terms of cross-sectional area, about 50 percent of the upper Pleistocene water-bearing deposits throughout the area shown on plate 15*A* have been dewatered by the drawdown of water level from native conditions to the levels of 1945. However, the reduction in transmissibility has been much more than 50 percent, because the permeable deposits which occur northwest of well 3/13–17E1 and including those at the Centinela Park well field of the city of Inglewood, have been wholly dewatered. Utilizing the generalized data of plate 15*A*, the calculated cross-sectional area of the initially saturated upper Pleistocene aquifers is 4.4 million square feet and by 1945 the dewatered area totaled 2.1 million square feet.

2. The Silverado water-bearing zone and correlative aquifers in the San Pedro formation of early Pleistocene age initially were fully saturated along all of the crestal reach from Los Cerritos (Long Beach) to the Baldwin Hills. In nearly all of the 8-mile reach southeast of El Segundo Boulevard, the top of the Silverado zone is more than 100 feet below sea level, and beneath Dominguez Gap is as much as 400 feet below sea level. However, between El Segundo Boulevard and the Baldwin Hills, the top of the Silverado zone and correlative deposits is several tens of feet above sea level on a large area. Thus, because of the decline of water level to near sea level, by 1945, extensive dewatering has occurred in the deposits in the 6-mile reach northwest of El Segundo Boulevard.

In terms of cross-sectional area, about 35 percent of the water-bearing beds of the San Pedro formation northwest of El Segundo Boulevard had been dewatered by 1945. Throughout the entire reach, only about 10 percent had been dewatered. However, in the 2-mile reach from near well 2/14–27J1 (city of Inglewood, well 16) southeast to the intersection of Century Boulevard and Western Avenue, the decline of water level by 1945 had dewatered about two-thirds of the thickness and only 30–50 feet of the Silverado zone remained saturated. No well data are available to determine whether the reduction in saturated cross section may have been partly compensated by a steepening of the hydraulic gradient. In any case, a drawdown of water levels to as much as 30 feet below sea level would essentially dewater the Silverado water-bearing zone in this reach and would prevent underflow to the west basin.

From the generalized data of plate 15, the calculated cross-sectional area of the Silverado water-bearing zone and correlative aquifers is 18 million square feet, of which about 12.8 million is south of El Segundo Boulevard and about 5.2 million is north; of the latter, about 2 million square feet had been dewatered by 1945. Thus, the saturated cross-sectional area of the lower Pleistocene aquifers, as compared with that of the upper Pleistocene aquifers, was about four times as great under initial conditions and about seven times as great in 1945.

CHANGE IN DIFFERENTIAL HEAD ACROSS THE BARRIER FEATURES

The average differentials in water level across the barrier features of the uplift between the Baldwin Hills and the southeast edge of

Dominguez Gap can be calculated approximately from water-level contour maps of the Silverado water-bearing zone by estimating average differential heads across measured segments of the barrier features and totaling these differentials, which are weighted in accord with the lengths of the respective segments. In this manner, average differentials in water level have been estimated for 1904, 1933, 1941, and 1945, from the data of plates 9 to 12. Results are summarized in table 15.

TABLE 15.—*Average water-level differentials, in feet, across the barrier features of the Newport-Inglewood uplift between the Baldwin Hills and Long Beach, 1904–45*

Year	Baldwin Hills to El Segundo Boulevard (6 miles)	El Segundo Boulevard to Long Beach (8 miles)	Totaled average from Baldwin Hills to Long Beach (14 miles)
1904	49	33	40
1933 (March)	29	37	34
1941 (April)	22	33	28
1945 (November)	32	40	36

The water-level differentials have been summed up separately for the 6-mile reach northwest of El Segundo Boulevard and the 8-mile reach to the southeast. The former parallels the area of partial dewatering along the crest, and also is the one with the poorer control on water-level differentials, especially across the Potrero fault north of Century Boulevard; here, the amount of drawdown of water level in the several fault blocks between the Potrero and Inglewood faults is irregular and largely unknown.

Although the average differentials presented in table 15 are only approximate and their derivation has required a considerable amount of extrapolation, they suggest with respect to the Silverado water-bearing zone and correlative deposits that:

1. In 1904 the differential in water levels was about 50 percent greater northwest of El Segundo Boulevard than to the southeast.
2. By 1933 the differential northwest of El Segundo Boulevard had decreased about 40 percent and was less than the differential to the southeast, which had increased slightly.
3. The average differential was least in 1941 only 28 feet for the over-all 14-mile reach.
4. If the average head differential between 1933 and 1941 is assumed to be the average of those 2 years, then the head differential northwest of El Segundo Boulevard in that 8-year period (26 feet) was just about half of that in 1904, whereas southeast of El Segundo Boulevard it was slightly higher than in 1904 (35 feet). If the water transmitted across the barrier features is proportional to the differential in head, as seems reasonable, if the permeability of the water-bearing beds is considered uniform along the full reach, and if the effect of de-

watering north of El Segundo Boulevard is ignored, the underflow into the Torrance-Inglewood subarea in the period 1933–41 can be estimated to be about 86 percent as great as in 1904 (product of differential head times cross-sectional area, for each segment).

5. In the same way, the underflow into the Torrance-Inglewood subarea as of 1945 can be estimated to be about the same as in 1904. If the dewatering along the crest north of El Segundo Boulevard is considered wholly effective in proportionately reducing the underflow to the west basin, then, the underflow as of 1945 would have been about 90 percent as great as in 1904, with respect to the Silverado zone and correlative deposits.

Of all water-bearing deposits of Pleistocene age along the reach from the Baldwin Hills to Los Cerritos—that is, the extensively dewatered upper Pleistocene deposits as well as the Silverado zone and correlative deposits of early Pleistocene age—it is estimated that the underflow as of 1945 was about 85 percent as great as in 1904.

METHODS OF ESTIMATING UNDERFLOW

The underflow to the Torrance-Inglewood subarea from the main coastal basin comprises two elements, (1) the underflow in the Gaspur water-bearing zone of Recent age, which passes into the west basin through the throat of Dominguez Gap, and (2) the underflow through all the aquifers of Pleistocene age, of which the Silverado water-bearing zone and correlative aquifiers constitute the principal conduit.

The Gaspur water-bearing zone is not cut by the barrier features of the uplift—specifically, the Cherry-Hill fault (pl. 12)—and thus no differential in water level has been developed. Accordingly, the underflow to the west basin through this aquifer can be estimated as the product of the permeability, the cross-sectional area, and the hydraulic gradient. The permeability has been estimated to be about 3,000 gpd per square foot (p. 31), the cross-sectional area at the throat between Dominguez Hill and Los Cerritos is about 72 foot-miles (width 1.2 miles parallel to the ground-water contours, and thickness about 60 feet), and the hydraulic gradient through the throat has been about 12 feet to the mile in recent years (pl. 11). Thus, the current underflow to the west basin through the Gaspur water-bearing zone is estimated at about 4 cfs, or about 2,900 acre-feet per year.

The quantity of underflow to the Torrance-Inglewood subarea through the deposits of Pleistocene age also could be estimated directly if: (1) the permeability of the water-bearing deposits from place to place along the crest of the uplift had been determined by means of a sufficient number of pumping tests to afford reliable control; (2) the average hydraulic gradient across the crest were known for the particular instants or periods of appraisal; and (3) the amount of withdrawal between the crest of the uplift and the inland boundary of the west basin were known, so it could be subtracted from the underflow passing

the crest. Neither the permeability nor the crestal hydraulic gradient can be evaluated with reasonable accuracy at this time. In the 3-mile reach from the top of Dominguez Hill to the Los Angeles River not a single water well taps the Silverado water-bearing zone immediately inland from the barrier faults. It is here that the greatest differential in pressure level now exists across the barrier features of the uplift. During this investigation an attempt was made, with the cooperation of the Los Angeles County Flood Control District, to utilize certain oil-test holes for obtaining data on the permeability and piezometric level of the Silverado zone within this critical reach; however, the negotiations were unsuccessful.

The importance of obtaining accurate data on the hydraulic gradient can be illustrated by the following example. If the average permeability along the crestal reach is assumed for the moment to be 1,000 gpd per square foot, the quantity of water transmitted across the saturated crestal section of the Silverado zone and correlative deposits in 1945 would have been about 3,400 acre-feet per year for each foot per mile of hydraulic gradient.

The quantity of underflow passing into the Torrance-Inglewood subarea through the Silverado water-bearing zone and correlative deposits could be estimated by another method. The axis of the pressure trough, as shown on plates 9 to 12, marks the boundary between water moving inland and water moving coastward. That axis has migrated inland in recent years because the draft from the Torrance-Inglewood subarea has increased about 50 percent while the underflow has remained roughly constant. The quantity of water withdrawn between the barrier and the axis of the pressure trough—that is, within the area underlain by a coastward gradient—is a measure of the replenishment by underflow. It is impossible to estimate this draft accurately at present. For example, the axis of the pressure trough as of 1945 passed through the main well field of the Dominguez Water Corp. (pl. 12, plant 14b). The proportion of water contributed to this well field from the inland side (coastward hydraulic gradient) and from the coastward side (landward hydraulic gradient) cannot be determined without constructing additional observation wells to indicate the steepness of the coastward gradient as compared to the landward gradient.

However, as plates 9 and 11 suggest, the coastward hydraulic gradient on the inland side of the trough of pressure relief is somewhat steeper than the landward gradient on the oceanward side of the cone. If, for purposes of rough calculation, it is assumed that the coastward hydraulic gradient to such pumping plants along the axis of the pres-

sure trough was twice as great as the inland gradient in 1945, and presuming that the transmissibility of the deposits on the two sides is the same, then the contribution from the inland side would be two-thirds of the total to such well fields. On the basis of this assumption, the underflow from the main coastal basin to the Torrance-Inglewood subarea through the Silverado water-bearing zone as of 1945 is estimated roughly to have been about 12,000 to 16,000 acre-feet per year. If the estimated underflow through the upper Pleistocene deposits and through the Gaspur water-bearing zone is added to this, the total contribution to the Torrance-Inglewood subarea by underflow from the main coastal basin in 1945 is estimated to have been within the range of 15,000 to 20,000 acre-feet.

FACTORS AFFECTING CURRENT AND FUTURE REPLENISHMENT

The net replenishment to the Torrance-Inglewood subarea from 1933 to 1941 has been estimated at about 34,000 acre-feet per year (p. 148–155). Although the withdrawal as of 1945 had increased to some 78,000 acre-feet (table 8), or to about 160 percent of the average yearly draft of the thirties, the net replenishment in 1945 is believed not to have differed greatly from that of the thirties. Because the average differential in the water level across the barrier features is believed to have increased by a few feet from the thirties into 1945 (p. 158), the underflow to the Torrance-Inglewood subarea probably was slightly greater in 1945 than in the thirties. Therefore, because the sum of the other elements of net replenishment is considered to have been about equal in years of average rainfall, the net replenishment of the middle forties presumably has been at least equal to and probably slightly in excess of that of the thirties.

The increase in draft during the war years drew down the water levels substantially in the Torrance-Inglewood subarea and steepened the landward hydraulic gradient along the coastal reaches of the basin. The ocean-water or subsea contribution, which is estimated to have been about 12,000 acre-feet per year in the thirties, is believed to have more than doubled by the end of 1945. Additional drawdown of the water levels in the Torrance-Inglewood subarea would increase the rate of ocean-water contribution in direct proportion to the increase in landward hydraulic gradient along the coastal reach.

If a decrease in draft should occur and water levels in the Torrance-Inglewood subarea should remain about constant for the next few years, and if water levels in the main coastal basin should be drawn down appreciably below the levels of 1945, contributions by underflow from the main coastal basin, which are believed to constitute about

half the current net replenishment to the subarea, would be reduced roughly in proportion to the decrease in average differentials across the barrier. The reduction in underflow probably would be slightly greater than the decrease in differential head because of the effect of additional dewatering along the crest of the uplift. Thus, it is to the interest of water users in the west basin that water levels inland from the barrier be maintained as high as is feasible—in other words, replenishment to the Torrance-Inglewood subarea is affected beneficially by conservation of the water supply and increased replenishment to the groundwater reservoir throughout the coastal plain in Los Angeles County.

REPLENISHMENT TO THE CULVER CITY SUBAREA

Under initial conditions and to date, replenishment to the Culver City subarea has been supplied very largely by infiltration of runoff from the south flank of the Santa Monica Mountains west of the Inglewood fault and from rainwater penetration beneath the Santa Monica plain and within Ballona Gap. Initially, some replenishment doubtless passed coastward across the Inglewood fault from the main coastal basin. Since the middle twenties, however, little if any water has entered the Culver City subarea from the Pleistocene deposits to the east, because water levels in those deposits consistently have stood lower on the inland side of the Inglewood fault than on the coastal side. In the "50-foot gravel," however, a coastward gradient still prevails across the Ingelwood fault and some water presumably passes into the Culver City subarea through this conduit.

In the crestal subbasin (between the Inglewood and Overland Avenue faults) withdrawal now is wholly from the San Pedro formation. The draft did not exceed a few hundred acre-feet per year until the middle thirties, when it increased to about 1,100 acre-feet per year (p. 108). Replenishment to the San Pedro formation is believed to be almost entirely from the north. As shown by the hydrographs for wells 2/14–7M1 and 18F1 (pl. 14), the water level declined at a gentle rate of about 0.6 foot per year in the early thirties, but it had declined at more than double that rate since 1936. The water-level trend in these observation wells must be interpreted with caution, because a general decline of water level in the subbasin would be expected to have occurred in response to drawdown of water levels to the south (escape area), east, and west, as well as to the increased withdrawal in the subbasin itself. Nevertheless, the evidence suggests that the replenishment under present conditions is somewhat less than the draft.

Replenishment to the Charnock subbasin as of 1904 was from: (1) the north by infiltration of rainfall and runoff on the Santa Monica

plain; (2) the east by movement of water from the crestal subbasin, probably largely through the "50-foot gravel," which is not cut by the Overland Avenue fault; and (3) by direct penetration of water from the land surface in the part of the subbasin within Ballona Gap. The concentrated withdrawal from the Charnock and Sepulveda well fields (p. 97 and pl. 12) has developed and maintained a central ground-water depression in which water levels have stood several tens of feet below sea level for the past two decades. Because of this great drawdown of water level, replenishment to the central part of the Charnock subbasin has been derived in part from the south since the late twenties. On the other hand, the general drawdown of water level within the Culver City subarea has largely dewatered the "50-foot gravel," and replenishment from the crestal subbasin to the east probably has about ceased, except for possible contributions across the Overland Avenue fault.

The draft from the Charnock subbasin is estimated to have ranged from 12,500 acre-feet in 1941 to 7,000 acre-feet in 1945. The hydrographs for wells 2/15–11E3 and 24C1 (pl. 14) suggest that in 1945 the replenishment was about equal to the estimated draft of 7,000 acre-feet. The water-level contours of plate 12 suggest that the hydraulic gradient from the north was then about 2½ times as steep as that from the south, and thus—assuming uniform permeability of the water-bearing material—that more than two-thirds of the replenishment was from the north. With respect to replenishment from the south, the water-level contours of plates 9–12 suggest that some of this replenishment moves northward from south of the Ballona escarpment, possibly in part from the crestal subbasin around the south end of the Overland Avenue fault.

The coastal area apparently receives almost all its replenishment from the Santa Monica upland to the north and by direct infiltration of rainwater in Ballona Gap. Through the thirties, when water levels stood below sea level, it also received substantial recharge from the ocean. For the past two decades no replenishment has moved westward across the Charnock fault. In fact, with the great differential in water levels that has existed across the Charnock fault since the late twenties, some water probably has moved inland across the fault.

The draft in the coastal area in the forties is estimated to have been between 2,000 and 3,000 acre-feet per year. The hydrographs for wells 2/15–16F1 and 22B4 (pl. 14) suggest that the replenishment from all sources has been at least equal to this draft in recent years.

CHEMICAL CHARACTER OF NATIVE AND CONTAMINATED GROUND WATERS

GENERAL NATURE OF THE CHEMICAL PROBLEMS

Locally, in the early twenties and more widely in the early thirties, certain wells near the coast from Ballona Gap to and beyond Redondo Beach began to yield saline water, leading ultimately to abandonment of some wells in which the salinity of the water became so great that it could no longer be used.

The districts in the Torrance-Santa Monica area in which the chloride content of some or all of the ground-water bodies exceeded 100 ppm in 1945–46 are shown on plate 16. These districts include several bodies containing water of native inferior quality—specifically, a part of the Wilmington district, a narrow zone extending along the north flank of the Palos Verdes Hills, the Gardena area, an area between Hawthorne and Inglewood, and a narrow strip along the west edge of the Baldwin Hills. They also include areas of inferior water in Dominguez Gap, along the coast from Redondo Beach to El Segundo, and in Ballona Gap, which have developed from progressive contamination during the past two decades; these are identified by diagonal ruling on plate 16.

The approximate extent of saline contamination in 1931–32 is also shown and represented by the boundaries of contaminated waters then containing more than about 100 ppm of chloride. Thus, the spread of contamination in the 14-year period is indicated by the relative position of the two boundaries.

In the Gardena area, the native waters of inferior quality occur within the shallow unconfined water body. In all the other districts underlain by water of more than 100 ppm of chloride, the inferior water is in the principal water body.

In Dominguez Gap, native waters of inferior quality occurring in the shallow unconfined body have become contaminated extensively during the past two decades. However, contamination has developed more widely in certain underlying water-bearing deposits in the principal water body—specifically in the Gaspur water-bearing zone and in the unnamed upper Pleistocene deposits to depths of 150 to 200 feet below land surface. In Dominguez Gap, the extent of contamination as shown on plate 16 relates to conditions in the principal water body and not to those in the shallow unconfined body.

Within the west basin and outside of the districts underlain by inferior waters as indicated on plate 16, a few wells tapping the principal water body yield water containing more than 100 ppm of chloride. Although these are not identified on plate 16, several of the wells are treated in the text beyond.

Because of the increased development of ground water in the west basin and the continuing decline in ground-water levels, local agencies that draw water from the basin or are concerned with the conservation of ground water have become increasingly alarmed by the spread of saline contamination.

Following sections of this report treat this problem of saline contamination by: (1) describing the chemical character and extent of waters of good quality and of inferior quality existing under native conditions; (2) describing the sources of saline contamination insofar as they can be identified; (3) determining the present extent of salt-water encroachment in the several water-bearing zones in the west basin; and (4) evaluating the possibilities for saline contamination to become more extensive in the future.

SCOPE AND SOURCES OF ANALYTICAL DATA

In connection with the canvass of water wells within the coastal plain by Mendenhall (1905a, 1905b) in 1903–4, the approximate dissolved-solids content of the water from about 2,500 wells in the Torrance-Santa Monica area was computed from their electrical conductances. Except for these determinations, only a few analyses are available for the period prior to 1929. The bulk of chemical analyses are for well waters sampled since that time—beginning chiefly in 1931–32, that is, sampling programs of the several active agencies began at about the time that local contamination problems became serious. At the present time, a large amount of analytical data has accumulated; this information includes both comprehensive analyses and those in which only one or two constituents, usually chloride or bicarbonate, have been determined. The scope of these data and the term of record by each contributing agency have been given in an earlier report (Sinnott and Garrett, 1946). In all, about 1,500 comprehensive analyses and about 12,000 field (partial) analyses have been made available for study. The Geological Survey has drawn freely upon this information in compiling the part of this interpretive report that deals with the chemistry of native and contaminated waters in the Torrance-Santa Monica area. From these data, representative analyses have been selected (table 30) to show the character of native waters and the progressive development of contamination in critical areas.

In addition to the large number of analyses, several interpretive reports relating to the problems of saline contamination have been made. Nearly all of these reports have been made by or for the Los Angeles County Flood Control District and chiefly discuss contamina-

460503—59——12

tion in Ballona Gap. Most of these have been cited earlier in this report (p. 9).

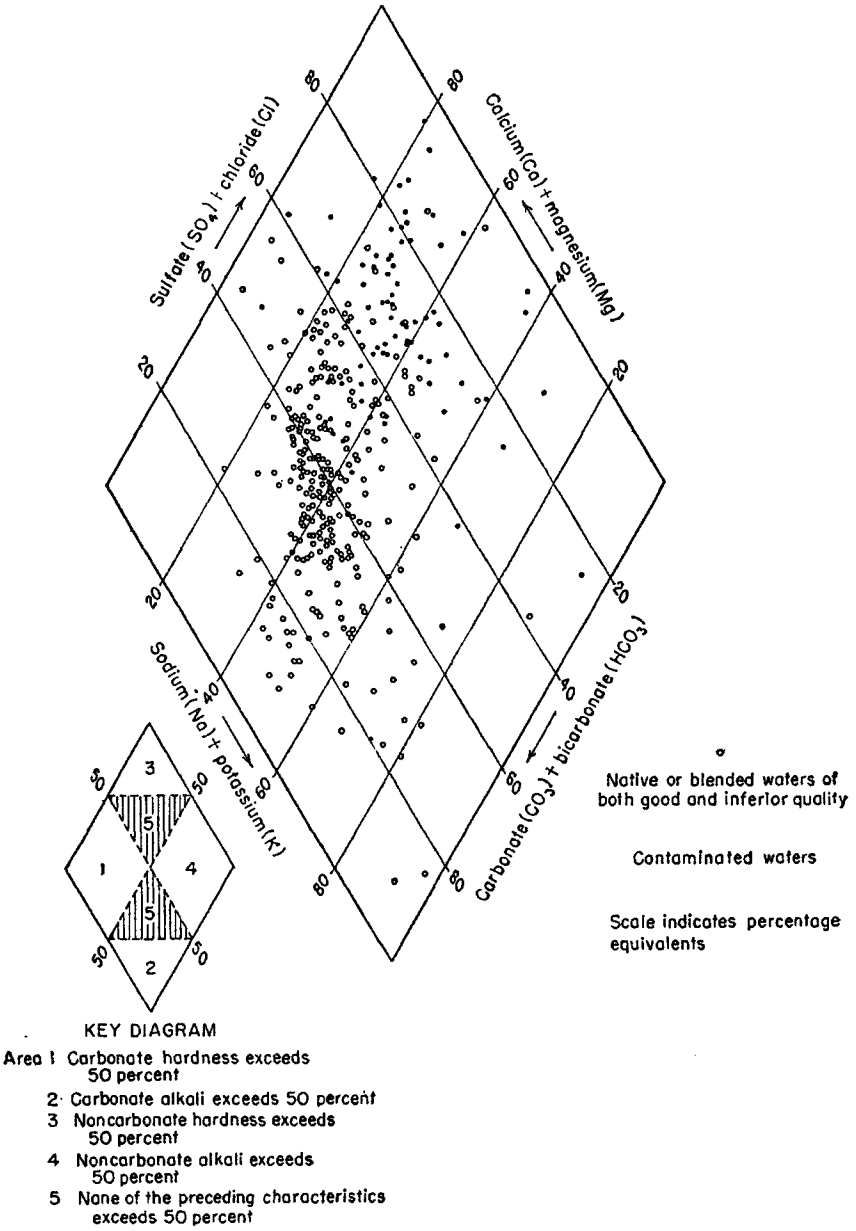
Beginning late in 1943 as a part of the field canvass, the Geological Survey sampled 427 water wells in the Torrance-Santa Monica area, subsequently 73 of these were resampled. About 46 wells in critical areas were sampled periodically to determine if any change in salinity was occurring. In addition, a number of wells were sampled repeatedly while pumping. In all, the Geological Survey made 667 field analyses, comprising determinations of electrical conductivity, soap hardness, and chloride. These analyses are presented in table 29. Also, the Geological Survey has made 12 preliminary analyses in which electrical conductivity, soap hardness, calcium, bicarbonate, sulfate, chloride, borate, and iodide were determined; and 21 comprehensive analyses were made. These 33 analyses are included in table 30.

Plate 17 shows the location of wells for which chemical analyses are available from all sources, and indicates by symbol the type of analysis made. This plate also shows the water-quality data of Mendenhall by means of contours which indicate the approximate content of dissolved solids in parts per million. Necessarily, some generalization has been made; however, these contours suggest the approximate quality of the ground water under native conditions. During the survey by Mendenhall the approximate dissolved-solids content of the samples from about 7,500 wells—of which about 2,500 were within the Torrance-Santa Monica area—was computed from determinations of their electrical conductances, corrected to 60°F. The relationship between electrical conductivity and the approximate dissolved-solids content of natural waters within the coastal plain in Los Angeles and Orange Counties has been set forth in a recent report (Piper, Garrett, and others, 1953, p. 10, 11, and pl. 3). This relationship is a simple one and in many cases obviates the need for a gravimetric determination of dissolved solids.

CHARACTER AND DISTRIBUTION OF NATIVE WATERS IN THE DEPOSITS COMMONLY PENETRATED BY WATER WELLS

RANGE IN CHEMICAL CHARACTER OF WATER FROM WELLS

Native waters tapped by wells in the Torrance-Santa Monica area vary widely in quality from excellent to markedly inferior. For purposes of this report, water is considered inferior when its dissolved-solids content is more than about 600 ppm (Piper, Garrett, and others, 1953, p. 50). In general, all the confined waters in that part of the area inland from the Newport-Inglewood uplift are of good to excellent quality and are suitable for all domestic and irrigation purposes



and for industrial use with only moderate treatment. These are chiefly calcium-bicarbonate waters; their chloride content ranges from 20 to 30 ppm and their hardness from 150 to 225 ppm. In this report, terms describing the general chemical character of a water are used in particular senses, as in the following examples: (1) Calcium bicarbonate designates a water in which calcium amounts to 50 percent or more of the bases and bicarbonate to 50 percent or more of the acids, in chemical equivalents; (2) sodium calcium bicarbonate designates a water in which sodium and calcium are first and second, respectively, in order of abundance among the bases but neither amounts to 50 percent of all the bases; and (3) sodium sulfate bicarbonate designates a water in which sulfate and bicarbonate are first and second in order of abundance among the acids, as above.

Coastward from the Newport-Inglewood uplift within the west basin, native waters of good quality range in character from calcium to sodium bicarbonate. Except locally, the chloride in confined waters here ranges about from 30 to 200 ppm, but those containing more than about 100 ppm are considered inferior because their dissolved-solids content is usually in excess of 600 ppm. Locally, the chloride content of certain presumed native confined waters is as high as 400 ppm, although it is possible that some of these have been contaminated in recent years.

Unconfined waters on both sides of the Newport-Inglewood uplift are generally inferior but are poorest in quality on the coastal side. The chloride in these waters is as great as 2,200 ppm and dissolved solids as much as 4,000 ppm.

To show the overall range in chemical character of waters in the Torrance-Santa Monica area, chemical analyses of 375 samples from 338 wells have been plotted on figure 9. This method of plotting well waters has been used earlier to show the chemical character of water from wells in the Long Beach-Santa Ana area. The plotted positions of the analyses on the graph are dependent upon the predominating chemical constituents in the water. Hence, water types can be recognized at once by inspection of the graph. Additional explanation is given on figure 9. This plate presents almost all of the analytical data available to the Geological Survey in graphic form. Included on the graph are analyses of (1) native waters of good quality, (2) native waters of poor quality, (3) native blended waters, and (4) contaminated waters—those native waters that have been modified by the addition of inferior waters from sources exterior to the initial native water body.

The native waters of diverse character can be divided in a general way into several types; each type is more or less characteristic of a

Area 1 Carbonate hardness exceeds 50 percent
2 Carbonate alkali exceeds 50 percent
3 Noncarbonate hardness exceeds 50 percent
4 Noncarbonate alkali exceeds 50 percent
5 None of the preceding characteristics exceeds 50 percent

FIGURE 9.—Chemical character of 375 water samples from 338 wells in the Torrance-Santa Monica area, 1929–46.

stratigraphic range. The zones of water quality associated with certain stratigraphic ranges are discussed later in this section.

ZONES OF WATER QUALITY

In the Long Beach-Santa Ana area, eight distinct vertical ranges of water quality have been discriminated within the deposits tapped by water wells (Piper, Garrett, and others, 1953, p. 17–18). Each of these except the uppermost—that occupied by the body of unconfined water—coincides roughly with a particular stratigraphic zone. In general, the waters of the several ranges as delineated differ from each other in chemical character. The difference in character is striking between certain ranges and between others it is minor. Similarly, in the Torrance-Santa Monica area each zone of water quality coincides in a general way with a particular stratigraphic range. As in the Long Beach-Santa Ana area, differences in character between adjacent ranges may be small, and water of uniform character does not necessarily exist throughout the lateral extent of any one range. However, although the full stratigraphic sequence of the Long Beach-Santa Ana area prevails in the Torrance-Santa Monica area, only six ranges of water quality have been discriminated. Certain of these ranges span stratigraphic intervals identical with those of their counterparts in the Long Beach-Santa Ana area to the east; others span a more inclusive stratigraphic interval.

In both the Long Beach-Santa Ana and the Torrance-Santa Monica areas the uppermost range is that occupied by the semiperched and essentially unconfined water body in the upper part of the alluvial deposits of Recent age in Dominguez and Ballona Gaps and in the topmost part of the upper Pleistocene deposits beneath the Torrance plain. Commonly, the semiperched water body in both the Recent and Pleistocene deposits is separated from the underlying principal water body by a few tens of feet of relatively impermeable layers of silt and clay.

The five ranges in the principal confined ground-water body in the Torrance-Santa Monica area have been assigned numbers identical to those used for comparable ranges in the Long Beach-Santa Ana area In downward succession, these five ranges are as follows:

Range 1.—The lower division of the Recent deposits, which includes the Gaspur water-bearing zone of Dominguez Gap and the "50-foot gravel" of Ballona Gap. In Dominguez Gap the Gaspur water-bearing zone is 40 to 60 feet thick and its base is about 120 feet below land surface. In Ballona Gap, the base of the "50-foot gravel" is about 50 feet below land surface, and its thickness ranges from 10 to 40 feet. Locally the "50-foot gravel" is in hydraulic continuity with underlying permeable Pleistocene deposits. The extent of the

Gaspur water-bearing zone and the "50-foot gravel" is shown on plate 18.

Range 2.—The Long Beach-Santa Ana area, the uppermost Pleistocene deposits beneath the Downey plain, is not differentiated from range 3 in the Torrance-Santa Monica area.

Range 3.—The unnamed upper Pleistocene deposits, including the "200-foot sand" and strata correlative with or in hydraulic continuity with those deposits, ranges in thickness from a feather edge at the Baldwin and Palos Verdes Hills to as much as 300 feet along the synclinal trough within the west basin. The base of this range commonly is from 200 to 300 feet below land surface in the west basin.

Range 4.—In the Long Beach-Santa Ana area—the uppermost part of the San Pedro formation beneath the Downey plain—is not differentiated in the Torrance-Santa Monica area.

Range 5.—The upper part of the San Pedro formation, including the "400-foot gravel" of the area between Gardena and Inglewood, but excluding the Silverado water-bearing zone. In general, this is the stratigraphic equivalent of range 5 of the Long Beach-Santa Ana area. In the west basin, this range is thickest in the synclinal trough (as much as 200 feet); along the crest of the Newport-Inglewood uplift, although this range is present, it is substantially thinner. Along much of the coast from Redondo Beach to Santa Monica the range decreases in thickness to a feather edge or is entirely absent. Along the synclinal trough the base of this range is about 300 feet below land surface in Inglewood, about 400 feet below at Gardena, and as much as 700 feet below in Dominguez Gap, near the intersection of Alameda Boulevard and Carson Street. In Ballona Gap, just inland from the Newport-Inglewood uplift—specifically, in 1/14–32M and 2/14–5D—the San Pedro formation has been divided tentatively into an upper, a middle, and a lower part (fig. 14). However, the separation is intended primarily for local subdivision of the formation on the basis of water-bearing zones and is derived chiefly from examination of logs of wells at the Sentney plant of the Southern California Water Co. Although the upper part of the San Pedro formation here may not be correlative with any part of range 5, as here defined, it has been found most feasible to include the waters yielded from this upper part of the San Pedro formation in that range.

Range 6.—The middle and lower parts of the San Pedro formation, including the Silverado water-bearing zone of the Torrance-Inglewood subarea and the main water-bearing zone in Ballona Gap coastward from the Newport-Inglewood uplift—the essential correlative of the

Silverado zone. Within the west basin the thickness of this range is as much as 600 feet between Wilmington and Redondo Beach, but northward from Gardena the thickness commonly does not exceed 200 feet and in Inglewood it is as little as 50 feet. The depth of its base is shown by the contours of plate 2. In Ballona Gap, just inland from the Newport-Inglewood uplift, the aggregate thickness of the middle and lower parts is probably about 230 feet, and the top of the middle part is about 290 feet below land surface. In the Long Beach-Santa Ana area, range 6 included the lower part of the Silverado water-bearing zone; there the upper part was included in range 5. However, range 6 includes the full vertical extent of the Silverado zone. In other respects, range 6 of the two areas is essentially common.

Range 7.—The upper division of the Pico formation underlies nearly all the west basin. This range contains the deepest fresh waters known to occur in the area, although its waters are brackish locally north of Ballona Gap. Its vertical range has been described on pages 57–59. The depth of its base, where known, is shown on plate 8.

On following pages the waters contained in the six ranges of the Torrance-Santa Monica area are described in detail; on plates 18 and 19 are plotted the wells from which native waters have been selected that are considered representative of the respective ranges tapped. For each of the waters so selected, the dissolved solids content and a "binomial symbol" are shown on the plates 18 and 19. The binomial symbol is written in the form of a decimal fraction. The first term denotes the percentage of hardness-causing constituents among the bases—that is, of calcium and magnesium; the second term denotes the percentage of bicarbonate—and carbonate calculated to bicarbonate—among the acids. For example, the symbol 60.75 would indicate a water in which the calcium and magnesium amount to 60 percent of all the bases, in terms of chemical equivalents, and in which bicarbonate (including carbonate, if present) amounts to 75 percent of all the acids.

The complement of this binomial symbol indicates the percentage amounts of non-hardness-causing constituents or "alkalis" among the bases, and of noncarbonate acids. In the example here given, the complement is 40.25, which indicates 40 percent sodium and potassium [the "percent sodium" of Scofield (1933, p. 22–23)] and 25 percent sulfate and chloride, in chemical equivalents.

The analyses selected as representative for native waters are listed on table 16 and are grouped according to their respective ranges.

TABLE 16.—*Analyses of representative native ground waters*

CHEMICAL CHARACTER OF THE WATERS

UNCONFINED WATERS

In general, the native unconfined waters in the Torrance-Santa Monica area are of poor quality. Only locally are they used for domestic or irrigation purposes. Commonly, the high salinity of the water and the low permeability of the shallow deposits discourage extensive development.

The unconfined waters in Dominguez Gap generally range from 175 to 2,200 ppm in chloride content and from 1,000 to 12,900 ppm in dissolved solids; they are chiefly sodium sulfate to sodium sulfate, chloride waters. Typically, the bicarbonate content is high, ranging from 250 to 1,100 ppm. It is likely that these unconfined waters have been concentrated by evaporation and, locally, by addition of saline waters at land surface, and thus they do not represent native waters. Therefore, no conclusion can be set forth here in regard to the chemical character of these waters under purely native conditions. Probably, however, their chloride content was usually more than 100 ppm.

Near Gardena, about in secs. 24 to 27, T. 3 S., R. 14 W., and in secs. 29 and 30, T. 3 S., R. 13 W. (pl. 16), many domestic wells tapped the unconfined water body in 1903, as shown by the well canvass of that time. As of 1946, the body is tapped by about 100 active wells. The salinity of these unconfined waters is low enough at least locally, to be used for domestic purposes and for irrigation. Their chloride content ranges from 50 to 2,200 ppm but commonly it is from 300 to 500 ppm. An analysis of water from well 3/14–26G2 (table 30) indicates a sodium, calcium chloride water. No other complete analyses of the unconfined water in this area have been made, so far as known, but it is inferred that the proportion of sulfate and bicarbonate in these waters is somewhat lower than in Ballona Gap. On the basis of determinations of electrical conductivity, the dissolved solids are estimated to range from 1,000 to 4,000 ppm.

In Ballona Gap, as of 1903, many domestic and stock wells 10 to 30 feet deep tapped the shallow water body. At that time the dissolved solids in these unconfined waters ranged from 750 to more than 2,000 ppm, but chiefly were about 1,000 ppm; all estimates were based on determinations of electrical conductivity. Locally, however, the dissolved solids of these waters ranged from 1,500 to 2,300 ppm. Presumably, the water quality as determined in 1903 was essentially native. Because of the gradual drawdown of the water levels in Ballona Gap during the twenties and early thirties, many of these shallow wells went dry. Others were abandoned as a result of deterioration in the quality of the water. By the middle thirties none of these early shallow wells were in use. About all that is known concerning the quality of the unconfined water body in recent years has been obtained from 19 shallow wells bored by the Los Angeles County Flood Control District since 1936; almost all these wells were located in the reach between Lincoln and Centinela Boulevards. That agency has made complete analyses of water from two of these wells and partial analyses from five others. The two complete analyses (2/15–23Q1 and 23Q2, table 30) indicate that locally in sec. 23 the shallow unconfined waters are sodium sulfate to sodium, calcium sulfate waters. The partial analyses, which span a more extensive reach, show a chloride content ranging from 170 to 300 ppm. On the other hand, samples taken in 1943–45 from well 2/15–23M2, adjacent to the Ballona Creek channel and 13 feet deep, ranged in chloride content from 2,600 to 11,580 ppm. The channel here is within the reach of tidal water; doubtlessly, this accounts for the very high salinity of water from that well.

The chemical data for the unconfined water in Ballona Gap are so incomplete that its regional chemical character is not known, either under native conditions or in recent years. The complete analyses

from wells 2/15–23Q1 and Q2 (table 30) are probably not of native waters but instead, they concern waters concentrated by evaporation, by the possible addition of saline waters at land surface, or by infiltration of ocean water. However, from knowledge of the native quality of the unconfined body in other areas, it is reasonable to expect that even under native conditions the sulfate content was somewhat high.

Inland from the Newport-Inglewood zone, but proximate to it, little is known in regard to the character of the shallow waters because of the dearth of chemical analyses. One well, 3/13–27B1, in 1932 yielded a sodium, calcium bicarbonate, chloride water. The chloride and dissolved-solids contents of this water were 181 and 954 ppm, respectively. The well is 8 feet deep and taps Recent deposits. The chemical character of the unconfined waters beneath the Downey plain has been discussed in an earlier report (Piper, Garrett, and others, 1953, p. 21, 26, 51).

CONFINED WATERS

WATERS IN RANGE I (GASPUR WATER-BEARING ZONE AND "50-FOOT GRAVEL")

The Gaspur water-bearing zone extends from the coast through Dominguez Gap and inland to Whittier Narrows. Only the coastal 8-mile segment is within the Torrance-Santa Monica area, however (pl. 18). Inland from the Newport-Inglewood uplift the native waters of the Gaspur zone contain about 250 to 350 ppm of dissolved solids and about 175 to 225 ppm of hardness. All are calcium bicarbonate waters. Across the Newport-Inglewood belt and within the west basin, the native waters gain in dissolved solids about 25 to 40 percent, so that concentrations are as much as 450 ppm, largely owing to an increase in sulfate, chloride, sodium, and calcium. This increase may be due to contributions of water from the westerly "arm" of the Gaspur zone. However, at the present time much of the Gaspur zone throughout its extent in the west basin is either incipiently or definitely contaminated either from local sources or from the ocean to the extent that the native character of the water is completely obscured (pl. 16).

The "50-foot gravel" in Ballona Gap contained water ranging from 650 to 750 ppm of dissolved solids in 1903–4; this estimate is based upon determinations of electrical conductance. Locally, however, the dissolved-solids content was at least 850 ppm. Fragmentary data available suggest that ocean-water intrusion had not then occurred. In general, the water in the "50-foot gravel" initially was of substantially better quality than the unconfined water in the overlying shallow deposits.

Comprehensive analyses are not available to show the chemical character of native waters in the Gap—contamination of the "50-foot gravel" had started before extensive sampling of well waters was begun. The available analyses indicate that the dissolved solids have increased to about 1,000 to 1,500 ppm in recent years.

Inland from the Inglewood fault, well 2/14–5D9 (Southern California Water Co., Sentney plant, well 9) taps the full thickness of the "50-foot gravel." That well in 1940 yielded calcium, sodium bicarbonate water containing 747 ppm of dissolved solids. In 1945 it yielded a calcium sulfate, bicarbonate water whose dissolved solids had increased to 958 ppm.

Inland from Ballona Gap, well 2/14–1M1, 80 feet deep, yielded water in 1935 containing 27 ppm of chloride, showing that at least locally the water from the "50-foot gravel" was then as low in chloride as that from deeper aquifers.

WATERS IN RANGE 3 (UNNAMED UPPER PLEISTOCENE DEPOSITS)

Within the west basin the chemical character of waters in the unnamed upper Pleistocene deposits is known almost wholly from analyses of waters from wells tapping the "200-foot sand" or correlative extensions in the Torrance-Inglewood subarea (pl. 18). Beneath the central part of the Torrance plain south of Rosecrans Avenue, under native conditions the "200-foot sand" yielded water in which the dissolved solids ranged about from 300 to 500 ppm and which was of the calcium, sodium bicarbonate type. Analyses made since 1929 (particularly chloride determinations by the Geological Survey for 1944–45) show that the chloride content of these native waters ranges about from 50 to 90 ppm. The upper limit here placed on their chloride content may be too low; water from two wells (3/14–22R2 and 26Q3) in 1943 contained 155 and 121 ppm of chloride, respectively (table 29), and dissolved solids were less than 600 ppm, according to determinations of electrical conductivity. However, data showing these to be native waters are lacking, and the chloride content may have been increased by local contamination. On the other hand, in sec. 26, T. 3 S., R. 14 W., the chloride content of waters taken in 1944–45 from wells tapping the unnamed upper Pleistocene deposits is as low as 22 ppm (table 29, wells 3/14–25N3, 26P1, and 26Q5).

North of Rosecrans Avenue, and especially in the area between Hawthorne and Inglewood, the unnamed upper Pleistocene deposits contain water in which the dissolved solids range about from 500 to 700 ppm and the chloride from 125 to at least 250 ppm. Analyses are not available to define the character of these waters closely, chiefly because wells tapping the unnamed deposits for which an-

alyses are available also tap the underlying San Pedro formation. However, these waters are of native inferior character.

Southeast of Gardena, in sec. 31, T. 3 S., R. 13 W., the unnamed upper Pleistocene deposits now (1948) contain water which probably is contaminated locally. Under native conditions these deposits yielded water ranging in dissolved solids from 400 to 500 ppm (pl. 17). Analyses of water samples collected periodically by the Geological Survey in 1941–42 from wells in sec. 31 suggest that confined water in these unnamed upper Pleistocene deposits may contain somewhat more than 500 ppm of dissolved solids locally; also, they suggest an increase in salinity during that period in certain wells tapping these deposits (Piper, Garrett, and others, 1953, p. 264).

To the south, about in sec. 19, T. 4 S., R. 13 W., the unnamed upper Pleistocene deposits yield water in which the chloride content (based on water samples from 2 wells, each 180 feet deep) is about 25 ppm and the dissolved solids content is about 300 ppm. Here the water from that depth is of excellent quality and is considered free of contamination. However, water from wells not more than 100 feet deep—inferred to tap the upper part of the unnamed deposits—is of poorer quality. In 1941–42 that water ranged from 62 to 409 ppm in chloride content and from 350 to 1,050 ppm in dissolved solids. Waters of both poor and good quality in sec. 19 are believed to be native, however.

WATERS IN RANGE 5 (UPPER PART OF THE SAN PEDRO FORMATION)

In the west basin, the character of waters from range 5 (the upper part of the San Pedro formation) is known only from data of wells tapping the "400-foot gravel" in the synclinal trough beneath the Torrance plain. Analyses are available for four wells in T. 3 S., R. 14 W., and for one well in T. 2 S., R. 14 W., all of which tap only the "400-foot gravel." Of these five analyses, three are for waters considered representative for the "400-foot gravel." These are 3/14–10C1, analysis of August 21, 1945; 3/14–15G1, analysis of 1940; and 3/14–23L1, analysis of December 5, 1940 (table 30 and pl. 19). In these analyses the dissolved solids range from 323 to 359 ppm; from north to south, the ratio of calcium to other bases increases somewhat, with a corresponding decrease in the ratio of bicarbonate to other acid radicals. Also from north to south, chloride decreases from 38 to 28 ppm, and sulfate increases from 42 to 69 ppm. The content of 69 ppm of sulfate at well 23L1—the southernmost of the three—marks that water as being different from the water in the underlying Silverado water-bearing zone, which here contains less than 34 ppm of sulfate. The other two analyses do not conform to the regional character as described. For example, well 3/14–15D1 yields a water

definitely poorer in quality than the type water. In 1930 this well yielded a calcium, sodium chloride water in which the dissolved solids and chloride content were 576 and 198 ppm, respectively. This water has about the same amount of dissolved solids as that known to occur in the overlying unnamed upper Pleistocene deposits west of Hawthorne. Thus, analysis 3/14–15D1 probably represents a blend of waters from the "400-foot gravel" and from the unnamed deposits above.

In Ballona Gap, east of the Inglewood fault, the upper part of the San Pedro formation is tapped by several wells at the Sentney plant of the Southern California Water Co. (wells 2/14–5D5, 5D7, and 5D10); also by several public-supply wells of the city of Beverly Hills (wells 32M3 and 32K1). Chemical analyses are available for these wells. As shown on figure 14 and as discussed on pages 210–212, the character of these waters has varied between wide limits; however, as there explained, this fluctuation presumably does not represent a trend toward contamination but probably results from the blending with inferior native waters that existed in sec. 32. The waters were initially sodium bicarbonate waters; later analyses show a slight trend toward sodium, calcium bicarbonate waters. Chloride ranges generally from 62 to 173 ppm.

WATERS IN RANGE 6 (MIDDLE AND LOWER PARTS OF THE SAN PEDRO FORMATION)

Throughout its known extent in the west basin, except near the coast and locally elsewhere, the Silverado water-bearing zone of the middle and lower parts of the San Pedro formation yields native waters of excellent quality (pl. 19). These range from sodium, calcium bicarbonate to sodium bicarbonate waters.

In the southeastern part of the west basin, in and near Dominguez Gap, wells tapping the Silverado water-bearing zone yield sodium bicarbonate water, in which the dissolved solids range from 210 to 250 ppm, the hardness generally ranges from 70 to 85 ppm, and the chloride content is about 25 ppm. From east to west across Dominguez Gap, the sulfate seems to diminish; at well 4/13–14Q4 the sulfate content is about 35 ppm, and at well 21Q1 it is negligible. In Dominguez Gap most of the waters selected as representative of the Silverado water-bearing zone, as shown on plate 19, are from the upper or central parts of the zone. These waters are similar in hardness content to waters from wells tapping the upper part of the Silverado zone northeast of the Signal Hill uplift, where they range in hardness about from 66 to 91 ppm; those from the lower part of the Silverado zone range in hardness about from 15 to 28 ppm.

Along the northeast flank of Palos Verdes Hills in T. 4 S., R. 14 W., and in the southwest corner of T. 4 S., R. 13 W., the

Silverado water-bearing zone contains waters markedly different from those in the same zone beneath Dominguez Gap.

These markedly different waters are essentially sodium bicarbonate waters in which the bicarbonate is as high as 389 ppm; they differ from typical Silverado waters to the north and to the northeast in that (1) their sodium content is somewhat in excess of 100 ppm and (2) their chloride content commonly ranges from 50 to 75 ppm higher than that of the typical Silverado waters. The chloride is as high as 129 ppm (4/14–35E2) and sulfate commonly is less than 3 ppm. The high chloride content of these waters doubtless is due to blending with connate sodium chloride water occurring locally in the Silverado water-bearing zone beneath the flank of the Palos Verdes Hills (Piper, Garrett, and others, 1953, p. 57–58, and p. 230 analyses for well 5/13–6D1). This connate water is considered native, but since its inclusion with marine sediments it has been modified by the usual processes of base exchange and sulfate reduction, and, in addition, it has been diluted by land-derived waters. Analyses of water from well 5/13–6D1 are typical of this diluted connate water; the chloride and dissolved solids content are about 450 and 1,200 ppm, respectively. To the north, the effect of blending with this connate water does not extend more than about half a mile; wells 4/13–30K1 and 4/14–16L3, each about three-quarters of a mile northeast of the Palos Verdes Hills, yield water containing only 24 ppm of chloride. To the east, water from wells 4/13–31E3 and E4 shows the effect of blending with the connate water, although such blending has not been particularly deleterious; the chloride content of water from both wells in 1932 was less than 70 ppm. To the southeast, the extent of the connate water is not known, but evidence from electric logs of oil wells suggests that it may underlie the eastern part of Terminal Island.

In the west basin northwest of Dominguez Gap and extending about to Inglewood—that is, through the known extent of the Silverado water-bearing zone—the waters are consistently harder and higher in proportion of calcium and magnesium among the bases than those from this zone in Dominguez Gap. For example, the hardness ranges about from 100 to 275 ppm; north of Rosecrans Avenue, it is commonly more than 200 ppm. In these sodium, calcium bicarbonate waters the dissolved solids range about from 250 to 500 ppm but commonly are about 300 to 350 ppm. Across this central part of the west basin, from northeast to southwest—that is, from the crest of the Newport-Inglewood uplift to the coast—certain trends in chemical character are suggested by available data. These trends are as follows:

1. Near, but coastward, from the crest of the Newport-Inglewood uplift, the sulfate in the Silverado waters is at least 30 ppm. Westward, the sulfate di-

minishes rapidly and becomes low or negligible at the axis of the syncline; in general, it remains small or negligible to the coast.

2. Near, but coastward from the crest of the Newport-Inglewood uplift, the chloride content of the Silverado waters is probably not more than 36 ppm. This chloride content is reasonably constant to within about 2 miles of the coast; under native conditions it increased to about 90 ppm at the coast.

Adjacent to the coast, from the Ballona escarpment to and beyond Redondo Beach, native water no longer occurs in the Silverado water-bearing zone; as of 1946 this coastal strip was moderately to intensely contaminated. The chemical features of this contamination, and minor lateral differences in native waters found here initially will be discussed later.

Inland for 2 miles or more from the crest of the Newport-Inglewood uplift, from Dominguez Hill on the south to near Inglewood on the north, wells tapping the Silverado water-bearing zone yield water characteristically different from that in the central part of the west basin. As shown by analyses of water from wells 3/13–6G1, 3/13–8L2, and 3/14–1G1 (table 30), these are predominantly calcium bicarbonate waters; they differ chiefly in chloride and sulfate content from those waters coastward from the Newport-Inglewood uplift. In these waters, chloride is about 26 ppm and sulfate about 75 ppm.

Beyond the known extent of the Silverado zone (pl. 19), waters of excellent quality occur in the middle and lower parts of the San Pedro formation correlative with it. Analyses of water from well 2/14–22P1 at Inglewood, from wells 2/14–4N1 and 5D6, north of the Baldwin Hills, and from well 2/14–14C2, east of the Baldwin Hills, are representative. These wells contain calcium bicarbonate to sodium bicarbonate waters; their range in constituents and character may be determined from table 30, plate 19, and from table 16.

In sec. 5, T. 2 S., R. 14 W., available analyses indicate that water in the lower and middle parts of the San Pedro formation is sodium bicarbonate water and possibly is of somewhat better quality than that from the upper part of the formation (fig. 14).

In the Ballona Gap, about from the Inglewood fault to the coast, native waters in the San Pedro formation range from calcium, sodium bicarbonate to calcium bicarbonate waters. They contain about 40 to 70 ppm of chloride (usually about 60 ppm), nearly 100 ppm, and locally more than 200 ppm of sulfate, and about 480 to 650 ppm of dissolved solids. Thus, compared to waters inland from the Inglewood fault, their content of dissolved solids is higher than in the waters in the middle and lower parts of the San Pedro formation to the east. Also, they differ in character from the waters in the San Pedro formation yielded to wells just south of the Ballona escarpment (pl. 19, also p. 215). Native waters from wells 2/15–11J1 and 23P1

460508—59——13

in Ballona Gap were anomalous in character (as compared to the type waters in the gap) but were roughly similar to the waters south of the escarpment; this fact suggests some blending of the two types of water.

As of 1946, in the coastal part of the gap the waters in both the San Pedro formation and the overlying "50-foot gravel" of Recent age were contaminated; the extent and degree of contamination will be discussed later.

In the area just south of the Ballona escarpment, about in secs. 26 and 34, T. 2 S., R. 15 W., analytical data suggest that the waters under native conditions generally ranged from 80 to 100 ppm of chloride, from 30 to 50 ppm of sulfate (but usually less than 40 ppm) and from 500 to 600 ppm of dissolved solids. They were sodium bicarbonate to sodium, calcium bicarbonate waters and are represented by analyses of water from wells 2/15–26B1, 34A1, 34H1, and 34K1 (table 30: well 26B1, Mar. 29, 1932; well 34A1, Nov. 18, 1929; well 34H1, Jan. 8, 1930). Their chemical character is shown by figure 11, which compares them to representative waters of the San Pedro formation in Ballona Gap. (See also discussion of contamination at Playa del Rey.)

WATERS OF THE UNDIFFERENTIATED PLEISTOCENE DEPOSITS

To the north of Ballona Gap, and particularly beyond the north limit of T. 2 S., water-bearing zones are so discontinuous that a regional stratigraphic correlation has not been made (p. 45). Here, as may be expected, the waters from these several zones range considerably in quality and show striking local differences in character. Nevertheless, the over-all range in character is not markedly greater than that of the waters in the San Pedro formation immediately to the south in Ballona Gap. This also is to be expected because of the presumed hydraulic continuity with those deposits. Analyses of waters from wells 1/14–19R1, 1/14–20M1, 1/15–28B2, and 32A1 are believed to illustrate the range in chemical character of these waters (table 30 and pl. 19).

Typical of water from wells tapping the undifferentiated Pleistocene deposits is a nonsystematic fluctuation of dissolved solids, particularly chloride, in recurrent analyses for any given well over a period of several years. The chloride content in these waters ranges from 40 to 268 ppm and the sulfate content ranges about from 5 to 212 ppm. They range from calcium bicarbonate to sodium bicarbonate waters. Definite evidence of local contamination in these deposits cannot be proved because of the great range in proportion of individual constituents and because of the great range of dissolved solids as a whole. However, definitely inferior waters in these Pleistocene

deposits may be derived through upward movement from the underlying Pliocene rocks.

WATERS IN RANGE 7 (UPPER DIVISION OF PICO FORMATION)

For the Torrance-Santa Monica area, information on the chemical quality of water from the upper division of the Pico formation is obtained from analyses of water from six widely separated wells—1/15–25C1, 2/14–27J1, 2/15–1C5, 3/14–17J1, 4/13–12A2, and 5/13–3H. (See table 30 and pl. 19.) Three of the analyses (3/14–17J1, 4/13–12A2, and 5/13–3H) are from wells in or near the Torrance-Inglewood subarea. In these the dissolved solids range from 452 to 750 ppm, the chloride from 52 to 130 ppm, and the bicarbonate from 413 to 487 ppm. All are sodium bicarbonate waters. For the three the average percent sodium is 83. Thus, these are potable waters, although they are not desirable for irrigation because of their high percent sodium. In well 4/13–12A2 (city of Long Beach, North Long Beach well 6) the water was dark brown and the temperature was about 104°F. Although color and temperature could have been reduced by treatment, the yield of the well was considered too low to make treatment economical and the well was abandoned.

Of the other three analyses, one is from a well in the eastern part of Inglewood (2/14–27J1) and the others are from wells north of Ballona Gap, which are inferred to tap the upper division of the Pico formation or correlative deposits. In these the total solids range from 1,225 to 2,663 ppm, the chloride from 66 to 1,363 ppm, and the bicarbonate from 396 to 1,266 ppm. All these waters are unfit for ordinary uses.

Thus, available analytical data suggest that the waters in the upper division of the Pico formation north of Inglewood are saline and unusable; however, south of Inglewood, locally at least, they are of a quality suitable for some uses, although they may require treatment.

In the descriptions of native waters in the water-bearing zones of the Torrance-Santa Monica area of Recent and Pleistocene age, the silica content of the waters was not discussed because it does not appear to be a distinctive characteristic of any of the several ranges. The silica content of these waters was from 10 to 30 ppm, commonly less than 20 ppm. However, of the analyses of waters from the upper division of the Pico formation, four analyses indicate a considerably higher silica content, ranging from 35 to 59 ppm. Because of this greater concentration in the waters of the upper Pico, silica might be used as a diagnostic constituent in a critical study dealing with blended native waters yielded from wells tapping both the upper division of the Pico formation and the overlying water-bearing zones.

WATERS AT THE CENTINELA PARK WELL FIELD OF THE CITY OF INGLEWOOD

At the Centinela Park well field of the city of Inglewood, wells on opposite sides of the Potrero fault yield water with marked differences in chemical character. Elsewhere along the faults of the uplift, at least south to Dominguez Gap, differences are minor. Hydrologic information shows conclusively that the fault here is a substantial hydraulic barrier. Chemical evidence confirms the existence of that barrier. At this well field, seven wells were sampled in 1944–45 by the Geological Survey. Of the wells so sampled, five were east of (inland from) the Potrero fault and two were west of it. Inland from the fault, the chloride content of the water ranged from 25 to 56 ppm; coastward from the fault but adjacent to it, the chloride content ranged from 121 to 156 ppm. (For type analyses, see wells 2/14–22N3 and 2/14–27D3, table 30.) Inland from the fault, the waters are calcium bicarbonate in character and the dissolved-solids content is about 375 ppm. To the west, across the fault, well 2/14–27D3 also yields calcium bicarbonate water but the dissolved solids content is about 450 ppm. Although not cited here, chemical data from wells about a mile to the southwest, in sec. 28, T. 2 S., R. 14 W., suggest that the increase occurs chiefly in chloride and sulfate, with a proportionate increase in calcium and sodium. Only at well 28E1 (city of Inglewood well 23) is the increase in cations wholly in sodium. However, the character of water from this well probably is anomalous; transverse faulting south of the well may separate it from the others in sec. 28 for which chemical data are available.

At the Centinela field, both the "200-foot sand" and the water-bearing zones in the San Pedro formation are tapped by many of Inglewood's public-supply wells. However, water levels here are now (1948) at or below sea level and the "200-foot sand" is almost wholly dewatered; thus, in recent years the water has been withdrawn almost entirely from the San Pedro formation.

POTENTIAL CONTAMINANTS OF FRESH-WATER BODIES IN THE TORRANCE-SANTA MONICA AREA

Fresh waters in the Torrance-Santa Monica area, which have become contaminated, or which have received an increase in salinity, are a result of a mixture with certain waters, either moderately or excessively high in total solids. These latter waters have their source either outside the fresh-water zones, with migration into those zones after discharge at or near the land surface, or by establishment of favorable gradients through permeable deposits, or both, or inside the fresh-water zones, occupying either a part of a permeable zone stratigraphically equivalent to that containing the fresh water, or a con-

tiguous zone or zones that may be either younger or older than that containing fresh water, but requiring a suitable gradient and hydraulic continuity to advance into the fresh-water zone.

EXTERIOR CONTAMINANTS

Contaminants that initially are outside zones containing fresh water under native conditions and that require hydraulic continuity and a favorable gradient toward those zones in order to mingle with the fresh waters are: (1) ocean water, (2) industrial wastes, and (3) oil-field brines.

OCEAN WATER

As in the Long Beach-Santa Ana area, ocean water is an obvious potential contaminant in the Torrance-Santa Monica area because water-bearing zones, at places along the coast from Santa Monica to the Palos Verdes Hills and beneath San Pedro Bay, crop out on the ocean floor and are inferred to be in hydraulic continuity with the ocean; because certain areas, specifically the coastal parts of Dominguez and Ballona Gaps, have been or are now being overrun by ocean water within the tidal range; and because the water levels near the coast widely have been drawn down below sea level.

In the coastal part of Dominguez Gap, the original tidal flats have been filled in and dikes have been constructed along both the Los Angeles River and Dominguez Channel with the result that inland movement of tidal water is restricted to those water courses; in the Los Angeles River, the extreme inland reach of oceanic water during the highest tides is 0.95 mile or to a point about a quarter of a mile south of Anaheim Street. To the northwest in Ballona Gap, tidal marshes extend inland nearly to Lincoln Boulevard. In the old channel of Ballona Creek, the tidal range was about the same as in the adjacent marsh; in the new channel, completed early in 1938, the inland reach of tidal water is about to Inglewood Boulevard, 1 mile farther inland and about 3 miles from the coast.

To show the chemical character of ocean water, two analyses are given in table 31—a "standard" analysis and an analysis of water from San Pedro Bay. For these representative analyses, ocean water generally ranges from 34,100 to 34,500 ppm in solids, and from 18,400 to 19,000 ppm in chloride. Magnesium is about three times as abundant as calcium; however, in native ground waters, calcium is the more abundant. In ocean water, the bicarbonate content is about 140 ppm; in native ground waters, bicarbonate may be as great as 400 to 500 ppm, but normally it is about 250 to 300 ppm.

INDUSTRIAL WASTES

Wastes discharged as a result of industrial activity become potential contaminants of fresh-water zones in the Torrance-Santa Monica area when (1) they are discharged into natural or artificial water courses that traverse that area, or (2) they are discharged at land surface in sumps and pits and are allowed to evaporate and seep away.

Four water courses traverse the Torrance-Santa Monica area. These are the Los Angeles River, Dominguez Channel, and Compton Creek, which are all in and near the Dominguez Gap, and Ballona Creek, in the Ballona Gap. The conditions of industrial-waste disposal in Dominguez Gap have been discussed at length in an earlier report (Piper, Garrett, and others, 1953, p. 80–83). Wastes discharged to the Los Angeles River inland from Dominguez Gap commonly are sodium chloride or sodium sulfate waters and in most cases are considerably less concentrated than oil-field brines. However, the analyses here cited suggest that in recent years, disposal of wastes into the Los Angeles River inland from Dominguez Gap has been carried on to a lesser degree than formerly.

Within the west basin, the chief point of disposal of waste to the Los Angeles River (in 1946) is just upstream from Wardlow Road. Here are the skimming sumps of the Oil Operators, Inc. From these sumps, oil-field brines have been discharged to the Los Angeles River at a rate that averaged 4.4 cfs from 1928 through 1943. These brines have ranged in chloride content from 9,000 to 16,000 ppm since 1932 and at times of low natural runoff the brines have made up the total flow of the river.

The Dominguez Channel is used for disposal of oil-field brines from the Dominguez and Rosecrans fields and of saline wastes from the several oil refineries in the industrial area west of Long Beach. As shown by analyses of water taken from Dominguez Channel by the Geological Survey in 1942–43, the water of the channel has ranged at least from 145 to 10,000 ppm of chloride throughout its reach southeast of Main Street to Wilmington Avenue. For at least a part of the time, the volume of wastes carried by the Dominguez Channel has been as much or more than that carried by the Los Angeles River.

Inland from the west basin, Compton Creek discharges to the Los Angeles River about 5.5 miles from the coast and 0.3 mile inland from the Cherry-Hill fault. In 1942–43 from analyses by the Geological Survey, the chloride content in the lower reach of Compton Creek ranged from 62 to 132 ppm. Although the indicated concentration is low, the creek carries organic material which makes the water very turbid and foul-smelling. For approximately the same period through which the water samples were taken, the mean flow in the creek was about 10 cfs; the minimum flow was 3 cfs.

Available chemical analyses for Ballona Creek suggest that, at least at times, the creek has received contributions of water of marked salinity. For instance, the highest chloride sample reported (4,354 ppm) was obtained in 1932 from a spring discharging from the northwest bank of Ballona Creek, 700 feet upstream from Higuera Street (in 2/14–5M). A comprehensive analysis was not made, hence the chemical nature of the saline water is not known. Most of the samples collected from the creek have contained only a few hundred parts of chloride. The lowest concentration known was for a sample taken from the creek February 11, 1936 by Dr. Carl Wilson; this sample had a chloride content of 15 ppm. A series of five analyses, two by Dr. Wilson in 1936 and three by the California Division of Water Resources in 1937–38, indicate that the streamflow then ranged in character from a sodium chloride water to a sodium, calcium bicarbonate water. None of the comprehensive analyses suggest additions of oil-field brines during that period; fluctuations in chloride content are accompanied by a corresponding change in sulfate content. If such chloride fluctuation had resulted from addition of oil-field brine, little or no change in sulfate would have occurred. Koch (1940, p. 18) reports that a sample taken in December 1939 from a small creek flowing into Ballona Creek from the Baldwin Hills (sampling point in 2/14–5N, about 100 feet north of Jefferson Boulevard) contained 2,630 ppm of chloride. This creek, according to the report, carries much of the surface runoff of the Inglewood oil field. However, the extent to which the Ballona Creek has been used as a means of disposal for oil-field brines is purely conjectural in the absence of analyses of creek flow showing such discharge.

From the early thirties to 1938, extensive sections of Ballona Creek were paved with concrete. As of 1938, the channel was paved with an impervious lining from Crenshaw Boulevard for about 4 miles downstream to LaSalle Avenue, which is about 0.75 mile upstream from the Overland Avenue fault (pl. 2). From LaSalle Avenue to the coast, about 5 miles, only the sides of the channel are paved (1946). The tidal reach now extends inland about 3.1 miles, or to Inglewood Boulevard. Thus, since 1938, it has been only in the 2-mile reach from LaSalle Avenue to Inglewood Boulevard that the channel bottom has been open to receive influent seepage from the creek discharge. This 2-mile reach spans the Charnock subbasin and the coastward 0.75-mile segment of the crestal subbasin. It is not known whether substantial seepage losses from the creek occur in this reach, but certainly a potential threat of contamination exists at such times as the creek carries water unfit for use. Coastward from Inglewood Boulevard, seepage contributions, if any, are from the saline tidal waters.

OIL-FIELD BRINES

There are eight major oil fields in the Torrance-Santa Monica area—the Inglewood, Potrero, Rosecrans, and Dominguez fields along the Newport-Inglewood uplift and the Playa del Ray, El Segundo, Torrance, and Wilmington fields along the coast (pl. 18).[14] In addition, there are two minor fields—Lawndale and Beverly Hills—from which production is small. In all these fields most of the connate waters raised to the land surface are separated from the oil by settling or by mechanical or chemical dehydration. Analyses of the connate waters for four of these fields are given in table 31.[15] For the several oil fields, methods of brine disposal are described as completely as possible insofar as such information was made available to the Geological Survey.

Yield of oil-field brines.—The total amounts of brines pumped from the several oil fields in the Torrance-Santa Monica area are substantial. Table 17 shows the quantities of these brines discharged by each oil field for the year 1940, from records published by the California Division of Oil and Gas (1940–41, p. 28, 30).

TABLE 17.—*Quantities of water produced from oil fields in the Torrance-Santa Monica area in 1940*

[Data from publications of the California Division of Oil and Gas]

Oil field	Fluid yield (barrels)	
	Annual	Daily average
Beverly Hills	90, 141	247
Inglewood	3, 705, 140	10, 150
Potrero	337, 368	924
Rosecrans	1, 556, 879	4, 265
Dominguez	3, 291, 324	9, 017
Playa del Rey	3, 833, 257	10, 500
El Segundo	1, 179, 636	3, 232
Lawndale	79, 730	218
Torrance	1, 695, 170	4, 644
Wilmington	759, 856	2, 082

The total withdrawal of brines from these 10 fields in the Torrance-Santa Monica area as of 1940 was about 45,000 barrels a day or about 2,200 acre-feet a year, which is about 3 percent as great as the quantity of ground water pumped from the west basin alone in that same year.

Inglewood field.—The Inglewood oil field covers much of the Baldwin Hills north of Inglewood. The discovery well was completed late in 1924, and 150 productive wells had been drilled by September

[14] Two of the fields, Dominguez and Wilmington, are discussed at length by Piper, Garrett and others (1953, p. 70, 78) but those discussions will be briefed here.

[15] For analyses of connate waters from the Dominguez and Wilmington fields, see Piper and others (1953, table 29).

1925. The field has been developed almost entirely by the Kettleman and Inglewood Corp., Standard Oil Co. of California, Tidewater Associated Oil Co., Shell Oil Co., and the Texas Co. As of 1946, at least two companies, the Tidewater Associated Oil Co. and the Standard Oil Co. of California, ran the brines from their producing wells into settling ponds from which the overflow was piped chiefly to the city of Los Angeles Hyperion outfall sewer, which follows the north flank of Baldwin Hills and the south edge of Ballona Gap to the ocean. A part of the Standard Oil Co. waste water reportedly is discharged (1946) to Ballona Creek about half a mile upstream from Lincoln Boulevard, or well within the tidal reach. As of 1946, the Tidewater Associated Oil Co. discharged about 2,650,000 gallons of waste fluid each month. Although none of the brines from the Inglewood field are known to have been discharged to Ballona Creek above tidewater as of 1946, the analysis of the flow of a small stream from the north slope of Baldwin Hills (sampled in 1939 with a chloride content of 2,630 ppm) suggests that at least a diluted connate water was then discharged at land surface

Potrero field.—The Potrero field, east of Inglewood, was discovered in 1927, and by mid-1941 about 26 wells were in production. It is reported that, in the early thirties, the brines either were diverted into unlined ditches and sumps where they drained to the southwest, or they were hauled to a dump in Centinela Creek within the city of Inglewood until a city ordinance was passed to prohibit such practice. As of 1946 most of the production has been from wells of the Basin Oil Co., and waste brines are discharged to the Los Angeles County Sanitation District sewer system.

Rosecrans field.—This field occupies the west-central part of T. 3 S., R. 13 W., about 2 miles west of Compton. The chief operators in the field are the Union Oil Co. and the Barnsdall Oil Co. The Union Oil Co. carries (1946) the oil with its admixed brine from each well to a central dehydrating system. From there, the brine is pumped to a skimming pond near the intersection of Rosecrans Avenue and Main Street. This pond is used by the several companies operating in the field. The effluent from this pond reportedly is piped to a Los Angeles County sewer line. Of the total quantity so disposed, the Union Oil Co. in 1946 reportedly contributed about 57,000 barrels a month.

Dominguez field.—The Dominguez oil field was discovered in 1923 and has been developed largely by the Shell Oil Co. and the Union Oil Co. Since about 1930, at least a part of the waste fluids from the oil wells in this field have been piped to the plant of the Deepwater Chemical Co. for extraction of iodine. This plant is about 0.1 mile north and 1 mile west of the intersection of Wilmington Avenue and

Victoria Street, on the northwest flank of Dominguez Hill. The effluent from the plant is piped (1946) to an outfall on the Dominguez Channel about 0.4 mile northwest of Avalon Boulevard. When the plant is idle, the brines are piped to the Dominguez Channel through the same line.

Other means of disposal of brines formerly were employed by at least one of the operating companies (Piper, Garrett, and others, 1953, p. 70). In 1932, the Shell Oil Co. reportedly released brines into a ravine high on the southwest flank of Dominguez Hill and into the crater of a blown-out oil well near the crest of Dominguez Hill, just west of Wilmington Avenue and about 0.3 mile south of Victoria Street. It is understood that this practice was discontinued late in 1932. The quantity of brine so discharged at the land surface is not known, but if such disposal had been practiced since 1923, several hundred acre-feet of waste brine could have percolated to permeable deposits formerly saturated with fresh water.

Playa del Rey field.—This field is divided into two areas: (1) The ocean front or Venice area, along the coastal front of Ballona Gap, which was discovered in 1929; and (2) the Del Rey Hills area, almost wholly in sec. 27, T. 2 S., R. 15 W., which was discovered in 1931. In the Venice area, the brines from wells operated by the Union, Ohio, and Barnsdall Oil companies are piped to a plant operated by the Dow Chemical Co. for extraction of iodine. As of 1946, about 460,000 gpd was treated. The effluent from the plant is piped to a canal which is open to tidewater a short distance north of the plant. The brine treated by the plant constitutes almost the total water production of the field, although locally small amounts of brine may be discharged at land surface and allowed to drain away. The area occupied by this field is or has been overrun by tidal water of salinity equal to or greater than that of the connate brines.

In the Del Rey Hills part of the field, the brines are collected from the individual wells and then are piped into the city of Los Angeles Hyperion outfall sewer.

El Segundo field.—The El Segundo field, which is just east of the city of El Segundo, was discovered in August 1935 and was completely developed by late 1938. Waste fluids from wells east and southeast of El Segundo are piped (1946) to a main disposal line that crosses Sepulveda Boulevard at El Segundo Boulevard. Waste fluids from active wells in a minor producing area within the city of El Segundo, south of the city's water-treatment plant at Holly Avenue and Maryland Street, are conveyed to this line through a pipe running south on Center Street. The main disposal line runs west along El Segundo Boulevard, thence to the Standard Oil Co. refinery where, presumably, the brine is discharged to the ocean.

Torrance field.—The Torrance field is about 7.5 miles long; it reaches nearly to the Wilmington field on the east and to within about a mile of the coast on the west. The first productive well was completed in 1922, and peak production was reached in 1924. As of mid-1941, most of the production was from the southeastern part of the field.

From investigation of means of brine disposal in this field, it appears that (1946) many of the smaller companies discharge the brines from their wells to small sumps—usually one for each well—from which the brines evaporate or seep away. For the southeastern part of the field, brines from about 300 acres each of the Superior Oil Co. and of the Standard Oil Co. are piped to a skimming pond, about 1,500 feet east of Normandie Avenue and 0.9 mile south of Sepulveda Boulevard. From the pond, the brines are piped to the Los Angeles County sewer farm, which is between Vermont Avenue and Figueroa Street and about 0.8 mile south of Sepulveda Boulevard. In 1946, about 20,000 gpd of waste fluids were discharged to the sewer farm. Previous to about 1940, the fluids were conveyed from the skimming sump to the sewer farm by an open ditch. A large sump, just southwest of the intersection of Hawthorne Avenue and Torrance Boulevard, is reported to be used for disposal of waste fluids from wells of the Del Amo Estate Co.; from this sump, the fluids reportedly are allowed to evaporate or seep away. Disposal methods of waste fluids from the western part of the field are not known.

Thus, in the Torrance field it is possible that at least several hundred acre-feet of saline brines have passed from the land surface into the ground-water bodies, although only in sec. 9, T. 4 S., R. 14 W., are they inferred to have reached deposits tapped by an active water well.

Wilmington field.—The Wilmington oil field is west of the Los Angeles River and extends inland for a distance of about a mile to 3 miles from the Cerritos Channel and the innermost basins of the Los Angeles harbor. The first well of commercial importance was drilled here late in 1936. By the early forties, more than 900 wells were in production. At least three of the principal operators pipe their brines directly to tidewater (1946). However, many operators reportedly discharge brine into sumps or at land surface. Such disposal is of no serious consequence in the eastern two-thirds of the field, because that area now is underlain at shallow depth by contaminated waters which are no longer used. In the western third of the field, however, water wells not more than 75 feet deep yielded water of fair quality in the early forties; hence, in this western area, these brines are a potential contaminant, not only of the shallow water-bearing zones but also of the underlying Silverado water-bearing zone, by passage from the shallow zones through defective

well casings, or by slow downward movement through intervening deposits that are not wholly impermeable.

INTERIOR CONTAMINANTS

The native interior contaminants in the Torrance-Santa Monica area are chiefly those inferior waters that have been described earlier. These include:

1. Unconfined and semiperched waters in the Dominguez and Ballona Gaps and beneath the Torrance plain. Locally in the gaps these contain as much as several thousand ppm of dissolved solids; their concentration probably has been increased both by contamination and by evaporation. Beneath the Torrance plain the dissolved-solids content of the unconfined waters ranges from 1,000 to 4,000 ppm.
2. Waters in the southernmost reach of the Gaspur water-bearing zone in Dominguez Gap. Here, this water-bearing zone has been extensively invaded by exterior contaminants; it, in turn, can contaminate deeper water-bearing zones now containing water of good quality.
3. Native connate or diluted connate water confined in the San Pedro formation adjacent to or underlying the northeast and east flanks of the Palos Verdes Hills. This is sodium chloride water and locally, at least, contains 1,200 ppm of dissolved solids.

Of the three sources, the first and second are the most critical. Wells tapping underlying aquifers must pass through these two, and where the inferior shallow water has a higher head than the deeper water of good quality, downward circulation will occur if well casings are defective. Both in Dominguez Gap and beneath the Torrance plain, water levels in underlying zones are several tens of feet below levels in the inferior water bodies above.

CONTAMINATION OF THE NATIVE FRESH WATERS

GENERAL EXTENT OF WATER-QUALITY DEPRECIATION

As stated earlier, a few wells near the coast began to yield salty water in the late twenties. Subsequently, many of these wells were abandoned because contamination became so intense that the water could no longer be used. On plate 16 are shown the districts in the Torrance-Santa Monica area in which one or more of the groundwater bodies contained more than about 100 ppm of chloride in 1945–46. In certain of the districts, inferior waters existed under native conditions. In the Ballona and Dominguez Gaps, and along the coast from Playa del Rey to the Palos Verdes Hills, however, the extent of waters containing more than 100 ppm of chloride has resulted largely from saline contamination in the last 20 years, primarily from exterior sources. The inland advance of contamination along the coast since 1931–32 is indicated on plate 16 by the change in the position of the line showing 100 ppm of chloride.

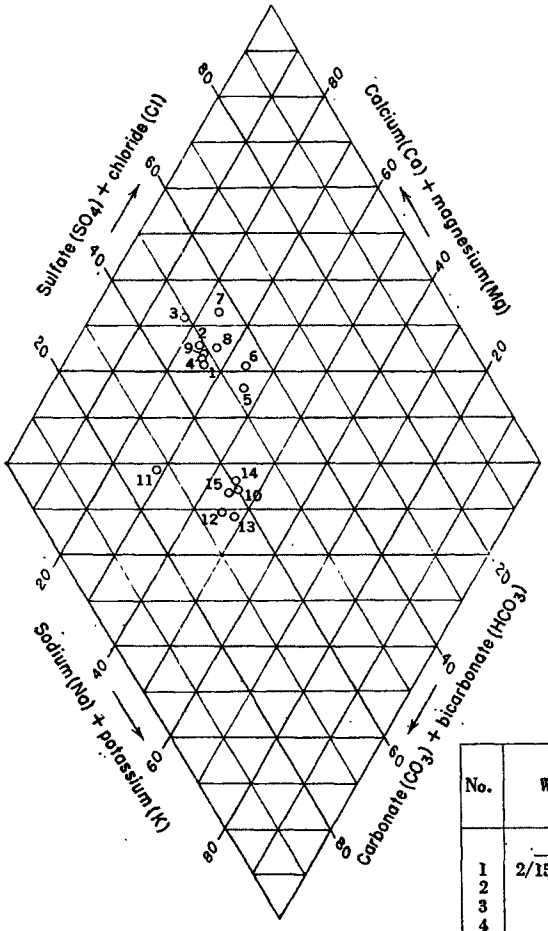
MODIFICATIONS IN CHEMICAL CHARACTER OF CONTAMINATED WATERS

For both the Torrance-Santa Monica area and the Long Beach-Santa Ana area, contaminated waters are, almost without exception, not a simple blend of a native and a saline water. Instead, chemical reactions have occurred either concurrently with, or subsequent to, blending with the contaminant to the extent that the nature of the contaminant is completely or substantially disguised. Most commonly, these reactions involve (1) base exchange and (2) sulfate reduction.

1. For many of the contaminated waters in the Torrance-Santa Monica area, successive analyses of water from a given well during its period of active contamination show a definite increase in calcium along with the customary increase in chloride. Hence, these analyses might erroneously be taken as evidence to show blending with a calcium-chloride contaminant. However, no contaminant has been known to exist in the Torrance-Santa Monica area in which calcium predominates as an alkali radical. Therefore, this calcium enrichment, resulting from blending with a contaminant in most cases known to predominate in sodium among the bases, must be due to a modification in the ratios of calcium, magnesium, and sodium to each other. This modification is known as base exchange.

The fact that the base exchange process goes on extensively has become well-established. It can occur because the zeolite and glauconite minerals and certain clay-forming minerals have the property of holding the bases (calcium, magnesium, sodium, and potassium) loosely and in variable proportions. In the presence of a natural water, with whose chemical composition it is not in equilibrium, any of these particular minerals (and possibly some types of organic matter associated with sedimentary deposits) has the property of releasing to the water a part of the base or bases most loosely held and of absorbing from the water an equivalent amount of the base or bases for which it has a stronger bond. This process of exchanging bases goes on until an equilibrium is reached between the proportions of the several bases in the mineral and in the water, or until the exchangeable bases are exhausted in one or the other. With respect to the chemical character of the water, the effect is an increase in one or more bases and an ion-for-ion decrease in one or more of the remaining bases. Thus, if a sediment in equilibrium with a calcium bicarbonate water be subjected to contact with a water in which sodium predominates among the bases, a part of that sodium will be removed and will be replaced by calcium and to a smaller extent by magnesium in an ion-for-ion proportion. Hence, from this base-exchange phenomenon may arise the illusion that a calcium-rich contaminant has invaded the aquifer.

2. In both the Long Beach-Santa Ana area and the Torrance-Santa Monica area, many of the waters known to be contaminated by ocean water contain less sulfate than would result from a simple mixture of native water and the ocean water in the proportions indicated by the total amount of chloride present. This sulfate removal probably is due to the reduction of sulfate to sulfide, either by the action of anaerobic bacteria or by the action of organic material, with the concurrent production of CO_2 in either case, which would increase the bicarbonate content of the water. In brines associated with petroleum, chemical analyses show the sulfate content to be low or zero, doubtless because the hydrocarbons have reacted with the sulfate and have resulted in the formation of hydrogen sulfide; the hydrocarbons in turn are oxidized to form carbon dioxide and water.



For a more complete discussion of these phenomena and for a bibliography relating thereto, reference should be made to the report on chemical character of waters in the Long Beach-Santa Ana area (Piper, Garrett, and others, 1953, p. 85–91).

CONTAMINATION IN BALLONA GAP

SUMMARY OF NATIVE WATER QUALITY

The geologic conditions in Ballona Gap and the hydraulic relations between the "50-foot gravel" and the underlying San Pedro formation have been summarized on pages 94 to 98. It is inferred that the difference in chemical character between waters yielded from the "50-foot gravel" and from the San Pedro formation was not great under native conditions. Water from wells tapping the "50-foot gravel" ranged about from 650 to 750 ppm of dissolved solids, although local wells presumably tapping the "50-foot gravel" yielded water containing at least 850 ppm of dissolved solids. Data concerning the chemical quality of water from wells tapping the San Pedro formation are fragmentary; the dissolved solids content probably ranged about from 480 to 650 ppm, although locally it was probably nearly as great as in the "50-foot gravel." These data represent the conditions as of 1903–4 and are based on determinations of electrical conductance of water from the wells sampled.

Chemical analyses of samples taken since about 1929 suggest that—at least for the period preceding that of extensive contamination—wells within Ballona Gap, tapping the "50-foot gravel" or underlying zones, yielded water markedly different from that yielded by wells tapping the San Pedro formation just south of the Ballona escarpment. In Ballona Gap, the waters contained from 40 to 70 ppm of chloride (the higher part of the range is confined to the shallower deposits), and nearly 100 to more than 200 ppm of sulfate. South of the Ballona escarpment, particularly in secs. 26 and 34, T. 2 S., R. 14 W., native water contained 80 to about 100 ppm of chloride and usually less than 40 ppm of sulfate. Figure 10 compares the chemical character of native or only incipiently contaminated waters in Ballona Gap to those immediately south of the Ballona escarpment. The principles of the procedure in plotting chemical character of waters on a so-called trilinear diagram have been described by Piper (1945). Also, figure 9 explains the chemical character of waters in the Torrance-Santa Monica area relative to their plotted positions on the diagram. On figure 10 the waters from Ballona Gap and from the area south of the gap plot in two separate fields, chiefly because of the difference in ratio of calcium and magnesium to sodium, and of bicarbonate to sulfate.

No.	Well	Parts per million		
		Dissolved solids	Cl	SO_4
	Waters in Ballona Gap

15	34K1	483	100	30

FIGURE 10.—Chemical character of selected native waters in Ballona Gap compared to waters just south of the Ballona escarpment.

However, this distinction in water character is not universal. For example, two wells in the gap, 2/15–11J1 and 23P1, in 1930–31 yielded water somewhat similar to that from wells tapping the San Pedro formation immediately south of the Ballona escarpment. The water in well 2/15–23P1 may represent a blend with a northward-extending lobe of the waters occurring south of the escarpment; it is difficult, however, to see how such a blend could have reached well 11J1 without appearing first in wells 2/15–24C1 and 14A1 (pl. 19). Thus, the chemical evidence here presented suggests that under native conditions, little, if any, water moved from the gap to the deposits south of the escarpment, or vice versa. Although the type native waters selected from secs. 26 and 34, T. 2 S., R. 15 W., are sodium, calcium bicarbonate waters, the analyses of water from wells 2/15–34A1 and 34K1 (table 30) suggest that, at least part of the time, sodium bicarbonate waters were present locally.

On the west flank of Baldwin Hills, well 2/14–18F1 in 1925 yielded water containing 182 ppm of chloride, 143 ppm of sulfate, and 823 ppm of dissolved solids. This water is probably a native blend in which waters from pre-Pleistocene deposits have moved into the San Pedro formation and are tapped by that well. The analysis represents a water similar to, but less concentrated than that from well 5/14–12C1 (table 30), on the east flank of the Palos Verdes Hills; this well is believed to tap pre-Pleistocene deposits in an area presumed to be free of contamination from surface-disposed brines. Analyses of water from well 2/14–18F1 in 1932 and 1945 show definite contamination, in which oil-field brine doubtless has contributed most, although not all, of the observed salinity.

For the shallow unconfined waters in Ballona Gap, too few analyses have been made to gain definite knowledge of their chemical character, either under native conditions or during the development of contamination. However, under native conditions dissolved solids commonly ranged from 800 to 1,000 ppm, but locally they are inferred to have been as high as 5,000 ppm. For water from several wells tapping the unconfined body in secs. 22, 23, and 24, T. 2 S., R. 15 W., the chloride concentration in 1930–32 was about 200 to 400 ppm—not inordinately high for shallow unconfined waters near the coast. However, because the unconfined waters can be expected to differ markedly with local conditions, these analyses are of little value for determining the quality of the unconfined waters elsewhere within the gap. It is concluded that the native unconfined waters at shallow depth in Ballona Gap generally were somewhat inferior and locally were greatly inferior to the waters in the underlying aquifers of the principal water body.

GENERAL FEATURES AND EXTENT OF CONTAMINATION

The study of the history and progress of contamination in Ballona Gap is complex and is rendered difficult for three reasons:

1. Before 1930 only a few comprehensive analyses of Ballona Gap waters were made. Because of this dearth of analyses, some locally native water types in the gap may have been considered in this report as definitely or incipiently contaminated.
2. Only locally in the areas of contamination has the salinity increase been sufficiently great to afford definitive knowledge of the chemical character or the source of the contaminant.
3. The directions in which contaminated waters and contaminants move within the gap are influenced locally by hydrologic barriers which transect the San Pedro formation but do not transect the "50-foot gravel" (p. 94). Therefore, the paths taken by the contaminated waters during the period of development to date (1946) have depended not only upon the hydraulic gradient and the amount of hydraulic connection between the "50-foot gravel" and the underlying water-bearing beds of the San Pedro formation, but they also depend upon the barrier partitions within that formation.

Since 1930 many active wells have been sampled periodically. Consequently, a large number of analyses are available for study for the period 1930–46, and much can be learned regarding the chemical character and contamination of the waters during this period.

Information is not available to indicate the time contamination began in Ballona Gap. As of 1930–32, however, waters containing more than 100 ppm of chloride occurred within the "50-foot gravel" or the underlying water-bearing deposits of the San Pedro formation beneath about 5,100 acres, or about 8 square miles, along the coast and extending inland to the vicinity of Sepulveda Boulevard (pl. 16). In this area, the chloride concentration then ranged from 100 to about 400 ppm, and the dissolved solids commonly ranged from 800 to 2,000 ppm. The extent of contamination between the Charnock and Overland Avenue faults as of 1930–32 is not known because analyses are not available. However, in the middle and late thirties, wells south of Ballona Creek in this block yielded water containing as much as 500 ppm of chloride (wells 2/15–13K2 and K4), and it is inferred that this area was contaminated as early as 1930–32.

At the north edge of the Baldwin Hills, and some 6 miles inland from the coast, chiefly in sec. 5, T. 2 S., R. 14 W., an area of about 250 acres was underlain by contaminated waters in 1930–32. Of six wells for which analytical data are available, the chloride content of five wells was in excess of 500 ppm and was 254 ppm in the sixth. The contamination extended northward beyond well 2/14–5F2 and southward beyond well 2/14–8D1. The greatest concentration was in well 5N1 (5,414 ppm of chloride). Fragmentary analytical data suggest that the waters were not contaminated between the coastal

460508—59——14

and inland areas as of 1930–32, although native water containing more than 100 ppm of chloride existed along the west flank of the Baldwin Hills; this is shown by a chloride concentration of 182 ppm in well 2/14–18F2 in 1925.

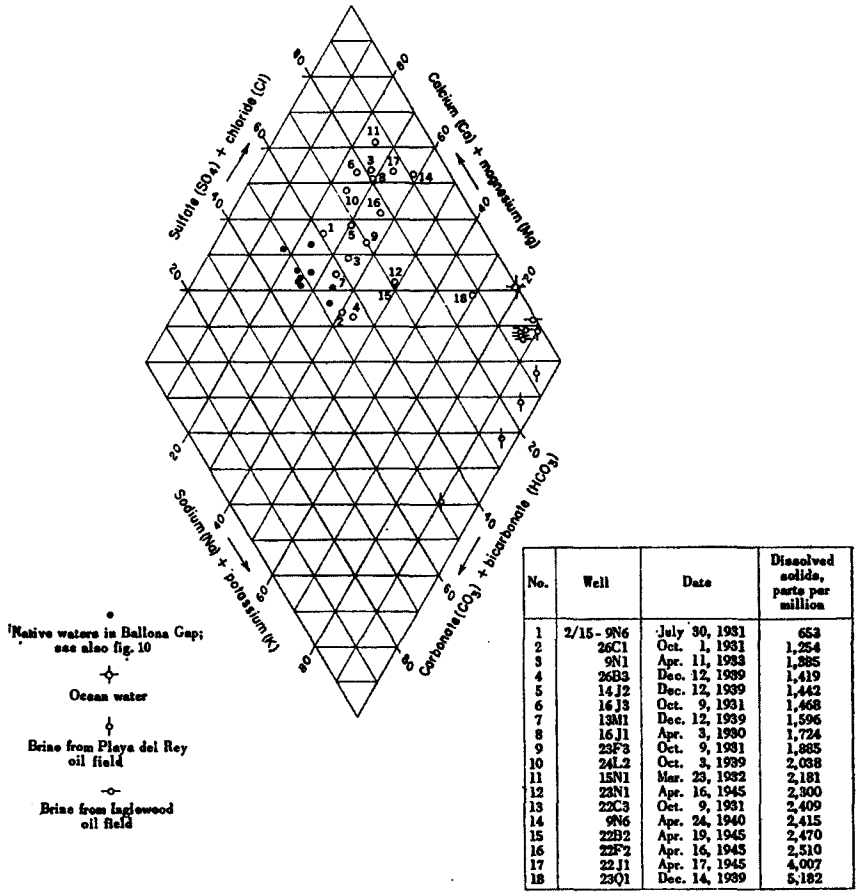
As of 1946, nearly all of Ballona Gap coastward from the Overland Avenue fault was underlain by contaminated waters; this coastal area of contamination had extended to some 7,300 acres, or about 11.4 square miles, an increase of about 2,200 acres in 15 years (pl. 16). The movement of the saline front had been generally northward across the gap; coastward from the Charnock fault, it had advanced from 0.4 to 0.9 mile; inland between that fault and the Overland Avenue fault, it probably had advanced about 1 mile in the 15 years. As of 1946, essentially all the area coastward from Lincoln Boulevard was underlain by water with a chloride content greater than 500 ppm.

At the north edge of the Baldwin Hills, in sec. 5, T. 2 S., R. 14 W., the area of contamination probably remained about constant from 1930 into 1946, although its front may have moved northward because of the large withdrawals from the wells of the Southern California Water Co. and the city of Beverly Hills in 2/14–5C and 2/14–5D.

Between the coastal area of contamination and the area north of the Baldwin Hills, a third area of contamination developed on the west flank of the Hills in the thirties and early forties. By 1946, about 200 acres east of the intersection of Overland Avenue and Jefferson Boulevard was underlain by water containing more than 500 ppm of chloride (pl. 16). The focus of this contamination is presumed to be in the vicinity of well 2/14–7K1, because water from this well contained 18,810 ppm of chloride in 1939.

In contrast to the general contamination in the gap, an area about 0.15 mile wide and 0.8 mile long, inland from the Charnock fault and south of Ballona Creek, was still uncontaminated as of 1940—according to analyses of samples from wells 2/15–24C1 and 24F3. So far as known, the main water-bearing zone in this narrow strip then contained less than 60 ppm of chloride; as of 1945, it probably was no more than incipiently contaminated.

CONTAMINATION NEAR THE COAST



In the coastal area of contamination, saline encroachment presumably began in the twenties and abandonment of wells started about 1930. For example, two wells of the Venice Consumers Water Co. in sec. 16, T. 2 S., R. 15 W., about 1 mile from the ocean, were abandoned in 1930 because of salinity. Abandonment of wells at the Marine plant of the city of Santa Monica in 2/15–9N began about 1933, although at least one or two of the wells were used into 1941. In 1940, well 2/15–9N7 (well 5 of the city of Santa Monica) yielded

water containing over 1,100 ppm of chloride. For the interval from 1930 to 1945, sharp increases in salinity were restricted chiefly to wells within 1.5 to 2 miles of the coast. Records of chloride analyses for selected wells are plotted on plate 20 to show the rate of salinity increase in the coastal area of contamination in Ballona Gap. Analyses were made chiefly by Los Angeles County Flood Control District, California Division of Water Resources, and Los Angeles Department of Water and Power. In general, the chloride increase has been greatest in wells less than about 1.5 miles from the coast. Except for these badly contaminated wells, and some local wells not shown here, the graphs indicate that, for the area as a whole, salinity has not definitely increased since the middle thirties; in fact, many of the well waters have had a slight decrease in salinity in recent years. For this coastal area of contamination, chemical evidence does not suggest any regional quality gradient between the "50-foot gravel" and the San Pedro formation.

The information regarding the zones tapped is too meager to indicate whether any definite relation exists between depth of zone tapped and water quality. Tentatively it may be concluded that, at least for the coastal part of the gap, no uniform vertical gradation in quality exists. Therefore, the two water-bearing zones are not discussed separately in dealing with contamination here, but instead, they are treated as containing a single contaminated water body.

CHEMICAL FEATURES OF CONTAMINATION

In the coastal area of contamination many of the well waters have become grossly contaminated; in 1945, at least one well (2/15–22J1) yielded water in which the dissolved-solids content was more than 4,000 ppm. To show the manner in which chemical character of the contaminated waters has changed with increase in concentration, figure 11 is plotted to show a number of the more highly contaminated waters in order of increasing concentration. Also plotted on the graph are the group of native waters from figure 10. Figure 11 shows that the points representing the contaminated waters scatter to the right and range upward. In terms of character change, departure to the right indicates an increase in the proportion of sulfate or chloride and a similar increase in the proportion of sodium. The shift upward and increased concentration denotes an increase in calcium and magnesium and a proportionate loss of sodium. Inferentially, the increase in alkaline earths at the expense of the sodium might be interpreted to indicate that a high-calcium or high-magnesium contaminant is present in Ballona Gap. However, neither here nor in the Long Beach-Santa Ana area has such a contaminant been found. Therefore, the increase in alkaline earths is presumed to be due to

FIGURE 11.—Chemical character of native and contaminated waters in the coastal part of Ballona Gap.

base exchange, in which the sodium in the incoming contaminant is replaced nonuniformly by calcium or magnesium, or both. As will be noted on figure 11, the occurrence of base exchange disguises completely any possible gradation in quality toward that of known contaminants. As shown on the illustration it is obvious that, as salinity of the water increases, the path of the plotted points does not head toward the plots for either ocean water or a typical oil-field brine. If the degree to which base exchange has occurred could be determined and a correction made in the position of the plotted points, then a trend toward one or the other of the possible contaminants might actually occur.

Although, as shown by figure 11, no consistent trend in chemical character occurs with increasing concentration, it will be noted from data presented below that from the coast to about 1.5 miles inland,

or about to Lincoln Boulevard, chloride increase is attended by an increase in sulfate in about the proportion to be expected if ocean water were the contaminant. The progress of contamination from Lincoln Boulevard inland to near Sepulveda Boulevard indicates that the sulfate content of the contaminated waters has increased above that which could possibly result from the addition of sulfate carried into the aquifers by ocean water alone. Hence, inferentially, the encroachment of ocean water into Ballona Gap extends about to Lincoln Boulevard, or nearly as far as the 500 ppm chloride contour shown on plate 16.

To show the proportionate amount of sulfate increase in the coastal strip, analyses of contaminated water from three wells have been selected (2/15–9N6, 16J1, and 26C1, all within 1.75 miles of the coast) and are compared to hypothetical mixtures of native waters with ocean water. Table 18 shows these contaminated waters and the corresponding hypothetical mixtures, based on an equality of chloride concentration. As the table shows, only 9N6 contained an excess sulfate content (8 percent) but, because of possible analytical errors in the determination of that constituent, this small excess is not considered to be sufficient to rule out ocean water as the contaminant. On the other hand, analysis 26C1 showed a deficiency of 42 percent in sulfate content. In this case, however, a loss in sulfate is

TABLE 18.—*Contaminated water from wells 2/15–9N6, 16J1, and 26C1, in comparison with hypothetical mixtures of the presumed native water with ocean water*

Native water mixed with ocean water	4.06	3.83	11.09	4.46	4.00	10.52
Excess (+) or deficiency (−) of the contaminated waters with respect to native and ocean water mixtures, as follows:						
Water of 2/15-9N6	+14.22	−3.27	−10.71	−.26	+.50	----------
Water of 2/15-16J1	+9.12	+2.92	−10.48	+1.70	−.14	----------
Water of 2/15-26C1	+2.48	+3.67	−1.33	+6.39	−1.67	----------

not diagnostic, because the process of sulfate reduction is common in both native and contaminated waters—it certainly could have occurred here. Referring again to the table, all the contaminated waters are lower in sodium and higher in the sum of calcium and magnesium than the hypothetical mixtures. This discrepancy is due to base exchange in the direction of calcium enrichment and is to be expected. Hence, its occurrence will not, in itself, invalidate the postulation of ocean-water contamination of those well waters whose analyses are examined here.

In contrast, table 19 presents the sulfate content of water from a number of wells inland from the 500 ppm chloride contour, but coastward from Sepulveda Boulevard. The sulfate content of these waters is compared to that which would result from mixtures of native water with ocean water, based on an equality of chloride concentration. As may be seen from the table, all the analyses cited show more sulfate in the contaminated water than could possibly have resulted from an ocean water-native water blend. The excess of sulfate, expressed as the percent of excess over that contained in the hypothetical blend, ranges from 31 to 440 ppm for waters in the confined body. Well 2/15–23Q1, tapping the unconfined body, yielded water in which the percent excess of sulfate with respect to the native confined water is 1,240 ppm. Thus, considering the change in sulfate concentration that has occurred, the shallow water could be causing part of the contamination. Hence, for the coastal part of Ballona Gap, the concentration of sulfate suggests that ocean-water contamination doubtless has occurred inland about to and possibly beyond Lincoln Boulevard. From Lincoln Boulevard to Sepulveda Boulevard, the shallow water in the unconfined body may be the principal contaminant. However, it is likely that the boundary between the ocean-water and high-sulfate-water contamination is very irregular and indefinite.

In an attempt to define the position of this boundary, and to identify the contaminant inland from Lincoln Boulevard, three other chemical characteristics of potential contaminants were considered. These characteristics are (1) bicarbonate content, (2) calcium-magnesium ratio, and (3) borate content. The study of these characteristics failed to provide a better definition of the boundary.

1. The bicarbonate content in ocean water is about 140 ppm; in the shallow unconfined waters of Ballona Gap it commonly is about 500 to 700 ppm but in one locality it is as great as 1,670 ppm; in oil-field brines from the Inglewood field—according to six available analyses—it ranges from 297 to about 2,000 ppm and averages 1,350 ppm. In native waters in Ballona Gap it probably ranged about from 275 to 300 ppm. Therefore, a Ballona Gap native water contaminated by ocean water alone would decrease in bicarbonate, but if the contaminant were either shallow unconfined water, or an oil-field brine, the

[1] Native water selected is that from well 2/15-9N3, analysis of Apr. 11, 1933.

bicarbonate content of the contaminated water would increase slightly and irregularly. A study of the analyses of contaminated waters throughout the coastal part of Ballona Gap indicates that in such waters a bicarbonate content of 400 to 500 ppm is common and that, with very few exceptions, notably at the Marine plant of the city of Santa Monica, the increase in chloride is attended by an increase in bicarbonate. Well 2/15–9N6, at the Marine plant, yielded water that decreased in bicarbonate from 308 ppm in 1931 to 226 ppm in 1940. Over the same period, the chloride content increased from 81 to 930 ppm. However, here the bicarbonate loss is considerably more than would result from ocean-water contamination alone. In general, the conclusion was reached that, for this coastal area of Ballona Gap, bicarbonate is useless as a criterion for determination of the sources of contaminants.

2. The calcium-magnesium ratio for ocean water, computed from equivalents per million, is 0.19; for oil-field brines from the Inglewood field, it ranges from 0.28 to 1.04 and averages 0.56, according to six available analyses; for shallow, unconfined waters, it appears to be less than 1 (well 2/15–23Q1, 0.57; well 23Q2, 0.73). For presumed native waters in Ballona Gap, the ratio ranges from 1.2 to 2; hence, it would be expected that native waters rendered inferior by blending with any of the known contaminants, would show a decrease in calcium-magnesium ratio concurrent with salinity increase; of course, for only moderate contamination the decrease would be slight. According to computations (not presented here), such a decrease in calcium-magnesium ratio does not occur. Actually, with increase in salinity of randomly selected native waters, a considerable scatter (from 0.9 to 2.5) occurs in the value of the ratio; therefore, such a ratio could be of little value in discriminating the source of a contaminant.

In contrast, waters in Dominguez Gap that were contaminated by ocean water have a much lower calcium-magnesium ratio than waters contaminated by oil-field brines (at least, for chloride concentrations less than 1,000 ppm). There, in water contaminated from the ocean, the ratio averages about 0.6, whereas in

waters primarily contaminated by oil-field brine, the ratio averages about 2.3 (Piper, Garrett, and others, 1953, p. 190). That is, a calcium-magnesium ratio much greater than 0.6 would seem to indicate a contaminant other than ocean water. In regard to those waters in Dominguez Gap, the base-exchange reactions, which usually occur with blending of native waters and saline waters and which cause much irregularity in the proportion of bases, was operative to only a small extent. On the other hand, in Ballona Gap, the great irregularity in calcium-magnesium ratios in contaminated waters doubtless results from base-exchange reactions which prevent the use of that ratio as a diagnostic characteristic.

3. The borate content in ocean water is about 25 ppm. In presumed native waters of Ballona Gap, the borate content commonly ranges from 0.3 to 0.8 ppm, although some of these native waters—particularly those which may represent a blend with waters from the flank of the Santa Monica Mountains—contain as much as 1.4 ppm. Therefore, if a contaminated water with 500 ppm of chloride contains more than about 1.5 to 2 ppm of borate, it is inferred that some saline water other than ocean water has been the cause of such contamination. Little is known concerning the borate content of potential contaminants in Ballona Gap; however, a sample of water from Ballona Creek, collected in 1931, contained 350 ppm of chloride and more than 5 ppm of borate. Although not in Ballona Gap, and cited for example only, a sample of water collected in 1932 from the Los Angeles River just downstream from the sumps of Oil Operators', Inc., contained 14,289 ppm of chloride and 169 ppm of borate. Fragmentary data not presented here suggest that oil-field brines in the Los Angeles basin contain several times as much borate as ocean water (Piper, Garrett, and others, 1953, p. 67 and table 8).

Information on the borate content of contaminated waters in the coastal part of Ballona Gap shows that at least 13 wells have yielded water containing more than about 1.5 ppm of borate (for waters in which the chloride content is not appreciably more than 500 ppm). Of these 13 wells, 8 are in sec. 23, T. 2 S., R. 15 W.; all of the wells are in that part of the coastal reach of Ballona Gap about from Lincoln Boulevard to Centinela Boulevard. For 12 of these wells, the borate content ranges from 1.6 to 3.4 ppm. The additional well, 2/15–23N1, yielded water in 1931 containing 7.6 ppm. Nearly all of these wells are farther inland than the presumed inland extent of ocean-water contamination, as determined on the basis of sulfate content. However, throughout the area in which the 13 foregoing wells are located, other wells, equally saline, contain only slightly larger amounts of borate than is presumed to have occurred in the native waters; many of these wells yield high-sulfate waters. Therefore, it is concluded that the borate content of contaminated waters inland from Lincoln Boulevard is of virtually no value in attempting to delimit the inland extent of ocean-water contamination, because no definite borate-chloride ratio seems to exist.

With respect to possible contamination from Ballona Creek, the available analyses of side inflows and creek water are listed in table 20.

The points where the samples were taken are shown by corresponding numbers on plate 17. The table shows that waters discharged into the creek are of sufficiently great sulfate and chloride content to cause contamination of ground waters within the coastal reach inland from tidewater; that is, providing that the materials beneath and adjacent to the creek are sufficiently permeable to permit appreciable seepage from the creek. Regarding such seepage, the California Division of Water Resources (1933, p. 26) notes that, "Discharge during summer usually penetrates into creek bottom before reaching tidewater." At the time of this observation, August 1931, the flow in the creek was estimated at 3 cfs.

As discussed on page 187, the channel of Ballona Creek is paved with an impervious lining inland from La Salle Avenue; however, coastward from this avenue the bottom of the channel is unlined. The analyses (table 20) of creek water suggest that, if seepage has occurred here, the waters so introduced into the ground-water body may have caused a substantial part of the contamination. From La Salle Avenue inland, the ground-water bodies are protected from saline waters flowing within the creek channel. La Salle Avenue is 0.7 mile inland from the fault separating the Charnock and the crestal subbasins; hence, both basins are subject to possible contamination from the creek channel at the present time.

In regard to the sources of contamination in the coastal part of Ballona Gap, it may be concluded that inland at least as far as Lincoln Boulevard and including the abandoned Marine plant of the city of Santa Monica, ocean water has caused most if not all of the contamination. The presence of a landward hydraulic gradient from the early twenties to the late thirties coincides with this conclusion. The conclusion regarding an oceanic source of contamination is in general agreement with that of the Los Angeles County Flood Control District, which was the result of extensive work in Ballona Gap by that agency (Koch, 1940, p. 16).

The Los Angeles County Flood Control District also prepared the first detailed map showing contamination conditions in Ballona Gap. This map (Koch, 1940, pl. 2) shows lines of equal salinity and designates a suggested boundary between sea-water intrusion and oil-field brine pollution.

Inland about from Lincoln Boulevard to Sepulveda Boulevard, water from the shallow, unconfined body tentatively is presumed to be the chief cause of contamination, although near Lincoln Boulevard the contaminant may have been a blend of ocean water and unconfined water. Although confirmatory information is not available, it is likely that Ballona Creek has been an important factor in contaminating the shallow water body, at least as far inland as La Salle Avenue. Nowhere in this coastal part of Ballona Gap has it been possible to identify any contamination from oil-field brines. In part, this may stem from the difficulty of applying any of the criteria that ordinarily may be used in recognition of a blend of oil-field brine with native water.

CONTAMINATION ON THE WEST FLANK OF BALDWIN HILLS

An area of contamination developed on the west flank of the Baldwin Hills in the thirties; by 1946, about 200 acres east of the intersection of Overland Avenue and Jefferson Boulevard was underlain by water containing more than 500 ppm of chloride (pl. 16). Evidence suggesting that the contamination originates in the Baldwin

Hills is afforded by a sample of water (collected in 1939 from well 2/14–7K1), which contained 18,810 ppm of chloride. Referring to table 31, the chloride content of brines from the Inglewood oil field, based on six analyses, ranges from 17,500 to 20,000 ppm. The depth of well 2/14–7K1 is not known, but it is high on the west flank of the Baldwin Hills and presumably taps the San Pedro formation.

The location of well 7K1 is such that contamination by ocean water is physically impossible, because the base of these water-bearing deposits is more than 100 feet above sea level (pl. 2). Hence the well doubtless is contaminated by oil-field brines. It is to be expected that such highly contaminated waters would percolate through the water-bearing deposits and ultimately would contaminate wells in Ballona Gap. Evidence of this fact is provided from two analyses of water from well 2/15–7P2 (table 30). In June 1945 the well yielded water containing 600 ppm of chloride; in February 1946 it yielded water containing 1,100 ppm. During that period the sulfate content increased from 152 to 156 ppm; the comparatively small increase in sulfate is consistent with brine contamination considering the small amount of sulfate present in the brines of the Inglewood field. These two analyses are plotted on figure 12. The analyses are so plotted on this graph that the vertical height of a given constituent represents the amount of that constituent in equivalents per million. The oil-field brine contamination has reached at least as far south as wells 2/14–18F1 and 18F2; to the west it presumably extends into sec. 12, but chemical evidence showing its exact extent is lacking. As shown by plate 2, the permeable sand and gravel of the San Pedro formation crop out extensively to the north, east, and south of well 2/14–7K1, and any brines discharged at the land surface can readily move down the westerly dipping beds to the Overland Avenue fault.

CONTAMINATION ON THE NORTH FLANK OF BALDWIN HILLS

About 300 acres, located chiefly in sec. 5, T. 2 S., R. 14W., was underlain by contaminated waters in 1930–32. The contamination extended northward beyond well 2/14–5F2 and southward into the Baldwin Hills beyond well 8D1. Inferentially, this area became contaminated some years earlier than the coastal area. By 1931 several wells in 2/14–5P yielded water containing from 1,000 to 5,400 ppm of chloride. Because this contamination apparently is due to blending with oil-field brines, as will be explained, the contamination could have started at any time after 1924, which was the year of initial development in the Inglewood oil field. Analyses from three highly contaminated wells in this area are available: analyses 2/14–5N1, March 23, 1932; 2/14–5P1, October 22, 1931; and 2/14–5P3, October 2, 1931. Their chemical character is shown on figure 12. Of the

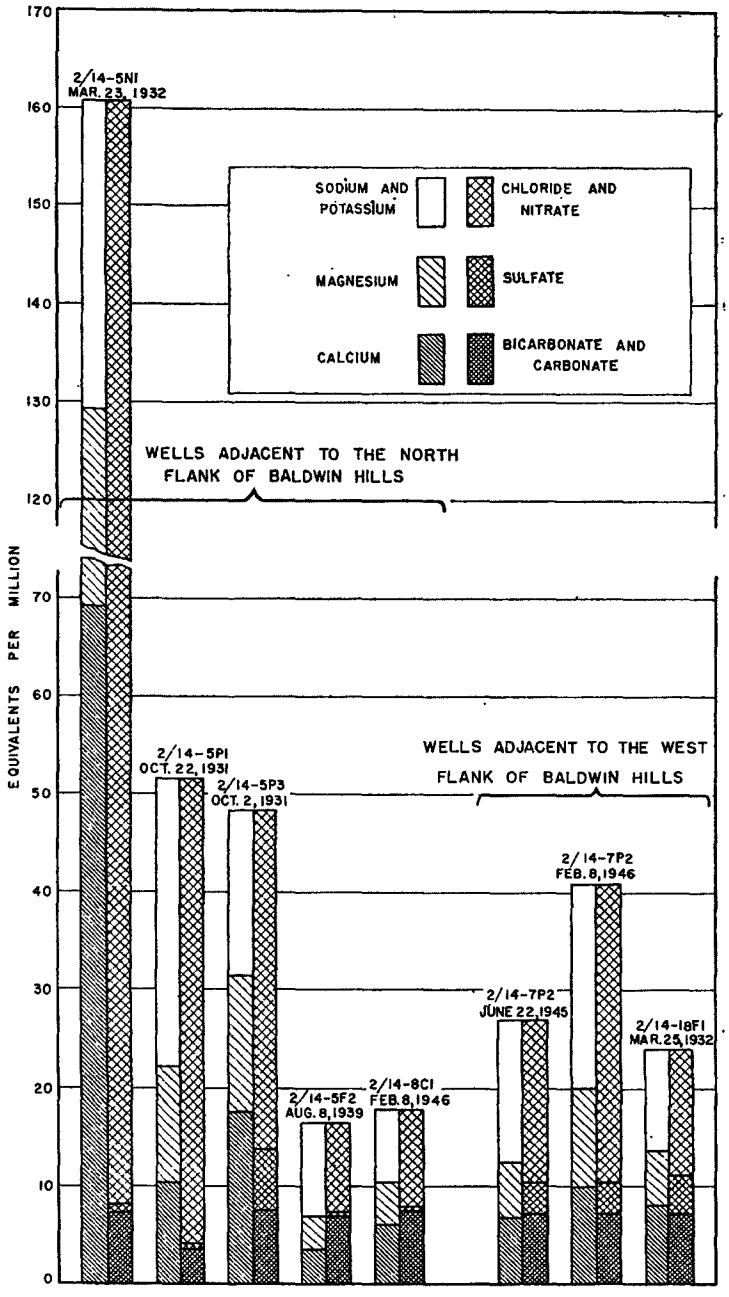

FIGURE 12.—Chemical character of contaminated waters from wells in Ballona Gap adjacent to the west and north flanks of Baldwin Hills.

analyses given, only 5P3 shows an appreciable amount of sulfate; however, in relation to the concentration of dissolved solids, that sulfate content is proportionally far less than in most of the contaminated waters toward the coast. Because the brines from the Inglewood field are low in sulfate—ranging from 13 to 56 ppm (table 31)—the low sulfate in the contaminated waters is a reasonably good indication of the source. Although well 5P1 contained 2.9 ppm and well 5P3 contained 3.5 ppm of borate, this constituent does not assist in isolating the source, because no analyses of borate in Inglewood brines are available.

Although it is possible that the contamination could have originated from Ballona Creek, such an origin is unlikely because of the following three important factors:

1. Because of the position of the contaminated area shown on plate 16 and because of the position of the more highly contaminated wells, a source to the south rather than to the north is the more logical.
2. Existing analyses of water samples from Ballona Creek upstream from the contaminated area fail to show the presence of waters sufficiently saline to cause the observed concentration in the contaminated wells.
3. Contamination from Ballona Creek would have resulted in definite impairment of the waters from one or more of the Sentney plant wells of the Southern California Water Co.

Hence, it is concluded that contamination here has been the result of discharge of oil-field brines from the Inglewood oil field.

Although the wells in 2/14–5P were strongly contaminated by 1931, recurrent chloride determinations from two wells, 2/14–5C1 and 5F2, plotted on figure 13, suggest that the concentration at these wells was not appreciably higher in the early forties than it was in 1931. Well 5C1, 0.2 mile east of the Sentney plant of the Southern California Water Co., taps essentially the same range as well 5D6 (Sentney plant,

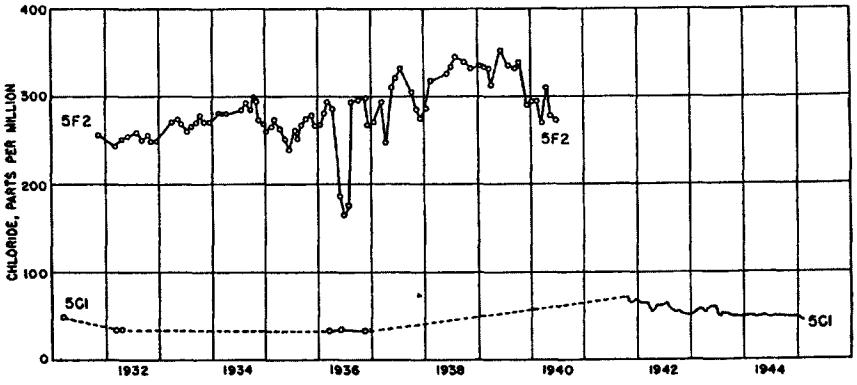

FIGURE 13.—Chloride content of waters from wells 2/14–5C1 and 2/14–5F2. Analyses chiefly by Los Angeles County Flood Control District.

well 6), and is about at the north edge of the contamination. Well 5F2, within the area of contamination, is about 0.2 mile south of 5C1. It is 260 feet deep and taps the upper part of the San Pedro formation. Well 5F2, although of irregular chloride content, showed an increase in salinity into 1939, then it showed a decrease. Well 5C1 may have reached a peak at about the same time as 5F2; chloride determinations on 5C1 from 1941 into 1945 show a decrease in chloride into 1944, then a leveling off at about 50 ppm. Well 5F2 yielded contaminated water containing very little sulfate and is assumed to be contaminated by oil-field brines.

To determine the current status of salinity in the area shown as contaminated in 1930–32 (pl. 16), an electrical-conductivity traverse was made on well 2/14–5P1 in July 1946. This unused well is located about 1,750 feet southeast of Ballona Creek and about 1,500 feet north of the flank of the Baldwin Hills. The measured depth was then 179 feet below land surface. The casing is perforated in gravel, 20 to 32 feet below land surface. As computed from values of specific conductance, the dissolved solids in the water within the casing, from water surface at 13 feet to 88 feet below land surface, ranged from 4,600 to 4,800 ppm. From 89 to 176 feet below land surface, the dissolved solids ranged from 7,400 to 8,000 ppm. In 1931 a sample from the well contained 2,856 ppm of dissolved solids; thus, at least at this one well, the salinity concentration has intensified appreciably during the 15-year period. Well 5N1, 1,000 feet northwest of 5P1, yielded water containing 8,528 ppm of dissolved solids in 1932; this well was not found in 1946, and its salinity at that time could not be determined.

WELLS AT THE SENTNEY PLANT OF THE SOUTHERN CALIFORNIA WATER CO.

In the NW¼ sec. 5, T. 2 S., R. 14 W., analyses of water from the Sentney plant wells of the Southern California Water Co. show that they yield waters with erratic fluctuations in chemical concentration; these analyses strongly suggest a blending of waters of different and distinct types. Although, as of 1946, all the active wells yielded presumably native water, distinct vertical differences in chloride concentration occur; water with the lowest chloride content is yielded from the lowest part of the water-bearing beds. Well 5C1, 0.2 mile east of the Sentney plant and perforated below 277 feet, yielded water containing 44 ppm of chloride in 1945. Well 5D6, perforated below 326 feet, yielded water containing 49 ppm of chloride in 1945. Well 5D4, for which the perforated interval is not known, yielded water containing as much as 219 ppm of chloride in 1936. The records of chloride content of water yielded from seven wells of the Sentney plant have been plotted on figure 14, together with the record of

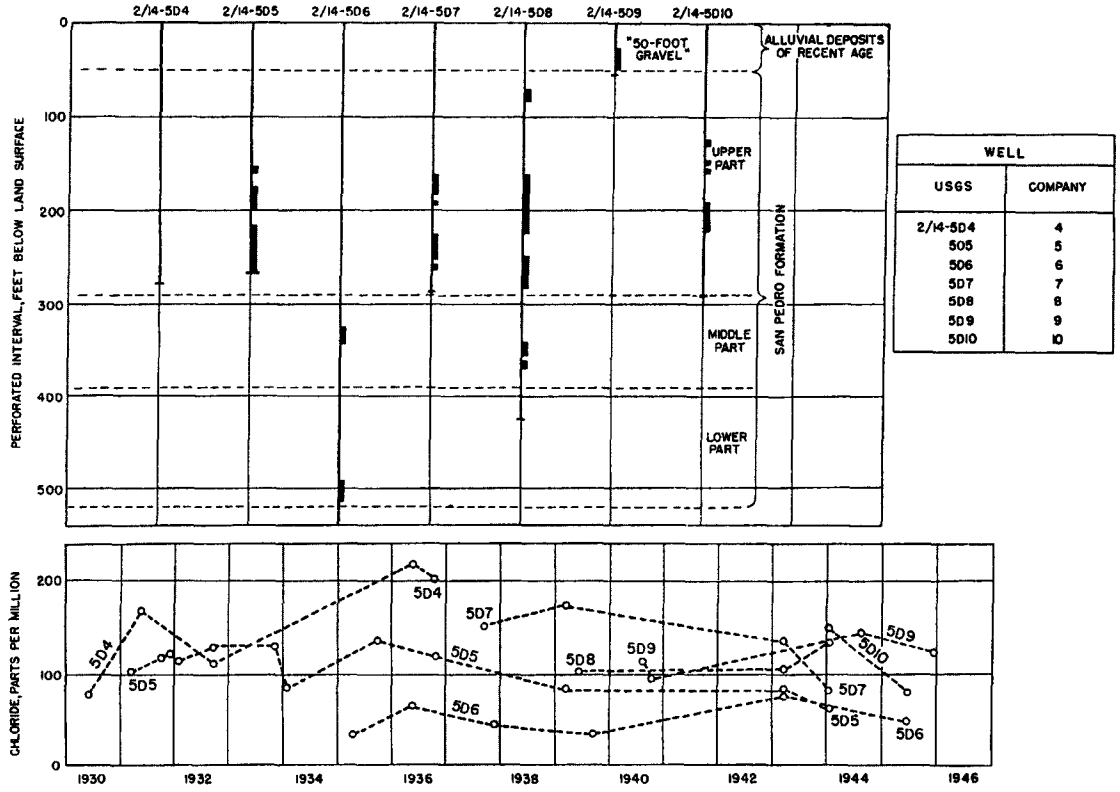

FIGURE 14.—Chloride content of waters and record of perforations for seven wells at the Sentney plant, Southern California Water Co.

perforations for these wells. Three conclusions may be drawn in part from the figure:

1. Well 5D6, which taps the middle and lower parts of the San Pedro formation, yielded water of the best quality, but as of 1943 the quality approached that of water yielded from the upper part of the formation.
2. Essentially no difference in chloride concentration exists between waters in the "50-foot gravel" of Recent age (well 5D9) and in the underlying upper part of the San Pedro formation. However, the former has yielded water definitely higher in sulfate than that from the San Pedro formation. Since 1944 analyses of water from well 5D9 tapping only the "50-foot gravel," have shown an increase in dissolved solids, which has been due chiefly to an increase in calcium and in sulfate.
3. For the respective zones tapped, only a comparatively small range in chloride content exists—as of 1944, from about 65 to 150 ppm. For the span of the records, no definite progressive contamination is indicated, with the possible exception of well 5D4, which has not been pumped since about 1936.

The heaviest production from the Sentney plant is from the upper part of the San Pedro formation—which here includes the main aquifers. Well 5F2, which is 0.4 mile southeast and was definitely contaminated in the thirties, also once yielded water from the upper part of the San Pedro formation. Because a steep cone of pressure relief has been maintained at the Sentney plant for many years (pls. 9–12 and 14) it might be expected that, at least by 1946 wells at the Sentney plant would have become contaminated from the south—that is, from the same source that caused well 5F2 to become saline. The fact that these wells have not yielded definitely contaminated water suggests a hydraulic discontinuity between the Sentney plant and the contaminated water body to the south. However, the hydrographs for wells 5D5 and 5F2 plotted on plate 14, suggest that no hydraulic separation exists. Accordingly, it is concluded that the bulk of the northward-migrating contaminant was withdrawn through wells 5F2, 5C1, and possibly other wells, in the thirties and early forties, and that a small marginal interception was withdrawn through wells 5D4 and 5D7 in the middle thirties (fig. 14).

Under native conditions, inferior waters occurred in sec. 32, T. 1 S., R. 14 W; in 1931 wells 32M1 and M3 yielded water containing 227 and 304 ppm of chloride, respectively. It is believed that these waters have migrated in part to the Sentney plant wells and have caused some of the observed fluctuations in chloride.

From existing analyses of water from the Sentney plant wells, it is inferred that as of 1946 the active wells were not contaminated, and that the recent fluctuations in chloride are not an indication of incipient contamination, but instead, they are a result of blending with inferior waters present to the north and east.

RATE OF ADVANCE OF THE CONTAMINATION FRONT

In Ballona Gap the greatest advance of the contamination front in the last 16 years has been in the Charnock subbasin. From 1930–32 to 1945–46 the front has advanced about 1 mile, and in 1946 it was about 0.6 mile from the Charnock well field of the Southern California Water Co. This advance is estimated at an average rate of about 350 feet per year; the direction of advance is to the northwest and is in response to the hydraulic gradient developed by withdrawals from the Charnock field. If the front continues to advance at the same average rate, it will reach the Charnock field in 8 to 10 years. However, as the front moves closer to the field, it is expected that the rate of movement will be accelerated by the steeper gradient.

As of November 1945 (pl. 12), the hydraulic gradient to the well field from the northwest was about 30 feet per mile; from the southeast, about 15 feet per mile at the saline front. Thus, if the transmissibility of the deposits to the north and to the south is equal, about two-thirds of the supply is derived from the north and one-third from the south. The water now yielded from the Charnock well field contains about 50 ppm of chloride, about 700 ppm of dissolved solids, and 400 ppm of hardness (table 30). The saline waters just south of Ballona Creek in the Charnock subbasin contain as much as 500 ppm of chloride, 2,000 ppm of dissolved solids, and 800 ppm of hardness (table 29). If such saline waters eventually should reach the Charnock plant wells and should be withdrawn with the native waters in a proportion of 1:2, the resulting blend would contain about 200 ppm of chloride, 1,100 ppm of dissolved solids, and 500 ppm of hardness.

In the coastal area, contamination has advanced along about a 3-mile front, chiefly in secs. 14, 15, and 16, T. 2 S., R. 15 W. Part of the advance as shown on plate 16 is conjectural because of the scarcity of wells that could be used to locate the front more precisely. However, for the 16-year period the greatest advance appears to be along the west boundary of sec. 14 and in sec. 15, where it was from 0.7 to 0.9 mile. This represents an average yearly rate of about 260 feet, although for most of the front the rate is probably not more than half so great.

CONTAMINATION FROM PLAYA DEL REY TO REDONDO BEACH

In the coastal reach from Playa del Rey southward to and somewhat beyond Redondo Beach—essentially the 11-mile reach from the Ballona escarpment to the Palos Verdes Hills—salt water has invaded the main water-bearing zone and now extends inland from half a mile to nearly 2 miles (pl. 16). Locally, this contaminated water contains as much as 5,000 ppm of dissolved solids.

460508—59——15

Under the native conditions of coastward ground-water movement it is believed that waters of good or fair quality existed to the coast along essentially all of the reach from Playa del Rey to Redondo Beach. As of 1904, Mendenhall (1905b) canvassed 13 wells from Manhattan Beach to Redondo Beach that were less than 0.7 mile from the coast. Of these, all except three yielded water containing less than 600 ppm of dissolved solids. Only one well, in 3/15–36H (Mendenhall 273, Redondo), yielded water containing more than 1,000 ppm of dissolved solids. North of Manhattan Beach no wells had been drilled near the coast as of 1904—except near Playa del Rey in 2/15–34E (Mendenhall 80 and 81, Redondo), 0.4 mile inland from the coast. There, the main water-bearing zone yielded water containing 710 ppm of dissolved solids as of 1904.

So far as known, contamination within this coastal reach was first noted between 1912 and 1918—in well 4/14–6F1, at Hermosa Beach and 0.6 mile inland from the coast (p. 244). In the reach of greatest current inland advance at El Segundo, contamination was first reported in 1921 in wells of the Standard Oil Co.—in 3/15–13D and 14A (pl. 16). Well 3/15–14A2, about 0.6 mile inland from the coast, yielded water containing 90 ppm of chloride in 1920; this water was considered essentially native to the range tapped. Beginning in 1921, its quality deteriorated rapidly, however (fig. 20).

From 1920 to the early thirties, withdrawal from the Torrance-Inglewood subarea of the west basin increased substantially, largely because of the construction of a number of well fields supplying new industrial plants. As has been shown, water levels were lowered to and below sea level throughout most of the subarea. As a result of this lowering of water level, contamination of wells had occurred along most of the coastal reach from El Segundo to Redondo Beach by 1932.

The inland front of contaminated waters containing more than 100 ppm of chloride as of 1930–32 is shown on plate 16. At that time the greatest inland extent of the contaminated waters was about 1.3 miles at El Segundo; the least extent was not more than half a mile near Century Boulevard and at Hermosa Beach. Along the full 11-mile reach, the area then underlain by contaminated waters was about 5,000 acres, or nearly 8 square miles.

As of 1946, the front of waters containing more than 100 ppm of chloride, as shown on plate 16, ranged from half a mile inland near Century Boulevard to 1.7 miles at El Segundo. At Redondo Beach, the front then was 1.1 miles inland from the coast. From 1932 into 1946, the greatest advance of the saline front occurred between El Segundo and Manhattan Beach and was as much as 0.5 mile. However, the average advance of encroachment between Playa del Rey and Redondo Beach in the 14 years was about 0.3 mile, and the in-

crease in the area underlain by contaminated water was about 1,700 acres.

The withdrawal of water along the coastal reach is largely concentrated at five well fields or local centers of pumping. Analytical data relating to the active wells in these fields have been taken more or less continuously for many years. Thus, the rate of contamination, the chemical character of the contaminated waters, and the source or sources of contamination can be appraised best by analysis of conditions at these several well fields.

WELL FIELD AT PLAYA DEL REY

Just south of the Ballona escarpment in the vicinity of Playa del Rey, water is yielded only from the main water-bearing zone of the San Pedro formation, which here immediately underlies the dune-sand deposits and which, at least locally, is in hydraulic contact with them. At well 2/15–34A2 (Palisades del Rey Water Co. well 4) the main water-bearing zone is about 130 feet thick, and its top is about 30 feet above sea level. The log for this well is considered to be representative and is shown on plate 3*C*.

The Palisades del Rey Water Co. pumps water from two fields. The field in 2/15–34K is about 0.4 mile from the ocean; there two wells have been drilled, of which one (2/15–34K1) is now active. The other field, in 2/15–34A and 2/15–27R, is about 0.9 mile from the ocean and about 0.5 mile from the escarpment; there four wells have been drilled, and one (2/15–34A1) is now active. Of the two fields, that in 2/15–34K is the older; well 2/15–34K1 (Palisades del Rey Water Co. well 1) was drilled in 1924. The first well in field 2/15–34A (2/15–34A1) was drilled about in 1930.

Waters yielded from the two fields were chemically alike and ranged from sodium, calcium bicarbonate to sodium bicarbonate waters, although in the available analyses sodium always made up at least 44 percent of all the bases. In these waters under native conditions, the sulfate content was usually less than 40 ppm. Good series of chloride determinations are available for wells 2/15–34A1 and 34K1 and are plotted on figure 15. As shown in these chloride analyses, both wells became definitely contaminated by 1945, and well 2/15–34A1 was incipiently contaminated in the early thirties. Contamination now is much more serious at well 2/15–34K1, not only because the chloride content is nearly twice that at well 2/15–34A1, but also because the rate of contamination increase is many times greater, as indicated by the slope of the chloride graph.

A striking difference in character change of the two waters is shown by the graph of bicarbonate in water from the two wells (fig. 15). In 1929, both wells yielded water containing over 300 ppm of bicarbonate.

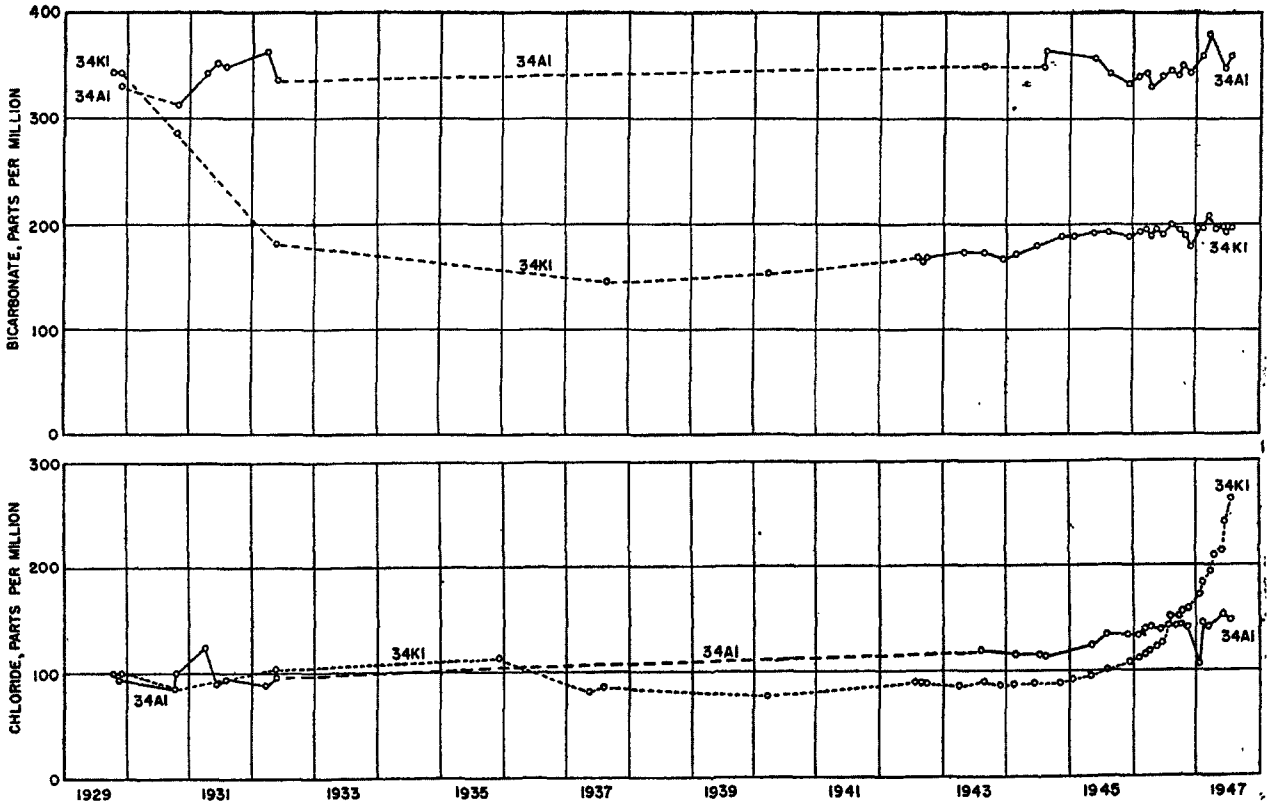

FIGURE 15.—Chloride and bicarbonate content of waters from wells 2/15-34A1 and 34K1 (Palisades del Rey Water Co. wells 3 and 1).

By 1932, the bicarbonate in well 34K1 had decreased to about 150 ppm; well 34A1 remained about the same through the period of record. Since about 1940, well 34K1 has shown an increase in bicarbonate to almost 200 ppm. The loss in bicarbonate in water from this well is accompanied by a loss of bases, chiefly in calcium and to a minor degree in sodium. It is interesting to note that the bulk of the bicarbonate loss in well 34K1 occurred during a period of very slight chloride increase. A possible explanation of the chemical behavior of this well is that the aquifer tapped by the well was being partly recharged by local rainfall on the sand-dune area. The San Pedro formation here is known to be in local hydraulic contact with the sand-dune deposits (p. 125, pl. 13).

Because the chloride increase in water from well 34K1 has become pronounced since 1945, with no corresponding gain in bicarbonate, it is tentatively concluded that the well is now within the area contaminated by ocean water. Furthermore, because the well is now within the area in which a regional inland gradient exists, it is expected that it soon will yield water unfit for use.

WELL FIELD OF THE CITY OF EL SEGUNDO

PERTINENT GEOLOGIC FEATURES

At the well fields of the city of El Segundo in sec. 12, T. 3 S., R. 15 W., two distinct water-bearing zones in the deposits of Pleistocene age are tapped by wells. Recent deposits here consist solely of sand dunes and are non-water-bearing. The upper of the two Pleistocene aquifers is the "200-foot sand" of the unnamed deposits of upper Pleistocene age; here it ranges from 30 to 40 feet in thickness. The lower aquifer is the Silverado water-bearing zone and ranges from 70 to 140 feet in thickness. At the main well field of the city of El Segundo in 3/15–12L, only the upper 30 to 40 feet of the Silverado water-bearing zone is sufficiently coarse to permit perforation of well casings; the lower part, which is as much as 100 feet thick, consists of fine sand and some silt. In the NE¼ sec. 12, the logs of three municipal wells indicate a much more irregular lithology. Here also, the upper 30 to 40 feet of the Silverado water-bearing zone is permeable sand and gravel; however, in two of the three wells a basal gravel is present which is sufficiently permeable to yield water. The Silverado water-bearing zone is separated from the "200-foot sand" in the upper Pleistocene deposits by an impervious clay layer which is 15 to 40 feet thick. Both aquifers here dip gently southward (pl. 3*C*).

SUMMARY OF NATIVE WATER QUALITY

Inland from the coast, toward the axis of the syncline underlying the Torrance plain (pl. 2), it has been possible to distinguish between the quality of the water in the unnamed upper Pleistocene deposits

and that of the water in the Silverado water-bearing zone beneath, because chemical analyses are available for waters from certain wells tapping the upper zone only and from other wells tapping the Silverado zone only. In sec. 12, T. 3 S., R. 15 W., however, all wells tap both zones and thus yield blends of waters from the two aquifers. Necessarily, therefore, a description of native conditions here will be confined to these blended waters. An analysis of water from well 3/15–12L1, sampled March 4, 1930, is selected as representative of the native water throughout the local extent of the tapped water-bearing zones. From this analysis and from others, made before contamination had become more than incipient, it is inferred that these waters ranged about from 390 to 425 ppm in dissolved solids and contained less than 100 ppm—probably from 85 to 92 ppm—of chloride. The early (1929–30) analyses of water from wells of this field, particularly those from well 12L1, show an interesting fluctuation in sulfate content. For example, the analysis of 12L1 for February 13, 1931, shows that sulfate is absent. Other analyses of water from 12L1 for that period show that sulfate ranged from a trace to 35 ppm.

PROGRESS OF WATER-QUALITY DEPRECIATION

Table 21 lists all the wells drilled by the city of El Segundo and gives their status in 1946. Of the ten wells listed, seven were drilled at the main field near the city's water treatment plant at Grand Avenue and Maryland Street; only two wells, 12L5 and 12L7, were active in 1946. Of the other three wells, two are about 0.4 mile northeast of the main plant, and well 12B1, the latest one drilled, is about 0.2 mile north of the first-mentioned wells. All three are now active. Chloride analyses for wells 12L1, 12L3, and 12L6, plotted

TABLE 21.—*History and chloride content of public-supply wells of the city of El Segundo*

[5] Active in December 1946.

on figure 16, show the development of contamination at the main field. Because of the fluctuation in chloride content for well 12L1 in 1930–31, it is thought that contamination was then incipient; by 1936 the increase in chloride content was positive. However, only in well 12L6 did salinity increase to a degree that made the water unusable. Wells 12L1 and L3 were abandoned because of mechanical difficulties; doubtless, the salinity of the water yielded by these wells would have increased appreciably above the amounts shown on the graph if pumping had been continued.

The two active wells at the main field as of 1946 (nos. 12L5 and 12L7) both yielded water containing more than 200 ppm of chloride at the end of that year. As shown by the graphs (fig. 16), the chloride content was about stable to mid-1946, and then it increased substantially. It is believed that if these wells are pumped almost continuously, within a relatively short time the chloride will increase at an accelerated rate—similar to the increase shown by the graph for well 12L6 in 1944–45 (fig. 16). Both of these active wells tap the same water-bearing zones that are tapped by wells 12L1, L3, and L6 (which were abandoned earlier). As shown later (p. 224), although both water-bearing zones are about equally contaminated, the upper of the two zones may be slightly more saline. Figure 16 also shows the chloride concentration of waters from wells 12G1 and 12G2. In contrast to chloride graphs for wells at the field in 3/15–12L, the graphs for both wells in 12G show a decrease in salinity (to a greater extent in well G2 than in well G1). Well 12G1 yields more water from a stratigraphically lower part of the Silverado water-bearing zone than any other city well. The monthly combined withdrawal for the two wells also has been plotted on figure 16. It will be noted that the chloride decrease has occurred over a period when withdrawals were nearly constant.

CHEMICAL FEATURES OF CONTAMINATION

As described earlier, at the main field of the city of El Segundo the trend of contamination is toward ever-increasing salinity and resultant abandonment of the wells; however, at the more recently developed field to the northeast in 3/15–12G, the trend since about 1941 is toward a decreasing salinity. In well 12G1 the water has almost returned to its native character. For all the wells of the city of El Segundo, the following description treats the manner in which contamination has occurred and suggests a possible source of this contamination. Although the analyses for any single well do not span the entire period of record, a series has been selected arbitrarily to show progressive increase in chloride content. These analyses have been plotted on a trilinear graph (fig. 17) which shows the salinity trend at the main field. Although some departure from a definite

FIGURE 17.—Chemical character of native and progressively contaminated waters at the main well field of the city of El Segundo.

trend occurs, in general, as contamination progresses, the water is enriched chiefly in chloride and in calcium. Inasmuch as no known calcium-chloride contaminant is known to exist locally, it is assumed that the contaminant is a sodium-chloride saline in which base exchange has occurred during blending with the native water.

To determine the source of contamination at this field, use is made of the chloride-bicarbonate ratios of the progressively contaminated waters for which the analyses have been plotted on figure 17. Figure 18 shows these ratios plotted against the chloride content; hypothetical

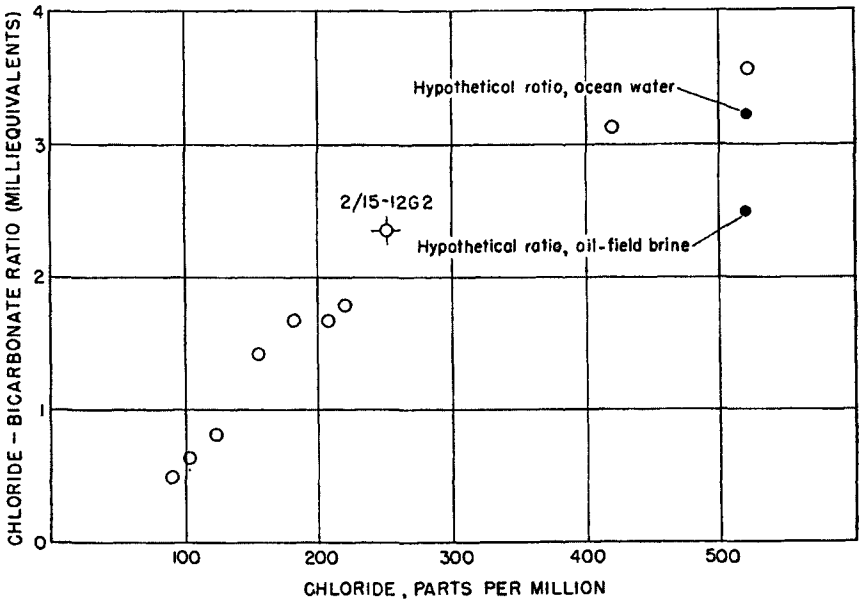

FIGURE 18.—Chloride-bicarbonate ratios of progressively contaminated waters at the main well field of the city of El Segundo.

ratios for a sea-water mixture and an oil-field brine mixture with a native water are plotted also. Sea water is strongly suggested as the source of contamination. That is, for the contaminated water containing 520 ppm of chloride, the Cl–HCO_3 ratio is 3.58; for the ocean-water and brine mixtures with native water, computed to the same chloride concentration, the ratios are 3.21 and 2.49, respectively. The points representing the actual analyses fall on a reasonably well defined curve which approaches the point representing the ocean-water mixtures more closely than that representing the oil-field brine mixture.

The analysis used in computing the hypothetical mixture of brine and native waters was furnished by the Richfield Oil Corp. The water analyzed was from Richfield well El Segundo No. 2 (in 3/14–18G) and was yielded through perforations from 7,243 to 7,319 feet below

the land surface—presumably from rocks of upper Miocene age (pl. 7). The constituents cited below were determined from a sample collected and analyzed by the Richfield Oil Corp. for the Geological Survey; quantities are reported in parts per million (except pH which is reported in percent):

	Parts per million		Parts per million
Silica	81	Chloride	9,390
Iron and aluminum oxides	3	Dissolved solids	24,561
Hydroxyl	0	Suspended solids	207
Carbonate	0	Water soluble organic matter (approx.)	5,300
Bicarbonate	1,946	pH	[1] 7.8
Sulfate	26		

[1] In percent.

Although the trend in chloride-bicarbonate ratios suggests ocean water as the contaminant, the other possible diagnostic constituent, sulfate, is not entirely confirmed by table 22. In the table, the actual sulfate content of the progressively contaminated waters is compared with the sulfate content that would be present if sea water alone had caused the chloride increase. In most of the contaminated waters sulfate is shown to be present in excess; this fact suggests a source of sulfate in addition to that brought in with sea water.

TABLE 22.—*Comparison of actual and hypothetical sulfate content in progressively contaminated waters in the main well field of the city of El Segundo*

Well	Date of sample	Chloride (ppm)	Sulfate (ppm)		Excess (+) or deficiency (−) of sulfate (ppm)
			Actual	Hypothetical [1]

[1] Computed from a hypothetical mixture of sea water and a native water of 14 ppm sulfate, for which mixture the chloride content is identical to that of the actual contaminated water under comparison.

In regard to contamination at wells 12G1 and 12G2, the salinity increase has not yet become sufficiently intense that the source can be identified. It is inferred that the cause of contamination is the same at the two fields. If such is the case, the chemical character of the contaminated waters would be expected to be the same in both areas. As a check on this inference, the analysis of water from well 12G2 for February 7, 1942, has been selected for comparison. This analysis represents the most saline water of record taken from this well. The chloride-bicarbonate ratio for well 12G2 plotted on figure 18 falls close to the generalized curve. The value of 74 ppm for sulfate

is in excess of that brought in by sea water by about the same amount as in the wells in the main field (in 3/15–12L).

For the main field, the Geological Survey in 1945 conducted a series of pumping tests on well 12L6 in order to determine, if possible, which of the two water-bearing zones tapped would yield water of better quality. Figure 19 shows the electrical-conductivity values

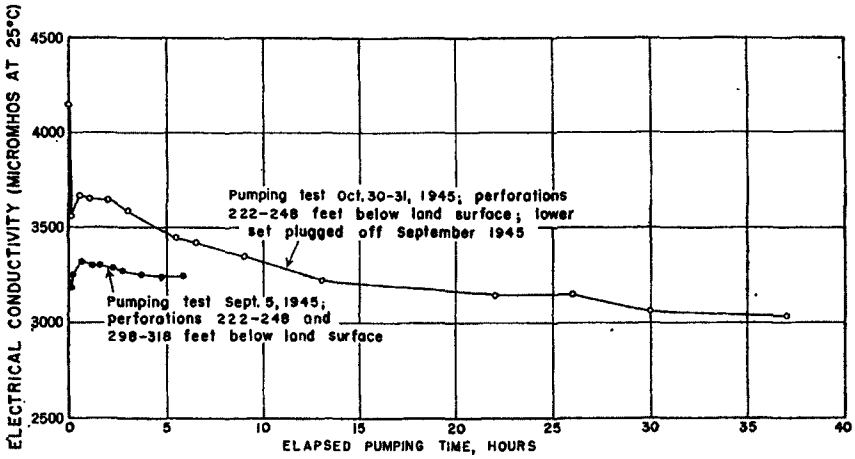

FIGURE 19.—Character of water discharged from well 3/15–12L6 (city of El Segundo, well 7) during pumping tests of September 5 and October 30–31, 1945.

obtained from two separate tests, on September 5 and October 30–31, 1945. During the test on September 5, the well yielded water through perforations from 222 to 248 feet and from 298 to 318 feet below land surface. The lower perforations were then plugged, and during the test of October 30–31 the well yielded water from only the shallower of the two water-bearing zones. The test of September 5 is believed to have been too short for the water from the well to have reached constant quality. During the pumping test of October 30–31 the water yielded initially was poorer but after 13 hours of continuous pumping it was of better quality than that yielded during the short span of the September test. The graphs are not conclusive but the results are included here as a matter of record.

WELL FIELDS OF THE STANDARD OIL CO. AND OF THE GENERAL CHEMICAL CO. AT EL SEGUNDO

The well field of the Standard Oil Co. of California is between El Segundo Boulevard and Rosecrans Avenue and is west of Sepulveda Boulevard, in sec. 13, T. 3 S., R. 15 W. Immediately east of Sepulveda Boulevard, in 3/14–18N, are the wells of the General Chemical Co. These two well fields are treated together here because they tap the same water-bearing zones, and conditions of contamination are common to both.

In this area, wells tap both the "200-foot sand" of upper Pleistocene age and the Silverado water-bearing zone of the San Pedro formation (pl. 3*C*). The "200-foot sand" here is about 20 feet thick, and its top is about 150 feet below the land surface and 50 feet below sea level. Commonly it is separated from the underlying Silverado water-bearing zone by 20–30 feet of impervious silt or clay.

The Silverado water-bearing zone in sec. 13 ranges in over-all thickness from about 150 feet in the northwestern part to about 250 feet in the eastern part (along Sepulveda Boulevard). This thickness includes beds of silt or clay of irregular occurrence. In general, the Silverado zone here spans three more or less distinct parts, which in downward succession are: (1) the principal water-bearing member, which is chiefly sand and gravel and about 100 feet thick; (2) an interbed of silt or clay from 20 to 50 feet thick; and (3) a basal member, which consists of alternating thin layers of sand, gravel, and silt, about 100 feet thick. The bottom of the Silverado zone is about 300 feet below sea level along Sepulveda Boulevard (pl. 2). Logs of wells in 3/15–13D and 14A, about 0.7 mile from the coast, suggest that the basal member grades westward into a layer of nearly uniform silt, and that the thickness of the upper member of the Silverado zone decreases to about 70 feet; the character of the zone here is similar to that at the main well field of Manhattan Beach, 2.4 miles southeast.

SUMMARY OF NATIVE WATER QUALITY

In the "200-foot sand," water is inferred to have been somewhat inferior under native conditions. As of 1903–4, a well in the southeast angle of the intersection of Rosecrans Avenue and Sepulveda Boulevard (Redondo, no. 150), which tapped the "200-foot sand," yielded water containing 630 ppm of dissolved solids. This well was about 1.4 miles inland from the ocean. Because of the comparatively poor quality of water in the "200-foot sand" in this area, it has been tapped by few wells. For the well fields here discussed, only three are known to have yielded water from this zone—wells 3/14–18N3 and 18N4 of the General Chemical Co. and well 3/15–13H1 of the Standard Oil Co. All other wells of these two companies tap solely the Silverado water-bearing zone; some tap the upper part, some the basal part, and some tap both.

In the Silverado water-bearing zone, under native conditions, two somewhat distinct water types existed in sec. 13, T. 3 S., R. 15 W. In the western part of sec. 13 and in the northeastern part of sec. 14, the native water was similar to but perhaps of somewhat poorer quality than that at the city of El Segundo main well field. Both waters contained about 400 ppm of dissolved solids, were calcium, sodium bicarbonate waters and contained substantially equal quan-

tities of chloride; however, the waters at the Standard Oil Co. field may have been somewhat higher in bicarbonate, with a corresponding increase in calcium and sodium. In the eastern part of sec. 13, where nearly all the producing wells of the company are now located, the native water was of somewhat better quality than those described above. These native waters ranged from sodium, calcium bicarbonate to sodium bicarbonate in character and contained from 330 to 375 ppm of dissolved solids and from 50 to 60 ppm of chloride. This difference in quality in the two parts of the field is presumed to result from the deeper penetration of wells in the eastern portion of the section; these waters from the deeper part of the range penetrated agree closely in quality with those that have been yielded from the Silverado water-bearing zone to the east. With respect to sulfate content, a slight difference existed in native waters from the two parts of the field. To the west, they contained about 15 ppm; to the east, the content was probably less than 10 ppm in the upper part and was negligible in the lower part of the range penetrated.

HISTORY OF WELL DRILLING AND ABANDONMENT

Since the first two wells of the Standard Oil Co. were placed in operation in 1914, withdrawal of water from the field has been continuous and has increased in quantity until, as of 1945, the 11 active wells yielded 4,780 acre-feet of water. Table 23 lists the 25 wells drilled by the company before 1946 and shows their status as of January 1946 and the chloride content of their water. For the six producing wells abandoned by 1930, the latest analysis indicated chloride in excess of 200 ppm in each; for the five wells abandoned from 1930 to 1946, only one appears to have yielded water containing more than 200 ppm of chloride at the time of abandonment. At least three of the latter group were abandoned because of mechanical difficulties or gradually diminishing yield. Although the various reports seem inconclusive, it appears that company wells 1 to 8 were abandoned because of excessive salinity. By 1922 salinity became apparent in this area, several years earlier than anywhere else along the coast. For the contaminated but still active wells along the east edge of sec. 13, the salinity increase is only slight; generally an increase in dissolved solids of not more than 25 percent has occurred.

CHEMICAL FEATURES OF CONTAMINATION

A study of the analytical data available for the wells in sec. 13, T. 3 S., R. 15 W., and also for those adjacent to the east, has disclosed that the contaminated waters there are of two general types with respect to change in chemical character and time of such change.

[1] Unites States Geological Survey.
[2] Earliest analysis available.
[3] An analysis is available in which the chloride content is 91 ppm; date of analysis unknown.
[4] Abandoned after construction because of insufficient thickness of water-bearing strata.
[5] Presumed inactive, but status not known definitely.
[6] Presumed active as of Jan. 1, 1946.

1. In several of the earlier wells, notably 3/15–13E1, 13F1, and 14A2, contamination occurred at a comparatively early date and was characterized by a somewhat sudden increase of chloride and sulfate and by an increase in dissolved solids to more than 5,000 ppm.

2. In the wells just west of Sepulveda Boulevard, contamination has occurred to only a slight degree and is characterized by a small increase in chloride, by only a small increase in sulfate, and by a suggested concurrent but irregular decrease in bicarbonate.

These two water types will be described separately and graphs will be presented to show how contamination has occurred in each case.

For the first type, in which sulfate has increased markedly, figure 20 shows the extent to which sulfate and chloride increases are coincident with the advance of contamination. To show that the sulfate content of these waters is more than that which could have been brought in by sea water, figure 21 gives chloride and sulfate analyses plotted graphically for well 13G2, also the hypothetical content of

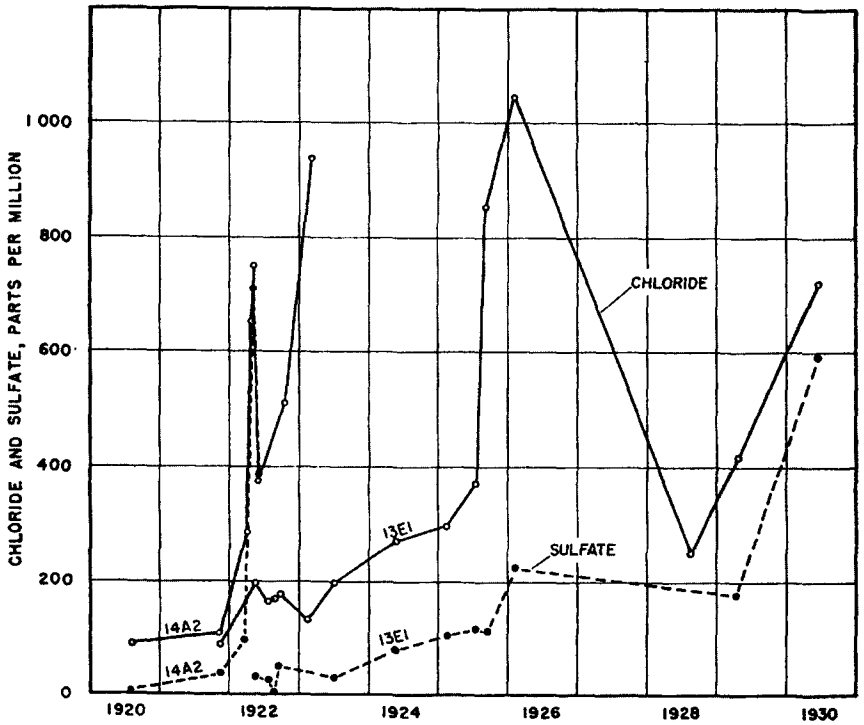

FIGURE 20.—Chloride and sulfate content of progressively contaminated waters from wells 3/15–13E1 and 14A2 (Standard Oil Co. wells 4b and 3).

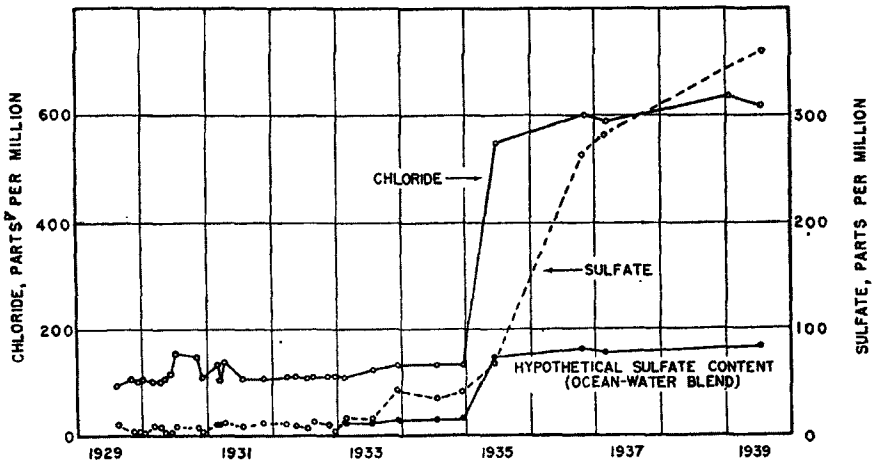

FIGURE 21.—Chloride content and actual and hypothetical sulfate content of progressively contaminated waters from well 3/15–13G2 (Standard Oil Co. well 7).

sulfate in the contaminated water if sea water had been the sole contaminant. The graph for this well shows that sulfate increase began in 1933; definite chloride contamination began in 1935. As of 1939, the increase in sulfate was about five times as great as that which would have been brought in by sea water. Obviously a high-sulfate contaminant must have contributed to the deterioration of the water in these wells.

The Standard Oil Co. conducted pumping tests in 1923, 1929, and 1930, respectively, for three wells that yielded contaminated water at an early date—3/15-14A2, 13F2, and 13E1; a series of water samples was collected from each of the wells until the quality of the effluent became constant. Each well tapped the Silverado water-bearing zone. Figure 22 shows the chloride analyses plotted for the three wells. Presumably, the pump had been idle for several days prior to each test. The following facts are significant:

1. The water yielded initially from each well was highly contaminated, but the water taken in the succeeding samples improved substantially in quality.
2. For each well, the water representative of the Silverado water-bearing zone at the time of the test contained less than 350 ppm of chloride; this water was yielded only after extended pumping—8 hours for well 13E1 and about 160 hours for well 14A2.

Accordingly, it is inferred that the water causing the contamination was coming from a source outside the Silverado zone; and that, while each pump was idle, a relatively small amount of the contaminant moved through the well casing and collected within the Silverado zone immediately outside the well casing. With continued pumping, the supply of concentrated contaminant was exhausted, and the water then yielded indicated the concentration of the regional contaminant in the Silverado zone. If the more concentrated contaminant had been invading the Silverado zone directly, the water quality would have deteriorated or remained about constant during prolonged pumping, because the saline water would have been replenished as rapidly as it was withdrawn. Contamination of this nature has been encountered in Santa Ana Gap and was described in an earlier report (Piper, Garrett, and others, 1953, p. 115–118).

The graph for well 14A2 in 1923 shows a regionally contaminated water containing about 120 ppm of chloride—little more than the native chloride concentration of about 90 ppm. For the three wells, a local source of contamination apparently supplied a small amount of highly saline water; the water yielded after prolonged pumping reflects the regional contamination in the Silverado zone, which contained less than 200 ppm of chloride in the middle twenties and 200 to 400 ppm about 1930. It is inferred that the more concentrated contaminant withdrawn through the wells during the first hours of

460508—59——16

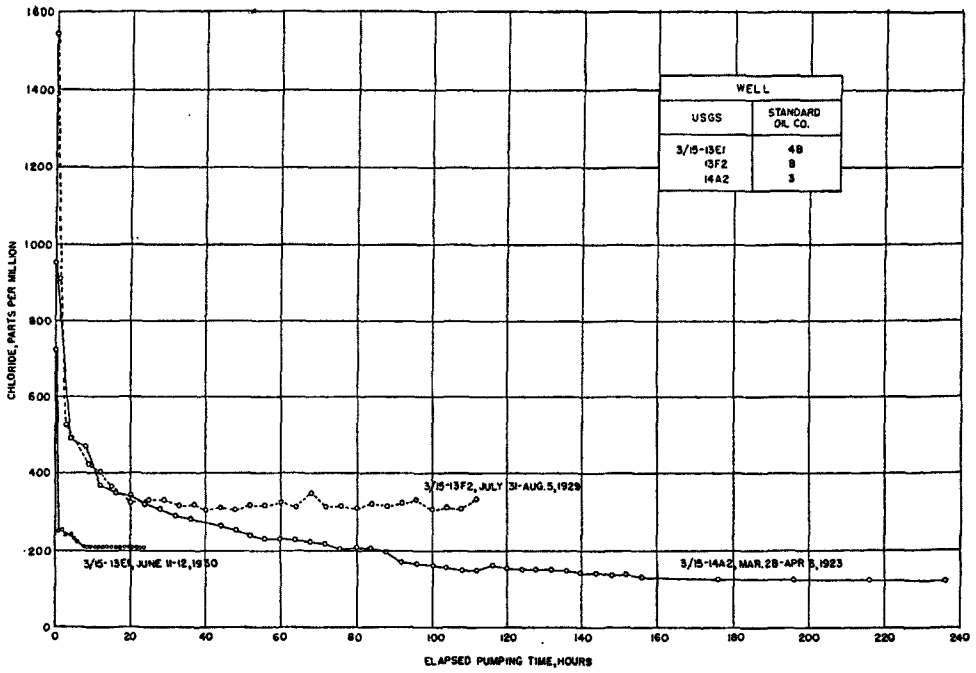

FIGURE 22.—Chloride content of waters from wells 3/15–13E1, 13F2, and 14A2, in relation to duration of pumping.

pumping must have entered the Silverado zone by passing down through the well casings from the overlying "200-foot sand." Because the well casings were not perforated opposite this overlying aquifer, the concentrated contaminant must have entered the casing through leaks.

As a further demonstration of the type of contamination occurring here locally, table 24 compares the contaminated water from well 3/15–13E1 with a hypothetical water formed by a mixture of ocean water and a native water to the same chloride content. The table shows that a large excess of sulfate is present in the contaminated water, also that a large excess of calcium and magnesium is present above that which could be accounted for solely by base exchange following ocean-water contamination. The excess of calcium and magnesium amounts to 14.13 equivalents per million, and is nearly equal to the sulfate excess of 14.26 equivalents per million. Hence, the local contaminant was doubtless a calcium sulfate or calcium, magnesium sulfate water at the time of mixture with the ground water.

TABLE 24.—*Contaminated water from well 3/15–13E1 (Standard Oil Co., well 4b) in comparison with a hypothetical mixture of a presumed native water with ocean water*

For the wells along the eastern boundary of the Standard Oil Co. property, just west of Sepulveda Boulevard, contamination has been far less intensive, and at least three wells—3/15–13H2, J2, and R5—yielded essentially native water as of January 1946. Graphs showing the chloride content of waters from these wells have been presented on figure 23. Wells 3/15–13A1, A2, and A3 all tap essentially the entire thickness of the Silverado water-bearing zone, which here is only about 100 feet thick. The graph for well 13A1 suggests a slight but reasonably consistent increase in chloride from 1931 to 1939; those for

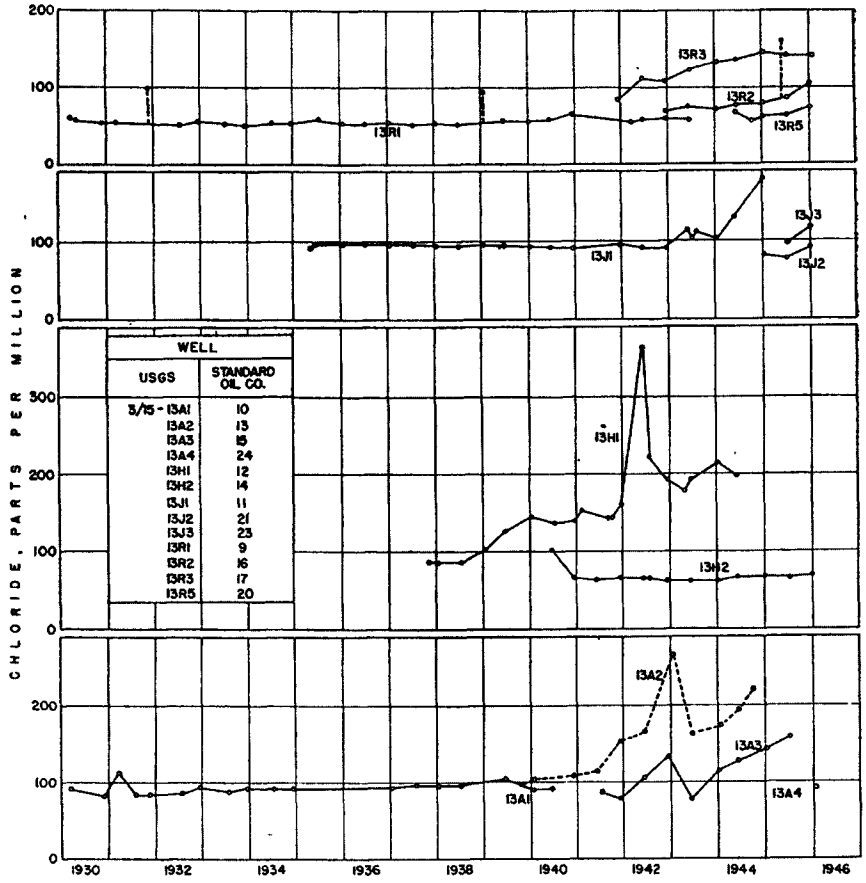

FIGURE 23.—Chloride content of waters from selected wells of the Standard Oil Co. at El Segundo.

wells A2 and A3 indicate a sharp increase in chloride in the early forties. The greatest recorded concentration of chloride for well 13A2—268 ppm—was accompanied by a sulfate content of 66 ppm; this is considerably more than that which could have been brought in with ocean water. For wells 3/15–13H1 and 13H2, the graphs show that definite contamination has occurred at well 13H1, and that well 13H2 yielded essentially native water as of January 1946. Well 13H1 taps the full range of the Silverado zone, and well H2 taps only the basal part. Thus, the contamination here is in the upper part of the Silverado zone.

Of the three wells 3/15–13J1, 13J2, and 13J3, well 13J1 taps the full thickness of the Silverado water-bearing zone, well 13J2 taps the middle part, and well 13J3 taps the middle and lower parts. Well 13J1 became contaminated in 1943, and the other two were incipiently contaminated in January 1946; here, also, the upper part of the Silver-

ado zone is the most saline. Of wells 3/15–13R1, 13R2, 13R3, and 13R5, well 13R1 taps about the middle part of the water-bearing zone, 13R2 taps only the lower part, 13R3 taps the upper part, and 13R5 taps both the middle and lower parts. The water from well 13R3 is the most saline; this fact indicates that here again the water in the upper part of the Silverado zone is markedly of poorer quality than that from the middle and lower parts. Contamination in the upper part of the zone in 13R began in late 1941, and therefore, it is roughly coincident with the onset of contamination adjacent to the north.

To the east, at the property of the General Chemical Co. in 3/14–18N, an analysis of water from well 18N3, in 1930, suggests that here, as to the west, waters contained about 60 ppm of chloride under native conditions. Of the three wells of the General Chemical Co. for which chemical analyses are available, wells 3/14–18N3 (company well 3) and 18N4 (company well 4) tap both the "200-foot sand" in the unnamed upper Pleistocene deposits and the Silverado water-bearing zone beneath. Inferentially, well 18N5 also taps both zones. Because of the low chloride content of water initially yielded from 18N3 (about 60 ppm), that well probably drew most of its water from the Silverado zone and drew a comparatively minor part from the "200-foot sand."

To show the progress of contamination at the well field of the General Chemical Co., chloride determinations on waters from the three wells have been plotted on figure 24. The graph for well 18N3 indicates that contamination here reached a peak in 1940 and since then has decreased markedly; as of January 1946, water from these wells was only very slightly contaminated.

If the graphs of figure 24 are compared with those of figure 23, it will be noted that this contamination peak occurred not only in well 3/14–18N3, but also in wells 3/15–13A2, 13A3, and 13H1, of the Standard Oil Co.; for these latter three wells, however, the peak occurred about in 1942, 2 years later than in well 18N3. This contamination seems to be superimposed on a regional trend toward increasing ground-water salinity which, as of 1945–46, was only moderate. In an attempt to discover whether this superimposed contamination showed a sulfate-chloride pattern similar to that in several of the early wells of the Standard Oil Co. (fig. 21 and p. 231), computations were made to determine, for periods of peak salinity, whether more sulfate had entered the wells than could be accounted for if sea water were the sole contaminant. The data concerning sulfate excess or deficiency for the four wells is given in table 25. The data contained therein indicate that the sulfate content during peak salinity was in excess of that to be expected from an ocean-water blend, and that the sulfate-chloride pattern was essentially

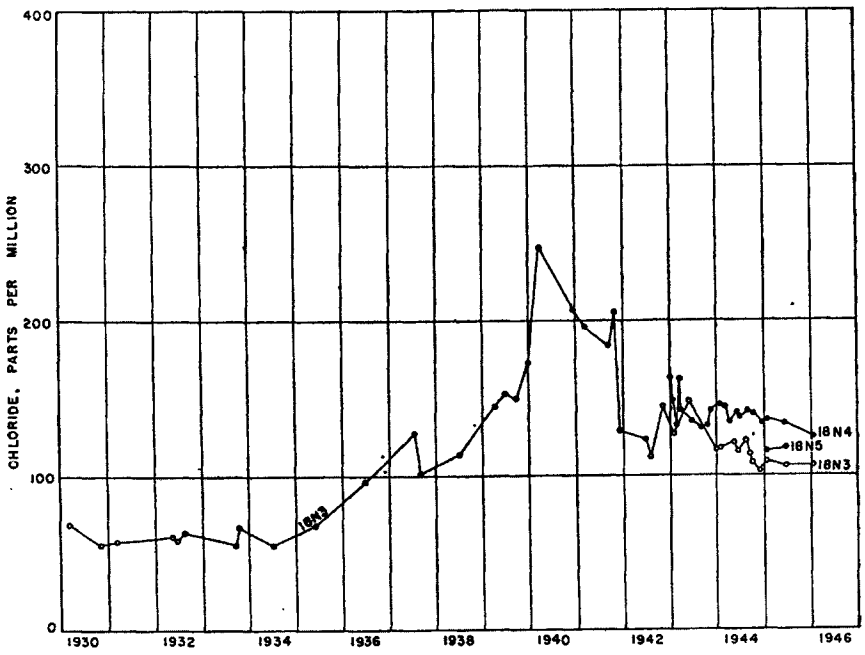

FIGURE 24.—Chloride content of waters from wells 3/14-18N3, 18N4, and 18N5 (General Chemical Co., wells 3, 4, and 5).

similar to that of the earlier contaminant in wells 3/15–13E1 and 14A2, about a mile to the west. For wells 3/15–13A2, A3, and H1 (fig. 23), the chloride peaks of 1942 had essentially disappeared as of mid-1943, and for each well the chloride concentration had returned to the projected normal increase in regional contamination. Furthermore, the abnormal chloride concentration began and ended within a period of 2 years in wells 13A2 and A3 and within one year in well 13H1.

For well 3/14–18N3, the chloride peak of 1940 had essentially disappeared as of 1942. However, as shown by figure 24, the chloride content of waters from the wells of the General Chemical Co. continued to decrease from 1942 into 1946, this fact indicates that the regional contamination front had not yet reached this well field by the end of 1945. Also, as of 1945, the sulfate content of water from the General Chemical Co. wells was only slightly greater than normal; this indicates that the local contaminant has been almost entirely removed or dissipated.

Probably this high-sulfate contaminant is not the cause of the regional contamination, which has progressed much more gradually, and which, for the active wells near Sepulveda Boulevard, has resulted in a maximum concentration only slightly in excess of 200

TABLE 25.—*Sulfate content of contaminated water from certain wells in sec. 18, T. 3 S., R. 14 W., and sec. 13, T. 3 S., R. 15 W., in comparison with hypothetical sulfate content resulting from mixture of a presumed native water with ocean water*

Well	Analysis (parts per million)			Sulfate content resulting from mixture with sea water (parts per million)[1]	Excess (+) or deficiency (−) of the contaminated water with respect to the hypothetical mixture (percent)

[1] Based on a native water with presumed chloride and sulfate content of 60 and 5 ppm, respectively.

ppm of chloride—in wells 3/15–13A2. As for the wells of the city of El Segundo, ocean-water intrusion is inferred to have caused the regional contamination, although the change in chemical character of the contaminated waters from the wells near Sepulveda Boulevard has not been great enough to furnish diagnostic proof of such a source.

The source of the high-sulfate contaminant is not known. However, from the occurrence and movement of this contaminant, as described in previous pages, it is inferred that it originated at or near land surface. If waste water containing sulfuric acid were discharged at land surface, it would be neutralized by downward percolation through the soil zone and surface deposits, and it would pick up calcium and, to a lesser degree, magnesium (p. 231).

From land surface to a depth of about 140 feet, the underlying deposits are permeable dune sand or beach deposits, which rest upon the "200-foot sand" of upper Pleistocene age. Well logs indicate that a bed of silt, 10 to 30 feet thick, underlies the "200-foot sand" and separates it from the Silverado zone beneath. Thus, some of the water discharged at land surface doubtless could have seeped through the dune sand to the "200-foot sand" and could then have moved laterally on top of the subjacent silt bed. The lateral movement would have been in the direction of ground-water flow. Downward movement into the Silverado water-bearing zone would occur only where the silt bed was absent, or where it could move through defective well casings.

It is inferred that the high-sulfate contaminant, which has been described in waters from wells 3/15–13E1, 13F2, and 14A2 (p. 227), was derived by downward percolation to the "200-foot sand" and entered these wells through defective or leaky casings. It is inferred further that between the early twenties and the early forties, this high-sulfate contaminant migrated eastward about 1 mile to wells 3/15–13A2 and 13H1 (company wells 13 and 12). In 1935 the con-

taminant reached well 13G2 (fig. 23). Apparently, the "200-foot sand" is not present at well 13G2, and thus, the high-sulfate contaminant must have migrated into the upper part of the Silverado water-bearing zone before reaching this well. Doubtless at some place west of well 13G2 the "200-foot sand" is in direct hydraulic connection with the upper part of the Silverado zone.

Apparently, at the well field of the General Chemical Co. (3/14–18N) the bulk of contamination has entered the casings from the "200-foot sand," and the underlying Silverado water-bearing zone has been comparatively free of contamination. For example, a series of samples taken June 2, 1943, from well 3/14–18N3, during a 24-hour period of operation after a 3-month shutdown, yielded the following quantities of chloride: At start of test, 760 ppm; after pumping 1 hour, 360 ppm; after pumping 24 hours, 148 ppm. Presumably, a relatively small amount of contaminated water migrated downward through the well casing from the "200-foot sand" to the Silverado zone and was soon removed by pumping. (For a parallel example, see discussion of pumping tests of wells 3/15–13E1 and 14A2 (p. 229).)

WELL FIELD OF THE CITY OF MANHATTAN BEACH

Of the 11 public-supply wells of the city of Manhattan Beach, 6 were drilled in a small tract near the intersection of Eighth Street and Sepulveda Boulevard in the NE¼ sec. 25, T. 3. S., R. 15 W. This tract, initially the only well field of the city, is 0.8 mile from the ocean and 1.3 miles south of the large well field of the Standard Oil Co. at El Segundo. With one exception, these six wells tap only the Silverado water-bearing zone, which here ranges in thickness from 30 feet (well 25H1) to 120 feet (well 25A3). That exception, well 3/15–25H1, taps 14 additional feet of coarse sand, 240 feet below the lower assigned limit of the Silverado water-bearing zone. Well 3/15–30D1 (city well 8), which is about 400 feet east of this well field, also taps the Silverado water-bearing zone.

The "200-foot sand" in the unnamed upper Pleistocene deposits was reported to be present in only one well at the main well field—no. 3/15–25H1 (city well 1)—but it was not tapped by that well. About 1 mile east, logs of three additional wells drilled by the city—wells 3/14–30H1, 30A2, and 29D3 (city wells 9, 10, and 11)—show that there the thickness of the Silverado water-bearing zone ranges from 120 feet in well 30H1 (city well 9) to 250 feet in well 29D3 (city well 11); the "200-foot sand" there has been tapped by well 30H1 but the other two wells tap only the Silverado zone.

SUMMARY OF NATIVE WATER QUALITY

Analyses of water from wells in the main field in 1930 indicate that the water in the Silverado water-bearing zone contained from 70 to

80 ppm of chloride and 20 to 35 ppm of sulfate. It is inferred that this water was essentially native. This inferred native water contained about 250 ppm of bicarbonate and 350 ppm of dissolved solids.

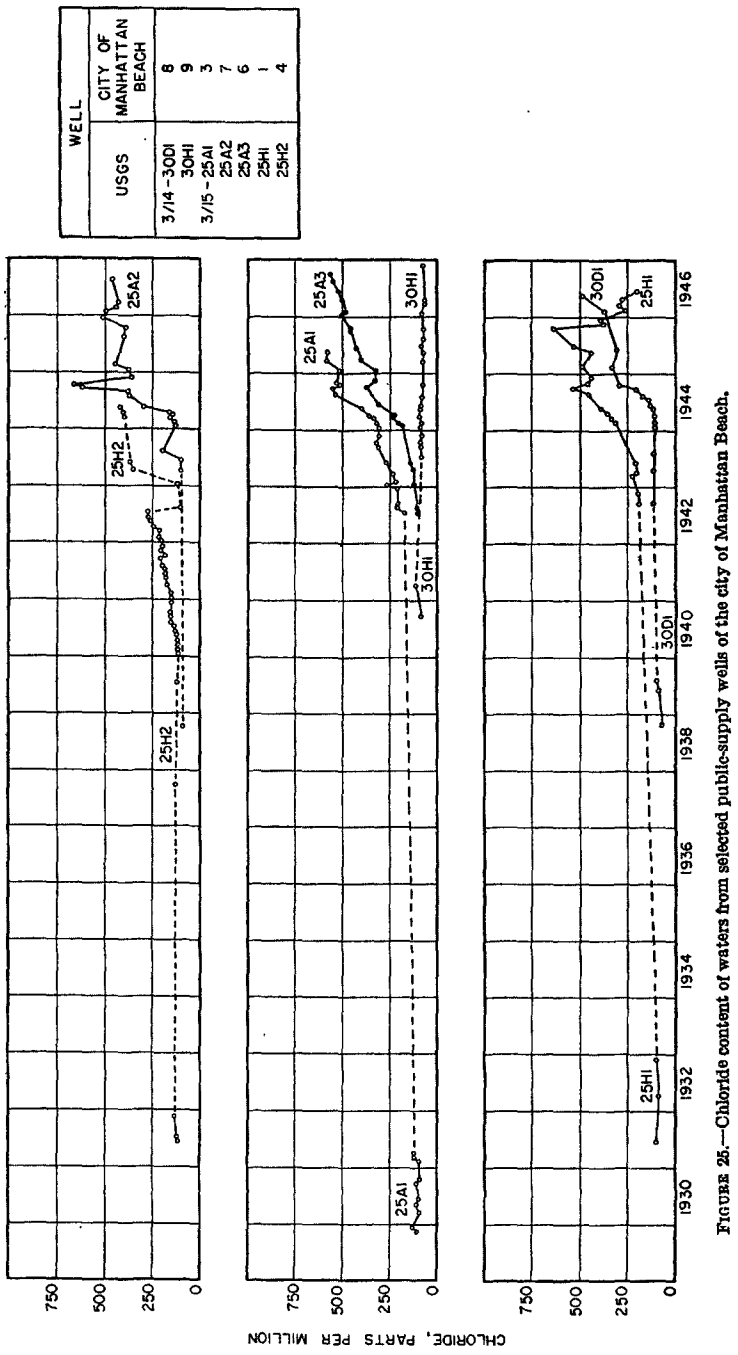
The chloride content of waters from six of the municipal wells has been plotted on figure 25. As shown by this figure, the chloride content of water from well 3/15–25A1 (city well 3) ranged from 76 to 120 ppm from 1929 to 1931; however, definite contamination did not develop until 1940 (in well 25H2). As of 1944, all wells in the main field yielded water containing more than 300 ppm of chloride.

By 1946 only wells 25A2 and A3 at the main field were still being utilized; both yielded water containing about 500 ppm of chloride. The three municipal wells near Aviation Boulevard, however, 3/14–29D3, 30A2, and 30H1, as of 1946 yielded native water of excellent quality. (See table 30.)

CHEMICAL FEATURES OF CONTAMINATION

To show the general change in chemical character of the waters at the main well field because of the progress of contamination, selected analyses have been plotted on figure 26. The graph indicates a trend characteristic of contaminated waters along the seaward margin of the coastal plain—that is, toward an increase in chloride, or chloride and sulfate, and with the ratio of sodium to calcium plus magnesium remaining more or less constant; for high-sodium contaminants, such as ocean water and oil-field brines, this approximately constant ratio could be explained only through ionic readjustment by base exchange. The starting point (well 3/14–30D1, analysis of Oct. 20, 1938) represents a water assumed to be essentially native. As revealed by the analytical data (table 30), the drift toward the apex of the graph has resulted almost entirely from an increase in chloride; sulfate has increased very slightly, and bicarbonate has decreased. The slight increase in sulfate renders unlikely the existence of a high-sulfate contaminant here. Thus, the two possible sources of contamination are oil-well brines and ocean water. The sulfate content of the progressively contaminated waters suggests that of the two sources, ocean water has been the source at this field (fig. 27). On this figure both chloride-bicarbonate and chloride-sulfate ratios have been plotted against the chloride content, as determined from all available complete analyses of the contaminated waters. Also plotted on the graph are the points showing, respectively, blends of an essentially native water with ocean water, and with a typical oil-well brine. The illustration shows two pertinent features:

1. The points representing the chloride-bicarbonate ratios of the well waters fall slightly closer to the line indicating the ocean-water blend than to that of the oil-field brine blend. For waters with chloride content of more than 450 ppm,



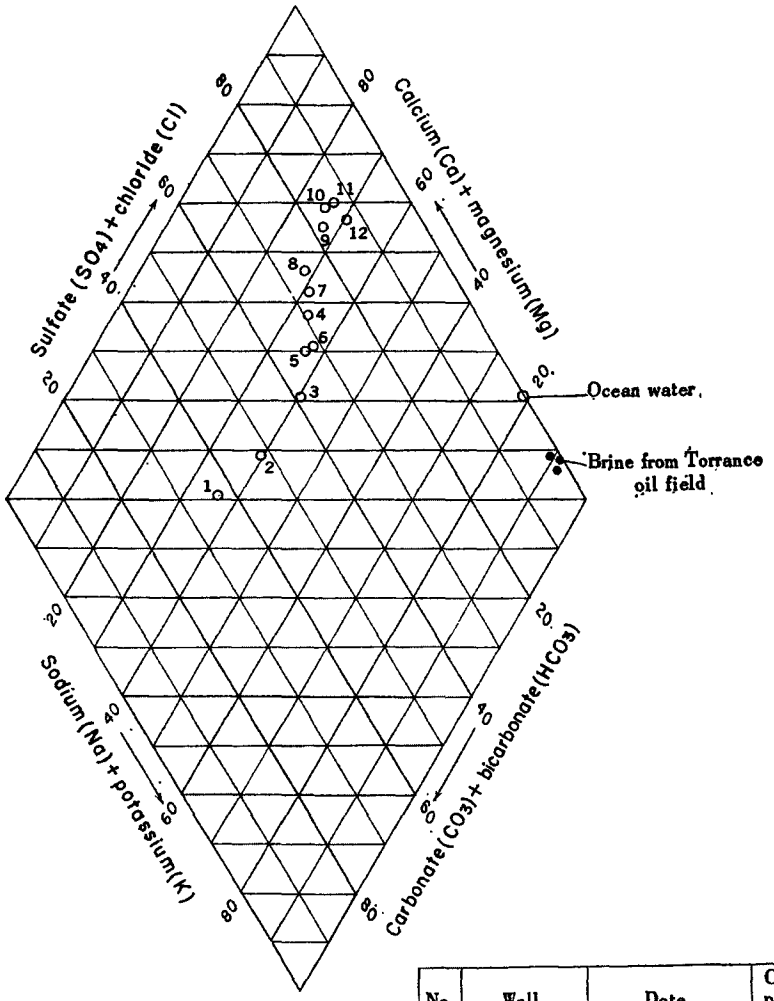


FIGURE 25.—Chloride content of waters from selected public-supply wells of the city of Manhattan Beach.

A-1137

No.	Well	Date	Chloride, parts per million
1	3/14-30D1	Oct. 20, 1938	67
2	30D1	Mar. 31, 1944	111
3	30D1	Aug. 15, 1944	172
4	3/15-25H1	June 11, 1943	203
5	3/14-30D1	Sept. 25, 1944	212

7	30D1	Oct. 29, 1944	303
8	30D1	Feb. 5, 1946	371
9	3/15-25A1	Aug. 15, 1944	545
10	25A1	Sept. 25, 1944	561
11	3/15-25A2	Sept. 15, 1944	631
12	25A2	Sept. 25, 1944	677

FIGURE 26.—Chemical character of contaminated waters from selected public-supply wells of the city of Manhattan Beach.

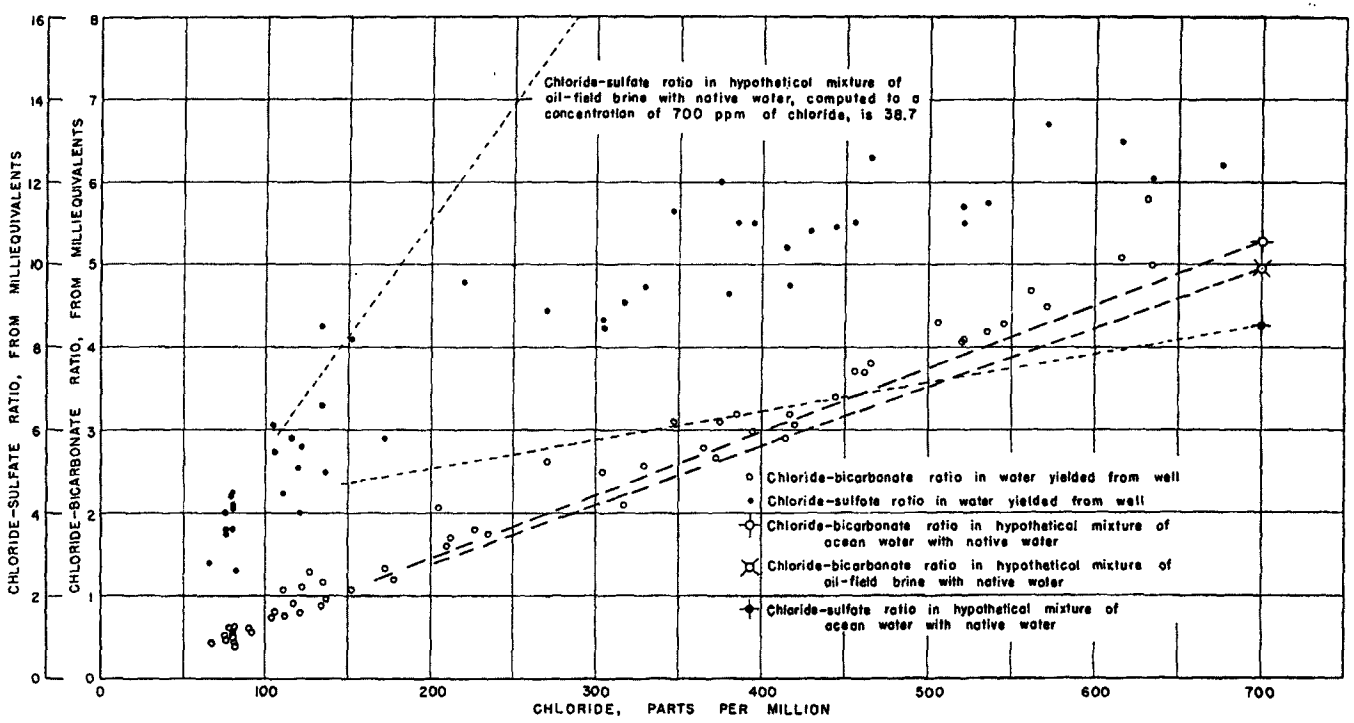

FIGURE 27.—Relationship of chloride, bicarbonate, and sulfate in contaminated waters from public-supply wells of the city of Manhattan Beach.

the digression of the plotted points from the ocean-water blend represents a decrease of bicarbonate amounting to about 7 percent. For the line indicating the oil-field brine blend the loss would have to be about 13 percent. However, this evidence certainly is not diagnostic with respect to selection between the two sources.

2. For values of chloride above 300 ppm the points representing the chloride-sulfate ratios of the well waters are alined much closer to the trend of the line indicating the ocean-water blend than to that of the oil-field brine blend. That is, the contaminated well waters contain much more sulfate than could have been brought in by oil-field brines, but slightly less than the computed amount carried in by ocean water. Of the two features, the chloride-sulfate ratio presents the only definite evidence of ocean-water contamination.

So far as is known from existing analytical data, brines from the western part of the Torrance oil field contain almost as much sulfate as the inferred native water at the main well field of the city of Manhattan Beach. Hence, waters contaminated with such a brine would be expected to show no increase in sulfate with increase in contamination. The analyses of the contaminated waters do show an increase in sulfate; however, this increase is less than that resulting from a simple blend of native water with ocean water, as shown by figure 27. This lack of agreement possibly could be explained to be a result of sulfate reduction if substantiating evidence could be found. However, because of the rapidity with which sulfate reduction may occur and the difficulty of obtaining confirmatory analyses, its occurrence at any given place is necessarily an inferential matter. However, not only does the sulfate content of these waters become greater with increase in contamination, but, as indicated by figure 27, the trend of the chloride-sulfate ratio is about parallel to the hypothetical chloride-sulfate ratio for a simple ocean-water mixture. Thus, it is concluded that ocean water is the contaminant at the Manhattan Beach well field.

VERTICAL RANGE OF CONTAMINATION

As described earlier, all wells at the main field of the city of Manhattan Beach, except well 25H1, yield from a single aquifer—the Silverado water-bearing zone. Well 25H1 taps both the Silverado zone and a 14-foot sand, 240 feet below that zone. In October 1944 and in January 1945, the Geological Survey made conductivity traverses in well 3/15–25H1 to determine: (1) if any range in quality existed between the waters yielded from the two zones; and (2) if any vertical range in quality existed in the water entering the casing through the perforations reported to be 221 to 240 feet below land surface opposite the Silverado zone. The data obtained from those traverses are shown on figure 28, from which the following conclusions have been drawn:

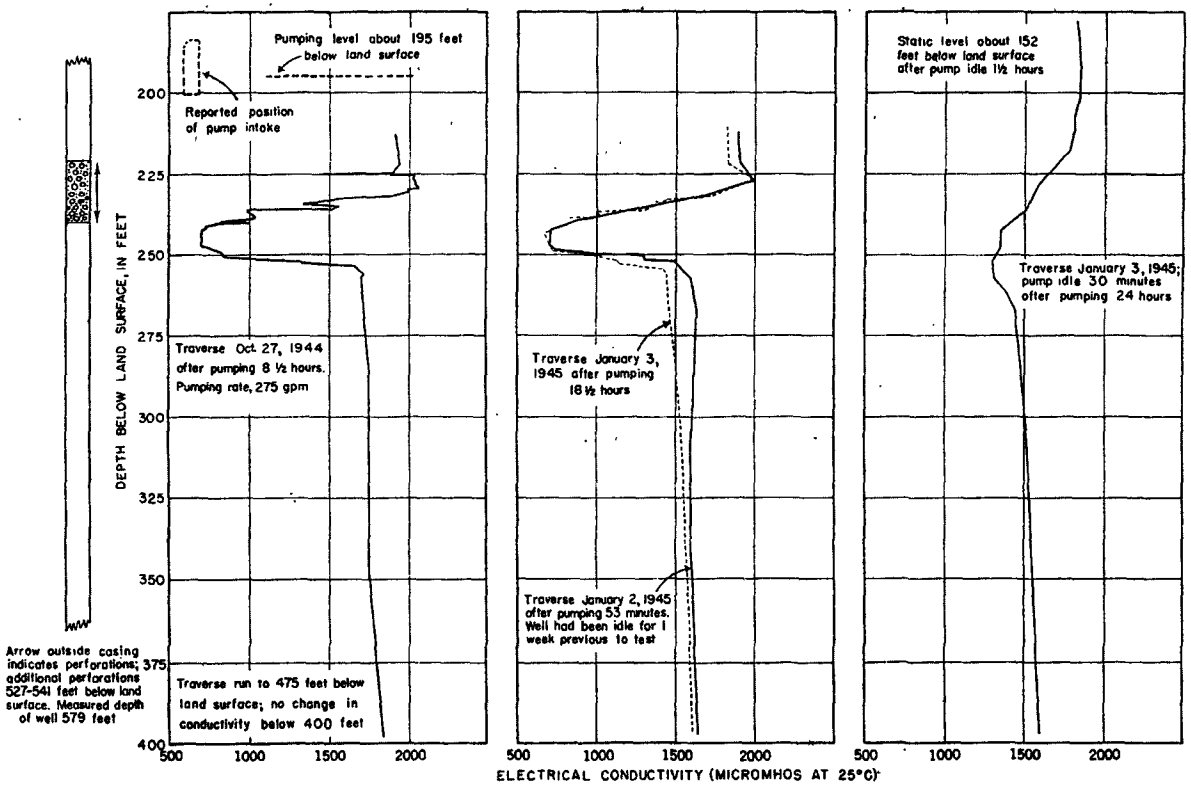

FIGURE 28.—Conductivity traverses in well 3/15-25H1 (city of Manhattan Beach well 1), Oct. 27, 1944, and Jan. 2-3, 1945.

1. The quality of the water from the deeper perforations (527–541 feet) was somewhat better than the water admitted to the pump intake. The amount of water yielded through these perforations was small, probably about 25 gpm.
2. Fresh water entered the well from 248 to 256 feet below land surface; there, the conductivity decreased from about 1,500 to 700 micromhos (dissolved solids about from 900 to 400 ppm). The casing reportedly is not perforated at this depth; thus the water must have entered either through unreported perforations or through a leaking casing.
3. Saline water entered the casing from 230 to 243 feet below land surface. The concentration of this water was indeterminate, but the conductivity was greater than 1,850 (dissolved solids greater than about 1,100 ppm).
4. Under nonpumping conditions, the saline water entering through the perforations 221–240 feet below land surface moved down to displace the fresh water at 248–256 feet and at 527–541 feet. Doubtless this saline fluid not only displaced the water in the casing, but it also invaded these lower water-bearing zones while the pump was idle.

WELLS IN AND NEAR REDONDO BEACH

To the south of 190th Street, near the coast, the Silverado water-bearing zone and the "200-foot sand" cannot be discriminated as separate entities. From here southward to the Palos Verdes Hills, the materials penetrated by wells are permeable throughout nearly their entire thickness (pl. 3*C*). Beneath the dune sand, which extends from land surface about to sea level, the water-bearing material tapped by wells is considered to be within the Silverado water-bearing zone. Wells have penetrated this zone to a depth as great as 400 feet below sea level (well 4/14–17E1 and 5N1). A comparison of drillers' logs of wells in the western part of sec. 8, T. 4 S., R. 14 W., suggests a local division of the Silverado zone into an upper and a lower part, separated by a few tens of feet of clay. Records of water levels in well 4/14–8E1, which taps only the upper part, and in well 8D1, which taps both the upper and lower parts, show little difference in altitude of water level in the two parts from the middle to the late thirties. Since about 1941, however, as shown by measurements at these two wells, the water level in the lower part has been slightly higher than that in the upper. Available chemical analyses suggest some slight difference in quality of water from the two parts; also, even where the separating clayey layer is not present, the deeper water is of appreciably better quality.

SUMMARY OF NATIVE WATER QUALITY

Water of native quality is represented by analyses of water from wells of the California Water Service Co. in sec. 31, T. 3 S., R. 14 W., and from random wells in secs. 5, 8, and 17, T. 4 S., R. 14 W. According to these analyses, the native waters contained 50 to 60 ppm of chloride, and about 300 to 360 ppm of dissolved solids; the sulfate content decreased from north to south. In sec. 31 the sulfate content

of these native waters was about 40 ppm; in sec. 5, from 15 to 12 ppm; in sec. 17, from about 7 ppm to only a trace. The native waters range from sodium, calcium-bicarbonate waters in the northern part of the area to sodium bicarbonate waters in the south. For the central part of the area, the analysis of October 6, 1931 of well 4/14–5N2 (table 30) has been selected to be representative of a native water of good quality. Locally, near the coast, inferior waters existed under native conditions according to early records. For example, by 1908, about half a mile from the coast in 4/14–7J, brackish water containing noticeable quantities of hydrogen sulfide gas was reported at depths of less than 185 feet below land surface. The water below that depth was utilized from about 1905 to 1930 by several public-supply wells of the California Water Service Co. It is reported to have been of good quality until it became contaminated late in the twenties.

PROGRESS OF WATER-QUALITY DEPRECIATION

The earliest known occurrence of water-quality depreciation in the Redondo Beach area is indicated by a series of analyses from well 4/14–6F1, which was drilled in 1912 by the Southern California Edison Co. The chloride content of the water from that well was 79 ppm. By late 1918 the chloride content had increased to 462 ppm. The public-supply wells of the California Water Service Co. in 4/14–7J were abandoned prior to 1931 because of saline contamination. Also, well 4/14–17E1, which was drilled in 1929 and perforated at intervals from 253 to 400 feet below land surface, yielded water containing 404 ppm of chloride in October of that year. Thus, as of 1930, the front of contaminated water extended inland at least 0.8 mile at Redondo Beach.

The general progress of contamination in the Redondo Beach area since 1930 is best shown by the chloride plots for several wells with good analytical records. These have been plotted on figure 29 and include well 4/14–5N2, which, since 1932, has an excellent record of chloride determinations made by the Los Angeles County Flood Control District. Definite contamination in this well began in 1938, and it increased so rapidly that the well was abandoned in 1945. Also plotted on figure 29 are chloride determinations on waters from wells 4/14–8D1 and 8E1, which were badly contaminated when abandoned in 1942 and 1943, respectively; well 8C1, which was incipiently contaminated as of 1946; and well 3/14–31A1, which in mid-1947 still yielded water of excellent quality. The trend of chloride for well 8C1 is anomalous; on the basis of trends shown by the chloride graphs for wells 5N2, 8D1, and 8E1, it would be expected that when the chloride content increased beyond 100 ppm, the slope of the curve would become much steeper and ultimately would result in the abandonment of

Mr. Samuel P. Schuchat, Executive Officer
California State Coastal Conservancy
1330 Broadway, 13th Floor
Oakland, CA 94612-2530

Dear Mr. Schuchat:

Final Report—Audit of California State Coastal Conservancy's Propositions 12, 13, 40, and 50 Bond Funds

The Department of Finance, Office of State Audits and Evaluations, has completed its audit of the California State Coastal Conservancy's (Conservancy) Propositions 12, 13, 40, and 50 bond funds for the period ending June 30, 2008.

The Conservancy's response to the report observations and our evaluation of the response are incorporated into this final report. As requested in the draft report and based on our evaluation of the Conservancy's response, the Conservancy is required to submit a detailed corrective action plan addressing Finding 1. This corrective action plan should be submitted within 60 days from the date of this transmittal.

Please mail your corrective action plan to:

Department of Finance
Office of State Audits and Evaluations
300 Capitol Mall, Suite 801
Sacramento, CA 95814

In accordance with Finance's policy of increased transparency, this report will be placed on our website. Additionally, pursuant to Executive Order S-20-09, please post this report in its entirety to the Reporting Government Transparency website at http://www.transparency.ca.gov/ within five working days of this transmittal.

We appreciate the assistance and cooperation of the Conservancy. If you have any questions regarding this report, please contact Diana Antony, Manager, or Beliz Chappuie, Supervisor, at (916) 322-2985.

Sincerely,

Response 15

Evaluation of Response 26

EXECUTIVE SUMMARY

In accordance with the Department of Finance's (Finance) bond oversight responsibilities, we audited the California State Coastal Conservancy's (Conservancy) funding under Propositions 12, 13, 40, and 50 as of June 30, 2008. The audit objectives were to determine whether bond funds were awarded and expended in compliance with applicable legal requirements and established criteria, and to determine if the Conservancy had adequate project monitoring processes in place. We identified the following control and accountability issues requiring corrective action.

- Since 2001 the Conservancy issued approximately $13 million in bond-funded loans without clear authority or adequate controls. Additionally, approximately $2.9 million in loan repayments have been received and deposited in the Conservancy Fund, which is used for general operations and support funding.

- The Conservancy did not establish formal program guidelines; project awarding criteria; and grant applications to document its project merit review process. Also, the Conservancy website included limited or incomplete information about ongoing programs and efforts, regional priorities, and funding opportunities. Subsequent to our audit, the Conservancy made efforts to address some of these issues.

- The Conservancy's fiscal oversight and monitoring of bond funds needs improvement. Specifically, project scopes and budgets lack detail, match contributions are not enforced, grantees are paid for non-budgeted items, and project monitoring is inconsistent and inadequately documented.

- Bond project status is incomplete and does not fully comply with bond reporting requirements. To address this observation, the Conservancy is developing the Coastal Conservancy Project Management Database to track its projects.

The recommendations in this report are intended to assist management in improving operations and accountability for bond funds.

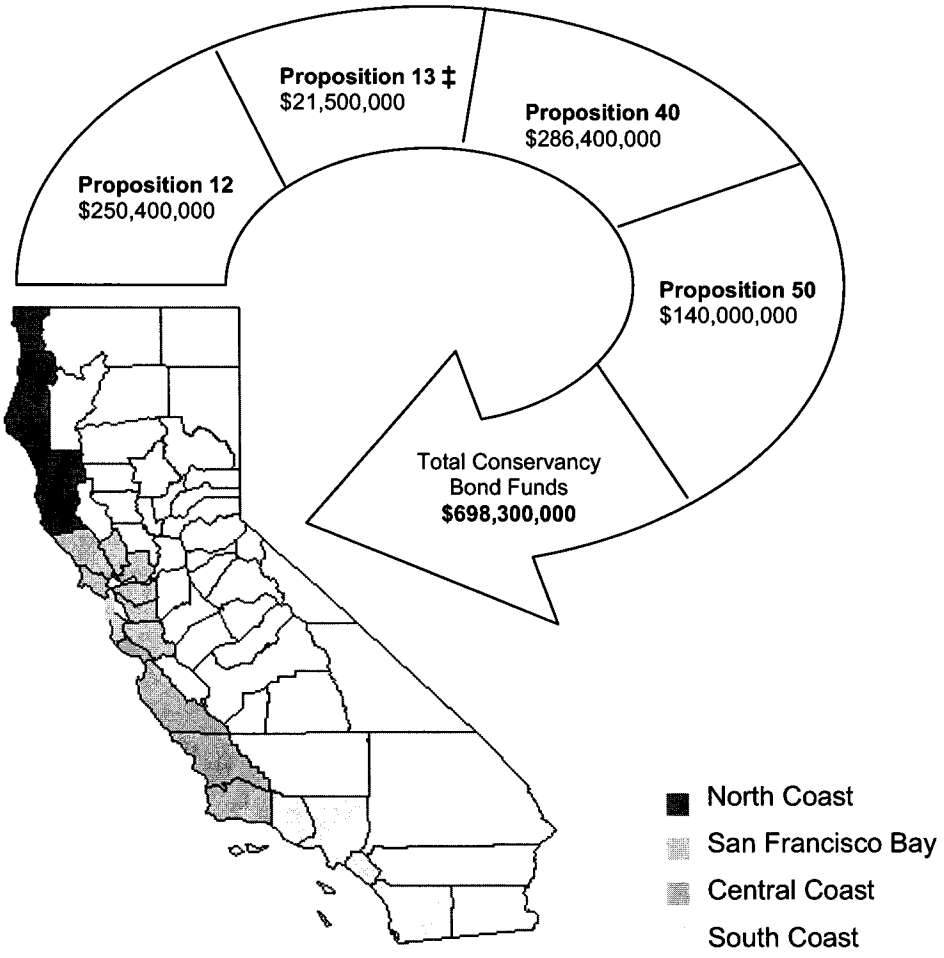
BACKGROUND, SCOPE, AND METHODOLOGY

BACKGROUND

Between March 2000 and November 2002, California voters passed the following four bond measures totaling $10.1 billion:

- Proposition 12—The Safe Neighborhood Parks, Clean Water, Clean Air, and Coastal Protection Bond Act of 2000
- Proposition 13—The Safe Drinking Water, Clean Water, Watershed Protection, and Flood Protection Act
- Proposition 40—The California Clean Water, Clean Air, Safe Neighborhood Parks, and Coastal Protection Act of 2002
- Proposition 50—The Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002

These propositions authorized the sale of bonds to finance a variety of resource programs. Administered by a number of state departments, agencies, boards, and conservancies, the proceeds from these bonds support a broad range of programs that protect, preserve, and improve California's water and air quality, open space, public parks, wildlife habitats, and historical and cultural resources. Bond proceeds are expended directly by the administering departments on various capital outlay projects, and are also disbursed to federal, state, local, and nonprofit entities in the form of grants, contracts, and loans.



California State Coastal Conservancy

The California State Coastal Conservancy (Conservancy) was established in 1976 through Division 21 of the Public Resources Code. The Conservancy's mission is to act with others to preserve, protect, and restore the resources of the California coast, ocean, and the San Francisco Bay Area. Their vision is of a beautiful, restored, and accessible coastline, ocean and San Francisco Bay Area. The Conservancy Board's seven members are appointed by the Governor and California Legislature. The Legislative Oversight Committee meets with the board and participates in its activities. The committee is made up of three members of the Senate and three members of the Assembly.

The Conservancy staff of 77 consists of executive management, program and project managers, legal, and administrative staff. There are four regional program managers directing a staff of 34 project managers, who are responsible for initiating and developing the projects, selecting the grantee and then managing the projects.

In total, the Conservancy administers over $698.3 million in allocated bond funds over four primary state regions as shown in Figure 1.

Figure 1. Propositions 12, 13, 40, and 50 Funds Allocated to the Conservancy as of June 30, 2008

Source: Propositions 12, 13, 40, and 50 Bond Acts.

Notes:

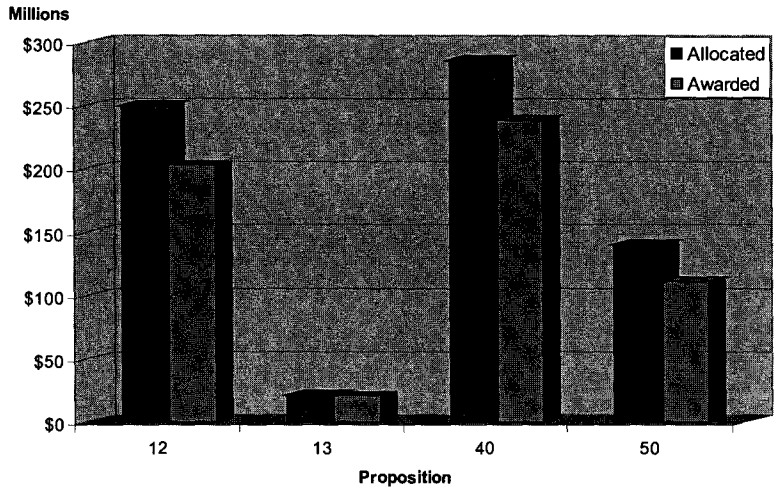
‡ A specific allocation amount of Proposition 13 Bond funds for the Conservancy was not identified. The Conservancy received Proposition 13 funding through the Department of Water Resources' allocation.

Bond Funded Projects

The Conservancy awarded bond funds to various types of projects as defined in the bond act and Conservancy's enabling legislation. These projects are grouped in the four program areas defined in the Conservancy's strategic plan:

1. Public accessways (to and along the shore)—construction of new facilities, repairs to existing facilities, acquisition of land or offers to dedicate real property, development of the coastal trail, and waterfront development and repair.

2. Resource conservation—land acquisitions, natural resource restoration and enhancement, land use conflict resolution, and watershed restoration.



3. San Francisco Bay area conservation—construction of public accessways, natural resource restoration and protection, acquisition of open space and agricultural conservation easements.

4. Ocean program—protection of ocean and coastal resources.

These main program areas are further subdivided into nine sub-programs that correspond to chapters in the enabling legislation and the Ocean Program (see Appendix A).

The Conservancy has awarded $567 million (81 percent) of the $698.3 million allocated from Proposition 12, 13, 40, and 50 as shown in Figure 3.

Figure 3. Bond Funds Allocated* and Awarded as of June 30, 2008

Source: Bond acts and the Conservancy's accounting records.

Notes: *Amounts include statewide costs.

SCOPE

The audit was conducted to determine whether Proposition 12, 13, 40, and 50 bond funds were awarded and expended in compliance with applicable legal requirements and established criteria, and to determine if the Conservancy has adequate project monitoring processes in place. Proposition 84 funds were not included in this audit; however, several programs audited will be receiving Proposition 84 funding. Therefore, because we tested the controls and processes in place for awarding and monitoring under the current programs, the observations and recommendations may be applicable to Proposition 84 programs.

Our review did not include an assessment of the bond authorization, issuance, and sale processes, or an examination of the efficiency or effectiveness of program operations. Further, no assessment was performed on the reasonableness of the land acquisition costs or the conservation value of acquired land or projects completed.

METHODOLOGY

To determine whether bond funds were awarded and expended in compliance with applicable legal requirements and established criteria, and whether the Conservancy had adequate monitoring processes, we performed the following procedures:

- Reviewed applicable bond acts and Conservancy's grant management policies, procedures, including the strategic plan and other legal provisions and regulations.

- Interviewed key personnel responsible for administering bond funds to obtain an understanding of how the Conservancy oversees various project stages: pre-award, award, interim monitoring, closeout, and post-close monitoring.

- Examined a sample of project files to determine if the projects stayed within scope and cost. The sample of projects was selected from two sub-programs; System of Public Accessways and Coastal Resource Enhancement, which represent 52 percent of total bond awards (see Appendix B for list of projects tested).

- Performed nine separate Conservancy grant audits (See Appendix C for list and link to audit reports).

- Identified and assessed the project tracking methods to determine its adequacy for monitoring projects.

- Reviewed a sample of expenditures to verify accuracy of recorded and reported financial information.

- Reviewed the reasonableness of Conservancy's administrative expenditures charged to bond funds.

Multiple discussions were held with the Conservancy throughout our audit fieldwork to discuss and provide specific project review details. Recommendations were developed based on interviews with Conservancy management and key staff directly responsible for administering bond funds and review of documentation made available to us. This audit was conducted during the period December 2008 through April 2009.

Except as noted, this audit was conducted in accordance with *Government Auditing Standards*, issued by the Comptroller General of the United States. In connection with this audit, there are certain disclosures required by *Government Auditing Standards*. Finance is not independent of the audited entity, as both are part of the State of California's Executive Branch. As required by various statutes within the California Government Code, Finance performs certain management and accounting functions. These activities impair independence. However, sufficient safeguards exist for readers of this report to rely on the information contained herein.

The audit identified the following observations requiring corrective action. As noted in the Scope section of this report, although this audit did not include Proposition 84 funding, several programs audited received Proposition 84 funds. Consequently, the following observations and recommendations may also pertain to Proposition 84 programs.

Observation 1: Lack of Accountability Over Bond-Funded Loans

The Conservancy issues bond-funded loans without clear authority or adequate controls. Specifically, the Conservancy's funding agreements include repayment clauses specifying amounts due by a certain date(s); however, the Conservancy classifies these as "grants with repayments" instead of loans. Because loan authority is vested in the legislature (or other rule making body) the Conservancy should cite or obtain legislative authority. In accordance with generally accepted budgetary and accounting principles, we interpret these as loans. The following control weaknesses were noted:

Loan Receivables are Not Recorded
Since 2001 the Conservancy issued approximately $13 million in bond-funded loans without properly recording the outstanding receivables. Although short-term receivables are recorded in the Conservancy Fund (Fund 0565) when the first payment is due, that date in some cases can be as long as 10 years. During that time, the amounts due are manually tracked by contract managers and not recorded in the Conservancy's accounting system.

Based on Conservancy grant audits performed by Finance in March 2010[1], loan repayment terms were inconsistently and inadequately enforced. In two cases, the loan repayments for a $300,000 loan and a $2,000,000 loan were late by over three years and three months, respectively.

The State Administrative Manual (SAM) section 7622 establishes Account No. 2100, Loans and Advances Receivable, as the summary account of long-term loans and advances receivable. The loan accounting entries will depend on the legal authority for the loan, the type of funds involved, and whether the loan will cross fiscal years.

Loan Repayments Recorded as Revenues in Conservancy Fund
Loan repayments are recorded as revenues in Fund 0565 instead of the bond fund of origin. According to the Conservancy, approximately $2.9 million in loan repayments have been received and deposited in Fund 0565. The Conservancy uses Fund 0565 for general operations and support funding.

The Conservancy claims Public Resources Code section 31011 requires it to remit all "funds received" to Fund 565 and establish separate accounts within the fund. However, Government Code section 16303 requires moneys subsequently returned to be credited to the originating appropriation and fund.

[1] See Appendix C for list and link to separately issued grant audit reports.

Therefore, bond loan repayments should be deposited into the bond fund of origin. Additionally, the Conservancy never established separate accounts in Fund 0565 precluding effective identification of bond funds. Because the Conservancy uses Fund 0565 for support-type costs, bond funds are at risk of misuse. For example, during Finance's March 2006 Conservancy bond audit, bond funds were directly charged over $37,000 in ineligible supports costs, including over $10,000 for yoga classes. The Conservancy subsequently repaid the bond funds and moved the costs to Fund 0565.

Proper internal accountability is required to ensure bond funds are separately tracked for future use, reappropriation, or other disposition by the Legislature. Generally accepted budgetary and accounting principles require loan repayments to be deposited into the same fund from which the original loans were made. Without proper recording of loan receivables and repayments, the bond funds are at risk of misappropriation and misuse.

Recommendations:

A. Cite or obtain legislative authority and develop and implement a loan program accordingly.

B. Identify and document all outstanding bond loan receivables. Record bond loans as receivables in the Conservancy's accounting system in accordance with SAM section 7622. Maintain supporting documentation for these amounts.

C. Record bond loan repayments in the bond fund of origin. Discontinue depositing bond loan repayments in Fund 0565. Transfer prior bond loan repayments from Fund 0565 to the bond fund of origin. Maintain supporting documentation for these amounts.

D. Provide a detailed Corrective Action Plan addressing the findings and recommendations within 60 days from the date of this report. The corrective action plan should include milestones and target dates to correct all deficiencies.

Observation 2: Project Awarding Process Needs Improvement

As of June 30, 2008, the Conservancy awarded $567 million in bond funds without established formal program guidelines, specific project awarding criteria, project application forms, or website announcements in place.

The Conservancy does not utilize program specific guidelines and criteria to award bond funds as required by the bond act, the Public Resources Code Division 21, and the Conservancy's enabling legislation. Instead, the Conservancy uses its Strategic Plan as its basis to fund all projects while considering applicable local plans; however, the Strategic Plan is broad and reflects only general requirements applicable to all projects.

General Criteria Used by the Conservancy

- *Promotion of the Conservancy's statutory programs and purposes*
- *Consistency with purposes of the funding source*
- *Public support*
- *Location (must benefit coastal, ocean resources, or the San Francisco Bay region)*
- *Need (desired project or result will not occur without Conservancy participation)*
- *Greater-than-local interest*

Source: Strategic Plan

Additionally, the Conservancy does not have a formal awarding process or a grant applications process to document its project merit review. Without bond-specific program criteria and application review documentation, the merit for selected projects is not transparent.

In awarding projects, the Conservancy works with the Conservancy's partners—public agencies and nongovernmental organizations—to identify potential projects. However, information on the Conservancy website about ongoing programs and efforts, regional priorities, and funding opportunities is limited. Agendas for upcoming Board meetings do not list projects under evaluation and therefore may limit external opportunities for involvement. Additionally, with 34 Conservancy program staff and 4 regional managers performing project reviews, establishing a formalized awarding process is critical to ensure project consistency.

Public Resources Code, Division 21, sections 31205, 31254, and 31303 require "The Conservancy to request the commission, local public agencies, nonprofit organizations, and other public and private groups to assist in the development of *criteria and guidelines for the submission, evaluation, and determination of priority of projects* (coastal restoration, coastal resource enhancement, and urban waterfront restoration). After considering comments received from such sources and ensuring that adequate opportunity for public review and comment has been provided, the *conservancy shall adopt guidelines and criteria for the administration of the coastal program authorized under this chapter.*"

Water Code section 79505.6 (a) (1) states, by March 15, 2004, each state agency disbursing grants or loans pursuant to this division shall develop project solicitation and evaluation guidelines.

Government Code section 13402 states that state agency heads are responsible for the establishment and maintenance of a system or systems of internal accounting and administrative control within their agencies. This responsibility includes documenting the system, communicating system requirements to employees, and assuring that the system is functioning as prescribed and is modified, as appropriate, for changes in conditions.

The Conservancy Strategic Plan states, "The administration, Legislature, academia, interest groups, and the general public need to be informed of programmatic, strategic, and project planning and development, upcoming opportunities for participation, and of the outcomes of these projects and other decisions."

Subsequent to this audit, the Conservancy recently made several efforts to address some of these issues, including grant applications and project selection criteria posted to its website.

Recommendations:

A. Develop program specific guidelines and criteria outlining the submission, evaluation, and project priority process and determinations.

B. Publish the above guidelines and funding opportunities on the Conservancy website.

C. Document merit review activities clearly indicating how projects meet the program's established awarding criteria.

D. Provide related staff training.

Observation 3: Project Matching Funds May Not be Maximized

The Conservancy does not enforce or monitor grantees' required match contributions. For 12 projects reviewed, grant budgets and work plans indicated total available match contributions of over $7.3 million. For example, grant agreements for two of the projects reviewed, California State University at Monterey Bay and City of Pacifica, specifically stated, "Conservancy funds shall not be disbursed until matching funds are committed"; however, the Conservancy never verified the match contribution.

Additionally, although staff project recommendations indicate match contributions, the final grant agreements and work plans do not consistently include the match requirement language. Most state departments require grantees to report match contributions via the reimbursement request forms. This allows the department to monitor and confirm grantee's match contributions. The Conservancy Request for Disbursement form does not require match reporting.

Public Resources Code section 5096.651 requires priority be given to projects with a match contribution. In addition, the Conservancy's 2007 Strategic Plan (see text box above) identified the match need and assumed Conservancy funds would be matched by at least 2 to 1.

Matching Funds Priority

"The Conservancy's recently completed Five-Year Capital Infrastructure Plan for fiscal years 2008-09 to 2012-13 identified a need for approximately two times the dollar amount assumed to be available to the Conservancy. Additionally, like this strategic plan, it also assumes the Conservancy's funds will be matched by at least 2–1."

Source: Conservancy Strategic Plan

Recommendation: Monitor and verify match contributions prior to disbursement. Include a match reporting section in the reimbursement request form and require submission of match documentation.

Observation 4: Project Fiscal Oversight Needs Improvement

The Conservancy lacks adequate project fiscal oversight. Based on a review of 12 projects, the following control weaknesses were noted:

- *Detailed work plans and budgets are not consistently received or documented prior to project commencement.* The Conservancy awards projects based on estimated scope and costs with the condition that detailed work plans and budgets will be submitted and approved prior to commencing project work. However, based on a review of 12 projects, 3 of 12 detailed work plans and 5 of 12 expenditure budgets were missing. Without clearly defined scopes and budgets, the Conservancy's ability to monitor projects and ensure successful completion is at risk.

  State Contracting Manual defines scope as, "The work, service, or product to be performed, rendered, or provided. Clear and concise language must be used to describe the scope."

- *Grantee reimbursements are not consistent with grant budgets.* Based on an audit performed by Finance in 2010 of Sonoma Land Trust, Sears Point Grant, the grantee was reimbursed for $58,862 in overhead costs.

Overhead was not a grant approved budget line item. In addition, the grantee billed and was reimbursed for *budgeted* salary rates instead of *actual* salary cost. Half-way through the contract term, the total markup was $22,775 over actual costs. (See Appendix C for link to grant audit report.)

Grant agreements require grantees to submit a Request for Disbursement form with supporting documentation. However, the Conservancy allows grantees to use their own invoices, which do not always reflect budgeted items. Consequently, the claimed costs are not consistent with the approved budgets.

- *The Conservancy lacks formal monitoring procedures leading to inconsistent reviews and limited documentation.* Project managers are responsible for performing site visits of restoration, enhancement, and public access projects to ensure projects stay within scope and cost; however, there is no guidance defining required site visit intervals, areas to review, or documentation required.

  During the review of the Malibu Lagoon Restoration project, documentation was limited and the project manager was unable to provide adequate justification for the project's eight amendments that modified the scope and increased total funding from $300,000 to $925,259. Additionally, although the file included a detailed budget for the initial award, the subsequent amendments included only lump sum amounts providing little to no justification for the 208 percent funding increase. The project manager was not in charge during the amendment approvals.

- *Post-close monitoring is not performed.* Once a project is closed, the post-monitoring requirement is intended to ensure the project is adequately maintained as specified in the grant agreement. Two of four closed projects reviewed lacked a project monitoring plan. The Conservancy acknowledged post monitoring is not being performed or documented on a consistent basis. The Conservancy relies on grantees, other state agencies, or non-profits in the area to alert them about project issues. Although Conservancy grant agreements include early termination for failure to perform and notification in the case of a change in ownership, these are defensive measures. The Conservancy should be proactive. Other state agencies require long-term management plans with periodic condition reports, including site photos.

- *Project status is inaccurate and incomplete.* A comparison of accounting records with reported project status[2] indicated a difference of over $172 million in project awards. Public Resources Code section 5096.686 and Water Code section 79575 require annual project and expenditure summary reports. According to the Conservancy, the website has not been updated due to limited staffing resources; however, they are in the process of developing the Coastal Project Management Database to track its projects.

Recommendations:

A. Develop a standard application with workplan/budget templates including directions on how to complete it. Define the level of detail needed for different project types to ensure consistency among the program staff.

B. Standardize reimbursement forms to match the approved grant budgets. Include template in program guidelines along with clear definition of eligible costs.

[2] Project status is posted on Natural Resource Agency's "Proposition 40/50 Awards Website".

C. Develop and implement monitoring procedures outlining site visit intervals, areas to review, and project documentation required.

D. Require grantees to submit a maintenance and operation plan at project close-out and require periodic project condition reports.

E. At year-end, reconcile project database information to accounting records to ensure all bond projects are accurately recorded. Complete the Coastal Project Management Database and update the website accordingly.

F. Provide related staff training.

California State Coastal Conservancy's Sub-Programs

Public Resources Code section	Program Name	Program Purpose
31119(a)	Coastal Education	To undertake educational projects for pupils in kindergarten to grade 12, relating to the preservation, protection, enhancement, and maintenance of coastal resources.
31150-31156	Preservation of Agricultural Lands	For the purpose of acquiring fee title, development rights, easements, or other interests in land and undertaking improvements to and development of lands located in the coastal zone in order to prevent loss of agricultural land to other uses and to assemble agricultural lands into parcels of adequate size permitting continued agricultural production. All feasible action will be taken to return to private use or ownership all lands acquired, with appropriate use restrictions.
31160-31165	San Francisco Bay Area Conservancy Program	The Conservancy may undertake projects and award grants to the nine counties of the San Francisco Bay Area that will help achieve the following goals: • To improve public access to, within, and around the bay, coast, ridgetops, and urban open spaces, without having a significant adverse impact on agricultural operations and environmentally sensitive areas and wildlife through completion and operation of regional bay, coast, water, and ridge trail systems, and local trails connecting to population centers and public facilities, and through preservation of related facilities. • To protect, restore, and enhance watersheds, scenic areas, natural habitats, connecting corridors, and other open-space resources of regional importance. • To assist in the implementation of the policies and programs of the California Coastal Act of 1976, the San Francisco Bay Plan, and other adopted plans. • To promote, assist, and enhance projects that provide open space and natural areas that are accessible for recreational and educational purposes.
31200-32215	Coastal Restoration Projects	For the purpose of restoration of areas of the coastal zone that, because of scattered ownerships, poor lot layout, inadequate park and open space, incompatible land uses, or other conditions, are adversely affecting the coastal environment or impeding orderly development. Grants shall be utilized to assemble parcels of land within designated coastal restoration areas, for the redesign of those areas, and installation of public improvements required for those areas.
31220	Integrated Coastal and Marine Resource Protection	To improve and protect coastal and marine water quality and habitats, the Conservancy may undertake coastal watershed, coastal and marine habitat water quality, sediment management, and living marine resources protection and restoration projects. In consultation with the State Water Resources Control Board, the Conservancy will develop projects consistent with Public Resources Code section 30915, which provides approval for projects that restore and protect the water quality and environment of coastal waters, estuaries, bays, and near shore waters.
31251-31270	Coastal Resource Enhancement Projects	For the purpose of enhancement of coastal resources that, because of indiscriminate dredging or filling, improper location of improvements, natural or human-induced events, or incompatible land uses, have suffered loss of natural and scenic values. Assembly of parcels of land is used to improve resource management, relocation of improperly located or designed improvements, and for other corrective measures to enhance the natural and scenic character of the areas.
31300-31316	Urban Waterfront Restoration	To promote the restoration of the state's vital urban waterfronts by developing environmentally sound areas through the creation of parks, open space, visitor serving facilities, and housing for all income levels will promote tourism, public access, and private sector development.
31350-31356	Reservation of Significant Coastal Resource Areas	The Conservancy is vested with the authority to acquire, hold, protect, and use interests in key coastal resource lands to assure coastal resource sites shall be reserved for public.
31400-31410	System of Public Accessways	To implement a system of public accessways by acquiring land or any interest therein, or to develop, operate, or manage lands for public access purposes to and along the coast.
35500-35650	California Ocean Protection Act	To ensure that California maintains healthy, resilient, and productive ocean and coastal ecosystems for the benefit of current and future generations.

List of Projects Reviewed at State Coastal Conservancy

#	Grantee Name	Project Name	Amount	Program	Public Resources Code
1	California State University Monterey Bay Foundation	Santa Barbara Channel Marine Mapping Project	$400,000	Integrated Coastal and Marine Resource Protection	Division 26 Chapter 1
2	Cambria Community Services District	East West Ranch Coastal Trail Improvements	$345,000	System of Public Accessways	Division 21 Chapter 9
3	City of Malibu	Malibu Civic Center Stormwater Improvement Project	$1,000,000	Resource Enhancement	Division 21 Chapter 6
4	City of Pacifica	San Pedro Creek Watershed: Capistrano Bridge Fish Passage Improvements	$545,000	Resource Enhancement	Division 21 Chapter 6
5	County of Humboldt	Humboldt Fish Passage Improvement Program	$594,272	Resource Enhancement	Division 21 Chapter 6
6	County of Santa Barbara	Isla Vista Beach Accessway Improvements (stair reconstruction)	$250,000	System of Public Accessways	Division 21 Chapter 9
7	Gold Ridge Resource Conservation District	Salmon Creek Ranch Implementation	$610,000	Resource Enhancement	Division 21 Chapter 6
8	Mendocino Land Trust	Mendocino Coastal Trail Program, Phase 1	$200,000	System of Public Accessways	Division 21 Chapter 5
9	Peninsula Open Space Trust	Pillar Point Bluff Coastal Trail	$433,550	System of Public Accessways	Division 21 Chapter 9
10	Resource Conservation District of the Santa Monica Mountains	Malibu Lagoon Restoration	$4,316,800	Resource Enhancement	Division 21 Chapter 6
11	Smith River Alliance, Inc.	Mill Creek Implementation Phase I	$1,000,000	Resource Enhancement	Division 21 Chapter 5.5
12	Sonoma Land Trust	Estero Americano Nature Preserve Enhancement	$45,965	Resource Enhancement	Division 21 Chapter 5.5
		Total	**$9,740,587**

Coastal Conservancy

October 7, 2010

Mr. David Botelho, CPA
Chief, Office of State Audits and Evaluations
915 L Street
Sacramento, CA 95814-3706

RE: An Audit of State Bond Fund – California State Coastal Conservancy Propositions 12, 13, 40, and 50

Dear Mr. Botelho:

This is the California State Coastal Conservancy's ("Conservancy's") official response to the above referenced audit report. We found few surprises in the document, having had numerous conversations with your staff during the audit process. We appreciated their openness and professionalism. While we have disagreements about some of the report's conclusions and recommendations, in several areas we are in general agreement and have either begun or completed corrective actions. We respond below to the report as it is organized, with brief overall comments on the four major issues described in the Executive Summary, and with longer discussions for specific issues and recommendations.

Executive Summary Observations

Observation 1: The Conservancy has made loans without proper authority and has deposited returned funds into the Coastal Conservancy Fund instead of the bond fund of origin.

Response to Observation 1: There is specific unambiguous language in Division 21 of the Public Resources Code authorizing the Conservancy to seek repayments of grants (Public Resources Code section 31118). The same legislative bill through which that statute enacted was enacted also amended section 31101 to require that funds received by the Conservancy be deposited in the State Coastal Conservancy Fund (Fund 0565).

Observation 2: The Conservancy does not have formal program guidelines; project awarding criteria; and grant applications. The Conservancy's website has limited or incomplete information about ongoing efforts, regional priorities, and funding opportunities.

1330 Broadway, 13th Floor
Oakland, California 94612-2512
510·286·1015 Fax: 510·286·0470

Response to Observation 2: The Conservancy has had project selection guidelines for many years and periodically updates them. In response to the audit, the Conservancy has recently standardized its grant application among its regions. The Conservancy website has been updated to include the standardized grant application, more information about funding opportunities, and additional information about ongoing efforts will be added. In addition, the Conservancy has a Strategic Plan (Plan) that has been posted on its website and guides the development and funding of projects according to the Plans' goals.

Observation 3: Fiscal oversight and monitoring of bond funds needs improvement. Project scopes and budget lack detail, match contributions are not enforced, grantees are paid for non-budgeted items, and project monitoring is inconsistent and inadequately documented.

Response to Observation 3: We disagree that there is an endemic problem with the detailing of project scopes and budgets or paying for non-budgeted items. The audit is vague about the nature of this assertion and any problems that have arisen.

Non-budgeted items: The Conservancy does not pay invoices unless they are consistent with a work program and budget in the corresponding grant-agreement file. This issue identified in this audit appears to arise from a particular project in which a negotiated overhead rate was authorized but was not sufficiently documented in the agreement. This was a rare occurrence and in no way resulted in inappropriate use of funds.

Matching funds: The auditors misunderstood the nature of matching funds. For most projects the Conservancy did not require specific matching amounts, only that the project had sufficient resources for completion. Thus, there were no specific matching requirements to be enforced.

Project monitoring: We are improving post-project monitoring. The Conservancy has developed standardized post-project monitoring requirements that can be tracked and recorded in the Conservancy's project database and will begin staff training to implement its post project monitoring program this fall.

Observation 4: Bond project status is incomplete and does not fully comply with bond reporting requirements.

Response to Observation 4: We have developed a process for project managers to document project status when processing invoices. We are working to complete all required bond reporting.

Detailed Observations and Responses

Observation 1: Lack of Accountability Over Bond-Funded Loans: The Conservancy issues loans without clear authority or adequate controls. The Conservancy classifies its loans as "grants with repayments." These are actually loans made with unclear authority.

Detailed Response: Chapter 1551, Statutes of 1984, in adding Public Resources Code section 31118 to the Conservancy's enabling legislation, clearly authorizes the Conservancy to "seek repayments of funds granted pursuant to this division on terms and conditions as it deems appropriate to carry out the provisions of this division." Conservancy staff worked directly with the author of the bill on this and other provisions it contained. The purpose of this section of law is to authorize the Conservancy to make its grants repayable when warranted. This practice, as carried out by the Conservancy over the years since is clearly authorized, and no additional authorization is needed.

Loan Receivables are Not Recorded: Repayable grants should be considered loans and should be recorded within the Conservancy's accounting system. Loans are currently tracked by contract managers not the accounting department. This has led to some loan repayments becoming overdue.

Detailed response: The payback provisions in some grants do not make them loans requiring that they be recorded as loans receivable. Many of the repayment provisions are conditional. Repayments may be required in some cases if property is sold, or if expected matching funds come through or if there is revenue of some kind associated with the project for which the grant was originally made. There are very few of these repayable grants to begin with. While the current system using the contract manager and project manager to enforce the payback provisions has worked in general, in some cases, for various reasons, public agencies and nonprofit organizations have not been able to repay portions of grants. In order to ensure centralization of the grant-repayment function, we will direct our contracts unit to bill grantees in accordance with the repayment schedule in the grant agreement. Copies of the billing will be provided to the contract manager and to the accounting unit, and follow up will be made if payment is not received within a timely manner.

Loan Repayments Recorded as Revenues in Conservancy Fund: Instead of putting repaid funds into the bond fund of origin the Conservancy has deposited these funds in the Coastal Conservancy Fund. This fund is used for general operations and support. The Conservancy claims that Section 31011 of the Public Resources Code requires it to place repaid funds into the Coastal Conservancy Fund, but Government Code Section 16303 requires that returned funds be credited to the originating appropriation and fund. Because the Conservancy and the Controller have not established separate accounts within the Coastal Conservancy Fund, it is hard to identify what money in that fund should be identified as bond funds. This has led to the improper use of bond funds, most notably $37,000 of support costs, including $10,000 for yoga classes identified in a 2006 audit. These funds had to be returned and other funds used instead.

Detailed response: The Conservancy does not "claim" that Section 31011 of the Public Resources Code requires that it place repaid funds into the Coastal Conservancy Fund. The statute says: "Unless otherwise provided in this division, any funds received by the conservancy pursuant to this division shall be deposited in the State Coastal Conservancy Fund." This section of the Public Resources Code was enacted after the enactment of Government Code Section 16303 and is more specific. Thus, if the two statutes were to conflict, section 31011 would normally prevail.

We strongly disagree that bond funds were misused in that repaid funds were not identified as bond funds. First we disagree that repayments into the Coastal Conservancy Fund should always or perhaps ever be classified as bond funds. But in the unlikely event we are incorrect on this point and repaid funds are classified as bond funds, each of the bond funds that are the subject of this audit allows for their use for state administrative expenses. Additionally, repayments placed in the Coastal Conservancy Fund are subject to appropriation by the Legislature. They cannot be used for administration or any other purpose without the approval of the Governor and Legislature. The practice of putting repayments into the Coastal Conservancy Fund is well known by the Legislature and the Department of Finance and is part of the Conservancy's Long Term Financial Strategy that is updated and discussed by the Conservancy on a yearly basis in a public meeting. Whether repaid funds were returned to a bond appropriation or fund, or to the State Coastal Conservancy Fund, their use for administration was legal and anticipated in the language of the bond acts that generated this money.

The above is true even for the subsidized yoga classes from 2005/06. Rather than dispute that issue at the time it was raised in a previous audit, we decided to switch this expenditure to a non-bond support appropriation. But expenditures for these classes were nothing out of order. They were part of the Conservancy wellness program authorized pursuant to Executive Order W-119-95, which provides in part that core wellness programs, including exercise programs, shall be developed, and that every state department shall dedicate resources to Work Site Health Promotion. Of the $8,360 which paid for these classes, $3,822 was paid by staff contributions, leaving $4,538 as the state's contribution for the $2005/06 fiscal year. It is well documented that exercise provides health benefits, and the cost of yoga to the state is considerably less than other state-recommended options such as subsidies to health club memberships. We consider it inappropriate that the audit brought up this finding from 2006 to justify the position on deposits into the Coastal Conservancy Fund.

Recommendations:

A. Cite or obtain legislative authority and develop and implement a loan program accordingly.

   Response: We have cited what we consider to be unequivocal statutory authority to seek repayments of grant funds.

B. Identify and document all outstanding bond loan receivables. Record bond loans as receivables in the Conservancy's accounting system in accordance with SAM section 7622. Maintain supporting documentation for these amounts.

   Response: We have identified all outstanding bond loan receivables. We believe that we are in compliance with the Conservancy's enabling legislation and applicable Government Codes and SAM sections.

C. Record bond loan repayments in the bond fund of origin. Discontinue depositing bond loan repayments in Fund 0565. Transfer prior bond loan repayments from Fund 0565 to the bond fund of origin. Maintain supporting documentation.

Response: We will continue to follow the law.

D. Provide a corrective action plan.

Response: We will comply with this requirement as detailed above.

Observation 2: Project Awarding Process Needs Improvement: The Conservancy has authorized hundreds of millions of dollars without program guidelines, specific awarding criteria, project application forms, or website announcements in place. The Conservancy does not have a formal awarding process or a grant applications process to document its project merit review. The merit of projects is not transparent. The Conservancy's website does not have sufficient information to tell potential grantees of its priorities and funding opportunities. Projects under development are not included in project agendas. With the high number of Conservancy program staff and managers consistency cannot be ensured without more process for awarding grants. The Conservancy has not followed statutes and its own plans in developing program guidelines.

Detailed response: The Coastal Conservancy has a very successful track record, having funded well over 1,200 projects since its inception. The Conservancy's substantial record of success includes such accomplishments as: helping to protect more than 150,000 acres of wetlands, wildlife habitat, farmland, recreational lands and scenic open space; helping to build over 400 access ways and 100's of miles of trails such as the California Coastal Trail, the San Francisco Bay and Ridge Trails; assisting to complete over 100 urban waterfronts to reclaim properties for recreational use and economic development; and leading the planning and restoration for many complex stakeholder processes including the nationally significant San Francisco Bay Salt Pond Restoration project.

The Conservancy has formally adopted project selection criteria, and a formal, transparent awarding process that follows statute. The Conservancy marries these formal criteria and processes with hands-on involvement with prospective and awarded grantees to encourage innovation and excellence to the extent practicable within each project. The audit suggests problems where they do not exist and are unlikely to arise, and it fails to acknowledge the effectiveness of the processes in place. We assert that this is clearly a case of "if it ain't broke, don't fix it."

The Conservancy long ago formally adopted "Project Selection Criteria" in accordance with the requirements of Division 21, the Conservancy's enabling legislation, and has modified the criteria from time to time, most recently June 4, 2009. The Conservancy uses its project selection criteria, provisions of Division 21, bond-act criteria, Strategic Plan criteria, the occasional Budget Act criteria, and significant public input from stakeholder groups to identify important projects and make funding recommendations.

Conservancy staff is entrepreneurial and geographically arrayed. As directed in Division 21 of the Public Resources Code, the Conservancy works with local and state government officials and nonprofit organizations to develop projects that meet state and regional goals. It generally does not institute grant rounds but instead has an open grant process. Applications can be and are made, and these are considered at any time. There are several advantages to a rolling application process. For example, prospective grantees do not have to prematurely submit an application before a project is adequately developed, and Conservancy staff can provide needed guidance to improve projects before the application is submitted. We believe that this process improves the quality of the applications received and ultimately of the projects that are funded.

These procedures are an efficient process for awarding grants that meets statewide and regional needs. Awards are made at open public hearings. The staff reports are detailed, including the rationale for the project and its priority, how it meets the requirements of the Conservancy's enabling legislation and funding sources, and how it meets both strategic plan goals and project selection guidelines. The public is invited to speak on each project and the Conservancy's board, by public vote, may modify or reject any proposal. This is a very transparent process.

With respect to the form of grant applications, based on discussions with the auditors, we have created a uniform grant application that is posted on our website. There is now more information available to the public concerning priorities and how to apply for funding.

The Conservancy has followed applicable statutes in the development of project selection criteria, the development of a strategic plan and five-year infrastructure plan, and in its compliance with bond act requirements. Proposition 50 requires new guidelines to be developed unless guidelines already exist that are sufficient. Conservancy guidelines predate the passage of this bond act. The bond act's sponsors were aware of the existence of the Conservancy's guidelines and placed the language in the measure in part so that the Conservancy did not have to develop new ones.

Recommendations:

A. Develop program specific guidelines and criteria outlining the submission, evaluation, and project priority process and determination.

   Response: We have updated the Conservancy's website with information helpful to potential grantees and have standardized our grant application. Given existing project selection criteria, the detailed language authorizing each program contained in Division 21 of the Public Resources Code, the specific language contained in various bond acts, and our strategic and infrastructure plans, we do not believe additional work in this area is warranted or an efficient use of scarce dollars or staff resources.

B. Publish the above guidelines and funding opportunities on the Conservancy website.

Response: The website has been and will continue to be upgraded with new information.

C. Document merit review activities clearly indicating how projects meet the program's established awarding criteria.

Response: This is already done in great detail in our staff reports.

D. Provide related staff training.

Response: Conservancy staff is provided periodic training in-house in both formal and informal settings.

Observation 3: Project Matching Funds May Not be Maximized: In some cases it appears that the Conservancy has required matching funds but either grant contracts and work programs and budgets do not include this requirement, and/or requests for reimbursements do not include a way to track matching funds.

Detailed Response: In general Coastal Conservancy grants require that all funds needed to complete a project are in hand before Conservancy funds may be used. The amount of Conservancy funds in proportion to the overall cost of a project is negotiated prior to the project being brought for final approval by the Conservancy's board.

The Conservancy always seeks to ensure that any project it funds has multiple funding sources. The Conservancy funds a greater portion when applicants have limited funds available for high priority projects, but on balance, our project funds are well leveraged. Between 1987 and 2009, Conservancy funds were matched with non-state funding by nearly 2-1. We will continue to leverage funding to the extent practicable.

The staff reports and resolutions brought to the Conservancy describe the various funding sources that will be used to complete a project, but usually do not require a specific match either in cash or in-kind services. The requirement is that the project be completed, and that Conservancy funds do not surpass a specified amount. The audit mistakenly interprets various sections of staff reports which describe expected sources of funding, as required matching funds. They are not requirements unless specific, mandatory language is included in the resolution approving the Conservancy's grant. As a result of the audit we have adopted more standard "matching fund" language for our staff reports to clarify.

Recommendation: Monitor and verify match contributions prior to disbursement. Include a match reporting section in the reimbursement request form and require submission of match documentation.

Response: Conservancy staff works with grantees before projects begin to ensure that funding is available to complete the project and that the cost estimates for each project are accurate. Our chief goal

is to ensure that the project is completed as described. We are less concerned whether or not a grantee provides a set amount of funds as opposed to in-kind services to get the job done, or whether the grantee changes funding sources during the project. Since we generally do not have set matching fund requirements, there is no value added in requiring documentation other than that detailing that the project has been completed as contracted. This is done through an end audit of each project.

Observation 4: Project Fiscal Oversight Needs Improvement: The Conservancy lacks adequate project fiscal oversight. Based on a review of 12 projects, the following control weaknesses were noted:

The Conservancy does not agree with this finding. The Conservancy received audit reports for only seven of the nine projects listed in Appendix C. Of the $17,855,138 audited in those seven reports, the auditors questioned only $78,645 in expenditures. Upon review, those expenditures were found to be appropriate. The specific contract did not reference an agreed upon rate schedule, and the file lacked complete documentation, but we do not agree that this constituted a lack of adequate fiscal oversight. Nonetheless we have ensured that these corrections have been made since we take our fiscal responsibilities very seriously and we are proud that the vast majority of our project audits have found no problems at all.

Detailed Responses

- Detailed work plans and budgets are not consistently received or documented prior to project commencement.

  Response: Invoices are not paid without detailed work plans and budgets being part of a contract file. Initial review of invoices is conducted by our contract staff, who do not forward them to our project and accounting staff if work plans and budgets are missing.

- Grantee reimbursements are not consistent with grant budgets.

  Response: This issue concerns overhead payments made to the Sonoma Land Trust that the auditors claim were not authorized by the contract. However, as we explained to the auditors in a memo, there was an agreement negotiated between our North Coast Program Manager and the Executive Director of the Land Trust that authorized 15% overhead for all contract items. It is worthwhile to note that this agreement was reached within the context of a larger negotiation, initiated by the Conservancy, regarding the billing rates of the Sonoma Land Trust. This negotiation resulted in a substantial rate reduction, nearly 50% for their Executive Officer and other staff. These negotiated rates were also memorialized in an email, but not transferred to a formal agreement or placed in the contract file. We disagree that overhead payments were not authorized.

- The Conservancy lacks formal monitoring procedures, leading to inconsistent reviews and limited documentation.

  Response: We have now established a project-monitoring process that will be documented in our project database. As for the Malibu Lagoon Restoration project, amendments do not lack documentation. These amendments were authorized by the Conservancy's board. The grant agreement amount was increased to fund subsequent phases of a complex project, not to cover cost overruns, and there is a detailed work program for each amendment.

- Post-close monitoring is not performed.

  Response: Post-close monitoring has been accomplished informally during visits of the project managers to their geographic areas. Most of the conservation easement acquisitions that we have funded already have monitoring requirements. We are now implementing a formal monitoring system for other projects.

- Project status is inaccurate and incomplete.

  Response: As noted, we are behind in entering data into the bond database. This is due to lack of staff resources in part due to required furloughs. Additional resources have been assigned to this task.

Recommendations:

A. Develop a standard application with workplan/budget templates including directions on how to complete it. Define the level of detail needed for different project types to ensure consistency among the program staff.

   Response: We have developed a standard grant application that is now in use. We have templates for workplans and budgets and use them where it makes sense. The Conservancy funds many types of projects, and these templates do not work for all projects.

B. Standardize reimbursement forms to match the approved grant budgets. Include templates in program guidelines along with clear definition of eligible costs.

   Response: We have a standard reimbursement form that has been used for years, and we have now made use of that form mandatory for all projects. We have guidelines related to overhead and indirect costs.

C. Develop and implement monitoring procedures outlining site visit intervals, areas to review, and project documentation required.

Response: We have developed procedures to accomplish this. We are in the process of training staff and implementing these procedures.

D. Require grantees to submit a maintenance and operation plan at project close-out and require periodic project condition reports.

Response: Maintenance and operation requirements are included as conditions of grants or as contract terms when warranted. They are not apposite to all types of projects or needed in all cases. The periodic condition of projects will be monitored through the new process.

E. At year-end, reconcile project database information to accounting records to ensure all bond projects are accurately recorded. Complete the Coastal Project Management Database and update the website accordingly.

Response: This is in process.

Thank you for the opportunity to respond to the audit of Conservancy administered State bond funds.

Sincerely,

Original signed by:

Samuel Schuchat
Executive Officer
California Coastal Conservancy

The Conservancy's response to the draft audit report has been reviewed and incorporated into the final report. In evaluating the response, we provide the following comments:

Observation 1

The Conservancy states that grants with repayment provisions are not considered loans and therefore should not be recorded as a receivable. However, irrespective of the type of financial instrument, loan or grant, the transaction should be recorded as a long-term receivable due and payable to the state within the originating fund. Proper accountability is necessary to ensure bond funds are separately tracked for future use and reappropriation.

In addition, based on subsequent consultation with bond counsel at the State Treasurer's Office (STO) and pursuant to the attached September 11, 2008 memorandum, there could be additional reporting requirements and potential tax implications. We strongly recommend the Conservancy consult with the STO and Finance's Fiscal Systems and Consulting Unit (FSCU) to determine specific recording and reporting requirements.

Please provide us a Corrective Action Plan within 60 days of this report including the final resolution based on consultation with the STO and FSCU.

Observation 2

In response to this finding, the Conservancy created a grant application form and posted it on their website. However, we continue to recommend program-specific guidelines and program-specific criteria for the submission, evaluation, and awarding of grants.

Observation 3

The Conservancy has taken steps to address this observation by clarifying definitions and adopting more standard "matching fund" language for its staff reports. In those instances where match is required, the Conservancy should implement procedures to verify and document matching contributions.

Observation 4

Although the Conservancy does not agree with this finding, it has taken corrective actions. In addition, at the time the draft report was issued, two grant audits were still in progress. To date, all grant audits listed in Appendix C have been completed and issued.

State of California State Treasurer's Office

MEMORANDUM

Date: September 11, 2008

To: General Obligation Bond Program Administrators

From: Geoff Palmertree, Manager
Interim Finance Section
Public Finance Division
State Treasurer's Office

Subject: Returned Grant Funds

Departments that administer grant[1] programs funded by general obligation bonds occasionally have grant funds returned by the grantee. This memo is intended to answer frequently asked questions concerning departments' obligations in such situations.

Should the department notify the State Treasurer's Office (STO)? Yes. The Tax Compliance Certificate executed by each department requires the department to immediately notify the STO when grant funds are returned to the department. Returned grant funds are considered unspent bond proceeds, which must be tracked in order for the State to comply with federal tax law requirements.

What information should the department provide to the STO? The following information should be provided to the STO:

- Date the original grant was made
- Amount of the original grant
- The name of the bond act and the number of the bond fund from which the grant was made
- Date and amount of grant funds returned
- Plan for re-granting the funds

What should the department do with the returned grant funds? The returned grant funds should be placed in the bond fund from which the original grant was made and re-granted as soon as possible. If the returned funds can be re-granted and disbursed within 60 days, the STO will not need to track interest earnings on the funds. If the returned funds are not re-granted and disbursed within 60 days, the STO will engage the State's arbitrage rebate consultant to perform the necessary calculations until the funds are re-granted and disbursed. Please notify the STO of the date on which the funds are re-granted and disbursed.

[1] A grant is a transfer of money for a specific purpose, without any obligation or condition to directly or indirectly repay any amount. However, a condition requiring a grant to be returned if the grantee does not meet the requirement of the grant (e.g., a change in use of the project, or if the project is completed under budget) does not prevent the transfer from being a grant.

Immediately notify the STO if for any reason the department will be unable to re-grant the returned funds.

Should the department establish a written policy regarding re-granting of returned grants? Yes. The STO recommends that the department establish a formal written policy providing that all returned grants will be the first dollars disbursed for other eligible grants so long as the necessary appropriation is in place.

What if the returned grant includes some sort of penalty or is otherwise in excess of the original grant amount? Any returned amount in excess of the original grant is not considered bond proceeds and does not need to be tracked for federal tax law purposes. However, a variety of State laws could apply and govern the use of moneys derived from or associated with bond proceeds. These laws could include the bond act itself, laws applicable to a particular program or recipient, and other laws and regulations. The STO recommends that the department consult their legal counsel or the Attorney General's Office in such situations.

What are the record retention requirements for the returned grants? Records relating to a general obligation bond funded grant program, including those related to a returned grant and the subsequent re-granting of the funds, must be retained for 35 years from the date of the original grant. See the July 2, 2008 memo from the STO regarding records retention for additional information.

We hope the above information is helpful. If you have any questions that are not addressed by this memo, please contact Melinda Chan at mchan@treasurer.ca.gov or (916) 653-3445.

COASTAL CONSERVANCY

Staff Recommendation
December 8, 2005

BALLONA WETLANDS ENHANCEMENT PLANNING

File No. 04-088
Project Manager: Mary Small

RECOMMENDED ACTION: Authorization to disburse up to $200,000 to the Santa Monica Bay Restoration Foundation for planning, data collection, and other activities associated with the restoration of the Ballona Wetlands and to implement the Santa Monica Bay Plan, adopted by the Conservancy on August 2, 2001. The project area is in Los Angeles County.

LOCATION: West of Lincoln Boulevard and south of the Marina del Rey along the Ballona Creek Channel in Los Angeles County. A portion of the project is in the City of Los Angeles and a portion is in unincorporated Los Angeles County (Exhibits 1 & 2).

PROGRAM CATEGORY: Coastal Resource Enhancement and Public Access

---

EXHIBITS

Exhibit 1: Project Location Map

Exhibit 2: Project Area and Watershed Map

Exhibit 3: Letters of Support

RESOLUTION AND FINDINGS:

Staff recommends that the State Coastal Conservancy adopt the following resolution pursuant to Sections 31251-31270 and 31400 et seq. of the Public Resources Code:

"The State Coastal Conservancy hereby authorizes disbursement of an amount not to exceed two hundred thousand dollars ($200,000) to Santa Monica Bay Restoration Foundation for planning, technical review, data collection and public outreach to support the restoration of the Ballona Wetlands, approved by the Conservancy on December 2, 2004. This authorization is subject to the condition that prior to disbursement of funds, the Conservancy's Executive Officer shall approve the work plan, budget and the contractor for this work."

Staff further recommends that the Conservancy adopt the following findings:

"Based on the accompanying staff report and attached exhibits, the State Coastal Conservancy hereby finds that:

1. The proposed project authorization is consistent with Public Resources Code Sections 31251-31270, regarding the Conservancy's mandate to protect and enhance coastal resources.
2. The proposed project authorization is consistent with Public Resources Code Sections 31400-31409, regarding the Conservancy's mandate to assist in the development of a system of public accessways to and along the coast.
3. The proposed project is consistent with the Project Selection Criteria and Guidelines adopted by the Conservancy on January 24, 2001.
4. The project serves greater than local need.
5. The Santa Monica Bay Restoration Foundation is a nonprofit organization existing under Section 501(c)(3) of the U.S. Internal Revenue Code and which purposes are consistent with Division 21 of the Public Resources Code."

PROJECT SUMMARY:

This authorization would provide funding to advance the efforts of the Santa Monica Bay Restoration Foundation (Foundation) to improve the health of the Santa Monica Bay by helping to restore the former Ballona Wetlands and to implement the Santa Monica Bay Plan. If approved, the Foundation would engage in restoration planning activities, including technical review, collecting data and public outreach. This work would be closely coordinated with and would complement the Conservancy's authorization of December 2, 2004 and other state efforts to restore the 600-acres of the historic Ballona Wetlands owned by the California Department of Fish and Game (DFG) and the State Lands Commission (SLC).

The Santa Monica Bay Restoration Foundation is a non-profit organization that was created in 1991 to implement the priorities of the Santa Monica Bay Restoration Plan and to support the work of the Santa Monica Bay Restoration Commission. The Foundation has a number of on-going initiatives including research, public education, and planning. Restoration of the Ballona Wetlands is a priority activity in Santa Monica Bay Restoration Plan. For the past several years, the Santa Monica Bay Restoration Commission has been actively involved in developing and implementing a watershed management plan for the Ballona Creek Watershed. One of the top priorities of that plan is the restoration of the Ballona Wetlands.

The Ballona Creek watershed is approximately 130 square miles and is the largest watershed draining to Santa Monica Bay. It includes much of the City of Los Angeles as well as the cities of West Hollywood, Beverly Hills and Culver City. Approximately 80% of the watershed is urbanized and it is home to more than 1.5 million people. The Ballona Wetlands are located at the mouth of that watershed and offer one of the largest opportunities to restore coastal wetlands in southern California. The site provides habitat for threatened and endangered species, including the Belding's savannah sparrow and the California brown pelican.

Site Description:

It is estimated that the historic wetland complex at the mouth of Ballona Creek once occupied 2000-acres. Much of that area has been developed. However the State of California now owns

600-acres of the former wetland complex. The Department of Fish and Game owns 540 acres, and that land was purchased with funds provided from the Conservancy to the Wildlife Conservation Board. The State Lands Commission owns 60-acres, including a newly created freshwater marsh and adjacent vacant land..

The project area has been substantially altered during the last century, significantly reducing the quantity and quality of the wetlands. Major human activities that have affected the ecological function of this site include past oil field development, channelization of Ballona Creek, and the construction of the Marina del Rey lagoon, which involved deposition of dredge material onto project area. In addition, several major roadways cross the site and it is surrounded by residential and commercial development.

Despite the degradation of site resources resulting from prior development, significant wetland habitat remains within the Ballona Wetlands. Plant species within the project site include wetland indicators such as pickleweed, marsh heather, saltgrass, arrowgrass and glasswort, and a variety of upland and exotic species including brome, iceplant, oxalis, and ryegrass. Bird surveys indicate that the site is used seasonally by a variety of migratory shorebirds, as well as by typical shoreline residents (gulls, terns, and ducks) and typical upland birds including small raptors. Bird species of special interest observed in the project area include nesting pairs of Belding's Savannah sparrow and foraging use by California least terns.

Project History:

There have been more than twenty years of intense conflict about land use at this site. Several development proposals and regulatory approvals have resulted in litigation, some of which continues today. In 2001, the Trust for Public Land entered into a purchase agreement with Playa Capital Company, the former landowner. Through this purchase agreement, the Department of Fish and Game ultimately took title to 540 acres of the property during the past year. The Conservancy provided $10 million for that acquisition.

The Conservancy has long supported enhancement and public access at the Ballona Wetlands. The first Conservancy project at this site was a 1986 grant to the National Audubon Society for environmental education facility associated with a proposed site restoration. That project was never implemented due to the ongoing conflicts about development at the site. Beginning in the late 1980s, the Conservancy provided funding for planning and implementation of enhancements to the nearby Ballona Lagoon and holds easements for resource enhancement over much of the land bordering the Lagoon.

More recently, the Conservancy has provided funding to the Friends of Ballona Wetlands for dune restoration and invasive plant removal on the southwestern portion of the project area. Last year, the Conservancy approved two grants for projects in the Ballona Creek Watershed that helped implement the Santa Monica Bay Restoration Plan. One of these grants was awarded to the Ballona Wetlands Foundation to develop the Ballona Outdoor Learning and Discovery (BOLD) project. It is a condition of the grant that the BOLD project be developed to be consistent with the larger restoration project.

In December 2004, the Conservancy authorized funds for development of restoration alternatives, feasibility analysis of these alternatives and development of preliminary cost estimates. A consultant team has been hired to develop a conceptual restoration plan. The project is currently collecting data and analyzing existing conditions. Restoration planning for the site will take a minimum of three years. Staff anticipates returning to the Conservancy for authorization to complete this analysis once a preferred alternative has been selected.

PROJECT FINANCING:

Proposition 12, Coastal Conservancy	$200,000
Total Project Cost	**$200,000**

The Conservancy funding would be derived from an appropriation of funds specifically designated for the restoration or acquisition of the Ballona Wetlands in the 2000 park bond, Proposition 12. Public Resources Code Section 5096.352(f) provides that $25 million is available to the Conservancy for this purpose.

CONSISTENCY WITH CONSERVANCY'S ENABLING LEGISLATION:

This project would be undertaken pursuant to Chapter 6 of the Conservancy's enabling legislation, Public Resources Code Sections 31251-31270, Coastal Resource Enhancement Projects. The project would enhance the natural and scenic character of resources within the coastal zone. As discussed below, consistent with Section 31252, the project is consistent with the policies and objectives of Division 20 of the Public Resources Code.

This project would be undertaken pursuant to Chapter 9 of the Conservancy's enabling legislation, Public Resources Code Sections 31251-31270, Coastal Access. If approved, the planning studies would include analysis of opportunities to enhance the California Coastal Trail and create new public access opportunities at this site.

CONSISTENCY WITH CONSERVANCY'S STRATEGIC PLAN GOAL(S) & OBJECTIVE(S):

Consistent with **Goal 5 Objective A** of the Conservancy's Strategic Plan, the proposed project would help the Conservancy to restore and enhance up to 600 acres of coastal wetland and adjacent habitat. When implemented, this project will complete 60% of the total acreage target for Southern California.

Consistent with **Goal 1 Objective C** of the Conservancy's Strategic Plan, the proposed project area could provide a new segment of the Coastal Trail. As discussed above, the project is located at the intersection of the California Coastal Trail and the Ballona Creek Trail, and may offer a significant opportunity for the development of improved connections between these trails.

CONSISTENCY WITH CONSERVANCY'S PROJECT SELECTION CRITERIA & GUIDELINES:

The proposed project is consistent with the Conservancy's Project Selection Criteria and Guidelines adopted January 24, 2001, in the following respects:

Required Criteria

1. **Promotion of the Conservancy's statutory programs and purposes:** See the "Consistency with Conservancy's Enabling Legislation" section above.
2. **Consistency with purposes of the funding source:** See the "Project Financing" section above.
3. **Support of the public:** There is broad public support for developing a restoration plan for this site. The project is supported by the Department of Fish and Game and the State Lands Commission. Letters of support are attached as Exhibit 4.
4. **Location:** The proposed project would be located within the coastal zone of Los Angeles County.
5. **Need:** Conservancy funds are needed to provide resources for the Foundation to provide planning assistance.
6. **Greater-than-local interest:** The proposed project will help advance the largest coastal wetland restoration project in Los Angeles County. The site provides habitat for threatened and endangered species, including the Belding's savannah sparrow and the California brown pelican. The site also provides valuable and scenic open space and public access opportunities in the heart of congested Los Angeles County.

Additional Criteria

7. **Urgency:** More than 98% of the coastal wetlands in the Southern California bight have been destroyed or degraded. This project offers an opportunity to restore and enhance 600 acres of habitat.
8. **Resolution of more than one issue:** Restoration of the Ballona Wetlands will address a number of goals, including: enhancement of wetland and adjacent habitat, creation of compatible public access opportunities, and improvement of coastal water quality.
9. **Readiness:** Restoration planning for the Ballona Wetlands is already underway. If approved, the Foundation will begin work immediately.
10. **Realization of prior Conservancy goals:** "See "Project History" above.
11. **Cooperation:** This authorization will provide resources to improve coordination with the Santa Monica Bay Restoration Commission. The Santa Monica Bay Restoration Commission includes representatives from local government, state government and many stakeholder organizations.

CONSISTENCY WITH LOCAL COASTAL PROGRAM POLICIES:

In the late 1980s, the California Coastal Commission certified two separate Land Use Plans that covered this project area. No Local Coastal Program was ever completed for the Ballona Wetlands area and the two Land Use Plans are now out of date. However the proposed project is consistent with the policies of the Coastal Act. The project goals are consistent with the Coastal Act goals as stated in Section 30001.5, the project will protect, enhance and restore the natural resources of the site and expand public recreational opportunities consistent with conservation of those resources. Specifically, Section 30231 states that coastal wetlands shall be maintained and restored. The project is consistent with Section 30240(a), in that it will help ensure that environmentally sensitive habitat areas are protected against significant disruption of habitat values. As stated in Section 30251, the project will protect the scenic resources and open space of the project site.

CONSISTENCY WITH LOCAL WATERSHED MANAGEMENT PLAN/ STATE WATER QUALITY CONTROL PLAN:

A Watershed Management Plan for the Ballona Creek Watershed was completed by an interagency/stakeholder task force this year. The purpose of the plan is to identify opportunities to improve water quality and restore habitat. The restoration of the Ballona Wetlands is specifically identified as a priority activity in the watershed.

COMPLIANCE WITH CEQA:

Under 14 California Code of Regulations (CCR) Section 15262, feasibility and planning activities are categorically exempt from California Environmental Quality Act (CEQA) review. Similarly, 14 CCR Section 15306 exempts basic data collection, research, and resource evaluation activities which do not result in a serious or major disturbance to an environmental resource. Upon approval, staff will file a Notice of Exemption for the project.

California Coastal Conservancy Public Meeting 1/19/2012
Comments Item 5.

The project must be denied because its primary premise is a fallacy.

This body is not entitled to provide over Six Million dollars to promote a project promoting a primary premise that is not supported by fact but only creative narrative.

The people expect more. We demand supportive facts.

The factually unsupported premise which is not supported by evidence in this Staff Report as stated on page 3 proposes to "restore" an "ecosystem" "by reconnecting the site to the ocean and creek.

Reconnection of the site to the ocean is a demonstrable fallacy.

The truth as supported by factual government surveys is presented by the United States Geological Survey and the State of California Director of Public Works in a map prepared prior to the construction of Marina del Rey, a Federal Project.

The USGS and the State present proof that the ocean did not connect to the site. This is demonstrable fact.

The USGS Beverly Hills Quadrangle Map produced in 1954 demonstrates no connection of the site to the ocean whatsoever, only a creek to ocean connection.

This is simple to determine by looking at the map before you and you may view the original copy, which is here. ATTACHMENT 1

Either Staff is wrong in its narrative unsupported by fact, or the U.S. Geological Survey and State of California Director of Public Works are wrong.

The Staff Report contains no facts to support its contention that the site was connected to the ocean.

The Federal map does provide clear evidence Staff is wrong.

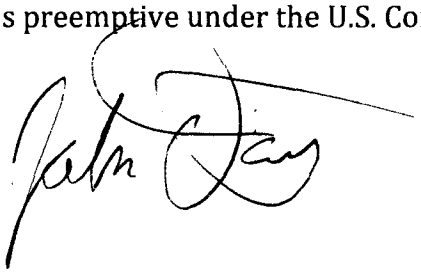
The Staff Report contention is only supported narrative, which under the CEQA Public Resource Code is not to be considered as legal evidence.

The Government Map was clearly based on factual surveys of the land.

The Staff Report premise is FALSE. The site was never connected to the ocean. Only the Lagoon was connected prior to the installation of tide gates when the creek was channelized. The Lagoon is still subject to tidal flows.

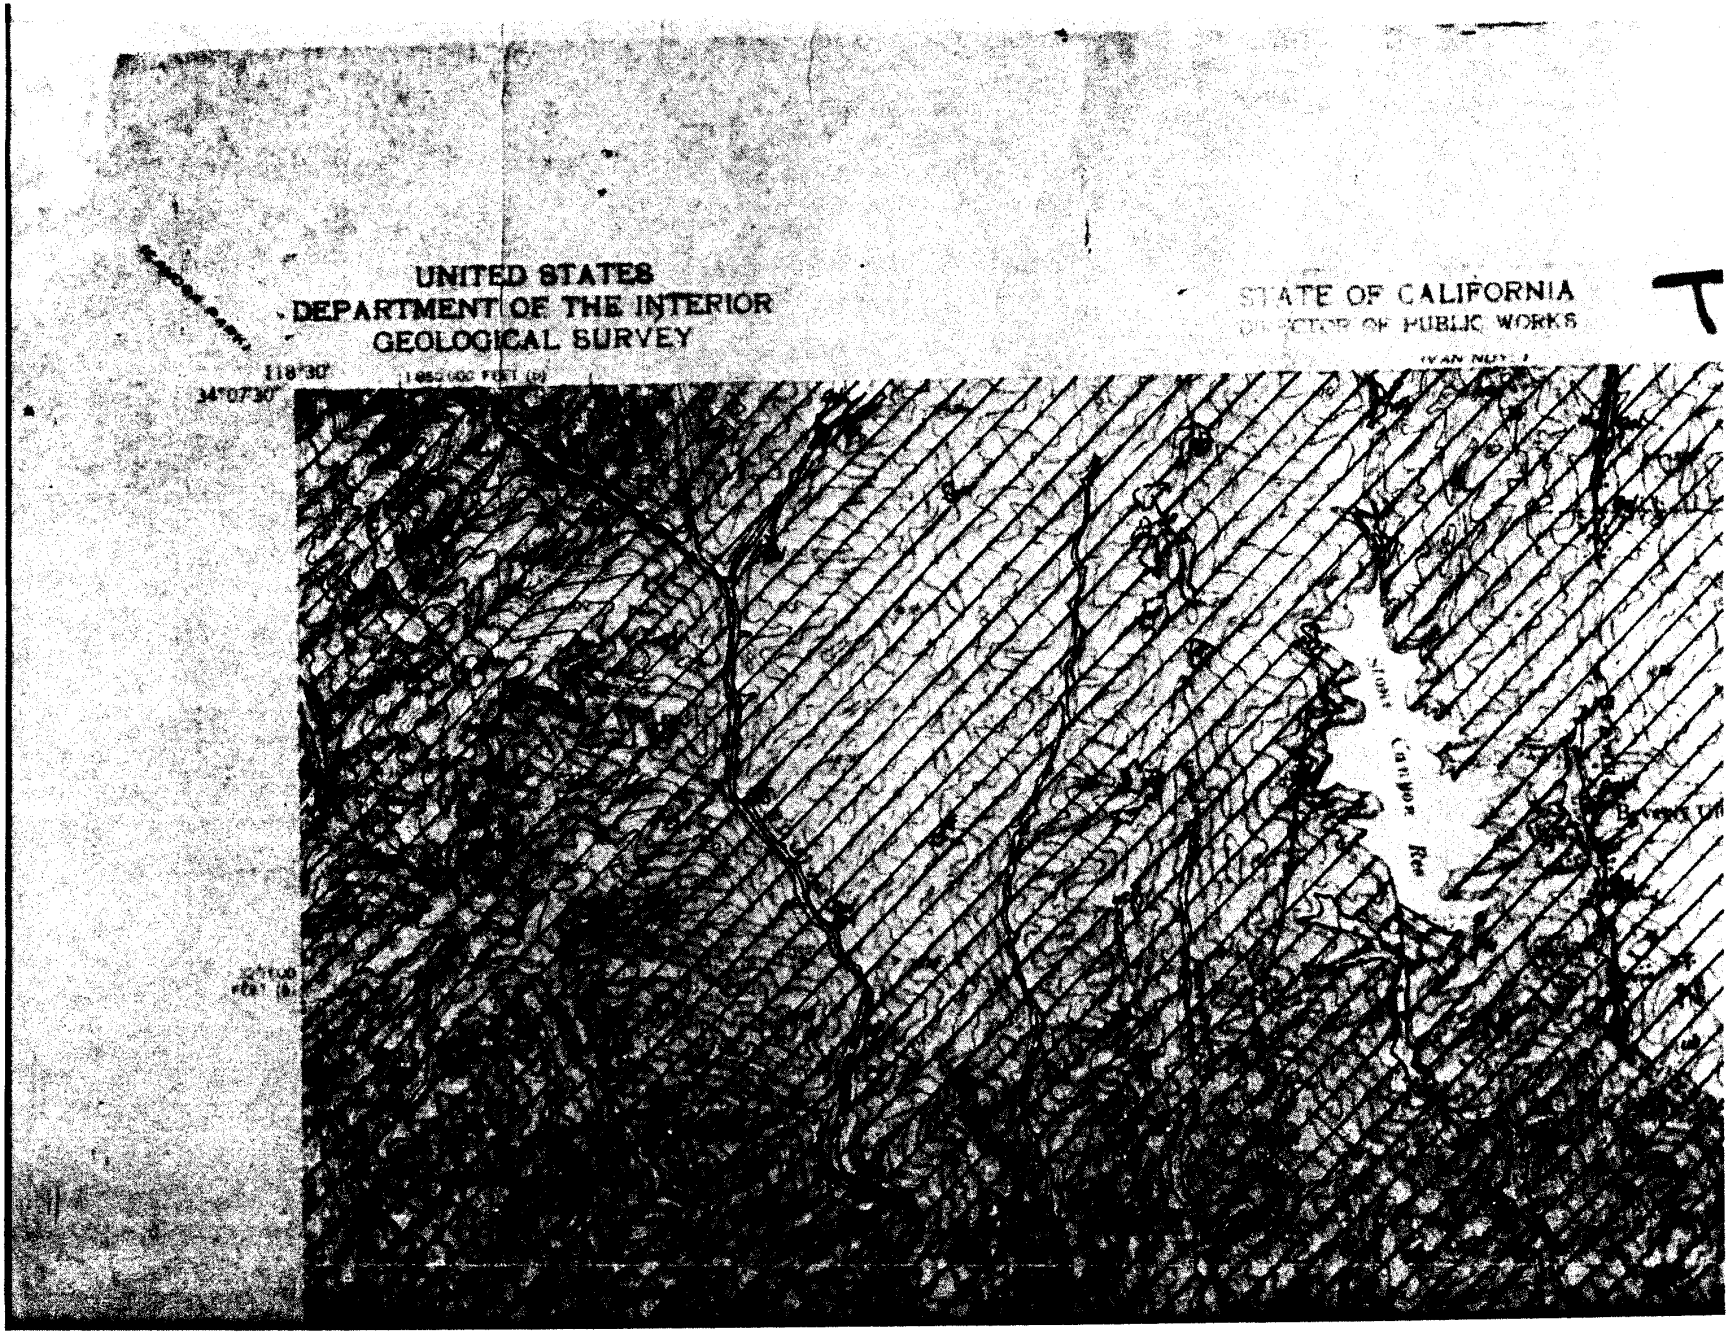
Pleases request Staff to respond with facts that demonstrate the State and Federal Government were wrong or deny the permit in absence of this necessary evidence.

The completion of Marina del Rey Harbor allowed for more salt water to into the marshlands that at any prior point in historical times, yet this fact is ignored by Staff.

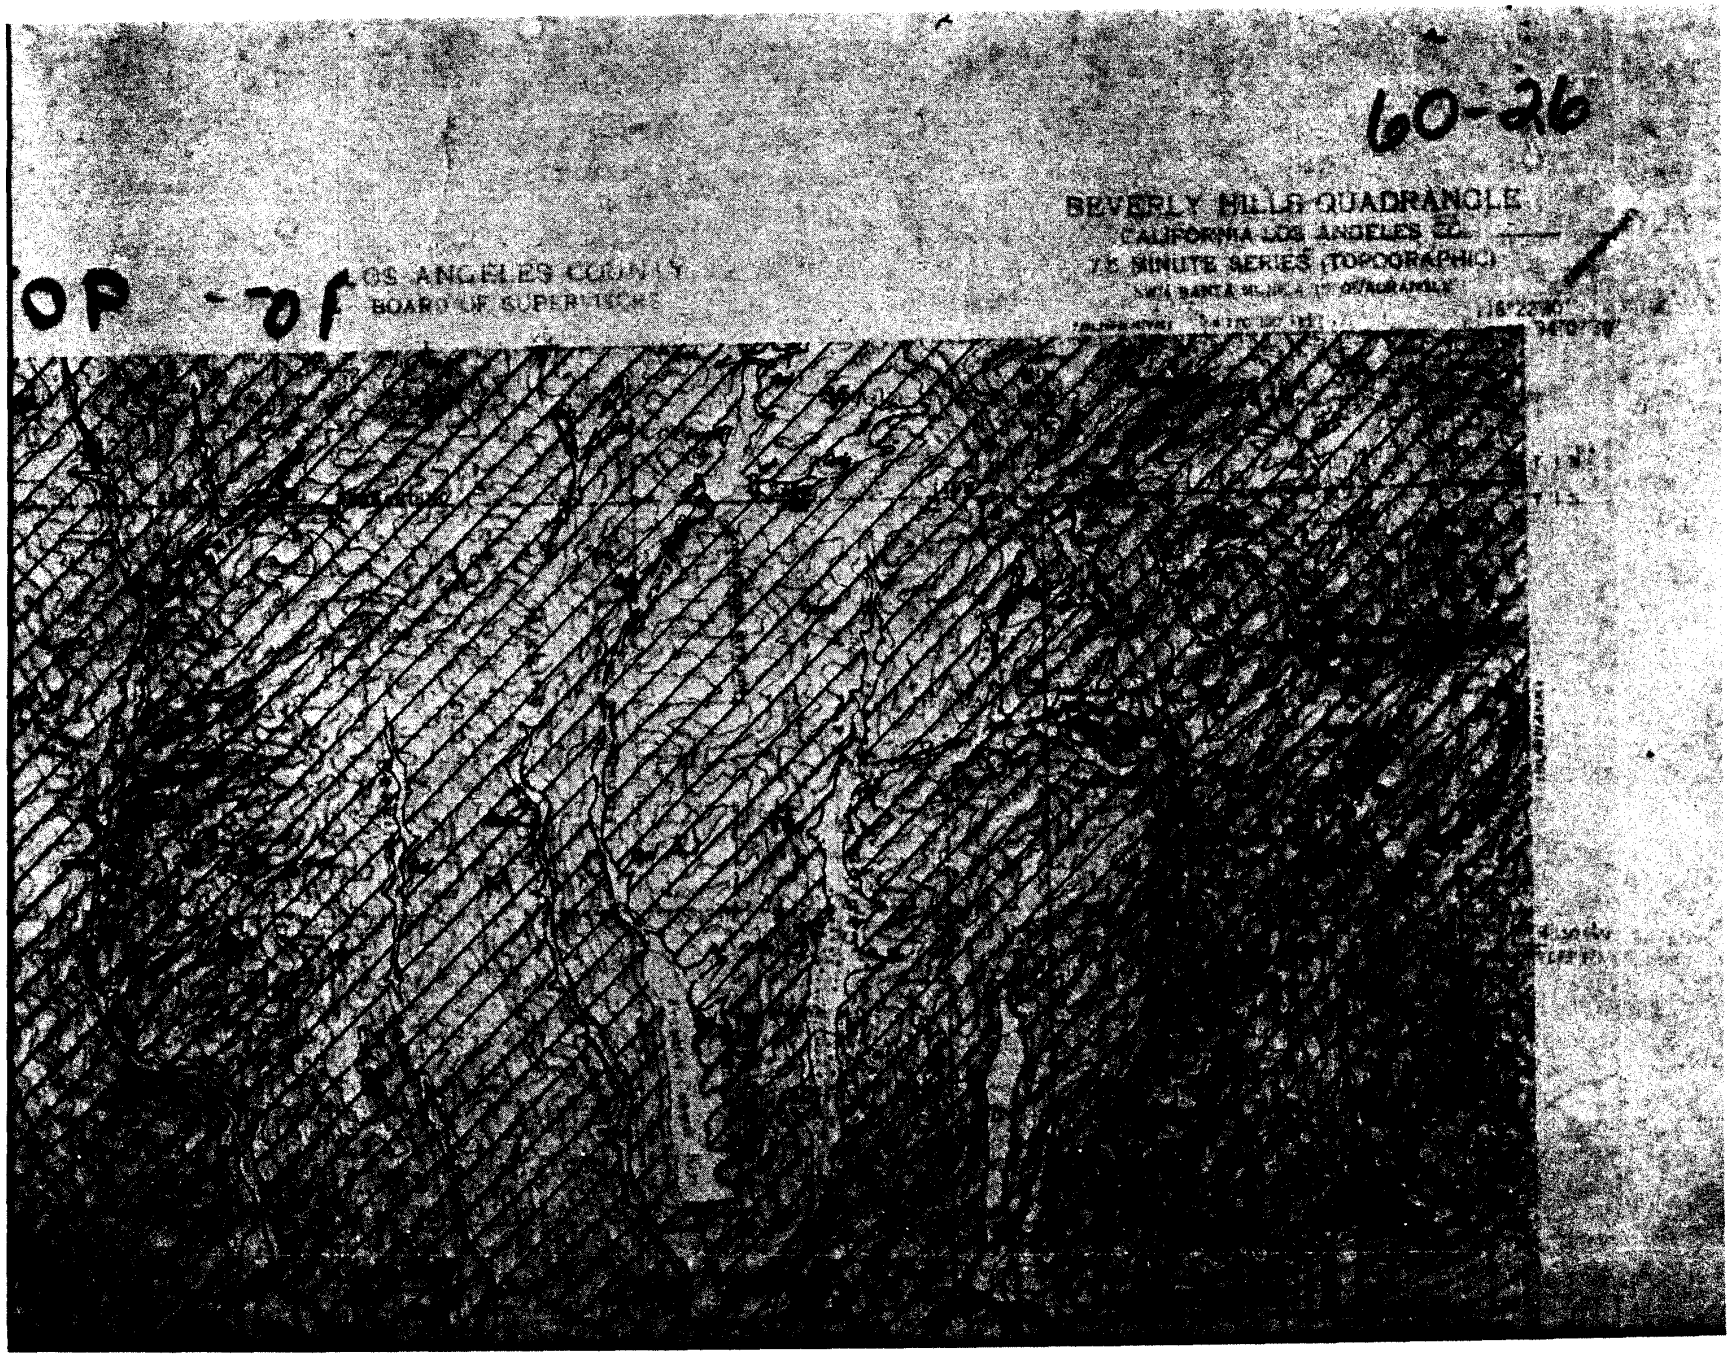


U.S. Public Law 780 Governs the land. ATTACHMENT 2

U.S. House of Representatives Document 389 on page 4 states that some materials will from the harbor construction will be placed to replenish the local beaches. Page 6 describes widening and improving beaches. Page 10 states, "The project is an integral part of the general plan for development of the shoreline of Santa Monica Bay. The General Plan of Improvement is shown as the last page. It to demonstrates no connection of the ocean to the site. ATTACHMENT 3



Staff ignores the federal interest entirely and the fact that dredge spoils were placed on local beaches, not only on lowlands.



Staff failed to conduct a through investigation backed by fact and has ignored the federal interest in the land which is preemptive under the U.S. Constitution Supremacy Clause.

Interest on judgments.

SEC. 57. The last sentence of subsection (b) of section 2516 of Title 28, United States Code, is amended by inserting immediately after the word "allowed" where it appears in such sentence the words "for any period", so that such subsection will read as follows:

"(b) Interest on judgments against the United States affirmed by the Supreme Court after review on petition of the United States shall be paid at the rate of four percent per annum from the date of the filing of the transcript of the judgment in the Treasury Department to the date of the mandate of affirmance. Such interest shall not be allowed for any period after the term of the Supreme Court at which the judgment was affirmed.".

Fees.

SEC. 58. Subsection (a) of section 2520 of Title 28, United States Code, is amended by striking out where it appears in such subsection the words "and the hearing of any case before the court, a judge, or a commissioner", so that such subsection will read as follows:

"(a) The Court of Claims shall by rules impose a fee not exceeding $10, for the filing of any petition.".

SEC. 59. (a) Chapter 165 of Title 28, United States Code, is amended by adding at the end thereof a new section to be designated as section 2521 entitled "Subpoenas" and to read as follows:

"§ 2521. Subpoenas

"Subpoenas requiring the attendance of parties or witnesses and subpoenas requiring the production of books, papers, documents or tangible things by any party or witness having custody or control thereof, may be issued for purposes of discovery or for use of the things produced as evidence in accordance with the rules and orders of the court. Such subpoenas shall be issued and served and compliance therewith shall be compelled as provided in the rules and orders of the court.".

(b) The analysis to chapter 165 of Title 28, United States Code, immediately preceding section 2501 of such title, is amended by adding at the end thereof a new item 2521 to read as follows:

"2521. Subpoenas.".

Approved September 3, 1954.

Public Law 780 — CHAPTER 1264

September 3, 1954
[H. R. 9859]

AN ACT

Authorizing the construction, repair, and preservation of certain public works on rivers and harbors for navigation, flood control, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled,

River and Harbor Act of 1954.

TITLE I—RIVERS AND HARBORS

SEC. 101. That the following works of improvement of rivers and harbors and other waterways for navigation, flood control, and other purposes are hereby adopted and authorized to be prosecuted under the direction of the Secretary of the Army and supervision of the Chief of Engineers, in accordance with the plans and subject to the conditions recommended by the Chief of Engineers in the respective reports hereinafter designated: *Provided*, That the provisions of section 1 of the River and Harbor Act approved March 2, 1945 (Public, Numbered 14, Seventy-ninth Congress, first session), shall govern with respect to projects authorized in this title; and the procedures therein set forth with respect to plans, proposals, or reports for works of improvement for navigation or flood control and for irrigation and purposes incidental thereto, shall apply as if herein set forth in full:

59 Stat. 10.

Wisconsin.

Cornucopia Harbor, Wisconsin: House Document Numbered 434, Eighty-third Congress, at an estimated cost of $220,000;

Sheboygan Harbor, Wisconsin: House Document Numbered 554, Eighty-second Congress, at an estimated cost of $217,200;

Michigan.

Holland Harbor, Michigan: House Document Numbered 282, Eighty-third Congress, at an estimated cost of $574,400: *Provided*, That local interests will contribute 25 per centum of the cost of dredging Section B, but not to exceed $45,500, in addition to the local cooperation required by the project document;

Crooked and Indian Rivers, Michigan: House Document Numbered 142, Eighty-second Congress, at an estimated cost of $225,000:

Saginaw River, Michigan: In accordance with the report of the Chief of Engineers, dated June 7, 1954, at an estimated cost of $4,496,800;

Ohio.

Toledo Harbor, Ohio: House Document Numbered 620, Eighty-first Congress, at an estimated cost of $512,000;

Ashtabula Harbor, Ohio: House Document Numbered 486, Eighty-third Congress, at an estimated cost of $4,900,000;

DEPARTMENT OF THE ARMY,
Washington 25, D. C., May 11, 1954.

The SPEAKER OF THE HOUSE OF REPRESENTATIVES.

DEAR MR. SPEAKER: I am transmitting herewith a report dated August 8, 1952, from the Chief of Engineers, Department of the Army, together with accompanying papers and an illustration, on a preliminary examination and survey of Harbor at Playa del Rey, Calif., and a review of reports on Playa del Rey Inlet and Basin, Venice, Calif., with a view to determining whether any improvement of the locality is warranted at the present time, authorized by the River and Harbor Act approved on August 26, 1937, and requested by a resolution of the Committee on Commerce, United States Senate, adopted on June 2, 1936.

47022—54——1

REVIEW BY STATE DIVISION OF WATER RESOURCES OF PROPOSED REPORT OF THE CHIEF OF ENGINEERS, UNITED STATES ARMY, ON PLAYA DEL REY INLET AND BASIN, VENICE, CALIF.

INTRODUCTION

In accordance with the provisions of section 1 of Public Law 14, 79th Congress, the proposed report of the Chief of Engineers, United States Army, on Playa del Rey Inlet and Basin, Venice, Calif., together with the reports of the Board of Engineers for Rivers and Harbors and of the district and division engineers, was transmitted by the Chief of Engineers on March 31, 1952, to Mr. Frank B. Durkee, director of public works, the official designated by Gov. Earl Warren as his representative in such matters. The report was received and referred to the State engineer on April 7, 1952, for review and report thereon. Thereafter, the reports were transmitted by the State engineer to Seth Gordon, director, department of fish and game; Rufus W. Putnam, executive officer of the State lands commission; Newton B. Drury, chief, division of beaches and parks of the department of natural resources; and G. T. McCoy, State highway engineer.

Authority for report

The report was prepared pursuant to a resolution adopted June 2, 1936, which reads as follows:

> *Resolved by the Committee on Commerce of the United States Senate*, That the Board of Engineers for Rivers and Harbors, created under section 3 of the River and Harbor Act approved June 13, 1902, be, and is hereby, requested to review the reports on Playa Del Rey Inlet and Basin, Venice, California, printed in House Document No. 1880, 64th Congress, 2d session, with a view to determining whether any improvement of the locality is warranted at the present time.

Further authorization was contained in Public Law 392, 75th Congress, approved August 26, 1937, which reads in part as follows:

> SEC. 4. The Secretary of War is hereby authorized and directed to cause preliminary examinations and surveys to be made at the following-named localities, * * * harbor at Playa Del Rey, California * * *.

A review of reports on Playa del Rey Inlet and Basin, Venice, Calif., and preliminary examination of the harbor at Playa del Rey, Calif., dated May 26, 1939, was submitted by the district engineer in accordance with the foregoing authorizations. The district engineer's report was reviewed by the Board of Engineers for Rivers and Harbors, and a report of survey scope was authorized by the Chief of Engineers on April 6, 1944, to determine the advisability and cost of improvement and the local cooperation required.

Recommendations of the Chief of Engineers

The following is quoted from the proposed report of the Chief of Engineers now under review:

> After full consideration of the reports secured from the district and division engineers, and after affording local interests full opportunity to be heard, the Board recommends provision of a harbor at Playa del Rey, Calif., to consist of 2 entrance jetties each about 2,300 feet long; an entrance channel 20 feet deep, 600 feet wide, and 1,925 feet long; an interior channel 20 feet deep, 600 feet wide, and 5,600 feet long; a central basin 10 feet deep; and 2 side basins 20 feet deep and 10 side basins 10 feet deep, separated by mole-type piers; the dredged material to be utilized for construction of the piers and for deposition on adjacent lowlands and beaches; all generally in accordance with the plan of the district engineer and the comments herein, and with such modifications thereof as in the discretion

B-78

abandoned due to low production and salt-water intrusion, leaving 111 wells on low production.

Local interests consider that the proposed harbor at Playa del Rey would be an integral unit of an adopted general plan for development of the Santa Monica Bay shoreline. This plan includes widening and improving beaches, providing adequate bath houses, parking areas, picnic facilities, special recreation centers, bathing and wading beaches, fishing piers, youth organization camps, tourist parks with cabin and trailer accommodations, and a bird refuge.

Cost of proposed works

In the report of the district engineer, the total first cost of the project is given as $25,603,000, with a Federal first cost of $9,098,000 and non-Federal first cost of $16,505,000. The total annual carrying charges would be $919,920, and the annual benefits would be $1,529,000. The benefit-cost ratio of the proposed harbor project would be 1.7 to 1.

The Board of Engineers for Rivers and Harbors, in reviewing the report of the district engineer, reevaluated the costs and benefits estimated by the district engineer. In considering both the evaluated and intangible benefits, the Board stated in its report that the Federal interest in the proposed improvement would be served by Federal participation to the extent of providing and maintaining the entrance jetties, entrance channel, interior channel, and central basin shown on the maps accompanying the district engineer's report, all at an estimated first cost of $6,151,000 for construction exclusive of aids to navigation, and $25,000 annually for maintenance, with local interests providing and maintaining all other works including dredging of the side basins at an estimated first cost of $19,427,000.

The Board of Engineers for Rivers and Harbors also reduced the benefits allocated by the district engineer to sport fishing vessels from $280,000 to $47,000, making the total annual benefits $1,296,000. Subsequent to the submission of the report by the district engineer, the United States Coast Guard submitted a revised estimate of $42,000 for first cost of aids to navigation, an increase of $17,000, making a total first cost of the project of $25,620,000. The total annual carrying charges are estimated by the Board to be $933,025, of which $277,555 is Federal, and $655,470 is non-Federal, giving a benefit-cost ratio of 1.4. The recommendation of the Board of Engineers for Rivers and Harbors as to Federal participation is concurred in by the Chief of Engineers.

Local contributions

At its meeting on April 25, 1946, the City Council of Los Angeles adopted a report declaring that the public interest and welfare of the city of Los Angeles and vicinity require the provision of additional small craft facilities by means of construction of a small craft harbor at Playa del Rey, assisting the Federal Government in such undertaking by assuming those obligations required under Federal law in connection [redacted]project.

By resolu[redacted]pted September 28, 1948, and June 7, 1949, the Board of Su[redacted] of the County of Los Angeles declared that the public interest and welfare of the county of Los Angeles and its citizens require that provision be made for additional small craft facilities by means of construction of a small craft harbor at Playa del

B-80

Department of Natural Resources

Newton B. Drury, chief, Division of Beaches and Parks of the Department of Natural Resources, on June 18, 1952, stated that the thoughts expressed in the comments previously submitted to the district engineer on January 6, 1949 still reflect the reaction of the division to the project.

The comments, submitted by Gen. Warren T. Hannum, director of natural resources, on January 6, 1949, are as follows:

(*a*) It is found that plan of development as proposed in the district engineer's report would provide a greatly needed harbor for light craft vessel, and as a harbor refuge for such craft cruising along the coast.

(*b*) That the proposed harbor development is in general in conformity with the county master plan as approved by the State Park Commission.

(*c*) That there is no State cooperation proposed in the plan, the city of Los Angeles having expressed its desire and willingness to meet the requirements of local cooperation as set forth by the district engineer.

(*d*) That the incidental benefits to the State park system, due to the deposit of sand on the beaches both upcoast and downcoast from the proposed entrance jetties would be very great.

It is recommended, therefore, that the report be approved with a favorable comment indicating the advantages to the State park system from the deposit of sand on the Santa Monica beaches.

CONCLUSIONS

The following conclusions are submitted with respect to improvements recommended by the Chief of Engineers in his proposed report on Playa del Rey Inlet and Basin, Venice, Calif., giving consideration to (*a*) need for the project (*b*) engineering feasibility and effectiveness of the proposed works, and (*c*) economic justification for the project:

1. The improvements will provide a desirable addition to small-craft facilities along the southern California coast. The project is an integral part of the general plan for development of the shoreline of Santa Monica Bay.

2. Local interest in and approval of the project have been demonstrated by resolution of the city council of the city of Los Angeles, and by resolution of the Board of Supervisors of the County of Los Angeles, giving assurance that the county will assume those non-Federal contributions and obligations in connection with the project which are required by Federal law.

3. The improvements appear to be of sound and adequate design and feasible of construction and operation.

4. Construction of the proposed harbor will introduce ocean water inland a distance of more than 1 mile, and increase the rate of saline contamination of ground waters of the west coast basin. Except in this respect, the proposed works will not conflict with any beneficial consumptive use, present or future, of water for domestic, municipal, stock water, irrigation, mining, or industrial purposes.

RECOMMENDATIONS

It is recommended that the plan of improvement for the small-craft harbor at Playa del Rey Inlet and Basin, Venice, Calif., as recommended by the Chief of Engineers, be authorized for construction, and that Federal funds be appropriated for the purpose.

Honorable Chair Bosco, Distinguished Commissioners,

Attachments will be submitted to the Governing Board on March 29, 2012.

I hereby request this public body instruct its Staff to schedule an emergency meeting in accordance with the Bagley Keene Act section 11125.5(b) to rescind its approval of File No. 04-088 on January 19, 2012 for the following reasons;

1. NON-COMPLIANCE DEPARTMENT OF FINANCE ATTACHMENT 1

Final Report—Audit of California State Coastal Conservancy's Propositions 12, 13, 40, 50 Bond Funds

The Department of Finance, Office of State Audits and Evaluations, has completed its audit of the California State Coastal Conservancy's (Conservancy) Propositions 12, 13, 40, and 50 bond funds for the period ending June 30, 2008.

Staff Project Manager Mary Small **failed to require Potential Grantee**, the Santa Monica Bay Restoration Foundation, **to fill out a Grant Application Form** on the Conservancy Website.

Background:

2. FALSEFICATION OF PUBLIC RECORDS ATTACHMENT 2

Staff falsified a Form SCC 08-08, Work Transmittal.
The Form was initialized by;
Executive Director - Sam Schuchat
Project Manager - Mary Small
Legal - Elena Eger

Staff filled out the form as follows:

Will this project receive federal or other outside funding? Yes___ No X

The January 19, 2012 **Staff Report contradicts on page 6** :

*"The SMRBF in-kind **funds would come from U.S. EPA funding** provided to the SMRBF for its staff **and from a U.S. EPA Wetland Program Development Grant** received for work at Ballona"*

3. INCOMPLETE PUBLIC RECORDS ATTACHMENT 2

Staff failed to complete Form SCC 08-08, Work Transmittal.
The Form was initialized by;
Executive Director - Sam Schuchat
Project Manager - Mary Small
Legal - Elena Eger

Is the Grantee a Nonprofit Organization Yes___ No__ - NOT CHECKED
If nonprofit: Is the status file complete and current Yes___ No___ - NOT CHECKED
GRANT / CONTRACT AMMENDMENTS REVIEW - BLANK
MAIL OUT APPROVALS - BLANK
APPLICATION - BLANK
GRANT TRANSMITTAL - BLANK
REVIEW OF AGREEMENT - BLANK

4. DISCRIMINATION ATTACHMENT 3

Staff Project Manager Mary Small has improperly lobbied private individuals, private businesses, State and Federal Officials and entities prior to the release of the Staff Report, thusly, discriminating against all others by failing to provide the same comment opportunity prior to the issuance of the Staff Report.

Further Discrimination has taken place because only one Potential Grantee has been selected by Staff Project Manager Mary Small, excluding all others that may have chosen to apply.

authorization of this Board, represented to the Army Corp of Engineers on June 28, 2010 that:

Coastal Conservancy is supplying most of the funding toward the in-kind local sponsor efforts.

The Governing Board has not authorized Mary Small to represent the Coastal Conservancy at a meeting of the Army Corp of Engineers and the Local Sponsor (Santa Monica Bay Restoration Authority). The Conservancy is neither a partner nor is there any MOU to with the SMRBA, which is under contract to the USACE. Minutes of other such meetings provide evidence that Mary Small also discussed;

A. Changing the scoping of an Environmental Protection Act process began by the USACE in 2005.

B. Using only the Conservancy's Alternatives.

C. Attempting to gain in kind credits from the USACE.

D. Further documents provided by the USACE provide evidence that the local sponsor, never provided any funding to the USACE whatsoever nor did it provide any in-kind credit.

E. Resumes provided to the Coastal Conservancy by potential contractors for this Project include studies finished and paid for by federal funding stated in the resume(s) as part of the Lower Ballona Creek Feasibility Studies of the Joint EIR/EIS (2005) initiated by the USACE.

7. VIOLATIONS OF CALIFORNIA CONTRACT CODE ATTACHMENT 6

Staff Project Manager Mary Small failed to comply with the California Contract Code Notification and Conflict requirements, Sections 10140-10141 and 10515-10518.

Staff Project Manager Mary Small conducted a Request for Services for Contractors in 2009, and again in 2010 in regard to a Project not noticed to the Public or Governing Board until 2012, both in non-compliance with California Contract Code.

Staff Project Manager Mary Small purports to have initiated another Request for Services in February 2012 with responses due on the 29th of that month outside in non-compliance with the California Contract Code.

8. VIOLATIONS OF BAGLEY KEENE ATTACHMENT 6

Staff failed to obtain permission from the Governing Board to hire contractors to complete studies.

9. QUID PRO QUO INFERED ATTACHMENT 7

Sincerely,

John Davis

To: <jd@johnanthonydavis.com>

Mr. Davis, I apologize for the delay in responding to your request. I have been unable to locate any records within the possession of the State Water Resources Control Board that are responsive to your requests. The attached two documents may be of interest to you, however, in that they indicate that the Santa Monica Bay Restoration Project's relationship with the Santa Monica Bay Restoration Foundation (Foundation) pre-dated the conversion of the Santa Monica Bay Restoration Project to the Santa Monica Bay Restoration Commission (Commission). Also, as I explained to you by telephone, the Commission staff is currently undertaking a number of steps to more clearly distinguish the Commission from the Foundation. Unfortunately, some of those steps are taking some time. I will let you know when I receive a timetable for those steps from Commission staff.

Sincerely,
Phil

California State Water Board
Att: Phil Wyels
Re: Status Request Public Record Request

Councel Wyels,

The California Public Records Act requires that Agencies subject to the Act reply to request for records
within 10 days after a request is made.

The State Water Resources Board has not complied with the law in this respect in regard to the request for
records made on 2/7/12.

SWRCB Ltr to Davis re PRAs.pdf

Dear Mr. Davis:

Pursuant to our phone conversation of yesterday, February 6, 2012, in which you provided a warning to me that the Conservancy should be informed that the Santa Monica Bay Foundation allegedly is appropriating public resources for private gain, attached please find the State Water Resources Control Board's (SWRCB) August 15, 2011 legal memo addressing your contentions and a September 13, 2011 letter to you regarding the same.

As analyzed in the SWRCB memo, especially in #3, pp. 4-5 of that memo, your contentions that the Foundation is improperly utilizing public resources for private use, namely in your assertions yesterday when you identified as improper the fact that the Foundation uses the same mailing address as the SWRCB's Los Angeles office, are specifically addressed. Frances McChesney, Esq., Office of the Chief Counsel for the SWRCB concludes in that memo that the Foundation is not improperly appropriating public resources for its private use.

The Conservancy intends to proceed with its grant to the Foundation approved as Item #5 at its January 19, 2012 meeting.

Sincerely,

Elena Eger

I am planning to attend the meeting, and I'm trying to get some more support letters and maybe attendees. You have no idea how much pleasure I would get from foiling your opponents. I can either stand up during the hearing, or if you want, I can instead meet you and the board between the tour and the meeting (since you must be going to feed them someplace) and just chat informally.

Your choice. I'm free at about 11:30 and have a meeting at 3 pm. In between I am at your service.

Hi Shelley-
Do you have time to talk about our Jan meeting? I know you have a board meeting this week, so we could also do this via email – or next week, but before next Fri I'd like to work through some ideas:

1) Tour – we'll probably do a tour the morning of the meeting, I think maybe the tour we did with Colonel Toy – view from Cabora Rd and then walk out to boyscout platform
2) Press – do you think we could use this meeting as an opportunity to get either local papers and/or try for LA Times to cover the project? I am worried that once the agenda is out Marcia will use as opportunity to get bad press. Our agenda will be mailed out Jan 6th
3) Public support – who could we have come to support the project at the meeting or with letters? Geraldine is critical (at least her letter) but how about MRCA?, Joe Geever?, Ballona Creek Renaissance?, Friends?, Miguel Luna?, Audubon? HtB? Baykeeper?

Thanks,
Mary

Hi Miguel
Happy New year! Hope you are well.

Is there any chance you would be willing to send a letter of support to the Coastal Conservancy for authorization of funding to continue design of the restoration project? I don't know if Shelley contacted you, but it would be great to get community groups weighing in who support ecological restoration. Our meeting will be in LA, so I expect there will be some opposition.

Please let me know if you have any questions or need more info.
Thanks,
Mary

Subject: Letter for Coastal Conservancy Board

Dear Geraldine,
When we spoke a month or so ago, I asked if you would provide a letter to Sam Schuchat and his Board regarding your interest in the Ballona Wetlands restoration project. The January meeting of the Conservancy Board will be in Los Angeles and Sam will ask the Board to approve a large sum for continuing the planning and permitting of the restoration project, so your support of the project and interest in providing mitigation funding is important. Do you still intend to provide a letter and can I help with drafting? Also, we will give the Board members a tour of the wetland and briefing on the restoration plan before or after the Board meeting. As soon as we have a date I will send you an invitation and hope that you could come along.

Thank you Geraldine,
Shelley

Subject: support letter for SCC board meeting?

Hello Mark,
Happy New Year. I am emailing to see if Heal the Bay would be willing to send a letter of support to the Coastal Conservancy for the recommendation that we authorize $6.5M for the design and engineering of the proposed restoration project? My draft staff report is attached along with a sample letter. I know you have talked to Shelley about the project, but I would be happy to give you an update at any time. Of course I understand if you are not prepared to take a position on this project at this point, but our meeting will be in Culver City, so I expect there will be some opposition.

Please let me know if you have any questions or need more info.
Thanks,
Mary

Subject: Re: [REPLY] Fw: Coastal Conservancy funding to complete Ballona Wetlands restoration planning

Shelley,

Please accept my apologies for this late response. Cathi and I were away on a 2 1/2 week driving trip to the Seattle area for a holiday visit with our kids and grandkids. Then after returning late last Thursday, we've been focused on moving Cathi's 93-year-old mom in with us. I'm just now beginning to turn more of my attention to a backlog of BCR and other matters.

Unfortunately I have an important 3pm meeting at Culver City Hall on the afternoon of the 1pm SCC board meeting at the Scenic Overlook. If I were able to speak on the restoration planning agenda item before about 2:40pm, it could work. Otherwise (or in addition) I might be able to get Bobbi Gold or another knowledgeable BCR board member to represent us.

As for a BCR support letter, I'm pretty sure that would not be a problem. This is on my list of things to bounce off the board prior to our next board meeting.

Here's to a great new year, despite the challenges ahead!
Jim

Hello Jim,
I hope you had a lovely Christmas and a happy new year! I did enjoy a nice break.

You may have heard that the Board of the Coastal Conservancy will meet in LA on Jan. 19 and will consider a request from their staff to authorize funding to complete the Ballona Wetlands restoration planning. The request is for about $6.3M and most will go to consultants for additional engineering (through final design), to create a public access master plan, and to do extensive hydraulic modeling as required by Army Corp permitting (the major expense). About $240k will come to SMBRF to fund Diana's position as well as monitoring on the site for the next three years. I don't know if there will be active opposition to this but I am preparing for that nonetheless. Also I see this as a good opportunity to let the SCC board members see the great support that exists in our community for restoration at Ballona.

Please let me know if you are able to support by letter or by attending the meeting. It was posted today on SCC website http://scc.ca.gov/2012/01/06/coastal-conservancy-public-meeting-january-19-2012/
I am attaching the staff report for the item and a couple of example support letters as well. Thank you Jim!

Hi
Sorry I didn't send this to you earlier, I meant to send it before the holidays, but forgot. I was wondering if your agencies would send a support letter to Coastal Conservancy for the requested authorization for funds for engineering and final design for Ballona. Our meeting will be in LA so I expect there will be some opposition and it is a huge funding request since we decided to do the EIR and permitting for the whole project.

If you could attend the site tour of Ballona and the meeting (both on Jan 19th) that would be great too.

Please let me know if you have any questions or need more info.
Thanks

I was just talking to Shelley and we were wondering if you could send a staff person to the meeting even if you don't want to sign a letter? Maybe Meredith or someone on her staff could come to talk about the need to open the site to public access and restore nature in the city?

This authorization doesn't commit to any one project, we still will be going through CEQA and NEPA.

Thanks

Hi Joe

Nice to talk to you this morning, and thanks for agreeing to come to the Coastal Conservancy meeting in Jan. It will be on Jan 19th at the Baldwin Hills Scenic Overlook starting around noon. Ballona funding (draft staff report attached) will be the first major item on the agenda. We are planning to take the Board on a tour of Ballona that morning. The tour and meeting are open to the public and details will be posted on our website by the 6th of Jan.

As I mentioned, we (Shelley and I) would be happy to provide additional information to you &/or your chapters at any point. Since we are finally getting ready to initiate the public environmental review, now would be a good time to get you engaged.

Thanks,
Mary

Thanks

Sorry, the plan is to have the tour from roughly 9-11:30 and then start the meeting at noon or 12:30 – something like that. We're afraid that if we do the tour after the meeting none of the board members will come.

I'll call Barbara today to get her ideas and see if they will help with the tour, come to the mtg or send a letter
Mary

Cc: 'Joan Cardellino (Joan Cardellino)'; Diana Hurlbert
Subject: RE: Letter for Coastal Conservancy Board

Mary, here are some thoughts from me and Diana:

1) Tour – we'll do the tour anytime that works for your members but it seems tight to finish it by 9:15 in order to get them all to Baldwin Hills Overlook for a 10 am meeting. I know we have the Toy meeting the day before so right after the board meeting makes most sense. Could you convince your members to stick around for it?
2) Press – this is troubling. It'll be hard for us to get good press on a $7M expenditure... we can spin this if we get the right people. What if we did a brief presentation on the Monitoring Report before hand? We'll have beautiful hard copies, it's over 400 pages and very impressive and did not cost a lot for the amount of work and info. I think it makes SCC and SMBRC look great. Could we make this the press focus, i.e. with Molly Peterson at least? I'll give her a call for starters.
3) Support – I will talk with Geever, Jim Lamm, Miguel, Lisa Fimiana, Baykeeper, HTB, Nate from Rosendahl's office, Napolitano from Knabe's and Karly from MRT's. I can't say who will show up or do a letter but I will make the asks. I'll also ask Pestrella. Can you talk to MRCA Mary? Also what about the Corps – Rick Liefiled's support would be very meaningful, or Toy's if we can get it. Maybe a letter from Toy with Rick or someone else attending the meeting?

We'll draft a support letter asap and run it by you.
Shelley

To: Mary Small
Subject: RE: board presentation
Date: Wednesday, January 11, 2012 6:55:23 PM

Hi Mary,
I think the presentation looks good. I think we should include some comparative data to show the need for restoration – e.g. the seed bank data, the exotic veg data and some of the animal data (birds and herps). I saw what karina sent you and it doesn't help us – we need numbers like "99% invasive plants" and "lowest seed bank of any so cal wetland". we also need her graphs that show huge percent exotic veg. versus tiny percent native veg, etc. along with those photos of invasive plants that you already included.

I also think we should mention the TMDL –or not the TMDL itself, but we can list the impairments listed on the 303d list, note that TMDL implementation would be consistent with the restoration and that we can work with partners on my governing board and other agencies and leverage resources that would go into implementing the TMDL.

I can help with slides – why don't you send me one or two in your formatting and I will make some with the graphs imentioned and see if you like them. Or rather, since you have to finish by tomorrow and I am out of the office all day, we will ask karina to insert some graphs. Okay with you?

Cc:	msmall@scc.ca.gov
Subject:	graphs needed for SCC board presentaiton
Date:	Thursday, January 12, 2012 7:57:56 AM

Hi Karina,

Thank you for the bullets you prepped for Mary, they are helpful. The photos are also perfect. What we still need for the presentation are graphics or numbers that will really make our case. Mary needs to complete the presentation today so can you and your team help us prep the following ASAP?

- one map of existing conditions that shows the site today: an aerial photo with transparent overlay of BASIC habitat types - how much is wetland, how much is upland/vacant lot style. goal is to illustrate how little of the site can be said to be funcitoning habitat.

- one simple graph showing predominance of invasive species - the one in the BWER draft TMDL is fine, can you please send that to mary? we need to say "x percent of the site is covered with 99% invasive vegetation" or whatever the actual numbers are. rather than "dominate by invasives" which could mean only 55% covered.

- some species diversity numbers/charts that show how extremely depaupurate poor Ballona is. not just "reduced relative to other wetlands" but "lowest seed bank abundance and diversity of any wetland in southern california" - but i need you to give me the right language so i am not mis-stating anything. please give me those #s or charts or langauge for seed bank, veg, mammals, birds, fish and herps separately and we'll decide which ones to mention in our presentation.

- any other features of the site or results from your surveys that really illustrate to non-scientists how desperate is the need to restore ecological function and habitat at the site.

I am sorry to ask you for all this today, I hope you or one of your team has time. I think you have all this info readily accessible - f there is someihting i've requested that is a big pain check with me and we'll decide if it's really needed. please call my cell or email, i will be out of the office all day but checking my phone compulsively. also please suggest other stuff if you think of it - you know these data better than we do! thank you KJ talk to you later today.

DEPARTMENT OF DEFENSE Department of the Army; Corps of Engineers Notice of Intent To Prepare an Environmental Impact Statement/ Environmental Impact Report for the Ballona Creek Ecosystem Restoration Feasibility Study, Los Angeles County, CA AGENCY: Department of the Army, U.S. Army Corps of Engineers, DoD. ACTION: Notice of intent. --

---

SUMMARY: The Los Angeles District intends to prepare an Environmental Impact Statement/Environmental Impact Report (EIS/EIR) to support a cost-shared ecosystem restoration feasibility study with the Santa Monica Bay Restoration Commission. The proposed project study areas has been degraded by encroachment of non-native plants, placement of fill from Marina Del Rey, interruption of the hydrologic regime, trash accumulation, and varied attempts at bank protection along the creek using rock and concrete. Direct benefits of the proposed project include improved habitat and water quality, reductions in waste and trash, and aesthetics. The watershed is an important resource for both recreational uses and for fish, and wildlife and further degradation could jeopardize remaining. The purpose of the feasibility study is to evaluate alternatives for channel modification, habitat restoration (coastal and freshwater wetlands and riparian), recreation, and related purposes along the lower reach of the Ballona Creek. DATES: A public scoping meeting will be held on September 29, 2005 at 6 p.m. ADDRESSES: U.S. Army Corps of Engineers, Los Angeles District, CESPL-PD, P.O. Box 532711, Los Angeles, CA 90053 and Santa Monica Bay Restoration Commission, 320 West 4th Street, Los Angeles, CA 90013. FOR FURTHER INFORMATION CONTACT: Shannon Dellaquila, Project Environmental Manager, at (213) 452-3850 or Malisa Martin, Project Study Manager at (213) 452-3828. SUPPLEMENTARY INFORMATION: 1. Authorization This study was prepared as an interim response to the following authorities provided by Congress under Section 216 of the Flood Control Act of 1970, which states: The Secretary of the Army, acting through the Chief of Engineers, is authorized to review the operation of projects the construction of which has been completed and which were constructed by the Corps of Engineers in the interest of navigation, flood control, water supply, and related purposes, when found advisable due the significantly changed physical or economic conditions, and to report thereon to Congress with recommendations on the advisability of modifying the structures or their operation, and for improving the quality of the environment in the overall public interest; supplemented by House Resolution on Public Works and Transportation dated September 28, 1994 which states: **The Secretary of the Army is requested to review the report of the Chief of Engineers on Playa del Rey Inlet and Basin, Venice, California, published as House Document 389, Eighty-third Congress, Second Session,** and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at present time, in the interest of navigation, hurricane and storm damage reduction, environmental restoration, and other purposes at Marina del Rey Harbor, Los Angeles, California, with consideration given to disposal of contaminated sediments from the entrance channel required under the existing operation and maintenance program at Marina del Rey. 2. Background The Ballona Creek Ecosystem

degradation issues, which has led to uncoordinated and sometimes redundant and unsuccessful improvement measures. 4. Proposed Action and Alternative The Los Angeles District will investigate and evaluate all reasonable alternatives to address the problems and need stated above. In addition to a without project (No Action) Alternative, both structural and non-structural environmental measures will be investigated. An assessment of the feasibility of removing impervious surfaces from the Ballona Channel will also be evaluated. Proposed restoration measures include: re-grading and removal of fill, remove invasive and non-native plant species, reintroduction of a water source and installation of native plants to restore previously filled coastal wetlands. Other measures to be evaluated include features to improve or restore tidal regime in Oxford Basin, the Grand and Venice canals, and Ballona and Del Rey Lagoons; the potential for in stream wetland development in Centinela, Sepulveda and Ballona Creek; sediment loading in the upper watershed; and related recreation and educational opportunities. 5. Scoping Process The scoping process is on-going, and has involved preliminary coordination with Federal, State, and local agencies and the general public. A public scoping meeting is scheduled for Thursday September 29th from 6-8 p.m. at the Rotunda Room of the Veteran's Memorial Building, 4117 Overland Avenue, Culver City, CA. This information is being published in the local news media, and a notice is being mailed to all parties on the study mailing list to ensure that public will have an opportunity to express opinions and raise any issues relating to the scope of the Feasibility Study and the Environmental Impact Study/Environmental Impact Report. The public as well as Federal, state, and local agencies are encouraged to participate by submitting data, information, and comments identifying relevant environmental and socioeconomic issues to be addressed in the study. Useful information includes other environmental studies, published and unpublished data, alternatives that could be addressed in the analysis, and, potential mitigation measures associated with the proposed action. All comments will be considered in the project development. Concerns may be submitted in writing to the Santa Monica Bay Restoration Commission, or to the Los Angeles District (see ADDRESSES). Comments, suggestions, and request to be placed on the mailing list for announcements should be sp101.usace.army.mil. Availability of the Draft EIS/EIR The Draft EIS/EIR is scheduled to be published and circulated in December 2007, and a public hearing to receive comments on the Draft EIS/EIR will be held after it is published. Dated: September 13, 2005. Alex C. Dornstauder, Colonel, U.S. Army, District Engineer. [FR Doc. 05-18651 Filed 9-19-05; 8:45 am] BILLING CODE 3710-KF-M

Hi Mr. Mayfield, attached is the congressional and corp docs we discussed.

The document states an joint EIS/EIR process was begun in 2005 per the request of Congress.

The Santa Monica Bay Restoration Commission is noted as the lead agency for CEQA in the joint EIR/EIS.

It also states that at least one scoping hearing has already occured.

My question is does DFG plan on beginning another EIR process for the same area that is already been started by the SMRBC and Corp. If so, how can there be two lead agencies.

To me, logic indicates the SMRBC should be lead.

Thanks,

John Davis

Ballona Ecosystem Restoration Planning Management Meeting
June 28, 2010
3:00-5:00pm

Attendees:

Josephine Axt, USACE	Ed Demesa, USACE	Julian Serafin, USACE
Rene Vermeeren, USACE	Ben Nakayama, USACE	Rhiannon Kucharski, USACE
Diana Hurlbert, SMBRC	Sean Bergquist, SMBRC	Kathy Anderson, USACE
Larry Smith, USACE	Mary Small, Coastal Conservancy (by phone)	

I. Mary Small: Coastal Conservancy is supplying most of the funding toward the in-kind local sponsor efforts.

II. Ed Demesa: Corps Process Overview
   a. We are coming up to our first major milestone (F3)
      i. Baseline and future without project conditions; preliminary alternatives analysis
         1. Describes problems and opportunities, planning objectives
         2. This product will be the basis for future steps
      ii. Next milestone (F4A/F4)
         1. Formulation, evaluation and comparison of alternatives
         2. F4A: SPD requirement, Alternative Formulation Briefing
      iii. (F5) Public Draft Feasibility Report
         1. Headquarters Policy and Public Review
   b. Josephine Axt: New Review Guidance (Estimated at $500,000; IEPR is federally funded)
      i. Agency Technical Review (ATR) - Requires coordination with the planning center of expertise, and coordinates a team of reviewers from another Corps Division
      ii. Model certifications required
      iii. Independent External Peer Review (IEPR)
      iv. Note for budget: call out what IEPR is estimated to cost, and that it does not have to be cost shared
      v. Diana Hurlbert: Under each discipline, there are costs for responding to comments. Are those related to ATR?
         1. Josephine Axt: Yes. There is a formal comment and response system that must be used for ATRs (DrChecks)
   c. Kathy Anderson: Partnership
      i. Communication
         1. Sean Bergquist: Communication has been much better since Rhiannon has taken over as Lead Planner.
         2. Mary Small: Rhiannon has been great in communication.
      ii. Cost share
         1. Sean Bergquist: Our cost share component is 100% in-kind. It is anticipated that most of that work is and will continue to be in the wetlands.
            a. We are finished our F3 equivalent (2006)
            b. We are also finished our alternatives development and analysis (2008)
               i. We want to make sure that all of the products feed in to the Corps process and products.
            c. The Corps and us on not on the same timeline.

a. Definition: Ballona Creek from the Pacific Ocean to Cochran, Del Rey Lagoon; and Centinela and Sepulveda Channels from Ballona Creek to where they go underground.

2. Grand canal is out.
3. Sean Bergquist: We have always planned on the daylighted part of Ballona Creek up to Cochran.
4. Coordination needs to go through Diana Hurlbert and Rhiannon Kucharski.

ii. Costs

1. Ed Demesa: For in-kind credit, it is important to let the PDT know what work the sponsor is doing, even if it will not be submitted for in-kind credit.
2. Sean Bergquist: Historical analysis of the watershed is in the works. We are also working with UCLA to do a watershed budget.
3. Sean Bergquist: When things have to be redone, how does the cost share work?
    a. Hydraulic study
        i. Rene Vermeeren: Our H&H models are in DRAFT form and have not yet had the first ATR. They are not ready for use on alternatives.
4. SMBRC Governing Board will have to sign the PMP and FCSA amendments.
5. In construction phase, can the cost of the land/property be used toward sponsor in-kind credit?
    a. Kathy Anderson: Yes, as long as the constructed project uses those lands. The state paid $140 million in 2005 for the property that makes up areas A, B and C.

iii. In-kind submittals

1. Mary Small: Is there really much more additional work that needs to be done to review the submittals? How much is left to be done by the Army Corps depends on the in-kind submittals?
    a. Diana and Rhiannon can work together with each PDT member to work through these. Set up meetings ASAP.
    b. Kathy Anderson: The whole PDT needs to sit down and go through the PMP, in-kind and costs step-by with SMBRC.
2. Mary Small: I am worried about the water quality report in terms of the data being what is needed per the Corps and less worried about the write-up
    a. Confirm with James Chieh that the data is what is needed.

c. Kathy Anderson: Sponsor financial capability?

i. Even in light of cost increases, the sponsor has enough money to fund all of their study activities and even begin phase I construction (Area B).
ii. Corps needs to get details of sponsor plans for "phase I" in Area B and determine if this must be added as a future without project condition or not.

IV. Action items are noted in RED.

Ballona Coordination Meeting Minutes
June 2, 2010
10am

Attendees:

Mary Small, Coastal Conservancy	Diana Hurlbert, SMBRC	Heather Schlosser, USACE
Julian Serafin, USACE	Rhiannon Kucharski, USACE	
Ben Nakayama, USACE	Robert Browning, USACE	Robert Grimes, USACE

I. In kind submittals
   a. For In-kind submittals, Mary, Sean and Diana tried to break down the submittals per the PMP, but had a hard time. Please see in-kind spreadsheet submitted last week.
   b. SMBRC and Coastal Conservancy will submit the In Kind Submittal sheets that correspond with each document from the website, along with reference to the document or file they correspond to and a link to that document on the web.

II. PMP updates
   a. Mary Small is concerned that the revised PMP does not reflect the products they have completed, and very concerned about the cost increases.
   b. Mary Small: Have all the PMP sections looked at the same project area? Parts still refer to Ballona Lagoon, Grand Canal, Venice Canals and Oxford Basin, which are no longer in the study area.
      i. All sections should include: Del Rey Lagoon; Areas A, B and C; Ballona Creek from the Ocean to Cochran; and Centinela and Sepulveda Channels from where they daylight to Ballona Creek.
   c. Mary and Diana requested that the Corps add geographic location to the PMP amendment chapter. The scopes of work are confusing because they do not make the study area clear.
   d. Mary: Why have the F3 economics costs gone up?
      i. Ben Nakayama: Economics had to re-run their model due to the revised flood plain hence their cost increase. The potential flooded parcels went from 6000 to 600.
      ii. Sponsor wants to understand why the economics costs for F3 doubled. The model was originally run at a larger scope (6000 parcels) and is now being re-run at a smaller scope (600 parcels). That should not cost double. There should be economies of scale.
      iii. Ben Nakayama: The model had to be completely re-run for the new parcels. This along with added review costs are the reasons behind the cost increase.
   e. Review Guidance has led to approximately $505k in cost increases. $260k of that is for Independent External Peer Review (IEPR), which is NOT cost shared. The other levels of review such as Agency Technical Review (ATR) and model certification ARE cost shared.
      i. Rhiannon will send another copy of the review guidance.
   f. The Coastal Conservancy is worried that there will be no political appetite to support a feasibility study at this cost level.

Ballona Telecon Minutes
March 29, 2010

Attendees:

Rhiannon Kucharski, USACE	Kathy Anderson, USACE	Larry Smith, USACE
John Killeen, USACE	James Chieh, USACE	Frank Wu, USACE
Julian Serafin, USACE	Michael Hallisy, USACE	Patrick Singh, USACE
Mary Small, Coastal Conservancy		Sean Berqquist, SMBRC

I. Introductions
II. PMP update
    a. DRAFT SOW Amendment Chapter distributed
    b. Cost estimates
        i. Frank Wu: Coastal Engineering F3 Baseline Conditions
            1. Need to incorporate PWA information in to the appendix
    c. SMBRC Board will have to buy off on the updated PMP and cost estimates
        i. At this Thursday's meeting they are asking the Board to generally support the study
        ii. Cost increase approval will have to come through the Coastal Conservancy's Board
    d. FCSA amendment would come after the PMP update is complete
        i. Have to work with Corps Legal Counsel and SMBRC Legal/Board
    e. Study Area
        i. For F4, the Corps suggests focused study area of A,B & C plus the Creek up to the I-405, and the Centinela Channel and Sepulveda Wash
            1. H&H and Survey and Mapping Sections believe this focused area is best due to cost considerations
            2. Per Frank Wu: Coastal Engineering work has focused on A, B, & C
        ii. Sponsors feel that we need to keep Ballona Creek up to Cochran Boulevard. Otherwise, the map is okay.
    f. Rhiannon and Kathy will set up a meeting between the sponsors and Survey and Mapping (Alan Nichols).[1]
    g. URS and the Corps are in negotiations for the Plan Formulation and Environmental Appendix
III. Corps work Audit
    a. Environmental Resources Branch (ERB)
        i. Review of sponsor work
        ii. Fish survey of creek and channels
        iii. Work with SAC on HEP evaluation
            1. Including scope of work to score A, B & C and the creek between the marsh areas
            2. Mary can re-start the Conservancy agreement with the SAC to possibly fund them.
                a. Larry will send Mary the scope of work he has written.
    b. Cultural Resources
            1. Write-up from PWA, which summarizes a library record search
                a. Corps and Conservancy both feel that the write-up is inadequate

[1] Action items marked in GREEN

1. Sponsor needs to keep records of the in-kind and the values in case of an audit.

ii. Mary Small: What is the best way to do that?

iii. Kathy Anderson: We can have a separate meeting to go through the in-kind line by line with Kathy, Rhiannon, Sean and Mary.

iv. Mary Small: Is it what we spend on the product that gets credited or is it what the federal government would have spent to do the same thing?

1. It is up to the PDT to QA/QC the products and agree to the accounting both in amount and content.
2. Coastal Conservancy would feel more comfortable if the in-kind is credited at the value they spent on the product.

V. Coordination

a. Corps requests going forward

i. Each PDT member needs to coordinate with their equivalent on the sponsor's contractor team(s)

1. Rhiannon will send a PDT list to Sean and Mary so that coordination contacts can be filled in next to the corresponding PDT member(s).

b. Sponsor requests

i. Tie up the in-kind process and update more often

c. Our coordination meetings from now on will be the last Wednesday of every month at 10am.

VI. Other Discussion

a. Bike tour with Congresswoman Harman April 9th.

i. Kathy will forward info to Mary and Sean.

TIME/ACTIVITY		TRANSP/REMARKS

Outline for the presentation

(Mary)
Background

- 600 acres owned by the state, DFG and State Lands
- Designated State Ecological Reserve
- Purchased for the purpose of wetland restoration

Project Partners, introduce Shelley

(Shelley)
Need For Restoration, Site Mgt

- Currently no open public access, very restricted
- Site management issues: homeless encampments, trespass, trash, eyesore

Need for restoration, biology

- Very degraded ecological resources – key findings of baseline assessment
- Regional significance – wetland loss around SM Bay and throughout So CA

Proposed project

- Description of grand vision
- Ecological benefits
- Sustainability – adaption to SLR, restoration of ecological processes
- Public access components

Planning process to date 2 slides(?)

- Public and Science Based Process
- Evaluation of broadest possible range of alternatives
- Refinement and assessment of preferred alternative –ideas we rejected, scaling down due to cost considerations, planning for phased implementation

(Mary)
Recommended action:

1) Authorization for a grant of $250 K to SMBRC to fund their ongoing work to advance this restoration project, including continuation of data collection, agency coordination and technical review and oversight.

2) Authorization of $6.25 million to be contracted by SCC through competitive environmental services contracts for specific technical studies that are needed to complete the environmental review and permitting.

Description of the technical work (what will be done and why so expensive)
This authorization would provide funds for several specific scopes of work to support environmental impact review and permitting of the restoration project.

- Soils and Geotechnical assessment – Some soil sampling has been completed onsite, however the main cost for implementation of the project will be soil management.. To

Some individuals think that this site is providing important habitat as is. This is a case of shifting baselines, the site does provide some habitat, but is severely degraded. Example - data pt from Karina's work?. To restore estuarine wetlands at Ballona, the land needs to be reconnected to the ocean.

- Can project be done with volunteers and without bulldozers?

The project that we are recommending is enormous in scale. It involves uncovering the wetlands that were buried with the construction of the marina and that have been cut off from the ocean for almost 90 years. We will work to continue working with youth groups and volunteers to implement portions of this restoration.

- Money would be better spend buying small parcels in the neighborhood

Some neighbors to the project have advocated that the restoration of the wetlands is a poor investment and the bond money should be spent to acquire small parcels (each 3-5 acres) rather than to restore the ecological reserve.

Funds are limited to Ballona, consequences if not approved, who will pay for construction?

Conclusion:
Even though this is a major investment and a controversial project, your staff recommends that you approve it. The ecological restoration of the Ballona wetlands is a rare opportunity to bring back coastal wetlands and to develop an urban natural area that will enhance the lives of millions of Californians. To really restore this site we have to implement a big vision and in order to do that we

Questions I will need to be prepared to answer:
Consequences if not approved
Who will pay for construction?
Why not grant all funds to SMBRC?

Great, let's meet before maybe 11?
Downtown would be easy for me but I could also fly to LAX and meet at LMU, if we do that maybe we could meet a little earlier?

Sam can't make it, this rescehduled time didn't work for him.

Hi Shelley
Attached is a draft of the grant agmt to the SMBRF for the $240K. We'll need to develop a work plan and budget separately.

Can you take a quick review and let me know if it looks ok? Elena has asked me to produce this draft quickly as it seems the best way to respond to our most recent PRA from Mr. Davis.

Thanks
Mary

REQUEST FOR SERVICES

Ballona Wetlands Ecological Reserve
Environmental Analysis and Permit Assistance

May 11, 2009

Contract Type: Environmental Professional Services

Scope:
Perform environmental analysis and assist in applying for permits for habitat enhancement and public access improvements at the Ballona Wetlands Ecological Reserve in Los Angeles.

Submittal Deadline: **June 1, 2009**
Proposals should be submitted electronically in adobe acrobat format and must be received at the Conservancy by June 1, 2009.

Contact: Mary Small, California Coastal Conservancy, msmall@scc.ca.gov

REQUEST FOR SERVICES

Ballona Wetlands Ecological Reserve
Civil and Geotechnical Engineering and Permit Assistance

February 8, 2010

Contract Type: Civil Engineering and Geotechnical Professional Services

Scope: Provide engineering and geotechnical evaluations, design and related services for the proposed wetland restoration design of the Ballona Wetlands Ecological Reserve in Los Angeles. Technical studies, evaluations, and designs will be of sufficient detail to support completion of a project level EIR/EIS and preparation and processing of a Section 408 permit through the Army Corp of Engineers.

Submittal Deadline: February 29, 2012

Proposals should be submitted electronically in adobe acrobat format and must be received at the Conservancy by February 29, 2012.

Contact: Mary Small, California Coastal Conservancy, msmall@scc.ca.gov

Reserve in Los Angeles County. Services are needed to complete engineering and geotechnical evaluations, hydrology, technical studies, design and related services to support completion of a project level EIR/EIS and preparation and processing of a Section 408 permit through the Army Corp of Engineers. One contract will be for Civil and Geotechnical Engineering and a second contract will be for Hydrology and Engineering Design Analysis.

Dear Mr. Davis:

Your request below does not constitute a request for a record pursuant to the Public Records Act. Rather, your request is for an analysis of statutory law. I am ethically prohibited from providing counsel to anyone other than my client. Assuming that you are not a lawyer, I am also ethically bound to suggest to you that you obtain your own counsel to advise you on such matters. You may utilize the California State Bar website for referrals to counsel at www.calbar.ca.gov.

Sincerely,

Elena Eger

Senior Staff Counsel

Dear Mr. Davis:

This correspondence contains the Coastal Conservancy's (Conservancy) response to your March 21, 2012 Public Records Act request, below.

The Conservancy does not possess any responsive records to either of your numbered requests. However, we direct you to Government Code Sections 4525 *et seq*. and 14 California Code of Regulations Sections 13870 *et seq.* for our contracting process.

Sincerely,

Elena Eger

PUBLIC CONTRACT CODE SECTION 10140-10141

10140. **Public notice of a project shall be given by publication once a week for at least two consecutive weeks or once a week for more than two consecutive weeks if the longer period of advertising is deemed necessary by the department, as follows:** (a) **In a newspaper of general circulation published in the county in which the project is located**, or if located in more than one county, in such a newspaper in a county in which a major portion of the work is to be done. (b) **In a trade paper of general circulation published** in San Francisco for projects located in County Group No. 1, as defined in Section 187 of the Streets and Highways Code, or **in Los Angeles for projects located in County Group No. 2, as defined in said Section 187, devoted primarily to the dissemination of contract and building news among contracting and building materials supply firms. The department may publish the notice to bidders for a project in additional trade papers or newspapers of general circulation that it deems advisable.** 10141. The notice shall state the time and place for the receiving and opening of sealed bids, describing in general terms the work to be done and that the bids will be required for the entire project and for the performance of separate designated parts of the entire project, when the department determines that segregation is advisable.

The prohibition of this subdivision shall not apply to a contract requiring the person's services as an expert witness in a civil case or to a contract for the continuation of an attorney's services on a matter he or she was involved with prior to leaving the university. (c) This section does not prohibit the rehire or reappointment of University of California employees after retirement, consistent with university administrative policies, nor does it apply to inventors and authors of intellectual property licensed under technology transfer agreements. 10518. (a) Except as otherwise provided in subdivision (b), each contractor who enters into a contract with a University of California campus for ten thousand dollars ($10,000) or more shall be assigned an identification number by the chancellor of that university campus. Each contractor who has been assigned a number shall list it on each contract the contractor enters into with the university campus, regardless of the amount of the contract. In the case of a corporation or firm, the chancellor's assigned number shall be used exclusively on each contract with that particular chancellor's campus. The assigned number shall remain unchanged regardless of future name changes. (b) If the identification numbers cannot be tracked centrally by the Regents of the University of California, then the regents, and not the chancellors, shall assign the identification numbers.

Hi Barbara,
Thanks for agreeing to support the recommendation for funding for engineering work at Ballona. Attached is the draft staff report, the project will be heard at our Jan 19th meeting at the Baldwin Hills Scenic Overlook. As you can see it's a pretty big authorization, so we'd love your support. I think we may take the Board on a tour of Ballona that morning and then the meeting will start around 12:30. It would be great to have MRCA join us for either the tour or the meeting.

Thanks also for the message about the early action plan grant. When you have time submit any final billing or just a letter stating that the work is all done and I'll close it out.

Hope you are doing well and have a great holiday.
Mary

California Coastal Conservancy
Att: E.Eger
Re: Reply

Dear E. Eger,

The request for public records submitted on 2/14/2012 remains outstanding.

The Commission still needs to reply to this request within 10 days of the submission date. I do expect a reply by 2/24/2012 as
the Public Records Act requires under law.

I also would take issue with your recent email stating that I made a DEMAND of the Commission. This is far from true.

In fact my email stated the INTENDED PURPOSE of the email and made no demands as you stated to me in your email to me.

Prior to that, you inferred in another email that I made statements and or asserted things that I clearly did not.

I corrected you once alreadyin writing, and find I must do so yet again.

Your accuracy in characterizing my telephonic conservations or written documents should not be clouded by your misconceptions
as I do not find it to be professional in your role as a State Attorney.

Regards,

John Davis

Mr. Davis:

This is in partial response to your PRA, below and your request of yesterday at 5:15 p.m. in which you demand that we not share your communications with "any private business" and in which you characterize such communications as "private".
While we will provide you with your requests to the extent possible and in compliance with the PRA, we must clarify to you that communications between you, as a member of the public, and the Conservancy, a public agency, are not considered under the PRA and thus not by the Conservancy to be "private communications", subject to any privilege or exception under the Act. Indeed, we will continue to share communications to you or from you with our other Ballona project partners, irrespective of whether the partner is a public or private organization, when we, at our sole discretion, determine that dissemination to be useful for our project purposes.
I would also like to clarify for you for your future purposes that my title is not "council" but "counsel", that is, I am a lawyer, not a member of a council.
Sincerely,

Elena Eger

California Coastal Conservancy
Att: Council E. Eger
Re: Public Records Request

This is a public records request made pursuant to the California Public Records Act. Each numbered item is a separate and distinct request for public records. This letter is only intended to for the California Coastal Conservancy and NOT FOR ANY PRIVATE BUSINESS, unless requested by such a business via the California Public Records Act.

1. Provide any and all emails to and received by the California Coastal Conservancy

As I stated in my email of yesterday to you, we intend to comply with your records request to us of 2/14. We are working on compiling the records that you have requested. Please clarify whether you wish to receive the emails pertaining to correspondence among Mr. Valor, Ms. Luce and Conservancy staff with respect to the Item #5 on the 1-19-12 agenda only.

Please clarify that you are referring to the Conservancy when you make reference to the "Commission" in your message below.

As to your other allegations contained in your email below, I remind you that, as I said yesterday, we will make no further comment, which, of course, does not mean that we agree or disagree with your interpretations. Again, unless you are requesting a record from us under the Public Records Act, we do not intend to make further explanatory comments to you.

Sincerely,

Elena Eger

Dear Mr. Davis:

In response to your inquiry below, I am providing you with the link to our website's contents of Item 5, Ballona Restoration Project, approved at the Conservancy's 1-19-12 public meeting unanimously. All my references are to the contents in this link. http://scc.ca.gov/webmaster/ftp/pdf/sccbb/2012/1201/20120119Board05_Ballona_Wetlands.pdf.

I believe in your message below you are referencing Exhibit 4. This record reads at the bottom of the page in the key: "Existing habitat units based on field survey conducted by the California Department of Fish and Game, October – December 2000. Map created by GreenInfo Network October 20, 2011." The Conservancy's logo is next to this statement.

With respect to the remainder of your email to us, below, except for our response to your last statement regarding the Conservancy's

our restoration partner on this project. We direct you to the Conservancy's website at www.scc.ca.gov, Ballona restoration for identification of our project partners on this project.
With respect to whether DFG provided the Conservancy with permission to put our logo on this proposed restoration design, please note that the Conservancy is a project partner with DFG and that within this partnership, the Conservancy acts as the lead in restoration planning with the full agreement of the other project partners, including the DFG.
Sincerely,

Elena Eger

Att: Elena Eger Legal Council
CC Mary Small Project Manager
Re: Item 5 January 19th 2012 Meeting

Hello Council Eger,

Mary Small directed me to you to answer a question about the hearing noted above.

The attached map was presented as a projection.

It bears the seal of the State Coastal Conservancy. The small text below the legend is hard to read but it
does reference the California Dpt. of Fish and Game in 2011. The text is not clear. It appears to say Ballona Wetlands units.....summary conducted the California Dpt of Fish and Game .....Map created by .....October 20, 2011.

Could you provide the correct reading of this text?

For what purpose did Fish and Game produce this map?

Did Fish and Game provide specific permission for the Conservancy to place its seal (logo) on this

To: msmall@scc.ca.gov; eeeger@scc.ca.gov
Subject: State Water Board Legal's Memo to our Governing Board

Mary & Elena--

The attached memo to our Governing Board may help with some background. It was not only given to our Governing Board, it is posted on our website, and was forwarded to John Davis and Patricia McPherson, among others. It addresses virtually all of the accusations made against the Foundation and Commission.

Attached also is a direct letter to John Davis from SWRCB legal noting how Foundation staff and contractors legally serve the SMBRC. For example, I am a contractor to the Foundation, but I am authorized to act on behalf of the Commission. He refuses to acknowledge that, which will never change. However, the documents speak for themselves.

One reason he may be contacting you (again) is that SWRCB legal told him that any future PRA queries to the Commission must be directed to me. He simply won't do that so he seeks ways around it. It would be entirely appropriate for you to re-direct any queries relevant to the SMBRC to me.

Call me if/when questions arise.

State Lands Commission owns approximately 60 acres, including the Freshwater Marsh and the Expanded Wetlands parcel. The State Coastal Conservancy (SCC) is taking the lead in funding for planning and restoring the property. Together, the three agencies are working with stakeholders, scientific experts and other agencies to develop a plan for restoration of this extraordinary resource. Their goals are to:

- Restore and enhance salt-water influenced wetland habitats to benefit endangered and threatened species, migratory shorebirds, waterfowl, seabirds, and coastal fish and aquatic species. Restoration of seasonal ponds, riparian and freshwater wetlands, and upland habitats will be considered where beneficial to other project goals or biological and habitat diversity;

- Provide for wildlife-dependent public access and recreation opportunities compatible with the habitats, fish, and wildlife conservation;

- Identify and implement a cost-effective, ecologically beneficial, and sustainable (low maintenance) habitat restoration alternative.

Milestone 7.1c: Secure funding source (approximately $50 million, total project cost $100–200 million) sufficient to complete first phase implementation of preferred alternative by 2010.

Implementation Lead: Coastal Conservancy
Implementation Partners: State Parks, SCWRP, NMFS

Role of the SMBRC: Participate

On Fri, Sep 28, 2012 at 2:52 PM, Johntommy Rosas

Bay watershed ecosystem and their preservation and restoration is a high priority of the Bay Restoration Commission. Wetlands are areas of transition between land and water, where soils, plants, and animals are adapted to periods of inundation and saturation. Wetlands are one of the most productive ecosystems in nature, providing essential habitat for a variety of species, including birds, fish, reptiles, invertebrates, and mammals. Wetlands act as natural filters which are able to absorb and remove pollutants from the water. They are also valuable in providing flood protection, groundwater recharge, recreational use, and aesthetic

channelization of Ballona Creek have all reduced what was once a 2,200-acre coastal estuary to less than 200 degraded acres today. Poor tidal exchange, polluted runoff, and invasive plants and animals also impact the wetlands.

In 2004, the State of California took title to 600 acres of the former Ballona Wetlands in Los Angeles. The property is now owned by two state agencies, the Department of Fish and Game (DFG) and the State Lands Commission (CSLC). DFG took title to approximately 540 acres of the former wetlands. DFG also holds title to a section of Ballona Creek. The

SECTION I

INTRODUCTION

Project Understanding

Psomas has unmatched technical engineering knowledge of the Ballona Wetlands that spans 25 years. No other firm has been involved or has more engineering knowledge of the wetlands and its surroundings than Psomas. We have extensive knowledge of the infrastructure of the surrounding community as well as The Gas Company facilities throughout the area as a result of our extensive previous work in the community surrounding the Ballona Wetlands. This extensive historical knowledge, has provided us with unique insight and understanding of the opportunities for the restoration plan and the Conservancy's goals for this project.

The State Coastal Conservancy through the PMT team has developed a conceptual plan to restore the Ballona Wetlands ecosystem. It will comprise diverse habitat ranging from sub-tidal through various marshland conditions to upland habitat. The objective of this restoration program is to reintroduce and revive critical wetland habitat and provide a remarkable natural open space for the public benefit. The Ballona Wetlands Restoration Project will enhance the coastal environment for reintroduction of target animal and plant species that left the area because of human development and related loss of the coastal wetland.

The existing Ballona Wetlands have suffered from more than a century of human neglect and abuse that has resulted in a highly degraded habitat area. Much of the area was used for disposal of dredging spoils from construction of Marina Del Rey and the Ballona Creek flood control channel. The Ballona Creek flood control channel was constructed to provide flooding protection for development of lands upstream from the original wetlands; however, the channel also severed the historic natural connection between the freshwater creek and the ocean. As a result, many of the historic ecological functions of the wetlands were lost and no longer support the wide variety of native species that once inhabited the area.

The PMT and their consultant team have studied several alternatives that would allow the reconstruction of a coastal wetland environment and reintroduction of the native species common to these wetlands. While a number of alternatives have been analyzed, a preferred alternative has been developed that involves the removal of segments of the Ballona Creek levees and the reconstruction of a portion of the Ballona Creek channel on an alignment that more closely represents a natural meandering water course. Implementation of this plan will require a technical analysis and review and approval by the County of Los Angeles and U.S. Army Corps of Engineers (USACE) with a Section 408 permit.

More specifically, the preferred project proposes to implement restoration of areas on the north and south sides of the existing Ballona Creek on lands adjacent to Marina Del Rey within Los Angeles County (County) Area A and City of Los Angeles Area B, as well as some restoration in Area C in the City of Los Angeles. This work will generally include:

- Build in flexibility of delivery to address availability of funding. Staged or phased delivery through master planning the construction sequencing.
- The removal of the north and south Ballona Creek levees to allow tidal and stormwater interaction within the Ballona Wetlands Ecological Reserve area.

- Construction of new perimeter levees along the perimeter and strategic alignments within the restoration area to provide the flood protection of existing developed areas when the existing levees are removed.
- Grading to create a restored condition allowing multiple habitat regimes from sub-tidal to upland conditions.
- Execute the proposed construction through a master planned and phased program designed to reduce the environmental impacts as much as possible, balancing earthwork within the Reserve area.
- Assist the PMT in coordinating with and addressing the concerns of the many governmental agencies and other interested parties.

Project Objectives

Consistent with the Conservancy's stated goals, our project team's approach will be driven by the following three primary objectives and secondary objectives for the Civil/Geotechnical team:

Primary Objectives:

- Working with the PMT and Hydrology consultant team, obtain Section 408 approval from the USACE for the levee removal and its supporting analysis.
- Analyze impacts and mitigations for incorporation into the environmental analysis.
- Prepare plans and supporting documents for the grading and infrastructure at the appropriate level for the restoration project.

Secondary Objectives:

- Assist the PMT in obtaining approvals in the most efficient and effective manner. The process to obtain a 408 approval is by design not clearly defined to allow for the many existing conditions in USACE facilities.
- Assist the PMT in addressing the issues and concerns of the community and interested parties. Many groups and agencies are interested in this restoration. They each view it in different terms. Our goal is to provide information and support that is appropriately tailored for public presentation of our technical information in a non-technical manner.
- Ensure that the proposed design elements are sensitive to the environmental goals of the project. The overarching goal of restoring a natural wetland system must be the primary focus in our design.

SECTION II

MANAGEMENT

To meet the objectives of the project as described in Section I, Psomas developed an approach and work plan that identifies the design elements and sequences the work in an efficient and logical manner to allow the Conservancy to realize the restoration potential of this unique site.

Each project team member brings their particular strengths and capabilities that, when combined, cover all aspects of work required to meet the project objectives. The sections of work are identified in the work plan for each of the disciplines responsible for a technical aspect of the project. This section outlines the tasks that each team member will perform and sequencing of performance.

Sequence 1 – Project Initiation

Our first step will be to organize and coordinate our efforts with the project team. This includes preparation of this, more detailed schedule and work plan, developed in conjunction with other project team members and the PMT. The work plan identifies our primary sequences of work with specific tasks with sub-tasks. The schedule will identify Psomas activities and work items being provided by other project team members. Our primary objectives in the project initiation phase are two-fold: understanding the specifics of the work to be delivered and planning that work. We must gain a full understanding of the process we will pursue, the constraints we may encounter, and the steps to address these constraints in order to continue our progress. This understanding extends to the entire Psomas team. An initial full-day workshop start-up meeting will be held with the County agencies as the applicant for the 408 permit. This meeting is intended to provide an orientation for the County staff, and to outline rough expectations that will be refined more fully as the project progresses. A series of meetings and a coordination effort will then be undertaken to refine the procedures and technical criteria to be utilized. Our deliverable will be the final version of this work plan.

Sequence 2 – Data Gathering

During this stage we will gather existing data including topographic survey, record documents for easements, previous geotechnical analyses, utilities, and other constraints that may influence the final design. While the technical sections define specific tasks in more detail, a brief description of the tasks are described below.

- Topographic Survey – The currently available topographic survey is over 10 years old, having been compiled over a period of years from 1998 to 2000. It is also on a different datum than required by the USACE. Through aerial photographic compilation methods, we will prepare an updated topographic survey of existing conditions at 40-scale for areas A, B and C. Prior to undertaking the topographic survey, we will meet with the USACE and the County to discuss the project survey datum. Unless specifically required by an agency, we would use the latest datum adjustment developed for the area by Los Angeles County.

- Boundary and Easements – One of the requirements for any restoration project is the understanding of the legal encumbrances of the property. Using the existing ALTA survey

provided in AutoCAD format by the Coastal Conservancy, we will compile an exhibit showing existing easements, rights of way, lease areas, etc. on the property and their planned disposition. For example, whether an easement is to remain or be vacated, or a new one provided. The boundary will be translated as needed to correspond to the coordinate base used for the new aerial topography, which will be established based on USACE and County requirements.

- Utility Mapping –Utility records already obtained from our previous work on the site (as well as work by another consultant, PWA) will be reviewed, additional records search will be conducted as required, and the known utility lines within and adjacent to Areas A, B, and C will be plotted. Utility type, location, and size will be identified as available.

- Aerial Photography – Along with the topographic survey, a 40-scale color orthographic presentation quality aerial photograph will be prepared that overlays the topographic survey.

- Previous Geotechnical Analyses – Group Delta, will review previous analysis, both historical and recently conducted. All available data will be compiled to help determine the need and location for additional field exploration and site analysis related to soils, seismic, and liquefaction conditions, as well as settlement, structural, and grading requirements.

- Locations of Geotechnical Test – Locations for the additional geotechnical investigation bore holes and test pits that may be required will be identified. A construction stake will be placed at each of the test locations. Approximately 60 locations will be initially required. These locations will be referenced as a data layer on the topographic survey.

- Geotechnical Field Exploration – Upon receiving approval for field exploration, subsurface exploration for a number of borings will be performed ranging from 25 to 70 feet deep along the proposed levees and at appropriate locations of expected improvements. Site clean-up will occur to leave the boring trenching locations in a similar condition as prior to the start of work, with any excess materials removed and disposed of per applicable regulation.

- Geotechnical Analysis – Geotechnical, environmental, and chemical analysis of the sample materials obtained during the field exploration will be conducted.

- Habitat Surveys – If habitat survey information is available, Psomas can work with the appropriate consultant to prepare a data layer that is aligned on the topographic survey.

- Specific Design Survey – Field-surveyed information will be gathered including channel cross sections, top of the levees for end protection implementation, and at existing storm drain culverts and pipes in and adjacent to the property along Culver Boulevard, Jefferson Blvd, Lincoln Boulevard, Fiji Way, and the existing Ballona Creek levees.

- Constraints Map – Using the information and data compiled above, a constraints map will be created for use by all team members. This "Base" map is intended to identify all existing conditions to provide the foundation for future design analysis. An overall map as well as stand-alone map for all three areas will be prepared.

The data gathering components described above have been developed under the assumption that we will have to develop a substantially complete design (at least 70% documents) in order to satisfy Los Angeles County and the USACE requirements. If these agency requirements can be met with a 30% design level of effort, then the topographic survey and related data can be used when the final design documents are prepared.

Due to delays that will occur due to avoidance of sensitive habitats such as nesting seasons, and time to obtain approvals for geotechnical field investigations, the Data Gathering Sequence will overlap with the Preliminary 30% Design Sequence. Final deliverables will include a fully completed design and rectified aerial survey, a fully reviewed constraints map and report, and all geotechnical field exploration.

Sequence 3 – EIR/EIS Support

A great deal of work has already been completed for the EIR/EIS including evaluation of road and levee alignments, investigation of utilities relocation impacts, grading quantities expected, phasing and staging of construction, etc. Psomas will provide additional support as needed to refine or clarify issues identified in the EIR/EIS analysis that relate to the roads, grading, and infrastructure elements of the work. The extent of additional studies and support is not defined at this time and will only be clarified as the EIR/EIS impacts and mitigation measures are refined. These studies will draw upon the already extensive amount of work and analysis that has previously been prepared by the EIR/EIS team. This EIR/EIS Support phase does not have a distinct schedule and may occur throughout the process.

Sequence 4 – Design Services

The design services discussed below are structured to provide various levels of design that may be required for the EIR/EIS and to meet the USACE Section 408 permit requirements as well as requirements from other reviewing agencies. These levels of design can be considered as 30% or preliminary design, 70% design documentation and 100% full construction documents. The level of effort required to obtain the 408 permit is not clear at this time for several reasons as listed below. As the project progresses, the actual requirements to be provided will be more clearly defined.

- The USACE requirements for the 408 approval as described in their own Clarification Guidance Memo are not clearly defined, by design, to allow for the many conditions that exist with USACE Facilities.
- The USACE Western Region has issued few major 408 permits within the memory of their current staff. It is therefore more difficult to determine the level of work that will be required for approval.
- The 408 permit requires approval from USACE Headquarters in Washington D.C. This adds another layer of review and process to the permit.
- Los Angeles County is the public agency responsible for ongoing operation and maintenance of the Ballona Creek flood control channel and levees and will be the applicant for the 408 permit.
- The Department of Fish and Game has a major interest as the landowner and steward of the natural resources on the site that could shape or adjust the construction and sequencing through the process.
- There are many interested parties and stakeholders who will have input into our work which will require adjustments throughout the process.

To address these uncertainties, we have organized the design portion of our work plan into three submittal efforts. This includes a sequenced design process roughly corresponding to 30%, 70%, and 100% complete drawings and supporting documentation. Performing work in these three design stages is intended to provide the project team with a framework for a logical progression through the approval process without the need to commit to more work effort than may be required to meet the project objectives. By providing sufficient scope and budget for design and approval work through 100% documents, the Conservancy can budget for and implement a full documentation of the design should that level of effort be required to meet the Section 408 permit requirements or other project related approvals that may be needed to meet the project objectives.

30% Preliminary Design (Eight Months – by December 2012)

Psomas will manage and be responsible for all services provided by our team. We have listed the disciplines by the team member.

Civil and Survey – Psomas (See Sections III and V)

Geotechnical – Group Delta (See Section IV)

Structural – JCE (See Section VI)

The application to the USACE will initially be submitted with a Preliminary Design Report in the July / August time frame, with the first formal submittal at approximately the 30% design level in the December time frame. This submittal is considered the formal Preliminary submittal. Coordination and review will have occurred up to this formal submittal to gain USACE concurrence with our proposed methodology and proposed construction. The goal of this Preliminary submittal is to provide a total package of our analysis to obtain written USACE concurrence of our proposed construction, and the specific technical requirements for 408 approval.

70% Design Documents (Six Months – January to June 2013)

We anticipate that County and USACE comments to the 30% submittal will help define the direction and responses for our 70% submittal. This 70% level of design effort would involve preparing detailed design calculations and analysis to address the USACE comments. The specific tasks defined for this sequence is outlined in Sections III through VI.

Our intent is that the formal 70% application package to the USACE will provide all the analysis and detail necessary to gain approval for a 408 permit. Coordination and review with the USACE will occur prior to the 70% submittal to clarify and fully understand the intent of all of their 30% comments so that the 70% application package is complete and understandable. This 70% submittal therefore should be considered the formal "Technical" submittal. We expect that the USACE will conduct a detailed technical plan checking process of all of the information provided.

100% Construction Documents (Six Months – June to December 2013)

As in any technical review, additional comments and questions from the USACE are expected. This 100% construction documents phase is expected to include the work efforts necessary to answer their questions and incorporate their comments up to the time a formal 408 permit approval is issued.

Work effort during this 100% stage will include coordination, processing, and updates to address plan check comments to the 70% design documents through the various public agencies for design and permit approval for the construction work. The 70% construction cost estimate will be updated when the plans are at an approval stage. We anticipate that approvals and clearance letters will be required from all appropriate agencies:

SECTION III

SURVEY

The Survey Work Plan is organized into four tasks corresponding to the four primary areas of effort. These tasks are:

- The initial survey establishment.
- The preliminary survey and collection of physical and legal/informational data.
- The production efforts.
- The support related to easements documentation.

The first three areas are in direct support, and a prerequisite of, the design effort. The last area will be provided toward the end of the process after design is approved to the level that easements can be granted to appropriate agencies. These tasks are intended to all be completed during the overall Data Gathering efforts.

I. Initial Survey Establishment Work:

This initial stage of the Survey Work Plan is intended as the detailed planning stage to define the efforts necessary for the rest of the project. There can be some scheduling overlap with the next stages, but this will be limited to field information that will not be adjusted if the datum or coordinate system adjusts. The first priority is to define the horizontal coordinate system and vertical datum to be used for all aspects of the project design. Coordination with the County of Los Angeles and the U.S. Army Corps of Engineers is necessary to obtain concurrence for the selected datum. The limits of topographic work and determination of available data from other sources will also be considered and determined. Coordination with the team will be undertaken to determine the parameters of the field survey data to be collected to satisfy the design team needs. Review of the available legal and ALTA information, record utility and infrastructure, and other available and pertinent documentation.

A. Scope:

1. Meeting with County of Los Angeles
2. Coordination with team and agencies
3. Review available records and information

B. Deliverables in Report Format only:

1. Establish Vertical Datum
2. Establish Horizontal Coordinate System
3. Establish Limits of Aerial Topography and Sections for the Channel
4. Establish locations for specific field collection of data
5. Establish process for integration of all data into base information

II. Preliminary Survey and Collection of Data:

In coordination with access availability due to nesting season constraints, field survey will be conducted to collect the aerial and field determined data necessary for design. The field work will commence immediately upon receiving an access permit from DFG. Some of the field work will ultimately be in or adjacent to

nesting areas. That portion of the field data collection will be postponed until clearance for access is given by project ornithologist after approximately July 31, 2012. This remaining field survey effort in or adjacent to the nesting areas should be conducted and completed within a few weeks of the ornithologist's clearance date and is intended to complete the field data collection efforts without overlap into the next year's breeding season. However, if additional field survey collection is needed in support of progressing design beyond this time frame, and potential into the breeding season for next year, clearance from the project ornithologist will again be obtained. Aerial targets will be located, some of which will double as benchmarks for each project area. We will arrange for the collection of ortho-photographic data by aerial flight for the production of a topographic survey file. Field collection of the cross sections for the Ballona Channel and other upstream channels will be conducted. This will include collection of data for the location and orientation of structures within and adjacent to the Channel. Full sectional data will be collected from the end of the Ballona levees to the west to the start of the fully concrete lined portion of the channel east of Lincoln Boulevard. Channel flow line will be collected east of this point to verify horizontal and vertical alignment with design sections created from as-built plans to the limits identified on "Figure 1 – Initial Input on Survey and Geotech Plan". Cross sections for the tidal channels within Area B will be collected and integrated with sectional information provided separately. Detailed topographic transects will be collected initially in Area A and Area C north of Culver Boulevard followed by the other areas as clearance is given for access. Collection of field survey will also be conducted to determine the bridge underside and cross sectional configuration of the three bridge crossings adjacent to the area – Lincoln Boulevard, Culver Boulevard, and the Pacific Avenue extension. Office survey will be conducted to compile and integrate the data collected. All field collected data will be incorporated into the overall topographic electronic file. Input of the available legal and ALTA information, record utility and infrastructure, and other available and pertinent documentation will be incorporated into the base files for use by the design team. After completion of the dredging operation currently planned for the mouth of the Marina Channel opening, we will incorporate the as-built information into the base files.

A. Sub-Tasks:

1. Set Aerial Targets.
2. Run horizontal and vertical closures for datum integration.
3. Collect existing cross sectional data (500' spacing plus upstream and downstream of bridges) through project limits.
4. Verify as-built channel data upstream and downstream of channel.
5. Collect existing topographic transect data.
6. Collect existing bridge cross sectional data.
7. Collect aerial ortho-photo data.
8. Collect existing structures data.
9. Collect existing public and private utilities record data.
10. Collect record easements and boundary data.
11. Collect habitat areas data.
12. Collect geotechnical testing locations and elevations.
13. Collect Gas Company facilities information.
14. Translate/ rotate Lidar data into our horizontal and vertical datum using project control information provided with Lidar data.
15. Review horizontal and vertical datum with USACE.
16. Collect specific tidal data through Lidar and/ or other appropriate methodology USACE information.
17. Sections generated through field data collection will commence at the end of the Marina del Rey levee to the west, to the bridge at State Route 90.

18. Cross sections for the Ballona channel east of State Route 90, Centinela channel and Sawtelle channel will be created from as-built data and will be verified with a single point at the flow line at each location.
19. At a high tide event and a low tide event, collect tidal elevation readings of water surface elevations on the north and south side of the southerly bank of the Ballona in Area B adjacent to the Los Angeles County tidal gage. Compare and integrate our benchmark with county gage date to verify datum.

B. Deliverables in Report Format:

1. Description of found data
2. Draft utilities cadd file
3. Draft boundary, easements, and constraints cadd file

III. Base Data Production:

After and during the collection of field data, production of the base survey data will be conducted. This will also include setting of field monumentation at various levels of survivability. Design and construction benchmarks will be set with relatively permanent monumentation for future use. While temporary wooden stakes or paint marks will be provided for guidance and control of the geotechnical investigation and miscellaneous data collection needs. The survey data to be provided to the team will include a commercially available area wide photograph at a pixel size of 18" that is sufficient for presentation graphics, an ortho-rectified aerial flight generated photograph of the limits of the aerial topography with a pixel size of 4" or less site specific presentation material, a digital terrain model electronic file, a variety of cadd details and sections describing the specific survey data necessary for design, and hardcopy plots of the data provided. Exhibits are attached for the limits of the aerial topo, verification of upstream cross sections, transects, and geotechnical investigation.

A. Sub-tasks:

1. Produce topographic data.
2. Produce photographic data.
3. Produce survey control.
4. Produce detailed design survey.
5. Produce exhibits detailing survey provided.
6. Produce constraints map.

B. Deliverables in Electronic and/or Report Format:

1. Aerial Photo of the area.
2. Aerial Photo of the project limits.
3. DTM file (autocadd).
4. DEM file (ArcGIS).
5. List and coordinates of Benchmarks/Survey Control.
6. Cadd files and hardcopy of channel cross sections.
7. Cadd files and hardcopy of detailed design survey areas.
8. Cadd file and hardcopy of final utilities.

9. Cadd file and hardcopy of constraints exhibit
10. Cadd file and hardcopy of geotechnical investigation locations.
11. Final report of survey results.
12. After integration of dredge information – update:

    a. DTM.
    b. Channel Cross Sections.

IV. Easements Support:

Once the design has been approved by both L.A. County and the USACE to a level the Project Management Team feels comfortable with, we will prepare legal descriptions and exhibits to identify the appropriate areas necessary for maintenance responsibilities, storm drain structures, and relocated facilities as necessary.

A. Sub-Tasks:

1. Identify and create easements areas.
2. Coordination with team and agencies in review and finalization of easements areas.

B. Deliverables:

1. Legal Descriptions and Exhibits.
2. Plan check revisions.

GROUP DELTA CONSULTANTS

1.0 INTRODUCTION

Group Delta Consultants, Inc. (GDC) has prepared this work plan for a Geotechnical Investigation for the Ballona Wetland Restoration Project, located in Los Angeles, California.

1.1. Purpose

The purpose of this work plan is to outline and define the procedures for obtaining the necessary access and work permits, performing the field exploration, sample recovery, site cleanup, laboratory testing, geotechnical analyses, and report delivery for the project. A discussion of measures that will be taken to identify and avoid disturbance of the natural habitat, including any mitigation measures, if necessary, is also provided.

1.2. Site Description

The Ballona Wetlands project area consists of over 600 acres and is located in the northwest corner of the Los Angeles Basin, just south of Marina Del Rey. The area is subdivided into 3 portions: Area A, B, and C, as shown in Figure 1. The Ballona Creek Channel runs in an east-west direction through the site. Major streets including Lincoln Boulevard, Culver Boulevard, and Jefferson Boulevard intersect within the project area as well.

Area A is currently fenced off and is undeveloped, and historically in the past had been used as a dumping ground for dredge material. To a lesser extant, dredged material has also been placed in Areas B and C. Area B contains unfilled wetlands with abandoned agricultural fields and freshwater marsh. Area C is mostly undeveloped except for a few sports fields.

1.3. Project Description

The Ballona Wetlands restoration includes the reintroduction and revival of critical wetland habitat, including target animal and plant species, and the creation of a natural open space for the public benefit. The restoration plan will include the following (shown in Figure 1):

Ballona Creek Channel Restoration

- Removal (breaches) of the existing north and south levees in 4 locations, and the lowering and realignment of the channel for the creation of a natural meandering channel.

Area A

- Mass grading, soil excavation and removal, and hauling of previously placed dredged materials.

- Construction of flood protection levees along the north perimeter of the site using the excavated soils.
- Realignment and restoration of the Fiji Channel wetland area

Area B

- Construction of flood protection levees along the north side of Culver Boulevard, and the west portion of the area
- Full restoration of wetlands between the new levees and the realigned Ballona Channel, and managed restoration of the wetlands area located south of the new levees (construction of buried culverts).
- Fill placement in a stockpile area bordered by Culver Boulevard, Jefferson Boulevard, and Lincoln Boulevard.

Area C

- Fill placement in stockpile areas in locations on the north and south sides of Culver Boulevard.

Other Areas

- Construction of a pedestrian and bicycle bridge spanning the Ballona Creek Channel near Culver Boulevard, and an at-grade bicycle roadway along the new levee in Area B.

The implementation of the restoration plan will require a technical analysis and review, and approval by the U.S. Army Corps of Engineers (USACE) along with a Section 408 permit.

GROUP DELTA CONSULTANTS

1.0 INTRODUCTION

Group Delta Consultants, Inc. (GDC) has prepared this work plan for a Geotechnical Investigation for the Ballona Wetland Restoration Project, located in Los Angeles, California.

1.1. Purpose

The purpose of this work plan is to outline and define the procedures for obtaining the necessary access and work permits, performing the field exploration, sample recovery, site cleanup, laboratory testing, geotechnical analyses, and report delivery for the project. A discussion of measures that will be taken to identify and avoid disturbance of the natural habitat, including any mitigation measures, if necessary, is also provided.

1.2. Site Description

The Ballona Wetlands project area consists of over 600 acres and is located in the northwest corner of the Los Angeles Basin, just south of Marina Del Rey. The area is subdivided into 3 portions: Area A, B, and C, as shown in Figure 1. The Ballona Creek Channel runs in an east-west direction through the site. Major streets including Lincoln Boulevard, Culver Boulevard, and Jefferson Boulevard intersect within the project area as well.

Area A is currently fenced off and is undeveloped, and historically in the past had been used as a dumping ground for dredge material. To a lesser extant, dredged material has also been placed in Areas B and C. Area B contains unfilled wetlands with abandoned agricultural fields and freshwater marsh. Area C is mostly undeveloped except for a few sports fields.

1.3. Project Description

The Ballona Wetlands restoration includes the reintroduction and revival of critical wetland habitat, including target animal and plant species, and the creation of a natural open space for the public benefit. The restoration plan will include the following (shown in Figure 1):

Ballona Creek Channel Restoration

- Removal (breaches) of the existing north and south levees in 4 locations, and the lowering and realignment of the channel for the creation of a natural meandering channel.

Area A

- Mass grading, soil excavation and removal, and hauling of previously placed dredged materials.

- Construction of flood protection levees along the north perimeter of the site using the excavated soils.
- Realignment and restoration of the Fiji Channel wetland area

Area B

- Construction of flood protection levees along the north side of Culver Boulevard, and the west portion of the area
- Full restoration of wetlands between the new levees and the realigned Ballona Channel, and managed restoration of the wetlands area located south of the new levees (construction of buried culverts).
- Fill placement in a stockpile area bordered by Culver Boulevard, Jefferson Boulevard, and Lincoln Boulevard.

Area C

- Fill placement in stockpile areas in locations on the north and south sides of Culver Boulevard.

Other Areas

- Construction of a pedestrian and bicycle bridge spanning the Ballona Creek Channel near Culver Boulevard, and an at-grade bicycle roadway along the new levee in Area B.

The implementation of the restoration plan will require a technical analysis and review, and approval by the U.S. Army Corps of Engineers (USACE) along with a Section 408 permit.

2.0 SCOPE OF WORK

2.1. General

The following subsections outline our scope of work planned for the Geotechnical Investigation of the project. The investigation will collect soil data to be used for the analyses of the various components of the restoration. Our scope of work in this phase of the project includes pre-exploration activities, field work (i.e. drilling and sampling of soil), laboratory testing, geotechnical analyses, and report preparation.

The site investigation activities will be focused in the areas containing the main features of the restoration project, including the proposed perimeter levees, borrow area, stockpile areas, and portions of the existing Ballona Channel to be breached and those portions that will remain. The field work will include the drilling and sampling of soil from approximately 65 small diameter borings (4 to 8 inches) that will be range in depths from 20 to 70 feet. Depending on results of the analyses, additional borings may be considered.

2.2. Pre-Exploration Activities

2.2.1. Access and Permits

Prior to any drilling and sampling activities, permit approval for access and performing the subsurface investigation from the following agencies will be required for all explorations at the site:

- California Department of Fish and Game (CDFG) – Access for survey and to conduct geotechnical investigation permit
- California Coastal Commission (CCC) – exemption letter
- Regional Water Quality Control Board – 401 certification
- United States Army Corps of Engineers (USACE) – nationwide permit, including a Pre-Construction Notification (PCN) and Essential Fish Habitat (EFH) assessment
- Sempra Energy (Southern California Gas Company) – utilities and gas well clearance
- County of Los Angeles Flood Control – Access to conduct investigation permit
- City of Los Angeles – Jefferson and Culver Boulevards right of way permit

GDC has performed a site reconnaissance for selecting the exploratory boring locations and to identify entrance and access routes for review and approval by the appropriate agencies. GDC will contact Underground Service Alert (DigAlert) to perform utility clearance of any other public utilities.

2.2.2. Site Habitat Avoidance Plan

Existing Habitat

Dredged materials from the excavations of Ballona Creek and construction/expansion of Marina Del Rey have historically been placed at the site. As such, much of the site's habitat has been altered relative to the site's native historic habitat. The deposition of the dredged material has altered original elevation contours and has resulted in the development of a variety of plant community types.

Previous investigations have identified plant species present within the project area. A list is included in Appendix A of this document (WRA 2010). Several maps have been prepared showing potential jurisdictional wetland areas for different agencies (United States Army Corps of Engineers, California Coastal Commission, and California Department of Fish and Game), as well as locations of special status plant species in the project area (WRA 2011). These maps were used as guidelines in our selection of

exploration locations and are presented in Figures 3 to 9. Each map shows the proposed boring locations.

Based on previous studies of the site, it is understood that pickleweed salt marsh and salt pan/mudflat areas are to be avoided to the greatest extent possible as exploration sites and in planning access routes to the individual exploration sites. Likewise the coastal scrub is to be carefully traveled on only if necessary. Below is a list of plant species of concern that were previously identified by a prior study (Weston 2009) of Area A:

- Saltpan/mudflats: no vascular plants occur in the salt flats
- Pickleweed salt marsh: *Salicornia virginica, Frankenia salina, Jaumea carnosa, Distichlis spicata, Sueada californica*
- Transition zone: *Atriplex lentiformis breweri* (generally at pickleweed saltmarsh margin, may occur upland as well)
- Riparian scrub: *Baccharis salicifolia, Salix lasiolepis, Salix leavigata*
- *Baccharis scrub: Baccharis pilularis*
- Coastal scrub: *Artemesia californica, Marrubium vulgare, Isomeris aborea, Malosma (Rhus) laurina, Sambucas mexicana, Cucurbita foetidissima, Rhus integrifolia*

A 2011 study also documented breeding areas of the Belding's savannah sparrow within the Ballona Wetlands which are to be avoided during the months of May to July. Site exploration in these areas (Figures 8 and 9) may not be performed during the breeding season.

Habitat Avoidance and Monitoring Measures

Prior to drilling and in support of obtaining the necessary drilling permits, a site reconnaissance and document review were conducted of the vegetation and animal habitats present within the project site, to determine optimal access routes to the exploration locations with minimal disturbance to the natural habitat. The exploration locations will be verified for sufficient space to accommodate the drilling equipment and operation. Plant groups and individual plants of concern will be identified and documented during reconnaissance by a field biologist. An on-site biologist will continually oversee the progress of the sampling program to avoid unnecessary damage to native vegetation. A cultural resource representative will also be present during the sampling program.

Among the criteria for choosing soil sampling/exploration locations is proximity to sensitive vegetation as well as potential to cause disturbance of habitats. Prior to any sampling activities, the exploration locations will be carefully planned and verified to avoid sensitive vegetation to the greatest extent possible. Access routes to and from

each location were mapped for review and approval by the governing agencies. The routes were selected to maximize the usage of the existing access entrances and pathways, and minimize disturbance to the native habitat. Potential exploration sites that cannot be accessed without substantial native plant disturbance will be eliminated, and alternative sites will be chosen. Figure 2A shows a proposed location plan of exploration. The proposed entrance and access routes to the locations are further discussed in Section 2.3.

Figures 3 to 9 show the proposed exploration locations overlain on existing habitat areas. As noted, areas such as the breeding grounds of the Belding's savannah sparrow, primarily in the western portion of Area B, will not commence until after July and will be completed prior to the next May. Areas A and C show less coverage of sensitive habitat and are planned to be drilled first.

During the field exploration, drill rigs and associated support trucks will follow along a single path to minimize any impact to sensitive habitat. Prior to mobilizing, the drill equipment operators will be made familiar with plant species of concern, and the vehicles will be escorted along the pre-scouted route to the exploration locations by the field biologist.

After the field exploration activities are completed, a field team will follow the routes used by the drilling equipment to access the sampling locations to confirm that no sensitive habitat was adversely impacted. Any areas where vehicle traffic resulted in depressions in the soil will be re-graded by hand with shovels. Any tire or tread tracks will be raked to minimize track depressions. Special attention will be given to the salt flat areas and any disruption will be repaired to the satisfaction of the governing agencies. Should any damage to plants occur, it will be recorded in a field logbook and photographed, and a reasonable level of remediation will be performed to restore the site to its original condition.

2.3. Field Exploration

2.3.1. Overview

Approximately 65 boring explorations are proposed (Figure 2A), with drilling depths expected to range from about 20 to 70 feet for each exploration. The proposed borings will supplement previous borings performed at the site (Figure 2B). The borings are generally planned in the following areas of the restoration:

- New Perimeter levees
- Borrow / cut area
- Stockpile areas
- Existing Ballona Channel levees
- Near existing gas wells

The borings will characterize the subsurface conditions in these areas and provide data to complete a range of analyses needed, such as static and seismic stability (temporary and long-term), settlement, deformations, liquefaction, seepage, soil suitability, and seismic hazard. The location, spacing, and depths of the proposed borings were selected based on the analyses necessary for the area of the restoration and recommended criteria from the USACE. For example, for the perimeter levees, the USACE (EM1110-2-569, Design Guidance for Levee Underseepage) recommends:

"An extensive subsurface geotechnical investigation along the levee systems should be conducted and supplemented with geophysical investigation techniques as appropriate. A minimum target level of subsurface explorations should be a series of explorations approximately every 1,000 feet, consisting of an exploration at the riverside toe, at the landside toe, and a deep exploration at the levee crest."

The borings were also positioned to provide information for other features of the restoration, including rock protection areas, pedestrian bridge crossing Ballona Channel, and culverts in Area B. Shallow borings are planned primarily for locations such as the borrow area where the suitability of the excavated material for embankment construction will be analyzed. Deeper borings are planned in areas such as the new perimeter levees, where static and seismic stability will be analyzed.

The explorations will be performed under the technical supervision of GDC's field engineer/geologist. The field engineer/geologist will maintain detailed logs of the drilling activities and soils and groundwater levels encountered. Air monitoring will be performed during the investigation. If evidence of potentially hazardous materials is detected, the exploration will be stopped and project management will immediately be notified for direction.

2.3.2. Access Routes

Entrance to the site and routes to each of the proposed explorations were selected to minimize the distance traveled within the site and to avoid various sensitive areas of the existing habitats. Figures 2 through 9 show the proposed entrance and access routes overlain on various maps of jurisdiction areas, sensitive habitat, and existing wells at the site. These proposed routes may continue to be adjusted based on field conditions and consultation from various habitat experts.

The figures illustrate the intention of the routes to minimize disturbance to the habitat. The following exceptions are noted:

- USACE jurisdictional area (Figure 3) – The proposed route between A-CPT010 and A-CPT012 in Area A and the proposed route to access B-CPT029, B-RW030, and B-CPT031 in Area B traverses through a wetland area. B-RW030 and B-CPT031are also located within a non-wetland waters area.

- CCC jurisdictional area (Figure 4) – In addition to having the same affected areas described for USACE jurisdictional areas, proposed exploration HSA051 is located within a wetland area in Area B. Also, within Area C, the proposed route between C-CPT060 and C-HSA061 may require traversing through a wetland area.
- CDFG jurisdictional area (Figure 5) – Explorations B-RW027, B-RW028, B-RW032, B-RW033, B-CPT034, and B-CPT042 are located within the CDFG jurisdictional area. Also, within Area C, the proposed route between C-CPT060 and C-HSA061 may require traversing through the CDFG jurisdictional area.
- Special status plant species (Figure 6) – B-RW027, B-RW028, B-CPT029, B-CPT052, B-RW053, B-CPT054, C-CPT060, and C-HSA06 are located near special status plant species
- Belding's savannah sparrow breading areas (Figure 8) – The breeding areas are largely within Area B and are particularly dense within the west portion. A-HSA064 in Area A , and B-HSA051 in Area B are also noted to be near breeding locations.

It is also noted that fence removal is proposed in two areas along the existing Ballona Channel. The fence will be repaired after the borings are finished.

- B-RW027 and B-RW028 in Area B. – Access to these locations will be made directly from the existing pathway on the south levee.
- A-RW025 and A-RW026 in Area A – Access to these locations are proposed to be made from Area A onto the bike path on the north levee. If access cannot be made from this location, we propose the explorations be reached by driving the drill rig along the bike path, with access from Pacific Avenue (located west of project site).

2.3.3. Schedule

Borings that do not impact the site habitat will be performed as soon as all the necessary permitting approvals are granted. It is understood that it may take up to two months to receive all the permit approvals. The duration of the boring program is expected to be approximately 2-3 weeks. Borings planned near sensitive areas such as the Belding's savannah sparrow breeding grounds (primarily located in the west portion of Area B) will not begin until after July 2012 and are expected to be completed within approximately 1-2 weeks.

A subsequent phase of exploration will be required if there are changes in the project such as changes in the location of levees or if the results from the current exploration necessitate further testing. It is anticipated any additional exploration occur after the 408 submittal and would be performed in early 2013.

2.3.4. Drill Equipment

The site investigation will be performed by means of truck-mounted rotary wash and hollow stem drilling rigs, and cone penetration testing (CPT) trucks. One to two support trucks (pick up trucks) will accompany each drill rig. The drilling method used in a given area will depend on the information needed for the analyses. Below is a description of the drilling methods (outlined in detail in USACE Engineering Manual 1110-1-1804):

Rotary Wash

The rotary wash method uses typical drilling techniques to advance the hole by removing the soil cuttings with water or bentonite based drill mud. Samples are typically taken at discrete depth intervals of 5 feet. This method is applicable for any type of soil and the standard penetration test (SPT) blow counts obtained in rotary wash borings are not affected by hydrostatic pressure, since water and drilling mud is continuously circulating through this method to stabilize the drill hole and remove cuttings. The diameter of the hole is typically 4 inches. The rotary wash borings will be used in areas such as the levees. The dimensions of a typical rig are about 32 feet (working height) × 32 feet (length) × 8.5 feet (width).

Hollow Stem Auger

Hollow stem augers can be drilled relatively quickly and does not use drilling mud. They will be used in areas where the proposed borings will be shallow and generally above the groundwater table. Samples are typically taken at discrete depth intervals of 5 feet. The diameter of the hole is typically 8 inches. The hollow stem auger borings will be used in locations such as the borrow and stockpile areas. The dimensions of a typical rig are about 27.5 feet (working height) × 25 feet (length) × 8.5 feet (width).

Cone Penetration Test

The CPT involves hydraulically pushing a 3.6-cm (1.4-in.) diameter probe into the earth while performing two measurements, cone resistance and sleeve friction resistance. The probe is normally pushed from a special heavy duty truck but can also be performed from a trailer or drilling rig. As the probe is advanced, electronic instruments measure and record both the tip resistance and the frictional resistance on the sleeve. The tip and frictional resistance are then analyzed, using available correlations, to estimate soil classification, density, strength, and compressibility of the subsurface materials. Unlike soil borings, in which drive samples are typically taken at discrete intervals, the CPT provides a continuous record of soil properties with depth. Hence, the CPT can define the subsurface soil profile with much higher resolution than a soil boring, often detecting thin layers that are easily missed with conventional drilling and sampling. The CPT is a fast method and is ideal for sands, silts, clays, and soft soils. Because there are no soil cuttings, the CPT is ideal for environmentally sensitive areas. CPT explorations will be used throughout the site to characterize the subsurface conditions and collect data for

use in liquefaction analyses, and levee design. The dimensions of a typical CPT rig are about 15 feet (height) × 35 feet (length) × 9.5 feet (width).

2.3.5. Soil Sampling

Soil samples will be obtained for field classification and laboratory testing. Both discrete and composite samples will be taken for geotechnical, chemical, and agronomy testing. The samples will be sealed, labeled, and packaged for transport to the geotechnical, environmental and/or chemical laboratories where they will be tested. During sampling, project archeologist and cultural resource representatives will also be onsite to observe the soils samples taken from the ground.

Geotechnical Sampling

Both relatively undisturbed modified California ring samples and Standard Penetration Test (SPT) drive samples will be taken in the borings at depth intervals of no greater then 5 feet. In addition, representative bulk samples will be taken within the upper 5 feet of select subsurface exploration locations by a shovel and placed into polyethylene bags. The locations of all sampling will be indicated on the boring logs. All samples will be sealed to prevent moisture loss and returned to our laboratory for additional visual examination and laboratory testing.

The SPT sampling will be performed in accordance with ASTM D1586, using a standard 2-inch outside diameter, 1.375-inch inside diameter, split-spoon sampler. The modified California ring sampler will be performed in accordance with ASTM D3550 utilizing a 3-inch O.D. split-barrel sampler lined with 1-inch high brass rings. Both sample types will be driven into the soil using a 140-pound hammer falling a distance of 30 inches. The number of blows required to drive the sampler 18 inches into the soil will be recorded on the boring logs. The hammer of system of each rig will be calibrated and the energy transfer ratio will be provided (ASTM D4633). For preliminary calculations an energy transfer ratio of 75 % will be used.

Chemistry Sampling

In addition to samples obtained for geotechnical testing, GDC will obtain discrete and composite samples for chemical testing, as directed by the project environmental consultant. Environmental samples will be obtained and handled under appropriate protocol and chain of custody.

Agronomy Sampling

Agronomy soil sampling will be performed within the borrow area of Area A. at the following depths: surface, old marsh surface (which will consist of buried organic matter/stems/roots, and one foot below the design depth.

2.3.6. Completion of Borings

Upon completion, all borings will be backfilled with tamped cuttings and/or bentonite/cement slurry. CPTs will be grouted. Drill mud will be placed in approved drums and stored onsite at an approved designated location until testing and disposal can be performed. Drum testing and disposal will be performed by an appointed representative obtained by GDC. Any waste or excess material created during physical investigations of the site will be disposed of by GDC or an appointed representative obtained by GDC. Clean up of the site, including spills and damage, will be performed such that the site is left in a state similar to that prior to the start of work.

As indicated in the site habitat avoidance plan (Section 2.2.2), after all of the sampling activities are completed, a field team will follow the routes used by the drilling equipment to access the sampling locations to confirm that no sensitive habitat was adversely impacted. Any areas where vehicle traffic resulted in depressions in the soil will be re-graded by hand with shovels. Any tire or tread tracks will be raked to minimize track depressions. Special attention will be given to the salt flat areas and any disruption will be repaired to the satisfaction of the governing agencies. Should any damage to plants occur, it will be recorded in a field logbook and photographed, and a reasonable level of remediation will be performed to restore the site to its original condition.

2.4. Laboratory Testing

Laboratory testing will be conducted on the soil samples collected in the field. The purpose of laboratory testing is to determine geotechnical, chemical, and agronomy properties of the encountered soils. Lab testing will be assigned based on the encountered soils and will be conducted according to ASTM standards. Additional testing may be performed on selected samples as necessary.

Geotechnical Testing

GDC presently anticipates the following geotechnical laboratory tests to be performed on representative samples in accordance with current and applicable ASTM standards:

- Moisture Content & Dry Unit Weight
- Testing for shear strength (Direct Shear, Triaxial, Vane, etc.)
- Consolidation
- -200 Sieve Wash
- Expansion Index
- Atterberg Limits
- Grain Size
- Compaction
- Corrosivity (sulfate, chloride, pH, resistivity)
- R-value

Samples that are known to have contaminants will be sent to a certified and approved laboratory that specializes in geotechnical testing of contaminated samples.

Chemistry Testing

In addition to the sampling performed for geotechnical purposes, sampling is planned for environmental testing. Samples designated for chemical testing for contaminants will be taken to an approved chemical or environmental laboratory. Samples for environmental testing will be taken under appropriate protocol and chain of custody. The scope of environmental sampling and evaluation of the chemical test results will be performed by the project environmental consultant.

Agronomy Testing

The testing will be performed as directed and will include pH, salinity, sodium and the five soluble and exchangeable major nutrients, sulfate, boron, USDA texture, organic matter content, micronutrients, and neutralization/ acid generation potential (N/AGP).

2.5. Geotechnical Analyses and Report

To evaluate the geotechnical issues associated with the proposed restoration, GDC will perform the following engineering analyses using the data acquired from the investigation:

- Document review of previous documents, reports, and maps.
- Data evaluation/compilation and analysis of the geotechnical field and laboratory data produced from previous and the current investigation
- Drafting of all boring logs and CPT soundings, including representative cross-sections through the site
- Seismic evaluation including seismic hazard analyses of the major faults impacting the site and deformation analyses of the levee slopes during an earthquake event
- Soil suitability / disposal analysis of the soils to be excavated from Area A to assess its suitability for use in the construction of the proposed levees, including any transportation issues and disposal options
- Levee analyses including stability, seepage, settlement, liquefaction, and deformation for the construction of the perimeter levees in Areas A and B, the effect of the soil excavation near existing and new levees, and the breaches and realignment of the existing Ballona Channel levees
- Ground improvement evaluation for the new levee construction, stockpile areas, and proposed pedestrian / bicycle bridge spanning the Ballona Channel west of Culver Boulevard.

- Stockpile analyses including stability and the effect of settlement from the surcharge of the stockpile on nearby existing roadways (i.e., Culver Boulevard and Jefferson Boulevard), the Ballona Channel, and buried utilities.
- Pedestrian / bicycle bridge analyses, including recommendations for the foundations, and associated grading.
- Mitigation measures for ground improvement (i.e., stone columns, deep dynamic compaction, deep soil mixing), drainage systems, monitoring programs, and excavation and/or replacement of unsuitable materials.
- Additional analyses, if necessary, based on review comments.

Findings and recommendations from the analyses will be summarized in memorandums and reports in support of the 408 permit approval.

APPENDIX A

LIST OF PLANT SPECIES

(Source: WRA report dated August 2011)

Wetland Indicator Status

OBL	Always found in wetlands	>99% frequency
FACW	Usually found in wetlands	67-99%
FAC	Equal in wetland or non-wetlands	34-66%
FACU	Usually found in non-wetlands	1-33%
UPL	Upland/Not listed (upland)	<1%

Family	Scientific Name	Common Name	Wetland Indicator Status
Plant species documented from the Ballona Wetlands[1] Project Site. Species names given according to Hickman (1993) or Jepson Interchange (2010). Old names (Hickman 1993) are given in parentheses, as needed.			
DICOTS			
Aizoaceae	*Aptenia cordifolia*	Baby sun rose	UPL
Aizoaceae	*Carpobrotus chilense*	Sea-fig	UPL
Aizoaceae	*Carpobrotus edulis*	Sour-fig (Hottentot-fig)	UPL
Aizoaceae	*Delosperma litorale*	Seaside delosperma	UPL
Aizoaceae	*Malephora crocea*	Red-flowered iceplant	UPL
Aizoaceae	*Mesembryanthemum crystallinum*	Crystalline iceplant	UPL
Aizoaceae	*Mesembryanthemum nodiflorum*	Slender leaf iceplant	UPL
Aizoaceae	*Sesuvium verrucosum*	Western sea-purslane	FACW
Aizoaceae	*Tetragonia tetragonioides*	New Zealand spinach	UPL
Amaranthaceae	*Amaranthus albus*	White tumbleweed	FACU
Amaranthaceae	*Amaranthus californicus*	Amaranth/Ca. pigweed	FACW
Amaranthaceae	*Amaranthus deflexus*	Pigweed	UPL
Amaranthaceae	*Amaranthus tamariscanus*	Indehiscent pigweed	FACU
Amaryllidaceae	*Narcissus tazetta*	Paper white narcissus	UPL
Anacardiaceae	*Malosma laurina (Rhus laurina)*	Laurel sumac	UPL
Anacardiaceae	*Rhus integrifolia*	Lemonade berry	UPL
Anacardiaceae	*Schinus molle*	Peruvian pepper tree	UPL
Anacardiaceae	*Schinus terebinthifolius*	Brazilian pepper tree	UPL

[1] Species list adapted from 08/18/2006 Ballona Wetlands Floral Compendium

Family	Scientific Name	Common Name	Wetland Indicator Status
Apiaceae	*Apium graveolens*	Celery	FACW
Apiaceae	*Apium leptophyllum*	Marsh parsley	UPL
Apiaceae	*Conium maculatum*	Poison hemlock	FACW
Apiaceae	*Foeniculum vulgare*	Fennel	FACU
Apocynaceae	*Nerium oleander*	oleander	UPL
Araliaceae	*Hedera canariensis*	Algerian ivy	UPL
Asteraceae	*Ambrosia acanthicarpa*	Ragweed/Annual bursage	UPL
Asteraceae	*Ambrosia chamissonis*	Ragweed/Beach bur	UPL
Asteraceae	*Ambrosia psilostachya*	Western ragweed	FAC
Asteraceae	*Artemisia californica*	California sage brush	UPL
Asteraceae	*Artemisia douglasiana*	California/Douglas' mugwort	FACW
Asteraceae	*Artemisia dracunculus*	Dragon sagewort/Tarragon	UPL
Asteraceae	*Symphyotrichum subulatum* var. *ligulatum*	Marsh aster/Slender aster	UPL
Asteraceae	*Baccharis pilularis*	Coyote brush	UPL
Asteraceae	*Baccharis salicifolia*	Mule fat	FACW
Asteraceae	*Brickellia californica*	Brickellbush	FACU
Asteraceae	*Centaurea melitensis*	Tocalote	UPL
Asteraceae	*Centaurea repens*	Russian knapweed	UPL
Asteraceae	*Chaenactis glabriuscula*	Yellow chaenactis	UPL
Asteraceae	*Chamomilla suaveolens*	Pineapple weed	UPL
Asteraceae	*Chondrilla juncea*	Skelton weed	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Asteraceae	*Chrysanthemum coronarium*	Garland daisy	UPL
Asteraceae	*Cichorium intybus*	Chicory	UPL
Asteraceae	*Cirsium vulgare*	Bull thistle	UPL
Asteraceae	*Conyza bonariensis*	Flax-leaved horseweed	UPL
Asteraceae	*Conyza canadensis*	Horseweed	FAC
Asteraceae	*Conyza coulteri*	Sticky conyza	FAC
Asteraceae	*Cotula australis*	Cotula	UPL
Asteraceae	*Cotula coronopifolia*	Brass buttons	FACW
Asteraceae	*Encelia californica*	California bush sunflower	UPL
Asteraceae	*Ericameria ericoides (Haplopappus e.)*	Goldenbush/Mock	UPL
Asteraceae	*Ericameria pinifolia (Haplopappus p.)*	Goldenbush	UPL
Asteraceae	*Euryops pectinatus*	Euryops daisy	UPL
Asteraceae	*Euthamia occidentalis (Solidago occidentalis)*	Western goldenrod	OBL
Asteraceae	*Filago sp.*	Filago	UPL
Asteraceae	*Gazania linearis (G. longiscapa)*	African daisy	UPL
Asteraceae	*Gazania scaposa*	African daisy	UPL
Asteraceae	*Gnaphalium bicolor*	Cudweed	UPL
Asteraceae	*Gnaphalium californicum*	California cudweed	UPL
Asteraceae	*Gnaphalium canescens* ssp. *beneolens*	Everlasting cudweed	UPL
Asteraceae	*Gnaphalium ramosissimum*	Pink cudweed	UPL
Asteraceae	*Gnaphalium stramineum (G. chilense)*	Chilean cudweed	FAC

Family	Scientific Name	Common Name	Wetland Indicator Status
Asteraceae	*Grindelia camporum (G. robusta)*	Gum plant	FACU
Asteraceae	*Hedypnois cretica*	Cretan weed	UPL
Asteraceae	*Helianthus annuus*	California sunflower	FAC
Asteraceae	*Deinandra fasciculata (Hemizonia f.)*	Common tarweed	UPL
Asteraceae	*Deinandra paniculata (Hemizonia p.)*	San Diego tarweed	FACU
Asteraceae	*Centromadia parryi australis (Hemizonia p. ssp. a.)*		FAC
Asteraceae	*Heterotheca grandiflora*	Telegraph weed	UPL
Asteraceae	*Heterotheca villosa (Chrysopis v.)*	Hairy goldenaster	UPL
Asteraceae	*Hypochaeris glabra*	Smooth cat's ear	UPL
Asteraceae	*Jaumea carnosa*	Fleshy jaumea	OBL
Asteraceae	*Lactuca eucra*	-	-
Asteraceae	*Lactuca serriola*	Prickly lettuce	FAC
Asteraceae	*Lactuca virosa*	Wild lettuce	UPL
Asteraceae	*Lessingia filaginifolia (Corethrogyne filaginifolia)*		UPL
Asteraceae	*Malacothrix saxatilis*	Cliff aster	UPL
Asteraceae	*Osteospermum fruticosum (Dimorphotheca f.)*	African daisy	UPL
Asteraceae	*Picris echioides*	Bristly ox-tongue	FAC
Asteraceae	*Senecio vulgaris*	Common groundsel	UPL
Asteraceae	*Silybum marianum*	Milk thistle	UPL
Asteraceae	*Solidago californica*	California goldenrod	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Asteraceae	*Euthamia occidentalis (Solidago o.)*	Western goldenrod	OBL
Asteraceae	*Sonchus asper* ssp. *asper*	Prickly sow thistle	FAC
Asteraceae	*Sonchus oleraceus*	Common sow thistle	NI
Asteraceae	*Stephanomeria exigua*	Small wire lettuce	UPL
Asteraceae	*Stephanomeria virgata*	Tall stephanomeria	UPL
Asteraceae	*Taraxacum officinale*	Dandelion	FACU
Asteraceae	*Xanthium spinosum*	Spiny cocklebur	FAC
Asteraceae	*Xanthium strumarium*	Rough cocklebur	FAC
Bataceae	*Batis maritima*	Salt wort	OBL
Boraginaceae	*Cryptantha intermedia*	White forget-me-not/popcorn flower	UPL
Boraginaceae	*Heliotropium curassavicum (H. ocellatum)*	Salt heliotrope	UPL
Brassicaceae	*Brassica nigra*	Black mustard	UPL
Brassicaceae	*Brassica rapa*	Field mustard	UPL
Brassicaceae	*Cakile maritima*	Sea-rocket	FACW
Brassicaceae	*Coronopus didymus*	Lesser swine cress	UPL
Brassicaceae	*Erysimum insulare* ssp. *suffrutescens*	Island wallflower	UPL
Brassicaceae	*Guillenia lasiophylla*	California mustard	UPL
Brassicaceae	*Hirschfeldia incana (Brassica geniculata)*	Field mustard	UPL
Brassicaceae	*Lepidium latifolium*	Broad-leaved peppergrass	FACW
Brassicaceae	*Lepidium virginicum* var. *pubescens (L. pubescens)*	Tall peppergrass	FACU

Family	Scientific Name	Common Name	Wetland Indicator Status
Brassicaceae	*Lobularia maritima*	Sweet alyssum	UPL
Brassicaceae	*Raphanus sativus*	Wild radish	UPL
Brassicaceae	*Sinapis alba (Brassica cf. hirta)*	White mustard	UPL
Brassicaceae	*Sisymbrium altissimum*	Tumble-mustard	UPL
Brassicaceae	*Sisymbrium irio*	London rocket	UPL
Cactaceae	*Opuntia ficus-indica*	Indian-fig	UPL
Cactaceae	*Opuntia littoralis*	Coastal prickly pear	UPL
Caprifoliaceae	*Sambucus mexicana*	elderberry	FAC
Caryophyllaceae	*Polycarpon tetraphyllum*	Four-leaved allseed	UPL
Caryophyllaceae	*Spergula arvensis*	Spurry starwort	UPL
Caryophyllaceae	*Silene gallica*	Common catchfly/ windmill pink	UPL
Caryophyllaceae	*Spergularia bocconei*	Boccone's sand-spurrey	UPL
Caryophyllaceae	*Spergularia macrotheca*	Salt marsh sand-spurrey	FAC
Caryophyllaceae	*Spergularia marina*	Hairy sand-spurrey	OBL
Caryophyllaceae	*Spergularia villosa*	Sand-spurrey	UPL
Chenopodiaceae	*Atriplex californica*	California saltbush	FAC
Chenopodiaceae	*Atriplex lentiformis*	Saltbush	FAC
Chenopodiaceae	*Atriplex patula*	Spear oracle	FACW
Chenopodiaceae	*Atriplex rosea*	Tumbling oracle	FACU
Chenopodiaceae	*Atriplex semibaccata*	Australian saltbush	FAC
Chenopodiaceae	*Atriplex triangularis*	Spearscale	FACW

Family	Scientific Name	Common Name	Wetland Indicator Status
Chenopodiaceae	*Bassia hyssopifolia*	Bassia	FAC
Chenopodiaceae	*Beta vulgaris*	Beet	FACU
Chenopodiaceae	*Chenopodium album*	White goosefoot/ Lambs-quarters	FAC
Chenopodiaceae	*Chenopodium ambrosioides*	Mexican tea	FAC
Chenopodiaceae	*Chenopodium berlandieri*	Pitseed goosefoot	UPL
Chenopodiaceae	*Chenopodium botrys*	Jerusalem oak	FACU
Chenopodiaceae	*Chenopodium murale*	Shiny-leaf goosefoot	UPL
Chenopodiaceae	*Chenopodium pumilio*	Glomerate goosefoot	UPL
Chenopodiaceae	*Salicornia bigelovii*	Annual pickleweed	OBL
Chenopodiaceae	*Arthrocnemum subterminale*	Parish's pickleweed	OBL
Chenopodiaceae	*Sarcocornia pacifica (Salicornia virginica)*	Common pickleweed	OBL
Chenopodiaceae	*Salsola tragus*	Russian thistle	FACU
Chenopodiaceae	*Suaeda calceoliformis (S. depressa* var. *erecta)*	Horned sea-blite	FACW
Chenopodiaceae	*Suaeda esteroa*	Sea-blite	UPL
Chenopodiaceae	*Suaeda taxifolia*	Woolly sea-blite	FACW
Convolvulaceae	*Calystegia macrostegia* var. *cyclostegia*	Coast morning glory	UPL
Convolvulaceae	*Convolvulus arvensis*	Bindweed	UPL
Convolvulaceae	*Cressa truxillensis* var. *vallicola*	Alkali weed	FACW
Convolvulaceae	*Dichondra occidentalis**	Western ponysfoot	UPL
Crassulaceae	*Crassula argentea*	Jade plant	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Crassulaceae	*Crassula connata*	Pygmy weed	FAC
Cucurbitaceae	*Citrullus lanatus*	Watermelon	UPL
Cucurbitaceae	*Cucurbita foetidissima*	Calibazilla	UPL
Cupressaceae	*Cupressus arizonica* ssp. *arizonica*	cypress	UPL
Cuscutaceae	*Cuscuta californica*	California dodder	UPL
Cuscutaceae	*Cuscuta indecora*	Big-seed alfalfa dodder	UPL
Cuscutaceae	*Cuscuta pentagona (C. campestris)*	Five-angled dodder	UPL
Cuscutaceae	*Cuscuta salina*	Saltmarsh dodder	UPL
Euphorbiaceae	*Chamaesyce albomarginata*	Rattlesnake weed	FACU
Euphorbiaceae	*Chamaesyce maculata*	Spotted spurge	UPL
Euphorbiaceae	*Chamaesyce polycarpa*	Smallseeded sandmat	UPL
Euphorbiaceae	*Chamaesyce serpens*	Matted sandmat	UPL
Euphorbiaceae	*Croton californicus*	California Croton	UPL
Euphorbiaceae	*Euphorbia esula*	Leafy spurge	UPL
Euphorbiaceae	*Euphorbia peplus*	Petty spurge	UPL
Euphorbiaceae	*Ricinus communis*	Castor bean	FACU
Fabaceae	*Acacia longifolia*	Australian wattle	UPL
Fabaceae	*Acacia decurrens*	Green wattle	UPL
Fabaceae	*Acacia neriifolia*	Wattle	UPL
Fabaceae	*Albizia lophantha (A. distachya)*	Albizia	UPL
Fabaceae	*Astragalus trichopodus*	Ocean locoweed	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Fabaceae	*Bauhinia variegata*	Orchid tree	UPL
Fabaceae	*Ceratonia siliqua*	Carob	UPL
Fabaceae	*Hoffmannseggia glauca*	Pig nut, Hog-potato	FACU
Fabaceae	*Lotus purshianus*	Spanish clover/Bird's foot trefoil	UPL
Fabaceae	*Lotus scoparius*	Deerweed	UPL
Fabaceae	*Lotus strigosus*	Strigose lotus	UPL
Fabaceae	*Lupinus bicolor*	Miniature lupine	UPL
Fabaceae	*Lupinus chamissonis*	Coastal bush lupine	UPL
Fabaceae	*Lupinus excubitus* ssp. *hallii*	Hall's lupine	UPL
Fabaceae	*Lupinus longifolius*	Longleaf bush lupine	UPL
Fabaceae	*Lupinus succulentus*	Arroyo lupine	UPL
Fabaceae	*Lupinus truncatus*	Lupine	UPL
Fabaceae	*Medicago polymorpha (M. hispida)*	California burclover	UPL
Fabaceae	*Melilotus albus*	White sweetclover	FACU
Fabaceae	*Melilotus indica*	Sourclover	FAC
Fabaceae	*Phaseolus limensis*	Large lima bean	UPL
Fabaceae	*Spartium junceum*	Spanish broom	UPL
Fagaceae	*Quercus agrifolia*	Coast live oak	UPL
Fagaceae	*Quercus x virginica*	Hybrid live oak	UPL
Frankeniaceae	*Frankenia salina*	Alkali heath	FACW
Geraniaceae	*Erodium botrys*	Storksbill/broad-lobed filaree	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Geraniaceae	*Erodium cicutarium*	Storksbill	UPL
Geraniaceae	*Pelargonium zonale*	Garden Geranium	UPL
Grossulariaceae	*Ribes malvaceum*	Chaparral currant	UPL
Hamamelidaceae	*Liquidambar styraciflua*	liquidambar	UPL
Hydrophyllaceae	*Phacelia ramosissima* var. *austrolitoralis*	Branching phacelia	UPL
Juglandaceae	*Juglans regia*	English walnut	UPL
Lamiaceae	*Marrubium vulgare*	Horehound	FAC
Lythraceae	*Ammannia sp.*	Red stem	OBL
Lythraceae	*Lythrum hyssopifolium*	Hyssop loosestrife	FACW
Malvaceae	*Malacothamnus fasciculatus*	Bush mallow/Chaparral	UPL
Malvaceae	*Malva nicaeensis*	Bull mallow	UPL
Malvaceae	*Malva parviflora*	Cheeseweed mallow	UPL
Malvaceae	*Malvella leprosa*	Alkali mallow	FAC
Moraceae F	*Ficus carica*	Edible fig	UPL
Moraceae	*Morus alba*	White mulberry	NI
Myoporaceae	*Myoporum laetum*	Lollypop tree	UPL
Myrtaceae	*Eucalyptus camaldulensis*	Red gum	UPL
Myrtaceae	*Eucalyptus globulus*	Blue gum	UPL
Myrtaceae	*Eucalyptus tereticornis*	Forest red gum	UPL
Myrtaceae	*Eucalyptus viminalis*	Manna gum	UPL
Myrtaceae	*Luma apiculata (Eugenia sp.)*	temu	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Nyctaginaceae	*Abronia umbellata*	Pink sand verbena	UPL
Oleaceae	*Fraxinus velutina*	Arizona/Velvet	FACW
Oleaceae	*Olea europaea*	Olive	UPL
Onagraceae	*Camissonia bistorta*	California sun cup	UPL
Onagraceae	*Camissonia cheiranthifolia* var. *suffruticosa*	Beach evening	UPL
Onagraceae	*Camissonia lewisii*	Lewis' evening primrose	UPL
Onagraceae	*Camissonia micrantha*	Miniture sun cup	UPL
Onagraceae	*Epilobium ciliatum*	Willow-herb	FACW
Onagraceae	*Oenothera elata* ssp. *hookeri*	Hooter's evening primrose	FACW
Onagraceae	*Oenothera elata* ssp. *hirsutissima*	Hairy evening primrose	FACW
Oxalidaceae	*Oxalis pes-caprae*	Bermuda buttercup	UPL
Papaveraceae	*Eschscholzia californica*	California poppy	UPL
Plantaginaceae	*Plantago lanceolata*	English plantain	FAC
Plantaginaceae	*Plantago major*	Common plantain	FACW
Plumbaginaceae	*Limonium californicum*	Sea lavender	OBL
Polygonaceae	*Eriogonum fasciculatum*	California buckwheat	UPL
Polygonaceae	*Eriogonum gracile*	Slender buckwheat	UPL
Polygonaceae	*Eriogonum parvifolium*	Dune buckwheat	UPL
Polygonaceae	*Polygonum arenastrum*	Common knotweed	FAC
Polygonaceae	*Polygonum lapathifolium*	Willow weed	OBL
Polygonaceae	*Rumex crispus*	Curly dock	FACW

Family	Scientific Name	Common Name	Wetland Indicator Status
Polygonaceae	*Rumex maritimus (Rumex fueginus)*	Golden dock	OBL
Polygonaceae	*Rumex salicifolius*	Willow dock	OBL
Primulaceae	*Anagallis arvensis*	Scarlet pimpernel	FAC
Ranunculaceae	*Clematis sp.*	clematis	UPL
Rosaceae	*Adenostoma fasciculatum*	Chamise	UPL
Rosaceae	*Heteromeles arbutifolia*	Toyon	UPL
Rosaceae	*Prunus persica*	Peach	UPL
Rosaceae	*Pyracantha sp.*	Firethorn	UPL
Rosaceae	*Rosa californica*	California rose	FAC
Rubiaceae	*Galium angustifolium*	Narrowleaf bedstraw	UPL
Salicaceae	*Populus fremontii*	Fremont cottonwood	FACW
Salicaceae	*Salix exigua (S. hindsiana)*	Narrow-leaved willow	OBL
Salicaceae	*Salix gooddingii*	Black willow	OBL
Salicaceae	*Salix laevigata*	Red willow	UPL
Salicaceae	*Salix lasiolepis*	Arroyo willow	FACW
Saururaceae	*Anemopsis californica*	Yerba mansa	OBL
Scrophulariaceae	*Verbascum virgatum*	Wand mullein	UPL
Scrophulariaceae	*Cordylanthus maritimus*	Bird's beak	OBL
Solanaceae	*Datura wrightii (D. meteloides)*	Jimsonweed	UPL
Solanaceae	*Lycium ferocissimum*	African boxthorn	UPL
Solanaceae	*Lycopersicon esculentum*	Tomato	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Solanaceae	*Nicotiana glauca*	Tree tobacco	FAC
Solanaceae	*Petunia parviflora*	Wild Petunia	FACW
Solanaceae	*Solanum americanum (S. nodiflorum)*	Small-flowered nightshade	FAC
Solanaceae	*Solanum douglasii*	Douglas's Nightshade	FAC
Solanaceae	*Solanum nigrum*	Black nightshade	FACU
Solanaceae	*Solanum sarrachoides*	Hairy nightshade	UPL
Solanaceae	*Solanum xanti*	Chaparral nightshade	UPL
Tropaeolaceae	*Tropaeolum majus*	Garden nasturtium	UPL
Typhaceae	*Typha domingensis*	Southern Cattail	OBL
Typhaceae	*Typha latifolia*	Broad-leaved Cattail	OBL
Ulmaceae	*Ulmus parvifolia*	Chinese elm	UPL
Urticaceae	*Urtica dioica* ssp. *holosericea (U. holosericea)*	Hoary nettle	FACW
Urticaceae	*Urtica urens*	Dwarf nettle	UPL
Verbenaceae	*Verbena lasiostachys*	Common verbena	FAC
Verbenaceae	*Lantana camara*	Orange-flowered lantana	NI
Zygophyllaceae	*Tribulus terrestris*	Puncture vine	UPL
MONOCOTS			
Alismataceae	*Sagittaria montevidensis* ssp. *calycina*	Arrowhead	OBL
Arecaceae	*Phoenix canariensis*	Canary island date palm	UPL
Arecaceae	*Phoenix dactylifera*	Date palm	UPL
Arecaceae	*Washingtonia robusta*	Slender fan palm	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Cyperaceae	*Carex praegracilis*	Clustered field sedge	FACW
Cyperaceae	*Cyperus eragrostis*	Galingale/Tall flat sedge	FACW
Cyperaceae	*Cyperus esculentus*	Yellow nutsedge	FACW
Cyperaceae	*Cyperus involucratus (C. alternifolius)*	Umbrella plant	OBL
Cyperaceae	*Eleocharis macrostachya*	Pale spike rush	OBL
Cyperaceae	*Eleocharis montevidensis*	Dombey's spike rush	FACW
Cyperaceae	*Schoenoplectus americanus (Scirpus a.)*	Olney bulrush	OBL
Cyperaceae	*Schoenoplectus californicus (Scirpus c.)*	California bulrush/Tule	OBL
Cyperaceae	*Bolboschoenus maritimus* ssp. *paludosus (Scirpus m.)*	Prairie burush	OBL
Cyperaceae	*Bolboschoenus robustus (Scirpus r.)*	Saltmarsh bulrush	OBL
Iridaceae	*Chasmanthe aethiopica*	Adams iris	UPL
Iridaceae	*Iris pseudacorus var. alba*	Horticultural iris	OBL
Juncaceae	*Juncus acutus* var. *leopoldii (J. a.* var. *sphaerocarpus)*	Spike-rush	FACW
Juncaceae	*Juncus balticus*	Wire rush	OBL
Juncaceae	*Juncus bufonius* var. *occidentalis (J. sphaerocarpus)*	rush	FACW
Juncaceae	*Juncus mexicanus*	Mexican rush	FACW
Juncaginaceae	*Triglochin maritima* (likely a misidentification of *T. concinnum)*	Arrow grass	OBL
Liliaceae	*Agave americana var. striata*	Giant agave	UPL
Liliaceae	*Agave attenuata*	Foxtail agave	UPL

Family	Scientific Name	Common Name	Wetland Indicator Status
Liliaceae	*Yucca gloriosa*	Spanish dagger	UPL
Liliaceae	*Aloe vera*	Medicinal aloe	UPL
Poaceae	*Agrostis viridis (A. semiverticillata)*	Bentgrass	OBL

SECTION V

CIVIL

Psomas has an exceptionally long history of working in the area of this restoration project – over 25 years. Psomas will prepare preliminary engineering designs for the following components of the levee breach plan and permit requirements through the duration of the design portion of the project. Civil design elements and support will include the three stages outlines in Section II.

30% Preliminary Design (Eight Months – by December 2012)

The design elements during this Sequence include:

- Preliminary Design Report preparation.
- Overall site plan to be prepared based on the grading schemes developed by PWA/ESA.
- Layout and preliminary design for stabilizing and protecting the ends of the portions of the existing levees to remain.
- Assist PWA/ESA with civil constraints related to the preliminary geometric alignment and stability design for the north levee and maintenance path along Fiji Road and Lincoln Boulevard.
- Preliminary geometric alignment and stability design for the south levee and maintenance path along Culver Boulevard.
- Preliminary geometric alignment and integration of an access/pedestrian/bike path along one or more of the levees.
- Preliminary design and details for protection of the portions of the levee sections that will remain.
- Review of previous studies and refined preliminary design studies and coordination for the ultimate horizontal and vertical alignment of Lincoln Boulevard to assist in determining the location of the perimeter levee in Area A.
- Documentation of the existing gas wells and pipelines that may be impacted by the restoration program.
- Develop exhibits showing the planned construction sequencing for removing the levees and grading the restoration site.
- Provide technical support for maintenance requirements of the infrastructure elements of the design to be incorporated into the operations and maintenance requirements related to the restoration work.
- Prepare preliminary grading plans for Areas B and C that will be used for placement of soil material that is excavated from the Area A and B restoration sites.
- Develop studies and alternatives for transporting excavated soil material from the restoration site to the fill placement areas in Areas B and C.

- Prepare written narrative and exhibits that describe temporary and permanent erosion and sediment transport measures that could be implemented at the restoration site and the fill placement sites.
- Prepare a preliminary hydrology and drainage report in accordance with the City of Los Angeles requirements for the drainage areas associated with Areas B and C.
- Prepare an earthwork analysis of the restoration area grading design and fill disposal areas that identify the earthwork volumes and incorporate shrinkage factors as identified by the geotechnical consultant.
- Preliminary Utility Analysis – Review all utilities affected by the restoration project grading. Priority will be given to those utilities that must be removed or relocated. Those affected agencies will be identified and approached to determine their requirements. A constraints matrix will be populated with the pertinent criteria and actions necessary. If appropriate, applications will be made to initiate their review, but execution of work will not be included in this phase.
- Prepare preliminary plans for a new bike trail to be located on the new north side perimeter levee. These preliminary plans will be prepared using County of Los Angeles requirements.
- If not addressed by a third party development entity, prepare preliminary plans for reconstruction of the existing sports fields located within Area C. The existing sports fields may be removed as part of the overall grading design of the area.
- Constructability Analysis – Conduct a constructability analysis of the preliminary design to determine the options for physical delivery of the project. Review durations and sequencing of work, timing in addressing of constraints, availability and test timing of materials, etc. Options will be reviewed with the team to determine the most appropriate courses of action and acceptable options.
- Prepare an Engineer's Estimate of Probable Construction Costs –This estimate of probable construction costs will be based on the preliminary design documents. At this stage the estimate will be at a level sufficient for overall budgeting purposes with appropriate contingencies. Through later stages, this estimate will be refined as additional information and analysis is available. The estimate will be developed for the Phase 1 project as well as a general estimate for the entire project.
- Preliminary Hydrology and Hydraulic Analysis – Conduct an analysis of the local hydrology within Areas B and C, and then evaluate the capacity of existing and proposed drainage structures and areas.
- Stormwater Pollution Prevention Plan (SWPPP) – In coordination with the Psomas team and other PMT team members, prepare the overall project SWPPP to identify the specific sediment transport impacts due to storm events, and the mitigations necessary during the construction process. This report will be prepared in conjunction with the preparation of the erosion control plans.

- Erosion Control Plans – Prepare an overall erosion control plan and separate erosion control plan details and exhibits to address the construction phases that may be utilized.

Deliverables

1. Project Schedule
2. Overall Project Site Plan
3. Preliminary Levee Removal Plans/Details
4. Preliminary Levee Protection Design and Details
5. Preliminary Grading Plan – Area B and C
6. Preliminary Earthwork Analysis Areas A, B and C
7. Bike Trail Plans
8. Preliminary Gas Well / Pipelines Abandonment Plans (Diana to lead processing)
9. Construction Sequencing Exhibit
10. Project Meetings
11. Assist with Application and Permit Processing
12. Excavated Materials Transportation Study
13. Preliminary Erosion and Sediment Control Plan
14. Preliminary Hydrology and Drainage Report for Area B and C Fill Locations1
15. Preliminary Existing Utility Analysis and Exhibit
16. Constructability Analysis Report
17. Preliminary Engineers Estimate of Probable Construction Costs
18. Design Coordination
19. Permit Application and Processing Support

70% Design Documents (Six Months – January to June 2013)

The design elements during this Sequence include:

- Refine, add detail, and prepare final technical design and details for stabilizing and protecting the ends of the proposed levees and the portions of the levees to remain. This would include identifying

the size, thickness, toe down and extent of riprap or concrete facing protection including backing systems.

- Refine, add detail, and prepare final design, layout and details of the maintenance access road and bike trail on the proposed levees.
- Documentation of coordination with the Gas Company for disposition of their existing wells and pipelines.
- Provide input to other consultants to take advantage of our local knowledge during the preparation of their restoration and final grading plans and details in accordance with County of Los Angeles and City of Los Angeles requirements.
- Refine, add detail to, and prepare final grading plans for the disposal grading in Area B and the fill placement areas in Area C.
- If required, prepare or refine and add detail to the grading plans and layouts for reconstruction of the sports facilities within Area C south of Culver Boulevard.
- Refine, add detail to, and finalize earthwork calculation reports for inclusion with permit application documents submitted to Los Angeles City and County, and the USACE.
- Refine, add detail to, and finalize the SWPPP documentation and Erosion Control plans for grading and construction activity in Area A, B and C in accordance with State requirements as well as the local specific requirements of the City and County of Los Angeles.
- Refine, add detail to, and prepare final hydraulics calculations and reports for drainage devices to be constructed with grading activities in Areas B and C.
- Prepare a Haul Route Application, exhibits and supporting documents for submittal to the City of Los Angeles for transport of earthwork across public streets to the disposal areas in Areas B and C.
- Refine, add detail, and prepare updated final engineers estimate of probable construction costs based on the 70% design documents.
- Refine the 408 application package to the USACE for the70% submittal.
- Prepare a Conditional Use Permit (CUP) application for the County of Los Angeles for export of more than 100,000 cubic yards from a site as required by County codes. The CUP process for LA County may also require approval of the haul route that will be processed through the City of Los Angeles.
- Prepare other applications and submit plans, calculations, reports and other supporting documents for the grading, bridges, and levee modifications to the other applicable agencies for review. This would include the County and City of Los Angeles, Fish and Game, and FEMA.
- Provide coordination services for design work as well as relocation work undertaken by the Gas Company and other utility franchises to remove and relocate facilities which interfere with the planned work.
- Participate in meetings with the PMT and other consultant team members, and other public agencies or local groups as directed.

- Provide peer review of plans, documents and calculations prepared by other consultants. Specifically our focus will be on the grading design and hydrology/hydraulics package that will be reviewed by LA County as part of the grading permit and levee modification process.

Deliverables

1. Detailed Levee Removal Plans and Details
2. Detailed Levee Protection Plans/Details
3. Grading Plans – Areas B and C
4. Detailed Bike Trail Plans
5. Pedestrian/Bike Bridge Plans/Details
6. Final Gas Well/Pipeline Abandonment Exhibit and Coordination
7. Sports Facilities Final Grading Plans
8. Construction Sequencing Plan
9. Haul Route Plan/Permit
10. SWPPP/Local Erosion Control
11. Local Hydrology Report for Storm Drain Culverts
12. Culvert Hydraulics Report
13. Earthwork Calculations
14. Engineers Estimate of Probable Construction Costs

100% Construction Documents (Six Months – June to December 2013)

Work effort during this 100% stage will include coordination, processing, and updates to address plan check comments to the 70% design documents through the various public agencies for design and permit approval for the construction work. The 70% construction cost estimate will be updated when the plans are at an approval stage. We anticipate that approvals and clearance letters will be required from the following agencies:

- County of Los Angeles
- City of Los Angeles
- USACE
- The Gas Company

- Coastal Commission
- Department of Fish & Game
- FEMA
- Other utility providers

Any or all of the services listed during the 70% phase may be refined and adjusted to complete this process. Therefore, we have not relisted these services and tasks in this section. There is one additional service during this phase which is that we will assist the Hydrology Consultant in assembling and preparing the application to FEMA for a Conditional Letter of Map Revision (CLOMR) for adjustment of flood zones. During this time we will also provide updates to the environmental impacts analysis and mitigation measures as appropriate.

Deliverables

1. Detailed Levee Removal Plans and Details
2. Detailed Levee Protection Plans/Details
3. Grading Plans – Areas B and C
4. Detailed Bike Trail Plans
5. Pedestrian/Bike Bridge Plans/Details
6. Structural Report
7. Detailed Geotechnical Report
8. Final Gas Well/Pipeline Abandonment Exhibit and Coordination
9. Sports Facilities Final Grading Plans
10. Construction Sequencing Plan
11. Haul Route Plan/Permit
12. SWPPP/Local Erosion Control
13. Local Hydrology Report for Storm Drain Culverts
14. Culvert Hydraulics Report
15. Earthwork Calculations
16. Engineers Estimate of Probable Construction Costs
17. Supporting Information for CLOMR

SECTION VI

STRUCTURAL

JCE Structural Engineers will be engaged during the preliminary design phase to provide support services related to bridge and structural design. This will include:

30% Preliminary Design (Eight Months – by December 2012)

- Preliminary Bridge Analysis – Prepare options for a pedestrian/bike bridge crossing of the Ballona Creek adjacent to the existing Culver Boulevard Bridge. A number of options may be reviewed initially from both a structural and aesthetic standpoint. This might include free spanning the entire width of the Ballona Creek to multiple piers within the creek bed.
- Initial Constructability Review – The potential options for bridge design will be reviewed including order of magnitude costs, construction impacts, staging requirements, and environmental impacts. After a full understanding of the options, a preferred option will be selected.
- Preliminary Bridge Design – When the preferred option is selected, prepare preliminary structural drawings and supporting structural calculations.
- Structures Design – Structural design drawings and supporting calculations will be prepared for the structural elements associated with the levee and drainage conveyance structures.
- Structural Consultation – Coordinate with the team and review the proposed construction and provide input about the impacts and risks associated with the construction proposed.

Deliverables

1. Project Schedule.
2. Preliminary Structural Analysis.
3. Preliminary Structural Design for all structures.
4. Preliminary Structural Design for levee reinforcement
5. Preliminary Bridge Report.

70% Design Documents (Six Months – January to June 2013)

This will be the completed technical submittal to include structural design. Refinements to the design reports and products from the 30% submittal will be provided to execute this final design and will include:

1. Formal Technical Structural Analysis.

2. Formal Technical Structural Design for all structures.
3. Formal Technical Structural Design for levee reinforcement
4. Formal Technical Bridge Design.

100% Construction Documents (Six Months – June to December 2013)

As in any technical review, additional comments and questions from the USACE are expected. This 100% construction documents phase is expected to include the work efforts necessary to answer their questions and incorporate their comments up to the time a formal 408 permit approval is issued.

1. Final Structural Analysis.
2. Final Structural Design for all structures.
3. Final Structural Design for levee reinforcement
4. Final Bridge Design.

SECTION VII

QA / QC

Quality is one of the cornerstones of our company and a key part of the Psomas culture. Quality is not a product, yet without it, we have nothing to sell. A principal of our quality philosophy is that the job be done right the first time:

"Do it once, do it right"

We wish to fulfill or exceed the expectations and needs of our clients and will do so by providing quality services. As stated in our Key Beliefs, "We believe quality is achieved through teamwork, adherence to firm-wide procedures and the setting of high standards."

Quality assurance at Psomas is a company-wide approach, supported by specific procedures, to ensure delivery of accurate, coordinated, and complete maps, plans, specifications, reports, stakes, and/or other engineering, surveying and planning deliverables in support of the client's requirements identified in the client's contract.

As mentioned above, quality is what we are about at Psomas. The concept and importance of quality is taught to every employee. Guidelines are set out in the Project Manager's Manual, Engineering Design Manual, Survey Procedures Manual, and the Construction Staking Manual (the manuals) for every task in a project. These guidelines are augmented by the project work plan and the project quality assurance plan that identifies and lays out the procedures for specific project tasks. These manuals were written by the leaders of Psomas who have committed to them fully. By following the guidelines we assure our clients that their project will conform to requirements.

Approach

The entire company participates in quality assurance. Quality work is what Psomas must furnish to a client in order to compete successfully for new work. Some of the procedures utilized to help assure that quality work is performed are discussed in this manual. The Psomas commitment to excellence is incorporated in the manuals.

Quality assurance at Psomas includes all activities that are sometimes known in the engineering profession as either quality assurance (primarily strategies) or quality control (primarily detailed procedures for implementing the quality assurance strategies). Quality assurance is a Psomas commitment to the quality of all contract documents and deliverables. It starts with a thorough understanding of the project, organizing a highly qualified project team, and applying skilled planning, surveying and engineering. This approach is consistently presented in the manuals.

As most of the deliverables provided by Psomas are related to constructing something, quality assurance, focuses on project planning, design reviews and checking procedures whose purpose is to assure that Psomas deliverables:

- Are sufficiently clear to be understood, administered, and enforced by all participants exercising only a moderate degree of professional expertise.
- Reflect acceptance and constructability by using local and/or readily available materials and construction methods.
- Will incur virtually no additional costs resulting from design errors and/or omissions.

- Meet the governmental agency's requirements.
- Meet the client's expectations.

Responsibilities

Psomas

Psomas has the responsibility for the accuracy and completeness of the maps, plans, specifications, construction cost estimates, reports, and stakes under its scope of work, and should meet that responsibility through the implementation of the quality assurance plan.

Principal-in-Charge (PIC)

The PIC leader is responsible for ensuring that the project managers and sub-consultants fully understand the scope, contract terms, and work plan. The PIC is responsible for approving Psomas' responsibilities as a consultant, including quality assurance requirements. Mike Crehan of Psomas is the PIC for the Psomas team.

Quality Control Manager (QCM)

The quality control manager is responsible for managing and ensuring proper execution of the quality control plan and procedures established for the project. Ross Barker of Psomas is the QCM for Psomas engineering and the Psomas team. Matt Rowe of Psomas is the QCM for Survey efforts. Mike Reader of Group Delta is the QCM for geotechnical efforts. Juan Carlos Esquivel of JCE is the QCM for structural efforts.

Project Manager

The project manager is responsible for managing the establishment of quality assurance procedures appropriate to the project requirements. A number of project managers are assigned including John Chiappe of Psomas for survey and Tom Swantko for geotechnical. Each sub-consultant will also have a project manager assigned.

Technical Manager – Engineering/Surveying/Planning/Construction (E/S/P/C)

In support of the project manager, the technical manager(s) has the prime responsibility for selecting the design criteria, reviews, and checking procedures that form the detailed components of the quality assurance plan. Andrew Nickerson of Psomas is one of our engineering technical managers.

Project Engineer/Surveyor/Planner (E/S/P)

The project engineer/surveyor/planner assist the project manager and the technical manager(s) in establishing the appropriate design and review criteria, ensure that the review and checking forms are properly used and work to produce designs that are accurate, complete and coordinated.

Project Team

All members of the project staff assist in providing a high quality of work.

Procedures

The Quality Assurance Plan

- Deliverables for the project should be well defined, including their related schedule. These should include such items as design criteria, reports, schematics, contract drawings, specifications, calculations, cost estimates, etc. These deliverables will be listed in the work plan.
- Description of the specific quality assurance procedures to be applied to various elements of the services to include the level of frequency of review required. Include or make references to specific procedures for verifying computer programs, preparing and checking calculations, checking of drawings, drafting standards to be used, and coordination checking. These descriptions will be listed in the work plan.
- Identification of elements of the project, if any, requiring special quality assurance attention or emphasis. Include applicable standards of quality of practice to be met, level of completeness, or extent of detail required. For this project, that will include review of processes for construction phasing/staging, secondary hydraulic impacts to existing facilities, and limitations for environmental impact.
- As outlined in the work plan definition of quality assurance responsibilities and authorities within the project team. List names of key personnel, by discipline, responsible for design as well as for checking, including project organization chart.
- Estimation of the resources required for the quality assurance functions to include specific timing, budgets, and manpower requirements. Include these quality assurance functions in overall project

schedule. Identify deliverables to be reviewed at each stage (i.e. 35 percent, 65 percent, and 100 percent).

- Submittal of plans and computations at the preplanned milestones (i.e. 35 percent, 65 percent and 100 percent levels) should be accompanied by a statement that **Psomas** has been following its quality assurance plan. This may include copies of appropriate lists of deliverables, tables and plan sheet punch lists that show columns for checking, revisions, back checking, and quality control reviews. Documentation of quality control procedures is considered to be a requisite element of each review submittal, as described in the technical manuals.

Technical Review of Plans

Prior to the final submittal, the QCM shall perform an internal quality assurance review with the technical managers E/S/P/C and engineers experienced in the appropriate discipline(s). The purpose of the review is to satisfy the QCM that the plans and special provisions are of quality acceptable to the client **as well as Psomas**. The criteria for acceptance will be products of neat appearance, well organized, technically and grammatically correct, checked, signed and stamped by the drafter, designer, checker and engineer, as appropriate.

Checking Procedure

In keeping with Psomas policy and sound engineering practice, all design analyses, calculations, drawings, specifications, cost estimates, other contract documents, and reports produced by the Company are to be checked prior to submission to clients or agencies. Detailed procedures for the checking of various types of documents are defined in the Psomas Technical Manuals. Staff involved in design are expected to be well versed in these procedures.

The Technical Managers are normally responsible for the quality assurance review, as overseen by the QCM. The reviews are conducted independently of the project c/s/p who prepared the design. A set of check prints will be formalized to document the checking process. If the technical manager is directly involved in the project, the project manager will arranged with another senior e/s/p to perform the review.

Different colors are used to identify the various stages of the checking process.

- Yellow is used to indicate agreement, and all lines, dimensions, and written text are to be yellowed-in if correct.
- Red is used to indicate required corrections and additions.
- Green is used by the project c/s/p to indicate approval of changes, plus additional changes as agreed to by the technical manager.
- Blue is used to indicate that changes to the document original have been made.
- Green is also used to verify that the change to the document original is correct.
- Black is used for non-record comments or instructions.

Check prints are formalized through the addition of a check print stamp. On the stamp, each participant in the checking process signs on the appropriate line, indicating that that stage of the process is completed.

Checklists

Checklists are provided in the Technical Manuals for normal E/S/P/C activities. These checklists should be reviewed by the project manager, technical manager and project engineer/surveyor/planner (e/s/p) prior to beginning the project. This review will determine which checklist items will be included in the design. As each element of the design is completed, the project e/s/p should initial the checklist items that have been completed. The technical manager initials the checklist items as the final review progresses.

QCM and PIC Review of Plans

In addition to the technical manager's quality assurance review, the Quality Control Manager and PIC reviews all deliverables. The purpose of these reviews is not to supplement or replace the technical manager's review, but to add a perspective which is to confirm that the deliverables committed to the client are all included, and that the deliverables meet the level of client expectations that were originally proposed by Psomas.

Additional Requirements

As Psomas is the lead for a multi-disciplinary technical team, when responding to a client on these quality assurance issues, the following will also be a requirement in addition to the above. That Psomas:

- Define the requirements for documentation for the filing of design notes, calculations, drawings, and supporting materials, and for the specific assigned responsibilities in satisfying these requirements.
- Define procedures for resolving differing technical viewpoints.
- Define design change control procedures to be employed.
- Define internal approval procedures.
- Define external communication procedures and protocol.

Reference to Manuals (Available in the Psomas Intranet to all employees):

- **Project Management Manual**

- Quality assurance exists throughout all aspects and phases of project management at Psomas, and thus all parts of the Project Management Manual. The team leader must be satisfied that the project manager clearly understands each new project, including the following:

    - Contractual arrangements
    - Detail scope
    - Standards to be used
    - Tasks/responsibilities
    - Schedules/budget
    - Deliverables

- **Technical Manuals**

Important elements of quality assurance incorporated in the technical manuals include the following:

- Design criteria collection
- Definition of design standards and/or agency manuals to be used
- Design criteria review forms
- Drafting standards to be used (client or Psomas)
- Computer calculation review forms
- Review forms/checklists for:

    - *Technical Managers of E/S/P/C Services*
    - *Project Engineers*
    - *Engineers*
    - *Surveyors*
    - *Draftspersons*

During the project planning and start-up phase, the PIC and QCM will work with the project and technical managers to select the checking and review forms applicable to a particular project. They may add additional review and checking items that are unique for that project. These will be included in the project work plan.

SECTION VIII

SUMMARY

This work plan outlines the sequence of work, specific tasks, and general timeline goals for the efforts the Psomas team will provide. However, we consider it a flexible, living document that will adjust as the project progresses. This must occur as the design considerations and permitting process evolve and additional considerations are discovered and addressed. Flexibility in the scope schedule has been built into the work plan.

As previously stated, our goal at the end of the project is to obtain a USACE Section 408 permit, obtain other jurisdictional permits, and provide a set of documents sufficient to satisfy the further development of the project.

REQUEST FOR DISBURSEMENT

Name of Grantee/Contractor: PSOMAS	Agreement Number: 11-101	Invoice Number: 81966
Address (include zip code): 555 S. Flower Street, Ste. #4400 Los Angeles, CA 90071	**Project Name:BALLONA WETLANDS ECOLOGICAL RESERVE**	
	Billing Period Covered: From: 4/27/2012	To: 5/31/2012

Work Plan Task Number and Name *(insert rows as needed for work plan)*	Task Budget	Costs Incurred this Period	Total Cost to Date	Remaining Balance
Task 1. Project Initiation	$ 52,980.00	$ 12,945.00	$ 34,555.00	$ 18,425.00

BALLONA WETLANDS RESTORATION BILLING BACKUP

Billing Period Ending May 31, 2012
Job No. 1CCC010100

Task 1	PROJECT INITIATION
	Civil:
	The effort during this second billing period (May) continued the project initiation begun last month. From a management standpoint, this included our weekly technical team conference calls, internal team meetings and conference calls, and a site orientation tour with additional Psomas engineering staff. We prepared and submitted two of the work plan sections - the Survey Workplan and the QA/QC Workplan. Our subconsultant Group Delta also prepared and submitted their Geotechnical Workplan. Psomas provided a section to the overall H & H Workplan addressing the local drainage analysis process. And finally related to Workplan efforts, we commenced the overall Psomas Team Workplan. During this billing period, the four deliverables provided were the Survey, Geotechnical, QA/QC, and H&H Workplan sections.
	Geotech:
	During this second billing period (May), Group Delta staff attended meetings and coordinated regarding their geotechnical issues, and continued their research efforts. The deliverable they provided was the Geotechnical Work Plan. Billing was received from Group Delta for these efforts and is included in the payment request. A more detailed description of their efforts is included on their invoice.
	Structural:
	The structural engineer's (JCE) involvement has still not been initiated.
	Survey:
	Survey continued heavily with field and office support for the aerial topography, channel cross sectional data collection and preparation, site specific data collection, the Survey Workplan, and coordination of survey needs for the project. The aerial survey will still require near-term adjustment for incorporation of the transects for eathwork quantity estimates, and channel cross sectional data. This is expected to be completed next month. A third adjustment may be necessary if and when data for the channel dredging is provided. This adjustment should only have a minor effect on the downstream portion of the hydraulics model. This data is not expected for a number of months. Deliverables included two items, the Survey Workplan and the boundary and aerial survey.

BALLONA WETLANDS RESTORATION BILLING BACKUP

Billing Period Ending May 31, 2012
Job No. 1CCC010100

Task 2	DATA GATHERING	
		Civil: The utility data collection was completed. We initiated the local hydrology of the upstream basin analysis which will be utilized for the Psomas local hydrology model for conduit and conveyence sizing, as well as incorporation into the overall hydrology analysis. No deliverables wer required beyond those described in Task 1.
		Geotech: See description above in Task 1
		Structural:
		Survey: Field data continued to be collected. Collection was expanded to include areas within Area A, and along the existing Ballona Creek levees. See the Task 1 description for further detail.

Project Manager Thomas Swantko

Project LA962A Ballona Wetland Restoration - Engineering

During this period, we prepared a Geotechnical workplan that included locations of 65 explorations for investigation of the subsurface condition throughout the project and outlined our approach to working around protected habitats, describing the type of equipment and tasks to be performed. This included preparation of boring location plans overlaid on maps of protected areas, review of proposed locations by other members of the team and making adjustments as appropriate. Site walks were also performed to review access issues and to become familarized with the site areas. We also participated in weekly team meetings/calls; attended a review meeting with LA County; met with the Gas Company and walked the site with the group. We reviewed requirements of the U.S. Army Corp regarding the investigation and analysis required for leevees, which were used in development of the workplan. We went to Psomas to discuss surveying of boring locations in the field and reviewed archived geotechnical reports of past investigations conducted with the project limits. This previous borings were plotted on a map of the area. We assisted with input to the project description and QC documents, including discussion of construction staging and potential use of a cofferdam.

EXHIBIT 10

California Department of Fish and Game
Att: C. Bonham Executive Director
Att: All California Fish and Game Commissioners
Re: Ballona Wetlands Ecological Preserve
California Contract Code Violation by DFG
California Water Code Violations by DFG

September 14, 2012

Executive Director Bonham,

A Notice of Exemption was filed by this Agency on August 13, 2012 and signed by Agency Staff Person Ed Pert, then transmitted to the California Office of Planning and Research. The Project title is:

GEOTECHNICAL AND BIOLOCICAL DATA COLLECTOIN TO SUPPORT HABITAT RESTORATION AND MANAGEMENT PLANNING ACTIVITIES AT THE BALLONA WETLANDS ECOLOGICAL PRESERVE.

Attachment 1. (DFG NOI)

I hereby notify this agency that it is currently in violation of California Law in regard to the afore said noticed project.

A Contractor acting on behalf of the Agency has been hired in violation of California (Contract Code Notification and Conflict Requirements pursuant to Sections 10140-10141 and 10515-10518). The Contractors name is Psomas. The Contractor was hired by the California Coastal Conservancy.

Attachment 2 (Psomas Proposal to Coastal Conservancy)

The Coastal Conservancy approved the agreement with Psomas on April 20th, 2012.

Attachment 3 (Standard Agreement by Coastal Conservancy)

Psomas submitted a Request for Disbursement to the Coastal Conservancy for the work dated June 27, 2012.

Attachment 4 (Request for Disbursement from Psomas)

CALIFORNIA CONTRACT CODE

The contractor hired by the Coastal Conservancy and currently representing the California Department of Fish and Game was hired by the Conservancy without compliance with California Contract Code Notification and Conflict Requirement pursuant to Sections 10140-10141 and 10515-10518.

In my request submitted to the California Coastal Conservancy on August 23, 2012, pursuant to the California Public Records, Request No. 5 read as follows:

5. ***Provide any and all records*** *that demonstrate that the Agency complied* ***with California Contract Code Notification and Conflict Requirement*** *pursuant to Sections 10140-10141 and 10515-10518 of California Contract Code* ***in regard to Conservancy File Number 04-088, Ballona Wetlands Restoration Engineering and Technical Studies approved by the Governing Board on 1/19/2012 as it relates to contractors hired by the Agency in accordance with that approval.***

Attachment 5 (John Davis PRA to Coastal Conservancy)

The Coastal Conservancy responded that it had no records responsive to this request No. 5. The Agency purported to respond to items 1-4, the Conservancy only responds to request No. 5. as follows:

We do not possess any further responsive records to your August 23, 2012 request.

Sincerely,

Elena Eger
Senior Staff Attorney
California Coastal Conservancy
1330 Broadway, Ste. 1300
Oakland, CA 94612
510-286-4089 tele/voicemail
510-286-0470 fax

Therefore, there is no public record to demonstrate the contractor currently acting on behalf of the DFG has been hired in conformance with the aforesaid requirements of California Contract Code Notification and Conflict Code Sections 10140-10141 and 10515 -10518. For this reason other qualified contractors were not offered the same opportunity to submit a proposals, resulting in discrimination, and the current contractor may be conflicted, as there is no proof to the contrary available as a public record.

My response to the Conservancy transmitted to the Agency on September 13th is attached. It confirms no such records exist.

Attachment 7 (Reply to Coastal Conservancy by John Davis)

STATE WATER CODE

The Contractor representing DFG is currently conducting geotechnical borings in the State Ballona Ecological Preserve.

Attachment 8 (DFG CCC Application)

Attachment 9 (CCC NOE)

Such borings on behalf of DFG will be extracted and will contain Waters of the State of California extracted from the underground as defined by (California Water Code Section 13710). The three aquifers that will be intercepted by such borings are the Bellflower Aquitard, Ballona Aquifer, and Silverado Aquifer. The Silverado aquifer extends South of the Palos Verdes peninsula and is a source of drinking water.

As a consequence of extracting groundwater (Waters of the State) from extracted geotechnical borings, the aforesaid contractor acting on behalf of this Agency is drilling water wells as defined by (California Water Code 13710).

California Water Code Section 13710

"Well" or "water well" *as used in this chapter,* ***means any artificial excavation constructed by any method for the purpose of extracting water from****, or injecting water into,* ***the underground****. This definition shall not include: (a) oil and gas wells, or geothermal wells constructed under the jurisdiction of the Department of Conservation, except those wells converted to use as water wells; or (b) wells used for the purpose of (1) dewatering excavation during construction, or (2) stabilizing hillsides or earth embankments.*

A map produced by the United States Department of the Interior Geological Survey demonstrates the aforesaid aquifers and their depth from MSL.

Attachment 10 (USGS Cross-Sectional Map)

The aforesaid map is contained in GEOLOGICAL SURVEY WATER-SUPPLY PAPER 1464.

Attachment 11 (USGS Water Supply Report)

The Contractor acting on behalf of DFG is therefore, artificially excavating and constructing by method of geotechnical borehole and extraction thereof containing water from the underground is, therefore, constructing a Water Well as defined by the California Water Code.

To drill such a water well, the Contractor must have a State License in accordance with the California Code of Regulations.

C57 - Water Well Drilling Contractor

California Code of Regulations
Title 16, Division 8, Article 3. Classifications

A well drilling contractor installs and repairs water wells and pumps by boring, drilling, excavating, casing, cementing and cleaning to provide a supply of uncontaminated water.

Authority cited: Sections 7008 and 7059, Reference: Sections 7058 and 7059 (Business and Professions Code)

When such a water well is drilled Well Completion Reports DWR-188 must be filed with the California Department of Water Resources according to the Department of Water Resources website @

http://www.water.ca.gov/groundwater/well_info_and_other/well_completion_reports.cfm

Therefore, no public record associated with this project demonstrates the contractor acting on behalf of DFG has a C-57 permit or has filed and or will file any Well Report on behalf of the DFG pursuant to (California Water Code 13710) regarding "geotechnical borings". The contractor was not authorized by DFG to construct a water well and is doing so without formal permission of the Agency. Oversight by the Agency has failed.

In summary, the California Department of Fish and Game cannot prove to the public its aforesaid contractor was hired by the State of California within the requirements of (California Contract Codes 10140-10141 and 10515-10518).

The California Department of Fish and Game cannot prove to the public geotechnical borings portrayed by the aforesaid contractor for DFG **do not** meet the criteria of the definition of water well in accordance with (California Water Code 13710)

CADFG did not engage the aforesaid contractor to drill water wells.

For these reasons, I request the Executive Director of the California Department of Fish and Game, Charles Bonham to cease the aforesaid contractors drilling activities if and until the provisions of California Code are fully addressed by this Agency.

I request that this document be submitted to the California Fish And Game Commission prior to their next meeting.

I finally request that this document a submission for scoping in regard to the Ballona Wetlands Ecological Reserve Project currently being undertaken by this Agency.

Please reply to these concerns in a timely fashion.

Sincerely,

John Davis
PO 10152
Marina del Rey Ca. 90295

NOTICE OF EXEMPTION

TO:	**Office of Planning and Research** **1400 Tenth Street, Room 121** **Sacramento, CA 95814** **Tel#: (916) 322-2318** **Fax#: (916) 322-3785**	**FROM:**	**Calif. Dept of Fish and Game-R5** **3883 Ruffin Road** **San Diego, CA 92123** **Tel#: (858) 467-4201** **Fax#: (858) 467-4299**

PROJECT TITLE: **Geotechnical and biological data collection to support habitat restoration and management planning activities at the Ballona Wetlands Ecological Reserve**

PROJECT LOCATION (CITY AND COUNTY): **City and County of Los Angeles, south of Marina del Rey and north of Play del Rey.**

PROJECT DESCRIPTION: The approximately 600-acre Ballona Wetlands Ecological Reserve is the largest remaining tidal wetland area remaining in the Los Angeles area, and restoration and management of this degraded wetland is the focus of this project. To create a restoration plan baseline data collection of multiple resources on-site is necessary. Data collection will include geotechnical soil borings, and biological assessments and sampling. Geotechnical soil borings will be located primarily in areas that are already disturbed, and will be taken during the non-breeding season (August – February) to avoid impact to breeding birds. Borings will be 4-8 inches in diameter and from 20 to 70 feet deep. Boring holes will be filled with tailings or bentonite when completed, and the site restored to pre-drilling conditions. Specific boring locations, and access to those locations for drilling equipment, will be selected in consultation with biologists and archeologists familiar with the property. Biological and archeological monitors will accompany and guide the boring work to ensure that any sensitive biological or cultural resources are avoided to the maximum extent possible. Soil borings are expected to only take 2-3 weeks to complete. Biological sampling will consist of general observation data collection, trap and release of wildlife and fish specimens, vegetation sampling, and other technical studies.

NAME OF PUBLIC AGENCY APPROVING PROJECT: **California Department of Fish and Game-R5**

NAME OF AGENCY CARRYING OUT PROJECT: **California Coastal Conservancy, Santa Monica Bay Restoration Commission, and consultants**

EXEMPT STATUS (CLASS AND GUIDELINES SECTION): **Class 4 (15304) and Class 6 (15306)**

REASONS WHY PROJECT IS EXEMPT:

- **Minor public alterations in the condition of land, water, and/or vegetation which do not involve removal of healthy, mature, scenic trees (Class 4).**
- **Basic data collection, research, experimental management, and resource evaluation activities which do not result in a serious or major disturbance to an environmental resource (Class 6).**

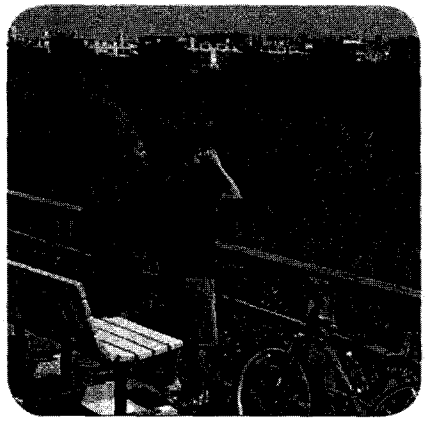
PSOMAS

PROPOSAL FOR

BALLONA WETLANDS ECOLOGICAL RESERVE CIVIL AND GEOTECHNICAL ENGINEERING AND PERMIT ASSISTANCE



PRESENTED TO

STATE OF CALIFORNIA COASTAL CONSERVANCY

Coastal Conservancy

FEBRUARY 29, 2012

Balancing the Natural and Built Environment

PSOMAS

Balancing the Natural and Built Environment

February 29, 2012

Ms. Mary Small
Deputy Executive Officer
California Coastal Conservancy
1330 Broadway, 13th Floor
Oakland, CA 94612-2530

Email: msmall@scc.ca.gov

Subject: Proposal for Ballona Wetlands Ecological Reserve
Civil and Geotechnical Engineering and Permit Assistance

Dear Ms. Small:

Psomas is pleased to present our proposal to assist the California Coastal Conservancy in restoring the Ballona Wetlands Ecological Reserve to a more natural state. Having been involved in the planning and design of the Ballona Wetlands and its surrounding natural areas starting 25 years ago, we are uniquely qualified and share a passion to continue to assist in restoring and protecting this rare natural resource.

Psomas brings the following benefits to the project.

- **Unmatched technical civil and geotechnical engineering knowledge of the Wetlands and its opportunities and constraints that goes back 25 years.**
  No other firm has been as involved or has more engineering knowledge of the Ballona Wetlands and its surrounding area than Psomas.

- **Long-term successful working relationship with the involved agencies, stakeholders and neighborhoods.**
  These relationships are a result not only of our past work at the Wetlands, but also from Psomas' 65-year history in the Los Angeles region. Over a dozen agencies at the local, state and federal level will be involved, in addition to about a half dozen diverse neighborhoods and stakeholders.

- **Detailed knowledge of adjacent infrastructure and key issues.**
  We have intimate knowledge of local utility facilities and the requirements for abandonment, relocation and/or protection in place. We have conducted a wide variety of engineering and environmental studies in the Reserve area and are therefore familiar with the issues of the watershed area surrounding the wetlands. *In*

555 South Flower Street
Suite 4400
Los Angeles, CA 90071-2416

Tel 213.223.1400
Fax 213.223.1444
www.psomas.com

addition to the engineering and environmental studies, we have also addressed sensitive issues including:

- Evaluating nearby street lighting and landscape compatibility
- Archeology
- Habitat protection
- Hydrology and hydraulics
- Sediment transport
- Salinity modeling and
- Stormwater quality impact issues.

- **Current experience processing a Section 408 permit through the Los Angeles District of the US Army Corps of Engineers (USACE)**
  Psomas is in the final stages of processing a 408 permit through the USACE for the City of Los Angeles on the North Spring Street Historic Bridge widening project. In addition, other members of our team are currently working on projects that involve a 408 permit.

We'd also like to directly address a few issues mentioned in your Request for Services.

- **DVBE Participation — *Two DVBE Firms on Psomas' Team***
  Psomas has included two Disabled Veteran Business Enterprise (DVBE) firms on our team to help bring this project to a successful conclusion. We will ensure they receive as a minimum the percentage of work stated as a goal in Public Contract Code Section 10115.

- **Principal-Level Involvement on the Team — *Four Psomas Principals on Team***
  The four key Psomas staff that will be involved in this project are Principals of the firm. And all of them have worked on projects in the Ballona Wetlands region while employed at Psomas – either directly on the wetlands or adjoining areas such as the Playa Vista Development. One of these Principals, Jacob Lipa, has been providing services on this project and its environs for 25 years – all while working at Psomas. His institutional knowledge of the site will prove invaluable during the course of this project.

We thank you for this opportunity and look forward to continuing to work with you in bringing the restoration of the Ballona Wetlands Ecological Reserve to fruition.

Sincerely,
PSOMAS

Michael J. Crehan, PE
Project Director / Principal

Honorable Chair Bosco, Distinguished Commissioners,

Attachments will be submitted to the Governing Board on March 29, 2012.

I hereby request this public body instruct its Staff to schedule an emergency meeting in accordance with the Bagley Keene Act section 11125.5(b) to rescind its approval of File No. 04-088 on January 19, 2012 for the following reasons;

1. NON-COMPLIANCE DEPARTMENT OF FINANCE ATTACHMENT 1
Final Report—Audit of California State Coastal Conservancy's Propositions 12, 13, 40, 50 Bond Funds

The Department of Finance, Office of State Audits and Evaluations, has completed its audit of the California State Coastal Conservancy's (Conservancy) Propositions 12, 13, 40, and 50 bond funds for the period ending June 30, 2008.

Staff Project Manager Mary Small **failed to require Potential Grantee**, the Santa Monica Bay Restoration Foundation, **to fill out a Grant Application Form** on the Conservancy Website.

Background:

On January 24, 2011 The **California Department of Finance Issued a Final Report – Audit** of the California State Coastal Conservancy. The Report Found that ;

*The Conservancy did not establish formal program guidelines: project awarding criteria; and **grant applications** to document its project merit review process.*
Also, the Conservancy website included limited or incomplete information about ongoing programs and efforts, regional priorities, and funding opportunities.

On October 7, 2010, Executive Director Samuel Schuchat responded to the Audit.

*The **Conservancy website has been updated to included the standardized grant application**, more information about funding opportunities.*

The Conservancy has formally adopted project selection criteria, and a formal, transparent awarding process that follows statute.

*It generally does not institute grant rounds but instead has an **open grant process. Application can be and are made, and these are considered at any time.***

*With respect to the form of **grant applications**, based on discussions with the auditors, we have created a **uniform grant application** that is posted on our website. There is now more information available to the public concerning priorities and how to apply for funding.*

*We have developed a **standard grant application that is now in use**.*

A. Staff Project Manager Mary Small failed to obtain any written documentation to identify the Potential Grantee,no address, no agent name, nor an account to which the grant could be deposited is recorded.

B. Staff Project Manager Mary Small had no paperwork whatsoever from the Potential Grantee prior to January 19, 2012 nor did the Potential Grantee request funding. Staff did not provide public notice that such Grant Funds were available to other qualified entities.

C. Staff Project Manager Mary Small failed to determine if the private business, Santa Monica Bay Restoration Foundation was legally operating out of a State Water Board Office, the Los Angeles Regional Water Quality Control Board. Filings with the California Secretary of State show the private business is operating out of a State Office. There is no legal authority allowing for this.

D. Staff Project Manager Mary Small failed to disclose the fact she was a Director of the Corporation of the Proposed Grantee in 2006 creating an appearance of impropriety.

2. FALSEFICATION OF PUBLIC RECORDS ATTACHMENT 2

Staff falsified a Form SCC 08-08, Work Transmittal.
The Form was initialized by;
Executive Director - Sam Schuchat
Project Manager - Mary Small
Legal - Elena Eger

Staff filled out the form as follows:

*Will this project receive federal or other outside funding? Yes___ No X_*

The January 19, 2012 **Staff Report contradicts on page 6** :

*"The SMRBF in-kind **funds would come from U.S. EPA funding** provided to the SMRBF for its staff **and from a U.S. EPA Wetland Program Development Grant** received for work at Ballona"*

3. INCOMPLETE PUBLIC RECORDS ATTACHMENT 2

Staff failed to complete Form SCC 08-08, Work Transmittal.
The Form was initialized by;

4. DISCRIMINATION ATTACHMENT 3

Staff Project Manager Mary Small has improperly lobbied private individuals, private businesses, State and Federal Officials and entities prior to the release of the Staff Report, thusly, discriminating against all others by failing to provide the same comment opportunity prior to the issuance of the Staff Report.

Further Discrimination has taken place because only one Potential Grantee has been selected by Staff Project Manager Mary Small, excluding all others that may have chosen to apply.

Moreover, Discrimination has taken place in that only a select group of Potential contractors was noticed by Staff Project Manager Mary Small, in non-compliance with the California Contract Code, excluding all other qualified firms.

5. PREJUDICE OF PROCESS ATTACHMENT 4

Staff Project Manager Mary Small requested Potential Grantee to help write Staff Report.

Staff Project Manager Mary Small worked with Potential Grantee to engage in media spin to avoid scrutiny.

6. STAFF REPORT EXCLUDED VITAL INFORMATION ATTACHMENT 5

The Staff Report is ambiguous. It describes the Grantee in detail with no supporting documentation whatsoever.

The Staff Report does not establish terms of compliance for the Proposed Grantee nor for entities that will complete the described studies.

The Staff Report does not define that contractors will be hired. Staff Project Manager Mary Small discussed hiring contractors with the Potential Grantee and others before the Staff Report was approved, purposely avoiding the requirement under the Bagley Keene Act for the Governing Board to approve contractors and Notice requirements of the California Contract Code.

Legal Staff Elena Eger encouraged Staff Project Manager Mary Small to complete a grant agreement form because I requested it pursuant to the Public Records Act. The form should have been completed without my request for it.

The Staff Report failed to inform this Board that a Federal Environmental Protection Act Process was initiated by the Army Corp of Engineers Los Angeles in 2005 that governs the Ballona Wetlands.

Staff has failed to inform the Governing Board and Public that the Project Manager, Mary Small, lobbied the Department of Fish and Game to ignore the EIS Notice published in the Federal Register, in favor of a new EIR/EIS process desired by the Project Manager and the Proposed Grantee, without informing and seeking authorization from this Governing Board. This clearly constitutes interference with a legally noticed federal NEPA process. Furthermore Staff Project Manager Mary Small failed to inform this Governing Board that the entire area is governed by U.S. Public Law 780, the Rivers and Harbors Act of 1954, which is the subject of the EIS process currently being conducted by the USACE.

In the Minutes of the Ballona Ecosystem Restoration Planning Management Committee, obtained from the USACE by FOIA Staff Project Manager Mary Small, without the

authorization of this Board, represented to the Army Corp of Engineers on June 28, 2010 that:

Coastal Conservancy is supplying most of the funding toward the in-kind local sponsor efforts.

The Governing Board has not authorized Mary Small to represent the Coastal Conservancy at a meeting of the Army Corp of Engineers and the Local Sponsor (Santa Monica Bay Restoration Authority). The Conservancy is neither a partner nor is there any MOU to with the SMRBA, which is under contract to the USACE. Minutes of other such meetings provide evidence that Mary Small also discussed;

A. Changing the scoping of an Environmental Protection Act process began by the USACE in 2005.

B. Using only the Conservancy's Alternatives.

C. Attempting to gain in kind credits from the USACE.

D. Further documents provided by the USACE provide evidence that the local sponsor, never provided any funding to the USACE whatsoever nor did it provide any in-kind credit.

E. Resumes provided to the Coastal Conservancy by potential contractors for this Project include studies finished and paid for by federal funding stated in the resume(s) as part of the Lower Ballona Creek Feasibility Studies of the Joint EIR/EIS (2005) initiated by the USACE.

7. VIOLATIONS OF CALIFORNIA CONTRACT CODE ATTACHMENT 6

Staff Project Manager Mary Small failed to comply with the California Contract Code Notification and Conflict requirements, Sections 10140-10141 and 10515-10518.

Staff Project Manager Mary Small conducted a Request for Services for Contractors in 2009, and again in 2010 in regard to a Project not noticed to the Public or Governing Board until 2012, both in non-compliance with California Contract Code.

Staff Project Manager Mary Small purports to have initiated another Request for Services in February 2012 with responses due on the 29th of that month outside in non-compliance with the California Contract Code.

8. VIOLATIONS OF BAGLEY KEENE ATTACHMENT 6

Staff failed to obtain permission from the Governing Board to hire contractors to complete studies.

9. QUID PRO QUO INFERED ATTACHMENT 7

The attached e-mails contain an inference of a quid pro quo. The request for a support letter is accompanied by a discussion of bond money provisions. In one email a support letter request exists alongside a discussion to close out another matter, without specificity.

10. INIMIDATION AND HARRASSNMENT OF PUBLIC BY LEGAL STAFF VIOLATING STATE LAW AND AGENCIES PRIVACY POLICY
ATTACHMENT 8

Legal Staff Elena Eger has attempted to intimidate and harass me by copying private business persons on emails to me which disclose my private address, even after I requested the practice cease in writing, in clear contradiction to Information Practices Act (Civil Code section 1798 et seq.) and the Agencies Privacy Policy.

Staff has violated the Conservancy Privacy Policy by the aforesaid action(s).

Privacy Policy

Pursuant to Government Code § 11019.9, all departments and agencies of the State of California shall enact and maintain a permanent privacy policy, in adherence with the Information Practices Act of 1977 (Civil Code § 1798 et seq.), that includes, but is not necessarily limited to, the following principles:

(a) Personally identifiable information may only be obtained through lawful means.

(b) The purposes for which personally identifiable data are collected shall be specified at or prior to the time of collection, and any subsequent use of the data shall be limited to and consistent with the fulfillment of those purposes previously specified.

(c) Personal data may not be disclosed, made available, or otherwise used for a purpose other than those specified, except with the consent of the subject of the data, or as required by law or regulation.

(d) Personal data collected shall be relevant to the purpose for which it is needed.

(e) The general means by which personal data is protected against loss, unauthorized access, use, modification, or disclosure shall be posted, unless the disclosure of those general means would compromise legitimate agency objectives or law enforcement purposes.

Each department shall implement this privacy policy by:

- *Designating which position within the department or agency is responsible for the implementation of and adherence to this privacy policy;*
- *Prominently posting the policy physically in its offices and on its internet website, if any;*
- *Distributing the policy to each of its employees and contractors who have access to personal data;*
- *Complying with the Information Practices Act (Civil Code § 1798 et seq.); the Public Records Act (Government Code § 6250 et seq.); Government Code § 11015.5, and all other laws pertaining to information privacy;*
- *Using appropriate means to successfully implement and adhere to this privacy policy.'*

Sincerely,

John Davis

To: <jd@johnanthonydavis.com>

Mr. Davis, I apologize for the delay in responding to your request. I have been unable to locate any records within the possession of the State Water Resources Control Board that are responsive to your requests. The attached two documents may be of interest to you, however, in that they indicate that the Santa Monica Bay Restoration Project's relationship with the Santa Monica Bay Restoration Foundation (Foundation) pre-dated the conversion of the Santa Monica Bay Restoration Project to the Santa Monica Bay Restoration Commission (Commission). Also, as I explained to you by telephone, the Commission staff is currently undertaking a number of steps to more clearly distinguish the Commission from the Foundation. Unfortunately, some of those steps are taking some time. I will let you know when I receive a timetable for those steps from Commission staff.

Sincerely,
Phil

California State Water Board
Att: Phil Wyels
Re: Status Request Public Record Request

Councel Wyels,

The California Public Records Act requires that Agencies subject to the Act reply to request for records
within 10 days after a request is made.

The State Water Resources Board has not complied with the law in this respect in regard to the request for
records made on 2/7/12.

Please advise as to if or when the State Agency will reply.

Thanks,

John Davis

California State Water Board
Att: Phil Wyels
Re: Public Record Request

Dear Mr. Wyeles,

This is a request for public records pursuant to the California Public Records Act. Each numbered request is distinct.

1. Please provide any record of any law, regulation, or policy of the State Water Board which allows
a private business to operate out of a State Water Board Office.

2. Please provide any record of any law, regulation,or policy that allows a private business to use a State Water Board Office as a corporate street address of principal office in California, and or as a mailing address of the corporation, and or mailing address of the corporation, and or address of a corporate Chief Executive Officer, and or of a corporate secretary, and or of a corporate financial agent.

3. Please provide any law, and or regulation, and or policy that allows any State Water Board Commission to
designate a private business as its "FISCAL AGENT"

4. Please provide any law, and or regulation, and or policy that allows any State Water Board Commission to designate a private business to receive, manage, and to treat money granted by the U.S. Government to the State of California as revenue of the private business.

Thank you for your continued assistance,

John Davis

Attachments:	SWRCB memo2011aug re accusations.pdf SWRCB Ltr to Davis re PRAs.pdf

Dear Mr. Davis:

Pursuant to our phone conversation of yesterday, February 6, 2012, in which you provided a warning to me that the Conservancy should be informed that the Santa Monica Bay Foundation allegedly is appropriating public resources for private gain, attached please find the State Water Resources Control Board's (SWRCB) August 15, 2011 legal memo addressing your contentions and a September 13, 2011 letter to you regarding the same.

As analyzed in the SWRCB memo, especially in #3, pp. 4-5 of that memo, your contentions that the Foundation is improperly utilizing public resources for private use, namely in your assertions yesterday when you identified as improper the fact that the Foundation uses the same mailing address as the SWRCB's Los Angeles office, are specifically addressed. Frances McChesney, Esq., Office of the Chief Counsel for the SWRCB concludes in that memo that the Foundation is not improperly appropriating public resources for its private use.

The Conservancy intends to proceed with its grant to the Foundation approved as Item #5 at its January 19, 2012 meeting.

Sincerely,

Elena Eger

I am planning to attend the meeting, and I'm trying to get some more support letters and maybe attendees. You have no idea how much pleasure I would get from foiling your opponents. I can either stand up during the hearing, or if you want, I can instead meet you and the board between the tour and the meeting (since you must be going to feed them someplace) and just chat informally.

Your choice. I'm free at about 11:30 and have a meeting at 3 pm. In between I am at your service.

Subject: RE: Letter for Coastal Conservancy Board

Hi Shelley-
Do you have time to talk about our Jan meeting? I know you have a board meeting this week, so we could also do this via email – or next week, but before next Fri I'd like to work through some ideas:

1) Tour – we'll probably do a tour the morning of the meeting, I think maybe the tour we did with Colonel Toy – view from Cabora Rd and then walk out to boyscout platform
2) Press – do you think we could use this meeting as an opportunity to get either local papers and/or try for LA Times to cover the project? I am worried that once the agenda is out Marcia will use as opportunity to get bad press. Our agenda will be mailed out Jan 6th
3) Public support – who could we have come to support the project at the meeting or with letters? Geraldine is critical (at least her letter) but how about MRCA?, Joe Geever?, Ballona Creek Renaissance?, Friends?, Miguel Luna?, Audubon? HtB? Baykeeper?

Thanks,
Mary

Hi Bryant
I was wondering if you would be willing to send a letter of support (samples attached) to the Coastal Conservancy for the Ballona wetlands project. Also attached is the draft staff recommendation. The Conservancy will be considering this authorization in LA on Jan 19th, we will take the board on a quick tour of the site before the meeting. If you have time, it would be great to have you attend either of those events too.

This is the request for all funding to complete the environmental review, 100% engineering, and all of the hydrology/hydraulics modeling that the Army Corps is requiring for its permit to modify the flood control levees. The later analysis is the about half of the cost estimate.

Since the meeting will be in LA, opponents of the project are likely to show up. This approval is pretty critical to moving the project forward. If the Conservancy Board gets frightened away from large scale, ecological restoration then I think we will have very limited options for the future.

Thanks for your consideration and please let me know if you have any questions.

Hi Miguel
Happy New year! Hope you are well.

Is there any chance you would be willing to send a letter of support to the Coastal Conservancy for authorization of funding to continue design of the restoration project? I don't know if Shelley contacted you, but it would be great to get community groups weighing in who support ecological restoration. Our meeting will be in LA, so I expect there will be some opposition.

Please let me know if you have any questions or need more info.
Thanks,
Mary

Mr. Doug Bosco, Chairman
State Coastal Conservancy
1330 Broadway, #1300
Oakland, CA 94612
Attn: Mary Small

RE: Proposed Conservancy Authorization for Ballona Wetlands Restoration Engineering and Technical Studies

Dear Chairman Bosco:

I am writing to encourage the Conservancy to authorize funding for the Ballona Wetlands Ecological Reserve Restoration Project planning process. These authorizations would enable the development of technical assessments and engineering design, technical review and agency coordination to support environmental impact analysis and permit applications for the restoration of the Ballona Wetlands Ecological Reserve (BWER).

The Ballona Wetlands Ecological Reserve is 600 acres, surrounded by urban Los Angeles County. The BWER provides valuable and scenic open space in the heart of congested Los Angeles County and offers one of the largest and most promising opportunities for coastal wetland restoration in the region. When restored and opened to the public, the site will allow millions of residents and visitors a rare opportunity to experience a coastal wetland. I support this project because it will help to move the restoration of the Ballona Wetlands Ecological Reserve closer to fruition. Thank you for your consideration of this project.

Sincerely,

Subject: Letter for Coastal Conservancy Board

Dear Geraldine,
When we spoke a month or so ago, I asked if you would provide a letter to Sam Schuchat and his Board regarding your interest in the Ballona Wetlands restoration project. The January meeting of the Conservancy Board will be in Los Angeles and Sam will ask the Board to approve a large sum for continuing the planning and permitting of the restoration project, so your support of the project and interest in providing mitigation funding is important. Do you still intend to provide a letter and can I help with drafting? Also, we will give the Board members a tour of the wetland and briefing on the restoration plan before or after the Board meeting. As soon as we have a date I will send you an invitation and hope that you could come along.

Thank you Geraldine,
Shelley

Subject: support letter for SCC board meeting?

Hello Mark,
Happy New Year. I am emailing to see if Heal the Bay would be willing to send a letter of support to the Coastal Conservancy for the recommendation that we authorize $6.5M for the design and engineering of the proposed restoration project? My draft staff report is attached along with a sample letter. I know you have talked to Shelley about the project, but I would be happy to give you an update at any time. Of course I understand if you are not prepared to take a position on this project at this point, but our meeting will be in Culver City, so I expect there will be some opposition.

Please let me know if you have any questions or need more info.

Jim Lank comes through! Karina or Elena can you please print a copy for me when you get in the office tomorrow? Thank you.

Shelley,

Emails have been flying today, with the end result that BCR is a strong supporter of the requested authorization. See the attached letter. Should we bring copies to give to the board and staff?

As I said before, both Bobbi Gold and I plan to be at the Scenic Overlook for the 1pm meeting start. Bobbi plans to be there for the whole discussion of the agenda item, while I'll stay as long as I can. Both of us plan to sign in to speak on the item. As part of that, I assume it would be appropriate to read the letter, at least in part. If not, let me know.

I hope the tour and meeting both go well. FYI, I'll be leaving soon for another meeting.

Thanks again for your quick response with the helpful cost information.

Subject: Re: [REPLY] Fw: Coastal Conservancy funding to complete Ballona Wetlands restoration planning

Shelley,

Please accept my apologies for this late response. Cathi and I were away on a 2 1/2 week driving trip to the Seattle area for a holiday visit with our kids and grandkids. Then after returning late last Thursday, we've been focused on moving Cathi's 93-year-old mom in with us. I'm just now beginning to turn more of my attention to a backlog of BCR and other matters.

Unfortunately I have an important 3pm meeting at Culver City Hall on the afternoon of the 1pm SCC board meeting at the Scenic Overlook. If I were able to speak on the restoration planning agenda item before about 2:40pm, it could work. Otherwise (or in addition) I might be able to get Bobbi Gold or another knowledgeable BCR board member to represent us.

As for a BCR support letter, I'm pretty sure that would not be a problem. This is on my list of things to bounce off the board prior to our next board meeting.

Here's to a great new year, despite the challenges ahead!

Subject: Coastal Conservancy funding to complete Ballona Wetlands restoration planning

Hello Jim,
I hope you had a lovely Christmas and a happy new year! I did enjoy a nice break.

You may have heard that the Board of the Coastal Conservancy will meet in LA on Jan. 19 and will consider a request from their staff to authorize funding to complete the Ballona Wetlands restoration planning. The request is for about $6.3M and most will go to consultants for additional engineering (through final design), to create a public access master plan, and to do extensive hydraulic modeling as required by Army Corp permitting (the major expense). About $240k will come to SMBRF to fund Diana's position as well as monitoring on the site for the next three years. I don't know if there will be active opposition to this but I am preparing for that nonetheless. Also I see this as a good opportunity to let the SCC board members see the great support that exists in our community for restoration at Ballona.

Please let me know if you are able to support by letter or by attending the meeting. It was posted today on SCC website http://scc.ca.gov/2012/01/06/coastal-conservancy-public-meeting-january-19-2012/
I am attaching the staff report for the item and a couple of example support letters as well. Thank you Jim!

Subject: Ballona Wetlands presentation materials at SCC meeting

Mary,

I am interested in getting a copy of your slide presentation from yesterday's SCC Board meeting. Can you email it to me?

I am also interested in seeing the source documents that were used to make Dr. Luce's point that very little of the site is now functioning habitat.

Are they in the recently released SMBRC's Ballona Wetlands Baseline Assessment Program reports? The SMBRC has a website, ballonarestoration.org, with the Baseline Assessment Program report, unfortunately, most of these documents do not open when clicked upon. They are posted here:
http://santamonicabay.org/smbay/ProgramsProjects/HabitatRestorationProject/BaselineAssessmentReport/tabid/203/Default.aspx

Please call me or email if you can help.

Thanks, Rex Frankel, 310-738-0861

Hi Joe

Nice to talk to you this morning, and thanks for agreeing to come to the Coastal Conservancy meeting in Jan. It will be on Jan 19th at the Baldwin Hills Scenic Overlook starting around noon. Ballona funding (draft staff report attached) will be the first major item on the agenda. We are planning to take the Board on a tour of Ballona that morning. The tour and meeting are open to the public and details will be posted on our website by the 6th of Jan.

As I mentioned, we (Shelley and I) would be happy to provide additional information to you &/or your chapters at any point. Since we are finally getting ready to initiate the public environmental review, now would be a good time to get you engaged.

Thanks,
Mary

Date: Tuesday, December 13, 2011 1:11:00 PM

Thanks

Sorry, the plan is to have the tour from roughly 9-11:30 and then start the meeting at noon or 12:30 – something like that. We're afraid that if we do the tour after the meeting none of the board members will come.

I'll call Barbara today to get her ideas and see if they will help with the tour, come to the mtg or send a letter
Mary

Subject: RE: Letter for Coastal Conservancy Board

Mary, here are some thoughts from me and Diana:

1) Tour – we'll do the tour anytime that works for your members but it seems tight to finish it by 9:15 in order to get them all to Baldwin Hills Overlook for a 10 am meeting. I know we have the Toy meeting the day before so right after the board meeting makes most sense. Could you convince your members to stick around for it?
2) Press – this is troubling. It'll be hard for us to get good press on a $7M expenditure... we can spin this if we get the right people. What if we did a brief presentation on the Monitoring Report before hand? We'll have beautiful hard copies, it's over 400 pages and very impressive and did not cost a lot for the amount of work and info. I think it makes SCC and SMBRC look great. Could we make this the press focus, i.e. with Molly Peterson at least? I'll give her a call for starters.
3) Support – I will talk with Geever, Jim Lamm, Miguel, Lisa Fimiana, Baykeeper, HTB, Nate from Rosendahl's office, Napolitano from Knabe's and Karly from MRT's. I can't say who will show up or do a letter but I will make the asks. I'll also ask Pestrella. Can you talk to MRCA Mary? Also what about the Corps – Rick Liefiled's support would be very meaningful, or Toy's if we can get it. Maybe a letter from Toy with Rick or someone else attending the meeting?

We'll draft a support letter asap and run it by you.
Shelley

Subject: RE: Letter for Coastal Conservancy Board

Hi Shelley-
Do you have time to talk about our Jan meeting? I know you have a board meeting this week, so we could also do this via email – or next week, but before next Fri I'd like to work through some ideas:

1) Tour – we'll probably do a tour the morning of the meeting, I think maybe the tour we did with Colonel Toy – view from Cabora Rd and then walk out to boyscout platform
2) Press – do you think we could use this meeting as an opportunity to get either local papers and/or try for LA Times to cover the project? I am worried that once the agenda is out Marcia will use as opportunity to get bad press. Our agenda will be mailed out Jan 6th
3) Public support – who could we have come to support the project at the meeting or with letters? Geraldine is critical (at least her letter) but how about MRCA?, Joe Geever?, Ballona Creek Renaissance?, Friends?, Miguel Luna?, Audubon? HtB? Baykeeper?

Thanks,
Mary

Subject: RE: board presentation
Date: Wednesday, January 11, 2012 6:55:23 PM

Hi Mary,
I think the presentation looks good. I think we should include some comparative data to show the need for restoration – e.g. the seed bank data, the exotic veg data and some of the animal data (birds and herps). I saw what karina sent you and it doesn't help us – we need numbers like "99% invasive plants" and "lowest seed bank of any so cal wetland". we also need her graphs that show huge percent exotic veg. versus tiny percent native veg, etc. along with those photos of invasive plants that you already included.

I also think we should mention the TMDL –or not the TMDL itself, but we can list the impairments listed on the 303d list, note that TMDL implementation would be consistent with the restoration and that we can work with partners on my governing board and other agencies and leverage resources that would go into implementing the TMDL.

I can help with slides – why don't you send me one or two in your formatting and I will make some with the graphs imentioned and see if you like them. Or rather, since you have to finish by tomorrow and I am out of the office all day, we will ask karina to insert some graphs. Okay with you?
Shelley

Hi Shelley
Attached is a draft powerpoint, I want to keep it as simple as we can. There are several extra slides at the end, I just want one picture I can leave up when I walk through the actual requested action, maybe just the bird with its head in the water?

There are two slides about the baseline monitoring program – I think we only need one of them, do you prefer lots of words or just a picture.

I am sending in .pdf because the actual powerpoint is too big. If you want me to ftp the powerpoin so you can edit directly, let me know. I have to finish this by tomorrow night.

Thanks!
Mary

Subject:	graphs needed for SCC board presentaiton
Date:	Thursday, January 12, 2012 7:57:56 AM

Hi Karina,
Thank you for the bullets you prepped for Mary, they are helpful. The photos are also perfect. What we still need for the presentation are graphics or numbers that will really make our case. Mary needs to complete the presentation today so can you and your team help us prep the following ASAP?

- one map of existing conditions that shows the site today: an aerial photo with transparent overlay of BASIC habitat types - how much is wetland, how much is upland/vacant lot style. goal is to illustrate how little of the site can be said to be funcitoning habitat.

- one simple graph showing predominance of invasive species - the one in the BWER draft TMDL is fine, can you please send that to mary? we need to say "x percent of the site is covered with 99% invasive vegetation" or whatever the actual numbers are. rather than "dominate by invasives" which could mean only 55% covered.

- some species diversity numbers/charts that show how extremely depaupurate poor Ballona is. not just "reduced relative to other wetlands" but "lowest seed bank abundance and diversity of any wetland in southern california" - but i need you to give me the right language so i am not mis-stating anything. please give me those #s or charts or langauge for seed bank, veg, mammals, birds, fish and herps separately and we'll decide which ones to mention in our presentation.

- any other features of the site or results from your surveys that really illustrate to non-scientists how desperate is the need to restore ecological function and habitat at the site.

I am sorry to ask you for all this today, I hope you or one of your team has time. I think you have all this info readily accessible - f there is someihting i've requested that is a big pain check with me and we'll decide if it's really needed. please call my cell or email, i will be out of the office all day but checking my phone compulsively. also please suggest other stuff if you think of it - you know these data better than we do! thank you KJ talk to you later today.

Subject: please review these two paragraphs
Date: Tuesday, December 13, 2011 9:09:00 AM

Hi
I'm wrapping up my staff report and I needed to add a little more detail about what SMBRF will do with the grant funds and who you are. Can you please review this and let me know if you have any edits? If you can get it to me today, that'd be great.
Mary

The recommended grant to the SMBRF would provide funds for data collection, technical review and agency coordination to support the proposed restoration project. The SMBRF has implemented a multidisciplinary baseline data collection program using volunteers, students and professional technical experts. The baseline report is the first comprehensive assessment of biological and physical resources at the BWER. It was just published and is available online: http://www.ballonarestoration.org. This grant would allow the SMBRF to conduct additional targeted studies based on the resources identified in the baseline assessment as needed to support the environmental impact analysis of the proposed project. In addition, the SMBRF will continue coordination of the agency review, identification of funding partners, and technical review of work products associated with this project.
The SMBRF is a non-profit organization that was created in 1991 to implement the priorities of the Santa Monica Bay Restoration Plan and to support the work of the Santa Monica Bay Restoration Commission. The SMBRF has a number of initiatives including research, public education, and planning, to support these goals. The SMBRF and the Seaver College of Science and Engineering at Loyola Marymount University (LMU) created the Center for Santa Monica Bay Studies to engage in multidisciplinary research on environmental and social issues affecting Santa Monica Bay and its watershed, and to contribute to policies and actions that improve the environmental condition of the Bay. The partnership with LMU has been very valuable to the data collection efforts, SMBRF has used student volunteers to conduct fieldwork and some faculty have coordinated their own research to support the baseline assessment, resulting in hundreds of hours of field work being donated to the project.

DEPARTMENT OF DEFENSE Department of the Army; Corps of Engineers Notice of Intent To Prepare an Environmental Impact Statement/ Environmental Impact Report for the Ballona Creek Ecosystem Restoration Feasibility Study, Los Angeles County, CA AGENCY: Department of the Army, U.S. Army Corps of Engineers, DoD. ACTION: Notice of intent. --

---

SUMMARY: The Los Angeles District intends to prepare an Environmental Impact Statement/Environmental Impact Report (EIS/EIR) to support a cost-shared ecosystem restoration feasibility study with the Santa Monica Bay Restoration Commission. The proposed project study areas has been degraded by encroachment of non-native plants, placement of fill from Marina Del Rey, interruption of the hydrologic regime, trash accumulation, and varied attempts at bank protection along the creek using rock and concrete. Direct benefits of the proposed project include improved habitat and water quality, reductions in waste and trash, and aesthetics. The watershed is an important resource for both recreational uses and for fish, and wildlife and further degradation could jeopardize remaining. The purpose of the feasibility study is to evaluate alternatives for channel modification, habitat restoration (coastal and freshwater wetlands and riparian), recreation, and related purposes along the lower reach of the Ballona Creek. DATES: A public scoping meeting will be held on September 29, 2005 at 6 p.m. ADDRESSES: U.S. Army Corps of Engineers, Los Angeles District, CESPL-PD, P.O. Box 532711, Los Angeles, CA 90053 and Santa Monica Bay Restoration Commission, 320 West 4th Street, Los Angeles, CA 90013. FOR FURTHER INFORMATION CONTACT: Shannon Dellaquila, Project Environmental Manager, at (213) 452-3850 or Malisa Martin, Project Study Manager at (213) 452-3828. SUPPLEMENTARY INFORMATION: 1. Authorization This study was prepared as an interim response to the following authorities provided by Congress under Section 216 of the Flood Control Act of 1970, which states: The Secretary of the Army, acting through the Chief of Engineers, is authorized to review the operation of projects the construction of which has been completed and which were constructed by the Corps of Engineers in the interest of navigation, flood control, water supply, and related purposes, when found advisable due the significantly changed physical or economic conditions, and to report thereon to Congress with recommendations on the advisability of modifying the structures or their operation, and for improving the quality of the environment in the overall public interest; supplemented by House Resolution on Public Works and Transportation dated September 28, 1994 which states: **The Secretary of the Army is requested to review the report of the Chief of Engineers on Playa del Rey Inlet and Basin, Venice, California, published as House Document 389, Eighty-third Congress, Second Session,** and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at present time, in the interest of navigation, hurricane and storm damage reduction, environmental restoration, and other purposes at Marina del Rey Harbor, Los Angeles, California, with consideration given to disposal of contaminated sediments from the entrance channel required under the existing operation and maintenance program at Marina del Rey. 2. Background The Ballona Creek Ecosystem

Restoration study area lies within Los Angeles County, CA and includes portions of Marina del Rey, Culver City, Playa del Rey, and the City of Los Angeles. The study area, a component of the greater Ballona Creek Watershed, includes the lower reach of Ballona Creek extending southwest from Cochran Avenue, in Los Angeles, to Pacific Ocean in Marina del Rey. specific features of the Ballona Creek watershed, including existing and historic wetland areas, the Ballona Lagoon, Del Rey Lagoon, Venice Canal, Grand Canal, the Oxford Drain and the Ballona Channel and tributaries, will be addressed in this study. The greater Ballona Creek system drains a watershed of approximately 329 square kilometers (81,300 acres), and is the largest tributary that drains into the Santa Monica Bay. Ballona Creek collects runoff from several partially urbanized canyons on the south slopes of the Santa Monica Mountains as well as from intensely urbanized areas of West Los Angeles, Culver City, Beverly Hills, Hollywood, and parts of Central Los Angeles. The urbanized areas account for 80 percent of the watershed area, and the partially developed foothills and mountains make up the remaining 20 percent. The watershed boundary includes the Santa Monica Mountains on the north, the unincorporated area known as Baldwin Hills, and the City of Inglewood on the south. The Ballona Creek Ecosystem Restoration study footprint's southern boundary is defined by the Westcheste Bluffs, which run southwest from the San Diego (405) Freeway beyond Loyola Marymount University. The western boundary extends from the Pacific Ocean. The eastern boundary begins where Ballona Creek daylights at Cochran Avenue and Venice Boulevard in a section of Los Angeles known as the Mid City. Tributaries of Ballona Creek include Centinela Creek, Sepulveda Canyon Channel, Benedict Canyon Channel, and numerous storm drains. The Ballona Creek watershed ecosystem has been altered by intense land development, encroachment of non-native plants, trash accumulation, and varied attempts at bank protection along the creek using rock and concrete. Although an important function of the Ballona Creek is as a flood control channel, the lower watershed is still an important resource for both recreational uses and for fish and wildlife habitat. Further impairment could jeopardize remaining habitat. This study will evaluate opportunities for habitat restoration (including wetland and riparian habitat), improvements to water quality, trash mitigation, and recreation and related purposes along the lower reach of the Ballona creek. 3. Problems and Needs At least ninety (90) percent of historic coastal wetlands in California have been lost due to filing, dredging, flood control and intensive development. Within the Lower Ballona Creek Watershed, remaining fragmented wetland areas have been degraded due to diminished hydraulic function, poor water quality and introduction of exotic plants and animals. While functioning wetland systems and riparian habitat remain, they are stressed. Channelization of the Ballona Creek and filling of historic wetland and riparian areas have contributed to degradation and loss of habitat due to impeded tidal exchange and circulation. Contaminated stormwater runoff and trash loading has degraded Ballona Creek water quality. Habitat alteration and loss has decreased biodiversity and overall ecological health, threatening the survival of native endangered species such as the California least tern (Sterna antillarum brown), snowy plover (Charadrius alexandrinus), and the Belding's Savannah Sparrow (Sandwichensis beldingi). The current design of the Flood Control channel has resulted in a lack [[Page 55117]] of recreational opportunities and is considered aesthetically challenged. At present there is no integrated approach and partnership amongst stakeholders to resolve lower Ballona Creek in-stream and wetland

degradation issues, which has led to uncoordinated and sometimes redundant and unsuccessful improvement measures. 4. Proposed Action and Alternative The Los Angeles District will investigate and evaluate all reasonable alternatives to address the problems and need stated above. In addition to a without project (No Action) Alternative, both structural and non-structural environmental measures will be investigated. An assessment of the feasibility of removing impervious surfaces from the Ballona Channel will also be evaluated. Proposed restoration measures include: re-grading and removal of fill, remove invasive and non-native plant species, reintroduction of a water source and installation of native plants to restore previously filled coastal wetlands. Other measures to be evaluated include features to improve or restore tidal regime in Oxford Basin, the Grand and Venice canals, and Ballona and Del Rey Lagoons; the potential for in stream wetland development in Centinela, Sepulveda and Ballona Creek; sediment loading in the upper watershed; and related recreation and educational opportunities. 5. Scoping Process The scoping process is on-going, and has involved preliminary coordination with Federal, State, and local agencies and the general public. A public scoping meeting is scheduled for Thursday September 29th from 6-8 p.m. at the Rotunda Room of the Veteran's Memorial Building, 4117 Overland Avenue, Culver City, CA. This information is being published in the local news media, and a notice is being mailed to all parties on the study mailing list to ensure that public will have an opportunity to express opinions and raise any issues relating to the scope of the Feasibility Study and the Environmental Impact Study/Environmental Impact Report. The public as well as Federal, state, and local agencies are encouraged to participate by submitting data, information, and comments identifying relevant environmental and socioeconomic issues to be addressed in the study. Useful information includes other environmental studies, published and unpublished data, alternatives that could be addressed in the analysis, and, potential mitigation measures associated with the proposed action. All comments will be considered in the project development. Concerns may be submitted in writing to the Santa Monica Bay Restoration Commission, or to the Los Angeles District (see ADDRESSES). Comments, suggestions, and request to be placed on the mailing list for announcements should be sp101.usace.army.mil. Availability of the Draft EIS/EIR The Draft EIS/EIR is scheduled to be published and circulated in December 2007, and a public hearing to receive comments on the Draft EIS/EIR will be held after it is published. Dated: September 13, 2005. Alex C. Dornstauder, Colonel, U.S. Army, District Engineer. [FR Doc. 05-18651 Filed 9-19-05; 8:45 am] BILLING CODE 3710-KF-M

Agreed. The doc he references was for a completely different project, a feasibility study in which SMBRC was the local sponsor for the Corps' study. The EIR/EIS that we want to start is for a separate project, i.e. the BWER restoration/enhancement project. As the landowner, DFG will be the lead agency.

Suggested response.
1) The EIS/EIR process begun in 2005 was for the Army Corps' Lower Ballona Ecosystem Restoration Feasibility Study, that project and the associated environmental review has not been completed and is not moving forward at this time. The EIR/S process for the proposed enhancement project will be separate.
2) The CEQA statute where lead agency is defined is Public Resources Code Section 21000.
3) DFG as landowner intends to be the lead agency on the proposed enhancement project that will be analyzed in the EIR/EIS.

Ca DFG
Att: Mr. Mayfield

Hi Mr. Mayfield, attached is the congressional and corp docs we discussed.

The document states an joint EIS/EIR process was begun in 2005 per the request of Congress.

The Santa Monica Bay Restoration Commission is noted as the lead agency for CEQA in the joint EIR/EIS.

It also states that at least one scoping hearing has already occured.

My question is does DFG plan on beginning another EIR process for the same area that is already been started by the SMRBC and Corp. If so, how can there be two lead agencies.

To me, logic indicates the SMRBC should be lead.

Thanks,

John Davis

Subject: FW: request for services - ballona wetlands

The California State Coastal Conservancy is requesting proposals for consultant services for two separate contracts related to the proposed enhancement of the Ballona Wetlands Ecological Reserve in Los Angeles County. Services are needed to complete engineering and geotechnical evaluations, hydrology, technical studies, design and related services to support completion of a project level EIR/EIS and preparation and processing of a Section 408 permit through the Army Corp of Engineers. One contract will be for Civil and Geotechnical Engineering and a second contract will be for Hydrology and Engineering Design Analysis.

   a. We are coming up to our first major milestone (F3)
      i. Baseline and future without project conditions; preliminary alternatives analysis
         1. Describes problems and opportunities, planning objectives
         2. This product will be the basis for future steps
      ii. Next milestone (F4A/F4)
         1. Formulation, evaluation and comparison of alternatives
         2. F4A: SPD requirement, Alternative Formulation Briefing
      iii. (F5) Public Draft Feasibility Report
         1. Headquarters Policy and Public Review
   b. Josephine Axt: New Review Guidance (Estimated at $500,000; IEPR is federally funded)
      i. Agency Technical Review (ATR) - Requires coordination with the planning center of expertise, and coordinates a team of reviewers from another Corps Division
      ii. Model certifications required
      iii. Independent External Peer Review (IEPR)
      iv. Note for budget: call out what IEPR is estimated to cost, and that it does not have to be cost shared
      v. Diana Hurlbert: Under each discipline, there are costs for responding to comments. Are those related to ATR?
         1. Josephine Axt: Yes. There is a formal comment and response system that must be used for ATRs (DrChecks)
   c. Kathy Anderson: Partnership
      i. Communication
         1. Sean Bergquist: Communication has been much better since Rhiannon has taken over as Lead Planner.
         2. Mary Small: Rhiannon has been great in communication.
      ii. Cost share
         1. Sean Bergquist: Our cost share component is 100% in-kind. It is anticipated that most of that work is and will continue to be in the wetlands.
            a. We are finished our F3 equivalent (2006)
            b. We are also finished our alternatives development and analysis (2008)
               i. We want to make sure that all of the products feed in to the Corps process and products.
            c. The Corps and us on not on the same timeline.

2. Mary Small: It was always our understanding that the Corps would use our restoration alternatives. It makes us nervous that this was never in writing. We have done our F4 equivalent.
3. Because of Federal funding starts and stops, the Corps is still in the F3 process, while the sponsor has completed alternatives analysis (F4 equivalent).
4. Diana Hurlbert: We want to make sure you are maximizing our products, and we want to understand what if any deficiencies are found.
5. Josephine Axt: In-kind has to be formally submitted, directly applicable to the project and it must be understood that in-kind increases increase the overall budget increases.
    a. Mary Small: We fear that our in-kind is not properly reflected in the PMP.
    b. Rhiannon Kucharski: This may be the case. We need to go in detail in to this upon receipt of in-kind submissions, quality check them and revisit the PMP.
6. Sean Bergquist: For credit, do we get credit for what we paid or for what it would have cost the Corps to do the same work?
    a. Josephine Axt: The in-kind credit needs to match the estimate for that work in the PMP. Likewise, if the work costs more than estimated, credit will only be given for up to the estimated amount.

iii. Ed Demesa: As the project goes up the chain, we have to be careful for policy issues. When the project is competing nationally, it starts to become a factor. The cost of land acquisition is part of the project costs. We can only credit up to 35% of total project costs.

iv. Mary Small: If the Corps falls too behind, we will work with Corps Regulatory for a permit for their activities (NEPA/CEQA, design, permitting, and Phase 1 construction).
1. Josephine Axt: If you are going full steam ahead, what is your timeline?
2. Sean Bergquist: We purchased the property in 2005, and have to do something with the property in the near future. There is no set deadline, but they must show the state that something is being done.
    a. In about 4 years, they would like to be constructing something.
    b. Early phase: Do South portion of Area B, South of Jefferson and below Gas Company (low areas, reconnect tidal flows)
3. Ed Demesa: The law to partially build a project and receive credit for a larger project applies only to flood control when there is imminent need. Unfortunately, that law does not apply to ecosystem restoration. There is not an authority for us to give credit for it down the line. So, this may be something you want to consider for a WRDA request to change the authorization.

III. Project Status
a. Corps is working on baseline (F3) right now. Due to H&H delays, the milestone will most likely happen early in FY11.
b. PMP amendment
    i. Study area
        1. Will be clearly defined in the PMP amendment (to the satisfaction of all parties).

a. Definition: Ballona Creek from the Pacific Ocean to Cochran, Del Rey Lagoon; and Centinela and Sepulveda Channels from Ballona Creek to where they go underground.

2. Grand canal is out.
3. Sean Bergquist: We have always planned on the daylighted part of Ballona Creek up to Cochran.
4. Coordination needs to go through Diana Hurlbert and Rhiannon Kucharski.

ii. Costs

1. Ed Demesa: For in-kind credit, it is important to let the PDT know what work the sponsor is doing, even if it will not be submitted for in-kind credit.
2. Sean Bergquist: Historical analysis of the watershed is in the works. We are also working with UCLA to do a watershed budget.
3. Sean Bergquist: When things have to be redone, how does the cost share work?
    a. Hydraulic study
        i. Rene Vermeeren: Our H&H models are in DRAFT form and have not yet had the first ATR. They are not ready for use on alternatives.
4. SMBRC Governing Board will have to sign the PMP and FCSA amendments.
5. In construction phase, can the cost of the land/property be used toward sponsor in-kind credit?
    a. Kathy Anderson: Yes, as long as the constructed project uses those lands. The state paid $140 million in 2005 for the property that makes up areas A, B and C.

iii. In-kind submittals

1. Mary Small: Is there really much more additional work that needs to be done to review the submittals? How much is left to be done by the Army Corps depends on the in-kind submittals?
    a. Diana and Rhiannon can work together with each PDT member to work through these. Set up meetings ASAP.
    b. Kathy Anderson: The whole PDT needs to sit down and go through the PMP, in-kind and costs step-by with SMBRC.
2. Mary Small: I am worried about the water quality report in terms of the data being what is needed per the Corps and less worried about the write-up
    a. Confirm with James Chieh that the data is what is needed.

c. Kathy Anderson: Sponsor financial capability?

i. Even in light of cost increases, the sponsor has enough money to fund all of their study activities and even begin phase I construction (Area B).
ii. Corps needs to get details of sponsor plans for "phase I" in Area B and determine if this must be added as a future without project condition or not.

IV. Action items are noted in RED.

Lower Ballona Creek Ecosystem Restoration Study Monthly Coordination Meeting Minutes
April 28, 2010
10-11am

Attendees:

Mary Small, CC	Sean Bergquist, SMBRC	Rhiannon Kucharski, USACE
Kathy Anderson, USACE	James Chieh, USACE	

I. Comments to the DRAFT Corps F3 products and the DRAFT PMP update are due by the next coordination meeting, May 26, 2010.
   a. Comment from Sean related to updated costs/project area: SMBRC considers lower Ballona Creek to be everything from Cochran Avenue to the Ocean.
   b. Sean is concerned about how SMBRC can come up with matching funds and/or in-kind work for a study totaling $6.2 million (the updated estimated study cost total)
      i. Mary: We may not be able to get approval for the cost increases

II. Frank Wu was not able to attend today's meeting. He will contact Mary and Sean independently to discuss his question on the Engineering and Design Section i, Task 3 from the PMP.

III. In-kind submittals
   a. Mary and Sean will try to submit the first set within one week.

IV. Water Quality Analysis
   a. Document forthcoming from SCCWRP (early June)
   b. Document forthcoming from Geosyntech (June)
      i. Delay due to 2 very dry seasons
   c. Some data is already available on the website (Ballonarestoration.org)
      i. Some prior reports from previous years are available
   d. The Corps (James Chieh) will need to translate and analyze the data and put it into the Appendix Report.
      i. Sean will send everything that is currently available to James Chieh, Cc Rhiannon ASAP. This will include the Geosyntech scope of work and cost estimate for water quality data analysis.

V. Other Discussion
   a. There will be a site tour with the Corps, URS and Sean on May 5, 2010.
   b. Kathy: We were able to request $345k for FY11, but need to get amended FCSA executed.
      i. Mary: We need to credit in-kind work before amending the FCSA. We hope this will bring down the overall study cost.

VI. Action items noted in ORANGE.

Ballona Coordination Meeting Minutes
June 2, 2010
10am

Attendees:

Mary Small, Coastal Conservancy	Diana Hurlbert, SMBRC	Heather Schlosser, USACE
Julian Serafin, USACE	Rhiannon Kucharski, USACE	
Ben Nakayama, USACE	Robert Browning, USACE	Robert Grimes, USACE

I. In kind submittals
   a. For In-kind submittals, Mary, Sean and Diana tried to break down the submittals per the PMP, but had a hard time. Please see in-kind spreadsheet submitted last week.
   b. SMBRC and Coastal Conservancy will submit the In Kind Submittal sheets that correspond with each document from the website, along with reference to the document or file they correspond to and a link to that document on the web.

II. PMP updates
   a. Mary Small is concerned that the revised PMP does not reflect the products they have completed, and very concerned about the cost increases.
   b. Mary Small: Have all the PMP sections looked at the same project area? Parts still refer to Ballona Lagoon, Grand Canal, Venice Canals and Oxford Basin, which are no longer in the study area.
      i. All sections should include: Del Rey Lagoon; Areas A, B and C; Ballona Creek from the Ocean to Cochran; and Centinela and Sepulveda Channels from where they daylight to Ballona Creek.
   c. Mary and Diana requested that the Corps add geographic location to the PMP amendment chapter. The scopes of work are confusing because they do not make the study area clear.
   d. Mary: Why have the F3 economics costs gone up?
      i. Ben Nakayama: Economics had to re-run their model due to the revised flood plain hence their cost increase. The potential flooded parcels went from 6000 to 600.
      ii. Sponsor wants to understand why the economics costs for F3 doubled. The model was originally run at a larger scope (6000 parcels) and is now being re-run at a smaller scope (600 parcels). That should not cost double. There should be economies of scale.
      iii. Ben Nakayama: The model had to be completely re-run for the new parcels. This along with added review costs are the reasons behind the cost increase.
   e. Review Guidance has led to approximately $505k in cost increases. $260k of that is for Independent External Peer Review (IEPR), which is NOT cost shared. The other levels of review such as Agency Technical Review (ATR) and model certification ARE cost shared.
      i. Rhiannon will send another copy of the review guidance.
   f. The Coastal Conservancy is worried that there will be no political appetite to support a feasibility study at this cost level.

g. The language in the PMP needs to itemize what the additional costs would go towards.
    i. Rhiannon will send the detailed cost estimates from each PDT member.
h. The Coastal Conservancy believes their GIS work should decrease the revised GIS costs.
    i. This can be investigated further in conjunction with the in-kind review process. USACE will ask Dave Bianco to review the GIS products and scope and cost estimate after the formal in-kind submittal.

III. Coordination

a. Heather Schlosser: It is hard to assure proper coordination when the Corps is trying to complete the baseline F3 this year, while the sponsor is well in to alternatives analysis in the wetlands areas (A, B, C).
    i. Mary and Diana, what do you see as the Corps' role in this feasibility study?
        1. Mary Small: The discussion was that the Corps would focus on the Creek (there aren't state funds for that) and that the wetlands study would go forward separate from the larger feasibility study, but feed in to the project as in-kind credit. The restoration of the wetlands (A, B, C) is being led by SMBRC in conjunction with the State of California.
        2. SMBRC and Coastal Conservancy are both interested in the Creek as well.
            a. Heather Schlosser: Are you willing to cost share the implementation phase of a recommended alternative that includes the Creek and Wetlands?
            b. Mary Small: Our funding strategy for implementing the restoration is the value of the land. However, the Coastal Conservancy's focus is the restoration planning at the wetlands.

IV. Executive Management Meeting

a. Aim to have this in June. SMBRC and Coastal Conservancy will send potential dates and times to Rhiannon Kucharski, who will coordinate with USACE management schedules.

Ballona Telecon Minutes
March 29, 2010

Attendees:

Rhiannon Kucharski, USACE	Kathy Anderson, USACE	Larry Smith, USACE
John Killeen, USACE	James Chieh, USACE	Frank Wu, USACE
Julian Serafin, USACE	Michael Hallisy, USACE	Patrick Singh, USACE
Mary Small, Coastal Conservancy		Sean Berqquist, SMBRC

I. Introductions
II. PMP update
    a. DRAFT SOW Amendment Chapter distributed
    b. Cost estimates
        i. Frank Wu: Coastal Engineering F3 Baseline Conditions
            1. Need to incorporate PWA information in to the appendix
    c. SMBRC Board will have to buy off on the updated PMP and cost estimates
        i. At this Thursday's meeting they are asking the Board to generally support the study
        ii. Cost increase approval will have to come through the Coastal Conservancy's Board
    d. FCSA amendment would come after the PMP update is complete
        i. Have to work with Corps Legal Counsel and SMBRC Legal/Board
    e. Study Area
        i. For F4, the Corps suggests focused study area of A,B & C plus the Creek up to the I-405, and the Centinela Channel and Sepulveda Wash
            1. H&H and Survey and Mapping Sections believe this focused area is best due to cost considerations
            2. Per Frank Wu: Coastal Engineering work has focused on A, B, & C
        ii. Sponsors feel that we need to keep Ballona Creek up to Cochran Boulevard. Otherwise, the map is okay.
    f. Rhiannon and Kathy will set up a meeting between the sponsors and Survey and Mapping (Alan Nichols).[1]
    g. URS and the Corps are in negotiations for the Plan Formulation and Environmental Appendix
III. Corps work Audit
    a. Environmental Resources Branch (ERB)
        i. Review of sponsor work
        ii. Fish survey of creek and channels
        iii. Work with SAC on HEP evaluation
            1. Including scope of work to score A, B & C and the creek between the marsh areas
            2. Mary can re-start the Conservancy agreement with the SAC to possibly fund them.
                a. Larry will send Mary the scope of work he has written.
    b. Cultural Resources
            1. Write-up from PWA, which summarizes a library record search
                a. Corps and Conservancy both feel that the write-up is inadequate

[1] Action Items marked in GREEN

b. NEPA agency coordination for cultural must be done by a federal agency; it cannot be done by the sponsor or their contractor.
    i. Michael Bever and Bob Stark, with Jones and Stokes and John Killeen need to be in touch with eachother.
2. John Killeen has completed a full record search in the last few months
    a. He is re-writing the F3 input based on the new, more adequate record search.
3. NOTE: Important burials located in the Northwest corner of Area C that have been determined eligible that will need serious consideration for avoidance or mitigation.
4. Also, cultural will have to look at channel as a resource. Where we are pulling out channel, if we decide to, will have to be investigated by cultural.

c. Coastal Engineering
    i. Draft F3 Appendix complete
d. Geotech
    i. Diaz-Yourman contract
    ii. Contract oversite
e. H&H
    i. Baseline Hydrology and Hydraulic Appendices
    ii. Baseline Groundwater Appendix
    iii. Sedimentation will be done during F4 analysis due to funding availability
        1. PWA is looking at sedimentation modeling in their contract with the sponsor. Mary will send their scope of work.
    iv. Water Quality Appendix – We are relying on this product from the sponsor (SCCWRP).
        1. Mary will get us the Appendix as it is available.
f. Socioeconomics
    i. Efforts to date have been on the flood risk management component
        1. Originally the work was going to be done in-house, in L.A.
        2. Original structure inventory and database, site surveys
            a. Subsequent to that work, the H&H floodplain mapping was updated with a fairly significantly reduced floodplain delineation, which demanded that the economics be updated. This update was based on the first revision of the draft Hydraulic Appendix
            b. Update to the economics work will be done through Albuquerque District Economics Section
                i. Finalize F3 analysis
            c. FLO-2D data conversion to HEC format
                i. Will be done through Sacramento District
g. PWA and Jones and Stokes are doing on-going work. Mary will send both scopes of work.

IV. In-kind process (Kathy Anderson)
a. To date there has been no in-kind logged in to the Corps financial system. We need to catch up on that. It should be done yearly.
b. Update in-kind numbers in PMP and in cost summary spreadsheet.
    i. List all in-kind work in a table with associated amount spent on the work, along with a list of work already scoped and contracted to be done. Also, Shelly Luce of SMBRC would need to sign the official submittal.

1. Sponsor needs to keep records of the in-kind and the values in case of an audit.

ii. Mary Small: What is the best way to do that?

iii. Kathy Anderson: We can have a separate meeting to go through the in-kind line by line with Kathy, Rhiannon, Sean and Mary.

iv. Mary Small: Is it what we spend on the product that gets credited or is it what the federal government would have spent to do the same thing?

1. It is up to the PDT to QA/QC the products and agree to the accounting both in amount and content.
2. Coastal Conservancy would feel more comfortable if the in-kind is credited at the value they spent on the product.

V. Coordination

a. Corps requests going forward

i. Each PDT member needs to coordinate with their equivalent on the sponsor's contractor team(s)

1. Rhiannon will send a PDT list to Sean and Mary so that coordination contacts can be filled in next to the corresponding PDT member(s).

b. Sponsor requests

i. Tie up the in-kind process and update more often

c. Our coordination meetings from now on will be the last Wednesday of every month at 10am.

VI. Other Discussion

a. Bike tour with Congresswoman Harman April 9th.

i. Kathy will forward info to Mary and Sean.

DRAFT
ITINERARY FOR
COL R. MARK TOY
MEETING WITH SANTA MONICA BAY RESTORATION COMMISSION AND VISIT TO BALLONA CREEK

26 MAY 2011

TIME/ACTIVITY		TRANSP/REMARKS
THURSDAY – 26 MAY 2011		**UNIFORM: ACUs**
0830	Depart SPL for Loyola-Marymount University (LMU) – 1 LMU 310-338-2700 PAX: Monica Eichler Stuart Strum Dan Swenson	Govt vehicle Driver: Phil Serpa Rick Leifield Josephine Axt
0920	Arrive LMU – Santa Monica Bay Restoration Commission Staff Office (SMBRC)	Location: University Hall Room ECC1857 Note: Met by Stuart Strum and Dan Swenson
0930	Executive Management Meeting with SMBRC and California State Coastal Conservancy (CC) Los Angeles County Public Works Dr. Shelley Luce, Executive Director, SMBRB Mary Small, Deputy Executive Officer, Coastal Conservancy Mark Prestrella, Deputy Director	

TIME/ACTIVITY		TRANSP/REMARKS
THURSDAY – 26 MAY (Continued)		
	Agenda: - Introductions - Project Overview – SMBRC/CC o Project goals and regional importance o Planning Process (Science Advisory Committee and Public Meetings) o Proposed Project o Schedule - Partnership with Corps: Discussion (All) o 408 Permit – Outstanding Questions o Status of Feasibility Study o Discussion of Future Coordination	
1100	Depart for Ballona Creek PAX: See above	Govt Vehicle Driver: Phil Serpa
1110	Ballona Creek Site Visit - Overview of the Site - Ballona Channel - Muted Tidal Wetland SMBRC/CC and LAPW Participants: Dr. Luce, Mary Small and Mark Prestrella	
1210	Depart for Ballona Creek for SPL PAX: See above Note: Lunch enroute	Govt Vehicle Driver: Phil Serpa
1330	Arrive SPL

Attachments:	talking points ballona board item.docx

Hi

Shelley, I am hoping that you will share the presentation of this item to the Conservancy board with me. Attached is an outline of what I am thinking we should cover, please take a look and give me your thoughts. My suggestion is that I'd introduce the project and you, you'd cover the need for restoration and the proposed project and then I could go through the details of the proposed action. I am thinking we will have a short (10ish slide) powerpoint with few words but good pictures. I can pull a draft of it together.

Diana, I am hoping you can fill in the highlighted sections in the attached to help me think about how to explain the work that will done if approved, why it's so expensive and why we are going with this approach, as opposed to phasing differently etc.

Thanks,
Mary

Outline for the presentation

(Mary)
Background

- 600 acres owned by the state, DFG and State Lands
- Designated State Ecological Reserve
- Purchased for the purpose of wetland restoration

Project Partners, introduce Shelley

(Shelley)
Need For Restoration, Site Mgt

- Currently no open public access, very restricted
- Site management issues: homeless encampments, trespass, trash, eyesore

Need for restoration, biology

- Very degraded ecological resources – key findings of baseline assessment
- Regional significance – wetland loss around SM Bay and throughout So CA

Proposed project

- Description of grand vision
- Ecological benefits
- Sustainability – adaption to SLR, restoration of ecological processes
- Public access components

Planning process to date 2 slides(?)

- Public and Science Based Process
- Evaluation of broadest possible range of alternatives
- Refinement and assessment of preferred alternative –ideas we rejected, scaling down due to cost considerations, planning for phased implementation

(Mary)
Recommended action:

1) Authorization for a grant of $250 K to SMBRC to fund their ongoing work to advance this restoration project, including continuation of data collection, agency coordination and technical review and oversight.

2) Authorization of $6.25 million to be contracted by SCC through competitive environmental services contracts for specific technical studies that are needed to complete the environmental review and permitting.

Description of the technical work (what will be done and why so expensive)
This authorization would provide funds for several specific scopes of work to support environmental impact review and permitting of the restoration project.

- Soils and Geotechnical assessment – Some soil sampling has been completed onsite, however the main cost for implementation of the project will be soil management. To

reduce construction costs, the project is designed to balance cut and fill onsite. To effectively implement that program, we have to have clear understanding of soil characteristics – which soils can be used to construct levees, which soils should be used to create upland habitat, etc.

- Landscape Architect to design public access improvements. Conceptual designs for public access improvements have been included in the project from the very start. Now that we have a project description for the land-form of the restoration, it will be important to design the public access improvements. One of the major benefits of this project will be to create a new natural area in the urban center of Los Angeles. We intend to design public access amenities
- Civil engineering – design of levees and construction details up to ___% details of proposed work…
- Hydraulics and Hydrology – evaluation of flood risk and uncertainty details of proposed work…

In addition to environmental impact review, this project will need the following permits: Coastal Commission CDP, LA RWQCB permit, and an Army Corps Section 408 permit. Much of the additional technical work that is recommended in this action will be needed to comply with the 408 permit process.

The 408 permit is a permit issued by the Corps to modify an existing flood control project. After Hurricane Katrina, these permit requirements became much stricter and more comprehensive. This permit will have to be approved in DC and will require that the project have ___% design completed. *Explain why so expensive…*

Over the past several months, the project management team has been in conversation with the ACOE and internally discussing the best path forward given the significant costs to complete the design and hydraulic/hydrology studies.

We considered several options of initial projects that would involve installation of tide gates or breaches rather than full levee removal. Tide gate projects were determined to be less desirable because they do not restore full tidal range, are unable to adapt to sea level rise and have higher maintenance costs. We also considered a moving forward only with a smaller Phase 1 project that would restore wetlands north of the channel.

This would reduce the design and technical review costs now, but if we were ever to implement the full restoration project, we would have to go through some of the permit processes again. Our estimate is that the total planning costs would increase by *X-XX* amt in the end.

Of course the actual amount will be determined through contractor selection process and evaluation of proposals, but we have based this recommendation on a comprehensive, conservative but complete estimate to finish all of the pre-project work.

Acknowledge Some Opposition

- Is restoration needed, impacts to existing resources?

Some individuals think that this site is providing important habitat as is. This is a case of shifting baselines, the site does provide some habitat, but is severely degraded. Example - data pt from Karina's work?. To restore estuarine wetlands at Ballona, the land needs to be reconnected to the ocean.

- Can project be done with volunteers and without bulldozers?

The project that we are recommending is enormous in scale. It involves uncovering the wetlands that were buried with the construction of the marina and that have been cut off from the ocean for almost 90 years. We will work to continue working with youth groups and volunteers to implement portions of this restoration.

- Money would be better spend buying small parcels in the neighborhood

Some neighbors to the project have advocated that the restoration of the wetlands is a poor investment and the bond money should be spent to acquire small parcels (each 3-5 acres) rather than to restore the ecological reserve.

Funds are limited to Ballona, consequences if not approved, who will pay for construction?

Conclusion:
Even though this is a major investment and a controversial project, your staff recommends that you approve it. The ecological restoration of the Ballona wetlands is a rare opportunity to bring back coastal wetlands and to develop an urban natural area that will enhance the lives of millions of Californians. To really restore this site we have to implement a big vision and in order to do that we

Questions I will need to be prepared to answer:
Consequences if not approved
Who will pay for construction?
Why not grant all funds to SMBRC?

NOTES

Cost of other wetland restoration projects – engineering and environmental review

South Bay Salt Ponds Initial Planning, EIR and Phase I Design (15,000 acres)	$23 M
Batiquitos Lagoon	$5 M
San Elijo Lagoon	$1.9 M
S San Diego Bay Salt Ponds	$550K

Questions we need to answer:

Why is this so expensive?
    How does it compare to the costs other wetland restoration projects?
Is it needed? Is it a waste of money?
Is this the right alternative?
Will there be more habitat destruction than restoration
Who will implement the project?
Wouldn't we be better off with ngos and volunteers?
What about long term management?

Key Points
Plan developed with extensive scientific review and public input
Plan goals: habitat restoration, sustainability, public access, lower maintenance cost
Funds are specific to Ballona

Let's meet downtown at 11 am at Bottega Louie, it's on the corner of 7th and Grand. We can eat or just have coffee for as long as we want there, and then head over. Sound good?

Great, let's meet before maybe 11?
Downtown would be easy for me but I could also fly to LAX and meet at LMU, if we do that maybe we could meet a little earlier?

Sam can't make it, this rescehduled time didn't work for him.

> **Subject:** RE: timelines...

The 1st works for me. As for timeline this is what I am shooting for....

Early Feb for Nick's revised engineering/construction PD
Late Feb/early March for summary NOP/NOI to be circulated
March/April for Habitat/Adaptive Mgmnt Plan
Early May for draft geotech, recreation/Area C, hydraulics, traffic, and 30% engineering/design
Working over summer on & circulating admin draft chapters and finalizing reports, recreation/Area C etc.
Finalizing Public review Draft for circulation in late Sept.

Please keep in mind that we will be creating and circulating draft chapters for review as information is available. All document preparation will be on concurrent paths. Keeping to the timeline depends mostly on how responsive reviewers are to deadlines for comment (ie. a 2 week turn around). The consultants are all aware of these targets and have committed to meeting them.

Subject: Re: timelines...

Hi
Sorry if I misspoke I feel like I have promised dates that we haven't met so many times that I instinctively underestimate when we'll get things done. It would be super valuable to have some key milestones on a schedule that we all are working off of- MRCA asked for that too. I can draft it up nxt week or you guys can send it to me.

I think there may be a role for Sci input going fwd but after I'm not sure I think we should have more SAC mtgs. Do you guys have time on the 1st? I think there are a few things we should touch base on and I could meet before or immediately after our mtg w ACOE.

Thanks
Mary

> Hi Mary,
> I wanted to check in on our timelines but I forgot to mention yesterday. I've been shooting for end of Feb. release of the NOP/NOI and public review draft of EIR/EIS in Sept. 2012. In the SAC meeting I thought I heard you say something longer than that – a few months until the NOP comes out. Also in the SAC meeting we kind of indicated there could be more SAC meetings to resolve

things that we were discussing and I didn't think that was part of our plan. I do think we can continue discussion of relevant things with SAC members as we write the draft EIR, and reconvene if necessary. Is that what you were thinking?

Talk to you Monday!

Hi

Do you think there is any chance that we could get a commitment from LA Co to fund the permit process before Jan? Then I could add them as matching funds to my staff report.

Mary

Hi Shelley
Attached is a draft of the grant agmt to the SMBRF for the $240K. We'll need to develop a work plan and budget separately.

Can you take a quick review and let me know if it looks ok? Elena has asked me to produce this draft quickly as it seems the best way to respond to our most recent PRA from Mr. Davis.

Thanks
Mary

REQUEST FOR SERVICES

Ballona Wetlands Ecological Reserve
Environmental Analysis and Permit Assistance

May 11, 2009

Contract Type: Environmental Professional Services

Scope:
Perform environmental analysis and assist in applying for permits for habitat enhancement and public access improvements at the Ballona Wetlands Ecological Reserve in Los Angeles.

Submittal Deadline: **June 1, 2009**
Proposals should be submitted electronically in adobe acrobat format and must be received at the Conservancy by June 1, 2009.

Contact: Mary Small, California Coastal Conservancy, msmall@scc.ca.gov

From: Mary Small
To: "Ivan Medel"
Cc: "Shelley Luce"; "Karina Johnston"; "Diana Hurlbert"

Date: Wednesday, February 08, 2012 4:48:00 PM
Attachments: Ballona Civil Engineering and Geotech.pdf
Ballona Hydrology and Engineering.pdf

Hi Ivan
Could you post the following on the homepage of the Ballona Restoration Project website?

The California State Coastal Conservancy is requesting proposals for consultant services for two separate contracts related to the proposed enhancement of the Ballona Wetlands Ecological Reserve in Los Angeles County. Services are needed to complete engineering and geotechnical evaluations, hydrology, technical studies, design and related services to support completion of a project level EIR/EIS and preparation and processing of a Section 408 permit through the Army Corp of Engineers. One contract will be for Civil and Geotechnical Engineering and a second contract will be for Hydrology and Engineering Design Analysis.

Please unhighlight the text above but insert hyperlinks to the attached docs to the highlighted text to the RFS, does that make sense?

Thanks,
Mary

REQUEST FOR SERVICES

Ballona Wetlands Ecological Reserve
Civil and Geotechnical Engineering and Permit Assistance

February 8, 2010

Contract Type: Civil Engineering and Geotechnical Professional Services

Scope: Provide engineering and geotechnical evaluations, design and related services for the proposed wetland restoration design of the Ballona Wetlands Ecological Reserve in Los Angeles. Technical studies, evaluations, and designs will be of sufficient detail to support completion of a project level EIR/EIS and preparation and processing of a Section 408 permit through the Army Corp of Engineers.

Submittal Deadline: February 29, 2012

Proposals should be submitted electronically in adobe acrobat format and must be received at the Conservancy by February 29, 2012.

Hello all-
Here's some more information about the Coastal Conservancy's contractor selection process. It is a quick process and I am hoping PMT members will assist us so I want to be sure you are aware of the schedule.

I am really hoping the PMT will help in reviewing proposals and that staff from the County and Corp will participate on the selection panel. These contracts are for work to support the County's 408 submittal. Here's the schedule for the review/selection:

- Proposals will be submitted electronically to me on 2/29
- I will post them on a secure site by 3/1 for PMT review
- PMT will select the top 3 or 4 firms we'll interview for each contract by 3/5
- PMT will do a detailed review of the written proposals of the top proposals by 3/13
- Interviews will be in LA on 3/13 – all day

I am assuming the selection panel will be Diana, me, and a representative from the County and the Corps. If anyone else wants to spend March 13th interviewing firms, please let me know.

Att: Executive Director Schuchat, Please Send This Letter to All California Coastal Conservancy Governing Board and Management.

This is a request for public records made pursuant to the California Public Records Act. Each numbered item is a distinct request for public records.

1. Please provide any and all public records that demonstrate compliance with California Public Contract Code Section 10140-10141 in regard to the California Coastal Conservancy approval onf January 19, 2012 of File No. 04-088 which approved money to be disbursed for engineering, hydrologic analyses, geotechnical assessments, and public design.

2. Please provide any and all public records that demonstrate compliance with California Public Contract Code Section 10515-10518 in regard to the California Coastal Conservancy approval on January 19, 2012 of File No. 04-088 which approved money to be disbursed for engineering, hydrologic analyses, geotechnical assessments, and public design.

No such records have been requested or received by me to date.

See Attached Approval for File No. 04-088

Thank you,

John Davis
PO 10152

PUBLIC CONTRACT CODE SECTION 10140-10141

10140. **Public notice of a project shall be given by publication once a week for at least two consecutive weeks or once a week for more than two consecutive weeks if the longer period of advertising is deemed necessary by the department, as follows:** (a) **In a newspaper of general circulation published in the county in which the project is located**, or if located in more than one county, in such a newspaper in a county in which a major portion of the work is to be done. (b) **In a trade paper of general circulation published** in San Francisco for projects located in County Group No. 1, as defined in Section 187 of the Streets and Highways Code, or **in Los Angeles for projects located in County Group No. 2, as defined in said Section 187, devoted primarily to the dissemination of contract and building news among contracting and building materials supply firms. The department may publish the notice to bidders for a project in additional trade papers or newspapers of general circulation that it deems advisable.** 10141. The notice shall state the time and place for the receiving and opening of sealed bids, describing in general terms the work to be done and that the bids will be required for the entire project and for the performance of separate designated parts of the entire project, when the department determines that segregation is advisable.

PUBLIC CONTRACT CODE SECTION 10515-10518

10515. (a) No person, firm, or subsidiary thereof who has been awarded a consulting services contract may submit a bid for, nor be awarded a contract on or after July 1, 2003, for the provision of services, procurement of goods or supplies, or any other related action that is required, suggested, or otherwise deemed appropriate in the end product of the consulting services contract. (b) Subdivision (a) does not apply to either of the following: (1) Any person, firm, or subsidiary thereof who is awarded a subcontract of a consulting services contract that amounts to no more than 10 percent of the total monetary value of the consulting services contract. (2) Consulting services contracts that comply with Article 2.5 (commencing with Section 10510.4). (c) (1) Subdivision (a) does not apply to any person, firm, or subsidiary awarded a consulting services contract by a University of California medical center when the provision of service, procurement of goods or supplies, or any other related action required, suggested, or otherwise deemed appropriate in the end product of the consulting services contract, is necessary to avoid a competitive disadvantage in the hospital industry, improve patient care, protect the privacy of patient information, or avoid significant delay and additional expense. (2) The University of California shall report within 30 days on any exemption granted under paragraph (1) to the Joint Legislative Budget Committee and the Department of Finance. The report shall include a description of the circumstances that warranted the exemption, the effects of the exemption on patient care or patient privacy, and a calculation of the projected costs savings to the institution as a result of the exemption. 10516. No officer or employee of the University of California shall engage in any employment, activity, or enterprise from which the officer or employee receives compensation or in which the officer or employee has a financial interest if that employment, activity, or enterprise is sponsored or funded, or sponsored and funded, by any university department through or by a university contract unless the employment, activity, or enterprise is within the course and scope of the officer's or employee's regular university employment. No officer or employee in the university shall contract on his or her own individual behalf as an independent contractor with any university department to provide services or goods. This section shall not apply to officers or employees of the university with teaching or research responsibilities, nor shall it apply to student employees for payment for additional campus activities or engagements outside of the scope of their primary university employment. 10517. (a) No retired, dismissed, separated, or formerly employed person of the University of California employed with the university or otherwise appointed to serve in the university may enter into a contract in which he or she engaged in any of the negotiations, transactions, planning, arrangements, or any part of the decisionmaking process relevant to the contract while employed in any capacity by any university department. The prohibition of this subdivision shall apply to a person only during the two-year period beginning on the date the person left university employment. (b) For a period of 12 months following the date of his or her retirement, dismissal, or separation from the University of California, no person employed in the university or otherwise appointed to serve in the university may enter into a contract with any university department, if he or she was employed by that department in a policymaking position in the same general subject area as the proposed contract within the 12-month period prior to his or her retirement, dismissal, or separation.

The prohibition of this subdivision shall not apply to a contract requiring the person's services as an expert witness in a civil case or to a contract for the continuation of an attorney's services on a matter he or she was involved with prior to leaving the university. (c) This section does not prohibit the rehire or reappointment of University of California employees after retirement, consistent with university administrative policies, nor does it apply to inventors and authors of intellectual property licensed under technology transfer agreements. 10518. (a) Except as otherwise provided in subdivision (b), each contractor who enters into a contract with a University of California campus for ten thousand dollars ($10,000) or more shall be assigned an identification number by the chancellor of that university campus. Each contractor who has been assigned a number shall list it on each contract the contractor enters into with the university campus, regardless of the amount of the contract. In the case of a corporation or firm, the chancellor's assigned number shall be used exclusively on each contract with that particular chancellor's campus. The assigned number shall remain unchanged regardless of future name changes. (b) If the identification numbers cannot be tracked centrally by the Regents of the University of California, then the regents, and not the chancellors, shall assign the identification numbers.

Hi Barbara,
Thanks for agreeing to support the recommendation for funding for engineering work at Ballona. Attached is the draft staff report, the project will be heard at our Jan 19th meeting at the Baldwin Hills Scenic Overlook. As you can see it's a pretty big authorization, so we'd love your support. I think we may take the Board on a tour of Ballona that morning and then the meeting will start around 12:30. It would be great to have MRCA join us for either the tour or the meeting.

Thanks also for the message about the early action plan grant. When you have time submit any final billing or just a letter stating that the work is all done and I'll close it out.

Hope you are doing well and have a great holiday.
Mary

Hi Mary,

Mark forwarded me your email about the Ballona technical study support letter for the SCC board meeting. We discussed it at our department meeting this week, and will send in a letter. Is an electronic copy fine, or do you need a hard copy? Also, should I just send it to you?

Additionally, Alix Hobbs would like to join our meeting while you are at Heal the Bay to discuss some of our Coastal Conservancy projects and potential future ideas. Is it okay with you if she joins for the second half of the meeting?

Thanks,
Sarah

California Coastal Conservancy
Att: E.Eger
Re: Reply

Dear E. Eger,

The request for public records submitted on 2/14/2012 remains outstanding.

The Commission still needs to reply to this request within 10 days of the submission date. I do expect a reply by 2/24/2012 as
the Public Records Act requires under law.

I also would take issue with your recent email stating that I made a DEMAND of the Commission. This is far from true.

In fact my email stated the INTENDED PURPOSE of the email and made no demands as you stated to me in your email to me.

Prior to that, you inferred in another email that I made statements and or asserted things that I clearly did not.

I corrected you once alreadyin writing, and find I must do so yet again.

Your accuracy in characterizing my telephonic conservations or written documents should not be clouded by your misconceptions
as I do not find it to be professional in your role as a State Attorney.

Regards,

John Davis

California Coastal Conservancy
Att: Elana Eger Councel
Re: Reply to your communication

Counsel Eger,

Please pardon my typo in your title.

Also, I still do not understand why a State Agency would share my letter, and personal email
address with a private business, unless requested pursuant to the Public Records Act. I am not
sure what other private businesses you intend to copy on my letters to the State Agency using State facillities.

I do understand that you will continue to provide my emails to this State Agency with private businesses:

" Indeed, we will continue to share communications to you or from you with our other Ballona project partners, irrespective of whether the partner is a public or private organization, when we, at our sole discretion, determine that dissemination to be useful for our project purposes.".

How does the Coastal Conservancy define the term "partner" as used in your statement?

How, at the Coastal Conservancy, is a determination made at its sole discretion whether the dissemination
of my email to the State Agency would be useful for the Conservancy's project purposes?

What entity of the Coastal Conservancy is entitled to make such a determination and under what authority?

These are fair questions given that my letters to you have already been shared with a private business.

Thank you for your continued assistance.

John Davis

Mr. Davis:

This is in partial response to your PRA, below and your request of yesterday at 5:15 p.m. in which you demand that we not share your communications with "any private business" and in which you characterize such communications as "private".
While we will provide you with your requests to the extent possible and in compliance with the PRA, we must clarify to you that communications between you, as a member of the public, and the Conservancy, a public agency, are not considered under the PRA and thus not by the Conservancy to be "private communications", subject to any privilege or exception under the Act. Indeed, we will continue to share communications to you or from you with our other Ballona project partners, irrespective of whether the partner is a public or private organization, when we, at our sole discretion, determine that dissemination to be useful for our project purposes.
I would also like to clarify for you for your future purposes that my title is not "council" but "counsel", that is, I am a lawyer, not a member of a council.
Sincerely,

Elena Eger

Subject: PUBLIC RECORDS REQUEST FROM JOHN DAVIS

California Coastal Conservancy
Att: Council E. Eger
Re: Public Records Request

This is a public records request made pursuant to the California Public Records Act. Each numbered item is a separate and distinct request for public records. This letter is only intended to for the California Coastal Conservancy and NOT FOR ANY PRIVATE BUSINESS, unless requested by such a business via the California Public Records Act.

1. Provide any and all emails to and received by the California Coastal Conservancy

from the following email address in regard and prior to Item 5 of the Conservancy hearing on January 19, 2012: sluce@santamonicabay.org

2. Provide any and all emails to and received by the California Coastal Conservancy from the following email address in regard and prior to Item 5 of the Conservancy hearing on January 19, 2012: svalor@santamonicabay.org

3. Provide any and all emails to and received by the California Coastal Conservancy from the following email address AFTER the Conservancy hearing on January 19, 2012: sluce@santamonicabay.org

4. Provide any and all emails to and received by the California Coastal Conservancy from the following email address AFTER the Conservancy hearing on January 19, 2012: svalor@santamonicabay.org

6. Provide any and all emails sent by the Conservancy to following email address in regard and prior to Item 5 of the Conservancy hearing on January 19, 2012: sluce@santamonicabay.org

7. Provide any and all emails sent by the Conservancy to following email address in regard and prior to Item 5 of the Conservancy hearing on January 19, 2012: svalor@santamonicabay.org

8. Provide any and all email sent by the California Coastal Conservancy to following email address in AFTER the Conservancy hearing on January 19, 2012: sluce@santamonicabay.org

9. Provide any and all email sent by the California Coastal Conservancy to following email address in AFTER the Conservancy hearing on January 19, 2012: svalor@santamonicabay.org

Thank you for your assistance,

John Davis
PO 10152

Dear Mr. Davis:

As I stated in my email of yesterday to you, we intend to comply with your records request to us of 2/14. We are working on compiling the records that you have requested. Please clarify whether you wish to receive the emails pertaining to correspondence among Mr. Valor, Ms. Luce and Conservancy staff with respect to the Item #5 on the 1-19-12 agenda only.

Please clarify that you are referring to the Conservancy when you make reference to the "Commission" in your message below.

As to your other allegations contained in your email below, I remind you that, as I said yesterday, we will make no further comment, which, of course, does not mean that we agree or disagree with your interpretations. Again, unless you are requesting a record from us under the Public Records Act, we do not intend to make further explanatory comments to you.

Sincerely,

Elena Eger
Senior Staff Counsel
California Coastal Conservancy

Subject: Davis' Requests for Information
From: "Elena Eger" <eeger@scc.ca.gov>
Date: Wed, February 15, 2012 6:45 pm
To: <jd@johnanthonydavis.com>
Cc: "'Mary Small'" <msmall@scc.ca.gov>, "'Sam Schuchat'" <sschuchat@scc.ca.gov>, "'Dick Wayman'" <dwayman@scc.ca.gov>, "'Shelley Luce'" <sluce@santamonicabay.org>, <svalor@santamonicabay.org>

Dear Mr. Davis:

In response to your inquiry below, I am providing you with the link to our website's contents of Item 5, Ballona Restoration Project, approved at the Conservancy's 1-19-12 public meeting unanimously. All my references are to the contents in this link. http://scc.ca.gov/webmaster/ftp/pdf/sccbb/2012/1201/20120119Board05_Ballona_Wetlands.pdf.

I believe in your message below you are referencing Exhibit 4. This record reads at the bottom of the page in the key: "Existing habitat units based on field survey conducted by the California Department of Fish and Game, October – December 2000. Map created by GreenInfo Network October 20, 2011." The Conservancy's logo is next to this statement.

With respect to the remainder of your email to us, below, except for our response to your last statement regarding the Conservancy's

dissemination of your correspondence to and with us, which we responded to in my earlier email to you of yesterday at 11:32 a.m., we wish to direct your attention to the Public Records Act (PRA), which provides the public with the mechanism to request a public record from a public agency. Additionally, we wish to direct your attention to the Ballona Restoration website, linked on our Conservancy website at www.scc.ca.gov , which among other resources, has project documents and provides a calendar of upcoming meetings, if any, where you have the opportunity to seek clarification and information regarding the restoration project.

We have cooperatively provided you with both oral and written clarifications on requests you have made to us for information or on allegations you have made that we or our project partners are violating particular laws or practices or conducting our respective project business improperly. In fact, since the Conservancy unanimously approved Item 5 for Ballona Restoration Planning, on 1-19-12, we responded to every one of your requests for records under the PRA or for explanations or to answer your allegations, which now amount to some 16 written requests to date for both information and records in the 18 business days from our 1-19-12 meeting, except for two requests for information and one request for records, received yesterday. Additionally, you have spoken by phone with six of our staff numerous times each, none of which were records requests but were rather in the nature of your seeking more information or explanation from us. Despite our willingness to provide you with explanations and/or clarifications, we continue to receive more requests for the same information from you, often accompanied by accusations of improper behavior.

In compliance with our obligations under the Public Records Act, we will continue to provide our records to you upon written request for such records. However, we will not be responding to your further requests for non-record information or explanation or to your allegations of improper business practices beyond this request, below. We cannot conduct our regular business in service of the public and continue to respond to your almost-daily and, if daily, often numerous daily requests for non-record information or to answer your allegations. Despite our willingness to provide you with explanations, clarifications and information, our good-faith responses back to you seem to be unsatisfactory to you since you follow-up often with yet another request for the same information. Continuing this "asked and answered" process seems an unproductive use of public resources.

So, with respect to your statement that DFG produced this map, please note that as cited above here, GreenInfo Network produced the map for the Conservancy and its project partners/team's use; DFG is

our restoration partner on this project. We direct you to the Conservancy's website at www.scc.ca.gov, Ballona restoration for identification of our project partners on this project.
With respect to whether DFG provided the Conservancy with permission to put our logo on this proposed restoration design, please note that the Conservancy is a project partner with DFG and that within this partnership, the Conservancy acts as the lead in restoration planning with the full agreement of the other project partners, including the DFG.
Sincerely,

Elena Eger

Subject: RE: Davis call to Eger of 2-6-12

California Coastal Conservancy
Att: Elena Eger Legal Council
CC Mary Small Project Manager
Re: Item 5 January 19th 2012 Meeting

Hello Council Eger,

Mary Small directed me to you to answer a question about the hearing noted above.

The attached map was presented as a projection.

It bears the seal of the State Coastal Conservancy. The small text below the legend is hard to read but it
does reference the California Dpt. of Fish and Game in 2011. The text is not clear. It appears to say Ballona Wetlands units.....summary conducted the California Dpt of Fish and Game .....Map created by .....October 20, 2011.

Could you provide the correct reading of this text?

For what purpose did Fish and Game produce this map?

Did Fish and Game provide specific permission for the Conservancy to place its seal (logo) on this

map for official purposes such as for grant approvals?

I understand the Conservancy is a partner of Fish and Game in the Ballona preserve.

However it is unclear if Fish and Game authorized the use of this map for purposes of another Agency
to consider in its grant process.

Please DO NOT CC ANY PRIVATE BUSINESSES ON MY E-Mail COMMUNICATIONS anymore. This is met
to be a private communication between myself and the State Agency, and not to be shared with any private
business, whatsoever.

Again,

Thank you for your assistance,

John Davis

Subject: State Water Board Legal's Memo to our Governing Board

Mary & Elena--

The attached memo to our Governing Board may help with some background. It was not only given to our Governing Board, it is posted on our website, and was forwarded to John Davis and Patricia McPherson, among others. It addresses virtually all of the accusations made against the Foundation and Commission.

Attached also is a direct letter to John Davis from SWRCB legal noting how Foundation staff and contractors legally serve the SMBRC. For example, I am a contractor to the Foundation, but I am authorized to act on behalf of the Commission. He refuses to acknowledge that, which will never change. However, the documents speak for themselves.

One reason he may be contacting you (again) is that SWRCB legal told him that any future PRA queries to the Commission must be directed to me. He simply won't do that so he seeks ways around it. It would be entirely appropriate for you to re-direct any queries relevant to the SMBRC to me.

Call me if/when questions arise.

State Lands Commission owns approximately 60 acres, including the Freshwater Marsh and the Expanded Wetlands parcel. The State Coastal Conservancy (SCC) is taking the lead in funding for planning and restoring the property. Together, the three agencies are working with stakeholders, scientific experts and other agencies to develop a plan for restoration of this extraordinary resource. Their goals are to:

- Restore and enhance salt-water influenced wetland habitats to benefit endangered and threatened species, migratory shorebirds, waterfowl, seabirds, and coastal fish and aquatic species. Restoration of seasonal ponds, riparian and freshwater wetlands, and upland habitats will be considered where beneficial to other project goals or biological and habitat diversity;

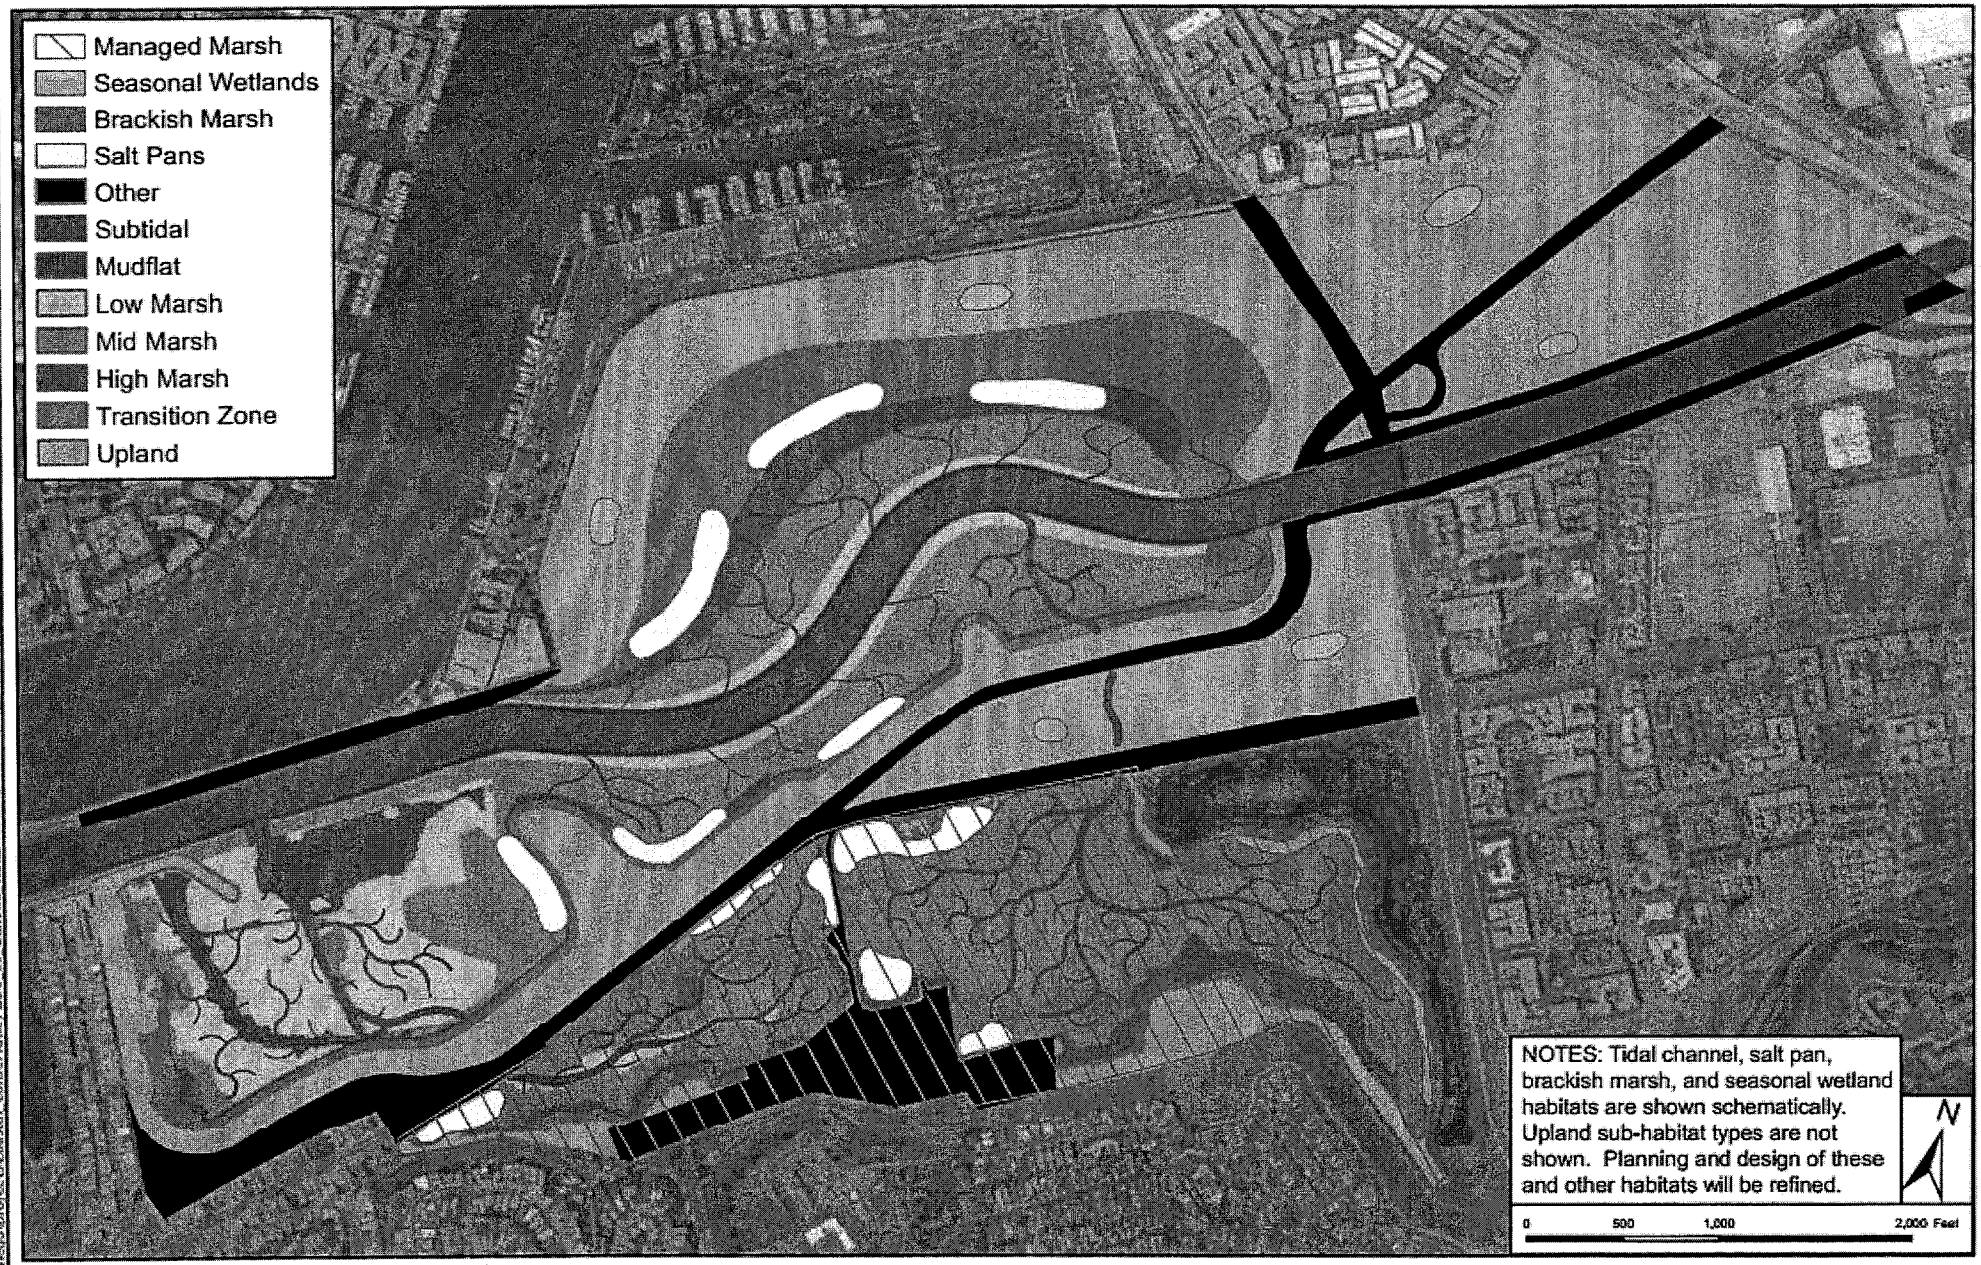
- Provide for wildlife-dependent public access and recreation opportunities compatible with the habitats, fish, and wildlife conservation;

- Identify and implement a cost-effective, ecologically beneficial, and sustainable (low maintenance) habitat restoration alternative.

Milestone 7.1c: Secure funding source (approximately $50 million, total project cost $100–200 million) sufficient to complete first phase implementation of preferred alternative by 2010.

Implementation Lead: Coastal Conservancy
Implementation Partners: State Parks, SCWRP, NMFS

Role of the SMBRC: Participate



On Fri, Sep 28, 2012 at 2:52 PM, Johntommy Rosas

Bay watershed ecosystem and their preservation and restoration is a high priority of the Bay Restoration Commission. Wetlands are areas of transition between land and water, where soils, plants, and animals are adapted to periods of inundation and saturation. Wetlands are one of the most productive ecosystems in nature, providing essential habitat for a variety of species, including birds, fish, reptiles, invertebrates, and mammals. Wetlands act as natural filters which are able to absorb and remove pollutants from the water. They are also valuable in providing flood protection, groundwater recharge, recreational use, and aesthetic

channelization of Ballona Creek have all reduced what was once a 2,200-acre coastal estuary to less than 200 degraded acres today. Poor tidal exchange, polluted runoff, and invasive plants and animals also impact the wetlands.

In 2004, the State of California took title to 600 acres of the former Ballona Wetlands in Los Angeles. The property is now owned by two state agencies, the Department of Fish and Game (DFG) and the State Lands Commission (CSLC). DFG took title to approximately 540 acres of the former wetlands. DFG also holds title to a section of Ballona Creek. The

SECTION I

INTRODUCTION

Project Understanding

Psomas has unmatched technical engineering knowledge of the Ballona Wetlands that spans 25 years. No other firm has been involved or has more engineering knowledge of the wetlands and its surroundings than Psomas. We have extensive knowledge of the infrastructure of the surrounding community as well as The Gas Company facilities throughout the area as a result of our extensive previous work in the community surrounding the Ballona Wetlands. This extensive historical knowledge, has provided us with unique insight and understanding of the opportunities for the restoration plan and the Conservancy's goals for this project.

The State Coastal Conservancy through the PMT team has developed a conceptual plan to restore the Ballona Wetlands ecosystem. It will comprise diverse habitat ranging from sub-tidal through various marshland conditions to upland habitat. The objective of this restoration program is to reintroduce and revive critical wetland habitat and provide a remarkable natural open space for the public benefit. The Ballona Wetlands Restoration Project will enhance the coastal environment for reintroduction of target animal and plant species that left the area because of human development and related loss of the coastal wetland.

The existing Ballona Wetlands have suffered from more than a century of human neglect and abuse that has resulted in a highly degraded habitat area. Much of the area was used for disposal of dredging spoils from construction of Marina Del Rey and the Ballona Creek flood control channel. The Ballona Creek flood control channel was constructed to provide flooding protection for development of lands upstream from the original wetlands; however, the channel also severed the historic natural connection between the freshwater creek and the ocean. As a result, many of the historic ecological functions of the wetlands were lost and no longer support the wide variety of native species that once inhabited the area.

The PMT and their consultant team have studied several alternatives that would allow the reconstruction of a coastal wetland environment and reintroduction of the native species common to these wetlands. While a number of alternatives have been analyzed, a preferred alternative has been developed that involves the removal of segments of the Ballona Creek levees and the reconstruction of a portion of the Ballona Creek channel on an alignment that more closely represents a natural meandering water course. Implementation of this plan will require a technical analysis and review and approval by the County of Los Angeles and U.S. Army Corps of Engineers (USACE) with a Section 408 permit.

More specifically, the preferred project proposes to implement restoration of areas on the north and south sides of the existing Ballona Creek on lands adjacent to Marina Del Rey within Los Angeles County (County) Area A and City of Los Angeles Area B, as well as some restoration in Area C in the City of Los Angeles. This work will generally include:

- Build in flexibility of delivery to address availability of funding. Staged or phased delivery through master planning the construction sequencing.
- The removal of the north and south Ballona Creek levees to allow tidal and stormwater interaction within the Ballona Wetlands Ecological Reserve area.

- Construction of new perimeter levees along the perimeter and strategic alignments within the restoration area to provide the flood protection of existing developed areas when the existing levees are removed.
- Grading to create a restored condition allowing multiple habitat regimes from sub-tidal to upland conditions.
- Execute the proposed construction through a master planned and phased program designed to reduce the environmental impacts as much as possible, balancing earthwork within the Reserve area.
- Assist the PMT in coordinating with and addressing the concerns of the many governmental agencies and other interested parties.

Project Objectives

Consistent with the Conservancy's stated goals, our project team's approach will be driven by the following three primary objectives and secondary objectives for the Civil/Geotechnical team:

Primary Objectives:

- Working with the PMT and Hydrology consultant team, obtain Section 408 approval from the USACE for the levee removal and its supporting analysis.
- Analyze impacts and mitigations for incorporation into the environmental analysis.
- Prepare plans and supporting documents for the grading and infrastructure at the appropriate level for the restoration project.

Secondary Objectives:

- Assist the PMT in obtaining approvals in the most efficient and effective manner. The process to obtain a 408 approval is by design not clearly defined to allow for the many existing conditions in USACE facilities.
- Assist the PMT in addressing the issues and concerns of the community and interested parties. Many groups and agencies are interested in this restoration. They each view it in different terms. Our goal is to provide information and support that is appropriately tailored for public presentation of our technical information in a non-technical manner.
- Ensure that the proposed design elements are sensitive to the environmental goals of the project. The overarching goal of restoring a natural wetland system must be the primary focus in our design.

Section1
Introduction

Playa Capital Company, LLC; Playa Phase 1 Commercial Land Company, LLC; and affiliate companies (collectively "PCC") are developing a large tract of land (Playa Vista) north of Los Angeles International Airport for residential, commercial, community serving, and wildlife habitat uses (herein referred to as the "Site"). As part of this development, residual chemical contamination from past industrial operations and other land-use activities at the site is being investigated and remediated, as necessary. Camp Dresser & McKee Inc. (CDM) has prepared this Soil and Groundwater Remediation Plan (RP) on behalf of PCC to address contaminants of concern in soil and groundwater present within the Campus Area portion of the proposed development, which is planned for commercial land use. This document is submitted in response to Cleanup and Abatement Order No. 98-125 (CAO, attached as Appendix A), issued by the California Regional Water Quality Control Board, Los Angeles Region (RWQCB), in December 1998. The CAO directs PCC to initiate a phased cleanup and abatement program that addresses discharges of contaminants into soil and groundwater from historical land use and former manufacturing operations.

1.1 Purpose and Organization of Report

The purpose of this RP is to develop, evaluate, and select potential remedial alternatives to address soil and groundwater impacted with contaminants of concern in the Campus Area of the Site and to propose remedial actions for soil and groundwater contamination in each source area. The report is organized into ten separate sections. A brief description of each section is provided below:

The remainder of Section 1 provides a summary of the approach to remediation in the Campus Area along with the regulatory context for remedial activities, which is the framework for remediation activities described in this RP.

Section 2, *Site Characteristics*, provides a brief description of the Site history, historical investigations and operations, and regional and Site-specific geology and hydrogeology.

Section 3, *Remedial Objectives and Goals*, provides a discussion of media-specific Remedial Objectives (ROs) and Remedial Goals (RGs) applicable to a list of Chemicals of Potential Concern (COPCs) for the purposes of protecting human health and groundwater quality in the Campus Area. This section also evaluates the list of COPCs to identify specific chemicals of concern (COCs) and source areas.

Section 4, *Known Nature and Extent of Contamination*, provides a brief summary of the nature, extent, and fate and transport of contamination is provided in this section, along with the distribution of COCs in soil and groundwater. Finally, nine source

areas are identified based on a comparison of historical COPC concentrations in soil and groundwater contamination data with RGs described in Section 3.

Section 5, *Identification of Remedial Technologies and Process Options*, covers the first step in the remedial alternative evaluation process, namely the identification of response actions, potential remedial technologies and process options capable of meeting the ROs.

Section 6, *Development of Remedial Alternatives*, develops a series of remedial alternatives from an array of the retained general response actions, remedial technologies, and process options identified in Section 5. A conceptual-level description of each remedial alternative is provided.

Section 7, *Evaluation of Remedial Alternatives*, evaluates each remedial action alternative in relation to the seven evaluation criteria established in the National Contingency Plan (NCP) (40 CFR Part 300.430). Although the Site does not fall under the jurisdiction of the NCP, the seven evaluation criteria were chosen for this section to ensure a complete and comprehensive evaluation of each remedial alternative. The recommended remedial alternative is highlighted at the end of this section.

Section 8, *Proposed Remedial Action*, provides an overview of the proposed remedial actions for soil and groundwater in each source area. The overview is followed by detailed descriptions of the proposed remedial action for the nine source areas. Finally, the section presents a remedial implementation plan that outlines the phases of implementation for the proposed remedial actions to achieve optimal effectiveness.

Section 9, *Monitoring and Contingency Plan*, provides the basis for a Monitoring and Contingency Plan that will be prepared following remedial design activities and prior to remedial action implementation.

Finally, Section 10 provides a reference list of sources used in preparing this document.

1.2 Overview of Approach to Remediation and Mitigation

Investigation and characterization of contamination in the Campus Area at Playa Vista has been the subject of numerous reports prepared during the past nearly twenty years. This section briefly summarizes how those past efforts relate to this RP, and outlines the strategies, methods, and goals of Site cleanup developed in those documents to set the context for the detailed discussion of remediation for soil, groundwater, and soil gas contamination set out in this RP for the Campus Area portion of the Site development.

1.2.1 The Playa Vista Site Development

The Site, located in western Los Angeles, encompasses 1,087 acres of land north of the Los Angeles International Airport and just south of the community of Marina del Rey (Figure 1-1, *Site Location Map*). The Site is divided into four planning areas identified as Areas A, B, C, and D (Figure 1-1).

The Site is being developed in two phases. The Phase 1 Development Area (parts of Area D and the freshwater marsh in Area B) is fully entitled and is under construction. The easterly-most portion of the Phase 1 Development Area, known as the Campus Area, is planned for mixed-use commercial development. As discussed below, this portion of the Phase 1 development includes areas where Hughes Aircraft Company and other industrial operations were once located (Figure 1-2, *Area D Features Map*). Residential development and a limited amount of mixed-use commercial development will also occur at the westerly end of the Phase 1 Development Area (i.e., western portion of Area D).

The Campus Area consists of approximately 114 acres of Area D that were used from the 1940s to the 1990s by the former Hughes Aircraft Company and the former McDonnell Douglas Helicopter Company for the manufacture, research, development and testing of electronics, aircraft, and other equipment[1]. Historically, structures, asphalt pavement, aircraft taxiways, and a runway covered approximately 80 percent of the Campus Area.

The types of chemicals historically used by Hughes Aircraft Company and other industrial operators in the Campus Area included VOCs and semi-volatile organic compounds (SVOCs), petroleum hydrocarbons, metals, pesticides, and polychlorinated biphenyls (PCBs). Based on reviews of industrial records, interviews of former employees, and extensive sampling of the property, it was determined that some of these chemicals were either stored and/or used in the Campus Area in locations of previous industrial activity, such as a former drum storage area, former underground storage tanks, several clarifiers, utility trenches, former degreaser area, sumps and a former storm drain discharge. Investigations of these locations have revealed several areas of environmental concern in the Campus Area, which this RP intends to address.

Additionally, the City of Los Angeles Office of the Chief Legislative Analyst (CLA, 2001), with input from independent consultants and various City departments and State agencies, issued a report in May 2001 that investigated the potential public health and safety impacts, and appropriate mitigations if any, associated with naturally-occurring compounds and other environmental conditions in portions of the Phase 1 Development Area of the Site (see Figure 1-2). The CLA report addressed soil

[1] The Campus Area consists of Tracts 49104-04 and 52092

gas (methane, hydrogen sulfide (H_2S), and benzene, toluene, ethyl benzene, xylene (BTEX)), subsidence, and earthquake fault impacts. Specifically, the study addressed five primary questions, which are presented below along with a summary of the CLA findings:

1. Is the Southern California Gas Company Playa Del Rey Gas Storage Facility located in the adjacent Playa Del Rey area leaking and, therefore, a source of the methane observed at the Site and a risk to workers and future residents?

   The CLA concluded the gas storage facility is not the source of methane observed at the Site; there is no evidence to suggest the storage facility is leaking or improperly maintained; and there is no evidence that the gas storage facility presents a danger to workers or future residents at the Site.

2. Is the extent of the methane observed at the Site fully defined and can it be mitigated?

   The CLA concluded the numerous extensive studies of methane concentrations "yielded a data set that is more than adequate for the assessment of potential methane hazards and for the design of appropriate mitigation measures." Further, the report recommended that a methane mitigation system be implemented to prevent, detect, and monitor the presence of methane for future development (CLA, 2001, Table 2-1). The report noted that mitigation measures would vary depending upon the concentration of methane present.

3. Is there significant subsidence at the Site currently, or will future methane mitigation cause subsidence issues that may undermine the structural integrity of future building structures?

   The CLA concluded that "no significant or clearly defined trend of increased subsidence" was observed in the vicinity of the Site. The report noted that a minimal level of settlement and uplift was observed, however, design measures are adequate to address such occurrences. Further, the report concluded that there is no evidence the proposed methane mitigation measures would result in increased potential for subsidence in the area.

4. Is there an active earthquake fault at the Site that presents an unacceptable risk to workers and future residents?

   The CLA concluded that the geologic and geophysical data do not support the existence of the postulated Lincoln Boulevard fault. In addition, the CLA report also noted that the Division of Geology and Mines was reviewing offshore seismic data to ascertain if observed

anomalies were indicative of offshore faults.[2] Subsequent to the issuance of the CLA report, the City of Los Angeles Planning and Land Use Management Committee issued a statement on behalf of the Division of Geology and Mines that there are several plausible explanations for the anomalies, and "it appears that the anomalies could be associated with depositional features characteristic of stream channels."

5. Is there BTEX and H_2S contamination associated with the methane that presents a health risk to workers and future residents?

   The CLA concluded the potential health risks associated with BTEX and H_2S soil gas emissions are below the benchmarks established by the U.S. Environmental Protection Agency (USEPA), Department of Toxic Substances Control (DTSC), Office of Environmental Health Hazard Assessment (OEHHA) and other regulatory agencies to indicate insignificant risk, and therefore no further investigation or remediation is warranted.

PCC and other developers at the Site will implement appropriate methane mitigation measures at new buildings in the Phase 1 Development Area, including those proposed in the Campus Area in accordance with City of Los Angeles building codes.

1.2.2 The Regulatory Process for the Site

The California Environmental Protection Agency (Cal/EPA) has designated the RWQCB as the lead agency for the Site. A copy of the letter reporting that designation is included in Appendix B.

The RWQCB has provided oversight for remedial activities at the Site since the 1980s, and in 1998 issued a CAO, which directs PCC to address discharges of contaminants into soil and groundwater from past industrial operations at the Site (RWQCB, 1998). Specifically, the CAO defines several requirements: to implement free product recovery, to monitor groundwater on a quarterly basis, and to design and implement appropriate soil and groundwater remediation.

To achieve these goals, PCC conducted a Site-wide soil and groundwater assessment to supplement previous studies and to better define the nature and extent of contamination. PCC submitted to the RWQCB a Soil Remedial Action Plan (SRAP) addressing portions of the Campus Area (CDM, 1999a), later extended to the entire Phase 1 Development Area (PCC, 2000), and a Groundwater Treatment System Evaluation (IESI, 1999a). Both documents recommended additional activities in order to finalize soil and groundwater remediation plans (see Appendix A). Under the oversight of the RWQCB, PCC performed these additional activities for the Campus

[2] These anomalies were observed approximately ½ mile west and ¼ north of the sites.

Area. Using these results, this RP addresses areas of concern within the Campus Area that require further remediation.

1.2.3 General Approach For Addressing Environmental Contamination

PCC has developed both a risk-based and resource-protection approach to the investigation and remediation of contamination for the Site development, based on several important principles:

- PCC will address chemical contamination that presents human health risks at the Site in a conservative fashion. Where uncertainty is present, PCC remediation will base it's decisions in favor of public health protection;
- During remediation, PCC will address potentially complete human exposure pathways (i.e., ways in which exposure may occur as opposed to purely hypothetical exposure pathways) as its first priority. PCC will also implement mitigation measures to prevent or reduce, as appropriate, potential exposures that may occur while remediation is underway;
- PCC will also work to protect resources (e.g., groundwater), even though no direct human exposure to contaminants in this water is likely now or in the foreseeable future[3];
- PCC will employ an approach to Site cleanup that addresses the needs and concerns of all involved regulatory agencies.

PCC's general approach to addressing contaminated areas of the Site is outlined in the flow diagram in Figure 1-3, *Summary of Approach to Remediation for the Phase 1 Site Development.*

In support of this approach, various numerical remediation goals or triggers have been developed in a series of stand-alone documents. Particularly important are the Site-specific health-based remediation goals (HBRGs) and soil remediation triggers (SRTs). The documents in which they have been developed, and the relationship of those documents to other environmental reports for the Site, are shown in Figure 1-4, *Flow of Information Among Playa Vista Environmental Reports.*

1.2.3.1 Health-Based Remediation Goals

Remediation has been completed for most areas of the Site where chemical releases had been identified. However, residual contamination is still present in some areas and this RP evaluates whether further remediation is needed to protect human health. Initially, for purposes of identifying residual contamination that would require

[3] Presently, groundwater at the Site, which is of poor quality due to high TDS, sulfate, and chloride levels unrelated to Site activities, is not used as a source of drinking water. Prospectively, the Covenants, Conditions, and Restrictions (CC&Rs) adopted for the Site will prohibit use of groundwater for such purposes.

remediation, PCC considered comparing contaminant levels with the relevant PRGs developed by the USEPA. (PRGs are non-Site-specific quantitative levels for contaminants expected to be protective of human health). However, USEPA developed these PRGs without consideration of indoor air exposures, which is the primary exposure pathway at the Site. Additionally, EPA's PRGs assume certain site conditions, not all of which exist at the Site.

For these and other reasons, PCC developed its own media-specific HBRGs. HBRGs are concentrations of chemical contaminants in soil, groundwater, and soil gas that will protect the public from unacceptable exposures to these chemicals at the Site. Calculating these concentrations involves, in general terms, deciding how people might be exposed to Site contaminants, and then establishing levels of these contaminants that are sufficiently low to ensure that exposures would not represent threats to human health. The methodology for calculating HBRGs is the subject of considerable Cal/EPA and USEPA guidance. This guidance was followed in developing the HBRGs.

The PCC-developed HBRGs take into account the indoor air exposure pathway and other specific Site conditions (IESI, 2000; 2001a) using standard risk assessment methods, and are designed to assist PCC in identifying contaminated areas and environmental media (soil, groundwater, and soil gas) that would need to be addressed during remediation to ensure the protection of human health. Additional details regarding the development of HBRGs that are applicable to the Campus Area remediation are presented in Section 3.

1.2.3.2 Soil Remediation Triggers

PCC developed SRTs to identify soil contamination requiring remediation to protect shallow groundwater as a resource (IESI, 2001b). SRTs are concentrations of chemical contaminants in soil that will protect shallow groundwater resources at the Site. These values are based on protecting groundwater resources, not on potential human health risk. Calculating these concentrations involves, in general, establishing how leachable COPCs in soil could migrate to groundwater, quantifying this migration, and then determining levels of such COPCs in soil that are sufficiently low to ensure that concentrations of COPCs in groundwater will not exceed acceptable levels.

SRTs were developed for both the upper (USRTs) and lower strata (LSRTs) in the shallow hydrologic zone to address the very different geological conditions of these units. Additional details regarding the development of SRTs that are applicable to the Campus Area remediation are presented in Section 3.

1.2.3.3 Application of HBRGs and SRTs in Campus Area Remediation

In this RP, HBRGs and SRTs are used to identify and prioritize areas in the Campus Area that require remediation. Essentially, they are remediation triggers; these

numerical goals may not be the final cleanup criteria. The RWQCB will determine final cleanup goals.[4]

Identifying areas where remediation is potentially required is based on exceedances of HBRGs, SRTs, and/or protection goals. Appropriate remediation technologies to address these areas are then designed and implemented. This process is discussed in more detail in Section 8.

Specific remedial technologies comprising the recommended remedial action will be implemented within each source area based on a comparison of source area-specific soil and groundwater contamination with appropriate HBRGs, SRTs, and other resource protection goals. The decision process is complex because, in some cases, remediation in one medium (e.g., groundwater) will address contamination in another medium. In such cases, it may not be necessary to apply a full suite of remedial technologies for both soil and groundwater contamination. Where remediation in one medium (e.g., groundwater) will address contamination in another (e.g., soil), the proposed remediation is limited to the most appropriate media and justification for such action is provided.

Remedial efforts for the Campus Area, especially for groundwater, may require relatively long periods of time to complete. In order for development of the Campus Area to proceed concurrently with implementation of the remedial measures identified in this RP, additional mitigation of potential human exposures may be necessary to ensure protection of human health prior to completion of remedial activities. This mitigation will take several forms. During construction, worker health and safety will be addressed through the existing *Construction Safety Standards* that cover the Site. In addition, certain engineered and institutional controls may be implemented as part of construction and development activities. Engineered and institutional controls may include vapor intrusion barriers and certain land use restrictions designed to restrict potential uses and activities within the Campus Area once construction and implementation of all components of the remedial alternative are completed. These mitigation measures would remain in affect as long as necessary.

[4] The process of determining final cleanup levels will consider, as appropriate, a number of factors, including, for example, a comparison of residual contaminant levels to HBRGs, PRGs, SRTs and other resource protection goals; a post-remediation cumulative risk assessment; and the technical feasibility of achieving greater contamination reduction.

Section2
Site Characteristics

This section sets out the current understanding of the known or suspected contaminant source(s), the known lateral extent of impacts to groundwater, soil, and soil gas, and the vertical extent of impacts to groundwater, as compiled from previous investigation reports. This section also discusses the potential fate and transport mechanisms affecting the observed contaminants. Specifically, this section presents the current understanding of contaminant mass; groundwater flow directions and velocities; contaminant phase distribution and partitioning between soil, groundwater, and soil gas; mechanisms of biotic and abiotic contaminant transformation; and the current understanding of the temporal variability of such processes.

The data and information presented in this section are important in identifying remedial options capable of addressing COPCs within the Campus Area. This information is also relevant to the development of ROs discussed in Section 3.

The site-specific information presented in this section includes:

- A description of the Campus Area and historical operations;
- A summary of historical investigations at this location;
- An interpretation of Site geology and hydrogeology with respect to subsurface contaminant transport; and
- A conceptual understanding of the fate and transport of dissolved phase contaminants and natural attenuation mechanisms including advection, dispersion, matrix diffusion, sorption, volatilization, and biotic or abiotic transformation.

2.1 Site Description

This Remediation Plan is limited to areas of concern within the Campus Area of the Site (Figure 2-1, *Project Location Map),* which lies within the eastern region of the Area D planning area.

The Campus Area consists of approximately 114 acres of Area D that were used from the 1940s to the 1990s by the former Hughes Aircraft Company and the former McDonnell Douglas Helicopter Company for the manufacture, research, development and testing of electronics, aircraft, and other equipment.

Historically, aircraft manufacturing, metal plating, machining, painting, ordnance development and manufacturing, aircraft cleaning and maintenance, aircraft testing, and aerospace research were conducted at the Campus Area. During such

operations, structures, asphalt pavement, aircraft taxiways, and a runway covered approximately 80 percent of the Campus Area (McLaren Environmental Engineering, [MEE], 1987a, b).

As part of the historical operations, numerous chemicals were used for industrial activities. MEE indicated the following compounds were stored and handled at the Campus Area: VOCs, SVOCs, total petroleum hydrocarbons (TPH), metals, pesticides, and PCBs (MEE, 1987a).

More recently, mass grading, decommissioning of building structures, and construction of underground utilities and roadways has occurred within the Campus Area. These activities are ongoing and will be carefully coordinated with the remediation activities proposed in this RP.

2.2 Historical Investigations

Investigation and remediation of the Campus Area has been ongoing since 1983. These activities and results are described in numerous reports and documents.[5]

The compounds historically detected in Campus Area soil and groundwater include VOCs, phenol, metals, PCBs, TPH, and pesticides. Light non-aqueous phase liquid (LNAPL) hydrocarbons continue to be encountered west of Building 11, in the form of a hydrocarbon sheen. A summary of groundwater data collected within the Campus Area since the issuance of the CAO in 1998 is attached as Appendix C. A summary table of historical soil investigations conducted within the Campus Area is attached as Appendix D.

Unrelated to past human activities at the Site, naturally-occurring methane, H_2S, and associated naturally-occurring hydrocarbons are also present in the subsurface in many locations throughout the Site. The findings of the *Report of Sampling and Analysis of Soil Gas for Methane within Eastern Portion of Area D at Playa Vista* (CDM, 2001a) indicate that methane concentrations in the Campus Area are among the lowest detected throughout the Site (CLA, 2001).

2.2.1 Distribution of VOCs in Subsurface

The most recent, comprehensive summaries of soil data collected during the historical investigations are provided in reports prepared by CDM and EEC. Findings of these investigations indicated that chlorinated VOCs (primarily 1,1-Dichloroethene [1,1-DCE], 1,1-Dichloroethane [1,1-DCA], cis-1,2-Dichloroethene [cis-1,2-DCE], and Trichloroethene [TCE]) and fuel hydrocarbons were found in a limited number of soil samples. In August and September 1999, CDM conducted a soil and groundwater

[5] Refer to Aqua Science Engineers, Inc. 1996; Brown and Caldwell (B&C), 1998a, 1998b, 1999a, 1999b, CDM, 1999a, 1999b, 1999c, 1999d; 2000a, 2000b; Environmental Engineering & Contracting Services (EEC), 2001a, 2001b, 2001c, 2001d; ENSR Consulting and Engineering, 1997; Geomatrix Consultants, Inc. 2001; Integrated Environmental Services, Inc. (IESI), 1999a, 2000, 2001a, 2001b, 2001c, 2001d, 2001e, 2001f, 2001g; MEE 1987a, 1989a. References for these and other relevant reports are provided in Section 10.

investigation of a portion of the Campus Area. A total of 60 soil borings were advanced and samples collected at depths of approximately 6 and 12 feet below ground surface (ft bgs); six of the borings were advanced to the water table. Results of the investigation were presented in the *Soil and Groundwater Investigation Report, Former Dream Works Project Area, Playa Vista Site (SGI1)* (CDM, 2000a). In December 1999 and January 2000, CDM conducted an additional soil and groundwater investigation in the balance of the Phase I project area, including the remainder of the Campus Area. The investigation included 61 soil borings. The results of the investigation were summarized in the *Soil and Groundwater Investigation Phase 1 Project (Excluding Former Dream Works Project) Report (SGI2)* (CDM, 2000b). Finally, EEC conducted several investigations and soil excavation activities in the Campus Area from March through October, 2001 (EEC, 2001a, 2001b, 2001c, 2001d). The results from these activities are provided in Appendix F.

In accordance with the provisions of the CAO, sampling of groundwater monitoring wells has been performed quarterly since March 1999. Results of the most recent quarterly groundwater sampling, which provide groundwater data from 62 groundwater monitoring wells throughout the Campus Area, were presented in the *First Quarter 2002 Groundwater Monitoring and Progress Report* (CDM, 2002). These data represent the most recent, comprehensive summaries of groundwater data collected in the Campus Area. The chlorinated VOCs that were detected in Campus Area groundwater samples most frequently and at the highest concentrations include the following: Tetrachloroethene (PCE), TCE, 1,1-DCE, 1,1-DCA, cis- and trans-1,2-DCE and Vinyl Chloride (VC).

A VOC groundwater summary concentration map for the Campus Area, summarizing detected chlorinated and non-chlorinated organic compounds from the first quarter 2002 analytical results is provided as Figure 2-2, *First Quarter 2002 Groundwater Sampling VOC Concentration Summary Map.* These data are also provided in Appendix C (Tables C-2 through C-13), along with groundwater monitoring well construction details, analytical testing methods and sample holding times, quality control samples, and other relevant data presented previously in the *First Quarter 2002 Groundwater Monitoring and Progress Report* (CDM, 2002).

Separate VOC groundwater plume contour maps are provided for 1,1-DCE, cis-1,2-DCE, trans-1,2-DCE, VC, and 1,1-DCA for each impacted water bearing zone (Bellflower Aquitard and the Ballona Aquifer) in Figure 2-3, *1,1-Dichloroethene Concentration Summary Map - Bellflower Aquitard,* through Figure 2-12, *1,1-Dichloroethane Concentration Summary Map - Ballona Aquifer.* Data for other groundwater contaminants such as PCE, TCE, and methylene chloride (MC) (commonly referred to as dichloromethane) are presented in Figure 2-2 and Appendix C. The interpreted extent of groundwater impacted by PCE, TCE, and MC suggest that the lateral extent of these contaminants is isolated and therefore plume maps have not been provided.

2.2.2 Groundwater Treatment System

In 1994, Secor International Incorporated (SECOR) started operating a groundwater treatment system to remediate chlorinated VOCs. There were 10 extraction wells discharging to the system. Historically, treated groundwater from this system has been discharged to Centinela Channel under National Pollution Discharge Elimination System (NPDES) permit #CAG834001.

In 1999, the RWQCB approved the temporary suspension of active groundwater treatment due to Site development activities (RWQCB, 1999). The groundwater treatment system was taken off-line on June 19, 2000.[6]

During the third quarter 2000, a new and more efficient water treatment system, designed to treat a wider range of contaminants was installed north of Building 2. Since then, the system has been used predominantly to treat dewatering and purge water.[7] Quarterly and annual NPDES reports on discharges of treated dewatering and purge water have been submitted to the RWQCB (IESI, 2001c, 2001d, 2001e, 2001f, 2001f, 2001g, ; IESI, 2002a, and 2002b), and continue to be submitted as such activities are ongoing.

2.3 Geology and Hydrogeology

This section presents regional and Site geology and hydrogeology, as interpreted from previous Site investigations. A generalized cross section of the geology and hydrogeology beneath the Campus Area is shown in Figure 2-13, *Generalized Cross Section.*

2.3.1 Regional Geology

The Site is in the Los Angeles Basin, which is at the juncture of three southern California physiographic provinces: the Transverse Ranges to the north, the Peninsular Ranges to the east and southeast, and the continental borderland to the west (Wright, 1991). The basin is a central alluvial lowland that slopes gently to the south and is bordered by highlands and their foothills. The basin overlies a structural depression where deposition occurred since late Cretaceous time.

The great relief of the present basin floor began forming during the middle-Miocene period, and has since been filled with both marine and continental sediments. The primarily fine-grained marine sediments were deposited during marine transgressions. The primarily coarse-grained continental sediments were deposited during marine regressions. Fine-grained marine deposits typically form aquitards, whereas stream deposits from the surrounding uplifted areas (San Gabriel Mountains, Santa Ana, and Puente Hills) and coarser marine deposits (Yerkes, et. al., 1965) form aquifers.

---

[6] A report documenting the decommissioning of the groundwater treatment system was submitted to the RWQCB in December 2000 (SECOR, 2000).

[7] On July 31, 2000, the RWQCB gave written approval to include construction dewatering as an additional influent source for the treatment system (RWQCB, 2000).

The Site is more specifically located in the Ballona Gap, a lowland between the Beverly Hills and the Baldwin Hills that extends to the coast and the southerly adjacent Ballona Bluffs (Poland et al, 1959; Barrows, 1974). The Ballona Gap resulted from erosion by the ancestral and present-day Los Angeles River.

The generalized Los Angeles Basin stratigraphy described below is based on descriptions presented by Yerkes, et. al., 1965; California Department of Water Resources (DWR), 1961; Poland, et. al., 1956; Poland, et. al., 1959; and Blake, 1991. In order of shallow to deeper, the formations generally encountered are:

Recent alluvium. These deposits consist primarily of unconsolidated stream gravel, sand, silt, and clay with some interbedded littoral and estuary or bay sediments near the ocean. The Recent alluvium includes the Bellflower aquiclude and Ballona aquifer.

Lakewood formation. This Pleistocene aged deposit contains primarily shallow marine silt, sand, and gravel. The Lakewood formation is absent beneath the Site.

San Pedro formation. Silt, clay, sand, and gravel comprise this formation. This deposit, dating from the upper Pleistocene, represents the transition from neritic to nonmarine deposition. The San Pedro formation includes the Silverado aquifer.

Pico formation. This marine-derived (bathyal and neritic) formation is composed of poorly consolidated micaceous siltstone and claystone, interbedded with shale and sandstone. The Pico formation is upper Pliocene to upper Pleistocene in age. The upper portion of the Pico formation contains potable groundwater with mid and lower portions of the formation containing saline groundwater (Poland, et. al., 1959).

2.3.2 Regional Hydrogeology

The Site is located within the Santa Monica Basin, a sub-basin of the Los Angeles County Coastal Plain (DWR, 1961).

The aquifers and aquitards in the Los Angeles Basin are formations created during the Recent and Pleistocene Epochs. The Recent and Pleistocene deposits are similar in composition, since their depositional environments were similar. The following summarizes the significant hydrostratigraphic units in the vicinity of the Site (DWR, 1961; Poland, et. al., 1959):

Bellflower Aquiclude/Aquitard The uppermost hydrostratigraphic unit beneath the Site is the Bellflower aquiclude (Recent alluvium), which is a sequence of low permeability continental, marine and wind-blown deposits consisting primarily of clay and silty clay (DWR, 1961). Although this sequence is regionally classified as an aquiclude (DWR, 1961), site-specific data indicate that recharge to the underlying aquifer, although minimal, occurs in this sequence. Therefore, for this RP, the Bellflower aquiclude is considered to be a semi-confining layer and will be referred to as the Bellflower aquitard.

Ballona Aquifer. Below the Bellflower aquitard is the Ballona aquifer (Recent alluvium), which is encountered in the Ballona Gap north of the Ballona Bluffs and merges into the Gage/Gardena aquifer to the southeast. Although the Ballona aquifer is considered Recent in age, at least part of the aquifer may have been deposited in the late Pleistocene. The Ballonaquifer is often times called the "50-foot Gravel" aquifer because it is generally encountered 50 feet below native grade, and primarily consists of stream deposited coarse sand, rounded to sub-rounded gravel, and cobbles (up to 5 inches in diameter) of granitic and metamorphic origin. The Ballona aquifer ranges in thickness from less than 10 feet near the coast to 40 feet near Beverly Hills. The base of the aquifer is approximately 40 to 60 feet below sea level in the vicinity of the Site (DWR, 1961).

Silverado Aquifer. Further below, the Silverado aquifer was deposited during the Pleistocene Epoch (San Pedro formation). The Silverado is composed primarily of marine and non-marine sand and gravel. The Silverado can be up to 500 feet thick in parts of the Los Angeles Basin. Locally, the elevation of the base of the aquifer is estimated to be approximately 200 feet below mean sea level (MSL) (DWR, 1961), although Site-specific data indicate this dimension is somewhat variable.

2.3.3 Site Geology

Site geologic conditions have been determined based on lithologic logs from numerous monitoring wells and soil borings and from published reports of regional and local geology (MEE, 1987a). Monitoring well locations and the locations of transect lines for four geologic cross-sections are shown on Figure 2-14, *Cross -Section Location Map.* The four geologic cross-sections, Figure 2-15, *Geological Cross-Section A-A'* through Figure 2-18, *Cross Section D-D'*, summarize geologic conditions, as recorded during the recent drilling and monitoring well installation performed by CDM (CDM, 2001b). The Site geologic description focuses on the near-surface water-bearing geologic units encountered beneath the Campus Area. These units include the Bellflower aquitard and Ballona aquifer of the recent alluvium, and the Silverado aquifer of the San Pedro formation.

Soil borings show that the shallow soil zone beneath the Campus Area consists of fine- to medium-grained sand. The sand is interpreted to have been derived from water and wind erosion of the sand deposits on the Playa del Rey Bluff, and it varies from 2 to 10 feet in thickness (MEE, 1987a). The sandy soil deposits are thickest at the base of the Playa del Rey Bluff and become thinner to the north. The sand is unconsolidated, loosely compacted, and its permeable nature allows downward percolation of fluids. The shallow sand is shown on the geologic cross-sections (Figure 2-15 through Figure 2-18). Some of the shallow soils also reflect non-native fill materials that originated from the Playa del Rey Bluff (used beneath existing buildings) and clean imported fill for placement under existing or proposed roads. The characteristics of these shallow non-native fill materials are variable.

The Bellflower aquitard (Recent alluvium) underlies the surficial sands throughout the Campus Area. The Bellflower aquitard consists mostly of clay and silty sand layers with smaller lenses of clays, silts, and silty sands throughout. The Bellflower aquitard is depicted as "clay" and "silty sand" on the geologic cross-sections (Figure 2-15 through Figure 2-18) and is approximately 10 to 40 feet thick. The upper half of the Bellflower tends to be dominated by clays, and the lower half tends to be dominated by silty/clayey sands. For the purposes of remedial alternatives evaluation and design, the Bellflower aquitard will be subdivided into two zones: the "upper Bellflower aquitard", which is comprised generally of less permeable soils; and the "lower Bellflower aquitard", which is comprised generally of more permeable soils.

The Ballona aquifer (Recent alluvium) underlies the Bellflower aquitard throughout the Campus Area. The Ballona aquifer consists of mostly well graded to poorly graded sands and gravels, and is approximately 10 to 40 feet thick. The Ballona aquifer is depicted as "sand" on the geologic cross-sections (Figure 2-15 through Figure 2-18). The Silverado aquifer of the San Pedro formation lies unconformably beneath the Ballona aquifer throughout most of the Campus Area.

Regional geological studies by DWR (1961) and Poland, et. al. (1959) identified the presence of a fault underlying a portion of the Central Basin. This fault, named the Charnock fault, was thought to act as a partial barrier to groundwater flow in the Central Basin especially in the deeper aquifers (DWR, 1961). MEE (1987a, b) postulated that the Charnock fault offset some of the deeper formations in the western portion of Area D, including the Silverado aquifer of the San Pedro formation. The MEE (1987a) interpretation is based primarily on a recent geophysical study performed at the Site, using high-resolution seismic surveys and geologic data from local oil wells and Site monitoring wells, found no evidence of the Charnock fault at the Site (Davis and Namson, 2000). The Site seismic survey showed that geologic units used as seismic "reflectors" are continuous across the entire Site to a depth of 4,500 feet (Davis and Namson, 2000). The authors concluded that the Charnock fault may actually bend east of the Site, be deeper than 4,500 feet at the Site, or it may actually truncate north of the Site. The authors found no evidence of faulting at the Site in the past 4 million years (Davis and Namson, 2000).

2.3.4 Site Hydrogeology

As presented in Section 2.3.2, the hydrogeologic units beneath the Site generally consist of, from top to bottom, thin surficial sands (2 to 10 feet thick), the Bellflower aquitard (about 30 feet thick for the sum of the upper and lower Bellflower aquitard), the Ballona aquifer (about 10 to 40 feet thick), and the Silverado aquifer (about 60 feet to 100+ feet thick). The upper and lower Bellflower aquitard are in hydraulic communication with the underlying Ballona aquifer, based on the interpretation of water level data and the presence of Site-originated contaminants in the Ballona aquifer. However, this vertical hydraulic communication is limited by the low transmissivity of the Bellflower aquitard soils, particularly those belonging to the

upper Bellflower aquitard. MEE (1987a) depicts the Ballona and Silverado aquifers in direct hydraulic communication and suggests that they act as a single aquifer.

2.3.4.1 Beneficial Uses of Groundwater

In accordance with the California Porter-Cologne Water Quality Control Act and the federal Clean Water Act, the RWQCB has established a Water Quality Control Plan for the Los Angeles River Basin (the "Basin Plan"). The function of the Basin Plan, which is amended from time to time, is to preserve and enhance water quality, and to protect the beneficial uses of all regional waters including groundwater (RWQCB, 1994).

Existing beneficial uses designated in the Basin Plan for Coastal Watersheds of Los Angeles and Ventura Counties (RWQCB, 1994) include municipal and domestic supply; agricultural supply; industrial process supply; and industrial service supply. The Basin Plan sets forth a number of general objectives for all groundwater, and specific mineral objectives for most basins. Mineral objectives for naturally-occurring chemicals in the Santa Monica Basin include, among others, Total Dissolved Solids (TDS) [1,000 milligrams per liter (mg/L)][8], sulfate (250 mg/L), and chloride (200 mg/L).

The Silverado aquifer is a regionally significant source of drinking water, although groundwater samples collected from Silverado wells in the Campus Area indicate this water-bearing unit is of poor quality for drinking water purposes as a result of naturally-occurring minerals. Analytical data from monitoring wells screened within the Silverado aquifer, indicate high TDS concentrations ranging from 660 to 2,600 mg/L (Appendix C; Table C-10), well above both the Maximum Contaminant Level (MCL) (Secondary) of 500 mg/L, and the recommended level in the Basin Plan (1,000 mg/L) for drinking water. In addition, elevated concentrations of chloride (as high as 770 mg/L) and sulfate (as high as 850 mg/L) have also been detected in Silverado aquifer monitoring wells located within the Campus Area (Table C-10).

Groundwater quality, particularly given the levels of naturally-occurring minerals, is also considered degraded within the lower Bellflower aquitard and Ballona aquifer as a consequence of the site's proximity to brackish or saline water. Monitoring wells screened within these water-bearing units have shown elevated concentrations of TDS (as high as 13,000 mg/L)[9], chloride (as high as 4,400 mg/L), and sulfate (as high as 3,600 mg/L) (Table C-10).

---

[8] The RWQCB, as a matter of general policy, also assumes that water with TDS as high as 3,000 mg/L has the potential to be potable (RWQCB, 1994). However, such potability would require treatment of these naturally-occurring solutes to a level at or below 500 mg/L, the state and federal standard for drinking water. Such treatment is very costly, and currently is not a cost-effective technology.

[9] The 13,000 mg/L TDS concentration was observed at perimeter Campus Area monitoring well C-66; typical TDS concentrations in the Campus Area range from approximately 1,000 to 4,000 mg/L (See Appendix C).

The nearest potential public water supply well was located at Venice Polytechnic High School, approximately 1.5 miles north of the Site. The subject well was capped in 1960 and is not active. The next closest public supply wells are located approximately 2.5 miles north of the Site in the City of Santa Monica. The nearest irrigation well is located approximately 1.5 miles southeast of the Site at the Hillside Memorial Park Cemetery (MEE, 1987a). Records indicate that the irrigation well is screened across multiple, deep hydrologic zones ranging in depth from 188 to 590 feet below ground surface (bgs), and therefore not likely to be influenced by the shallow groundwater at the Site.

2.3.4.2 Groundwater Elevations and Flow Directions

Potentiometric contour maps depicting groundwater elevations and flow direction in the Bellflower aquitard and the Ballona and Silverado aquifers (Figure 2-19, *Potentiometric Surface Map for the Bellflower Aquitard* through Figure 2-21, *Potentiometric Surface Map for the Silverado Aquifer*) were last presented in the First Quarter 2002 Groundwater Monitoring and Progress Report (CDM, 2002).

The groundwater elevations in Campus Area wells screened in the Bellflower aquitard ranged between 2.39 feet below MSL (C-72be) and 8.07 feet above MSL (EMS-2) (Figure 2-19). A summary of groundwater elevation data at all monitoring wells in the Campus Area is included in Appendix C (Table C-1). The apparent groundwater flow direction across the Bellflower aquitard is toward the northeast at an apparent gradient of 0.002 ft./ft. (Figure 2-19).

Groundwater contours show a "mound" and a depression in the Campus Area that impact local flow within the Bellflower aquitard. The observed groundwater "mound" (Figure 2-19) may be explained by water leaking from the large catch basin in that area.

The depression is most likely due to Groundwater extraction or dewatering for construction purposes within the Bellflower aquitard occurs near C-72be. These groundwater extraction activities are currently ongoing.

Groundwater elevation levels measured in Ballona aquifer wells ranged between 2.92 (C-72ba) feet below MSL and 4.70 (C-73ba) feet above MSL. The apparent groundwater flow direction for the Ballona aquifer in the Campus Area is toward the northeast at an apparent gradient of 0.0008 ft./ft. (Figure 2-20).

Groundwater elevations for Silverado aquifer wells in the Campus Area (C-30 C-65d, C-87, and C-88) ranged between 2.01 (C-88) and 3.77 (C-30) feet above MSL (Figure 2-21). The groundwater flow direction across the Site within the Silverado aquifer based on the January 2002 data is toward the northeast at an apparent gradient of 0.001 ft./ft. (Figure 2-21).

Table 2-1, *Hydraulic Gradient and Flow Direction to the Shallow Water Bearing Limits Beneath the Campus Area*, summarizes hydraulic gradient and flow direction for the shallow water-bearing units beneath the Campus Area. The gradients and flow directions have been consistent over the past year for all of the aquifers. The only exception is the Bellflower aquitard data from June 2001, which are influenced by construction dewatering activities.

Geologic cross-sections (Figure 2-15 through Figure 2-18) show water level data from January 2002 for a number of the well pairs (i.e., adjacent wells completed in the Bellflower aquitard and Ballona aquifer). Water levels in these well pairs generally indicate only a slight downward vertical gradient from the Bellflower aquitard to the Ballona aquifer.

2.3.4.3 Aquifer Pumping Tests

McLaren Environmental Engineering (1987)

Hargis performed a series of short-term aquifer pumping tests and one 36-day pumping test between 1984 and 1985. The following summarizes the findings of these pumping tests as reported by MEE (MEE, 1987b).

Monitoring wells were pumped for 40- to 410-minute time periods using submersible pumps. Water production varied from 1.7 to 45.3 gallons per minute (gpm). MEE used the Jacob straight-line method to estimate transmissivity from each of the wells tested. This method assumes a homogenous, isotropic, and fully confined aquifer. Transmissivity estimates for each of the wells tested are summarized in Table 2-2, *Hydraulic Conductivity Estimates for Shallow Water Bearing Units.*

The transmissivity estimates ranged from 100 to 32,000 gallons per day per foot (gpd/ft) (13 to 4,278 ft^2), suggesting large differences in the aquifer characteristics within the Campus Area. Monitoring wells C-18, C-19, C-20, C-21, C-23, C-24, C-27, C-28, and C-30, which are screened within both the Bellflower and Ballona units, yielded an average transmissivity estimate of 19,000 gpd/ft, (2,540 ft^2/day) with values ranging from 8,000 to 32,000 gpd/ft. Monitoring wells C-16 and C-17, which are screened in the Bellflower aquitard, yielded an average transmissivity estimate of 3,000 gpd/ft (401 ft^2/day), with values ranging from 100 to 4600 gpd/ft (13 to 615 ft^2/day).

Wells C-29 and C-31 are screened within the Silverado aquifer. Well C-31 is located west of the purported Charnock fault zone, and it has an estimated transmissivity of 10,000 gpd/ft (1,337 ft^2/day). Well C-29 was drilled into the Silverado aquifer east of the purported fault, and it has an estimated transmissivity of 31,000 gpd/ft (4,145 ft^2/day). The Silverado is known to have lateral heterogeneities that could account for the difference between the estimated transmissivities derived from the two short-term pumping tests.

MEE (1987a) performed a 36-day pumping test in the Campus Area using extraction well EW-1 and seven observation wells (C-18, C-36, C-37, C-53, C-54, C-55, and C-56). All but one of the observation wells was screened in both the Bellflower aquitard and the Ballona aquifer. One well, C-53, was screened in the Silverado aquifer. Transmissivities in the observation wells ranged from 18,000 to 34,000 gpd/ft (2,407 to 4,546 ft^2/day), with an average of 29,000 gpd/ft (3,877 ft^2/day).

McLaren/Hart (1991)

McLaren/Hart also performed a pumping test in the Campus Area during February 1991 (McLaren, 1991). Extraction well EW-3 was pumped in a step-wise fashion for a 24-hour period. Pressure readings were recorded in observation wells EW-1, EW-1A, EW-2, EW-4, EW-8 and EW-9 during the test, and inter-well permeabilities were estimated using a curve-matching modeling technique. The pumping test results estimated aquifer permeabilities ranging from 0.481 darcies to 30.05 darcies (McLaren, 1991). CDM converted these permeabilities to hydraulic conductivities using the conversion factor published in Fetter (1980). Converted hydraulic conductivity values range from 1.16 to 72.18 feet per day (ft/day), with an average value of 17.3 ft/day.

The groundwater observation wells used during the test were screened across both the Bellflower aquitard and the Ballona aquifer. Since the Bellflower aquitard is thought to be less permeable because of its finer grained composition, these hydraulic conductivity values may be lower than for only the Ballona aquifer.

2.3.4.4 Groundwater Flow Velocities

Groundwater flow velocities may be estimated using hydraulic conductivity, hydraulic gradient, and effective porosity estimates and applying Darcy's Equation. This equation states that the average linear groundwater flow velocity (i.e., seepage velocity) through a saturated porous medium is given by:

$$Vx = K(dh/dl)/çe$$

Where Vx = average linear groundwater velocity parallel to the groundwater flow direction.

K = hydraulic conductivity

çe = effective porosity

dh/dl = average hydraulic gradient

Table 2-3, *Groundwater Velocities with Shallow Water Bearing Units*, summarizes groundwater velocities using hydraulic gradient and hydraulic conductivities presented in Sections 2.3.4.2 and 2.3.4.3.

2.4 Fate and Transport of Contaminants in Groundwater

Groundwater in the Bellflower aquitard and Ballona aquifer has been sampled periodically since 1984 for priority pollutants including VOCs, SVOCs, metals, pesticides, and PCBs. With respect to the Campus Area, the primary classes of contaminants in groundwater are VOCs and TPH. The VOCs include chlorinated ethenes, namely PCE, TCE, cis-1,2-DCE, trans-1,2-dichloroethene (trans-1,2-DCE), 1,1-dichloroethene (1,1-DCE), and VC. They also include chlorinated ethanes; namely tetrachloroethane (PCA), 1,1,1-trichloroethane (1,1,1-TCA), 1,1,2-trichloroethane (1,1,2-TCA), 1,1-DCA, 1,2-DCA, and chloroethane (CA). TPH consists of refined fuel hydrocarbons, including BTEX.

The fate and transport of these organic chemicals in groundwater is affected by a variety of chemical, physical and biological processes. Some of these processes are destructive and result in contaminant mass removal from the groundwater. Destructive mechanisms include both chemical and biological processes. Others are non-destructive and do not result in a change in contaminant mass or migration ability. Non-destructive mechanisms include sorption, dispersion, matrix diffusion, dilution from recharge, and volatilization. Typically the most important processes contributing to the ultimate fate of groundwater contaminants is biodegradation. The significance of biodegradation is discussed in Section 2.4.4.

The following factors are important in evaluating the fate and transport of the groundwater contaminants within the Campus Area:

- Groundwater flow directions and velocities in the Bellflower aquitard and Ballona aquifer;
- Implementation of remedial programs at source areas; and
- Natural attenuation (including adsorption, biodegradation, matrix diffusion, and dispersion).

Each of these factors is discussed below.

2.4.1 Migration Pathways

In the Campus Area, the majority of the contaminant mass is located adjacent to the source areas in the stratified, lower hydraulic conductivity material of the Bellflower aquitard. The lateral migration of contaminants from the source areas in this unit is generally in a north to northeast direction and is limited by the presence of less permeable soils with a groundwater flow velocity of approximately 0.09 feet per day (Table 2-3). However, plume migration will likely be slower than predicted by the calculated groundwater velocity due to the effects of contaminant adsorption and biotransformation (as much as several times slower, depending on the hydrophobicity and biological fate of the migrating compound).

Downward vertical migration in the Bellflower aquitard is also expected to be limited by the presence of fine-grained layers and hydraulic anisotropies in the aquitard. However, the presence of contaminants in the Ballona aquifer indicates that some contaminants have migrated vertically through the entire aquitard thickness. This is important because groundwater velocities in the Ballona aquifer (and presumably the lower Bellflower aquitard) are higher than in the upper Bellflower aquitard. As such, the Ballona aquifer is the most important medium for lateral migration of groundwater contaminants in the Campus Area.

Once the contaminants have reached the more permeable portions of the Bellflower aquitard (lower Bellflower aquitard) or deeper Ballona aquifer, lateral mobility is greatly enhanced. Much of the organic contaminant mass, however will be adsorbed to naturally-occurring organic material in soils near the source locations.

2.4.2 Implementation of Remedial Programs at Source Areas

Source area remedial activities have already been implemented at numerous locations in the Campus Area (see Section 4). The majority of these actions involved excavation of contaminated soils. These source-specific actions are important because they have removed contaminants that might have otherwise migrated to underlying groundwater.

Remedial actions proposed as part of this document will be designed to remove as much of the remaining contaminant mass from groundwater, unsaturated zone soil, and saturated zone soil, as technically feasible.

2.4.3 Natural Attenuation Processes

Various naturally-occurring processes affect the transport of contaminants in saturated zone soil and groundwater. Most of these mechanisms or processes combine to limit the rate of contaminant migration. However, other processes, such as desorption of adsorbed contaminants and matrix diffusion may prolong the time necessary for groundwater remediation. The following mechanisms also affect the fate and transport of contaminants in the Campus Area groundwater systems:

- Biological transformation (biodegradation);
- Adsorption to and desorption from the aquifer media;
- Matrix diffusion;
- Abiotic degradation;
- Volatilization; and
- Advection and dispersion.

Biological transformation processes, including biodegradation, are summarized below, while the other processes/mechanisms are described briefly in Appendix E.

2.4.4 Biological Transformation

The principal contaminants in groundwater at the Campus Area are chloroethanes (e.g,. 1,1,1-trichloroethane) and chloroethenes (e.g., TCE) and their respective family of metabolic products. Other contaminants are fuel hydrocarbons, including gasoline. Groundwater conditions underlying the Campus Area are conducive to biodegradation of the more oxidized forms of chlorinated VOCs such as source contaminants (e.g., 1,1,1-TCA and TCE). The biological mechanisms for biodegradation of petroleum hydrocarbons and reductive dechlorination of chlorinated ethenes and ethanes are more fully described in Appendix E.

In general terms, the biodegradation of petroleum hydrocarbons such as BTEX and other organic compounds (e.g., naturally-occurring organic materials such as humic substances), serve as the carbon and energy sources (i.e., electron donors) for microorganisms. These carbon and energy sources are biodegraded/biotransformed, thereby driving groundwater reducing conditions to an anaerobic state (dissolved oxygen [DO] < 1.0 mg/L). Furthermore, the metabolism of these compounds can employ chlorinated VOCs as electron acceptors. In the process of acting as electron acceptors, the chlorinated VOCs are reductively dechlorinated (reduced). The sequential reduction of chlorinated VOCs eventually leads to the production of innocuous end-products such as ethene/ethane.

A schematic pathway for the primary contaminants and their degradation products is shown in Figure 2-22, *Biotransformation Pathways*. For TCE, a common source contaminant historically used within the Campus Area, reductive dechlorination could eventually result in the formation of non-toxic ethene and ethane. However, incomplete reductive dechlorination could lead to the accumulation of intermediate toxic products (e.g., VC), although the lower chlorinated contaminants may subsequently degrade to innocuous carbon dioxide through oxidation processes. TCA, an additional source contaminant used historically in the Campus Area, is subject to abiotic transformations under aerobic and anaerobic conditions, and biological transformations under anaerobic conditions. TCA transformations and breakdown products are also summarized in Figure 2-22. The abiotic and biotic pathways are important to the ultimate fate of chloroethanes. In particular, 1,1,1-TCA may be transformed abiotically to form 1,1-DCE that can then undergo reductive dechlorination to form VC, and ultimately over time ethene and ethane. Under anaerobic conditions, 1,1,1-TCA may also be rapidly transformed by biotic processes into 1,1-DCA, which may be further reduced to CA. CA is relatively stable biologically under anaerobic conditions, but is transformed rapidly to ethanol and chloride by an abiotic hydrolysis reaction.

The redox conditions of groundwater in the Campus Area that control the biodegradation are briefly described in Appendix E.

2.4.5 Summary

The high organic content and low permeability of the soils in the upper Bellflower aquitard appear to have prevented the groundwater contaminant plume from significant horizontal migration in this water-bearing unit. As a result, the majority of the contaminant plume remains close to the probable source areas. However, the contaminant plume has moved vertically into the relatively more permeable lower Bellflower aquitard and Ballona aquifer, and subsequently downgradient in these water-bearing units.

The low organic content and relatively high permeability soils of the Ballona aquifer allow relatively faster dispersion of the VOC contaminant plume compared to the Bellflower aquitard. Some biotransformation and biodegradation of VOCs in the Ballona aquifer also occurs. VOCs are attenuated laterally downgradient through various natural attenuation mechanisms in the Ballona aquifer, and do not appear to migrate vertically below the aquifer to the underlying Silverado aquifer to any significant extent. Data collected from monitoring wells screened in the Silverado aquifer indicate the continued absence, or near detection limit concentrations, of contaminants in this water-bearing unit.

Groundwater data obtained for the Campus Area suggest that biodegradation, abiotic degradation, adsorption/desorption, matrix diffusion, and advection/dispersion are the current dominant factors influencing the fate and transport of observed groundwater contaminants. The most significant attenuation mechanism in the lower Bellflower and Ballona aquifers appears to be dispersion through horizontal transport in this aquifer.

Groundwater data indicate that sulfate concentrations (Appendix C), although an order of magnitude less than in the Bellflower aquitard, are substantially above levels known to inhibit reductive dechlorination (e.g., approximately 50 mg/L). In addition, the lack of significant ethene/ethane production in the Ballona aquifer indicates limited dechlorination activity. Data suggest that only limited quantities of VC, and other highly reduced VOCs, are generated as a result of reductive dechlorination processes occurring in the Ballona aquifer. Rather, most of the highly reduced VOCs detected in the Ballona aquifer are a result of the dechlorination processes occurring in the Bellflower aquitard and subsequent vertical migration of VC. Redox conditions, including elevated sulfate concentrations, and low DOC concentrations in the Ballona aquifer groundwater likely limit further reductive dechlorination from occurring once the chlorinated contaminants reach the Ballona aquifer. Such limitations may be overcome through engineered remediation systems.

Section3
Remedial Objectives and Goals

This section identifies media-specific Remedial Objectives (ROs) and Remedial Goals (RGs) for remedial activities within the Campus Area. ROs and RGs have been developed considering the significant human exposure pathways present at the Site, effects on environmental resources and future planned commercial use. To set such ROs and RGs requires identifying, in turn, media of concern, significant human exposure pathways, and COPCs.

3.1 Establishing ROs and RGs

Establishing ROs is an essential step in the process of identifying and evaluating potential remedial action alternatives ("the Alternatives"). ROs are qualitative statements of what remediation is expected to achieve to protect human health and environmental resources.

The ROs then serve as the foundation for setting quantitative RGs to address contamination within the Campus Area. Protection of human health will be addressed through the use of HBRGs, which are quantitative criteria used to guide remediation to address contamination that could reach potential receptors at unacceptable levels. Protection of environmental resources, specifically shallow groundwater, will be addressed through the use of SRTs, which are quantitative criteria used to identify soils that require remediation, so that contaminants do not reach groundwater at unacceptable levels. HBRGs and SRTs are essentially triggers for remediation, but not necessarily the final cleanup levels. Importantly, for many COPCs, the final cleanup levels will end up being more protective than HBRGs and SRTs, to the extent technically feasible.

3.1.1 Media of Concern

ROs are developed for each medium of concern, and are designed to address the types of chemicals found in these media. This RP focuses on soil and groundwater as the critical media of concern. Soil gas is also a potential medium of concern as a result of potential "off-gassing" of volatile contaminants from groundwater and/or soil. However, because the proposed remedial actions for soil and groundwater will address the significant sources of such off-gassing, and certain mitigation measures will address potential exposures during and after remediation, contaminants in soil gas are not addressed directly in this RP as a medium of concern.

3.1.1.1 Soils

For the Campus Area, the focus of remediation is on unsaturated zone soils that extend from ground surface to approximately 15 feet bgs, and on shallow groundwater. Further, as described in the next section (3.1.2), remediation is intended to reduce or eliminate both the migration of vapors from the subsurface to buildings and the migration of COPCs from subsurface soils to groundwater. Preventing the

transport of COPCs away from subsurface sources is, therefore, a critical aspect of evaluating remedial alternatives.

Contaminated soils in the Campus Area are located within the unsaturated portion of the upper Bellflower aquitard as illustrated in Figure 3-1, *Conceptual Model for Transport of COPCs in Soil of Upper Bellflower Aquitard.* As the conceptual model shows, contaminated soil gas occurs as the result of contaminants partitioning across phases including: (1) groundwater to soil vapor, and (2) soil to vadose zone moisture to soil vapor. Once present in soil vapor, some release of contaminants to the atmosphere will occur at the ground surface.

The conceptualized soil layers of the unsaturated upper Bellflower aquitard act as zones of equilibration between phases. Transport of COPCs from groundwater (originating from the capillary fringe) to the surface will be retarded to an extent determined by the adsorption capacity of the soil and varying contaminant concentrations with depth in the soil. Transport of COPCs to the ground surface from vadose zone impacted soil will occur in a similar manner.

3.1.1.2 Groundwater

For groundwater, the focus of remediation is on water-bearing intervals in the Bellflower aquitard, Ballona aquifer, and the Silverado aquifer. As discussed in Sections 2.3 and 2.4, contamination is currently limited to the Bellflower aquitard and Ballona aquifer; all existing data demonstrate the continued absence or near detection limit concentrations of contaminants in the Silverado aquifer.

Accordingly, this RP focuses on contaminants in groundwater that are present within the Bellflower aquitard and Ballona aquifer. Proposed remedial activities factor in the potential for migration of contaminants from the Bellflower aquitard and Ballona aquifer to the underlying Silverado aquifer. Specifically, the proposed remedial activities address the ability to provide continued protection of the underlying Silverado aquifer. This topic is addressed further in Sections 6, 7, and 8.

3.1.2 Potential Exposure Pathways

In order to develop ROs to guide remediation, an understanding of the exposure scenario that applies to a site's circumstances is necessary. Developing an exposure scenario involves identifying the potentially exposed population (e.g., construction workers, occupants, etc.) and all of the ways this population might be exposed to COPCs. To develop an exposure scenario for each potentially affected population, the many potential exposure pathways by which people might be exposed are evaluated to identify those pathways in the Campus Area that could present an actual source of exposure. By definition, exposure pathways—the ways in which a population comes into contact with environmental contamination—must include a source of chemicals, a release and transport mechanism from the source to a population, and a route of exposure (e.g., inhalation, ingestion, dermal contact). IESI identified the exposure pathways for each potentially exposed population at the Site during the development of a conceptual exposure model (CEM) (Figure 3-2, *Conceptual Exposure Model for*

Commercial Development). As explained in that model, certain pathways will not exist in the Campus Area. For example, no residential development is planned for the Campus Area; therefore, residents are not considered a potentially exposed population for this area.

Stated another way, only "complete" exposure pathways are considered in developing ROs. An exposure pathway is deemed "complete" if all elements—source, release and transport, route of exposure, and population—are present. If any element is missing, no exposure will occur. Furthermore, although a pathway is potentially complete, in many instances exposure is expected to be too small to be significant for human health impacts. Relative to the Campus Area, IESI judged several potential exposure pathways as complete as part of its development of HBRGs (IESI, 2000, 2001a). The selection of these pathways as complete has been reviewed and approved by OEHHA. They include:

- Incidental ingestion of surface soil (construction workers);
- Dermal contact with surface soil (construction workers);
- Inhalation of particulate matter suspended in air from surface soil (operations, construction workers);
- Inhalation of vapors migrating from subsurface soil and groundwater to ambient (outdoor) air (operations/office workers, construction workers, and children in day care); and
- Inhalation of vapors migrating from subsurface soil and groundwater to indoor air (operations/office workers and children in day care).

Importantly, direct contact with, or ingestion of, contaminated subsurface soils and groundwater by future occupants, maintenance and repair personnel or children in day care are deemed incomplete pathways. Workers in buildings and children in day care will be separated from subsurface contamination by several feet or more of clean fill, pavement, building foundations, and/or landscaping, once construction is complete. Maintenance and repair personnel who may have to work in subsurface areas will generally be working in clean fill. Where their activities take them into deeper areas, they will be subject to the same health and safety procedures that apply to construction workers. Furthermore, remediation efforts are expected to reach levels appropriate for protection of future workers, day-care children and the groundwater resource. Since these goals are lower than those needed to protect construction workers and others that may excavate into areas of residual contamination, future risks for maintenance/repair workers are not expected to be significant.

Similarly, contact with, or ingestion of, contaminated groundwater is also deemed an incomplete pathway. Shallow groundwater within both the Bellflower aquitard and Ballona aquifer is not currently used on-site for either drinking water or irrigation and

such potential future uses will be prevented by CC&Rs that shall apply to the owners or users of the property. Additionally, the natural mineral content of these waters preclude their use for either drinking water or irrigation without additional treatment. Individual users would find such treatment impracticable, and a supplier of public drinking water would have to assure that the water was treated to meet MCLs. The significance of this determination is thus minimal, meaning only that the groundwater will not occur (discussed in more detail below).

A full discussion of how pathways were selected as complete from among the larger universe of potential exposure pathways can be found in the HBRG Protocol and subsequent Commercial Area HBRG Report and Addendum Report (IESI, 1999b; IESI, 2000; IESI, 2001a).

In consideration of the above potentially complete pathways, priorities for managing possible human health risks associated with current Campus Area contamination and future development therefore should focus on:

- Interrupting potential upward migration of vapors from groundwater or soil to commercial buildings to be constructed above contaminated groundwater or soil;
- Removing contaminant mass, particularly from source areas, so that contaminant concentrations in downgradient areas decrease over time, thereby limiting future contaminant migration and potential human exposure; and
- Preventing unacceptable direct contaminant exposures to workers.

Finally, some park spaces will probably be included within the Campus Area. Planned remediation and subsequent park development are anticipated to address any potential health risks associated with recreational exposures. However, remedial plans will be reviewed, as appropriate, to ensure compliance with future use scenarios for park areas.

3.1.2.1 Exposure Pathways Not Addressed by this Remediation Plan

For the purposes of developing ROs, one potential exposure pathways is not addressed in this RP. As discussed above, a potential exists for construction worker exposure during remediation and development of the Campus Area. However, the Site health and safety procedures, already in place, and certain risk management protocols that apply to the Campus Area development will protect construction workers and maintenance workers against such exposures. Because subsurface contamination within the Campus Area is well characterized, and under extant health and safety procedures, workers will be informed, trained, and equipped to work safely with known and unknown contamination. As such, this RP does not propose additional remediation measures to address the complete exposure pathways associated with construction workers.

3.1.3 Chemicals of Potential Concern (COPCs)

The initial list of COPCs identified for the Site (including the Campus Area and areas extending beyond the Campus Area) by IESI included almost all chemicals detected in the Campus Area, including many that actually present little or no threat to human health (IESI, 2000, IESI, 2001a). The IESI list is presented in Appendix I.

To identify those COPCs pertinent to the Campus Area portion of the Site, CDM reduced IESI's list of COPCs to only those chemicals detected during comprehensive soil and groundwater investigations since March 1999 in the Campus Area. These media-specific COPCs, specific to the Campus Area of the Site, are presented in Table 3-1, *List of Chemicals of Potential Concern for Soil,* and in Table 3-2, *List of Chemicals of Potential Concern for Groundwater.*

3.1.4 Identification of Remedial Objectives

Based on the analysis described above, this section sets out the media-specific ROs developed for Campus Area soil and groundwater. For each media, the ROs are designed to meet the two overall objectives of: (1) protecting human health, and (2) protecting the groundwater resource.

3.1.4.1 Soil Remedial Objectives

Soil ROs for the protection of human health are:

- The selected remedial actions shall reduce soil concentrations of COPCs to levels protective of human health, considering exposure pathways and potential future receptors in the Campus Area;
- The selected remedial actions shall prevent exposure of the public to VOC vapors from soil at concentrations above acceptable levels; and
- At a minimum, the selected remedial actions shall reduce COPC concentrations in source area soils to the HBRG levels specifically developed for contaminants in the Campus Area.

The soil RO for the protection of the groundwater resource is:

- The selected remedial actions will seek to reduce COPCs in source area soils so that the groundwater resource can be protected, to the extent technically feasible (see groundwater resource protection RO below).

3.1.4.2 Groundwater Remedial Objectives

Remedial groundwater actions in the Campus Area will be implemented to assure the primary goal of protecting human health. As discussed above, the most significant risks to human health are associated with exposures to VOCs off-gassing from groundwater. In addition, even though all direct exposure pathways (e.g., ingestion or dermal contact) for contaminants in groundwater are currently incomplete, and are unlikely to be completed in the foreseeable future, the proposed remedial actions will

seek to further reduce COPC concentrations beyond that necessary for the protection of human health, as a means to protect the groundwater resource. As applied in this RP, ROs established for the protection of human health must be achieved by the proposed remedial actions, while the proposed remedial actions will seek to achieve the RO for the protection of the groundwater resource to the extent technically feasible.

Groundwater ROs for the protection of human health are:

- The selected remedial actions shall reduce groundwater concentrations of all Site-originated COPCs to levels protective of human health, considering complete exposure pathways and potential future receptors within the Campus Area;
- The selected remedial actions shall prevent exposure of the public to VOC vapors from groundwater at concentrations above acceptable levels; and
- Specifically, the selected remedial action shall reduce COPC concentrations in groundwater in the Campus Area to the HBRG levels specifically developed for the Campus Area.

The RO intended to protect the groundwater resource, above and beyond that necessary to protect human health, is:

- The remediation will seek to reduce Campus Area COPC concentrations to levels equal to the Maximum Contaminant Levels ("MCLs"), to the extent technically feasible, even though MCLs would apply only if the groundwater were to be supplied as drinking water, a highly unlikely scenario.

3.2 Proposed Remedial Goals

RGs are quantitative expressions of contaminant concentrations that are used in this RP to identify areas where remediation is needed, to provide an initial indication of the amount of reduction of contamination needed, and to guide the selection of remedial actions appropriate to meet the desired reduction. In effect, the RGs used to develop proposed remedial actions in this RP are more like remediation triggers. They are not being proposed at this time as final cleanup levels. Such final levels are more appropriately set, once the necessary remedial actions have been implemented and performance data are available to use in determining those levels.

Like the ROs, this RP uses both a set of RGs developed to protect human health (HBRGs) and a set to protect the groundwater resource (SRTs). The methods used to develop these quantitative RGs, which are fully developed in documents outside this RP, are briefly described below.

3.2.1 Health Based Remediation Goals

HBRGs are calculated concentrations of chemical contaminants in soil, groundwater, and soil gas that will protect the public from unacceptable exposures to these chemicals in the Campus Area. Calculating these concentrations involves, in general, deciding how people might be exposed to Campus Area contaminants, and then establishing levels of these contaminants that are sufficiently low to ensure that exposures would not represent threats to human health.

Development of HBRGs applicable to the Campus Area follows the protocol methods approved in June 1999 by the RWQCB and OEHHA for soil HBRGs. The approved methodology involves several basic steps, including:

1. Identifying and assessing the toxicity of the COPCs;
2. Developing a conceptual exposure model;
3. Calculating unit risk and unit hazard levels; and
4. Integrating the results to calculate HBRGs.

This methodology closely follows guidance developed by Cal/EPA (e.g., 1992) and USEPA (e.g., 1989, 1996, 1997). Key details of that guidance are discussed below. A more complete discussion of the approach used to develop HBRGs is available in several documents, including the HBRG Protocol, the HBRG Report (covering soils), and Addendum to HBRG Report (covering soil gas and groundwater) submitted to the RWQCB by Integrated Environmental Services, Inc. (IESI) (1999b, 2000, 2001a). Set out in the following subsections is a brief summary of the steps used to develop HBRG levels for the Campus Area.

3.2.1.1 Chemicals of Potential Concern for HBRG Development

Typically, chemicals detected in environmental media (soils, groundwater, soil gas) are screened to select a subset of chemicals that would account for all, or nearly all, risk and hazard. For the Campus Area, however, only minimal screening was done to the list of COPCs detected at the Site (see Appendix I). However, because inorganic constituents in groundwater do not partition into soil gas or vapor phases, these chemicals are not considered COPCs for exposure pathways involving exposure to vapors migrating from the subsurface. Rather, soil gas COPCs were selected from those chemicals that may migrate as vapors in the environment and were found in groundwater during recent monitoring. Other than this adjustment, no additional screening of detected chemicals was performed.

3.2.1.2 Conceptual Exposure Model

HBRGs were generated using exposure estimates for all complete pathways considered above. Other pathways included in Figure 3-2 are either incomplete or insignificant. Details of the exposure assessments are found in IESI (2000, 2001a).

All exposure estimates for the development of HBRGs applicable to the Campus Area were based on the concept of reasonable maximum exposure (RME). As defined in Cal/EPA and USEPA guidance, RME is an exposure well above the average but still within the upper range of those possible. Use of the RME approach is conservative, and ensures that even individuals with the greatest exposure are protected.

3.2.1.3 HBRG Calculations

The process of calculating HBRGs for potentially affected populations and complete exposure pathways requires the use of several simple transport models to estimate attenuation factors and exposure algorithms to estimate RME. A convenient means to integrate these calculations is to first calculate cancer risk or noncancer hazard associated with unit concentrations of COPCs. Because the relationship between cancer risk or hazard to COPC concentration is linear, cancer risks and noncancer hazards change proportionally with different levels of COPC concentrations in groundwater or soil gas. For example, if cancer risk for a groundwater concentration of 1 milligram per liter (mg/L) is 1 in one million, cancer risk for a concentration of 2 mg/L is 2 in one million.

3.2.1.3.1 Attenuation Factors

Calculation of cancer risk and noncancer hazard for exposure to COPC vapors in either outdoor or indoor air requires estimating attenuation factors for each COPC for each medium (soil, groundwater, and soil gas). A similar attenuation factor (termed a particle emission factor) is required to estimate air concentrations of particulate matter suspended in air from surface soil. Attenuation factors are ratios of contaminant concentrations in air to those in soil, groundwater, or soil gas. For instance, an attenuation factor for migration of contaminants from groundwater to indoor air of 1×10^{-4} indicates that indoor air concentrations in milligrams per cubic meter (mg/m^3) are predicted to be 10,000 times less than groundwater concentrations in mg/L.

Attenuation factors for migration of vapors to indoor air were calculated using electronic spreadsheet models developed by USEPA and based on the Johnson and Ettinger model for vapor intrusion. Similarly, attenuation factors for migration of vapors from groundwater to outdoor air were calculated using a series of spreadsheet models developed by Groundwater Services Inc. (GSI), which are based on Risk-Based Corrective Action (RBCA) methods defined by American Society for Testing and Materials (ASTM) recommendations. Attenuation factors for release of vapors and particulate matter from soil to outdoor air were estimated using methods employed by USEPA to calculate soil-screening levels often used as PRGs.

Attenuation factors developed using methods described above appear to be reasonable, if not overly conservative, for the Site. Flux chamber analyses performed at the former Test Site 2 area in a residential portion of the Phase 1 Development Area (west of the Campus Area) indicated very low vapor fluxes, less than 0.1 microgram per square meter per minute (µg/(m2/min)). Dr. C.E. Schmidt of Red Bluff, California, performed these analyses in January 2002 under subcontract to CDM. Flux

samples were taken from areas where elevated soil gas VOC concentrations (greater than 1,000 ppbv) were detected at depth and were analyzed for VOCs in accordance with EPA Method No. TO-14. The results of the investigation indicate that the surface emissions are extremely low. For example, using data from sampling location TS2-FLX-17, flux of VC at the soil surface was estimated to be <0.0010 µg/(m2/min) even though VC was present at 2,200 ppbv at 12 feet bgs at nearly co-located SG-5. Although elevated VOC concentrations have been measured at depth beneath the Site, no significant surface emissions from these subsurface source areas have been detected. Low flux rates at the surface are indicative of significant attenuation of vapors in soil gas as they move vertically to the soil surface.

3.2.1.3.2 Target Risks and Hazards

HBRGs are calculated using target cancer risks or hazard indices that are "acceptable" to California and federal regulatory agencies. In essence, a level of risk or hazard that can be accepted at the Site is chosen, and then concentrations of COPCs in soil, groundwater, and soil gas are calculated to ensure this target is not exceeded.

A target cancer risk of 1×10^{-6} (1 in one million) is the most protective standard commonly used in human health risk management decisions. HBRGs for carcinogens are therefore set at levels such that incremental cancer risks for individual COPCs will not be greater than 1 in one million. This low target risk is chosen to account for the potential for receptors to be exposed to more than one carcinogenic COPC. That is, by choosing a low "acceptable" risk for exposure to individual chemicals, additive impacts from exposure to several chemicals present at their HBRG are also kept low. Generally, acceptable risk from exposure to multiple chemicals should not exceed 1×10^{-5}. Using a target risk of 1×10^{-6} therefore is protective even if 10 chemicals are present at their HBRGs. Examination of Site data indicates that few chemicals are likely to present at such concentrations, confirming that the approach used to develop HBRGs will be protective for cumulative effects of multiple chemical exposures.

For noncancer health effects, a target Hazard Index (HI) of 0.2 is selected for use in commercial areas. This target is one-fifth of the standard target of one. This low target is also selected to account for the potential for receptors to be exposed to more than one chemical that might cause noncancer health effects. The approach used is conceptually the same as that described above for addressing exposure to multiple carcinogens. Using a target HI of 0.2 for individual chemicals suggests that up to 5 chemicals could be present at their HBRGs without exceeding an overall HI of 1. Because hazards are added only for chemicals that affect the same target organ(s), cumulative impacts would only be seen if all chemicals present at their HBRGs also had similar toxicity profiles. Thus, a "safety factor" of 5 is appropriate for considering cumulative impacts for noncarcinogens. Finally, many chemicals demonstrate both carcinogenic and noncarcinogenic effects. For these chemicals, HBRGs based on cancer risks are almost always lower than those based on noncancer hazards. This finding reduces the potential for the occurrence of multiple chemicals at HBRGs based on noncarcinogenic effects.

HBRGs are calculated as the ratio of target risk or hazard to the risk or hazard for a unit concentration of chemical in an environmental medium—1 mg/L for groundwater, 1 milligram per kilogram (mg/kg) for soil and 1 milligram per cubic meter (mg/m^3) for soil gas. For example, if the calculated cancer risk for a COPC present in groundwater at a concentration of 1 mg/L is 2×10^{-5}, and the HBRG is to be calculated so that possible exposure will not result in a cancer risk greater than the target risk of 1×10^{-6}, then the HBRG is calculated as 1×10^{-6} divided by 2×10^{-5}, which equals 0.05 mg/L. Unit risks and hazards for these calculations assumed additive cancer risk and noncancer hazard. That is, for each scenario, unit risks and hazards were separately summed for all exposure pathways involving a given environmental medium.

HBRGs for several chemicals that demonstrate both carcinogenic and other toxic properties were calculated for both cancer and noncancer effects. HBRGs adopted are the more stringent (i.e., more public health protective) of these two estimates and typically based on cancer risks.

3.2.1.3.3 "Reality Checks" for HBRGs

HBRGs for soil could exceed saturation limits and those for groundwater could exceed solubility limits. Concentrations that exceed saturation or solubility limits imply that free product is present. Thus, use of HBRGs alone to identify locations where remediation could be required might allow, in such cases, free product to remain in place. Therefore, when an HBRG for a given chemical exceeded saturation or solubility limits, the saturation or solubility limit was substituted for the calculated HBRG.

3.2.1.3.4 Campus Area HBRGs

Table 3-3, *Final Commercial HBRGs for Organic COPCs in Campus Area Soil,* and Table 3-4, *Final Commercial HBRGs for Inorganic COPCs in Campus Area Soil,* present the HBRGs approved by the RWQCB for the list of Campus Area soil COPCs. Proposed Groundwater HBRGs are presented in Table 3-5, *Final Commercial HBRGs for Organic COPCs in Campus Area Groundwater.* The complete list of HBRGs based on the Site-wide COPC list is included in Appendix I.

3.2.2 Soil Remediation Triggers

SRTs are calculated concentrations of chemical contaminants in soil that will protect shallow groundwater resources within the Campus Area. Calculating these concentrations involves, in general, establishing how leachable COPCs in soil could migrate to groundwater, quantifying this migration, and then determining levels of COPCs in soil that are sufficiently low to ensure that concentrations of these chemicals in groundwater will not exceed acceptable levels (IESI, 2001b).

SRTs aim to protect the quality of the groundwater resource, not to address human health risk. However, as shown in the final calculations of SRTs below, the SRTs are all lower than corresponding HBRGs. In part this is due to the fact that exposure pathways for direct contact with, or ingestion of, contaminated soil or groundwater

are not considered complete within the Campus Area. Thus, the soil and groundwater HBRGs are tied primarily to the risk of off-gassing of VOCs from these media. SRTs, on the other hand, are back-calculated to assure that the groundwater quality will not exceed the groundwater protection RO, which seeks to achieve MCLs. Because MCLs are themselves health-based standards, the effect is that SRTs are more conservative than the corresponding HBRGs. Such SRTs will help ensure that residual soil contamination in the Campus Area will not migrate in significant amounts to shallow groundwater beneath source areas, and subsequently, be carried in groundwater to currently un-impacted areas.

The methodology for making the calculations is the subject of considerable Cal/EPA and USEPA guidance, which has been used in developing SRTs for the Campus Area.

Development of SRTs involves several basic steps, including:

1. Identifying COPCs that can leach to groundwater;
2. Identifying soil and hydrogeologic characteristics that are essential to predicting soil to groundwater migration;
3. Developing a conceptual subsurface model;
4. Estimating COPC migration potentials using appropriate models; and
5. Calculating acceptable concentrations in soil using MCLs as target "acceptable" groundwater concentrations.

As with the preceding discussion of HBRG development, the following subsections set out a summary of how the steps in this methodology were used to develop SRTs. A fuller discussion can be found in *Soil Remediation Triggers, Campus Area at Playa Vista* (IESI, 2001b).

3.2.2.1 Chemicals of Potential Concern for SRT Development

IESI developed SRTs for 18 organic chemicals found in source area soils in the Campus Area (IESI, 2001b). The 18 chemicals included, but were not limited to, all organic contaminants detected in groundwater at concentrations greater than their applicable MCLs.

3.2.2.2 Conceptual Exposure Models

IESI used site-specific soil and hydrogeological data obtained during Campus Area characterization activities to define a conceptual model of the subsurface (Figure 3-1).

Data collected from beneath the Campus Area indicate that analysis of migration of COPCs in groundwater can be adequately characterized assuming two basic water-bearing units. As discussed in more detail in Section 2.4.1, first encountered groundwater exists in the upper Bellflower aquitard. This aquitard consists primarily of clays and silts, and is characterized by limited hydraulic flow. Below the upper Bellflower aquitard is the lower Bellflower aquitard, which also consists primarily of

low permeable soils although increased fractions of silty/clayey sands make this water-bearing unit slightly more hydraulically conductive than the upper Bellflower aquitard. Due to the hydraulic properties of the upper Bellflower aquitard, COPCs that migrate away from source areas must first migrate vertically through the upper Bellflower aquitard before they can migrate horizontally away from the source area in the lower Bellflower aquitard (and Ballona aquifer).

3.2.2.3 Determining Migration Potential and Calculating SRTs

Because protection of groundwater in sources areas (protection of upper Bellflower aquitard), and protection of groundwater outside of source areas (protection of lower Bellflower aquitard) involve different migration pathways, two sets of SRTs were developed (IESI, 2001b). Details of the approach and the development of SRTs are available in IESI (2001b). The first set of SRTs, USRTs, are designed to protect the upper Bellflower aquitard; the second, LSRTs, are designed to protect the lower Bellflower aquitard.

SRTs were developed using two transport models in series. First, leaching of COPCs from soil to groundwater was estimated using VLEACH. This model was developed by USEPA and is commonly used to predict vertical (downward) migration of chemicals in the vadose zone to groundwater. The Summers Model used the output from VLEACH to predict concentrations of COPCs in groundwater downgradient from source areas. Together, the two models provide a conservative prediction of COPC concentrations in groundwater directly beneath a source of soil contamination.

To run the models, certain decisions had to be made with respect to the contamination and the nature of the unsaturated zone. Contamination was defined, using Site-specific data, in 1-foot intervals, overlaid on the soil zones described above, from the soil surface to first encountered groundwater (i.e., upper Bellflower aquitard). Downward migration of this contamination is a function of precipitation and infiltration, soil-water partitioning, vaporization and vapor migration, as well as the soil characteristics of the unsaturated zone. These interactions are resolved by the VLEACH model, as discussed by IESI (2001b).

IESI indicated that data collected from soil boring and monitoring well logs could be used to adequately characterize the unsaturated zone for the VLEACH model by assigning three soil layers to this zone. The three layers are denoted as upper, middle, and lower, with the lower layer in communication with the first encountered groundwater. Each soil layer was defined using Site-specific estimates for properties such as dry bulk density, porosity, and moisture content (IESI, 2001b).

The calculated results from running the models are shown in Table 3-6, *Soil Remediation Triggers.* This table presents both USRTs and LSRTs developed under the approach described above. In all instances, USRTs and LSRTs are substantially lower than corresponding HBRGs.

3.3 Chemicals of Concern

Media-specific COCs for the Campus Area, which are those chemicals requiring remedial action to meet the ROs, are identified in this section. The COCs were identified for the Campus Area based on the presence of Site COPCs that have been detected at concentrations exceeding RGs for the protection of human health, or the protection of the groundwater resource. Specifically, results from historical soil investigations that exceed soil HBRGs, LSRTs, and USRTs were identified as COCs. Similarly, the results from all groundwater monitoring investigations that exceed groundwater HBRGs were identified as COCs. As an additional protective measure, groundwater data exceeding California Title 22 MCLs were also identified as COCs. A summary of the COCs identified for Campus Area soil and groundwater, including all RGs (i.e., HBRGs, LSRTs, USRTs, and MCLs) is provided in Table 3-7, *Media-Specific Chemicals of Concern and Remedial Goals*.

For soil, COCs identified based on exceedances of soil HBRGs are: PCE, copper, cadmium; total chromium, and vanadium. Additional COCs for soil based on concentrations that exceed LSRTs include: TCE; cis-1,2-DCE; trans-1,2-DCE; VC; 1,1-DCE; 1,1,1-TCA; 1,1-DCA; 1,2-DCA; MC; benzene; toluene; arsenic; and total chromium. No additional COCs were identified based on soil concentrations that exceed USRTs.

For groundwater, COCs identified based on exceedances of groundwater HBRGs are: 1,1-DCE; VC; and benzene. Additional COCs for groundwater based on concentrations that exceed MCLs include: PCE; TCE; 1,1,1-TCA; 1,1,2-TCA; 1,1-DCA; 1,2-DCA; cis-1,2-DCE; trans-1,2-DCE; 1,4-Dichlorobenzene (1,4-DCB); MC; toluene; ethylbenzene; and xylenes.

Remedial activities discussed later in this document focus on the above COCs, and areas and media where exceedances of RGs occur. COC-based remediation assures both human health and the groundwater resource are protected.

3.4 Application of Remedial Objectives and Goals

To summarize, the quantitative RGs -- HBRGs and SRTs - developed for this RP are used in the sections that follow to identify areas where remediation is needed. This identification will provide an initial indication of the amount of reduction of contamination needed, and guide the selection of remedial actions appropriate to meet the desired reduction. Stated another way, HBRGs are used to identify areas where remedial actions are necessary to address the presence of COCs that pose a potential threat to human health, if unabated, while SRTs are used to identify areas where remedial actions are necessary for the protection of the groundwater resource.

HBRGs and SRTs may not be final cleanup standards, but rather remediation triggers for the Campus Area. Remediation is planned for areas where current concentrations of COCs exceed these numerical criteria, but selection of remedial alternatives considers other factors, including the various means to reduce contaminant mass and

media concentrations to the extent feasible. For example, active remediation (e.g. groundwater extraction, enhanced biodegradation, or other) may be followed by MNA, to further reduce COC concentrations in the subsurface.

Section4
Known Nature and Extent of Contamination

This section presents information on the extent of COCs in soil and groundwater in the Campus Area. Source Areas (SAs) were identified by comparing media-specific data to the RGs presented in Section 3 as well as considering historical Campus Area activities and usage. Data showing COCs that exceeded the RGs (HBRGs and LSRTs) resulted in the identification of nine potential SAs.

4.1 Identification of Source Areas

As presented previously, numerous investigations have been conducted in the Campus Area to identify impacted soils and groundwater. These investigations have been performed by MEE; IESI, B&C, Environmental Engineers and Contractors (EEC), ENSR Consulting and Engineering (ENSR), SECOR, Geomatrix, CDM, and others. A comprehensive list of the primary Campus Area investigation and characterization reports is presented in Section 2.2. In addition, summary tables of groundwater and soils data collected in the Campus Area are presented in Appendices C and D.

From these data, nine SAs were identified based on COC exceedances of HBRGs for soil and groundwater (i.e., protection of human health) or LSRT exceedance for soil (i.e., protection of the groundwater resource). The nine SAs and their general locations are depicted in Figure 4-1, *Source Areas in the Campus Area.* The SA numbers in Figure 4-1 match Site Location I.D.s provided in the summary of historical investigations (Appendix D).

Table 4-1, *Chemicals of Concern Identified by Media for Each Source Area* identifies the nine SAs as well as the COCs for groundwater and soil at each SA that exceed the RGs presented in Section 3. Additionally, groundwater data exceeding California Title 22 MCLs, a criterion of the ROs, were included in Table 4-1 for completeness. Similarly, soil data exceeding soil USRT values that are designed to protect first encountered groundwater to MCLs, are included in Table 4-1. The significance of groundwater data exceeding MCLs and soil data exceeding USRTs are discussed further in Section 8.

At several of these SAs, some historical remediation activities have been conducted to remove impacted soil that posed a potential threat to human health and/or the groundwater resource.

4.2 Summary of Soil and Groundwater Data and Historical Remedial Activities at the Source Areas

A summary of the identified SAs, existing or formerly impacted soil and/or groundwater; and any historical remedial activities, are presented below. For ease of discussion, the following sections summarize historical detections in soil that exceed the HBRGs, LSRTs, and USRTs, and HBRGs for groundwater. Contaminants in groundwater that exceed MCLs are also summarized in Table 4-1.

4.2.1 SA No. 1- Former Underground Storage Tanks (UST) South of Former Building 5

This area included a 1,500-gallon UST that was used to store cutting oils (MEE, 1987a). Soil samples were collected from four soil borings and analyzed for VOCs, TPH, and PCBs (MEE, 1987a). TCE, PCE, benzene and MC were detected above the soil LSRTs and USRTs. PCBs and TPH were also found in soil samples obtained from this location. The UST at this location and an adjacent 500-gallon UST, were initially abandoned in place in 1992 and remained so until nearby Buildings 5 and 6 were decommissioned in 1998. In 1998, the USTs and some soils were removed (B&C, 1999). Four stockpiles samples were collected and analyzed for PCBs, VOCs, TPH, and metals. All analytes were below the remediation criteria. After removal of the USTs, seven borings (GP-53 through G-58, and GP-60) were advanced in November 1998 to depths between 5 and 20 feet bgs to delineate the vertical and lateral extent of impacted soil. Soil samples were collected from the borings at depths between 5 and 20 feet bgs. Several VOCs were observed below the soil LSRTs and USRTs (B&C, 1999).

An additional investigation was performed during the Soil and Groundwater Investigation (SGI1) Report for the Phase 1 project area (CDM, 2000a). Two soil borings (D37 and D38) were advanced to a maximum depth of 13 feet bgs in the vicinity of the former USTs to better delineate the lateral extent of VOC impacted soil. Laboratory reports of these soil samples indicate that chlorinated VOCs were not present above laboratory reporting limits. Groundwater samples collected in this area, however, indicate the presence of VOCs. Groundwater samples collected from monitoring well C-86ba, which is screened from 45 to 55 feet bgs, during the first quarter of 2002 indicate the presence of several VOCs, including 1,1-DCA (690 µg/L), cis-1,2-DCE (110 µg/L), and VC (200 µg/L) (CDM, 2002).

For SA-1, VC exceeded the groundwater HBRGs. PCE, TCE, and benzene exceeded the soil LSRTs (Table 4-1). However, confirmation soil sampling conducted following the excavation and tank removal did not indicate any VOC detection exceeding LTRSs.

4.2.2 SA No. 2- Southwest Corner of Former Building 12

This area consists of a former Plating Shop, two associated former clarifiers, and a former test sump located near the southwest corner of former Building 12. The test sump received waste containing 1,1,1-TCA, acetone, and other solvents as well as cleaning agents from the plating operations. Soil sampling conducted in 1987 (MEE, 1987a) indicated that VOCs were present, extending from the bottom of the sump down to the water table. Trans-1,2-DCE, 1,1-DCE, 1,1-DCA, benzene, MC and TCE were detected in soil samples and concentrations ranged from 0.004 to 7.9 mg/kg. (MEE 1987a). From 1988 to 1989, the former Building 12 clarifiers and sump were removed and the adjacent soil excavated (MEE, 1989). Confirmation sample results did not indicate any VOC concentrations exceeding LSRTs and USRTs. However, additional investigations by ENSR in 1997 and CDM in 1999 detected VOCs in this area. B&C also conducted sampling of the area in 1998 and metals analysis showed cadmium at 21 mg/kg and total chromium at 360 mg/kg (B&C, 1999b).

In December 2000 and January 2001, nine soil samples were collected from six borings. Samples were analyzed for VOCs and the following compounds with concentrations exceeding soil LSRTs and/or USRTs were detected: cis-1,2-DCE (0.86 to 2.25 mg/kg), VC (0.01 mg/kg), 1,1-DCA (0.039 to 0.191 mg/kg), and TCE (0.038 to 1.23 mg/kg), and PCE (0.007 to 0.264 mg/kg).

Groundwater samples collected from monitoring well C-09, which is screened from 25 to 35 feet bgs, during the first quarter of 2002 indicate the presence of several VOCs, including cis-1,2-DCE (14,000 µg/L), VC (13,000 µg/L), 1,1-DCA (3,300 µg/L), and 1,1-DCE (130 µg/L) (CDM, 2002).

For SA-2, VC and 1,1-DCE exceeded the groundwater HBRGs. Cadmium and Total Chromium exceeded the soil HBRGs. 1,1-DCA, cis-1,2-DCE, trans 1,2-DCE, TCE, and MC exceeded soil LSRTs. 1,1-DCE, VC, PCE, and benzene exceeded only soil USRTs. (Table 4-1).

4.2.3 SA No. 3- Central Area of Former Building 12

A former plating shop and circuit board lab were located in the south central region of former Building 12 and were operated from 1961 to 1975. Operations at this location included plating, etching, stripping and degreasing. In 1997 ENSR advanced four borings in the area. Soil samples were analyzed for VOCs, TPH and metals. All analytes were below soil HBRGs and LSRTs (ENSR, 1997).

A total of 48 geoprobe soil samples from 12 borings (GP18 through GP-28; and GP-33) were collected at depths between 5 and 20 feet bgs in 1998 (B&C, 1999b). The maximum VOC concentrations detected in the soil samples were TCE (1.2 mg/kg), 1,1-DCA (0.42 mg/kg), and cis-1,2-DCE (1.8 mg/kg). Total chromium was detected at 890 mg/kg. Five additional soil samples (310 series) were also collected during this investigation and analyzed for metals. Total chromium and copper were detected at 1,700 mg/kg and 2,100 mg/kg respectively.

Groundwater samples collected from monitoring well C-89be, which is screened from 23 to 38 feet bgs, during the first quarter of 2002 indicated the presence of several VOCs, including VC (840 µg/L), cis-1,2-DCE (300 µg/L), and 1,1-DCA (96 µg/L) (CDM, 2002).

For SA-3, VC exceeded groundwater HBRGs. Copper and total chromium exceeded soil HBRGs and cis-1,2-DCE exceeded LSRTs. 1,1-DCA and TCE exceeded soil USRTs (Table 4-1).

4.2.4 SA No. 4– Former Drum Storage Area (near Former Building 34)

The former Drum Storage Area was located south to southwest of former Building 34 and was used for approximately 25 years for the storage of drums containing kerosene, lubricating oils, cutting oils, hydraulic oils, degreasers, solvents and antifreeze (MEE, 1987a). The storage drums were placed on an asphalt-covered area, on five gravel covered spill tarps, and on a leakage collection tray that drained into an underground sump. Soil analyses from 1986 detected elevated concentrations of 1,1,1-TCA (30 mg/kg), 1,1-DCE (340 mg/kg), 1,1,-DCA (121 mg/kg), and PCE (340 mg/kg), as well as lesser concentrations of several other VOCs and fuel components (MEE, 1987a).

VOC-impacted soil within the former Drum Storage Area was excavated in 1988 (MEE, 1989b). A total of 23 confirmation soil samples were collected and analyzed for TPH, VOCs and PCBs. Several VOCs were detected in soils including 1,1-DCE, TCE, PCE, and 1,1,1-TCA. Total TPH concentrations were detected up to 6,100 mg/kg. PCBs were not detected above reporting limits.

An additional investigation was performed during the SGI1 for the Phase 1 project area (CDM, 2000a). Two soil borings (D44 and D45) were advanced to maximum depths of 12 and 6 feet bgs, respectively. The samples were analyzed for VOCs, TPH, MTBE, and metals. Laboratory results for these soil samples indicated that all analytes were below LSRTs or HBRGs.

More recently, a soil investigation was conducted from March 28, 2001 to April 3, 2001 to assess the extent of the remaining VOC-impacted soil (EEC, 2001c - see Appendix F). A total of 63 soil samples were collected from 24 locations at depths ranging from 1 to 13 feet bgs and analyzed for TPH, VOCs and metals. TPH and several VOCs were detected in soils, including 1,1-DCA (0.003 to23 mg/kg), 1,1,1-TCA (0.0031 to 510 mg/kg), 1,1-DCE (0.007 to 14 mg/kg), PCE (0.003 to 130 mg/kg), VC (0.0058 to 0.76 mg/kg) and toluene (0.0054 to 63 mg/kg).

Based on these findings, five areas around the former drum storage area were identified for excavation. In April 2001, potentially impacted soil from 4 feet bgs to approximately 12.5 feet bgs was excavated from each identified area (EEC 2001c -see Appendix F). Following the excavation, confirmation soil samples were collected and analyzed for VOCs. PCE (0.0068 to 15 mg/kg), 1,1-DCE (0.011 to 2 mg/kg), 1,1-DCA

(0.0084 to 2.8 mg/kg), VC (0.0052 to 1.1 mg/kg), and MC (0.022 to 0.94 mg/kg) were detected in soil samples.

Groundwater samples collected from monitoring well C-74be, which is screened from 17 to 32 feet bgs, during the first quarter of 2002 indicated the presence of several VOCs, including 1,1-DCA (6,200 µg/L), VC (270 µg/L), cis-1,2-DCE (21 µg/L), and TCE (14 µg/L), and chloroethane (CET) (2,400 µg/L) (CDM, 2002).

For SA-4, VC exceeded the groundwater HBRGs . PCE, TCE, cis-1,2-DCE, trans-1,2-DCE, 1,1-DCA, 1,1-DCE, 1,2-DCA, VC, 1,1,1-TCA, benzene, and toluene exceeded soil LSRTs (Table 4-1).

4.2.5 SA No. 5- Former UST and Degreaser Pit West of Building 11

During a drilling program in 1983, fuel hydrocarbon free product was observed on groundwater in the vicinity of the USTs located in this area (MEE, 1987a). Since 1987, fuel hydrocarbon free product recovery was subsequently conducted at monitoring wells TB-04, TB-07, TB-11, and TB-12 in the vicinity of Building 11. The results of the fuel hydrocarbon recovery conducted on an approximate monthly basis since March 1999 are provided in Appendix C (Table C-5). Measurable free product has not been observed since April 2000, and only a hydrocarbon sheen has recently been observed in groundwater at these wells (CDM, 2002). First quarter 2002 monitoring data indicated an exceedance of the groundwater HBRG for benzene at monitoring well TB-12 (14,000 µg/L, see groundwater data provided in Appendix C).

Soil samples in this area were collected in 1985 during the drilling of monitoring wells TB-06, TB-07, and TB-08 [Hargis & Associates (HA), 1986]. The samples were analyzed for VOCs and benzene and toluene were detected at 80 mg/kg and 77 mg/kg, respectively. As noted above, leaking UST was subsequently discovered and was taken out of service. Four USTs and associated piping were removed in September of 1996 (AquaScience Engineers, 1996). Confirmatory soil samples were collected from beneath the product piping and from the excavated soil piles and analyzed for TPH and BTEX. The sample results were below LSRTs and USRTs. The excavations were lined with 6-millimeter thick plastic sheeting and backfilled with the excavated soil and clean imported fill sand from an on-Site stockpile.

Soil samples were collected to assess the vertical and lateral extent of contamination at two boring locations southwest of Building 11 near the Degreaser Pit (MEE, 1987a). Soil borings SB-21 and SB-22 were sampled at depths of 0.5, 2.5, 4.5, 9.5, 14.5, and 19.5 feet bgs. VOCs detected in soil included TCA (0.004 to 0.021 mg/kg), TCE (0.002 to 0.13 mg/kg), benzene (0.034 to 1.064 mg/kg), toluene (0.004 to 0.60 mg/kg), MC (0.009 to 0.45 mg/kg), and xylenes (0.68 to0. 862 mg/kg). AquaScience removed soils to a depth of 2 feet bgs in this area in 1996 (AquaScience, 1996).

Groundwater samples collected from monitoring well C-48, which is screened from 35 to 45 feet bgs, during the first quarter of 2002 indicated the presence of benzene at a concentration of 30 µg/L (CDM, 2002). For SA-5, benzene exceeded the groundwater HBRG and also the LSRT for soil. Toluene, benzene, and MC also exceeded LSRTs (see Table 4-1).

4.2.6 SA No. 6–Former Building 35

Former Building 35 was used for painting, metal plating, and heat-treating. A chromate waste sump, neutralization pit, concrete clarifier and a vapor degreaser were located in and outside of the northeastern quadrant of the building. The sump and pit were lined with fiberglass in 1986/1987 (MEE, 1987a) and they were removed when the building was decommissioned in 1998.

In 1986, MEE performed Site assessment work in the vicinity of former Building 35 and collected samples from SB-14 in the chromate sump area. Benzene and arsenic were detected at concentrations of 0.512 and 10.11 mg/kg, respectively. In 1997, ENSR conducted additional sampling (20 soil samples from ten borings). The samples were analyzed for TPH, metals, VOCs, and SVOCs. Several VOCs including PCE (0.001 to 4.1 mg/kg), TCE (0.004 to 1.2 mg/kg), and cis-1,2-DCE (0.002 to 0.13 mg/kg) exceeded LSRTs. (ENSR, 1997). Vanadium detected in one soil sample at a concentration of 120 mg/kg.

An organic waste sump was located outside of the southwest corner of former Building 35. It received waste solvents and paint sludge from paint booths inside the building (MEE, 1987a). In 1986, MEE collected eight soil samples from C-48 located near the sump, and benzene and MC were detected at concentrations of 0.44 and 0.99 mg/kg, respectively (MEE, 1987a). This sump was removed and the area was excavated to 8 ft bgs in 1998 (MEE, 1989a).

In the fourth quarter of 1998, Building 35 was decommissioned and the chromate waste sump and neutralization pit were excavated and removed during demolition activities (B&C, 1999b). The chromate waste sump and neutralization pit cavities were later backfilled with clean soil to grade.

In January 2000, CDM advanced three borings in the vicinity of the northeast quadrant of former Building 35. Soil samples were collected and analyzed for VOCs and metals. Benzene (0.47 to 6.1 mg/kg) and toluene (3.2 to 100 mg/kg) were detected (CDM, 2000b). Metal concentrations did not exceed soil LSRTs and HBRGs. Arsenic concentrations were below soil HBRGs.

In October of 2001, EEC advanced additional soil borings at the location of former Building 35 (EEC, 2001d - see Appendix F). 116 soil samples were analyzed for VOCs, SVOCs, TPH and metals. EEC encountered soil impacted by PCE and TCE at concentrations in excess of LSRTs. The location of the observed impacted soil was at the northwest quadrant of the former Building 35 at a depth of 20 feet and shallower. TPH concentrations were not detected above the laboratory reporting limits. Metal

concentrations did not exceed soil LSRTs. Arsenic concentrations did not exceed soil HBRGs.

A grab sample of groundwater was taken using geoprobe technology at a depth of 35 ft bgs (the first fully saturated zone). The groundwater analytical results for the grab sample did not indicate an exceedance of groundwater HBRGs.

For SA-6, no exceedance of the groundwater HBRGs has recently been observed at this location (CDM, 2002). PCE, TCE, MC, toluene and benzene exceeded LSRTs. Cis-1,2-DCE exceeded USRTs. Based on the recent investigation results conducted by Geomatrix/CDM and EEC, these compounds are listed as COCs (Table 4-1). Vanadium slightly exceeded the soil HBRGs in one isolated location. This isolated exceedance of the HBRGs is not considered significant and vanadium is not listed as a COC. Arsenic exceeded the soil HBRG in only one isolated sample location. Furthermore, the sample result was only slightly higher than one standard deviation of the established background level of 5.2 mg/kg for the Site, indicating that the arsenic is most likely naturally-occurring and not related to previous industrial activities. Therefore, this isolated exceedance of the HBRG is not considered significant and arsenic is not included as a COC for this SA (Table 4-1).

4.2.7 SA No. 7- Storm Drain Discharge Site

Prior to 1954, treated industrial wastewater from several industrial waste clarifiers and neutralization sumps on the north side of the Plant Site was discharged into this area. A shallow drainage ditch directed runoff in a northerly direction adjacent to the parking lot. Soil analyses from 1986 indicated the presence of benzene (0.066 to 0.7 mg/kg), and MC (0.098 to 1.2 mg/kg) (MEE, 1987a).

In December 1988 and January 1989, MEE excavated shallow soil in the vicinity of the storm drain outlet (MEE, 1989a). The excavation was extended laterally at least 5 feet beyond the drainage ditch to a depth of approximately 1-foot bgs. Approximately 100 cubic feet of soil was removed. Confirmation samples analyzed for VOCs (USEPA Methods 8020 and 8010) did not contain detectable concentrations of VOCs. Based on the results of confirmation samples analyzed for TPH (2,000 mg/kg), an additional foot of soil was removed from the area. Analysis of subsequent confirmation samples for TPH did not indicate detectable concentrations of TPH (MEE, 1989a).

In March of 2001, EEC removed the storm drain outlet catch basin. The area was excavated and 13 confirmation samples were collected (EEC, 2001a - see Appendix F). During the excavation of the storm drain outlet catch basin, a leach line was observed and additional confirmation sample was collected to determine the presence of any chemicals. Soil excavation confirmation samples were analyzed for VOCs (USEPA Method 8260B), SVOCs (USEPA Method 8270), TPH (USEPA Method 8015M with carbon chain speciation), California Assessment Manual (CAM) Metals (USEPA Method 6010B), mercury (USEPA Method 245.1A), and chromium VI (USEPA Method 7196A). VOCs did not exceed LSRTs and USRTs. Detected metal

concentrations were below HBRGs. Chromium VI was not detected (EEC, 2001a). TPH was detected at concentrations of 2,907 to 6,399 mg/kg.

Additional soil sampling to confirm the presence or absence of VOCs (previously detected at concentrations greater than LSRTs in the vicinity of well C-49) was conducted in October 2001 (EEC, 2001a). VOCs did not exceed LSRTs and USRTs.

First quarter 2002 groundwater sampling results from the closest monitoring well to this area (C-49), which is screened from 20 to 30 feet bgs, indicated the presence of 1,1-DCA (320 µg/L), cis-1,2-DCE (710 µg/L), 1,4-diclorobenzene (1,4-DCB, 58 µg/L), and VC (14 µg/L), as well as several other VOCs at lesser concentrations (CDM, 2002).

For SA-7, no exceedance of the groundwater HBRGs have recently been observed. Before excavation, MC and benzene concentrations exceeded the soil LSRTs at well C-49 located within SA-7. However, recent investigations conducted by EEC in 2001 did not detect these compounds near locations where previous detections from 1986 sampling were observed. Therefore MC and benzene are not listed as COCs in Table 4-1.

4.2.8 SA No. 8- Sumps, Clarifiers, and Former Vapor Degreaser Northeast Corner of Building 14 to Northeast Corner of Building 15

This source area consists of the Building 14 clarifier system including two concrete clarifiers and sumps that handled cutting oils and solvents from machining operations prior to 1985. In addition, it includes the former above-floor vapor degreaser area , at the northeast corner of Building 15 which was operated until 1994. Soil samples collected adjacent to the clarifier in 1986 indicated that VOCs were present, including benzene (0.042 to 0.2 mg/kg), and TCE (0.31 to 0.42 µg/kg) at location SB-23 (MEE, 1987a). Impacted soils associated with the trenches and clarifiers could not be excavated because this would have impaired the structural integrity of the now designated historic building. More recently, the Building 14 clarifiers and Building 15 trenches were cleaned and inspected (CDM, 2000a). Soil samples collected as part of the SGI1 in August 1999 confirmed the presence of chlorinated VOCs beneath the foundation. Soil concentrations were observed at five feet bgs for TCE (0.320 mg/kg), cis-1,2-DCE (0.043 mg/kg), and PCE (0.046 mg/kg) (CDM, 2000a).

In January 2001, two soil samples were collected from one boring (Geomatrix/CDM) and analyzed for TPH and VOCs. PCE (0.887 mg/kg) and TCE (0.128 mg/kg) exceeded USRTs.

Groundwater samples collected from monitoring well C-78be, which is screened from 17 to 32 feet bgs, during the first quarter of 2002 indicated the presence of several VOCs, including cis-1,2-DCE (800 µg/L), trans-1,2-DCE (99 µg/L), PCE (2.3 µg/L), and VC (100 µg/L) (CDM, 2002).

For SA-8, VC exceeded the groundwater HBRG. 1,2-DCA, cis-1,2-DCE, and benzene exceeded the LSRTs for soils. 1,1-DCE, TCE, PCE, and trans-1,2-DCE exceeded the USRTs (Table 4-1).

4.2.9 SA No. 9 - Existing Clarifier and Former Vapor Degreaser Pit Building 15 Center Bay and Utility Trenches in Building 15 North Bay

A 10,000-gallon concrete clarifier, backfilled degreaser pit, and sump are located in the western part of the Center Bay of Building 15 near Column H-33. The clarifier intercepted system drains from rinse tanks. The vapor degreaser pit was backfilled in the 1960's. The initial investigation of this area, conducted in 1986, showed detects in soil samples for 1,1-DCA (0.08 mg/kg), MC (0.08 mg/kg to 0.6 mg/kg), PCE (0.2 mg/kg to 0.4 mg/kg), and TCE (0.56 mg/kg to 9.2 mg/kg) (MEE, 1987a). Subsequent sampling in the area of the clarifier, degreaser pit, and sump, conducted by ENSR (1997) and Geomatrix/CDM (2000) confirmed the presence of VOCs in soils with detections of cis-1,2-DCE (1.5 mg/kg), PCE (12 mg/kg), and TCE (24 mg/kg). In May 2001, EEC collected 12 soil samples from four borings for additional characterization of this area. The samples were analyzed for VOCs. The sample results did not exceed soil USRTs and LSRTs.

Utility trenches located in the north bay of Building 15 run the length of the building (760 feet) and collected drips of solvents and cutting oils (MEE, 1987a). In 1986, MEE collected 16 soil samples from five borings within the trenches. Various VOCs were detected including benzene (0.073 mg/kg), 1,2-DCA (0.2 mg/kg), trans-1,2-DCE (2.8 mg/kg), and TCE (5 mg/kg) (MEE, 1987a). The trenches were pressure washed in 1994 after operations ceased. In April 1999, CDM collected two soil samples from two borings and analyzed for VOCs, metals, BTEXs, and MTBE. VOCs including TCE (5.4 mg/kg), cis-1,2 -DCE (0.77 mg/kg) and trans 1,2-DCE (0.24 mg/kg) and low concentrations of metals were detected. BTEX and MTBE were not detected above the laboratory reporting limits (CDM, 2000a).

Groundwater samples collected from monitoring well C-77be, which is screened from 15 to 25 feet bgs, during the first quarter of 2002 indicated the presence of several VOCs, including cis-1,2-DCE (900 µg/L) and trans-1,2-DCE (21 µg/L) (CDM, 2002).

For SA-9, no exceedances of the groundwater HBRGs were observed. PCE exceeded soil HBRGs at one location near the clarifier. PCE, TCE, cis-1,2-DCE, and MC, exceeded LSRTs. Trans-1,2-DCE, benzene, 1,1-DCA exceeded USRTs (Table 4-1).

4.3 Summary of Soil Gas Results

During the week of December 18 through 22, 2000, soil gas samples were collected in the vicinity of Buildings 14, 15, 16 and 21 within the Campus Area. A total of 221 soil gas samples were collected from depths of 3 to 5 feet below ground surface. Appendix I, *Soil Gas Results*, presents a description of the methods that were used to collect and analyze the samples, as well as a table of the results.

To summarize the findings, 5 of the 221 sample locations were found to have soil gas concentrations that exceeded the final HBRGs for organic compounds in commercial soil gas (IESI 2001). These HBRGs are shown in Appendix H.

All five of the sample locations with HBRG exceedances were located at the western end of Building 15, the area that has been identified above as SA-9.

Section5
Identification of Remedial Technologies and Process Options

The next step in selecting potential remedial alternatives is to identify technologies and process options that should be considered for the Campus Area.

This section presents remedial technologies and process options that have been identified as capable of meeting ROs in the Campus Area. For groundwater, these were screened remedial technologies and process options on the basis of technical feasibility. The remedial technologies and process options retained following this screening are described and evaluated in more detail in this section. For soils, no screening was done because the list of potentially applicable soil remediation technologies is limited.

5.1 Groundwater Remedial Technologies and Process Options

5.1.1 General Response Actions

The first step, at this point, is to identify general response actions, which are defined as actions that, singly or in combination, will meet the ROs defined in Section 3 or will provide a baseline for comparison with other actions. From this set, a subset of remedial alternatives is developed.

General response actions for the Campus Area include both passive and active measures to mitigate groundwater contamination. Passive measures include those that involve no active engineered technology(ies) for containment or treatment of groundwater, such as monitoring only of contaminant plume migration and/or biodegradation and attenuation, or use restrictions (e.g., land or groundwater). Active measures include the installation of systems that will contain and/or treat contaminated groundwater. The general response actions for the Campus Area are shown in Table 5-1, *General Response Actions for Groundwater.*

The general response actions listed in Table 5-1 provide a basis upon which to identify and then screen remedial technologies. Process options associated with the remedial technology are also identified. Once screened, acceptable technologies and process options are incorporated into remedial action alternatives that satisfy ROs defined in Section 3.

5.1.2 Preliminary Screening of Groundwater Technologies and Process Options

The first step, at this point, is to identify general response actions, which are defined as actions that, singly or in combination, will meet the ROs defined in Section 3 or will provide a baseline for comparison with other actions. From this set, a subset of remedial alternatives is developed.

Each remedial technology may have several process options (e.g., enhanced bioremediation, air sparging, *in situ* chemical oxidation, etc.), which refer to the specific material, equipment, or method used to implement a technology. The identified remedial technologies and process options applicable to groundwater remediation within the Campus Area are presented in Table 5-2, *Initial Screening of Groundwater Remediation Technologies and Process Options*. In the initial screening, process options were evaluated on the basis of technical feasibility, i.e. whether there were compatible with Campus Area characteristics (e.g., physical features) and chemical characteristics of the COCs, and on their overall effectiveness. Process options considered clearly infeasible or not applicable for the Campus Area were eliminated as indicated by shading in Table 5-2. In particular, these groundwater process options were eliminated from further consideration:

- Slurry walls, grout curtains, sheet piles, and reactive gates. Due to the lack of a competent geologic unit to "seat" the base of the barrier (e.g., bedrock or competent clay unit), these technologies would likely not reduce vertical migration of VOCs. In as much as the potential for vertical migration of contaminants from the Ballona aquifer to the Silverado aquifer exists, lateral migration may occur if VOCs migrate vertically into the Ballona or Silverado aquifers;

- Phytoremediation was screened because the root systems of the plants are not expected to extend fully through the Bellflower aquitard, the hydrostratigraphic unit where phytoremediation has a higher probability of mass removal; and

- *Ex situ* membrane treatment technologies. These technologies are not as reliable as other technologies available for VOC removal.

The no-action response was retained as a baseline alternative.

5.1.3 Evaluation of Retained Groundwater Technologies and Process Options

The retained technologies and associated process options surviving the initial screening in Section 5.1.2 were deemed potentially applicable to the Campus Area and evaluated further based on three criteria: effectiveness, implementability, and cost.

The effectiveness analysis focuses on the relative merits of process options, when compared to other processes within the same technology type. The criteria used in the effectiveness evaluation are:

- The ability of the process option to address the estimated volume of contaminated media and to attain ROs;

- Potential environmental and health impacts during implementation of the process option; and

- Reliability of the process option with respect to Campus Area contaminants and conditions.

The implementability evaluation considers the technical and administrative feasibility of the process options. Process options that are clearly ineffective or incompatible with the Campus Area were previously eliminated. This analysis focuses primarily on institutional implementability, including:

- Ability to obtain necessary regulatory permission (i.e., permitting), and
- Availability of appropriate process option services (e.g., vendors, technicians).

At this stage of the evaluation, cost is less significant than either effectiveness or implementability, and therefore plays a limited role in the screening of process options. Each process option is evaluated based on its costs being high, medium, or low relative to other process options in the same technology type.

Process options for groundwater, arranged according to remedial technologies and general response actions, are listed in Table 5-3, *Relative Comparison of Retained Groundwater Technologies and Process Options*. This table summarizes the screening of process options for effectiveness, implementability and cost. Process options clearly infeasible or inappropriate based on the evaluation criteria were eliminated from further consideration, as indicated by shading in the table. The evaluations of each of the remaining remedial actions and process options are described in the following subsections.

5.1.3.1 No Further Action (NFA)

Under this alternative, no remedial action would be undertaken.

Although this option is technically feasible and inexpensive, it is not effective in preventing future contaminant migration or removing the contaminants from the Campus Area. Nonetheless, the evaluation of no further action provides a baseline by which all other alternatives are evaluated.

5.1.3.2 Monitored Natural Attenuation (MNA)

MNA is an *in situ* remediation technology that relies on naturally-occurring processes (including biodegradation, dispersion, matrix diffusion, sorption, volatilization, and chemical degradation) to reduce the concentration, and in some instances, mass of contaminants in groundwater and soils. MNA is recognized by the USEPA and the State of California as a viable method of remediation that can be evaluated and compared to other remediation strategies. This method of groundwater remediation may be used as the sole remediation technology when it: (1) is combined with some degree of source control; (2) is shown to be fully protective of human health and the environment; and (3) meets ROs within a reasonable time frame. An established monitoring program is required to evaluate the effectiveness of MNA. MNA may

also be used in combination with other process options as a concurrent technology, or implemented following the completion of other technologies.

The effectiveness of MNA is dependent on the types of contaminants, and the chemical, physical, and biological characteristics of the soil and groundwater at a particular location. In areas of elevated contaminant concentrations (e.g., source areas), MNA effectiveness as a stand-alone technology is low because it likely would not meet the RO that requires the reduction of groundwater concentrations to levels protective of human health and the groundwater resource in a timely fashion, as compared with other technologies. However, MNA may be more effective if implemented with appropriate risk control measures, or after alternate remedial technologies have resulted in a reduction of contaminant mass. MNA is easily implemented and requires moderate costs over the lifetime of the project. MNA is therefore retained as a remediation technology.

5.1.3.3 Institutional Controls

Institutional controls function to prevent or reduce public contact with contaminated media and have little or no effect on the presence of contaminants. Examples of institutional controls include Site use restrictions (e.g., deed restrictions) and public education. These are discussed below.

Use Restrictions

Use restrictions are an institutional control mechanism in which a governing body regulates the access or use of a site. For the Campus Area, restrictions may be imposed to ensure that the land use is limited to commercial development, unless otherwise allowed by governing regulatory agencies in the future. In addition, institutional controls can be established through legally enforceable prohibitions, such as CC&RS that preclude private withdrawals of groundwater. Institutional restrictions on groundwater use is a typical component of a remedial action, because they prevent public use of untreated groundwater.

However, because use restrictions alone do not meet the RO that requires the sources of contaminants to be reduced or eliminated; their effectiveness is low. Use restrictions may require regulatory permitting and cooperation with state and local agencies, which may be troublesome to obtain, making them moderately implementable. On the other hand, establishing and enforcing such restrictions is only moderately expensive. Thus, use restrictions are retained as a process option, which may apply to a number of remedial technologies.

Public Education

Public education can be used to facilitate protection of human health. This requires educating the public about the potential risks associated with exposure to contaminated groundwater. Water quality information can be disseminated through fact sheets, public meetings, and local news media announcements.

Public education alone does not meet the RO that requires the sources of contaminants to be reduced or eliminated; therefore, the effectiveness is low. Public education via fact sheets and public meetings is easily coordinated and highly implementable. The cost for such actions is typically low to moderate compared to other response actions. Public education is retained as a process option due to the high implementability and low to moderate cost of this option, despite its limited effectiveness.

5.1.3.4 Hydraulic Containment

Of the various forms of hydraulic containment, a general response action, vertical barriers (slurry walls, grout curtains, and sheet piling) were eliminated from further consideration in Section 5.1.2. However, two other types of surface water infiltration reduction are retained and discussed below.

Source Area Capping

Infiltration of surface water into contaminated areas of the Campus Area contributes to contaminants leaching into groundwater as the contaminants are desorbed from soil and transported down into groundwater. Capping source areas will reduce this risk. In addition, some capping will result from development activities such as the placement of concrete, asphalt, building structures, or clay capping material over areas with soil contamination.

Source area capping is considered to be moderately effective because it is possible to meet the RO of reducing groundwater concentrations and contaminant migration; however, it does not reduce the presence of contaminant mass in the source areas. This process option is considered highly implementable because it can be completed as part of the Campus Area development and its costs are low with respect to other response actions. Potential source area capping is therefore retained as a process option.

Storm Water Diversion/Control

Storm water run-on near source areas may pond under conditions of high rainfall and percolate vertically through the soils, creating additional recharge that serves to increase the mobility of contaminants. Storm water diversion or control structures could serve to reduce the volume of water infiltration through source areas and reduce the vertical and lateral migration of VOCs.

Storm water diversion/control is considered to be moderately effective because it is possible to meet the RO of reducing groundwater concentrations by reducing migration of COCs from source areas to groundwater; however, it does not reduce the presence of contaminant mass in the source areas. This process option is considered highly implementable because it can be completed as part of the Campus Area development and its costs are low with respect to other response actions. Storm water diversion/control is therefore retained as a process option.

5.1.3.5 Groundwater Collection/Extraction

The principal means of recovering contaminated groundwater is through altering of the groundwater gradient to enhance and/or control contaminant movement. This response is typically accomplished by artificially influencing an existing gradient via groundwater extraction wells and/or by placing groundwater interceptor drains downgradient of the contaminated area, which options are discussed below.

Groundwater Extraction Wells

Groundwater extraction wells are commonly used as a method to influence groundwater flow and to recover contaminants. Extraction wells are used to contain the migration of a contaminant plume and/or reduce contaminant mass in groundwater. Such wells would be located within and/or downgradient of the source areas. In general, extraction wells are versatile under a variety of environmental conditions and have design and operating flexibility. Extraction wells may be used singly, or in multiples, to sufficiently contain the spread of a groundwater contaminant plume. Multiple wells should be positioned in such a way that their radii of influences overlap, thereby minimizing the potential for downgradient plume migration.

Groundwater extraction wells are considered to be moderately to highly effective because they potentially meet ROs of reducing groundwater contaminant concentrations. Extraction wells are highly implementable, and have relatively moderate capital and maintenance costs, although long-term operation may be expected. Extraction wells are retained as a process option.

Dual Phase Extraction

Dual phase extraction (DPE) is an *in situ* remediation technology that, for the purposes of this RP, is categorized under the groundwater collection/extraction general response action. DPE involves the extraction of groundwater and soil vapor at a common location, and typically consists of a "pipe within a pipe" configuration. Groundwater is extracted from a well screened across the water table using a submersible pump, while soil vapor is extracted by applying a vacuum to the wellhead. The groundwater flow to the DPE well results in removal of dissolved contaminant mass and helps to control or reverse the spread of dissolved contaminants from the source areas. Groundwater extraction also results in a cone of depression exposing additional vadose zone soil from which VOCs can be removed via soil vapor flow. Thus, the soil vapor flow results in remediation of vadose zone and exposed saturated zone soils through volatilization and removal of VOCs in extracted soil gas.

DPE is considered to be moderately to highly effective because it has the potential of meeting all of ROs for the shallow Bellflower aquitard, provided that the lithology of this unit is permeable enough to allow for an effective vapor extraction flow rate. The implementability of DPE is moderate, with the collection and treatment of off-gas

vapors and groundwater requiring treatment and regulatory permits. The cost of DPE is considered moderate. DPE is retained as a process option.

Interceptor Drains

Groundwater can also be removed by the installation of subsurface drains to intercept groundwater as it migrates beneath the Campus Area. Such drains would consist of perforated pipe in trenches backfilled with porous media. Subsurface drains or interceptor trenches may be used as an effective containment remedy.

Interceptor drains would be moderately effective at meeting the ROs to reduce groundwater contaminant concentrations. Considering the depth and spatial distribution of contamination within the Campus Area, interceptor drains have only a low to moderate implementability. This process option is most cost-effective when implemented in conjunction with concurrent soil excavation activities. As such, costs are moderate to high, but may vary depending on whether excavation is concurrent. Interceptor drains are therefore screened from further consideration.

5.1.3.6 Treatment

Treatment technologies include *in situ* and *ex situ* alternatives as described in the sections below.

In Situ Treatment

The three process options surviving the initial screening under *in situ* treatment alternatives are enhanced bioremediation, chemical oxidation, and air sparging.

Enhanced Bioremediation

Enhanced bioremediation is a groundwater technology that involves injection of an electron acceptor, electron donor, microorganisms, and/or nutrients to stimulate or enhance the biodegradation of VOCs. For chlorinated VOCs found within the Campus Area, the enhanced bioremediation technology typically involves induction of reduced groundwater environments. As such, biodegradable organic carbon (electron donor) would be injected in sufficient quantities to sufficiently lower the groundwater-reducing environment and stimulate the rapid, reductive dechlorination of VOCs. It is important to note that some of the chlorinated VOCs detected in the Campus Area (e.g., VC and cis-1,2-DCE), may also be biodegraded under oxidizing groundwater environments. Thus, injection of air into the subsurface or the application of oxygen releasing compounds may also be useful in the Campus Area, although such approaches may be complicated by the already reduced groundwater environment. Inherent challenges that may affect the feasibility of this process option include the ability to adequately deliver amendments to the subsurface; the presence of competing electron acceptors/donors; the presence of a microbial consortia capable of degrading the VOCs; and the possibility of forming additional toxic intermediates, such as VC.

Enhanced bioremediation is considered to be moderately to highly effective because it has the potential of meeting all ROs, provided that adequate delivery of amendments to the subsurface can be achieved. The implementability of enhanced bioremediation is moderate as it will require subsurface injection permits, and the costs are moderate. Enhanced bioremediation is retained as a process option.

Chemical Oxidation

In situ chemical oxidation involves the delivery of chemical oxidants to convert subsurface contaminants to innocuous end products (e.g., water, chloride ions, and carbon dioxide). The most common field application of chemical oxidation is based on Fenton's Reagent addition, whereby hydrogen peroxide is injected with an iron catalyst creating hydroxyl free radicals. These hydroxyl free radicals result in relatively non-specific chemical reactions that destroy organic compounds in the subsurface, including contaminants such as chlorinated solvents found at the Campus Area. Proprietary catalysts may also be used in the injection process to increase the efficiency of reactions; such reactions are referred to as Fenton's-Like Reactions. Permanganate is also a common chemical oxidant used in the application of chemical oxidation. Inherent challenges that may affect the feasibility of this process option include the ability to adequately deliver amendments to the subsurface (i.e., affected by permeability of soils); the presence of highly reduced subsurface conditions and high organic soils or naturally-occurring reduced metals that consume excessive amounts of chemical oxidant; and the potential mobilization of naturally-occurring metals in the subsurface.

Similar to enhanced biodegradation, the effectiveness of *in situ* chemical oxidation is considered to be highly variable, depending on the soil characteristics of the targeted treatment zone. For example, the effectiveness would be low in the native soils of the upper Bellflower aquitard as a result of presumably poor distribution of amendments and highly reduced subsurface conditions. The effectiveness of this process option may be moderate if applied to more permeable water-bearing zones, or in conjunction with infiltration galleries. The implementability of chemical oxidation is moderate as it would require subsurface injection permits, and the costs are moderate. Chemical oxidation is screened from further consideration, primarily due to the presence of highly reduced subsurface conditions that make this process option less desirable as compared with other *in situ* process options (e.g., enhanced bioremediation).

Air Sparging

Air sparging involves the installation of wells in contaminated groundwater areas to inject air into the saturated zone. The induced airflow enhances the volatilization of the VOC contaminants from groundwater into the vadose zone. Once in the vadose zone, the VOCs can be removed via soil vapor extraction (SVE). The application of this technology is highly dependent on the hydraulic conductivity, the zone of influence (ZOI) of the air injection and vapor extraction wells, and the airflow rate sustained through the contaminated zones. Preferential flow paths established for airflow have the potential for limiting the contaminant contact area and limiting the effectiveness of the sparging process. It should be noted that the injection of air may

alter the groundwater reducing environment, thereby limiting any further reductive dechlorination of chlorinated contaminants. However, such introduction of air may lead to an oxidizing environment, thereby creating conditions in which oxidative biodegradation of some chlorinated VOCs (e.g., VC and cis-1,2-DCE) may occur.

Similar to other *in situ* technologies, the effectiveness of air sparging is considered to be highly variable, depending on the soil characteristics of the targeted treatment zone. For example, the low permeable soils characteristic of the Bellflower aquitard are expected to complicate the recovery of volatilized contaminants, thereby limiting the effectiveness of this technology. Furthermore, the addition of air to the saturated zone will interfere with biological, reductive dechlorination processes. For these reasons, air sparging was screened from further consideration, even though it is considered to be low to moderate in implementability and have moderate costs.

Ex situ Treatment

Inherent to all *ex situ* treatment options is that groundwater is removed from the subsurface to the surface for treatment. Groundwater collection/extraction is achieved through the use of either extraction wells or interceptor drains, or a combination of both. A review of the process options focused on determining the appropriate treatment process for the removal of chlorinated organic compounds in groundwater. The required treatment efficiency is dictated by limits on discharge to an on-Site water treatment facility, Public Owned Treatment Works (POTW), storm drain, and/or surface discharge.

Air Stripping

Air stripping towers have been used effectively for removing numerous dissolved VOCs from groundwater waste streams. Contaminated water enters the stripping tower at the top and is evenly distributed across the internal packing media through distributor nozzles or weirs. Clean air is introduced into the bottom of the tower below the packing using a forced air blower, and flows upward through the packing. As the falling contaminated water flows countercurrent to the rising air stream, VOCs are stripped from the water and enter the air stream. Volatilized organics are then discharged to the atmosphere or an off-gas treatment system. The internal packing media acts to increase the total surface area available for mass transfer of the organic contaminants from the liquid to the vapor stream. Treated water falls from the packing into the stripper basin and exits the tower.

The extent of compound removal by air stripping is governed by many factors, including contaminant concentrations in groundwater, temperature of the air and water, the air-to-water ratio, and contaminant physical properties (e.g., Henry's Law constant). Air stripping tower performance may also be influenced by the presence or absence of various inorganic compounds and suspended solids in the groundwater. Groundwater with elevated hardness may result in calcium and magnesium salt deposits in the tower packing media. Elevated iron (concentrations over 5 mg/L) or

manganese concentrations, when oxidized in the air stripper, will result in metal hydroxide precipitation, which can severely foul the packing media and reduce its effectiveness to remove VOCs. In addition, elevated total suspended solids (TSS) concentrations in the groundwater can also result in solids deposition on the tower packing and reduce liquid-to-air mass transfer.

Groundwater within the Campus Area contains moderately high concentrations of iron and suspended solids that may require pretreatment. Pretreatment equipment could include multi-media filters to remove TSS, followed by greensand filters (if necessary) to remove iron. An alternative approach to pretreatment equipment may be the use of proprietary chemical complexing agents that prevent iron from precipitating in the air stripping tower. The need for pretreatment should be explored during the remedial design phase to identify the appropriate combination of pretreatment steps.

The majority of VOCs found within the Campus Area exhibit relatively high Henry's Law constants and, therefore, are expected to be effectively treated with air stripping. For this reason, air stripping is considered highly effective. The implementability of this technology is moderate. The cost of air stripping is moderate relative to other *ex situ* treatment options. Air stripping is retained as a process option.

Ultraviolet Enhanced Chemical Oxidation

The chemical destruction of organic compounds through oxidation is a common practice in many industrial processes. The process involves mixing the influent water with one or more chemical oxidizers, such as ozone and/or hydrogen peroxide, followed by irradiating the water with ultraviolet (UV) radiation. As a result of these reactions, the organic compounds are transformed to less harmful compounds. Advantages of this process are that the contaminants are destroyed rather than being transferred to another media and that it does not generate significant air emissions or other residual waste that will require further treatment. Furthermore, this technology is also applicable to highly soluble contaminants, which are not effectively treated with the carbon adsorption technologies. Potential disadvantages are high operating costs (electrical power and chemical oxidizers) and reduced effectiveness if ozone-demanding or hydroxyl radical-trapping substances occur in the water. In addition, post-treatment using carbon adsorption may be necessary to remove incomplete oxidation byproducts.

UV-enhanced chemical oxidation is a highly effective technology that is applicable for the treatment of all VOCs found in the Campus Area groundwater. This technology is considered low to moderately implementable and does not generate significant air emissions or residual wastes that will require substantial regulatory permitting. Although this process option has high costs relative to other process options, UV-enhanced chemical oxidation is retained as a potential polishing treatment technology.

Biological Treatment

As discussed in the enhanced bioremediation *in situ* treatment process option (Section 5.1.3.6), organic contaminants may be readily biodegraded to innocuous end products under the appropriate environmental conditions. The biological treatment of groundwater often involves the induction of oxidized or reduced groundwater conditions, or a combination of both in series, to achieve the desired removal efficiency. Biological treatment systems may be difficult to maintain relative to other treatment alternatives and require the collection and disposal of sludge materials (i.e., waste products).

Despite moderate effectiveness and implementability, biological treatment is characterized by high operational costs and, therefore, screened from further consideration as a process option.

Activated Carbon Adsorption

One process option for organics removal from both liquid and gaseous phases is activated carbon adsorption. Activated carbon adsorption is most often carried out in a pressurized vessel that contains a bed of granular activated carbon. Contaminated liquid or vapor enters a pressurized vessel and is evenly distributed over the granular activated carbon. As the contaminated stream flows through the activated carbon media, organic compounds are adsorbed onto the micro-porous surfaces of the activated carbon by an electrical attraction. When the porous surfaces of the carbon become saturated with adsorbed organic material, the carbon must be replaced with new or thermally regenerated carbon media. Activated carbon adsorption is a surface attraction phenomenon influenced by several factors including physical properties of the carbon and contaminant compounds, and system characteristics such as dissolved solids concentration, temperature, and pH. Depending on the composition of the waste stream, pretreatment steps such as multi-media filtration or clarification might be necessary to enhance the removal efficiency and life of activated carbon filters. Carbon adsorption is typically used for vapor waste streams when contaminant concentrations are less than 1,000 parts per million by volume (ppmv). Operating life before carbon exhaustion is primarily a function of the flow rate and the concentration of organic compounds in the influent stream.

The majority of VOCs found within the Campus Area exhibit relatively high adsorption capacities, and therefore will be effectively treated with activated carbon. However, the more soluble and volatile compounds such as VC will likely require other treatment technologies to achieve desired removal efficiencies. Furthermore, groundwater within the Campus Area contains several reduced metals (e.g., reduced iron and manganese) that, if not removed or complexed, may oxidize and plug the carbon media.

Overall, activated carbon is considered to be moderately to highly effective. This technology is highly implementable. The costs of carbon adsorption are moderate to high and depend on the frequency of carbon bed exhaustion, which require carbon

replacement or regeneration and disposal of spent carbon and concentrated wastes. Activated carbon adsorption is retained as a process option.

Synthetic Resin Adsorption

VOCs can be adsorbed using various synthetic resins in place of activated carbon. In contrast to activated carbon, which will adsorb a wide variety of chemicals, synthetic resins are designed to selectively adsorb particular chemicals or families of chemicals. In certain applications, this is advantageous because only chemicals of concern are removed. However, this selectivity may also result in synthetic resins being inappropriate or incapable of treating all contaminants in a waste stream, and overly expensive (because additional resins or treatment trains may be needed) for certain treatment applications where a wide variety of chemicals must be removed. Synthetic resin adsorption systems are typically constructed as on-Site regenerative systems because the resins may be regenerated more than 1,000 times without any loss of adsorptive capacity, and because limited infrastructure exists to perform off-Site recycling of the resins, as is the case with activated carbon. Thus, long-term liabilities common with off-Site disposal of carbon will be limited by using a synthetic resin adsorption system. Also, synthetic resins typically have a greater tolerance for high moisture content vapor streams than activated carbon systems.

Synthetic resin adsorption systems are considered to be only moderately effective and implementable, primarily due to the emerging status of this technology. Furthermore, the presence of elevated suspended solids or solids formed by the precipitation of reduced metals such as iron and manganese can foul the bed requiring possible pretreatment measures. Synthetic resin adsorption costs are considered moderate to high as on-Site regenerative systems generally have greater capital costs than typical carbon adsorption systems that employ off-Site regeneration or disposal, although the operating costs may be lower. Due to the emerging status and potentially high costs of this process option relative to other options, synthetic resin adsorption is screened from further consideration.

Thermal Oxidation

Thermal oxidation units destroy VOC vapors through thermal destruction mechanisms. In this process, VOC vapors are preheated, thoroughly mixed, and combusted at high temperatures (e.g., 1,200 to 1,600 ^{o}F), forming carbon dioxide and water. The primary advantage of thermal destruction is that the contaminant is chemically altered so that it is no longer toxic. Thermal oxidation units are most efficiently applied for treating off-gas containing 1,000 to 5,000 ppmv of combustibles. Thermal oxidation systems require auxiliary fuel (e.g., natural gas or propane) when treating low-concentration waste streams.

Thermal oxidation units are characterized by simple operation and high compound destruction efficiencies. However, it is unlikely that VOC concentrations in the vapor stream to be treated will remain high enough to make this a cost-competitive treatment approach. Furthermore, treated vapor streams will likely require scrubbing processes to remove hydrogen chloride, which makes this option more costly than

other alternatives. For these reasons, thermal oxidation is screened from further consideration as a process option.

Catalytic Oxidation

Catalytic oxidation is a process very similar to thermal oxidation; however, a catalyst module is attached to the combustion chamber exhaust. The VOC-laden vapor is directly preheated (electrically, or more frequently with natural gas or propane) to reach a temperature to initiate the catalytic oxidation of the VOCs. Then, the preheated vapor stream is passed through a bed of solid catalysts where the VOCs are rapidly oxidized. VOCs are thermally destroyed at temperatures typically ranging from 600 to 1,000 ^{o}F. Operating the combustion chamber at temperatures lower than required for thermal oxidation units improves fuel economy when treating dilute waste streams. Catalytic oxidation is best applied for treating off-gas containing 100 to 3,000 ppmv of contaminants.

Catalytic oxidation may be a highly effective technology for discrete vapor waste streams; however, it is unlikely that a catalyst capable of addressing all VOCs of concern for the anticipated waste streams is available. Furthermore, treated vapor streams will likely require scrubbing processes to remove hydrogen chloride, which makes this option more costly than other alternatives. For these reasons, catalytic oxidation is screened from further consideration as a process option.

Vapor Condensation

Vapor condensation units may be used when the contaminant concentrations are high and waste stream flow rates are low. Condensation is typically accomplished by refrigeration or with liquid nitrogen. The effectiveness of this technology is determined by the vapor pressure and temperature characteristics of the contaminants present. Because condensation of the contaminants is rarely complete, an additional method of treatment is typically required.

Vapor condensation is considered to be an ineffective treatment technology because long-term waste stream contaminant concentrations are expected to be low and flow rates are expected to be high. For these reasons, vapor condensation is screened from further consideration as a process option.

Oxidant-Impregnated Materials

High-surface-area materials impregnated with chemical oxidants such as permanganate may be used to treat VOC-laden vapor waste streams, especially those with VC. Examples of such materials impregnated with permanganate are zeolite and alumina. The VOC-laden waste streams are passed through canisters containing these materials, resulting in rapid oxidation of the VOC contaminants. The lifespan of a canister depends on both the concentration of VOCs and the flow rate of the waste stream. Once expended, the canisters will require replacement and disposal.

Oxidant-impregnated materials are considered to be moderately effective and implementable, primarily due to the emerging status of this technology. The costs of

this technology are considered moderate to high, depending on the required frequency of canister replacement. Oxidant-impregnated materials are therefore retained as a process option.

5.1.3.7 Disposal

Disposal technologies are subdivided into on-Site and off-Site discharge. Two On-Site discharge options were considered for the Campus Area: surface discharge of treated water, and discharge of treatment system off-gas of to the atmosphere. Similarly, two off-Site discharge options were considered for the Campus Area: discharge of treated water to a storm sewer, and discharge of treated water to a local POTW via a sanitary sewer collection system.

On-Site Disposal

Surface Discharge

This option discharges treated groundwater to a surface feature, such as the Riparian Corridor present at the Site. Effluent limits for surface discharge would be determined based on appropriate NPDES discharge permits. It is anticipated that secondary treatment would likely be required to improve the quality of discharge water. Such steps may require polishing to reduce TDS and sulfate concentrations that are elevated in portions of the Campus Area groundwater.

Surface discharge is considered to be a highly effective disposal alternative. This option is moderately implementable because it will require regulatory permitting. The cost of surface discharge could either be moderate to high relative to other discharge options, with the primary factor based on the degree of treatment required under the NPDES permit. Surface discharge is retained as a process option.

Atmospheric Emission

Many of the treatment technologies presented previously in this section transfer contaminants from the liquid to the gas phase. It is possible that, without treatment, the discharge of these contaminants to the atmosphere will exceed state and federal air quality regulations, thereby requiring that the off-gas be treated prior to discharge to the atmosphere. Off-gas treatment is used to remove the contaminants from a vapor stream (e.g., air stripper off-gas) prior to discharge to the atmosphere. Technologies potentially applicable for treating vapors prior to atmospheric emissions were described in Section 5.1.3.6.

Atmospheric emission is considered to be a highly effective disposal alternative, provided that necessary pretreatment of vapors is performed. This option is moderately implementable, as it will require regulatory permitting. The cost of atmospheric emissions is moderate relative to other alternatives. Atmospheric emission is retained as a process option.

Off-Site Disposal

Storm Sewer Discharge

This option discharges treated groundwater to a storm sewer present within or adjacent to the Campus Area. Discharge of treated groundwater would require an NPDES permit and local public works approval, and a sampling program to meet compliance with discharge permit requirements. As stated in Section 2, groundwater generated from construction activities and groundwater sampling efforts is currently discharged to Centinela Channel under NPDES permit #CAG834001. Groundwater generated from remedial actions may be discharged under the existing permit, provided that the treatment will be sufficient to comply with discharge requirements, and the upper limits of discharge flow are not exceeded. Alternatively, the existing NPDES permit may be modified, and/or additional permits may be requested to meet the demands of treated groundwater discharge generated by implementing remedial actions and future changes to construction dewatering, etc.

Storm sewer discharge is considered to be a highly effective disposal alternative. This option is moderately implementable, as it will require regulatory permitting. The cost of storm sewer discharge is moderate relative to other alternatives. Storm sewer discharge is retained as a process option.

Publicly Owned Treatment Works Discharge

Extracted groundwater may be discharged to a local POTW provided that the necessary permits may be obtained from the facility and regulatory agencies. Also, a piping network to such a facility must exist to handle the desired flows. The nearest POTW to the Campus Area is the Hyperion Treatment Plant, which is operated by the City of Los Angeles. The Hyperion Treatment Plant is located immediately southwest of the Los Angeles Airport. Pretreatment of groundwater would likely be required to meet applicable discharge requirements.

The implementability of this process option is quite variable and would depend largely on the feasibility of alternative discharge options (e.g., NPDES discharge), and the flows for which an industrial user's permit from the City of Los Angeles would be acceptable. For low flow rates (e.g., less than 50,000 gallons per day), the implementability would be considered moderate to high, while higher flow a rates would be considered to have a low implementability. The discharge to a POTW has been retained for further consideration, pending further evaluation of the other discharge flows and alternative process options. This option, if allowed, would be highly effective with moderate to high costs depending on the level of pretreatment required.

5.1.3.8 Summary of Retained Technologies and Process Options for Groundwater

The evaluation of retained technologies and process options is based on criteria including effectiveness, implementability, and cost. Table 5-3 summarizes the technologies and process options that were considered, the relative ranking for the three criteria, and whether the alternative was retained or screened from further

consideration. Each of the retained process options is considered for further evaluation in Section 6 as part of the development and description of remedial action alternatives.

5.2 Remedial Technologies and Process Options for Soil

Typically, an evaluation of remedial technologies and process options is performed to identify the preferred remedial technology, as was done with groundwater in previous sections. However, because a majority of the known contaminants are VOCs, SVE is the most appropriate remedial technology. Excavating soil impacted by non-volatile contaminants, such as metals, is also applicable. In addition, excavation is also applicable for removing historical source area equipment (e.g. clarifiers). Excavation and SVE are remediation technologies with long and proven track records for addressing VOCs in soils. In addition, excavation is a proven technology for addressing non-volatile contaminants such as inorganic compounds.

This section describes the tasks associated with using excavation and/or SVE. Detailed explanations and plans for each source area requiring remediation of soil are presented in Section 8. In addition to the active soils remediation to be accomplished via excavation and/or SVE technologies, infiltration of direct precipitation and runoff will be impeded by a number of features of site development. Development features including buildings, asphalt roadways, and concrete areas all serve to restrict the percolation of water at the ground surface. In this manner, the potential for leaching of limited residual contamination that may remain after active remediation will be further reduced. Because these features of the Campus Area development are not explicit components of the soils or groundwater remediation, they are not quantitatively evaluated herein. Their contribution to the protection of the groundwater resource should be fully acknowledged, however.

5.2.1 Soil Vapor Extraction

SVE removes VOCs from soil without excavation and will be used in situations where excavation of soil is insufficient or not feasible to meet ROs. SVE may be considered for use alone, or in conjunction with, excavation activities. DPE, which was considered in Section 5.1.3.5 and retained for further consideration, combines SVE with groundwater extraction at a single extraction well.

An SVE (and DPE) system typically consists of a blower, a control panel, an air-water separator, a particulate filter, valving, gauges, piping, and a vapor treatment system. The type of vapor treatment system selected is based on the nature and concentrations of the contaminants. Petroleum hydrocarbons can be treated with catalytic or thermal oxidizers or granular activated carbon (GAC) vapor treatment vessels. Chlorinated hydrocarbons may require additional off-gas treatment for hydrochloric acid with oxidizers, or additional treatment for VC, if present, with GAC and oxidant-impregnated material vessels (Section 5.1.3.6). A schematic of a typical DPE extraction system is provided in Figure 5-1, *Schematic of Dual Phase Extraction System.*

An SVE extraction system would be similar to that of a DPE extraction system, although the screened interval would be limited to the unsaturated zone soils and no groundwater extraction or treatment would be occur.

An SVE (and DPE) system requires the installation of extraction wells within or near the zone of contamination. SVE wells would be installed at each appropriate location, along with vadose zone monitoring points to measure the vadose zone area of influence.

SVE (and DPE) is considered to be moderately to highly effective because it has the potential of meeting all ROs for unsaturated portions of the upper Bellflower aquitard, provided that the lithology of this unit is permeable enough to allow for an effective vapor extraction flow rate. The implementability of SVE (and DPE) is moderate, with the collection and treatment of off-gas vapors and groundwater (DPE only) requiring treatment and regulatory permit. The cost of SVE is considered moderate.

The no-action response was retained as a baseline alternative.

Section 6
Development of Remedial Alternative

The purpose of this section is to develop remedial alternatives to address soil and groundwater contamination within the Campus Area. The remedial alternatives for groundwater are formed by using combinations of general response actions, remedial technologies, and process options that survived the screening processes in Section 5. Remedial alternatives for soil include either excavation or SVE, which were the two methods considered appropriate for active remediation of soils within the Campus Area. The description of the remedial alternatives presented in this section provides a conceptual-level understanding of each alternative, sufficient to allow comparison of the alternatives in Section 7. The selected remedial alternative is developed in more detail in Section 8.

6.1 Development of Remedial Alternatives for Groundwater

The retained general response actions, remedial technologies, and process options for groundwater from the screening processes in Section 5, (summarized in Table 5-3) are:

- No Further Action;
- Monitored Natural Attenuation (includes monitoring and evaluating a variety of naturally-occurring physical, chemical, and biological processes);
- Institutional Controls (includes use restrictions (e.g., use and deed restrictions) and public education to limit exposure to potentially impacted media);
- Hydraulic Containment (includes source area capping and stormwater diversion and control measures to limit surface water recharge and contaminant mobility);
- Groundwater Collection/Extraction (includes groundwater extraction wells and/or DPE wells to remove contaminant mass in groundwater and/or soils and control contaminant migration);
- Treatment (in situ treatment via enhanced biodegradation, and ex situ treatment of various wastes using air stripping, UV-enhanced chemical oxidation, activated carbon adsorption, and oxidant-impregnated materials); and
- Disposal (includes on-Site discharge of treated groundwater, and discharge of treatment system off-gas to the atmosphere, as well as off-Site discharge of treated water to a storm sewer, and discharge of groundwater to a local POTW).

These retained remedial technologies and process options were combined to create four remedial alternatives for the Campus Area groundwater:

1. No Further Action;

2. Monitored Natural Attenuation;

3A. Enhanced Biodegradation in Source Areas and Monitored Natural Attenuation Downgradient (Note the term "Downgradient" refers to those portions of the Campus Area that are hydraulically downgradient of the former Plant Site from where the source areas are located); and

3B. Groundwater Extraction in Source Areas and Monitored Natural Attenuation Downgradient

6.2 Description of Alternatives for Groundwater

Process options contained within each alternative are shown in Table 6-1, *Remedial Technologies and Process Options Comprising the Remedial Alternatives*. In some instances, the process options are common to all of the alternatives, while in other cases; the process options are common to only one or two alternatives. The process options included in the alternatives are described in the following sections.

6.2.1 Process Options Common to Each Alternative

6.2.1.1 Use Restrictions

Use restrictions for the Campus Area exist, and are being updated currently to add explicit restrictions on groundwater use. For each alternative presented in this section, these use restrictions will explicitly restrict groundwater use within the Campus Area during and after construction and implementation of all components of the remedial alternative.

Prospectively, PCC anticipates that other deed restrictions, CC&Rs and/or or negative easements may be implemented that would apply to the ownership or use of the property and further restrict potential uses and activities on the Site to prevent potential exposure.

6.2.1.2 Source Area Capping and Stormwater Diversion and Control

As part of the Campus Area development, a reduction in surface water infiltration is expected through various source area capping and storm water diversion and control measures. Capping will be accomplished through the construction of new buildings and infrastructure (e.g., parking structures, sidewalks, and roads). Similarly, construction of storm water drains and surface grading and other storm water management completed as part of the development will limit surface water run-on near source areas. Both measures will reduce surface water infiltration that during conditions of high rainfall otherwise accumulates and percolates through the soils, a circumstance which increases the mobility of contaminants. Thus, these measures

will limit the mobility of contaminants in source area soils and their vertical migration to groundwater.

6.2.2 Alternative 1 - No Further Action (Includes Monitoring)

The no further action alternative provides a baseline for comparison to other alternatives. In this alternative, by definition, no remedial actions are taken to control groundwater contaminant migration from or within the Campus Area, with the exception of capping and stormwater diversion and control measures which will occur as part of the Campus Area development.

6.2.3 Alternative 2 - Monitored Natural Attenuation

MNA is an *in situ* remedial technology that relies on the natural fate and transport, and attenuation, processes to mitigate contaminant concentrations. The effectiveness of the MNA technology is evaluated through groundwater monitoring of contaminant concentrations. Contaminant mass bound to saturated soils and in groundwater is expected to decrease with time under MNA.

A brief evaluation of the fate and transport of contaminants, including natural attenuation processes occurring within the Campus Area, is presented in Sections 2.4 and Appendix E. Because the fate and transport properties, and therefore the attenuation characteristics, of the two main water-bearing units (i.e., Bellflower aquitard and Ballona aquifer) are significantly different, the two units are described separately in the following subsections. Additional remedial actions for groundwater (e.g., groundwater extraction) are not considered under this alternative; however, remedial actions for soils would be addressed, as necessary, through excavation or SVE (Section 6.3).

6.2.3.1 MNA in the Bellflower Aquitard

The primary mechanisms for natural attenuation within the Bellflower aquitard appear to be biodegradation and retardation. MNA would be an effective remedial technology provided that the integrated effects of natural attenuation mechanisms bring about a reduction in contaminant mass and attenuation of COC concentrations below levels of concern. Under this alternative, groundwater data would be collected to document the active processes in contaminant mass reduction/attenuation and to predict the future migration and concentrations of COCs in the groundwater.

As presented in Section 2, both a low flow setting and biotransformation of VOCs have contained the majority of the contaminant plume in close proximity to the source areas in the Bellflower aquitard. The generally high organic content (see data in Appendix C) and low permeability of the soils in this unit appear to have limited the contaminant plume from significant horizontal migration in this unit. However, the contaminant plume has moved vertically into the relatively more permeable Ballona aquifer, and subsequent lateral contaminant movement has occurred in this unit.

After collecting initial data required to predict future contaminant migration or attenuation, a long-term monitoring plan is required for MNA. The long-term monitoring would be used to document and verify the predictive results. Assuming a sufficient number of monitoring wells exist to document the migration and fate of the contaminant plume, Bellflower aquitard monitoring wells located between the Campus Area perimeter and the former Plant Site (e.g., wells C-80be through C-83be) would serve as sentinel wells to document that the limited horizontal contaminant plume in this water-bearing unit does not migrate to the property boundary. Sampling and groundwater analyses under an approved monitoring program would be conducted semi-annually. Because groundwater movement in this unit is expected to be only approximately 10 to 20 feet between sampling events (or approximately 20 to 40 feet/years) based on hydraulic conductivity data from Section 2, and the contaminants would be further retarded by the generally impermeable silty-sand and high organic soils. Monitoring would collect data for VOCs, electron acceptors, metabolic byproducts, and potential electron donating compounds.

6.2.3.2 MNA in the Ballona Aquifer

Groundwater contamination from the Bellflower aquitard has also migrated vertically into the Ballona aquifer, where the primary mechanisms for natural attenuation are significantly different. By contrast, the soluble contaminants are not significantly retarded in the gravel-sand lithology of the Ballona aquifer. The comparatively lower organic carbon content of soils (generally an order of magnitude lower than found in the Bellflower aquitard – Appendix C) helps to explain the decreased retardation in the Ballona aquifer. In addition, preliminary evaluations (Section 2.4 and Appendix E) suggest that only limited biodegradation may be occurring once the contaminants enter the Ballona aquifer. This condition is likely due to the low concentration and rapid biological utilization of dissolved organic carbon (DOC) entering the Ballona aquifer simultaneously with the VOCs, as well as elevated concentrations of sulfate that interfere with reductive dechlorination reactions.

Although contaminants are not significantly retarded in the Ballona aquifer, the relatively low organic content and high permeability soils of the Ballona aquifer allow for rapid dispersion. VOCs are attenuated as the plume migrates downgradient in the Ballona aquifer, and have not migrated vertically below the Ballona aquifer to any significant extent.

Under this alternative, additional information would be collected to assess the level of natural attenuation that is occurring in the Ballona aquifer. The most significant attenuation mechanism in the Ballona aquifer appears to be dispersion through horizontal transport in this aquifer, and to a lesser extent, biodegradation and adsorption.

After establishing the rates of attenuation by the various mechanisms active within the Ballona aquifer, long-term monitoring will collect data to simulate the fate and transport of the contaminant plume and to predict the future extent of contaminants concentrations. Simple analytical models should be sufficient to predict the two-

dimensional transport of the contaminant plume in this semi-confined aquifer. Assuming a sufficient number of monitoring wells exist to document the migration and fate of the contaminant plume, perimeter wells in the Ballona aquifer would serve as sentinel wells. Sampling and groundwater analyses under an approved monitoring program would be conducted semi-annually and would include analyses for VOCs, electron acceptors, metabolic byproducts, and potential electron donating compounds. Groundwater movement in this zone is expected to be approximately 15 to 50 feet between sampling events (or approximately 35 to 100 feet/year), and because of lower retardation factors in this gravel and sand aquifer, higher advective movement of the contaminant plume is expected.

Results from this monitoring would be used to trigger contingency remedial evaluations or actions if elevated concentrations of VOCs than expected migrate into areas of lower VOC concentrations (see Section 9). Under this MNA alternative, if such a trigger threshold were exceeded, the remedial actions described below for Alternatives 3A and B would be implemented.

6.2.4 Alternative 3A – Enhanced Biodegradation in Source Areas and MNA Downgradient

Alternative 3A includes all of the elements of Alternative 2 and adds EAB treatment to the source areas in the Bellflower aquitard and the areas of vertical migration in the Ballona aquifer. EAB is a groundwater remedial technology that requires injecting sufficient biodegradable organic carbon (electron donor) into an aquifer to stimulate the rapid reductive dechlorination of VOCs. By inducing highly reduced groundwater conditions, EAB may improve both the extent and rate of dechlorination reactions. The available data indicate a microbial community exists that is capable of dechlorinating COCs (e.g., TCE and 1,1,1-TCA) to innocuous end products such as ethene and ethane. A key assumption is that the Campus Area groundwater has relatively low levels of competing electron acceptors, such that only a minimal addition of organic compound is necessary to achieve and sustain a highly reduced groundwater environment. Otherwise, EAB may not be cost-effective.

This alternative focuses on the *in situ* reduction of contaminant mass in both aquifers to achieve ROs. EAB within source areas would reduce the contaminant mass in the Bellflower aquitard and consequently, reduce VOC mass migration into the Ballona aquifer. In the Ballona aquifer, EAB would reduce VOC migration downgradient by reducing the mass at locations where it enters from the overlying Bellflower aquitard. Thus, EAB would be implemented only at points where VOC mass migrates vertically into the Ballona aquifer. MNA would be implemented in downgradient areas of the contaminant plume.

The brief evaluation of biogeochemistry parameters presented in Section 2.4 and Appendix E has been used to assess the potential for implementing this alternative. As described for Alternative 2, the hydrogeology and biogeochemistry of the Bellflower aquitard and Ballona aquifer are significantly different and, therefore, the

rate and extent of enhanced reductive dechlorination would be different. Therefore, EAB for each of the two units is described separately in the following subsections.

6.2.4.1 Enhanced Anaerobic Biodegradation in the Source Areas Bellflower Aquitard

This alternative would include injection of a concentrated electron donor solution (e.g., sodium or ethyl lactate) in the generally silty-sand, high-organic content soils within the source areas. The conceptual design assumes a delivery radius of influence of approximately 10 feet using injection wells, or a larger treatment zone through the use of recirculation wells. The actual injection method would be determined during remedial design activities and would be dependent on the source area hydrogeologic conditions within the saturated regions of the upper and lower Bellflower aquitard. Sulfate concentrations in the Bellflower aquitard are generally in excess of 1,000 mg/L (see Appendix C); thus, it is anticipated that optimal treatment would take several months to sufficiently lower this competing electron acceptor to allow more rapid detoxification. Electron donor concentrations from a single injection are expected to persist in the Bellflower aquitard for several months due to low transport potential from the target area. The actual injection frequency and radius of influence would be determined during the remedial design. It is anticipated that enhanced biodegradation of VOCs would be evident within a 6-month period.

Evaluation of the effectiveness of EAB requires monitoring for declining sulfate and VOC concentrations to measure the shift of contaminant mass to the detoxification products, ethene and ethane. The conceptual design includes five new monitoring wells in the Ballona aquifer and five new wells in the Bellflower aquitard to monitor the reduction in contaminant mass, changes in biogeochemistry of the groundwater near the source areas, and distribution of the substrate over the contaminated area. Sampling and groundwater analyses would be conducted quarterly for the first year, then semi-annually until ROs are achieved. These analyses would include VOCs, electron acceptors, metabolic byproducts, and potential electron donating compounds under an approved monitoring program. In addition, MNA sampling would be conducted at monitoring wells in the downgradient plume, but not the source wells, as described under Alternative 2.

6.2.4.2 Enhanced Anaerobic Biodegradation in the Source Area Ballona Aquifer

EAB in the Ballona aquifer targets contaminant concentrations in the gravel/sand below the source areas in the Bellflower aquitard. This alternative includes an array of injection wells screened in the gravel/sand of the Ballona aquifer beneath the source areas, or the use of recirculation wells.

Under the injection array scenario, electron donor solution (e.g., sodium or ethyl lactate) would be injected with water to dilute the electron donor concentration and drive it from each injection point. Current estimated groundwater velocities in the Ballona aquifer range from 0.2 to 0.6 feet/day. Under this flow range, it is assumed that the dispersion and biotransformation of electron donor would require re-injection

of high strength lactate every 120 days. Electron donor solutions would be injected at concentrations not to exceed 2,000 mg/L *in situ*. The injection arrays would be plumbed in series to allow equal distribution of substrate by a pump from a holding tank. Periodic injections would not require a storage tank. The actual injection concentration and timeframe would be determined with data from pump tests performed during the remedial design.

An engineering design test would be required to determine the rate of substrate utilization and dispersion through the aquifer. This test would likely operate for a period of several months. Data collected would include sulfate reduction rate, substrate utilization rate, and production of detoxification products (e.g., ethene and ethane).

Evaluation of EAB for this alternative includes monitoring for declines in sulfate and VOC concentrations with a continual shift of contaminant mass to the detoxification products, ethene and ethane. The conceptual design includes five new downgradient monitoring wells in the Bellflower and five new wells in the Ballona to monitor for the reduction in contaminant mass, changes in biogeochemistry of the groundwater, and distribution of the substrate over the contaminated area. Sampling and groundwater analyses would be conducted quarterly for the first year and semi-annually until ROs are achieved. These analyses would include VOCs, electron acceptors, metabolic byproducts, and potential electron donating compounds under an approved monitoring program. In addition, MNA sampling would be conducted at monitoring wells in the downgradient plume, but not the source wells, as described under Alternative 2.

6.2.4.2 Enhanced Anaerobic Biodegradation in Vadose Zone Soils

Under this alternative, two approaches would be evaluated for remediating those source areas that have vadose zone soils above HBRGs. Preferably, EAB would be implemented in such a way as to target the vadose zone soils. This could be done by injecting the amendments above the targeted soils and allowing infiltration of the amendment to enhance biodegradation of the vadose zone contaminants *in situ*. Alternatively, SVE would be used for vadose zone treatment at these source areas. The selection of the most appropriate approach would be made during the RD.

6.2.5 Alternative 3B – Groundwater Extraction in Source Areas and MNA Downgradient

Alternative 3B consists of the MNA elements described for Alternative 2 together with groundwater extraction in source areas.

Source Area Groundwater Extraction

Groundwater extraction under this alternative is intended to remove VOC mass from groundwater associated with identified source areas. Although the extraction wells would be located primarily for mass removal purposes, they would also be sited to contain contaminant migration as a secondary objective. VOC mass removal has

distinct and quantifiable advantages to enhance VOC plume control by reducing high concentrations of VOCs within the source areas.

The final design for the extraction system would be determined through data collection, modeling, and evaluation efforts during the remedial design. A conceptual approach has been developed for a groundwater extraction and treatment program for this alternative evaluation. The conceptual extraction system consists of three types of extraction wells: one for the upper Bellflower aquitard, one for the lower Bellflower aquitard, and one for the Ballona aquifer. In some instances, DPE would be used to address vadose zone and saturated zone remediation concurrently with groundwater remediation.

Upper Bellflower Aquitard
DPE would be used to extract groundwater from the uppermost water-bearing unit. DPE has the advantage of not only extracting groundwater, but also further removing VOCs from previously saturated soils via volatilization within an induced cone of depression. In addition, if VOCs were present within the vadose zone in the vicinity of the DPE well, they would be removed via the vapor extraction effects of DPE. This remediation of vadose zone soils would protect further contamination from the underlying groundwater. To monitor performance of DPE, new monitoring wells screened in the upper Bellflower aquitard and a limited number of vapor monitoring points would be installed. The number and location of DPE wells, performance monitoring wells, and vapor monitoring points would be determined by the extent of soil contamination above remediation trigger values.

DPE engineering design testing would be required at the time of implementation to collect design data concerning the achievable ZOI at different extraction rates. For the purposes of this RP, it is assumed that a ZOI of 20 feet is achievable at a groundwater extraction rate of approximately 1 gpm and a vapor extraction rate of approximately 50 standard cubic feet per minute (scfm) per DPE well. The assumed drawdown of water table would be approximately 7 feet at the DPE well.

Several design assumptions have been made about the layout and size of the DPE system in order to evaluate the cost of this component of the alternative. The remedial design would revisit these assumptions subsequent to collecting additional groundwater data with considering Campus Area construction plans that would be available during design activities. Conceptually, there would be the option for a central vapor treatment unit housed within the groundwater treatment system or satellite treatment systems depending on technical feasibility, cost, and development needs. Extracted groundwater and vapors would be piped to treatment systems for processing. Blowers would be used for vapor extraction and be capable of inducing a vacuum of approximately 15 inches of mercury at the wellhead.

Lower Bellflower Aquitard
It has been assumed that an extraction rate of 5 gpm is required to achieve a capture zone of approximately 100 feet per well within the lower Bellflower aquitard. Extracted groundwater would be conveyed in pipelines to a new treatment plant (described below). The location of wells and piping would take into account development plans and would be coordinated with the project developer.

Ballona Aquifer
For this unit, it has been assumed that a pumping rate of 25 gpm is needed to produce a groundwater capture zone approximately 1,300 feet in diameter.

Groundwater and Vapor Treatment
As discussed in Section 5.1, extracted groundwater would be discharged either for reuse in the Riparian Corridor, the current, permitted storm sewer discharge into Centinela Creek Channel (east of Centinela Avenue and south of Teale Street), or to a POTW. Additional analysis would be performed during remedial design to select the discharge option and to determine the type of treatment that would be required.

Currently, there is a groundwater treatment plant located to the north of Buildings 1 and 2 in the Campus Area. This plant is treating groundwater that is produced from construction dewatering and groundwater sampling activities. It is assumed, however, that this plant would not be available for use in this alternative. Instead a new treatment plant would be constructed in the Campus Area.

For alternative costing and evaluating purposes, it is assumed that extracted groundwater would be treated, as necessary depending on ultimate disposal requirements, for VOC removal using shallow tray air strippers with vapor treatment by activated carbon adsorption. Because VC is poorly adsorbed on carbon, the activated carbon unit vapor effluent would flow through a second unit containing zeolite coated with potassium permanganate. The permanganate units would remove VC in the vapor phase by chemical oxidation. It should be noted that some contaminants exist in groundwater that may not be effectively treated using air stripping technologies, such as 1,2-DCA and MC. However, these contaminants are only observed in localized areas and occur at low enough concentrations such that air stripping methods on a combined waste stream may be sufficient for treatment. If, however, air stripping is demonstrated to be not adequate, additional treatment may be required to address such contaminants (e.g., wellhead treatment at select locations using oxidative technologies).

For air stripper off-gas, two parallel vapor treatment units would be used. The vapor treatment units would be sized to treat vapors from both the DPE system and off-gassing from the air strippers (if centrally treated). The total vapor flow would be divided into two streams, each processed by activated carbon units in series and a single zeolite/potassium permanganate unit for VC polishing.

6.3 Development of Remedial Alternatives for Soil

As described earlier, the majority of the known contaminants are VOCs and would be addressed using SVE, or DPE, as the preferred remedial technology. However, soil impacted by non-volatile contaminants, such as inorganic compounds (e.g., metals), would be addressed using excavation. Excavation would also be performed, as appropriate, to remove any historical source area equipment (e.g., clarifiers). As noted previously in Section 5.1, the effectiveness of soil remediation will be further enhanced by various "capping" features of the Campus Area development, including buildings, roadways, and selected landscaped areas. Although not an actual component of the remedial measures discussed in this RP, the benefits of impeding the infiltration of precipitation or surface water are an important consideration in the overall protectiveness of the remedies.

Remedial actions for soil impacted with VOCs would be addressed using SVE (or DPE), as appropriate. SVE would be applied to the unsaturated portion of the upper Bellflower aquitard, while DPE would be applied to both the unsaturated and saturated portions of the upper Bellflower aquitard as described in Section 6.2. This remediation of vadose zone soils would be protective of further contamination of the underlying groundwater. To monitor performance of SVE, vapor monitoring points would be installed. If DPE were implemented, then additional monitoring wells screened in the upper Bellflower aquitard may be installed to monitor groundwater, as necessary. The number and location of SVE/DPE wells, vapor monitoring points, and performance monitoring wells would be determined by the extent of soil contamination above LSRT values.

SVE/DPE engineering design testing would be required during remedial design to collect design data concerning the achievable ZOI at different extraction rates. For the purposes of this RP, it is assumed that a ZOI of 20 feet for the SVE system, or vapor portion of the DPE system would be achieved. It is assumed that the vapor extraction rate would be approximately 50 scfm per DPE well.

The remedial design would revisit the above assumptions subsequent to the collection of additional data and with consideration of Campus Area construction plans that would be available during design activities. Conceptually, there would be either a central vapor treatment unit housed within the groundwater treatment system or satellite treatment systems (depending on cost and/or development needs). Extracted vapors (and groundwater) would be piped to treatment system(s) for processing. Blowers would be used for vapor extraction, each capable of inducing a vacuum of approximately 15 inches of mercury at the wellhead. Vapor treatment would be accomplished by the methods described in Section 6.2.5.

Excavation would be performed to address non-volatile contaminants (e.g., metals) or removal of source area equipment, as needed. The proposed areas of excavation would be based on the data obtained from the existing investigations. Additional information regarding the necessary depths and areal extents of excavations would be obtained during the implementation of the proposed remedial actions, which would

be used to supplement and guide the excavation activities, as appropriate (see Section 5.2). Based on field screening and confirmatory soil sampling results, the excavations may be extended laterally and vertically.

Section 7
Evaluation of Remedial Alternatives

This section evaluates remedial alternatives developed in Section 6 with regard to seven evaluation criteria based on similar criteria used for CERCLA remedial actions. Although CERCLA is not applicable to this Site these criteria provide a meaningful approach for evaluating the remedial alternatives developed in Section 6.

The seven criteria for comparing the developed alternatives are:

- Overall protection of human health and the environment;
- Compliance with ROs;
- Long-term effectiveness and permanence;
- Reduction of toxicity, mobility, or volume through treatment;
- Short-term effectiveness;
- Implementability; and
- Cost

The seven evaluation criteria fall into two categories, namely threshold criteria and primary balancing criteria. Threshold criteria are requirements that each alternative must meet to be eligible for selection as the preferred alternative. Threshold criteria include overall protection of human health and the environment and compliance with ROs. Primary balancing criteria are used to weigh relative effectiveness and cost among alternatives. These balancing criteria are long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability; and cost.

The application of all of the criteria to the four alternatives are discussed below and the results of this evaluation are summarized in Table 7-1, *Groundwater Remedial Alternatives Seven Criteria Evaluation Matrix.*

- Alternative 1 – No Further Action;
- Alternative 2 – Monitored Natural Attenuation;
- Alternative 3A – Enhanced Biodegradation in Source Areas and Monitored Natural Attenuation Downgradient;
- Alternative 3B – Groundwater Extraction in Source Areas and Monitored Natural Attenuation Downgradient;

7.1 Protection of Human Health and the Environment

This evaluation criterion addresses the ability of each alternative to adequately protect human health and the environment. The assessment of overall protection also draws on the assessments conducted using other evaluation criteria, especially long-term effectiveness and permanence, and short-term effectiveness.

Each alternative is evaluated against this criterion to determine whether specific elements of each alternative eliminate, reduce, or control risks posed by exposure via potential complete exposure pathways.

Evaluation of Alternatives

Alternatives 1 and 2 provide the least protection for human health and the environment. Neither alternative has an active engineered component that provides source reduction nor migration control of contaminated groundwater. However, as long as institutional controls regarding groundwater use are in effect, there would not be an increase in the long-term potential for human exposure through groundwater use. Under these alternatives, groundwater contaminants would potentially be allowed to further migrate vertically and downgradient into the Ballona aquifer. However, Alternative 2 includes groundwater monitoring that would provide early warning of contaminant migration at downgradient monitoring wells. Alternative 2 would also fully quantify and document the reductions of VOC mass as a result of the various physical, chemical and biological processes that are inherent to MNA. Although such documentation may indicate significant mass reduction with time, Alternative 2 would rate lower than Alternatives 3A and 3B on a relative scale because it does not include an active engineered component. An advantage of Alternatives 1 and 2 is that there are no risks associated with treatment residuals, because none are created. The relative overall rating for protection of human health and the environment for Alternative 1 is low, and low to moderate for Alterative 2.

Compared to Alternatives 1 and 2, Alternatives 3A and 3B would provide significant reduction in long-term risks to human health and the environment by removing contaminant mass from the source areas, which will result in long-term decreases in VOC concentrations in downgradient areas. MNA would be applied at downgradient locations to fully quantify and document the reductions of VOC mass at downgradient locations and verify the overall protection of human health and the environment. The relative overall rating for protection of human health and the environment for Alternatives 3A and B is high.

7.2 Compliance with Remedial Objectives

This evaluation criterion addresses whether each alternative would meet ROs for soils or groundwater in the Campus Area. The ROs developed in Section 3 have two primary objectives: (1) protection of human health, and (2) protection of the groundwater resource. Because the ROs established for protection of human healthhave the same objective as the first evaluation criterion, the first and second

criteria are essentially the same. This second threshold criterion, therefore, is only meaningful with respect to the resource protection ROs.

Evaluation of Alternatives

Alternatives 1 and 2 do the least to meet the ROs, because neither alternative has an active component to address source area remediation, and both alternatives would allow potential further migration of contaminants. The relative overall rating for compliance with ROs for Alternatives 1 and 2 is low.

Alternatives 3A and 3B have active components designed to meet ROs in source areas, with MNA applied to the downgradient portions of the Campus Area. The main difference between these alternatives is the technology used to reduce VOC mass at source locations (3A uses enhanced biodegradation and 3B uses groundwater extraction, and DPE if applicable). Under Alternative 3B, groundwater extraction at source locations with a DPE component would be accompanied with removal and treatment of soil vapors, which would provide an immediate and added level of conservatism for meeting ROs. Alternatives 3A and 3B would meet the ROs for protection of human health. The relative overall rating for compliance with ROs for Alternatives 3A and 3B is high.

7.3 Long-Term Effectiveness and Permanence

The evaluation of alternatives under this criterion assesses the results of a remedial alternative in terms of the risk remaining within the Campus Area after ROs are met. The primary focus of this evaluation is the extent and effectiveness of the controls that may be required to manage the risk posed by treatment residuals and/or untreated wastes.

Untreated waste primarily refers to groundwater contaminants not removed from the aquifer. Treatment residuals would include spent carbon or oxidant-impregnated material canisters, if used for VOC removal. Remaining risk associated with VOC contaminants not removed from the aquifer relates to the effectiveness of each alternative at preventing or reducing contaminant migration and meeting ROs. Also considered in evaluating the performance of each alternative is the relative magnitude of treatment residuals. The actual types and magnitude of the treatment residuals would depend on the type of treatment technology used.

Evaluation of Alternatives

Alternatives 1 and 2 are ranked lowest for this criterion because neither alternative has an active engineered component that provides migration control or VOC mass reduction at source locations. Although natural attenuation processes (e.g., adsorption, dispersion, and biodegradation) would continue to attenuate contaminant concentrations in the Bellflower aquitard, the rates of attenuation are likely too slow to fully prevent vertical migration and influx of contaminants into the Ballona aquifer without some form of active source control. Thus, contaminated groundwater would potentially continue to migrate vertically from the Bellflower

aquitard to the Ballona aquifer in source areas, and horizontally in the Ballona aquifer in downgradient areas. The potential for further downgradient contaminant migration in the Ballona aquifer exists, although this plume may be currently under steady-state conditions as the result of natural attenuation processes. One other factor: Alternatives 1 and 2 would not generate any treatment residuals. Nonetheless, the relative overall rating for long-term effectiveness and permanence for Alternatives 1 and 2 is low.

Alternative 3A employs enhanced biodegradation to provide VOC mass reduction at source locations. While enhanced biodegradation would result in lower mass of VOCs in the source areas, this alternative could potentially result in limited amounts of untreated mass migrating downgradient of the source areas. However, the risk associated with such migration would be minimal because groundwater contaminants do not exceed HBRG values in downgradient portions of the Campus Area. Regardless, MNA would be employed at downgradient locations to document the extent of VOC migration and mass removal. No treatment wastes would be generated under this alternative.

Under Alternative 3B, groundwater extraction at source locations would result in a reduction of VOC mass at source locations. Similar to Alternative 3A, Alternative 3B would employ natural attenuation processes at downgradient locations. Given the current understanding of MNA in the Campus Area, this would result in a limited amount of untreated mass migrating downgradient of the source areas. In either case (Alternative 3A or 3B), MNA would ensure that any untreated mass migration from source areas is being reduced by naturally occurring processes.

Under Alternative 3B, the primary residual waste generated would likely be spent GAC and zeolite/potassium permanganate from treatment of contaminated groundwater and extracted vapors. The spent GAC and zeolite could potentially be reactivated off-Site. The transportation and reactivation of this residual would be conducted in accordance with applicable regulations and would present minimal long-term risks because contaminants adsorbed to the GAC would be destroyed during the reactivation process. The amounts of treatment residuals produced would be proportional to the contaminant mass-loading rate (i.e., function of contaminant concentrations and flow rates).

The relative overall rating for long-term effectiveness and permanence for Alternatives 3A is high, and moderate to high for Alternative 3B. The difference in ratings reflect the absence of residual wastes generated under Alternative 3A as compared to 3B.

7.4 Reduction of Toxicity, Mobility or Volume Through Treatment

This evaluation criterion addresses the preference under CERCLA guidance for selecting remedial actions that employ treatment technologies that permanently and

substantially reduce toxicity, mobility or volume of the hazardous substances as their principal element. This preference is satisfied when treatment is used to reduce the principal threats at a site through destruction of toxic contaminants, irreversible reduction in contaminant mobility, or reduction of total volume of contaminated media.

This evaluation for each remedial alternative focuses on the following factors:

- The treatment processes and the materials to be treated;
- The degree of expected reduction in toxicity, mobility or volume;
- The degree to which treatment is irreversible;
- The type and quantity of treatment residuals that would remain following treatment;
- The amount of material that would be destroyed or treated.

Evaluation of Alternatives

Under Alternatives 1 and 2, standing alone, no active treatment would be employed to reduce the toxicity, mobility, or volume of contaminants, although naturally-occurring processes would continue to meet these objectives to a limited extent. The relative overall rating for long-term effectiveness and permanence for Alternatives 1 and 2 is low.

Enhanced biodegradation would be used to address VOC contamination at source locations under Alternative 3A, while Alternative 3B would employ groundwater extraction to accomplish the same goal. Both alternatives would incorporate MNA for downgradient treatment. If enhanced biodegradation were to perform optimally, biodegradation could potentially remove more contaminant mass than groundwater extraction technologies. If conditions for enhanced biodegradation could not be maintained properly, then groundwater extraction would most likely remove more VOC mass. It is important to note that incomplete biotransformation reactions could potentially increase the toxicity of contaminants (e.g., through accumulation of toxic intermediates such as VC). Complete biotransformation reactions, however, would result in the irreversible destruction of contaminants to innocuous end-products *in situ*, without the production of any residual wastes to dispose of at the surface. For comparison purposes, it has been estimated that enhanced biodegradation and groundwater extraction would result in a similar contaminant mass reduction.

The relative overall rating for this criterion is high for Alternatives 3A and 3B.

7.5 Short-Term Effectiveness

This evaluation criterion addresses the effects of the alternative during the construction and implementation phase until ROs are met. The following factors are addressed for each alternative:

- Protection of workers and the community. This factor examines risk that results from the construction and implementation of the proposed remedial action and the effectiveness and reliability of protective measures;
- Environmental impacts. This factor addresses potential adverse environmental impacts that may result from the construction and implementation of an alternative. This factor also evaluates the reliability of the available mitigation measures to prevent or reduce potential impacts; and
- Time until ROs are achieved. This factor estimates the time period that would be required to meet ROs.

Evaluation of Alternatives

Alternatives 1 and 2 do not have significant proactive measures and therefore score low with respect to short-term effectiveness. Alternative 1 has no construction or implementation phase. Alternative 2 does pose slight risks to the workers during construction of new monitoring wells; however, these risks are easily addressed and are not beyond general construction hazards associated with construction projects, and other remedial alternatives considered in this evaluation. Because of the limited construction activities, no significant environmental impacts are expected from Alternatives 1 or 2. These two alternatives score low for short-term effectiveness.

Under Alternative 3A, enhanced biodegradation would be used to reduce VOC mass at source locations. Enhanced biodegradation of chlorinated VOCs requires an acclimation time to overcome the presence of alternative electron acceptors such as sulfate, and would require preliminary testing to provide a basis for design of this technology given the elevated sulfate concentrations. Therefore, the short-term effectiveness is ranked lower for this alternative than for Alternative 3B, which incorporates groundwater extraction and treatment in source areas. It should be noted that enhanced biodegradation may achieve a greater reduction of VOC mass than obtained by groundwater extraction in the long-term. The relative overall rating for short-term effectiveness is moderate to high for Alternative 3A.

Under Alternative 3B, groundwater extraction in addition to soil vapor extraction (through SVE and/or DPE) would occur at source locations. The immediate removal and treatment of soil vapors, in areas of both soil and groundwater concern, using DPE would likely provide an engineered component with short-term benefits in the vadose zone. While EBG would provide greater long-term benefits, the relative overall rating for short-term effectiveness is high for Alternative 3B largely because of the ability of DPE to remove contaminant mass immediately upon startup.

7.6 Implementability

This evaluation criterion addresses the technical and administrative feasibility of implementing an alternative and the availability of various services and materials required during its implementation. The evaluation of this criterion would consider the following factors:

- Technical Feasibility
  - Construction and Operation - This relates to the technical difficulties and unknowns associated with a technology;
  - Reliability of Technology - This focuses on the likelihood that technical problems associated with implementation would lead to schedule delays or render a selected technology inappropriate or ineffective;
  - Ease of Undertaking Additional Remedial Actions - This includes consideration of potential future additional remedial actions and whether the alternative would interfere or assist in the implementation of additional remedial actions; and
  - Monitoring Considerations - This addresses the ability to monitor the effectiveness of the remedial action and an evaluation of risks of exposure should monitoring be insufficient to detect a system failure.
- Administrative Feasibility
  - Coordination with other agencies, including the need for agreements with parties other than RWQCB for construction and operation of the remedy (e.g., grading permits).
- Availability of Services and Materials
  - Availability of necessary equipment, specialists, and provisions to ensure any necessary additional resources; and
  - Availability of services and materials plus the potential for obtaining competitive bids.

Evaluation of Alternatives

Technical Feasibility: Construction and Operation

The groundwater extraction, treatment, and conveyance technologies included in Alternatives 3B, and the monitoring technologies included in Alternatives 2, 3A, and 3B are widely used. No significant difficulties are expected in construction and operation of these technologies. The enhanced biodegradation components of Alternative 3A would require preliminary *in situ* testing to determine whether conditions can be produced within the formations in a timely fashion to implement

enhanced biodegradation given the elevated concentrations of competing electron acceptors (e.g., sulfate).

Technical Feasibility: Reliability of Technology
The groundwater extraction, treatment, conveyance and monitoring technologies in Alternative 3B are generally known to be proven and reliable. For enhanced bioremediation, if preliminary testing results indicate that the delivery of amendments would be difficult; that the amount of required amendment is high; or that sulfate cannot be removed in a timely fashion, then the feasibility of the approach could be affected.

Technical Feasibility: Ease of Undertaking Additional Remedial Actions
None of the alternatives would interfere with the implementation of future response actions in the Campus Area.

Technical Feasibility: Monitoring Considerations
All alternatives except Alternative 1 include a monitoring program to provide early warning of changes in contaminant concentrations that could require modifications in extraction rates, amendment injection rates, monitoring well locations, or treatment methods to ensure attainment of ROs.

Administrative Feasibility
There are not likely to be any significant administrative feasibility issues associated with implementation of Alternatives 1 or 2, although Alternative 2 would require easily obtainable permits for monitoring well installation. Implementation of Alternatives 3A and 3B would require acquisition of permits including but not limited to the construction of extraction wells, treatment facilities, and conveyance piping. In addition, implementing Alternative 3B would require resolution of administrative issues associated with discharge of treated groundwater to the Riparian Corridor, a storm drain, or a POTW. Alternative 3A would require permits for injecting the amendments required for enhanced biodegradation.

Availability of Services and Materials
Implementation of Alternative 3B would require fabrication of treatment plant equipment and a treatment building. Required services and materials are available, including qualified contractors for construction and operation of the technologies under consideration. Similarly, services and materials necessary to implement enhanced biodegradation are readily available.

The relative overall rating for this criterion is high for Alternative 1 because there are no significant issues that could impact implementability of this alternative. Alternative 2 rates as moderate to high for implementability due to the need to obtain well installation permitting, and the MNA sampling and reporting that is required as part of this alternative. Alternative 3A is ranked low to moderate because it requires preliminary testing of enhanced bioremediation to evaluate the feasibility of this approach, as well as permits for subsurface injection of amendments. Alternative 3B is

assigned a moderate ranking because of the administrative issues associated with construction and disposal permitting.

7.7 Cost

This criterion addresses the total cost of each alternative. This considers likely capital, and Operations and Maintenance (O&M) expenditures. The following cost elements are considered for each alternative:

- Direct capital costs, which include the construction, labor, equipment, land, Site development, and utility service costs;
- Indirect capital costs, which include engineering fees, license and permit costs, startup costs, and contingencies; and
- O&M costs, which include operating labor, maintenance materials and labor, pumping and treatment energy, monitoring, and other post-construction costs necessary for the continuous effective operation of the alternative.

Evaluation of Alternatives

Alternative 1 has no costs.

Alternative 2 capital costs include installation of new monitoring wells in the Ballona aquifer, development of an MNA sampling plan, and performing MNA modeling. O&M costs include: semi-annual sampling, water quality analysis for VOCs, purge water disposal, reporting, and groundwater modeling support.

Alternative 3A capital and O&M costs include all of the costs indicated above for Alternative 2 plus costs for an enhanced biodegradation system in the source areas. The system would include substrate injection points, additional performance monitoring wells, and injection equipment. The number of amendment injections and locations that would be needed would govern the capital and O&M costs. These costs would be best determined by preliminary testing results and performance monitoring results following the first injection.

Capital and O&M costs for Alternative 3B include all of the costs indicated above for Alternative 2 plus costs for a groundwater (and soil vapor) extraction and treatment system in the source areas. Treated water would be discharged to the Riparian Corridor, a storm drain, or a POTW. The system would include DPE extraction wells, lower Bellflower aquitard and Ballona aquifer extraction wells, performance monitoring wells, and a treatment plant which would likely utilize air stripping with GAC treatment of the off-gas and DPE vapor streams.

It is assumed that the source area extraction and DPE wells would operate for three years, at which time the concentrations of all COCs are assumed to have decreased to below HBRGs and mass removal rates have reached asymptotic levels.

To be consistent with the ratings used for other criteria in Table 7-1, this criterion is used as cost effectiveness rather than cost. For example, the alternative with the lowest cost rates as high for cost effectiveness. For this evaluation, Alternative 1 is ranked high (i.e., lowest cost); Alternative 2 is ranked moderate to high; and Alternatives 3A and 3B are ranked low (i.e., highest cost).

7.8 Overall Evaluation of Alternatives

A summary of this evaluation, which highlights differences among alternatives in meeting the seven criteria, is presented in Table 7-1. This table shows that alternatives 3A and 3B had very similar overall ratings. The differences are related primarily to two issues:

- The uncertainty regarding the effectiveness, design parameters, and acclimation times required for EAB implementation weighed against the absence of residual wastes generated at the surface (as compared with groundwater extraction);
- The advantages of EAB implementation in areas where low permeable materials limit the use of groundwater extraction technologies.

It is recognized that EAB in source areas could aid in achieving the ROs. It is necessary, however, to consider the uncertainty associated with this component when selecting the remedial approach. It is proposed that Alternative 3B be implemented as the preferred alternative in such a way as to benefit from supplemental EAB, were appropriate.

Based on the criteria evaluated in this section, Alternative 3B (Groundwater Extraction in Source Areas and Monitored Natural Attenuation Downgradient) is identified as the preferred remedial alternative. Since it is recognized that an EAB component could aid in achieving the ROs, it is proposed that Alternative 3B be implemented as the preferred alternative, with further consideration of the EAB during the early phases of remedial action implementation, as appropriate. This topic is further discussed in the detailed review of the proposed remedial action in the next section.

Section 8
Proposed Remedial Action

This section describes the proposed remedial plans for soil and groundwater contamination. It includes discussion of the approach used to select the appropriate remedial technologies for each SA. This section also describes the use and implementation of institutional controls in conjunction with the recommended remedial actions, finally, the approach for implementing the remedial actions.

8.1 Overview of Proposed Remedial Action

Remedial activities identified in this section address the areas and media where COC exceedances of the RGs (HBRGs, LSRTs, USRTs, and MCLs) occur, thereby assuring that both human health and the groundwater resource are protected. Exceedances of HBRGs and LSRTs will be the thresholds for selecting active remediation systems, while exceedances of USRTs and MCLs will generally be addressed through passive remedial technologies such as MNA.

As determined in the analyses presented in Sections 5, 6 and 7, the recommended active remedial technology for addressing COC-impacted groundwater is groundwater extraction or DPE/SVE at the source areas, with passive remediation (MNA) of the downgradient portion of the plume. Treatment at source areas will generally consist of groundwater extraction or DPE/SVE for the upper Bellflower aquitard, and groundwater extraction in both the lower Bellflower aquitard and Ballona aquifer. MNA will apply downgradient in the Ballona aquifer, which is the primary unit where low concentrations of COCs extend laterally downgradient from the source areas. Once active remedial measures are completed in source areas, residual concentrations of COCs in source areas are expected to be sufficiently low for application of MNA, consistent with achieving the ROs.

For impacted soil at source locations, vapor extraction (SVE or DPE) for volatile COCs will be the preferred active treatment technology. Excavation will be implemented in areas impacted by non-volatile COCs (e.g., metals). Furthermore, future migration of contaminants to groundwater is expected to be minimized as a result of the construction of impervious surfaces as part of the Campus Area development.

8.1.1 Source Area Remedial Technology Selection

A summary of proposed remedial actions for both groundwater and soil contamination is provided in Table 8-1, *Proposed Remedial Action at Source Areas*. Table 8-1 identifies the specific remedial technologies selected for each source area (i.e., DPE, groundwater extraction, SVE, excavation, and MNA), as well as additional data collection activities required to refine the lateral extent of contamination and to optimize the proposed remedial action. The specific application of the preferred alternative for each source area is discussed below. Additional data collection activities are discussed briefly below and are outlined in Section 8.4, *Remedial*

Implementation Plan. A detailed description of additional data collection activities will be provided to the RWQCB prior to implementing the proposed remedial action.

Specific remedial technologies will be implemented within each source area based on a comparison of source area-specific soil and groundwater contamination with the appropriate HBRGs, LSRTs, USRTs, and MCLs.[10] Active remediation of soils is triggered through an exceedance of soil HBRGs or LSRTs, while active remediation of groundwater is triggered through an exceedance of HBRGs. MNA, a passive remedial technology, will be applied in some capacity to all source areas and will be the sole remediation technology for only a limited number of areas. Where the technology applied in one medium (e.g., groundwater) will address contamination in another medium (e.g., soil), the proposed remediation is limited to the most appropriate medium and justification for such action is provided.

The basic decision process is best illustrated by the following subsections which address the question of whether active remediation of soils is triggered (i.e., if soil contamination exceeds HBRGs or LSRTs) in the source areas.

8.1.1.1 Soil Contamination Exceeds HBRGs or LSRTs (i.e., Requires Active Soils Remediation)

If soil concentrations exceed either soil HBRGs or LSRTs (protection of lower Bellflower aquitard groundwater resource), remediation of the source areas will be accomplished using SVE or soil excavation. Furthermore, active groundwater remediation will be initiated where groundwater COCs exceed HBRGs, or where soils concentrations exceed LSRTs and either (1) the distribution of COCs in groundwater indicate a residual source exists in groundwater, or (2) technical evaluation demonstrates that soil remediation alone may not sufficiently reduce groundwater concentrations. The remedial technology(ies) will be selected from several possibilities including DPE and groundwater extraction. The selected technology(ies) will be used along with passive groundwater remediation (i.e., MNA), as appropriate. The basis for determining when the operation of active groundwater remedial technologies may be turned off in favor of passive remedial technologies, such as MNA, is presented in Section 9, *Monitoring and Contingency Plan*.

If active groundwater remediation is not triggered, MNA for groundwater may be applied in conjunction with either SVE or excavation to address the vadose zone soils that exceed HBRGs or LSRTs.

[10] The HBRGs and LSRTs presented in Section 3 are used to identify areas and media where residual contamination is sufficient to warrant remediation, and to guide the implementation of the most appropriate remedial technology(ies). As such, the HBRGs and LSRTs are used as remediation "trigger" criteria. However, as described previously, the HBRGs and SRTs may not be the final cleanup criteria. For example, if remediation efforts continue to be effective at reducing contaminant levels, remedial systems may continue to operate even after chemical concentrations drop below HBRGs and/or SRTs. The RWQCB will determine final cleanup goals as remediation is completed or further remediation becomes technically infeasible.

8.1.1.2 Soil Contamination is Less Than HBRGs or LSRTs (i.e., No Active Soils Remediation)

Where concentrations of COCs in soils do not exceed soil HBRGs or LSRTs, no active remediation of soils is required. In this case, if underlying groundwater is contaminated above HBRGs for groundwater (suggesting an upgradient source), active groundwater remediation will be implemented, along with or followed by MNA, as appropriate.

Where concentrations of COCs in groundwater do not exceed HBRGs for groundwater, groundwater concentrations will be compared to MCLs and soil concentrations to USRTs. If MCLs are exceeded MNA will most likely be implemented. If USRTs (protection of upper Bellflower units) are exceeded and there are no indications of impacts to groundwater, MNA will most likely be implemented.[11] If neither MCLs nor USRTs are exceeded, no remediation is necessary and the source area can move to NFA status.

IESI estimated the amount of contaminant mass removal from soils that could potentially be accomplished by using the application of soil remedial triggers (i.e., remediation of vadose zone soils at concentrations greater than soil HBRGs and LSRTs). IESI's preliminary calculations are based on a simple radial diffusion model and Site-specific data regarding the lateral and vertical dimensions of impacted vadose zone soils. IESI's conclusions suggest that remediation of vadose zone soils to the HBRG and LSRT values would potentially address 80 to 90 percent of the VOC mass in the vadose zone. When one considers the typical over design of remedial systems (e.g., the addition of extra SVE wells to account for "dead zones" along the perimeter of the targeted remediation area), it is reasonable to expect that the "remediated mass" could potentially exceed the upper-bound mass removal calculated by IESI. IESI's preliminary calculation of VOC mass removed from the vadose zone is attached as Appendix G.

8.2 Source Area Specific Remedial Plans

The proposed remedial measures will be accomplished using one or more approaches. Impacted groundwater will be extracted and treated at a central water treatment plant (WTP). Figure 8-1, *Conceptual Layout of Source Area and Downgradient Groundwater Extraction and Treatment System,* provides the conceptual layout of the WTP and related interconnecting pipelines. The WTP will be designed to accommodate groundwater extracted from downgradient wells, if the criterion discussed in Section 8.1.1.2 demonstrates such wells are necessary. Where appropriate, DPE will be implemented to address VOC impacted soil at source locations. Treatment of vapors from DPE wells will occur either at a central treatment system or at strategically located satellite treatment units. Placement of the satellite treatment units will be determined based on a variety of criteria, including cost and development needs. For SA soils impacted by non-volatile contaminants (metals), surgical excavation of the impacted soil will be performed.

[11] MNA will also be used outside SAs identified in this RP where USRTs are exceeded.

A schedule for the remedial measures is proposed in Section 8.5. The following discussion describes remedial measures proposed for each identified source location.

8.2.1 SA No. 1 – Former UST South of Building 5

Figure 8-2, *Conceptual Layout of Remediation of Former UST South of Building 5 (SA-1)*, depicts the conceptual layout of one DPE well and two groundwater extraction wells at SA-1. Figure 8-3, *Conceptual Cross-Section for SA-1*, provides the complementary conceptual cross-section for this source area.

DPE will be implemented to address both groundwater and impacted soil such that the ZOI for vapor extraction will encompass locations where VOCs in the upper Bellflower aquitard soil (including existing fill material) exceed LSRTs.

Groundwater extraction from the lower Bellflower aquitard will be performed near former monitoring well C-64. Groundwater extraction in the Ballona aquifer will be performed approximately 50-feet downgradient from the former location of monitoring well C-64. Additional soil samples will be collected north of monitoring well C-64. Soils that exceed LSRTs will be addressed by implementing additional SVE or DPE. Excavation of soils is not anticipated to be necessary as all COCs in soil are volatile and DPE and/or SVE will likely achieve ROs.

8.2.2 SA No. 2 – Southwest Corner of Building 12

Figure 8-4, *Conceptual Layout for Remediation of Building 12 (SA-2 and SA-3)*, depicts the conceptual layout for multiple DPE wells and groundwater wells at the southwest corner of Building 12 (SA-2). Figure 8-5, *Conceptual Cross-Section for SA-2*, provides the complementary conceptual cross-section for this source area.

Soil impacted by metals above HBRGs (cadmium and total chromium) will be surgically excavated, while DPE and groundwater extraction will target VOC removal. DPE will be implemented such that the ZOI for vapor extraction encompasses locations where VOCs in upper Bellflower aquitard soils exceed LSRTs. Groundwater extraction will be implemented from the lower Bellflower aquitard and Ballona aquifer in the southwest corner of former Building 12, at locations upgradient of the C-76 monitoring wells.

Additional data collection will include obtaining a grab groundwater sample from the Ballona aquifer in the area downgradient of C-76 and upgradient of C-84. The results from the grab sample will be compared to the RGs (Section 3) and used to evaluate the need for additional groundwater extraction in the Ballona aquifer downgradient of C-76.

8.2.3 SA No. 3 – Central Area of Former Building 12

Figure 8-4, *Conceptual Layout for Remediation of Building 12 (SA-2 and SA-3)*, depicts the conceptual layout for DPE and groundwater extraction wells at the central portion of Building 12 (SA-3). Figure 8-6, *Conceptual Cross-Section for SA-3*, provides the complementary conceptual cross-section for this source area.

Surgical excavation of soils will be used to address soil impacted by metals above HBRGs (copper and total chromium), while DPE and groundwater extraction will target VOC removal. DPE will be implemented such that the ZOI for vapor extraction includes locations where VOCs in the upper Bellflower aquitard soils exceed LSRTs. Groundwater extraction will be implemented for the lower Bellflower aquitard at a point located upgradient of monitoring well C-89be.

In addition, a 4-inch diameter monitoring well will be installed downgradient of C-89be and screened in the Ballona aquifer. A grab sample of groundwater will be collected from this monitoring well and the analytical results will be used to evaluate the need for additional groundwater extraction in this area.

8.2.4 SA No. 4 – Former Drum Storage Area (near Building 34)

Figure 8-7, *Conceptual Layout for Remediation of the Former Drum Storage Area (near Building 34)*, depicts the conceptual layout for multiple DPE wells and groundwater extraction wells (one screened in the lower Bellflower and one screened in the Ballona aquifer) at SA-4. Figure 8-8, *Conceptual Cross-Section for SA-4*, provides the complementary conceptual cross-section for this source area.

DPE will be implemented such that the ZOI for vapor extraction encompasses soil in the upper Bellflower aquitard where VOC concentrations exceed LSRTs. LSRT exceedances have been observed in two areas: near monitoring well cluster C-74 (at the bottom and margins of the soil excavation performed in 2001 by EEC), and near former monitoring well C-45. Groundwater extraction in the lower Bellflower aquitard will occur immediately upgradient of monitoring well C-74, and near monitoring well C-45. Groundwater extraction in the Ballona aquifer will occur downgradient of these two locations, at a single location between monitoring well C-74 and monitoring well C-75.

8.2.5 SA No. 5 – Former UST and Degreaser Pit West of Building 11

Figure 8-9, *Conceptual Layout of Remediation for Former UST and Degreaser Pit West of Building 11 (SA-5)*, depicts the conceptual layout for three DPE wells to be located west of Building 11 (SA-5). Figure 8-10, *Conceptual Cross-Section for SA-5*, provides the complementary conceptual cross-section for this source area.

DPE will be implemented such that the ZOI for vapor extraction will address VOCs in the upper Bellflower aquitard soils that exceed LSRTs; where hydrocarbon sheen has been previously observed in monitoring wells (i.e., TB-04, TB-07, TB-11, and TB-12); and where the benzene HBRG for groundwater was exceeded (TB-12).

8.2.6 SA No. 6 – Building 35

Figure 8-11, *Conceptual Layout for Remediation of Building 35 (SA-6)*, depicts the conceptual layout for seven DPE wells to be located within the northeast corner of former Building 35 (SA-6). Figure 8-12, *Conceptual Cross-Section for SA-6*, provides the complementary conceptual cross-section for this source area.

DPE at the northeast corner of the former Building 35 will be implemented such that the ZOI for vapor extraction will address areas in the upper Bellflower aquitard where soil is impacted by VOCs in excess of LSRTs. Additional soil matrix or soil vapor data may be acquired during the DPE pilot testing to ensure that the ZOI of extraction extends to all areas where soil concentrations exceed the LSRTs.

Groundwater extraction from the lower Bellflower aquitard will be implemented at the northeast corner of the former Building 35 (immediately west of the former chromate waste sump and former neutralization pit). An additional lower Bellflower aquitard groundwater extraction well will be installed, if necessary, to capture groundwater contamination under the northeast quadrant of the former Building 35. A 4-inch diameter Ballona aquifer monitoring well will be installed at the extreme northeast corner of the former building to assess conditions in the Ballona aquifer. If analytical results obtained from the monitoring well samples exceed the RGs presented in Section 3, then the 4-inch diameter Ballona aquifer monitoring well will be converted to an extraction well and groundwater extraction will be implemented at this location.

Application of DPE at the former organic sump (southwest corner of former Building 35) has not been proposed because the exceedance of soil LSRTs for the COC at this location (benzene) was observed below groundwater levels. Furthermore, the benzene observed in the soil samples likely did not originate from the organic sump, and is therefore not a likely source location for the COC observed. Groundwater extraction performed downgradient from this location is expected to address impacted groundwater associated with this location.

8.2.7 SA No. 7 – Storm Drain Discharge Site

Figure 8-13, *Storm Drain Discharge Site (SA-7)*, depicts boring sampling data and associated data for the storm drain discharge site. Figure 8-14, *Conceptual Cross-Section for SA-7*, provides the complementary conceptual cross-section for this source area.

Data collected in 1987 by MEE at C-49 indicated exceedances of LSRTs by MC and benzene. More recently, soil borings advanced in 2001 by EEC at three locations in a radial pattern immediately around C-49 did not detect MC or benzene in soil. Therefore, MNA has been selected as the appropriate remediation method for this location. Monitoring well C-49 will be placed on the MNA sampling list.

8.2.8 SA No. 8 – Sumps, Clarifiers, and Former Vapor Degreaser Northeast Corner of Building 14

Figure 8-15, *Conceptual Layout of Remediation for Building 15 (SA-8 and SA-9)*, depicts the conceptual layout for multiple DPE wells to be installed within the area of Building 15 to address SA-8 and SA-9. Figure 8-16, *Conceptual Cross-Section for SA-8*, provides the complementary conceptual cross-section for this source area.

Three DPE wells and one groundwater extraction well screened in the lower Bellflower are proposed for implementation to address source contamination at the northeast corner of Building 14 (SA-8). The DPE wells will be installed such that the ZOI for vapor extraction will encompass locations where VOCs exceed LSRTs in the upper Bellflower aquitard. Notably, LSRTs are exceeded in only two areas: 1) at former soil boring location 4-1 (near monitoring well C-78be), and 2) at monitoring well C-36.

Groundwater extraction will be implemented in the lower Bellflower aquitard downgradient of monitoring well C-78be. A 4-inch diameter monitoring well will be installed in the Ballona aquifer downgradient of C-78be. If analytical data obtained from the groundwater monitoring well samples exceed the criteria presented in Section 3, then the 4-inch diameter monitoring well will be converted to an extraction well.

8.2.9 SA No. 9 – Existing Clarifier and Former Vapor Degreaser Pit Building 15 Center Bay

Figure 8-15, *Conceptual Layout of Remediation for Building 15 (SA-8 and SA-9)*, depicts the conceptual layout for multiple DPE wells to be installed within the area of Building 15 to address SA-8 and SA-9. Figure 8-17, *Conceptual Cross-Section for SA-9*, provides the complementary conceptual cross-section for this source area.

Four, or potentially five, DPE wells (or SVE wells, as appropriate) are proposed to address source area contamination in the center bay of Building 15 (SA-9). The existing clarifier will be removed. Surgical excavation of soils (in the vicinity of former soil boring 226-11) will be performed to remove soil impacted by PCE above soil LSRTs and/or HBRGs to the extent technically feasible, based on access restrictions. If soils exceeding LSRTs cannot be fully removed, DPE will be implemented such that the ZOI for vapor extraction will encompass soil in the upper Bellflower aquitard that exceed LSRTs. The potential implementation of DPE at this location represents the "fifth" DPE well for SA-9. To supplement existing data, soil

and groundwater samples may be collected in the vicinity of floor trenches. Locations where soil concentrations are found to exceed LSRTs will be addressed using DPE.

Groundwater extraction will be implemented in the lower Bellflower aquitard immediately downgradient of former soil boring 226-11. Groundwater extraction from the Ballona aquifer at a single location along the northern, downgradient edge, of Building 15 will also be implemented.

8.3 Downgradient Specific Remedial Plans

As determined in the analyses presented in Sections 5, 6 and 7, the recommended alternative for addressing impacted groundwater includes source area contaminant and MNA for the downgradient portions of the plume. MNA applied to the upper and lower Bellflower aquitard and Ballona aquifer should show a reduction in contaminant mass. As stated previously, the Ballona aquifer is the primary unit where low concentrations of COCs extend laterally downgradient from source areas. As such, implementation of the MNA technology within the downgradient areas of the Campus Area will focus primarily on the Ballona aquifer, although both upper and lower Bellflower aquitard monitoring locations will be included, as needed. The details of the MNA sampling and analyses will be submitted to the RWQCB prior to implementation of the remedial action.

8.4 Remedial Implementation Plan

A detailed remedial design (RD) will be prepared prior to complete implementation of the remedial action (RA). By way of example, flow diagrams of the proposed implementation activities for Alternative 3B are provided in Figure 8-18, *Remedial Design Activities*, and Figure 8-19, *Remedial Action Activities*.

8.4.1 Remedial Design

The RD will include preparation of detailed engineering design documents, including plans, specifications, drawings and schedules for implementing each of the components of the remedy. An outline of the activities and data to be developed as part of the complete RD effort will be discussed with the RWQCB. The preliminary design will describe the conceptual design of the system, specify the additional data required to further refine the remedial concepts, and provide the appropriate level of engineering design specifications, construction schedule, and cost estimates to complete the RD. This phase will also include additional data collection required for final design (e.g., vapor permeability, physical parameters, hydraulic conductivity, etc.).

Groundwater Extraction in Source areas

Implementation of the DPE component of the remedy will install in phases. This approach will facilitate confirmation of design criteria, including extraction rates and ZOI. The conceptual number of DPE wells and their placement have been designed using a ZOI of approximately 20 feet. Initially, one DPE well will be installed at each of the source areas near the apparent center of contaminant mass based on historical

data. A series of tests will be conducted at this well to validate the appropriateness of the technology; obtain design criteria to ensure appropriate placement and adequate coverage of system; estimate initial VOC mass removal rates; and to size required equipment.

Two types of testing will be performed at the initial well, "quick tests" and "extended test(s)". Both of these tests will use portable DPE equipment and treatment systems. The quick tests will be 1-day test (maximum) and is expected to provide information on the permeability of soils surrounding the test well and on the approximate amount of contaminant mass that is in groundwater and vadose zone soils within the treatment zone of the well. A quick test will be performed at each of the source area locations. The quick test results will be used to determine the placement of additional DPE wells, and to make modifications to design specifications, if necessary. The quick test results will also be used to select one representative location for performing an extended DPE test. The extended test(s) will be conducted for a period of up to five days. Results of the extended test will be used to provide design information for the proposed treatment plant.

Monitoring wells will be installed to collect water level data to estimate the ZOI of the DPE wells during operation. Additionally, triple-depth piezometer clusters will be used for water level measurement. Water level monitoring will be conducted using data-loggers set to logarithmic frequency. Static pressures and groundwater elevations will be periodically checked at nearby monitoring wells.

Vapor monitoring probes will be installed into the vadose zone around the DPE wells. These probes will be used to collect subsurface static pressure and respiration gas data to estimate the ZOI of the vapor extraction portion of DPE.

The groundwater extraction systems in the lower Bellflower aquitard and Ballona aquifer source areas are intended to reduce contaminant mass and limit the migration of contaminants to downgradient areas. Contaminant removal and containment efficiency by these extraction systems require placement of wells based on an understanding of the hydraulic properties of the Campus Area. Existing hydraulic data from previously performed pumping tests will be used to complete the design of the source area groundwater extraction system in the lower Bellflower aquitard and in the Ballona aquifer. No additional aquifer tests in the lower Bellflower aquitard are necessary for the RD of the source area extraction systems. The assumed maximum capture zone width of the source area extraction wells designed for this hydrologic zone will be sufficiently large to contain the areas of concern. These assumptions will be verified, or modified as necessary, during the initial period of DPE operation.

To verify the hydraulic pumping characteristics of the Ballona aquifer and finalize the design of the source area extraction systems, a single groundwater extraction well screened in the Ballona aquifer will be installed in the source areas. This well will be used in step testing during RD to evaluate the relationship between groundwater

capture zone and extraction rates. The proposed step test will be completed for a minimum of three different pumping rates.

Regional hydrogeologic data for the Ballona aquifer have ranged from 3.1 $x10^{-3}$ feet per second to 7.7 to 10^{-3} feet per second (DWR, 1961). The need for additional groundwater monitoring wells or piezometers to monitor hydraulic head during the step tests will be evaluated once the location of the extraction well is selected, and based on expected ZOI and the proximity of existing monitoring wells. Existing monitoring wells will be used during the proposed step test, as feasible.

8.4.2 Remedial Action Implementation

The RA implementation phase will include construction of the groundwater treatment plant, remaining source area extraction wells, downgradient extraction wells, and remaining portions of the DPE system.

Groundwater Treatment Plant Construction

The extent of groundwater treatment construction required prior to discharge will be evaluated during RD and will be dependent upon the actual discharge option selected (e.g., reuse in the Riparian Corridor; discharge into Centinela Creek Channel, or to a POTW). It is likely, however, that the selected treatment process would include air-strippers, GAC, and oxidant-impregnated canisters for vapor streams. A conceptual flow diagram for the treatment of extracted groundwater and collected vapor is presented in Figure 8-20, *Groundwater/Vapor Treatment Flow Diagram*. Under this conceptual depiction, the vapor streams would be treated by activated carbon units (in series) and a single zeolite/potassium permanganate unit for VC polishing. The vapor treatment units would be sized to treat vapors from both DPE wells and the air stripping units. The central vapor treatment unit for vapor would consist of two parallel units. At satellite treatment locations specific factors such as anticipated adsorbent bed life may be used to justify a single unit at these locations. The actual treatment requirements and process details will be finalized during RD.

The location of the groundwater treatment plant was selected for this RP by considering several issues, including:

- Minimizing the total length of subsurface piping from the source areas to the treatment system;
- Proximity to treated groundwater discharge location (assumed to be the Riparian Corridor); and
- Minimizing visibility and blending treatment plant in with surrounding features.

The proposed treatment plant location is in the vicinity of former Building 35 and was shown previously in Section 8 (Figure 8-2)

Source area extraction systems will be turned on incrementally as all necessary equipment installation and piping to the treatment plant are complete.

DPE Implementation

The results from the initial DPE well testing will be used to complete the RD for this component of the remedy, including number and location of the remaining DPE wells. The additional DPE wells, equipment and underground piping to the treatment plant will then be installed. DPE system operation will commence in a step-wise fashion when the treatment plant is ready to treat DPE-extracted groundwater and vapors.

Source Area Groundwater Extraction Implementation

Source area groundwater extraction wells in the lower Bellflower aquitard, and those remaining for the Ballona aquifer, will be installed incrementally. Groundwater extraction at these locations will commence in a step-wise fashion when the treatment plant is ready to treat groundwater extracted from these systems, and all necessary piping to the treatment plant is in place.

Performance Monitoring Well Installation

Groundwater monitoring wells will be installed to monitor extraction performance and source removal. These additional monitoring wells will supplement existing monitoring wells and will be used for the performance-monitoring program. The location, aquifer being monitored, groundwater analyses, and sampling frequency will be described in a separate submittal to the RWQCB.

8.5 Summary of Approach for Remedial Actions

The foregoing proposed remedial action plan has been developed through a comprehensive set of steps, starting with identification of ROs and RGs for the Campus Area. Then, a set of remedial technologies and process options were developed that could address the nature and extent of known contamination in the Campus Area, and, in turn refined into a set of four potential remedial alternatives. Using widely-accepted evaluation criteria, a final alternative — 3B Groundwater Extraction in Source Areas and MNA Downgradient — was selected.

This 3B Alternative involves both source area and groundwater remediation. It will also involve active and passive components, as determined by which RGs need to be achieved. At this stage, conceptual layouts of the required remediation have been proposed, but many aspects of the final action will need to be refined during the RD phase. Additionally, as discussed in the next section, the proposed approach will have the flexibility to accommodate new data and other possible contingencies.

Section 9
Monitoring and Contingency Plan

This section establishes the basis for the future development of a Monitoring and Contingency Plan (MCP) for the proposed remedial action, Alternative 3B (Groundwater Extraction in Source Areas and MNA Downgradient). Information presented in this section will be expanded in the MCP document that will be submitted to the RWQCB after the completion of RD activities, and prior to RA implementation.

9.1 Description of Plan

The overall objectives of the MCP will be three-fold:

- Outline the procedures for establishing a database to optimize the performance and efficiency of the RA, and evaluate shut-down criteria for individual components of the RA;
- Ensure that human health and the environment remain protected during the implementation of the selected remedial alternative;
- Provide sufficient performance-monitoring data to adequately evaluate the ability of the remedial alternative to meet the ROs.

To meet these objectives, the MCP will have a groundwater monitoring program to evaluate the effectiveness of the preferred remedial alternative. Proposed groundwater monitoring activities identified in the MCP will be subject to revision based on a periodic evaluation of data collected during the early phases of RA implementation.

This plan will also describe actions to be taken (i.e., contingencies) in the event that the monitoring or other information reveals that additional steps should be undertaken to protect human health or the environment. The contingencies will be activated by "triggers" that are pre-determined action levels or conditions. Finally, the MCP will present the criteria by which the remedial systems will be shutdown.

9.2 Monitoring Program

The monitoring program will be used to monitor performance of the remedial systems in attaining the Campus Area ROs and RGs. The monitoring program component of the MCP will be developed as part of the RD; however, modifications to this program may be appropriate during the early phases of RA implementation based on actual conditions encountered.

The monitoring program data will be used to evaluate changes in the overall extent of the COCs in soils and groundwater in the Campus Area over time. In addition, the groundwater data will be used to:

- Evaluate the mass removal effectiveness of various components of the RA;
- Confirm that the RA is achieving the ROs set for the Campus Area;
- Evaluate the significance of natural attenuation processes throughout the operation of the RA; and
- Evaluate the need to implement contingency measures.

The MCP will include provisions for performance monitoring locations; analytical requirements; field methods; QA/QC guidelines; and reporting requirements.

With respect to monitoring wells, the locations will be selected considering (1) existing monitoring wells (2) the likely location of groundwater extraction wells that will be installed in the RA; and (3) the historical monitoring data results. The MCP will specify the water-bearing unit in which the monitoring wells will be screened, the proposed frequency of sampling, analytical target list, and intended purpose. All proposed monitoring and groundwater extraction wells required by the MCP will be installed during the RA phase.

9.3 Contingency Program

The purpose of any contingency program is to establish a mechanism by which meaningful changes in circumstances will be addressed in the design or operation of the remedial systems. Such a program will be structured around "triggers," the action levels or conditions that require a response, and "contingencies," the responsive actions to a trigger. Here, the point of the MCP contingency program is to allow contingency measures to be implemented where the triggers indicate that additional action is needed to protect human health or the groundwater resource. The contingency program that will be developed and submitted with the MCP will cover the following:

- The conditions that trigger a responsive action (i.e., triggers);
- The means of reviewing analytical data obtained from the monitoring program to determine if triggers are met;
- The contingency action to be taken in a response to a triggering event; and
- The reporting requirements when contingencies are triggered.

9.3.1 Identification of Triggers

The types of information or events that would trigger the implementation of a contingency action may be analytical results, observations conducted during the monitoring program, or events like the drilling of a new supply well. Specific triggers will be developed and submitted with the MCP considering the following factors:

- VOC concentration trends;
- Migration of VOCs in groundwater;
- Potential for impact to water supply wells; and
- Natural attenuation.

9.3.2 Identification of Contingencies

Contingencies are defined as a systematic set of site-specific, pre-determined responses to triggers that may be encountered during the implementation of a selected remediation alternative. Contingencies will be implemented if data, observations or events indicate that additional action is needed to protect human health or the groundwater resource In addition, some contingencies may be implemented to modify the scope of the monitoring program in response to changes in field conditions or groundwater quality, thus increasing the flexibility of the monitoring program based on an ongoing evaluation of the results of the monitoring program. Specific contingency measures will be developed and submitted as part of the Campus Area MCP.

At a minimum, the adequacy of ongoing remedial measures and the need for contingency measures will be considered on an annual basis as part of the groundwater monitoring program. Contingency measures will be implemented if groundwater monitoring indicates that additional action is needed to protect human health or the groundwater resource.

Any contingencies implemented and the corresponding triggers will be described in the data submittal or monitoring report prepared following that monitoring event. The MCP will identify any trigger conditions that would cause immediate agency notification upon discovery of the condition.

9.4 Shut-down Criteria and Post Shut-Down Monitoring

Performance monitoring data collected in accordance with the MCP will be evaluated to determine the effectiveness of individual components of the RA to meet the ROs, and for terminating portions of the remedial system, as appropriate. The primary performance monitoring data for source area systems are extracted contaminant concentrations and contaminant mass removal time trends. The MCP will contain proposed shut-down criteria for approval by the RWQCB. These criteria will be used to determine final cleanup levels as remediation is completed, or when further remediation becomes technically infeasible. As stated previously, HBRGs and SRTs will be used to identify and prioritize areas in the Campus Area that require remediation. However, the eventual cleanup goals are, to a significant extent, technology-based. Thus, the HBRGs and SRTs may not be the final clean up standards for the Campus Area. It is also expected that the RWQCB would also consider MNA data collected and evaluated

throughout the implementation of the RA. Where appropriate as a remedial response, MNA would continue until submittal of a Campus Area Closure Plan.

9.4.1 Shut-Down of Source Area Extraction

Source area extraction of both groundwater and vadose zone vapors (collected through the operation of DPE/SVE) would continue until reaching aquifer and media specific shut-down criteria approved by the RWQCB. The rationale that will guide the development of such criteria, which will be submitted in the MCP, is outlined below for each active component of the proposed remedial action:

Shut-Down Criteria for Groundwater Extraction

Consistent with the ROs, groundwater remediation in the source areas will be undertaken with the dual objectives of protecting human health and the groundwater resource. As such, groundwater extraction from the source area wells will continue, at a minimum, until performance-monitoring results indicate that all COC concentrations are below the RWQCB-approved HBRG values. To address the groundwater resource protection aspect of the ROs, the remediation will further seek to reduce Site COC concentrations to levels equal to MCLs, to the extent technically feasible. As noted previously, MCLs are standards that must be met before water can be supplied as drinking water. This is a highly unlikely scenario, since such water use from the Campus Area groundwater is restricted by CC&Rs and the water has other qualities (taste, color and smell) that make it an unlikely source of drinking water. Nonetheless, the groundwater extraction system will be run until it is no longer technically feasible to achieve MCLs by active remediation. The criteria for determining when this is so will be proposed in the MCP and will be assessed against the performance data that will be collected under the MCP monitoring program. It is also expected that the RWQCB would consider MNA data collected and evaluated throughout the implementation of the RA. Where appropriate as a remedial response that follows active remediation, MNA would continue until submittal of a Campus Area Closure Plan.

Shut-Down Criteria for Vapor Phase Extraction Component of DPE

Operation of the vapor extraction portion of the DPE or SVE remedy would continue until the effluent vapor concentrations and mass removal rates have reached asymptotic conditions. Rebound testing of the vapor extraction well(s) would be performed on a semi-annual basis for two years to verify that asymptotic conditions have been met.

Post Groundwater and Vadose Zone Vapor Extraction

It is expected that post-extraction groundwater monitoring of the upper Bellfower aquitard would continue on a semiannual basis for 2 years after the last DPE well has been shut down. If during the period of monitoring the concentration of a COC were found to rebound above the HBRGs, the affected extraction well would be operated until the conditions described above are met again. After 2 years of monitoring of the source area extraction wells, if no exceedances of HBRGs occur, the extraction wells would be permanently shut down. An evaluation of using MNA to address any

residual contamination would be performed prior to requesting closure of the Campus Area active remediation systems from the RWQCB.

9.5 Reporting Requirements

Following each monitoring event completed in accordance with the MCP, a data submittal or monitoring report, as appropriate, would be prepared and submitted to the RWQCB. The contents and schedule for these reports will be discussed in further detail upon submittal of the detailed scope of work for the groundwater-monitoring program, which will be submitted prior to the implementation of the RA. On an annual basis, an Annual Summary Report will be submitted to the RWQCB that includes data presented in each monitoring report along with an evaluation of remedial system performance.

The Annual Summary Report will include an evaluation of the potential effectiveness of MNA as compared to active groundwater extraction. Once MNA becomes an approved remedial approach to replace the active remedial components, it would continue until submittal of a Campus Area Closure Plan to the RWQCB.
This section establishes the basis for the future development of a Monitoring and Contingency Plan (MCP) for the proposed remedial action, Alternative 3B (Groundwater Extraction in Source Areas and MNA Downgradient). Information presented in this section will be expanded in the MCP document that will be submitted to the RWQCB after the completion of RD activities, and prior to RA implementation.

9.6 Description of Plan

The overall objectives of the MCP will be three-fold:

- Outline the procedures for establishing a database to optimize the performance and efficiency of the RA, and evaluate shut-down criteria for individual components of the RA;
- Ensure that human health and the environment remain protected during the implementation of the selected remedial alternative;
- Provide sufficient performance-monitoring data to adequately evaluate the ability of the remedial alternative to meet the ROs.

To meet these objectives, the MCP will have a groundwater monitoring program to evaluate the effectiveness of the preferred remedial alternative. Proposed groundwater monitoring activities identified in the MCP will be subject to revision based on a periodic evaluation of data collected during the early phases of RA implementation.

This plan will also describe actions to be taken (i.e., contingencies) in the event that the monitoring or other information reveals that additional steps should be undertaken to protect human health or the environment. The contingencies will be activated by "triggers" that are pre-determined action levels or conditions. Finally, the MCP will present the criteria by which the remedial systems will be shutdown.

9.7 Monitoring Program

The monitoring program will be used to monitor performance of the remedial systems in attaining the Campus Area ROs and RGs. The monitoring program component of the MCP will be developed as part of the RD; however, modifications to this program may be appropriate during the early phases of RA implementation based on actual conditions encountered.

The monitoring program data will be used to evaluate changes in the overall extent of the COCs in soils and groundwater in the Campus Area over time. In addition, the groundwater data will be used to:

- Evaluate the mass removal effectiveness of various components of the RA;
- Confirm that the RA is achieving the ROs set for the Campus Area;
- Evaluate the significance of natural attenuation processes throughout the operation of the RA; and
- Evaluate the need to implement contingency measures.

The MCP will include provisions for performance monitoring locations; analytical requirements; field methods; QA/QC guidelines; and reporting requirements.

With respect to monitoring wells, the locations will be selected considering (1) existing monitoring wells (2) the likely location of groundwater extraction wells that will be installed in the RA; and (3) the historical monitoring data results. The MCP will specify the water-bearing unit in which the monitoring wells will be screened, the proposed frequency of sampling, analytical target list, and intended purpose. All proposed monitoring and groundwater extraction wells required by the MCP will be installed during the RA phase.

9.8 Contingency Program

The purpose of any contingency program is to establish a mechanism by which meaningful changes in circumstances will be addressed in the design or operation of the remedial systems. Such a program will be structured around "triggers," the action levels or conditions that require a response, and "contingencies," the responsive actions to a trigger. Here, the point of the MCP contingency program is to allow contingency measures to be implemented where the triggers indicate that additional action is needed to protect human health or the groundwater resource. The contingency program that will be developed and submitted with the MCP will cover the following:

- The conditions that trigger a responsive action (i.e., triggers);
- The means of reviewing analytical data obtained from the monitoring program to determine if triggers are met;

- The contingency action to be taken in a response to a triggering event; and
- The reporting requirements when contingencies are triggered.

9.8.1 Identification of Triggers

The types of information or events that would trigger the implementation of a contingency action may be analytical results, observations conducted during the monitoring program, or events like the drilling of a new supply well. Specific triggers will be developed and submitted with the MCP considering the following factors:

- VOC concentration trends;
- Migration of VOCs in groundwater;
- Potential for impact to water supply wells; and
- Natural attenuation.

9.8.2 Identification of Contingencies

Contingencies are defined as a systematic set of site-specific, pre-determined responses to triggers that may be encountered during the implementation of a selected remediation alternative. Contingencies will be implemented if data, observations or events indicate that additional action is needed to protect human health or the groundwater resource In addition, some contingencies may be implemented to modify the scope of the monitoring program in response to changes in field conditions or groundwater quality, thus increasing the flexibility of the monitoring program based on an ongoing evaluation of the results of the monitoring program. Specific contingency measures will be developed and submitted as part of the Campus Area MCP.

At a minimum, the adequacy of ongoing remedial measures and the need for contingency measures will be considered on an annual basis as part of the groundwater monitoring program. Contingency measures will be implemented if groundwater monitoring indicates that additional action is needed to protect human health or the groundwater resource.

Any contingencies implemented and the corresponding triggers will be described in the data submittal or monitoring report prepared following that monitoring event. The MCP will identify any trigger conditions that would cause immediate agency notification upon discovery of the condition.

9.9 Shut-down Criteria and Post Shut-Down Monitoring

Performance monitoring data collected in accordance with the MCP will be evaluated to determine the effectiveness of individual components of the RA to meet the ROs, and for terminating portions of the remedial system, as appropriate. The primary performance

monitoring data for source area systems are extracted contaminant concentrations and contaminant mass removal time trends. The MCP will contain proposed shut-down criteria for approval by the RWQCB. These criteria will be used to determine final cleanup levels as remediation is completed, or when further remediation becomes technically infeasible. As stated previously, HBRGs and SRTs will be used to identify and prioritize areas in the Campus Area that require remediation. However, the eventual cleanup goals are, to a significant extent, technology-based. Thus, the HBRGs and SRTs may not be the final clean up standards for the Campus Area. It is also expected that the RWQCB would also consider MNA data collected and evaluated throughout the implementation of the RA. Where appropriate as a remedial response, MNA would continue until submittal of a Campus Area Closure Plan.

9.9.1 Shut-Down of Source Area Extraction

Source area extraction of both groundwater and vadose zone vapors (collected through the operation of DPE/SVE) would continue until reaching aquifer and media specific shut-down criteria approved by the RWQCB. The rationale that will guide the development of such criteria, which will be submitted in the MCP, is outlined below for each active component of the proposed remedial action:

Shut-Down Criteria for Groundwater Extraction

Consistent with the ROs, groundwater remediation in the source areas will be undertaken with the dual objectives of protecting human health and the groundwater resource. As such, groundwater extraction from the source area wells will continue, at a minimum, until performance-monitoring results indicate that all COC concentrations are below the RWQCB-approved HBRG values. To address the groundwater resource protection aspect of the ROs, the remediation will further seek to reduce Site COC concentrations to levels equal to MCLs, to the extent technically feasible. As noted previously, MCLs are standards that must be met before water can be supplied as drinking water. This is a highly unlikely scenario, since such water use from the Campus Area groundwater is restricted by CC&Rs and the water has other qualities (taste, color and smell) that make it an unlikely source of drinking water. Nonetheless, the groundwater extraction system will be run until it is no longer technically feasible to achieve MCLs by active remediation. The criteria for determining when this is so will be proposed in the MCP and will be assessed against the performance data that will be collected under the MCP monitoring program. It is also expected that the RWQCB would consider MNA data collected and evaluated throughout the implementation of the RA. Where appropriate as a remedial response that follows active remediation, MNA would continue until submittal of a Campus Area Closure Plan.

Shut-Down Criteria for Vapor Phase Extraction Component of DPE

Operation of the vapor extraction portion of the DPE or SVE remedy would continue until the effluent vapor concentrations and mass removal rates have reached asymptotic conditions. Rebound testing of the vapor extraction well(s) would be performed on a semi-annual basis for two years to verify that asymptotic conditions have been met.

Post Groundwater and Vadose Zone Vapor Extraction

It is expected that post-extraction groundwater monitoring of the upper Bellfower aquitard would continue on a semiannual basis for 2 years after the last DPE well has been shut down. If during the period of monitoring the concentration of a COC were found to rebound above the HBRGs, the affected extraction well would be operated until the conditions described above are met again. After 2 years of monitoring of the source area extraction wells, if no exceedances of HBRGs occur, the extraction wells would be permanently shut down. An evaluation of using MNA to address any residual contamination would be performed prior to requesting closure of the Campus Area active remediation systems from the RWQCB.

9.10 Reporting Requirements

Following each monitoring event completed in accordance with the MCP, a data submittal or monitoring report, as appropriate, would be prepared and submitted to the RWQCB. The contents and schedule for these reports will be discussed in further detail upon submittal of the detailed scope of work for the groundwater-monitoring program, which will be submitted prior to the implementation of the RA. On an annual basis, an Annual Summary Report will be submitted to the RWQCB that includes data presented in each monitoring report along with an evaluation of remedial system performance.

The Annual Summary Report will include an evaluation of the potential effectiveness of MNA as compared to active groundwater extraction. Once MNA becomes an approved remedial approach to replace the active remedial components, it would continue until submittal of a Campus Area Closure Plan to the RWQCB.

Subject: Former Fire Training Burn Pit Area - Phase 1 Project Area
Additional Soil and Groundwater Characterization Activities
Playa Vista Site, Los Angeles
CDM Project No.: 10610-32621-DATA

Dear Ms. Nevarez:

Camp Dresser & McKee Inc. (CDM) is submitting this letter report for soil and in-situ groundwater sampling conducted at the former Fire Training Burn Pit (FTBP) within the Phase 1 Project Area of the Playa Vista Site (Figure 1). This work was completed at the request of Playa Capital Company, LLC (PCC) in preparation for further development plans in the vicinity of the former FTBP. On January 30, 2001, Integrated Environmental Services, Inc., (Integrated) submitted a work plan to the Los Angeles Regional Water Quality Control Board (LA-RWQCB) to conduct additional groundwater investigation activities at the FTBP area. The work plan was approved by LA-RWQCB on July 27, 2001.

This letter report describes the recent site characterization and sampling activities completed at the former FTBP area, including rationale, technical approach, and results. For ease of presentation, figures and tables related to these most recent activities are included at the end of this letter report in Attachments A and B, respectively.

1.0 BACKGROUND

1.1 Geologic and Hydrogeologic Conditions

Two primary lithologic sequences exist in the shallow subsurface of the former FTBP, including a finer-grained unit of silty sand, silt and clay from ground surface to approximately 15 feet bgs (3 feet below mean seal level [msl]) and a coarser-grained sandy unit (including both poor- and well-graded sands) to an approximate depth of 40 feet bgs (30 feet below msl, the maximum depth investigated). Both lithologic sequences are part of the Bellflower aquitard, the uppermost hydrogeologic unit at the Site. A distinctive clay layer (3 to 10 feet thick) underlies the former FTBP area between depths of approximately 10 to 15 feet bgs (2 feet above msl to 3 feet below msl).

Groundwater is encountered at depths between 4 and 8 feet bgs (average elevation of 6.5 feet above msl measured in May 2001) in the former FTBP area. Groundwater flow for the Bellflower aquitard in this area is generally in a northerly direction at an approximate gradient of 0.004 feet/feet. Groundwater flow is generally perpendicular to and away from the Ballona Bluffs. The groundwater flow direction is depicted on Figure 2.

1.2 Summary of Historical Activities

Based on available documentation, the former FTBP was used between the early 1960s and mid-1980s to train fire fighters to handle chemical and fuel fires. The pit was unlined and surrounded by a one-foot high berm. Based on soil boring analytical results from *Remediation Report, First Phase, West Side Soils* (McLaren Environmental Engineering [MEE], 1987), soils impacted with petroleum hydrocarbons and volatile organic compounds (VOCs) extended vertically to a depth of 19.5 feet below ground surface (bgs) in the center of the bermed area.

The 1987 MEE report recommended that the former FTBP be dewatered, excavated and backfilled. Remediation of the pit began in March 1988. Approximately 1,815 cubic yards of soil were excavated from within the bermed area to a depth of 17 feet bgs. Shallow groundwater was encountered during excavation. Based on the evaluation of 20 confirmation soil samples collected from within the excavation area, with results below the clean-up criteria approved by the LA-RWQCB in June 1987, the excavation was considered complete. The excavation was backfilled with 15 feet of gravel and capped with 2 feet of native soil (MEE, 1988).

Subsequent investigations and monitoring activities were conducted after excavation activities were complete, which are summarized in the following sections. Analytical results from soil and groundwater investigations in the former FTBP are illustrated on the figures included in Attachment C.

1.2.1 Soil and Groundwater Investigation - January and February 2000

Soil and groundwater samples were collected in January and February 2000 as part of the LA-RWQCB approved *Soil and Groundwater Investigation Work Plan (SGIWP II), Phase I Project Area* (CDM, November 1999) to assess the extent of any remaining VOCs and TPH in groundwater and soil. During the investigation, 13 shallow borings (D-65 through D-77) were advanced in the FTBP area and soil samples collected at depths of 6 and 12 feet bgs. Ground surface was 11 to 12 feet above msl and sample depths ranged from 0 to 6 feet above msl. Four cone penetrometer test (CPT) borings were advanced in the vicinity of the former FTBP area to depths ranging from 31 to 44 feet bgs (to elevations of approximately 30 feet below msl). Also, three groundwater monitoring wells (MW-1F, MW-2F and MW-3F) were installed south of the former FTBP. The depths of the wells ranged from 10 to 16 feet bgs (bottom of wells at approximately 3 feet above msl). In-situ groundwater samples were collected at eight locations: samples were collected from borings CPT-1A, CPT-2A, CPT-3, CPT-4A, FTBP-1-24, HP-67, HP-72 and HP-73.

Results of the investigation were presented in the *Soil and Groundwater Investigation Report - Phase I Project* (CDM, May 2000). Soil and groundwater analytical results from historical investigations are illustrated on figures included in Attachment C (Figures C-1 and C-2, respectively). Significant findings are summarized as follows:

- Although chlorinated VOCs were detected in soil samples, concentrations were lower than the concentrations detected in confirmation samples collected in 1987 and lower than the approved 1987 clean-up levels (i.e., less than 1,000 times the corresponding maximum contaminant levels [MCLs]). Non-chlorinated VOCs were not detected in soil samples. TPH was detected in boring D-67; fuel fingerprinting indicated the detection was quantified in the motor oil range.

- Chlorinated VOCs were detected at concentrations greater than laboratory reporting limits in four (HP-67, HP-73, CPT-3 and CPT-4A) of the eight in-situ groundwater samples collected in the vicinity of the former FTBP. The highest concentrations were detected in the sample collected at 12 feet bgs (0 feet msl) in HP-73: cis-1,2-dichloroethene (cis-1,2-DCE) was detected at 760 micrograms per liter (µg/L); 1,1-dichloroethane (1,1-DCA) at 51 µg/L; 1,1-dichloroethene (1,1-DCE) at 26 µg/L, trans-1,2-DCE at 28 µg/L; trichloroethene (TCE) at 8.6 µg/L; and vinyl chloride at 11 µg/L. Tetrachloroethene (PCE) was detected in the sample collected at 12 feet bgs from HP-67 at a concentration of 71 µg/L.

- Chlorinated VOCs were detected in the three newly installed shallow groundwater monitoring wells. The highest concentrations were detected in well MW-3F: TCE (940 µg/L), 1,1-DCE (130 µg/L), 1,1-DCA (100 µg/L), trans-1,2-DCE (110 µg/L), cis-1,2-DCE (1,500 µg/L), PCE (16 µg/L) and vinyl chloride (42 µg/L).

- Non-chlorinated VOCs were detected at concentrations greater than the respective laboratory reporting limits in four of the in-situ groundwater samples and in one of the shallow monitoring well samples. Detections of non-chlorinated VOCs, however, were limited to benzene and toluene. Benzene was detected at concentrations just slightly higher than the reporting limit of 0.50 µg/L in samples collected from HP-72, HP-73, and CPT-4A, and in monitoring well sample MW-3F at a concentration of 1.4 µg/L; toluene was detected in sample CPT-2A at a concentration of 1.2 µg/L.

- TPH concentrations were detected within the shallow in-situ groundwater samples in the former FTBP. Fuel fingerprinting indicated that the TPH consisted of heavier hydrocarbons quantified in crude oil/motor oil range. Lighter hydrocarbons were detected in monitoring well MW-3F at a concentration of 450 µg/L.

Based on the results of this soil and groundwater investigation, subsequent field activities were conducted in April and May 2000 to further assess the extent of VOC and TPH contamination in soil and groundwater in the vicinity of the former FTBP.

1.2.2 Soil and Groundwater Investigation - April and May 2000

On April 7, 2000, CDM submitted an addendum to SGIWP II to implement the additional investigation activities. Field activities were conducted in April and May 2000 and included the advancement of two borings (D-117 and D-118) to depths of 15 feet bgs (to 3 feet below msl), and installation and sampling of three additional groundwater monitoring wells (MW-4F, MW-5F and MW-6F). Soil samples were collected at the above five boreholes. Samples were collected at multiple depths from each borehole up to a maximum depth of approximately 11.5 feet (0.5 feet above msl) and analyzed for VOCs and TPH. Significant findings from this investigation include:

- VOC analyses indicated the presence of chlorinated compounds, primarily TCE and cis-1,2-DCE, in soil samples collected from borings D-117, D-118, MW-4F and MW-6F. The maximum VOC concentrations were detected in these borings at depths of approximately 10 feet bgs (2 feet above msl), which corresponds to the upper portion of the clay layer underlying the former FTBP. Non-chlorinated VOCs (acetone and methyl tert-butyl ether [MTBE]) were only detected in the sample collected from MW-5F at a depth of 9.5 feet bgs (0.5 feet above msl) and at relatively low concentrations. TPH compounds were detected in the shallowest samples (i.e., 3.5 feet bgs, or 7 feet above msl) collected from borings MW-5F and MW-6F at concentrations of 17 and 15 milligrams per kilogram (mg/kg), respectively.

- Chlorinated VOCs, predominantly cis-1,2-DCE, were detected in two (MW-4F and MW-6F) of the newly-installed groundwater monitoring wells. The highest concentrations were reported in well MW-4F. Cis-1,2-DCE, TCE and vinyl chloride were detected in groundwater at concentrations of 110, 1.6 and 11 µg/L, respectively. Non-chlorinated VOCs and TPH compounds were not detected in any of the three wells at concentrations greater than the laboratory reporting limits.

1.2.3 Quarterly Groundwater Monitoring

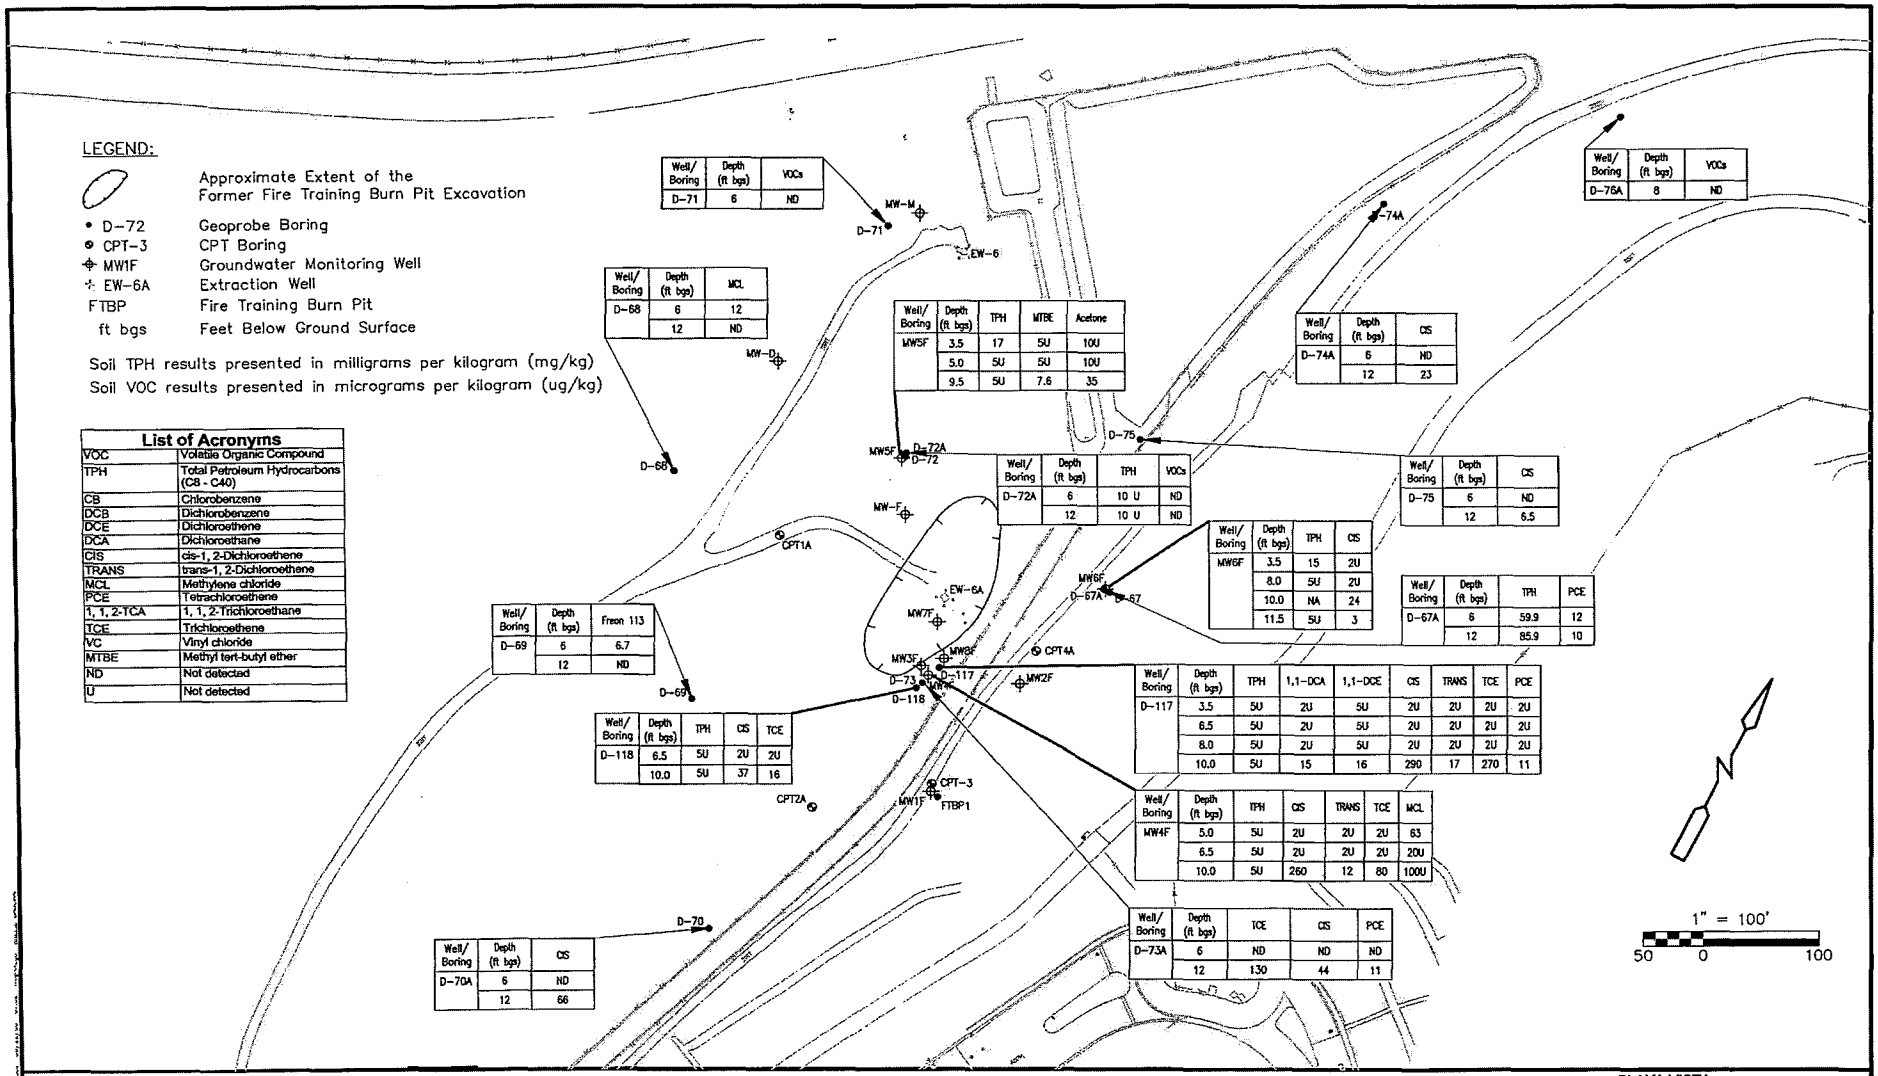
Six groundwater monitoring wells (EW-6A, MW-1F, MW-2F, MW-3F, MW-F and MW-M) located in the vicinity or down gradient of the former FTBP have been monitored at least twice during quarterly events since quarterly monitoring began in 1999. Of these six wells, two (MW-F and MW-M) are located down gradient of the former excavation and have slotted intervals beginning at depths of at least 30 feet bgs or deeper. Well MW-F has a slotted interval in both the Bellflower aquitard and Ballona aquifer (32.6 to 52.6 feet bgs) and MW-M is slotted within the Ballona aquifer (40 to 60 feet bgs). The other four wells screen the Bellflower aquitard at much shallower depths (bottom of slotted intervals

are 16 feet bgs or shallower). Analytical results from quarterly groundwater monitoring events for wells located in the vicinity of the former FTBP are summarized on tables included in Attachment D.

Low concentrations of chlorinated compounds have been detected in the deep down gradient wells MW-F and MW-M; however, the detections have been limited to cis-1,2-DCE. The maximum cis-1,2-DCE concentrations have been detected in well MW-M. Between March 1999 and May 2001, cis-1,2-DCE concentrations have remained consistently less than 8.1 µg/L. Non-chlorinated VOCs have not historically been detected in either of these two deep wells. TPH compounds have not been detected above laboratory reporting limits in wells MW-F and MW-M.

With respect to the four shallow wells in the vicinity of the former FTBP, the maximum chlorinated VOC concentrations have been detected in well MW-3F, which is located at the southern edge of the former excavated area and screens the Bellflower aquitard between 3 and 10 feet bgs (2 to 9 feet above msl). In May 2001, concentrations of cis-1,2-DCE and TCE were reported at750 and 170 µg/L, respectively. Vinyl chloride has also historically been detected in this well, with the most recent concentration at 9.3 µg/L (CDM, 2001).

The detection of non-chlorinated VOCs at concentrations greater than laboratory reporting limits in the shallower monitoring wells has been limited to benzene in wells EW-6A and MW-3F. The highest benzene concentration was reported in well EW-6A at 3.9 µg/L in January 2001. Non-chlorinated VOCs have not been detected in any of these wells at concentrations greater than laboratory reporting limits since January 2001. TPH has only been detected one time in any of the shallow wells; TPH was detected in well EW-6A at a concentration of 230 µg/L in January 2001.



2.0 SCOPE OF WORK

This work was completed at the request of PCC in preparation for further development plans in the vicinity of the former FTBP. The work plan approved by the LA-RWQCB (Integrated, June 29, 2001) included the collection of three in-situ groundwater samples down gradient of the former FTBP excavation. These three samples were to be analyzed for TPH with carbon chain identification to assess TPH contamination down gradient of the former FTBP area. Subsequently the scope of work was expanded to include the following:

- At each of the three originally proposed sample locations, in-situ groundwater samples were collected at two depths to provide data on the vertical distribution of contamination. Target samples depths were determined using current water level data from nearby monitoring wells and historical lithologic information. The uppermost groundwater sample was collected at the first encountered groundwater (within coarser-grained materials); whereas the second sample was collected

Notes:

VOC = Volatile Organic Compound
PCE = Tetrachloroethene; TCE = Trichloroethene; TCA = Trichloroethane; DCE = Dichloroethene; DCA = Dichloroethane; CFM = Chloroform; MCL = Methylene chloride; CBN = Chlorobenzene; DCB = Dichlorobenzene; BDM = Bromodichloromethane; CET = Chloroethane; CMT = Chloromethane; DCP = Dichloropropane; TCB = Trichlorobenzene; and VC = Vinyl chloride.

Samples analyzed by EPA Method 8260B.
Only analytes detected in one or more samples are listed.
All concentrations are reported in micrograms per liter (µg/L).
U = Not detected at a concentration greater than the reporting limit shown.
UB = Methylene chloride detected less than 5 times the concentration reported in the method blank.
J = Detected at an estimated concentration between method detection and laboratory reporting limits.
If left blank, analyte was either not analyzed or not reported.

Sample Type:
K = Split sample

PERMIT: OVERALL RATING__S__

1. Current copy of facility NPDES permit available on-site.	S
2. Correct name and mailing address of permittee identified on NPDES permit.	S
3. Facility is as described in permit.	S
4. a. Notification given to RWQCB of process/production modifications, collection system expansions, etc. that impacted quality/quantity of discharge or changes to the facility or increased discharge. b. Permit modification received, if required, prior to changes.	N
5. Recent permit modifications, amendments or compliance orders on file.	N
6. Number of discharge outfalls the same as listed in the permit.	S
7. Name of receiving waters listed correctly in the permit.	S
8. Permit status (i.e., current, expired, or extended)	Extended
9. Permit renewal application submitted to the RWQCB within 180 days of expiration date.	N
10. Other:	
Notes:	

RECORDS/REPORTS OVERALL RATING__S__

1. NPDES records maintained for the time period required (3 years):	Yes
2. a. Spills and bypasses reported and documented as required by the permit. b. Follow-up written documentation given as required by the permit (within 5 days in most cases).	Yes
3. Discharge Monitoring Report (DMR) evaluation: a. The responsible person or designee signs and certifies the DMR. (Yes) b. The facility monitors more frequently than required by the permit. (N) c. All data collected are summarized on the DMR. (Yes) d. Data reported on DMR consistent w/ analytical results. (Yes) e. Coliform concentrations calculated as required by the permit (e.g., median, geometric mean). (Yes) f. Numerical values for minimum detection limits are reported on DMR when laboratory reports "Not Detected" or "0" (for example, MDL= 3, Report: "<3" on DMR). (Yes) g. "Less than values" properly carried through loading calculations. (Yes) h. Flow measurement period used for loading calculations brackets the sampling period. (Yes) i. Influent and effluent loading rates properly calculated, if required. (Yes) j. Number Exceeding (N.E.) properly reported on all DMRs and annual reports. (Yes)	S
4. Reports completed in time frame and frequency as required by the permit (not all reports required for all facilities): a. Discharge Monitoring Reports (Yes) b. Biosolids Monitoring Reports (Yes) c. Biosolids Management Reports (Yes) d. CSO/ I&I Reports (N) e. Compliance Schedule Reports (N) f. Pretreatment Reports (N) g. Other	S

5. Sampling and analytical records (for water and biosolids) include: a. Dates, times, and location of sampling (Yes) b. Names of individuals performing sampling (Yes) c. Analytical methods (Yes) d. Results of analyses (Yes) e. Dates of analyses (Yes) f. Time of analyses, as necessary to verify holding times (Yes) g. Analysts' names or initials (Yes) h. Instantaneous flow at grab sample stations, if required (Yes)	S
6. Plant records include: a. Daily plant operational records or log book (Yes) b. Equipment maintenance records and schedules (Yes) c. CSO/lift station check records or log book (N) d. Records of auxiliary power checks (N) e. Spill Prevention Control and Countermeasure (SPCC) plan (N) f. Pollution Prevention Plan (P3) (Yes) g. Influent and Effluent flow measurement records maintained for the past three years (Yes) h. Other	S
7. All records and reports required by the permit appear to be organized and available for inspection.	S

FACILITY SITE REVIEW: OVERALL RATING_ S____

1. All treatment units and supporting equipment are in service and mechanically functioning properly.	S
2. Hydraulic and organic loadings are consistent with the fact sheet and plant design criteria. a. Are there signs of overloading to the facility and collection system, including I&I and septage loading?	S
3. Peak flows remain within the established plant capacity. a. If flows have exceeded capacity, has the RWQCB been notified?	N
4. Lift stations are properly monitored, maintained, have a back-up power source and are not subject to chronic spills and/or overflows.	N
5. Odors are adequately controlled, resulting in limited complaints.	S
6. Residual chlorine monitoring is well documented and sampling/monitoring is representative of the discharge. a. If a UV system is used, the dosage intensity, tubes, and alarms are adequate, maintained and documented.	S
7. Housekeeping procedures are adequate to prevent release of pollutants to environment: a. Adequate dikes and secondary containment b. Spill containment and clean-up c. Signs of spillage to soil, groundwater, or surface water d. Storm water and leachate management from storage piles e. Leaking pipes, pumps, etc. f. Drum and chemical storage areas g. Minimization of pollutants entering storm water outfalls h. Other open dumps or debris piles i. Other	S
8. Signs of tank deterioration and/or settlement.	N
9. Safety concerns may interfere with proper operation, maintenance, and/or monitoring.	N
10. Material Safety Data Sheets (MSDS) are available for stored chemicals.	S

FACILITY SITE REVIEW: OVERALL RATING_S___

11. Equipment available for spill cleanup and containment.		N
12. Other:		
Notes:		

EFFLUENT/RECEIVING WATERS: OVERALL RATING_S___

1. Recent DMR history () (outfall number(s) **002**): a. Violations of discharge limits (N) b. Spills/bypasses (N) c. Fish kills or other receiving water impacts (N) d. WET results are in accordance with the permit (N) e. If effluent limit violations have been identified, what actions has the facility taken to eliminate or reduce their reoccurrence?	S
2. DMR spot check conducted for the months of a. Internal lab sheets and contract lab results properly transferred to DMRs b. Monthly average, weekly, maximum, etc. values calculated per the permit and are correct c. Influent and effluent loadings reported d. DMR is accurate and complete for each outfall	N/A
3. Appearance of effluent during inspection: a. The effluent(s) was viewed during the inspection. b. Excessive foam, scum, or sheens present: **None** c. Cloudy and/or color: **Slightly turbid** d. Excessive solids: **None** e. Other:	S
4. Appearance of receiving water(s) during inspection: a. The receiving water(s) was viewed during the inspection b. Distinctly visible foam or sheens on receiving water c. Biosolids accumulation or deposits of solids below discharge point(s) d. Distinctly visible plume from discharge(s) to receiving water e. Discharge creates objectionable odor at or near receiving water f. Other:	N/A
Notes:	

FLOW MEASUREMENT: OVERALL RATING__S___

1. Flow Measurement devices and methods: **Influent Measurement** Primary Device (e.g., Parshall flume, weir, etc.): **Venturi meter (flume)** Secondary Device (e.g., transducer, float, strip gauge, etc.): **Effluent Measurement** Primary Device: **None** Secondary Device: Other method of estimating flow:_____	S
2. Flow measurement devices designed to meet permit requirements ("continuous measured," "continuous record," etc.).	N
3. Flow measurement location is representative of the actual discharge (considering return and bypass lines, etc.).	N
4. Flumes a. Approach channel straight for at least 10 times the maximum head height in flume. b. Flow enters flume evenly distributed across the channel and free of turbulence, boils, or other disturbances. c. The flume is clean and free of debris or deposits. d. All flume dimensions appear accurate, level, and plumb. e. Flume head being measured properly. f. Flume is appropriately sized to measure the existing range of flows. g. No obstructions downstream causing inaccurate flow measurement due to excessive "submergence" in flume. h. Proper flow tables being used.	N
5. Weirs a. Approach channel straight for at least 10 times the maximum head height. b. Flow in the approach channel is evenly distributed and free of turbulence, boils, or other disturbances. c. No solids accumulation in the bottom of the approach channel. d. Weir crest is located at least two times the maximum head height off the floor of the flow channel. e. The weir plate is level, plumb and without distortions. f. Weir is beveled on downstream side if plate is >1/8 inch thick. g. No leakage around the weir plate. h. Measuring point located at least 3 times the maximum head height behind (upstream of) the weir. i. There is free-fall and access for air below the nappe of the weir (i.e., water doesn't cling to the weir plate). j. Weir sized properly to measure the existing range of flows. k. Proper flow tables being used for weir type and size.	N
6. Secondary flow device properly installed and maintained, and operating without interference from foam, turbulence, webs, etc.	N
7. Date of last flow meter calibration: Performed by: **Mike Allen (Instrumentation Supervisor) and/or other staff**	S
8. Calibration checks by plant personnel routinely performed.	S
9. Calibration records (external and internal checks) maintained.	N
10. Other:	

Notes:
Final effluent flow is determined from the venturi meter readings of the influent flow. By approximately October of 2005, a flow meter will be installed at the end of each clarifier for effluent measurement.

SAMPLING (SELF-MONITORING PROGRAM): OVERALL RATING_S___

1. Sampling locations, type, methods, and frequencies conform to the NPDES permit for all required samples (including influent, effluent, biosolids, receiving stream, etc.).	S*
2. Sampling locations and methods provide representative samples. a. Grab samples are collected during peak flow conditions rather than low-stress conditions. b. Composite sampling procedures comply with the permit (time vs. flow weighted).	S111
3. Automatic samplers and other sampling equipment are properly cleaned.	N
4. Samples are preserved using methods listed in 40 CFR, Part 136 (e.g., chilled, acidified, etc.).	N
5. Sample containers are as listed in 40 CFR, Part 136.	N
6. Chain-of-custody is maintained and documented.	S
7. Samples are collected using approved protocols: a. Coliform sample taken directly into sterilized container. b. BOD samples are taken prior to disinfection or reseeded. c. Oil and grease collected directly into a glass container. d. Other:	S
8. Other:	

Notes:

I collected final effluent samples at the Outfall 002 station. The samples were stored in ice-chests prior to submittal to the State Laboratory. Analysis results were in compliance with their respective discharge limitations.

LABORATORY: OVERALL RATING__S___

1. On-site lab is certified? a. List parameters analyzed on-site that are used for DMR reporting: **See MRP No. 1492 (not including parameters listed in item 8 of the following page)** b. List additional parameters analyzed for internal monitoring and process control: **TSS, VSS, DO, nitrite, ammonia, pH, BOD, COD, settleable Solids**	Yes
2. EPA-approved analytical procedures are used in the on-site laboratory	S
3. Adequate equipment and procedures used for on-site analyses: a. BOD and CBOD b. TSS c. pH d. Dissolved Oxygen e. Residual Chlorine f. Temperature g. Other	N
4. On-site laboratory records include: a. Calibration and maintenance of equipment b. Equipment operating instructions and manuals	S
5. Adequate spare parts and supplies for on-site analyses.	N
6. Results of latest external DMR QA study are available and are acceptable. Date of last review: _____	N
7. Satisfactory refrigeration in use.	S
8. Certified contract laboratory being used: Laboratory name: **Fruit Growers Laboratory** Visited (no) Address: **853 Corporation Street, Santa Paula, CA**	

LABORATORY:

OPERATIONS AND MAINTENANCE:

OVERALL RATING__S___

1. Preliminary treatment units (bar screens, comminuters, grit channels, etc.) properly maintained with wastes properly disposed.	S
2. Adequate oxygen maintained in aerated treatment systems.	S
3. No operational problems caused by hydraulic "short-circuiting" in treatment units.	N
4. Biosolids wasting/return rates adequate to maintain system equilibrium.	S
5. O&M Manuals and supporting information organized and maintained for use: a. Plant O&M Manual b. Equipment manuals c. Plant engineering drawings d. Collection system drawings available or in development e. Maintenance records/costs	S
6. Routine and preventive maintenance items are scheduled and performed on time.	N
7. The amount of maintenance activities and parts in back-log is acceptable.	N
8. Operational problems contributing to plant upset, excessive odors, effluent violations, etc.	S
9. Level of operator certification as required by the permit and staffing level as specified in O&M Manual.	S
10. Auxiliary power available as required by the permit and operates the necessary treatment units.	S
11. Alarm systems for power and equipment failure.	S
12. Treatment control procedures are established for emergencies.	N
13. Hydraulic surges are handled without excessive solids wash-out or bypasses.	N
14. Spare pumps and parts readily available.	N
15. Facility appears to be well operated and maintained.	S
16. Other:	

Notes:

BIOSOLIDS/SOLID WASTE HANDLING AND DISPOSAL: OVERALL RATING_N____

1. Biosolids/solid waste disposal/reuse method (e.g., land application, landfill, etc.):	N
2. Biosolids/solid waste disposal/reuse location(s) (provide name or other identifier for disposal location):	N
3. The above processes are in accordance with the permit.	N
4. Storage at facility: a. Adequately sized for periods of inclement weather b. Controls leachate, runoff, and public access	N
5. Recent analytical results for metals (biosolids) are within permit limits.	N
6. Biosolids land application records include: a. Farm maps and land owner agreements b. Soil nutrient analyses done within the last year for active sites c. Records showing loading rate to each site d. Pathogen/Vector reduction records (pH or temp. logs, etc.)	N

7. Other:		

Notes:

COMPLIANCE SCHEDULES: OVERALL RATING_N____

1. Facility is subject to a compliance schedule in either its permit or in an order.	Yes / No
2. Items in the compliance schedule, which are currently due, have been completed (includes both the permit and orders).	N
3. The permittee has a plan to comply with items in the compliance schedule coming due in the future (includes both the permit and orders).	N
4. Written notification to RWQCB of compliance with scheduled items as required by the permit.	
5. Other:	

Notes:

PRETREATMENT: OVERALL RATING_N____

1. The facility has/participates in an approved pretreatment program. a. POTW has approved pretreatment program? b. Name of POTW running industrial facility's pretreatment program: ____Hyperion Wastewater Treatment Plant	Yes / No Yes / No
2. The latest annual report is available for review.	N
3. Procedures are sufficient to ensure that all required industrial users are subject to POTW pretreatment permits.	N
4. Effluent toxicity has not been identified as a result of WET testing.	N
5. Environmental and/or operational problems caused by: a. Restaurant cooking grease discharged into system b. Commercial discharges (e.g., mobile detailers, carpet cleaners) c. Food processing waste d. Industrial toxics e. Other industrial discharges:_____	N
Notes:	

STORM WATER: OVERALL RATING_S____

1. a. Facility storm water discharges are covered under the facility's individual NPDES permit or the California General Permit for Storm Water Discharges Associated with Industrial Activity (NOI is available). b. If no, should the facility have submitted an NOI for coverage under the California General Permit for Storm Water Discharges Associated with Industrial Activity (NPDES CAS000001).	Yes
2. The facility had a storm water pollution prevention plan (SWPPP) available for on-site review.	S
3. Pollutant sources (materials and practices) are adequately controlled (inside, undercover).	S
4. Appropriate BMPs deployed.	N
5. BMPs are being maintained (e.g., waddles and hay bales are intact).	S
6. Designated outfalls and sampling locations are identified.	S
7. Other:	
Notes: **Staff can access an electronic copy of the SWPPP with an intranet connection. The hard copy is kept at their administration offices in downtown Los Angeles. Housekeeping near stormwater sampling sites appeared satisfactory.**

INSPECTION REPORT

A-1650

RECEIVED
2009 JUN 9 AM 8 36
CALIFORNIA REGIONAL WAT
QUALITY CONTROL BOARD
LOS ANGELES REGION

Facility Narrative

On April 7, 2009 a USEPA contractor inspected the City of Los Angeles – Hyperion Treatment Plant in Playa Del Rey, CA. Discharges from the facility are regulated by Regional Water Board Order No. R4-2005-0020 (NPDES Permit No. CA0109991). The primary purpose of the inspection was to determine the accuracy and reliability of the Discharger's self-monitoring and reporting program. The primary on-site facility representatives were Ron Bell (Shift Supervisor) and Jeff Beller (Laboratory Manager II). The weather at the time of inspection was sunny with no signs of recent precipitation.

The City of Los Angeles (City or Discharger) owns and operates the Hyperion Treatment Plant (Facility) which discharges disinfected (through Outfall 001) / non-disinfected (through Outfall 002) secondary treated municipal wastewater to the Pacific Ocean within Santa Monica Bay. The Facility is part of a joint outfall system commonly known as the Hyperion Treatment System which consists of the wastewater collection system, the Hyperion Treatment Plant, and three upstream wastewater treatment plants: Donald C. Tillman Water Reclamation Plant (Tillman WRP), Los Angeles-Glendale Water Reclamation Plant (LAGWRP), and Burbank Water Reclamation Plant (Burbank WRP) (owned and operated by the City of Burbank). The Hyperion Treatment System collects, treats, and disposes of sewage from the entire City (except the Wilmington - San Pedro Area, the strip north of San Pedro, and Watts) and from a number of cities and agencies under contractual agreements. Approximately 85% of the sewage and commercial/industrial wastewater comes from the City. The remaining 15% comes from the contract cities, business zones and agencies. There are approximately four million people in the Hyperion Treatment System Service Area.

The Hyperion Treatment System is an interconnected system and includes approximately 6,500 miles of sewer lines located within the City (including trunk sewers in contract cities, business zones and agencies) and additional sewer lines under the control of the contract cities and agencies. The contract cities and agencies operate their respective collection systems that are tributary to the City's main trunk lines. Sludge from the City's two upstream plants is returned to the wastewater collection system and flows to the Facility for treatment. Discharges from Tillman WRP and LAGWRP are regulated by NPDES Permit Numbers CA0056227 and CA0053953, respectively. In addition, sludge generated from the Burbank WRP is also returned to the City of Burbank sewer system for discharge to the Hyperion Treatment System for treatment at the Hyperion Treatment Plant. The influent to the Burbank WRP can be diverted to the Hyperion Treatment System during periods of emergency. The operations of the Burbank WRP are regulated under NPDES Permit No. CA0055531.

The Facility has two ocean outfalls. Outfall 001 is commonly referred to as the "one-mile outfall". It is a 12-foot diameter outfall terminating approximately 5,364 feet west-southwest of the Facility at a depth of approximately 50 feet below the ocean surface. This outfall is permitted for emergency discharge of chlorinated secondary treated effluent during extremely high flows, power failures, and preventive maintenance, such as routine opening and closing the outfall gate valve(s) for exercising and lubrication (occurred twice since the last inspection). However, during intense storms or storms associated with Facility power outages, direct discharge of nondisinfected storm water overflow is also permitted at this outfall. This Order requires the City to notify the Regional Water Board and USEPA in advance of any planned preventive maintenance that results in discharges through Outfall 001 (the Regional Water Board was informed prior to the two scheduled preventive maintenance activities that occurred since the last inspection). Outfall 002 is commonly referred to as the "five-mile outfall". It is a 12- foot diameter outfall terminating approximately 26,525 feet (8.1 km) west-southwest of the Facility at a depth of approximately 187 feet (57 m) below the ocean surface. This outfall is located North of Outfall 001 and ends in a "Y" shaped diffuser consisting of

two 3,840-foot legs. This is the only outfall permitted for the routine discharge of nondisinfected secondary treated effluent.

The Facility has a dry weather average design treatment capacity of 450.0 million gallons per day (mgd) and a wet weather peak hydraulic capacity of approximately 850.0 mgd. The instantaneous influent flow was 311.0 mgd at 10:30 AM.

The Facility also accepts dry weather urban runoff that is diverted from storm drains into the City's collection system from April 1 to October 31. The City plans to extend this diversion operation from the dry summer months to year-round in order to conform to the six-year compliance schedule for bacteria concentration during winter dry weather, contained in the Santa Monica Bay Beach Dry-weather Bacteria TMDL regulation (Resolution No. 02-004 and Resolution No. 2002-022) adopted by the Regional Water Board.

Discharge monitoring reports (DMRs) for Outfall 002 for the months of November and December 2008, and January 2009 were reviewed as a component of this inspection. The review included a comparison of reported monitoring results versus requirements and limitations contained within the permit. The Discharger had three consecutive months of ammonia performance goal exceedances from November 2008 to January 2009. The facility's effluent quality is discussed in the 'Major Findings' and 'Effluent and Receiving Waters' section of this report.

Members from the Discharger's laboratory conduct the self-monitoring activities. Effluent samples for Outfall 002 are collected from a sink off of the discharge line (refer to Photo 4). Sample collection location and methods appeared to provide representative samples. All samples are analyzed at the on-site laboratory.

Major Findings

Effluent and Receiving Waters

1. Regional Water Board Order No. R4-2005-0020, Section I.A.2 of the permit requires the Discharger to "submit a written report to the Regional Board and USEPA on the nature of the exceedance, the results of the investigation as to the cause of the exceedance, and the corrective actions taken or proposed corrective measures with timetable for implementation" if there are three consecutive months of performance goal exceedances. The Discharger had three consecutive months of ammonia exceedances from November 2008 to January 2009. The Discharger's January 2009 monthly monitoring report discusses the nature of the exceedances and the potential cause, but does not discuss corrective actions or associated timetables.

Self-Monitoring Program

1. Regional Water Board Order No. R4-2005-0020, Monitoring and Reporting Program (MRP) 1492 (Attachment T) III.B/C require that "Pollutants shall be analyzed using the analytical methods described in 40 CFR 136". Some of the parameters analyzed from composite samples require a preservation temperature at or below 6 degrees F, as specified by the sample preservation requirements in 40 CFR 136. The Facility did not maintain thermometers installed in the influent and effluent composite samplers (refer to Photos 3 and 5). Therefore, the Discharger cannot demonstrate compliance with the sample preservation requirements specified in 40 CFR Part 136.

PERMIT: **OVERALL RATING: S**

INSPECTED ITEM	EVAL
1. Current copy of facility NPDES permit available on-site.	S
2. Correct name and mailing address of permittee identified on NPDES permit.	S
3. Facility is as described in permit.	S
4. a. Notification given to Regional Water Board of process/production modifications, collection system expansions, etc. that impacted quality/quantity of discharge or changes to the facility or increased discharge. b. Permit modification received, if required, prior to changes.	N N
5. Recent permit modifications, amendments or compliance orders on file.	N
6. Number of discharge outfalls the same as listed in the permit.	S
7. Name of receiving waters listed correctly in the permit.	S
8. Permit status (i.e., Current, Expired, or Extended)	Current
9. Permit renewal application submitted to the Regional Water Board at least 180 days prior to the expiration date.	N
10. Other:	N
Notes: ***This section was rated "satisfactory" because all items reviwed were rated satisfactory.***	

RECORDS/REPORTS: **OVERALL RATING: S**

INSPECTED ITEM	EVAL
1. NPDES records maintained for the time period required (5 years): The following records and reports were requested and observed: - ***Machinery Calibration Logs*** - ***Work Orders*** - ***November 2008, December 2008, and January 2008 DMRs*** - ***Operation and Maintenance Reports (i.e. for the One Mile Outfall)*** - ***2008 Biosolid Annual Report***	Yes
2. a. Did the facility document any spills or bypasses during the period reviewed? b. Spills and bypasses reported and documented as required by the permit (i.e.- as soon as possible, but no later than 24 hours from the time the permittee first became aware of the circumstances). c. Follow-up written documentation given as required by the permit (within 5 days in most cases).	No N N
3. Discharge Monitoring Report (DMR) and/or Self Monitoring Report (SMR) evaluation: a. The responsible person or designee signs and certifies the DMRs/SMRs. b. The facility monitors more frequently than required by the permit. c. All data collected are summarized on the DMRs/SMRs. d. Data reported on DMRs/SMRs is consistent w/ analytical results. e. Coliform concentrations calculated as required by the permit (e.g., median, geometric mean). f. Numerical values for minimum detection limits are reported on DMRs/SMRs when laboratory reports "Not Detected" or "0" (for example, MDL= 3, Report: "<3" on DMR). g. "Less than values" properly carried through loading calculations. h. Flow measurement period used for loading calculations brackets the sampling period. i. FACILITY SITE REVIEW: **OVERALL RATING: S**

INSPECTED ITEM	EVAL
1. All treatment units and supporting equipment are in service and mechanically functioning properly. ***The Plant provides full secondary treatment for the wastewaters received. Preliminary and primary wastewater treatment consists of screening, grit removal, and primary sedimentation with coagulation and flocculation. In secondary treatment, the primary effluent is biologically treated in a high purity oxygen activated sludge process comprised of a cryogenic oxygen plant, 9 secondary reactor modules and 36 secondary clarifiers. Each secondary reactor module is designed to handle 50 mgd of flow which results in a total treatment capacity of 450 mgd of primary effluent. After clarification, non-disinfected secondary effluent is discharged into Santa Monica Bay through a five mile submerged outfall pipe. A discharge of up to 325 mgd flows by gravity to the outfall, or is pumped at the Effluent Pumping Plant when flows exceed 325 mgd.*** ***Solid fractions recovered from wastewater treatment processes include grit, primary screenings, primary sludge and skimmings, thickened waste activated sludge, digested sludge screenings and digester cleaning solids. The fine solids (grit, primary screenings, digested sludge screenings, digester cleaning solids) that consist of primarily inorganic materials are hauled away to landfills. The remaining solid fractions (primary sludge, skimmings, and thickened waste activated sludge) are anaerobically digested onsite. The digested solids are screened and dewatered using centrifuges. The biosolids are beneficially reused offsite for land application and composting projects. The digester gas is cleaned and piped to the Los Angeles Department of Water and Power's Scattergood Steam Generating Plant, located immediately adjacent to the plant. The exported digester gas is used as fuel in the generation of electricity. In return, the generating plant provides steam for digester heating. During interruptions in the export of steam from the DWP Scattergood Steam Generation Plant, digester gas can be used as fuel for in-plant boilers that provide steam to heat the anaerobic digesters.***	S
2. Hydraulic and organic loadings are consistent with the fact sheet and plant design criteria. a. Are there signs of overloading to the facility and collection system, including I&I and septage loading?	S S
3. Peak flows remain within the established plant capacity. a. If flows have exceeded capacity, has the Regional Water Board been notified?	S N
4. Lift stations are properly monitored, maintained, have a back-up power source and are not subject to chronic spills and/or overflows.	N
5. Odors are adequately controlled, resulting in limited complaints.	S
6. Residual chlorine monitoring is well documented and sampling/monitoring is representative of the discharge. a. If a UV system is used, the dosage intensity, tubes, and alarms are adequate, maintained and documented.	S N

Facility Narrative

On October 6 and 7, 2009 a USEPA contractor inspected the City of Los Angeles – Hyperion Treatment Plant in Playa Del Rey, CA. Discharges from the facility are regulated by Regional Water Board Order No. R4-2005-0020 (NPDES Permit No. CA0109991). The primary purpose of the inspection was to determine the accuracy and reliability of the Discharger's self-monitoring and reporting program. The primary on-site facility representatives were Mike Ruiz (Shift Supervisor II) and Mahesh Pujari (Senior Chemist). The weather at the time of inspection was sunny with no signs of recent precipitation.

The City of Los Angeles (City or Discharger) owns and operates the Hyperion Treatment Plant (Facility). The Facility provides secondary level treatment in a process train which consists of screening, grit removal, primary sedimentation with coagulation and flocculation, activated sludge biological treatment, and secondary clarification. Sludge processing includes anaerobic digestion prior to disposal in a landfill or reuse by land application.

The Facility discharges secondary treated municipal wastewater through two outfalls to the Pacific Ocean within Santa Monica Bay. Outfall 001 discharges disinfected secondary effluent while Outfall 002 discharges nondisinfected secondary effluent, the outfalls are discussed in more detail later in this 'Facility Narrative' section. The City's Hyperion Treatment System, which includes both the sewer system and the Facility, is designed to collect and treat wastewaters generated within the City. The City sewer system services approximately 600 square miles. The system consists of approximately 15 interceptor sewer lines servicing four wastewater treatment plants including the Facility, and three upstream wastewater treatment plants: Donald C. Tillman Water Reclamation Plant (Tillman WRP), Los Angeles-Glendale Water Reclamation Plant (LAGWRP), and Burbank Water Reclamation Plant (Burbank WRP) (owned and operated by the City of Burbank). The Hyperion Treatment System collects, treats, and disposes of sewage from the entire City (except the Wilmington - San Pedro Area, the strip north of San Pedro, and Watts) and from 29 cities and agencies under contractual agreements. Approximately 85% of the sewage and commercial/industrial wastewater comes from the City. The remaining 15% comes from the contract cities, business zones and agencies. There are approximately four million people in the Hyperion Treatment System service area.

The Hyperion Treatment System is an interconnected system which supports approximately 6,500 miles of sewer lines located within the City (including trunk and interceptor sewers in contract cities, business zones and agencies) and additional sewer lines under the control of the contract cities and agencies. The contract cities and agencies operate their respective local collection systems that are tributary to the City's trunk and interceptor lines. Sludge from two of the City's two upstream plants is returned to the wastewater collection system and flows to the Facility for processing. Discharges from Tillman WRP and LAGWRP are regulated by NPDES Permit Numbers CA0056227 and CA0053953, respectively. Sludge generated from the Burbank WRP is discharged to the Hyperion Treatment System's North Outfall Sewer for processing at the Facility. In addition, the influent to the Burbank WRP can be diverted to the Hyperion Treatment System during periods of emergency. The operations of the Burbank WRP are regulated under NPDES Permit No. CA0055531.

As previously stated, the Facility has two ocean outfalls. Outfall 001 is commonly referred to as the "one-mile outfall". It is a 12-foot diameter outfall terminating approximately 5,364 feet west-southwest of the Facility at a depth of approximately 50 feet below the ocean surface. This outfall is permitted for emergency discharge of chlorinated secondary treated effluent during extremely high flows, power failures, and preventive maintenance, such as routine opening and closing (exercising) the outfall gate valve(s) and for lubrication. Regional Water Board Order No. R4-2005-0020

requires the City to notify the Regional Water Board and USEPA in advance of any planned preventive maintenance that results in discharges through Outfall 001. The City provides prior written notice to the Regional Water Board when preventive maintenance has been scheduled, typically once a quarter. Outfall 002 is commonly referred to as the "five-mile outfall". It is a 12-foot diameter outfall terminating approximately 26,525 feet (8.1 km) west-southwest of the Facility at a depth of approximately 187 feet (57 m) below the ocean surface. This outfall is located north of Outfall 001 and ends in a "Y" shaped diffuser consisting of two 3,840-foot legs. This outfall is permitted for routine discharge of non-disinfected secondary treated effluent.

Hyperion also provides the West Basin Municipal Water District (West Basin) with secondary effluent for additional treatment and sale to various clients. West Basin operates a Water Recycling Facility in El Segundo and has a contract to receive up to 70 mgd of secondary effluent from Hyperion Treatment Plant for advanced treatment. The secondary effluent is pumped from the southwest corner of the Plant to the West Basin Facility via a West Basin operated pump station. West Basin Facility provides tertiary treatment and/or advanced treatments such as microfiltration and reverse osmosis (RO) to the Hyperion secondary effluent to produce Title 22 and high purity recycled water. The Title 22 recycled water is used for beneficial irrigation and industrial applications (which included cooling water and boiler feed water). The RO treated recycled water is injected into the West Coast Basin Barrier Project to control seawater intrusion. The waste brine from West Basin Facility is discharged to the ocean through Hyperion's five-mile outfall via a waste brine line from West Basin Facility. Although the waste brine is discharged through Hyperion's outfall, it is regulated under separate waste discharge requirements and NPDES permit.

The Facility has a dry weather average design treatment capacity of 450.0 million gallons per day (mgd) and a wet weather peak hydraulic capacity of approximately 850.0 mgd. The instantaneous influent flow was 349.7 mgd at 11:05 AM on October 7, 2009.

The Facility continues to accept and treat dry weather urban runoff that is diverted from storm drains into the City's collection system from April 1 to October 31. The City plans to extend this diversion operation from the dry summer months to year-round in order to conform to the six-year compliance schedule for bacteria concentration during winter dry weather, contained in the Santa Monica Bay Beach Dry-weather Bacteria TMDL regulation (Resolution No. 02-004 and Resolution No. 2002-022) adopted by the Regional Water Board.

Members from the Discharger's operations and laboratory teams conduct self-monitoring activities. Effluent samples for Outfall 002 are collected from a sink that pulls effluent from the discharge line. Sample collection location and methods appeared to provide representative samples. All samples are analyzed at the on-site laboratory.

Discharge monitoring reports (DMRs) for Outfall 002 for the months of May, June, and July 2009 were reviewed as a component of this inspection. The review included a comparison of reported monitoring results versus requirements and limitations contained within the permit. Permit limit exceedances were identified and are presented in the 'Major Findings – Effluent and Receiving Waters' component of this report.

The Major Findings stated in the previous inspection report have not been corrected. The Discharger continues to exceed and report ammonia performance goals as previously documented; however the Discharger has not provided a corrective action plan or timetable for compliance. In addition, the Discharger's composite samplers still do not have thermometers to document that sample temperatures are at or below 6 degrees F as required by 40 CFR 136.

Major Findings

Effluent and Receiving Waters

1. Regional Water Board Order No. R4-2005-0020, Section I.A.2 requires the Discharger to comply with a Settleable Solids Daily Maximum concentration of 3.0 ml/L. On July 16, 2009 at 1:00 PM the Settleable Solids Daily Maximum concentration was 25.0 ml/L (refer to Exhibit 1).

2. Regional Water Board Order No. R4-2005-0020, Section I.A.2 requires the Discharger to "submit a written report to the Regional Board and USEPA on the nature of the exceedance, the results of the investigation as to the cause of the exceedance, and the corrective actions taken or proposed corrective measures with timetable for implementation" if there are three consecutive months of performance goal exceedances. The Discharger had nine consecutive months of ammonia exceedances from November 2008 to July 2009. The Discharger's July 2009 DMR discusses the nature of the exceedances and the potential cause, but does not discuss corrective actions or associated timetables.

Self-Monitoring Program

1. Regional Water Board Order No. R4-2005-0020, Monitoring and Reporting Program (MRP) 1492 (Attachment T), III.B requires that "Pollutants shall be analyzed using the analytical methods described in 40 CFR 136". Some of the parameters analyzed from composite samples require a preservation temperature at or below 6 degrees C, as specified by the sample preservation requirements in 40 CFR 136. The Facility did not maintain thermometers in the influent and effluent composite samplers. Therefore, based on these findings, the Discharger cannot demonstrate compliance with the sample preservation requirements specified in 40 CFR Part 136.

2. Regional Water Board Order No. R4-2005-0020, Monitoring and Reporting Program (MRP) 1492 (Attachment T), III. C requires that "Proper chain of custody procedures must be followed". Sample chain of custody could be questioned due to the transfer of samples between the operations and laboratory teams. The current operational practice is for influent and effluent samples to be placed by the operations team in an unsecure refrigerator located in the loading dock area of the laboratory/administration building with sample collection data and signed chain of custody. The laboratory team eventually removes the samples, data, and chain of custody from the unsecure refrigerator and delivers them to the on-site laboratory. Therefore, based on these findings, the Discharger cannot demonstrate compliance with valid chain of custody protocols.

Operations and Maintenance

1. Regional Water Board Order No. R4-2005-0020, Standard Provisions (Attachment S), Provision C requires that the "discharger shall, at all times, properly operate and maintain all facilities and systems of treatment". On July 14, 2009 the Facility shut down solids wasting operations to accommodate some scheduled preventive maintenance activities. Those preventive maintenance activities had an unscheduled delay of 16 hours and created a situation in which some solids were washed out of the secondary clarifiers. At 1:00 PM on July 16, 2009 the Facility's effluent exceeded its settleable solids daily maximum concentration limit (25.0 ml/L vs

permitted 3.0 ml/L). Therefore, based on these findings, the Discharger failed to properly operate and maintain all facilities and systems of treatment.

FACILITY SITE REVIEW: **OVERALL RATING: S**

INSPECTED ITEM	EVAL
1. All treatment units and supporting equipment are in service and mechanically functioning properly. ***The Facility provides full secondary treatment for the wastewaters received. Preliminary and primary wastewater treatment consists of screening, grit removal, and primary sedimentation with coagulation and flocculation. In secondary treatment, the primary effluent is biologically treated in a high purity oxygen activated sludge process comprised of a cryogenic oxygen plant, nine secondary reactor modules and 36 secondary clarifiers. Each secondary reactor module is designed to handle 50 mgd of flow which results in a total treatment capacity of 450 mgd of primary effluent. After clarification, non-disinfected secondary effluent is discharged into Santa Monica Bay through a five mile submerged outfall pipe. A discharge of up to 325 mgd flows by gravity to the outfall, or is pumped at the Effluent Pumping Plant when flows exceed 325 mgd.*** ***The solids management operations were not inspected as a component of this inspection. The Facility hauls grit, primary screenings, skimmings, and other inorganic materials offsite for disposal at landfills. Biosolids are processed on-site by means of anaerobic digestion and beneficially reused for land application and composting.***	S
2. Hydraulic and organic loadings are consistent with the fact sheet and plant design criteria. a. Are there signs of overloading to the facility and collection system, including I&I and septage loading?	S S
3. Peak flows remain within the established plant capacity. a. If flows have exceeded capacity, has the Regional Water Board been notified?	S N
4. Lift stations are properly monitored, maintained, have a back-up power source and are not subject to chronic spills and/or overflows.	N
5. Odors are adequately controlled, resulting in limited complaints.	S
6. Residual chlorine monitoring is well documented and sampling/monitoring is representative of the discharge. a. If a UV system is used, the dosage intensity, tubes, and alarms are adequate, maintained and documented.	S N
7. Housekeeping procedures are adequate to prevent release of pollutants to the environment: a. Adequate dikes and secondary containment b. Spill containment and clean-up c. Signs of spillage to soil, groundwater, or surface water d. Storm water and leachate management from storage piles e. Leaking pipes, pumps, etc. f. Drum and chemical storage areas g. The Virtual Estuary
New GIS tool for exploration and analysis
By Sandra Fox, St. Johns River Water Management District, and Stephen Bourne, PBS&J

This article as a PDF .

A GIS tool developed by a team of experts is helping scientists more effectively study complex coastal and estuary systems.

In this portion of the estuary displayed in ArcScene, the high tide polygon (red line) and low tide polygon (solid dark blue) along with a digital elevation model (DEM) of the area

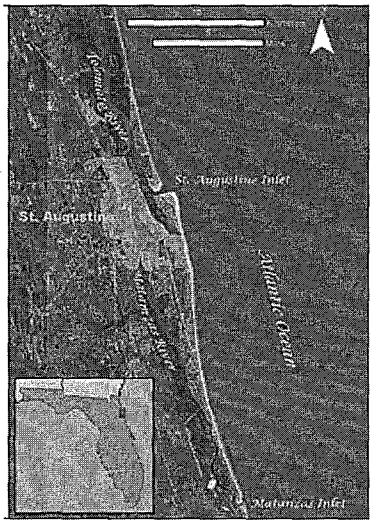
Coastal flooding from extreme weather events threatens millions of lives and properties along U.S. coastlines every year. Especially hard hit are areas along the Atlantic Ocean and the Gulf of Mexico where over 60 percent of homes and businesses are within 500 feet of the shoreline. Yet, the ability to explore and study complex coastal environments with accuracy and speed has been limited, if not impossible. Affordable hydrologic models that work well on inland studies simply don't translate to coastal applications. However, more sophisticated supercomputer-based modeling techniques are cost prohibitive.

In a pioneering effort, the St. Johns River Water Management District (SJRWMD) led a team of experts from academia, government, and industry in the development of the Analytical Framework for Coastal and Estuarine Studies (ACES) GIS tool, one of the first comprehensive coastal and estuarine tools. Still under development, ACES is designed to help scientists accurately monitor and manage the health of a complex estuary from within the Arc Hydro hydrologic environment. *[Arc Hydro is a data model template for use with water resources applications that has been developed by Esri in collaboration with key state, national, and international contributors.]*

This tool has been used to support estuarine and coastal studies for the Guana/Tolomato/Matanzas Estuary, also a National Estuary Research Reserve for SJRWMD, as well as water quality studies in the Gulf of Mexico. *[The National Estuarine Research Reserves are "living laboratories" that help researchers better understand coastal communities and find methods for dealing with the challenges these areas face.]*

Cooperative Development

SJRWMD is responsible for regulating water use and protecting wetlands, waterways, and drinking water supplies along Florida's sensitive eastern coastline from Fernandina Beach to Vero Beach. The agency's Surface Water Quality Monitoring (SWQM) has used Arc Hydro to develop specialized hydrologic tools such as an automated pollution load screening model and a drainage area spatial data summary tool.



Yet, while greatly beneficial, these hydrologic tools were unable to account for tidal influences, which directly impact water quality in estuarine waters. This limited the agency's ability to accurately manage water quality throughout the region.

SJRWMD put together a technical team to develop ACES that included experts from SJRWMD, University of Florida, The Nature Conservancy, U.S. Geological Survey, and PBS&J, a consulting firm. The agency also put in place an expert review team that would be responsible for evaluating the end product developed by the technical team. The review team included the members from the Center for Research in Water Resources at the University of Texas, Austin; U.S. Army Corps of Engineers' Engineer Research and Development Center; and PBS&J.

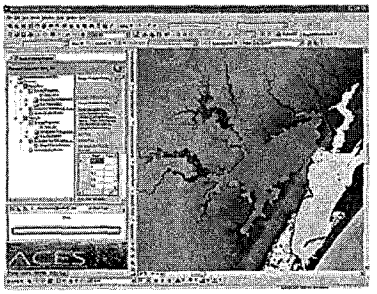
The technical team's first task was to establish a master plan for the tool development from proof of concept to production. SJRWMD stipulated that the tool must be applicable to all SJRWMD estuaries and include existing GIS-based tools and enhanced Arc Hydro geodatabases developed by SWQM. Goal-driven brainstorming sessions helped keep the technical team on track throughout the development process. The initial brainstorming sessions and literature review focused on the nature of

an estuary, estuarine hydrodynamics, estuarine classification, existing GIS-based modeling technologies for estuaries, and synthetic modeling of water quality in estuaries.

The team found that the first step in approaching the study of estuaries was the creation of a GIS-based workbench tool that could integrate multiple sources. Water in coastal areas frequently comes from multiple sources. These might include surface water flow, incoming tides, manmade waterways, and even in some cases groundwater. The tool had to allow for the creation of virtual estuaries and estimation of bulk parameters of the estuaries and facilitate development and integration of other models into the same framework.

The St. Augustine Inlet to the Guana/ Tolomato/Matanzas Estuary is a barrier that was accurately characterized with the ACES tool. The Matanzas Inlet is one of Florida's few remaining natural, unmanaged inlets.

Conceptual Controls



In the initial development phase of the ACES project, the technical team developed an estuary control volume conceptual model that connects features in the estuary physical model with elements contributing to the control volumes such as waters from coastal bases, oceanic constituents, riverines, and intracoastal waterways. Groundwater influence was not considered in this initial application since the influence is likely small as compared to the other elements.

The team relied on a simple multiple linear regression (MLR) tool for evaluating relationships between constituents emanating from drainage areas and the measured values of water quality in the control volume. A more robust estimate of contributing areas may be obtained by using an iterative process that compared predicted and measured values while modifying the drainage area contribution. Throughout the effort, the team communicated extensively regarding various topics ranging from the deceptively simple, such as the definition of an estuary, to the complex and controversial modeling approach.

Coastal Possibilities

The ACES prototype tool is composed of a GIS-based database of spatial and temporal data that describes the environment and an accompanying ArcMap-based toolset. Using ACES, scientists can essentially build a virtual model of the estuary they are interested in using topographic, bathymetric, and tidal datum data.

Within an Arc Hydro model, ACES can be used to determine estuarine bulk parameters (such as total area, high and low tide, volume, depth, and tidal flow) related to the shape of the estuary. With data related to flow rates into and out of the estuary, more complex parameters can be derived, such as residence time (the time water stays within a system) and flushing potential (an estuary's ability to flush a harmful substance).

ACES was used to find the volume of Copano Bay in Texas at several tidal levels to estimate pollutant loadings in the bay. Each colored polygon shows the shoreline for a different water level.

Using this information, the relative importance of tidal versus land-based flow on estuarine hydrodynamics can be assessed. Relationships between estuary water quality and flow rates can also be investigated. Using the ACES regression model capabilities, scientists can find the correlative relationships between the influential factors of upstream riverine drainage, coastal drainage, and estuarine non-point source pollution.

Prototype in Action

An ACES prototype was used to support estuarine and coastal studies for the Guana/ Tolomato/Matanzas Estuary, which is also a National Estuary Research Reserve for SJRWMD. Guana/Tolomato/Matanzas encompasses approximately 73,000 acres of salt marsh and mangrove tidal wetlands, oyster bars, estuarine lagoons, upland habitat, and offshore seas in northeast Florida. Along the northern section of the reserve, the Tolomato and Guana rivers meet the waters of the Atlantic Ocean. The southern section follows the Matanzas River, which extends from Moses Creek south of Pellicer Creek.

The ACES tool was also used to support a water quality study of Copano Bay in south Texas, a project sponsored by the Texas Commission on Environmental Quality. A popular fishing and recreation site, Copano Bay is a large watershed with source waters from Aransas Bay and several rivers. Dr.

Stephanie Johnson, then a doctoral student in the Center for Research in Water Resources at the University of Texas under Dr. David Maidment, wanted to develop an accurate water quality model for the bay. Johnson had already acquired estuary depth measurements, which she converted to volumes to model the processes within the bay.

"To complete this study, I needed basic information, such as the bay volume and symmetry, which I could have calculated by hand using available contour maps, though it would have been a tedious process," said Johnson. Working with the ACES development team, Johnson used the ACES program to automatically develop the necessary estuary volume versus depth curve for use when computing the total maximum daily load of pollutants. "Through the ACES program, I was also able to create highly visual images that I incorporated into my larger water quality model and used to communicate with various nontechnical stakeholders," added Johnson.

In the near future, environmental scientists at SJRWMD will use ACES to explore the estuaries along the northeastern coast of Florida, including the mouth of the St. Johns River, the Indian River Lagoon, and the Nassau and St. Marys rivers. ACES presents a wealth of possibilities for the exploration and analysis of estuaries at universities and within water management districts. This tool will continue to evolve in functionality and application to help coastal experts more easily explore and understand complex coastal environments.

PREFACE

This working paper is one of a series focused on the Marina del Rey being prepared as part of the Coastal Zone Planning and Management Project at the University of Southern California. The overall project has been conducted jointly by the Center for Urban Affairs and the Graduate Program of Urban and Regional Planning under a grant from the U.S. Department of Commerce to the U.S.C. Sea Grant Program. This paper was undertaken to provide an orderly, accurate presentation of the decision process which has led to the Marina's present status.

We believe that the study will be of value to the Los Angeles County Department of Small Craft Harbors in its future Marina development activities. Although the department has been our principal source of information, an outsider's view of past events is sometimes useful. The principal value, however, will accrue to other coastal communities which are considering marina development but do not have the experience which Los Angeles has gained.

Obviously, there are many aspects of the Marina which we have not investigated in depth here. Among these are current activity patterns, developer behavior, environmental conditions, effects on surrounding areas, and the internal governance of the Marina. Furthermore, it has not been our intention to identify individuals who have advocated various

B-132

policies. Other papers in the series will deal with many of these factors.

We would like to thank the following people at the Los Angeles County Department of Small Craft Harbors for their cooperation in providing reference documents and for the time they spent with us in interviews: Victor Adorian, Director; Donald Deise, Assistant Director; James Quinn, Chief of Operations and Development; Leo Bialis, Harbor Controller; and Richard Landon, Property Manager. Ben H. Southland, of Gruen Associates, who represented this consulting firm in their land use planning for the Marina, offered a number of valuable insights concerning its development.

We also recognize the important roles played by Ronald Linsky, Director of Sea Grant Programs at U.S.C.; Jerome Milliman, Director of the Center for Urban Affairs; and Professor Robert Warren in making the initial contacts which allowed us to proceed on this study.

CHAPTER I. INTRODUCTION

The Marina del Rey, on Santa Monica Bay in Los Angeles County, is one of the largest man-made small craft harbors in the world, containing 375 acres of land and 405 acres of water. It is expected to have about 6,000 boats in slips and hundreds more in dry storage. Beyond this, it is a small community in itself with a resident population of 10,000 and a seasonal daytime population of about 30,000. The residential accommodations are supplemented by extensive commercial facilities including a shopping center, office buildings, and many restaurants. Public investment to date has been over $36,000,000 which has been funded by federal and county contributions as well as a revenue bond issue of $13,000,000. Total private investment is expected to reach $160,000,000 or more. Today the project is clearly a financial success for the County, both in terms of internal revenues and increased tax income.

The site of the Marina is totally owned by Los Angeles County but most of the land and some of the water area is leased to private developers. The County Department of Small Craft Harbors, the Small Craft Harbor Commission and the Marina Design Control Board regulate both the form of development and the operations of the lessees.

Obviously, this financially successful project has required extensive and continuous planning effort. The pattern of decisions must be seen as a dynamic process. Plans have been modified considerably over a

long period of time and will continue to change. Each action taken by the County and by developers was a response to possibilities and constraints at a specific point in time, as they were perceived by particular groups. Some comments will be made here concerning the significance of Marina development decisions for its users, the surrounding area, and the community as a whole. However, a more complete critique of the decision process will appear in a later working paper.

Stages of development

The stages of Marina development and planning will be presented in a roughly chronological sequence. The first stage, up to 1956, covers early schemes for use of the Marina site and the planning which led up to a tentative decision for extensive public investment in a small craft harbor there.

During the second stage, 1956-62, detailed economic studies were conducted to estimate the costs and revenues from the Marina. Arrangements for the use of general fund and revenue bonds were established for financing public expenditures. The land needed for Marina development was acquired by the County and construction of the basic form of the Marina was undertaken. In 1960, the first complete land use plan was prepared. Procedures for leasing land and water parcels were defined. Finally, the first lessees built their own structures and began to operate.

B-135

A third stage began in 1962 with a period of great difficulty brought on by storm damage and problems with financing. Up to 1967, every decision concerning the Marina had to be made with the goal of increasing revenues in order to meet debt service requirements. At present, many private structures and their arrangement reflect the market and financing conditions existing during this critical period which made low cost development necessary. More recent projects are of higher quality and higher cost. A revised land use plan was prepared in 1967 which updated the original plan. The new plan took account of experience gained during the intervening period, as well as the rapidly changing market conditions.

Currently the County contracts, when necessary, with economic and land use planning consultants who undertake studies and make recommendations to ensure that the continuing development of the Marina will be effective.

Important Public Issues

The Marina today appears to be a remarkably successful operation. However, from the point of view of public policy, a number of issues should be considered which will be relevant to decision-making concerning other marinas. While we will not attempt to answer these questions in this descriptive paper, they have guided the selection of information to be presented.

The first issue is whether the Marina del Rey site should have been used

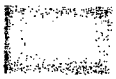
B-138

for a small craft harbor or for some other purpose. It can be assumed that local governments today must be constantly searching for revenue producing development. Rarely is a project carefully analyzed to determine whether its overall effect on the community will be the most favorable of all possible uses. Apparently, little consideration was given to uses other than a small craft harbor for this site and the possibilities for alternative uses were discarded long ago. Some other uses which might have been considered are industry, low density residence, a more or less natural estuary and park, and a recreation area like Marineland or even Disneyland. We are not necessarily suggesting that these uses are more suitable for the Marina site, but that a wide range of possibilities should be examined for all coastal zone sites.

Given that a marina has been assigned to the site, it should be considered whether the overall layout and the land use pattern have been handled well. For example, could the surge problem during the 1962-63 period have been avoided by better channel planning? Does the channel and basin arrangement result in acceptable water quality? Is the percent of the site filled as land appropriate? Have internal roads, links to external streets, and parking been well organized? Are high and low rise buildings properly balanced and arranged? Are residential and transient population densities too high or too low?

B139

Another category of issues concerns the financial and operating arrangements of the Marina. Were the public subsidies from the Federal government and the County general fund appropriate? Were the revenue bond issue and state loan handled well? Have leasing arrangements been fair and in the best interest of the County? Are public services adequate? Are Marina users paying their share of service costs?



Finally we come to the question of who should have the ultimate decision-making responsibility for marinas and other coastal zone development. If, as in the present case, the Department of Small Craft Harbors is given a major role in planning one would expect that water recreation uses, especially pleasure boating facilities, would be given precedence whenever possible. However if an agency with responsibility for all activities in the coastal zone were making decisions, perhaps a different land use scheme would have resulted.

In the remaining chapters of this report, we will turn to the chronolgy of Marina development.

B-138

FOOTNOTES

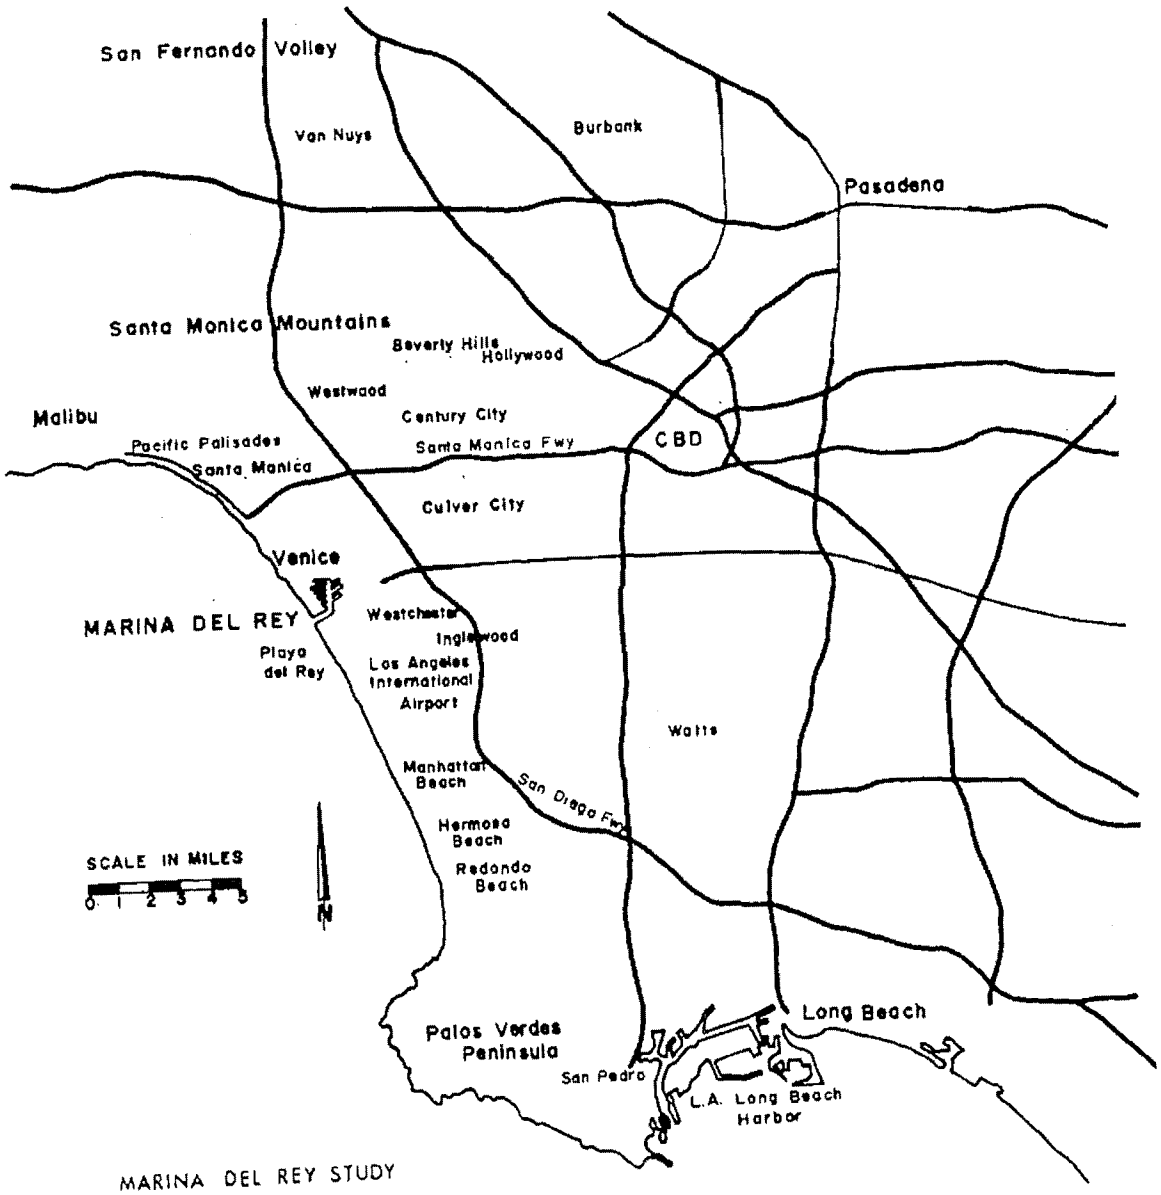
1 Note that boating dominated the early plans, but as time has passed, residential and other "landside" development have been allowed to expand considerably because of the need to pay back the revenue bonds. Apparently boat slips alone would not support the cost of the Marina.

B-139

CHAPTER II. THE PRE-DEVELOPMENT ERA

Natural Topography

Marina del Rey is located at the southern end of an area of beachfront lowlands which extend south from Pacific Palisades to the bluffs of Playa del Rey. Toward the east, the land slopes gradually upward to the Baldwin Hills, four miles inland. Until recently, the Marina area was known as Playa del Rey Inlet. Early in the 1800's the inlet had formed the mouth of the Los Angeles River but later the river rerouted itself so that it now enters the sea at Long Beach.



The concrete lined Ballona Creek Flood Control Channel, just south of the Marina site, was constructed in 1938. After the construction of the flood control channel, the Marina area was described as "1513 acres of salt marsh and low farm and residential lands." Residences were clustered along the shore since the area inland was subject to flooding by even moderate rainfall.[1]

Early Development Schemes

Indians once inhabited the area of the present Marina. There was fresh water from Ballona Creek, hunting and fishing were good, and there were clams in the lagoon. When Southern California came under the jurisdiction of the Spanish, the area was part of a large rancho used for raising cattle. The Rancho la Ballona, named for the town of Bayona in Spain, gave its name to Ballona Creek.

B-141

Moses Wicks, a real estate speculator began construction of a commercial harbor on the site in 1887. Although only 35, Wicks had been successful in land dealings after his graduation from law school and was able to capitalize $300,000 for the venture. The Santa Fe Railroad built a rail line to service the port and a pile-lined channel was begun. Construction proceeded to the point of creating a basin suitable for small boats before a collapse of the real estate market left the speculators without customers and stopped the construction.[2] The channel quickly deteriorated and the basin filled in until it was no longer naviagble.

In 1892 Abbot Kinney bagan developing the Venice area, complete with canals with the intention of replicating the character of Venice, Italy. This transformed what had been an ownerless beach into a vacation resort. Kinney remained active in the development of Venice throughout his life and was one of the successors to Wicks in encouraging the development of a harbor at Playa del Rey Inlet. His exact role here is not known, but in 1916 he made a statement of support and encouragement of the construction of a harbor in the House Document No. 1880 of the 64th Congress. This document reported the findings of the Corps of Engineers in studying the feasibility of such a commercial harbor.[3] The Corps' preliminary examination determined there was no justification for such a major undertaking. The commerce projected for such a harbor was uncertain since the site of the present area harbor at San Pedro and

B-142

Long Beach was considered far superior. Although it was thought that a small craft harbor might be useful, there was no provision for federal participation in such a project at that time.[4] Abbot Kinney's son, Thornton, tried to encourage the construction of a naval base at Playa del Rey in 1921 but failed to gain recognition for the project.[5]

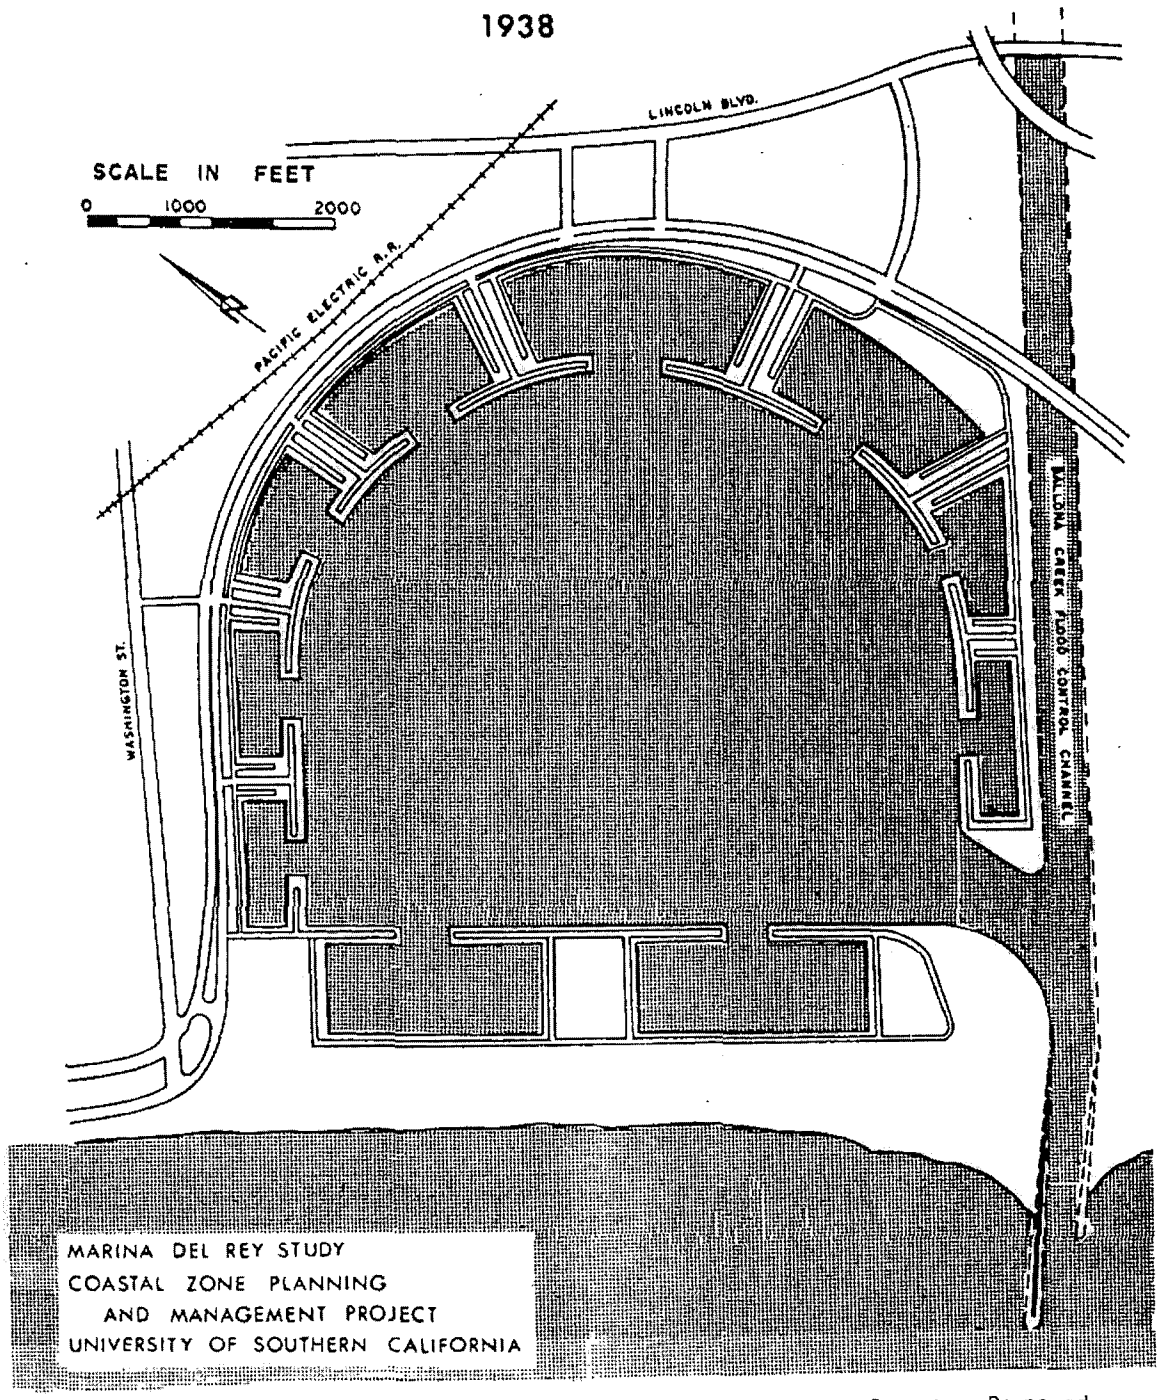
The Venice canals connected with the sea at Playa del Rey Inlet. After the construction of the Ballona Creek Flood Control Channel, tide gates into the channel became the only opening from the canals to the sea. The marshes drained into the canals and the canals into the channel.

As Venice grew, development crept southward towards Ballona Creek. Houses were built along the beach in the area known as the peninsula, so named because of the salt marshes behind the beach. A bridge over Ballona Creek at Pacific Avenue connected the peninsula with Playa del Rey. In 1930, a profitable oil well was discovered and soon 151 oil wells dotted the peninsula and the western side of the marshlands. The production of these wells decreased from a peak of 40,000 barrels a day in 1930 to 2,300 barrels a day in 1946 and their existence at that time was not seen as a serious obstacle to the construction of the marina.[6]

A proposal for a harbor was again raised in 1937 when Congress approved the Rivers and Harbors Act, Public Law 75-392, which "authorized and directed to cause a preliminary survey to be made ..." at Playa del Rey

B-143

Inlet.[7] Before the Corps of Engineers undertook the study, they requested that a certain amount of information be provided by the community. Accordingly, the Los Angeles County Regional Planning Commission was authorized to provide the information. For the first time, the proposal was for the construction of a recreational harbor, a concept which was made possible by Public Law 72-16 which had defined the term commerce to include "the use of waterways by seasonal passenger craft, yachts, houseboats, fishing boats, motor boats and other similar water craft whether or not operated for hire."



It is not known who inspired the inclusion of Playa del Rey Inlet in the 1937 Law. By this time, however, the perceived local need for recreational facilities, coupled with the unusual suitability of the area for small craft harbor development seems to have created a predisposition for the harbor among many groups.

Basic Marina Plans

The Regional Planning Commission produced a report in 1938 which envisioned a large open body of water (435 acres) surrounded by ten smaller berthing areas created by mole type piers jutting into the central basin. It's estimated cost was $9,750,000. The harbor was to accomodate 5,000 boats and include automobile garages, parking spaces, water and electrical outlets, restrooms, yacht clubs, boat repair

B-145

facilities, sport fishing boats, administration buildings, and possibly civic buildings such as a post office or library.[8] The physical plan was not based on thorough analysis, but was thought to be reasonable in light of the needs of the boating public. The amount of business assumed for the Marina was based on extrapolations from the demand for services at existing harbors. The final report, accompanied by a review of the findings of George F. Nicholson, consulting engineer, was completed in August 1938.[9] At this time, the Corps of Engineers was expected to begin their survey. World War II, however, delayed their action and the survey was not authorized until April 6, 1944.[10]

County plans and Corps of Engineers plans

The early plans for the marina at Playa del Rey Inlet were as speculative as the Marina itself. The plan developed by the Regional Planning Commission in 1938 and updated later as part of the Master Plan of Shoreline Development, was designed to provide needed information for the Corps of Engineers. The Corps wanted to know what kind of harbor the local community wanted. They wanted to know what activities would take place in the Marina and what interests would be served. The Corps of Engineers was unfamiliar with evaluating a recreational harbor proposal since they had been previously involved only in commercial harbor construction. Similarly, the Regional Planning Commission was not accustomed to dealing with the issues peculiar to a recreational harbor. At any rate,

B-146

they were reacting to a particular request for information on a project which could be fit into county plans but which was not yet adopted or thought to be imminent. Their plan drawings show little regard for property lines or city boundaries. The planners seem to have assumed that much more planning would be done before any marina would be built.

The action of the Regional Planning Commission and the pending action by the Corps of Engineers probably increased in people's minds the likelihood of a marina at Playa del Rey Inlet. The Shoreline Planning Association of California urged preliminary studies for such a marina. In response, the City of Los Angeles commissioned a study of the recreational development of the Los Angeles shoreline to be done by a private consultant, Madigan-Hyland.[11] The consultant postulated the future existence of the Marina del Rey to the point of saying that it would probably be open in 1953. Again the planners assumed that someone else would do more detailed plans for the Marina. Madigan-Hyland apparently based its projections on the plan developed by the Corps of Engineers. The Corps had not published its report yet but the general plan which accompanied the Corps' findings had been drawn in 1946, so that it was available to the consultants.

The Corps of Engineers report was finally completed in 1949.[12] The major purpose of this study was to determine whether or not the federal government would participate in the construction of the Marina. For this reason its plans

B-148

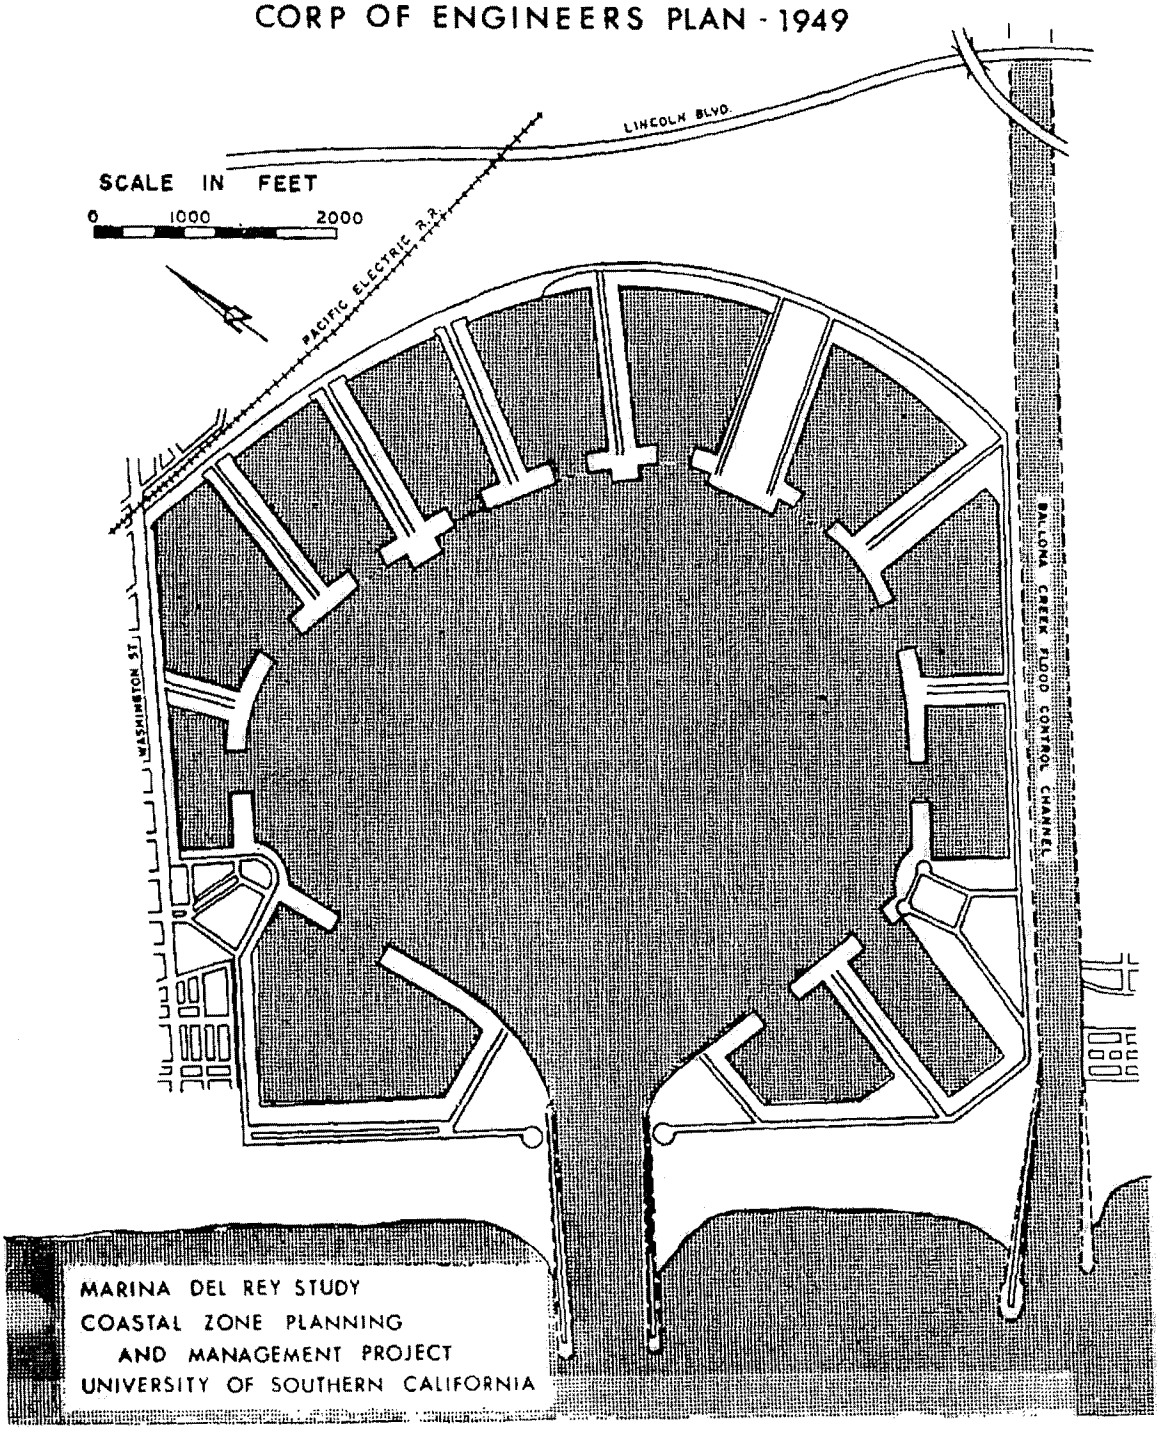
were more specific than any others had been. The plans, however, covered only the construction of the waterways and left land use and accompanying facilities out of their considerations. Only as it affected channel design did the Corps indicate the existence of boat repair yards, administration buildings and boating clubs.[13]

The harbor designed by the Corps of Engineers was similar to that envisioned by the Regional Planning Commission. There was to be a large central basin connected to the sea by a single channel. Twelve side basins with a capacity of 8000 boats would be twenty feet deep and be served by a twenty foot deep interior channel from the entrance. The rest of the water area was to be ten feet deep. The deeper areas were to be for boat repair, perhaps to accomodate larger commercial boats which would be harbored elsewhere.

Madigan-Hyland Plan.

The Madigan-Hyland plan for the coastline also was finished in 1949. Since theirs was a study of the entire Los Angeles County coast, Madigan-Hyland described the facilities to be included in the Marina primarily in relation to the entire County's coastal recreational facilities. It is not known if the consultant had been asked to determine what type of facilities should be specifically included in the Marina, or if they merely wished to influence the eventual planners of the Marina to give consideration to regional recreational needs.

B-148



Madigan-Hyland determined the number of parking spaces needed for a marina would be 1.5 spaces for each of 80% of the boat slips plus 1400 parking spaces for the general public. They apparently felt the public should have access to the Marina even if only for sight seeing. They suggested, however, that the way to pay for such public parking would be to collect a fee at the Marina entrance. No one but a boat owner with a pass would get into the Marina without paying.

While Madigan-Hyland probably based their recommendations for land and water use on a plan similar to that shown in the Corps of Engineers Plan of 1949, it is difficult to reconcile the activities and facilities they specify with the areas provided in the plan.

The major emphasis in the report is on the 8,000 small craft to be docked in slips located within bays built around the periphery of the circular harbor. Two additional bays are planned for marine related commercial and recreational use. The support facilities thought to be required for 8,000 craft are described, but no indication is given of the space allocated for these facilities. Two of the bays shown on the plans are adjacent to Washington Street, two to Ballona Creek Flood Control Channel, three back on to the ocean beach, and only four of the remaining five bays have any contiguous land area available for the location of the 11,000 parking spaces, the marine supply stores, restaurants, bars, and retail commercial facilities which are noted as

B-149

CORP OF ENGINEERS PLAN - 1949

Adapted from: U.S. Engineer Office, "General Plan of Improvement, Playa del Rey Harbor" Los Angeles, 1949.

B-150

necessary. The area which lies between Lincoln Boulevard and the marina's circumferential road is approximately 125 acres and would be inadequate for even a small share of the facilities described.

Four of the thirteen moles shown are large enough to accomodate harbor administration and maintenance operations as well as marine repair yards, but the remaining moles are only large enough to provide for a minimal number of the storage lockers to be rented to boat owners. Space on the moles is not sufficient for the garages recommended for rental to boat owners for their cars and paraphernalia, nor is it possible to find such space within feasible distance from the slips.

Numerous other discrepancies between narrative and plan are apparent, so that it is obvious that Madigan-Hyland's textual report on the Marina, considered by itself or in conjunction with the Corps of Engineers plan for the area, cannot be regarded as a complete land use plan. Again, it must have been assumed that other agencies would complete the planning work necessary before actual construction of the Marina.

While Madigan-Hyland's report had been addressed to County coastal recreational needs, the Corps of Engineers Plan, developed at the same time, concerned only the Marina. The major purpose of the report was to present a benefit-cost analysis to justify the federal government's participation in the Marina's construction. Considering tangible benefits only, they

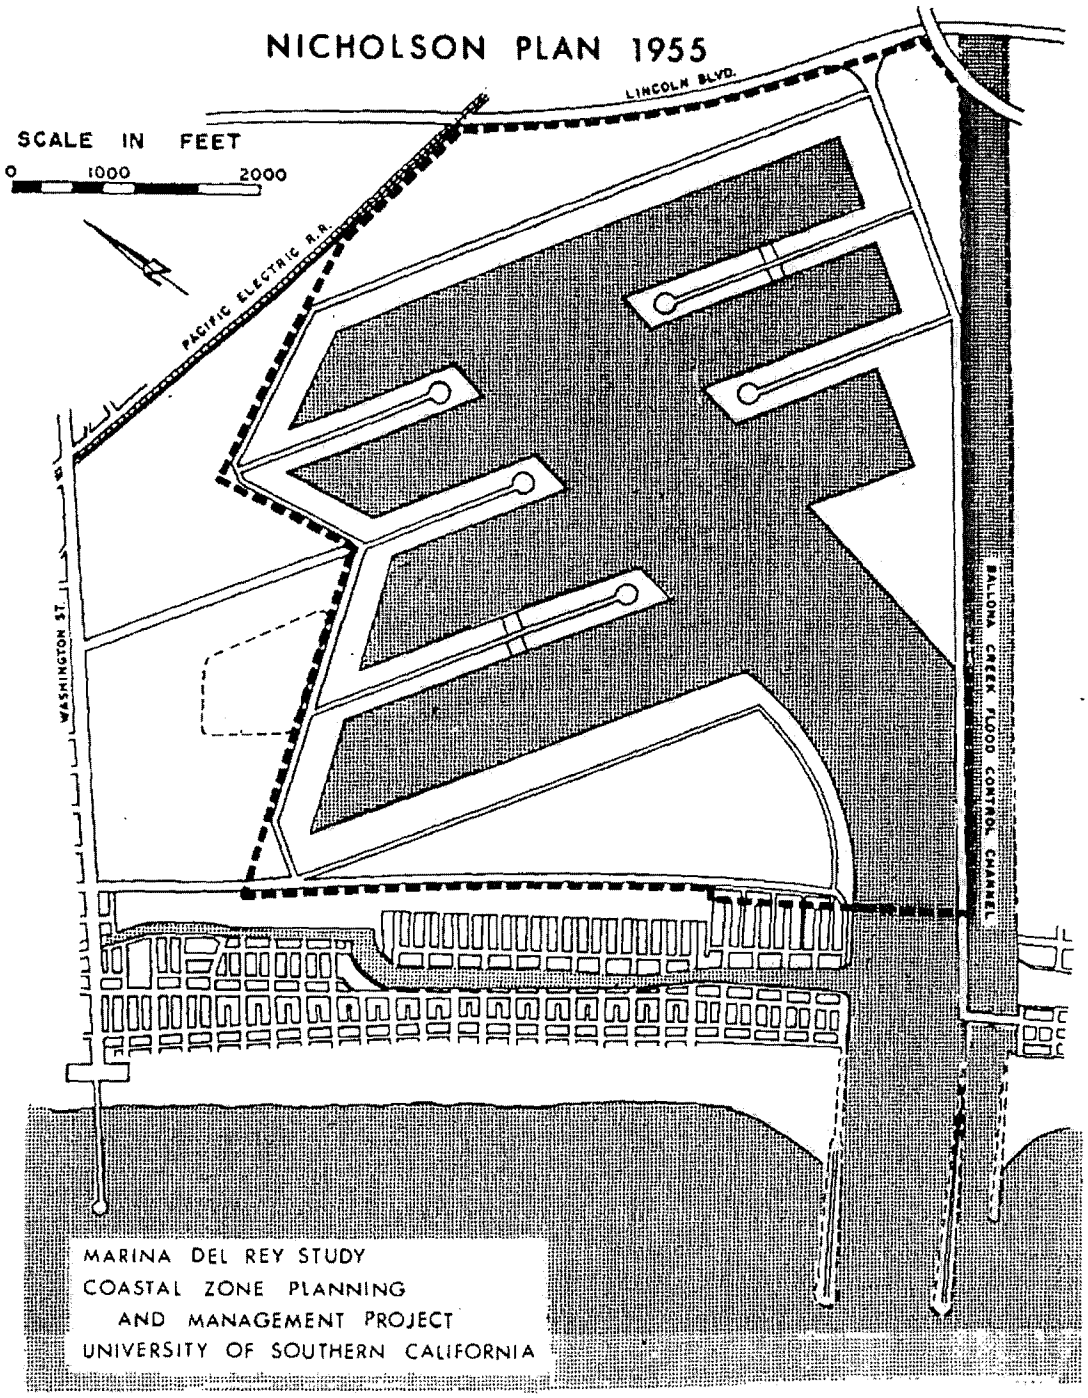
B-151

estimated that the benefit-cost ratio resulting from the proposed marina development would be 1.4 to 1. Along with this figure it is mentioned that federal participation is further legitimized by a higher percentage of marina costs to be borne by local interests, rather than by the federal government. The amount necessary to construct half of the main navigational features was finally recommended as the federal government share.[14]

In 1954, Congress passed Public Law 83-780 which "adopted and authorized to be prosecuted" the recreational harbor at Playa del Rey Inlet.[15] This decision had been recommended by the Secretary of the Army on the basis of the 1949 report by the Corps of Engineers. The legislation approved federal participation in the project in the event that the local authorities decided to go ahead with it.

Nicholson's Plans

In response to the federal support provided by Public Law 83-780 the Los Angeles County Board of Supervisors hired George F. Nicholson, consulting engineer, to prepare a schematic plan for a marina accompanied by an economic feasibility study. The Nicholson plan was a radical departure from the Corps of Engineers Plan of 1949. The Nicholson Plan eliminated the large central basin which characterized the earlier plans. The basin, it was reported was not required for navigation nor would it



B-152

be appropriate to the area the Marina was planned to occupy, a much smaller area than was previously contemplated. Also, it was thought that the mole design in the Corps of Engineers Plan would constrict the flow of water within the mooring basins.[16] Nicholson's Plan therefore, employed a straight main channel 1,000 feet wide with six side basins each 600 feet wide and one 625 feet wide. The plan was to accomodate 6000 boats in the water with dry storage for 2000. The entrance channel was moved so as to be directly adjacent to, but separate from Ballona Creek. This was done to avoid isolating a stretch of beach between Ballona Creek and the entrance channel. Ballona Creek was kept separate from the channel in order to avoid the difficult task of dismantling the existing jetty and to avoid the debris that the flood control channel carries.[17]

Beaches were planned at the end of four of the mooring basins with substantial parking areas for the public using the beaches.[18] Boat launching and boat repair also figured in the design. It was intended that motels would be located near the beaches on sites leased to private interests. Restaurants, yacht clubs, gas stations (auto and boat) and a large salt water lagoon and beach sand stockpile area completed the plan.

The radically different configuration of Nicholson's first plan for the harbor was decided upon, then, in order to provide: 1) protection against silting, 2) convenient land access, 3) reduced water contamination and 4) lower land acquisition costs.

B-153

Adapted from: George F. Nicholson, Schematic Plan, Long Beach, Calif. 1955

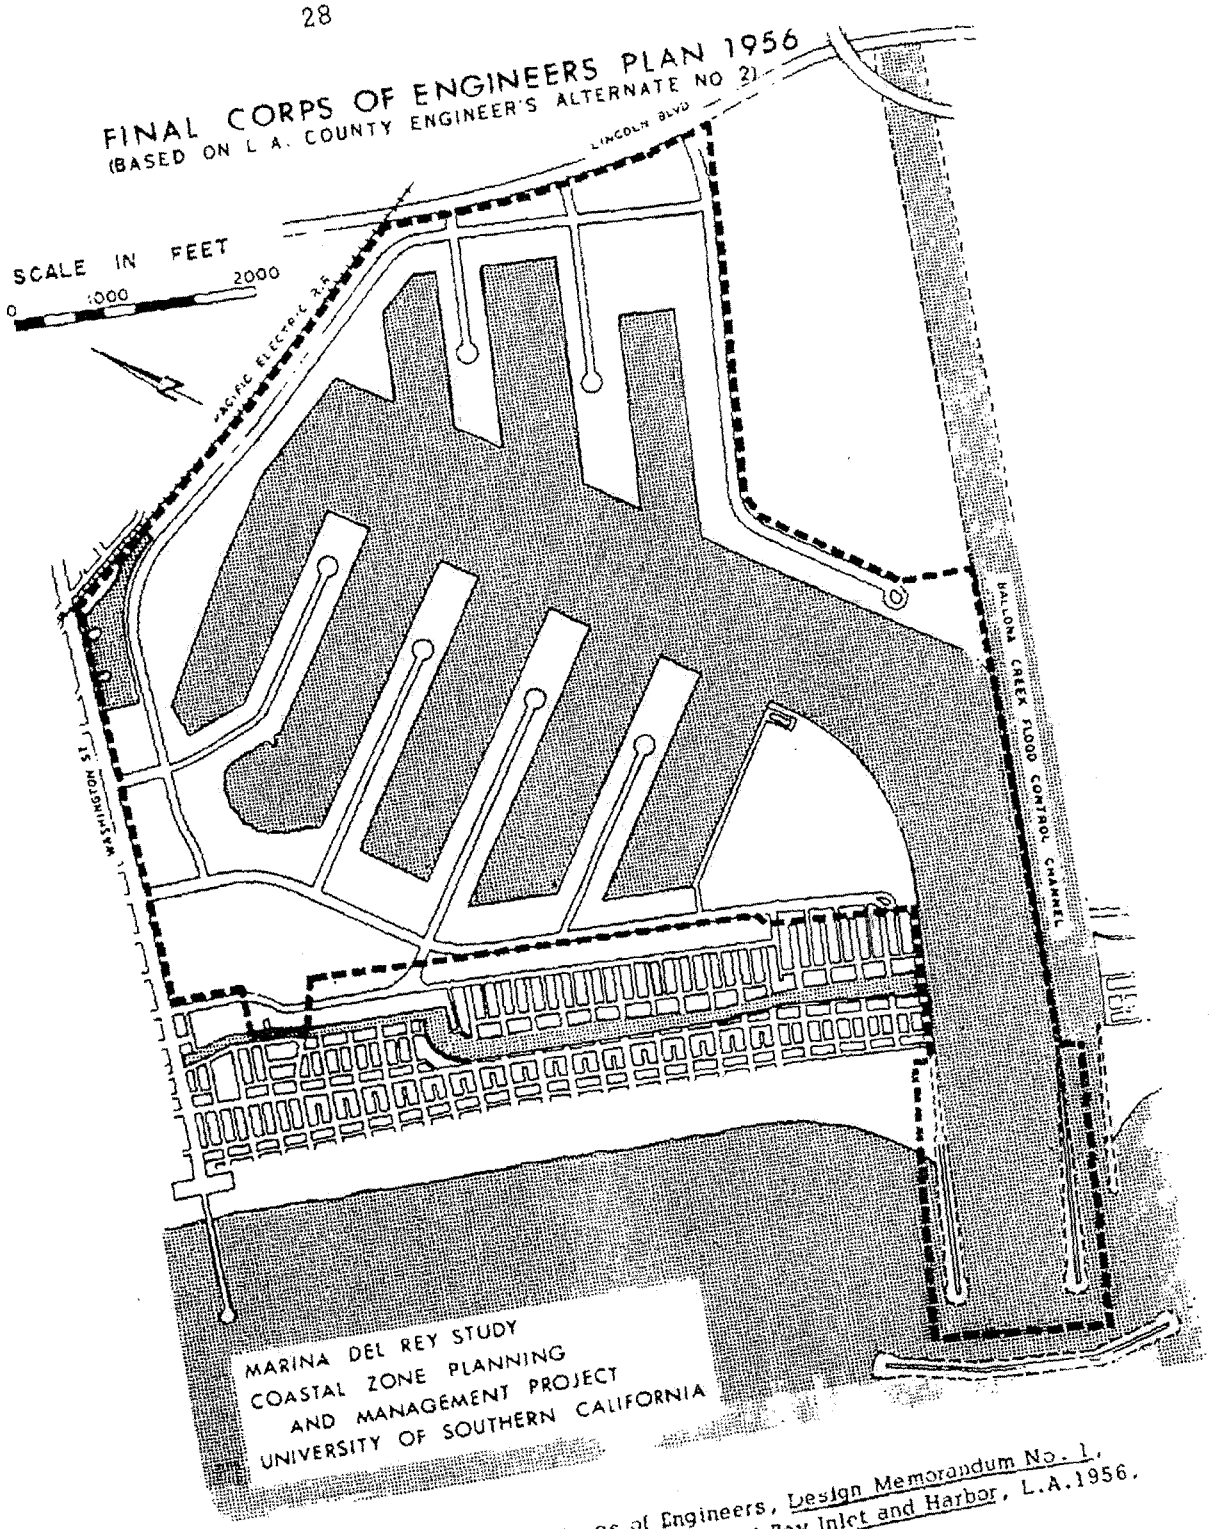
B-154

This plan was based on the assumption that the County could acquire all the land adjacent to and north of Ballona Creek from the ocean east to Lincoln Boulevard. A triangular parcel of land in the northeast section of the present marina which contained a salt pond was not included. The proposed boundary on the north side of the marina conformed partially to the boundary of the County of Los Angeles. The land with the salt pond, Lake Los Angeles, was within the City of Los Angeles and was used for recreation. Its cost was considered excessive and therefore it was excluded from the project area.[19]

The orientation of the side basins was determined in large part by the Venice Interceptor Sewer which ran directly across the middle of the Marina. It was planned to build the Marina in stages so that the first phase would include dredging the waterways up to the point at which the sewer line crossed the main channel. The sewer line thus ran along what was to become a mole on either side of the main channel.

The change in the basic round form of the Marina to Nicholson's design proposal did more than merely make for more efficient use of land and water area. The new design precluded the use of the Marina by small boats seeking protected waters for recreational boating. This greatly changed the character of the Marina from the traditional recreational harbor, to a berthing harbor whose waters are used only for entrance and exit. The Corps of Engineers commented on this loss of a sailing basin but said that the plan was acceptable

B-155



if cost had to be the governing factor.

This was perhaps the first example in Marina del Rey planning in which a policy decision for the public recreation facility imitated the private market: it is expensive to build a marina, therefore it should be designed only for those who can afford such expense. The change by Nicholson's plan eliminated a large part of the boating public--those who owned small boats which are unsuited for use in the open sea. By making the Marina primarily a berthing harbor, the Plan in effect limited its use to sea-going and therefore larger, more expensive boats.

The change in the character of the Marina is never acknowledged in any Marina plan documents. No consideration is given to the fact that the change would alter the demand for launching facilities, or that it might affect the optimal boat capacity for which the Marina should be planned. Looking back, it is believed that demand for slips for large boats was being expressed then and that small boats could be accomodated at inland lakes.

This is not meant to imply that land and cost construction are not valid, but only to say that within those constraints, certain harbors are possible, other are not. If the harbor is changed, the goals and the client which the harbor is to serve should be re-evaluated in these terms. If the goals and clients change, it should be the result of a conscious

B-156

B-157

policy decision rather than as an accident of design.

Nicholson submitted his plan to the County Engineers on October 23, 1955. Almost immediately the plan was revised. The Engineer's office made up three alternative plans. Alternate No. 1 was apparently very similar to Nicholson's original; Alternate No. 2 was drawn to appraise the use of additional land in the marina plan, and it conforms closely to the plan of the Marina today; Alternate No. 3 showed only two mooring basins on the east side of the main channel.[20] Nicholson was asked to render an opinion on the alternatives. He stated that he preferred his original scheme as modified by Alternate No. 1, but that Alternate No. 2 "should be given consideration if the additional land in the City of Los Angeles south of Washington Street and the Pacific Railway is added to the site."[21] He did say, however, that Alternate No. 2 would: 1) permit advantage in making street connections with Washington Street, 2) be better for boat races because the main channel is longer, 3) be added protection from southwest storms, and 4) take advantage of the salt water pond on the property on the north side of the marina.

Alternate No. 2 moved the north end of the main channel westward so that there was a sharper turn to the left when entering the marina from the sea. The channel was made wider and the side basins were changed so as to fit better in the new area. More water area was created in

B-158

the larger plan and therefore more cost for dredging was expected. The drawing of the new plan showed no industrial area and little commercial area. Instead, the larger areas on the perimeter of the marina were designated as future residential development.

On February 21, 1956 the Los Angeles County Board of Supervisors adopted Alternare No. 2 as the plan the county intended to use. The projected public and private cost of the Marina were estimated by Nicholson to be $24,351,000 for Nicholson's Plan of 1955 and $26,188,000 for Alternate No. 2.[22,23] The increase in cost was due mainly to the greater water area and the consequently lengthened bulkheads etc. Also the increased capacity caused higher costs allotted to mooring facilities and restrooms.

Alternate No. 2 was then sent to the Corps of Engineers for approval.[24] Simultaneously a revenue bond proposal was prepared for the November 1956 ballot which would give the County the authority to issue bonds to pay for its share of the cost of the marina.

Corps of Engineers: Design Memorandum No. 1.

In 1956, the Corps of Engineers, using the County's Alternate No. 2 produced their Design Memorandum No. 1.[25] This document defined the parts of the project for which the federal government was to be responsible. It set the engineering specifications for the exact outline of the water area, the depth of the water, the type of jetty to be built, etc.

B-159

The Memorandum reviews the discussions of cooperative arrangements between the federal and county governments which appear in House Document 389, 1954; in Public Law 83-780, 1954; and in the supporting text for Alternate No. 2. The document then defines more precisely the particular responsibilities each party would have. It also states that the federal government would pay for fifty percent of the main navigational features i.e. the main channel and entrance jetties.

The Corps of Engineers was in communication with the County government so that the County Board of Supervisors was able to adopt a resolution on October 23, 1956 (before Design Memorandum No. 1 was published in November 1956) which agreed to the terms of participation and the responsibilities which the County would have.[26]

On November 6, 1956, the voters of Los Angeles County passed a proposition allowing the County to issue revenue bonds for the construction of the Marina. The bonds were not issued until 1959, but acquisition of property and actual construction began before that. The date of the start of construction of the entrance jetties was December 1957.[27]

Before much progress on jetty construction had been made, the Corps of Engineers prepared Addendum No. 1 to their General Design Memorandum. The addendum made changes stemming from Corps observations and requests by local interests and consultants.[28] Boat launching

B-160

facilities were moved to the basin closest to the entrance on the east side of the main channel which necessitated making that basin narrower and shorter. The basin originally intended for boat launching was made wider. No reason is given for this change. The entrance channel was made deeper to minimize the wave effect caused by shallower water near the bend in the channel. The northern edge of the water area was moved slightly to make it conform to the city-county boundary line which passed through the Marina. The road system was changed so that better use could be made of the land area in the marina. The section of the perimeter road, which ran along the southern entrance jetty and crossed Ballona Creek at Pacific Avenue was eliminated from the plan.

As construction progressed the City of Los Angeles and the County of Los Angeles cooperated to make all the land within the Marina fall under County jurisdiction. The County adopted a resolution requesting that the area at the north end of the Marina adjacent to Washington Street be put under County jurisdiction while the City passed an ordinance to remove that land from within 29 the boundaries of the city. The ownership of the land was held by the County during this entire process.

Another section adjacent to the Marina remains within the City of Los Angeles. The beachfront property all along the west side of the Marina, known as the Venice "peninsula" is within the City. The portion of the entrance channel which passes through this strip also lies within city boundaries. In this

B-161

area, the city has adopted a special ordinance which allows the County Harbor Patrol to handle law enforcement in the channel.[30]

CHAPTER III. INITIAL DEVELOPMENT (1956-1962)

Economic Studies

Along with the plans for the physical development of the Marina del Rey site, Los Angeles County asked its consultants to determine whether the project would be economically feasible and desirable for the County.[1] The major questions apparently were:

1) Is it suitable for the County to purchase land and carry out the basic public works needed for a marina at this site?
2) If the County can do this, what should its further role be in development and operation of the Marina?
3) What pattern of land and water use would be most desirable for County government and for the community as a whole?
4) Presuming that some of the funds needed for capital investment would be borrowed, how much would be required and what is the most appropriate mechanism for borrowing?

The answers to such questions depend largely on estimates made concerning capital costs, operating costs, revenues, and benefits to the community resulting from the Marina. The "opportunity costs" of benefits foregone from other projects which might have been undertaken in lieu of the Marina and from other possible internal arrangements of the Marina should also be considered.

B-165

The first detailed economic study was conducted by George F. Nicholson, Consulting Engineer, in 1956 for the County Engineer.[2] This study displays two schematic plans, Alternate No. 2, based on a County Engineer's proposal, is much like the form of the Marina as it exists today. Costs, revenues, and benefits were estimated for a thirty year period. Two years later, Coverdale and Colpitts, Consulting Engineers, prepared a report for the Board of Supervisors. They took as given the plan presented as Alternate No. 2 in Nicholson's report and his cost estimates for it.[3] They also introduced some refinements into the long-run financial analysis. In 1959, Coverdale and Colpitts rechecked the principle data and modified some of their estimates. This later report was submitted to Stone and Youngberg, Municipal Financing Consultants in San Francisco.[4]

In 1960, Gruen Associates, Architects, Engineers, and Planners produced land use studies based on updated information concerning costs and revenues, which strongly influenced the County's leasing program.

Analysis Methods.

There are two basic ways of structuring the analysis of the desirability of any public investment. Cost-revenue analysis considers estimates of the dollar expenditures and revenues for a particular governmental unit to see if the project is financially feasible. A governmental unit often feels it can justify certain projects only if they pay for themselves. This was apparently true for Marina del Rey.[5]

B-166

Cost-benefit analysis takes into account all of the gains and losses, intangible as well as tangible, sustained by a defined population group, such as the population of Los Angeles County. Much of the criticism of public projects such as urban renewal, highway construction, etc. results from governmental use of costs and revenues while citizens are looking at costs and benefits.

The Nicholson and Coverdale-Colpitts studies use the cost-revenue framework almost exclusively. There were attempts, in the Nicholson and the Corps of Engineers reports to identify benefits and to compute an annual benefit-cost ratio.[6] These do not appear to be serious studies. No information is provided about the methods for benefit estimation, the list of intangible benefits is obviously incomplete, and intangible costs are not discussed. Furthermore, an increase in tax revenue is listed as the major local benefit--$1,417,810 out of $1,997,886 total local benefits. But most of these taxes are merely a transfer, for County residents, from the private to the public sector. Since such a transfer does not add anything to the community well-being, it cannot be called a benefit to the County. Only taxes from visitors residing outside the County are a benefit even in this limited sense.

Unfortunately, even after it is clear that a project is financially feasible, i.e., that it will more than break even in the long run, government often

continues to make decisions about the project as if profit maximization were the only goal. It would seem more reasonable to set reaching the break-even point as a necessary condition for undertaking some projects. Beyond this point, the criteria should shift to costs and benefits for the community as a whole. The distribution of benefits among population subgoups should also be examined.

Of course we cannot ignore the difficulty of getting some projects to the break-even point. Marina del Rey was such a project. For example, in 1956 it was necessary for the Small Craft Harbor Commission to obtain a loan from the County general fund to meet cost of operations after bond requirements were met. Until 1966 it was not clear that private investors would be able to get financing for their proposed development. Today, however, the project is clearly a financial success.

Development Costs

The overall development costs for a marina depend on the size of the project and the extent to which new waterways, landforms, and structures vary from previously existing conditions. Capital costs can be divided into six categories: planning, site acquisition, basic structures, secondary structures and landscaping, buildings, and interest. The following information about the costs in these categories is taken from the Nicholson and Coverdale-Colpitts reports, the "Marina del Rey Reporter," and the "Marina del Rey Fact Sheet." Some figures are consultants' estimates and

some are actual costs. The latter were used when available since early estimates are likely to be inaccurate.

Planning. This includes all engineering, economic, and land use studies done up to 1959. Actual expenditure: $543,000.[7] The cost of later land use plans are not known.

Site acquisition. Nicholson used the County Engineer's estimate of 1954 which indicated a total land cost of $2,000,000.[8] In 1959, after acquisition, actual land acquisition costs were found to be $9,286,834 with clearance costs an additional $2,433,000.[9] Of this total, the State of California provided a loan of $2,000,000.[10] Los Angeles County paid the remainder out of its general fund. The great discrepency between estimated and actual costs was apparently due to inflation and the growing awareness of the site's potential value between 1954 and the time of purchase in 1958-1960.

Basic structures. The dredging of channels and basins, the construction of jetties, rip-rap, and mole bulkheads were estimated by Nicholson to cost $9,697,000.[11] The actual cost is not available.

A breakwater was added to the project after storms caused extensive damage to boats and slips in the winter of 1962-63. This resulted in an additional cost of $4,200,000.

B-169

The Federal government paid a total of $4,600,000 toward dredging, construction of the main navigational features, and construction of the breakwater.[12]

Secondary structures. The estimate made by Nicholson for roads, walkways, parking areas, the boat launching facility, sewers, utilities and landscaping was $3,361,000.[13] The actual cost is not available. These publicly owned structures were paid for by County government and the revenue bond issue. The perimeter road system was paid for out of County Road funds in the amount of $775,000.

Buildings and slips. Most buildings in the Marina are owned by lessees---apartments, restaurants, stores, etc. as are all privately used boat slips. Public buildings include the administration building, Coast Guard Station and restrooms.

Up to July 1971, $105,000,000 had been invested by private developers. The County expects total private investment to reach $160,000,000 or more when all sites are being used.[14] This is vastly greater than Nicholson's 1956 estimate for private investment which was $11,747,000.[15]

Interest during construction. The Nicholson study did not include any amount for interest due on loans during the period of construction when no revenues are being received. This is properly a capital cost, as the Coverdale and Colpitts study points out.[16] They proposed that five years

B-170

interest be included in the bond issue which is intended to cover capital costs. This amounted to $3,437,500.

Capital cost summary. It is difficult to compare categories within the cost estimates with actual costs since they have not been aggregated in a consistent manner. However we can display the total capital costs, estimated and actual, for the Federal government, the County Road Fund and Los Angeles County.[17]

	Federal	County Road Fund	County	Total
Nicholson (1956 estimate)	2,177,000		12,264,000	14,441,000
Coverdale & Colpitts (1959 estimate)	2,320,000		17,120,000	19,440,000
Dept. of Small Craft Harbors (1971 actual)	4,600,000	775,000	30,875,000*	36,250,000

*These "County costs" include the $13,000,000 in revenue bonds which is really a private investment in the Marina.

Obviously, the actual public costs are greater than early estimates. A large part of this is due to inflation but another part is the result of increased intensity of development beyond early expectations. The cost of private development, as mentioned earlier, may be 15 times as much as originally predicted. A higher investment of private funds requires a higher investment of public funds for support facilities.

B-171

Operating costs. The annual costs to be borne by the County in operating Marina del Rey are a function of the scale and intensity of development, the range of activities occurring there, and the degree of involvement by County agencies.

Coverdale and Colpitts suggested that the Department of Small Craft Harbors limit its role to "...the administration of leases and the collection of rents, supervision of the aquatic activities, and maintenance of utilities, and that with one exception (public parking), the County will not be involved in any operation of facilities producing revenues."[18] Apparently this is the County's policy today. Therefore, public operating costs should be relatively low.

The Nicholson study listed the following annual operating costs for County government.[19]

Maintenance	39,144
Utilities	5,000
Depreciation	56,820
Administration	87,000
	$187,964

Coverdale and Colpitts' report states that the Department of Small Craft Harbors expected to spend the following amounts annually:[20]

Salaries and Wages	285,000
Other Maintenance and Operation Costs	121,000
	$406,000

This is in addition to a sum of $24,000 per year which would be used for new capital improvements.

B-172

Coverdale and Colpitts also suggested that total capital expenditures should be increased to $450,000 to cover the cost of additional ground maintenance and the salaries of traveling auditors who would periodically examine the books of lessees.[21]

Revenues. The Marina was to receive from lessees either a minimum land rent or payment of a percentage of their gross income, which ever was greater.[22] Some direct income from parking lots, etc. would also accrue to the Marina. The County as a whole would receive sales taxes and property taxes on the "possessory interest" of the lessees. Obviously the amount of these revenues will depend on the types of enterprise which have been developed and their financial success.

The Nicholson report provides the estimates shown in the table on the next page for the Marina after all development is complete.[23]

Coverdale and Colpitts used a similar system for categorizing revenues. They did a much more thorough job of explaining how estimates were made. Their estimates for complete development, expected by 1964 are shown in the table on page 46.[24] To reduce risk to the County, Coverdale and Colpitts suggested a minimum annual rental for each lessee to be set at $.06 per s.f. of land regardless of his gross income.[25] This would at least meet the County's annual operating and interest charges.

According to a recent report of the Department of Small Craft Harbors,

B-173

Activity	Units	Gross Income	Rate	County Revenue
Mooring slips	5,400 slips	$1,944,000	25%	$501,000
Boat storage and launching	2,000 boats stored 10,000 launching	120,000	25%	30,000
Marina chandlers		2,700,000	4%	120,000
Restaurants		2,000,000	4%	80,000
Motels	510,000 s.f.		$.15/s.f.	76,500
Boat repair	250,000 s.f.		$.10/s.f.	25,000
Sport fishing	115,000 passengers	400,000	10%	40,000
Industrial and commercial uses	2,500,000 s.f.		$.10/s.f.	250,000
Clubs	64,000 s.f.		$.10/s.f.	64,000
Trailer courts	400,000 s.f.		$.10/s.f.	40,000
Fuel sales	2,520 motor boats	252,000		12,000
Boat sales		2,000,000	3%	60,000
Permits				15,000
Public telephones			9½%	30,000
Parking	2,167 meters		$24/meter	52,000
Total annual county revenue				$1,338,500

Annual Revenue Estimates--Coverdale and Colpitts, 1959

Activity	Units	Gross Income	Rate	County Revenue
Anchorages-slips	6,100 slips	$1,976,400	25%	494,100
Boat storage and launching	3,000 boats stored 72,000 launchings	324,000	25%	81,000
Marine chandlers		1,825,000	6%	109,500
Restaurants	2 independent 4 club 20 snack bars	4,000,000	5%	200,000
Boat repair		2,000,000	6%	120,000
Boat sales	$5,700,000 sales	460,000 (commissions)	20%	92,200
Fuel sales	4,000,000 gallons		$.03/gal.	120,000
Clubs	3,200 members	576,000	15%	86,400
Cabanas	1,000 units	2,700,000	15%	405,000
Cabana-trailers	650 units	592,000	20%	120,000
Parking				304,000
Miscellaneous	39 sport fishing boats 10 stores, etc.			135,000
Total annual county revenues				$2,267,200

B-175

revenues now exceed $3 million annually and are increasing.[26] It is interesting to note that estimates for revenues did not change as much due to the effects of inflation as did the estimates for costs. Some of this stability is due to fixed lease conditions.

Economic justification. For a project such as Marina del Rey to be financially feasible to the County on a cost-revenue basis, the sum of discounted future net revenues must exceed total expenditures.[27] This is roughly equivalent to the basic model used by Coverdale-Colpitts with respect to the bond issue. It shows that the estimated revenues for 15 years will more than repay a bond issue of $12,500,000 and compound interest of 5½% each year on the outstanding bonds.[28] At the same time a reserve fund could be accumulated from excess revenues in the amount of $1,877,000. Using another repayment scheme, if total debt service payments, interest and principle were kept level for thirty years, a reserve fund in excess of $40,000,000 could accumulate.[29] The major differences (1) between pure cost-revenue analysis and the Coverdale and Colpitts approach are the cash-flow problem which became extremely important in this case and (2) the fact that only a limited part of the costs and revenues are considered.

Coverdale and Colpitts point out that their study is based on a conservative estimate of revenues. By 1959 they had revised their revenue estimates upward so that the 15 year scheme showed payment of a $13,000,000 bond

B-176

issue with a $4,479,000 reserve fund accumulation.[30]

Public and Private Roles

In this section, we will bring together information about public and private support of Marina del Rey development.

Federal. The U.S. Army Corps of Engineers paid for 50% of the cost of design and construction of the Marina's general navigational facilities. This includes channel dredging, jetties, and the breakwater. In addition the Corps contributes to the maintenance of these features.

The U.S. Coast Guard installed and maintains aids-to-navigation outside the channels. The Coast Guard also operates a rescue station at the Marina.

State. The State of California has supported the Marina in several ways. The first is through planning done by the Small Craft Harbors Commission and the Division of Small Craft Harbors. In 1962, they commissioned a state-wide master plan for boating facilities, which was completed in 1964.[31] Basically it is a long-range plan for Marinas as "harbors of refuge." The document also includes a survey of present and projected boat ownership and a description of existing facilities. The State also provided a loan of $2,000,000 to the County to pay part of the cost of land acquisition. These funds were provided from the State Lands Act

B-177

Fund, which was essentially General Fund money. The loan was authorized by State Assembly Bill 1784 in 1957. The loan period is 35 years after the first payment with an interest rate of 3 percent on the unpaid balance from the time of the loan. The first payment is expected before July 1972. At least one-half of the Marina's net revenues, after revenue bond requirements are met, must be applied to this loan.

County. The total share of Marina capital costs to be paid by Los Angeles County amounts to $17,875,000.[32] Of this, $15,875,000 apparently came entirely from the County general fund. The $2,000,000 State loan is included in the amount. An additional $13,000,000 was derived from the sale of revenue bonds in 1959. A large part of the general funds were needed to cover the cost of land acquisition and clearance beyond $2,000,000. In addition, some general fund money was loaned to the Marina to meet maintenance and operating expenses when revenues were not sufficient. This amount has since been paid back. Special State legislation and a resolution of bondholders was necessary to allow the latter expenditures.[33]

The construction of the peripheral road system, which cost $775,000 was paid for out of the County Road Fund.

In addition to the capital investments listed above, the County obviously has continuing costs associated with internal operations of the

B-178

Marina such as the provision of public services. The need for improvement of major streets near the Marina is also due in part to traffic generated by it. All such costs, whether paid by the State, County, or City must be considered in estimating the overall effect of Marina development.

The revenue bond principal and interest are to be paid off no later than October, 1999. The loan from the County general fund was to be repaid next in priority after operating and maintenance costs and bond interest payments. Presumably there is no obligation to repay the remaining County investment directly. However the estimated net increase in County taxes due to the development of the Marina may cover past and future general fund contributions by 1999. Property taxes for 1970-71 were $4,100,000 with an additional $330,000 in sales taxes and $55,000 in motel bed taxes.[34]

The revenue bond approach was approved by Los Angeles County in 1956 when two-thirds of the voters accepted a proposition stating: "Shall the Board of Supervisors of the County of Los Angeles be authorized to adopt the revenue bond method of financing small boat harbor improvements and facilities for public convenience in conjunction therewith, as provided by in Chapter 14, Part 2, Division 2, Tittle III of the Governmental Code of the State of California?"[35]

B-179

This allows the County, after the approval of the Board of Supervisors, to sell bonds for the construction of additional marinas. The amount of indebtedness is limited only by bond buyers' willingness to invest, which is in turn dependent on the expected demand for marina facilities, the soundness of the County's proposal, and the interest rate offered.[36] However, the County can be expected to be conservative since it must be concerned with its financial rating.

Bonds for the Marina del Rey were each of $1000 denominations, carrying an interest rate of 5.6 percent. They are to be redeemed according to an increasing schedule beginning with $130,000 in 1965 and ending with $810,000 in 1999.[37]

A number of accounts were established by the Bond Resolution to assure proper financial behavior from year to year. For example, the Bond Interest Reserve Account must contain an amount "...equal to the greater of (a) $250,000 or (b) the aggregate amount of interest due and payable on all bonds at the time outstanding on the next three succeeding interest payment dates."[38] Other accounts are Bond Interest, Bond Redemption, Maintenance and Operation Reserve, Construction, State Payment, County Rental, Replacement, and Improvement accounts. In total, these requirements amounted to about $3,000,000. Funds in these accounts may be invested in general obligation bonds of the United States government.[39]

B-180

The County may not incur additional indebtedness for development of the Marina del Rey except under specified conditions. No part of the Marina may be used by any public or private organization without compensation to the County.[40]

Private. Developers of Marina land and water facilities must obtain private financing for their projects. Some large developers may use their own resources but ordinarily they rely on lending institutions. This means that the projects must be well justified financially.

Each prime lessee obtains the use of a land and/or water parcel by competitive bid, usually for 60 years. His project must meet requirements established by the Director of the County Department of Small Craft Harbors, the County Engineer and the Marina Design Control Board. Minimum rental rates vary with the type of land or water use, but ordinarily the rate is a percent of gross receipts of the lessee. Subleases are allowed with the approval of the Director, and are quite common.[41] All leases contain provisions for periodic renegotiation in order to make adjustments for changing economic conditions.[42]

The Department of Small Craft Harbors regularly audits the accounts of the lessees to see that proper payment is being made to the County. Prices charged by lessees must be approved by the Director as being "...fair and reasonable, based on the following considerations. First,

B-181

that the property...is intended to serve a public use and to provide needed facilities to the public at a fair and reasonable cost; second that Lessee is entitled to fair and reasonable return upon his investment..."[43]

Improvements and personal property of lessees are subject to property taxation, as is possessory interest in leases.[44]

Land Acquisition

It was mentioned earlier that the area north of the Ballona Creek Flood Control Channel was low enough so that it was susceptable to periodic flooding. For this reason much of the land there was devoted to low intensity uses such as agriculture, oil fields, and gun club hunting preserves. In addition there were many large parcels which would simplify acquisition. It is not surprising therefore that this area was often considered for a large, ocean-oriented development. Originally, the proposed small craft harbor was to have been a City and County of Los Angeles project. The Los Angeles City Council adopted a report declaring that in the publics' interest the City and Council required provision of additional small craft facilities. In 1948, the County Board of Supervisors adopted a similar resolution. It was suggested that the County proceed with initial acquisition and development of the pilot phase, within County territory. If this initial work proved successful, then a harbor authority would be created under a joint powers agreement to carry out development of the remainder of the proposed development.

B182

In 1949, the County began to withold from sale all property within the proposed Marina site which was taken by it because of tax delinquency.[45] It was hoped that the State would purchase the required land and lease it to the County but the State Attorney General ruled that this was not possible. In 1958, the County was able to obtain the $2,000,000 State loan for land acquisition, to augment the County's investment.

On October 23, 1956, the Los Angeles County Board of Supervisors issued a formal order instructing the County Counsel to file condemnation action on all private property rights within the approved site of the proposed Playa del Rey Inlet and Harbor.[46]

Between March 1957 and January 1963 several hundred parcels were purchased by the County. Many of these parcels were on land near the beach which had been subdivided for residential use. The larger parcels were further inland and were often owned by corporations or clubs. The latter comprise most of the total of about 800 acres.

B-183

Land Use Plans, 1960

On May 1, 1960 Gruen Associates submitted A Development Plan for Marina del Rey Small Craft Harbor to Los Angeles County. Some revisions were made on September 15, 1960.[47] The introduction to the development plan states that, "The basic land use plan, the technical details and economic aspects of the Marina del Rey project have already been studied by the Department of Small Craft Harbors, Coverdale and Colpitts, George F. Nicholson and Associates, and the U.S. Corps of Engineers."[48] The Gruen work, therefore, is based on a study and review of previous efforts.[49] Although it is true that the outlines of the Marina, both exterior boundaries and land/water lines, were set at the time that the Gruen development plan was undertaken, and that several important land and water use policies seem to have been agreed upon by the County and previous consultants prior to Gruen's work, it remained for this plan to allocate recommended uses to specific areas; to detail the parcelling of land; to relate activities, facilities, revenue potentials, densities and circulation within the Marina; and finally, to consider the whole in relation to the surrounding area. Thus the Gruen plan is the first comprehensive land use planning effort applied to the Marina, and undoubtedly the major planning influence on its eventual development.

Leasable areas. In considering the Gruen plan, parallels naturally appear between its recommendations and those made in previous studies, referred to above. The parallels must not be drawn too closely with regard to the areas

B-184

allocated for specific uses, since the gross areas assumed by the consultants varied somewhat.

Gross Area in Marina del Rey (square feet)

Nicholson Plan	33,715,440	50
Alternate Plan No. 2	39,988,080	51
Corps of Engineers, Design Memorandum No. 1	35,893,440	52
Gruen Associates	33,976,800	53

In their economic feasibility study, Coverdale and Colpitts did not provide a figure for gross area, but use instead figures for square feet of leasable areas.

Leasable Area in Marina del Rey (square feet)

	Land	Water	Total	
Coverdale and Colpitts	12,908,000	6,106,000	19,014,000	54
Gruen Associates	17,472,723	6,337,766	23,810,489	55

Based on a figure of 35,893,440 square feet, Coverdale and Colpitts estimated approximately 16,969,440 square feet in non-leasable area such as roads, public parking lots, public recreational areas, administration centers, etc. Gruen Associates allowed only 10,166,311 square feet to be non-leasable out of 33,976,800 square feet gross area. A few

B-185

of the reasons that Gruen was able to reduce non-leasable area in comparison with the Coverdale and Colpitts estimate are as follows:

1. The area actually acquired was almost 2,000 square feet less than the 1958 estimate of area to be acquired.
2. Elimination of two of the three public beaches proposed in Alternate No. 2 on which Coverdale and Colpitts' recommendations are based. 56
3. Elimination of three recreational areas proposed in Alternate No. 2. 57
4. Reduction in acreage allotted to administration facilities. 58
5. A more efficient internal circulation plan which is estimated to have eliminated approximately a mile of roads.

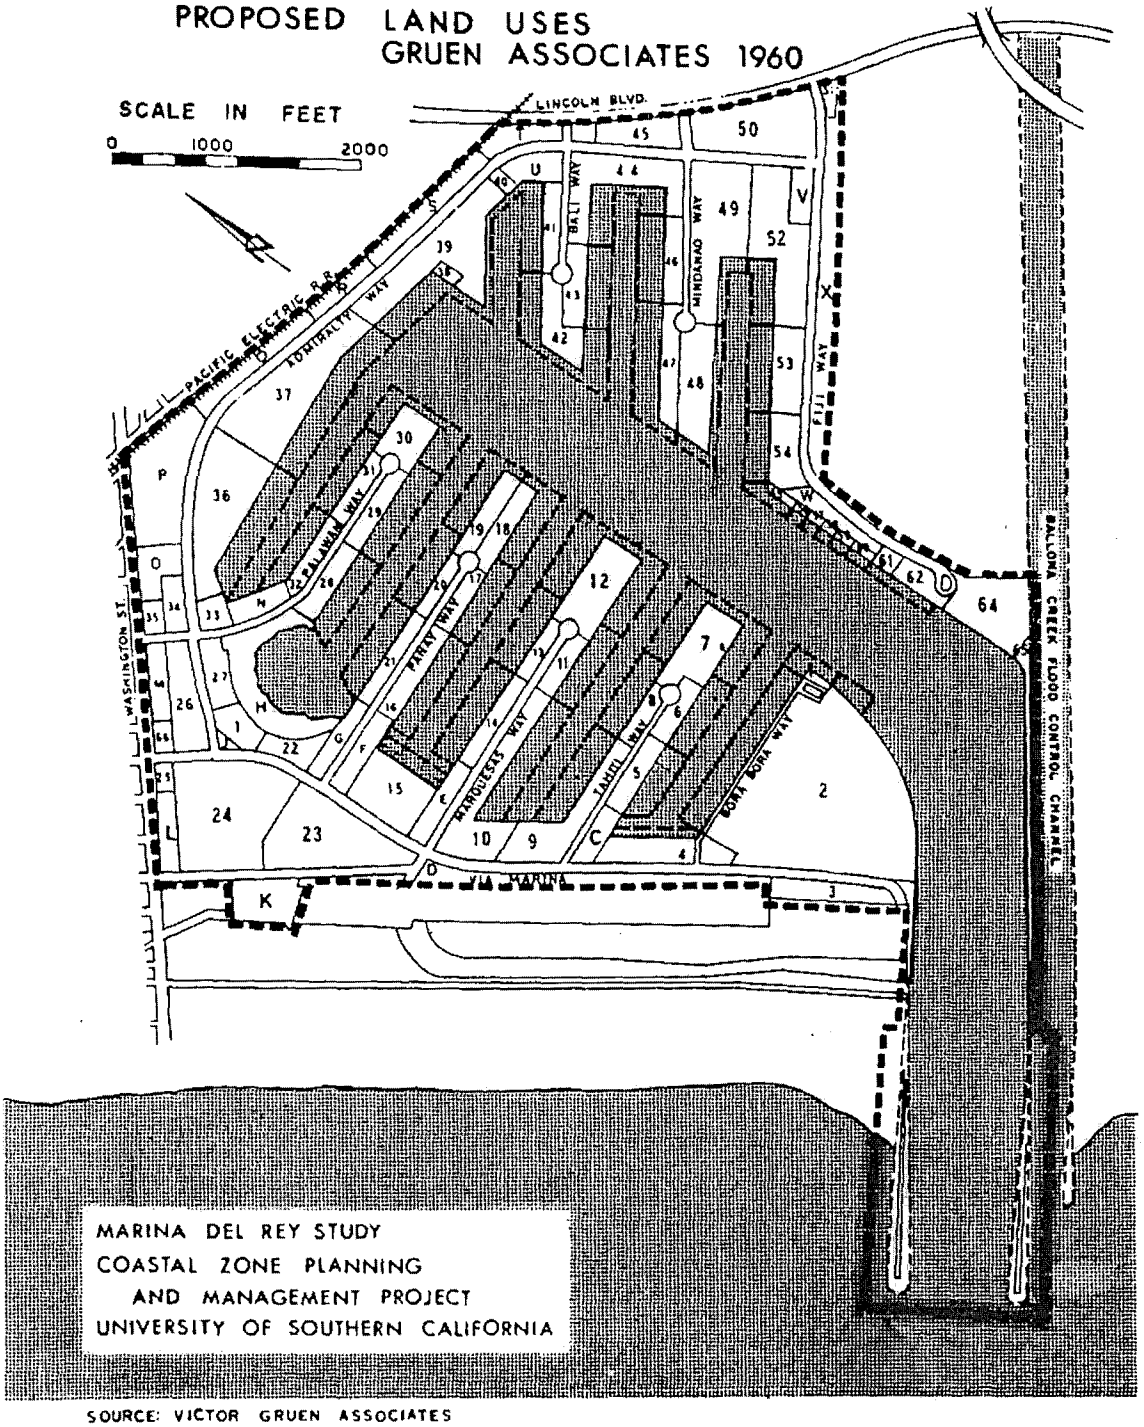
A single factor increasing non-leasable area is public parking, for which 1,349,300 square feet is provided in the Gruen Revised Development Plan and only 1,006,000 square feet in Coverdale and Colpitts recommendation.

Thus, working with a gross area smaller by 1,916,000 square feet than the area of Alternate No. 2, Gruen Associates achieved a leasable, or revenue-producing area larger by approximately 4,791,000 square feet than that estimated by Coverdale and Colpitts, based on the Alternate No. 2.

While part of this increase may be attributable in increased efficiency of the site arrangement, a major part must be considered the result of a change in policy regarding the ratio of revenue producing use to non-revenue producing use of Marina acreage. The need to meet development

B-186

and financing charges may have dictated this altered policy, which required the elimination of two public beaches and three recreational areas.



The Gruen land use plan. In general, the Gruen Plan is based on the standard planning policy of separation of uses. The west side of the Marina was planned for boat anchorages and related residential uses, the east side for marine-related and general commercial areas: boat launching facilities, sports fishing, piers and hotels and motels, with marine-related industrial uses located along a section of the southeastern boundary.[59] The plan, with the single exception of the remaining public beach, thus separated the activity patterns of the boat-owning and resident users of the Marina from the more casual boaters, visitors and shoppers.

Protection of slip renters and residents in the Marina from the general public was a matter of concern to several of the consultants. Madigan-Hyland recommended toll gates at Marina entrances, for which renters would have a pass.[60] Coverdale and Colpitts suggested that a curfew on the use of public parking, and thus on nonrenting members of the public in the Marina was "essential (so) that such activities of the public should not interfere with the comfort and convenience of those on leased property, especially those in cabanas and cabana-trailers, and others living on the site."[61] The Gruen approach, that of separating activities

is less rigid than either toll gates or a curfew hour, and is far more sensitive to the implications of publicly owned property.

Specific allocations of use to land and water parcels is shown on the plan, and in the accompanying tables. Some sectors of the Development Plan of more than routine interest to this study will be considered below.

B-195

Residential uses. Probably the greatest deviation in the Marina as planned from the Marina as developed appears to be in the very large number of permanent residents living in Marina apartments. By the end of 1970 there were 2,223 residential units at the Marina, with 5,095 planned for completion by mid 1972. Yet apartments were not mentioned in any of the consultant work of preliminary planning for the Marina. Rather, "cabanas" were considered feasible.

Alternate No. 2 shows the moles and basins surrounded by areas labelled "future residential development." Indeed Nicholson's criticism of the scheme included the comment that, "There appears to be an overemphasis on residential development and insufficient areas set aside for commercial and recreational development."[62] Yet, in Nicholson's work, only motels and trailers are mentioned as residential units. Presumably the Marina was to be surrounded by a most extensive trailer park.

Coverdale and Colpitts include only cabanas and cabana trailers as residential units. They describe cabana areas as available for "living quarters such as are provided in motels as well as in individual cabanas."[63] Cabana trailer areas are "not in the nature of trailer parks. They are not intended for the itinerant trailer owner. The trailer, once located at the site, must remain there."[64] Coverdale and Colpitts make it clear that the majority of occupants of both areas are expected to be permanent residents: they provide no recommendation for trailer parks.

B-196

Gruen Associates include motel-hotels, boatel-cabanas and trailers in their categories of living accomodations in the Marina, with varying densities and height limitations assigned to them.

Much of the consultants' seeming confusion in defining residential structures, as well as their omission of apartments from approved land uses, stems from legal advice provided to the County to observe caution in locating apartments in the Marina. It was uncertain at that time that apartments would be considered a proper use of public land acquired for a small craft harbor.[65] This made it difficult to obtain title insurance for apartments.

Gruen handled this problem by categorizing residences as boatels or cabanas which are "primarily a home ashore for persons spending as much time afloat as possible."[66] Height regulations for these living accomodations were three stories when located at either end of a mole. The central sections of moles were reserved for anchorages and related use. Structures on parcels located between the western Marina boundary and the peripheral road had no height limitations applied to them. Suggested uses for these parcels were motels, hotels, and cabanas and varying densities were supplied for each of them. All parcels at the north end of the Marina were similarly zoned and unrestricted as to height. Apartments were not mentioned in the May 1, 1960 plan.

B-197

Among the revisions to the original Gruen development plan, submitted in September of 1960, the word "apartment" was added to the suggested uses for six parcels, all except one located in the northern and western areas enjoying unrestricted height zoning. Because of the definitions used, the varied density regulation, and the distribution of height restrictions, no changes were necessitated by the addition of the apartment category. In effect, it had already been provided for.

This initiation of approved locations for apartments began a broadening policy for this use so that, at present, apartments fill most of the parcels in the northern and western sections on both mole and peripheral locations. There are no cabanas, cabana-trailers or house trailer parks in the Marina.

Non-revenue producing areas. In 1960, when the Gruen plan was presented to the County, the most urgent consideration for the Marina was to insure that it produced enough revenue to meet the financial obligations incurred by the bonds. The plan is responsive to this pressure. Gruen Associates have worked toward minimizing non-revenue/productive land and water area in relation to areas planned for uses which would return a profit to the County. 67

It would be poor government policy, however, to exclude the general public entirely from a recreational project acquired and developed in large part with

B-198

public funds. Gruen Associates recognized the problem of establishing a balance between the County's financial responsibility to private investors and its need to satisfy some recreational demands for the general public.

In essence, the Gruen approach to this problem was to require that by efficiency, by good planning practice and by closely administered controls, a minimum area allotted for public use would return a maximum satisfaction of public demand.

Parks and recreation: Of the total 17,472,723 square feet of land in the Marina, Gruen allocated approximately 2.2% for "Parks and Recreation" (Including Beach, Buffers, etc.) as follows:[68]

Parcel	Use	Development Plan (May 1960)[69]	Revised Development Plan (Sept. 1960)[70]
B	Park Site	18,000 sq. ft.	14,725 sq. ft.
D	Buffer Strip	43,000 sq. ft.	14,863 sq. ft.
H	Beach	380,000 sq. ft.	280,604 sq. ft.
J	Park Site	17,200 sq. ft.	18,170 sq. ft.
X	Buffer Strip	59,800 sq. ft.	62,797 sq. ft.
	Total	518,000 sq. ft.	391,159 sq. ft.

A serious effort is given to making this small area an effective increment in the development plan.

B-199

Los Angeles Lake, a salt water lake of approximately 364,000 square feet included in Alternate No. 2 provides the largest area in the Marina for public recreation. Every square foot is planned for use; a sand beach and picnic area, calm water for swimming bordering the beach, and for sailing dinghy-size boats in the wazer between the basin docks and the swimming area make up the facility. Two motels are placed to border the beach. A launch area is provided on the beach for hand-carried small boats. Two of the four public restrooms in the entire Marina are located here. Concessions provide rental boats, sailing instruction and refreshment and the whole is supported by 392,040 square feet of parking area, enough for 1150 cars.

Landscape areas: The importance of creating attractive surroundings in the limited areas open for public use is underscored in the Gruen plan. Public parking lots are to include planting areas. Buffer strips bordering the peripheral road are to be landscaped, as is a small site at the main entrance, where a memorial plaque will provide a theme center. A tiny park located on the main channel will provide a pleasant site for boat watchers. Parcels for private use bordering the peripheral road carry mandatory landscaping provisions. Planted divider strips on public roads, underground utility lines, strict sign controls, architectural and design review of all structures, and the prohibition of any curb parking would work together to provide a pleasant prospect for the visitor wherever he was permitted to travel within the Marina.

B-200

Planting charts and detailed design diagrams for public areas are included in the plan. Recognizing the difficult soil and climate conditions for planting, Gruen proposed an experimental nursery to develop hardy stock for supply to landscaped areas. All of these provisions lie within the control and are the responsibility of the Marina. Gruen emphasizes that proper design and maintenance of public area "will contribute much to the enjoyment of the Marina and act as an incentive to lessees to provide equally pleasant facilities."[71]

Unfortunately, the plans for beautification of public areas remain largely unfulfilled.

Portable boat launching: Unlike other consultants, Gruen Associates did not believe that portable boat launching would be a remunerative use of Marina land. They foresaw that the amount of space on land required to park cars and trailers, and the amount of protected water area required for boat maneuvering and boats waiting for retrieval would be extremely expensive in terms of Marina resources. Nonetheless they recognized that, as with public recreation areas, this demand from the non-renting general public would have to be met to some extent. In the Gruen development plan 1,197,800 square feet was allocated for portable boat facilities.

After submission, the original plan was evaluated by the Department of

B-201

Small Craft Harbors in consultation with Coverdale and Colpitts, economic consultants, as well as Gruen Associates, the authors of the Plan. Replies from more than 200 questionnaires, mailed by the County to prospective lessees for Marina parcels, were examined and considered. The changes made to the original plan were minor, such as the provision for three gas stations rather than two, or revised areas for specific parcels. All of these changes are reviewed in A Development Plan: Revised, submitted by Gruen to the County on September 15, 1960 which, together with the original Plan, constitute the final Master Plan for the Marina.

The provisions for portable boat launching submitted in the original Development Plan met with the criticism that there was more demand for portable boat launching than the plan provided for. Gruen did not accede to the demand but recommended instead that optional use for portable boats be added to the approved uses of two parcels in an adjoining basin. This was done, but the demand for portable boat launching facilities has never been great enough to require more than the facilities originally provided. This is generally attributable to boating conditions at the Marina. Neither the crowded Marina channels nor the often rough open ocean immediately beyond the breakwater provide suitable conditions for sailing boats under 15 feet in length. Fishing in the area is poor and no protected space is allotted for waterskiing.

Conclusions. It is difficult to retain much flexibility in land uses, short of

rebuilding, for a limited area requiring a high intensity of uses such as the Marina. Only two possibilities for flexibility were noted in the Gruen development plan: the first was for portable boat launching facilities, and the second for public parking, which was provided on a generous basis with the comment that any excess could easily be converted to other uses, should the need arise.

The economic necessity which precluded large areas for public use, and required intensive private development of revenue productive areas in the Marina was effectively met by the Gruen plan. It is the achievement of this goal which will make it most difficult to change activities and clients for the Marina when the priorities of needs are seen to change. Rebuilding may take place in private leaseholds at any time. However, increases in public space can be expected only when the Marina's debts are paid, and the demands of the general public can be accorded equal importance with those of private investors.

CHAPTER IV. LATER DEVELOPMENT (1962-71)

The Critical Period

The County's economic consultants had been optimistic about rapid development of Marina enterprises after the basic and secondary public improvements were complete. Nicholson's schedule indicated full private development almost immediately.[1] Coverdale and Colpitts expected this to occur after three years of operation.[2]

However, private development was limited at first. The Marina was opened to boat traffic in the summer of 1962. The Coverdale and Colpitts prediction, upon which the bond repayment schedule was based, implied that total annual County income would reach $2,000,000 by 1965. Actually, income in the fiscal year 1965-66 was only about $1,000,000. This was not sufficient to meet the minimum operating expenses and debt service requirements.[3] The Marina had to borrow $500,000 over a three year period from the County general fund to meet its obligations. As mentioned earlier, State legislation and a resolution of bondholders was required to do this.[4]

Unfortunately, this situation was not just a matter of slow response to the part of private developers. There had been some fundamental problem which jeopardized the overall success of the Marina project. The most dramatic problem was the "surge" problem which began soon after the Marina opened, but became especially difficult in the winter of 1962-63. Apparently, storms in the Pacific produced high waves which entered

B-209

through the wide entrance channel. Furthermore, the waves were augmented by reflection from the channel walls. The most critical wave action occurred in the side basins nearest the entrance.[5]

Considerable damage was done to boats and slips at this time. Ultimately about $5,600,000 in damage suits were threatened against the County.[6]

In addition, it was reported that:

> Reputable waterfront contractors have refused to accept even temporary responsibility for construction in the interior basins until positive protection of the harbor is in place. Maritime insurance agents are refusing to write hull insurance for boats berthing in the harbor. Property damage insurance recently has increased significantly for Los Angeles County lessees. Manufactures of floating equipment are refusing to guarantee their protection against wave conditions in Marina del Rey.[7]

Still, ultimately, only one settlement for $50,000 and another of unknown amount were paid.[8] These events discouraged potential developers of both water and land oriented enterprises. Fortunately the Corps of Engineers was already considering studies of the Marina using a scale model and wave action machine.[9] These studies were soon complete and recommendations were made. The Corps proposed the construction of a breakwater across the channel entrance and the sealing of the south jetty. This was expected to reduce the maximum wave height within the Marina to two feet.[10] The cost was about $4,600,000, with equal shares paid by Federal and County governments. By 1956, this project was completed and has apparently been successful in eliminating the surge problem.

B-210

Another environmental problem was particularly apparent at that time. Heavy concentrations of "red tide" made up of algae which discolor the water, have an unpleasant odor, and can poison fish and shellfish, appeared all along the coast and affected the Marina area.[11] No cure has been found for this periodic phenomenon although there have been no serious "red tides" recently.

During the "critical period", title companies were being cautious about insuring titles to land leased from the County. The terms of the revenue bond resolution required "active public use" of the Marina by sublessees. This was interpreted to mean that subleases for questionable uses could not be written for periods longer than one year and that the County could require a 25 percent annual turnover in sublessees.

An additional expense for lessees also appeared with a ruling from the Los Angeles County Tax Assessor that the land they had leased, as well as the structures they owned would be subject to property tax. A tax on "possessory interest" in leased land had to be paid by each lessee. This resulted in property taxes said to be about 60% higher than the amounts anticipated at the time leases were signed.[12]

All of these factors combined to put many lessees in financial jeopardy. In May 1962, the Marina del Rey Lessees Association was formed to see what could be done. At this time some lessees were ready to cancel

D-211

their contracts, preferring to take their losses rather than incur greater losses under the undue hardship conditions which they perceived.[13] Later they met with the Los Angeles County Assessment Appeals Board and worked out mutually acceptable arrangements. This led to some reduction of the possessory interest tax based on the time remaining on leases.

By 1967, most Marina problems had been resolved, consumer demand had increased and considerable new development had taken place. Revenues were sufficient to cover current costs, interest on bonds, and to retire bonds according to the required schedule. The period from 1962-67 had been a difficult one. During this time, much of the negotiation with lessees about private development took place and the policies established then continue to affect current decisions.

Land Use Plan 1967

In 1967 Gruen Associates completed a revised Land Use Study.[14] This was a review of Marina development that had taken place, under the original Plan, an evaluation of problems then current, and an examination of alternative planning strategies for the solution of those problems.

When this Land Use Study was begun, the Marina was still in a critical period of economic development. Revenues were not sufficient to cover bond payments as well as operating expenses.

B-212

Income Statement

Fiscal Year 1965-66 [15]

Gross rents	$1,095,851
Small Craft Harbor Expenses	724,068
Net Income	371,783
Bond Payments	$ 728,000
Deficit	356,717

According to the data then available to Gruen, the deficit was expected to drop to $175,000 for the fiscal year 1966-67, and to $100,000 the following year. It was expected that after 1968, loans from the County general fund would no longer be needed to meet the deficit.[16] It is clear, then, that the highest priority in planning for the Marina had still to be given to its potential for revenue production.

Leasing problems. Many of the difficulties which slowed the development of the Marina were discussed in the previous section of this chapter. The result of these difficulties was a period of low return from under-developed County real estate resources which extend for a longer period than had been anticipated.

In 1967, 53 leases for Marina land had been awarded, and 17 parcels still remained unleased and vacant.[17] In terms of development, only 35 parcels were considered to be fully developed: 10 leased parcels were vacant and 12 were only partially developed.[18] The 17 unleased

B-213

parcels were, of course, vacant. The visible effect of 39 empty or underdeveloped parcels on the Marina was to give it a dispersed and under-used appearance discouraging to investors.

County leasing arrangements for Marina properties stipulated three levels of rent which might be paid. The lowest rent was "holding rent" based on 1/3 of the specified square foot rent for a parcel. It was intended for the initial period in which the leased parcel was either undeveloped or under construction. In either case the parcel was incapable of producing a return for the lessee.[19]

"Square foot rent," sometimes called "minimum rent", was to be charged when construction was complete. The facility on the parcel was assumed to be in operation, but not yet successful. Each parcel was assigned a minimum square foot rent for land which varied, according to location and use, from 6 to 30 cents per square foot.[20] It was hoped that minimum rents would cover all costs to the County, including financing costs, for the operation of the Marina.

The normal return to the County was from "percentage rents", based on percentages of gross receipts earned on each successful parcel.[21] The specific percentage to be charged varied according to the type of business in which the lessee was engaged. Originally, the percentages of gross receipts to be charged ranged from 5% to 25%.[22] This schedule was revised in 1961 to range from $1\frac{1}{4}$% to 20%.[23]

B-214

Rents for each developed parcel were to be based on either square foot rents or percentage rents, whichever was greater, thus insuring that the County would cover its costs as soon as a parcel moved beyond the holding rent stage of its operation. Time limits for paying holding rents were specified in leases.[24] Had these time limits on holding rents been strictly enforced, Marina deficits would have been reduced, if not eliminated. General economic conditions, financing difficulties and the threat of lessee withdrawal made it impolitic to insist on these time constraints.

In 1967, 41 parcels in the Marina had been leased.[25] Eleven of the 41 were paying percentage rent, indicating a profitable operation for the County. Ten parcels were paying minimum rent, assumed to be a break-even level of revenue return for the County. Twenty were paying holding rent, which produced a net loss for the County.

Gruen noted that if all unleased parcels were let at minimum rent they would provide additional annual income to the County of only $184,145. This would not cover current deficits. Furthermore, there was no indication that parcels leased in the future would be developed, and thus move from holding to minimum rents, any more quickly than the parcels already leased. At holding rent, all parcels available for lease would bring in only an additional $61,380 per year.[26]

B-215

If, on the other hand, the 20 parcels then paying holding rent were developed to pay minimum rent, additional annual County income would amount to $447,509, a sum more than sufficient to cover annual deficits.

Emphasis, therefore, should be placed on encouraging more rapid completion of improvements on parcels already leased rather than on putting all parcels out for bid. The study recognizes the difficulty to the County of speeding development on leased parcels, since initiation of further construction must lie with the lessee. It was suggested, however, that the County encourage the development of temporary improvements such as public tennis courts or recreational areas on leased parcels. These uses would also provide the appearance of activity. Some income would be obtained by lessees while they awaited favorable financing opportunities for more intensive development. Landscaping, placed so as to be usable on sites destined for future completion, would mature in readiness for final development. This would enhance the appearance of the Marina in the interval. Finally, higher intensity use of parcels already in operation should be encouraged.

The break-through year, in which the Marina achieved an acceptable level of revenue was 1967. So far as is known, neither the temporary uses nor the landscaping improvements were implemented since the problems which suggested them did not continue.

Strategies for the future. Reviewing the analysis of rents, the Gruen study

B-216

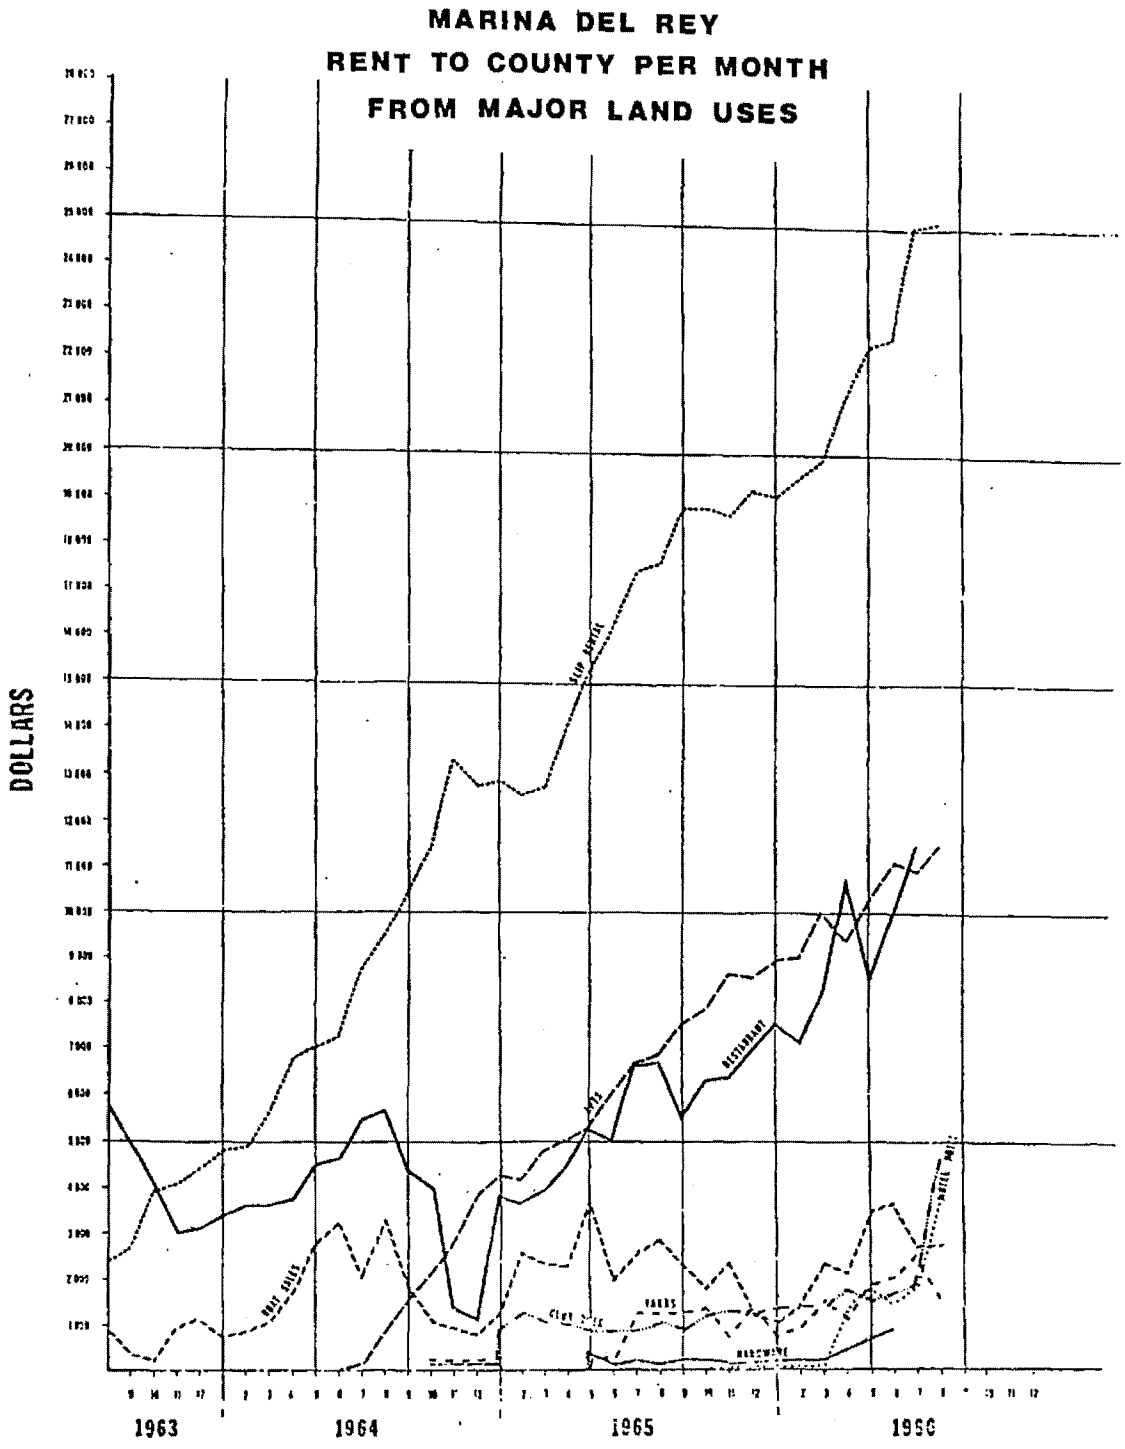
recommended against making the unleased parcels available for lease indiscriminately. Pointing out that undeveloped parcels, both leased and unleased, provided an opportunity for flexibility in strategies for revenue maximization, the study recommended that alternate strategies be examined to achieve a goal of optimum balance of land use. "This does not mean that the current land use plan and policies be rejected, but that certain emphases might be changed."[27]

Gruen considered 14 parcels as potential leaseholds and recommended that light of them be withheld from leasing for a time. Four of these parcels were designated as public parking to be converted to other uses as deemed necessary. Four parcels for commercial use should also be withheld. The remaining six, planned for a drive-in restaurant, two gas stations, and anchorages, apartments and related uses were to be leased immediately.

Recommendations for leasing were based partially on location, since key parcels which were empty detracted greatly from the appearance of the Marina. Another consideration was apparently needed. For example gas stations were needed to serve Marina residents and visitors. Proven operational success was also a factor, as in the case of anchorages and apartments.

Recommendations for withholding parcels from leasing were based on

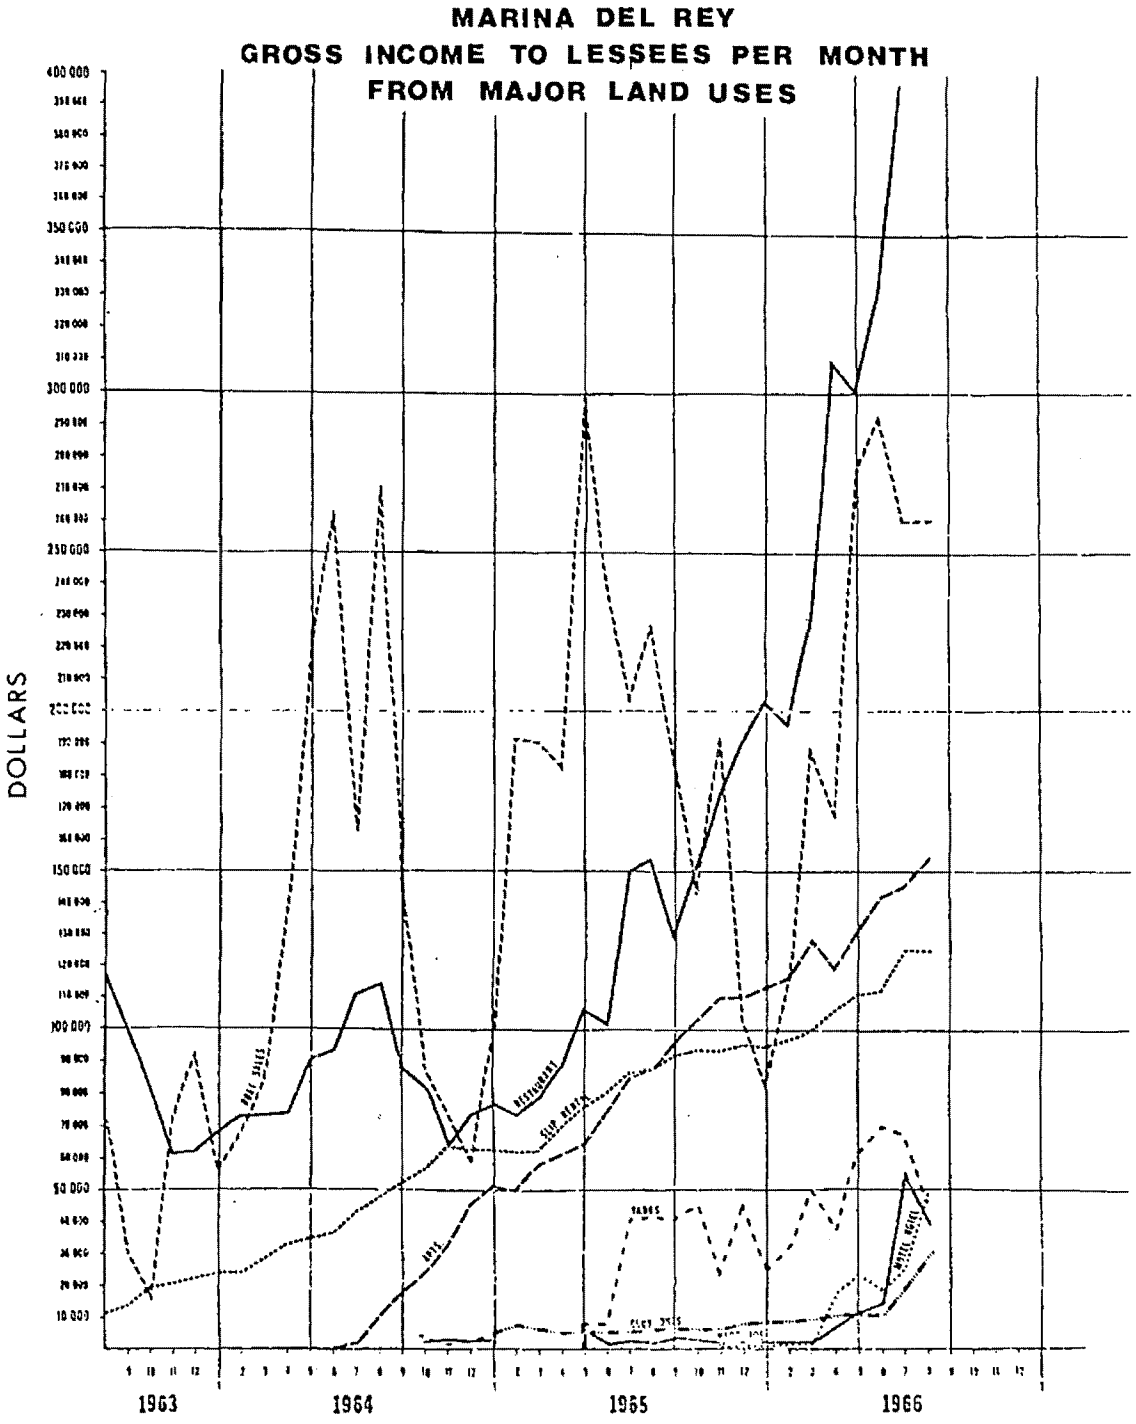
B-217



the need to reevaluate some land uses in the light of experience up to that time. Recommendations of particular interest to this study will be considered below.

Analysis of land use revenues. Examination of rents received by the County from August 1963 through August 1966, as shown on the following charts, indicates that boat slips, restaurants and apartments were the most revenue productive uses to the County. Relating area to revenue, rents received per square foot clearly show restaurants to be the most productive use, returning $.44 in rent per square foot. Boat slips produced $.41 per square foot if land alone is figured, but only $.08 if land and water area is considered. Apartments returned $.105 per square foot. No attempt is made to relate County costs for various uses to the rents received.

The analysis of revenues must be viewed in relation to several factors: gross revenues on which percentage rents are based, the percentages charged for varying uses and the areas of land required to produce the receipts. Thus, for example, restaurants are a highly intensive land use, producing the highest gross receipts in the Marina, $3,445,013 in 1965-66, but returning only $119,931 in rents at 3% of gross receipts. Boat slips, however, which grossed only $1,252,500 during the same period returned $250,495 on the basis of 20% of gross receipts charged as percentage rent. Ideally, costs to the County in terms of differing services required should



28

Source: Gruen Associates, Marina del Rey: Land Use Study, Los Angeles (March 1967)

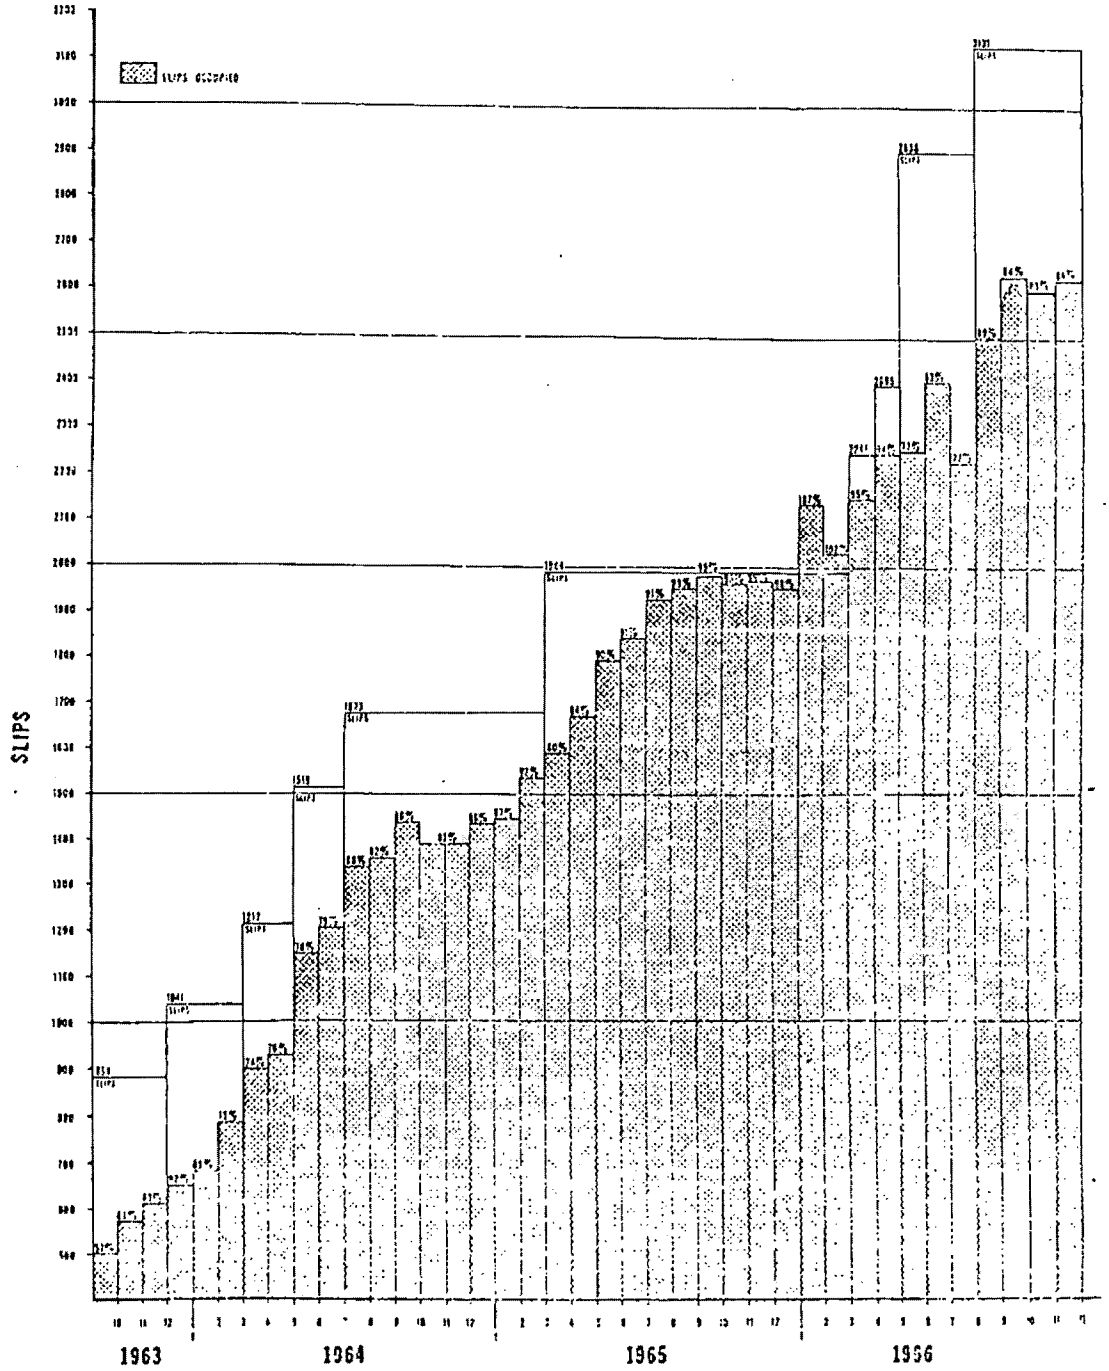
B-220

be figured into the land use revenue analysis to give a true assessment of productivity. The Land Use Study does not provide these figures, but in making recommendations for future planning strategies the study does consider the opportunity costs which would result if balanced and efficient land use were ignored.



The Land Use Study

In general the Land Use Study responds to the financial pressures still prevalent in Marina operations by recommending further development of those land uses which have proved profitable. Anchorages were, of course, the prime purpose for Marina development and were, in addition, a profitable enterprise, producing the largest single source of revenue in 1965-66. The Study recommends that more slips be provided as current occupancy reaches 90%. The following chart shows how occupancy tends to rise to meet newly constructed capacity.

Boat sales, a use related to anchorage, were also a highly successful operation, grossing $2,278,289 in 1965-66, but returning only $27,262 to the County because of the 1¼% rent charged on the gross receipts. Gruen sees the demand for boat sales as being directly related to the number of slips available. This, coupled with the low return, leads to a recommendation that the area available for boat sales be increased only in proportion to anchorages available.

EXECUTIVE SUMMARY

LOOKING ACROSS THE VAST URBANIZED LANDSCAPE in the Los Angeles Basin, it is almost impossible to imagine the natural landscape prior to human development. The remaining wetlands leave only a few clues about the past wetland complexes in this region. Nevertheless, the past is vital to understanding the foundation of landscape-processes, historical wetland distribution, and human impact that lend to a better understanding of sustainable restoration plans within the constraints of the contemporary landscape.

The primary goal of this project was to identify the characteristics of historical wetland habitat types and describe the historical form of major creeks in the Ballona Creek watershed. Our target time period was 1850-1890, just prior to contemporary impacts but after the migration of the Los Angeles River, which fundamentally altered the hydrology and morphology of the watershed. It is also a time period that is relatively data rich associated with information compiled around the time of statehood. We set forth to answer the following questions:

1. What was the extent (acreage) of persistent riparian, wetland, and associated floodplain habitat in the Ballona waterhshed?
2. What were the predominant types of wetlands in the watershed and what was the spatial distribution of these wetlands within the watershed?
3. What potential resources are available for stakeholders and scientists wanting to pursue further and more detailed research on this watershed?

Conclusions about historical wetland composition, extent, and distribution were based on a "weight of evidence" approach. Over 300 documents were compiled from 84 source institutions and origanized through a metadata catalogue. Data sources were digitized, georeferenced, and organized by subregions within the study area. Spatially referenced datasets were overlaid and augmented by textual citations, photographs and other non-geospatial data. The concordance between multiple data sources allowed us to draw conclusions that supported inferences about historical conditions. We assigned a certainty rating for interpretation, shape/size, and location of each polygon mapped based on the number and quality of corroborating pieces of evidence. Finally, historical herbaria records and bird observations were used to provide insight into the composition of historical plant communities.

EXTENT AND TYPE OF WETLANDS IN THE BALLONA WATERSHED

The Ballona watershed supported a great diversity of wetlands during the mid-late 19th century (FIGURE ES-1). The La Cienega wetlands and the Ballona Lagoon complex accounted for the majority of wetland area in the watershed. Various freshwater ponds, vernal pools, wet meadows, freshwater marshes and numerous springs were found throughout the watershed. We mapped 174 unique wetland polygon features comprising 14,149 acres. The dominant wetland types included alkali meadow (35%), valley freshwater wet meadow (10%), valley freshwater marsh (10%), brackish to salt marsh/tidal marsh (9%), and alkali flats (8%; TABLE ES-1).

*DOES NOT INCLUDE PACIFIC OCEAN

TABLE ES-1:
Summary of wetlands mapped on the Ballona Historical Ecology project.

We mapped 232 miles (373 km) of historical stream channels in the study area. Approximately 80% of the stream channels were intermittent (often discontinuous) washes. Across the valley floor most of the streams sank into porous soils or spread into the major wetland complexes of La Cienega and the Ballona Lagoon. This characteristic likely contributed to a significant amount of subsurface water flow and to the vast wetland complex at La Cienega. The exceptions were Ballona and Centinela Creeks, which were perennial streams lined with willow woodlands. Both streams provided freshwater input to coastal wetlands of Ballona Lagoon.

Freshwater seeps and springs were a characteristic feature of the Ballona Watershed. Although springs were present at a few locations throughout the Ballona Valley, 70% of the 45 mapped springs in the watershed were found in the Santa Monica Mountain foothills. These springs were clustered in the foothills and stopped abruptly at Franklin Canyon. This distribution could be the result of fault displacement or geologic composition. These springs played a notable role in downstream hydrology, where in several locations freshwater wetlands formed at their confluence (particularly in Rodeos de las Aguas near present day Beverly Hills). Many of these springs persist today and are unique remnant features from the historical landscape.

Data Products

In addition to this summary report, we developed several products designed to make the data compiled through this effort more readily available for exploration and use. Once collected, photographs, maps, and textual data were uploaded into an online metadata catalog. The catalog provides a means to organize and query historical documentation by spatial location, wetland descriptions, time period, and source. Bibliographic tables and information about source institutions may also be downloaded from this online database creating a secondary product for stakeholder use. This type of database creates a dynamic tool for the discovery of new information and allows for the creation of different hypothetical questions that can be explored by future researchers. The metadata catalogue, an associated geodatabase with spatially explicit data, raw data tables, and this summary report can be viewed and downloaded from **www.ballonahe.org**.

The contemporary Ballona watershed represents unique opportunities for restoration planning. The information in this report should provide a foundation for understanding the functional relationships of the various wetland complexes, lend support to the development of sustainable restoration plans, and facilitate consideration of natural landscapes into future planning for infrastructure and stormwater management.

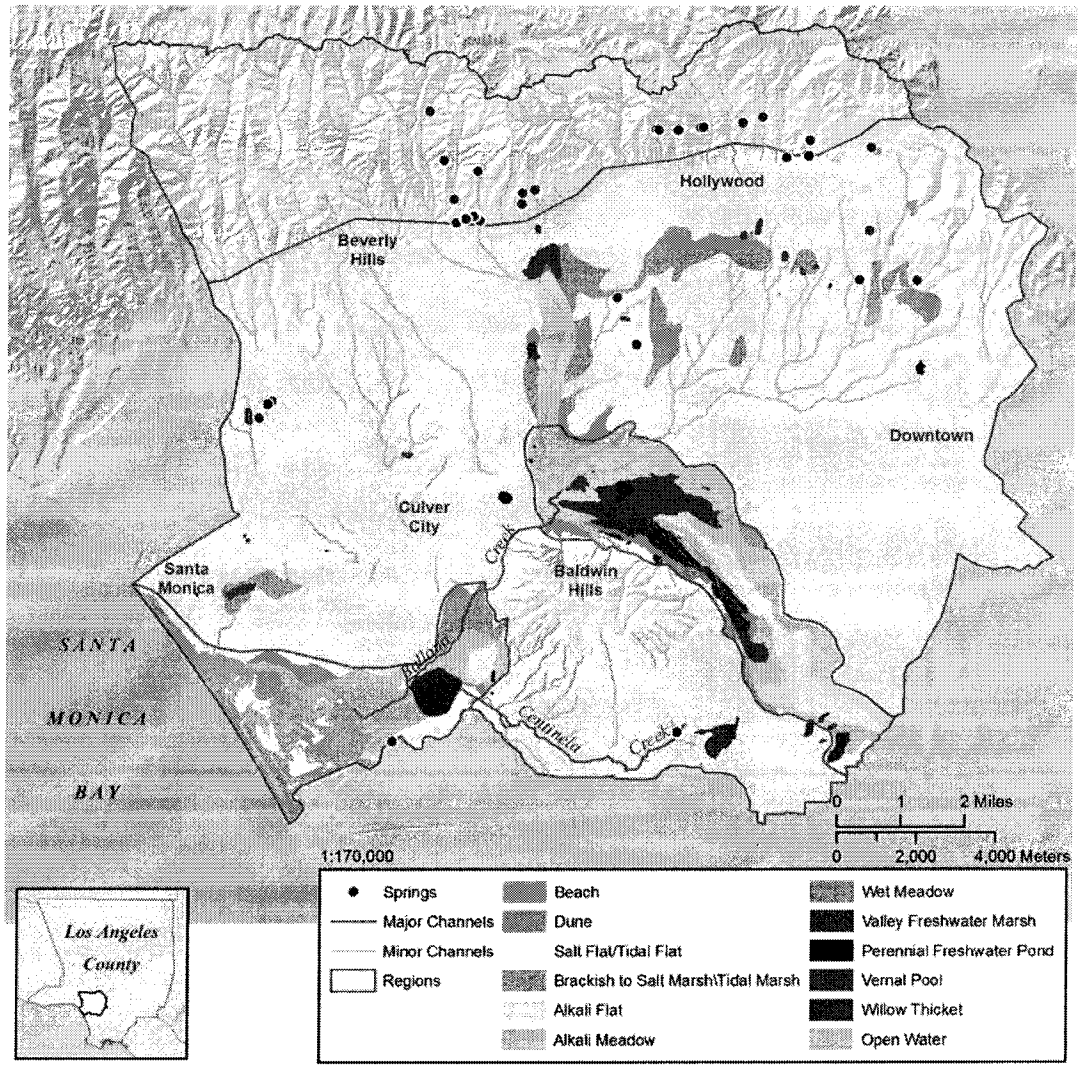

FIGURE ES-1: *Distribution of wetlands and associated features within the Ballona Watershed (1850–1890).*

INTRODUCTION

"Restoring the Ballona Creek watershed is a waste of time and money." Such commonly heard sentiments about highly urbanized watersheds used to be commonplace. Studies in California and other regions have shown that where underlying watershed processes remain intact, restoration options exist, even in highly urbanized settings (Zedler and Leach 1998, Ehrenfeld 2000). Historical ecology provides an understanding of how landscape-scale processes influence wetland extant and distribution under more natural conditions; thus it provides context for restoration planning by providing insight to natural ecosystem functions. (Kentula 1997, Kershner 1997, NRC 2001, White and Fennessy 2005, Kentula 2007).

The on-going planning efforts associated with the Ballona watershed can benefit from the insights of historical ecology. While the Ballona watershed is highly urbanized, it retains remnants of its historical natural resources mainly in the form of coastal wetlands and natural springs. Developing an understanding of potential restoration options in such landscapes depends upon a sound understanding of both contemporary conditions and historical ecological wetland functions. The historical perspective provides an understanding of the relationship between physical settings that support natural wetland functions, the driving forces behind ecosystem degradation and perhaps most importantly, the value of wetland ecosystems that remain intact (Stein et al. 2010). Our goal is to provide this unique perspective of the Ballona Watershed as a valuable tool for understanding not only the past, but for assessing present and future options for management and restoration.

Knowing the historical ecosystem processes associated with the Ballona watershed will provide insight into larger ecosystem processes that governed the greater Los Angeles/San Gabriel river basin. Previous historical ecological research on the San Gabriel River suggests that ecosystem processes were more dynamic and wetlands more diverse than previously expected (Stein et al. 2007). This sheds light on only one component of a larger interconnected system of rivers and wetland complexes, all tied together at some point in time by the Los Angeles River. This report provides information on one additional component of this system, accentuating the importance of historical research on the Los Angeles River to capture a more comprehensive understanding of inter-relatedness and unique qualities of Southern California wetland ecosystems.

PROJECT OBJECTIVES

The primary goal of this project was to identify the characteristics of historical wetland habitat types and describe the historical form of major creeks in the Ballona Creek watershed. To achieve this goal, we created a habitat map and comprehensive dataset describing the extent of creeks and diversity of habitats throughout the watershed. The target time period was prior to significant Euro-American modification (including the Spanish-Mexican ranching era) and just after the natural realignment of the Los Angeles River in 1825 from the Los Angeles Basin to the San Gabriel Valley. Specifically, we used historical ecological research to answer the following questions about the Ballona watershed:

1. What was the extent (acreage) of persistent riparian, wetland, and associated floodplain habitat in the Ballona waterhshed?
2. What were the predominant types of wetlands in the watershed and what was the spatial distribution of these wetlands within the watershed?
3. What potential resources are available for stakeholders and scientists wanting to pursue further and more detailed research on this watershed?

Data Products Available

In answering the above questions, we developed a geodatabase with spatially explicit data. This geodatabase can be used to identify the location and classification of historical habitat types. We also developed a web-portal for visualizing the historical distribution of wetlands relative to the contemporary environment, this executive summary report, and a series of tables that will provide resources to those wanting to pursue more detailed research of specific wetlands or specific time periods not examined for this project. These data sets can be viewed and downloaded from **www.ballonahe.org**. TABLE 1 provides an overview of each data set, including data format, source, and brief description.

Disclaimer

The information provided in this report should be viewed as metadata that supports a detailed understanding of how the GIS data layers for this project were created, interpreted from historical documents, and are best used. In addition, we provide a summary of the historical watershed characteristics. This report has a limited focus on interpreting these data. We did not interpret or analyze landscape change or discuss implications for management. While we documented historical habitat and creek patterns in the watershed, we did not investigate historical ecological dynamics such as how the migration of the Los Angeles River impacted hydrological dynamics of the watershed. The "Next Steps" section of this report (see page 34) provides a comprehensive overview of potential efforts that would provide a better understanding and documentation of historical processes and conditions of the Ballona Creek and adjacent watersheds.

WATERSHED BACKGROUND

Historical accounts of the Ballona watershed suggest a landscape with vast and diverse sources of water. Descriptions of groundwater fed wetlands, springs, creeks, and lagoons were abundant in the early literature (Mesmer 1904, Regan 1917). These descriptions also suggest that before most of the county's hydrology was constrained to concrete channels, the prairie-like lowlands were often flooded from seasonal rainfall contributing to a dynamic and diverse watershed (LAT 1906, Regan 1917, USEO 1939, Schiffman 2005).

Understanding the unique history of this watershed is important as it helps to identify the most appropriate target time period for this project. Prior to 1825, the Los Angeles River flowed through the Ballona watershed and into the Ballona Lagoon. However, beginning in 1825, the Los Angeles region experienced three consecutive years of heavy rains that inundated the lowland (LAT 1906, Reagan 1917). Along with years of unusually high precipitation, the residents during this period frequently mention a series of earthquakes that rocked the Los Angeles area (Regan 1917). While it may not be possible to fully determine the extent of each natural change, it was after *both* of these that the discharge of the Los Angeles River shifted south to San Pedro.

Despite the newly formed southward course of the Los Angeles River, the inland marshes of the Ballona watershed although hydrologically altered, did not dry up. In both the lowlands and the Santa Monica Mountains, fresh water springs flowed in a southwest direction and sustained much of the inland marshland of the Ballona Creek. Because our goal was to identify the historical landscape that is most representative of the contemporary hydrodynamics and it is doubtful the Los Angeles River will ever flow into the Ballona estuary again, we chose the post-Los Angeles River migration period (1850-1890) as our target time period. This was also just prior to significant changes in land use that likely had a dramatic impact on water resources in the region, such as a shift from ranching to agriculture which was quickly followed by urban development (Stein et al. 2007).

The Ballona watershed geology played a major role in shaping its ecological patterns. Major factors controlling this geologic template include the Newport-Inglewood fault, which created the Baldwin Hills and other outcrops, aeolian beach-derived sand deposits, and the Holocene history of various courses of the Los Angeles River. The eastern part of the watershed comprises well-drained soils of the Los Angeles River's broad alluvial fan (FIGURE 1). Where the coarse alluvial fan deposits diminish, giving way to finer grain soils, wetlands occurred. Wetlands formed in the trough aligned with the Baldwin Hills and faulting throughout the watershed. These geologic patterns expressed themselves in habitats found in the 19th century, such as the groundwater fed wetland complex at the base of the Baldwin Hills and the springs in the Santa Monica Mountain foothill regions.

METHODS

The following section provides a broad overview of the analytical process used to map wetlands in the study area and provides guidance the most effective use of the data relative to current restoration and management practices. Land use history was investigated as it related to wetland location, type, and extent. A detailed investigation of the history of land and water use for the Ballona watershed is, however, beyond the scope of this study.

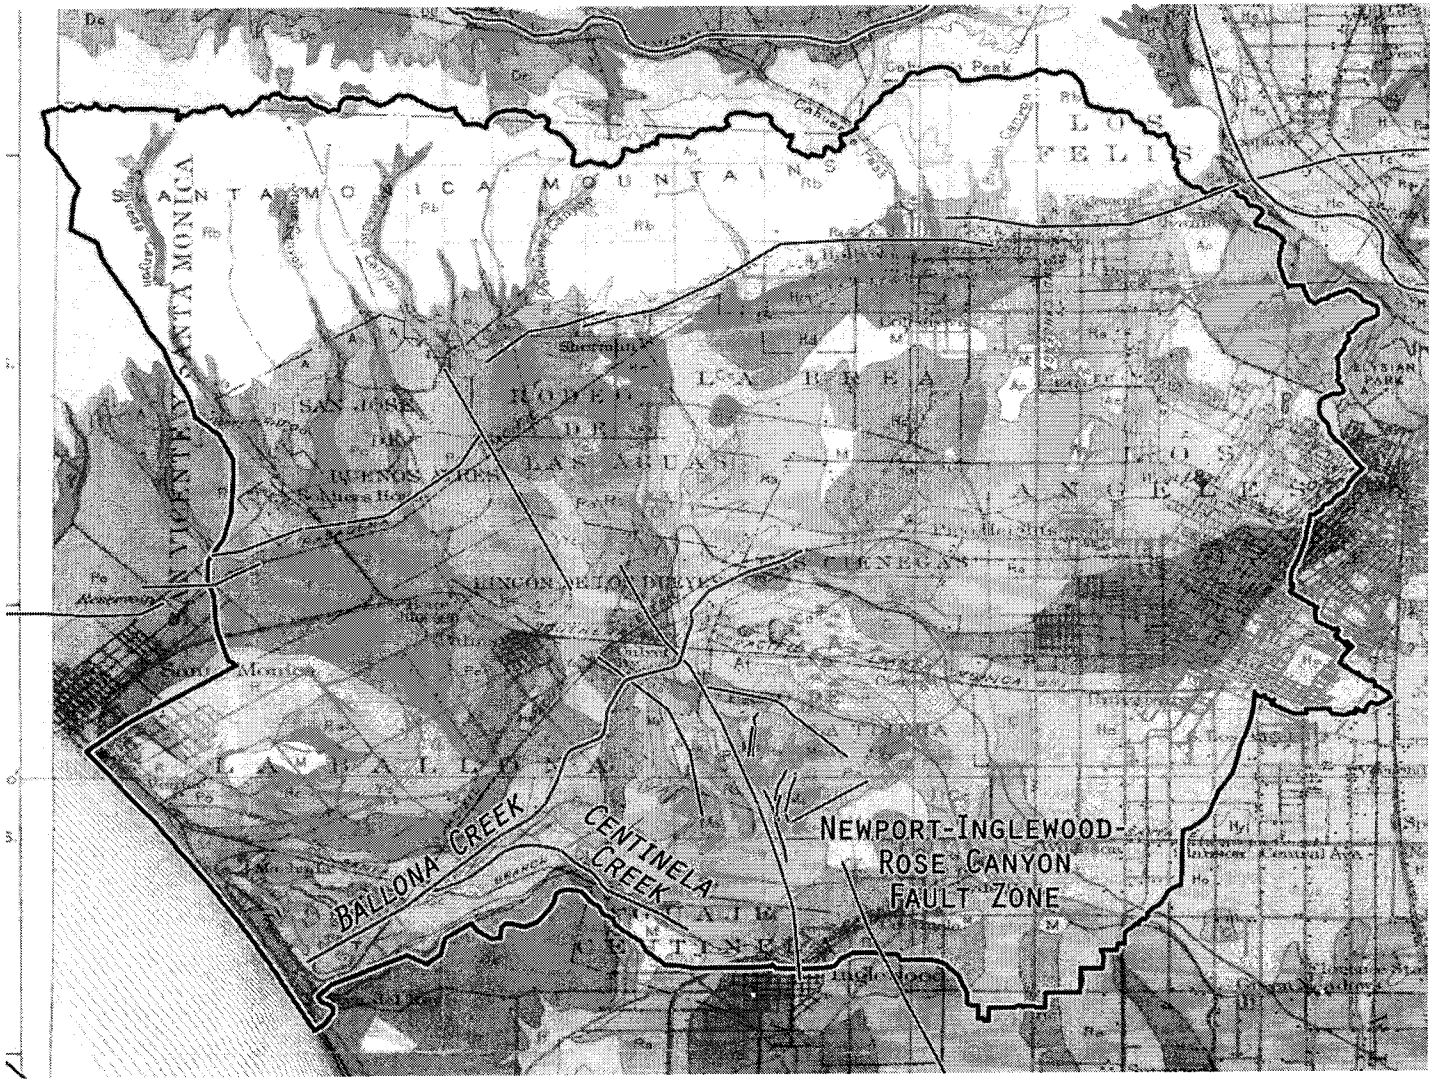

FIGURE 1:
Historical soil map (Nelson et al. 1917) demonstrating the extent of the historical Los Angeles River alluvial fan (dark yellow) within the Ballona watershed.

Our methodology can be divided into a series of phases; data collection/data compilation, synthesis/interpretation, and mapping. Each phase of the project represents a systematic and consistent process that has been developed by the San Francisco Estuary Institute (SFEI) and applied across many historical ecology projects throughout the state of California (e.g., Grossinger et al. 2006, Grossinger et. al. 2007, Stein et al. 2007, Grossinger et al. 2008, Beller et al. 2010, Beller et al. 2011). FIGURE 2 demonstrates the various phases of the project and the primary tasks completed in each phase.

Data Collection and Compilation

Mapping historical wetland features is dependent upon building a body of evidence to support habitat boundaries, classification interpretations, and

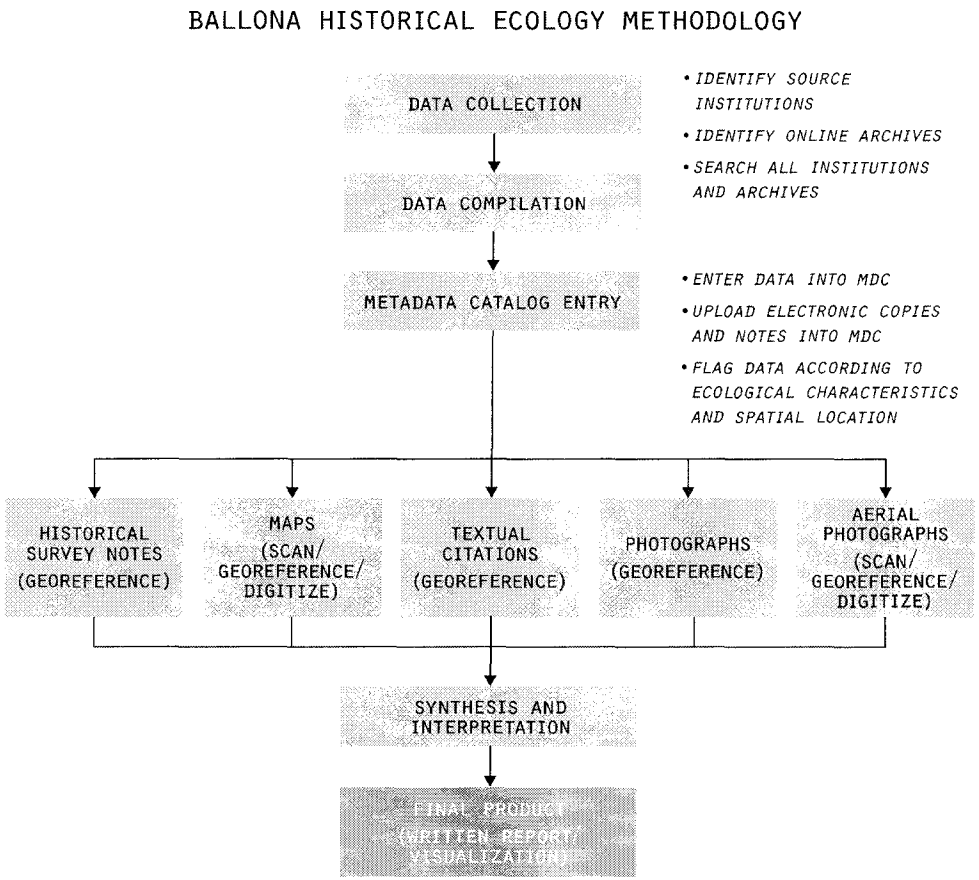

FIGURE 2: *Schematic illustration of research process for historical data acquisition and use in historical ecology. Methodology described in detail in the following sections.*

certainty of the features mapped. For this project, we visited 84 source institutions (50 physical archives and 34 online archives) throughout the state of California, although the majority of institutions are located in Southern California. These institutions included libraries, government agencies, historical societies, map archives, and other institutions housing related historical documents. One of the most notable collections investigated for this project was the Solano Reeves map collection found at the Huntington Library, which provided both early surveyor maps of Los Angeles County and field notes not attainable through other sources.

Over 300 documents were collected. The documents included written accounts, historical photographs (landscape and aerial), and historical maps. Our data collection efforts focused on 19th century sources; a few data sets from the 20th century (e.g. 1927 aerial photography, 1917 soil map) were also collected. The variety of data sets from overlapping time periods allowed for a comprehensive assessment of persistent wetland features and an in-depth interpretation of their classification. We relied on each overlapping dataset to understand the complexity of the ecological pattern and function of the landscape, and our confidence in conclusions about these features was commensurate with the supporting weight of evidence.

Written documents provided detailed insight, supplementing historical map interpretation and allowing for a more comprehensive depiction of the landscape. In some instances, textual data provided significant support for wetland features depicted on a historical map. For example, the following quote identifies the size of a depression and its associated flow regime:

> *"In the Northwest corner of the parcel secondly described in said order of partition, I found a depression cover about sixteen acres, which was filled up by the rains in winter so as to render it unfit for either cultivation or pasture."*
> ***-Solano (1893)***

This information allowed us to verify the size of the mapped feature and classify it as a vernal pool given the additional information about seasonality. Other quotes provided a general overview of the study area:

> *"In the medium part of this southwest course [Ballona Creek] it is bordered on either side by a rich plain of several thousand acres in area, and which, to some extent, it has served in irrigation for a long number of years. The lands irrigated are all within the rancho La Ballona and the waters have for many years been considered as appurtenant thereto."*
> ***-Hall (1888)***

> *"In several depressions or arroyos of the Santa Monica plain, and at the footing of that plain against the Centinela hills, as elsewhere better explained, there are a number of little water sources of the class called cienegas, and which have been referred to in this report, also as cienega springs, and sometimes as artesian springs. A belt of these sources in the ranchos La Brea, Rodeo de los Aguas, and Santa Monica, is found one to three miles out from the mountain's base, and nearly half way down the plain."*
> ***-Hall (1888)***

> *"Coldwater Canyon Creek; Ballona Creek basin; Los Angeles County; an intermittent stream, 3 or 4 miles long, draining a small area in the Santa Monica Mountains, and flowing southward and southeastward into Rodeo de las Aguas Rancho. Near the mouth of its canyon it receives streams draining from Franklin and Higgins canyons."*
> ***-Lee (1912)***

Historical photographs collected from the Los Angeles Public Library and the Huntington Library also provided insight into landscape conditions throughout the watershed. Some of the most useful photographs were those that did not have a principal focus on ecology, but depicted enough of the landscape to provide corroborating data. For example, the photograph in FIGURE 3 depicts recreational boating on Ballona Lake, which gave us insight into not only the size and extent of the dunes surrounding this feature, but also the cultural value of the physical landscape at this site.

A variety of unique historical thematic and reference maps were collected, many of which became the primary source of mapping. Some examples of these include the Hall irrigation maps (1888), a variety of soil maps (1903–1916), and diseño maps of California land grants (circa 1840). The Hall irrigation maps are two maps produced in conjunction with an irrigation report, Irrigation in California by the California State Engineer, William H. Hall in 1888. These two maps focused on water works, developments, and use within Southern California (Hall 1888). The maps provided an accurate depiction of natural hydrological features such as channels and springs (FIGURE 4).

Additionally, ecological features were accurately presented in the Hall irrigation map, allowing us to use the map as a primary source to digitize historical wetlands (FIGURE 5). Primary digitizing sources were those that we used as a primary source to create habitat boundaries (though thse boundaries may bave been further adjusted based on additional subsidiary evidence). Because of the maps' accuracy, composition, and time frame they served as a useful source, particularly in areas with large and diverse wetland complexes.

Similarly, the 1876 T-Sheet (Chase 1876; T-1432B) was another dataset that was key to the completion of this project. T-Sheets were produced between 1851 and 1900 by the United States Coast Survey. These accompanied surveys completed along the Southern California coastline (Grossinger et al, 2011). Specifically, the T-Sheet we utilized for this project included the Ballona Lagoon and immediate wetlands as surveyed in 1876. Produced at an unusually large scale (1:10,000),

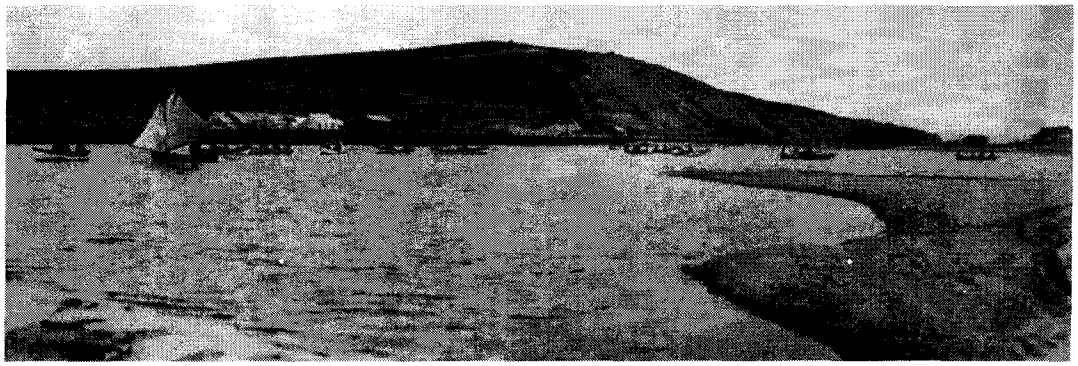

FIGURE 3:
Ballona Lake located at what is now Del Rey/Ballona Lagoon (photo courtesy of the Los Angeles Public Library).

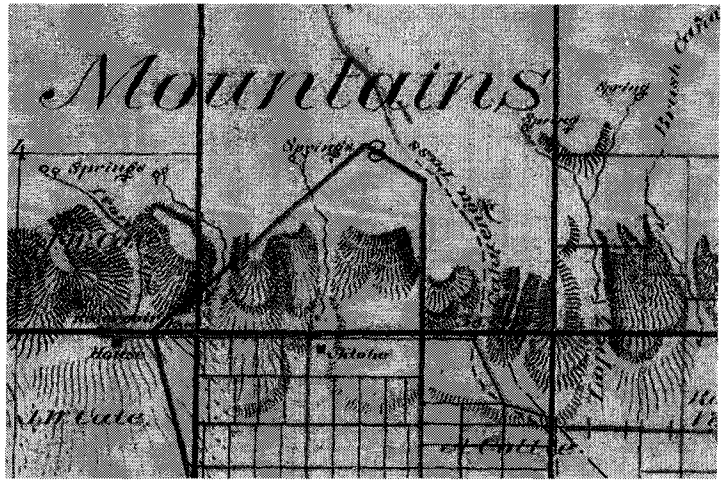

FIGURE 4: *Detail of Hall (1888) irrigation map demonstrating the location of springs in the Santa Monica Mountains.*

FIGURE 5: *Detail of Hall (1888) irrigation map demonstrating the level of detail in describing habitat types in the La Cienega area at the base of present day Baldwin Hills.*

this map provided a level of detail not available on other data sets. It was useful for mapping fine scale features within the estuary, especially when used in conjunction with other data sources (FIGURE 6).

We also obtained detailed ecological information from the General Land Office (GLO) Public Land Survey (PLS) survey notes. Initiated in 1785, the GLO Public Land Survey was carried out by dividing the land into a grid system. Land was divided into 36 mi2 townships and further divided into square mile sections. In California, Mexican land grant boundaries were not modified, though surrounding lands were assimilated into the township-range system. Surveyors ran the boundaries of these land divisions, including those of the Mexican land grants, taking note of distances and notes on the landscape including any significant human made and natural features to establish these boundaries. The GLO survey notes provide an array of detailed historical ecological descriptions that could be spatially referenced. Notes often included information about hydrology, soil types, and vegetation. At times, survey notes were extremely detailed, providing channel morphology descriptions, physical characteristics of trees, including species, height, and diameter, and wetland descriptions (Manies 1997). In the Ballona watershed, GLO surveys were conducted from 1850 to 1895, with the most frequent survey period being around 1870.

Metadata Catalog

Once collected, photographs, maps, and textual data were uploaded into an online metadata catalog. Given the collaborative nature of this project, being able to share data dynamically was important to reduce repetition of effort, to allow for collaborative viewing of data, and to

facilitate regional synthesis and ongoing investigations. The catalog provided the means to organize and query historical documentation by spatial location, wetland descriptions, time period, and source (FIGURE 7). Upon review and entry to the catalog, each source was assigned metadata such as year, author, and keywords pertaining to the item's ecological content. The assigning of metadata within the online catalog system allowed us to query our data sources by using simple to complex parameters in an efficient manner with relative ease. For example, we were able search citations by year or by year, location, author, and citation type (i.e., map, text, or photograph). The metadata catalog also allowed for data to be uploaded to a centralized location via ftp so that team members were able to download and access the data dynamically. Bibliographic tables

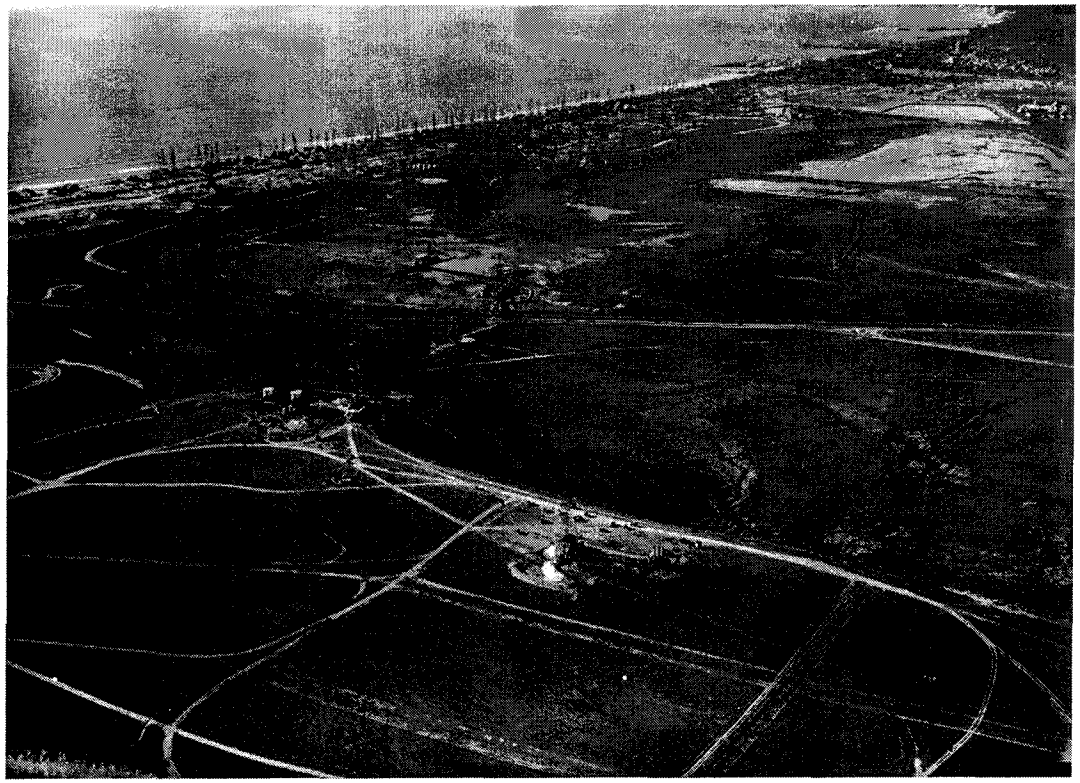
and information about source institutions may also be downloaded from this online database creating a secondary product for stakeholder use. These data products are available at **www.ballonahe.org**. This type of metadata catalog creates a living tool for the discovery of new information and allows for the creation of different questions that can be explored by future researchers.

Data Processing

Certain sources required further processing in the form of spatial reference assignments. Maps were georeferenced, GLO data was transferred to a point layer via linear referencing, and aerial photographs were orthorectified and mosaiced into a single data layer. This allowed us to assimilate a significant portion of our data sources into Geographic Information System (GIS) software for electronic mapping. Some data sources were not spatially referenced. These sources, including photographs and most textual documents, were still organized geographically via their metadata, printed, and compiled manually for use during the interpretation process. Over 150 maps were georeferenced. Textual citations with enough spatial detail were also georeferenced into a point layer. For this point layer, the associated textual description and citation were recorded in the features attribute table. Over 50 of these "specific location" points were digitized.



Mapping and Interpretation of Historical Documents

All mapping was completed using a Geographic Information System (GIS). ArcGIS 9.3 (ESRI) software was used to display, manipulate, and compare spatial data sources as well as create our final geospatial dataset. As discussed in the previous sections, data sources that could not be spatially referenced were printed and organized by very general regional spatial locations (as flagged in our metadata catalog). These data sources were reviewed as we mapped each of these regions and often provided valuable nuanced descriptions of wetlands in the study area that maps could not provide, such as details about tree species or plant composition not depicted on a map. Using GIS, data sources were organized and spatially overlayed with each other, which not only allowed us to view features across multiple datasets, but also allowed us to view change over time. Subsequently, this granted us the ability to better establish the shape, location, and identification of persistent wetland features while at the same time considering the variability (or lack thereof) in the physical and relational aspects of those features through different datasets.

The ability to compare the numerous historical data sources allowed us to build a body of evidence and assess the certainty of each persistent landscape feature mapped. Drawing upon methodological approaches used in previous studies in California, we documented each feature using multiple sources from varying years and authors to ensure accurate interpretation (Grossinger 2005, Grossinger et al. 2007). This was possible for many features, although others (notably some ponds and springs) were only documented by one source.

Usually, the most detailed and accurate datasets that fell within our target mapping period were used to map features. These sources included the Hall irrigation maps and historic topographic maps. After initial digitizing, other datasets were reviewed to determine if corroboration between them deemed it necessary to modify a given feature's properties, such as shape, location, attributes, and sometimes, identification.

Datasets that were produced within our target mapping period, 1850 to 1890, were given mapping priority. Datasets that fell outside of this range were used only as interpretation sources for already mapped features. Interpretation sources are those sources that gave us additional evidence in our interpretation but were not used as a mapping source. These datasets were not used as a mapping source because it is likely they depicted the landscape after significant modification by European settlement and could only be used as supporting evidence for persistent features found on earlier maps. Examples of these include the soil survey maps and aerial photographs. Whenever photographs or textual documents supported the interpretation of features their citation was added to the feature's attributes, specifically as an interpretation source. Seldom did photographs provide extreme corroboration, but there were times where photographs were vital. For example, a set of oblique aerial photographs taken over the Ballona Lagoon provided excellent corroborating evidence to the shape of included waterbodies (FIGURE 8).

Another important component of the mapping methodology involved transcribing and spatially referencing the GLO survey notes. A total of 1,913 survey points were produced with just over 900 points solely dedicated to describing natural features mapped by the GLO during their surveys. These data proved invaluable due to both their spatial and descriptive accuracy. GLO points were often used to confirm boundaries of habitat features. In several GLO survey notes surveyors would note when they entered or left an area of a given habitat type. Thus, it was common to find phrases such as "enter swamp" or "leave prairie" within GLO surveys. These points aided in modifing feature boundaries that were initially drawn from primary mapping sources. Ultimately, the GLO data resulted in a more refined physical shape in the wetland areas mapped and supported more detailed intepretation. These surveys were

FIGURE 8:

also aligned with known rain and drought cycles to better inform our interpretations.

Streams were mapped primarily from the historical aerial photographs and historical topographic maps (because of their improved spatial accuracy compared to older mapping sources). When available, other data sources were used to provide additional interpretation validation such as the Hall Irrigation Map (1888). All streams that were consistently present across the historical aerials, topographic maps, and irrigation map (Hall 1888) were digitized. However, we prioritized digitizing from the aerials because the spatial referencing was the most accurate. The topographic maps and irrigation maps were in this order of priority where the feature was no longer present on the aerials. The channel network in the watershed was not analyzed extensively due to two factors. First, preedominantly intermittent streams dominated the Ballona watershed; this likely is the result of porous soils, geology, and climatic conditions (Hall 1888). We were only able to identify two major channels that were perennial: Ballona Creek and Centinela Creek. Second, as would be expected, corroborating evidence for the remainder of the intermittent channel network was sparse.

Estimating Confidence in Mapped Polygons

Measuring and quantifying certainty is critical to the final interpretation and usefulness of historical ecology data. Following Grossinger (2005), feature attributes were developed to capture the estimated certainty of a mapped feature's interpretation, size, and location. Each feature was assigned these attributes to provide a concise assessment of how confident we are in its presence and habitat classification, and in its spatial accuracy (Grossinger and Askevold, 2005). Certainty levels were based primarily on the number, type (i.e. GLO versus historical topo) and quality (i.e. degree of detail and/or spatial accuracy) of the data sources (TABLE 2). For example, a feature such as a wet meadow may be supported by numerous and highly detailed independent data sources would be assigned a "high" value for interpretation certainty. On the other hand, a wet meadow referenced in only 1 or 2 more contemporary historical documents may

CERTAINTY LEVEL	INTERPRETATION	SIZE	LOCATION
HIGH "DEFINITE"	FEATURE DEFINITELY PRESENT BEFORE EURO-AMERICAN MODIFICATION	MAPPED FEATURE EXPECTED TO BE 90%–110% OF ACTUAL FEATURE SIZE	EXPECTED MAXIMUM HORIZONTAL DISPLACEMENT <50 METERS
MEDIUM "PROBABLE"	FEATURE PROBABLY PRESENT BEFORE EURO-AMERICAN MODIFICATION	MAPPED FEATURE EXPECTED TO BE 50%–200% OF ACTUAL FEATURE SIZE	EXPECTED MAXIMUM HORIZONTAL DISPLACEMENT <150 METERS
LOW "POSSIBLE"	FEATURE POSSIBLY PRESENT BEFORE EURO-AMERICAN MODIFICATION	MAPPED FEATURE EXPECTED TO BE 25%–400% OF ACTUAL FEATURE SIZE	EXPECTED MAXIMUM HORIZONTAL DISPLACEMENT <500 METERS

TABLE 2:
Certainty levels assigned to historical features on the Ballona Historical Ecology Project (after Grossinger et al. 2007).

receive a lower value. Confidence values were assigned not just on the number of data sources supporting the presence of a particular feature, but also on the quality and time period of the individual data source. For example, the Hall Irrigation map (1888) provided detailed information about wetlands mapped, as such, wetlands mapped from this source were given a consistently higher confidence value for interpretation than a feature found on a few coarse scale maps (such of topographic maps) that had very little detail. Estimation of certainty is critical to the scientific credibility of any study and reinforces why conclusions about historical conditions must be based on corroboration of multiple lines of independent evidence. Ultimately, land managers and other stakeholders can utilize these objective classifications of certainty to guide the decision making process by helping to determine how extensively results are applied to various land management and restoration activities.

Assessment of Historical Plant and Bird Communities

We also collected about the natural history of the study area, concentrating on plants and birds. For plants, all of the digitized herbarium records available from the state clearinghouse (Jepson Interchange) for Los Angeles County were obtained. Because these records contain many spelling errors and the locations are not reported in a standardized manner, they were sorted through (100,382 records) manually to extract those records from the Ballona watershed and to exclude exotic species, leaving 2,342 records of native species. These were updated with current nomenclature, sorted into families, and coded with the standard U.S. Fish and Wildlife Service codes for wetland indicator status. Each record was then assigned to a region within the watershed to develop species lists for each. For birds, we obtained nest and egg set records from the Western Foundation for Vertebrate Zoology for a suite of riparian indicator species: Black Phoebe, Common Yellowthroat, Black-headed Grosbeak, Least (Bell's) Vireo, Yellow Warbler, House Wren, Long-tailed Chat, Little Flycatcher, Western Wood-Pewee, Song Sparrow, Barn Swallow, and Cliff Swallow. Searches were not made for species associated with coastal wetland features. Region and nest condition notes were consolidated from these records as indicators of riparian vegetation.

RESULTS

A diversity of wetlands were mapped in the Ballona watershed during the target time period with four major types of wetlands dominating the watershed; coastal wetlands, the inland La Cienega complex (consisting of groundwater and surface water associated depressional wetlands), seeps and springs, and creeks (FIGURE 9). Particularly unique to this watershed was the continued legacy of the migration of the Los Angeles River and its effect on the nature and distribution of wetlands. During the target period of analysis, Ballona Lagoon was undergoing a transition from a wetland at the terminus of the large Los Angeles River watershed to a system associated with the smaller Ballona Creek watershed. The shift to a smaller watershed likely resulted in a reduction in the magnitude and frequency of high energy scouring flows experienced by the estuary. Historical analysis of the Ballona watershed is also complicated by the relatively early human impact beginning in the mid-19th century which escalated in pace into the early 1900s along this portion of the southern California coast.

A total of 174 unique wetland polygons were mapped comprising 14,149 acres (5,470 ha; TABLE 3). The dominant wetland types across the entire study area included alkali meadow (35%), valley freshwater marsh (10%), brackish to salt marsh/tidal marsh (9%), and alkali flats (8%). The watershed contained a wide diversity of wetlands ranging from vernal pools and alkali flats to wetland meadows and willow thickets (excluding willow-dominant riparian corridors). It is likely that our habitat map did not capture the total complexity of this landscape, due to a lack of documentation in the historical record, or inability to display using a habitat map. For example, textual citations describing features at a finer scale cannot be incorporated into a two-dimensional map, but lend depth to our understanding of habitat diversity. We hope to provide a cautioned insight into the complexity of this ecological system in the following pages.

TABLE 3:
Summary of wetlands mapped on the Ballona Historical Ecology project.

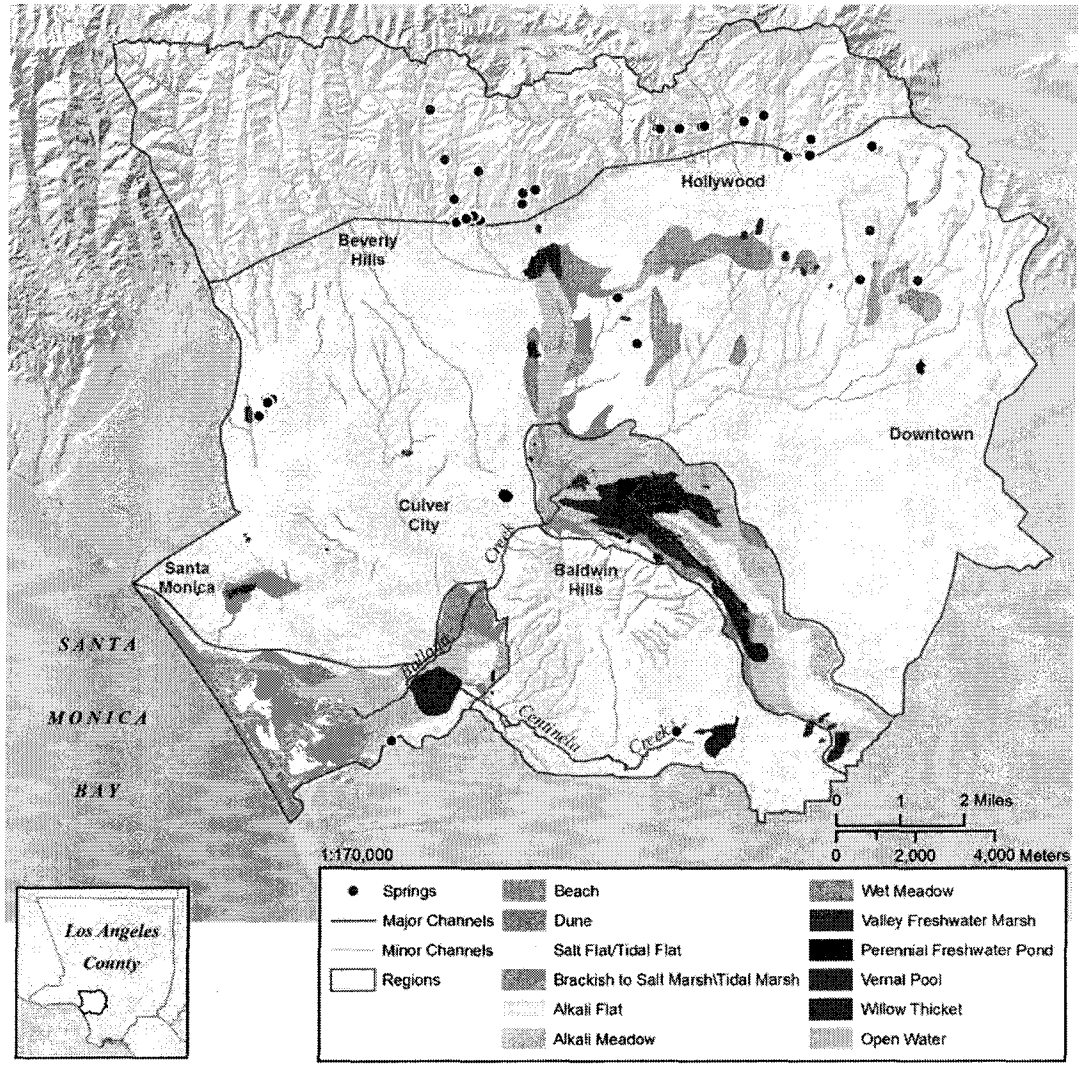

FIGURE 9: *Wetlands mapped for the Ballona Historical Ecology project.*

The historical location and extent of wetlands in the Ballona watershed was extensive compared to their contemporary distribution. Although discrete boundaries of historical wetlands can be challenging to identify in many instances, a few substantial wetland complexes were clearly evident, namely the La Cienega wetlands and the Ballona Lagoon complex. These complexes, in addition to other topographic and ecological factors, were used to organize the Ballona watershed into meaningful units of analysis. The four regions are Ballona Valley, Ballona Lagoon, Santa Monica Mountain Foothills (SAMO), and La Cienega. Key hydrologic features, Ballona and Centinela Creeks were discussed separately (FIGURE 10).

Each of these regions demonstrated a unique profile of wetland types (FIGURE 11). Two significant wetland complexes (La Cienega and Ballona Lagoon) supported the largest extent of wetland habitat in the watershed. Freshwater marsh surrounded by numerous other habitat types (primarily alkali meadows and flats) dominated a broad band of habitat making up the La Cienega complex. Brackish to salt/tidal marsh was the principal component making up the Ballona Lagoon complex, although various other habitat types were present as well. Elsewhere across the valley floor wetland habitat existed but was sparse with the exception of intermittent streams, which were in greater abundance. Various freshwater ponds, vernal pools, wet meadows, and freshwater marshes and numerous springs were found throughout the watershed.

We mapped 232 miles (373 km) of historical stream channels in the study area (FIGURE 10). One characteristic of the channels is their lack of continuity across the watershed, especially in the Ballona Valley region. With the exception of Ballona Creek, virtually every

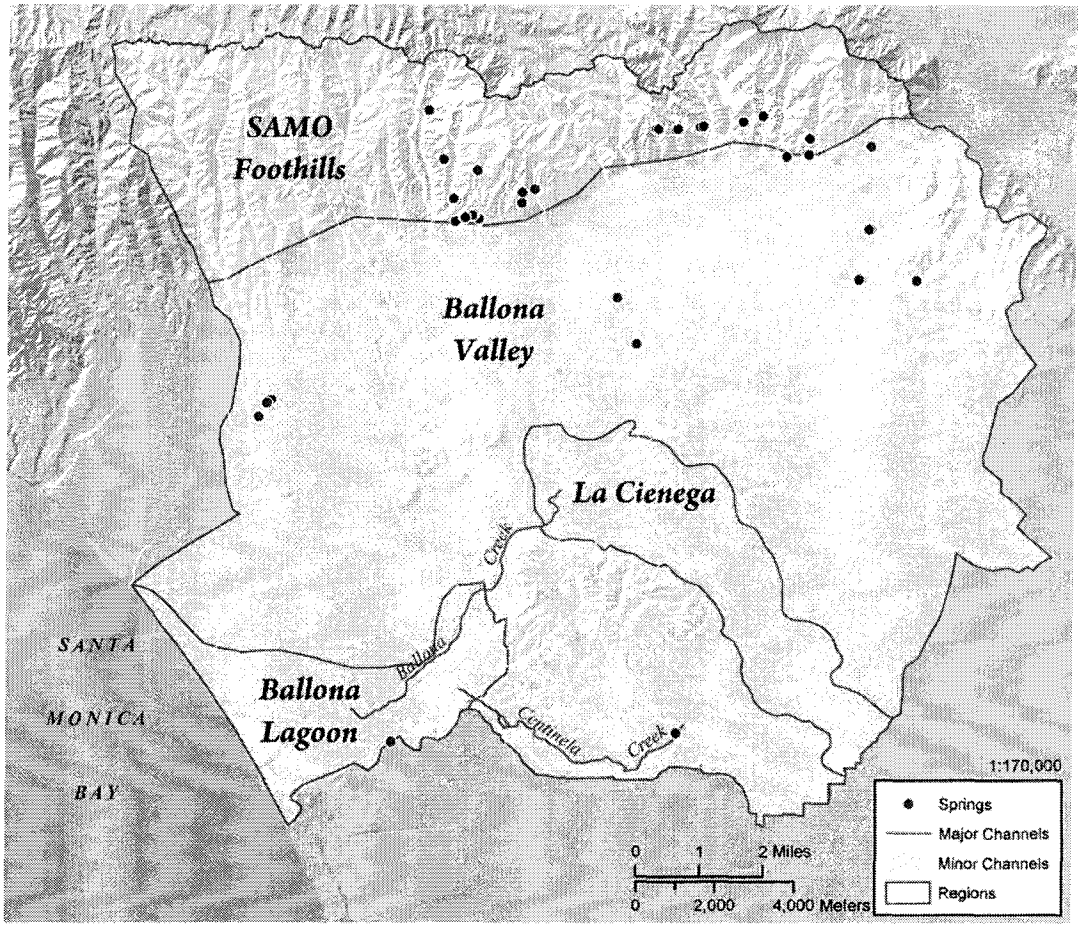

FIGURE 10: *Regions and distribution of springs mapped within the Ballona watershed.*

other channel either sank into porous soils or spread into the major wetland complexes of La Cienega and the Ballona Lagoon. While this characteristic may have contributed to a significant amount of subsurface water flow and consequently to the vast wetland complex at La Cienega, we were unable to discern if this pattern was naturally occurring or the result of land use changes (that may have lowered the water table) during our target time period.

Although springs were present at a few locations throughout the Ballona Valley, 70% of the springs in the Ballona Watershed were found in the Santa Monica Mountain foothills (primarily from Hall 1888; see FIGURE 10). These springs were clustered in the foothills and stopped abruptly at Franklin Canyon. This distribution could be the result of fault displacement or geologic composition.

In the following sections, a landscape profile of wetlands found within each of the regions identified in the study area. The landscape profile includes a review of wetland types, extent, and spatial distribution. In addition, we have included a discussion of stream characteristics within each region.

BALLONA VALLEY

Ballona Valley was the largest region in the study area, comprising the entire valley floor (FIGURE 12). Streams from the surrounding foothill regions drained into the valley floor and in many places disappeared as they flowed across alluvial fans with porous soils. However, in some places spring fed wetlands gave way to wetland and alkali meadows, the dominant wetland types within this region.

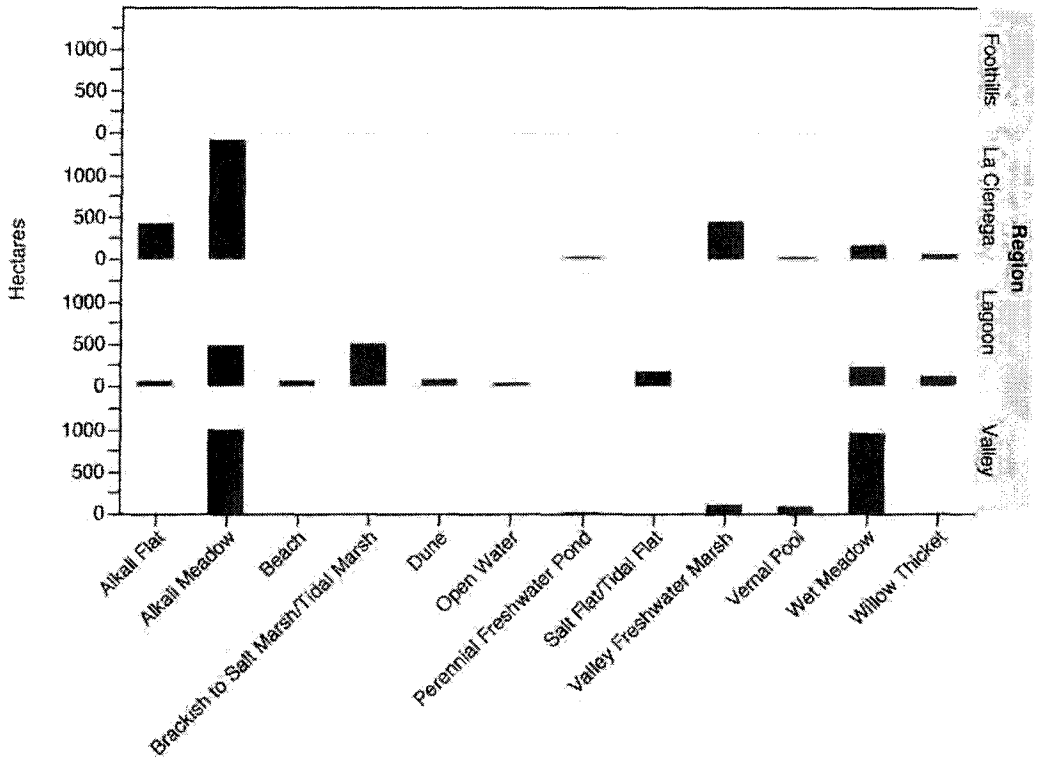

FIGURE 11: *Landscape profile for each region in the Ballona watershed.*

Wetlands

Wetland habitat, excluding streams and associated riparian areas, covered five percent (5,327 acres) of the Ballona Valley region. We mapped five different types of habitat on the valley floor: valley freshwater marsh (242 acres), wet meadow (2,370 acres), alkali meadow (2,479 acres), freshwater ponds (37 acres) and vernal pools (197 acres) (TABLE 4). With just two freshwater ponds and only one lake documented in the historical record, perennial water bodies were scarce throughout the region.

On the other hand, 12 vernal pools, and a significant vernal pool complex were present, probably comparable in flora to vernal pools described for the Los Angeles Coastal Prairie immediately to the south (Mattoni and Longcore 1997). Concentrations existed in both in the southwestern and southeastern portions of the region. One vernal pool located in the southwest portion of the Valley is noteworthy due to its size (16 acres) and an abundance of supporting historical documentation both in narrative and map form (Carson 1883, Solano 1893) (FIGURE 13). This wetland feature is also shown on a Solano Reeves (1893) map which indicates a channel connecting the depression to the Ballona Lagoon.

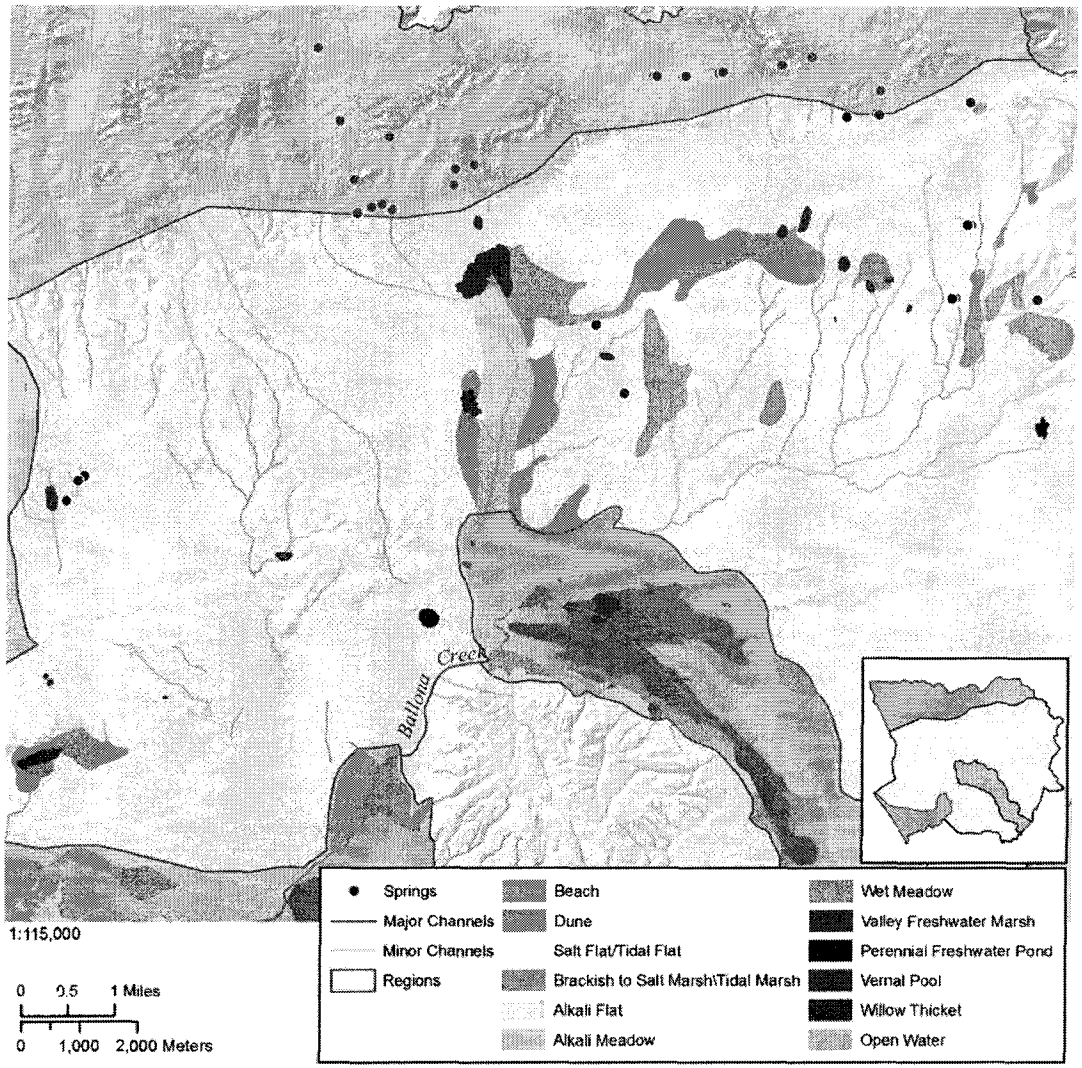

FIGURE 12: *Wetlands of the Ballona Valley region.*

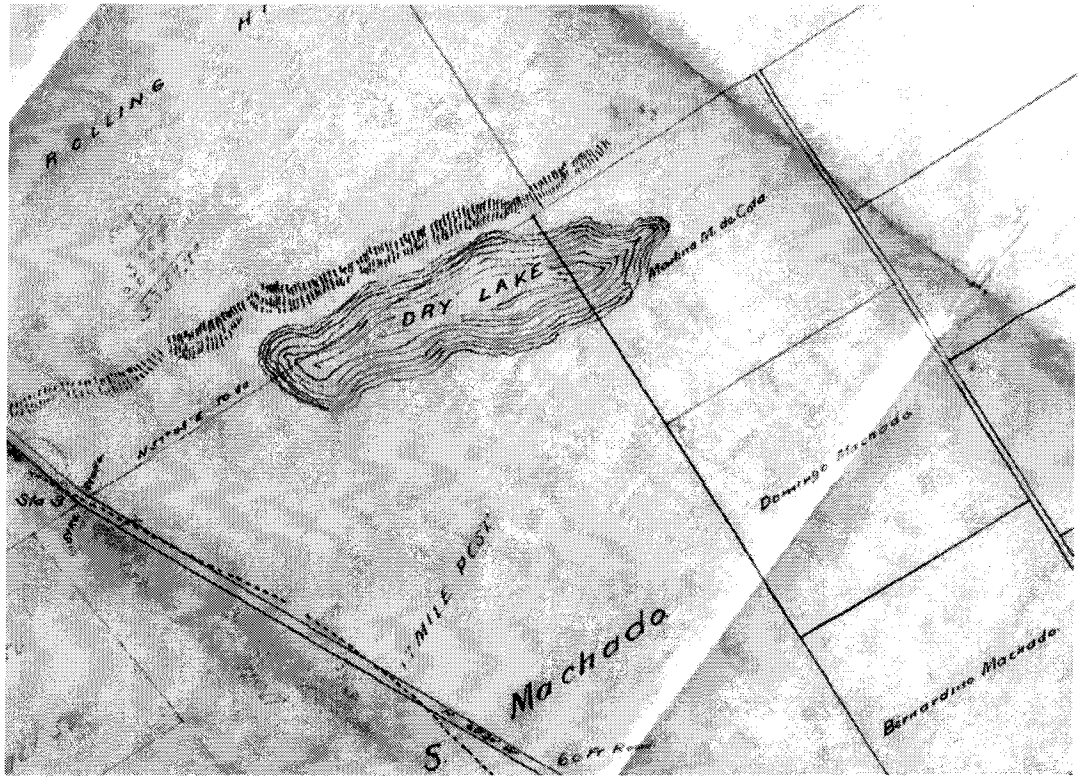

FIGURE 13:
Map (Solano 1893) showing the location of a large vernal pool adjacent to the Ballona Lagoon (Map courtesy of Huntington Library).

The central northern section of the Ballona Valley is also of special interest due to the area referred to as the "Rodeo de Las Aguas" or the "Round-up of the Waters" (Hancock 1949). In this area, streams ran down from the Santa Monica foothills and converged "each rainy season in a broad swamp or cienega" (Benedict 1934, Wilson 1959). This locale marks the northernmost extent of a band of wetland habitat that transitions into the La Cienega system to the south. Valley freshwater

FIGURE 14:
Early diseño map showing the location of a spring and fresh water marsh on Rancho de las Aguas. (Map courtesy of the Bancroft Library).

marsh transitions into wet meadow, which in turn becomes a huge swath of alkali meadow. This area is depicted in detail on historical topographic maps, the Hall irrigation maps, and a diseño of this area (FIGURE 14).

The remaining wetland habitat covering the northeastern sections of the Ballona Valley contained a few pockets of valley freshwater marsh, which, in most cases, were surrounded by wet meadow, the most prevalent habitat type in the area. As Ballona Valley's wet meadows were not clearly and frequently depicted on multiple data sources, polygons were primarily derived from the 1916 soil map offering lower levels of certainty across all categories.

Eleven springs were mapped within the Ballona Valley region. Although most of the springs were not coincident with other wetland features, they were often in close proximity. The absence of a direct physical connection between the springs and other wetlands features

may have been due to the limitations in spatial accuracy of historical data sources, rather than the true locations of the feature themselves. These springs likely played an important role in the early settlement patterns and ranching practices of this region as most settlements were typically located near reliable water sources. FIGURE 15 shows the use of one of these springs for aquaculture (notice a man standing in the background tending to the plants).

Streams

There were approximately 120 miles (193 km) of channels in the Ballona Valley region. Ballona and Centinela creeks are the only two streams consistently identified as perennial in the Ballona Watershed (Hansen 1866, CIU 1874, Hall 1888, Lee 1912, LAT 1914, Mathew 1917). These channels would have been associated with a range of facultative to obligate wetland plant species (as documented in herbaria specimens) but only our channel lines (not polygons) represent the extent of this vegetation. So although riparian and associated stream channel vegetation area is not reported separately, it would have been associated with these linear features, depending on the hydroperiod of the stream. The 1902 topographic map indicates that a few other creeks in the northeast section of Ballona Valley may be perennial, but lack of corroborating evidence limited the interpretation of these creeks' hydrology.

The only intermittent channels that continued out of the SAMO Foothills and down across the valley floor were Brown Canyon and the junction of Franklin and Coldwater Canyons (Giffin 1902, Lee 1912). The northeast section of the region also hosts a fairly continuous network of

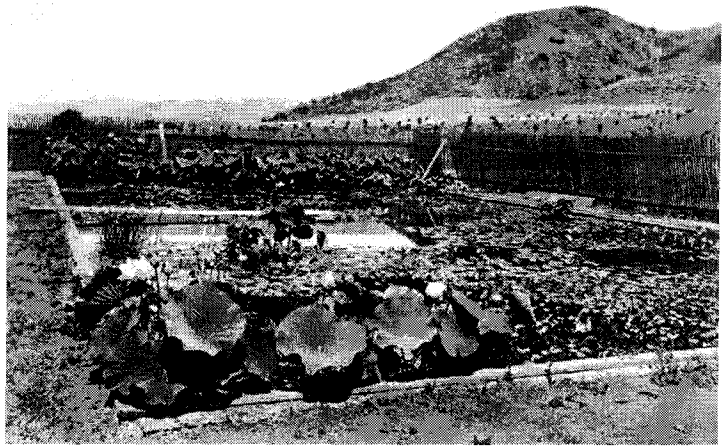

FIGURE 15:

streams that are likely dependent on groundwater presence, as are the springs, valley freshwater marsh, and wet meadow habitat present in that area (FIGURE 16).

Flora and Fauna

The plant species from the Ballona Valley supported the presence of freshwater wetlands, riparian elements, and some scrub (Appendix 1). The bird species confirmed this, but with some difficulty distinguishing between the foothills and the valley from the location data provided in the historical data sets. Obligate wetland plant species included whorled

marsh pennywort (*Hydrocotyle verticillata*), water parsely (*Oenanthe samentosa*), seaside heliotrope (*Heliotropium curassavicum*), chairmaker's bulrush (*Schoenoplectus americanus*), prairie bulrush (*Scirpus maritimus*), marsh milk-vetch (*Astragalus pycnostachyus*), swollen duckweed (*Lemna gibba*), common duckweed (*Lemna minor*), floating primrose willow (*Ludwigia peploides*), curlytop knotweed (*Polygonum lapathifolium*), silver weed cinquefoil (*Potentilla anserine*), yerba mansa (*Anemopsis californica*), and seep monkeyflower (*Mimulus guttatus*) (Appendix 1).

La Cienega

Located at the base of Baldwin Hills, the La Cienega region encompassed approximately 7,012 acres and the complexity of this region was one of the most intriguing aspects of the historical landscape given the contemporary lack of wetlands in this area (FIGURE 17). The historical extent of La Cienaga was large, stretching from present day Hollywood in the north to present day Inglewood in the south; roughly 10 miles in length and up to 3 miles wide in places (Denker 1881). Of the wetlands mapped in this complex, we were highly confident in both interpretation and location certainty. We had less confidence with shape certainty, which reflects the dynamic quality of this complex. In years with high rainfall, this complex was likely large and comprised different types of wetlands (more freshwater ponds and marshes) compared to dry years which probably supported more alkali flats and meadows.

Wetlands

This wetland complex was dominated by alkali meadow (58%), alkali flat (16%), and valley freshwater marsh (16%; TABLE 5). The internal

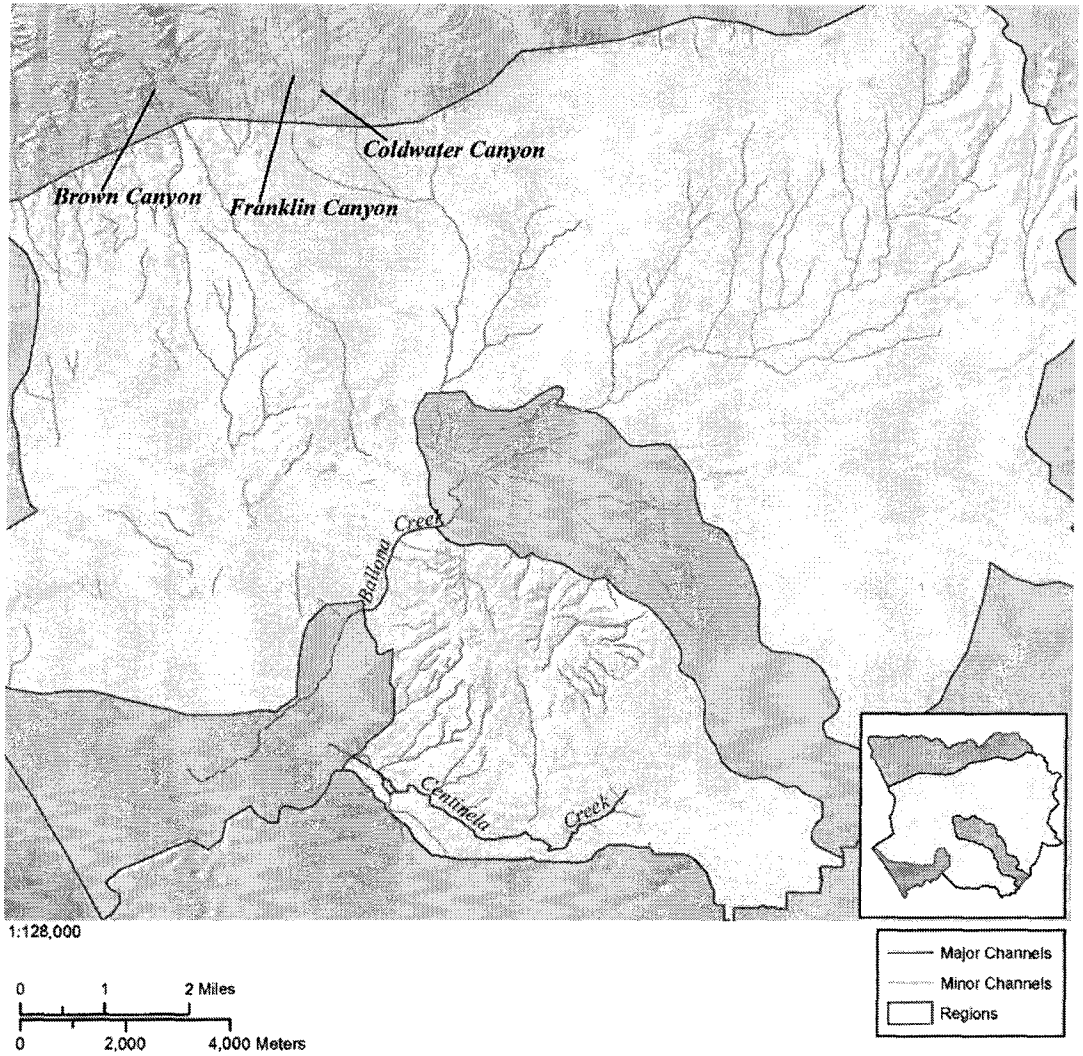

FIGURE 16: *Distribution of creeks and streams in the Ballona Valley region.*

habitat was dominated by valley freshwater marsh and alkali flat, and was surrounded by vast expanses of alkali meadow with wet meadow habitat dotting the periphery of the complex (FIGURE 18, FIGURE 19). The habitat composition also included numerous willow thickets and perennial freshwater ponds (as supported by the Solano Reeves maps). The southwest region of the system is host to a vernal pool complex as indicated by Hansen court dockets (Abila 1859) and consistent with those documented immediately to the south by Mattoni and Longcore (1997).

Streams

Approximately 18 miles (29 km) of streams and sloughs traversed the La Cienega region. We did not designate many permanent channels in this complex because data indicated that it was extremely dynamic; channels appeared to be continually changing location and even disappearing, as the greater wetland complex engulfed them during very wet seasons (Reagan 1915). An absence of any references to channel names in historical sources appears to support this theory.

TABLE 5:
Habitat types mapped in the La Cienega region of the Ballona Watershed.

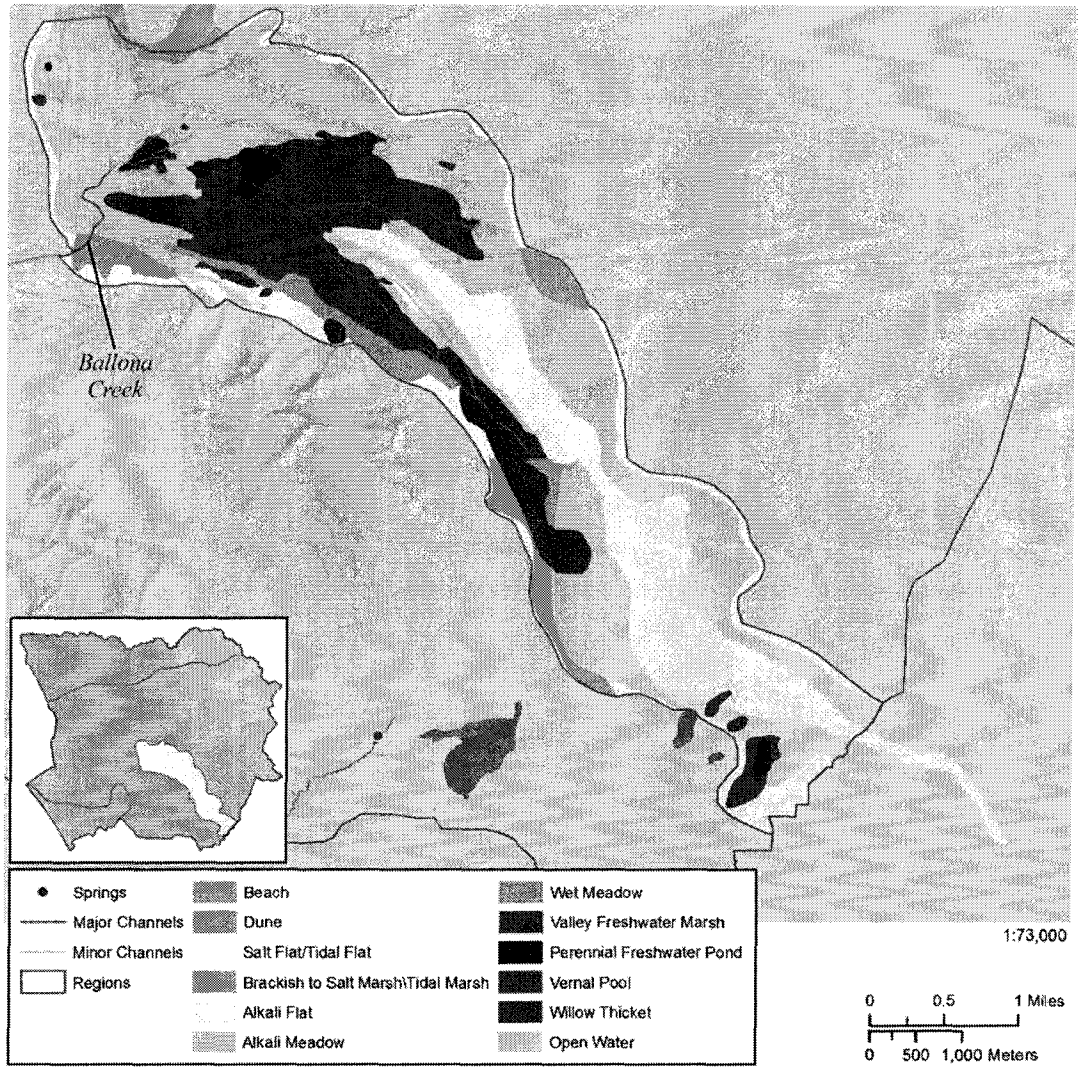

FIGURE 17: *Wetlands mapped within the La Cienega region. This complex extended beyond the watershed boundary.*

Flora and Fauna

Botanical records from La Cienega conclusively document the presence of extensive perennial and ephemeral freshwater wetlands and alkali meadows in this region (Appendix 2). Records indicated that La Cienega supported many types of sedge and rushes, and even rare species like marsh milk-vetch (Astragalus pycnostachyus var. lanosissimus; once thought extinct) and interestingly also Braunton's milk-vetch (Astragalus brauntonii). The language on the herbarium records describes the region mostly as "Cienega," but sometimes also "Cienega swamp," "Culver City marshland," and "marsh at Cienega." Bird nest records from our target species included Black Phoebe ("Under bridge across from Baldwin's sloughs") and Common Yellowthroat ("Tules, in swamp").

Ballona Lagoon

The Ballona Lagoon was a large (4,288 acres) and diverse system. The historical lagoon extended from the base of the bluffs to the south all the way to the intersection of Main St and Abbot Kinney to the north, and as far east as Overland Blvd. Historical narratives, such as Reagan (1917), provide strong support to suggest that the size of the greater wetland system was dynamic and heavily influenced by winter rains: "This area was called Ballona Swamp. In rainy winters Ballona Swamp extended over nearly all the low ground as far back as the present site of Culver City, then called "The Palms," and running over to the Inglewood Mesa, an area about ten miles square." (Chambers 1936).

This area encompassed a tremendous diversity of wetland habitat types, more so than any region within the study area (TABLE 6). This is likely due to the juxtaposition of freshwater and brackish environments

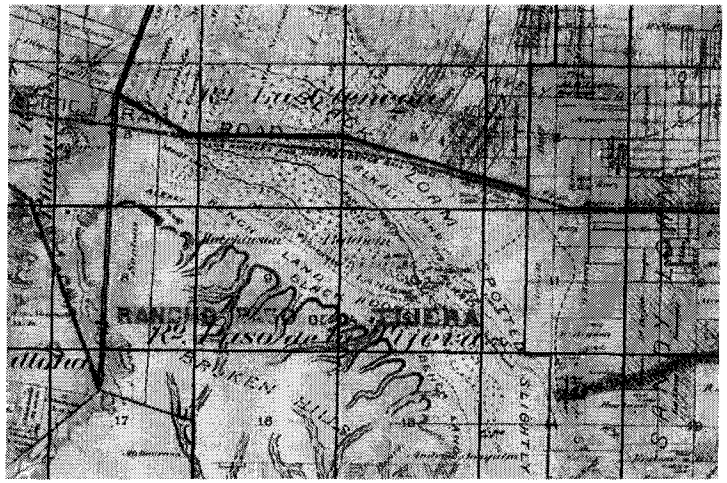

FIGURE 18: *Hall irrigation map (1888), notice the reference to alkali land. [courtesy of California State Archives].*

FIGURE 19: *Alkali lands in the La Cienega wetland complex at the base of Baldwin Hills (photo courtesy of Los Angeles Public Library, date unknown).*

and the complexity of the hydrodynamics of the system. This complexity was likely enhanced by the change in the volume of freshwater input and the assumed frequency of mouth opening associated with the re-alignment of the Los Angeles River. T-sheet analysis by Grossinger et al. (2011) focused specifically on mapping habitats as depicted by the T-sheet and did not include additional sources. As with other historical ecology studies (e.g., Beller et al. 2011), the use of additional historical data sources revealed additional information. For example, our research determined that the use of the term tidal in reference to habitat associated with the lagoon was too limiting. Our data suggests that at most times, this low energy system had only moderate or no tidal influence and was dominated by freshwater inputs from the watershed (see Jacobs et al. 2011). The textual sources indicate complete closure of the system from the ocean through substantial portions of the year, opening only during periods of significant rainfall (LAT 1887; see discussion in Jacobs et al. 2011). Consequently, we broadened our classification from tidal flat to salt flat/tidal flat and from tidal marsh to brackish to salt marsh/tidal marsh. In addition, we were able to map transitional estuarine–upland habitats not mapped on the T-sheet project such as the presence of willow groves and akali flats located at the confluence Centinela Creek and the inland extent of the estuary.

TABLE 6:
Distribution of habitats associated with the Ballona Lagoon.

Wetlands

The historical mouths of both Ballona and Centinela Creeks emptied into the lagoon complex at different locations (Lee 1912); the Centinela tributary further inland into a large willow thicket, and the Ballona tributary closer to the coast into the brackish to salt/tidal marsh habitat (FIGURE 20). The 1825 migration of the Los Angeles River dramatically reduced flow into the lagoon area and the wetland distribution that developed since that time likely reflected a process of equilibration to this new flow regime. As a consequence, efforts to obtain consistent corroborating evidence for the system were difficult. The documentation that exists, aside from the USCS T-sheet (Chase 1876), often provided conflicting and broad descriptions as to the historical habitat and ecological communities in the complex. Apparent inconsistencies in the historical record may have also resulted from the dynamism inherent in coastal lagoons leading to different physical and biological conditions at different points in time. What is clear is that the system was an expansive marshy area that supported both abundant wildlife, and later on, extensive human activity such as fishing, hunting and boating (Ingersoll 1908, Adler 1969, Wittenberg 1973).

Approximately half of the aggregate Ballona Lagoon area consisted of a freshwater and tidally affected saltmarsh and brackish habitats that transitioned into a more alkaline/freshwater system about 1.5 miles (2.4 km) inland. Historical habitat of the Ballona Lagoon coastal complex consisted of substantial amounts of brackish to salt marsh/tidal marsh habitat (29%), followed by salt flat/tidal flat (10%). Open water made up less than 3 percent of the lagoon and one of the more salient features of the complex was a long but narrow strip of open water referred to by some as a "lake" at what we call today Del Rey/Ballona Lagoon (Sheridan 1887). This strip of open water periodically emptied into the ocean at the documented location of seasonal tidal access (FIGURE 22). We found no evidence that the lagoon remained perennially open, but rather the textual sources indicate that access to the ocean depended on hydraulic forces during any given year (LAT 1887, Sheridan 1887, Hansen and Jackson 1889, Solano 1893). The migration of the Los Angeles River away from the lagoon transitioned the system into a lower energy system where only on rare occasions was there enough freshwater flow from Ballona Creek to break through the buildup of sediment along the coast. As a result, gradual build up of sediment around the terminus of the previous estuary formed dunes and created this "trapped" lake-like feature. The coastal dunes, which occupied four percent of the Ballona Lagoon coastal complex, played a significant role in the formation of the lake and the limited tidal access (see Jacobs et al. 2011).

Inland areas of the Ballona Lagoon were dominated by alkali meadow, with less wet meadow. Water from Centinela Creek also flooded into this area contributing to the formation of an extensive willow thicket which covered approximately 280 acres. Diseno maps

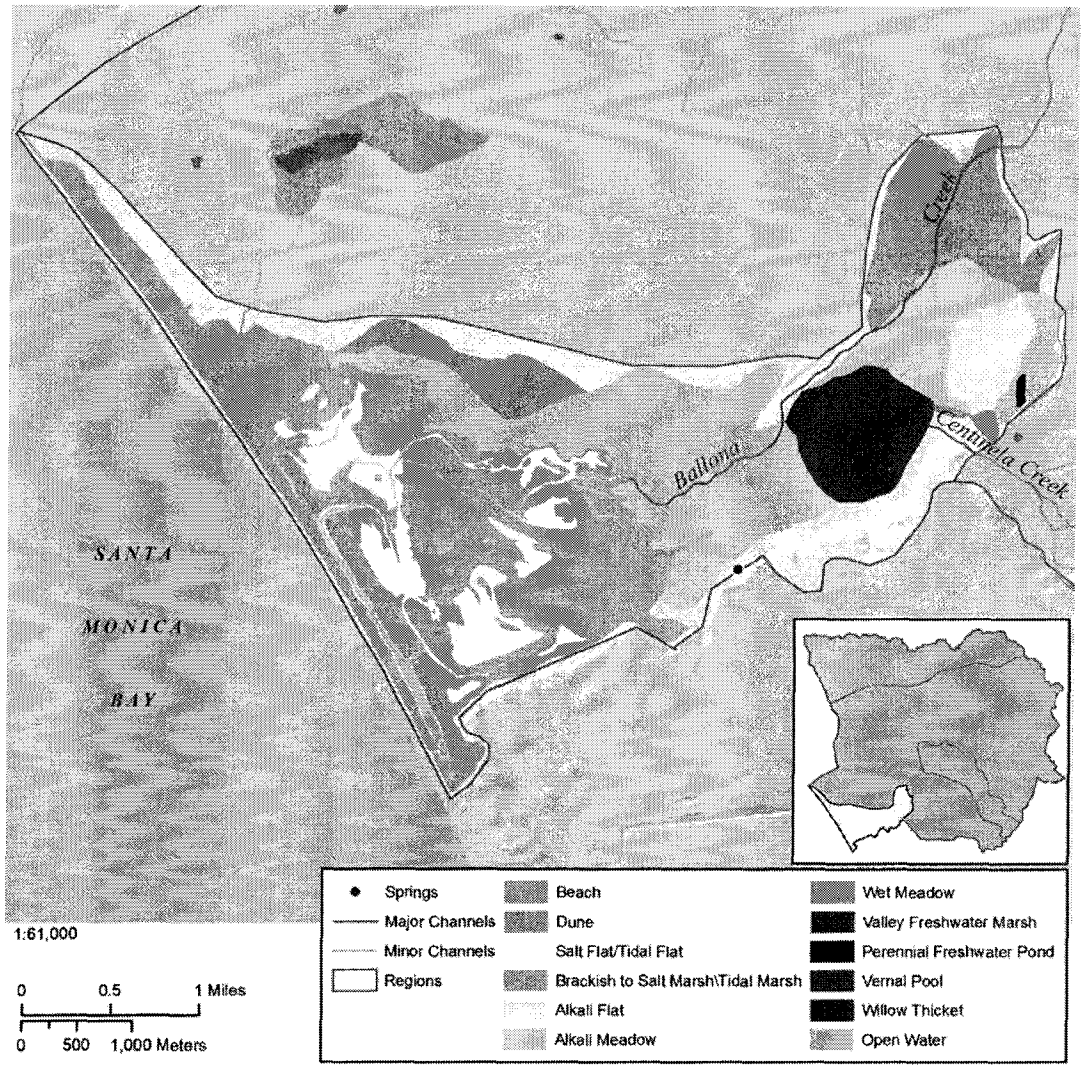

FIGURE 20: *Wetlands mapped in the Ballona Lagoon region of the Ballona Watershed.*

FIGURE 21:
Man boating on Ballona Lake (photo courtesy of Los Angeles Public Library, date unknown). Notice the dunes surrounding the lake.

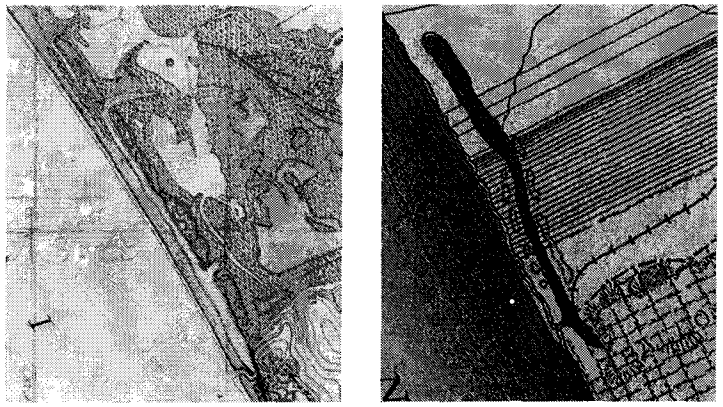

FIGURE 22:
Maps demonstrating the location of Ballona Lagoon (a) Chase T-sheet (1876) and b) Hall irrigation map (1887).

(FIGURE 23) clearly depict a large willow grove or thicket, and ancillary data sources such as the 1894 topographic map and alkali soils map support the delineation and classification of this wetland habitat. Alkali flat comprises 147 acres of the inland lagoon, and a single five-acre freshwater pond sits in a small depression on the southeastern edge of the system.

Streams and Tidal Channels

The coastal region of the Ballona Lagoon contained extensive drainage channel networks as illustrated in the USCS T-sheet (Chase 1876). These channel networks served in part to connect salt flat/tidal flat habitat, and ultimately drain into the long "lake" described previously. Ballona and Centinela creeks were the only substantial freshwater channels to enter the upper lagoon system. Ballona Creek terminated at the head of the tidal portion of the complex. Centinela Creek entered the upper lagoon region just south of Ballona Creek.

Flora

Herbarium records provide a picture of freshwater to brackish and some saltwater wetlands in this region (Appendix 3). Species of perennially open tidal wetlands (e.g., cordgrass) are not found in the older records. Rather, brackish, freshwater, and salt marsh species are represented in the records. All of the dune species are also recorded in this region as these habitats interweave with the wetlands. Of the riparian bird species we surveyed, Song Sparrows are recorded nesting in the tules at the Lagoon. The brids of the lagoon region and the changes in composition over time have been discussed previously by Cooper (2006).

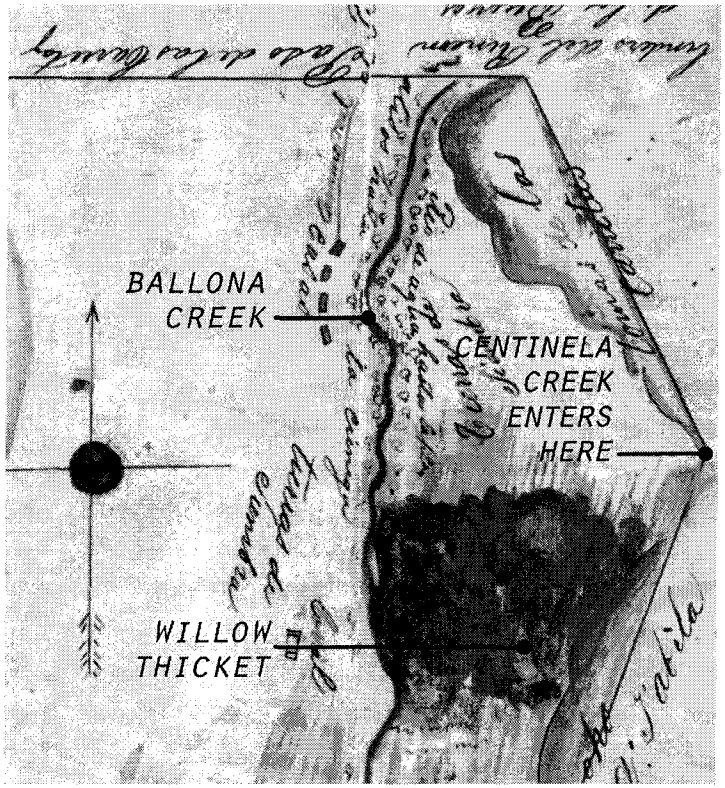

FIGURE 23:
Diseno map (circa 1860) demonstrating the location of a willow thicket at the confluence of Ballona and Centinela Creek (not shown on map). (Map courtesy of the Bancroft Library).

Santa Monica Mountain Foothills

Located in the northern-most section of the Ballona watershed, the Santa Monica Mountain Foothills (SAMO) are composed entirely of steep canyons (FIGURE 24). This region is dominated by approximately 97 miles of intermittent channels and 29 springs. No other wetland habitat type was documented in historical sources. According to one narrative source, "In the winter time, when the rains came the gullies ran full and overflowing from the mountain. That would only last for two or three days and then it would be gone" (Eckhardt, 1966).

One notable geographic trend is the absence of springs along the western section of the foothill region. This could be the result of local trends in geomorphic composition or displacement caused by faulting. These springs played a notable role in downstream hydrology, where in several locations freshwater wetlands formed at their confluence (particularly in Rodeos de las Aguas as discussed in the Ballona Valley regional description above). Many of these springs persist today and are unique remnant features from the historical landscape (FIGURE 25).

Flora and Fauna

The flora of the foothills includes the expected chaparral and coastal sage elements, but also documents the presence and diversity of the riparian habitats associated with perennial and ephemeral streams (Appendix 4). Obligate wetland species included cutlear water-parsnip (*Berula erecta*), saltmarsh baccharis (*Baccharis douglasii*), mosquito fern (*Azolla filiculoides*), California tule (*Scirpus californicus*), basket rush (*Juncus textilis*), rigid hedge nettle (*Stachys ajugoides*), valdiva duckweed (*Lemna valdiviana*), California loosestrife (*Lythrum californicum*), willow dock

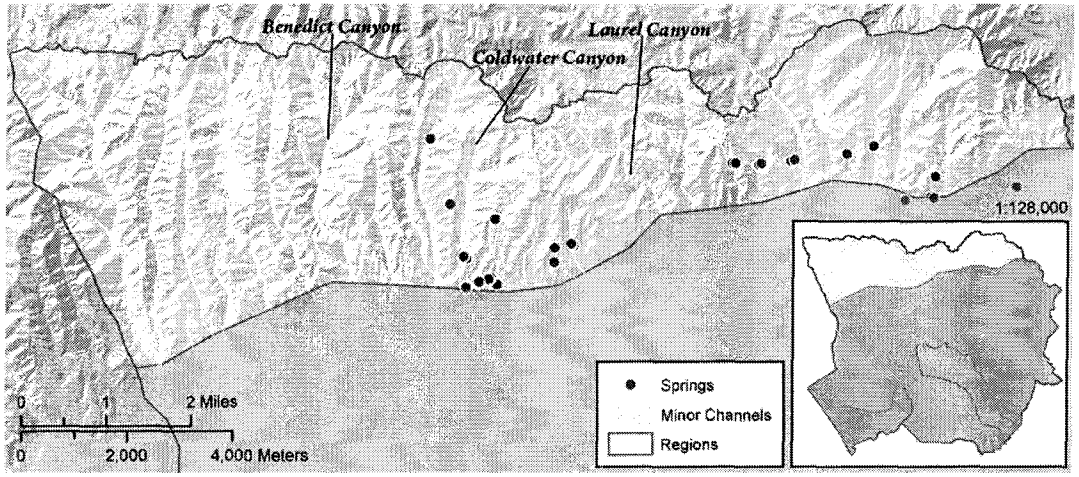

FIGURE 24:

FIGURE 25:
Bridge over Franklin Canyon, 1890 (photo courtesy of the Seaver Collection at the Natural History Museum).

(*Rumex salicifolius*), sago pondweed (*Stuckenia pectinata*), and seep monkey flower (*Mimulus guttatus*). The nest and egg records showed the breeding presence of a range of riparian-associated bird species, including Black-headed Grosbeak (in willows, "grape vine," and sycamores), the now-endangerd Least Bell's Vireo (in sycamores, willows, and "elder"), Yellow Warbler (in willows), House Wren (in willows), Long-tailed Chat ("blackberry vines in willow thicket," "tangle of briars"), Little flycatcher ("thicket, near stream"), and Western Wood-Pewee (in oaks).

Ballona and Centinela Creeks

Ballona and Centinela creeks were the dominant fluvial features in the Ballona watershed. Both channels played major roles in the formation, development and usage of the surrounding landscape. Likewise, both channels were the primary streams supplying water to the Ballona Lagoon.

Ballona Creek

Although we classified Ballona Creek as a perennial channel (Hall 1888, Giffin 1902, Adler 1969), we were surprised at how relatively little other historical information was available for the most significant channel in the watershed. In retrospect, we realized that this lack of information was related to the relatively short length of the fluvial channel. Contemporary channelized Ballona Creek is a fairly long hydrologic feature, but the historical span was only 5.7 miles (9.2 km) long prior to 1900, when expansive wetlands dominated the adjacent areas. The two ends of Ballona Creek were effectively subsumed by the La Cienega and Ballona Lagoon wetland complexes and the creek provide surface hydrologic linkage between these two larger wetland complexes (FIGURE 26).

Several smaller drainages flowed into the La Cienega wetlands, but none appeared to be continguous with Ballona Creek; therefore, we interpreted the origin of Ballona Creek proper to be at the outflow of the La Cienega complex.

As indicated by textual descriptions such as the one below and various map sources, the Creek's historical terminus was the Ballona wetland complex (Solano 1868, Carson 1883 Adler 1969). The contemporary location of the channel is remarkably similar but now extends substantially farther upstream and downstream than it did historically.

> *"Out from the central springs of the upper belt - on the ranchos La Brea and Rodeo de las Aguas - Ballona creek gathers its upper perennial waters, leads them south against the base of the Centinela hills. Here, reinforced by a little stream from the east, draining the springs of the ranchos La Cienega and Paso de la Tijera, it turns west and southwest, parallel with the hill's footing, into the Ballona flats and the sea five to six miles away" (Hall 1888).*

Where Ballona Creek flowed independently from the surrounding wetlands, narrative accounts support the description of a clear flowing "stream"lined with sycamores, willows and tules, which, on occasion, inundated the surrounding lands during times of flooding (LAT 1906, Robinson 1942, Wittenberg 1973). Tributaries of Ballona Creek originated far to the north (potentially via the Los Angeles River), and throughout the La Cienega wetland complex (LAT 1906). As described by Hall in 1888.

Centinela Creek

Centinela Creek was largely a spring fed channel just over 4.5 miles (7.2

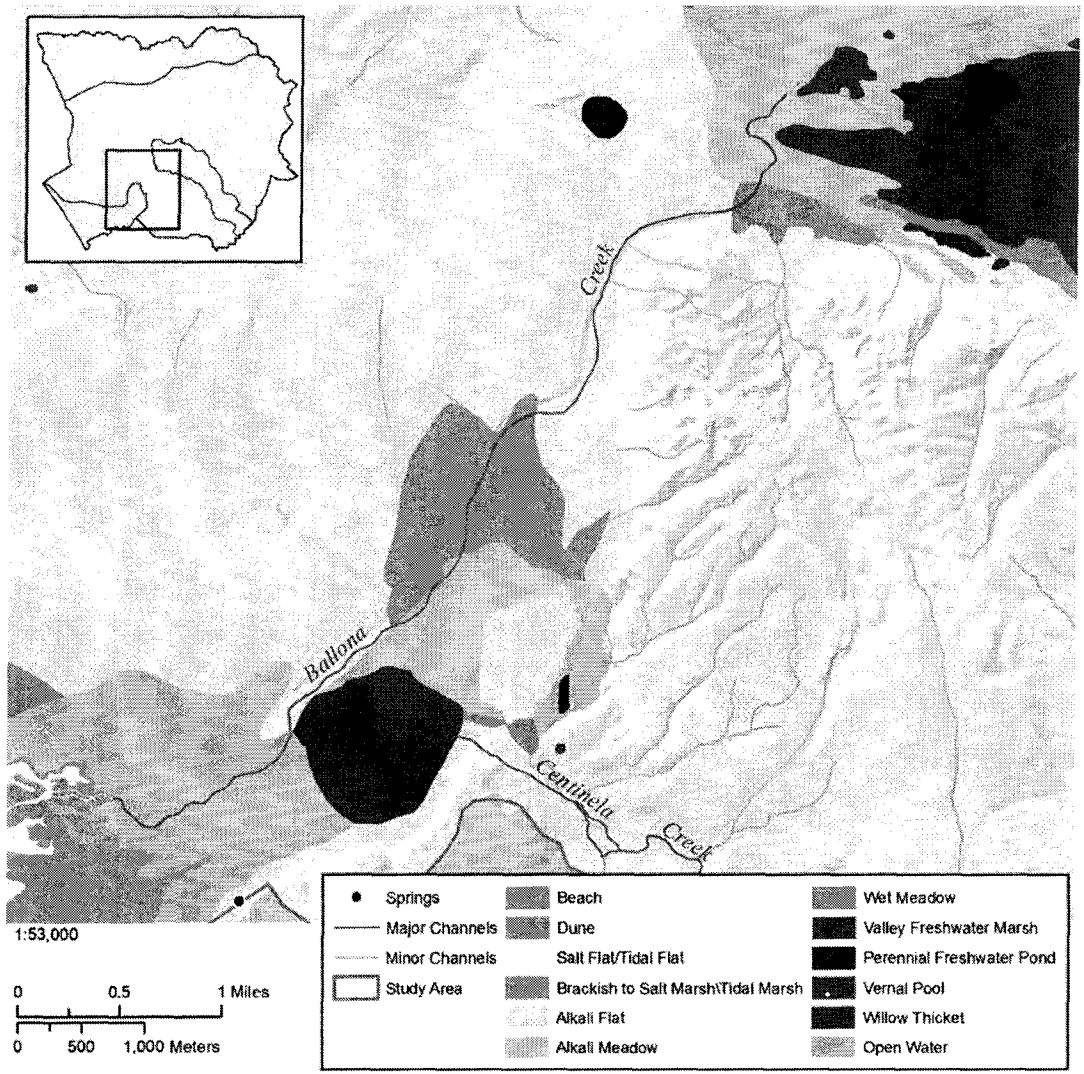

FIGURE 26: *Extent of Ballona Creek.*

km) long, originating at Centinela Springs (FIGURE 27) in the Inglewood area, and draining most of the lands in the surrounding region (Hansen 1867, CIU 1874). As with Ballona Creek, historical documentation was limited, and mainly focuses on the Centinela Springs and surrounding lands of Centinela rather than the Creek itself. Records indicate that the Creek was a perennial stream that provided consistent and ample flow for both domestic and agricultural uses (Hansen 1867, LAT 1873, CIU 1874). The surrounding lands and rich soils of Centinela produced a region ideal for agriculture (LAT 1873, CIU 1874). Several documents described the creek morphology, for example:

> *"The bottom of the Creek from the Spring to St. 16 is from 660 to 1320 feet wide, the banks, from 20 to 30 feet high and steep from station 16 North westerly the bottom widens out and the banks are less abrupt" (Hansen 1867).*

FIGURE 27: *Photograph of Centinela Springs (date unknown, photo courtesy of the Huntington Library).*

Compared to the channelized, short extent of contemporary Centinela Creek, historical Centinela Creek maintained significant sinuosity as it wound its way through the lands of Centinela. Depth and volume of the historical Creek was "over 75 miner's inches of water (3 acre feet/day)" (LAT, 1904). At its terminus, Centinela Creek emptied into the southeastern part of the Ballona Lagoon promoting the formation of a large willow thicket (Lee 1912; FIGURE 28).

Flora and Fuana

The plant records for Ballona Creek are found largely in the Lagoon category for the lower creek, frequently refered to as "Ballona Creek, near Mesmer." Other records are from the relatively short Culver City section between the marshes of the Cienega and the start of the coastal wetland complex. The flora of Centinela Creek was classified with Inglewood because insufficient records speificially identified the creek (Appendix 5). These records also show presence of vernal pools through the presence of spreading navarretia, which is found in vernal pools and alkali grasslands, and is now federally endangered. None of the riparian bird nest records were from this region.

OVERALL CONFIDENCE IN MAPPED POLYGONS

Estimated confidence in the historical analysis was based on three factors; interpretation of data sources, wetland location, and wetland shape. Interpretation of data sources and the shape of wetlands mapped had the highest confidence classifications (FIGURE 29). This is not

CERTAINTY	INTERPRETATION	SHAPE	LOCATION
HIGH	9	3	6
MEDIUM	91	48	75
LOW	0	49	19
TOTALS (%)	100	100	100

FIGURE 29:
Percentage of wetland area mapped in each certainty category.

surprising given the dynamic nature of wetlands in the study area. While a wetland feature may have been persistent on multiple sources it may have been much larger or smaller depending upon the amount of rainfall in any given year.

Certainty estimates based on habitat type were also analyzed. We were the most confident in our interpretation of alkali flats and valley fresh water marsh, both habitat types had certainty classifications of high for 80% of the associated polygons mapped. Salt/tidal flat had the lowest interpretation certainty given the inconsistency of the data sources for the Ballona Lagoon region with regard to tidal influence.

Habitat maps with the greatest confidence in shape and location were; alkali flats, beach, salt/tidal marsh, and salt/tidal flats. Beach, salt/tidal marsh, and salt/tidal flats were all mapped from the detailed USGS T-Sheet (Chase 1876). Given our knowledge of the detail and spatial accuracy of these maps we feel confident in the general location and shape of these features. The location and shape of vernal pools and willow thickets had the lowest confidence classification, with both receiving a classification of low in these categories for about 70% of the polygons mapped. This may reflect the dynamic nature of these habitat types. Vernal pools are heavily influenced by annual precipitation,

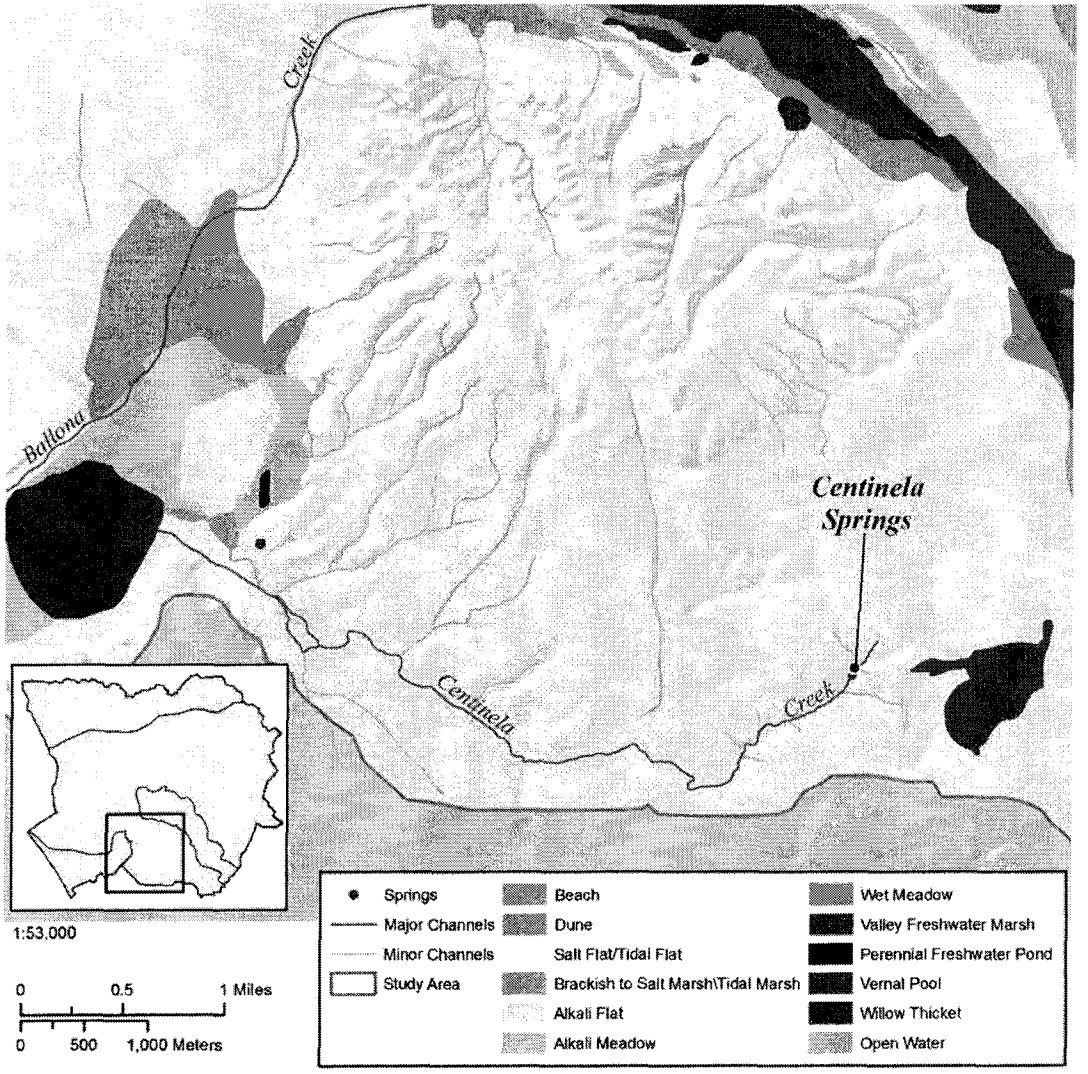

FIGURE 28: *Extent of Centinela Creek.*

therefore during dry years there were likely to be less data sources available documenting their location and shape with consistency. Willow thickets were only found on the early diseno and docket maps, but not present on any other maps from the late 19th century. It may be these thickets were so small they were not identified on more coarse scale maps. Also, it could be they were modified by humans early given their location relative to fresh water and the likely fertile soils they are found on.

SUMMARY

This research outlined above demonstrates the impressive complexity and diversity that was characteristic of southern California's wetland ecosystems. The dynamism of surface waters in combination with broad shallow aquifers supported vast expanses of alkali flats, alkali meadows, wet meadows, and salt/tidal associated wetlands. Vernal pools, freshwater ponds, and willow groves were also evident, contributing to a tremendous diversity of wetland habitats and consequently large amounts of biodiversity that were historically present within the watershed.

The question remains, how do we bridge this knowledge of the historical Ballona watershed to contemporary landscape management plans? The knowledge of reference conditions often creates considerable discussion about what should be restored, how, and where. We consider this discussion to be an extremely valuable process for restoration of wetlands within this watershed. Clearly, it is unrealistic to have the expectation that systems can be restored to their natural hydrodynamics. The vast alkali meadows of the La Cienega region cannot be realistically restored in the contemporary urbanized landscape. Application of the findings of this study is largely dependent on the extent of human modification, the confidence of historical interpretations, and the intended purpose of restoration. We do not believe the results from this study drive toward one specific endpoint, but may support numerous alternatives for a particular project. In fact, the ensuing discussions about restoration and the iterative process by which further understanding is developed are a valuable outcome from this project.

NEXT STEPS

This project provides significant insight into the historical landscape of the Ballona watershed. The development of living tools such as the metadata catalog and Ballona Historical Ecology website will hopefully encourage further historical research of wetland resources in this region. As stated at the beginning of this report, we provide a summary of the historical watershed characteristics. This report has a limited focus on the interpretation of data created. We do not interpret or analyze landscape change or discuss implications for management. Future efforts can build upon the foundation provided by this project through the exploration of key issues such as:

1. An analysis of how the ecosystem functioned over time, including factors that affected local and regional habitats. Broadening the temporal scale to include human impact would create a better understanding of the key drivers influencing changes within this unique landscape.
2. A more detailed analysis of the distribution of specific plant communities.
3. An examination of where the greatest losses occurred, both geographically and in terms of specific habitat types.
4. A linkage between our results and potential restoration options in light of current day landscape constraints.

The datasets and living tools provided on the Ballona Historical Ecology website may serve as valuable resources to initiate research in some of these areas.

A common theme running through some of the unanswered questions in this report is the lack of information about the historical ecology of the Los Angeles River. Attempts to understand the history of the Los Angeles River have been made through a variety of mediums (Gumprecht 1999, Elrick and FOLAR 2007). However, there has been little detailed work focusing on the historical wetland habitats, hydrodynamics and associated impacts of the Los Angeles River on connected systems such as the Ballona Watershed and the San Gabriel River watershed. We believe this report offers an opportunity to understand the value and need of such research, not just within the regional landscape but also to better understand the historical ecology of wetland ecosystems throughout Southern California.

In addition to furthering our understanding of the Los Angeles River, there is also a need to better connect the historical ecological research being performed throughout southern California with contemporary landscapes. For example, creating a cross-walk between contemporary and historical habitat classifications would be immensely helpful for restoration purposes. Likewise, the identification of specific sites that could be restored and the options for restoration given the historical ecology would be immensely helpful.

This project has provided a unique opportunity to collaborate across disciplines and within groups currently involved in historical ecology efforts throughout the state of California. We were able to create living tools such as the metadata catalog and the Ballona Historical Ecology website that allow for a coordinated exchange of information in both data collection efforts and visualization of the study area. These tools set a precedent for future research and lend to further development on future projects.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge the following individuals and organizations whose cooperation and assistance has been instrumental to the success for this project. We thank the California State Library and the Huntington Library for providing access to their data in digital format. Jim Shuttleworth and Steven Lipsahie of the Los Angeles County Department of Public Works provided us with workspaces, map resources, and access to the historical aerial photo collection. Randy Price from the City of Los Angeles Mapping Division also provided us with invaluable historical map resources. We thank Kris Tasick from the CSUN Map Library who helped in the collection and scanning of historical maps and aerial photos; and David Deis from CSUN Department of Geography who provided us with the graphic design of this final report. We thank the Geographical Information Center at CSU Chico, Jason Schwenkler and Darren Inks developed the associated website for this report. This report would not have been possible without the assistance of Jessica Hall. Her hard work, expertise, and scientific input were invaluable to this report. We thank Paula Schiffman and Sean Berquist for providing peer review comments that greatly improved the quality of the document. Funding for this project was provided by the Santa Monica Bay Restoration Commission.

Additional information on historical ecology in southern California, can be obtained from **www.csun.edu/~centergs/**. Digital products associated with this project can be obtained at **www.ballonahe.org**.

APPENDIX 1.
PLANT SPECIES RECORDED IN THE BALLONA VALLEY REGION

FAMILY	SPECIES	COMMON NAME	WETLAND
Apiaceae	*Hydrocotyle verticillata*	whorled marsh pennywort	OBL
Apiaceae	*Oenanthe sarmentosa*	water parsley	OBL
Apiaceae	*Tauschia arguta*	southern umbrellawort	
Asteraceae	*Ambrosia acanthicarpa*	annual bursage	
Asteraceae	*Ambrosia psilostachya*	western ragweed	FAC
Asteraceae	*Ambrosia psilostachya var. californica*	western ragweed	FAC
Asteraceae	*Chrysothamnus nauseosus*		
Asteraceae	*Conyza canadensis*	Canada horseweed	FAC
Asteraceae	*Corethrogyne filaginifolia*	common sandaster	
Asteraceae	*Corethrogyne filaginifolia var. virgata*	common sandaster	
Asteraceae	*Deinandra fasciculata*	common tarweed	
Asteraceae	*Erigeron foliosus*	leafy fleabane	
Asteraceae	*Gnaphalium leucocephalum*	white-headed cudweed	
Asteraceae	*Gnaphalium stramineum*	Small-flowered cudweed	
Asteraceae	*Grindelia camporum*	Great Valley gumweed	
Asteraceae	*Grindelia hirsutula*	hairy gumweed	FACW
Asteraceae	*Helianthus annuus*	common sunflower	FAC
Asteraceae	*Helianthus annuus subsp. lenticularis*	common sunflower	FAC
Asteraceae	*Hemizonia australis*	Asteraceae	
Asteraceae	*Heterotheca grandiflora*	telegraphweed	
Asteraceae	*Isocoma menziesii var. vernonioides*	white-flowered goldenbush	FAC
Asteraceae	*Lasthenia californica*	California goldfields	FACW
Asteraceae	*Lasthenia glabrata subsp. coulteri*	yellowray goldfields	FACW
Asteraceae	*Layia glandulosa*	White tidy-tips	
Asteraceae	*Lepidospartum squamatum*	scalebroom	
Asteraceae	*Malacothrix saxatilis var. tenuifolia*	cliff aster	

Family	Species	Common Name	Wetland
Asteraceae	*Pseudognaphalium leucocephalum*	white headed cudweed	
Asteraceae	*Pseudognaphalium microcephalum*		
Asteraceae	*Senecio californicus*	California Butterweed	
Asteraceae	*Senecio flaccidus var. douglasii*	Douglas' shrubby ragwort	
Asteraceae	*Stephanomeria exigua subsp. coronaria*	milk aster	
Asteraceae	*Uropappus lindleyi*	silver puffs	
Asteraceae	*Xanthium spinosum*	spiny cocklebur	FAC
Boraginaceae	*Amsinckia intermedia*	Eastwood's fiddleneck	
Boraginaceae	*Cryptantha muricata*	prickly cryptantha	
Boraginaceae	*Heliotropium curassavicum var. oculatum*	seaside heliotrope	OBL
Boraginaceae	*Plagiobothrys nothofulvus*	rusty popcornflower	FAC
Brassicaceae	*Erysimum capitatum*	western wallflower	
Brassicaceae	*Lepidium oblongum*	Wayside peppergrass	
Brassicaceae	*Lepidium strictum*	prostrate pepper grass	
Cactaceae	*Opuntia oricola*	chaparral pricklypear	
Caryophyllaceae	*Silene laciniata subsp. major*	Indian pink	
Chenopodiaceae	*Atriplex serenana*	saltscale	FAC
Chenopodiaceae	*Suaeda calceoliformis*	Pursh seepweed	FACW+
Chenopodiaceae	*Suaeda moquinii*	bush seepweed	FAC
Cistaceae	*Helianthemum scoparium var. vulgare*	common sun-rose	
Convolvulaceae	*Calystegia macrostegia subsp. cyclostegia*	south coast morning-glory	
Convolvulaceae	*Cressa truxillensis*	spreading alkaliweed	FACW
Cupressaceae	*Calocedrus decurrens*	incense cedar	
Cuscutaceae	*Cuscuta campestris*	field dodder	
Cyperaceae	*Carex praegracilis*	clustered field sedge	FACW-
Cyperaceae	*Cyperus eragrostis*	tall flatsedge	FACW

Family	Species	Common Name	Wetland
Cyperaceae	*Cyperus esculentus*	Yellow nutgrass	FACW
Cyperaceae	*Schoenoplectus americanus*	chairmaker's bulrush	OBL
Cyperaceae	*Scirpus maritimus*	prairie bulrush	OBL
Euphorbiaceae	*Chamaesyce albomarginata*	rattlesnake weed	
Euphorbiaceae	*Croton californicus*	California croton	
Fabaceae	*Astragalus pycnostachyus var. lanosissimus*	marsh milk-vetch	OBL
Fabaceae	*Astragalus trichopodus var. lonchus*	Santa Barbara milk-vetch	
Fabaceae	*Lathyrus vestitus subsp. laetiflorus*	wild sweetpea	
Fabaceae	*Lotus unifoliolatus*	American bird's foot trefoil	
Fabaceae	*Lupinus excubitus var. hallii*	Hall's bush lupine	
Fabaceae	*Lupinus longifolius*	long leaf bush lupine	
Fabaceae	*Pickeringia montana*	chaparral pea	
Fabaceae	*Trifolium ciliolatum*	foothill clover	
Fabaceae	*Trifolium obtusiflorum*	creek clover	FAC
Grossulariaceae	*Ribes aureum var. gracillimum*	golden currant	FACW
Hydrophyllaceae	*Nemophila menziesii*	baby blue eyes	
Hydrophyllaceae	*Phacelia distans*	common phacelia	
Hydrophyllaceae	*Phacelia minor*	California bluebell	
Iridaceae	*Sisyrinchium bellum*	blue-eyed grass	FAC
Juncaceae	*Juncus ambiguus*	saline toad rush	FACW
Lamiaceae	*Stachys ajugoides var. rigida*	rigid hedge nettle	
Lemnaceae	*Lemna gibba*	swollen duckweed	OBL
Lemnaceae	*Lemna minor*	common duckweed	OBL
Liliaceae	*Bloomeria crocea var. crocea*	common goldenstar	
Loasaceae	*Mentzelia affinis*	yellow blazing star	
Myricaceae	*Morella californica*	Myricaceae	FAC

Family	Species	Common Name	Wetland
Nyctaginaceae	*Abronia umbellata*	purple sand verbena	
Onagraceae	*Camissonia cheiranthifolia subsp. suffruticosa*	beach evening-primrose	
Onagraceae	*Epilobium canum subsp. canum*	California fuchsia	
Onagraceae	*Ludwigia peploides subsp. peploides*	floating primrose willow	OBL
Papaveraceae	*Platystemon californicus*	cream cups	
Papaveraceae	*Romneya coulteri*	Coulter's matilija poppy	RARE
Plantaginaceae	*Plantago erecta*	California plantain	
Platanaceae	*Platanus racemosa*	western sycamore	FACW
Poaceae	*Bromus grandis*	tall brome	
Poaceae	*Elymus condensatus*	giant wild rye	FACU
Poaceae	*Elymus triticoides*	alkali rye	FAC
Poaceae	*Eragrostis pectinacea*	tufted lovegrass	FAC
Poaceae	*Eragrostis pectinacea var. pectinacea*	tufted lovegrass	FAC
Poaceae	*Leptochloa panicea ssp. brachiata*	mucronate sprangeltop	
Poaceae	*Leptochloa uninervia*	Mexican sprangletop	FACW
Poaceae	*Leymus triticoides*	beardless wildrye	FAC
Poaceae	*Nassella cernua*	nodding needlegrass	
Poaceae	*Nassella pulchra*	purple needlegrass	
Poaceae	*Phalaris lemmonii*	Lemmon's canarygrass	FACW-
Poaceae	*Phalaris minor*	littleseed canarygrass	
Polygonaceae	*Polygonum lapathifolium*	curlytop knotweed	OBL
portulacaceae	*Calandrinia ciliata*	red maids	FACU
Primulaceae	*Dodecatheon clevelandii*	padre's shootingstar	
Rosaceae	*Potentilla anserina*	silver weed cinquefoil	OBL
Rosaceae	*Potentilla glandulosa*	Common cinquefoil	FAC
Salicaceae	*Salix lasiolepis*	arroyo willow	FACW

Family	Species	Common Name	Wetland
Saururaceae	*Anemopsis californica*	yerba mansa	OBL
Scrophulariaceae	*Castilleja exserta*	purple owl's clover	
Scrophulariaceae	*Kochia scoparia*	climbing penstemon	
Scrophulariaceae	*Linaria canadensis var. texana*	rough seeded blue toad flax	
Scrophulariaceae	*Mimulus guttatus*	seep monkeyflower	OBL
solanaceae	*Datura wrightii*	Jimson weed	
Ulmaceae	*Celtis laevigata*	western hackberry	
Urticaceae	*Hesperocnide tenella*	western stinging nettle	
Verbenaceae	*Verbena lasiostachys var. lasiostachys*	Common verbena	FAC

APPENDIX 2.
FLORA OF THE LA CIENEGA REGION AS DOCUMENTED IN HERBARIUM SPECIMENS

FAMILY	SPECIES	COMMON NAME	WETLAND
Apiaceae	*Oenanthe sarmentosa*	water parsley	OBL
Asclepiadaceae	*Asclepias fascicularis*	narrow leaf milkweed	FAC
Asteraceae	*Ambrosia acanthicarpa*	annual bursage	
Asteraceae	*Baccharis douglasii*	saltmarsh baccharis	OBL
Asteraceae	*Helianthus nuttallii subsp. parishii*	Los Angeles sunflower	FACW
Asteraceae	*Hemizonia australis*	Asteraceae	
Asteraceae	*Isocoma menziesii var. menziesii*	white-flowered goldenbush	FAC
Asteraceae	*Pluchea odorata*	salt marsh fleabane	
Asteraceae	*Pseudognaphalium stramineum*	Small flowered cudweed	FAC
Asteraceae	*Symphyotrichum defoliatum*	San Bernardino aster	
Asteraceae	*S. lanceolatum var. hesperium [=Aster hesperius]*		
Asteraceae	*Xanthium spinosum*	spiny cocklebur	FAC
Brassicaceae	*Hutchinsia procumbens*	prostrate hutchinsia	FAC
Brassicaceae	*Nasturtium gambelii*	Gambel's yellowcress	OBL
Chenopodiaceae	*Atriplex argentea var. mohavensis*	mohave saltbush	FAC
Chenopodiaceae	*Atriplex serenana var. davidsonii*	saltscale	FAC
Chenopodiaceae	*Atriplex triangularis*	spear leaved saltbrush	
Chenopodiaceae	*Salicornia virginica*	pickleweed	OBL
Chenopodiaceae	*Suaeda moquinii*	bush seepweed	FAC
Cornaceae	*Cornus californica*	Creek Dogwood	FACW
Cornaceae	*Cornus occidentalis*	Creek Dogwood	FACW
Cyperaceae	*Carex barbarae*	Santa Barbara sedge	FACW
Cyperaceae	*Carex praegracilis*	clustered field sedge	FACW
Cyperaceae	*Carex schottii*	Schott's sedge	OBL
Cyperaceae	*Cyperus esculentus*	Yellow nutgrass	FACW
Cyperaceae	*Cyperus niger var. capitatus*	black flatsedge	FACW

Family	Species	Common Name	Wetland
Cyperaceae	*Scirpus californicus*	California tule	OBL
Euphorbiaceae	*Chamaesyce serpens*	creeping spurge	FAC
Euphorbiaceae	*Euphorbia serpens*	creeping spurge	FAC
Fabaceae	*Astragalus brauntonii*	Braunton's milk vetch	
Fabaceae	*Astragalus funereus*	black milk vetch	
Fabaceae	*Astragalus pycnostachyus var. lanosissimus*	marsh milk-vetch	OBL
Fabaceae	*Lotus purshianus var. purshianus*	Spanish clover	
Juncaceae	*Juncus mexicanus*	mexican rush	FACW
Juncaceae	*Juncus phaeocephalus*	brownhead rush	FACW
Lamiaceae	*Stachys albens*	whitestem hedgenettle	OBL
Liliaceae	*Bloomeria crocea var. crocea*	common goldenstar	
Onagraceae	*Epilobium ciliatum*	fringed willowherb	FACW
Onagraceae	*Epilobium ciliatum subsp. ciliatum*	fringed willowherb	FACW
Onagraceae	*Ludwigia peploides subsp. peploides*	floating primrose willow	OBL
Poaceae	*Setaria parviflora*	marsh bristlegrass	
Polygonaceae	*Polygonum punctatum*	Common water smartweed	OBL
Rosaceae	*Potentilla anserina var. grandis*	silver-weed cinquefoil	OBL
Rubiaceae	*Galium trifidum var. pacificum*	Pacific Bedstraw	FACW
Typhaceae	*Sparganium erectum subsp. stoloniferum*	simplestem bur-reed	OBL

APPENDIX 3.
PLANT SPECIES RECORDED AT BALLONA LAGOON FROM HERBARIUM RECORDS

Family	Species	Common Name	Wetland
Aizoaceae	*Sesuvium verrucosum*	western sea-purslane	
Alismataceae	*Sagittaria montevidensis ssp. calycina*	hooded arrowhead	OBL
Amaranthaceae	*Amaranthus blitoides*	mat amaranth	FACW
Anacardiaceae	*Malosma laurina*	laurel sumac	
Anacardiaceae	*Rhus ovata*	sugar bush	
Apiaceae	*Bowlesia incana*	hoary bowlesia	FACW
Apiaceae	*Hydrocotyle verticillata*	whorled marsh pennywort	OBL
Apiaceae	*Oenanthe sarmentosa*	water parsley	OBL
Asclepiadaceae	*Asclepias fascicularis*	narrow leaf milkweed	FAC
Asteraceae	*Amblyopappus pusillus*	dwarf coastweed	FACW
Asteraceae	*Ambrosia acanthicarpa*	annual bursage	
Asteraceae	*Ambrosia chamissonis*	Silver Beachweed	
Asteraceae	*Ambrosia chamissonis var. bipinnatisecta*	Silver Beachweed	
Asteraceae	*Ambrosia psilostachya*	western ragweed	FAC
Asteraceae	*Ambrosia psilostachya var. californica*	western ragweed	FAC
Asteraceae	*Artemisia californica*	California sagebrush	
Asteraceae	*Artemisia douglasiana*	mugwort	FACW
Asteraceae	*Artemisia dracunculus*	herbaceous sagewort	
Asteraceae	*Aster subulatus var. ligulatus*	annual water-aster	
Asteraceae	*Baccharis douglasii*	saltmarsh baccharis	OBL
Asteraceae	*Baccharis pilularis*	coyote brush	
Asteraceae	*Baccharis salicifolia*	mulefat	FACW
Asteraceae	*Bidens laevis*	bur marigold	OBL
Asteraceae	*Centromadia parryi subsp. australis*	Parry's tarweed	FAC
Asteraceae	*Chaenactis glabriuscula*	yellow pincushion	
Asteraceae	*Chaenactis glabriuscula var. glabriuscula*	yellow pincushion	

Family	Species	Common Name	Wetland
Asteraceae	*Chaenactis glabriuscula var. lanosa*	yellow pincushion	
Asteraceae	*Chaenactis glabriuscula var. orcuttiana*	yellow pincushion	
Asteraceae	*Cirsium occidentale var. occidentale*	California thistle	
Asteraceae	*Conyza canadensis*	Canada horseweed	FAC
Asteraceae	*Corethrogyne filaginifolia*	common sandaster	
Asteraceae	*Deinandra fasciculata*	common tarweed	
Asteraceae	*Ericameria ericoides*	California goldenbush	
Asteraceae	*Euthamia occidentalis*	western goldenrod	OBL
Asteraceae	*Filago californica*	California Cottonrose	
Asteraceae	*Gnaphalium bicolor*	bicolored everlasting	
Asteraceae	*Gnaphalium californicum*	California cudweed	
Asteraceae	*Gnaphalium californicum*	California everlasting	
Asteraceae	*Gnaphalium ramosissimum*	pink everlasting	
Asteraceae	*Gnaphalium stramineum*	Everlasting Cudweed	FAC
Asteraceae	*Grindelia camporum*	Great Valley gumweed	
Asteraceae	*Helianthus annuus subsp. lenticularis*	common sunflower	FAC
Asteraceae	*Hemizonia australis*	Asteraceae	
Asteraceae	*Hemizonia fasciculata*	common tarweed	
Asteraceae	*Heterotheca grandiflora*	telegraphweed	
Asteraceae	*Jaumea carnosa*	marsh jaumea	OBL
Asteraceae	*Laennecia coulteri*	Coulter's horseweed	FAC
Asteraceae	*Lasthenia californica*	California goldfields	FACW
Asteraceae	*Lasthenia coronaria*	royal goldfields	
Asteraceae	*Lasthenia glabrata subsp. coulteri*	yellowray goldfields	FACW
Asteraceae	*Lasthenia gracilis*	needle goldfields	
Asteraceae	*Layia platyglossa*	White tidy-tips	

Family	Species	Common Name	Wetland
Asteraceae	*Lessingia filaginifolia*	common sandaster	
Asteraceae	*Logfia filaginoides*	California Cottonrose	
Asteraceae	*Malacothrix saxatilis var. tenuifolia*	cliff aster	
Asteraceae	*Pluchea odorata*	salt marsh fleabane	
Asteraceae	*Pseudognaphalium biolettii*	twocolor cudweed	
Asteraceae	*Pseudognaphalium canescens ssp. beneolens*	Wright's cudweed	
Asteraceae	*Pseudognaphalium microcephalum*		
Asteraceae	*Pseudognaphalium microcephalum*	white headed cudweed	
Asteraceae	*Senecio californicus*	California Butterweed	
Asteraceae	*Stephanomeria diegensis*	San Diego milk aster	
Asteraceae	*Stephanomeria exigua subsp. coronaria*	milk aster	
Asteraceae	*Stephanomeria virgata*	Tall stephanomeria	
Asteraceae	*Symphyotrichum subulatum*	eastern annual saltmarsh aster	FACW
Asteraceae	*Xanthium spinosum*	spiny cocklebur	FAC
Asteraceae	*Xanthium strumarium*	rough cockleburr	FAC
Boraginaceae	*Amsinckia eastwoodiae*	Eastwood's fiddleneck	
Boraginaceae	*Amsinckia intermedia*	Eastwood's fiddleneck	
Boraginaceae	*Amsinckia lycopsoides*	Eastwood's fiddleneck	
Boraginaceae	*Amsinckia spectabilis*	seaside fiddleneck	FACU
Boraginaceae	*Cryptantha clevelandii*	Cleveland's cryptantha	
Boraginaceae	*Cryptantha clevelandii var. florosa*	Cleveland's cryptantha	
Boraginaceae	*Cryptantha intermedia*	Clearwater cryptantha	
Boraginaceae	*Cryptantha leiocarpa*	coast cryptantha	
Boraginaceae	*Cryptantha microstachys*	Tejon cryptantha	
Boraginaceae	*Heliotropium curassavicum*	seaside heliotrope	OBL
Boraginaceae	*Heliotropium curassavicum var. oculatum*	seaside heliotrope	OBL

Family	Species	Common Name	Wetland
Brassicaceae	*Descurainia pinnata subsp. menziesii*	western tansymustard	
Brassicaceae	*Dithyrea californica*	California shieldpod	
Brassicaceae	*Dithyrea maritima*	beach shieldpod	RARE
Brassicaceae	*Erysimum insulare subsp. suffrutescens*	suffrutescent wallflower	
Brassicaceae	*Erysimum suffrutescens*	suffrutescent wallflower	
Brassicaceae	*Guillenia lasiophylla*	California mustard	
Brassicaceae	*Lepidium lasiocarpum*	shaggyfruit pepperweed	
Brassicaceae	*Lepidium nitidum*	shining pepperweed	
Brassicaceae	*Lepidium virginicum*	wild pepper grass	FACW
Brassicaceae	*Lepidium virginicum var. pubescens*	hairy pepperweed	FACW
Brassicaceae	*Rorippa curvisiliqua*	curvepod yellowcress	OBL
Brassicaceae	*Tropidocarpum gracile*	slender tropidocarpum	
Cactaceae	*Opuntia oricola*	chaparral pricklypear	
Capparaceae	*Isomeris arborea*	Coastal bladderpod	
Caryophyllaceae	*Cardionema ramosissimum*	Sand mat	
Caryophyllaceae	*Minuartia douglasii*	Douglas' stitchwort	
Caryophyllaceae	*Polycarpon depressum*	California manyseed	
Caryophyllaceae	*Spergularia macrotheca*	sticky sandspurry	FAC
Caryophyllaceae	*Spergularia marina*	salt marsh sand spurry	OBL
Chenopodiaceae	*Atriplex argentea*	silverscale saltbush	FAC
Chenopodiaceae	*Atriplex argentea var. mohavensis*	mohave saltbush	FAC
Chenopodiaceae	*A. argentea var. mohavensis [=Atriplex expansa]*	mohave saltbush	FAC
Chenopodiaceae	*Atriplex breweri*	quailbush	FAC
Chenopodiaceae	*Atriplex californica*	California saltbush	FAC
Chenopodiaceae	*Atriplex lentiformis*	big saltbush	FAC
Chenopodiaceae	*Atriplex lentiformis subsp. breweri*	quailbush	FAC

Family	Species	Common Name	Wetland
Chenopodiaceae	*Atriplex lentiformis subsp. lentiformis*	big saltbush	FAC
Chenopodiaceae	*Atriplex lentiformis var. breweri*	quailbush	FAC
Chenopodiaceae	*Atriplex leucophylla*	beach saltbush	FAC
Chenopodiaceae	*Atriplex patula subsp. hastata*	fathen saltweed	FACW
Chenopodiaceae	*Atriplex triangularis*	spear leaved saltbrush	
Chenopodiaceae	*Atriplex truncata*	wedgescale	FAC
Chenopodiaceae	*Salicornia europaea*	slender pickleweed	OBL
Chenopodiaceae	*Salicornia subterminalis*	Parish's pickleweed	OBL
Chenopodiaceae	*Salicornia virginica*	pickleweed	OBL
Chenopodiaceae	*Suaeda calceoliformis*	Pursh seepweed	FACW
Chenopodiaceae	*Suaeda taxifolia*	woolly seablite	FACW
Chenopodiaeceae	*Chenopodium berlandieri var. sinuatum*	Berlandier's goosefoot	
Convolvulaceae	*Calystegia macrostegia subsp. intermedia*	south coast morning-glory	
Convolvulaceae	*Calystegia soldanella*	beach morning glory	
Convolvulaceae	*Cressa truxillensis*	spreading alkaliweed	FACW
Crassulaceae	*Crassula connata*	sand pygmyweed	FAC
Crassulaceae	*Crassula connata var. erectoides*	sand pygmyweed	FAC
Crassulaceae	*Dudleya lanceolata*	lanceleaf liveforever	
Cucurbitaceae	*Cucurbita foetidissima*	calabazilla	
Cucurbitaceae	*Marah macrocarpus*	southern wild-cucumber	
Cuscutaceae	*Cuscuta californica*	chaparral dodder	
Cuscutaceae	*Cuscuta campestris*	field dodder	
Cuscutaceae	*Cuscuta salina*	saltmarsh dodder	
Cyperaceae	*Carex praegracilis*	clustered field sedge	FACW
Cyperaceae	*Cyperus eragrostis*	tall flatsedge	FACW
Cyperaceae	*Cyperus esculentus*	Yellow nutgrass	FACW

Family	Species	Common Name	Wetland
Cyperaceae	*Eleocharis macrostachya*	common spikerush	OBL
Cyperaceae	*Eleocharis montevidensis*	sand spikerush	FACW
Cyperaceae	*Eleocharis montevidensis var. montevidensis*	sand spikerush	FACW
Cyperaceae	*Isolepis cernua*	annual tule	OBL
Cyperaceae	*Schoenoplectus americanus*	chairmaker's bulrush	OBL
Cyperaceae	*Scirpus [=Schoenoplectus] californicus*	California tule	OBL
Cyperaceae	*Scirpus californicus*	California tule	OBL
Cyperaceae	*Scirpus maritimus*	prairie bulrush	OBL
Equisetaceae	*Equisetum hyemale subsp. affine*	common scouring rush	FACW
Equisetaceae	*Equisetum telmateia subsp. braunii*	giant horsetail	OBL
Euphorbiaceae	*Chamaesyce albomarginata*	rattlesnake weed	
Euphorbiaceae	*Chamaesyce polycarpa var. polycarpa*	small seeded spurge	
Euphorbiaceae	*Chamaesyce serpens*	creeping spurge	FAC
Euphorbiaceae	*Croton californicus*	California croton	
Euphorbiaceae	*Croton californicus var. californicus*	California croton	
Euphorbiaceae	*Croton californicus var. tenuis*	California croton	
Euphorbiaceae	*Croton setigerus*	dove weed	
Fabaceae	*Astragalus didymocarpus var. didymocarpus*	dwarf white milk vetch	
Fabaceae	*Astragalus pycnostachyus var. lanosissimus*	marsh milk-vetch	OBL
Fabaceae	*Astragalus trichopodus var. lonchus*	Santa Barbara milk-vetch	
Fabaceae	*Hoffmannseggia glauca*	Indian rushpea	FACU
Fabaceae	*Lotus heermannii*	Heermann's lotus	
Fabaceae	*Lotus scoparius*	deerweed	
Fabaceae	*Lotus scoparius var. scoparius*	deerweed	
Fabaceae	*Lotus strigosus*	Hairy Lotus	
Fabaceae	*Lotus strigosus var. strigosus*	Hairy Lotus	

Family	Species	Common Name	Wetland
Fabaceae	*Lotus unifoliolatus*	American bird's foot trefoil	
Fabaceae	*Lupinus bicolor*	miniature lupine	
Fabaceae	*Lupinus bicolor subsp. microphyllus*	miniature lupine	
Fabaceae	*Lupinus chamissonis*	dune bush lupine	
Fabaceae	*Lupinus excubitus*	grape lupine	
Fabaceae	*Lupinus excubitus var. hallii*	Hall's bush lupine	
Fabaceae	*Lupinus longifolius*	long leaf bush lupine	
Fabaceae	*Lupinus succulentus*	succulent lupine	
Fabaceae	*Lupinus truncatus*	truncated lupine	
Fabaceae	*Trifolium willdenovii*	tomcat clover	
Frankeniaceae	*Frankenia salina*	alkali seaheath	FACW
Frankeniaceae	*Frankenia salina*	alkali seaheath	FACW
Frankeniaceae	*Fraxinus latifolia*	alkali seaheath	FACW
Grossulariaceae	*Ribes malvaceum var. viridifolium*	chaparral currant	
Hydrophyllaceae	*Nemophila menziesii*	baby blue eyes	
Hydrophyllaceae	*Phacelia distans*	common phacelia	
Hydrophyllaceae	*Phacelia douglasii*	Douglas' phacelia	
Hydrophyllaceae	*Phacelia ramosissima*	south coast branching phacelia	
Hydrophyllaceae	*Phacelia ramosissima var. austrolitoralis*	south coast branching phacelia	
Hydrophyllaceae	*Phacelia stellaris*	Brand's phacelia	
Hydrophyllaceae	*Phacelia tanacetifolia*	tansy leafed phacelia	
Juncaceae	*Juncus bufonius*	toad rush	FACW
Juncaceae	*Juncus mexicanus*	mexican rush	FACW
Juncaceae	*Juncus textilis*	basket rush	OBL
Lamiaceae	*Lycopus americanus*	American water horehound	OBL
Lamiaceae	*Salvia carduacea*	thistle sage	

Family	Species	Common Name	Wetland
Lamiaceae	*Salvia columbariae*	chia sage	
Lamiaceae	*Stachys ajugoides*	bugle hedgenettle	OBL
Lamiaceae	*Stachys ajugoides var. rigida*	rigid hedge nettle	OBL
Lamiaceae	*Stachys albens*	whitestem hedgenettle	OBL
Lemnaceae	*Lemna minuscula*	least duckweed	OBL
Lemnaceae	*Lemna valdiviana*	valdivia duckweed	OBL
Lennoaceae	*Pholisma arenarium*	Desert pholisma	
Loasaceae	*Mentzelia affinis*	yellow blazing star	
Lythraceae	*Lythrum californicum*	California loostrife	OBL
Malvaceae	*Malacothamnus fasciculatus*	chaparral mallow	
Malvaceae	*Malvella leprosa*	alkali mallow	FAC
Malvaceae	*Malvella leprosa var. hederacea*	alkali mallow	FAC
Nyctaginaceae	*Abronia maritima*	red sand verbena	
Nyctaginaceae	*Abronia umbellata*	purple sand verbena	
Nyctaginaceae	*Abronia umbellata subsp. umbellata*	purple sand verbena	
Nyctaginaceae	*Abronia villosa*	desert sand verbena	
Nyctaginaceae	*Mirabilis laevis var. crassifolia*	California four o'clock	
Oleaceae	*Fraxinus velutina var. coriacea*	velvet ash	FACW
Onagraceae	*Camissonia bistorta*	California sun cup	
Onagraceae	*Camissonia cheiranthifolia subsp. suffruticosa*	beach evening-primrose	
Onagraceae	*Camissonia lewisii*	Lewis' evening primrose	
Onagraceae	*Camissonia micrantha*	miniature suncup	
Onagraceae	*Epilobium ciliatum subsp. ciliatum*	fringed willowherb	FACW
Onagraceae	*Epilobium pygmaeum*	smooth boisduvalia	OBL
Onagraceae	*Ludwigia peploides subsp. peploides*	floating primrose willow	OBL
Onagraceae	*Oenothera elata subsp. hirsutissima*	hairy evening primrose	FACW

Family	Species	Common Name	Wetland
Papaveraceae	*Eschscholzia californica*	California poppy	
Papaveraceae	*Platystemon californicus*	cream cups	
Papaveraceae	*Stylomecon heterophylla*	wind poppy	
Plantaginaceae	*Plantago erecta*	California plantain	
Poaceae	*Agrostis viridis*	green bentgrass	
Poaceae	*Distichlis spicata*	saltgrass	FACW
Poaceae	*Elymus condensatus*	giant wild rye	FACU
Poaceae	*Elymus glaucus*	blue wildrye	FACU
Poaceae	*Elymus triticoides*	alkali rye	FAC
Poaceae	*Hordeum brachyantherum*	meadow barley	FACW
Poaceae	*Hordeum intercedens*	vernal barley	FAC
Poaceae	*Koeleria macrantha*	prairie Junegrass	
Poaceae	*Leptochloa uninervia*	Mexican sprangletop	FACW
Poaceae	*Melica imperfecta*	smallflower melicgrass	
Poaceae	*Nassella pulchra*	purple needlegrass	
Poaceae	*Phalaris minor*	littleseed canarygrass	
Poaceae	*Setaria parviflora*	marsh bristlegrass	
Polemoniaceae	*Gilia clivorum*	purplespot gilia	
Polemoniaceae	*Linanthus parviflorus*	common linanthus	
Polemoniaceae	*Navarretia prostrata*	prostrate pincushionplant	OBL
Polygonaceae	*Eriogonum fasciculatum*	California buckwheat	
Polygonaceae	*Eriogonum gracile*	slender buckwheat	
Polygonaceae	*Eriogonum gracile var. gracile*	slender buckwheat	
Polygonaceae	*Eriogonum parvifolium*	seacliff buckwheat	
Polygonaceae	*Eriogonum parvifolium var. parvifolium*	seacliff buckwheat	
Polygonaceae	*Lastarriaea coriacea*	leather spineflower	

Family	Species	Common Name	Wetland
Polygonaceae	*Mucronea californica*	California spineflower	
Polygonaceae	*Mucronea californica var. suksdorfii*	California spineflower	
Polygonaceae	*Polygonum hydropiperoides*	swamp smartweed	OBL
Polygonaceae	*Polygonum lapathifolium*	curlytop knotweed	OBL
Polygonaceae	*Pterostegia drymarioides*	woodland pterostegia	
Polygonaceae	*Rumex maritimus*	golden dock	FACW
Polygonaceae	*Rumex salicifolius*	willow dock	OBL
Portulacaceae	*Calandrinia ciliata*	red maids	FACU
Portulacaceae	*Calyptridium monandrum*	common pussypaws	
Potamogetonaceae	*Ruppia cirrhosa*	spiral ditchgrass	OBL
Potamogetonaceae	*Ruppia maritima*	widgeongrass	OBL
Ranunculaceae	*Clematis ligusticifolia*	creek clematis	FAC
Ranunculaceae	*Delphinium parryi subsp. maritimum*	seaside larkspur	
Ranunculaceae	*Delphinium parryi subsp. parryi*	San Bernardino larkspur	
Rosaceae	*Potentilla anserina ssp. pacifica*	Pacific potentilla	OBL
Rosaceae	*Potentilla anserina subsp. pacifica*	silver-weed cinquefoil	OBL
Rosaceae	*Potentilla anserina var. grandis*	silver-weed cinquefoil	OBL
Rosaceae	*Potentilla multijuga*	ballona cinquefoil	OBL
Rubiaceae	*Galium angustifolium subsp. angustifolium*	narrowleaf bedstraw	
Salicaceae	*Populus fremontii*	Fremont cottonwood	FACW
Salicaceae	*Salix exigua*	sandbar willow	OBL
Salicaceae	*Salix laevigata*	red willow	
Salicaceae	*Salix lasiolepis*	arroyo willow	FACW
Saururaceae	*Anemopsis californica*	yerba mansa	OBL
Scrophulariaceae	*Antirrhinum coulterianum*	Coulter's snapdragon	
Scrophulariaceae	*Antirrhinum nuttallianum subsp. nuttallianum*	Nuttall's snapdragon	

Family	Species	Common Name	Wetland
Scrophulariaceae	*Castilleja exserta*	purple owl's clover	
Scrophulariaceae	*Collinsia heterophylla*	purple Chinese houses	
Scrophulariaceae	*Cordylanthus maritimus subsp. maritimus*	salt marsh bird's beak	OBL
Scrophulariaceae	*Mimulus guttatus*	seep monkeyflower	OBL
Solanaceae	*Datura wrightii*	Jimson weed	
Solanaceae	*Nicotiana clevelandii*	Cleveland's tobacco	
Solanaceae	*Solanum americanum*	common nightshade	FAC
Solanaceae	*Solanum douglasii*	Douglas' nightshade	FAC
Typhaceae	*Sparganium erectum subsp. stoloniferum*	simplestem bur-reed	OBL
Typhaceae	*Typha domingensis*	narrowleaf cattail	OBL
Typhaceae	*Typha latifolia*	broadleaf cattail	OBL
Urticaceae	*Urtica dioica subsp. holosericea*	giant creek nettle	FACW
Urticaceae	*Urtica urens*	dwarf nettle	
Verbenaceae	*Phyla lanceolata*	lanceleaf fogfruit	
Verbenaceae	*Phyla lanceolata*	lanceleaf fogfruit	FACW
Verbenaceae	*Verbena lasiostachys var. lasiostachys*	Common verbena	FAC
Zosteraceae	*Phyllospadix torreyi*	Torrey's surfgrass	OBL

APPENDIX 4.
FLORA OF THE SANTA MONICA MOUNTAIN REGION AS DOCUMENTED IN HERBARIUM RECORDS

Family	Species	Common Name	Wetland
Amaranthaceae	*Amaranthus blitoides*	mat amaranth	FACW
Amaranthaceae	*Amaranthus powellii*	Powell's amaranth	
Anacardiaceae	*Malosma laurina*	laurel sumac	
Anacardiaceae	*Rhus integrifolia*	lemonade berry	
Anacardiaceae	*Rhus ovata*	sugar bush	
Anacardiaceae	*Rhus trilobata*	skunkbush sumac	NI
Anacardiaceae	*Rhus trilobata var. pilosissima*	skunkbush sumac	NI
Apiaceae	*Apiastrum angustifolium*	wild celery	
Apiaceae	*Berula erecta*	cutleaf water-parsnip	OBL
Apiaceae	*Bowlesia incana*	hoary bowlesia	FACW
Apiaceae	*Daucus pusillus*	Wild carrot	
Apiaceae	*Lomatium lucidum*	shiny biscuitroot	
Apiaceae	*Sanicula arguta*	sharp toothed snakeroot	
Apiaceae	*Sanicula bipinnata*	poison sanicle	
Apiaceae	*Sanicula crassicaulis*	Pacific blacksnakeroot	
Apiaceae	*Tauschia arguta*	southern umbrellawort	
Asteraceae	*Achillea millefolium*	common yarrow	FACU
Asteraceae	*Acourtia microcephala*	sacapellote	
Asteraceae	*Ambrosia acanthicarpa*	annual bursage	
Asteraceae	*Ambrosia chamissonis*	Silver Beachweed	
Asteraceae	*Ambrosia confertiflora*	weak leaved burweed	
Asteraceae	*Ambrosia psilostachya*	western ragweed	FAC
Asteraceae	*Ambrosia psilostachya var. californica*	western ragweed	FAC
Asteraceae	*Artemisia californica*	California sagebrush	
Asteraceae	*Artemisia douglasiana*	mugwort	FACW
Asteraceae	*Artemisia dracunculus*	herbaceous sagewort	

Family	Species	Common Name	Wetland
Asteraceae	*Baccharis douglasii*	saltmarsh baccharis	OBL
Asteraceae	*Baccharis pilularis*	coyote brush	
Asteraceae	*Baccharis salicifolia*	mulefat	FACW-
Asteraceae	*Brickellia californica*	California brickellbush	FACU
Asteraceae	*Brickellia nevinii*	Nevin's brickellia	
Asteraceae	*Centromadia parryi subsp. australis*	Parry's tarweed	FAC
Asteraceae	*Chaenactis artemisiifolia*	artemisia leaved chaenactis	
Asteraceae	*Chaenactis glabriuscula var. glabriuscula*	yellow pincushion	
Asteraceae	*Cirsium occidentale*	California thistle	
Asteraceae	*Cirsium occidentale var. californicum*	California thistle	
Asteraceae	*Cirsium occidentale var. occidentale*	California thistle	
Asteraceae	*Conyza canadensis*	Canada horseweed	FAC
Asteraceae	*Corethrogyne filaginifolia*	common sandaster	
Asteraceae	*Corethrogyne filaginifolia var. virgata*	common sandaster	
Asteraceae	*Deinandra fasciculata*	common tarweed	
Asteraceae	*Dicoria canescens*	desert dicoria	
Asteraceae	*Encelia californica*	California sunflower	
Asteraceae	*Ericameria ericoides*	California goldenbush	
Asteraceae	*Ericameria linearifolia*	narrowleaf goldenbush	
Asteraceae	*Ericameria palmeri var. pachylepis*	broad scaled Palmer's goldenbush	
Asteraceae	*Ericameria parishii*	Parish's goldenbush	
Asteraceae	*Ericameria pinifolia*	pinebush	
Asteraceae	*Erigeron foliosus*	leafy fleabane	
Asteraceae	*Erigeron foliosus var. foliosus*	leafy fleabane	
Asteraceae	*Eriophyllum confertiflorum*	golden-yarrow	
Asteraceae	*Eriophyllum confertiflorum var. confertiflorum*	golden-yarrow	

Family	Species	Common Name	Wetland
Asteraceae	*Filago californica*	California Cottonrose	
Asteraceae	*Gnaphalium bicolor*	bicolored everlasting	
Asteraceae	*Gnaphalium californicum*	California cudweed	
Asteraceae	*Gnaphalium californicum*	California everlasting	
Asteraceae	*Gnaphalium canescens subsp. microcephalum*	white everlasting	
Asteraceae	*Gnaphalium ramosissimum*	pink everlasting	
Asteraceae	*Grindelia camporum*	Great Valley gumweed	
Asteraceae	*Grindelia hirsutula*	hairy gumweed	FACW
Asteraceae	*Gutierrezia californica*	California matchweed	
Asteraceae	*Gutierrezia sarothrae*	Matchweed	
Asteraceae	*Hazardia squarrosa var. grindelioides*	saw toothed goldenbush	
Asteraceae	*Hazardia squarrosa var. squarrosa*	saw toothed goldenbush	
Asteraceae	*Hemizonia fasciculata*	common tarweed	
Asteraceae	*Heterotheca grandiflora*	telegraphweed	
Asteraceae	*Heterotheca sessiliflora ssp. fastigiata*	erect goldenaster	
Asteraceae	*Isocoma menziesii var. vernonioides*	white-flowered goldenbush	FAC
Asteraceae	*Iva hayesiana*	San Diego marsh elder	FACW
Asteraceae	*Laennecia coulteri*	Coulter's horseweed	FAC
Asteraceae	*Lasthenia californica*	California goldfields	FACW
Asteraceae	*Lasthenia gracilis*	needle goldfields	
Asteraceae	*Layia platyglossa*	White tidy-tips	
Asteraceae	*Layia platyglossa subsp. campestris*	White tidy-tips	
Asteraceae	*Lepidospartum squamatum*	scalebroom	
Asteraceae	*Lepidospartum squamatum var. squamatum*	scalebroom	
Asteraceae	*Lessingia filaginifolia*	common sandaster	
Asteraceae	*Madia gracilis*	slender tarweed	

Family	Species	Common Name	Wetland
Asteraceae	*Madia sativa*	coast tarweed	
Asteraceae	*Malacothrix saxatilis var. tenuifolia*	cliff aster	
Asteraceae	*Monolopia lanceolata*	common monolopia	
Asteraceae	*Pluchea sericea*	arroweed	FACW
Asteraceae	*Pseudognaphalium biolettii*	twocolor cudweed	
Asteraceae	*Pseudognaphalium microcephalum*		
Asteraceae	*Pseudognaphalium microcephalum*	white headed cudweed	
Asteraceae	*Pseudognaphalium ramosissimum*	pink cudweed	
Asteraceae	*Pseudognaphalium stramineum*	Small flowered cudweed	FAC
Asteraceae	*Psilocarphus tenellus*	round woolly-marbles	FAC
Asteraceae	*Rafinesquia californica*	California chicory	
Asteraceae	*Senecio californicus*	California Butterweed	
Asteraceae	*Senecio flaccidus*	Douglas' shrubby ragwort	
Asteraceae	*Senecio flaccidus var. douglasii*	Douglas' shrubby ragwort	
Asteraceae	*Solidago californica*	California goldenrod	
Asteraceae	*Solidago velutina subsp. californica*		
Asteraceae	*Stebbinsoseris heterocarpa*	grassland stebbinsoseris	
Asteraceae	*Stephanomeria cichoriacea*	chicory leaved stephanomeria	
Asteraceae	*Stephanomeria diegensis*	San Diego milk aster	
Asteraceae	*Stephanomeria exigua subsp. coronaria*	milk aster	
Asteraceae	*Stephanomeria virgata*	Tall stephanomeria	
Asteraceae	*Stephanomeria virgata subsp. virgata*	Tall stephanomeria	
Asteraceae	*Symphyotrichum defoliatum [=Aster bernardinus]*	San Bernardino aster	RARE
Asteraceae	*Symphyotrichum greatae [=Aster greatae0*	Greata's aster	RARE
Asteraceae	*Venegasia carpesioides*	canyon sunflower	
Asteraceae	*Xanthium spinosum*	spiny cocklebur	FAC

Family	Species	Common Name	Wetland
Asteraceae	*Xanthium strumarium*	rough cockleburr	FAC
Azollaceae	*Azolla filiculoides*	mosquito fern	OBL
Berberidaceae	*Berberis nevinii*	Nevin's barberry	
Boraginaceae	*Amsinckia intermedia*	Eastwood's fiddleneck	
Boraginaceae	*Amsinckia punctata*		
Boraginaceae	*Cryptantha intermedia*	Clearwater cryptantha	
Boraginaceae	*Cryptantha micromeres*	minute flowered cryptantha	
Boraginaceae	*Cryptantha microstachys*	Tejon cryptantha	
Boraginaceae	*Cryptantha muricata*	prickly cryptantha	
Boraginaceae	*Cryptantha muricata var. jonesii*	prickly cryptantha	
Boraginaceae	*Pectocarya penicillata*	sagebrush combseed	
Boraginaceae	*Pedicularis densiflora*	Indian warrior	
Boraginaceae	*Plagiobothrys collinus*	Cooper's popcornflower	
Brassicaceae	*Arabis glabra*	smooth rock cress	
Brassicaceae	*Barbarea orthoceras*	American Wintercress	FACW
Brassicaceae	*Cardamine californica*	California toothwort	UPL*
Brassicaceae	*Caulanthus heterophyllus var. pseudosimulans*	San Diego wild cabbage	
Brassicaceae	*Descurainia pinnata subsp. menziesii*	western tansymustard	
Brassicaceae	*Erysimum capitatum subsp. capitatum*	western wallflower	
Brassicaceae	*Guillenia lasiophylla*	California mustard	
Brassicaceae	*Lepidium virginicum*	wild pepper grass	FACW
Brassicaceae	*Thysanocarpus curvipes*	common fringe-pod	
Brassicaceae	*Thysanocarpus laciniatus*	common lace pod	
Brassicaceae	*Tropidocarpum gracile*	slender tropidocarpum	
Cactaceae	*Opuntia littoralis*	coast prickly pear	
Cactaceae	*Opuntia vaseyi*	Vasey's prickly pear	

Family	Species	Common Name	Wetland
Campanulaceae	*Githopsis diffusa subsp. candida*	San Gabriel bluecup	
Campanulaceae	*Triodanis biflora*	Venus looking glass	
Capparaceae	*Isomeris arborea*	Coastal bladderpod	
Caprifoliaceae	*Lonicera interrupta*	chaparral honeysuckle	
Caprifoliaceae	*Lonicera subspicata var. denudata*	southern honeysuckle	
Caprifoliaceae	*Sambucus nigra ssp. caerulea*	blue elderberry	FAC
Caprifoliaceae	*Symphoricarpos mollis*	creeping snowberry	
Caryophyllaceae	*Polycarpon depressum*	California manyseed	
Caryophyllaceae	*Silene antirrhina*	sleepy silene	
Caryophyllaceae	*Silene laciniata*	Indian pink	
Caryophyllaceae	*Silene laciniata subsp. major*	Indian pink	
Chenopodiaceae	*Atriplex serenana*	saltscale	FAC
Chenopodiaceae	*Chenopodium californicum*	soaproot	
Chenopodiaeceae	*Chenopodium berlandieri*	Berlandier's goosefoot	
Cistaceae	*Helianthemum scoparium*	common sun-rose	
Cistaceae	*Helianthemum scoparium var. scoparium*	common sun-rose	
Cistaceae	*Helianthemum scoparium var. vulgare*	common sun-rose

RE: Additional Comments Re: Ballona Restoration NOI Comments

Dear Mr. Swenson and Mr. Lawhead:

I have these additional comments to add to the record regarding the proposed restoration of the Ballona Ecological Reserve. Please add them to the comments I have already mailed/delivered to you.

ALTERNATIVE RESTORATION PLAN

Please study seriously an ALTERNATIVE plan for restoration of the Ballona reserve. This plan would NOT entail major bulldozing and removing levees from the LA River.
This plan would have the following components:

1) Plan approved by Tongva Native Americans for their sacred site.
2) Plan may allow for minor earthmoving to make a couple of small channels for fresh water.
3) No water from Ballona Creek allowed into the wetlands until it is cleaned up to a tertiary level.
4) Use Bond funds available, from not doing an expensive major bulldozing/dredging/levee-building project, to buy buffer lands around the reserve to reduce road kill of Ballona wildlife in the area, and allow larger more stable populations of wildlife. Additional land would also make limited public trails less disturbing to wildlife, as they would have additional places to live.
5) Study the value of this plan for 5-10 years. Some alterations could be made during that time, based on the results.
6) Utilize local citizens who have been documenting/photographing this area for the past 20-30 years in the active science committee. Do not continue to relegate them to public comments of 2-3 minutes at in-frequent meetings, but rather make them integral participants in the science committees where they can communicate more fully with the other members. Some of them see wildlife that is never documented on the science cameras. Their input is CRITICAL to a

well-done evaluation of this area.
7) Continue to bring Los Angeles area students out to the wetlands to help clean-up the area, document flora and fauna, etc. so that they are interested in helping to watch over this land in the future.
8) Follow the natural course of the land/water. Please consult with Dr. Travis Longcore and his researchers on this.
9) Use this plan to teach the public that the first rule of restoration is to "Do No Further Harm". Teach the public that big expensive industrial solutions are not always the best, most permanent way to protect nature. A slower alternative that teaches people to respect nature, and allow its natural tendency to balance itself.

IF YOU WANT FURTHER INFORMATION ON SUCH A PLAN, LET ME KNOW AND I WILL WORK ON GETTING YOU MORE DETAILS. A PLAN LIKE THIS WOULD GIVE THE PUBLIC A REAL CHOICE, AND validate what the public is being told - that there IS NO preferred plan, that it is wide open on what will happen at Ballona.

OTHER COMMENTS:
1) I do not agree at all with bulldozing this site. But if you do, please reveal any background information regarding any bulldozing of Ballona, and if any company will benefit from mitigation credits, and any other financial connections to the restoration efforts, so that there is transparency on how and why these decisions are made.

2) REGARDING WATER STUDIES: Please study the impact of the water from Marina Del Rey on ANY proposed alternative for restoration. Marina Del Rey water is highly polluted from toxics from many boats (I have been told there are 7,000 boats there!). These boats have toxic chemicals applied to them to preserve them, and to run them, that leak into the water, plus people using the boats have been seen to dump liquids and trash into the water. Please test the water of Marina Del Rey very carefully and assess how that water will impact the wetlands, and how it could be kept separate from the wetlands.

2) Remove the trash (local groups and citizens can help on this issue) and find somewhere for homeless people to sleep. Don't make these issues a reason why the restoration has to be hurried.

Thank you very much.
Kathy Knight, MSW
(Have been volunteering and donating funds for 20 years to save and protect this precious ecosystem)
(310) 613-1175

P.S. THE REASON THAT IT IS CRITICAL TO STUDY THE WATER/GAS INTERACTION IS THAT THERE ARE MANY RESIDENTS AT PLAYA VISTA THAT COULD BE IMPACTED BY ANY changes.

October 22, 2012

Comments on NOI to Prepare Joint EIS/EIR on Ballona Wetlands Restoration

Dear Mr. Swenson and Mr. Lawhead:

I have been volunteering since 1992 to help protect the Ballona wetlands ecosystem from development and bulldozing. I am Conservation Chair of the Sierra Club Airport Marina Group, but these comments are my own. The Sierra Club will be making comments separately.

As I understand the proposed project is for a full review of the area of the Ballona Ecological Reserve. It has never had a federal review before. And based on this review, a proposal will be made for what should be done to help enhance this valuable resource. I have the following comments/questions and requests for studies:

1) This entire area is a registered Sacred Site for the indigenous people of Los Angeles, the Tongva Native Americans, who have been living in this area for the past 10,000 years. This area is called Sa'angna in their culture. They had a very deep respect for nature and kept this area as a beautiful paradise.

They have suffered horribly through the past 300 years from having their land taken from them and their culture disrespected. The Playa Vista developers dug up over 1400 of their ancestors' graves to build their development. It is time that this process is stopped. Please respect their wishes and their culture when considering how to treat this land.

2) PLEASE STOP ALL ALTERATIONS AND/OR CONSTRUCTION ACTIVITIES ON THIS LAND UNTIL THE EIS/EIR IS APPROVED.

I have been told that approximately 60 core drillings have been made on the land in the past month. What is that for? How has that activity impacted plants and animals on the site? Please keep the land unaltered until this process is approved.

3) PLEASE EXPLAIN WHY THE 2005 JOINT EIS/EIR IS NOT BEING FOLLOWED

Why instead is this very narrowly focused restoration plan with only a fraction of the Ballona ecosystem being studied?

Marina del Rey would be reviewed under House Document 389.
The Corp would then report back to Congress to recommend any changes thereto.
The entire Ballona Watershed was considered.
The process was funded by Congress.
The process was requested by Congress.

The 2005 NOI covered the Ballona ecosystem, including Marina Del Rey, the Playa Vista Urban Runoff Basin (aka Fresh Water Marsh). Please follow the 2005 NOI, not this shortened one. All of the adjacent bodies of water need to be included into the Ballona Wetlands Study Area (BWSA) including, but not limited to, the Marina Del Rey Harbor, Oxford Lagoon, Del Rey Lagoon, Venice Canals, and Santa Monica Bay. The Ballona Ecosystem needs to be studied as a whole. Its waters and wildlife are interactive, and you can't study one section properly without studying the whole.

The Sierra Club Airport Marina Group supports this restoration process to continue under the more inclusive 2005 NOI. (See attached letter of support).

4) WHY HASN'T A PUBLIC HEARING BEEN HELD FOR THE NOI?

This current process is not conducive to the public being able to make full comments. Local citizens have fought to save this land for many years. They deserve to hear each other speak at a public hearing, not just have the walk around displays on August 16, 2012. This process is critical at the NOI stage, where the groundwork is being set on what to study in the EIS/EIR.

It would be beneficial to the Army Corps and Fish & Game to hear their concerns and for the public to be able to ask them questions.

Please extend the Oct. 23rd NOI deadline until a public hearing by the Army Corps and CDFG can be held. This request was made at the August display event, but thus far it has not happened.

5) PLEASE ANALYZE AND ASSESS HOW THE PLAYA VISTA AND BALLONA WETLANDS GROUNDWATER WILL BE IMPACTED BY THE PROPOSED RESTORATION PLANS.

How much groundwater is being taken out of the aquifer currently by Playa Vista and sent to Hyperion?

How much more water will be withdrawn if Playa Vista Phase 2 is built? What effect will that have on the wetlands?

How much water can be withdrawn from the Playa Vista site and not take away from the wetlands' source of underground water?

What effect is the withdrawing of this amount of water and this depletion of the aquifer having currently on the Ballona wetlands ecosystem?

What is the impact if the aquifer beneath Playa Vista and Ballona (the Silverado aquifer) which is a potential drinking water aquifer, is needed for public use due to drought?

Ballona is a non-adjudicated basin. As I understand, this means that entities can take as much water as they want from underneath their property. For example, Playa Vista is withdrawing a large amount of water under their development to maintain their gas mitigation system. As far as we know, it is unmonitored and sent straight to Hyperion. The area seems much drier than usual, even more so than in previous drought years like this one.

6) HOW WOULD ANY CHANGE IN THE HYDROLOGY (ESPECIALLY ADDITION OR WITHDRAWAL OF WATER) OF THE AREA IMPACT THE MIGRATORY GAS UNDER THE PLAYA VISTA DEVELOPMENT?

After 5 years of Grassroots Coalition and their expert, Dr. Bernard Endres, warning the Los Angeles Dept. of Building and Safety that there was a problem of escaping gas at the Playa Vista site, the Dept. finally ordered a peer review study

by Exploration Technolgies, Inc. (ETI). This study showed that Grassroots Coalition was right - there was a large amount of gas coming out of the site (see attached 4-13-2000 ETI gas map attached).

ETI stated that this gas is highly migratory (January 19,1999 letter attached). Also the site is subject to significant earthquakes in the future that can alter both the subsurface methane concentrations migrating from subsurface sources and degrade any methane mitigation system (July 23, 1999 ETI letter attached).

A December 15, 1999 letter (attached) from ETI said the Playa Vista area is a "High Potential Methane Zone" and that no excavations should be made below the ground table water, and a report should be filed before pumping of any groundwater.

Doesn't this documentation regarding the serious gas issue at Playa Vista warrant very serious studies on the effects of adding or changing the water dynamics of the area? We think that ETI should be consulted on any proposed changes to the hydrology/tidal influence in this area.

Please address the concerns of Dr. Bernard Endres, Grassroots Coalition's expert in his June 7, 2000 document to LA City entitled "An Evaluation of Gas Migration and Environmental Hazards Existing at the Playa Vista Project" (attached). Dr. Endres wrote a book about the Playa Del Rey oilfield and was very familiar with its aspects. On Issue #6 in this document, he says an evaluation of the special problems created by the 50 ft. gravel zone (the old Los Angeles River bed) under Ballona Creek needs to be performed due to the fact that it allows gas to build to high pressures from a rising water table.

Also, it is our understanding that Southern California Gas Co. which stores 7 billion cubic feet of gas just west of Lincoln Blvd. in a sandstone rock formation approximately 6,000 ft. below the ground should be consulted. We have been told that they maintain the pressure of this gas in the rock formation through a system of pressure that changes with the tides going in and out of the area.

Finally, if any changes to the hydrology of the area were to exacerbate the gas problem at Playa Vista, the Marina, or the Gas Co., who would be responsible financially? Would there be any risk of liability from the State of California?

7) Why is the Playa Vista Urban Runoff Basin (aka Fresh Water Marsh) left out of this EIS/EIR proposal when it is part of the wetlands? Please include this area in the EIS/EIR. It is part of this Ballona ecosystem.

Why isn't the dewatering of the Playa Vista site going to the Fresh Water Marsh, instead of being sent to Hyperion?
It is our understanding that it was required through the Playa Vista Environmental Impact Report.

Also what will be the impact on the Ballona Ecological Reserve if the Fresh Water Marsh has to be dredged every 5-15 years to remove toxic contamination build up from street runoff, as stated will have to happen in the Playa Vista Phase 1 EIR?

It is also our understanding that the Fresh Water Marsh is being maintained by the Playa Vista developer with watering from tap water sources. How much water does this use, and how will it be maintained when the developers are gone? We are concerned that the Playa Vista homeowners will not be able to afford to keep the Fresh Water Marsh watered. What impact would that have on the Ballona Reserve?

8) BALLONA CREEK SHOULD NOT BE ALLOWED TO POLLUTE THE WETLANDS

Ballona Creek should not be allowed, with all its street run-off contamination from a wide area of the Los Angeles basin, to flow into the Ballona Reserve just to "bring water to the wildlife." This is using the Ballona Reserve as an End of the Line clean-up basin to clean up Ballona Creek before it enters Santa Monica Bay.

A full EIR needs to be done of opening up Ballona Creek into the wetlands before it would ever be happen due to its toxic contamination from many miles of runoff sources.

Are you going to do an EIS/EIR on the impact of changing Ballona Creek and letting it go into the wetlands?

I talked to a scientist on your technical advisory committee, Dr. Richard Ambrose, who agreed that opening up Ballona Creek into the reserve would bring contamination, but he said the animals would benefit from the water.

Please analyze and assess how the pollution from Ballona Creek would impact

plant and animal life.

The Ballona Reserve looks dry now, but that is because the rainfall for 2011-2012 is only half of normal. (See attached rainfall charts). This land has gone through periodic droughts and heavy rainfall seasons for many years. It is a seasonal wetland, not a year-round wetland.

Also, what are the positive effects of a drought? It is our understanding that during droughts some of the invasive non-native plants die off, giving the native plants more chance to re-generate. Are there any other benefits?

Also, please analyze the upland habitat needed for the wildlife of Ballona. We understand from a previous study that the wetlands were 2,000 acres surrounded by 6,000 acres of uplands. So uplands are a very important part of the system, and the current proposed project looks like it will create too much wetland area vs. upland area.

9) THE BALLONA WETLANDS CANNOT CLEAN UP TOXIC POLLUTION FROM BALLONA CREEK

If Ballona Creek is opened up into the wetlands, how will the sediment be taken out of the wetlands, and how will the toxics sent into it from the creek be removed? In a study done by Dr. Rimmon C. Fay who spent his life studying the Ballona wetlands and Santa Monica Bay, wetlands can absorb and handle a certain amount of sewage waste. But they cannot handle toxic waste. It builds up in the soil, gets absorbed into plants, and therefore by wildlife. Wetlands cannot break down toxic chemicals into non-toxic chemicals.

How much would it cost to remove this sediment and toxic contamination from the wetlands, and how often would it have to be done?

10) ANY NEW WATER INTO THE WETLANDS NEEDS TO BE FROM A CLEAN SOURCE SO AS TO NOT DAMAGE IT MORE.

Any new water should be treated to a tertiary level to protect the plants and animals. Otherwise, this area may have to be periodically dredged every 5-15 years just like the Fresh Water Marsh.

What would be the cost of cleaning up the Ballona Creek water to a tertiary level?

11) WHAT IS THE EFFECT OF THE 20' HIGH LEVEES ON THE RESTORATION PROPOSAL PUT FORTH BY THE COASTAL CONSERVANCY? (See attached document)

Will they have an impact on Playa Del Rey? If a tsunami came through, the levees might protect Playa Vista, but could the water end up rebounding west back through the wetlands to Playa Del Rey, instead of being gradually absorbed to the east of Lincoln Blvd.?

It should be studied how the wetlands would fare in a tsunami. For example I have been told that in the 1930's a tsunami 9 ft. high went east past the 405 freeway. Another one in 2011 in Northern California caused $44 million in damage to harbors.

Are these levees being put there to protect Playa Vista and the large commercial interests at the site? What is the cost to taxpayers of these levees?

12) WHAT IS THE ESTIMATED COST OF THESE STUDIES AND PROPOSED PLAN TO RESTORE THE BALLONA WETLANDS?

13) SLOWER RESTORATION ALTERNATIVE

Please review the attached 7 GUIDING PRINCIPLES document that is supported by the Ballona Wetlands Land Trust, Sierra Club, Ballona Institute, Ballona Ecosystem Education Project, Grassroots Coalition, and Wetlands Defense Fund.

What would be the cost of a slower restoration? For example, take more time to study the land and see the effects of an ongoing restoration.

Please study the advantage of this type of restoration as a legitimate proposal. It would not be a no-project alternative, but it would be much less invasive than the proposed bulldozing/dredging of the site.

A slower, more careful restoration process would help avoid the mistakes made in the past, such as at the El Segundo Dunes in the 1990's. There LAX did a restoration where they had a company come in and plant native california

buckwheat plants to help the endangered El Segundo Blue butterfly recover. However, it was observed that the numbers of this species was going down even more. Only after careful studying of the situation did Dr. Rudi Mattoni find out that the PARTICULAR type of california buckwheat planted there was helping the El Segundo Blue's competitor butterfly increase in numbers. It hatched earlier than the El Segundo Blue on this particular type of buckwheat, and ate the food source up before the El Segundo Blue hatched. After these plants were removed and replaced by the right type of California buckwheat the El Segundo Blue started recovering and now is doing well at the dunes.

A massive bulldozing, dredging of the wetlands could destroy alot of this valuable information.

How would any bulldozing/dredging hurt/impact threatened and endangered species out there, such as the California Gnatcatcher and the Least Bell's Vireo? Isn't it the law that the habitat of these rare animals should not be altered or destroyed?

Students from Los Angeles area schools could come out and help do surveys and restore one area at a time, helping to teach them about nature and helping them to feel connected to Ballona as their wetlands.

14) ACQUISITION OF BUFFER LAND AROUND THE RESERVE

Please study the cost effectiveness of using restoration money towards acquiring more buffer land around the reserve.

Wouldn't this have a more beneficial effect on the plants and wildlife than bulldozing/dredging?

This reserve is in a highly developed area and the amount of road kill is already very high. According to a study in 2010, approximately 3,500 animals a year are killed on the roads around Ballona (see attached summary of road kill study).

And another intense development, Playa Vista Phase 2 was approved by the Los Angeles City Council in 2010. It is a few blocks east of the Reserve. According to the Playa Vista Phase 2 EIR, it would generate 24,000 additional car trips daily.

If that land and other buffer lands at risk of development were acquired, wouldn't that prove to be very beneficial to restoring and protecting wildlife and native flora at the Reserve?

15) STUDY AND FOLLOW THE NATURAL DYNAMICS AND HISTORY OF THE ECOSYSTEM

What is the natural flow of water on this land during the past 200 years?

As evidenced in photos that we have seen, there was not an estuarine habitat here with full tidal flow. Most of the time the wetlands were closed to the ocean, except in a rainy season.

According to research done by Dr. Travis Longcore the wetlands were mostly closed to the ocean. **Please review his lecture, entitled "Closure Dynamics of Southern California Estuaries and Implications for Restoration" given May 22, 2012 to the Los Angeles Audubon Society.** It is available on the website of Grassroots Coalition (www.saveballona.org). Hearing his presentation is critical to understanding the NATURAL balance of this area.

Please analyze the benefits to the wetlands and the species there of it being closed most of the time to the ocean.

The reason this issue needs to be studied more is that many times "restoration plans" include expensive bulldozing/dredging that do not follow the natural flow of the land/water on the site. It is not only expensive to bulldoze and dredge to begin with, but it does not last and must be done again. For example, the 1983 bulldozing of Malibu Lagoon to restore it did not work, and it recently has been bulldozed again. What was the cost 30 years ago and what was the cost this year at Malibu and who paid for it? Thirty years from now it will probably have to be bulldozed again - at what cost?

Also, the Bolsa Chica wetlands were dredged out and it keeps filling in because it does not reflect the natural flow of water and runoff. So every 2 years, it must be re-dredged at a cost of approximately $3 million. It is our understanding that in 2011 it had to be dredged at a cost of $13.3 million. Where does this money come from? Where would be the source of this money if it were needed at Ballona to maintain an unnatural estuarine habitat?

This waste of taxpayer bond money is a tragedy, especially in hard economic times. Any restoration of Ballona should be one that will not have to be repeated. What would be the cost of following the natural dynamics of this area, vs. creating a situation that does not? What would be the cost of bulldozing/dredging an estuarine habitat at Ballona that does not naturally exist now?

16) DO NOT DISTURB THE SOIL PLACED ON THE BALLONA RESERVE FROM THE DREDGING OF MARINA DEL REY, BEFORE IT IS ANALYZED FOR ITS VALUE AND THE TONGVA NATIVE AMERICANS HAVE BEEN CONSULTED AND AGREED TO ANY DISTURBANCE

Land that was placed onto the Ballona Reserve just south of Fiji Way is very valuable land. It was placed there when the Ballona wetlands north were dug up and Marina del Rey was built. It would have the original soil from that area that may be valuable later to study, it has native plants growing on it, and it may have Native American artifacts/historical parts to it.

This land should not be disturbed without first consulting with the Tongva Native Americans, and should most likely be left there.

Also please consult the California Native Plant Society for their input on this restoration of Native Plants at the Ballona Reserve.

Please keep me informed of any events and information relating to this Ballona wetlands area.

Thank you very much.

BALLONA ECOSYSTEMS REJUVENATION

"SEVEN GUIDING PRINCIPLES"

1. 21st century, incremental, community involved ecosystem rejuvenation that is in harmony with natural laws . We are opposed to industrial-scale habitat conversion, including major bulldozing, which destroys existing ecosystems.

2. In appreciation of what is there now, recognize the resiliency of the ecosystems and identify areas that require no more than observation for the foreseeable future.

3. In recognition of the importance of gaining control of more acreage before it is built on, or otherwise negatively impacted, give priority to acquisition/addition of additional unprotected parcels of land at a reasonable price to the Ballona Wildlife Refuge, over restoration activities. Such land protection will increase habitat enhancing buffer zones for wildlife and plants, and decrease car trips in the area, which lead to animal road fatalities.

4. Utilize existing opportunities to access the refuge, such as the Ballona Creek bike path, and south earthen levy along Ballona Creek and install a walking/biking path around as much of the perimeter of the refuge as is ecologically feasible.

5. Utilizing existing infrastructure such as the old Pacific Railway bridge supports and other man made structures, along with materials that have the deepest sustainability, create wildlife, bicycle, and walking linkages that connect all areas of the ecosystems in a fashion that allow homo sapiens and animals alike, to safely go over or under all roads and waterways that divide the refuge.

6. In recognition of the importance of enhancing the beauty of the refuge, safety of birds and other mammals, and the reduction of light pollution, move all power, telephone, and cable lines underground, and remove the majority of street lighting.

7. Endangered, threatened, and imperiled species must be given priority for protection in any refuge alteration considerations.

Supported by numerous environmental and community groups, including Ballona Wetlands Land Trust, Sierra Club, Ballona Institute, Ballona Ecosystem Education Project, Grassroots Coalition and Wetlands Defense Fund

Re: 2012 Notice of Joint EIS/EIR

This letter responds to the Notice of Intent to conduct a joint EIS/EIR pursuant to the National Environmental Policy Act and the California Environmental Protection Act at the Ballona Wetlands Ecological Preserve in the State of California, County of Los Angeles, in 2012.

The Club has resolved to support the joint EIR/EIS process noticed in the Federal Register on September 20, 2005 by the U.S. ACE Los Angeles District and the Santa Monica Bay Restoration Commission, a State Agency, as the local sponsor.

The position of the Club is that the new Notice of Intent placed in the Federal Register on July 25, 2012 contradicts and duplicates the former EIS noticed in 2005.

The Secretary of the Army has stated in writing that the 2005 joint EIS/EIR process is not terminated and is therefore current.

The reasoning of the resolution is as follows:

Another EIS process has been introduced by LA USACE that interferes with and contradicts the current process. The Corp has begun a new process that duplicates and reduces the scope of the 2005 Environmental Process, without first terminating it.

The two processes cannot exist concurrently, because of duplication, and the requirement for the first study to be completed. The first study has been fully funded by the U.S. Congress and the latter process has not.

The second process proposes to change the course of Ballona Creek, and to dredge and fill wetlands, prior to the completion of the first process and before the Corp can report its recommendations back to Congress.

Furthermore, the second process proposes to reintroduce tidal flow to a freshwater wetland system that was not historically connected to the to the ocean to the degree the new process implies.

The National Oceanic and Atmospheric Administration warned against this project, as it would destroy valuable upland habitat.

The U.S. Clean Water Act designates four separate Section 303(d) Impaired Waterways that are present.

- Marina del Rey
- Upper Ballona Creek
- Ballona Creek Estuary
- Ballona Wetlands

The 2012 Notice proposes to divert one Impaired Waterway into another. It is illegal to further impair a waterway that is already impaired.

The resolution reads as follows and represents the Sierra Club official stance on both of the aforesaid environmental processes.

RESOLUTION

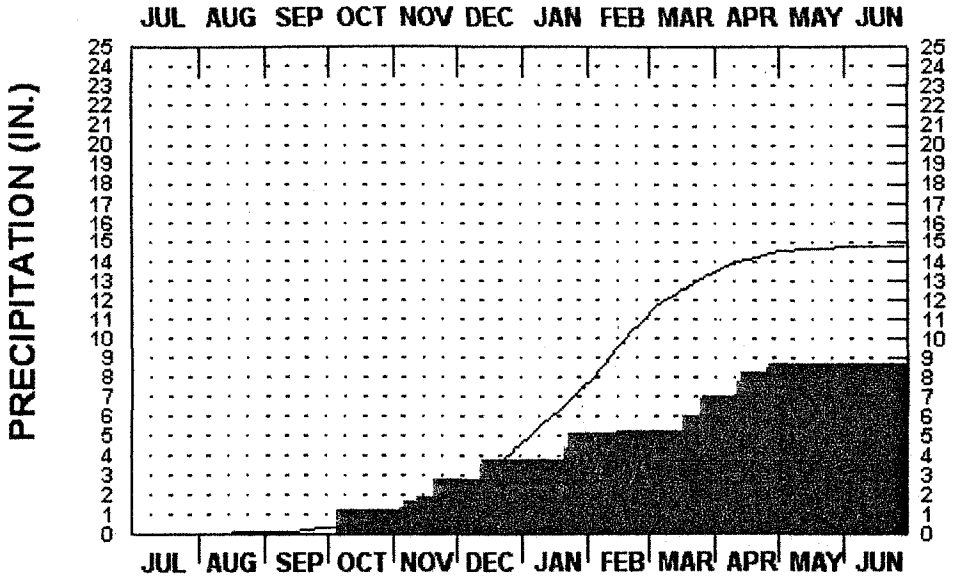
Whereas, the Airport Marina Regional Group of the Angeles Chapter Sierra Club has jurisdiction over Marina del Rey,

Whereas, The Club supports National Planning for Environmental Restoration, Recreational Boating, Storm Damage Reduction, and is Supportive of other purposes the Congress of the United States intended for Marina del Rey such as a youth hostel and camping facilities.

Whereas, The U.S. Army Corp of Engineers Environmental Impact Statement process noticed in the Federal Register in 2005 supports the same aforesaid purposes that the Sierra Club supports,

Therefore, be it resolved by the Airport Marina Regional Group, Angeles Chapter of Sierra Club, supports the completion of the 2005 Environmental Review process Noticed in the Federal Register to conduct a review of Marina del Rey: September 20, 2005 (Volume 70, Number 181) [Notices] [Page 55116-55117]

END



The Sierra Club supports a full range of alternatives for the restoration, which is called for in the 2005 Notice for Environmental Impact Statement pursuant to the National Environmental Policy Act. The Sierra Club does not support a limited range of alternatives as proposed by the 2012 Notice for an Environmental Impact Statement.

Sincerely,

Joe Young

Joe Young, Chair

SEASON-TO-DATE DOWNTOWN LOS ANGELES PRECIP FOR 2011-12 (BARS) VERSUS LONG-TERM AVERAGE (LINE TRACE)

'er the role of propofol, and
)th sides tried to use the
stimony of emergency
)om doctors to launch
)ening salvos.

Deputy Dist. Atty. David
'algren quizzed Cooper
)out the appropriate uses
'propofol.

"I've never seen or heard
'it used in a home setting, if
)at is what you are asking,"
)e said. She said that the
rug can endanger the respi-
)tory system and that hos-
)tal procedures require "a
erson whose only job is the
)onitoring of the sedation."

On cross-examination,
efense attorney J. Michael
lanagan asked her to con-
der a hypothetical situa-
)n that mirrored Murray's
)sertion to police that he
)ve Jackson only a small
nount of propofol — 25
lligrams — more than an
)ur before he stopped
eathing.

"If the patient was awake
d completely normal and
t sedated after the medi-
)ion [wore off] and then
)a subsequent problem...
ould not think it was re-
)d," she said.

But when Walgren asked
ether her conclusion was
)ed on the doctor's being
thful about the amount
ropofol he had given, she
l it was.

CURRENT REFERENCE REPORT/LETTER(S)	REPORT NO.	DATE(S) OF DOCUMENT	PREPARED BY
Methane Report	10610-22844-110.RT.GAS	10/14/98	Camp Dresser McK.
``	``	01/13/99	``

The referenced reports concerning recommendations for mitigation of methane gas for the First Phase of the Playa Vista development have been reviewed by the Grading Section of the Department of Building and Safety. The areal limits of the First Phase are shown on Figure 2-3 of the report. Most of the area is south of Ballona Creek and northeast of Lincoln Bl.

According to the report, significant levels of methane gas were detected on the southwest portion of the subject area. The report indicates that only buildings within the area of observed high concentrations of gas are recommended for mitigation measures. It is the experience of the Department that methane gas can be highly migratory and transient. Therefore, limiting mitigation measures to the area of high gas concentrations observed during the field investigation does not appear acceptable at this time. The reports are acceptable, provided the following conditions are complied with during site development:

1. All construction in the First Phase area shall comply with section 7104.2 of the Building Code and MGD #92.

2. Based upon the information in the report, the Second Phase area will also require mitigation for methane gas.

3. The use of a membrane or sealing materials other than 60 mil HDPE will require an approved Research Report.

4. The Gas Control Specialist shall review and approve the detailed plans prior to the issuance of any permits.

5. Installation of the gas mitigation devices shall be done under the observation and inspection of the Gas Control Specialist and the Department.

PEER REVIEW
METHANE GAS CONCERNS FOR THE PLAYA VISTA PROJECT

First, let me take this opportunity to thank you and Victor Penera for selecting me as the Peer Reviewer for this very high-profile project. It is gratifying to be selected, and even more to be appreciated, particularly, after completing our initial, cursory evaluation of the facts in this case. Our meeting on Tuesday with Bruce Harrigan and Tim Connors of Playa Capitol, went as well as could be expected under the circumstances. I can't imagine a much more difficult technical and legal situation for the City of Los Angeles.

In fairness to all parties and in spite of all the work completed thus far, there is a great deal of very important information regarding the sources of subsurface methane that have not been adequately developed for proper scientific judgments to be completed regarding the safety aspects of the planned development. My associate, Rufus LeBlanc and I spent most of the morning outlining the type of sampling approach that should be required to determine the necessary information. This objective is made considerably more difficult by the size of the project (over 1000 acres) and the variety of potential methane sources known to exist within the project area. This is compounded by the fact that the Playa Vista site in the City of Los Angeles will be subjected to significant earthquakes in the future that can alter both the subsurface methane concentrations migrating from subsurface sources and
degrade any methane mitigation system. As you know, the problem is far from trivial.

Also included with this letter is our first invoice for work completed in June. I divided the invoice into two work segments because the initial instructions by Bruce Harrigan to our Sales Manager,

Frank Levy were considerably more restrictive than those issued by you and Victor Penera in our initial conversations. We reviewed the initial report along with the list of questions and comments that were sent to us and found that we could not render a fair nor honest judgment based on the very limited information initially received. Additional reports sent by the City of Los Angeles, along with several published papers (obtained from Rice Library and our archived DOG files) were used to verify and add to the information that was required for us to write a brief summary (letter, June 24,1999) report on the status of the project. Our previous summary report stands and still represents our main views and data needs, that must be addressed in order to successfully conclude this project.

Enclosed please find a progress report which focuses on the methane sources and our initial recommendations for obtaining the data required to solve the problems. A regional methane map based on all available shallow gas data is included for your review.

Sincerely,
EXPLORATION TECHNOLOGIES, INC.

CURRENT REFERENCE REPORT/LETTER(S)	REPORT NO.	DATE(S) OF DOCUMENT	PREPARED BY
Methane Report	-	12/15/99(revised)	Sepich Assoc.
Peer Review Report	-	12/14/99	Exploration Tech.

PREVIOUS REFERENCE REPORT/LETTER(S)	REPORT NO.	DATE(S) OF DOCUMENT	PREPARED BY
Department letter	27706-01	11/19/99	Bldg&Safety

The referenced reports concerning methane mitigation and monitoring systems for the Fountain Park Apartments and the Marketing Pavilion have been reviewed by the Grading Section of the Department of Building and Safety. Sepich Associates is the methane gas consultant for Playa Vista Capital and has provided the recommendations for the monitoring and mitigation of methane gas. Exploration Technologies, Inc is the Peer Reviewer for the City of Los Angeles, Department of Building and Safety. Based upon the acceptance of the plans and report by the Peer Reviewer, the Department is accepting the recommendations for the monitoring and mitigation of methane gas on the site.

The Fountain Park Apartments and the Marketing Pavilion methane mitigation shall conform to all requirements specified in Chapter 71 of the Building Code and MGD#92, as stipulated for areas designated as a "High Potential Methane Zone". The methane monitoring system is to be operated continuously, in addition to data gathering and reporting, during occupancy of the buildings. Furthermore, all building construction shall comply with the following supplemental requirements. The report is acceptable, provided the following conditions are complied with during site development:

1. An affidavit shall be filed with the County Recorders Office, in which the owners state that they agree to take responsibility for contracting with a methane gas consultant to insure that the methane monitoring systems are functioning correctly and to submit a report

containing the results of the monitoring to the Department of Building and Safety and the Peer Reviewer, a minimum of every three months, until such time as it is agreed to revise this requirement.

2. Internet access to the methane monitoring data shall be provided to the Department of Building and Safety, Exploration Technologies, Inc and the Fire Department.

3. Additional soil gas survey and monitoring wells shall be required as deemed necessary by the Peer Reviewer; this shall be completed prior to the first footing inspection.

4. All of the abandoned oil wells on the Playa Vista Development shall be re-abandoned subject to the current standards of the State of California Department of Oil, Gas and Geothermal Resources; the Certificate of Occupancy for the initial buildings on this site shall be withheld until verification of complete abandonment has been provided.

5. Obtain clearance from the Fire Department for the methane gas design and monitoring system, and other environmental issues.

6. Obtain clearance from the Department of Public Works, Bureau of Engineering, for H2S, BETX and other environmental issues.

7. The methane mitigation design includes the capability, or option, of changing the passive methane mitigation system to an active methane mitigation system. The system shall be converted to an active system when the level of methane reaches 75 percent of the L.E.L. in the monitoring system located under the building foundation vapor barrier.

8. No excavations shall be made below the groundwater table.

9. Prior to pumping of any groundwater, a supplemental report shall be submitted to the Grading Section for approval.

10. Installation of the recommended monitoring and mitigation systems shall be inspected by the methane gas consultant for Playa Vista Capital and the Building Inspector.

11. All recommendations of the report which are in addition to or more restrictive than the conditions contained herein shall be incorporated into the plans.

12. The methane gas engineer shall review and approve the detailed plans prior to issuance of any permits. This approval shall be by signature on the plans which clearly indicates that the gas engineer has reviewed the plans and that the plans include the recommendations contained in their reports.

13. A continuous gravel/clean sand mixture blanket shall be provided beneath all building slabs. This blanket shall be a minimum of 12 inches in thickness. De-watering pipes, if any, shall be located in trenches beneath the blanket.

14. Methane roof vent risers shall be enclosed in a one-hour fire rated enclosure.

15. Fire Sprinklers shall be provided throughout the Building.

16. An emergency power supply shall be provided for all methane gas ventilation and monitoring systems.

17. Incorporate the mitigation/ventilation systems into the final building plans.

18. Obtain approval for the specified 60mm thick impermeable membrane.

19. Building plans shall include complete details for vent pipes through footings.

20. Obtain plan check approval from Electrical, Mechanical and Fire Department.

AN EVALUATION OF GAS MIGRATION AND ENVIRONMENTAL HAZARDS EXISTING AT THE PLAYA VISTA PROJECT

BY: Dr. Bernard Endres, Ph.D.
Oil & Gas Consultant

DATE: June 7, 2000

LOCATION: City of Los Angeles,
City Hall

ISSUE #2

- CAN A MONITORING AND MITIGATION SYSTEM BE DESIGNED AND OPERATED WITH 100% RELIABILITY OVER THE LIFETIME OF THE PROJECT?

- A GAS MEMBRANE THAT WILL RESIST THE RUPTURE FORCES OF LIQUEFACTION DURING AN EARTHQUAKE.

- OPERATION OF SENSORS AND EQUIPMENT IN A CORROSIVE AND H2S ENVIRONMENT

- COSTS OF MAINTAINING THE SYSTEM OVER THE PROJECT LIFETIME.

ISSUE #4

- THE CITY OF LOS ANGELES METHANE ORDINANCE IS NOT ADEQUATE TO DEAL WITH THE GAS AND GEOLOGICAL HAZARDS EXISTING AT PLAYA VISTA

- LIQUEFACTION SEISMIC HAZARD ZONE REQUIRES SPECIFICALLY DESIGNED GAS MEMBRANE BARRIERS.

- SENSORS AND MONITORING EQUIPMENT MUST OPERATE IN A CORROSIVE AND H2S ENVIRONMENT.

- NATIONAL ELECTRICAL CODE REQUIREMENTS FOR A GAS EXPLOSION RISK FROM ELECTRICAL SPARKS MUST BE COMPLIED WITH, INCLUDING GAS MIGRATION INFORMATION, IN ELECTRICAL VAULTS.

ISSUE #6

- AN EVALUATION OF THE SPECIAL PROBLEMS CREATED BY THE HIGHLY PERMEABLE 50 FOOT GRAVEL ZONE NEEDS TO BE PERFORMED.

- ALLOWS GAS TO BUILD TO HIGH PRESSURES FROM A RISING WATER TABLE.

- HIGH DEGREE OF GAS MOBILITY UNDER THE ENTIRE SITE, MAKING GAS LEVEL PREDICTIONS DIFFICULT, IF NOT IMPOSSIBLE TO MAKE WITH CONFIDENCE.

- HIGH SULFATE LEVELS GIVING RISE TO H2S PRODUCTION BY SULFATE REDUCING BACTERIA ALREADY VERIFIED AS PRESENT.

ISSUE #8

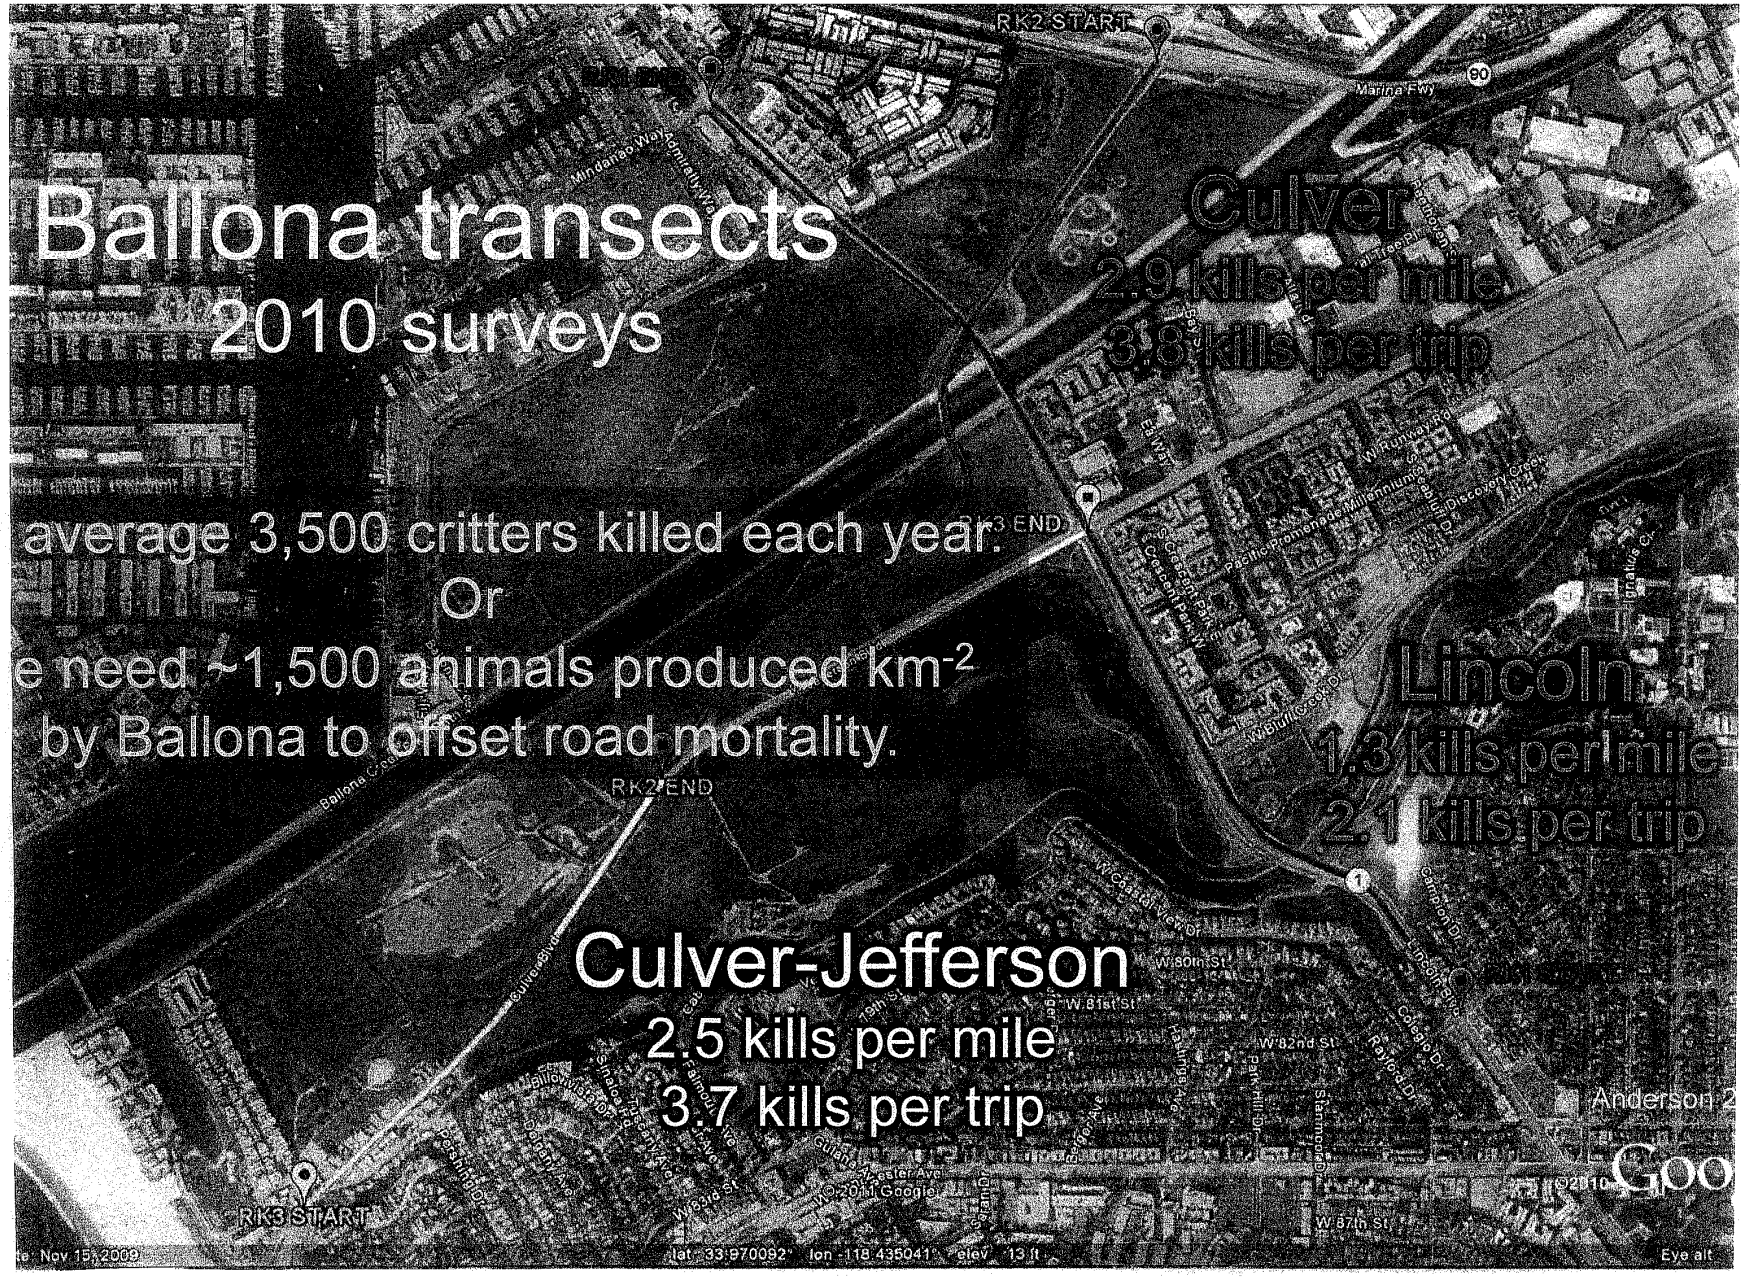
- AN EVALUATION OF THE GAS MIGRATION HAZARDS INTO THE SURROUNDING COMMUNITY

- GAS MITIGATION AND MONITORING IS REQUIRED FOR THE SURROUNDING RESIDENTIAL AND COMMERCIAL BUILDINGS, INCLUDING U.S. REGIONAL POST OFFICE.

- THE CITY NEEDS TO URGENTLY EVALUATE THEIR PERMITTING PRACTICES FOR HOUSING CURRENTLY BEING CONSTRUCTED OVER GAS WELLS SOLD BY SOCALGAS (INCLUDING SALES NOT APPROVED BY THE PUBLIC UTILITIES COMMISSION).

ISSUE #10

- EVALUATE THE SUBSIDENCE HAZARDS POSED BY THE LONG TERM FLUID PRODUCTION BY SOCALGAS AND ITS PREDECESSORS



- NEARLY 2 FEET OF SUBSIDENCE IN 1970, AND INCREASING.
- NO SUBSIDENCE MONITORING SINCE 1970.
- STRESS AND STRAIN BUILD-UP WILL CAUSE INCREASED GAS MIGRATION ALONG FAULTS AND COULD TRIGGER EARTHQUAKES ALONG THESE FAULTS.
- IMMEDIATE IMPLEMENTATION OF MONITORING IS REQUIRED, INCLUDING FOR MICRO-SEISMIC ACTIVITY, TO PROTECT AGAINST GAS MIGRATION AND DAMAGE TO COASTAL STRUCTURES.

ISSUE #12

- EVALUATE THE EXTREME DANGER POSED BY THE REPRESSURIZATION OF THE UNDERGROUND GAS STORAGE FIELD AND PLAYA DEL REY OILFIELD

- INCREASED RISK OF GAS MIGRATION IN HUGE QUANTITIES ALONG THE LINCOLN BOULEVARD FAULT AND ALONG WELL BORES.

- FAULT BLOCK 13-1, LOCATED AT THE BASE OF THE LINCOLN BOULEVARD FAULT, HAS REPRESSURIZED FROM 1700 PSI TO APPROXIMATELY 2400 PSI IN RECENT TIMES.

Questions, Comments, and Recommendations by Douglas Fay on the proposed Ballona Wetlands Restoration Project NOI

1. Corps Release no. 12-015 Posted 9/26/12 Re: Termination of existing process at the request of the Santa Monica Bay Restoration Commission (SMBRC), a Joint Power Authority with the County of Los Angeles (County).

Question: Will the termination of the existing feasibility study and accompanying EIS result in a project consistent with a comprehensive Santa Monica Bay Restoration Plan (SMBRP), or fragment the process?

Comments: My concern, and the concern of others, is the 2008 SMBRP is a significantly flawed document, with minimal public input. I have made several attempts to address my concerns publicly that have been denied by individuals in the SMBRC leadership rolls, the SMBRC Governing Board, members of the Santa Monica Bay Restoration Foundation (SMBRF), and submitted documentation to the California Coastal Commission (CCC).

A (partial) document analysis I prepared of the 2008 SMBRP addressed to the SMBRC Governing Board was submitted to Scott Valor. Months later Mr. Valor told me he did not give the time critical document to the Governing Board members. This is only one example of several deliberate and documented actions to exclude and deter me from this process.

Also, the SMBRC has recently approved the development of Parcel OT, a parking lot adjacent to the Oxford Lagoon a.k.a. the Oxford Retention

Basin and the Oxford Retention Basin Multi-Use Enhancement Project, both of which are under the County's control. The Oxford Lagoon is part of the historical Ballona Wetlands that is primarily used for urban flood control discharge and retention prior to entering the Marina Del Rey (MDR) harbor through mechanical gates.
The Oxford Retention Basin Multi-Use Enhancement Project increases/enhances public access, which in turn reduces terrestrial habitat value. There is no significant aquatic habitat value due to the drastic variation of salinity levels that are catastrophic to most marine animals. This shows that their actions are based on politics, not science and sound restoration principles.
Current management practices of the Oxford Lagoon contradict SMBRP Goals and Objectives A. PRIORITY ISSUE: WATER QUALITY Goal 1: Improve water quality through treatment or elimination of pollutant discharges, Goal 2: Improve water quality through pollution prevention and source control, B. PRIORITY ISSUE: NATURAL RESOURCES Goal 4: Create and support policies and programs to protect natural resources.

Questions: Are these acceptable practices in the eyes of the Corps and CDFG? Please explain and elaborate if needed.

Are other documents being censored without the Governing Board's knowledge jeopardizing their abilities to evaluate and vote on proposed projects? Please explain and elaborate if needed.

What policies and programs to protect natural resources have been created by the SMBRC and implemented by government agencies and municipalities within the Santa Monica Bay watershed? Please explain and elaborate if needed.

What is the "commission's proposed restoration project"?

Comment: I do not see a link to a website in this document, or have detailed knowledge of the commission's proposed restoration project, which makes it difficult, if not impossible to comment on with an acceptable degree of accuracy.

Recommendation: Reverse your decision to accept the request by the SMBRC and proceed with the existing 2005 process.
Provide ample opportunities for the public to be educated and engaged in drafting a restoration project through the existing process.
Assure the public that the non-profit Santa Monica Bay Restoration Foundation (SMBRF) and SMBRC will not be controlling the process.

Investigate any wrong doings to members of the public including, but not limited to, misappropriation of public funds.

2. Corps Public Notice: SPL-2010-1155, Date: August 24, 2012

SUMMARY:

Comment: Historical maps show breaching of sand and full tidal exchange in the Del Rey Lagoon area of the coastline.

Questions: Is the restoration of this historic exchange in the proposed Ballona Wetlands Restoration Project (BWRP)?

If, and I quote, "The proposed project is intended to return the daily ebb and flow of tidal waters", then why wouldn't the first step to a restoration be limited to restoring the historical breaching?

What is the percentage of the proposed project's intended return of daily ebb and flow of tidal waters compared to historical levels within the wetlands?

Comment: I attended a lecture by Dr. Travis Longcore on May 22, 2012 entitled, "Closure Dynamics of Southern California Estuaries and Implications for Restoration."

Recommendation: View this lecture, reference it in the EIS/EIR, and answer the following questions. If you cannot easily obtain a copy, I will provide a copy upon request.

Questions: Do you agree that the historical photos, maps, and plant life show that the Ballona Wetlands were primary a fresh water to brackish wetlands? Please explain your answer and elaborate if needed.

Is there any historical data that shows the Ballona Wetlands ever had full tidal flow (ocean levels of salinity) throughout the proposed project area (approximately 600 acres)? Please explain your answer and elaborate if needed.

Is there any historical data that shows natural berming/levees adjacent to the Ballona Creek and around the parameter of the proposed project? Please explain your answer and elaborate if needed.

Is preservation of the historical Ballona Wetlands a concern? Please

explain and elaborate if needed.

SUPPLEMENTARY INFORMATION:

Comment: This document states, "The Corps intends to prepare a joint EIS/EIR to assess the environmental effects associated with the proposed project. CDFG is the state lead agency for the EIR pursuant to the California Environmental Quality Act (CEQA)."

Questions: Is the Corps the Federal lead agency for the project, the EIR, or just the EIS?

Is CDFG the State lead agency for the project, the EIS, or just the EIR?

If CDFG is the lead agency, are they required to act as stewards of the public?

If so, why are the SCC, SMBRF, SMBRC, DRP, and others, appearing to be dominating all aspects of the proposed BWRP process with limited/controlled public input?

If the Corps and CDFG intend to jointly prepare a Draft EIS/EIR for the proposed BWRP, is one Scoping Meeting all that is legally required?

Comment: The Scoping Meeting(s) schedule was limited to 3 hours on 1 day. I was unable to attend due to a conflicting work schedule. Scott Valor told me the minimum that State law requires will be all that is provided throughout this process. I'm assuming this is true if the SMBRF, that Mr. Valor is associated with, is influencing the process.

Questions: If public participation is critical then shouldn't there have been more than one Scoping Meeting?

Comment: This document states, "7. Availability of the DEIS/EIR. The DEIS/EIR is expected to be published and circulated in late 2012. A public hearing will be held after its publication to field comments on the document."

Questions: Is one public hearing on the DEIS/EIR sufficient?

Will it be limited in time?

Will there be opportunity for question and answer sessions?

Will speaker time during public comment be limited?

If public participation is critical then shouldn't there be more than one Public Hearing?

1. Background.

Comment: The background description is limited and vague.

Question: Where are the "attached figures"?

Comment: There were not any attached figures in the Corps SPECIAL PUBLIC NOTICE download.

Questions: If the Ballona Creek a.k.a. Ballona Flood Control Channel is "a component feature of a federal flood risk management project," could a project increase flood risk?

Who owns the Ballona Creek/Flood Control Channel portion that bisects the State owned Ballona Wetlands?

Who is legally responsible for liabilities associated with altering the alignment of the Ballona Creek/Flood Control Channel?

Will there be special laws and/or regulations drafted specifically for the proposed project?

Has a Federal/State wetlands project partnership similar to this proposed project been completed before?

Comment: If so, please describe with references.

Recommendations: Study and describe all of the water bodies associated with the Ballona Wetlands and the development adjacent to the proposed project and adjacent water bodies, including, but not limited to, industrial, commercial, residential, recreational, flood plain, polluted waters, and Native American data.

Study and describe how an alteration of what I am assuming are Federal waters/land/boundaries with State land/waters/boundaries will be conducted including, but not limited to, jurisdiction, law enforcement, management, maintenance, funding and liability.

2. Project Purpose and Need.

Comments: Regarding the statement, "In addition, the wetland habitat and natural hydrological functions in the area have been substantially degraded."

Questions: How have the natural hydrological functions been substantially degraded? Please explain your answer and elaborate if needed.

Who is responsible? Please explain your answer and elaborate if needed.

Is the degradation of the natural hydrology of the project area ongoing? Please explain your answer and elaborate if needed.

If so, is the degradation legal or illegal?

Comment: Regarding the statement, "Restoration of coastal wetlands is needed in order to increase available nursery and foraging habitat for wildlife and to provide recreational and educational opportunities to the public."

Questions: Will a comprehensive plan including all coastal waters and water sources originating inland be more effective at maintaining and increasing biodiversity than limiting the scope of study to coastal wetlands within the proposed project site? Please explain your answer and elaborate if needed.

What does CEQA require?

What are the recreational and educational opportunities proposed?

Comment: I'm told my grandfather and father hunted ducks in the Ballona Wetlands area.

Questions: Will regulated hunting and fishing be allowed publicly in the proposed project area?

Will Native Americans be allowed to hunt and fish in the proposed project area? Please explain your answer and elaborate if needed.

Comment: Regarding the statement, "A restored, optimally functioning wetland would also benefit the adjacent marine environment and enhance

the quality of tidal waters."

Questions: How does a wetland enhance the quality of tidal waters?

Does the proposed project intend to introduce polluted water sources into the wetlands?

How do polluted waters including, but not limited to, waters laden with synthetic chemical compounds affect the health and reproductive cycle of living organisms? Please explain your answer and elaborate if needed.

Are there endangered or threatened species within and/or adjacent to the proposed project area?

Would the proposed project need maintenance and funding to remove introduced pollutants in perpetuity? Please explain your answer and elaborate if needed.

Comments: Not mentioned in the Project Purpose and Need is the need, or should I say intent, to construct flood and tsunami control levees in an effort to mitigate and protect recently developed structures. Also, the significant amount of earth/soils, that are proposed to be moved, to build the massive levees, will significantly increase the amount of ocean waters, and thereby decrease the need to restore fresh water sources that have been depleted.

Questions: Do any of the proposed project alternatives appear to be flood control mitigation for the Playa Vista development? Please explain your answer and elaborate if needed.

If so, is it an acceptable practice, both morally and financially, by the Corps and CDFG to move forward with an NOI when the preferred restoration project appears to be based on flood control mitigation for adjacent lands?

What is the cost incurred to date to develop what I'm assuming is the preferred proposed project alternative? Please explain your answer and elaborate if needed.

How much of the expenses to date have gone to, or through, CDFG? Please explain and elaborate if needed.

Are you aware that a Santa Monica Bay Restoration Account (SMBRA)

exists?

Has any money gone in or out of the SMBRA for this project, or any other project that you are aware of?

Is the proposed restoration funded by grants? Please explain and elaborate if needed.

Does CDFG have detailed accounting records for all financial activities related to the BWRP? Please explain and elaborate if needed.

Are there financial accounting records and/or audits available for public viewing?

If so, how is it accessed? Please explain and elaborate if needed.

If not, why? Please explain and elaborate if needed.

Comment: Regarding the statement, "The purpose of the project is to restore ecological functions of the site, in part, by enhancing tidal flow." When the County introduced/increased urban flood control waters into the Oxford Lagoon, removed sources of fresh water, and manually maintained tidal flushing, the migratory bird population dropped significantly. I have witnessed Mallard ducklings expire in the MDR harbor due to lack of fresh water access.

Question: How do you enhance migratory bird habitat by enhancing tidal flow?

3. Proposed Action.

Comment: Regarding the statement: "CDFG is proposing a large-scale restoration of the Ballona Wetlands Ecological Reserve. The proposed project entails restoring, enhancing, and establishing native coastal wetland and upland habitats in the approximately 600-acre Ballona Wetlands Ecological Reserve."

Questions: Is CDFG proposing a large-scale restoration, or is the large-scale restoration proposal coming from the SMBRF and/or other organizations? Please explain and elaborate if needed.

Why is the State Coastal Conservancy (SCC) taking the lead in funding for planning and restoration of the CDFG property? Please explain and

elaborate if needed.

What is the roll of California Department of Parks and Recreation (DPR)?

Will CDFG control the proposed "Long-term operations and management activities including inspections, repairs, clean-up, vegetation maintenance, and related activities," or will they be subcontracted?

If subcontracted to who will they subcontracted to and why? Please explain and elaborate if needed.

Comment: The 2008 SMBRP states, "Determine preferred alternative by 2009."

Question: Does CDFG have a preferred alternative?

Does the SMBRC have a preferred alternative? Please explain and elaborate if needed.

If so, why hasn't it been released to the public so we can accurately comment on the NOI?

If a draft has been released, where can I obtain a copy?

4. Alternatives Considered.

Comment: Regarding the statement, "The feasibility of several alternatives is being considered and will be addressed in the DEIS/EIR."

Questions: What are the alternatives and where did they come from? Please explain and elaborate if needed.

Is the Proposed Ballona Wetlands Restoration Plan (BWRP)(Draft), Prepared in conjunction with the Ballona Wetlands Land Trust, Save Ballona Wetlands, and Rimmon C. Fay, Ph.D. dated June 21, 1995, submitted to the Corps, County, and City of Los Angeles included in the proposed alternatives? Please explain and elaborate if needed.

Is it a document that both the Corps and CDFG have in their possession and has been studied by staff biologists and engineers? Please explain and elaborate if needed.

Recommendation: If not, obtain the BWRP draft document dated June 21,

1995. (I have a copy if needed) Study and describe the viability of implementing this alternative with acknowledgement of current conditions: ownership, development, etc.

5. Scoping Process.

Comments: The Scoping Meeting was conducted on August 16, 2012 from 4:00 to 7:00 p.m. One 3 hour meeting was all that was provided. Regarding the statement, "providing useful information such as published and unpublished data, and knowledge of relevant issues and recommending mitigation measures to offset potential impacts from proposed actions."

Questions: What is being done to improve the diminishing water quality within the MDR harbor? Please explain and elaborate if needed.

What is proposed project plan and/or mitigation for being impacted by poor water quality, pollutants, and invasive species originating from within the MDR harbor? Please explain and elaborate if needed.

How many industrial dischargers are permitted into the Santa Monica Bay? Please explain and elaborate if needed.

What are they reportedly discharging? Please explain and elaborate if needed.

What are the locations of discharge? Please explain and elaborate if needed.

What is the reported volume of discharge daily/annually? Please explain and elaborate if needed.

What mitigation measures are in place to ensure there is no negative impact to water quality, and biological diversity and quantities? Please explain and elaborate if needed.

Are there any legal discharge permits issued anywhere within the Ballona Creek Flood Control Channel (BCFCC)? Please explain and elaborate if needed.

Have there been any reported accidental spills into the BCFCC within the past 10 years?

If so, how many and what was spilled? Please explain and elaborate if needed.

What are the specifics: date, time, estimated quantity, etc. and result: beach closures, number of days, etc.? Please explain and elaborate if needed.

What is the current biological assessment of the Ballona Wetlands? Please explain and elaborate if needed.

What is the current biological assessment of the Marina Del Rey harbor? Please explain and elaborate if needed.

What is the current biological assessment of the Del Rey Lagoon? Please explain and elaborate if needed.

What is the current biological assessment of the Oxford Lagoon? Please explain and elaborate if needed.

What is the current biological assessment of the Ballona Creek including all tributaries? Please explain and elaborate if needed.

What is the current biological assessment of the Venice Canals? Please explain and elaborate if needed.

What is the current biological assessment of the Santa Monica Bay? Please explain and elaborate if needed.

What was the annual historic high catch, combined recreational and commercial, in tons, taken from the Santa Monica Bay, include the year and as much data as possible including, but not limited to, variety of fish, shellfish, crustaceans, mammals, and value (adjusted)? Please explain and elaborate if needed.

What is the current annual catch, combined recreational and commercial, in tons, taken from the Santa Monica Bay, include the year and as much data as possible including, but not limited to, variety of fish, shellfish, crustaceans, mammals, and value? Please explain and elaborate if needed.

What plants and animals, both terrestrial and marine, are currently proposed to be restored and/or introduced to the above listed waterbodies directly related to the proposed project including, but not limited to, the

Ballona Wetlands, MDR harbor, Del Rey Lagoon, Oxford Lagoon, Ballona Creek flood control channel including all tributaries, the Venice Canals, and the Santa Monica Bay? Please explain and elaborate if needed.

What is the current percentage of annual take/catch, combined recreational and commercial, within the Santa Monica Bay, as a percentage of historical recorded highs? Please explain and elaborate if needed.

What is the estimated annual take/catch, combined recreational and commercial, within the Santa Monica Bay, increase over a 10 year period, with the currently proposed Ballona Wetlands Restoration project when completed? Please explain and elaborate if needed.

What is the annual consumption cost of seafood imported and sold within the Santa Monica Bay watershed? Please explain and elaborate if needed.

Would it be better for our local economy to reduce our dependence on imported seafood? Please explain and elaborate if needed.

Would implementing a comprehensive Santa Monica Bay Restoration Plan that strives to restore biomass to historical levels create a significant amount of new jobs in areas of, but not limited to, research, fisheries, aquaculture, education, scuba industry, hospitality, marine resources management, tourism, etc.? Please explain and elaborate if needed.

Have you read the 2008 SMBRP?

Are you aware of the fact that there is no mention of artificial reefs in the 2008 SMBRP?

Comment: 2 years ago I asked SMBRC Governing Board member and (then) HTB president Mark Gold a question about artificial reefs in the Santa Monica Bay? His reply was something to the effect of, "We didn't discuss them." A year later when I repeated what I thought I heard he corrected me saying something to the effect of, "No, the definition of artificial reefs!"

Questions: Does the Corps and/or CDFG have knowledge of artificial reefs in the Santa Monica Bay? Please explain and elaborate if needed.

Does the Corps (Federal) and CDFG (State) have a uniform definition for "artificial reefs" that can be included in the proposed project glossary of

terms? Please explain and elaborate if needed.

Are you aware of the fact that there is no language whatsoever in the 2008 SMBRP to do enhancement projects within the Santa Monica Bay, even though that it is worded into the mission statement of the SMBRF?

Are you aware of the fact that the majority of restoration projects funded by the SMBRC/SMBRF have been improperly classified as enhancement projects? Please explain and elaborate if needed.

Have pilot tide pools at varying depth, configurations, material, size, etc. within the existing Ballona Creek flood control channel to test the viability of removing the existing levees been proposed? Please explain and elaborate if needed.

Comments: I was invited by a member of the SMBRC to attend and participate in the annual Bay Watershed Council (BWC) working group to draft the annual work plan held on Feb. 12, 2012. When I arrived I was told I could not participate. SMBRF staff Mark Abrams was present and hired to prevent members of the public from participating in the working groups. I attempted to suggest the pilot tide pools during public comment while attending this humiliating experience.

This unacceptable behavior of members of the SMBRC/SMBRF that authorized and enforced this action completely contradicts the "Letter From the Director" SMBRC Executive Director Shelley Luce in the SMBRC Annual Report 2011 which states, "We are planning new workshops and other mechanisms for getting public input on the BRP and annual work plans."

Question: What actions will the Corps and CDFG take to assure the public that the behavior of this magnitude will not continue to occur throughout the proposed project process? Please explain and elaborate if needed.

Comment: Other actions that contradict sound science and restoration principles surround decisions made aware to me by Dr. Wang. Dr. Wang told me he did not read the Montrose Settlement Restoration Plan (MSRP). Specifically, Appendix A1 Construct Artificial Reefs and Fishing Access Improvements and Appendix A3 Restore Full Tidal Exchange Wetlands. There was $40 million in Federal MSRP grant money available in 1995.

Questions: Did the SMBRC and/or SMBRF apply for MSRP grant(s) for the

Ballona Wetlands and/or Santa Monica Bay projects? Please explain and elaborate if needed.

Did CDFG or any State agency apply for MSRP grant(s) for the Ballona Wetlands and/or Santa Monica Bay projects? Please explain and elaborate if needed.

Comments: Dr. Wang also told me the SMBRC did not propose/apply to incorporate the County's Parcel OT (the parking lot adjacent to the Oxford Lagoon) to expand the Oxford Lagoon which would have increased the viability of wildlife significantly. The County is planning to build a massive luxury senior living facility that will abut the Oxford Lagoon further reducing wildlife viability.
This action contradicts SMBRP B. PRIORITY ISSUE: NATURAL RESOURCES Goal 5: Acquire land for preservation of habitat and ecological services.

Question: Is development of vacant land adjacent to coastal wetlands that are compromised through management practices in the best interest of sound restoration principles?

Other actions that concern me are the Total Maximum Daily Loads (TMDLs), imposed by a Heal The Bay (HTB) lawsuit, that may not reflect natural occurring levels of waterways and waterbodies. For example, the TMDL approved for the Malibu Lagoon may be much cleaner than what naturally occurs within a healthy lagoon triggering an approval for a restoration project based on false and/or misleading information.

What is the scientific opinion of the Corps and CDFG on the establishment and enforcement of TMDLs that may not reflect naturally occurring water quality standards of all waterbodies and waterways associated with the proposed project? Please explain and elaborate if needed.

FINAL SUMMARY AND RECOMMENDATIONS

Why am I so concerned about the outcome of the historical Ballona Wetlands and Santa Monica Bay area you might ask?
I was born in Santa Monica, Ca at St. Johns Hospital in 1962 and raised on Howard Street adjacent to the railroad tracks and the Oxford Lagoon. There was so much wildlife present in the area when I was young. Dozens of ducks would land in our yard. Salamanders, lizards, and snakes could easily be found. Cancer crabs could be caught in the MDR harbor by the bucket full. Catching your limit of fish in the Bay seemed much easier. The

tidepools at Palos Verdes and Paradise Cove were abundant with life. Now 40 years later, the effects of urban development and associated pollution without sufficient mitigation have significantly compromised all life forms.

My father was Dr. Rimmon C. Fay, a second-generation Santa Monica Bay fisherman who, through education and experiences, became a leading expert of the Santa Monica Bay and California coastal pollution issues starting in the 1950s. His independence and contributions to environmental protection and education were epic, including his contributions to save the Ballona Wetlands.

With PhDs in Chemistry and Oceanography, countless California ocean dives, hours at sea, days on the beach growing up and fifty years as an ocean lifeguard, as owner/operator of Pacific Bio Marine biomedical research, supply & education, as a founding member of the CCC, and many more contributions worthy of honor and respect, Rim's input in the 1995 Proposed BWRP Draft deserves recognition.

I have a lifetime of experience learning from my father, have served on a land use advisory committee in Monterey County, CA, have several professional certifications in multiple fields including PADI Master Scuba Diver Trainer, Emergency First Response Instructor, ASE Master Technician, Toyota Expert Technician and a BAR Smog Technician License. I have traveled throughout the Pacific region, have hundreds of logged dives, survived the 2004 Asian Tsunami, and have ten years of experience with upper watershed management including over 500 hours of heavy equipment operation and maintenance.

My knowledge of the Santa Monica Bay may never eclipse my fathers. I do believe that I have a better general knowledge than most and have an exceptional ability to identify and fix problems that are obviously broken. The library of Dr. Rimmon C. Fay is in storage awaiting a location were it can be housed, digitized, and made available for all academia on a website. Valuable historical data pertaining to the proposed project may be in his library. Funding to make this information accessible has not been secured.

What are the additional recommendations and desired outcome that I would like to see for the Ballona Wetlands and Santa Monica Bay?

Strongly consider the history of the Tongva Native Americans and respect the current concerns of Johntommy Rosas. If he has registered the Ballona Wetlands as a Sacred Site, the massive alterations proposed should not be allowed in perpetuity. Any enhancements should be harmonious, based on time proven science independent of the SMBRC/SMBRF influence, and focused on restoring an ecosystem that is as natural and maintenance free

as possible.
Restore the historical levels of fresh water to the aquifer below the wetlands through natural recharge and/or injection wells.
Restore the historic levels of fresh surface water
Restore the native terrestrial animals to historical levels to the greatest extent possible including deer and bats.
Explore creating the habitat necessary to allow for greatest diversity of terrestrial animals with minimal change to existing conditions.
Ban domestic animals, especially cats and dogs, from the Ballona Wetlands and adjacent walking/viewing areas.
Install fencing and/or concrete barriers to prevent wildlife from entering roadways.
Install large culverts with solar lighting for animals to cross under existing roadways. Raise the roadways if needed to allow reasonable mobility.
Do not remove the Ballona Creek flood control levees.
Implement pilot test tidepools throughout the Ballona Creek flood control channel with varying designs, locations, and conditions.
Cut openings into the concrete of the existing Ballona Creek levees to allow for native trees to grow, providing habitat and shade for wildlife.
Do not consider opening the wetlands to full tidal flush until the source of ocean water is of the highest quality. The current water quality of the MDR harbor and Playa Del Rey nearshore waters are unacceptable at this time.

Research and implement restoring staff and funding to CDFG so that they truly are the lead agency in this process. I'm told that CDFG funding has been reduced which reduces their effectiveness to educate and enforce locally is reduced. I recently read where the non-profit Santa Monica Baykeeper were making transects across the Bay looking for illegal activity in the Marine Protected Areas (MPAs) in an effort to warn boaters of a potential CDFG citation. This behavior is not a cost effective way to manage marine resources.

Remove the SMBRF from this process. If they have research and recorded data through grant funding acquired from the public, this information shall be given to CDFG. Allowing a non-profit to have the amount of control and influence over State agencies and commissions, with limited public accountability, is not in the general public's or the environment's best interest including the Ballona Wetlands.

Implement partnerships with local educational institutions in an effort to recruit students from Kindergarten to College to participate in research, education, restoration, maintenance, monitoring and management programs, including SCUBA training and certification.

Create and nonpartisan independent review board with membership that is not financially associated to the proposed project and has term limits for members.

Make restoring the abundance and diversity of marine life in the Santa Monica Bay to historical levels a top priority. This can be achieved by:
Removing all forms of industrial pollution (thermal, sewage waste, and desalination brine) discharged directly into the Bay and ban in perpetuity.
Fully mitigating for all of the sand historically placed on the shoreline through natural rock and artificial reefing to replace the lost nearshore habitat.
Fully mitigating the sediment discharged from Hyperion in mid to deep waters through natural rock and artificial reefing to restore and possibly enhance the lost habitat diversity that biomass requires.
Establish and manage a significant amount of kelp forest in the Santa Monica Bay from El Segundo to north of the Santa Monica Pier.
Restore the historical breach to the Del Rey Lagoon.
Drastically change how the waters within the MDR harbor are managed including, but not limited to: mandatory nets on all docks to remove floating debris, developing and implementing a vacuum system for in-water boat bottom cleaning, and stronger enforcement of illegal spills.

IN CONCLUSION

My family has been in this process for three generations. My grandfather instilled the love and respect of nature and all that it has to offer to my father. My father shared that experience with me. And now I'm nurturing the values taught to me into my young son and daughter.

It was at my father's memorial that I promised Tom Hayden, the only politician to finally stand beside my father and fight for healing the Santa Monica Bay rather than treat it as a dumping ground. It was a surprise and pleasure to see him this morning in passing to say hello and thanks.

If there was one quote that sets the tone for why I'm fighting for the historical Ballona Wetlands it would be, "so preservation of a historic wetland is not a concern."
You'll find that quote on page 4 of the HTB letter to the CCC in support of the controversial Malibu Lagoon Restoration project.

Please judge wisely and favor restoring nature over alternatives influenced by huge sums of money and those that can easily lose their way.

Respectfully submitted,

10/23/12

Subject: Notice of Intent to Prepare a Draft Environmental Impact Statement/Environmental Impact Report for the Ballona Wetlands Restoration Project, City of Los Angeles and Unincorporated Los Angeles County, California

Dear Dr. Swenson:

We have reviewed the Notice of Intent (NOI) for the proposed Ballona Wetlands Restoration Project in the city of Los Angeles and unincorporated Los Angeles County, California. The proposed project will restore ecological functions within the 600-acre Ballona Wetlands Ecological Reserve (Reserve) by increasing tidal flow throughout the project area, removing invasive species, and planting native vegetation.

We offer the following comments and recommendations regarding project-associated biological benefits and impacts based on our review of the NOI and our knowledge of declining habitats and species within Los Angeles County. We provide these comments pursuant to our responsibilities under the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 *et seq.*), Endangered Species Act of 1973 (87 Stat. 884, as amended; 16 U.S.C. 1531 *et seq.*), and in keeping with our agency's mission to work "with others to conserve, protect, and enhance fish, wildlife, and plants and their habitats for the continuing benefit of the American people."

To facilitate the evaluation of the proposed project from the standpoint of fish and wildlife protection, we request the draft Environmental Impact Statement/Environmental Impact Report (DEIS/EIR) consider the following specific information:

1. *Project Purpose* – According to the NOI the purpose of the proposed project is to restore ecological function to the Reserve. In southern California the effects of fragmentation have been shown to decrease the number of resident bird species, decrease the diversity of small rodents, and decrease the diversity and cover of native plant species (e.g., Alberts et al. 1993; Bolger et al. 1991, Bolger et al. 1997; Soulé et al. 1988). In general, the ecological

function of habitat is correlated with it contiguity. As stated by the Ballona Wetlands Science Advisory Committee[1]:

> "Alternatives with larger, contiguous, areas of diverse estuarine wetland habitat are more likely to sustain populations of associated species. Alternatives with fewer roads, wider transitions and more channels would have a higher quality of wetland habitat because they would be more remote from noise, lights, cars, and other human impacts. Alternatives with larger areas of contiguous wetland would also have fewer impacts from, and require less active management for, invasive plant and animal species."

To maximize the benefit of the restoration project for rare and sensitive wetland species and to reduce the costs of management over the long term, we recommend available resources be directed foremost toward the creation of contiguous habitat and that project alternatives and phasing be prioritized accordingly.

2. *Species* – The DEIS/EIR should include quantitative and qualitative assessments of the biological resources and habitat types that will be impacted by the proposed project and its alternatives. To assist you, we are providing the enclosed list of federally listed endangered, threatened, proposed, and candidate species to consider in association with the proposed restoration project.

   The assessment of direct, indirect, and cumulative project impacts to fish and wildlife associated habitats should consider all facets of the project (e.g., construction, implementation, operation, and maintenance). In addition, the DEIS/EIS should consider the potential benefits of the proposed restoration project for each federally listed species that is known to occur or has the potential to occur in or adjacent to the project area from a regional perspective. For example, the tidewater goby (*Eucyclogobius newberryi*) is unlikely to occur in the project area due to the current lack of suitable habitat; however, the Recovery Plan for this species identifies the Reserve as a potential site for reintroduction should suitable habitat be restored (Service 2005). The California least tern (*Sternula antillarum browni*) currently nests on Venice Beach and forages in the Reserve. The establishment of an additional nest site within the Reserve, less than 1 mile from Venice Beach, would provide the terns with an alternative for when heavy predation pressure results in their abandonment from Venice Beach.

   The analysis of impacts to biological resources and habitat types should include detailed maps and tables summarizing specific acreages and locations of all habitat types, as well as an updated assessment of the number and distribution of all Federal candidate, proposed, or listed species; State-listed species; and locally sensitive species, on or near the project site that may be affected by the proposed project or project alternatives.

---

[1] Memorandum to the Ballona Project Management Team, dated October 15, 2008. Retrieved from: http://www.santamonicabay.org/BWRP/BWRP_Documents/Feasibility%20Report/SAC%20recommendation.pdf.

3. *Habitats* – When evaluating the extent of proposed habitats restored within the project area, the DEIS/EIR should consider the dynamic nature of estuarine habitat (e.g., fluctuations in the distribution and quality of habitat over time) over both the short term (due to fluctuations in annual rainfall) and the long term (due to sea level rise). Upper salt marsh and upland habitats should be provided as a refuge for wading birds such as light-footed clapper rail (*Rallus longirostris levipes*) during high tides and to support pollinators of salt marsh plants such as salt marsh bird's beak (*Chloropyron maritimum* subsp. *maritimum*). Establishment of habitat with gentle slopes throughout the project area will allow for wetland fish and birds to adjust to sea level rise gradually over time.

4. *Existing Infrastructure* – The proposed project area is currently bisected by the Ballona Creek flood control channel, Culver Boulevard, Jefferson Boulevard, and Lincoln Boulevard. To maximize the extent of continuous habitat, we recommend that flood control protection for the surrounding residential and commercial development be relocated to the outside edge of the project area. Roadways and utilities should be relocated outside of the project area or otherwise raised above the flood zone on causeways to reestablish hydrologic continuity throughout the project area.

5. *Public Access* – Improving public access to the site will increase educational opportunities within the Reserve and help to foster public appreciation for native fish and wildlife resources; however, with increased public access, the Reserve will be vulnerable to increased degradation associated with human-generated disturbance, particularly unauthorized recreational use. To minimize degradation of restored habitats, we recommend long-term management of the Reserve include: (1) Regular inspections of recreational facilities, fencing and adjacent habitat to identify maintenance needs; (2) control of unauthorized human access to habitat areas; (3) fence maintenance; (4) trash removal; and (5) restoration of habitats impacted by unauthorized public uses. The increase in public access should be balanced with anticipated funding available for long-term management of Reserve.

We appreciate the opportunity to comment on the subject NOI. If you have any questions regarding these comments, please contact Christine Medak of this office at 760-431-9440, extension 298.

Sincerely,

for Karen A. Goebel
Assistant Field Supervisor

Subject: addendum to Bigelow comment re Ballona Restoration

Hello Ms McCormick,

I emailed a comment to you on 10/22/12 stating my views on the proposed Ballona Wetlands restoration.

I forgot to mention that I am a board member of a local nonprofit organization devoted to creek issues, Ballona Creek Renaissance.

However, I am writing to express my own personal opinion only, and not as a representative of BCR.

thank you,
Michele Bigelow

Re: Public Notice / Application No. SPL-2010-1155 (Scoping Comments on Ballona Wetlands Restoration Project

To Ms. McCormick, Mr. Lawhead, and Dr. Swenson, and to whom it may concern:

Thank you for your attention to this comment on the so-called "restoration" project in the publicly owned portions of the Ballona Wetlands.

First, we need a good baseline from which to work. There must be:

a.) new thorough inventories and counts of species (as well as a thorough review of existing research) so we have a better idea of what biota may be lost depending upon which alternative is chosen;

(To elaborate here, there must be a range of alternatives, and all the alternatives must calculate as best they can which species would win and which species would lose under each alternative in the near, mid, and far away time frames.) **All species (and certainly the federal and state endangered, threatened, rare, and species of concern species) must be considered in terms of what severe habitat alteration would do to those species in the near, mid, and far term.**

b. a thorough study on the hydrology of the Ballona Wetlands ecosystem -- both current (partially examining "dewatering" operations at Playa Vista) as well as historic.
****

The cart seems to be ahead of the horse in this process. **There is mention of five "preliminary" alternatives already advised by some groups. THERE MUST BE A REASONABLE RANGE OF ALTERNATIVES TO ABIDE BY NEPA AND CEQA. Besides the No Action / No Project Alternative which always must be offered, it is likely all the other alternatives are small variations of a major grandiose rearrangement of the ecosystem -- which is inadequate to satisfy the necessity to have a reasonable range of alternatives.**

Can you name any other DEIS/EIR that did not have a formal public scoping hearing accepting recorded vocal input by the public? Also, can you name any other project that already had 5 alternatives developed even before the scoping phase of a project?
****

In the past decade, we have lost a serious amount of upland coastal prairie habitat in the Ballona West Bluff area -- now 114 luxury homes. Please **discuss species that live in or depend on coastal prairies and upland areas in the Ballona area**, and the general food chain such as what birds eat what mammals or seafood, etc. How will each action alternative impact the critters that still survive despite widespread development following rodenticide use? Discuss this in the near, mid, and far terms.

****

I note a map on the Santa Monica Bay Restoration website which shows habitat types and has a Coastal Conservancy logo at the bottom. It says at the bottom that the map was from October 20, 2011, but then it also said that the study and I suppose a map of "existing habitats" in the Ballona area was conducted in 2007.

For each alternative presented, I call either for larger maps one can open up next to each other to compare "existing habitat" noted by CDFG alongside the grandiose plans for habitat alteration in the Preferred Alternative and what habitat types you see at Ballona after the large public works project is completed. Color the sections on the map accordingly please. It would also be good to see habitat maps in various phases of the bulldozing / earthmoving.

Also, please indicate for as many species as possible where some species would go in the meantime during the massive earthmoving / bulldozing phases of the proposed project.

Obviously there are plans for years or even decades of work for so-called "Ballona restoration." **Please indicate not only what CDFG "existing habitat types" are for certain sections of Ballona, but what the habitat types would be for various phases of the earthmoving project, and what you hope the habitat types in the various areas will be at the end of the project.**

****

Please discuss in the DEIS/DEIR what access there will be to the publicly-owned areas at the Ballona Wetlands at various stages of the Ballona "Restoration" project.

Are there any plans associated with this project, or under any of the alternatives, to transfer jurisdiction and oversight for the area from current overseeing agencies to some other agencies? Please elaborate as to why or why not.

Was the CDFG overview of species and mapping of habitat types half a decade ago considered sufficient by a range of biologists, or is there disagreement as to the thoroughness or timing or other aspects of this overview?

****

Will there be any attempted relocation or scaring away of certain species during some major ground-moving phases of the Ballona so-called "restoration" project? **Will different protocol be followed for species on federal or state Endangered Species Act lists, as versus other resident or visiting species in the area?** We need responses relating to **rare plant species as well as birds and other kinds of critters** of the area. **Will rare plants be relocated prior to bulldozing, and how will they be cared for in the interim, and will they be returned to the vicinity they were in before the bulldozing phase of their area?**

****

The NOP seems to indicate that the Ballona Wetlands area is pretty worthless unless it undergoes a major so-called "restoration" alternative based on massive bulldozing. I note that the "intent" of the project is to "return the daily ebb and flow of tidal waters", "maintain freshwater circulation", and to "augment the biological and physical functions and services in the project area".

When considering various alternatives, consider the term "return" and substantiate with valid studies that the ebb and flow of tidal waters which will take place at Ballona upon completion of that alternative is actually returning to an earlier era. As far as "maintain(ing) freshwater circulation", I assume you are calling the very polluted water of Ballona Creek to be "freshwater", is this correct?

****

As far as #6 on page 6 of the NOP, it claims that "A public scoping hearing to receive input on the scope of the DEIS/EIR was conducted on August 16th, 2012". I have been to a lot of hearings, scoping and otherwise, and this was no hearing, but instead just a gathering of some folks by some easels to peer at a few maps. Thus, **there still is a need for an actual**

public scoping hearing to receive formal input into the record on the Ballona so-called restoration plan. When will this hearing occur, or will it occur? Has there ever been a "public scoping hearing" before which did not feature oral input by the public into what the scope of the study related to the project will entail? Who was the ultimate decisionmaker who decided not to accept formal vocal input by the public, and was that person pressured to allow as little public input as possible in the scoping phase?

****

I notice under the third bullet point under the Proposed Action mentions "providing flood risk management for Culver Blvd. and surrounding developed areas". **Please (in your DEIS/EIR) mention which parts of the project are proposed in order to achieve "flood control."**

The NOP acts like only after grandiose restoration will the Ballona area be important for migrating birds, etc. It is the largest coastal wetland in L.A. County currently, and provides important habitat for many species.

****

The most hopeful part of the NOP seems to be the part near the end that mentions that "Other alternatives that may be considered include restoring smaller portions of the 600-acre site, alternative designs that would provide differing amounts of various habitat types, and alternative designs for enhanced tidal flow." I STRONGLY URGE that the BEEP alternative (Ballona Ecosystem and Education Project) BE INCLUDED AS A FORMAL ALTERNATIVE in the DEIS/EIR.

Are the five preliminary alternatives which have been advised thus far all grandiose massive bulldozing alternatives, or do any consider smaller-scale projects perhaps impacting just a portion of the Ballona wetland complex?

Please discuss every person that was formally on any of the groups which advised the "five preliminary alternatives" and discuss their employer and possible financial interest either in planning or carrying out the grandiose restoration plan, in getting paid to "monitor" such a plan, as well as discuss direct and indirect links of these people to the Playa Vista development and related investors. Thus, every person on the Ballona Wetlands Working Group, Science Advisory Committee, and the Agency Advisory Committee involved with developing or preliminarily approving the five preliminary alternatives must be discussed in relation to employer and financial interest in the Ballona Wetlands vicinity.

****

It is disingenuous for the NOP to claim that "Restoration of coastal wetlands is needed in order" "to provide recreational and educational opportunities to the public." Apparently one group controls access to the site and except for token tours, has been severely restricting or prohibiting access even to key members of groups which worked to get the state to purchase (theoretically to protect) the western part of the Ballona wetlands. Thus, there could be plenty of education and recreation going on, but the buddies of developers want to monopolize such.

Is meeting federal Total Maximum Daily Load targets considered a purpose for the project? If so, admit it in the documentation.

The fifth bullet point in the NOP discusses "maintenance of existing levels of flood risk management for areas surrounding the Ballona Wetlands site." **Is a purpose of a large so-called "restoration" scheme to enhance protection from floods, or just to maintain existing levels?**

Page 4 of the NOP talks of "conservative estimates" of "cubic yards of excavation" and "cubic yards of fill placement". What are less conservative estimates for the amount of excavated material and fill placement to be moved under varying alternatives for this project at Ballona?

Is it legally proper to divert a polluted "impaired" body of water (Ballona Creek) into another polluted "impaired" body of water (Ballona Wetlands)?

Please keep me updated as to when and where the formal scoping hearing will be on this project, and keep me updated on other aspects of the so-called "restoration" project as well.

Sincerely yours,

Bruce Campbell

To: McCormick, Donna
Subject: Comment on Ballona Wetlands Restoration Project

To Donna McCormick:

Here are my public comments on the Ballona Wetlands Restoration Project:

1. I would like the project to consider raising Culver Blvd and Jefferson Blvd. to allow the restored wetlands to have more continuity and be contiguous. I have observed many dead animals and birds on Culver Blvd. If the street was raised, waters/land could flow underneath.

2. I would like to see species impact reports on all known species in the area currently. This should help guide the project to determine the best restoration. While some species may be displaced, it is good to have that information. Also, studies should be done on what the restoration hopes to bring to the area in terms of species so that a full cost/benefit, from a species level, can be done.

3. If the proposed preferred alternative (#5) is adopted, it is my understanding that this would require ongoing dredging to maintain the area. What would be the financial impact to the City of Los Angeles and the State of California to maintain this dredging? What would be the environmental impact of this dredging to plants and wildlife. What are the alternatives to the dredging?

4. What actions will be taken to ensure respectful treatment of native american burial grounds or other sacred sites?

5. What will impact of bulldozing be on the existing native plants and species? What are the alternatives to large-scale bulldozing and has a cost-benefit analysis been performed? How long will it take for the plants and wildlife to return to the area if they are dug up/displaced/destroyed by bulldozing or other large scale digging? Could a less disruptive restoration accomplish the same ultimate goal of a restored wetland habitat?

6. What will be the impact of the proposed large berms on species, habitat and the water flow? Why do they need to be so large? What % of the existing habitat to restored will be effectively unusable due to the large proposed berms?

7. I signed up for the SMBRC newsletter and to be on their mailing list on March 5, 2012 with a confirmation from Donna Tuttle that I would be included from then on. I have received NO information, NO newsletter and NO notification of this comment period deadline (October 23, 2012). I believe the public has a right to be informed of this public project and request that SMBRC be more forthcoming, transparent and inclusive of the public in this process.

Sincerely,

Natalie Carrere
ndcarrere@yahoo.com

and YES, I would like to be included on the SMBRC email mailing list, as I requested back in March.

To: Swenson, Daniel P SPL
Subject: Comments to NOI for Draft EIS/EIR- SPL-2010-1155 Ballona Wetlands Restoration Project due 10.23.2012

Ballona Wetlands is "an example of a wetland where tides are excluded by a tide gate (PERL, 1989, Boland and Zedler 1991, PERL unpublished data)" as stated in the book TIDAL WETLAND RESTORATION, A SCIENTIFIC PERSPECTIVE AND SOUTHERN CALIFORNIA FOCUS by Joy B. Zedler, Principal Author,1996.

The plans are to restore outflows, not inflows. There is no tidal influence. Flood risk would be from Sea-Level Rise or Tsunamis, not natural in nature. The storm drain aspect of this plan needs to be emphasized as the major thrust. Dredge and fill activities would need to be analyzed from sediment flows upland.

You would need to consider the Land Use in the Community Plans surrounding and/or contributing to Ballona. In the case of the Hollywood Community Plan, there is increased density and, consequently, anticipated increases in sediment flows because of the overbuilding. Those natural systems in the upland are ignored in this project, yet contribute to any drainage problem.

Sediment Management Plans in LA County are 100 years old and lack the foresight of anticipated capital costs and operation and maintenance costs.

We cannot even be assured that Earthquake Fault Mapping is current for the area.

We do not know the age and condition of pipelines and storm drains, both by the City of Los Angeles or the County of Los Angeles and their relationship to Ballona as an outfall. The NPDES MS4 permit, current and pending, are factors for the Draft EIS.

The factors listed in PRACTICAL PROXIES FOR TIDAL MARSH ECOSYSTEM SERVICES: APPLICATION TO INJURY AND RESTORATION by Charles H. Peterson, Kenneth W. Able, Christin Frieswyk DeJong, Michael F. Piehler, Charles A. Simenstad, and Joy B. Zedler from ADVANCES IN MARINE BIOLOGY, VOLUME 54 states:

Tidal marshes are valued, protected and restored in recognition of their ecosystem services:

(1) high productivity and habitat provision supporting the food web leading to fish and wildlife,
(2) buffer against storm wave damage,
(3) shoreline stabilization,
(4) flood water storage,
(5) water quality maintenance,
(6) biodiversity preservation,
(7) carbon storage and
(8) socio-economic benefits.

It is questionable whether this wetland restoration fits that criteria in such a highly urbanized area with continued plans for density and population growth. Would a restored nearshore environment reduce the effects of continued urbanization.

The Southern California Bight studies, which hold pollution close to shore, should be considered.

TMDL Storm Means data from the sub-watersheds should be analyzed as point sources versus Ballona as an end source. Again, aspects and inadequacies in the upland watershed should addressed including destruction/alteration of Ballona Creek such as the Echo Park Lake. Also, major projects such as Farmers Field (NFL Football Stadium) and its impacts on the Ballona Creek Watershed should be considered.

The Port of LA is included Ballona Creek in Wetlands Banking. Does this banking take precedence over Ballona itself.

Subject: Re: Proposed Ballona Wetlands Restoration Project questions

Dear Mr. Fay,

You are correct that the close of the public comment period for the Ballona Wetlands Restoration Project NOP/NOI is October 23rd, at 5 pm (the close of business). In response to your other questions:

- You can send your comments to me electronically, however, if you send them to Donna.McCormick@icfi.com both Dr. Swenson and I will receive them at the same time.

- The Department of Fish and Game will accept your comments if they are postmarked by October 23rd.

- Comments received during the NOP/NOI scoping process are not individually responded to, but are considered in the development of the draft EIR/EIS that is still to be developed. Under CEQA, these comments do not require formal responses, but will be included in the draft EIR/EIS for the public to review. Comments received in the course of public review of the future Draft EIR/EIS will have formal responses in the Final EIR/EIS.

Thank you for submitting comments on the project.

David Lawhead
Staff Environmental Scientist
CA Dept. of Fish and Game

>>> <douglaspfay@aol.com> 10/20/2012 8:16 PM >>>
Dear Dr. Swenson & Mr. Lawhead,

It is my understanding that the Comment Period on the proposed BWRP ends October 23, 2012.

At what time of day on October 23, 2012 does the Comment Period close?

Can I send comments to you electronically by email before the deadline?

Will postmarked by October 23, 2012 submissions by postal mail be accepted?

Will all of my questions asked at this time (NOI) be answered and mailed to me prior to the Draft EIS/EIR being prepared?

Will acknowledgement of my comments and proposed alternatives be mailed to me prior to the Draft EIS/EIR being prepared?

Will a complete list of all letters, comments and questions and your replies be posted and available online prior to the Draft EIS?EIR being prepared?

I'm somewhat familiar with CEQA, but not the NOI process. If you could briefly elaborate on the format of comments on the NOI that is best for you, I would appreciate your reply ASAP by Monday, October 22, as the imposed deadline is near.

Respectfully submitted,

Douglas Fay

Questions, Comments, and Recommendations by Douglas Fay on the proposed Ballona Wetlands Restoration Project NOI

1. Corps Release no. 12-015 Posted 9/26/12 Re: Termination of existing process at the request of the Santa Monica Bay Restoration Commission (SMBRC), a Joint Power Authority with the County of Los Angeles (County).

Question: Will the termination of the existing feasibility study and accompanying EIS result in a project consistent with a comprehensive Santa Monica Bay Restoration Plan (SMBRP), or fragment the process?

Comments: My concern, and the concern of others, is the 2008 SMBRP is a significantly flawed document, with minimal public input. I have made several attempts to address my concerns publicly that have been denied by individuals in the SMBRC leadership rolls, the SMBRC Governing Board, members of the Santa Monica Bay Restoration Foundation (SMBRF), and submitted documentation to the California Coastal Commission (CCC).

A (partial) document analysis I prepared of the 2008 SMBRP addressed to the SMBRC Governing Board was submitted to Scott Valor. Months later Mr. Valor told me he did not give the time critical document to the Governing Board members. This is only one example of several deliberate and documented actions to exclude and deter me from this process.

Also, the SMBRC has recently approved the development of Parcel OT, a parking lot adjacent to the Oxford Lagoon a.k.a. the Oxford Retention

Basin and the Oxford Retention Basin Multi-Use Enhancement Project, both of which are under the County's control. The Oxford Lagoon is part of the historical Ballona Wetlands that is primarily used for urban flood control discharge and retention prior to entering the Marina Del Rey (MDR) harbor through mechanical gates.
The Oxford Retention Basin Multi-Use Enhancement Project increases/enhances public access, which in turn reduces terrestrial habitat value. There is no significant aquatic habitat value due to the drastic variation of salinity levels that are catastrophic to most marine animals. This shows that their actions are based on politics, not science and sound restoration principles.
Current management practices of the Oxford Lagoon contradict SMBRP Goals and Objectives A. PRIORITY ISSUE: WATER QUALITY Goal 1: Improve water quality through treatment or elimination of pollutant discharges, Goal 2: Improve water quality through pollution prevention and source control, B. PRIORITY ISSUE: NATURAL RESOURCES Goal 4: Create and support policies and programs to protect natural resources.

Questions: Are these acceptable practices in the eyes of the Corps and CDFG? Please explain and elaborate if needed.

Are other documents being censored without the Governing Board's knowledge jeopardizing their abilities to evaluate and vote on proposed projects? Please explain and elaborate if needed.

What policies and programs to protect natural resources have been created by the SMBRC and implemented by government agencies and municipalities within the Santa Monica Bay watershed? Please explain and elaborate if needed.

What is the "commission's proposed restoration project"?

Comment: I do not see a link to a website in this document, or have detailed knowledge of the commission's proposed restoration project, which makes it difficult, if not impossible to comment on with an acceptable degree of accuracy.

Recommendation: Reverse your decision to accept the request by the SMBRC and proceed with the existing 2005 process.
Provide ample opportunities for the public to be educated and engaged in drafting a restoration project through the existing process.
Assure the public that the non-profit Santa Monica Bay Restoration Foundation (SMBRF) and SMBRC will not be controlling the process.

Investigate any wrong doings to members of the public including, but not limited to, misappropriation of public funds.

2. Corps Public Notice: SPL-2010-1155, Date: August 24, 2012

SUMMARY:

Comment: Historical maps show breaching of sand and full tidal exchange in the Del Rey Lagoon area of the coastline.

Questions: Is the restoration of this historic exchange in the proposed Ballona Wetlands Restoration Project (BWRP)?

If, and I quote, “The proposed project is intended to return the daily ebb and flow of tidal waters”, then why wouldn’t the first step to a restoration be limited to restoring the historical breaching?

What is the percentage of the proposed project’s intended return of daily ebb and flow of tidal waters compared to historical levels within the wetlands?

Comment: I attended a lecture by Dr. Travis Longcore on May 22, 2012 entitled, “Closure Dynamics of Southern California Estuaries and Implications for Restoration.”

Recommendation: View this lecture, reference it in the EIS/EIR, and answer the following questions. If you cannot easily obtain a copy, I will provide a copy upon request.

Questions: Do you agree that the historical photos, maps, and plant life show that the Ballona Wetlands were primary a fresh water to brackish wetlands? Please explain your answer and elaborate if needed.

Is there any historical data that shows the Ballona Wetlands ever had full tidal flow (ocean levels of salinity) throughout the proposed project area (approximately 600 acres)? Please explain your answer and elaborate if needed.

Is there any historical data that shows natural berming/levees adjacent to the Ballona Creek and around the parameter of the proposed project? Please explain your answer and elaborate if needed.

Is preservation of the historical Ballona Wetlands a concern? Please

explain and elaborate if needed.

SUPPLEMENTARY INFORMATION:

Comment: This document states, “The Corps intends to prepare a joint EIS/EIR to assess the environmental effects associated with the proposed project. CDFG is the state lead agency for the EIR pursuant to the California Environmental Quality Act (CEQA).”

Questions: Is the Corps the Federal lead agency for the project, the EIR, or just the EIS?

Is CDFG the State lead agency for the project, the EIS, or just the EIR?

If CDFG is the lead agency, are they required to act as stewards of the public?

If so, why are the SCC, SMBRF, SMBRC, DRP, and others, appearing to be dominating all aspects of the proposed BWRP process with limited/controlled public input?

If the Corps and CDFG intend to jointly prepare a Draft EIS/EIR for the proposed BWRP, is one Scoping Meeting all that is legally required?

Comment: The Scoping Meeting(s) schedule was limited to 3 hours on 1 day. I was unable to attend due to a conflicting work schedule. Scott Valor told me the minimum that State law requires will be all that is provided throughout this process. I’m assuming this is true if the SMBRF, that Mr. Valor is associated with, is influencing the process.

Questions: If public participation is critical then shouldn’t there have been more than one Scoping Meeting?

Comment: This document states, “7. Availability of the DEIS/EIR. The DEIS/EIR is expected to be published and circulated in late 2012. A public hearing will be held after its publication to field comments on the document.”

Questions: Is one public hearing on the DEIS/EIR sufficient?

Will it be limited in time?

Will there be opportunity for question and answer sessions?

Will speaker time during public comment be limited?

If public participation is critical then shouldn't there be more than one Public Hearing?

1. Background.

Comment: The background description is limited and vague.

Question: Where are the "attached figures"?

Comment: There were not any attached figures in the Corps SPECIAL PUBLIC NOTICE download.

Questions: If the Ballona Creek a.k.a. Ballona Flood Control Channel is "a component feature of a federal flood risk management project," could a project increase flood risk?

Who owns the Ballona Creek/Flood Control Channel portion that bisects the State owned Ballona Wetlands?

Who is legally responsible for liabilities associated with altering the alignment of the Ballona Creek/Flood Control Channel?

Will there be special laws and/or regulations drafted specifically for the proposed project?

Has a Federal/State wetlands project partnership similar to this proposed project been completed before?

Comment: If so, please describe with references.

Recommendations: Study and describe all of the water bodies associated with the Ballona Wetlands and the development adjacent to the proposed project and adjacent water bodies, including, but not limited to, industrial, commercial, residential, recreational, flood plain, polluted waters, and Native American data.

Study and describe how an alteration of what I am assuming are Federal waters/land/boundaries with State land/waters/boundaries will be conducted including, but not limited to, jurisdiction, law enforcement, management, maintenance, funding and liability.

2. Project Purpose and Need.

Comments: Regarding the statement, “In addition, the wetland habitat and natural hydrological functions in the area have been substantially degraded.”

Questions: How have the natural hydrological functions been substantially degraded? Please explain your answer and elaborate if needed.

Who is responsible? Please explain your answer and elaborate if needed.

Is the degradation of the natural hydrology of the project area ongoing? Please explain your answer and elaborate if needed.

If so, is the degradation legal or illegal?

Comment: Regarding the statement, “Restoration of coastal wetlands is needed in order to increase available nursery and foraging habitat for wildlife and to provide recreational and educational opportunities to the public.”

Questions: Will a comprehensive plan including all coastal waters and water sources originating inland be more effective at maintaining and increasing biodiversity than limiting the scope of study to coastal wetlands within the proposed project site? Please explain your answer and elaborate if needed.

What does CEQA require?

What are the recreational and educational opportunities proposed?

Comment: I’m told my grandfather and father hunted ducks in the Ballona Wetlands area.

Questions: Will regulated hunting and fishing be allowed publicly in the proposed project area?

Will Native Americans be allowed to hunt and fish in the proposed project area? Please explain your answer and elaborate if needed.

Comment: Regarding the statement, “A restored, optimally functioning wetland would also benefit the adjacent marine environment and enhance

the quality of tidal waters."

Questions: How does a wetland enhance the quality of tidal waters?

Does the proposed project intend to introduce polluted water sources into the wetlands?

How do polluted waters including, but not limited to, waters laden with synthetic chemical compounds affect the health and reproductive cycle of living organisms? Please explain your answer and elaborate if needed.

Are there endangered or threatened species within and/or adjacent to the proposed project area?

Would the proposed project need maintenance and funding to remove introduced pollutants in perpetuity? Please explain your answer and elaborate if needed.

Comments: Not mentioned in the Project Purpose and Need is the need, or should I say intent, to construct flood and tsunami control levees in an effort to mitigate and protect recently developed structures. Also, the significant amount of earth/soils, that are proposed to be moved, to build the massive levees, will significantly increase the amount of ocean waters, and thereby decrease the need to restore fresh water sources that have been depleted.

Questions: Do any of the proposed project alternatives appear to be flood control mitigation for the Playa Vista development? Please explain your answer and elaborate if needed.

If so, is it an acceptable practice, both morally and financially, by the Corps and CDFG to move forward with an NOI when the preferred restoration project appears to be based on flood control mitigation for adjacent lands?

What is the cost incurred to date to develop what I'm assuming is the preferred proposed project alternative? Please explain your answer and elaborate if needed.

How much of the expenses to date have gone to, or through, CDFG? Please explain and elaborate if needed.

Are you aware that a Santa Monica Bay Restoration Account (SMBRA) exists?

Has any money gone in or out of the SMBRA for this project, or any other project that you are aware of?

Is the proposed restoration funded by grants? Please explain and elaborate if needed.

Does CDFG have detailed accounting records for all financial activities related to the BWRP? Please explain and elaborate if needed.

Are there financial accounting records and/or audits available for public viewing?

If so, how is it accessed? Please explain and elaborate if needed.

If not, why? Please explain and elaborate if needed.

Comment: Regarding the statement, “The purpose of the project is to restore ecological functions of the site, in part, by enhancing tidal flow.” When the County introduced/increased urban flood control waters into the Oxford Lagoon, removed sources of fresh water, and manually maintained tidal flushing, the migratory bird population dropped significantly. I have witnessed Mallard ducklings expire in the MDR harbor due to lack of fresh water access.

Question: How do you enhance migratory bird habitat by enhancing tidal flow?

3. Proposed Action.

Comment: Regarding the statement: “CDFG is proposing a large-scale restoration of the Ballona Wetlands Ecological Reserve. The proposed project entails restoring, enhancing, and establishing native coastal wetland and upland habitats in the approximately 600-acre Ballona Wetlands Ecological Reserve.”

Questions: Is CDFG proposing a large-scale restoration, or is the large-scale restoration proposal coming from the SMBRF and/or other organizations? Please explain and elaborate if needed.

Why is the State Coastal Conservancy (SCC) taking the lead in funding for planning and restoration of the CDFG property? Please explain and elaborate if needed.

What is the roll of California Department of Parks and Recreation (DPR)?

Will CDFG control the proposed “Long-term operations and management activities including inspections, repairs, clean-up, vegetation maintenance, and related activities,” or will they be subcontracted?

If subcontracted to who will they subcontracted to and why? Please explain and elaborate if needed.

Comment: The 2008 SMBRP states, “Determine preferred alternative by 2009.”

Question: Does CDFG have a preferred alternative?

Does the SMBRC have a preferred alternative? Please explain and elaborate if needed.

If so, why hasn’t it been released to the public so we can accurately comment on the NOI?

If a draft has been released, where can I obtain a copy?

4. Alternatives Considered.

Comment: Regarding the statement, “The feasibility of several alternatives is being considered and will be addressed in the DEIS/EIR.”

Questions: What are the alternatives and where did they come from? Please explain and elaborate if needed.

Is the Proposed Ballona Wetlands Restoration Plan (BWRP)(Draft), Prepared in conjunction with the Ballona Wetlands Land Trust, Save Ballona Wetlands, and Rimmon C. Fay, Ph.D. dated June 21, 1995, submitted to the Corps, County, and City of Los Angeles included in the proposed alternatives? Please explain and elaborate if needed.

Is it a document that both the Corps and CDFG have in their possession and has been studied by staff biologists and engineers? Please explain and elaborate if needed.

Recommendation: If not, obtain the BWRP draft document dated June 21, 1995. (I have a copy if needed) Study and describe the viability of

implementing this alternative with acknowledgement of current conditions: ownership, development, etc.

5. Scoping Process.

Comments: The Scoping Meeting was conducted on August 16, 2012 from 4:00 to 7:00 p.m. One 3 hour meeting was all that was provided. Regarding the statement, “providing useful information such as published and unpublished data, and knowledge of relevant issues and recommending mitigation measures to offset potential impacts from proposed actions.”

Questions: What is being done to improve the diminishing water quality within the MDR harbor? Please explain and elaborate if needed.

What is proposed project plan and/or mitigation for being impacted by poor water quality, pollutants, and invasive species originating from within the MDR harbor? Please explain and elaborate if needed.

How many industrial dischargers are permitted into the Santa Monica Bay? Please explain and elaborate if needed.

What are they reportedly discharging? Please explain and elaborate if needed.

What are the locations of discharge? Please explain and elaborate if needed.

What is the reported volume of discharge daily/annually? Please explain and elaborate if needed.

What mitigation measures are in place to ensure there is no negative impact to water quality, and biological diversity and quantities? Please explain and elaborate if needed.

Are there any legal discharge permits issued anywhere within the Ballona Creek Flood Control Channel (BCFCC)? Please explain and elaborate if needed.

Have there been any reported accidental spills into the BCFCC within the past 10 years?

If so, how many and what was spilled? Please explain and elaborate if

needed.

What are the specifics: date, time, estimated quantity, etc. and result: beach closures, number of days, etc.? Please explain and elaborate if needed.

What is the current biological assessment of the Ballona Wetlands? Please explain and elaborate if needed.

What is the current biological assessment of the Marina Del Rey harbor? Please explain and elaborate if needed.

What is the current biological assessment of the Del Rey Lagoon? Please explain and elaborate if needed.

What is the current biological assessment of the Oxford Lagoon? Please explain and elaborate if needed.

What is the current biological assessment of the Ballona Creek including all tributaries? Please explain and elaborate if needed.

What is the current biological assessment of the Venice Canals? Please explain and elaborate if needed.

What is the current biological assessment of the Santa Monica Bay? Please explain and elaborate if needed.

What was the annual historic high catch, combined recreational and commercial, in tons, taken from the Santa Monica Bay, include the year and as much data as possible including, but not limited to, variety of fish, shellfish, crustaceans, mammals, and value (adjusted)? Please explain and elaborate if needed.

What is the current annual catch, combined recreational and commercial, in tons, taken from the Santa Monica Bay, include the year and as much data as possible including, but not limited to, variety of fish, shellfish, crustaceans, mammals, and value? Please explain and elaborate if needed.

What plants and animals, both terrestrial and marine, are currently proposed to be restored and/or introduced to the above listed waterbodies directly related to the proposed project including, but not limited to, the Ballona Wetlands, MDR harbor, Del Rey Lagoon, Oxford Lagoon, Ballona

Creek flood control channel including all tributaries, the Venice Canals, and the Santa Monica Bay? Please explain and elaborate if needed.

What is the current percentage of annual take/catch, combined recreational and commercial, within the Santa Monica Bay, as a percentage of historical recorded highs? Please explain and elaborate if needed.

What is the estimated annual take/catch, combined recreational and commercial, within the Santa Monica Bay, increase over a 10 year period, with the currently proposed Ballona Wetlands Restoration project when completed? Please explain and elaborate if needed.

What is the annual consumption cost of seafood imported and sold within the Santa Monica Bay watershed? Please explain and elaborate if needed.

Would it be better for our local economy to reduce our dependence on imported seafood? Please explain and elaborate if needed.

Would implementing a comprehensive Santa Monica Bay Restoration Plan that strives to restore biomass to historical levels create a significant amount of new jobs in areas of, but not limited to, research, fisheries, aquaculture, education, scuba industry, hospitality, marine resources management, tourism, etc.? Please explain and elaborate if needed.

Have you read the 2008 SMBRP?

Are you aware of the fact that there is no mention of artificial reefs in the 2008 SMBRP?

Comment: 2 years ago I asked SMBRC Governing Board member and (then) HTB president Mark Gold a question about artificial reefs in the Santa Monica Bay? His reply was something to the effect of, “We didn’t discuss them.” A year later when I repeated what I thought I heard he corrected me saying something to the effect of, “No, the definition of artificial reefs!”

Questions: Does the Corps and/or CDFG have knowledge of artificial reefs in the Santa Monica Bay? Please explain and elaborate if needed.

Does the Corps (Federal) and CDFG (State) have a uniform definition for “artificial reefs” that can be included in the proposed project glossary of terms? Please explain and elaborate if needed.

Are you aware of the fact that there is no language whatsoever in the 2008 SMBRP to do enhancement projects within the Santa Monica Bay, even though that it is worded into the mission statement of the SMBRF?

Are you aware of the fact that the majority of restoration projects funded by the SMBRC/SMBRF have been improperly classified as enhancement projects? Please explain and elaborate if needed.

Have pilot tide pools at varying depth, configurations, material, size, etc. within the existing Ballona Creek flood control channel to test the viability of removing the existing levees been proposed? Please explain and elaborate if needed.

Comments: I was invited by a member of the SMBRC to attend and participate in the annual Bay Watershed Council (BWC) working group to draft the annual work plan held on Feb. 12, 2012. When I arrived I was told I could not participate. SMBRF staff Mark Abrams was present and hired to prevent members of the public from participating in the working groups. I attempted to suggest the pilot tide pools during public comment while attending this humiliating experience.

This unacceptable behavior of members of the SMBRC/SMBRF that authorized and enforced this action completely contradicts the “Letter From the Director” SMBRC Executive Director Shelley Luce in the SMBRC Annual Report 2011 which states, “We are planning new workshops and other mechanisms for getting public input on the BRP and annual work plans.”

Question: What actions will the Corps and CDFG take to assure the public that the behavior of this magnitude will not continue to occur throughout the proposed project process? Please explain and elaborate if needed.

Comment: Other actions that contradict sound science and restoration principles surround decisions made aware to me by Dr. Wang. Dr. Wang told me he did not read the Montrose Settlement Restoration Plan (MSRP). Specifically, Appendix A1 Construct Artificial Reefs and Fishing Access Improvements and Appendix A3 Restore Full Tidal Exchange Wetlands. There was $40 million in Federal MSRP grant money available in 1995.

Questions: Did the SMBRC and/or SMBRF apply for MSRP grant(s) for the Ballona Wetlands and/or Santa Monica Bay projects? Please explain and elaborate if needed.

Did CDFG or any State agency apply for MSRP grant(s) for the Ballona Wetlands and/or Santa Monica Bay projects? Please explain and elaborate if needed.

Comments: Dr. Wang also told me the SMBRC did not propose/apply to incorporate the County's Parcel OT (the parking lot adjacent to the Oxford Lagoon) to expand the Oxford Lagoon which would have increased the viability of wildlife significantly. The County is planning to build a massive luxury senior living facility that will abut the Oxford Lagoon further reducing wildlife viability.
This action contradicts SMBRP B. PRIORITY ISSUE: NATURAL RESOURCES Goal 5: Acquire land for preservation of habitat and ecological services.

Question: Is development of vacant land adjacent to coastal wetlands that are compromised through management practices in the best interest of sound restoration principles?

Other actions that concern me are the Total Maximum Daily Loads (TMDLs), imposed by a Heal The Bay (HTB) lawsuit, that may not reflect natural occurring levels of waterways and waterbodies. For example, the TMDL approved for the Malibu Lagoon may be much cleaner than what naturally occurs within a healthy lagoon triggering an approval for a restoration project based on false and/or misleading information.

What is the scientific opinion of the Corps and CDFG on the establishment and enforcement of TMDLs that may not reflect naturally occurring water quality standards of all waterbodies and waterways associated with the proposed project? Please explain and elaborate if needed.

FINAL SUMMARY AND RECOMMENDATIONS

Why am I so concerned about the outcome of the historical Ballona Wetlands and Santa Monica Bay area you might ask?
I was born in Santa Monica, Ca at St. Johns Hospital in 1962 and raised on Howard Street adjacent to the railroad tracks and the Oxford Lagoon. There was so much wildlife present in the area when I was young. Dozens of ducks would land in our yard. Salamanders, lizards, and snakes could easily be found. Cancer crabs could be caught in the MDR harbor by the bucket full. Catching your limit of fish in the Bay seemed much easier. The tidepools at Palos Verdes and Paradise Cove were abundant with life. Now 40 years later, the effects of urban development and associated

pollution without sufficient mitigation have significantly compromised all life forms.
My father was Dr. Rimmon C. Fay, a second-generation Santa Monica Bay fisherman who, through education and experiences, became a leading expert of the Santa Monica Bay and California coastal pollution issues starting in the 1950s. His independence and contributions to environmental protection and education were epic, including his contributions to save the Ballona Wetlands.
With PhDs in Chemistry and Oceanography, countless California ocean dives, hours at sea, days on the beach growing up and fifty years as an ocean lifeguard, as owner/operator of Pacific Bio Marine biomedical research, supply & education, as a founding member of the CCC, and many more contributions worthy of honor and respect, Rim's input in the 1995 Proposed BWRP Draft deserves recognition.
I have a lifetime of experience learning from my father, have served on a land use advisory committee in Monterey County, CA, have several professional certifications in multiple fields including PADI Master Scuba Diver Trainer, Emergency First Response Instructor, ASE Master Technician, Toyota Expert Technician and a BAR Smog Technician License. I have traveled throughout the Pacific region, have hundreds of logged dives, survived the 2004 Asian Tsunami, and have ten years of experience with upper watershed management including over 500 hours of heavy equipment operation and maintenance.
My knowledge of the Santa Monica Bay may never eclipse my fathers. I do believe that I have a better general knowledge than most and have an exceptional ability to identify and fix problems that are obviously broken. The library of Dr. Rimmon C. Fay is in storage awaiting a location were it can be housed, digitized, and made available for all academia on a website. Valuable historical data pertaining to the proposed project may be in his library. Funding to make this information accessible has not been secured.

What are the additional recommendations and desired outcome that I would like to see for the Ballona Wetlands and Santa Monica Bay?

Strongly consider the history of the Tongva Native Americans and respect the current concerns of Johntommy Rosas. If he has registered the Ballona Wetlands as a Sacred Site, the massive alterations proposed should not be allowed in perpetuity. Any enhancements should be harmonious, based on time proven science independent of the SMBRC/SMBRF influence, and focused on restoring an ecosystem that is as natural and maintenance free as possible.
Restore the historical levels of fresh water to the aquifer below the

wetlands through natural recharge and/or injection wells.
Restore the historic levels of fresh surface water
Restore the native terrestrial animals to historical levels to the greatest extent possible including deer and bats.
Explore creating the habitat necessary to allow for greatest diversity of terrestrial animals with minimal change to existing conditions.
Ban domestic animals, especially cats and dogs, from the Ballona Wetlands and adjacent walking/viewing areas.
Install fencing and/or concrete barriers to prevent wildlife from entering roadways.
Install large culverts with solar lighting for animals to cross under existing roadways. Raise the roadways if needed to allow reasonable mobility.
Do not remove the Ballona Creek flood control levees.
Implement pilot test tidepools throughout the Ballona Creek flood control channel with varying designs, locations, and conditions.
Cut openings into the concrete of the existing Ballona Creek levees to allow for native trees to grow, providing habitat and shade for wildlife.
Do not consider opening the wetlands to full tidal flush until the source of ocean water is of the highest quality. The current water quality of the MDR harbor and Playa Del Rey nearshore waters are unacceptable at this time.

Research and implement restoring staff and funding to CDFG so that they truly are the lead agency in this process. I'm told that CDFG funding has been reduced which reduces their effectiveness to educate and enforce locally is reduced. I recently read where the non-profit Santa Monica Baykeeper were making transects across the Bay looking for illegal activity in the Marine Protected Areas (MPAs) in an effort to warn boaters of a potential CDFG citation. This behavior is not a cost effective way to manage marine resources.

Remove the SMBRF from this process. If they have research and recorded data through grant funding acquired from the public, this information shall be given to CDFG. Allowing a non-profit to have the amount of control and influence over State agencies and commissions, with limited public accountability, is not in the general public's or the environment's best interest including the Ballona Wetlands.

Implement partnerships with local educational institutions in an effort to recruit students from Kindergarten to College to participate in research, education, restoration, maintenance, monitoring and management programs, including SCUBA training and certification.

Create and nonpartisan independent review board with membership that is

not financially associated to the proposed project and has term limits for members.

Make restoring the abundance and diversity of marine life in the Santa Monica Bay to historical levels a top priority. This can be achieved by:
Removing all forms of industrial pollution (thermal, sewage waste, and desalination brine) discharged directly into the Bay and ban in perpetuity.
Fully mitigating for all of the sand historically placed on the shoreline through natural rock and artificial reefing to replace the lost nearshore habitat.
Fully mitigating the sediment discharged from Hyperion in mid to deep waters through natural rock and artificial reefing to restore and possibly enhance the lost habitat diversity that biomass requires.
Establish and manage a significant amount of kelp forest in the Santa Monica Bay from El Segundo to north of the Santa Monica Pier.
Restore the historical breach to the Del Rey Lagoon.
Drastically change how the waters within the MDR harbor are managed including, but not limited to: mandatory nets on all docks to remove floating debris, developing and implementing a vacuum system for in-water boat bottom cleaning, and stronger enforcement of illegal spills.

IN CONCLUSION

My family has been in this process for three generations. My grandfather instilled the love and respect of nature and all that it has to offer to my father. My father shared that experience with me. And now I'm nurturing the values taught to me into my young son and daughter.

It was at my father's memorial that I promised Tom Hayden, the only politician to finally stand beside my father and fight for healing the Santa Monica Bay rather than treat it as a dumping ground. It was a surprise and pleasure to see him this morning in passing to say hello and thanks.

If there was one quote that sets the tone for why I'm fighting for the historical Ballona Wetlands it would be, "so preservation of a historic wetland is not a concern."
You'll find that quote on page 4 of the HTB letter to the CCC in support of the controversial Malibu Lagoon Restoration project.

Please judge wisely and favor restoring nature over alternatives influenced by huge sums of money and those that can easily lose their way.

Respectfully submitted,

Douglas Fay

Subject: Comment on Ballona Wetland NOP

To Whom It May Concern:

Please consider the following comments in preparation of the Draft Environmental Impact Report/Environmental Impact Statement for the Ballona Wetlands Restoration Project. These comments are submitted as a concerned citizen and practicing restoration ecologist. I have participated in many restoration project, revegetation and reclamation projects in California for the past 18 years.

First, the project description should be corrected to describe the project as wetlands “creation” not “restoration.” According to the International Society for Ecological Restoration, the term restoration properly used describes the process that will return a site to historical conditions with ecological functions that likely occurred in the past. Most of the alternatives that are described for the 'restoration' of Ballona wetlands include full daily tidal connection. According to the historic ecology of the area described in *Historical Ecology of the Ballona Creek Watershed* (Dark et al. 2011) this condition was unlikely. Quoting from the fact sheets on the Santa Monica Bay Restoration Commission website, " The loss of the historic connections between wetlands, its natural freshwater sources and the ocean …return the daily ebb and flow of tidal waters" appears mistaken. There was not a daily connection for much of the year in the historic Ballona wetlands. The 'restoration' alternatives generally being considered seem to be more appropriately termed 'creation'. These alternatives look like so many other coastal wetland plans that have been undertaken south of Los Angeles in Orange County and San Diego County.

Second, I have reviewed the baseline studies, and I find that the soil studies are not sufficient to make any decisions of the scope being discussed for the plans. And, further in reviewing the vegetation and avian studies, the areas where there is the least cover by exotic vegetation is found, coincidently with the greatest number of a rare and listed bird species is exactly where the most grading will occur in the alternatives presented. This makes no sense for a 'restoration' plan. The plan must preserve the existing and rare the Belding Savannah Sparrow population within the Ballona wetlands. There is no alternative that can mitigate for the loss of this population or its habitat.

Third, if the plan alternative preparer's have some idea for how the creek water, released from the engineered banks for the last mile, or so, run to the ocean will be managed, they have not indicated how this water will be cleaned of trash and toxic components coming down the creek.

Finally, I do not think that the restoration of Ballona wetlands needs to be this drastic based on the information presented thus far. I believe that the existing functions and values of the wetlands and adjacent upland areas could be restored and enhanced without such an expenditure of cash in the immediate future, to say nothing of the long term management will cost the tax payers of California. The goals of the project should be clearly stated. The draft plans should account for long term management and the cost of such management.

Sincerely,

Margot Griswold, Ph.D

Restoration Ecologist

Subject: Ballona Wetlands Restoration Project - Comments for Environmental Review Process

Dear Ms. McCormick:

Thank you for this opportunity to submit comments on the scope of the environmental review for the Ballona Wetlands Restoration Project. I am writing as a resident of the Villa Marina neighborhood, a community of 685 townhouses located directly adjacent to the Area C parcel.

I would like to provide comments on three specific issues that would directly affect our neighborhood.

1. Construction traffic during the restoration process.
We have heard mention that construction traffic during the restoration of Area C as well as the transportation of excess material from Areas A and B for stockpiling in Area C would be directed through the gateway entrance at La Villa Marina. Please analyze and explain, for each of the proposed alternatives you review, the impact of this scenario on surrounding neighborhoods (traffic, noise, air quality, parking), as well as how construction will impact commuter traffic on Lincoln Blvd., Culver Blvd., the 90 Marina Freeway, Mindanao, Fiji Way, Jefferson Blvd., or other adjacent roadways.

2. Public access following the restoration.
The addition of hiking/biking trails in Area C following the restoration will require points for the public to gain access. The availability of adequate parking for our neighborhood residents is already an issue – due to overflow from the nearby shopping center and weekend recreational traffic. Please analyze and explain, for each of the proposed alternatives you review, the impact on the Villa Marina neighborhood (traffic, noise, air quality, parking, littering, vandalism) of providing public access and/or parking at the La Villa Marina gateway, as well as alternatives using Culver Blvd. or other adjacent roadways.

3. Displacement and/or expansion of wildlife populations
The transportation and stockpiling/disposal of excess excavated material in Area C from the restoration of Areas A and B, as well as the restoration of Area C itself could disturb or displace wildlife. It is also expected that following restoration, native wildlife populations will increase. Please analyze and explain, for each of the proposed alternatives you review, the impact on surrounding neighborhoods of migrating wildlife due to displacement or expansion. Please also consider adopting a plan to educate neighborhood residents on what species they may begin to encounter and guidance on how to co-exist.

Again, thank you for this opportunity to respond.

FROM: Kathy Knight, (310) 613-1175, kathy.knight@verizon.net

RE: Additional Comments Re: Ballona Restoration NOI Comments

Dear Mr. Swenson and Mr. Lawhead:

I have these additional comments to add to the record regarding the proposed restoration of the Ballona Ecological Reserve. Please add them to the comments I have already mailed/delivered to you.

ALTERNATIVE RESTORATION PLAN

Please study seriously an ALTERNATIVE plan for restoration of the Ballona reserve. This plan would NOT entail major bulldozing and removing levees from the LA River.
This plan would have the following components:

1) Plan approved by Tongva Native Americans for their sacred site.
2) Plan may allow for minor earthmoving to make a couple of small channels for fresh water.
3) No water from Ballona Creek allowed into the wetlands until it is cleaned up to a tertiary level.
4) Use Bond funds available, from not doing an expensive major bulldozing/dredging/levee-building project, to buy buffer lands around the reserve to reduce road kill of Ballona wildlife in the area, and allow larger more stable populations of wildlife. Additional land would also make limited public trails less disturbing to wildlife, as they would have additional places to live.
5) Study the value of this plan for 5-10 years. Some alterations could be made during that time, based on the results.
6) Utilize local citizens who have been documenting/photographing this area for the past 20-30 years in the active science committee. Do not continue to relegate them to public comments of 2-3 minutes at in-frequent meetings, but rather make them integral participants in the science committees where they can communicate more fully with the other members. Some of them see wildlife that is never documented on the science cameras. Their input is CRITICAL to a well-done evaluation of this area.
7) Continue to bring Los Angeles area students out to the wetlands to help clean-up the area, document flora and fauna, etc. so that they are interested in helping to watch over this land in the future.
8) Follow the natural course of the land/water. Please consult with Dr. Travis Longcore and his researchers on this.
9) Use this plan to teach the public that the first rule of restoration is to "Do No Further Harm". Teach the public that big expensive industrial solutions are not always the best, most permanent way to protect nature. A slower alternative that teaches people to respect nature, and allow its natural tendency to balance itself.

IF YOU WANT FURTHER INFORMATION ON SUCH A PLAN, LET ME KNOW AND I WILL WORK ON GETTING YOU MORE DETAILS. A PLAN LIKE THIS WOULD GIVE THE PUBLIC A REAL CHOICE, AND validate what the public is being told - that there IS NO preferred plan, that it is wide open on what will happen at Ballona.

OTHER COMMENTS:
1) I do not agree at all with bulldozing this site. But if you do, please reveal any background information regarding any bulldozing of Ballona, and if any company will benefit from mitigation credits, and any other financial connections to the restoration efforts, so that there is transparency on how and why these decisions are made.

2) REGARDING WATER STUDIES: Please study the impact of the water from Marina Del Rey on ANY proposed alternative for restoration. Marina Del Rey water is highly polluted from toxics from many boats (I have been told there are 7,000 boats there!). These boats have toxic chemicals applied to them to preserve them, and to run them, that leak into the water, plus people using the boats have been seen to dump liquids and trash into the water. Please test the water of Marina Del Rey very carefully and assess how that water will impact the wetlands, and how it could be kept separate from the wetlands.

2) Remove the trash (local groups and citizens can help on this issue) and find somewhere for homeless people to sleep. Don't make these issues a reason why the restoration has to be hurried.

Thank you very much.
Kathy Knight, MSW
(Have been volunteering and donating funds for 20 years to save and protect this precious ecosystem)
(310) 613-1175

P.S. Please confirm that you have received this email. Thank you.

Subject: Ballona Wetlands Restoration Comments

To: Ms McCormick, representing the Ballona Wetlands Restoration Project (SCH number: 2012071090)

From: Jim Lamm, Culver City resident (310-839-6896, jim.lamm@sbcglobal.net)

Introduction

At this time, I am submitting a few comments as an individual for consideration in the Ballona Wetlands Restoration Draft EIS/EIR.

For purposes of identification, I currently serve as president of Ballona Creek Renaissance (www.ballonacreek.org), adjunct instructor in wetlands ecology at Antioch University-Los Angeles, and BCR's representative in long-running restoration planning process and on the Bay Restoration Advisory Committee, the Ballona Creek Watershed Task Force, and the Assembly District 47 Environmental Cabinet. A retired architect and Culver City Planning Commissioner, my past experience includes working with many similar processes and stakeholders as a project unit manager on the consultant team for Metro's Universal City Red Line Station and Mid-City Extension Preliminary Design for tunnels and stations above underground Ballona Creek and a related subterranean gas-triggered Reassessment Study.

Comments on Process

1. For starters, I strongly encourage an ongoing process that is open, flexible, transparent, inclusive and responsive to the diverse array of stakeholders as well as the unfolding data and analyses.
2. From my perspective as one who values active listening, clear communication, and consensus-building to the greatest extent possible, I request that major concerns be fully heard, acknowledged, addressed, and, where appropriate, taken into account in the Draft aand Final EIS/EIR and the restoration design and implementation.

Comments on Studies, Plans, and Implementation

The following brief comments start with my overall view and touch on some concerns which I share to various degrees with other stakeholders with whom I have talked:

3. Moving from all-important process issues, I personally appreciate the depth and breadth of the studies, site investigations, and conceptual planning to date. However, there are some areas which warrant further development and/or communication. As stated publicly in one of the last public planning workshops at Loyola Marymount University, I am intrigued by the concept of allowing Ballona Creek to interact more fully with the adjoining wetlands. That, in turn, could allow the wetlands to provide more ecological function and benefit to the entire Ballona Creek Watershed and beyond.

4. However, to help ensure the success of that or another restoration plan, please fully consider and analyze both the above-noted process points and the following:
    a. the potential impact on and/or integration of the partially restored existing dunes and salt marsh. This could include further consideration of larger and/or more diverse zones, such as muted tidal, and a possible reduced amount of full tidal.
    b. the legal and ecological ramifications of allowing the urban runoff-affected Ballona Creek waters to interact with the wetlands for both wet weather and dry weather conditions. My hope and understanding is that the current water quality efforts underway through TMDLs, capture devices, rain gardens, and such will enable Ballona Creek to meet the targeted standards by the time of the restoration implementation and that this will help ensure that the wetlands will not be overwhelmed by pollution and trash. What if this is not the case?
    c. the relative sustainability and appropriateness of a restored wetlands with an wide open channel to the ocean vs. a possibly more historically and geographically accurate intermittent inland-ocean connection as has occurred here and elsewhere along the coast through dunes and lagoons.
    d. The characteristics of constructed wetlands, restored wetlands, and constructed-restored hybrids vs. the options under consideration

At this point I will leave more detailed or additional comments to the next phase. Thank you very much for your consideration.

Subject: **Ballona Wetlands Restoration Project Comments**

I first want to express my appreciation for the work that has been done in developing and vetting the different alternatives for the restoration of Ballona Wetlands, and for the coordination that has gotten the project to this point in the planning process. I also appreciate the efforts to solicit and collect comments on this important project.

I am offering my input, under cover of this letter, in the attachment titled "Ballona Wetlands Restoration Project Comments, Keith Linker, October 23, 2012". However, I would first like to emphasize three main points, offered below in three bullet items, before delving into the detail provided in the attachment:

- First and foremost I strongly support this restoration and specifically the current alternative selected (attached, Figure 1a, dated 2012). As a resident of Playa Vista, I am far less concerned about short term truck traffic or other temporary construction related impacts to local residents/businesses or existing flora & fauna, and far more interested in and supportive of as full a restoration of the historic marsh and its function as is reasonably possible.

- Secondly, in the same vein, I fear the following goal: *"Refined alternatives should include preservation and enhancement of some upland and freshwater wetland habitat but should emphasize contiguous estuarine wetland habitat. Opportunities to create regionally significant habitat including vernal pools and native grasslands should be pursued, but not at the expense of the restoration of estuarine habitat."* has been compromised. Perhaps the reduction in the footprint of tidally influenced areas is due to pressure from opponents who may prefer to limit the minimal, short term impact of truck traffic removing excess soil, over the long term positive effect of increased wetland habitat. Whatever the reason, I want voice my concern over the potential of losing the opportunity to maximize the estuarine wetland habitat, as this is the primary driver of this project. To compromise the potential acreage that could be restored is to lose sight of the fundamental goal of this effort. It would be a loss to the vast number of species – including humans – that stand to benefit by regaining what was lost decades ago.

- Lastly, while the ecosystem functioning of this wetland is my primary interest, I believe it is critical to provide access (trails, boardwalks and overlooks) for people to see, first hand, the habitat that will exist in order to advance appreciation for and protection of this and other critical habitats. While there are many access areas planned, there are also many opportunities where access is not included, but could easily be offered.

Thank you again for the opportunity to comment on this incredible project.

Sincerely,

Keith Linker

Ballona Wetlands Restoration Project Comments
Keith Linker, October 23, 2012

ACCESS

TRAIL LINKAGES:

In order to encourage area residents and visitors to walk or bike through the wetland and better appreciate the natural beauty it has to offer, trails should connect to adjacent surrounding areas and should access each of the different ecosystem types at one or more location. This will encourage visitors to appreciate the wetland and increase the number of visitors who visit and appreciate the area and presumably care for and advocate for it. Examples include:

- In Area B: Linking the westerly terminus of the existing northerly path adjacent to West Jefferson Boulevard and the Freshwater Constructed Wetland to the south side of the intersection of Nicholson Street and Culver Drive or to a crossing of Jefferson and Culver near the existing signalized intersection; then linking the north side of Culver at that intersection to the beach ether at Argonaut Street, 62nd Street or other reasonable location.
- In Area B: Linking the north side of the intersection of Nicholson Street and Culver Drive to the beach ether at Argonaut Street, 62nd Street or other reasonable location.
- In Area B: Linking the west side of PCH, just north of West Jefferson Boulevard, to existing signalized intersection of Jefferson and Culver Boulevard; then linking the north side of Culver at that intersection to the beach ether at Argonaut Street, 62nd Street or other reasonable location.
- In Area C: Linking the north side of Culver Boulevard near the 90 Freeway to the east side of PCH near Fiji Way.

RECREATIONAL TRAILS:

The trail system should not only offer access to hikers and nature enthusiast, but should be open and accessible to joggers, bikers and dog walkers (on leash, of course). Trails should be wide enough to allow not only opposing traffic to safely pass with comfort but should allow for people traveling by different modes to overtake others traveling in the same direction safely and comfortably (suggested 12 foot wide DG or mulch pathways, either confined or unconfined with 2 foot shoulders). Include periodic widened areas ("Turnouts") along trails to facilitate passing, stopped travelers and parked maintenance vehicles. Alignment, sight distances and signage should consider all users with a focus on safety.

The opportunity to utilize this area for recreation and exercise is one that should not be missed, since those who are drawn for exercise – for example – may return to appreciate the natural habitat. The more people who appreciate the many aspects of the area, the better it will be protected and maintained, either through community advocacy, direct volunteer support or other formal or informal mechanism.

Ballona Wetlands Restoration Project Comments
Keith Linker, October 23, 2012

SCENIC OVERLOOKS:

As already mentioned, to encourage visitors who might not otherwise visit the wetland if they were not provided the opportunity to "get up close and personal" with the different ecosystems, the proposed overlooks, boardwalks and piers, should be expanded provided so each of the multiple ecosystem can be reasonably accessed. Not only will this offer an educational opportunity for students and casual visitors alike, it will reduce the potential for un-permitted access into areas that could both damage/disturb the flora and fauna and create safety/liability concerns. It would also minimize the disturbance of the resident species (particularly if signs or placards are placed strategically to indicate what activities are and are not permitted [e.g. take photos, but no fishing]). Specifically it is suggested that the following locations be considered:

- Include a boardwalk and scenic overlook in Area B near the Constructed Freshwater Wetland similar to the one offered in Area A for viewing both the Brackish Marsh and the Estuarine Low Marsh.
- Include a boardwalk and scenic overlook in west Area B to view the Estuarine Low Marsh at its interface with Ballona Creek. It is recognized however that flood control requirements and results of scour could preclude this option. Alternately, if an overlook were located on the north side of the Culver Blvd. crossing in Area A, this could accomplish the goal of offering an observation area in reasonable proximity to Ballona Creek.

PARKING AREAS:

While it makes sense to advocate for access generally, it is recognized that many "natural" areas can be "loved to death". In other words, habitat can clearly become compromised with too many people visiting the site, which not only can disturb the resident species, but can increase the potential for inappropriate use/access. Therefore, while a "formal parking/staging area (referenced on page 10 of the January 15, 2010 PWA Memo) is referenced for Areas A and B , it seems to make sense to limit the size/number of spaces to account for this possibility. It is also likely already considered, but worth making note that restrictions on time of use (e.g. dawn to dusk) and other controls be clearly established and strictly enforced (perhaps with the exception of permitted research work or Native American ceremonies) to prevent potential unintended uses. Presumably, LAPD & LA Sherriff Dept, CHP etc. will have input on this, which should be given due attention.

HABITAT

MAXIMIZING ESTUARINE HABITAT:

The interest/need to attempt to balance the soil onsite (i.e. minimize soil export [spoils]) is understood and appreciated. However, the primary goal of this project is restoring habitat and natural wetland functions. Therefore, it is critical to not lose sight of this goal and

continue to strive to maximize the potential areas for tidal influence, specifically “Intertidal Channels” and various “Marsh” areas.

MAXIMIZING “CRITICAL” HABITAT:

Early in the scoping process, a matrix was developed to rank the various benefits of each of the original 5 Alternatives. It is very important not to lose sight of this and particularly with regard to the most endangered habitats/species. It would be unforgivable to chip away at the many acres of tidal flats habitat that can be realized in certain alternatives by simply attempting to balance the soil movement onsite. Additionally, there appears to be two primary areas of lost opportunity. These are:

- Area B bounded by Jefferson, Culver and Lincoln. A culvert connects this area to Ballona Creek but virtually no Marsh habitat is created. Even if a small area of a couple acres adjacent to the proposed channel were lowered to allow tidal flows, this would be an easy way to improve the impact of this project. It would also reduce the isolation of the upstream marsh habitat (which already will be separated by a fairly lengthy culvert.
- North Area C, adjacent to Lincoln and Fiji Way. A culvert exists in this location, seawater will be introduced and available on the west side of Lincoln and could easily be connected to the east side of Lincoln. In fact, all the early alternatives (1-5) include a link for flow to pass under Lincoln, but in the current Proposed Restoration it does not. Discussion of why this change occurred has not been found.

WATER QUALITY

FULL TIDAL RESTORATION VIA OPEN TIDAL CHANNEL:

There seem to be two conflicting lines of thought regarding opening the marsh areas to full tidal influence. There is discussion of the potential for more “polluted” water from Ballona Creek impacting the wetlands, as well as discussion of the cleansing affect that wetlands have on these flows. I would like to weigh in on the side of favoring allowing the marsh ares to act as treatment for a portion of the flow from Ballona Creek. The alternative is discharge to the ocean and there is far less control on the fate of contaminants in that environment than there is in the wetland areas. Additionally, improving the quality of water discharged from Ballona Creek reduces negative impacts on local wildlife, thereby improving the opportunity for re-habitation of the wetlands themselves with the full diversity of flora and fauna anticipated.

Additionally, one means of combating ocean level rise is through siltation/deposition. The more areas which are sloped gently and receive an influx of water, the better, since these areas will tend toward keeping up with sea level rise (while perhaps not at the same rate, reducing the potentially dramatic effects is still a benefit.

Ballona Wetlands Restoration Project Comments
Keith Linker, October 23, 2012

LOCAL STORMWATER CAPTURE AND TREATMENT

Firstly I must enthusiastically applaud the inclusion of *"A small treatment wetland would also be constructed along the north boundary of Area C to treat off-site stormwater runoff that flows through this area before draining to Ballona Creek"*. This is a wonderful addition and a forward thinking approach to utilizing what is considered a liability (roadway and urban runoff) by making it an asset (source-water for wetland habitat) and having a positive overall impact on the quality of water in Ballona Creek.

To the degree that this approach can be applied elsewhere, I would like to strongly encourage it. Surface flow and even underground storm drains in adjacent roads and paths (Pacific Coast Highway, West Jefferson Boulevard, Culver Boulevard, Fiji Way, 90 Freeway, and Ballona Creek Bike Path) should be routed where possible into restored areas (seasonal wetlands, treatment wetlands, tidal areas, etc.). Not only will this offer additional treatment of storm water, improvement of quality of water in Ballona Creek, but would increase the flow/volume of water in seasonal wetlands, potentially increasing the habitat value by effectively increasing the depth and duration of seasonal influent water.

CARBON SEQESTRATION

MAXIMIZING TREE COVER AND WETLAND VEGETATION

Recognizing that one of the major unknowns of this project is the impact that sea level rise will have on the functioning of the project in the long term. Also, recognizing that, while it is not a stated goal of the project, maximizing the potential to sequester carbon dioxide in trees and wetland vegetation (cattails, bulrush, and similar salt/brackish water counterparts) should be a considered a positive potential project impact. While considering the constraints of including native plant materials, it makes sense to include trees or large shrubs in the upland habitat, which not only offer shade to the trail users but potentially offer habitat and foraging opportunities for targeted species. This may also offer opportunity to mound some of the deposit sites to allow for root systems of larger varieties of vegetation to become established and mature.

It would also make sense to maximize similar opportunities in the lower lying areas to realize multiple benefits. Including larger areas where wetland plans can become established, sequester carbon dioxide both above and below ground in the plant material, and potentially "build ground" by establishing root systems, colleting sediment, dying back and re-growing at higher levels as the organic and inorganic materials accumulate. The multiple benefits of this approach include carbon sequestration; fine sediment/pollutant removal, benthic habitat creation, ground building to offset sea rise, and simple aesthetic value to visitors.

Ballona Wetlands Restoration Project:
Overview

California's coastal wetlands support a wealth of precious wildlife habitat and play a crucial role in improving coastal water quality and reducing the harmful effects of floods and erosion on surrounding communities. Today, more than 95% of Southern California's wetlands have been lost due to human development – the largest loss of any state in the nation.

Rooted in years of scientific research and guided by community input, the Ballona Wetlands Restoration Project will revive critical wetland habitat and offer a remarkable natural space for the public's use and enjoyment. One of the most promising coastal wetland restoration opportunities in southern California, the Ballona Wetlands Restoration Project will return this highly degraded habitat into a thriving wildlife reserve and unique community asset.

The Ballona Wetlands

Stretching from Playa del Rey to Venice, the Ballona Wetlands once occupied a 2,000-acre expanse of critical coastal habitat. Now covering a 600-acre area, the Ballona Wetlands Ecological Reserve represents the largest opportunity for coastal wetland restoration in Los Angeles County. The site is owned by the state of California and managed by the California Department of Fish and Game as an ecological reserve. The State Coastal Conservancy and the California State Lands Commission are participating partners in the planning and restoration of the wetlands.

Why Restore the Ballona Wetlands?

More than a century of human neglect and abuse have left the Ballona Wetlands in a highly degraded state. Dredge spoils dumped on the wetlands during the construction of Marina del Rey and the Ballona Creek Flood Control Channel have severed the historic connection between the ocean and the freshwater creek. As a result, the site has lost many of the ecological functions of an estuarine wetland and it no longer supports many of the native species that once lived there.

Restoring the intrinsic structure and function of the Ballona Wetlands will give native species a chance to recover and thrive. The Ballona Wetlands Restoration Project will return the daily ebb and flow of tidal waters, maintain freshwater circulation, and support a more natural and healthy ecosystem. Creating suitable habitats and conditions will allow wetland vegetation to flourish and attract the insects, reptiles, amphibians, fishes, birds, and mammals that call wetlands home. As a restored site, the Ballona Wetlands will play a critical role as a migratory refuge for the millions of birds traveling from South American to Alaska each year. Further, this revitalization will provide the community with a valuable educational resource and an opportunity to create meaningful connections with the natural environment.

Who Is Planning the Project?

The Department of Fish and Game owns the land and is ultimately responsible for any changes to it. The Project Management Team includes the State Coastal Conservancy, the Department of Fish and Game, the State Lands Commission and the Santa Monica Bay Restoration Commission, the U.S. Army Corps of Engineers, and the Los Angeles County Department of Public Works. This team is working together to plan and design the restoration project. The Project Management Team also obtains input from the Ballona Wetlands Restoration Working Group, the Ballona Wetlands Science Advisory Committee, the Santa Monica Bay Restoration Commission Technical Advisory Committee, and the Agency Advisory Committee.

Who Is Funding the Restoration Project?

In 2004, the Costal Conservancy approved state board funds to support the planning and restoration of the Ballona Wetlands.

Ballona Wetlands Restoration Project

Advancing ecosystem health. Connecting communities with nature.

What are NEPA and CEQA and How Do They Apply to the Restoration Project?
The National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA) are federal and state laws, respectively, that require federal, state, and/or local agencies to identify the significant environmental impacts of a project and to provide documentation of these impacts.

Under NEPA and CEQA, the Ballona Wetlands Restoration project is required to prepare a rigorous Environmental Impact Statement (EIS) and Environmental Impact Report (EIR) to thoroughly evaluate all short-term and long-term environmental impacts and benefits of the project and project alternatives, so that a successful and comprehensive project can be implemented. As the land owner, the California Department of Fish and Game is the lead agency for CEQA. The federal process, NEPA, will be led by the U.S. Army Corps of Engineers.

How Do I Get Involved in the Project?
The CEQA/NEPA process provides multiple opportunities for the public to provide input on the alternative designs for evaluation in the environmental review process. Your first opportunity is during scoping under both CEQA and NEPA. During scoping, you can tell the lead agencies what topics and issues you believe need to be addressed in the environmental document and propose design alternatives for consideration.

Written comments on the scope of environmental review may be submitted at the scoping meeting or sent to the addresses listed below. **Comments will be accepted until October 23, 2012.**

Where Can I Get More Information About the Project?
Please visit www.ballonarestoration.org to learn more and find out how you can get involved. Here you will be able to access links to the project social media pages, read project informational documents, find answers to frequently asked questions ,and sign up for the project newsletter and email updates.

What is the purpose and need of this project? It is obviously thriving and diverse environment as you can see here http://www.flickr.com/photos/stonebird/sets/447673/ with endangered and endemic species so why fix what's not broke (bulldoze nests, aquatic life, native plants etc.)? If you don't want to sit thru this guys hour presentation http://www.youtube.com/watch?v=1viLaZaVhQY&feature=share some key points are made at :43 Dr. Longcore discusses fresh water benefits vs open to the ocean n closure protects beaches from bacteria from city runoff n bird crap; :40 and :25 talks about how historically it wasn't always all water n was closed to the ocean which can be healthy as having an upland habitat full of native plants is natural there.

Has "restoration"
worked for the nearby Oxford Flood Control Basin on Washington or the Bolsa Chica wetlands just south of here that has to be dredged out EVERY YEAR with taxpayers money which uses a lot of energy (And it's open to the ocean so there's dolphins there now that are not supposed to be n sometimes they even get stuck). Go look at Malibu Lagoon where they jut bulldozed--it's a disaster!

Where is the public participation? A friendlier alternative such as that done at the Grand Canal between Washington and the Marina can be done (there a judge ruled in favor of our less destructive restoration).

And besides all of this environmental crap - it will exacerbate traffic n pollution in the area as whats happening now with construction.

You will be however, sold on THIS video which I believe is propaganda http://www.youtube.com/watch?v=0nGYnpWs-uU of course building the Marina piled excess dirt upon the wetlands but these water "experts" (they are not habitat or species experts) behind this are getting paid a lot of money which I believe that this is a waste of taxpayers money for a levee system that will only benefit Playa Vista built on a flood plain which is why some of the walls are to be 20 feet high! Even in their video the wetlands it is depicted as a highly functioning ecosystem--let's look into CEQA NEPA and Fish & Game sections 404 & 408 clean water acts as this project will flood these limited wetlands with polluted water as they can only filter so many toxins out.

Does State Parks even have the funds to do this? The Army Core of Engineers? Look what they did to the LA River-water that should be going underground aquifers to be able to tap into that source later n instead it's channeled out into the ocean while we spend billions a year transporting water to LA. Let's do a friendlier less invasive restoration with volunteers and school groups pulling the few invasive weeds n replanting natives while learning about estuaries. SAVE THE OWLS FROGS SNAKES COYOTES RABBITS. The Sierra Club agrees! 95% of California's wetlands gone--don't bulldoze this one! Use the money for

viewing platforms, a trail for public access n a ranger.

I have done the research and am very involved in the community as is my family in Santa Monica, CA.

Sincerely,

Barbara Lonsdale

Re: Scoping Comments re Santa Monica Bay Restoration Commission ("SMBRC") April 2012 Notice of Preparation of Draft EIR on Ballona Wetlands

To Interested Parties:

My interests are in the people and the land of the 2012 Ballona Wetlands. I am a native American woman who cares deeply for what is happening to people, especially woman, who have historically always been underserved by the powers which operate things like heavy equipment, a use inferred in SMBRC's proposed "restoration" alternatives. The land and women always suffer first and the most. The SMBRC's process in this regard shows there are severe differences of opinion in this political issue. The controversy is sufficient to demand that alternatives outside the interests of the SMBRC Project Management Team be included going forward.

The public has a right and we demand we be heard on the issue of end-of-pipeline treatment at Ballona Wetlands. The wetlands have served the public for millenia, right now we are not be able to be on them or even to see them. With proposed

"restoration" alternatives all will be lost, but for the political controversy, which is adequate to demand alternatives outside the interests of the SMBRC Project Management Team.

Public hearings are necessary so the public can share our input to state objections or agreements thereto.

Ramona Merryman

Subject: Ballona Wetlands comment

Hi, I'd like to comment on the wetlands scope.
I currently bike the creek bikepath and would like to see an extension and addition as part of the restoration.

Add a a path that parallels the 91 freeway to the development that runs near culver blvd and then intersect with the existing path to venice beach.

also add a bridge at the old centinela creek railroad creek pylons to connect to the south side of the creek which would then create a circle around the entire wetland (fresh and salt).

a connection to the bluff paths below Loyola Marymount through playa vista, with connections down to playa del rey,

this would create a network of usable bike paths that would support rediscovery of the wetlands once recreated.

thanks

Re: Scoping Comments re Santa Monica Bay Restoration Commission ("SMBRC") April 2012 Notice of Preparation of Draft EIR on Ballona Wetlands

To Interested Parties:

My interests are in the fresh water flowing from City of Los Angeles storm drains into the 2012 Ballona Wetlands. My interests arise from my role as Vice President/Executive Administrator of the Gabrielino/Tongva Springs Foundation, which works to preserve Kuruvungna Springs, also known as State Historic Site 522, the ancestral home of the descendants of Los Angeles' native Tongva people.

Kuruvungna Springs today consists of numerous aquifers among what were once a series of vast aquifers and fresh water sources in and around Los Angeles. As stewards of Kuruvungna Springs, the Gabrielino/Tongva Springs Foundation monitors

the nourishment of the Greater Ballona watershed (including the Ballona Wetlands) with flowing fresh water. Fresh water from Kuruvungna Springs (and from the aquifers throughout the Los Angeles Basin) ultimately dilutes other sources (including known pollutants) in the ebb and flow of tidal water merging from SM Bay, Marina Del Rey Harbor and the Venice Peninsula in the 2012 Ballona Wetlands.

As the second World Water Forum wisely stated "Water is everybody's business," so I encourage any person interested in the environmental outcome of local water sources like Kuruvungna Springs to demand the scope a Draft EIR be widened from the SMBRC alternatives to include broad-based public interests and the welfare of spiritual seekers, scientific researchers, teachers, students, historians, nature lovers, pet owners, public transit advocates, animal wildlife and plant species (including rare, threatened, endangered and critically endangered animals and plants which now reside in the 2012 Ballona Wetlands).

This image is a proportional representation of the ratio of the volume of fresh water on planet Earth to the planet's entire surface area.

Fortunately for Santa Monica Bay and the 4.5 million residents of the greater Los Angeles Basin, the 2012 Ballona Wetlands continues to be nourished by freshwater from the Greater Ballona watershed, including Kuruvungna Springs, Centinela Creek, Centinela Springs, and run-off from fresh water aquifers including, without limitation of the foregoing, Nicholas, Laurel, Coldwater, Benedict and Stone canyons are now contributing to freshwater habitats in the Ballona Wetlands.

Summary

The Ballona Wetlands are an impressionable surface area of land which bears continual marks of all impacts upon it, whether originating from the weather, the tides, animal or sea life or from human activity. All of the alternatives now proposed by the SMBRC as wetlands "restoration" are improvements, with the exception of the CEQA-

NEPA-mandated "no action," alternative No. ___. Any one of the proposed "restoration" alternatives will result in sustained human impact on the wetlands and the habitats therein. The first impact of the proposed "restoration" are improvements in the form of vehicle tread impressions, then with freshly-dropped petrochemical residua originating from said vehicles, followed by vehicle-driven landscape, habitat and existing infrastructure demolition before improvement for proposed newly paved areas of indeterminate size, locale and purpose. SMBRC alternatives need to be clarified and alternatives outside the interests of SMBRC Project Management Team must broaden out to include recognition of the 2012 Ballona Wetlands as an historic bio-region with cultural and spiritual significance to the community at large. Alternatives which protect the Ballona Wetlands habitat for a large number of threatened and critically-endangered animals and plants (as designated in 1995 by the Santa Monica Bay Restoration Project ("SMBRP") the organization which was formalized into the SMBRC in 2003) must also be included. The Ballona Wetlands are a living eco-system dependent on the unique combination of fresh water provided by the Greater Ballona Watershed, and tidal waters from Santa Monica Bay, Marina Del Rey Harbor and the Venice Peninsula. SMBRC Project Management Team acknowledges the tidal waters are "impaired waterways" and have an interest in mitigating or cleaning up the water impairments, but right now there is a disconnect between what the people employed by the SMBRC Project Management Team, who are thinking about they need to do to keep their jobs, and the call for wider institutional recognition that the alternatives for "restoration" SMBRC now proposes have a vast and troubling impact on long-standing plans for an authentic wetlands restoration.

Introduction

These scoping comments are submitted as 1) A comment and critique of the proposed 2012 Ballona Wetlands Restoration alternatives published by the Santa Monica Bay Restoration Commission ("SMBRC"), a state entity staffed by public sector employees and appointees partnered with a non-profit private foundation (the Santa Monica Bay Restoration Foundation "SMBRF"), and; 2) As discrete environmental proposals currently outside of the proposed alternatives for consideration for possible inclusion into the upcoming Draft Ballona Wetlands Restoration Plan.

As I understand the situation right now, the SMBRC has requested the Army Corps of Engineers terminate a feasibility study and EIS to evaluate the proposed restoration alternatives published by SMBRC. As a result of the Army Corps of Engineers granting SMBRC's request, the permit applications necessary for any of the action plan alternatives submitted by the Restoration Project Team will now bear the name of the SMBRC as the permit applicant. The substitution of the SMBRC to sit in the place of the original permit applicant, the Army Corps of Engineers, is sufficient reason to include proposals which are outside SMBRC's proposed alternatives. There must be a controversy within the alternatives proposed by the SMBRC, because why else would the Army Corps of Engineers right now abandon the 2012 Ballona Wetlands

"restoration" project during this scoping period and why would the SMBRC walk away from Civil Works cost-shared project funds to pay for the "restoration" alternatives?

The SMBRC alternatives all raise the issue of wetlands restoration, but there is no mention of wetlands restoration impacts, which begins when the first work truck pulls off the pavement. Whether that first "restoration" work truck leaves tire tread marks on dry soil or skid track in a wet puddle, during the subsequent seasons of dry and wet, the land will bear the impact of that first truck for years, whether or not that first track is paved over or not. Core sample teams in Autumn 2012 have recently tractored grades inside the Ballona Wetlands as a part of SMBRC's pre-plan construction traffic access creation, which indicates a very laissez faire attitude by the Project Management Team toward critically endangered habitat.

The SMBRC alternatives all raise the issue of which resources to expend on the proposed wetlands restoration, but there is no credible consideration in any of the restoration alternatives for a true no action alternative, that is the action of keeping work trucks on the pavement and off of the 2012 Ballona wetlands. Whether the chosen alternative ultimately increases expended resources exponentially above a single work truck is cause to broaden the scope of the SMBRC alternatives now proposed because the SMBRC alternatives call for improvements to precede all "restoration" activities.

The SMBRC alternatives as designed will produce significant restoration impacts, not restoration results. For example, the habitat throughout the Ballona Wetlands exists to a large extent that no amount of field monitoring can prevent disruption to the cycle of a nesting Great Blue Heron, at one time a critically endangered species, who is in the middle of a cycle of its own wildlife restoration. This was witnessed in the behavior of a Project Management Team supporter on August 16, 2012, when a group of Herons were "spooked" by this man's wild yelling and wide gesticulations.

The SMBRC Project Management Team

It is a great concern that the Executive Director of the SMBRC, Shelley Luce, is also directing the Project Management Team of the proposed "restoration" alternatives. The narrow choice of alternatives proposed by the Project Management Team places the Executive Director of the SMBRC in a position of conflict of interests. The mission of the SMBRC is of a far wider scope than that of the Project Management Team, which involves each team member to think only about keeping their job, whereas the Executive Director of the SMBRC, Dr. Luce, must have a wider perspective to include the interests of the entire Santa Monica Bay.

I personally questioned several members of the Project Management Team, including Dr. Luce, Dr. Swenson, Mr. Lawhead and Ms. Johnston on subjects including what the current policies are of their respective agencies would be applied to the 2012 Ballona

Wetlands. The answers I received from these Project Management Team members was that controversy exists as to whether build dams and fish ladders. No one would acknowledge the fact the Ballona Wetlands have undergone a successful self-remediation from the time of the creation of Marina Del Rey, in spite of the actions of Playa Vista and its predecessors. A once-polluted bio-region has over time, using naturally available tidal flow combining fresh water, Bay water, Harbor and Peninsula water to provide habitat for many endangered and threatened animals and plants, with no help from trucks or heavy equipment. The proposed "restoration" alternatives need to be widened to include this fact.

SMBRC alternatives propose classic "jobs versus the environment" planning which goes that jobs are good for the economy, the proposed alternatives create "restoration" jobs, therefore, the "restoration" alternatives published by SMBRC are good for the economy. The alternatives now published by SMBRC use this oversimplified calculation to obscure that the millions of dollars proposed for the "restoration" ($100-$200 million estimate cost for Ballona Channel alone) act as subsidies to buoy Ballona Wetlands developer Playa Vista's pending liabilities for parkland (B.E.E.P. vs. Playa Vista (2012)), open space set-asides (Culver Boulevard ball fiends), mitigation (aging underground methane gas monitors), storm run-off (silting and dredging 24/7 in a hopeless battle against the sea) and community safety (local natural gas storage wells).

2012 Ballona Wetlands is where Playa Vista sits, mid-project, as a hyped-up private development zone financed by considerable amounts public money, and utilizing resources on public land (the Ballona Wetlands). The promises made by Playa Vista since its beginning in 1997 are now looming as liabilities with significant back-end exposure for a wide open-ended environmental consequence, for which no adequate mitigation could possibly be forthcoming. For Playa Vista their logic has always been to increase the density of the Ballona Wetlands with resources and improvements, beginning with heavy equipment operated by drivers driving in the wetlands without any supervision or plan, which is also business as usual among those employed by SMBRC Project Management Team.

There are miles of trails in the wetlands which the SMBRC alternatives propose to eliminate. The Project Management Team has said pedestrian traffic will damage the land by walking on it, but the proposed "restoration" alternatives call for massive bulldozers to destroy and demolish existing habitat and infrastructure in the name of "restoration". SMBRC has now closed the entire Culver Boulevard area to the public. If the SMBRC wants to keep the public from seeing the thriving natural habitat in the 2012 Ballona Wetlands, this is proof a controversy exists as to the proposed "restoration" alternatives sufficient to broad the scope of alternatives to include an "off-limits" policy for heavy equipment in the critical and endangered habitat areas. SMBRC's Project Management Team has attempted to minimize this controversy by putting out the story that non-opposition to the proposed "restoration"

alternatives signify the public's overwhelming fear of natural disasters and public health emergencies justifies the vast logical leap to bureaucratically-mandated improvements for fast-tracking new linear roadways and infrastructure.

The August 16, 2012 public scoping fair staged by SMBRC's Project Management Team was another step taken to minimize or marginalize any controversy to the proposed "restoration" alternatives. Project manager Donna McCormick said "ICE International is the company that has been hired as the consultant to coordinate and write the environmental report." "Sometimes when we have lots of information already we can provide that, but we don't have alternatives identified yet," McCormick explained. This is untrue. According to the SMBRC Executive Summary to the Bay Restoration Plan 2008 Update the original Bay Restoration Plan was developed in 1995 in "recognition of the need to restore and protect Santa Monica Bay's priceless natural resources." While in 2012 Ms. McCormick said "We could bring some of those things but they are in draft form and they could change, and then people would think that isn't what they saw in the scoping meeting." "So we basically thought that the most important thing was to get people's comments back to us," the project manager continued. "We want to make that available. This type of forum, we think, is much better for getting a lot of discussion coming back to us instead of setting up a microphone and having people speaking one after another." (http://www.argonautnewspaper.com/articles/2012/08/23/news_-_features/top_stories/1.txt). The truth is that any member of the Project Management Team present on August 16, 2012 speaking at a microphone for the public would have created a firestorm of controversy, and this fact is sufficient to demand that broadened alternatives from outside the Project Management Team which provide for habitat preservation, protection and an off-limits policy for heavy equipment in critical, endangered habitats must be included going forward. Rejection of this idea sends the message that the Project Management Team can use bond money raised for public works project to finance a public relations campaign to steer control of the 2012 Ballona Wetlands solely to the Project Management Team.

In a related matter on the subject of bond money paying for public relations to seize control of public land, members of the Project Management Team have put out disinformation about the Ballona Wetlands since 2004 when they began promoting a "salt water wetland habitat" as a necessity to protect buildings from storm run-off. The 600 acres of open space in the 2012 Ballona Wetlands is a sufficient buffer for El Nino and La Nina sized storms affecting run-off in the Ballona Channel according to a 2005 Notice of Intent. I understand there is a 2012 Notice of Intent pending, but I expect the pending 2012 Notice of Intent to be a self-serving document put out on behalf of the Project Management Team. Any public discussion of this would have created a firestorm of controversy, and this fact is sufficient to demand that broadened alternatives from outside the Project Management Team which provide for habitat preservation, protection and an off-limits policy for heavy equipment in critical, endangered habitats must be included going forward.

The Ballona Channel was built as a project of the federal government built over land condemned by the County of Los Angeles for flood protection. The Project Management Team has publically stated, and the proposed "restoration" alternatives make clear that the Project Management Team wants a lot of dirt from the Ballona Wetlands moved around to create a new 40 foot-high levy around a new fresh water retention basin in wild massive civil works project which may be the ultimate goal for the proposed "restoration." There are more alternatives for the Ballona Wetlands than to re-create the San Gabriel River end-of-pipe "solution" for high-density, high-traffic, high-resource dependent coastal populations masked as a proposed "restoration." Alternatives need to include more than concepts that in advance of a political agenda which do not work.

Secrecy

SMBRC's Science Advisory Committee has been closed to the public. Its minutes and contracts, however, specify the subject matter of the Committee is "estuary only." How come the Project Management Team's proposed "restoration" alternatives includes no data on the plant and animal, fresh water and salt water species who live in the 2012 Ballona Wetlands. This is evidence of a controversy between the Project Management Team and SMBRC's Science Advisory Committee, which is sufficient to demand the scope of the alternatives should be widened to include recognition of the Ballona Wetlands for is core historic, cultural, scientific role as a habitat and an enormous natural mechanism which is alive. In this regard, I refer you the Pachamama Accords of 2008, recognizing the rights of mother earth as a life form entitled to protection of the law from encroachment and predations of improvements.

Why does the State bureaucracy want to dump L.A.'s polluted urban street drainage into the Ballona Wetlands? Because they are under a court order to comply with a federal law that requires the massive L.A. urban region to stop allowing its storm drain system from funneling urban pollution to our ocean and beaches. But rather than planning and creating their long-promised upstream treatment system. The Ballona Wetlands are very remarkable because the land continues absorb fresh water and exude moisture while also being inundated by impaired waterways saturated with toxins and functions as an estuary for nationally-protected Ballona Creek.

The proposed "restoration" alternatives may include plans for the Ballona Wetlands to divert an already impaired waterway into another waterway which is also impaired. The fact that permitting an impaired waterway to join with another impaired waterway is a violation of the Clean Water Act of 1970 is sufficient reason to demand the scope of alternatives to be broadened to include an analysis of the fresh water species which live in the 2012 Ballona Wetlands because a survey of the fresh water species in the culverts along the northern edge of Culver Boulevard between Jefferson Boulevard and the 90 Freeway will give scientific proof that fresh water from the

Greater Ballona Watershed feeds habitats as far east as Sepuleveda Boulevard along the Ballona Channel.

Is the shape of the Ballona Channel subject to change as a result of any of the "restoration" alternatives published by the SMBRC? Is there a relationship between the SMBRC proposed "restoration" alternative and the needs of Playa Vista Phase II to re-calculate storm-water impacts based on run-off volumes now coming off of Playa Vista Phase I? There are $25 million worth of studies on water flow studies available to the Project Management Team, most of which concern the current and foreseeable fresh water dewatering of building foundations and sewage infrastructure serving Playa Vista. I also understand that the City of Los Angeles may share Playa Vista's liabilities for damages arising from water-borne pollution running towards the Ballona Wetlands.

Public Law 228 (1938)

Jurisdiction over the Ballona Channel was established by Public Law 228 of 1938. None of the proposed "restoration" alternatives recognize the fact that any variance which involves the Ballona Channel requires an Act of Congress to alter Public Law 228 and waive the Clean Water Act of 1970. Estimated costs for changing the course and function of Ballona Channel is $100-$200 million to create an under-evaluated flood control alternative. This seat-of-the pants proposed "restoration" alternative adequate show bureaucratic indifference to rare, threatened, endangered habitat and is sufficient to demand the scope of the alternatives should include rigorous application of the Clean Water Act on the Ballona Wetlands in vetting the final alternatives. (See posts on this here: http://ballona-news.blogspot.com/search/label/Restoring%20and%20Unpaving%20Local%20Open%20Spaces%20to%20Clean%20Up%20Santa%20Monica%20Bay%20Beaches).

Is the shape of the Ballona Channel subject to change as a result of any of the "restoration" alternatives published by the SMBRC? Is there a relationship between the SMBRC proposed "restoration" alternative and the needs of Playa Vista Phase II to re-calculate storm-water impacts based on run-off volumes now coming off of Playa Vista Phase I? There are $25 million worth of studies on water flow studies available to the Project Management Team, most of which concern the current and foreseeable fresh water dewatering of building foundations and sewage infrastructure serving Playa Vista. I also understand that the City of Los Angeles may share Playa Vista's liabilities for damages arising from water-borne pollution running towards the Ballona Wetlands. These questions all reveal a source of great controversy as political powers seek to re-shape the landscape at the cost of throwing off older values, which in this case is a California Ecological Preserve, sufficient reason to greatly widen the scope of alternatives going forward to include plans not of the SMBRC Project Management Team, but from scientists, students, community members and nature lovers.

When did SMBRC's mission of "improve water quality, conserve and rehabilitate natural resources, and protect the [Santa Monica] bay's benefits and values"ft change to "wants narrow range of alternatives limited to vehicle intrusions into sensitive critical fresh water and salt water habitats"? Questions about how the SMBRC changed that position is enough to open out the scope of alternatives to include the mission of maintaining the wildlife habitats (as to the State Ecological Preserve) and current fresh water flows onto the 2012 Ballona Wetlands.

The SMBRC Project Team and Playa Vista

Ballona is a biodiverse ecosystem which has had three natural habitat types persist since at least 1995: salt marsh, freshwater marsh and wildflower and sage covered uplands. Although since 1995 the total area of salt marsh, freshwater marsh and wildflower and sage covered uplands has been reduced (salt marsh, freshwater marsh areas have been by 2/3 reduced by Playa Vista development, wildflower and sage covered upland area reduced 95% by the Catellus housing development west of Lincoln south of Jefferson). Despite the reduction in habitat-available area, annually, and in cycles which have been observed for millennia, rare, endangered and critically-threatened species continue to reproduce in Ballona.

Under the proposed "restoration" alternatives, the freshwater marsh and the last remaining wildflower and sage covered uplands and their wildlife will be mostly eliminated. "Restoration" alternatives have plans for creating an urban pollution street drainage dump, and ignores the impact of the plan and execution of the proposed "restoration" on the rare, endangered and critically-threatened animals and plants of Ballona. The conclusion is that the designation of the Ballona Wetlands by the SMBRP in 1995 occurred when institutional values favored a relationship with existing animal and plant species who live in the Ballona Wetlands. In 2012 the institutional values of Playa Vista have been adopted by the SMBRC Project Management Team and only did so throughout a firestorm of controversy. There is a dream state which must come over a person who decides that the institutional values which form our work lives must somehow also aspire to provide a "higher good" to justify strong-arming the defenseless for a contractor-driven out-of-control mission from day one. This is sufficient reason to demand that alternatives outside the control of the SMBRC Project Management Team be included in every plan going forward from this time.

In the SMBRC Executive Summary to the Bay Restoration Plan 2008 Update the original Bay Restoration Plan was developed in 1995 in "recognition of the need to restore and protect Santa Monica Bay's priceless natural resources." Note that "The Santa Monica Bay Restoration Commission continues the mission of the Bay Restoration Project and the collaborative approach of the National Estuary Program but with a greater ability to accelerate the pace and effectiveness of Bay restoration efforts." (http://www.smbrc.ca.gov/about_us). The thinking that goes on in the heads

of people who work at their jobs with the SMBRC Project Management Team has devolved the Bay Restoration Plan to suit the needs of Playa Vista. This conceptual vacuity shows a controversy existed and still exists around the "greater ability to accelerate the pace and effectiveness of Bay restoration efforts." A "no action" alternative needs no acceleration to create an effective restoration, nature does that using wind, weather, tides, water, all substances which are found in the natural abundance in the 2012 Ballona Wetlands. This is an overwhelming reason to have a consensus that alternatives outside the control of the SMBRC Project Management Team be included in every plan going forward from this time.

The proposed "restoration" alternatives have risk of creating a ripple effect of restoration impacts from tires on the wetland to foreseeable newly paved areas.

The Project Management Team failed in the past to identify relationships between plants and animals in assessing the viability of habitat, for example the reproduction of endangered Blue Butterflies was attributed by advocates for the SMBRC to wildly speculative causes, but when a real-life scientific study was done, the reason the Blue Butterflies struggled was because tires on the ground had squashed and torn up the wild buckwheat the Blue Butterflies have eaten for thousands of years.

The Project Management Team has $6.2 million but have not assessed the risk to present day value. The scope of the "restoration" alternatives needs to be expanded to create accountability within the Project Management Team for their present insufficient species analysis.

Flood Control: Mandate or Raison D' Etre For the Project Management Team?

The proposed "restoration" alternatives published by SMBRC do not support a range of alternatives. "Dredge and fill" wants to widen the connection between the ocean and the 2012 Ballona Wetlands using vehicles, petrochemicals and pavement, all of which change the fundamental character of the wetlands, which is absorb fresh water at high tide and off-gas moisture during low tide and during the dry season.

Grave Desecrations

During construction of Playa Vista Phase I, Playa Vista unearthed long-buried human bodies belonging to members of the native Tongva people. Playa Vista attempted to cover up the number of graves it unearthed and its subsequent careless handling of human remains. Through political manueverings and favorable reporting in the media Playa Vista was able to avoid bad publicity. However during this period of public relations spin, Playa Vista promised to restore the remains to the site of their original interment. Right now the ancient graveyard of hundreds human bodies is still an open ditch, one mile long by 3 feet wide, 3 million cubic yards of soil disrupted and

removed. According to coverage in the May 31, 2012 "Argonaut" "several dozen fragile remains, were re-interred at Ballona Discovery Park in Playa Vista." There must be an alternative to the SMBRC alternatives which call for using heavy equipment to move massive amounts of water and earth and only give Playa Vista-grade promises to responsibly handle human remains.

Proposed Alternatives Outside the SMBRC Proposed "Restoration" Alternatives

New alternatives are needed in the interests of preserving and protecting the Ballona Wetlands:

1. Soil - New topsoil is habitat to rare, threatened and endangered plant life, including critical micro biota.
2. Ground water - Necessary for cyclical resurgence of seasonal life forms
3. Tidal inflow onto the Wetlands
4. Tidal outflow into the Bay, Channel, MDR Harbor and Venice Peninsula
5. Fresh water inflow from the Greater Ballona Watershed
6. Fresh water outflow from the Ballona Wetlands
7. Animal species (including migratory fowl and seasonal sea life) which rely on fresh water
8. Animal species (including migratory fowl and seasonal sea life) which rely on brackish water
9. Plant species (including annuals) which rely on fresh water
10. Plant species (including annuals) which rely on brackish water
11. As the site of the native Tongva village of Sa-Angna
12. For use as a natural outdoor sacred site for spiritual rites
13. For use as a natural outdoor classroom for students K-12, through post-doctorate studies
14. For use as an historic site illustrating the impact of human habitation on the wetlands

The current eco-system now in place in the Ballona Wetlands has value as a viable habitat for endangered and threatened animals and plant life.

Doing no harm to the habitat of the Ballona Wetlands means preserving the existing wildlife habitat for the Western Shrike, Kites, Harriers which are unique examples of wildlife in an urban setting.

The Ballona Wetlands are a native American sacred site, the location of "Sa-Angna," one-time village of the Tongva people native to Los Angeles. The Ballona Wetlands are also acknowledged for their significance as an intact local resource for outdoor classrooms for students studying a wide range of scientific disciplines.

Restoration results, for example, would further facilitate the habitat throughout the Ballona Wetlands to prevent disruption to the cycle of a nesting Great Blue Heron, at one time a critically endangered species, who is in the middle of a cycle of its own wildlife restoration.

The Vision

The action of doing nothing, means the SMBRC would stay conscious of the resources provided to it, without expending the earth and water resources which were ceded to the SMBRC. The action of establishing an "off-limits" policy to cyclical resources periodically available through atmospheric seasonal change.

Going forward a plan needs to protect the three existing wildlife habitats and existing trails and allows for fresh water inflow onto portions of the wetlands. If the SMBRC is doing their job, the results will that one day clean water will enter the Ballona Wetlands from the ocean--like it was 200 years ago.

Your very truly,

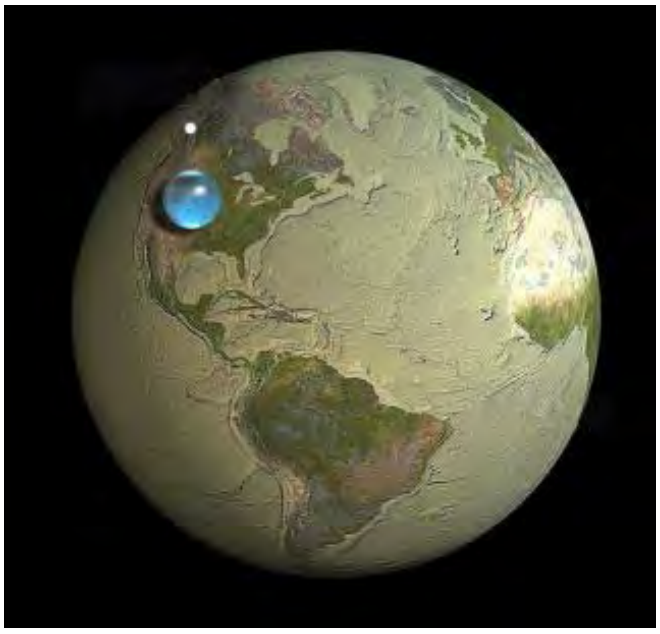
Re: Scoping Comments re Santa Monica Bay Restoration Commission ("SMBRC") April 2012 Notice of Preparation of Draft EIR on Ballona Wetlands



To Interested Parties:

My interests are in the fresh water flowing from City of Los Angeles storm drains into the 2012 Ballona Wetlands. My interests arise from my role as Vice President/Executive Administrator of the Gabrielino/Tongva Springs Foundation, which works to preserve Kuruvungna Springs, also known as State Historic Site 522, the ancestral home of the descendants of Los Angeles' native Tongva people.

Kuruvungna Springs today consists of numerous aquifers among what were once a series of vast aquifers and fresh water sources in and around Los Angeles. As stewards of Kuruvungna Springs, the Gabrielino/Tongva Springs Foundation

monitors the nourishment of the Greater Ballona watershed (including the Ballona Wetlands) with flowing fresh water. Fresh water from Kuruvungna Springs (and from the aquifers throughout the Los Angeles Basin) ultimately dilutes other sources (including known pollutants) in the ebb and flow of tidal water merging from SM Bay, Marina Del Rey Harbor and the Venice Peninsula in the 2012 Ballona Wetlands.

As the second World Water Forum wisely stated "Water is everybody's business," so I encourage any person interested in the environmental outcome of local water sources like Kuruvungna Springs to demand the scope a Draft EIR be widened from the SMBRC alternatives to include broad-based public interests and the welfare of spiritual seekers, scientific researchers, teachers, students, historians, nature lovers, pet owners, public transit advocates, animal wildlife and plant species (including rare, threatened, endangered and critically endangered animals and plants which now reside in the 2012 Ballona Wetlands).

This image is a proportional representation of the ratio of the volume of fresh water on planet Earth to the planet's entire surface area.

Fortunately for Santa Monica Bay and the 4.5 million residents of the greater Los

Angeles Basin, the 2012 Ballona Wetlands continues to be nourished by freshwater from the Greater Ballona watershed, including Kuruvungna Springs, Centinela Creek, Centinela Springs, and run-off from fresh water aquifers including, without limitation of the foregoing, Nicholas, Laurel, Coldwater, Benedict and Stone canyons are now contributing to freshwater habitats in the Ballona Wetlands.

Summary

The Ballona Wetlands are an impressionable surface area of land which bears continual marks of all impacts upon it, whether originating from the weather, the tides, animal or sea life or from human activity. All of the alternatives now proposed by the SMBRC as wetlands "restoration" are improvements, with the exception of the CEQA-NEPA-mandated "no action," alternative No. ___. Any one of the proposed "restoration" alternatives will result in sustained human impact on the wetlands and the habitats therein. The first impact of the proposed "restoration" are improvements in the form of vehicle tread impressions, then with freshly-dropped petrochemical residua originating from said vehicles, followed by vehicle-driven landscape, habitat and existing infrastructure demolition before improvement for proposed newly paved areas of indeterminate size, locale and purpose. SMBRC alternatives need to be clarified and alternatives outside the interests of SMBRC Project Management Team must broaden out to include recognition of the 2012 Ballona Wetlands as an historic bio-region with cultural and spiritual significance to the community at large. Alternatives which protect the Ballona Wetlands habitat for a large number of threatened and critically-endangered animals and plants (as designated in 1995 by the Santa Monica Bay Restoration Project ("SMBRP") the organization which was formalized into the SMBRC in 2003) must also be included. The Ballona Wetlands are a living eco-system dependent on the unique combination of fresh water provided by the Greater Ballona Watershed, and tidal waters from Santa Monica Bay, Marina Del Rey Harbor and the Venice Peninsula. SMBRC Project Management Team acknowledges the tidal waters are "impaired waterways" and have an interest in mitigating or cleaning up the water impairments, but right now there is a

disconnect between what the people employed by the SMBRC Project Management Team, who are thinking about they need to do to keep their jobs, and the call for wider institutional recognition that the alternatives for "restoration" SMBRC now proposes have a vast and troubling impact on long-standing plans for an authentic wetlands restoration.

Introduction

These scoping comments are submitted as 1) A comment and critique of the proposed 2012 Ballona Wetlands Restoration alternatives published by the Santa Monica Bay Restoration Commission ("SMBRC"), a state entity staffed by public sector employees and appointees partnered with a non-profit private foundation (the Santa Monica Bay Restoration Foundation "SMBRF"), and; 2) As discrete environmental proposals currently outside of the proposed alternatives for consideration for possible inclusion into the upcoming Draft Ballona Wetlands Restoration Plan.

As I understand the situation right now, the SMBRC has requested the Army Corps of Engineers terminate a feasibility study and EIS to evaluate the proposed restoration alternatives published by SMBRC. As a result of the Army Corps of Engineers granting SMBRC's request, the permit applications necessary for any of the action plan alternatives submitted by the Restoration Project Team will now bear the name of the SMBRC as the permit applicant. The substitution of the SMBRC to sit in the place of the original permit applicant, the Army Corps of Engineers, is sufficient reason to include proposals which are outside SMBRC's proposed alternatives. There must be a controversy within the alternatives proposed by the SMBRC, because why else would the Army Corps of Engineers right now abandon the 2012 Ballona Wetlands "restoration" project during this scoping period and why would the SMBRC walk away from Civil Works cost-shared project funds to pay for the "restoration" alternatives?

The SMBRC alternatives all raise the issue of wetlands restoration, but there is no mention of wetlands restoration impacts, which begins when the first work truck

pulls off the pavement. Whether that first "restoration" work truck leaves tire tread marks on dry soil or skid track in a wet puddle, during the subsequent seasons of dry and wet, the land will bear the impact of that first truck for years, whether or not that first track is paved over or not. Core sample teams in Autumn 2012 have recently tractored grades inside the Ballona Wetlands as a part of SMBRC's pre-plan construction traffic access creation, which indicates a very laissez faire attitude by the Project Management Team toward critically endangered habitat.

The SMBRC alternatives all raise the issue of which resources to expend on the proposed wetlands restoration, but there is no credible consideration in any of the restoration alternatives for a true no action alternative, that is the action of keeping work trucks on the pavement and off of the 2012 Ballona wetlands. Whether the chosen alternative ultimately increases expended resources exponentially above a single work truck is cause to broaden the scope of the SMBRC alternatives now proposed because the SMBRC alternatives call for improvements to precede all "restoration" activities.

The SMBRC alternatives as designed will produce significant restoration impacts, not restoration results. For example, the habitat throughout the Ballona Wetlands exists to a large extent that no amount of field monitoring can prevent disruption to the cycle of a nesting Great Blue Heron, at one time a critically endangered species, who is in the middle of a cycle of its own wildlife restoration. This was witnessed in the behavior of a Project Management Team supporter on August 16, 2012, when a group of Herons were "spooked" by this man's wild yelling and wide gesticulations.

<u>The SMBRC Project Management Team</u>

It is a great concern that the Executive Director of the SMBRC, Shelley Luce, is also directing the Project Management Team of the proposed "restoration" alternatives. The narrow choice of alternatives proposed by the Project Management Team places the Executive Director of the SMBRC in a position of conflict of interests. The mission of the SMBRC is of a far wider scope than that

of the Project Management Team, which involves each team member to think only about keeping their job, whereas the Executive Director of the SMBRC, Dr. Luce, must have a wider perspective to include the interests of the entire Santa Monica Bay.

I personally questioned several members of the Project Management Team, including Dr. Luce, Dr. Swenson, Mr. Lawhead and Ms. Johnston on subjects including what the current policies are of their respective agencies would be applied to the 2012 Ballona Wetlands. The answers I received from these Project Management Team members was that controversy exists as to whether build dams and fish ladders. No one would acknowledge the fact the Ballona Wetlands have undergone a successful self-remediation from the time of the creation of Marina Del Rey, in spite of the actions of Playa Vista and its predecessors. A once-polluted bio-region has over time, using naturally available tidal flow combining fresh water, Bay water, Harbor and Peninsula water to provide habitat for many endangered and threatened animals and plants, with no help from trucks or heavy equipment. The proposed "restoration" alternatives need to be widened to include this fact.

SMBRC alternatives propose classic "jobs versus the environment" planning which goes that jobs are good for the economy, the proposed alternatives create "restoration" jobs, therefore, the "restoration" alternatives published by SMBRC are good for the economy. The alternatives now published by SMBRC use this oversimplified calculation to obscure that the millions of dollars proposed for the "restoration" ($100-$200 million estimate cost for Ballona Channel alone) act as subsidies to buoy Ballona Wetlands developer Playa Vista's pending liabilities for parkland (B.E.E.P. vs. Playa Vista (2012)), open space set-asides (Culver Boulevard ball fiends), mitigation (aging underground methane gas monitors), storm run-off (silting and dredging 24/7 in a hopeless battle against the sea) and community safety (local natural gas storage wells).

2012 Ballona Wetlands is where Playa Vista sits, mid-project, as a hyped-up private development zone financed by considerable amounts public money, and

utilizing resources on public land (the Ballona Wetlands). The promises made by Playa Vista since its beginning in 1997 are now looming as liabilities with significant back-end exposure for a wide open-ended environmental consequence, for which no adequate mitigation could possibly be forthcoming. For Playa Vista their logic has always been to increase the density of the Ballona Wetlands with resources and improvements, beginning with heavy equipment operated by drivers driving in the wetlands without any supervision or plan, which is also business as usual among those employed by SMBRC Project Management Team.

There are miles of trails in the wetlands which the SMBRC alternatives propose to eliminate. The Project Management Team has said pedestrian traffic will damage the land by walking on it, but the proposed "restoration" alternatives call for massive bulldozers to destroy and demolish existing habitat and infrastructure in the name of "restoration". SMBRC has now closed the entire Culver Boulevard area to the public. If the SMBRC wants to keep the public from seeing the thriving natural habitat in the 2012 Ballona Wetlands, this is proof a controversy exists as to the proposed "restoration" alternatives sufficient to broad the scope of alternatives to include an "off-limits" policy for heavy equipment in the critical and endangered habitat areas. SMBRC's Project Management Team has attempted to minimize this controversy by putting out the story that non-opposition to the proposed "restoration" alternatives signify the public's overwhelming fear of natural disasters and public health emergencies justifies the vast logical leap to bureaucratically-mandated improvements for fast-tracking new linear roadways and infrastructure.

The August 16, 2012 public scoping fair staged by SMBRC's Project Management Team was another step taken to minimize or marginalize any controversy to the proposed "restoration" alternatives. Project manager Donna McCormick said "ICE International is the company that has been hired as the consultant to coordinate and write the environmental report." “Sometimes when we have lots of information already we can provide that, but we don’t have alternatives identified yet,” McCormick explained. This is untrue. According to the SMBRC Executive Summary to the Bay Restoration Plan 2008 Update the original Bay Restoration

Plan was developed in 1995 in "recognition of the need to restore and protect Santa Monica Bay's priceless natural resources." While in 2012 Ms. McCormick said "We could bring some of those things but they are in draft form and they could change, and then people would think that isn't what they saw in the scoping meeting." "So we basically thought that the most important thing was to get people's comments back to us," the project manager continued. "We want to make that available. This type of forum, we think, is much better for getting a lot of discussion coming back to us instead of setting up a microphone and having people speaking one after another." (http://www.argonautnewspaper.com/articles/2012/08/23/news_-_features/top_stories/1.txt). The truth is that any member of the Project Management Team present on August 16, 2012 speaking at a microphone for the public would have created a firestorm of controversy, and this fact is sufficient to demand that broadened alternatives from outside the Project Management Team which provide for habitat preservation, protection and an off-limits policy for heavy equipment in critical, endangered habitats must be included going forward. Rejection of this idea sends the message that the Project Management Team can use bond money raised for public works project to finance a public relations campaign to steer control of the 2012 Ballona Wetlands solely to the Project Management Team.

In a related matter on the subject of bond money paying for public relations to seize control of public land, members of the Project Management Team have put out disinformation about the Ballona Wetlands since 2004 when they began promoting a "salt water wetland habitat" as a necessity to protect buildings from storm run-off. The 600 acres of open space in the 2012 Ballona Wetlands is a sufficient buffer for El Nino and La Nina sized storms affecting run-off in the Ballona Channel according to a 2005 Notice of Intent. I understand there is a 2012 Notice of Intent pending, but I expect the pending 2012 Notice of Intent to be a self-serving document put out on behalf of the Project Management Team. Any public discussion of this would have created a firestorm of controversy, and this fact is sufficient to demand that broadened alternatives from outside the Project Management Team which provide for habitat preservation, protection and an off-

limits policy for heavy equipment in critical, endangered habitats must be included going forward.

The Ballona Channel was built as a project of the federal government built over land condemned by the County of Los Angeles for flood protection. The Project Management Team has publically stated, and the proposed "restoration" alternatives make clear that the Project Management Team wants a lot of dirt from the Ballona Wetlands moved around to create a new 40 foot-high levy around a new fresh water retention basin in wild massive civil works project which may be the ultimate goal for the proposed "restoration." There are more alternatives for the Ballona Wetlands than to re-create the San Gabriel River end-of-pipe "solution" for high-density, high-traffic, high-resource dependent coastal populations masked as a proposed "restoration." Alternatives need to include more than concepts that in advance of a political agenda which do not work.

Secrecy

SMBRC's Science Advisory Committee has been closed to the public. Its minutes and contracts, however, specify the subject matter of the Committee is "estuary only." How come the Project Management Team's proposed "restoration" alternatives includes no data on the plant and animal, fresh water and salt water species who live in the 2012 Ballona Wetlands. This is evidence of a controversy between the Project Management Team and SMBRC's Science Advisory Committee, which is sufficient to demand the scope of the alternatives should be widened to include recognition of the Ballona Wetlands for is core historic, cultural, scientific role as a habitat and an enormous natural mechanism which is alive. In this regard, I refer you the Pachamama Accords of 2008, recognizing the rights of mother earth as a life form entitled to protection of the law from encroachment and predations of improvements.

Why does the State bureaucracy want to dump L.A.'s polluted urban street drainage into the Ballona Wetlands? Because they are under a court order to comply with a federal law that requires the massive L.A. urban region to stop allowing its storm

drain system from funneling urban pollution to our ocean and beaches. But rather than planning and creating their long-promised upstream treatment system. The Ballona Wetlands are very remarkable because the land continues absorb fresh water and exude moisture while also being inundated by impaired waterways saturated with toxins and functions as an estuary for nationally-protected Ballona Creek.

The proposed "restoration" alternatives may include plans for the Ballona Wetlands to divert an already impaired waterway into another waterway which is also impaired. The fact that permitting an impaired waterway to join with another impaired waterway is a violation of the Clean Water Act of 1970 is sufficient reason to demand the scope of alternatives to be broadened to include an analysis of the fresh water species which live in the 2012 Ballona Wetlands because a survey of the fresh water species in the culverts along the northern edge of Culver Boulevard between Jefferson Boulevard and the 90 Freeway will give scientific proof that fresh water from the Greater Ballona Watershed feeds habitats as far east as Sepuleveda Boulevard along the Ballona Channel.

Is the shape of the Ballona Channel subject to change as a result of any of the "restoration" alternatives published by the SMBRC? Is there a relationship between the SMBRC proposed "restoration" alternative and the needs of Playa Vista Phase II to re-calculate storm-water impacts based on run-off volumes now coming off of Playa Vista Phase I? There are $25 million worth of studies on water flow studies available to the Project Management Team, most of which concern the current and foreseeable fresh water dewatering of building foundations and sewage infrastructure serving Playa Vista. I also understand that the City of Los Angeles may share Playa Vista's liabilities for damages arising from water-borne pollution running towards the Ballona Wetlands.

<u>Public Law 228 (1938)</u>

Jurisdiction over the Ballona Channel was established by Public Law 228 of 1938.

None of the proposed "restoration" alternatives recognize the fact that any variance which involves the Ballona Channel requires an Act of Congress to alter Public Law 228 and waive the Clean Water Act of 1970. Estimated costs for changing the course and function of Ballona Channel is $100-$200 million to create an under-evaluated flood control alternative. This seat-of-the pants proposed "restoration" alternative adequate show bureaucratic indifference to rare, threatened, endangered habitat and is sufficient to demand the scope of the alternatives should include rigorous application of the Clean Water Act on the Ballona Wetlands in vetting the final alternatives. (See posts on this here: http://ballona-news.blogspot.com/search/label/Restoring%20and%20Unpaving%20Local%20Open%20Spaces%20to%20Clean%20Up%20Santa%20Monica%20Bay%20Beaches)
.

Is the shape of the Ballona Channel subject to change as a result of any of the "restoration" alternatives published by the SMBRC? Is there a relationship between the SMBRC proposed "restoration" alternative and the needs of Playa Vista Phase II to re-calculate storm-water impacts based on run-off volumes now coming off of Playa Vista Phase I? There are $25 million worth of studies on water flow studies available to the Project Management Team, most of which concern the current and foreseeable fresh water dewatering of building foundations and sewage infrastructure serving Playa Vista. I also understand that the City of Los Angeles may share Playa Vista's liabilities for damages arising from water-borne pollution running towards the Ballona Wetlands. These questions all reveal a source of great controversy as political powers seek to re-shape the landscape at the cost of throwing off older values, which in this case is a California Ecological Preserve, sufficient reason to greatly widen the scope of alternatives going forward to include plans not of the SMBRC Project Management Team, but from scientists, students, community members and nature lovers.

When did SMBRC's mission of "improve water quality, conserve and rehabilitate natural resources, and protect the [Santa Monica] bay's benefits and values"ft change to "wants narrow range of alternatives limited to vehicle intrusions into sensitive critical fresh water and salt water habitats"? Questions about how the

SMBRC changed that position is enough to open out the scope of alternatives to include the mission of maintaining the wildlife habitats (as to the State Ecological Preserve) and current fresh water flows onto the 2012 Ballona Wetlands.[2]

The SMBRC Project Team and Playa Vista

Ballona is a biodiverse ecosystem which has had three natural habitat types persist since at least 1995: salt marsh, freshwater marsh and wildflower and sage covered uplands. Although since 1995 the total area of salt marsh, freshwater marsh and wildflower and sage covered uplands has been reduced (salt marsh, freshwater marsh areas have been by 2/3 reduced by Playa Vista development, wildflower and sage covered upland area reduced 95% by the Catellus housing development west of Lincoln south of Jefferson). Despite the reduction in habitat-available area, annually, and in cycles which have been observed for millennia, rare, endangered and critically-threatened species continue to reproduce in Ballona.

Under the proposed "restoration" alternatives, the freshwater marsh and the last remaining wildflower and sage covered uplands and their wildlife will be mostly eliminated. "Restoration" alternatives have plans for creating an urban pollution street drainage dump, and ignores the impact of the plan and execution of the proposed "restoration" on the rare, endangered and critically-threatened animals and plants of Ballona. The conclusion is that the designation of the Ballona Wetlands by the SMBRP in 1995 occurred when institutional values favored a relationship with existing animal and plant species who live in the Ballona Wetlands. In 2012 the institutional values of Playa Vista have been adopted by the SMBRC Project Management Team and only did so throughout a firestorm of controversy. There is a dream state which must come over a person who decides that the institutional values which form our work lives must somehow also aspire to provide a "higher good" to justify strong-arming the defenseless for a contractor-driven out-of-control mission from day one. This is sufficient reason to demand

[2] SMBRC Bay Restoration Plan 2008 Update, p.2, SMBRC.

that alternatives outside the control of the SMBRC Project Management Team be included in every plan going forward from this time.

In the SMBRC Executive Summary to the Bay Restoration Plan 2008 Update the original Bay Restoration Plan was developed in 1995 in "recognition of the need to restore and protect Santa Monica Bay's priceless natural resources." Note that "The Santa Monica Bay Restoration Commission continues the mission of the Bay Restoration Project and the collaborative approach of the National Estuary Program but with a greater ability to accelerate the pace and effectiveness of Bay restoration efforts." (http://www.smbrc.ca.gov/about_us). The thinking that goes on in the heads of people who work at their jobs with the SMBRC Project Management Team has devolved the Bay Restoration Plan to suit the needs of Playa Vista. This conceptual vacuity shows a controversy existed and still exists around the "greater ability to accelerate the pace and effectiveness of Bay restoration efforts." A "no action" alternative needs no acceleration to create an effective restoration, nature does that using wind, weather, tides, water, all substances which are found in the natural abundance in the 2012 Ballona Wetlands. This is an overwhelming reason to have a consensus that alternatives outside the control of the SMBRC Project Management Team be included in every plan going forward from this time.

The proposed "restoration" alternatives have risk of creating a ripple effect of restoration impacts from tires on the wetland to foreseeable newly paved areas.

The Project Management Team failed in the past to identify relationships between plants and animals in assessing the viability of habitat, for example the reproduction of endangered Blue Butterflies was attributed by advocates for the SMBRC to wildly speculative causes, but when a real-life scientific study was done, the reason the Blue Butterflies struggled was because tires on the ground had squashed and torn up the wild buckwheat the Blue Butterflies have eaten for thousands of years.

The Project Management Team has $6.2 million but have not assessed the risk to

present day value. The scope of the "restoration" alternatives needs to be expanded to create accountability within the Project Management Team for their present insufficient species analysis.

Flood Control: Mandate or Raison D' Etre For the Project Management Team?

The proposed "restoration" alternatives published by SMBRC do not support a range of alternatives. "Dredge and fill" wants to widen the connection between the ocean and the 2012 Ballona Wetlands using vehicles, petrochemicals and pavement, all of which change the fundamental character of the wetlands, which is absorb fresh water at high tide and off-gas moisture during low tide and during the dry season.

Grave Desecrations

During construction of Playa Vista Phase I, Playa Vista unearthed long-buried human bodies belonging to members of the native Tongva people. Playa Vista attempted to cover up the number of graves it unearthed and its subsequent careless handling of human remains. Through political manueverings and favorable reporting in the media Playa Vista was able to avoid bad publicity. However during this period of public relations spin, Playa Vista promised to restore the remains to the site of their original interment. Right now the ancient graveyard of hundreds human bodies is still an open ditch, one mile long by 3 feet wide, 3 million cubic yards of soil disrupted and removed. According to coverage in the May 31, 2012 "Argonaut" "several dozen fragile remains, were re-interred at Ballona Discovery Park in Playa Vista." There must be an alternative to the SMBRC alternatives which call for using heavy equipment to move massive amounts of water and earth and only give Playa Vista-grade promises to responsibly handle human remains.

Proposed Alternatives Outside the SMBRC Proposed "Restoration" Alternatives

New alternatives are needed in the interests of preserving and protecting the Ballona Wetlands:

1. Soil - New topsoil is habitat to rare, threatened and endangered plant life, including critical micro biota.
2. Ground water - Necessary for cyclical resurgence of seasonal life forms
3. Tidal inflow onto the Wetlands
4. Tidal outflow into the Bay, Channel, MDR Harbor and Venice Peninsula
5. Fresh water inflow from the Greater Ballona Watershed
6. Fresh water outflow from the Ballona Wetlands
7. Animal species (including migratory fowl and seasonal sea life) which rely on fresh water
8. Animal species (including migratory fowl and seasonal sea life) which rely on brackish water
9. Plant species (including annuals) which rely on fresh water
10. Plant species (including annuals) which rely on brackish water
11. As the site of the native Tongva village of Sa-Angna
12. For use as a natural outdoor sacred site for spiritual rites
13. For use as a natural outdoor classroom for students K-12, through post-doctorate studies
14. For use as an historic site illustrating the impact of human habitation on the wetlands

The current eco-system now in place in the Ballona Wetlands has value as a viable habitat for endangered and threatened animals and plant life.

Doing no harm to the habitat of the Ballona Wetlands means preserving the existing wildlife habitat for the Western Shrike, Kites, Harriers which are unique examples of wildlife in an urban setting.

The Ballona Wetlands are a native American sacred site, the location of "Sa-Angna," one-time village of the Tongva people native to Los Angeles. The

Donna McCormick
David Lawhead
Dr. Daniel Swenson

Ballona Wetlands are also acknowledged for their significance as an intact local resource for outdoor classrooms for students studying a wide range of scientific disciplines.

Restoration results, for example, would further facilitate the habitat throughout the Ballona Wetlands to prevent disruption to the cycle of a nesting Great Blue Heron, at one time a critically endangered species, who is in the middle of a cycle of its own wildlife restoration.

The Vision

The action of doing nothing, means the SMBRC would stay conscious of the resources provided to it, without expending the earth and water resources which were ceded to the SMBRC. The action of establishing an "off-limits" policy to cyclical resources periodically available through atmospheric seasonal change.

Going forward a plan needs to protect the three existing wildlife habitats and existing trails and allows for fresh water inflow onto portions of the wetlands. If the SMBRC is doing their job, the results will that one day clean water will enter the Ballona Wetlands from the ocean--like it was 200 years ago.

Your very truly,

Jack Neff

RE: Comments on NOI to Prepare Joint EIS/EIR for Ballona Wetlands Restoration.

Following are my comments/questions for the Ballona Wetlands scoping process:

1. Please address what happened to the 1995 and 2005 EIS process.
2. Please address what happened to the lower Ballona Creek Watershed Ecosystem Restoration Study, with its recommendation to "proceed into the feasibility phase to develop an ecosystem restoration and watershed management plan for the lower Ballona Creek watershed", signed by LT Col. John V. Guenther, ACOE, Sept. 2002. Where is this plan, and the feasibility study? Is it being used in this current effort?

3. Many studies have been done on the Ballona wetlands and are available, such as the Ballona Creek Watershed Management Plan:
(http://www.swrcb.ca.gov/water_issues/programs/nps/docs/conference2003/01markhorne.pdf)
and Historical ecology:
(ftp://ftp.sccwrp.org/pub/download/DOCUMENTS/TechnicalReports/671_BallonaHistoricalEcology.pdf)

   Will the current EIS/EIR process utilize all such previous works?

4. Much public funding has already been expended on such studies, yet there is $6.25 million allocated for new engineering studies and alternative designs. Is this a good and necessary use of taxpayer dollars and/or bond monies? Who receives this funding, who disburses it, and what is the oversight as to the value of services provided and results delivered? Are restoration project proponents linked to those disbursing or receiving funding—is there impropriety or even the appearance of such?
5. What are the relationships between the various public and private entities involved in this current restoration planning process, including consultants, and how are they

related to adjacent developer interests such as Playa Vista/Playa Capital, as well as developments in the Marina del Rey and Playa del Rey areas?

6. Are the proposed levees to protect developers' interests rather than for ecological function and restoration? Could there be unintended consequences to other areas of the Ballona valley, the wetlands or Playa del Rey--as in New Orleans recently where rebuilt higher levees caused unforeseen flooding in outlying parishes.

7. I understood the previous EIS process to be an integrated comprehensive watershed-wide plan, including more of the watershed, addressing water quality upstream as well. Wouldn't this be a more ecologically sound approach than piece-mealing parts of the Ballona watershed?

8. Ballona Creek is an impaired water body—shouldn't water be cleaned up along the way and before entering the proposed wetlands restoration area?

9. Please analyse the needs of existing wildlife before, during, and after the proposed restoration process, including crossing opportunities above or below roadways, possibly lifting parts of the roadways (Culver, Jefferson) to provide such crossings for animals and water. 3500 animals killed annually at Ballona, according to Dr. Sean Anderson, CSUCI. Playa Vista was required to create a Lincoln Blvd. wildlife undercrossing, which has not been adequately done. Please investigate this failure.

10. Consider how to work with and protect existing habitat, plants and wildlife. From Lessons in Native American Plant Gathering: "…how to live *with* nature…Native American cultures acquired vast experience in how to use, manage, respect, and coexist with other forms of life" *(*referencing *Before the Wilderness*, anthology documenting environmental management practices of California Indians, M. Kat Anderson, coeditor). Please consult with local Tongva as to how to restore this land.

11. Please consider gradual, natural restoration, by hand, using small equipment and tools. This would be an opportunity for school and community groups to be actively involved in restoration, increasing participation and education, with social and psychological benefits.

12. The video, “Restoring Southern California Wetlands”, is a biased production promoting a severe and destructive engineering project as restoration, by people who have an interest in such an engineered restoration. Unbiased scientific analysis is needed as to restoration goals and methods. Restoration is not an engineering project! It is a labor of love for the community.

13. Go slow—listen, look, learn. Protect and create nesting habitat, rookeries, perches. Assess the overall health of the ecosystem, use the Precautionary Principle to preserve what is there, work to enhance it.

14. Analyse impacts of SoCalGas/Sempra’s storage, facilities, pipelines, wells. Are there gases escaping into the air? Is there toxic residue in the soils and leaching into the water? Please consider potential for shutting down these operations in the future. Consider long-range possibility of acquiring bluff for upland habitat, to mitigate for loss of West bluff upland habitat, including vernal pools, above wetlands.

15. Please investigate the defective process of earlier EIRs for Playa Vista: CDFG granted a streambed alteration permit to create “Riparian Corridor” which feeds into “Freshwater Marsh”, thereby enabling the digging up of a Tongva sacred site and burial area. In a conversation with DFG staff, I was told that the permit would not have been granted had they known of the burials there (over 1000 destroyed). Was the knowledge of the burials hidden or not disclosed to CDFG--a material misrepresentation? The SRI archaeologist knew of the significant burials, having told me prior to the excavation that there was a large burial area there.

16. Please address another defect in the earlier Playa Vista EIR—the Programmatic Agreement (PA) between ACOE and Tongva tribal representatives was more than 10 years old, and was not properly updated or agreed to by current tribal members. Two of the original signators were deceased at the time of the purported updating. The PA was therefore not valid. The State Native American Heritage Commission wrote several letters to this effect, asking for a cease-and-desist on the burial destruction.

17. Please analyse earthquake and liquefaction potential in regard to proposed restoration, including tsunami risk and predicted sea-level rise.

18. The Ballona aquifer is a potential drinking water source—how might this be affected by proposed large-scale earthmoving, and possible salt-water intrusion

19. Dredging off Ballona Creek channel brings up highly toxic material. How will the wetlands and waters be protected and cleaned-up, particularly if such proposed large-scale earth-moving occurs?

Re: Ballona Wetlands Project
cultural resources impacts

Dear Ms. McCormick,

It has come to my attention that the California Department of Fish & Game (CDFG) is planning large-scale grading and construction on the Ballona Wetlands Ecological Reserve for the purpose of "restoration." If due diligence is carried out with the proper agencies (SHPO, NAHC, etc.) it will be noted that cultural resources on this land have been negatively impacted within the past 25 years, with numerous prehistoric Native American remains disturbed in the process. Needless to say, local Native Americans consider this to be a sacred site.

Rather than proceeding with an overhaul of questionable necessity, it is strongly urged that the lead agencies explore less invasive restoration measures. In light of the extreme cultural sensitivity therein, the remaining integrity of the Wetlands Reserve should be preserved and protected. I thank you for your consideration in this matter.

Sincerely,

E. Gary Stickel, Ph.D.

To: McCormick, Donna
Subject: Comments on the Scoping of Ballona
Importance: High

Dear Ms. McCormick,

As you surely know, many of us who helped 'save' the Ballona Wetlands, do not want what we call 'industrial development' in the 600 acres. Over the 60 years since the outfill from the development of the Marina was dumped there, a whole ecosystem has developed, and what we have there already is quite amazing, if one takes the time to look, explore, see, enjoy, live with. One person who has helped document the great diversity, color, variety, and astonishing life that is the Ballona Wetlands, is Jonathan Coffin. If one just goes to his site on flickr "stonebird' you will find thousands! of beautiful photos of the ecosystem, and wildlife that make it their home. How can one go in there and bulldoze this life, these gifts from nature? If anyone in our midst knows these wetlands like the back of their hand, loves them as his own, (and they are our own', all of ours), it is Jonathan. Many of us don't believe in 'industrial development' of these wetlands. We didn't work so hard to save them, to have them bulldozed! That is just what we were against for them then, and are now, wanting very much to avoid any industrialized machinery, extreme re-making, large disturbances of the Lives and ecosystems, that have been doing fine, thank you.

We believe in gentle, hand tool type 'restoration' done carefully and s l o w l y, so as to disturb as little as possible the lives and homes of the abundance or plants, soils, critters, etc. that make Ballona their home. And each phase of any such 'restoration' as we envision, will be done with utmost caution and study of exactly What is There, from the tiniest ant/bug/spider/bacteria, to the largest mammals, which are probably the coyotes. I implore you to listen to those who have lived close by for many years, have walked the area for surely many thousands of days combined, and know it. These are the folks any agency that has designs on this area need to be consulting with, meeting with, listening to! This only makes common sense! One cannot learn about and get to know a piece of land by a 'survey', by spending days, even months in such an area. It takes Years to get to know and love and appreciate a piece of land and what is born, flowers, lives, dies, grows, spawns, nests, feeds, on it and in it.

No one who knows and loves a piece of land the way many of us do, could possibly be approving of literally bulldozing it! It feels/seems/is unconscionable to us. That is where many of us come from. Changing the 'character' of the place, at this point, just seems too much like man thinking he can come in and make better, something that now only exists on paper.

So I implore you to please listen, and listen carefully, to those who would not bulldoze. Take a walk with them, and see it how they do, learn all you can about what is there, before one shovel

of dirt is moved. Maybe then you can have/will begin to have, such a deep appreciation of what is already there, and maybe then there can be a real dialogue about how to proceed in as gentle and non-disturbing way as possible...over time, not in a bulldozing, destructive, violent way, but in a way that respects what is already there as much as possible. We have salt flats, we have 'prairie' where the great blue heron feed until they are a year old, where gray foxes make their homes, and thousands of other living things that have filled niches that those who would bulldoze could well know nothing of. Only the people who intimately know Ballona discovered the rare, and we thought forever gone, native flower popping up! Along with other discoveries over time.

Thank you for taking my words to heart, and know that we are not totally against 'restoration'. But it needs to be gentle, slow, and with human hands and tools, using the knowledge of the ones who best know and love this wonderful piece of land and open space within our midst.

Sincerely,
Lola Verdurer Terrell
Ballona advocate

RE: **my official Scoping comments** to Scoping for Kill-It-To-Save-It Bulldozing Plans for La Ballona
August 20, 2012 revised/ extended October 20, 2012
(Bold type indicates subject matter to be addressed in detailed responses to this Scoping)

On behalf of nature: To whom it may concern: non-profit "partner" Santa Monica Bay "Restoration" Commission (SMBRC), Department of Fish & Game, California Coastal Commission, State Parks, and State of California

About a decade ago, I heard an outrageous debate on a L.A. area radio station over development vs. environment, both sides claiming to know best for the environment. The *place* that argument was over was La Ballona, the last large remaining refuge of wildness on Los Angeles' west side- I'd noticed on my way to the airport as one of the few places where traffic moved, the only place dark at night, the best place to hear a frog chorus... I concluded that was surely protected park land...

The first presenter in that radio debate said in essence: this *was* wasted land, it *was* going to be developed, and *if* environmentalists were smart, they'd work with developers to save those few westernmost acres worth saving. What? I couldn't believe I was hearing such pro-developer greenwashing tripe said out loud, on-air! Until another presenter argued it was *all* worth fighting for- to save it as a natural place.

I'd soon find out this was Los Angeles county's last, largest, & best surviving wetlands/ uplands complex, once ~3,000 acres in size, was tragically already "developed"- whittled down by that time to ~1,200 undeveloped acres, but not one inch of it had any protection of any kind from bulldozing & developer speculators intent on destroying it. That saving La Ballona was crucial for the survival of California's endemics (species that occur nowhere else), because only ~5% of the state's coastal wetland areas remained that hadn't been "developed" (almost always exclusively for human use). That saving the largest contiguous block of it, in as wild condition as possible, was essential for animals higher on the food chain (needing larger territories) to survive here. That Ballona was a critical stop for Monarch Butterflies, Snow Geese, & other migrating species. Along with many others, I got personally involved... community/ environmental/ church/ & political groups got involved... >126 groups formed a loose Coalition... to try to save La Ballona from bulldozers with press conferences, demonstrations/ movie pickets/ marches, street theatre, community education, a hunger strike- trying to find an pro-environmental way ahead, meeting with politicians, the would-be developers, & would-be tenants of Playa

Vista. Some local journalists risked their reputations to cover this "David vs. Goliath"-style story in a balanced way.

In the end, the city of Playa Vista got built despite community objection, killing plants & animals, sacrileging ancient native American gravesites- illegally removing the remains of hundreds of individuals to & from Santa Barbara- before reburying them elsewhere in Playa Vista, destroying remaining hydrology & habitat, and surrounding about half that remaining land. Playa Vista's sound-alarms do nothing to abate the endless burping of gasses that keep bubbling up, like they do at the Las Brea Tar Pits: Hydrogen Sulfate (stunting cognitive development in children), and leaking Natural gas that's already led to at least one death (a 1st-responder who illogically lit a match in an enclosed area that smelled of gas)- Natural gas that The Gas Company injects back into the salt domes beneath La Ballona for cheap-but-leaky storage. Playa Vista's earth movers heaped earth then ran over/ smashed possibly hundreds of capped gas/ oil well heads from the 1920's-1930's to make building pads. The Frenemies sold out to the developers, taking (a never-disclosed amount of) money to bless Playa Vista & defend its developers whenever they're attacked (to this day). The State bought half of what was left, paying way too much from the State's coffers (which only enabled developers cash to build quicker, when much of this land was wet & unbuildable anyway, and bank financing was otherwise hard for them to get)...

SMBRC is incompetent, and the process SMBRC started is already wrong; REMOVE THEM FROM THIS PROJECT AND IT'S LIKELY TO COLLAPSE FOR GOOD: Should the public idly stand by now that SMBRC/ other Frenemies of Ballona are trying to bulldoze & radically reshape the Public's 600 acres- "to kill it to save it" in the name of nature-annihilating "restoration"?... these same acres we fought to save from developers' bulldozing "Save it! Don't Pave It!"... when SMBRC's precedents (Steal-the-Bay) and its allies did little (or threw up obstacles) to save Ballona in the first place? SMBRC's "Kill it to save it" mentality, or Playa Vista's apologists' "Only 125 acres are worth saving", or developers' "Road lane expansion is necessary for all the traffic that's coming" (Hello! Frogs don't drive cars!) are among many incomprehensible nonsequiturs (the watershed is polluted; we must bulldoze downstream to clean it up), lies ("we don't have any plan yet"), and mis-conclusions based on mis-understandings (delta meander shapes observed at one point in time means that building fixed, randomly-curvy concreted channels would be good at Ballona) propagated about nature ("It's so degraded/ the invasives so bad that nothing in there is worth saving") & coastal wetlands generally (big salty holes for water storage are top priority (yet cleaning up or saving natural habitat at Marina del Rey is avoided, the Marina a bigger, saltier hole than ever existed in historic times that shares Ballona Creek's inlet/ outlet)... Since the State paid a record *$139,000,000 per acre* for these lands, doesn't that mean they extremely valuable in the condition they are in? This should completely disqualify SMBRC from doing anything at La Ballona, writing or sponsoring any of the Restoration Alternatives; the Community should be allowed to write at least half the total number of Final Alternatives, especially those emphasizing "Non-Bulldozer Phased Management," "Wildlife-Friendly," and "Historic" Alternatives; combining elements of these will automatically be more humane than the disasters that follow:

Having an argument about the highest & best use of land is one thing, having ASYMMETRICAL power & control of bulldozers & State backing to destroy LAND forever is another; SMBRC should be ineligible, particularly & completely disqualified, removed from any coastal or wetlands restoration project based on its track record:
And by "bulldozers/ bulldozing" I mean power & equipment emblematic of any mechanization regime for "industrial-scale habitat restoration;" this scale is almost always appropriate for permanently destroying/ altering/ degrading land; and almost never appropriate for restoring land back to natural conditions! Whether a Developer or Greenwashing "environmentalist" is in the cab of the bulldozer makes no difference to the flora & fauna being squished & maimed; widespread death is the same result. Having SMBRC, its predecessors, & allies in the driver's seat already has led to environmental crimes that are completely unacceptable & inapprorpiate for these 600 acres:

1) The creation of a toxic drain, funneling runoff from Playa Vista's parking lots & rooftops into a "Freshwater (sic) Marsh"- spewed into stolen wetlands (not internally: east of Lincoln, but greedily: west of Lincoln Boulevard), cutting down La Ballona's oldest & best mature native

willow grove (habitat needed to attract rare/ endangered birds) to do what?- plant willows! This is the "restoration" model of SMBRC, designed for & by humans; this may be professional landscaping, but THIS IS NOT restoration! Nature knows best, and we'd best get ourselves out of the way.

2) The total annihilation of the Malibu Lagoon west of the main channel of Malibu Creek, wrecking 3 bridges used as outdoor classrooms (over arms of a lagoon dug in 1983) and shortest route for Coastal (beach) Access. Of the many plants & animals (2 endangered species, & ~200 species of birds alone) that used Malibu Lagoon, nearly nothing lives there today, and won't for many years- nothing except bulldozers, and maybe MRSA bacteria (SMBRC was afraid to test for!) Both are environmental crimes, senseless "man-made" catastrophes based on ignorance and miscategorization of wetlands (Malibu & La Ballona Lagoons were seasonally-closed & brackish, not full-time-tidally-open deep salty estuary SMBRC is trying to build at Malibu) both will now never be the same. While the State is "under water" financially, the rape of Malibu Lagoon drained millions of dollars to execute wildlife, in a State Park; this is just criminal. The byproduct of a fatally flawed analysis (that high-organic, low-oxygen, brackish water that ducks use doesn't belong in coastal lagoons), and that alleged problems the rape of Malibu Lagoon intended to cure won't recur (where do fish & birds go to the bathroom?) Meanwhile, the rape of Malibu Lagoon did nothing to remove the upstream, human-caused sources of water pollution, or wildlife barriers (removal of Rindge Dam to give steelhead & other

fish a chance at upstream habitat as far as Ahmanson Ranch wasn't included); the same would be true at La Ballona.

As a foretaste of the "attractive nuisance" would happen all over Ballona, I've observed wide swaths recently cut through the plant material for the on-site coring operations (I believe this was done in support of this proposal) have opened avenues for unauthorized vehicle forays, trash & furniture dumping, and homeless encampments deeper in the wetlands. The width is excessive- looks like a road; Gas Company trucks seldom leave behind such an opening, or ensure locked gates close their driveways.

THE TOLL ON NATURE TAKES ITS TOLL ON THE PUBLIC: Malibu Lagoon was ~12 acres... La Ballona is ~600 acres but headed toward 0 if bulldozers have their way; there is just no "somewhere else" for coastal wetland dependent species in California to go- especially brackish (non-salt) wetlands- have almost all been wiped out! The coastal human community (that appreciates nature) in Malibu is exhausted, confused, angry, and broke from fighting these battles- that ultimately wind up in court out of the public's reach, because only a court ruling can knock sense into the thick skull of determined developers, and no level of government can really be trusted to keep tax money from being squandered, and keeping electeds constantly reminded to protect the environment,

Once in the cab of the bulldozer, the developers of what's now Playa Vista (City of Soviet-style prison blocks with neo-historic facades painted on, a future ghost town after the next large earthquake/ tsunami/ or after the state realizes it cant' pay claims from children getting brain damage from hydrogen sulfide & Natural gas leaking from the salt dome under Ballona/ south Marina) **could not be trusted... neither can SMBRC be trusted.**

"There is no right way to do a wrong thing!" SMBRC is now asking for the public's participation in the process of designing a "restoration" of acreage of La Ballona, but this is "putting the cart before the horse": Instead of producing a Purpose & Need, then Scoping, SMBRC has been disingenuous: hasn't officially "shown us their cards." During the scoping phase, SMBRC staffers denied in plain English that any "fix is in", or that SMBRC already has a plan. Without a doubt this is a lie: a range of at least 7 preliminary plans from bad to worse are already prepared (tellingly, a rough aerial sketch labelled "5A" illustrated a hardscaped Ballona Creek meander on an easel during SMBRC's initial August Scoping meeting- oops!) Choosing or blessing any of those pre-Scoping schemes cannot be allowed- if Malibu Lagoon's un-credible environmental documents were any guide, they are 1) Alternatives of unmitigatable damage to the environment ranging from bad to worse, 2) the current Coastal Commission's precedent for this will be to reject a pro-environmental compromise designed by

scientists: like one that met SMBRC's flawed Purpose & Need, retained direct coastal access, phased-in very small-scale channel dredging to allow native species to survive with room to move around its impacts, and retain a balance of seasonally brackish & seasonally salty wetlands. At the Scoping, SMBRC's staff urged us to put down everything we were thinking on an 8-1/2" x 11" paper for inclusion (that's enough?), but other staff told us right away there are several things "off the table": removing any roads, removing any structures, taking the Gas Company, acquiring any more land from Playa Vista or elsewhere. While their unwitting, unselfconscious, unvarnished honesty was delicious (as it's as surely a portal into SMBRC's covert "restoration" plans, as it is an index to its allied backers!) SMBRC might consider *professional* staff/ staff behavior next time...or not. There were at least 2 such "loose cannon" staffers (who also used the word "I" frequently at the Scoping!) But this was supposed to be Public Scoping Phase, not Public Self-Editing Phase: it is our job, not SMBRC's! to set the parameters. Of course, these "off the table" ideas staff mentioned would be the *top implementation priorities* of anyone designing Real Restoration (road traffic alone being the #1 cause of ~3,000 annual wildlife fatalities at Ballona). So I really can't help SMBRC because they're not really interested in hearing what the public has to say...

What kind of appropriate things a *qualified* lead agency should be doing *if Real Restoration was "on the table"*: (or more appropriately, because it's already so shriveled from its original size, Ongoing Management) for LaBallona:

1) "First, do no harm." Using this Precautionary Principle would have stopped the rape of Malibu Lagoon all at once, cold.
1A) "The first rule of intelligent tinkering is to save all the pieces," said Aldo Leopold. Just leave Ballona alone- for nature to continue its work- is not the worst thing for Ballona. Leaving it alone may be the best thing, yet somehow so hard to understand/ think straight once the bulldozer's keys have been turned, and bulldozer power's in *anyone's* hands.
On the Intelligent Tinkering front, I know slow, by-hand restoration can work because I've done it- part of the team managing "The Big Plant-In", a multi-year (2008-present) all-volunteer community restoration on the east bank of Grand Canal Lagoon on the east bank just south of Washington Boulevard Bridge, Venice. And I've tried to grow other beneficial Ballona Natives (like Ballona-native narrow-leaved Milkweed used by migrant & resident Monarch Butterflies) at our nurseries. Though not perfect, this tidally-influenced canal bank site (near the northern end of La Ballona's natural historic channel), was replanted with a self-sustaining community of tall native shrubs, wildflowers, herbs & grasses, the plant palette professionally designed, sourced & grown from Ballona-native genetics. Stored & growing in plant nurseries at 2 nearby schools, prescribed erosion control & native plants were placed at the lagoon- not by bulldozers- but all by volunteers using hand-tools: neighbors, school kids & collegians, service organizations, church groups, political campaigners... even foreign tourists, that generates community buy-in bulldozing never does. Dense non-native myoporum bushes that housed homeless people are gone, as are broken concrete slabs, Chilean pepper trees, castor bean, iceplant, annual garden flowers planted by under-educated locals... Existing native plants & grassy areas already there were retained, which paid off during a planting in 2010 when our volunteers discovered a mallard & nest under one of the retained shrubs on the site (she came back after about 1/2 an hour, successfully hatched & raised that brood). I've also noticed plant succession after we pu the natives back in many areas at the Big Plant-In. From our mostly-random planting, nature sorted things out: coyote bush engulfed surrounding smaller plants. Telegraph Weed & Coast Buckwheat at the highest & northern half gave way to Goldenbush, while pickleplant dominated closest to the (tidally-influenced) water's edge. Everlasting & Spiny Rush were overtaken by larger plants many places, but survived where other plantings perished in poor, gravelly soil. Weeds which plagued us from the 2nd year (mustard & non-native mallow) diminished, now choked out in most places by dense, self-seeding natives.
1B) Since the rape of Malibu committed in June 2012, the State would be foolish not to insist there be no project & no money-wasting at La Ballona or any other Southern California wetlands complex *Unless & Until* SMBRC/ State Parks/

Project contractors prove their ability to quickly grow back/ rapidly re-attract native, rare, & endangered species to re-inhabit to a thriving Malibu Lagoon. It took decades for nature to reclaim Malibu Lagoon and progressively bring natural diversity back since bulldozers carved lagoon channels out of ball fields built over earlier CalTrans' spoils (dumping grounds) in 1983. Even if this works and Malibu Lagoon were to look & function like it did before June 2012, supporting the same number of plant & animal species within say 2 years (this would be a miracle), this is not justification to bulldoze everything all at once; only small parts of La Ballona should be restored at a time, and experimentally, over a period of years in case anything goes wrong, taking no more than say 10% of a habitat or species so there are no extirpations at La Ballona. The animal capturing effort at Malibu was pathetic. And large & numerous quantities of native plants could have been boxed & kept at offsite nurseries for regrowing Malibu Lagoon quickly, but this was not done. Bulldozing everything at the same time -as if laying the foundation for an inanimate warehouse building- to instantly achieve all elements shown in the "ICF" plan is"magical thinking" that will not work and must not be allowed in any scheme. Do you know where Burrowing Owl habitat is for instance? I'm told they no longer live full-time in Ballona as they did until recently, but now only visits seasonally; what bulldozer power-take-off (PTO) attatchment is going to dig enough owl-acceptable replacement rodent holes for a sustainable population of them to live in after you've caved in all the rodent holes with bulldozers?

1C) Instead, SMBRC's likely to find catastrophic lagoon destruction encourages catastrophic foreign & weedy species invasion. Evidence of this is found at the industrial-scale "restoration" on west bank of the severed Ballona Lagoon in the Marina Peninsula (in City of LA, north of Lighthouse Bridge): as part of its "restoration", its 'genius' designers disturbed much of the upper canal bank soil & piled wood chip mulch on top (as lagoon soils are often alkaline, this probably tipped topsoil chemistry sharply toward

acidic). This spring, castor bean and other weeds explodeded, growing more thickly than ever, choking & towering over the native plants. But this invasion did not happen in adjacent areas south of Lighthouse bridge, where discovery & confirmation of the extremely rare Orcutt's Yellow Pincushion prevented both the scraping & mulching, as well as preventing the explosion of weeds. (For Malibu, SMBRC/ State Parks originally wanted to poison anything that escaped bulldozing with Agent Orange derivative "Round-up", but verbally removed it on the spot from the Malibu bulldozing hearing during the 2010 Coastal Commission due to audience outrage... yet had the proposers read the manufacturer's label, Round-up's prohibited from use anywhere near open water-courses).

2) FOR ECOLOGICAL HEALTH, CUt BACK ON SALT! We've already dug more salty holes (= harbors & channels) along the coast than nature'll ever need! So where is the apparent "need" for stormwater storage coming from? Southern California harbors & channels have displaced more brackish wetlands for salty- than ever existed in historic times. Nature has no need for more of this, so (Army Corps'/ L.A. County- driven) counterproductive element of floodwater storage posing as natural restoration should be scrapped. Instead, nature needs more of the brackish wetlands over the salty.

2A) DOES TABULA RAZA WORK? PROVE IT FIRST! *Besides* restoring Malibu Lagoon to pre-rape conditions, *before* running away to wreck Ballona on a large scale, the applicants' contractors should be required to *demonstrate they can "play God" for nature's benefit offsite*: Let the proposers prove the truth of their abiding faith in Tabula Raza (clean slate/ clean sheet of paper/ as if there was nothing there before) to those of us who don't believe it: Buy & close a distressed shopping center, excavate 2-12 acres of its parking lot, filling the bottom with a pond liner and salt water (with a pump for emergency drainage) to mimic the water column at La Ballona. Then, turn the contactors' bulldozers loose, filling the hole from sediment layers up to topsoil to plants & predators on top- to build the best mature brackish wetland & surrounding uplands money can buy. Setting the timeclock at "zero", and verifying their water column balancing success with regular corings, let's find out, if it can be done, how many years it will take to build a lush brackish wetland over salt table, and compare the quality of the resulting nature life support system. Let the contractors demonstrate their ability to build seasonal vernal pools, salt panne, crusty in the dry season, that support specialized animal communities, alkali flats, and stable drainage channels with bulldozers. Let them build vernal pools (recreating sediments laid down over millennia, & stock them with native seedbanks using bulldozers) like those lost to prior habitat destruction (such as the lost ones existing on the Ballona- adjacent 75 acre Westchester Blufftop field

west of Lincoln once used by raptors, now blanketed by contractors' houses. I'll predict the conclusion now: Recreating & balancing brackish wetlands above salty with bulldozers may be well-nigh impossible. If it even works, bulldozing champions will admit bulldozers & industrial-scale techniques don't do a good job, and most of the successful work will have been done slowly by hand. Habitat quality & species population & diversity will not match the original, and may be self-sustaining. Every honest bulldozer champion will concede minor repairing of the original La Ballona would be much easier. But this Tabula Raza project should be a mandatory prerequisite before bulldozing one inch of Ballona.

2A) Not one more inch of salt-water habitat type is needed! The creation of Marina del Rey itself (c. 1958-60) displaced 804 mostly-brackish acres, bringing far more salty water intrusion deeper & further inland than ever existed before Europeans arrived; (spectacular wetland losses at what's now Dana Point Harbor also comes to mind... that, to add insult to injury, also cost recreational users an irreplaceable surf break...)

2B) Global warming/ rising sea levels are on the way (3'- 4' higher by mid-21st Century) this means salt water is moving inland anyway. Farmers who grew celery, possibly beans there allegedly dumped "a couple feet on soil" on parts of Ballona in the past (those who use this as a hammer to justify bulldozing everything can't tell me where it is, where it came from (most likely native local soil dredging from other parts of Ballona) or how deep!) But what we actually need to do with that fill now is: Nothing! To wait! Admit our hubris & restrain our human urge to fool with it- if we just leave nature to work out the plant palette & its animals there, it will be *just right* as the sea levels rise over the next 40 years.

2C) The north Marina's polluted "Duck Pond" needs massive help: (unbelievably, it drains through to Mother's Beach!) including re-conversion to native plantings; this is another place for limited wetlands

restoration experimentation!

3) SPEND MONEY ON ACQUIRING MORE LAND FOR BALLONA INSTEAD OF WASTING MONEY TO DESTROY WHAT WE'VE GOT: Because so much of historic Ballona has already been destroyed (from ~3,000 acres, down to ~600), and wildness succeeds best (higher levels of the food chain) with the largest blocks of contiguous land possible, direct all efforts to acquire State funding to "Complete the Park": Add as many land parcels as possible for wild native plants & animals inside historic Ballona. Examples of this include a parcel of land at the north end of the southern remnant of Ballona Lagoon in Playa del Rey; currently within sight of its northern half, cut off by construction of Ballona Creek channelization (c.1938-40) Marina del Rey that extends to Venice. This land is for sale, and should be acquired by the state so this eminently "buildable" land doesn't become a 40' high wall of development that cuts off this viewshed. Another example is a long strip of land- a ~40' wide railway right of way adjacent to the southwest edge of western end the 90 Freeway that contains wetland (ditch with wetland plants) & upland species; if the Toyota dealership that owns it decides to culvert & pave it to maximize parked cars (the neighbors don't want this), Ballona plants & animals (like frogs that sing there, wading birds that eat them) would lose their habitat forever. Likewise, the retail garden center to the northeast, between the lanes of the 90 freeway, along with all other unpaved pieces within the CalTrans right of way should be merged or acquired to raise native plants for CalTrans & Coastal restorations, or made wild to extend the reach of native habitat... Unnecessary, useless, and destructive of native sites in the first place, travelers of the 90 freeway have nowhere to go; like the beneficial removal of San Francisco's Embarcadero Freeway, its complete dismantling west of the I-405 would save highway maintenance dollars, quiet our neighborhoods, be a great benefit to nature in the Ballona Valley, and never be missed in the future.

4) LAUNCH A COMMUNITY SUPPORt & EDUCATION program to enlist the public's help raising & maintaining sustainable populations of rare & native species from local genetics with organic methods in containers or yards.

I know the people of greater Ballona are interested in helping nature communally (group projects like the Big Plant-In) & individually (asking for native planting advice). This could extend to the greater Ballona valley as well (for cleaning projects on upstream watershed):

4A) Research and document Ballona Plant Lists & Ranges with coded & separate lists for: Recently extinct/ extirpated (last 100 years)/ Rare/ Endangered Native, Natives, Native American Plants (yerba mansa, tree tobacco, chia, etc.) Non-Native Beneficials (Anise, for its flower clusters that support butterflies.) Research and document Ballona Plant Lists & Ranges with coded & separate lists for: Invasive Pest Plants (Pampas Grass whose seed can blow 17 miles), & Weedy plants (non-native mustards & radish). Share Sourcing, Propagation, & Eradication methods for weedy & pest plants. Issues (ex.: using local biotic genetic material, & issues when it can't due to extirpation)

4D) Develop strategies to help nature offsite: (ex. planting native Narrow-leaved milkweed for Monarch butterflies. Jim K., one of our admirable neighbors on the Westchester Bluffs raises mass quantities of another species of milkweed plant in support of Monarch butterflies; he hosts resident & migrant populations around his yard.) (El Segundo Blue Butterflies. Bees or other "beneficial insects" (like pollinators or sensitive indicators of wild flora health). Hummingbirds. Other Wildlife-support: Cavity boxes (for bats, or bluebirds the Audubon Society wants to bring back) to make up for the loss of cavities in large-trunked trees. Feeders. Birdbaths. Reclaim & protect as much as possible of La Ballona real estate dominated by humans, focusing maximum benefits on species most at risk.

4E) Expand Education opportunities: Show tableau of plant groupings from each range type (from dunetop prairie to alkali flat), for use in grouping similar-need plants for gardeners, or educational garden (a long bed at area schools could sample a cross-section of Ballona's dune, lagoon, mineral flats, riparian, consolidated sandy bluff, prairie blufftop, vernal pools.)

5) GET THE WRONG PEOPLE & THEIR BAGGAGE OUT & the RIGHT PEOPLE IN.

5A) Homeless camps out of Ballona: I have nothing against homeless people- some are my friends. But the lone ranger who works Ballona has 3 or 4 other park properties to manage... For the time she's seen here, Ballona is not her favorite, and she doesn't like to patrol on foot. Slow- or No- action is taken on reports of chronically-occupied sites occupied by homeless individuals, small group camps,

& campfires (which also seem to attract large quantities of discards blanketing the ground that could literally send any present and future plan for Ballona up in smoke). More staff and a different mandate is needed to cover Ballona ground, and the homeless problem can only be solved by getting out of the truck for confrontation if necessary, & prompt eviction.

5B) BUST the dumpers: Tracking serial numbers on discarded televisions for instance can lead to the former owner, or unauthorized dumper, who can pay high fines or perform community service (hauling others' dumped junk) that can leverage the cleanup and spread the word that free dumping in Ballona is over.

5C) BRING IN RESEARCHERS & OBSERVERS: This is the way to conduct Scopings: by authorizing in appropriate people with minimal impact, to maximize beneficial knowledge of Ballona.

5D) CLEAN OUT THE RESERVE: A number of groups who worked hard to save Ballona used to do tours, cleanups, & abatement of invasives have been locked out of Ballona for several years by the Frenemies, who use this public land as their own estate; this is public land, their locks need to be cut, and their defacto taking needs to be reversed ASAP; an one-site storage container of theirs is in prime habitat, and needs to be hauled away now.

5E) BUILD THE VISITOR CENTER OFF THE RESERVE! The land area is so shrunken, we need every inch to work for nature; like all parkland, plopping a large building in the middle of the space- surrounded by a parking lot that will inevitably expand, is no good! At the east end of Playa del Rey are several building lots that might work well.

5F) FEND OFF PROPERTY ATTACKS ON THE RESERVE: An unauthorized gravel parking lot in Playa del Rey north of Gordon's Market & east the Matilla Center sits entirely on Ballona reserve lands. An unauthorized Friday carwash business conducts business there with hoses in the parking lot behind the Matilla Center, operating entirely on the State reserve; not only does the State receive no income from this, the car wash soap, dirt, and automotive fluids sink through the gravel into the wetlands; where's the EIR for that? Local architect Craig Fraulino publicly proposed using State lands (for free) to build an alley/ parking to serve the north "backs" of Culver Boulevard businesses, converting adjacent Titmouse Park (Los Angeles City) for a parking lot, and building a multi-storey parking garage over the

unauthorized gravel lot to accommodate businesses and Reserve vistors. As property lines begin immediately at the "backs" of these buildings, this is entirely on State lands. Several of these businesses have already dumped gravel on State Lands anyway- a defacto unauthorized alleyway for which they pay nothing... and because when nothing is done, the assumption is the owner (in this case, the State) doesn't care. When it was pointed out they haven't paid any money for this land, it's not for sale, their schemes have no scientific standing, they had no answer. Really, this property line should be immediately surveyed, fenced, closed, and lands restored by the State (there is a seasonal wetland just north of the buildings, & Silvery legless lizards have been found at the backs of the buildings). The ICF plan shows a black area along the backs of these businesses; the Legend describes it as "Other;" there is another large black block at the southe-central edge of the site where below The Gas Company property; this cannot go unexplained.

6) PROGRESSIVE Transportation NOW! Another large black mark slashing through the middle of La Ballona ICF map is the Culver Boulevard right-of-way, the main killing-grounds of La Ballona wildlife, whose speed limit is soon to be raised. Progressive Transportation here means: building a "complete steet", upending the dominance of cars everywhere, and reordering/ inverting our priorities to 1) Walking 2) Biking 3) Transit 4) Automobiles. Opportunities to apply this at La Ballona should be integral to nearly every Alternative, as they stop the slaughter of the *prime thing* people would visit want to see: WILDLIFE! First, put a stop sign at Culver & Pershing to slow the cars down. Convert 2 traffic lanes eastward from Culver Boulevard to parking lanes for Ballona visitors. 2nd, Sawcut & remove the foolish "Culver Loop." Divert all eastbound car traffic on Culver onto Jefferson with a row of steel bollards (only Fire & Police Departments can open), and another row of same bollards closing westbound Culver at the 91 freeway ramps. Sawcut & remove all but 1 lane (= 2 bike lanes) of existing paving between these 2 points; this is the new 2-way Culver bike trail. On the center top of the bridge over Lincoln, build a bike service station with water & parts, and binoculars for wildlife observation. 3rd, Provide a decomposed granite (d.g.) trail next to the bike trail. Rebuild the Los Angeles Pacific Railway (later Pacific Electric) on its historic alignment to Playa del Rey as a slow-moving, quiet

platform to observe wildlife from. Rebuild its bridge spanning its existing Art Deco abutments over Lincoln Boulevard. Store the rail cars (build copies of the ones at the Port of LA, built for the Waterfront Red Cars in San Pedro, which are exactly correct) into EZ storage (North side of Culver Boulevard, where it can meet the Culver City bus there. Skip the sight of roadkill, and enjoy the wildlife experience.

On behalf of nature- who knows best,

RE: **MY OFFICIAL SCOPING COMMENTS** to Scoping for Kill-It-To-Save-It Bulldozing Plans for La Ballona
August 20, 2012 revised/ extended October 20, 2012
(Bold type indicates subject matter to be addressed in detailed responses to this Scoping)

On behalf of nature: To whom it may concern: non-profit "partner" Santa Monica Bay "Restoration" Commission (SMBRC), Department of Fish & Game, California Coastal Commission, State Parks, and State of California

About a decade ago, I heard an outrageous debate on a L.A. area radio station over development vs. environment, both sides claiming to know best for the environment. The *place* that argument was over was La Ballona, the last large remaining refuge of wildness on Los Angeles' west side- I'd noticed on my way to the airport as one of the few places where traffic moved, the only place dark at night, the best place to hear a frog chorus... I concluded that was surely protected park land...

The first presenter in that radio debate said in essence: this *was* wasted land, it *was* going to be developed, and *if* environmentalists were smart, they'd work with developers to save those few westernmost acres worth saving. What? I couldn't believe I was hearing such pro-developer greenwashing tripe said out loud, on-air! Until another presenter argued it was *all* worth fighting for- to save it as a natural place.

I'd soon find out this was Los Angeles county's last, largest, & best surviving wetlands/ uplands complex, once ~3,000 acres in size, was tragically already "developed"- whittled down by that time to ~1,200 undeveloped acres, but not one inch of it had any protection of any kind from bulldozing & developer speculators intent on destroying it. That saving La Ballona was crucial for the survival of California's endemics (species that occur nowhere else), because only ~5% of the state's coastal wetland areas remained that hadn't been "developed" (almost always exclusively for human use). That saving the largest contiguous block of it, in as wild condition as possible, was essential for animals higher on the food chain (needing larger territories) to survive here. That Ballona was a critical stop for Monarch Butterflies, Snow Geese, & other migrating species. Along with many others, I got personally involved... community/ environmental/ church/ & political groups got involved... >126 groups formed a loose Coalition... to try to save La Ballona from bulldozers with press conferences, demonstrations/ movie pickets/ marches, street theatre, community education, a hunger strike- trying to find an pro-environmental way ahead, meeting with politicians, the would-be developers, & would-be tenants of Playa Vista. Some local journalists risked their reputations to cover this "David vs. Goliath"-style story in a balanced way.

In the end, the city of Playa Vista got built despite community objection, killing plants & animals, sacrileging ancient native American gravesites- illegally removing the remains of hundreds of individuals to & from Santa Barbara- before reburying them elsewhere in Playa Vista, destroying remaining hydrology & habitat, and surrounding about half that remaining land. Playa Vista's sound-alarms do nothing to abate the endless burping of gasses that keep bubbling up, like they do at the Las Brea Tar Pits: Hydrogen Sulfate (stunting cognitive development in children), and leaking Natural gas that's already led to at least one death (a 1st-responder who illogically lit a match in an enclosed area that smelled of gas)- Natural gas that The Gas Company injects back into the salt domes beneath La Ballona for cheap-but-leaky storage. Playa Vista's earth movers heaped earth then ran over/ smashed possibly hundreds of capped gas/ oil well heads from the 1920's-1930's to make building pads. The Frenemies sold out to the developers, taking (a never-disclosed amount of) money to bless Playa Vista & defend its developers whenever they're attacked (to this day). The State bought half of what was left, paying way too much from the State's coffers (which only enabled developers cash to build quicker, when much of this land was wet & unbuildable anyway, and bank financing was otherwise hard for them to get)...

SMBRC IS INCOMPETENT, AND THE PROCESS SMBRC STARTED IS ALREADY WRONG; REMOVE THEM FROM THIS PROJECT AND IT'S LIKELY TO COLLAPSE FOR GOOD: Should the public idly stand by now that SMBRC/ other Frenemies of Ballona are trying to bulldoze & radically reshape the Public's 600 acres- "to kill it to save it" in the name of nature-annihilating "restoration"?... these same acres we fought to save from developers' bulldozing "Save it! Don't Pave It!"... when SMBRC's precedents (Steal-the-Bay) and its allies did little (or threw up obstacles) to save Ballona in the first place? SMBRC's "Kill it to save it" mentality, or Playa Vista's apologists' "Only 125 acres are worth saving", or developers' "Road lane expansion is necessary for all the traffic that's coming" (Hello! Frogs don't drive cars!) are among many incomprehensible nonsequiturs (the watershed is polluted; we must bulldoze downstream to clean it up), lies ("we don't have any plan yet"), and mis-conclusions based on mis-understandings (delta meander shapes observed at one point in time means that building fixed, randomly-curvy concreted channels would be good at Ballona) propagated about nature ("It's so degraded/ the invasives so bad that nothing in there is worth saving") & coastal wetlands generally (big salty holes for water storage are top priority (yet cleaning up or saving natural habitat at Marina del Rey is avoided, the Marina a bigger, saltier hole than ever existed in historic times that shares Ballona Creek's inlet/ outlet)... Since the State paid a record *$139,000,000 per acre* for these lands, doesn't that mean they extremely valuable in the condition they are in? This should completely disqualify SMBRC from doing anything at La Ballona, writing or sponsoring any of the Restoration Alternatives; the Community should be allowed to write at least half the total number of Final Alternatives, especially those emphasizing "Non-Bulldozer Phased Management," "Wildlife-Friendly," and "Historic" Alternatives; combining elements of these will automatically be more humane than the disasters that follow:

HAVING AN ARGUMENT ABOUT THE HIGHEST & BEST USE OF LAND IS ONE THING, HAVING ASYMMETRICAL POWER & CONTROL OF BULLDOZERS & STATE BACKING TO DESTROY LAND FOREVER IS ANOTHER; SMBRC SHOULD BE INELIGIBLE, PARTICULARLY & COMPLETELY DISQUALIFIED, REMOVED FROM ANY COASTAL OR WETLANDS RESTORATION PROJECT BASED ON ITS TRACK RECORD: And by "bulldozers/ bulldozing" I mean power & equipment emblematic of any mechanization regime for "industrial-scale habitat restoration;" this scale is almost always appropriate for permanently destroying/ altering/ degrading land; and almost never appropriate for restoring land back to natural conditions! Whether a Developer or Greenwashing "environmentalist" is in the cab of the bulldozer makes no difference to the flora & fauna being squished & maimed; widespread death is the same result. Having SMBRC, its predecessors, & allies in the driver's seat already has led to environmental crimes that are completely unacceptable & inapprorpiate for these 600 acres:

1) The creation of a toxic drain, funneling runoff from Playa Vista's parking lots & rooftops into a "Freshwater (sic) Marsh"- spewed into stolen wetlands (not internally: east of Lincoln, but greedily: west of Lincoln Boulevard), cutting down La Ballona's oldest & best mature native willow grove (habitat needed to attract rare/ endangered birds) to do what?- plant willows! This is the "restoration" model of SMBRC, designed for & by humans; this may be professional landscaping, but THIS IS NOT restoration! Nature knows best, and we'd best get ourselves out of the way.

2) The total annihilation of the Malibu Lagoon west of the main channel of Malibu Creek, wrecking 3 bridges used as outdoor classrooms (over arms of a lagoon dug in 1983) and shortest route for Coastal (beach) Access. Of the many plants & animals (2 endangered species, & ~200 species of birds alone) that used Malibu Lagoon, nearly nothing lives there today, and won't for many years- nothing except bulldozers, and maybe MRSA bacteria (SMBRC was afraid to test for!) Both are environmental crimes, senseless "man-made" catastrophes based on ignorance and miscategorization of wetlands (Malibu & La Ballona Lagoons were seasonally-closed & brackish, not full-time-tidally-open deep salty estuary SMBRC is trying to build at Malibu) both will now never be the same. While the State is "under water" financially, the rape of Malibu Lagoon drained millions of dollars to execute wildlife, in a State Park; this is just criminal. The byproduct of a fatally flawed analysis (that high-organic, low-oxygen, brackish water that ducks use doesn't belong in coastal lagoons), and that alleged problems the rape of Malibu Lagoon intended to cure won't recur (where do fish & birds go to the bathroom?) Meanwhile, the rape of Malibu Lagoon did nothing to remove the upstream, human-caused sources of water pollution, or wildlife barriers (removal of Rindge Dam to give steelhead & other

fish a chance at upstream habitat as far as Ahmanson Ranch wasn't included); the same would be true at La Ballona.
As a foretaste of the "attractive nuisance" would happen all over Ballona, I've observed wide swaths recently cut through the plant material for the on-site coring operations (I believe this was done in support of this proposal) have opened avenues for unauthorized vehicle forays, trash & furniture dumping, and homeless encampments deeper in the wetlands. The width is excessive- looks like a road; Gas Company trucks seldom leave behind such an opening, or ensure locked gates close their driveways.

THE TOLL ON NATURE TAKES ITS TOLL ON THE PUBLIC: Malibu Lagoon was ~12 acres... La Ballona is ~600 acres but headed toward 0 if bulldozers have their way; there is just no "somewhere else" for coastal wetland dependent species in California to go- especially brackish (non-salt) wetlands- have almost all been wiped out! The coastal human community (that appreciates nature) in Malibu is exhausted, confused, angry, and broke from fighting these battles- that ultimately wind up in court out of the public's reach, because only a court ruling can knock sense into the thick skull of determined developers, and no level of government can really be trusted to keep tax money from being squandered, and keeping electeds constantly reminded to protect the environment,
Once in the cab of the bulldozer, the developers of what's now Playa Vista (City of Soviet-style prison blocks with neo-historic facades painted on, a future ghost town after the next large earthquake/ tsunami/ or after the state realizes it cant' pay claims from children getting brain damage from hydrogen sulfide & Natural gas leaking from the salt dome under Ballona/ south Marina) **could not be trusted... neither can SMBRC be trusted.**

"THERE IS NO RIGHT WAY TO DO A WRONG THING!" SMBRC is now asking for the public's participation in the process of designing a "restoration" of acreage of La Ballona, but this is "putting the cart before the horse": Instead of producing a Purpose & Need, then Scoping, SMBRC has been disingenuous: hasn't officially "shown us their cards." During the scoping phase, SMBRC staffers denied in plain English that any "fix is in", or that SMBRC already has a plan. Without a doubt this is a lie: a range of at least 7 preliminary plans from bad to worse are already prepared (tellingly, a rough aerial sketch labelled "5A" illustrated a hardscaped Ballona Creek meander on an easel during SMBRC's initial August Scoping meeting- oops!) Choosing or blessing any of those pre-Scoping schemes cannot be allowed- if Malibu Lagoon's un-credible environmental documents were any guide, they are 1) Alternatives of unmitigatable damage to the environment ranging from bad to worse, 2) the current Coastal Commission's precedent for this will be to reject a pro-environmental compromise designed by scientists: like one that met SMBRC's flawed Purpose & Need, retained direct coastal access, phased-in very small-scale channel dredging to allow native species to survive with room to move around its impacts, and retain a balance of seasonally brackish & seasonally salty wetlands. At the Scoping, SMBRC's staff urged us to put down everything we were thinking on an 8-1/2" x 11" paper for inclusion (that's enough?), but other staff told us right away there are several things "off the table": removing any roads, removing any structures, taking the Gas Company, acquiring any more land from Playa Vista or elsewhere. While their unwitting, unselfconscious, unvarnished honesty was delicious (as it's as surely a portal into SMBRC's covert "restoration" plans, as it is an index to its allied backers!) SMBRC might consider *professional* staff/ staff behavior next time...or not. There were at least 2 such "loose cannon" staffers (who also used the word "I" frequently at the Scoping!) But this was supposed to be Public Scoping Phase, not Public Self-Editing Phase: it is our job, not SMBRC's! to set the parameters. Of course, these "off the table" ideas staff mentioned would be the *top implementation priorities* of anyone designing Real Restoration (road traffic alone being the #1 cause of ~3,000 annual wildlife fatalities at Ballona). So I really can't help SMBRC because they're not really interested in hearing what the public has to say...

WHAT KIND OF APPROPRIATE THINGS A *QUALIFIED* LEAD AGENCY SHOULD BE DOING *IF REAL RESTORATION WAS "ON THE TABLE"*: (or more appropriately, because it's already so shriveled from its original size, Ongoing Management) for LaBallona:

1) "FIRST, DO NO HARM." Using this Precautionary Principle would have stopped the rape of Malibu Lagoon all at once, cold.

1A) "THE FIRST RULE OF INTELLIGENT TINKERING IS TO SAVE ALL THE PIECES," said Aldo Leopold. Just leave Ballona alone- for nature to continue its work- is not the worst thing for Ballona. Leaving it alone may be the best thing, yet somehow so hard to understand/ think straight once the bulldozer's keys have been turned, and bulldozer power's in *anyone's* hands.

On the Intelligent Tinkering front, I know slow, by-hand restoration can work because I've done it- part of the team managing "The Big Plant-In", a multi-year (2008-present) all-volunteer community restoration on the east bank of Grand Canal Lagoon on the east bank just south of Washington Boulevard Bridge, Venice. And I've tried to grow other beneficial Ballona Natives (like Ballona-native narrow-leaved Milkweed used by migrant & resident Monarch Butterflies) at our nurseries. Though not perfect, this tidally-influenced canal bank site (near the northern end of La Ballona's natural historic channel), was replanted with a self-sustaining community of tall native shrubs, wildflowers, herbs & grasses, the plant palette professionally designed, sourced & grown from Ballona-native genetics. Stored & growing in plant nurseries at 2 nearby schools, prescribed erosion control & native plants were placed at the lagoon- not by bulldozers- but all by volunteers using hand-tools: neighbors, school kids & collegians, service organizations, church groups, political campaigners... even foreign tourists, that generates community buy-in bulldozing never does. Dense non-native myoporum bushes that housed homeless people are gone, as are broken concrete slabs, Chilean pepper trees, castor bean, iceplant, annual garden flowers planted by under-educated locals... Existing native plants & grassy areas already there were retained, which paid off during a planting in 2010 when our volunteers discovered a mallard & nest under one of the retained shrubs on the site (she came back after about 1/2 an hour, successfully hatched & raised that brood). I've also noticed plant succession after we pu the natives back in many areas at the Big Plant-In. From our mostly-random planting, nature sorted things out: coyote bush engulfed surrounding smaller plants. Telegraph Weed & Coast Buckwheat at the highest & northern half gave way to Goldenbush, while pickleplant dominated closest to the (tidally-influenced) water's edge. Everlasting & Spiny Rush were overtaken by larger plants many places, but survived where other plantings perished in poor, gravelly soil. Weeds which plagued us from the 2nd year (mustard & non-native mallow) diminished, now choked out in most places by dense, self-seeding natives.

1B) SINCE THE RAPE OF MALIBU COMMITTED IN JUNE 2012, THE STATE WOULD BE FOOLISH NOT TO INSIST THERE BE NO PROJECT & NO MONEY-WASTING AT LA BALLONA OR ANY OTHER SOUTHERN CALIFORNIA WETLANDS COMPLEX *UNLESS & UNTIL* SMBRC/ STATE PARKS/ PROJECT CONTRACTORS PROVE THEIR ABILITY TO QUICKLY GROW BACK/ RAPIDLY RE-ATTRACT NATIVE, RARE, & ENDANGERED SPECIES TO RE-INHABIT TO A THRIVING MALIBU LAGOON. It took decades for nature to reclaim Malibu Lagoon and progressively bring natural diversity back since bulldozers carved lagoon channels out of ball fields built over earlier CalTrans' spoils (dumping grounds) in 1983. Even if this works and Malibu Lagoon were to look & function like it did before June 2012, supporting the same number of plant & animal species within say 2 years (this would be a miracle), this is not justification to bulldoze everything all at once; only small parts of La Ballona should be restored at a time, and experimentally, over a period of years in case anything goes wrong, taking no more than say 10% of a habitat or species so there are no extirpations at La Ballona. The animal capturing effort at Malibu was pathetic. And large & numerous quantities of native plants could have been boxed & kept at offsite nurseries for regrowing Malibu Lagoon quickly, but this was not done. Bulldozing everything at the same time -as if laying the foundation for an inanimate warehouse building- to instantly achieve all elements shown in the "ICF" plan is"magical thinking" that will not work and must not be allowed in any scheme. Do you know where Burrowing Owl habitat is for instance? I'm told they no longer live full-time in Ballona as they did until recently, but now only visits seasonally; what bulldozer power-take-off (PTO) attatchment is going to dig enough owl-acceptable replacement rodent holes for a sustainable population of them to live in after you've caved in all the rodent holes with bulldozers?

1C) INSTEAD, SMBRC'S LIKELY TO FIND CATASTROPHIC LAGOON DESTRUCTION ENCOURAGES CATASTROPHIC FOREIGN & WEEDY SPECIES INVASION. Evidence of this is found at the industrial-scale "restoration" on west bank of the severed Ballona Lagoon in the Marina Peninsula (in City of LA, north of Lighthouse Bridge): as part of its "restoration", its 'genius' designers disturbed much of the upper canal bank soil & piled wood chip mulch on top (as lagoon soils are often alkaline, this probably tipped topsoil chemistry sharply toward

acidic). This spring, castor bean and other weeds explodeded, growing more thickly than ever, choking & towering over the native plants. But this invasion did not happen in adjacent areas south of Lighthouse bridge, where discovery & confirmation of the extremely rare Orcutt's Yellow Pincushion prevented both the scraping & mulching, as well as preventing the explosion of weeds. (For Malibu, SMBRC/ State Parks originally wanted to poison anything that escaped bulldozing with Agent Orange derivative "Round-up", but verbally removed it on the spot from the Malibu bulldozing hearing during the 2010 Coastal Commission due to audience outrage... yet had the proposers read the manufacturer's label, Round-up's prohibited from use anywhere near open water-courses).

2) FOR ECOLOGICAL HEALTH, CUT BACK ON SALT! We've already dug more salty holes (= harbors & channels) along the coast than nature'll ever need! So where is the apparent "need" for stormwater storage coming from? Southern California harbors & channels have displaced more brackish wetlands for salty- than ever existed in historic times. Nature has no need for more of this, so (Army Corps'/ L.A. County- driven) counterproductive element of floodwater storage posing as natural restoration should be scrapped. Instead, nature needs more of the brackish wetlands over the salty.
